Use the **Platform Settings** page (**Devices** > **Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The **Status** column shows the device targets for the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings**.

Step 2 For an existing policy, you can **Copy** (), **Edit** (), or **Delete** () the policy.

Caution You should not delete a policy that is the last-deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is a good practice to deploy a different policy to those targets.

Step 3 To create a new policy, click **New Policy**.

a) Choose a device type from the drop-down list:

- **Threat Defense Settings** to create a shared policy for managed Firewall Threat Defense devices.
- **Chassis Platform Settings** to create a shared policy for managed Firewall Threat Defense chassis in multi-instance mode.

b) Enter a **Name** for the new policy and optionally, a **Description**.

c) Optionally, choose the **Available Devices** or **Available Chassis** where you want to apply the policy and click **Add** (or drag and drop) to add the selected devices. You can enter a search string in the **Search** field to narrow the list of devices.

d) Click **Save**.

- When you have selected a device and if the device is already applied with a policy, the **Confirm PFS Overwrite** dialog appears. To override the applied policy, click **OK**. The selected device is applied with the new policy.
- The system creates the policy and opens it for editing.

Step 4 To change the target devices for a policy, click **Edit** () next to the platform settings policy that you want to edit.

a) Click **Policy Assignment**.

b) To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** or **Available Chassis** list and click **Add**. You can also drag and drop.

c) To remove a device assignment, click **Delete** () next to a device, high-availability pair, or device group in the **Selected Devices** or **Selected Chassis** list.

d) Click **OK**.

After completing these steps, platform settings policies are created, edited, or deleted as needed, and device assignments are updated accordingly.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Chassis platform settings

Chassis platform settings reference information

Chassis platform settings apply to multiple-instance mode chassis. For more information, see Chassis platform settings, on page 256.

Configure ARP inspection

Configure ARP inspection to ensure that only valid ARP packets are accepted on your network, reducing the risk of ARP spoofing and related attacks.

- Apply ARP inspection policies to specific interfaces and security zones.
- Add static ARP entries for enhanced control and security.

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the Firewall Threat Defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the Firewall Threat Defense device drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the Firewall Threat Defense device to either forward the packet out all interfaces (flood), or to drop the packet.

Note The dedicated Management interface never floods packets even if this parameter is set to flood.

Use this task when you need to protect your network from ARP spoofing by validating ARP packets and controlling ARP traffic on selected interfaces and zones.

Use ARP inspection in environments where network security is a priority and static ARP entries are needed.

Before you begin

Make sure you have device access and permission to edit platform settings and ARP inspection policies.

- Have the list of interfaces and security zones where ARP inspection will be applied.
- Prepare the static ARP entries that you intend to add.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **ARP Inspection**.

Step 3 Add entries to the ARP inspection table.

a) Click **Add** to create a new entry, or click **Edit** if the entry already exists.

b) Select the desired options.

- **Inspect Enabled**—To perform ARP inspection on the selected interfaces and zones.
- **Flood Enabled**—Floods ARP requests that do not match static ARP entries to all interfaces except the originating or dedicated management interface. By default, this behavior is enabled.

  If you choose not to flood ARP requests, only requests that match static ARP entries are allowed.
- **Security Zones**—Add the zones that contain the interfaces on which to perform the selected actions. The zones must be switched zones. For interfaces not in a zone, type the interface name into the field in the Selected Security Zone list and click **Add**. The device applies these rules only if it includes the selected interfaces or zones.

c) Click **OK**.

Step 4 Add static ARP entries according to Add a static ARP entry, on page 856.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

ARP inspection is enabled on the selected interfaces and security zones. Only valid ARP packets are accepted, and static ARP entries are enforced. The policy is active after deployment.

Configure a banner

Configure a banner to display messages to users when they connect to the device command line interface (CLI). This helps inform users and discourage unauthorized access.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Banner**.

Step 3 Configure the banner.

These are some tips and requirements for banners.

- Use only ASCII characters. You can add line returns (press Enter), but do not use tabs.
- You can dynamically add the hostname or domain name of the device by including the variables **$(hostname)** or **$(domain)**.
- Although banners do not have an absolute length restriction, Telnet or SSH sessions close if the system does not have enough memory to process banner messages.
- Create a banner that discourages unauthorized access by avoiding the words "welcome" or "please," which may seem inviting. The sample banner provided discourages intruders.

```
You have logged in to a secure device.
If you are not authorized to access this device,
log out immediately or risk criminal charges.
```

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

The system displays the banner to users when they connect to the device CLI. The changes occur after you deploy the policy.

Configure DNS server settings

Configure DNS server settings to enable hostname resolution for data traffic on managed devices. This task allows you to set up DNS server groups, trusted DNS services, and interface-specific DNS lookups. These configurations support features such as access control rules, NAT, and application detection.

- Set up DNS server groups for resolving FQDNs used in data traffic.
- Configure trusted DNS servers for DNS snooping and application-based PBR.
- Enable DNS lookups on specific interfaces to control routing behavior.

The Domain Name System (DNS) servers are used to resolve hostnames to IP addresses. Data DNS settings apply to services that use FQDNs, such as access control rules and remote access VPN. Special management traffic uses separate DNS settings configured via CLI commands. This procedure applies only to data DNS servers. For management DNS settings, see the CLI **configure network dns servers** and **configure network dns searchdomains** commands.

Managed devices use routing lookups to determine the correct interface for DNS server communications. The system selects the routing table based on the interfaces enabled for DNS. Multiple DNS server groups can be configured to resolve different DNS domains, allowing internal and external DNS resolution as needed.

Trusted DNS servers

You can configure trusted DNS services for DNS snooping. DNS snooping is used to map the application domains to IPs in order to detect the application on the first packet. You can also include the already configured servers in DNS group, DHCP pool, DHCP relay and DHCP client as trusted DNS servers.

For application-based PBR, configure trusted DNS servers. Ensure DNS traffic passes through Firewall Threat Defense in clear text format (because encrypted DNS is not supported) for domain resolution and application detection.

Before you begin

- Ensure you have created one or more DNS server groups. For more information, see Create a DNS server group object, on page 2792.
- Ensure you have created interface objects to connect to the DNS servers.
- Ensure that the managed device has appropriate static or dynamic routes to access the DNS servers.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit a Threat Defense policy.

Step 2 Click **DNS**, and then click the **DNS Settings** tab.

Step 3 Check **Enable DNS name resolution by device**.

Step 4 Configure the DNS server groups.

a) Do any of these actions in the DNS server group list:

- To add a group, click **Add**. You cannot add another group once there are 30 filter domains configured within the existing list of server groups.
- To edit a group, click **Edit** (✎) next to the group.
- To remove a group, click **Delete** (🗑) next to the group. When you remove a group, you do not delete the DNS server group object. You remove it only from this list.

b) When adding or editing a group, configure the following settings, then click **OK**:

- **Select DNS Group**—Select an existing DNS server group object, or click **+** to create a new one.
- **Make as default**—Select this option to make this group the default group. Any DNS resolution request that does not match the filters for other groups will be resolved using the servers in this group.
- **Filter Domains**—For non-default groups only, enter a list of domain names separated by commas, such as example.com,example.net. Do not include spaces.

The group is used only for DNS resolutions for these domains. You can enter up to 30 separate domains across all groups in this DNS platform settings policy. Each domain name can contain up to 127 characters.

Note that these filter domains are not related to the default domain name for the group. The filter list can be different from the default domain.

Step 5 (Optional) Enter the **Expiry Entry Timer** and **Poll Timer** values in minutes.

These options apply to FQDNs specified in network objects only and do not apply to FQDNs used in other features.

- **Expire Entry Timer** specifies the minimum time-to-live (TTL) value for the DNS entry, in minutes. If the expiration timer is longer than the entry's TTL, the TTL is increased to the expire entry time value. If the TTL is longer than the expiration timer, the expire entry time value is ignored. Upon expiration, the entry is removed from the DNS lookup table. When you remove an entry, the device recompiles the table. Frequent removals can increase the processing load on the device. Some DNS entries can have very short TTL (as short as three seconds); use this setting to virtually extend the TTL. The default is 1 minute. The range is 1 to 65535 minutes.

  For systems running 7.0 or earlier, the expiration time is actually added to the TTL; it does not specify a minimum value.

- **Poll Timer** specifies the time limit after which the device queries the DNS server to resolve the FQDN defined in a network object. An FQDN is resolved periodically when either the poll timer has expired or the TTL of the resolved IP entry has expired, whichever occurs first.

Step 6 Enable DNS lookups on all interfaces or on specific interfaces. These choices also affect which routing tables are used.

Enabling DNS lookups on an interface is not the same as specifying the source interface for lookups. The Firewall Threat Defense always uses a route lookup to determine the source interface. Management-only interfaces other than the dedicated Management interface cannot be used.

- No interfaces selected—This setting enables DNS lookups on all interfaces. The Firewall Threat Defense checks the data routing table only.
- Specific interfaces selected but not the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on the specified interfaces. The Firewall Threat Defense checks the data routing table only.
- Specific interfaces selected plus the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on the specified interfaces and the Management interface. The Firewall Threat Defense checks the data routing table, and if no route is found, falls back to the management-only routing table.
- Only the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on Management. The Firewall Threat Defense checks only the management-only routing table.

Step 7 Configure Trusted DNS servers.

a) Click the **Trusted DNS Servers** tab.
b) By default, the existing DNS servers that are configured in DHCP pool, DHCP relay, DHCP client, or DNS server group are included as trusted DNS servers. If you want to exclude any of them, uncheck the appropriate check boxes.

c) To add trusted DNS servers, under **Specify DNS Servers**, click **Edit**.

d) In the **Select DNS Servers** dialog box, either choose a host object as the trusted DNS server or directly specify the IP address of the trusted DNS server:

1. To choose existing host objects, under **Available Host Objects**, select the required host object and click **Add** to include it to **Selected DNS Servers**. For information on adding the host objects, see Create a network object, on page 2815.
2. To directly provide the IP address (IPv4 or IPv6) of the trusted DNS server, enter the address in the given text field, and click **Add** to include it to **Selected DNS Servers**.
3. Click **Save**. The added DNS servers are displayed in the **Trusted DNS Servers** page.

Note You can configure a maximum of 12 DNS servers per policy.

To search for a DNS server that was added, using either the host name or the IP address, use the search field under **Specify DNS Servers**.

Step 8 Click **Save**.

What to do next

To use FQDN objects for access control rules, create an FQDN network object which can then be assigned to an access control rule. For instructions, see Create a network object, on page 2815.

Configure external authentication

Configure external authentication to allow management users to be authenticated using an LDAP or RADIUS server, as specified in an external authentication object. Centralized user management also enhances security for device access.

Note You must have administrator privileges to perform this task.

When you enable external authentication for management users, the Firewall Threat Defense verifies the user credentials with an LDAP or RADIUS server as specified in an external authentication object.

Sharing External Authentication Objects

External authentication objects can be used by the Firewall Management Center and Firewall Threat Defense devices. You can share the same object between the Firewall Management Center and devices. Alternatively, create separate objects. Note that the Firewall Threat Defense supports defining users on the RADIUS server, while the Firewall Management Center requires you to predefine the user list in the external authentication object. You can choose to use the predefined list method for the Firewall Threat Defense, but if you want to define users on the RADIUS server, you must create separate objects for the Firewall Threat Defense and the Firewall Management Center.

Note The timeout range is different for the Firewall Threat Defense and the Firewall Management Center, so if you share an object, be sure not to exceed the Firewall Threat Defense's smaller timeout range (1 to 30 seconds for LDAP, and 1 to 300 seconds for RADIUS). If you set the timeout to a higher value, the Firewall Threat Defense external authentication configuration will not work.

Assigning External Authentication Objects to Devices

For the Firewall Management Center, enable the external authentication objects directly on **Administration** > **Users** > **External Authentication**; this setting only affects Firewall Management Center usage, and it does not need to be enabled for managed device usage. For Firewall Threat Defense devices, you must enable the external authentication object in the platform settings that you deploy to the devices, and you can only activate one external authentication object per policy. An LDAP object with CAC authentication enabled cannot also be used for CLI access. Be sure that both the Firewall Threat Defense and the Firewall Management Center can reach the LDAP server, even if you are not sharing the object. The Firewall Management Center is essential to retrieving the user list and downloading it to the device.

Firewall Device Supported Fields

Only a subset of fields in the external authentication object are used for Firewall Threat Defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for the Firewall Management Center, those fields will be used. This procedure only covers the supported fields for the Firewall Threat Defense. For other fields, see *Configure External Authentication for the Firewall Management Center* in the *Cisco Secure Firewall Management Center Administration Guide*.

Usernames

Usernames must be Linux-valid usernames and be lowercase only, using alphanumeric characters plus period (.) or hyphen (-). Special characters such as at sign (@) and slash (/) are not supported. You cannot add these default internal users for external authentication—**root, daemon, bin, sys, sync, games, man, lp, mail, news, uucp, proxy, www-data, backup, list, irc, gnats, ntp, lldpd, bind, dhcp, qemu, rpcuser, rpc, sshd, radiusd, messagebus, admin, mysql, www, sfrna, snorty, sfsnort, sfremediation, nobody, samdme, extuser, p2puser, rloginUser**. You can only add external users (as part of the External Authentication object) in the Firewall Management Center; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the Firewall Management Center.

If you previously configured the same username for an internal user using the **configure user add** command, the Firewall Threat Defense first checks the password against the internal user, and if that fails, it checks the AAA server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported. For users defined on the RADIUS server, be sure to set the privilege level to be the same as any internal users; otherwise you cannot log in using the external user password.

Privilege Level

LDAP users always receive Config privileges. You can define RADIUS users as either config or basic users.

Before you begin

- SSH access is enabled by default on the management interface. To enable SSH access on data interfaces, see Configure Secure Shell (SSH) access, on page 1026.
- Inform RADIUS users of the following behavior to set their expectations appropriately:
  - The first time an external user logs in, Firewall Threat Defense creates the required structures but cannot simultaneously create the user session. The user simply needs to authenticate again to start

the session. The user will see a message similar to this: "New external username identified. Please log in again to start a session."

- If the user's Service-Type attribute is not defined or incorrectly configured in the RADIUS server and you use the RADIUS-defined users for authentication, the user will see a message similar to this: "Your username is not defined with a service type that is valid for this system. You are not authorized to access the system?".

  In some cases, the SSH clients close the CLI window on an unsuccessful SSH connection, even before displaying the failure message. Hence, ensure that the user's Service-Type attribute is correctly defined in the RADIUS server.

- Similarly, if the user's Service-Type authorization was changed since the last login, the user will need to re-authenticate. The user will see a message similar to this: "Your authorization privilege has changed. Please log in again to start a session."

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **External Authentication**, and then click the **Manage External Authentication Server** link.

You can also open the External Authentication screen by clicking **System** > **Users** > **External Authentication**.

Step 3 Click **Add External Authentication Object**.

Step 4 Configure an LDAP Authentication Object.

Step 5 Configure a RADIUS Authentication Object.

Step 6 Return to **Administration** > **Users** > **External Authentication**.

Step 7 Click **Refresh** ( ) to view any newly-added objects.

For LDAP when you specify SSL or TLS encryption, you must upload a certificate for the connection; otherwise, the server will not be listed on this window.

Step 8 Click **Slider enabled** ( ) next to the External Authentication object you want to use. You can only enable one object.

Step 9 Click **Save**; deploy configuration changes (see Deploy configuration changes, on page 193).

After completing this task, external authentication is enabled for management users. The system verifies user credentials with the configured LDAP or RADIUS server and grants access based on the authentication object and user privileges.

Configure an LDAP External Authentication Object

Configure external authentication to allow management users to be authenticated using an LDAP server.

Note You must have administrator privileges to perform this task.

Procedure

Step 1 In the **External Authentication Object** page, select **LDAP** from the **Authentication Method** drop-down list and enter appropriate values in these fields:

a) Enter a **Name**.

b) (Optional) Enter **Description**.

Step 2 Choose a **Server Type** from the drop-down list.

Step 3 For the **Primary Server** enter these values:

a) Enter a **Host Name/IP Address**.

Note If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

b) Change the **Port** from the default.

Step 4 Enter the **Backup Server** parameters.

Step 5 Enter **LDAP-Specific Parameters**.

- **Base DN**—Enter the base distinguished name for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com`. Alternatively click **Fetch DNs**, and choose the appropriate base distinguished name from the drop-down list.
- (Optional) **Base Filter**—For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)`.
- **User Name**—Enter a distinguished name for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at our example company has a `uid` value of `NetworkAdmin`, you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com`.
- **Password** and **Confirm Password**—Enter and confirm the password for the user.
- (Optional) **Show Advanced Options**—Configure the following advanced options.
  - **Encryption**—Click **None**, **TLS**, or **SSL**.

Note If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS**, the port resets to the default value of 389. If you choose SSL encryption, the port resets to 636.

  - **SSL Certificate Upload Path**—For SSL or TLS encryption, you must choose a certificate by clicking **Choose File**.

- (Not Used) **User Name Template**—Not used by the Firewall Threat Defense.
- **Timeout**—Enter the number of seconds before rolling over to the backup connection between 1 and 30. The default is 30.

Note The timeout range is different for the Firewall Threat Defense and the Firewall Management Center, so if you share an object, be sure not to exceed the Firewall Threat Defense's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the Firewall Threat Defense external authentication configuration will not work.

Step 6 (Optional) Set the **CLI Access Attribute** if you want to use a shell access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` shell access attribute to retrieve shell access users by typing `sAMAccountName` in the **CLI Access Attribute** field.

Step 7 Set the **CLI Access Filter**.

Choose one of these methods:

- To use the same filter you specified when configuring authentication settings, choose **Same as Base Filter**.
- To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell`, you can set a base filter of `(manager=shell)`.

The names on the LDAP server must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Step 8 Click **Save**.

Step 9 For LDAP, if you later add or delete users on the LDAP server, you must refresh the user list and redeploy the Platform Settings.

a) Choose **Administration** > **Users** > **External Authentication**.

b) Click **Refresh** ( ) next to the LDAP server.

If the user list changed, you will see a message advising you to deploy configuration changes for your device. The Firepower Theat Defense Platform Settings will also show that it is "Out-of-Date on *x* targeted devices."

c) Deploy configuration changes; see Deploy configuration changes, on page 193.

Configure a RADIUS Authentication Object

Configure external authentication to allow management users to be authenticated using a RADIUS server

Note You must have administrator privileges to perform this task.

Procedure

Step 1 In the **External Authentication Object** page, select **RADIUS** from the **Authentication Method** drop-down list and enter appropriate values in these fields:

a) Check the **Enabled Message Authenticator** check box to require the Message-Authenticator attribute in all RADIUS responses, ensuring that every response from the RADIUS server is securely verified by the Firewall Threat Defense.

This feature is enabled by default for new RADIUS servers. We recommend you enable it for existing servers after the upgrade. Disabling message authenticators may expose your firewalls to potential attacks. Ensure that your RADIUS server has the Message-Authenticator configuration.

b) Define users on the RADIUS server using the Service-Type attribute.

This is the list of supported values for the Service-Type attribute:

- Administrator (6)—Provides Config access authorization to the CLI. These users can use all commands in the CLI.
- NAS Prompt (7) or any level other than 6—Provides Basic access authorization to the CLI. These users can use read-only commands, such as **show** commands, for monitoring and troubleshooting purposes.

The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Alternatively, you can predefine users in the external authentication object (see Step Configure external authentication, on page 1013). To use the same RADIUS server for the Firewall Threat Defense and Firewall Management Center while using the Service-Type attribute method for the Firewall Threat Defense, create two external authentication objects that identify the same RADIUS server: one object includes the predefined **CLI Access Filter** users (for use with the Firewall Management Center), and the other object leaves the **CLI Access Filter** empty (for use with Firewall Threat Defenses).

c) Enter a **Name** and optional **Description**.

Step 2 For the **Primary Server**, enter a **Host Name/IP Address**.

Note If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

Step 3 (Optional) Change the **Port** from the default.

Step 4 Enter a **RADIUS Secret Key**.

Step 5 (Optional) Enter the **Backup Server** parameters.

Step 6 Enter **RADIUS-Specific Parameters**.

- **Timeout (Seconds)**—Enter the number of seconds before rolling over to the backup connection. The default is 30.
- **Retries**—Enter the number of times the primary server connection should be tried before rolling over to the backup connection. The default is 3.

Step 7 (Optional) Enter a comma-separated list of usernames in the **Administrator CLI Access User List** field. For example, enter `jchrichton, aerynsun, rygel`.

You may want to use the **CLI Access Filter** method for Firewall Threat Defense so you can use the same external authentication object with Firewall Threat Defense and other platform types. Note that if you want to use RADIUS-defined users, you must leave the **CLI Access Filter** empty.

Make sure that these usernames match usernames on the RADIUS server. The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Note If you want to only define users on the RADIUS server, you must leave this section empty.

Step 8 Click **Save**.

Enable a virtual-router-aware interface for platform external authentication

Enable a virtual-router-aware data interface for external authentication of the platform to allow Authentication, Authorization, and Accounting (AAA) management traffic to be routed through the data interface instead of the default management interface.

Authentication, Authorization, and Accounting (AAA) for the Firewall Threat Defense device is managed through the management interface of the device. You can also enable virtual-router-aware data interface, data sub-interface, port-channel, or sub port-channel to manage AAA for the Firewall Threat Defense device.

When enabled, the AAA route lookup is in the Virtual Routing and Forwarding (VRF) routing domain, and the AAA management traffic is forwarded to the data interfaces. These server configuration are supported when using virtual-router-aware data interfaces for AAA:

- RADIUS or LDAP servers for external authentication
- FQDN, IPv4, or IPv6 server addresses

To use a virtual-router-aware interface for external authentication of a Firewall Threat Defense device, modify its external authentication policy by associating the authentication servers with the virtual-router-aware interface of the device.

Before you begin

- Ensure that you have configured the required Virtual Routing and Forwarding (VRF) interface with a static route for the device. For information about configuring a VRF interface, see Configure a virtual router, on page 1165, and for information about adding a static route, see Add a static route, on page 1139.
- Ensure that security zones or interface groups with a single virtual-router-aware interface exists. For information about creating security zones and interface groups, see Create security zone and interface group objects, on page 744.
- Ensure that an external authentication server object is configured and enabled. For information on configuring an external authentication object, see External authentication for the Firewall Threat Defense, on page 148.
- If the primary authentication server is configured with the FQDN of the server, ensure that the backup authentication server, if configured, is also with its FQDN. In addition, configure the DNS server in the threat defense device's management interface. For information about the DNS server configuration, see Configure DNS.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **External Authentication** and edit the external authentication policy.

Step 3 In the **External Authentication** dialog box, the available security zone and interface groups are listed. To associate a virtual-router-aware interface with the external authentication servers, select the security zone or interface group having a single virtual-router-aware interface, and then do the following:

a) To associate the interface object with the primary authentication server, click **Add to Primary Server**.

b) (Optional) To associate the interface object with the backup authentication server, click **Add to Backup Server**. If the **Add to Backup Server** button is inactive, it means that a backup server for external authentication is not configured in the device. Configure a backup server from **System** > **Users** > **External Authentication**. For information about configuring a backup authentication server, see External authentication for the Firewall Threat Defense, on page 148.

Step 4 Click **OK**.

Step 5 Save and deploy the changes.

Configure fragment settings

Configure fragment settings to manage the handling of fragmented IP packets on your Firewall Threat Defense device. These settings help prevent Denial of Service (DoS) attacks and ensure applications that require packet fragmentation operate properly.

- Set limits for the number of fragments per packet and for fragments awaiting reassembly.
- Set the timeout for fragment reassembly.
- Allow fragments only if your network applications require them.

By default, the Firewall Threat Defense device allows up to 24 fragments per IP packet. It also allows up to 200 fragments awaiting reassembly. Applications such as NFS over UDP may require fragmented packets, but attackers often use fragmented packets in Denial of Service (DoS) attacks.

These settings establish the defaults for devices assigned this policy. You can override these settings for specific interfaces on a device by selecting **Override Default Fragment Setting** in the interface configuration. When you edit an interface, you can find the option on **Advanced** > **Security Configuration**. Select **Devices** > **Device Management**, edit a Firewall Threat Defense device, and select **Interfaces** to edit interface properties.

- Allow fragments only if required by your network applications.
- Override the default settings for specific interfaces when your configuration requires it.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Fragment Settings**.

Step 3 Configure the available options. To use the default settings, click **Reset to Defaults**.

- **Size (Block)**—The maximum number of packet fragments from all connections collectively that can be waiting for reassembly. The default value is 200 fragments. (One fragment equals one packet segment.)
- **Chain (Fragment)**—The maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets. Set this option to one to disallow fragments.
- **Timeout (Sec)**—The maximum number of seconds to wait for an entire fragmented packet to arrive. The default is five seconds. If all fragments are not received within this time, all fragments are discarded.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Deploy the policy to activate the new fragment settings on assigned devices. Monitor device performance and change fragment settings as needed.

Configure HTTP access

You can enable the HTTPS server to provide a health check mechanism for a cloud load balancer, for example, for the Firewall Threat Defense Virtual on AWS using an Application Load Balancer.

Use HTTPS with the Firewall Threat Defense only as described for health checks and management. You cannot configure the Firewall Threat Defense through a web interface in this management mode.

Configure HTTP access only on data interfaces, including interfaces you set as management-only. Use only data interfaces for HTTP access, not the dedicated Management interface. The Management interface is separate from the other interfaces on the device. Use the Management interface only to set up and register your device to the Firewall Management Center. It has a separate IP address and static routing.

Configure HTTPS access as described in this section. An access rule for the host IP address is not required.

Use HTTPS only on a reachable interface. If your HTTPS host is on the outside interface, initiate the management connection directly to it.

Before you begin

- Configure HTTPS and AnyConnect VPN module of Cisco Secure Client on separate TCP ports if both features are required on the same interface. For example, assign a different port to HTTPS, such as port 4443.
- Create network objects to define the hosts or networks that are allowed for HTTPS connections. You can add these objects as part of this procedure. If you plan to use object groups for IP addresses, ensure the groups exist in the rules. Select **Objects** to configure objects.

Note Use the **any-ipv4** or **any-ipv6** network object group instead of the system-provided **any** object.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **HTTP Access**.

Step 3 Check the **Enable HTTP Server** check box to enable the HTTP server.

Step 4 (Optional) Change the HTTP port. The default is 443.

Step 5 Identify the interfaces and IP addresses that allow HTTP connections.

Allow HTTP connections only from specific interfaces and client IP addresses by configuring this table. You may use network addresses instead of individual IP addresses.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make HTTP connections. Choose an object from the drop-down menu, or click + to add a new network object.

- **Available Zones/Interfaces**—Add the zones that contain the interfaces to which you will allow HTTP connections. For interfaces not in a zone, type the interface name into the field under the selected **Selected Zones/Interfaces** list. Then click **Add**. The device applies these rules only if it includes the selected interfaces or zones.

c) Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After you complete this task, the device enables HTTP access on the specified interfaces and IP addresses. Use secure connections for health checks or management.

Configure ICMP access

By default, you can send ICMP packets to any interface using either IPv4 or IPv6, with these exceptions:

- The Firewall Threat Defense does not respond to ICMP echo requests directed to a broadcast address.
- The Firewall Threat Defense only responds to ICMP traffic sent to the interface that traffic comes in on; you cannot send ICMP traffic through an interface to a far interface.

To protect the device from attacks, you can use ICMP rules to limit ICMP access to interfaces to particular hosts, networks, or ICMP types. ICMP rules function like access rules, where the rules are ordered, and the first rule that matches a packet defines the action.

If you configure any ICMP rule for an interface, an implicit deny ICMP rule is added to the end of the ICMP rule list, changing the default behavior. Thus, if you want to simply deny a few message types, you must include a permit any rule at the end of the ICMP rule list to allow the remaining message types.

We recommend that you always grant permission for the ICMP unreachable message type (type 3). Denying ICMP unreachable messages disables ICMP path MTU discovery, which can halt IPsec and PPTP traffic. Additionally ICMP packets in IPv6 are used in the IPv6 neighbor discovery process.

Before you begin

Make sure the required objects exist before you configure rules. Select **Objects** to configure objects. Create network objects or groups to specify the hosts or networks, and port objects to specify the ICMP message types you want to control.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **ICMP Access**.

Step 3 Configure ICMP rules.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **Action**—Whether to permit (allow) or deny (drop) matching traffic.
- **ICMP Service**—The port object that identifies the ICMP message type.
- **Network**—The network object or groupthat identifies the hosts or networks whose access you are controlling.
- **Available Zones/Interfaces**—Add the zones that contain the interfaces that you are protecting. If an interface is not in a zone, type the interface name into the field beneath the **Selected Zones/Interfaces** list, and click **Add**. A device applies these rules only if it includes the selected interfaces or zones.

c) Click **OK**.

Step 4 (Optional.) Set rate limits on ICMPv4 Unreachable messages.

- **Rate Limit**—Sets the rate limit of unreachable messages, between 1 and 100 messages per second. The default is 1 message per second.
- **Burst Size**—Sets the burst rate, between 1 and 10. The system sends this number of replies, but subsequent replies are not sent until the rate limit is reached.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

ICMP access rules take effect after you deploy the policy to the assigned devices. Your configuration permits or denies ICMP traffic for the hosts or networks you specified.

Configure NetFlow

Configure NetFlow to enable the collection and export of IP network traffic information from your device interfaces. This allows you to analyze traffic patterns, bandwidth usage, and identify sources and causes of network congestion.

The NetFlow feature enables you to collect IP network traffic information as it enters or exits an interface. The collected traffic information is sent as records to a NetFlow Collector server or NetFlow Analyzer. You can analyze the data from NetFlow and determine information such as source and destination of traffic, class of service, traffic pattern, bandwidth usage, type of traffic, traffic volume, and the causes of congestion.

With the native NetFlow configuration support, the traffic information collection that was enabled through syslogs flow exports has to be disabled.

NetFlow provides the option to configure the flow exporter and collectors along with flow event types that must be monitored.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **NetFlow**.

Step 3 Enable the **Enable Flow Export** toggle to enable NetFlow data export.

Step 4 Configure the general NetFlow parameters that control the frequency of events pushed to the collector.

a) **Active Refresh Interval**—For active connections, specify the time interval (in minutes) between flow-update events.

b) **Delay Flow Create**—Specify the delay (in seconds) before sending a flow-create event. If you do not enter any value, there is no delay and the flow-create event is exported as soon as the flow is created.

c) **Template Timeout Rate**—Specify the time interval (in minutes) at which the template records are sent to the collectors.

Step 5 Click **Add Collector** to configure the collector. See Add a collector in NetFlow, on page 1025.

Step 6 Click **Add Traffic Class** to configure the traffic class. See Add a traffic class to NetFlow, on page 1026.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, NetFlow will be enabled and configured on your device. Traffic data will be exported to the configured collector, allowing you to analyze network traffic patterns and usage.

Add a collector in NetFlow

Use this task when you need to export NetFlow data from Cisco Threat Defense devices to a collector for traffic analysis and monitoring.

This configuration is applicable to Cisco Threat Defense policies with NetFlow enabled.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Choose **NetFlow**.

Step 3 Enable the **Enable Flow Export** toggle to enable NetFlow data export.

Step 4 Click **Add Collector** to configure the collector. You can configure a maximum of five collectors.

Step 5 From the **Host** dropdown list, choose the collector host IP address (IPv4 only) of the NetFlow event collector or server to which the NetFlow packets must be sent. Alternatively, you can click the (+) icon to create a new network host.

Step 6 In the **Port** field, enter the UDP port on the collector to which the NetFlow packets must be sent.

Step 7 From **Available Interfaces or Interface Groups**, choose the interface or interface group through which the collector must be reached. You can choose multiple interfaces or interface groups. The Interface Group object can contain only one interface for a given device. A collector can be reached only through one interface. The object can include a virtual-router-aware interface. Loopback interface is not supported in NetFlow.

You can click the (+) icon to create a new interface group.

Step 8 Click **Add** to add the interfaces you chose. Alternatively, you can also enter the interface name and click **Add** to add the interface.

Step 9 Click **OK**.

Add a traffic class to NetFlow

Use this task when you need to monitor, filter, and export specific types of network traffic using NetFlow on a Threat Defense device. Adding a traffic class helps you focus on relevant traffic for security or operational analysis.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **NetFlow**.

Step 3 Click the **Enable Flow Export** toggle to export NetFlow data.

Step 4 Click **Add Traffic Class** to configure the traffic class.

Step 5 In the **Name** field, enter the name of the traffic class that must match the NetFlow events.

Step 6 In the **Type** field, choose the traffic class to filter the type of traffic you want to capture:

- **Default**—The traffic class that is matched if none of the traffic classes matches the traffic.
- **Access List**—The specific traffic class that must match the traffic captured for the NetFlow events.

Step 7 If you select **Access List** as the **Type**, then select the access list object from the **Access List Object** drop-down list.

Note You can also click the (+) icon to create a new extended access list object. See Configure an extended ACL object, on page 2775.

Step 8 In **Event Types**, check the checkboxes for the different NetFlow events that you want to capture and send to the collectors.

Step 9 Click **OK**.

Configure Secure Shell (SSH) access

If you enabled Firewall Management Center access on a data interface, such as outside, you should enable SSH on that interface using this procedure. This section describes how to enable SSH connections to one or more *data* interfaces on the Firewall Threat Defense.

Note SSH is enabled by default on the Management interface; however, this screen does not affect Management SSH access.

To use SSH, you do not also need an access rule allowing the host IP address. You only need to configure SSH access according to this section.

Data vs. Management SSH

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the Firewall Management Center. SSH for data interfaces shares the internal and external user lists with SSH for the Management interface. Other settings are configured separately. For data interfaces, enable SSH and access lists using this screen. SSH traffic for data interfaces uses the regular routing configuration. Routing for the Management interface configured during setup or at the CLI is not used.

For the Management interface, to configure an SSH access list, see the **configure SSH-access-list** command in the *Cisco Secure Firewall Threat Defense Command Reference*. To configure a static route, see the **configure network static-routes** command. By default, you configure the default route through the Management interface at initial setup.

Interface Access

You can SSH only to a reachable interface(including an interface in a user-defined virtual router); for example, if your SSH host is located on the outside interface, you can only initiate a management connection directly to the outside interface. When you enable SSH in a user-defined virtual router, and you want VPN users to access SSH, be sure to terminate the VPN on the same virtual router. If the VPN is terminated on another virtual router, then you must configure route leaks between the virtual routers.

Ciphers and Key Exchange

SSH supports the following ciphers and key exchange:

- Encryption—aes128-cbc, aes192-cbc, aes256-cbc, aes128-ctr, aes192-ctr, aes256-ctr
- Integrity—hmac-sha2-256
- Key exchange—dh-group14-sha256

SSH Stack

The Firewall Threat Defense uses the CiscoSSH stack, which is based on OpenSSH. CiscoSSH supports FIPS compliance and regular updates, including updates from Cisco and the open source community.

Maximum Attempts

After you make three consecutive failed attempts to log into the CLI using SSH, the device terminates the SSH connection.

Before you begin

- You can configure SSH internal users at the CLI using the **configure user add** command; see Add an internal user at the CLI, on page 145. By default, there is an **admin** user for which you configured the password during initial setup. You can also configure external users on LDAP or RADIUS by configuring **External Authentication** in platform settings. See Configure external authentication, on page 1013.
- You need network objects that define the hosts or networks permitted to make SSH connections to the device. You can add objects during the procedure. If you want to use object groups to identify a group of IP addresses, make sure the required groups already exist in the rules. Select **Objects** to configure objects.

Note You cannot use the system-provided **any** network object. Instead, use **any-ipv4** or **any-ipv6**.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **SSH Access**.

Step 3 Identify the interfaces and IP addresses that allow SSH connections.

Use this table to limit which interfaces will accept SSH connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make SSH connections. Choose an object from the drop-down menu, or click + to add a new network object.
- **Available Zones/Interfaces**—Add the zones that contain the interfaces to which you will allow SSH connections. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zones/Interfaces** list and click **Add**. You can also add loopback interfaces and virtual-router-aware interfaces. These rules will be applied to a device only if the device includes the selected interfaces or zones.

c) Click **OK**.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure an SMTP server

Configure an SMTP server to enable email alerts in Syslog. Ensure the source email address configured for Syslog is a valid account on the SMTP servers.

Before you begin

Ensure that the network objects for the primary and secondary SMTP server addresses exist. Define the objects using **Objects**. You can also create these objects when you edit the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **SMTP Server**.

Step 3 Select the network objects that identify the **Primary Server IP Address** and optionally, the **Secondary Server IP Address**.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, email alerts can be sent through Syslog using the specified SMTP servers.

Configure SNMP for a security device

Configure SNMP monitoring to allow network management stations to monitor the health and status of Cisco security devices. This task enables centralized visibility and management of devices using SNMP.

- Enable SNMP so that SNMP management stations can monitor devices.
- SNMP versions 1, 2c, and 3, including traps and read access, are supported. SNMP write access is not supported.

Simple Network Management Protocol (SNMP) defines a standard way for network management stations running on PCs or workstations to monitor the health and status of many types of devices, including switches, routers, and security appliances. You can use the SNMP page to configure a firewall device for monitoring by SNMP management stations.

SNMPv3 supports read-only users and encryption with DES(deprecated), 3DES, AES256, AES192, and AES128.

The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption and that were created using a version earlier than 6.5, you can continue to use those users for Firewall Threat Defense devices running versions 6.6 or earlier. However, you cannot edit those users and retain DES encryption or create new users with DES encryption. If your Firewall Management Center manages any Firewall Threat Defense devices running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those Firewall Threat Defense devices will fail.

Note

- You can configure SNMP only on Routed and Diagnostic interfaces.
- To create an alert to an external SNMP server, access **Administration** > **Alerts**.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **SNMP**.

Step 3 Enable SNMP, and configure basic options.

- **Enable SNMP Servers**—Whether to provide SNMP information to the configured SNMP hosts. You can deselect this option to disable SNMP monitoring while retaining the configuration information.
- **Read Community String**, **Confirm**—Enter the password used by a SNMP management station when sending requests to the Firewall Threat Defense device. The SNMP community string (also known as password) is a shared secret among the SNMP management stations and the network nodes. The security device uses this password to determine if the incoming SNMP request is valid. The password is a case-sensitive alphanumeric string of up to 32 characters; spaces and special characters are not permitted.
- **System Administrator Name**—Enter the name of the device administrator or other contact person. This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
- **Location**—Enter the location of this security device (for example, Building 42, Sector 54). This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
- **Port**—Enter the UDP port on which incoming requests will be accepted. The default is 161.

Step 4 (SNMPv3 only.) Add SNMPv3 users, on page 1038.

Step 5 Add SNMP hosts, on page 1041.

Step 6 Configure SNMP traps, on page 1043.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

SNMP protocol

SNMP protocol is an application-layer protocol that

- facilitates the exchange of management information between network devices, and
- is part of the TCP/IP protocol suite.

SNMP protocol support and access

Firewall Threat Defense provides support for network monitoring using SNMP Versions 1, 2c, and 3, and supports the use of all three versions simultaneously. The SNMP agent runs on the Firewall Threat Defense interface. You can monitor network devices using management systems (NMSs) such as OpenView network management system. Firewall Threat Defense supports SNMP read-only access with a GET request. SNMP does not support write access or the SNMP SET request, so you cannot make changes with SNMP.

You can configure the Firewall Threat Defense to send traps, which are messages sent to the management station when certain events occur. These messages are called event notifications. You can also use the NMS

to browse Management Information Bases (MIBs) on the security devices. MIBs are collections of definitions, and the Firewall Threat Defense maintains a database of values for each definition. To browse a MIB, issue a series of GET-NEXT or GET-BULK requests from the NMS to the MIB tree to get values.

The SNMP agent sends a notification to your management station when a specified event occurs, such as a network link going up or down. The notification includes an SNMP OID, which identifies the source device. The agent also replies when your management station requests information.

List SNMP terminology

This reference lists and defines the terms that are commonly used when working with SNMP.

Table 63: SNMP terminology

Term	Description
Agent	The SNMP server running on the Secure Firewall Threat Defense. The SNMP agent has these features: • responds to requests for information and actions from the network management station. • ontrols access to its Management Information Base, the collection of objects that the SNMP manager can view or change. • does not allow SET operations.
Browsing	Monitoring the health of a device from the network management station by polling required information from the SNMP agent on the device. This activity may include issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the network management station to determine values.
Management Information Bases (MIBs)	Standardized data structures for collecting information about packets, connections, buffers, failovers, and other items. MIBs are defined by the product, protocols, and hardware standards used by most network devices. SNMP network management stations can browse MIBs and request specific data or events be sent as they occur.
Network management stations (NMSs)	The PCs or workstations SET up to monitor SNMP events and manage devices.
Object identifier (OID)	The system that identifies a device to its NMS and indicates to users the source of information monitored and displayed.
Trap	Predefined events that generate a message from the SNMP agent to the NMS. Events include alarm conditions such as link-up, link-down, cold-start, warm-start, authentication events, or syslog messages. **coldStart**—The coldStart trap occurs when the SNMP agent starts after the SNMP configuration. This trap also occurs when the agent starts after a system reboot. **Note** For cluster and HA nodes, after a reload, if the interface reboot time exceeds 5 minutes (preset threshold), the trap is dropped. When the cluster and HA nodes have rebooted successfully, all other traps are sent as expected. The **SNMP-server enable traps SNMP coldstart** command is used to enable and disable transmission of these traps.

Describe MIBs and traps

MIBs are either standard or enterprise-specific. Standard MIBs are created by the IETF and described in various RFCs. Traps report significant events, such as errors or failures, on a network device. SNMP traps can be defined in standard or enterprise-specific MIBs. The IETF also creates standard traps, documented in various RFCs. SNMP traps are compiled into ASA software.

If needed, you can also download RFCs, standard MIBs, and standard traps from these locations:

http://www.IETF.org/

Browse the SNMP Object Navigator to look up Cisco MIBs, traps, and OIDs from this location:

https://snmp.cloudapps.cisco.com/Support/SNMP/do/BrowseOID.do?local=en

In addition, download Cisco OIDs by FTP from this location:

ftp://FTP.cisco.com/pub/mibs/oid/oid.tar.gz

List of supported tables and objects in MIBs

This reference lists the supported tables and objects for the specified MIBs, including details for each MIB such as counters, OIDs, and descriptions.

Remote Access VPN polling

Table 64: CISCO-REMOTE-ACCESS-MONITOR-MIB

Counter	OID	Description
Active Sessions	crasNumSessions (1.3.6.1.4.1.9.9.392.1.3.1)	The number of currently active sessions.
Users	crasNumUsers (1.3.6.1.4.1.9.9.392.1.3.3)	The number of users who have active sessions.
Peak Sessions	crasNumPeakSessions (1.3.6.1.4.1.9.9.392.1.3.41)	The number of peak RA sessions since system up.

Site-to-site VPN tunnel polling

Table 65: CISCO-REMOTE-ACCESS-MONITOR-MIB

Counter	OID	Description
LAN to LAN Sessions	crasL2LNumSessions (1.3.6.1.4.1.9.9.392.1.3.29)	The number of currently active LAN to LAN sessions.

Counter	OID	Description
Peak LAN to LAN Sessions	crasL2LPeakConcurrentSessions (1.3.6.1.4.1.9.9.392.1.3.31)	The number of peak concurrent LAN to LAN sessions since the system is up.

Connection polling

Table 66: CISCO-FIREWALL-MIB

Counter	OID	Description
Active Connections	cfwConnectionActive (1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.6)	The number of connections currently in use by the entire firewall.
Peak Connections	cfwConnectionPeak (1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.7)	The highest number of connections in use at any one time since system startup.
Connections Per Second	cfwConnectionPerSecond (1.3.6.1.4.1.9.9.147.1.2.2.3)	The current connections per second rate on the firewall.
Peak Connections Per Second	cfwConnectionPerSecondPeak (1.3.6.1.4.1.9.9.147.1.2.2.4)	The highest number of connections per second on the firewall since system startup.

NAT translation polling

Table 67: CISCO-NAT-EXT-MIB

Counter	OID	Description
Active Translations	cneAddrTranslationNumActive (1.3.6.1.4.1.9.9.532.1.1.1.1)	The total number of address translation entries that are currently available in the NAT device. This indicates the aggregate of the translation entries created from both the static and dynamic address translation mechanisms.

Counter	OID	Description
Peak Active Translations	cneAddrTranslationNumPeak (1.3.6.1.4.1.9.9.532.1.1.1.2)	The maximum number of address translation entries that are active at any one time since system startup. This value indicates the high watermark of address translation entries active at any one time since system startup. This object includes the translation entries created from both the static and dynamic address translation mechanisms.

Routing table entries polling

Table 68: IP-FORWARD-MIB

Counter	OID	Description
Active Translations	inetCidrRouteNumber (1.3.6.1.2.1.4.24.6)	The total number of current inetCidrRouteTable entries that are valid.

Interface duplex status polling

Table 69: CISCO-IF-EXTENSION-MIB

Counter	OID	Description
Duplex Status	cieIfDuplexCfgStatus (1.3.6.1.4.1.9.9.276.1.1.2.1.20)	This object specifies the configured duplex status for the given interface.
Detected Duplex Status	cieIfDuplexDetectStatus (1.3.6.1.4.1.9.9.276.1.1.2.1.21)	This object specifies the detected duplex status for the given interface.

Snort 3 intrusion EVENT rate polling

Table 70: CISCO-UNIFIED-FIREWALL-MIB

Counter	OID	Description
Snort 3 Intrusion event Rate	cufwAaicIntrusionEvtRate (1.3.6.1.4.1.9.9.491.1.5.3.2.1)	The rate at which intrusion events were recorded by Snort on this firewall, averaged over the last 300 seconds.

BGP MIB polling

Table 71: BGP MIB

Counter	OID	Description
BGP MIB **Note** • The SNMP MIB for BGP over IPv6 is not supported. • VRF or context-specific data cannot be queried or fetched.	bgpPeerState (.1.3.6.1.2.1.15.3.1.2)	The BGP peer connection state. **Values**: • 1: idle • 2: connect • 3: active • 4: opensent • 5: openconfirm • 6: established
	bgpPeerAdminStatus (.1.3.6.1.2.1.15.3.1.3)	**Description**: The desired administrative state of the BGP connection. **Values**: • 1: stop (neighbor shutdown) • 2: start (neighbor enabled)
	bgpPeerInTotalMessages (.1.3.6.1.2.1.15.3.1.12)	**Description**: The total number of messages received from the remote peer on this connection. **Range**: 0 to 4,294,967,295
	bgpPeerOutTotalMessages (.1.3.6.1.2.1.15.3.1.13)	**Description**: The total number of messages transmitted to the remote peer on this connection. **Range**: 0 to 4,294,967,295
	bgpPeerFsmEstablishedTransitions (.1.3.6.1.2.1.15.3.1.15)	**Description**: The total number of times the BGP FSM transitioned into the established state. **Range**: 0 to 4,294,967,295
	bgpPeerFsmEstablishedTime (.1.3.6.1.2.1.15.3.1.16)	

Counter	OID	Description
		Description: This timer shows how long your peer has been in the Established state (in seconds), or the time since your peer was last in the Established state. The timer resets to zero when you configure a new peer or restart the router. **Range**: 0 to 4,294,967,295

BGP peer-flap trap notification

Table 72: BGP4-MIB

Counter	OID	Description
BGP Peer-flap	bgpBackwardTransition (1.3.6.1.4.1.9.9.491.1.5.3.2.1)	The BGPBackwardTransition event is generated when the BGP FSM moves from a higher numbered state to a lower numbered state.

CPU utilization polling

Table 73: CISCO-PROCESS-MIB

Counter	OID	Description
CPU Total Utilization	cpmCPUTotal1minRev (1.3.6.1.4.1.9.9.109.1.1.1.1.7.1)	Total system CPU utilization for the last one minute.

Counter	OID	Description
Individual CPU Core Utilization	Associated parameters and values of cpmCPUTotal1minRev 1.3.6.1.4.1.9.9.109.1.1.1.1.7.2 to 1.3.6.1.4.1.9.9.109.1.1.1.1.7.(n+1)	Individual CPU core utilization values for the last one minute, where 'n' represents the number of cores. Examples: • 3.6.1.4.1.99.109.1.1.1.1.7.(n+2) - Aggregate system CPU utilization % (This value is the same as the system CPU usage from .3.6.1.4.1.9.9.109.1.1.1.1.7.1 in single context mode). • 3.6.1.4.1.99.109.1.1.1.1.7.(n+3) - Snort average CPU utilization % (total aggregate value of all snort instances) • 3.6.1.4.1.99.109.1.1.1.1.7.(n+4) - System PROCESS average % (average of "Sysproc" cores)

Note The SNMP OIDs 1.3.6.1.2.1.25.3.3 and 1.3.6.1.2.1.25.3.4 pertaining to CPU monitoring (hrProcessorTable and hrNetworkTable) were removed on ASA FirePOWER. You can view and MONITOR the CPU health details of the device only through its device manager.

In ENTITY-MIB, two new vendor OIDs were added for the dual EPM 2X100G and 4X200G cards of Secure Firewall 4200 for slot 2 and slot 3—cevFPRNM4X200Gng and cevFPRNM2X100Gng.

Add SNMPv3 users

Add SNMPv3 users to provide secure, authenticated, and encrypted SNMP management access to your device. This task ensures that only authorized users can access SNMPv3 features using specified authentication and encryption algorithms.

You create users for SNMPv3 only. These steps are not applicable for SNMPv1 or SNMPv2c.

Note SNMPv3 only supports read-only users.

SNMP users have a specified username, an authentication password, an encryption password, and authentication and encryption algorithms to use.

Note If you add a new cluster unit or replace a High Availability unit when using SNMPv3 with clustering or High Availability, SNMPv3 users are not replicated to the new unit. Remove the users, add them again, and redeploy your configuration to replicate users to the new unit.

For a successful SNMPv3 user authentication, the authentication key size should be equal to or larger than the encryption key size. For example, a user authentication using SHA-1 with AES256 fails, whereas authentication using SHA256 with AES256 succeeds.

Versions	Supported Algorithm		Deprecated Algorithm	
	Authentication	Encryption	Authentication	Encryption
< 6.4	MD5 and SHA	DES, 3DES, AES256, AES192, and AES128	-	-
6.5	SHA	3DES, AES256, AES192, and AES128	MD5*	DES**
6.6 and 6.7	SHA, and SHA256	3DES, AES256, AES192, and AES128	-	-
7.0+	SHA, SHA224, SHA256, and SHA384	3DES, AES256, AES192, and AES128	-	-

* If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for Firewall Threat Defense devices running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your Firewall Management Center manages any Firewall Threat Defensedevices running versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those devices will fail.

** If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for Firewall Threat Defensedevices running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your Firewall Management Center manages any Firewall Threat Defense devices running versions 7.0+, deploying a platform settings policy that uses DES encryption to those devices will fail.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Choose **SNMP** > **Users** tab.

Step 3 Click **Add** and completed the following:

a) Select the security level for the user from the **Security Level** drop-down list.

- **Auth**—Authentication but No Privacy, which means that messages are authenticated.
- **No Auth**—No Authentication and No Privacy, which means that no security is applied to messages.
- **Priv**—Authentication and Privacy, which means that messages are authenticated and encrypted.

b) Enter the name of the SNMP user in the **Username** field. Usernames must be 32 characters or fewer.

c) From the **Encryption Password Type** drop-down list, choose one of these options:

- **Clear text**—The Firewall Threat Defense device encrypts the password when you deploy the policy. In High Availability or cluster deployments, choose this option so that each unit localizes the SNMPv3 key with its own SNMP engineID.
- **Encrypted**—The Firewall Threat Defense device directly deploys the precomputed localized key in hexadecimal format.

Note Do not choose **Encrypted** for SNMPv3 users in High Availability or cluster deployments. An encrypted SNMPv3 password is a localized key that is generated from a specific SNMP engineID. Each High Availability or cluster unit has a unique SNMP engineID. If you deploy a localized key generated for one unit to its peer, SNMPv3 polling to the peer fails with an authentication error.

Choose **Clear text** so that each unit localizes the key during deployment.

d) In the **Auth Algorithm Type** drop-down list, select the type of authentication you want to use: SHA, SHA224, SHA256, or SHA384.

Note The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTD devices running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your Firewall Management Center manages any Firewall Threat Defenses running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those Firewall Threat Defenses will fail.

e) In the **Authentication Password** field, enter the password to use for authentication. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values.

Note The length of the password will depend on the authentication algorithm selected. For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

f) In the **Encryption Type** drop-down list, select the type of encryption you want to use: AES128, AES192, AES256, 3DES.

Note To use AES or 3DES encryption, you must have the appropriate license installed on the device.

Note The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for Firewall Threat Defenses running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your Firewall Management Center manages any Firewall Threat Defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those Firewall Threat Defenses will fail.

g) Enter the password to use for encryption in the **Encryption Password** field. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values. For encrypted passwords, the length of the password depends on the encryption type selected. The password sizes are as follows. Each xx is one octal.:

- AES 128 requires 16 octals
- AES 192 requires 24 octals
- AES 256 requires 32 octals
- 3DES requires 32 octals
- DES can be any size

Note For all passwords, the length must be 256 characters or fewer.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

Step 4 Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing these steps, SNMPv3 users are added with the specified authentication and encryption settings. The device is now configured for secure SNMPv3 management access.

Add SNMP hosts

Define SNMP hosts and their communication parameters to enable SNMP management stations to access and monitor the device. This task allows you to specify which hosts are permitted and how they communicate with the device.

Use Host to add or edit entries in the SNMP Hosts table on the SNMP page. These entries represent SNMP management stations allowed to access the Firewall Threat Defense device.

You can add up to 8192 hosts. Only 128 of this number can be for traps.

Note In 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices (7.3 and earlier, and some upgraded 7.4 FTDs).

Before you begin

Ensure that the network objects that define the SNMP management stations exist. Select **Device** > **Object Management** to configure network objects.

Note The supported network objects include IPv6 hosts, IPv4 hosts, IPv4 range and IPv4 subnet addresses.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Choose **SNMP** > **Hosts** tab.

Step 3 Click **Add** and completed the following:

a) In the **IP Address** field, either enter a valid IPv6 or IPv4 host or select the network object that defines the SNMP management station's host address.

The IP address can be an IPv6 host, IPv4 host, IPv4 range or IPv4 subnet.

b) Select the appropriate SNMP version from the **SNMP version** drop-down list.

c) (SNMPv3 only.) Select the username of the SNMP user that you configured from the **User Name** drop-down list.

Note You can associate up to 23 SNMP users per SNMP host.

d) (SNMPv1, 2c only.) In the **Community String** field, enter the community string that you have already configured, for read access to the device. Re-enter the string to confirm it.

Note This string is required, only if the string used with this SNMP station is different from the one already defined in the **Enable SNMP Server** section.

e) Select the type of communication between the device and the SNMP management station. You can select both types. Choose from:

- **Poll**—The management station periodically requests information from the device.

- **Trap**—The device sends trap events to the management station as they occur.

Note When the SNMP host IP address is either an IPv4 range or an IPv4 subnet, you can configure either **Poll** or **Trap**, not both.

f) In the **Port** field, enter a UDP port number for the SNMP host. The default value is 162. The valid range is 1 to 65535.

g) Select the interface type for communication between the device and the SNMP management station under the **Reachable By** options. You can select either the Management interface of the device or an available security zone/named interface. Choose from:

- **Device Management Interface**—Communication between the device and the SNMP management station occurs over the Management interface.
  - When you choose this interface for SNMPv3 polling, all configured SNMPv3 users are allowed to poll and are not restricted to the user chosen in 3.c, on page 1042. Here, SNMPv1 and SNMPv2c are not allowed from an SNMPv3 host.
  - When you choose this interface for SNMPv1 and SNMPv2c polling, the polling is not restricted at all to the version selected in 3.b, on page 1042.
- **Security Zones or Named Interface**—Communication between the device and the SNMP management station occurs over a security zone or interface.
  - Search for zones in the **Available Zones** field.
  - Add the zones that contain the interfaces through which the device communicates with the management station to the **Selected Zone/Interface** field. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zone/Interface** list and click **Add**. You can also choose a loopback interface and virtual-router-aware interfaces. The host will be configured on a device only if the device includes the selected interfaces or zones.

Note VTI tunnel interfaces are not supported for SNMP.

Step 4 Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure SNMP traps

Use SNMP traps to configure event notifications for Firewall Threat Defense. Traps are unsolicited notifications sent from the device to the management station for certain events, such as linkup, linkdown, and syslog event generation. Each SNMP trap includes an object ID (OID) for your device.

Some traps are not applicable to certain hardware models. These traps will be ignored if you apply the policy to one of these models. For example, not all models have field-replaceable units, so the **Field Replaceable Unit Insert/Delete** trap will not be configured on those models.

SNMP traps are defined in standard MIBs or in enterprise-specific MIBs. Standard traps are created by the IETF and documented in various RFCs. The Firewall Threat Defense software includes SNMP traps.

If needed, you can download RFCs, standard MIBs, and standard traps from http://www.IETF.org/.

Browse the complete list of CISCO MIBs, traps, and OIDs using the SNMP Object Navigator on the Cisco website: SNMP Object Navigator.

In addition, download CISCO OIDs by FTP: ftp://ftp.cisco.com/pub/mibs/oid/oid.tar.gz.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **SNMP** > **SNMP Traps** to configure SNMP traps (event notifications) for the Firewall Threat Defense device.

Step 3 Select the appropriate Enable Traps options. You can select either or both options.

a) Check **Enable All SNMP Traps** to select all traps in the subsequent four sections.

b) Check **Enable All Syslog Traps** to enable transmission of trap-related syslog messages.

Note SNMP traps are of higher priority than other notification messages because they are expected to be near real-time. When you enable all SNMP or syslog traps, it is possible for the SNMP process to consume excess resources in the agent and in the network, causing the system to hang. If you notice system delays, unfinished requests, or timeouts, you can selectively enable SNMP and syslog traps. You can also limit the rate at which syslog messages are generated by severity level or message ID. For example, all syslog message IDs that begin with the digits 212 are associated with the SNMP class; see Configure syslog rate limits, on page 1064.

Step 4 The event-notification traps in the **Standard** section are enabled by default for an existing policy:

- **Authentication** – Unauthorized SNMP access. This authentication failure occurs for packets with an incorrect community string.
- **Link Up** – One of the device's communication links has become available (it has "come up"), as indicated in the notification.
- **Link Down** – One of the device's communication links has failed, as indicated in the notification.
- **Cold Start** – The device is reinitializing itself such that its configuration or the protocol entity implementation may be altered.
- **Warm Start** – The device is reinitializing itself such that its configuration and the protocol entity implementation is unaltered.

Step 5 Select the desired event-notification traps in the **Entity MIB** section:

- **Field Replaceable Unit Insert** – A Field Replaceable Unit (FRU) has been inserted, as indicated. (FRUs include assemblies such as power supplies, fans, processor modules, interface modules, etc.)

- **Field Replaceable Unit Delete** – A Field Replaceable Unit (FRU) has been removed, as indicated in the notification
- **Configuration Change** – There has been a hardware change, as indicated in the notification

Step 6 Select the desired event-notification traps in the **Resource** section:

- **Connection Limit Reached** – This trap indicates that a connection attempt was rejected because the configured connections limit has been reached.

Step 7 Select the desired event-notification traps in the **Other** section:

- **NAT Packet Discard** – This notification is generated when IP packets are discarded by the NAT function. Available Network Address Translation addresses or ports have fallen below configured threshold.
- **CPU Rising Threshold** – This notification is generated when rising CPU utilization exceeds a predefined threshold for a configured period of time. Check this option to enable CPU rising threshold notifications:
  - **Percentage** – The default value is 70% for the high threshold notification; the range is 10 to 94%. The critical threshold is 95%.
  - **Period** – The default monitoring period is 1 minute; the range is 1 to 60 minutes.
- **Memory Rising Threshold** – This notification is generated when rising memory utilization exceeds a predefined threshold, thus reducing available memory. Check this option to enable memory rising threshold notifications:
  - **Percentage** – The default value is 70% for the high threshold notification; the range is 50 to 95%.
- **Failover** – This notification is generated when there is a change in the failover state as reported by the CISCO-UNIFIED-FIREWALL-MIB.
- **Cluster** – This notification is generated when there is a change in the cluster health as reported by the CISCO-UNIFIED-FIREWALL-MIB.
- **Peer Flap** – This notification is generated when there is BGP route flapping, a situation in which BGP systems send an excessive number of update messages to advertise network reachability information.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, SNMP traps are configured on the Firewall Threat Defense device, and event notifications will be sent to the management station for the selected events. This enables proactive monitoring and timely response to device events.

Configure SSL settings

This task enables you to configure SSL settings for remote access VPN sessions, allowing you to specify protocol versions, security levels, and available algorithms to ensure secure communication.

You must have administrator privileges and be in a leaf domain to perform this task.

Make sure that you are running a fully licensed version of the Secure Firewall Management Center. The SSL Settings are disabled if you are running Secure Firewall Management Center in evaluation mode. SSL Settings are also disabled if the licensed Secure Firewall Management Center version does not meet the export-compliance criteria. If you are using Remote Access VPN with SSL, your Smart Account must have the strong-crypto features enabled. For more information, see *License Types and Restrictions* in the *Cisco Secure Firewall Management Center Administration Guide*.

Before you begin

Ensure you have administrator privileges and are in a leaf domain. Verify that you are running a fully licensed version of the management center with strong-crypto features enabled if using Remote Access VPN with SSL.

Procedure

Step 1 Select **Devices** > **Platform Settings** and create or edit a Firewall Threat Defense policy.

Step 2 Select **SSL**.

Step 3 Add entries to the **Add SSL Configuration** table.

a) Click **Add** to create a new entry, or click **Edit** if the entry already exists.

b) Select the required security configurations from the drop-down list.

- **Protocol Version**—Specifies the TLS protocols to be used while establishing remote access VPN sessions.
- **Security Level**—Indicates the kind of security positioning you would like to set up for the SSL.

Step 4 Select the **Available Algorithms** based on the protocol version that you select and click **Add** to include them for the selected protocol. For more information, see Configure SSL settings, on page 1046.

The algorithms are listed based on the protocol version that you select. Each security protocol identifies a unique algorithm for setting up the security level.

Step 5 Click **OK** to save the changes.

What to do next

Select **Deploy** > **Deployment** and click **Deploy** to deploy the policy to the assigned devices.

Configure SSL settings

The Firewall Threat Defense device uses the Secure Sockets Layer (SSL) protocol and Transport Layer Security (TLS) to support secure message transmission for Remote Access VPN connection from remote clients. The SSL Settings window lets you configure SSL versions and encryption algorithms that will be negotiated and used for message transmission during remote VPN access over SSL.

Note Though you configure Firewall Management Center and Firewall Threat Defense to operate in a security certifications (UCAPL, CC, or FIPS) compliance mode, the Firewall Management Center allows configuration of unsupported ciphers. For example, in a FIPS enabled mode, management center allows configuring DH Group 5 which is not FIPS-compliant. However, VPN tunnel does not negotiate due to the non-compliant cipher usage.

Configure the SSL Settings at this location:

Devices > **Platform Settings**, and then click **SSL**.

Fields

Minimum SSL Version as Server—Specify the minimum SSL/TLS protocol version that the Firewall Threat Defense device uses when acting as a server. For example, when it functions as a Remote Access VPN Gateway.

TLS Version—Select one of these TLS versions from the drop-down list:

TLS V1	Accepts SSLv2 client hellos and negotiates TLSv1 (or greater).
TLSV1.1	Accepts SSLv2 client hellos and negotiates TLSv1.1 (or greater).
TLSV1.2	Accepts SSLv2 client hellos and negotiates TLSv1.2 (or greater).
TLSV1.3	Accepts SSLv2 client hellos and negotiates TLSv1.3 (or greater).

Note TLS 1.3 in remote access VPN requires Cisco Secure Client, Version 5.0 and above.

DTLS Version—Select the DTLS versions from the drop-down list, based on the selected TLS version. By default, DTLSv1 is configured on Firewall Threat Defense devices, you can choose the DTLS version as per your requirement.

Note Ensure that the TLS protocol version is higher than or equal to the DTLS protocol version selected. TLS protocol versions support these DTLS versions:

TLS V1	DTLSv1
TLSV1.1	DTLSv1
TLSV1.2	DTLSv1, DTLSv1.2
TLSV1.3	DTLSv1, DTLSv1.2

Diffie-Hellman Group—Choose a group from the drop-down list. Available options are Group1 - 768-bit modulus, Group2 - 1024-bit modulus, Group5 - 1536-bit modulus, Group14 - 2048-bit modulus, 224-bit prime order, and Group24 - 2048-bit modulus, 256-bit prime order. The default is Group1.

Elliptical Curve Diffie-Hellman Group—Choose a group from the drop-down list. Available options are Group19 - 256-bit EC, Group20 - 384-bit EC, and Group21 - 521-bit EC. The default value is Group19.

TLSv1.2 adds support for these ciphers:

- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-GCM-SHA384
- AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-GCM-SHA256
- RSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256

Note
ECDSA and DHE ciphers are the highest priority.

TLSv1.3 adds support for these ciphers:

- TLS_AES_128_GCM_SHA256
- TLS_CHACHA20_POLY1305_SHA256
- TLS_AES_256_GCM_SHA384

The SSL configuration table can be used to specify the protocol version, security level, and Cipher algorithms that you want to support on the Secure Firewall Threat Defense devices.

Protocol Version—Lists the protocol version that the Secure Firewall Threat Defense device supports and uses for SSL connections. Available protocol versions are:

- Default
- TLSV1
- TLSV1.1

- TLSV1.2
- TLSV1.3
- DTLSv1
- DTLSv1.2

Security Level—Lists the cipher security levels that Firewall Threat Defense device supports and uses for SSL connections.

If you have Firewall Threat Defense devices with evaluation license, the security level is Low by default. With Firewall Threat Defense smart license, the default security level is High. You can choose one of these options to configure the required security level:

- **All** includes all ciphers, including NULL-SHA.
- **Low** includes all ciphers, except NULL-SHA.
- **Medium** includes all ciphers, except NULL-SHA, DES-CBC-SHA, RC4-SHA, and RC4-MD5 (this is the default).
- **FIPS** includes all FIPS-compliant ciphers, except NULL-SHA, DES-CBC-SHA, RC4-MD5, RC4-SHA, and DES-CBC3-SHA, TLS_CHACHA20_POLY1305_SHA256.
- **High** includes only AES-256 with SHA-2 ciphers and applies to TLS version 1.2 and the *default* version.
- **Custom** includes one or more ciphers that you specify in the Cipher algorithms/custom string box. This option provides you with full control of the cipher suite using OpenSSL cipher definition strings.

Cipher Algorithms/Custom String—Lists the cipher algorithms that the Firewall Threat Defense device supports and uses for SSL connections. For more information about ciphers using OpenSSL, see https://www.openssl.org/docs/apps/ciphers.html

Ciphers supported by TLSv1.2 only

- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-GCM-SHA384
- AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384
- DHE-RSA-AES256-SHA256
- AES256-SHA256
- ECDHE-ECDSA-AES128-GCM-SHA256

- ECDHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-GCM-SHA256
- AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256
- DHE-RSA-AES128-SHA256
- AES128-SHA256

Note ECDSA and DHE ciphers are the highest priority.

Ciphers not supported by TLSv1.1 or TLSv1.2

- RC4-SHA
- RC4-MD5
- DES-CBC-SHA
- NULL-SHA

Syslog

Logging information

Logging information can help you identify and isolate network or device configuration problems.

- System logging (syslog) can be enabled for Firewall Threat Defense devices.
- Some security events can be sent to a syslog server.

Syslog messages

A syslog message is a log event that

- collects messages from devices to a server running a syslog daemon
- enables aggregation of logs and alerts for centralized management, and

- provides protected long-term storage for logs, supporting troubleshooting and incident handling.

System log configuration details

Devices can send their log messages to a UNIX-style syslog service. A syslog service accepts messages and either stores them in files or prints them, based on a simple configuration file.

Table 74: System logs for Secure Firewall Threat Defense

Logs related to	Details	Configure in
Device and system health, network configuration	This syslog configuration generates messages for features running on the data plane, that is, features that are defined in the CLI configuration that you can view with the **show running-config** command. This includes features such as routing, VPN, data interfaces, DHCP server, NAT, and so forth. Data plane syslog messages are numbered, and they are the same as those generated by devices running ASA software. However, Secure Firewall Threat Defense does not necessarily generate every message type that is available for ASA Software. For information on these messages, see *Cisco Secure Firewall Threat Defense syslog messages* at https://www.cisco.com/c/en/us/td/docs/security/firepower/Syslogs/b_fptd_syslog_guide.html. This configuration is explained in these topics.	**Platform settings**
Security events	This syslog configuration generates alerts for file and malware, connection, Security Intelligence, and intrusion events. For details, see *About sending syslog messages for security events* and subtopics in the *Cisco Secure Firewall Management Center Administration Guide*.	**Platform settings** and the **Logging** in an access control policy
(All devices) Policies, rules, and events	This syslog configuration generates alerts for access control rules, intrusion rules, and other advanced services as described in *Configurations supporting alert responses* in the *Cisco Secure Firewall Management Center Administration Guide*. These messages are not numbered. For information on configuring this type of syslog, see *Creating a syslog alert response* in the *Cisco Secure Firewall Management Center Administration Guide*.	**alert responses** and the **Logging** in an access control policy

You can set up multiple syslog servers and control the messages and events sent to each server. You can also configure varied destinations, such as console, email, or internal buffer.

Syslog message severity levels

The syslog message severity levels define the importance of system messages.

Table 75: Syslog message severity levels

Level Number	Severity Level	Description
0	**emergencies**	You cannot use the system.
1	**alert**	You need to take immediate action.

Level Number	Severity Level	Description
2	**critical**	The system has critical conditions to be addressed.
3	**error**	Error conditions.
4	**warning**	The system has warnings you should review.
5	**notification**	The system reports significant events you should monitor.
6	**informational**	Informational messages only.
7	**debugging**	The system generates only debugging messages Log at this level only temporarily, when debugging issues. This log level can generate many messages, which might affect system performance.

Note Firewall Threat Defense does not generate syslog messages with a severity level of zero (emergencies).

To optimize device storage space, use minimal logging. In this mode, only messages at the notification level or higher are logged. This setting reduces logs in system files. Minimal logging does not affect event logging or access control policy logging. Use CLI commands to manage logging levels. For details, see the system support logging commands in the *Cisco Secure Firewall Threat Defense Command Reference* guide.

Syslog message filters

Syslog message filter criteria

You can direct syslog messages to an output destination according to these criteria:

- Syslog message ID number

  (This does not apply to syslog messages for security events such as connection and intrusion events.)

- Syslog message severity level
- Syslog message class (equivalent to a functional area)

  (This rule does not apply to syslog messages for security events, including connection and intrusion events.)

You can create a message list with specific criteria, which you can then specify as the output destination is set. Alternatively, you can configure the Firewall Threat Defense device to send a particular message class to each type of output destination independently of the message list.

(Message lists do not apply to syslog messages for security events such as connection and intrusion events.)

Syslog message classes and associated message ID numbers

Note This topic does not apply to messages for security events (connection, intrusion, etc.)

You can use syslog message classes in two ways:

- Specify an output location for an entire category of syslog messages.
- Create a message list that specifies the message class.

Use the syslog message class to categorize syslog messages by type, such as features or functions of the device. For example, use the RIP class for RIP routing.

Syslog messages in the same class have the same three initial digits in their message ID numbers. For example, the syslog messages for the VPN client feature use ID numbers 611101 to 611323.

Most ISAKMP syslog messages include prepended objects that identify the tunnel. When available, these objects appear before the descriptive text of a syslog message. If the object is unknown when the syslog message is generated, the heading and value combination is omitted.

The objects are prefixed in this manner:

Group = *groupname*, Username = *user*, IP = *IP_address*

The term 'group' here refers to the tunnel-group configuration. The username is from the local database or AAA server. The IP address is the public IP address of the remote access client or Layer 2 peer.

See the message classes and the range of message ID numbers in each class in this table.

Table 76: Syslog message classes and associated message ID numbers

Class	Definition	Syslog Message ID Numbers
access-list*	Access Lists	106
application-firewall*	Application Firewall	415
auth	User Authentication	109, 113
botnet-traffic-filtering*	Botnet Traffic Filtering	338
bridge	Transparent Firewall	110, 220

*The management center web interface provisions these classes to facilitate creation of event lists. The device console does not display these classes.

Guidelines for logging

Restrictions for IPv6 logging

- IPv6 is supported. Syslog message can be sent using TCP or UDP.
- Ensure that the interface configured for sending syslogs is enabled, IPv6 capable, and the syslog server is reachable through the designated interface.
- You cannot use IPv6 for secure logging.

Syslog server configuration guidelines

- The syslog server must run a server program called syslogd. Windows includes a syslog server as part of its operating system.
- The syslog server operates based on the syslog-ng process of the firewall system. Do not use external configuration files, such as the *scwx.conf* file from SecureWorks. Because these files are not compatible with the device, using them causes parsing errors and the syslog-ng process fails.
- You can configure up to 16 syslog servers.
- Assign only one list or class to each syslog server and location.
- Do not configure Firewall Management Center as a primary syslog server. The Firewall Management Center can log some syslogs. However, it does not have adequate storage provision to accommodate large amounts of information from connection events for every sensor, especially when multiple sensors are used and all send syslogs.
- The syslog server should be reachable through the Firewall Threat Defense device. Configure the device to deny ICMP unreachable messages on the interface through which the syslog server is reachable, and to send syslogs to the same server. Enable logging for all severity levels. To prevent the syslog server from crashing, suppress the generation of syslogs 313001, 313004, and 313005.
- To view logs generated by the Firewall Threat Defense device, you must specify a logging output destination. If you enable logging without specifying a logging output destination, the Firewall Threat Defense device generates messages but does not save them to a location from which you can view them. You must specify each different logging output destination separately.
- The Firewall Threat Defense syslog supports one-way TLS for secure logging. It does not support client certificate authentication, trustpoint configuration for syslog, or mutual TLS (X.509 certificate authentication).

Interfaces for syslog configuration

- Determining the egress interface for the syslog:
  - If the specified management-only interface has management-access enabled, the management center will perform route table lookups and determine the egress interface (could be data or management) based on best routing logic.
  - If you configure a management-only interface as logging host, that does not have management-access enabled, the management center will use the interface regardless of routing table entries.

Thus, for the management center to always uses a dedicated management path for syslog traffic, configure the management interface without management-access, and then specify the interface in the logging host:

```
interface <management-interface>
management-only ----->Do not include management-access
logging host <management-interface> <syslog-server-ip>
```

- When the syslog rate exceeds 50,000 messages per second, ensure that a data interface is used as egress interface rather than a management interface.
- Configure the data interface as the syslog source interface for production monitoring and auditing. Use the management interface only for temporary testing. This approach ensures optimal syslog reliability and prevents rate-limiting on the management interface.

TCP and UDP connections for syslog

- If you use TCP as the transport protocol, the system opens 4 connections to the syslog server to ensure that messages are not lost. If you collect messages from many devices and the combined connection overhead is too much for the server, use UDP instead.
- The number of UDP connections for syslog is directly related to the number of CPUs on the hardware platform and the number of syslog servers you configure. At any point in time, there can be as many UDP syslog connections as there are CPUs times the number of configured syslog servers. The global UDP connection idle timeout applies to these sessions, and the default duration is two minutes. You can adjust this setting to close sessions more quickly, but the timeout applies to all UDP connections, not just syslog. This is the intended behavior.
- When the Firewall Threat Defense device sends syslogs via TCP, the connection takes about one minute to initiate after the syslogd service restarts.
- When the TCP logging host goes down, it takes approximately six minutes to change its connection status from *Connected* to *Not connected*. Logging relies on TCP to detect the channel state; until then, logging sends the logs through the channel. During this time, when you execute the **show log**, the output would display the TCP logging host as connected. Once the TCP channel is closed, the TCP logging host state is updated to *Not connected*.

Configure syslog logging for Firewall Threat Defense devices

This task enables you to configure syslog logging for Firewall Threat Defense devices, allowing you to monitor and manage system events efficiently.

Syslog logging helps track security events and system activity on your devices. If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages.

See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1058 for more information about platform settings that apply to security event syslog messages.

Before you begin

See requirements in Guidelines for logging, on page 1056.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **Syslog** from the table of contents.

Step 3 Click **Logging Setup** to enable logging, specify FTP server settings, and specify Flash usage. For more information, see Configure logging and basic settings, on page 1059.

Step 4 Click **Logging Destinations** to enable logging to specific destinations and to specify filtering on message severity level, event class, or on a custom event list. For more information, see Enable logging destinations, on page 1061.

You must enable a logging destination to see messages at that destination.

Step 5 Click **E-mail Setup** to specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages. For more information, see Configure syslog messages to be sent to an e-mail address, on page 1062.

Step 6 Click **Events List** to define a custom event list that includes an event class, a severity level, and an event ID. For more information, see Create a custom event list, on page 1063.

Step 7 Click **Rate Limit** to specify the volume of messages being sent to all configured destinations and define the message severity level to which you want to assign rate limits. For more information, see Configure syslog rate limits, on page 1064.

Step 8 Click **Syslog Settings** to specify the logging facility, enable the inclusion of a time stamp, and enable other settings to set up a server as a syslog destination. For more information, see Configure syslog settings, on page 1065.

Step 9 Click **Syslog Servers** to specify the IP address, protocol used, format, and security zone for the syslog server that is designated as a logging destination. For more information, see Configure a syslog server, on page 1066.

After you complete these steps, your Firewall Threat Defense device sends system events to the specified destinations for monitoring and analysis.

Firewall Threat Defense platform settings that apply to security event syslog messages

Security events include connection, Security Intelligence, intrusion, and file and malware events. Some syslog settings configured on the **Syslog** page and its tabs apply to syslog messages for security events. However, most settings only apply to messages for events related to system health and networking. This reference lists the settings that apply to syslog messages for security events.

Settings that apply to syslog messages for security events:

- **Logging Setup** tab:
  - **Send syslogs in EMBLEM format**
- **Syslog Settings** tab:
  - **Enable Timestamp on Syslog Messages**
  - **Timestamp Format**
  - **Enable Syslog Device ID**

- **Syslog Servers** tab:
  - All options on the **Add Syslog Server** form and the list of configured servers.

Configure logging and basic settings

Enable logging and configure syslog settings so the system generates and manages logs for data plane events. This setup ensures log data is archived and available for analysis or reporting.

Perform this task when you need to generate syslog messages for data plane events and manage log storage on your device. You can manipulate saved logging data. You can also specify actions for certain syslog messages, extract data for reporting, or track statistics using scripts.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1058.

Before you begin

- Determine where logs should be stored, such as an FTP server or flash memory.
- Understand the desired logging level (critical, alerts, emergencies, errors, etc)
- Identify if logging should be enabled on standby or failover units.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Logging Setup** in your device's configuration interface.

Step 3 Enable logging and configure basic logging settings.

- **Enable Logging**—Turns on the data plane system logging.
- **Enable Logging on the Failover Standby Unit**—Turns on logging for the standby device, if available.
- **Send syslogs in EMBLEM format**—Enables EMBLEM format logging for every logging destination. If you enable EMBLEM, you must use the UDP protocol to publish syslog messages. EMBLEM is not compatible with TCP.

  The EMBLEM syslog format is a Cisco-specific convention that is built upon the RFC 3164 and RFC 5424 standards. When EMBLEM is enabled, the syslog message prints a colon (:) after the <PRI> field, which differs from the RFC 5424 format.

Note Syslog messages in RFC5424 format, typically displays the priority value (PRI). However, in Firewall Management Center, if you want to display the PRI value in the syslog messages of the managed Firewall Threat Defense device, ensure to enable the EMBLEM format. Also, the device ID does not appear in EMBLEM-formatted syslog messages.

- **Send debug messages as syslogs**—Redirects debug trace output to the syslog. The syslog message number is 711001 and the default logging level is set to debug. To view these messages, ensure logging is enabled at the console and configured for the debug syslog message number and level.
- **Memory Size of Internal Buffer**—Specify the size of the internal buffer to which syslog messages are saved if the logging buffer is enabled. When the buffer fills up, it is overwritten. The default is 4096 bytes. The range is 4096 to 52428800 bytes.

Step 4 (Optional) Configure the syslog message logging to the Firewall Management Center.

a) Select **All Logs** to send supported troubleshooting syslog messages that meet the selected severity.

b) Select **VPN Logs** to send supported VPN troubleshooting syslog messages that meet the selected severity.

a) Choose the syslog severity level for the logging messages in the **Logging Level** drop-down list.

- The logging level for **All Logs** is set to **critical** by default. You can choose to send syslog messages with severity levels **critical**, **alerts**, or **emergencies** to the Firewall Management Center.
- The logging level for the VPN messages is set to **errors** by default.

  VPN troubleshooting syslogs can add excessive load on the Firewall Management Center. Hence, enable this option with caution. Also, when you configure a device with site-to-site or remote access VPN, it automatically enables sending VPN syslogs to the management center by default. We recommend that you limit the logging level to **error** and above to restrict the excessive flow of syslogs to the Firewall Management Center, especially in case of RAVPN, where multiple devices are involved.

For information on the levels, see Syslog message severity levels, on page 1051.

Step 5 (Optional) Save log buffer contents to an FTP server before the buffer is overwritten.

- Enable **FTP Server Buffer Wrap** and enter the necessary destination information in the following fields.
- **IP Address**—Select the host network object that contains the IP address of the FTP server.
- **User Name**—Enter the username to use when connecting to the FTP server.
- **Path**—Enter the path, relative to the FTP root, where the buffer contents should be saved.
- **Password/ Confirm**—Enter and confirm the password used to authenticate the username to the FTP server.

Step 6 (Optional) Save log buffer contents to flash memory before overwriting.

- Check the **Flash** checkbox
- Specify **Maximum flash to be used by logging (KB)** (range: 4-8044176 KB).
- Specify **Minimum free space to be preserved (KB)** (range: 0-8044176 kilobytes.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Logging is enabled and syslog messages are generated and stored based on your configuration. Log data is archived as specified and is accessible for further analysis or reporting.

Enable logging destinations

Enable logging destinations to ensure that syslog messages are received at the specified destination. This task allows you to control which messages are sent by applying message filters to each destination.

To see messages at a logging destination, enable the destination and specify a message filter.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1058.

Before you begin

Before you begin, ensure you have access to the system and the necessary permissions to configure logging destinations.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Logging Destinations**.

Step 3 Click **Add** to enable a destination and apply a logging filter, or edit an existing destination.

Step 4 In the **Logging Destinations** dialog box, select a destination and configure the filter for that destination:

a) Choose the destination to enable in the **Logging Destination** drop-down list. You can create one filter for each destination. Examples include Console, E-Mail, Internal buffer, SNMP trap, SSH Sessions, and Syslog servers.

Note Console and SSH session logging works in the diagnostic CLI only. Enter **system support diagnostic-CLI**.

b) In **Event Class**, choose the filter that will apply to all classes not listed in the table.

You can configure these filters:

- **Filter on severity** —Select the severity level. Messages at this level or higher are sent to the destination
- **Use Event List** —Select the event list that defines the filter. You create these lists on the **Event Lists** page.
- **Disable Logging** —Prevents messages from being sent to this destination.

c) To create filters for each event class, click **Add** for a new filter or edit an existing filter. Select the event class and severity level to limit messages in that class. Click **OK** to save the filter.

For an explanation of the event classes, see Syslog message classes and associated message ID numbers, on page 1053.

d) Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, the selected logging destinations will receive syslog messages according to the filters you have configured.

Configure syslog messages to be sent to an e-mail address

Enable syslog messages to be delivered as e-mails to designated recipients so administrators receive important system notifications directly through e-mail.

You can set up a list of recipients for syslog messages to be sent as e-mails.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1058.

Before you begin

- Configure an SMTP server on the platform settings page
- Configure logging and basic settings, on page 1059
- Setup Email as the Logging Destination

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Email Setup**.

Step 3 Specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages.

Step 4 Click **Add** to enter a new e-mail address recipient of the specified syslog messages.

Step 5 Set the desired severity level for syslog messages for each recipient.

The severity filter ensures only messages of the specified level and higher are sent via e-mail. For information on the levels, see Syslog message severity levels, on page 1051.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Syslog messages are sent as e-mails to the specified recipients according to the configured severity level.

Create a custom event list

Create a custom event list to control which syslog messages are sent to a logging destination. This allows you to filter messages based on event class, severity, and message identifier for more granular control.

An event list is a custom filter you can apply to a logging destination, allowing greater control over which messages are sent. Normally, you filter messages for a destination based solely on severity. Using an event list, you can fine-tune filters using event class, severity, and message ID.

Creating a custom event list is a two-step process. You create a custom list in the **Event Lists**, and then use the event list to define the logging filter for the various types of destination, in the **Logging Destinations**.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1058.

Before you begin

Ensure you have access to the system where syslog event lists can be configured.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Events List**.

Step 3 Click **Add** to create a new list or click an existing list to edit.

a) Enter a unique name for the event list in the **Name** field; avoid spaces.

b) Set criteria to filter messages by severity or event class, select the **Severity/Event Class** tab and add or edit entries.

For information on the available classes see Syslog message classes and associated message ID numbers, on page 1053.

For information on the levels, see Syslog message severity levels, on page 1051.

Certain event classes do not apply to devices in transparent mode. If you configure these options, the system does not use or deploy them.

c) To identify messages specifically by message ID, select the **Message ID** and add or edit the IDs.

You can enter a range of IDs using a hyphen, for example, 100000-200000. Each message ID you enter must contain six digits. For information on how the initial three digits map to features, see Syslog message classes and associated message ID numbers, on page 1053.

For specific message numbers, see Cisco ASA Series Syslog Messages.

d) Click **OK** to save the event list.

Step 4 Click **Logging Destinations** and add or edit the destination that should use the custom event list filter.

See Enable logging destinations, on page 1061.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

The system creates the custom event list and applies it to the logging destination you select.

Configure syslog rate limits

Limit the rate at which syslog messages are generated, reducing log flooding and ensuring that important messages are not lost.

Syslog message generation can overwhelm logging systems if not managed properly. Configure rate limits for severity levels or specific message IDs to ensure efficient log management. When limits set for severity level and message ID conflict, the message ID limit takes precedence.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1058.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Rate Limit**.

Step 3 To limit message generation by severity level, click **Logging Level** > **Add**, then configure these options:

- **Logging Level**—Specify the severity level for the rate limit. For information on the levels, see Syslog message severity levels, on page 1051.
- **Number of messages**—The maximum number of messages of the specified type allowed in the specified time period.
- **Interval**—The number of seconds before the rate limit counter resets.

Step 4 Click **OK**.

Step 5 To limit message generation by syslog message ID, click **Syslog Level** > **Add**, then configure these options:

- **Syslog ID**—Specify the syslog message ID to be rate limited. For specific message numbers, see Cisco ASA Series Syslog Messages.
- **Number of messages**—Enter the maximum number of messages allowed in the specified interval.
- **Interval**—Set the interval (in seconds) for the rate limit counter to reset.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Syslog message generation is limited based on configured severity levels or message IDs, preventing excessive log messages and supporting efficient log management.

Configure syslog settings

Configure syslog settings to manage how syslog messages are generated and sent to external syslog servers. You can specify the facility code, timestamp, device ID, and control message severity and suppression.

General syslog settings let you choose what information is included in syslog messages sent to syslog servers. This information includes the facility code, timestamp, device ID, severity levels, and message suppression. If you configure devices to send syslog messages about security events (such as connection and intrusion events), some settings do not apply to messages that relate to security events. See *Threat Defense Platform Settings That Apply to Security Event Syslog Messages* in the *Cisco Secure Firewall Management Center Administration Guide*.

Before you begin

Make sure you have access to the device and the permissions needed to change syslog settings.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Syslog Settings**.

Step 3 Choose a system log facility from the **Facility** list as required by your syslog server.

Most UNIX systems use the default LOCAL4(20). Change the facility if your network devices use the same codes. In most cases, you do not need to set the facility value for security event logs.

Step 4 Select the **Enable timestamp on each syslog message** check box to include the date and time a message was generated in the syslog message.

Step 5 Select the desired **Timestamp Format**:

- **Legacy (MMM dd yyyy HH:mm:ss)**: Default format without a timezone (always UTC).
- **RFC 5424 (yyyy-MM-ddTHH:mm:ssZ)**: Uses ISO 8601 with “Z” indicating UTC.

Step 6 To add a device identifier at the start of messages, check the **Enable Syslog Device ID** check box and select the identifier type:

- **Interface**—Use the IP address of a specific interface.

Note VTI tunnel interfaces are not supported for Syslog.

- **User Defined ID**—Enter a custom text string (up to 16 characters).
- **Host Name**—Use the device’s hostname.

Step 7 Use the Syslog Message table to adjust severity or suppress messages:

Change a message's severity level or disable its generation if necessary. By default, syslog entries for NetFlow are enabled and appear in the table.

a) To suppress redundant messages due to NetFlow, select **Netflow Equivalent Syslogs**.

This adds the messages to the table as suppressed messages.

Note If any of these syslog equivalents are already in the table, your existing rules are not overwritten.

b) To add a rule, click **Add**.
c) Select the message number (Syslog ID) to change, from the **Syslog ID** drop-down list.
d) Choose the new severity level from the **Logging Level** drop-down list or select **Suppressed** to disable the generation of the message. Usually, you do not change both the severity level and disable the message. However, you can modify both fields if you want.
e) Click **OK** to add the rule to the table.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Configure a syslog server

This task enables you to configure a syslog server for your device, allowing you to collect and monitor system-generated messages for security and operational visibility.

To configure a syslog server to handle messages generated from your system, perform this task.

If you want this syslog server to receive security events such as connection and intrusion events, see also Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1058.

Note In version 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, you must use separate Platform Settings policies for merged and unmerged devices. This requirement also applies to version 7.3 and earlier, and to some Firewall Threat Defense devices upgraded to version 7.4.

Before you begin

- See requirements in Guidelines for logging, on page 1056.
- Make sure your devices can reach your syslog collector on the network.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Syslog Server**.

Step 3 Check the **Allow user traffic to pass when TCP syslog server is down (Recommended)** check box, to allow traffic if any syslog server that is using the TCP protocol is down.

Note

- This option is enabled by default. Unless required, we recommend that you allow connections through the threat defense device when the external TCP syslog server is unreachable by the device.
- When the **Allow user traffic to pass when TCP syslog server is down** option is disabled in Firewall Management Center version 6.2.x or earlier, it remains in the Disabled state even after upgrading to version 6.3 or later. You must manually enable this option.
- If this option is disabled and more than one TCP syslog server is configured on the device, user traffic is allowed if at least one server is reachable by thethreat defense device. This option only blocks traffic when none of the configured TCP syslog servers are reachable. The device generates a syslog message that describes the root cause of denied traffic.

  ```
  %FTD-3-414003: TCP Syslog Server intf : IP_Address /port not responding. New connections
  are denied based on logging permit-hostdown policy
  ```

Step 4 In the **Message queue size (messages)** field, enter the queue size for storing syslog messages on the security appliance when the syslog server is busy. The minimum is 1 message. The default is 512. Specify 0 to allow an unlimited number of messages to be queued (subject to available block memory).

If the number of messages exceeds the configured queue size, the excess messages are dropped, resulting in missing syslog entries. To determine the ideal queue size, you need to identify the available block memory. Use the **show blocks** command to know the current memory utilization. For more information on the command and its attributes, see *Cisco Secure Firewall ASA Series Command Reference Guide*. Contact Cisco TAC for assistance.

Step 5 Click **Add** to add a new syslog server.

a) In the **IP Address** drop-down list, select a network host object containing the IP address of the syslog server.

b) Choose the protocol, either TCP or UDP, and enter the port number used for communication between the Firewall Threat Defense device and the syslog server.

UDP is faster and uses fewer resources than TCP on the device.

The default port for UDP is 514. You must manually configure port 1470 for TCP. Valid non-default port values for either protocol are 1025 through 65535.

c) Check the **Log messages in Cisco EMBLEM format (UDP only)** check box to specify whether to log messages in Cisco EMBLEM format (available only if UDP is selected as the protocol).

The EMBLEM syslog format is a Cisco-specific convention that is built upon the RFC 3164 and RFC 5424 standards. Hence, when EMBLEM is enabled, the syslog message prints colon (:) after <PRI> field.

Note Syslog messages in RFC5424 format typically displays the priority value, referred to as PRI. However, in Firewall Management Center, only when you enable logging in Cisco EMBLEM format, the PRI value in the syslog messages of the managed Firewall Threat Defense is displayed. Also, the device ID does not appear in EMBLEM-formatted syslog messages.

d) Check the **Enable Secure Syslog** check box to encrypt the connection between the device and server using SSL or TLS over TCP.

Note You must select TCP as the protocol and its port value ranging between 1025 and 65535 to use this option. Upload the certificate required to communicate with the syslog server on the **Devices** > **Certificates** page. Then, upload the certificate from the Firewall Threat Defense device to the syslog server to complete the secure relationship and allow it to decrypt the traffic. The **Enable Secure Syslog** option is not supported on the device Management interface.

e) Select **Device Management Interface** or **Security Zones or Named Interfaces** to communicate with the syslog server.

- **Device Management Interface**: Send syslogs out of the Management interface. We recommend that you use this option when configuring syslog on Snort events.

Note The **Device Management Interface** option does not support the **Enable Secure Syslog** option.

- **Security Zones or Named Interfaces**: Select the interfaces from the list of **Available Zones** and click **Add**. You can also add virtual-router-aware interfaces.

Important The Firewall Threat Defense data plane (Lina) syslog messages cannot be sent out through the diagnostic interface. Configure other interfaces or the Management interface (Br1/Management0) to send out the data plane syslog messages.

f) Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Configure timeouts

Configure timeout values for console sessions and protocol connections in a Threat Defense policy to manage session durations and optimize device resource usage.

You can set the global idle timeout durations for the connection and translation slots of various protocols. If the slot has not been used for the idle time specified, the resource is returned to the free pool.

You can also set a timeout for console sessions on the device.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Timeouts**.

Step 3 Configure the timeouts you want to change.

For any setting, select **Custom** to specify your own value or **Default** to use the system default value. In most cases, the maximum timeout is 1193 hours.

You can disable some timeouts by selecting **Disable**.

- **Console Timeout**—The idle time until a connection to the console is closed, range is 0 or 5 to 1440 minutes. The default is 0, which means the session does not time out. If you change the value, existing console sessions will continue to use the previous timeout value. The updated timeout will apply only to new connections.
- **Translation Slot (xlate)**—The idle time until a NAT translation slot is freed. This duration must be at least 1 minute. The default is 3 hours.
- **Connection (Conn)**—The idle time until a connection slot is freed. This duration must be at least 5 minutes. The default is 1 hour.
- **Half-Closed**—The idle time until a TCP half-closed connection closes. A connection is considered half-closed if both the FIN and FIN-ACK have been seen. If only the FIN has been seen, the regular connection timeout applies. The minimum is 30 seconds. The default is 10 minutes.
- **UDP**—The idle time until a UDP connection closes. This duration must be at least 1 minute. The default is 2 minutes.
- **ICMP**—The idle time after which general ICMP states are closed. The default (and minimum) is 2 seconds.
- **RPC/Sun RPC**—The idle time until a SunRPC slot is freed. This duration must be at least 1 minute. The default is 10 minutes.

  In a Sun RPC-based connection, if the parent connection is deleted or times out, a new child connection might not be treated as part of the parent–child relationship. As a result, the new connection could be evaluated according to the system's policy or rules. After the parent connection times out, existing child connections remain valid only until their own timeout value is reached.
- **H.225**—The idle time until an H.225 signaling connection closes. The default is 1 hour. To close a connection immediately after all calls are cleared, a timeout of 1 second (0:0:1) is recommended.
- **H.323**—The idle time after which H.245 (TCP) and H.323 (UDP) media connections close. The default (and minimum) is 5 minutes. Because the same connection flag is set on both H.245 and H.323 media connections, the H.245 (TCP) connection shares the idle timeout with the H.323 (RTP and RTCP) media connection.
- **SIP**—The idle time until a SIP signaling port connection closes. This duration must be at least 5 minutes. The default is 30 minutes.

- **SIP Media**—The idle time until a SIP media port connection closes. This duration must be at least 1 minute. The default is 2 minutes. The SIP media timer is used for SIP RTP/RTCP with SIP UDP media packets, instead of the UDP inactivity timeout.
- **SIP Disconnect**—The idle time after which SIP session is deleted if the 200 OK is not received for a CANCEL or a BYE message, between 0:0:1 and 0:10:0. The default is 2 minutes (0:2:0).
- **SIP Invite**—The idle time after which pinholes for PROVISIONAL responses and media xlates will be closed, between 0:1:0 and 00:30:0. The default is 3 minutes (0:3:0).
- **SIP Provisional Media**—The timeout value for SIP provisional media connections, between 1 and 30 minutes. The default is 2 minutes.
- **Floating Connection**—When multiple routes exist to a network with different metrics, the system uses the one with the best metric at the time of connection creation. If a better route becomes available, then this timeout lets connections be closed so a connection can be reestablished to use the better route. The default is 0 (the connection never times out). To make it possible to use better routes, set the timeout to a value between 0:0:30 and 1193:0:0. This timer does not apply to connections through virtual tunnel interfaces (VTI). If a connection through a VTI gets stuck, you must manually clear it.
- **Xlate PAT**—The idle time until a PAT translation slot is freed, between 0:0:30 and 0:5:0. The default is 30 seconds. You may want to increase the timeout if upstream routers reject new connections using a freed PAT port because the previous connection might still be open on the upstream device.
- **TCP Proxy Reassembly**—The idle timeout after which buffered packets waiting for reassembly are dropped, between 0:0:10 and 1193:0:0. The default is 1 minute (0:1:0).
- **ARP Timeout**—The number of seconds between ARP table rebuilds, from 60 to 4294967. The default is 14,400 seconds (4 hours).

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

The configured timeout values are applied to the Threat Defense policy. Sessions and protocol connections will now use the specified timeout durations after you deploy the policy.

Synchronize time on FTD devices

Use a Network Time Protocol (NTP) server to synchronize the clock settings on your devices. We recommend you configure all Firewall Threat Defenses managed by a Firewall Management Center to use the same NTP server as the Firewall Management Center. Depending on the platform and configuration, the Firewall Threat Defense synchronizes either directly with the configured NTP server or through Firewall Management Center. If the Firewall Threat Defense's configured NTP servers are not reachable for any reason, it synchronizes its time with the Firewall Management Center.

The device supports NTPv4.

Note If you are deploying Firewall Threat Defense on the Firepower 4100/9300 chassis, you must configure NTP on the Firepower 4100/9300 chassis so that Smart Licensing will work properly and to ensure proper timestamps on device registrations. You should use the same NTP server for the Firepower 4100/9300 chassis and the Firewall Management Center.

Before you begin

- If your organization has one or more NTP servers that your Firewall Threat Defense can reach, use the same NTP server or servers for your devices that you have configured for Time Synchronization on the **Administration** > **Configuration** page on your Firewall Management Center.
- If you selected **Use the authenticated NTP server only** when configuring NTP server or servers for the Firewall Management Center, for your devices use only the NTP server or servers that are configured to authenticate with the Firewall Management Center. (The managed devices will use the same NTP servers as the Firewall Management Center, but their NTP connections will not use authentication.)
- If your device cannot reach an NTP server or your organization does not have one, use the **Via NTP FROM Management Center** option as discussed in this procedure.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Time Synchronization**.

Step 3 Configure one of these clock options:

- **Via NTP FROM Management Center**: (Default). The managed device gets time FROM the NTP servers you configured for the Firewall Management Center (except for authenticated NTP servers) and synchronizes time with those servers directly. However, if any of these are true, the managed device synchronizes time FROM the Firewall Management Center:
  - The Firewall Management Center's NTP servers are not reachable by the device.
  - The Firewall Management Center has no unauthenticated servers.

Note NTP synchronization behavior and NTP status output can differ between Firewall Threat Defense Virtual devices and Secure Firewall 3100 appliances when the devices are configured to synchronize time through Firewall Management Center.

- Firewall Threat Defense Virtual devices synchronize directly with the NTP servers configured on Firewall Management Center. If the configured NTP servers become unreachable, the device uses Firewall Management Center as the fallback NTP source.
- Secure Firewall 3100 appliances synchronize with Firewall Management Center instead of directly synchronizing with the external NTP servers configured on Firewall Management Center. In NTP status output, Firewall Management Center can appear as 127.0.0.2.
- On Secure Firewall 3100 appliances, the **ntpq -pn** command can display 127.0.0.2 as the active NTP source, indicating synchronization with Firewall Management Center rather than with external NTP servers.

Example:

```
# ntpq -pn
remote           refid      st t when poll reach   delay   offset   jitter
==============================================================================
127.0.0.2       .FMC.      16 u   10   64   377    0.123    0.045    0.010
```

When you configure Secure Firewall 3100 appliances to synchronize directly with NTP servers instead of synchronizing through Firewall Management Center, and the configured NTP servers become unreachable, the appliance falls back to its local system clock. In this case, the appliance does not use Firewall Management Center as the fallback NTP source.

Consider these platform-specific differences when interpreting show **ntp** and **ntpq -pn** output during NTP validation and troubleshooting.

- **Via NTP FROM**: If your Firewall Management Center is using NTP servers on the network, select this option and enter the fully-qualified DNS name (such as NTP.example.com), or IPv4 or IPv6 address, of the same NTP servers you specified in **Administration** > **Configuration** > **Time Synchronization**. If the NTP servers are not reachable, the Firewall Management Center acts as an NTP server.

When multiple NTP servers are configured, the device uses the NTP server that is deemed appropriate based on the criteria defined in RFC. Thus, the status "Being used" for a specific NTP server indicates that the server is currently used by the device.

Step 4 Click **Save**.

After completing these steps, the Firewall Threat Defense Virtual device synchronizes its clock with the configured NTP server, Management Center, or the local system clock, depending on platform behavior and configuration.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Configure a time zone for a device

By default, your device uses the UTC time zone. To set a different time zone for the device, use this procedure.

The time zone you specify is used only in policies that use time-based policy application.

Procedure

Step 1 Select **Devices** > **Platform Settings** and create or edit a Firewall Threat Defense policy.

You can also create time zone objects from the **Objects** > **Time Zone** page.

Step 2 Create a new time zone object by clicking +.

Step 3 Select the time zone.

Step 4 Click **Save**.

What to do next

- Create time range objects, select applicable time ranges in access control and prefilter rules, and assign the parent policies to devices associated with the correct time zone.
- Deploy configuration changes; see Deploy configuration changes, on page 193.

Configure UCAPL/CC compliance

Configure Unified Capabilities Approved Products List (UCAPL) or Common Criteria (CC) compliance to ensure your Secure Firewall Threat Defense device meets security certifications and export-controlled feature requirements.

Use this task when you need to enable security certifications compliance for your device. This is required for export-controlled features and may be necessary for regulatory or organizational compliance.

For more information about this setting and how to enable it for the Firewall Management Center, see the *Cisco Secure Firewall Management Center Administration Guide*.

Caution After you enable this setting, disabling it is not possible. To return the appliance to standard mode, reimage the appliance.

Before you begin

- Secure Firewall Threat Defense devices cannot use an evaluation license; your Smart Software Manager account must be enabled for export-controlled features.
- Secure Firewall Threat Defense devices must be deployed in routed mode.
- You must have administrative privileges to perform this task.

- Security certifications compliance mode cannot be changed if the Firewall Threat Defense device is in high availability. Change the security certifications compliance mode before you create the high availability pair.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **UCAPL/CC Compliance**.

Step 3 To *permanently* enable security certifications compliance on the appliance, you have two choices:

- To enable security certifications compliance in Common Criteria mode, choose **CC** from the drop-down list.
- To enable security certifications compliance in Unified Capabilities Approved Products List (UCAPL) mode, choose **UCAPL** from the drop-down list.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing these steps, your device operates in the selected compliance mode (UCAPL or CC), and the policy is enforced once deployed.

Configure a performance profile

Configure the performance profile to control how CPU cores are allocated between the data plane and Snort processes on supported devices. This configuration optimizes device performance for VPN, improves intrusion prevention, or balances the workload.

The performance profile determines how the CPU cores on the device are assigned to two of the main system processes: the data plane (Lina) and Snort. The data plane handles VPN connections, routing, and basic layer 3/4 processing. Snort provides advanced inspection for intrusion and malware prevention, URL filtering, application filtering, and other deep packet inspection features.

If you use both basic and advanced features, keep the performance profile unchanged. The system is designed to provide a balanced assignment of cores to these processes. This assignment differs based on the hardware model.

However, if you use the device primarily for VPN, or for intrusion and other advanced inspection, you can skew the performance profile so that more cores are assigned to the more heavily used features. This change can improve system performance.

Before you begin

- These settings apply to systems running release 7.3+ only.
- Performance profile is supported on these device types:
  - Firepower 4100/9300

- Secure Firewall 3100/4200 (7.4+)
- Secure Firewall 6100(10.0+)
- Secure Firewall Threat Defense Virtual

- Changing the performance profile is not supported on units in a cluster or high-availability group, or those configured for multi-instance.
- The minimum number for core allocation is 2. Cores are assigned in even numbers based on the selected performance profile.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Performance Profile**.

Step 3 Select a profile:

- **Default**—This is the recommended setting and is the best option if you configure both VPN and intrusion inspection.
- **VPN Heavy with prefilter fastpath**—If you primarily use the device as a VPN endpoint or headend, and you configure rules in the prefilter policy to fastpath VPN traffic, you can choose this option to assign the majority of CPU cores to the data plane. The allocation is 90% data plane, 10% Snort.
- **VPN Heavy with inspection**—If you primarily use the device as a VPN endpoint or headend, but do not use the prefilter policy to fastpath VPN traffic, you can choose this option to assign the majority of CPU cores to the data plane. This option assumes that you leave intrusion inspection, URL filtering, and other advanced functions that use Snort, to a different device in the network. The allocation is 60% data plane, 40% Snort.
- **IPS Heavy**—If you do not configure VPN, but you do use the device for intrusion prevention, you can choose this option to assign the majority of CPU core to the Snort process. The allocation is 30% data plane, 70% Snort.

Step 4 Click **Save**.

Step 5 Deploy the policy to apply your configuration.

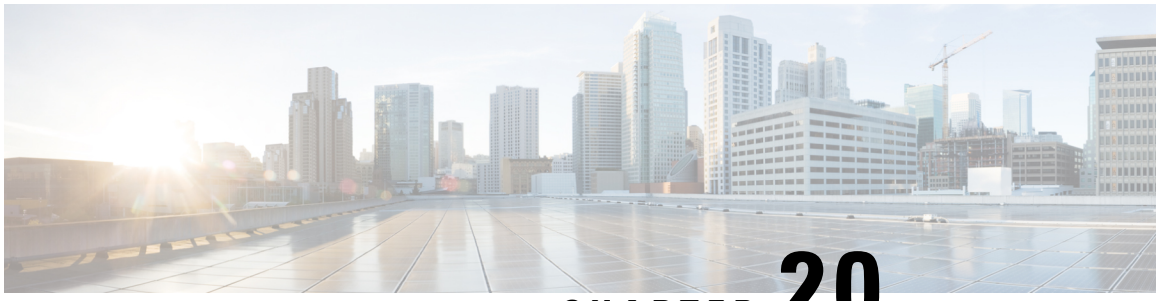
Step 6 After deployment completes, reboot each affected device to apply the new core assignments.

After completing these steps, the device will use the selected performance profile and allocate CPU cores according to your configuration. The new core assignments take effect after you reboot the device.

History for platform settings

This reference provides a historical overview of feature additions, changes, and removals for platform settings in Secure Firewall releases. Use this information to track platform settings support and modifications across software versions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Device management services supported on user-defined VRF interfaces	7.6.0	7.6.0	Device access management is now supported on user-defined Virtual Routing and Forwarding (VRF) interfaces. See: Platform Settings
View diagnostic syslog messages in the Unified Events table.	7.6.0	Any	You can now configure Firewall Threat Defense devices to send all device syslogs to your Firewall Management Center. Go to the Firewall Threat Defense platform settings policy assigned to your managed devices and select **All Logs** under the **Logging to Secure Firewall Management Center** setting. Once you have enabled the logging settings, you can view the device syslogs as a new event type called **Troubleshoot Events** in the **Unified Events** table.
Support for Firepower Platform Settings policy is removed.	7.6.0	7.6.0	The provision to manage a Firepower Platform Settings policy is removed.
Device management services supported on user-defined VRF interfaces	7.4.1	7.4.1	Device management services configured in the Firewall Threat Defense platform settings (NetFlow, SSH access, SNMP hosts, syslog servers) are now supported on user-defined Virtual Routing and Forwarding (VRF) interfaces. Platform restrictions: Not supported with container instances or clustered devices.
Chassis platform settings for the Secure Firewall 3100.	7.4.1	7.4.1	New platform settings for multi-instance chassis on the Secure Firewall 3100. New/modified screens: • **Devices** > **Platform Settings** > **Add** > **Chassis Platform Settings** • **Devices** > **Platform Settings** > **Edit** > **Chassis Platform Settings** > **DNS** • **Devices** > **Platform Settings** > **Edit** > **Chassis Platform Settings** > **SSH** • **Devices** > **Platform Settings** > **Edit** > **Chassis Platform Settings** > **Time Synchronization** • **Devices** > **Platform Settings** > **Edit** > **Chassis Platform Settings** > **Time Zones** • **Devices** > **Platform Settings** > **Edit** > **Chassis Platform Settings** > **Syslog** Supported platforms: Secure Firewall 3100
Performance profile support for the Secure Firewall 3100/4200.	7.4.0	7.4.0	The performance profile settings available in the platform settings policy now apply to Secure Firewall 3100/4200 devices.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Loopback interface support for DNS, HTTP, ICMP, NetFlow, SNMP and SSH.	7.4.0	7.4.0	You can create a loopback interface and use it for: • DNS • HTTP • ICMP • NetFlow • SNMP • SSH New/modified screens: • **Devices** > **Platform Settings** > **DNS** > **DNS Settings** **Devices** > **Platform Settings** > **HTTP Access** > **Add** **Devices** > **Platform Settings** > **ICMP Access** > **Add** • **Devices** > **Platform Settings** > **Network flow** > **Add Collector** • **Devices** > **Platform Settings** > **SNMP** > **Hosts** > **Add** • **Devices** > **Platform Settings** > **SSH Access** > **Add**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Merged Management and Diagnostic interfaces.	7.4.0	7.4.0	For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available. If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically. If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Note that support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. Merged mode also changes the behavior of AAA traffic to use the data routing table by default. The management-only routing table can now only be used if you specify the management-only interface (including Management) in the configuration. For platform settings, this means: • You can no longer enable HTTP, ICMP, or SMTP for Diagnostic. • For SNMP, you can allow hosts on Management instead of Diagnostic. • For Syslog servers, you can reach them on Management instead of Diagnostic. • If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices. • DNS lookups no longer fall back to the management-only routing table if you do not specify interfaces. New/modified screens: • **Devices** > **Device Management** > **Interfaces** New/modified commands: **show management-interface convergence**
Performance profile for CPU core allocation.	7.3.0	7.3.0	You can adjust the percentage of system cores assigned to the data plane and Snort to adjust system performance. The adjustment is based on your relative use of VPN and intrusion policies. If you use both, leave the core allocation to the default values. If you use the system primarily for VPN (without applying intrusion policies), or as an IPS (with no VPN configuration), you can skew the core allocation to the data plane (for VPN) or Snort (for intrusion inspection). We added the **Performance Profile** page to the platform settings policy.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
TLS 1.3 in Remote Access VPN.	7.3.0	7.3.0	You can now use TLS 1.3 to encrypt remote access VPN connections. Use threat defense platform settings to specify that the device must use TLS 1.3 protocol when acting as a remote access VPN server. TLS 1.3 adds support for the following ciphers: • TLS_AES_128_GCM_SHA256 • TLS_CHACHA20_POLY1305_SHA256 • TLS_AES_256_GCM_SHA384 This feature requires Cisco Secure Client, Version 5.0 and above. New/modified screens: **Devices** > **Platform Settings** > **New Policy** > **Add/Edit Threat Defense Settings** > **SSL** > **TLS version**
Multiple DNS server groups for resolving DNS requests.	7.2.0	7.2.0	You can configure multiple DNS groups for the resolution of DNS requests from client systems. You can use these DNS server groups to resolve requests for different DNS domains. For example, you could have a catch-all default group that uses public DNS servers, for use with connections to the Internet. You could then configure a separate group to use internal DNS servers for internal traffic, for example, any connection to a machine in the example.com domain. Thus, connections to an FQDN using your organization's domain name would be resolved using your internal DNS servers, whereas connections to public servers use external DNS servers. We changed the **Platform Settings** > **DNS** page.
Network object support for HTTP, ICMP, and SSH platform settings.	7.1.0	7.1.0	You can now use network object groups that contain network objects for hosts or networks when configuring the IP addresses in the Threat Defense Platform Settings policy.
Support to specify trusted DNS servers.	7.1.0	7.1.0	The option to specify DNS servers that you can trust for address resolution while using direct internet access was introduced. We added a tab for configuring the trusted DNS servers when configuring direct internet access: **Devices** > **Platform Settings** > **DNS** > **Trusted DNS Servers**.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Platform settings using the MD5 authentication algorithm or DES encryption for SNMPv3 users can not be deployed to Firewall Threat Defense devices running Versions 7.0+.	7.0.0	7.0.0	The MD5 authentication algorithm and DES encryption for SNMPv3 users on Firewall Threat Defense were deprecated in Version 6.5. If your deployment includes SNMPv3 users using the MD5 authentication algorithm or DES encryption that were created using Version 6.4 or earlier, you can continue to use those users for Firewall Threat Defense devices running Version 6.7 or earlier. However, you cannot edit those users and retain the MD5 or DES settings, and you cannot create new users with the MD5 or DES settings. If your Firewall Management Center manages any Firewall Threat Defenses running Versions 7.0+, deploying a platform settings policy with SNMP v3 users using the MD5 authentication algorithm or DES encryption to those Firewall Threat Defenses will fail. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Hosts**
Specify SHA224 or SHA384 for SNMPv3 users' authorization algorithm.	7.0.0	7.0.0	You can now select SHA224 or SHA384 for SNMPv3 users' authorization algorithm. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Users**
Specify time zone for device.	6.6.0	6.6.0	Specify a local time zone for a managed device, for use in time-based policy application. New/modified screens: **Devices** > **Platform Settings** > **Time Zone**
Specify the Management interface for SNMP communication.	6.6.0	6.6.0	You can now select the Management interface for communication between the device and the SNMP management station. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Hosts**
Specify SHA256 for SNMPv3 users' authorization algorithm.	6.6.0	6.6.0	You can now select SHA256 for SNMPv3 users' authorization algorithm. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Users**
DES encryption and the MD5 authentication algorithm for SNMPv3 users on Firewall Threat Defense have been deprecated.	6.5.0	Any	We recommend that you not use the MD5 authentication algorithm or DES encryption for SNMPv3 users on Firewall Threat Defense devices, as these options have been deprecated. If your deployment includes SNMPv3 users using the MD5 authentication algorithm or DES encryption that were created using a Version 6.4 or earlier, you can continue to use those users. However, you cannot edit those users and retain the MD5 or DES settings, and you cannot create new users with the MD5 or DES settings. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Users**
Allow user traffic to pass when TCP syslog server is down.	6.3.0	6.3.0	We recommend that you allow connections through the threat defense device when the external TCP syslog server is unreachable by the device. The **Allow user traffic to pass when TCP syslog server is down (Recommended to be enabled)** option in the Platform Settings is Enabled by default.
Limit number of SSH login failures.	6.3.0	6.3.0	When a user accesses any device via SSH and fails three successive login attempts, the device terminates the SSH session.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
External authentication added for SSH.	6.2.3	6.2.3	You can now configure external authentication for SSH access to the Firewall Threat Defense using LDAP or RADIUS. New/modified screens: **Devices** > **Platform Settings** > **External Authentication**
Support for UC/APPL compliance mode.	6.2.1	6.2.1	You can enable security certifications compliance in CC mode or UCAPL mode. Enabling security certifications compliance does not guarantee strict compliance with all requirements of the security mode selected. For more information on hardening procedures, refer to the guidelines for this product provided by the certifying entity. New/modified screens: **Devices** > **Platform Settings** > **UC/APPL Compliance**
SSL settings for remote access VPN.	6.2.1	6.2.1	The Firewall Threat Defense device uses the Secure Sockets Layer (SSL) protocol and Transport Layer Security (TLS) to support secure message transmission for Remote Access VPN connection from remote clients. You can configure SSL versions and encryption algorithms that will be negotiated and used for message transmission during remote VPN access over SSL. New/modified screens: **Devices** > **Platform Settings** > **SSL**
External authentication for SSH and HTML removed.	6.1.0	6.1.0	Due to changes to support converged management access, only local users are supported for SSH and HTML to data interfaces. Also, you can no longer SSH to the logical Diagnostic interface; instead you can SSH to the logical Management interface (which shares the same physical port). Previously, only external authentication was supported for SSH and HTML access to Diagnostic and data interfaces, while only local users were supported to the Management interface. New/modified screens: **Devices** > **Platform Settings** > **External Authentication**
Firepower Threat Defense support.	6.0.1	6.0.1	This feature was introduced. New/modified screens: **Devices** > **Platform Settings**

CHAPTER 20

FlexConfig policies

These topics describe how to configure and deploy FlexConfig policies.

- FlexConfig policy overview, on page 1083
- Requirements and prerequisites for FlexConfig policies, on page 1104
- Guidelines and limitations for FlexConfig, on page 1105
- Customize device configuration with FlexConfig policies, on page 1105
- Examples for FlexConfig, on page 1120
- Migrate FlexConfig policies, on page 1127
- History for FlexConfig, on page 1128

FlexConfig policy overview

A FlexConfig policy is a container of an ordered list of FlexConfig objects that

- includes a series of Apache Velocity scripting language commands, ASA software configuration commands, and variables that you define
- contains FlexConfig objects that are essentially programs that generate a sequence of ASA commands that will then be deployed to the assigned devices, and
- configures the related feature on the Firewall Threat Defense device.

FlexConfig policy usage and limitations

Firewall Threat Defense uses ASA configuration commands to implement some features, but not all features. There is no unique set of Firewall Threat Defense configuration commands. Instead, the point of FlexConfig is to allow you to configure features that are not yet directly supported through Firewall Management Center policies and settings.

Caution We recommend using FlexConfig policies only if you are an advanced user with a strong ASA background and at your own risk. You may configure any commands that are not prohibited. Enabling features through FlexConfig policies may cause unintended results with other configured features.

Contact the Cisco Technical Assistance Center for support concerning FlexConfig policies that you have configured. The Cisco Technical Assistance Center does not design or write custom configurations on any customer's behalf. Cisco expresses no guarantees for correct operation or interoperability with other features. FlexConfig features may become deprecated at any time. For fully guaranteed feature support, you must wait for the Firewall Management Center support. When in doubt, do not use FlexConfig policies.

Recommended usage for FlexConfig policies

Use FlexConfig policies in two main scenarios to ensure proper firewall configuration and functionality.

- You are converting from ASA to Firewall Threat Defense, and there are compatible features you are using (and need to continue using) that Firewall Management Center does not directly support. In this case, use the **show running-config** command on the ASA to see the configuration for the feature and create your FlexConfig objects to implement it. Experiment with the object's deployment settings (once/every time and append/prepend) to get the right setting. Verify by comparing **show running-config** output on the two devices.
- You are using Firewall Threat Defense but there is a setting or feature that you need to configure, e.g. the Cisco Technical Assistance Center tells you that a particular setting should resolve a specific problem you are encountering. For complicated features, use a lab device to test the FlexConfig and verify that you are getting the expected behavior.

The system includes a set of predefined FlexConfig objects that represent tested configurations. If the feature you need is not represented by these objects, first determine if you can configure an equivalent feature in standard policies. For example, the access control policy includes intrusion detection and prevention, HTTP and other types of protocol inspection, URL filtering, application filtering, and access control. The ASA implements these functions using separate features. Many features are not configured using CLI commands, so not every policy appears in the output of the **show running-config** command.

Note At all times, keep in mind that there is not a one-to-one overlap between ASA and Firewall Threat Defense. Do not attempt to completely recreate an ASA configuration on a Firewall Threat Defense device. You must carefully test any feature that you configure using FlexConfig.

CLI commands in FlexConfig objects

A managed device uses ASA configuration commands to configure some features. Although not all ASA features are compatible with the device, some features can work on the managed device but you cannot configure them through Firewall Management Center policies. You can use FlexConfig objects to specify the CLI required to configure these features.

ASA documentation resources

When using FlexConfig to manually configure a feature, you are responsible for knowing and implementing the commands according to the proper syntax. FlexConfig policies do not validate CLI command syntax. For more information about proper syntax and configuring CLI commands, use the ASA documentation as a reference:

- ASA CLI configuration guides explain how to configure a feature. Find the guides at https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-installation-and-configuration-guides-list.html
- ASA command references provide additional information sorted by command name. Find the references at https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-command-reference-list.html

Determine the ASA software version and current CLI configuration

Determine the ASA software version and examine the current CLI-based configuration to identify which ASA CLI configuration guides to use for instructions on configuring a feature.

Because the system uses ASA software commands to configure some features, you need to determine the current ASA version used in software running on the Firewall Threat Defense device. This version number indicates which ASA CLI configuration guides to use for instructions on configuring a feature. You also should examine the current CLI-based configuration and compare it to the ASA configuration you want to implement.

Keep in mind that any ASA configuration will be very different from a Firewall Threat Defense configuration. Many Firewall Threat Defense policies are configured outside of the CLI, so you cannot see the configuration by looking at the commands. Do not try to create a one-to-one correspondence between an ASA and Firewall Threat Defense configuration.

To view this information, make an SSH connection to the device's management interface and issue the following commands:

- **show version system** and look for the Cisco Adaptive Security Appliance Software Version number. (If you issue the command through the Secure Firewall Management Center CLI tool, omit the **system** keyword.)
- **show running-config** to view the current CLI configuration.
- **show running-config all** to include all the default commands in the current CLI configuration.

You can also issue these commands from within Firewall Management Center using this procedure.

Procedure

Step 1 Choose **Troubleshooting** > **Health** > **Monitor**.

Step 2 Click the name of the device targeted by the FlexConfig policy.

You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.

Step 3 Click **View System and Troubleshoot Details**.

Step 4 Click **Advanced Troubleshooting**.

Step 5 Click **Threat Defense CLI**.

Step 6 Choose the **Device**, then choose **show** as the command, and type **version** or one of the other commands as the parameter.

Step 7 Click **Execute**.

For version, search the output for the Cisco Adaptive Security Appliance Software Version number.

You can select the output and press Ctrl+C, then paste it into a text file for later analysis.

Prohibited CLI commands

The purpose of FlexConfig is to configure features that are available on ASA devices that you cannot configure on Firewall Threat Defense devices using Firewall Management Center.

Thus, you are prevented from configuring ASA features that have equivalents in Firewall Management Center. The following table lists some of these prohibited command areas.

In addition, some **clear** commands are prohibited because they overlap with managed policies, and can delete part of the configuration for a managed policy.

The FlexConfig object editor prevents you from including prohibited commands in the object.

Prohibited CLI Command	Description
AAA	Configuration blocked.
AAA-Server	Configuration blocked.
Access-list	Advanced ACL, Extended ACL, and Standard ACL are blocked. Ethertype ACL is allowed. You can use standard and extended ACL objects defined in the object manager inside the template as variables.
ARP Inspection	Configuration blocked.
As-path Object	Configuration blocked.
Banner	Configuration blocked.
BGP	Configuration blocked.
Clock	Configuration blocked.
Community-list Object	Configuration blocked.
Copy	Configuration blocked.
Delete	Configuration blocked.
DHCP	Configuration blocked.
Enable Password	Configuration blocked.
Erase	Configuration blocked.

Prohibited CLI Command	Description
Fragment Setting	Blocked, except for **fragment reassembly**.
Fsck	Configuration blocked.
HTTP	Configuration blocked.
ICMP	Configuration blocked.
Interface	Only **nameif**, **mode**, **shutdown**, **ip address** and **mac-address** commands are blocked.
Multicast Routing	Configuration blocked.
NAT	Configuration blocked.
Network Object/Object-group	Network object creation in the FlexConfig object is blocked, but you can use network objects and groups defined in the object manager inside the template as variables.
NTP	Configuration blocked.
OSPF/OSPFv3	Configuration blocked.
pager	Configuration blocked.
Password Encryption	Configuration blocked.
Policy-list Object	Configuration blocked.
Prefix-list Object	Configuration blocked.
Reload	You cannot schedule reloads. The system does not use the **reload** command to restart the system, it uses the **reboot** command.
RIP	Configuration blocked.
Route-Map Object	Route-map object creation in the FlexConfig object is blocked, but you can use route map objects defined in the object manager inside the template as variables.
Service Object/Object-group	Service object creation in the FlexConfig object is blocked, but you can use port objects defined in the object manager inside the template as variables.
SNMP	Configuration blocked.
SSH	Configuration blocked.
Static Route	Configuration blocked.
Syslog	Configuration blocked.
Time Synchronization	Configuration blocked.

Prohibited CLI Command	Description
Timeout	Configuration blocked.
VPN	Configuration blocked.

Template scripts

You can use scripting language to control processing within a FlexConfig object. Scripting language instructions are a subset of commands supported in the Apache Velocity 1.3.1 template engine. The Apache Velocity engine is a Java-based scripting language that supports looping, if/else statements, and variables.

To learn how to use the scripting language, see the *Velocity Developer Guide* at http://velocity.apache.org/engine/devel/developer-guide.html.

FlexConfig variables

You can use variables in a FlexConfig object in cases where part of a command or processing instruction depends on runtime information rather than static information. During deployment, the variables are replaced with strings obtained from other device configurations, depending on the type of variable.

FlexConfig variable types

Variables are replaced with strings based on the type of variable.

- Policy object variables are replaced with strings obtained from objects defined in Firewall Management Center.
- System variables are replaced with information obtained from the device itself or from policies configured for it.
- Processing variables are loaded with the contents of policy object or system variables as during script execution. For example, in a loop, you iteratively load one value from a policy object or system variable into a processing variable, then use the processing variable to form a command string or perform another action. These processing variables do not show up in the Variables list within a FlexConfig object. Also, you do not add them using the **Insert** menu in the FlexConfig object editor.
- Secret key variables are replaced with the single string defined for the variable within the FlexConfig object.

Variables start with the $ character, except for secret keys, which start with the @ character. For example, $ifname is a policy object variable in this command, whereas @keyname is a secret key.

```
interface $ifname
key @keyname
```

Note The first time you insert a policy object or system variable, you must do so through the **Insert** menu in the FlexConfig object editor. This action adds the variable to the **Variables** list at the bottom of the FlexConfig object editor. You must type in the variable string on subsequent uses, even when using system variables. If you are adding a processing variable, which does not have an object or system variable assignment, do not use the **Insert** menu. If you are adding a secret key, always use the **Insert** menu. Secret key variables do not show up in the Variables list.

Whether a variable is resolved as a single string, a list of strings, or a table of values depends on the type of policy object or system variable you assign to the variable. (Secret keys always resolve to a single string.) You must understand what will be returned in order to process the variables correctly.

Variable processing

At runtime, a variable can resolve to any of these: a single string; a list of strings of the same type; a list of strings of different types; or a table of named values. Variables that resolve to multiple values can have a determinate or indeterminate length. To process the values correctly, you must understand what will be returned.

The main possibilities include these scenarios.

Single value variables

If a variable always resolves to a single string, use the variable directly without modification in the FlexConfig script.

For example, the predefined text variable tcpMssBytes always resolves to a single value (which must be numeric). The **Sysopt_basic** FlexConfig then uses an if/then/else structure to set the maximum segment size based on the value of another single-value text variable, *tcpMssMinimum*.

Implementation methods

The implementation of single value variables depends on the variable type:

- **Standard text variables**: Use the variable directly in the FlexConfig script. For example, the predefined text variable tcpMssBytes always resolves to a single numeric value.
- **Secret key variables**: Always use the **Insert** menu to add the variable, even for second and subsequent uses. These variables do not show up in the Variables list within the FlexConfig object.
- **Policy object variables for network objects**: Equate to a single IP address specification (host address, network address, or address range). You must know what type of address to expect because ASA commands require specific address types.

Note Policy object variables for network objects also equate to a single IP address specification, either a host address, network address, or address range. However, in this case, you must know what type of address to expect, because the ASA commands require specific address types. For example, if a command requires a host address, using a network object variable that points to an object that contains a network address will result in an error during deployment.

TCP MSS configuration using single value variables

The **Sysopt_basic** FlexConfig uses an if/then/else structure to set the maximum segment size based on the value of another single-value text variable, tcpMssMinimum:

```
#if($tcpMssMinimum == "true")
  sysopt connection tcpmss minimum $tcpMssBytes
#else
  sysopt connection tcpmss $tcpMssBytes
#end
```

In this example, you would use the **Insert** menu in the FlexConfig object editor to add the first use of $tcpMssBytes, but you would type in the variable directly on the #else line.

Multiple value variables with same type values

Several policy object and system variables resolve to multiple values of the same type. For example, an object variable that points to a network object group resolves to a list of the IP addresses within the group. Similarly, the system variable $SYS_FW_INTERFACE_NAME_LIST resolves to a list of interface names.

You can also create text objects for multiple values of the same type. For example, the predefined text object enableInspectProtocolList can contain more than one protocol name.

Processing characteristics

Multiple value variables that resolve to a list of items of the same type are frequently of indeterminate length. For example, you cannot know beforehand how many interfaces on a device are named, as users can configure or unconfigure interfaces at any time.

You would typically use a loop to process multiple value variables of the same type. For example, the predefined FlexConfig **Default_Inspection_Protocol_Enable** uses a #foreach loop to go through the enableInspectProtocolList object and process each value.

```
policy-map global_policy
    class inspection_default
    #foreach ( $protocol in $enableInspectProtocolList)
    inspect $protocol
    #end
```

In this example, the script assigns each value in turn to the $protocol variable, which is then used in an ASA **inspect** command to enable the inspection engine for that protocol. In this case, you simply type in $protocol as a variable NAME. You do not use the **Insert** menu to add it, because you are not assigning an object or system value to the variable. However, you must use the **Insert** menu to add $enableInspectProtocolList.

The system loops through the code between #foreach and #end until there are no values remaining in $enableInspectProtocolList.

Multiple value variables with different types

You can create multiple value text objects and have each value serve a different purpose. For example, the predefined **netflow_Destination** text object should include three values in this order: interface name, destination IP address, and UDP port number.

Objects defined in this way should have a determinate number of values to make them easier to process.

Processing multiple value variables

Use the get method to process these objects. Type **.get(*n*)** at the end of the object name, replacing *n* with an index into the object. Start counting at 0, even though the text object lists its values starting at 1.

NetFlow destination configuration example

The predefined **netflow_Destination** text object should have 3 values, in order, interface name, destination IP address, and UDP port number.

The Netflow_Add_Destination object uses this line to add the 3 values from netflow_Destination to the ASA **flow-export** command:

```
flow-export destination $netflow_Destination.get(0) $netflow_Destination.get(1)
$netflow_Destination.get(2)
```

In this example, you would use the **Insert** menu in the FlexConfig object editor to add the first use of $netflow_Destination, and then add **.get(0)**. But you would type in the variable directly for the **$netflow_Destination.get(1)** and **$netflow_Destination.get(2)** specifications.

Multiple value variables that resolve to a table of values

Some system variables return a table of values. These variables include the string MAP in their names. For example, $SYS_FTD_ROUTED_INTF_MAP_LIST is one such variable. The routed interface map returns data in a table of values. Line breaks have been added for clarity.

Variable structure and processing

These variables return data that includes a table of named values for each item. For example, the ROUTED interface MAP returns data that looks like this (line returns added for clarity):

```
[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=,
intf_logical_name=outside},

{intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=,
intf_logical_name=inside},

{intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=},

{intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=management}]
```

In the above example, information is returned for 4 interfaces. Each interface includes a table of named values. For example, intf_hardwarare_id is the name of the interface hardware name property, and returns strings such as GigabitEthernet0/0.

This type of variable is typically of indeterminate length, so you need to use looping to process the values. You also need to add the property name to the variable name to indicate which value to retrieve.

IS-IS interface configuration

For example, IS-IS configuration requires that you add the ASA **ISIS** command to an interface that has a logical name in interface configuration mode. However, you enter that mode using the interface's hardware name. Thus, you need to identify which interfaces have logical names, then configure just those interfaces using their hardware names. The ISIS_Interface_Configuration predefined FlexConfig does this using an if/then structure nested in a loop. In this code, you can see that the #foreach scripting command loads each interface MAP into the $INTF variable, then the #if statement keys off the intf_logical_name value in the MAP ($INTF.intf_logical_name), and if the value is in the LIST defined in the isisIntfList predefined text variable, enters the interface command using the intf_hardwarare_id value ($INTF.intf_hardwarare_id). You would need to edit the isisIntfList variable to add the names of the interfaces on which to configure IS-IS.

```
#foreach ($intf in $SYS_FTD_ROUTED_INTF_MAP_LIST)
 #if ($isIsIntfList.contains($intf.intf_logical_name))
  interface $intf.intf_hardwarare_id
   isis
   #if ($isIsAddressFamily.contains("ipv6"))
   ipv6 router isis
   #end
 #end
#end
```

Evaluate device variable results

To evaluate what a variable returns, create a simple FlexConfig object that processes variables and shows their resolved values in a configuration preview.

This method allows you to test and analyze variable resolution without deploying potentially invalid configuration commands to devices.

Procedure

Step 1 Create a simple FlexConfig object that processes an annotated list of variables.

Example:

```
Following is a network object group variable for the
IPv4-Private-All-RFC1918 object:

$IPv4_Private_addresses

Following is the system variable SYS_FW_MANAGEMENT_IP:

$SYS_FW_MANAGEMENT_IP

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

$SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST

Following is the system variable SYS_FTD_ROUTED_INTF_MAP_LIST:

$SYS_FTD_ROUTED_INTF_MAP_LIST
```

```
Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

$SYS_FW_INTERFACE_NAME_LIST
```

Step 2 Assign the FlexConfig object to a FlexConfig policy.

Step 3 Assign the policy to a device.

Step 4 Save the policy.

Step 5 Preview the configuration for that device.

The preview shows the resolved values.

Step 6 Select the preview text, copy it, then paste the output into a text file for analysis.

Example:

```
###Flex-config Prepended CLI ###

###CLI generated from managed features ###

###Flex-config Appended CLI ###
Following is a network object group variable for the
IPv4-Private-All-RFC1918 object:

[10.0.0.0, 172.16.0.0, 192.168.0.0]

Following is the system variable SYS_FW_MANAGEMENT_IP:

192.168.0.171

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

[dns, ftp, h323 h225, h323 ras, rsh, rtsp, sqlnet, skinny, sunrpc,
xdmcp, sip, netbios, tftp, icmp, icmp error, ip-options]

Following is the system variable SYS_FTD_ROUTED_INTF_MAP_LIST:

[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=,
intf_logical_name=outside},

{intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=,
intf_logical_name=inside},

{intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=},

{intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=management}]

Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

[outside, inside, management]
```

Note Do not deploy this FlexConfig to the device, however, because it will not contain any valid configuration commands. You would get deployment errors. After obtaining the preview, delete the FlexConfig object from the FlexConfig policy and save the policy.

You can analyze the resolved variable values in the text file to understand what each variable returns for the device.

FlexConfig policy object variables

A policy object variable is associated with a specific policy object configured in the Object Manager. When you insert a policy object variable in a FlexConfig object, you give the variable a name and select the object associated with it.

Policy object variable types

Although you can give the variable the exact same name as the associated object, the variable itself is not the same thing as the associated object. You must use the **Insert** > **Insert Policy Object** > ***Object Type*** menu in the FlexConfig object editor to add the variable for the first time to the script in the FlexConfig to establish the association with the object. Simply typing in the name of the object preceded by a $ sign does not create a policy object variable.

You can create variables to point to these types of objects. Ensure that you create the right type of object for each variable. To create objects, go to the **Objects** page.

- **Text Objects**—For text strings, which can include IP addresses, numbers, and other free-form text such as interface or zone names. Select **FlexConfig** > **Text Object** from the table of contents, then click **Add Text Object**. You can configure these objects to contain a single value or multiple values. These objects are highly flexible and built specifically for use within FlexConfig objects. For detailed information, see Configure FlexConfig text objects, on page 1112.
- **Network**—For IP addresses. You can use network objects or groups. Select **Network** from the table of contents, then select **Add Network** > **Add Object** or **Add Group**. If you use a group object, the variable returns a list of each IP address specification within the group. Addresses can be host, network, or address ranges, depending on the object contents. See Networks, on page 2813.
- **Security Zones**—For interfaces within a security zone or interface group. Select **Interface** from the table of contents, then select **Add** > **Security Zone** or **Interface Group**. A security zone variable returns a list of the interfaces within that zone or group for the device being configured. See Interfaces, on page 2810.
- **Standard ACL Object**—For standard access control lists. A standard ACL variable returns the name of the standard ACL object. Select **Access List** > **Standard** from the table of contents, then click **Add Standard Access List Object**. See Access lists, on page 2775.
- **Extended ACL Object**—For extended access control lists. An extended ACL variable returns the name of the extended ACL object. Select **Access List** > **Extended** from the table of contents, then click **Add Extended Access List Object**. See Access lists, on page 2775.

- **Route Map**—For route map objects. A route map variable returns the name of the route map object. Select **Route Map** from the table of contents, then click **Add Route Map**. See Configure a route map, on page 2847.

FlexConfig system variables

System variables are replaced with information obtained from the device itself or from policies configured for it. To add a variable for the first time in the FlexConfig script and establish its association with the system variable, use the **Insert** > **Insert System Variable** > ***Variable NAME*** menu in the FlexConfig object editor. Typing the system variable name with a preceding $ sign does not create a system variable in the context of the FlexConfig object.

Before using a variable, check the typical value it returns. Refer to Evaluate device variable results, on page 1092.

Table 77: System variables

NAME	Description
SYS_FW_OS_MODE	The operating system MODE of the device. Possible values are ROUTED or TRANSPARENT.
SYS_FW_OS_MULTIPLICITY	Whether the device is running in SINGLE or multiple context MODE. Possible values are SINGLE, MULTI, or NOT_APPLICABLE.
SYS_FW_MANAGEMENT_IP	The MANAGEMENT IP address of the device
SYS_FW_HOST_NAME	The device hostname
SYS_FTD_INTF_POLICY_MAP	A MAP with INTERFACE NAME as key and POLICY-MAP as value. This variable returns nothing if there are no INTERFACE-based service policies defined on the device.
SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST	The LIST of protocols for which inspection is ENABLED.
SYS_FTD_ROUTED_INTF_MAP_LIST	A LIST of ROUTED INTERFACE maps on the device. Each MAP includes a set of named values related to ROUTED INTERFACE configuration.
SYS_FTD_SWITCHED_INTF_MAP_LIST	A LIST of SWITCHED INTERFACE maps on the device. Each MAP includes a set of named values related to SWITCHED INTERFACE configuration.
SYS_FTD_INLINE_INTF_MAP_LIST	A LIST of INLINE INTERFACE maps on the device. Each MAP includes a set of named values related to INLINE set INTERFACE configuration.
SYS_FTD_PASSIVE_INTF_MAP_LIST	A LIST of PASSIVE INTERFACE maps on the device. Each MAP includes a set of named values related to PASSIVE INTERFACE configuration.
SYS_FTD_INTF_BVI_MAP_LIST	A LIST of Bridge Virtual INTERFACE maps on the device. Each MAP includes a set of named values related to BVI configuration.

NAME	Description
SYS_FW_INTERFACE_HARDWARE_ID_LIST	A LIST of the HARDWARE names for interfaces on the device, such as GigabitEthernet0/0.
SYS_FW_INTERFACE_NAME_LIST	A LIST of logical names for interfaces on the device, such as inside.
SYS_FW_INLINE_INTERFACE_NAME_LIST	A LIST of logical names for interfaces configured as PASSIVE or ERSPAN PASSIVE.
SYS_FW_NON_INLINE_INTERFACE_NAME_LIST	A LIST of logical names for interfaces that are NOT part of INLINE sets, such as all ROUTED interfaces.

Predefined FlexConfig objects

The predefined FlexConfig objects provide tested configurations for select features. Use these objects if you need to configure these features, which otherwise cannot be configured using the management center. Note that some objects might become obsolete as features are added to the GUI.

This table lists the available objects. Make note of the associated text objects. You must edit these text objects to customize the behavior of the predefined FlexConfig object. The text objects make it possible for you to customize the configuration using the IP addresses and other attributes required by your network and device.

If you need to modify a predefined FlexConfig object, copy the object, make changes to the copy, and save it with a new name. You cannot directly edit a predefined FlexConfig object.

Although you might be able to configure other ASA-based features using FlexConfig, the configuration of those features has not been tested. If an ASA feature overlaps with something that you can configure in Firewall Management Center policies, do not attempt to configure it through FlexConfig.

For example, Snort inspection includes the HTTP protocol, so do not enable ASA-style HTTP inspection. You cannot add **http** to the enableInspectProtocolList object; this restriction prevents you from misconfiguring your device. Instead, configure the access control policy to perform application or URL filtering, as needed, to implement your HTTP inspection requirements.

Table 78: Predefined FlexConfig objects

FlexConfig Object Name	Description	Associated Text Objects
Default_Inspection_Protocol_Disable	Disables protocols in the global_policy default policy map.	disableInspectProtocolList
Default_Inspection_Protocol_Enable	Enables protocols in the global_policy default policy map.	enableInspectProtocolList
Inspect_IPv6_Configure	Configures IPv6 inspection in the global_policy policy map, logging and dropping traffic based on IPv6 header contents.	IPv6RoutingHeaderDropLogList, IPv6RoutingHeaderLogList, IPv6RoutingHeaderDropList.
Inspect_IPv6_UnConfigure	Clears and disables IPv6 inspection.	—

FlexConfig Object Name	Description	Associated Text Objects
ISIS_Configure	Configures global parameters for IS-IS routing.	isIsNet, isIsAddressFamily, isISType
ISIS_Interface_Configuration	Interface level IS-IS configuration.	isIsAddressFamily, IsIsIntfList Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST
ISIS_Unconfigure	Clears the IS-IS router configuration on the device.	—
ISIS_Unconfigure_All	Clears the IS-IS router configuration from the device, including the router assignment from the device interface.	—
NGFW_TCP_NORMALIZATION	Modifies the default TCP normalization configuration.	—
Policy_Based_Routing	To use this example configuration, copy it, modify the interface name, and use the r-map-object text object to identify a route map object in the object manager.	—
Policy_Based_Routing_Clear	Clears Policy Based Routing configurations from the device.	—
Sysopt_AAA_radius	Ignores the authentication key in RADIUS accounting responses.	—
Sysopt_AAA_radius_negate	Negates the Sysopt_AAA_radius configuration.	—
Sysopt_basic	Configures sysopt wait time, maximum segment size for TCP packets, and detailed traffic statistics.	tcpMssMinimum, tcpMssBytes
Sysopt_basic_negate	Clears sysopt_basic detailed traffic statistics, wait time, and TCP maximum segment size.	—
Sysopt_clear_all	Clears all sysopt configurations from the device.	—
Sysopt_noproxyarp	Configures noproxy-arp CLIs.	Uses system variable SYS_FW_NON_INLINE_INTF_NAME_LIST
Sysopt_noproxyarp_negate	Clears Sysopt_noproxyarp configurations.	Uses system variable SYS_FW_NON_INLINE_INTF_NAME_LIST
Sysopt_Preserve_Vpn_Flow	Configures syopt preserve VPN flow.	—
Sysopt_Preserve_Vpn_Flow_negate	Clears the Sysopt_Preserve_Vpn_Flow configuration.	—

FlexConfig Object Name	Description	Associated Text Objects
Sysopt_Reclassify_Vpn	Configures sysopt reclassify vpn.	—
Sysopt_Reclassify_Vpn_Negate	Negates sysopt reclassify vpn.	—
Threat_Detection_Clear	Clear the threat detection TCP Intercept configuration.	—
Threat_Detection_Configure	Configure threat detection statistics for attacks intercepted by TCP Intercept.	threat_detection_statistics
Wccp_Configure	This template provides an example for configuring WCCP.	isServiceIdentifier, serviceIdentifier, wccpPassword
Wccp_Configure_Clear	Clears WCCP configurations.	—

Deprecated FlexConfig objects

This table lists objects that configure features you can now configure natively in the GUI. Discontinue using these objects at the earliest convenience.

Table 79: Deprecated predefined FlexConfig objects

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.3	DHCPv6_Prefix_Delegation_Configure	Configure one outside (Prefix Delegation client) and one inside interface (recipient of delegated prefix) for IPv6 prefix delegation. To use this template, copy it and modify the variables. Associated text objects: pdoutside, pdinside Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST	Interface IPv6 Settings.
7.3	DHCPv6_Prefix_Delegation_UnConfigure	Removes the DHCPv6 prefix delegation configuration.	Interface IPv6 Settings.
6.3	Default_DNS_Configure	Configure the Default DNS group, which defines the DNS servers that can be used when resolving fully-qualified domain names on the data interfaces. Associated text objects: defaultDNSNameServerList, defaultDNSParameters	Platform settings.

Deprecated Version	FlexConfig Object	Description	Now Configure In
6.3	DNS_Configure	Configure DNS servers in a non-default DNS server group. Copy the object to change the name of the group.	**DNS Server Group** in the object manager.
6.3	DNS_UnConfigure	Removes the DNS server configuration performed by Default_DNS_Configure and DNS_Configure. Copy the object to change the DNS server group names if you altered DNS_Configure.	**DNS Server Group** in the object manager.
7.2	Eigrp_Configure	Configures EIGRP routing next-hop, auto-summary, router-id, eigrp-stub. Associated text objects: eigrpAS, eigrpNetworks, eigrpDisableAutoSummary, eigrpRouterId, eigrpStubReceiveOnly, eigrpStubRedistributed, eigrpStubConnected, eigrpStubStatic, eigrpStubSummary	For all EIGRP objects, see EIGRP, on page 1257. The system does allow you to deploy post-upgrade, but also warns you to redo your EIGRP configurations. To help you with this process, we provide a command-line migration tool.
7.2	Eigrp_Interface_Configure	Configures EIGRP interface authentication mode, authentication key, hello interval, hold time, split horizon. Associated text objects: eigrpIntfList, eigrpAS, eigrpAuthKey, eigrpAuthKeyId, eigrpHelloInterval, eigrpHoldTime, eigrpDisableSplitHorizon Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST	
7.2	Eigrp_Unconfigure	Clears EIGRP configuration for an autonomous system from the device.	
7.2	Eigrp_Unconfigure_all	Clears all EIGRP configurations.	
7.4	Netflow_Add_Destination	Creates and configures a Netflow export destination. Associated text objects: Netflow_Destinations, netflow_Event_Types	Platform settings.
7.4	Netflow_Clear_Parameters	Restores Netflow export global default settings.	Platform settings.

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.4	Netflow_Delete_Destination	Deletes a Netflow export destination. Associated text objects: Netflow_Destinations, netflow_Event_Types	Platform settings.
7.4	Netflow_Set_Parameters	Sets global parameters for Netflow export. Associated text objects: netflow_Parameters	Platform settings.
6.3	TCP_Embryonic_Conn_Limit	Configures embryonic connection limits to protect against SYN Flood Denial of Service (DoS) attacks. Associated text objects: tcp_conn_misc, tcp_conn_limit	Service policy.
6.3	TCP_Embryonic_Conn_Timeout	Configures embryonic connection timeouts to protect against SYN Flood Denial of Service (DoS) attacks. Associated text objects: tcp_conn_misc, tcp_conn_timeout	Service policy.
7.2	VxLAN_Clear_Nve	Removes the NVE 1 configured when VxLAN_Configure_Port_And_Nve is used from the device.	For all VxLAN objects, see Configure VXLAN Interfaces, on page 804. If you configured VXLAN interfaces with FlexConfig in a previous version, they continue to work. In fact, FlexConfig takes precedence in this case—if you redo your VXLAN configurations in the web interface, remove the FlexConfig settings.
7.2	VxLAN_Clear_Nve_Only	Clears the NVE configured on the interface when deployed.	
7.2	VxLAN_Configure_Port_And_Nve	Configures VLAN port and NVE 1. Associated text objects: vxlan_Port_And_Nve	

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.2	VxLAN_Make_Nve_Only	Sets an interface for NVE only. Associated text objects: vxlan_Nve_Only Also uses system variables SYS_FTD_ROUTED_MAP_LIST and SYS_FTD_SWITCHED_INTF_MAP_LIST	
7.2	VxLAN_Make_Vni	Creates a VNI interface. After deploying this you have to unregister and re-register the device to properly discover the VNI interface. Associated text objects: vxlan_Vni	

Predefined text objects

There are several predefined text objects. These objects are associated with variables used in the predefined FlexConfig objects. In most cases, you must edit these objects to add values if you use the associated FlexConfig object, or you will see errors during deployment. Although some of these objects contain default values, others are empty.

For information on editing text objects, refer to Configure FlexConfig text objects, on page 1112.

Name	Description	Associated FlexConfig Object
defaultDNSNameServerList (Deprecated.)	The DNS server IP address to configure in the Default DNS group. Starting with version 6.3, configure DNS for the data interfaces in the Threat Defense Platform Settings policy.	Default_DNS_Configure
defaultDNSParameters (Deprecated.)	The parameters to control DNS behavior for the default DNS server group. The object contains separate entries, in order, for retries, timeout, expire-entry-timer, poll-timer, domain-name. Starting with version 6.3, configure DNS for the data interfaces in the Threat Defense Platform Settings policy.	Default_DNS_Configure
disableInspectProtocolList	Disables protocols in the default policy map (global_policy).	Disable_Default_Inspection_Protocol
dnsNameServerList	The DNS server IP address to configure in a user-defined DNS group.	DNS_Configure

Name	Description	Associated FlexConfig Object
dnsParameters	The parameters to control DNS behavior for a non-default DNS server group. The object contains separate entries, in order, for retries, timeout, domain-name, name-server-interface.	DNS_Configure
enableInspectProtocolList	Enables protocols in the default policy map (global_policy). You are prevented from adding protocols whose inspection conflicts with Snort inspection.	Enable_Default_Inspection_Protocol
IPv6RoutingHeaderDropList	The list of IPv6 routing header types that you want to disallow. IPv6 inspection drops packets that contain these headers without logging the drop.	Inspect_IPv6_Configure
IPv6RoutingHeaderDropLogList	The list of IPv6 routing header types that you want to disallow and log. IPv6 inspection drops packets that contain these headers and sends a syslog message about the drop.	Inspect_IPv6_Configure
IPv6RoutingHeaderLogList	The list of IPv6 routing header types that you want to allow but log. IPv6 inspection allows packets that contain these headers, but sends a syslog message about the existence of the header.	Inspect_IPv6_Configure
isIsAddressFamily	The IPv4 or IPv6 address family.	ISIS_Configure ISIS_Interface_Configuration
IsIsIntfList	List of logical interface names.	ISIS_Interface_Configuration
isIsISType	IS Type (level-1, level-2-only or level-1-2).	ISIS_Configure
isIsNet	Network entity.	ISIS_Configure
isServiceIdentifier	When false, uses the standard **web-cache** service identifier.	Wccp_Configure
netflow_Destination	Defines a single NetFlow export destination's interface, destination, and UDP port number.	Netflow_Add_Destination
netflow_Event_Types	Defines the types of events to be exported for a destination as any subset of: **all**, **flow-create**, **flow-defined**, **flow-teardown**, **flow-update**.	Netflow_Add_Destination

Name	Description	Associated FlexConfig Object
netflow_Parameters	Provides the NetFlow export global settings: active refresh interval (number of minutes between flow update events), delay (flow create delay in seconds; default 0 = command will not appear), and template time-out rate in minutes.	Netflow_Set_Parameters
PrefixDelegationInside	Configures the inside interface for DHCPv6 prefix delegation. The object includes multiple entries, in order, interface name, IPv6 suffix with prefix length, and prefix pool name.	None, but could be used with a copy of DHCPv6_Prefix_Delegation_Configure.
PrefixDelegationOutside	Configure the outside DHCPv6 prefix delegation client. The object includes multiple entries, in order, interface name and IPv6 prefix length	None, but could be used with a copy of DHCPv6_Prefix_Delegation_Configure.
serviceIdentifier	Dynamic WCCP service identifier number.	Wccp_Configure
tcp_conn_limit (Deprecated.)	Parameters used for configuring the TCP embryonic connection limits. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Limit
tcp_conn_misc (Deprecated.)	Parameters used for configuring the TCP embryonic connection settings. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Limit, TCP_Embryonic_Conn_Timeout
tcp_conn_timeout (Deprecated.)	Parameters used for configuring the TCP embryonic connection timeouts. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Timeout
tcpMssBytes	Maximum segment size in bytes.	Sysopt_basic
tcpMssMinimum	Checks whether to set maximum segment size (MSS), which is set only if this flag is true.	Sysopt_basic

Name	Description	Associated FlexConfig Object
threat_detection_statistics	Parameters used for threat detection statistics for TCP Intercept.	Threat_Detection_Configure
vxlan_Nve_Only	Parameters for configuring NVE-only on interface: • logical name of interface • IPv4 address (optional for routed interface) • IPv4 netmask (optional for routed interface)	VxLAN_Make_Nve_Only
vxlan_Port_And_Nve	Parameters used for configuring ports and NVE for VXLAN: • vxlan port • source interface (logical name) • type (peer or mcast) • Peer IP Address or default-mcast-group	VxLAN_Configure_Port_And_Nve
vxlan_Vni	Parameters used for creating VNI: • Interface number (1-10000) • segment-id (1-16777215) • nameif (Logical Name of the interface) • type (routed or transparent) • IP address (used in case of routed mode device) or bridge-group number (used in case of transparent mode device) • netmask (If device is in routed mode) or unused	VxLAN_Make_Vni
wccpPassword	WCCP password.	Wccp_Configure

Requirements and prerequisites for FlexConfig policies

This topic outlines the model support, domain requirements, and user role prerequisites required to configure and deploy FlexConfig policies.

Administrator

Guidelines and limitations for FlexConfig

Be cautious with FlexConfig deployments, as configuration mistakes trigger rollbacks that can disrupt your network.

- If you make a mistake in the FlexConfig policy, the system will roll back all changes included in the deployment attempt that includes the failed FlexConfig. Because rollback due to a failed deployment includes clearing the configuration, this can be disruptive to your network.
- Consider timing deployments that include FlexConfig changes to non-business hours. Also, consider isolating the deployment so it includes just FlexConfig changes and no other policy updates.

When you use the VxLAN_Make_VNI object, you must deploy the same FlexConfig to all units in a cluster or high availability pair before you form the cluster or high availability pair. The Management Center requires the VXLAN interfaces to match on all devices before forming the cluster or high availability pair.

The **webvpn keepout** command must be configured only within the global webvpn configuration mode. The webvpn group-policy attributes or username attributes configuration modes do not support the **keepout** command. Do not include the **keepout** command in a group-policy FlexConfig object.

If you configure any service that applies to connections, such as SIP inspection, go to the device CLI and enter the **clear conn** command to clear connections. When the connections are rebuilt, the new configuration is applied to the sessions.

QoS rules and service policy rules (in the access control policy) are translated to commands on the firewall. This includes creating policy maps. There can be only one policy map per interface. The system automatically combines QoS and service policy configurations in a single policy map per interface.

However, you can also create policy maps manually using FlexConfig. For lower-end firewalls, such as the Secure Firewall 3100, you can create up to 64 policy maps in the configuration. For more powerful firewalls, such as the Firepower 4100, you can create up to 128. Be careful not to exceed this limit, or deployment will fail. You can view the device configuration from the CLI or use the deployment transcript to see how rules are translated to commands.

Customize device configuration with FlexConfig policies

Use FlexConfig policies to customize the configuration of a Firewall Threat Defense device when standard configuration methods are insufficient.

Before using FlexConfig, try to configure all the policies and settings you need using the other features in Firewall Management Center. FlexConfig is a method of last resort to configure ASA-based features that are

compatible with Firewall Threat Defense but which are not otherwise configurable in Firewall Management Center.

Before you begin

Follow these steps to customize device configuration with FlexConfig policies:

Procedure

Step 1 Determine the CLI command sequence that you want to configure.

If you have a functioning configuration on an ASA device, use **show running-config** to get the sequence of commands that you need. Make adjustments to items such as interface names and IP addresses as needed.

If this is for a new feature, it is best to try to implement it on an ASA device in a lab setting to verify that you have the correct command sequence.

For more information, see the following topics:

- Recommended usage for FlexConfig policies, on page 1084
- CLI commands in FlexConfig objects, on page 1084

Step 2 Choose **Objects** > **FlexConfig** > **FlexConfig Object**.

Examine the predefined FlexConfig objects to determine if any will be able to generate the commands you need. Click **View** ( ) to see the object contents. If an existing object is close to what you want, start by making a copy of the object, and then edit the copy. See Predefined FlexConfig objects, on page 1096.

Examining the objects will also give you an idea of the structure, command syntax, and expected sequencing for a FlexConfig object.

Note If you find any objects that you will use, either directly or as copies, examine the Variables list at the bottom of the object. Make note of the variable names, except those in all capitals that start with SYS, which are system variables. These variables are text objects that you will probably need to edit and define overrides for, especially if the default value column shows the object has no value.

Step 3 If you need to create your own FlexConfig objects, determine what variables you will need and create the associated objects.

The CLI you need to deploy might contain IP addresses, interface names, port numbers, and other parameters that you might want to adjust over time. These are best isolated into variables, which point to objects that contain the necessary values. You might also need variables for strings that are part of the configuration and could change over time.

Also, determine if you need different values for each device to which you will assign the policy. For example, you might want to configure the feature on three devices, but you might need to specify a different interface name or IP address on a given command for each of these devices. If you need to customize the object for each device, ensure that you enable overrides when creating the object and then define the override values per device.

See the list of topics for an explanation of the various types of variables and how to configure the related objects when necessary.

- FlexConfig variables, on page 1088
- FlexConfig policy object variables, on page 1094
- FlexConfig system variables, on page 1095
- Configure FlexConfig text objects, on page 1112

Step 4 If you are using the predefined FlexConfig objects, edit the text objects used as variables.

See Configure FlexConfig text objects, on page 1112.

Step 5 (If necessary) Configure FlexConfig objects, on page 1107.

You need to create objects only if the predefined objects cannot do the job.

Step 6 Configure the FlexConfig policy, on page 1113.

a) Set target devices for a FlexConfig policy, on page 1114.

You can also assign the policy to devices when you create the policy. The policy must have at least one assigned device before you can preview it.

b) Preview the FlexConfig policy, on page 1115.

You must save changes before you can preview the policy.

Verify that the generated commands are the ones intended, and that all variables are resolving correctly.

Step 7 Choose **Deploy** > **Deployment** in the menu bar.

a) Select the devices assigned to the policy, and click **Deploy**.

Wait for deployment to complete.

Step 8 Verify the deployed configuration, on page 1116.

Step 9 (If necessary) Remove features configured using FlexConfig, on page 1118.

Unlike other types of policy, simply unassigning a FlexConfig from a device might not remove the related configuration. If you want to remove a FlexConfig-generated configuration, follow the cited procedure.

If you are removing a feature because it is now directly supported by the product, check Convert from FlexConfig to managed feature, on page 1119.

Configure FlexConfig objects

Before you begin

Keep the following in mind:

- FlexConfig objects translate into commands that are then deployed to the device. These commands are already issued in global configuration mode. Therefore, do not include the **enable** and **configure terminal** commands as part of the FlexConfig object.

- Determine what types of variables you will need, and create any policy objects that you will require. You cannot create objects for variables while editing a FlexConfig object.
- Ensure that your commands do not conflict in any way with the VPN or access control configuration on the devices.
- If there is more than one set of commands for an interface, only the last set of commands is deployed. Therefore, we recommend you not use beginning and ending commands to configure interfaces. For an example of configuring interfaces, refer to the ISIS_Interface_Configuration predefined FlexConfig object.

There are several predefined FlexConfig objects that you can use directly, or you can make copies if you need to edit them. You can also create your own objects from scratch. A FlexConfig object's content can range from a single simple command string to elaborate CLI command structures that use variables and scripting commands to deploy commands whose content can differ from device to device or deployment to deployment.

You can also create FlexConfig policy objects when defining FlexConfig policies.

Procedure

Step 1 Choose **Objects** > **FlexConfig** > **FlexConfig Object** .

Step 2 Do one of the following:

- Click **Add FlexConfig Object** to create a new object.
- Click **Edit** ( ) to edit an existing object.
- Click **View** ( ) to see the contents of a predefined object.
- If you want to edit a predefined object, click **Clone** ( ) to create a new object with the same contents.

Step 3 Enter a **Name** and optionally, a description for the object.

Step 4 In the object body area, enter the commands and instructions to produce the required configuration.

The object content is a sequence of scripting commands and configuration commands that generate a valid ASA software command sequence. The Firewall Threat Defense device uses ASA software commands to configure some features. For more information on scripting and configuration commands, refer to:

- Template scripts, on page 1088
- CLI commands in FlexConfig objects, on page 1084

You can use variables to supply information that can be known only at runtime, or which can differ from device to device. You simply type in processing variables, but you must use the **Insert** menu to add variables that are associated with policy objects or system variables, or which are secret keys. For a complete discussion of variables, refer to FlexConfig variables, on page 1088 .

- To insert system variables, choose **Insert** > **Insert System Variable** > ***Variable Name*** . For a detailed explanation of these variables, see FlexConfig system variables, on page 1095 .
- To insert policy object variables, choose **Insert** > **Insert Policy Object** > ***Object Type*** , selecting the appropriate type of object. Then, give the variable a name (which can be the same name as the associated policy object), select the object to associate with the variable, and click **Save** . For a detailed explanation

of these types, see FlexConfig policy object variables, on page 1094 . For more detail on the procedure, see Add a policy object variable to a FlexConfig object, on page 1110 .

- To insert secret key variables, choose **Insert** > **Secret Key** and define the variable name and value. For more detail on the procedure, see Configure secret keys, on page 1111 .

Note You must use the **Insert** menu to create a new policy object or system variable. However, for subsequent uses of that variable, you must type it in, $ included. This is also true for system variables: the first time you use it, add it from the **Insert** menu. Then, type it out for subsequent uses. If you use the **Insert** menu more than once for a system variable, the system variable is added to the Variables list multiple times, and the FlexConfig will not validate, meaning you cannot save your changes. For processing variables (those not associated with a policy object or system variable), simply type in the variable. If you are adding a secret key, always use the **Insert** menu. Secret key variables do not show up in the Variables list.

Step 5 Choose the deployment frequency and type.

- **Deployment** —Whether to deploy the commands in the object **Once** or **Everytime** . The only way to choose the right option is to test the results of deployment.

  Start by selecting **Everytime** . Then, after you attach the object to a FlexConfig policy, deploy the configuration. After a successful deployment, come back to the FlexConfig policy and preview the configuration for one of the assigned devices as described in Preview the FlexConfig policy, on page 1115 . If the section labeled `###CLI generated from managed features ###` contains commands that clear or negate the commands in the object, and the `###Flex-config Appended CLI ###` section contains the commands to reconfigure the feature, you know that **Everytime** is the right option.

  Even if you do not see negate commands, make some minor change to the device configuration, then run another deployment. If the deployment completes successfully, you can check the deployment transcript (see Verify the deployed configuration, on page 1116). If you see that the commands were issued again (even when they were already configured) without error, then you can keep **Everytime** .

  Change to **Once** only if the system does not first negate the commands in the object before issuing them again, or if the deployment results in errors that are specific to the command. In some cases, the system does not allow you to issue a command that is already configured, but this is the exception.

  Some additional tips:

  - If the FlexConfig object points to system-managed objects such as network or ACL objects, choose **Everytime** . Otherwise, updates to the objects might not get deployed.
  - Use **Once** if the only thing you do in the object is to clear a configuration. Then, remove the object from the FlexConfig policy after the next deployment.

- **Type** —Select one of the following:
  - **Append** —(The default.) Commands in the object are put at the end of the configurations generated from the Firewall Management Center policies. You must use Append if you use policy object variables, which point to objects generated from managed objects. If commands generated for other policies overlap with those specified in the object, you should select this option so your commands are not overwritten. This is the safest option.

- **Prepend** —Commands in the object are put at the beginning of the configurations generated from the Firewall Management Center policies. You would typically use prepend for commands that clear or negate a configuration.

Step 6 (Optional.) Click **Validate** ( ) above the object body to check the integrity of the script.

The object is always validated when you click **Save**. You cannot save an invalid object.

Step 7 Click **Save** .

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 193.

Add a policy object variable to a FlexConfig object

You can insert variables into a FlexConfig policy object that are associated with other types of policy object. When the FlexConfig is deployed to a device, these variables resolve to the names or content of the associated object.

Use the following procedure for the first use of a policy object variable in a FlexConfig object. If you need to refer to the object again, type in the variable (including the $ sign). To understand how to use these variables, see Variable processing, on page 1089.

Before you begin

For information on editing a FlexConfig Object, see Configure FlexConfig objects, on page 1107.

Procedure

Step 1 While editing a FlexConfig Policy Object, choose **Insert** > **Insert Policy Object** > ***Object Type***, selecting the appropriate type of object.

Step 2 Enter a name for the variable, and optionally, a description.

The name must be unique within the context of the FlexConfig object. It cannot include spaces. You are allowed to use the exact same name as the object associated with the variable.

Step 3 Select the object to associate with the variable and click **Add** to move it to the **Selected Object** list.

You can associate a variable with a single object only.

Note For text objects, you can select any of the predefined objects as needed. However, many of these objects have no default values. You must update the objects to add the required values either directly or as overrides for the device to which you will deploy the FlexConfig object. Trying to deploy a FlexConfig without updating these objects typically results in deployment errors.

Step 4 Click **Save**.

The variable appears in the Variables list at the bottom of the FlexConfig object editor.

Configure secret keys

Secret keys allow you to mask sensitive information such as passwords in FlexConfig objects, preventing the dissemination of sensitive information while providing special treatment for these variables.

A secret key is any single-string variable whose content you want to mask, such as passwords. The system provides special treatment for these variables to help you prevent the dissemination of sensitive information.

Secret key variables do not show up in the Variables list in the FlexConfig object.

Unlike other types of variables, you can use the **Insert** command every time you need to insert a given secret key variable. With respect to processing, these variables behave like single-value text object variables; see Single value variables, on page 1089.

Note Any data defined in a secret key variable is masked from users except when previewing a FlexConfig policy. In addition, if you export a FlexConfig policy, the content of any secret key variable is erased. When you import the policy, you will need to manually edit each secret key variable to enter the data.

Before you begin

For information on editing a FlexConfig Object, see Configure FlexConfig objects, on page 1107.

Procedure

Step 1 While editing a FlexConfig Policy Object, choose **Insert** > **Secret Key**.

Step 2 In the **Insert Secret Key** dialog box, do any of the following:

- To create a new key, click **Add Secret Key**, then fill in the following information and click **Add**.
  - **Secret Key Name**—The name of the variable. This name appears in the FlexConfig object prefixed with @.
  - **Password**, **Confirm Password**—The secret string, which is masked with asterisks as you type.
- To insert a secret key variable in the FlexConfig object, select the check box for the variable.
- To edit the value of a secret key variable, click **Edit** ( ) for the variable. Make your changes and click **Add**.
- To delete a secret key variable, click **Delete** ( ) for the variable.

Step 3 Click **Save**.

Configure FlexConfig text objects

Use text objects in FlexConfig objects as the target of policy object variables. You can use variables to supply information that can be known only at runtime, or which can differ from device to device. During deployment, variables that point to text objects are replaced by the content of the text object.

Text objects contain free-form strings, which can be keywords, interface names, numbers, IP addresses, and so forth. The content depends on how you will use the information within a FlexConfig script.

Before creating or editing a text object, determine exactly what content you will need. This includes how you intend to process the object, which will help you decide between creating a single string or multiple string object. Read these topics:

- FlexConfig variables, on page 1088
- Variable processing, on page 1089

Procedure

Step 1 Choose **Objects** > **FlexConfig** > **Text Object**.

Step 2 Do one of these steps:

- Click **Add Text Object** to create a new object.
- Click **Edit** (✎) to edit an existing object. You are allowed to edit the predefined text objects, which is required if you intended to use the predefined FlexConfig objects.

Step 3 Enter a **Name** and optionally, a description for the object.

Step 4 (New objects only.) Choose a **Variable Type** from the drop-down list:

- **Single**—If the object should contain a single text string.
- **Multiple**—If the object should contain a list of text strings.

You cannot change the variable type after you save the object.

Step 5 If the variable type is **Multiple**, use the up and down arrows to specify a **Count**.

Rows are added or removed from the object as you change the number.

Step 6 Add content to the object.

You can either click in the text box next to a variable number and type in a value, or you can set up device overrides for each device that will be assigned a FlexConfig object that uses the text object. You can also do both, in which case the values configured in the base object act as default values in cases where an override does not exist for a given device.

When editing predefined objects, it is a good practice to use device overrides, so that the system defaults remain in place for other users who might need to use the object in different FlexConfig policies. The approach you take depends on the requirements of your organization.

Tip Some predefined objects require multiple values where each value serves a specific purpose. Read the description text carefully to determine the expected values in the object. In some cases, the instructions specify that you must use overrides instead of changing the base values. In the case of enableInspectProtocolList, you are prevented from entering protocols whose inspection is incompatible with Snort inspection.

If you decide to use device overrides, do the following.

a) Check the check box of **Allow Overrides**.
b) Expand the Overrides area (if necessary) and click **Add**.

   If an override already exists for the device, click edit for the override to change it.

c) On **Targets** in the Add Object Override dialog box, select the device for which you are defining values and click **Add** to move it to the Selected Devices list.
d) Click **Override**, adjust the **Count** as needed, then click in the variable fields and type in the values for the device.
e) Click **Add**.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 193.

Configure the FlexConfig policy

Configure a FlexConfig policy to manage device configurations using shared policies that can be assigned to multiple devices.

A FlexConfig policy contains two ordered lists of FlexConfig objects, one prepended list and one appended list. For an explanation of prepend/append, see Configure FlexConfig objects, on page 1107.

FlexConfig policies are shared policies that you can assign to multiple devices.

Procedure

Step 1 Choose **Devices** > **+ Show more** > **FlexConfig**.

Step 2 Do one of the following:

- Click **New Policy** to create a new FlexConfig Policy. You are prompted to enter a name. Optionally, select devices in the Available Devices list and click **Add to Policy** to assign devices. Click **Save**.
- Click **Edit** (✎) to edit an existing Policy. You can change the name or description by clicking them in edit mode.
- Click **Copy** (⧉) to create a new policy with the same contents. You are prompted for a name. Device assignments are not retained for the copy.

- Click delete to remove a policy you no longer need.

Step 3 Select the FlexConfig objects required for the policy from the **Available FlexConfig** list and click > to add them to the policy.

Objects are automatically added to the prepended or appended list based on the deployment type specified in the FlexConfig object.

To remove a selected object, click **Delete** ( ) next to an object.

Step 4 For each selected object, click **View** ( ) next to the object to identify the variables used in the object.

Except for system variables, which start with SYS, you need to ensure that the objects associated with the variables are not empty. A blank or brackets with nothing between them, [ ], indicate an empty object. You will need to edit these objects before deploying the policy.

Note If you use object overrides, those values will not show up in this view. Thus, an empty default value does not necessarily mean that you have not updated the object with the required values. Previewing the configuration will show whether the variables resolve correctly for a given device. See Preview the FlexConfig policy, on page 1115.

Step 5 Click **Save**.

What to do next

- Set target devices for the policy; see Set target devices for a FlexConfig policy, on page 1114.
- Deploy configuration changes; see Deploy configuration changes, on page 193.

Set target devices for a FlexConfig policy

This task allows you to assign or change device assignments for a FlexConfig policy after creation.

When you create a FlexConfig policy, you can select the devices that use the policy. You can subsequently change device assignments for the policy as described below.

Note Normally, when you unassign a policy from a device, the system automatically removes the associated configuration upon the next deployment. However, because FlexConfig objects are scripts for deploying customized commands, simply unassigning a FlexConfig policy from a device does not remove the commands that were configuring by the FlexConfig objects. If your intention is to remove FlexConfig-generated commands from a device's configuration, refer to Remove features configured using FlexConfig, on page 1118.

Procedure

Step 1 Choose **Devices** > **+ Show more** > **FlexConfig** and edit a FlexConfig policy.

Step 2 Click **Policy Assignments**.

Step 3 On **Targeted Devices**, build your target list:

- Add—Choose one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**. You can assign the policy to devices, high availability pairs, and clustered devices.
- Delete—Click **Delete** ( ) next to a single device, or select multiple devices, right-click, then choose **Delete Selection**.

Step 4 Click **OK** to save your selection.

Step 5 Click **Save** to save the FlexConfig policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Preview the FlexConfig policy

The FlexConfig policy preview allows you to validate and troubleshoot your configuration before deployment. It translates FlexConfig objects into CLI commands and resolves variables based on device-specific configurations.

Preview a FlexConfig policy to see how the FlexConfig objects get translated into CLI commands. The preview shows the commands that will be generated for a selected device from the scripts and variables used in the FlexConfig objects. The variables are resolved based on the configuration for the device, so you get a clear idea of what will be deployed.

Use the preview to look for potential problems in the FlexConfig objects. Correct the objects until the preview shows the expected results.

You must preview the configuration separately for each device, because the variables can resolve differently based on the device configuration.

Procedure

Step 1 Choose **Devices** > **+ Show more** > **FlexConfig** and edit a FlexConfig policy.

Step 2 If there are any pending changes, click **Save**.

The preview shows results only for those FlexConfig objects that were in the most recently saved version of the policy. You must save the policy to see a preview of newly-added objects.

Step 3 Click **Preview Config**.

Step 4 Choose a device from the **Select Device** drop-down list.

The system retrieves information from the device and configured policies, and determines what CLI commands will be generated on the next deployment to the device. You can select the output and use Ctrl+C to copy it to the clipboard, where you can paste it into a text file for further analysis.

The preview includes the following sections:

- Flex-config Prepended CLI—These are the commands generated by FlexConfigs that are prepended to the configuration.
- CLI generated from managed features—These are commands generated for policies configured in the Firewall Management Center. Commands are generated for new or changed policies since the last successful deployment to the device. These commands do not represent all commands needed to implement the assigned policies. No commands in this section are generated from FlexConfig objects.
- Flex-config Appended CLI—These are the commands generated by FlexConfigs that are appended to the configuration.

Step 5 Click **Close** to close the preview dialog.

Verify the deployed configuration

This task helps you confirm that your FlexConfig policy deployment completed successfully and that the device configuration matches your expectations.

After you deploy a FlexConfig policy to a device, verify that the deployment was successful and that the resulting configuration is what you expected. Also, verify that the device is performing as expected.

Procedure

Step 1 To verify that deployment was successful:

Check the deployment status and review any error messages or warnings.

- Click **Notifications** in the menu bar, which is unnamed between **Deploy** and **System**.

  The icon looks like one of the following, and it might include a number if there are errors:

  - **Indicates No Warnings** — Indicates no warnings or errors are present on the system.
  - Indicates **One or More Warnings** — Indicates one or more warnings and no errors are present on the system.
  - **Indicates One or More Errors** — Indicates one or more errors and any number of warnings are present on the system.

- On **Deployments**, verify that the deployment was successful.
- To see more detailed information, especially for failed deployments, click **Show History**.
- Select the deployment job in the list of jobs in the left column.

  Jobs are listed in reverse chronological order, with the most recent job at the top of the list.

- Click download in the **Transcript** column for the device in the right column.

The deployment transcript includes commands sent to the device, and any responses returned from the device. These responses can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands that you sent through FlexConfig. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

Note There is no distinction made in the transcript between commands sent for managed features and those generated from FlexConfig policies.

For example, the following sequence shows that Firewall Management Center sent commands to configure GigabitEthernet0/0 with the logical name outside. The device responded that it automatically set the security level to 0. Firewall Threat Defense does not use the security level for anything. Messages relevant to FlexConfig are in the CLI Apply section of the transcript.

```
========= CLI APPLY =========

FMC >> interface GigabitEthernet0/0
FMC >>  nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

Step 2 Verify that the deployed configuration includes the expected commands.

You can do this by making an SSH connection to the device's management IP address. Use the **show running-config** command to view the configuration.

Alternatively, use the CLI tool within Secure Firewall Management Center.

- Choose **Troubleshooting** > **Health** > **Monitor** and click the name of the device.

  You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.

- Click **Advanced Troubleshooting**.
- Click **Threat Defense CLI**.
- Select **show** as the command, and type **running-config** as the parameter.
- Click **Execute**.

  The running configuration appears in the text box. You can select the configuration and press Ctrl+C, then paste it into a text file for later analysis.

Step 3 Verify that the device is performing as expected.

Use the **show** commands related to the feature to see detailed information and statistics. For example, if you enabled additional protocol inspections, the **show service-policy** command provides this information. The exact commands to use are feature-dependent and should be mentioned in the ASA configuration guide and command reference you used to learn how to configure the feature.

If commands that show statistics indicate that numbers are not changing (for example, hit counts, connection counts, and so forth), the configuration might be valid but not meaningful. If you know that traffic is going through the device that should show up in statistics, look for what is missing in your configuration. For example, NAT or access rules might be dropping or changing traffic before a feature can act on it.

You can use the **show** commands from an SSH session or through the Firewall Management Center CLI tool.

However, if the **show** command that you need to use is not available directly within the Firewall Threat Defense CLI, you will need make an SSH connection to the device to use the commands. From the CLI, enter the following command sequence to enter Privileged EXEC mode within the diagnostic CLI. From there, you should be able to enter these otherwise unsupported **show** commands.

```
> system support diagnostic-cli
Attaching to Diagnostic CLI ... Press 'Ctrl+a then d' to detach.
Type help or '?' for a list of available commands.
firepower> enable
Password: <press enter, do not enter a password>
firepower#
```

Remove features configured using FlexConfig

This task allows you to manually remove configuration commands that were deployed using FlexConfig when unassigning the FlexConfig policy from a device might not remove all of the configuration.

If you decide you need to remove a set of configuration commands you configured using FlexConfig, you might need to manually remove that configuration. Unassigning the FlexConfig policy from a device might not remove all of the configuration.

To manually remove the configuration, you create new FlexConfig objects to clear or negate the configuration commands.

Before you begin

To determine if you need to manually remove some or all of the configuration generated by an object:

1. Examine the configuration preview, as described in Preview the FlexConfig policy, on page 1115. If the **###CLI generated from managed features ###** section contains the clear or negate commands to remove all of the commands in the FlexConfig object, then you can simply remove the object from the FlexConfig policy, save, and redeploy.
2. Remove the object from the FlexConfig policy, save the change, then preview the configuration again. If the **###CLI generated from managed features ###** section still does not include the required clear or negate commands, you must follow this procedure to manually remove the configuration.

Follow these steps to remove features configured using FlexConfig:

Procedure

Step 1 Choose **Objects** and create the FlexConfig Objects to clear or negate the configuration commands.

If a feature has a **clear** command that can remove all configuration settings, then use that command. For example, the predefined ISIS_Unconfigure_All object contains a single command that removes all ISIS-related configuration commands:

```
clear configure router isis
```

If there is not a **clear** command for the feature, you need to use the **no** form of each command you want to remove. For example, the predefined Sysopt_basic_negate object removes the commands configured through the predefined Sysopt_basic object.

```
no sysopt traffic detailed-statistics

no sysopt connection timewait
```

You would typically configure a FlexConfig object that removes configurations as a prepended, deploy once object.

Step 2 Choose **Devices** > **+ Show more** > **FlexConfig** and create a new FlexConfig policy or edit the existing policy.

If you want to preserve the FlexConfig policy that deploys the configuration commands, create a new policy specifically for negating the commands, and assign the devices to the policy. Then, add the new FlexConfig objects to the policy.

If you want to completely remove the FlexConfig configuration objects from all devices, you can simply delete those commands from the existing FlexConfig policy and replace them with the objects that negate the configuration.

Step 3 Click **Save** to save the FlexConfig policy.

Step 4 Click **Preview Config** and verify that the clear and negation commands are generating correctly.

Step 5 Choose **Deploy** > **Deployment** in the menu bar, select the device, and click **Deploy**.

Wait for deployment to complete.

Step 6 Verify that the commands were removed.

View the running configuration on the device to confirm that the commands are removed. For more detailed information, see Verify the deployed configuration, on page 1116.

Step 7 While editing the FlexConfig policy, click **Policy Assignments** and remove the device. Optionally, remove the FlexConfig Objects from the policy.

Assuming that the FlexConfig policy simply removes the unwanted configuration commands, there is no need to keep the policy assigned to the device after the removal is complete.

However, if the FlexConfig policy retains options that you still want configured on the device, remove the negation objects from the policy. They are no longer needed.

Convert from FlexConfig to managed feature

This procedure converts deprecated FlexConfig commands to newly supported managed features after a software upgrade.

Each software release adds managed features to the product. These are features you configure directly through policies controlled outside of FlexConfig. This can deprecate FlexConfig commands that you are currently using. Your configurations are not automatically converted. After the upgrade, you cannot assign or create FlexConfig objects using the newly deprecated commands. After upgrading software, examine your FlexConfig policies and objects.

If a feature configured through FlexConfig becomes available as a managed feature, convert the configuration to the managed feature instead of using FlexConfig. In most cases, your existing FlexConfig configurations continue to work after the upgrade, and you can still deploy. However, using deprecated commands may cause deployment issues in certain situations. Configuring a feature in both the GUI and FlexConfig is not supported.

Note Use the migration tool instead of this procedure if the tool supports the feature configuration you are migrating.

Procedure

Step 1 Remove the FlexConfig, as explained in Remove features configured using FlexConfig, on page 1118.

Step 2 Configure the settings in the newly supported managed feature.

The release notes have a list of new features for the release.

Examples for FlexConfig

This topic provides a collection of practical examples for implementing FlexConfig policies.

Configure precision time protocol (ISA 3000)

The Precision Time Protocol (PTP) is a time-synchronization protocol developed to synchronize the clocks of various devices in a packet-based network. These device clocks are generally of varying precision and stability. The protocol is designed specifically for industrial, networked measurement and control systems, and is optimal for use in distributed systems because it requires minimal bandwidth and little processing overhead.

A PTP system is a distributed, networked system consisting of a combination of PTP and non-PTP devices. PTP devices include ordinary clocks, boundary clocks and transparent clocks. Non-PTP devices include network switches, routers and other infrastructure devices.

You can configure the Firewall Threat Defense device to be a transparent clock. The Firewall Threat Defense device does not synchronize its clock with the PTP clocks. The Firewall Threat Defense device will use the PTP default profile, as defined on the PTP clocks.

When you configure the PTP devices, you define a domain number for the devices that are meant to function together. Thus, you can configure multiple PTP domains, and then configure each non-PTP device to use the PTP clocks for one specific domain.

Before you begin

Determine the domain number configured on the PTP clocks that the device should use. This example assumes the PTP domain number is 10. Also, determine the interfaces through which the system can reach the PTP clocks in the domain.

These are the guidelines for configuring PTP.

- This feature is only available on the Cisco ISA 3000 appliance.

- Cisco PTP supports multicast PTP messages only.
- PTP is available only for IPv4 networks, not for IPv6 networks.
- PTP configuration is supported on physical Ethernet data interfaces, whether stand-alone or bridge group members. It is not supported on the management interface, subinterfaces, EtherChannels, Bridge Virtual Interfaces (BVI), or any other virtual interfaces.
- PTP flows on VLAN subinterfaces are supported, assuming the appropriate PTP configuration is present on the parent interface.
- You must ensure that PTP packets are allowed to flow through the device. PTP traffic is identified by UDP destination ports 319 and 320, and destination IP address 224.0.1.129, so any access control rule that allows this traffic should work.
- In Routed firewall mode, you must enable multicast routing for PTP multicast groups. In addition, if an interface on which you enable PTP is **not** in a bridge group, you must configure the interface to join the IGMP multicast group 224.0.1.129. If the physical interface is a bridge group member, you do not configure it to join the IGMP multicast group.

Follow these steps to configure Precision Time Protocol on an ISA 3000 device:

Procedure

Step 1 (Routed mode only) Enable Multicast routing, and configure the IGMP group for the interfaces.

In Routed mode, you must enable Multicast routing. In addition, for stand-alone physical interfaces, that is, those that are not bridge group members, you must also configure the interface to join the 224.0.1.129 IGMP group. You cannot configure bridge group members to join an IGMP group, but PTP configuration on bridge group members will work without the IGMP join.

Perform this procedure for each device on which you will configure PTP.

Note Write down the hardware names of each PTP-clock-facing interface on each device, for example, GigabitEthernet1/1.

a) Choose **Devices** > **Device Management**, and edit the device.
b) Click **Routing**.
c) Choose **Multicast Routing** > **IGMP**.
d) Check the **Enable Multicast Routing** check box.
e) Click **Join Group**.
f) Click **Add**, and in the **Add IGMP Join Group Parameters** dialog box, configure the following options and click **OK**.
   - **Interface**—Select the PTP-clock-facing stand-alone interface.
   - **Join Group**—Click **+** to add a new network object. Create a Host object with the address 224.0.1.129. When configuring additional interfaces, simply select this object. (See Create a network object, on page 2815.)

Repeat this step for each PTP-clock-facing stand-alone interface on the device.

g) Click **Save** on the Routing page.

Step 2 Create the FlexConfig object to enable PTP globally and on the interface.

This procedure assumes that the PTP-clock-facing interface is the same on every device you are configuring. If you have used different interfaces on different devices, you need to create separate objects for each distinct combination. For example, if you use GigabitEthernet1/1 on devices A and B, GigabitEthernet1/2 on devices C and D, and both GigabitEthernet1/1 and 1/2 on devices E and F, you need 3 separate FlexConfig objects, and subsequently, 3 separate FlexConfig policies (explained in the next step).

a) Choose **Objects** > **FlexConfig** > **FlexConfig Object**.

b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

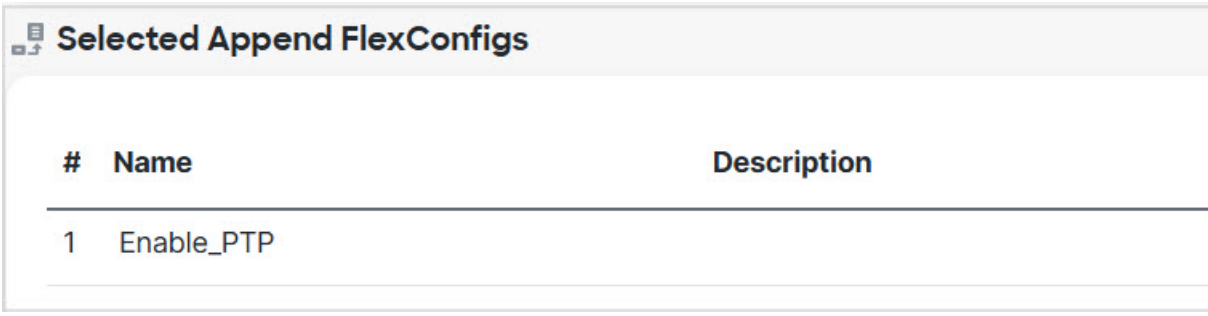
- **Name**—The object name. For example, Enable_PTP.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features. This ensures that any other changes you make to interface configuration are configured before these commands.
- **Object body**—In the object body, type the commands needed to configure PTP globally and on each PTP-clock-facing interface. For example, the commands needed for the global configuration for PTP domain 10 and the interface configuration on GigabitEthernet1/1 are:

```
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
 ptp enable
```

The object body should look similar to the following:

Step 3 Create the FlexConfig policy and assign it to the devices.

If you created multiple FlexConfig objects for different combinations of PTP-clock-facing interfaces, you need to create separate FlexConfig policies for each object, and assign those policies to the correct devices based on the interfaces you need to configure. Repeat this procedure for each group of devices.



a) Choose **Devices** > **+ Show more** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the PTP FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the PTP FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the PTP commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
 ptp enable
```

Step 4 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 1116.

Step 5 Verify the PTP configuration on each device.

From an SSH or Console session into each device, verify the PTP settings:

```
> show ptp clock
 PTP CLOCK INFO
  PTP Device Type: End to End Transparent Clock
  Operation mode: One Step
  Clock Identity: 34:62:88:FF:FE:1:73:81
  Clock Domain: 10
  Number of PTP ports: 4
> show ptp port
 PTP PORT DATASET: GigabitEthernet1/1
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 1
  PTP version: 2
  Port state: Enabled

 PTP PORT DATASET: GigabitEthernet1/2
```

```
 Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
 Port identity: Port Number: 2
 PTP version: 2
 Port state: Disabled

PTP PORT DATASET: GigabitEthernet1/3
 Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
 Port identity: Port Number: 3
 PTP version: 2
 Port state: Disabled

PTP PORT DATASET: GigabitEthernet1/4
 Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
 Port identity: Port Number: 4
 PTP version: 2
 Port state: Disabled
```

Configure automatic hardware bypass for power failure (ISA 3000)

Configure automatic hardware bypass to ensure network traffic continues to flow between interface pairs during power outages on ISA 3000 devices.

You can enable hardware bypass so that traffic continues to flow between an interface pair during a power outage. Supported interface pairs are copper interfaces GigabitEthernet 1/1 and 1/2; and GigabitEthernet 1/3 and 1/4. If you have a fiber Ethernet model, only the copper Ethernet pair (GigabitEthernet 1/1 and 1/2) supports hardware bypass.

When hardware bypass is active, traffic passes between these interface pairs at layer 1. The Firewall Threat Defense CLI will see the interfaces as being down. No firewall functions are in place, so make sure you understand the risks of allowing traffic to pass through the device.

In CLI Console or an SSH session, use the **show hardware-bypass** command to monitor the operational status.

Before you begin

For hardware bypass to work:

- You must place the interface pairs in the same bridge group.
- You must attach the interfaces to access ports on the switch. Do not attach them to trunk ports.

We recommend that you disable TCP sequence number randomization globally using the Threat Defense Service Policy attached to the access control policy assigned to the device. By default, the ISA 3000 rewrites the initial sequence number (ISN) of TCP connections passing through it to a random number. When hardware bypass is activated, the ISA 3000 is no longer in the data path and does not translate the sequence numbers. The receiving client receives an unexpected sequence number and drops the connection, so the TCP session needs to be re-established. Even with TCP sequence number randomization disabled, some TCP connections will have to be re-established because of the link that is temporarily down during the switchover.

Follow these steps to configure automatic hardware bypass for power failure:

Procedure

Step 1 Create the FlexConfig object to enable automatic bypass.

a. Choose **Objects** > **FlexConfig** > **FlexConfig Object**.

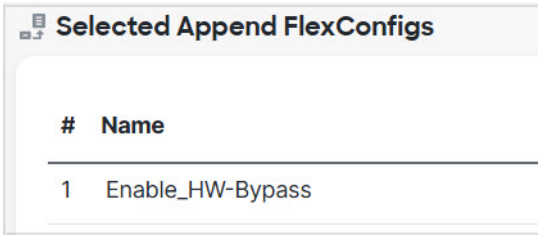
b. Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Enable_HW-Bypass.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to enable automatic hardware bypass. For example, the commands needed for both possible interface pairs:

```
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

The object body should look similar to the following:

Step 2 Create the FlexConfig policy and assign it to the devices.



a. Choose **Devices** > **+ Show more** > **FlexConfig**.

b. Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c. Select the hardware bypass FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d. Click **Save**.

e. If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f. Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the hardware bypass FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the hardware bypass commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 1116.

What to do next

If you want to manually invoke hardware bypass or manually turn it off, you need to create two FlexConfig objects:

- One that manually starts bypass, which would contain one or both of the following commands, depending on whether you want to invoke bypass for both pairs:

```
hardware-bypass manual GigabitEthernet 1/1-1/2
hardware-bypass manual GigabitEthernet 1/3-1/4
```

- One that manually turns off bypass, which would contain one or both of the following commands:

```
no hardware-bypass manual GigabitEthernet 1/1-1/2
no hardware-bypass manual GigabitEthernet 1/3-1/4
```

You would then need to add one or the other object to the FlexConfig policy, and deploy changes, to either turn bypass on or off. You would also need to immediately remove the object from the FlexConfig policy after deployment. If you manually invoke bypass, you would then need to repeat the process to turn it off

again. Thus, using this manual method requires frequent and careful editing of the FlexConfig policy and additional deployments.

Migrate FlexConfig policies

This task migrates ECMP, VXLAN, and EIGRP policies from FlexConfig objects to the management center UI to enable direct policy management.

Attention This section on migrating FlexConfig policies is applicable only for migrating ECMP, VXLAN, and EIGRP policies.

The ECMP, VXLAN, and EIGRP policies were configured using the FlexConfig objects and policies in earlier versions of the Firewall Management Center. You can now directly configure these policies in the management center UI. When you are upgrading the management center from earlier versions, the FlexConfig configuration is retained. However, to manage the policies from the UI, you must redo the configuration in the corresponding **Device (Edit)** > **Routing** page and remove the configuration from FlexConfig. To automate creation of the policies in the UI, Firewall Management Center provides an option to migrate the policies from FlexConfig to the UI. However, it does not remove the migrated policies from the FlexConfig. For post-migration procedure, refer to Step 7, on page 1128.

Before you begin

- Ensure that the deployed FlexConfig policy is up-to-date and not out-of-date. The migration option will be available only if the policy is up-to-date on at least 1 device. Migration does not take place for those devices that have out-of-date policies.
- If the policy is configured in both FlexConfig and the management center:
  - Migration will not be initiated if the policy is already configured at **Device (Edit)** > **Routing**.
  - During deployment, the management center displays an error message. Example EIGRP migration error message—*EIGRP is configured through FlexConfig object and also under Device Listing ->Routing EIGRP for the device. Maintain the EIGRP configuration in either Routing EIGRP or FlexConfig.*
- If the network objects used in the policy exist in the management center, during migration, they are reused. During migration, when a network object that is matching the IP configuration is not available, a new network object is created as *bb* appended with a timestamp and integer, like ***bb_<timestamp>_<integer>***. For more than one such network object, the integer variable in the name would be incremented by one.

Follow these steps to migrate FlexConfig policies:

Procedure

Step 1 Choose **Devices** > **+ Show more** > **FlexConfig**, click **Edit** (✎) against the FlexConfig policy that you want to migrate.

Step 2 Click **Migrate Config**.

Note Once migration starts, both **Migrate Config** and FlexConfig **Edit** options are not available.

The **Migrate Config** option is not available, when:

- There are no applicable FlexConfig CLIs to be migrated.
- The FlexConfig policy is not associated with any FlexConfig objects.
- There are no devices that are associated with the FlexConfig policy.

Step 3 In the **Migrate Flex Configuration** dialog box, select the device to which you wish to migrate the configuration, and then click **Ok**.

The migration progress is displayed as task notification. When the migration is complete, click the *View Details* link and download the migration report (PDF format).

Step 4 To view the policy changes, choose **Events & Logs** > **Analysis** > **Audit Logs** and click on the *Flex Config Migration* message.

Step 5 To view the FlexConfig migration report, choose **Events & Logs** > **Analysis** > **Audit Logs** and click on the *Flex Config Migration* message. To view the complete migration report, click the **Report** icon.

Step 6 Verify the migrated configuration settings in the corresponding **Device (Edit)** > **Routing**. page.

Step 7 To remove the specific policy config from FlexConfig for the device, in the management center, do the following:

a) Identify the migrated FlexConfig policy for the device.
b) Use the copy option and create duplicate of the FlexConfig policy.
c) Remove the corresponding CLI objects from the duplicated FlexConfig policy.
d) Associate the device to the duplicated FlexConfig policy.

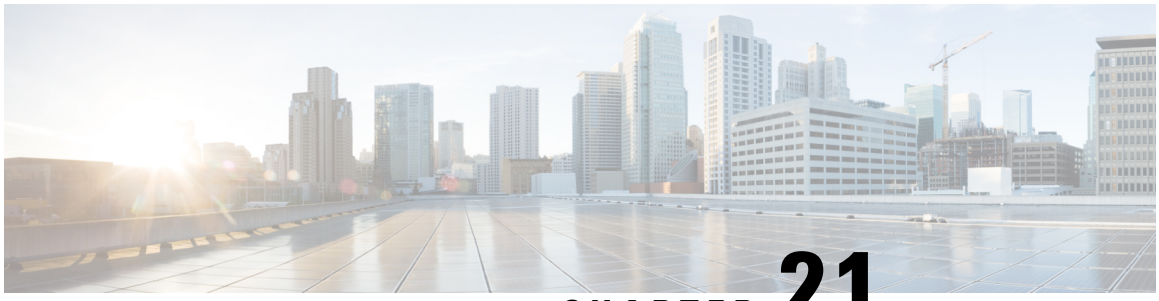
Step 8 Save and deploy the configuration.

History for FlexConfig

This reference provides a summary of feature changes by release for the FlexConfig policy.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Quick recovery after data plane failure for the Firepower 1000/2100 and Firepower 4100/9300	7.4.1	7.4.1	If the data plane process crashes, the system now reloads only the data plane process instead of rebooting the device. Along with the data plane process reload, Snort and a few other processes also get reloaded. However, if the data plane process crashes during bootup, the device follows the normal reload/reboot sequence, which helps avoid a reload process loop from occurring. This feature is enabled by default for both new and upgraded devices. New/modified CLI commands: **data-plane quick-reload**, **no data-plane quick-reload**, **show data-plane quick-reload status** Supported platforms: Firepower 1000/2100, Firepower 4100/9300 Platform restrictions: Not supported in multi-instance mode. See: *Cisco Secure Firewall Threat Defense Command Reference* and Cisco Secure Firewall ASA Series Command Reference.
Migration tool support.	7.3.0	Any	Support to migrate Flex configured ECMP, VXLAN, and EIGRP policies to management center was introduced. New/modified screens: **Devices** > **FlexConfig** > **Migrate FlexConfig**
Removal of BFD configuration in FlexConfig.	7.3.0	Any	Support to configure BFD policies directly in the management center user interface was introduced. Hence, FlexConfig support to configure BFD policies was removed.
Removal of priority-queue.	7.2.5	7.2.5	Support to configure priority-queue in threat defense was removed.
Removal of EIGRP configuration in FlexConfig.	7.2.0	Any	Support to configure EIGRP directly in the management center user interface was introduced. Hence, FlexConfig support to configure EIGRP policies was removed.
Removal of PBR configuration.	7.1.0	7.1.0	Support to configure the PBR directly in the FMC user interface was introduced. Hence, FlexConfig support to configure PBR for FTD 7.1 and higher was removed. New/modified commands: **policy-route route-map***routemap-object-name*.
Removal of ECMP zone creation support in FlexConfig.	7.1.0	Any	Support to configure the ECMP zones directly in the FMC user interface was introduced. Hence, FlexConfig support to configure ECMP zones was removed.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Precision Time Protocol (PTP) configuration for ISA 3000 devices.	6.5.0	Any	You can use FlexConfig to configure the Precision Time Protocol (PTP) on ISA 3000 devices. PTP is a time-synchronization protocol developed to synchronize the clocks of various devices in a packet-based network. The protocol is designed specifically for industrial, networked measurement and control systems. We now allow you to include the **PTP** (interface mode) command, and the global commands **PTP mode e2etransparent** and **PTP domain**, in FlexConfig objects. New/modified commands: **show PTP**.
Deprecated FlexConfig objects.	6.3.0	Any	Several features that in previous releases you configured using FlexConfig are now directly supported in FMC. You need to remove these FlexConfig objects if you are using them, and convert your configuration to use the new objects. These are the deprecated FlexConfig objects and text objects. • **Default_DNS_Configure**, including the defaultDNSNameServerList and defaultDNSParameters text objects. Now, please configure DNS for the data interfaces using the Platform Settings policy. • **TCP_Embryonic_Conn_Limit**, and the tcp_conn_misc and tcp_conn_limit text objects. Configure these features in the FTD Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device. • **TCP_Embryonic_Conn_Timeout**, and the tcp_conn_misc and tcp_conn_timeout text objects. Configure these features in the FTD Service Policy.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
FlexConfig updates.	6.2.1	Any	As per the Government Certification requirements, all sensitive information like password, shared keys in system-provided or user-defined FlexConfig object should be masked using secret key variables. After you update the FMC to Version 6.2.1+, all sensitive information in FlexConfig Objects are converted to secret key variable format. In addition, these new FlexConfig templates are added: • **Default_DNS_Configure** template allows you to the default DNS group, which is used to resolve hostnames for commands or features that resolve names through the data interfaces. • **TCP Embryonic connection limit and timeout configuration** template allows you to configure embryonic connection limits/timeout CLIs to protect from SYN Flood DoSAttack. • **Turn on threat detection configure and clear** templates allow you to configure threat detection statistics for attacks intercepted by TCP Intercept. • **IPV6 router header inspection** template allows you to configure of IPV6 inspection header for selectively allow/block certain headers with different types (e.g. allowing RH Type 2,mobile). • **DHCPv6 prefix delegation** template allows you to configure one outside (PD client) and one inside interface (recipient of delegated prefix) for IPv6 prefix delegation.
FlexConfig.	6.2.0	Any	The FlexConfig feature allows you use the FMC to deploy ASA CLI template-based functionality to FTD devices. This feature allows you to enable some of the most valuable ASA functions that are not currently available on FTD devices. This functionality is structured as templates and objects that work together in a policy. The default templates are officially supported by Cisco TAC. New/modified screens: • **Devices** > **FlexConfig** • **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Objects** • **Objects** > **Object Management** > **FlexConfig** > **Text Object**

CHAPTER 21

Static and Default Routes

This chapter describes how to configure static and default routes on the Firewall Threat Defense.

- Static and default routes overview, on page 1135
- Requirements and prerequisites for static routes, on page 1138
- Guidelines for static and default routes, on page 1138
- Add a static route, on page 1139
- Reference for routing, on page 1140

Static and default routes overview

To route traffic to a non-connected host or network, define a route to the host or network, using static or dynamic routing. Generally, you must configure at least one static route: a default route for all traffic that is not routed by other means to a default network gateway, which is typically the next-hop router.

Default routes

The simplest option is to configure a default static route to send all traffic to an upstream router, relying on the router to route the traffic for you. A default route identifies the gateway IP address to which the Firewall Threat Defense sends all IP packets for which it does not have a learned or static route. A default static route is simply a static route with 0.0.0.0/0 (IPv4) or ::/0 (IPv6) as the destination IP address.

Default route configuration requirements

You should always define a default route.

The Firewall Threat Defense has separate routing tables for data interfaces and for management-only interfaces (including the special Linux Management interface). You can only add a default route for the data routing table. The Firewall Threat Defense automatically adds a default route in the management-only routing table that sends traffic to the Linux Management interface, where a separate route lookup occurs in the Linux routing table. You can add static routes to the Linux routing table that can be used by Management using the Firewall Threat Defense CLI **configure network static-routes** command.

Note The *default* Linux route is set with the **configure network ipv4** or **configure network ipv6** command.

Static routes

You might want to use static routes in the following cases:

Use cases for static routes

- Your networks use an unsupported router discovery protocol.
- Your network is small and you can easily manage static routes.
- You do not want the traffic or CPU overhead associated with routing protocols.
- In some cases, a default route is not enough. The default gateway might not be able to reach the destination network, so you must also configure more specific static routes. For example, if the default gateway is outside, then the default route cannot direct traffic to any inside networks that are not directly connected to the Firewall Threat Defense.
- You are using a feature that does not support dynamic routing protocols.
- Virtual routers use static routes to create route leaks. Route leaks enable flow of traffic from an interface of a virtual router to another interface in another virtual router. For more information, refer to Virtual router interconnection, on page 1156.

Route to null0 interface to drop unwanted traffic

Access rules let you filter packets based on the information contained in their headers. A static route to the null0 interface is a complementary solution to access rules. You can use a null0 route to forward unwanted or undesirable traffic so the traffic is dropped.

Performance and routing benefits

Using static null0 routes provides a favorable performance profile. You can also use static null0 routes to prevent routing loops. BGP can leverage the static null0 route for Remotely Triggered Black Hole routing.

Note Though routing traffic to a null0 interface to blackhole it helps to drop unwanted traffic, this method increases the `no-route` ASP drops.

Route priorities

- Routes that identify a specific destination take precedence over the default route.
- When multiple routes exist to the same destination (either static or dynamic), then the administrative distance for the route determines priority. Static routes are set to 1, so they typically are the highest priority routes.
- When you have multiple static routes to the same destination with the same administrative distance, refer to Equal-cost multi-path routing, on page 1149.
- For traffic emerging from a tunnel with the Tunneled option, this route overrides any other configured or learned default routes.

Transparent firewall mode and bridge group routes

For traffic that originates on the Firewall Threat Defense device and is destined through a bridge group member interface for a non-directly connected network, you need to configure either a default route or static routes so the Firewall Threat Defense device knows out of which bridge group member interface to send traffic. Traffic that originates on the Firewall Threat Defense device might include communications to a syslog server or SNMP server. If you have servers that cannot all be reached through a single default route, then you must configure static routes. For transparent mode, you cannot specify the BVI as the gateway interface; only member interfaces can be used. For bridge groups in routed mode, you must specify the BVI in a static route; you cannot specify a member interface. For more information, refer to MAC address and route lookups, on page 135.

Static route tracking

The static route tracking feature provides a method for tracking the availability of a static route and installing a backup route if the primary route should fail. For example, you can define a default route to an ISP gateway and configure a backup default route to a secondary ISP in case the primary ISP becomes unavailable.

Static route tracking implementation

One of the problems with static routes is that there is no inherent mechanism for determining if the route is up or down. They remain in the routing table even if the next hop gateway becomes unavailable. Static routes are only removed from the routing table if the associated interface on the Firewall Threat Defense device goes down.

The Firewall Threat Defense device implements static route tracking by associating a static route with a monitoring target host on the destination network that the Firewall Threat Defense device monitors using ICMP echo requests. If an echo reply is not received within a specified time period, the host is considered down, and the associated route is removed from the routing table. An untracked backup route with a higher metric is used in place of the removed route.

When selecting a monitoring target, you need to make sure that it can respond to ICMP echo requests. You can choose any network object as the target, but consider using one of these options:

- The address of the ISP gateway (for dual ISP support)
- The address of the next hop gateway (if you are concerned about gateway availability)
- A server on the target network, such as a syslog server, with which the Firewall Threat Defense device needs to communicate
- A persistent network object on the destination network

Note A PC that may be shut down at night is not a good choice.

You can configure static route tracking for statically defined routes or default routes obtained through DHCP or PPPoE. You can only enable PPPoE clients on multiple interfaces with route tracking configured.

Requirements and prerequisites for static routes

Requirement	Description
Model support	Firewall Threat Defense
Supported domains	Any
User roles	Administrator Network Admin

Guidelines for static and default routes

Firewall mode and bridge groups

Configure static routes according to your firewall mode and interface requirements.

- In transparent mode, static routes must use the bridge group member interface as the gateway; you cannot specify the BVI.
- In routed mode, you must specify the BVI as the gateway; you cannot specify the member interface.
- Static route tracking is not supported for bridge group member interfaces or on the BVI.

Supported network address

Ensure your network addresses meet static route requirements.

- Static route tracking is not supported for IPv6.
- The Firewall Threat Defense does not support Class E routing, so a Class E network is not routable in static routes.

Clustering

Consider these limitations for clustering and multiple context mode configurations.

- In clustering, static route tracking is only supported on the control node.

Network object group

You cannot use a range of network objects or a network object group having a range of IP addresses in a static route.

ASP and RIB Route Entries

All routes and its distance installed on the device are captured in the ASP routing table. This is common for all static and dynamic routing protocols. Only the best distance route is captured in the RIB table.

Add a static route

A static route defines where to send traffic for specific destination networks. You should at a minimum define a default route. A default route is simply a static route with 0.0.0.0/0 as the destination IP address.

To configure routes for redundant manager access data interfaces, see Configure a redundant manager access data interface, on page 910.

Procedure

Step 1 Click the **Routing** tab. (May be required) From the virtual routers drop-down list, select the virtual router for which you are configuring a static route.

Step 2 Select **Static Route**, and click **Add Routes**.

Step 3 Click **IPv4** or **IPv6** depending on the type of static route that you are adding. Choose the **Interface** to which this static route applies.

For transparent mode, choose a bridge group member interface name. For routed mode with bridge groups, you can choose either the bridge group member interface for the BVI name. To "black hole" unwanted traffic, choose the **Null0** interface.

For a device using virtual routing, you can select an interface that belongs to another virtual router. You can create such a static route if you want to leak traffic from this virtual router into the other virtual router. For more information, refer to Virtual router interconnection, on page 1156.

Step 4 From the **Available Network** list, choose the destination network.

To define a default route, create an object with the address 0.0.0.0/0 and select it here.

Note Although you can create and choose a Network Object Group containing a range of IP addresses, the Firewall Management Center does not support using ranges in static routes.

Step 5 In the **Gateway** or **IPv6 Gateway** field, enter or choose the gateway router that is the next hop for this route. You can provide an IP address or a Networks/Hosts object.

When you are using static-route configuration for virtual routers to leak routes, do not specify the next hop gateway.

Step 6 In the **Metric** field, enter the number of hops to the destination network. Valid values range from 1 to 255; the default value is 1.

The metric is a measurement of the "expense" of a route, based on the number of hops (hop count) to the network on which a specific host resides. Hop count is the number of networks that a network packet must traverse, including the destination network, before it reaches its final destination. The metric is used to compare routes among different routing protocols. The default administrative distance for static routes is 1, giving it precedence over routes discovered by dynamic routing protocols but not directly connected routes. The default administrative distance for routes discovered by OSPF is 110. If a static route has the same administrative distance as a dynamic route, the static route takes precedence. Connected routes always take precedence over static or dynamically discovered routes.

Step 7 (Optional) For a default route, click the **Tunneled** check box to define a separate default route for VPN traffic.

You can define a separate default route for VPN traffic if you want your VPN traffic to use a different default route than your non VPN traffic. For example, traffic incoming from VPN connections can be easily directed towards internal networks, while traffic from internal networks can be directed towards the outside. When you create a default route with the tunneled option, all traffic from a tunnel terminating on the device that cannot be routed using learned or static routes, is sent to this route. You can configure only one default tunneled gateway per device. ECMP for tunneled traffic is not supported.

Step 8 (IPv4 static route only) To monitor route availability, enter or choose the name of an SLA (service level agreement) Monitor object that defines the monitoring policy, in the **Route Tracking** field.

For more information, refer to Configure an SLA monitor, on page 2865.

Step 9 Click **Ok**.

Reference for routing

This section describes underlying concepts of how routing behaves within the Firewall Threat Defense.

Path determination

Routing protocols use metrics to evaluate what path will be the best for a packet to travel. A metric is a standard of measurement, such as path bandwidth, that is used by routing algorithms to determine the optimal path to a destination. To aid the process of path determination, routing algorithms initialize and maintain routing tables, which include route information. Route information varies depending on the routing algorithm used.

Path determination process

Routing algorithms fill routing tables with a variety of information. Destination or next hop associations tell a router that a particular destination can be reached optimally by sending the packet to a particular router representing the next hop on the way to the final destination. When a router receives an incoming packet, it checks the destination address and attempts to associate this address with a next hop.

Routing tables also can include other information, such as data about the desirability of a path. Routers compare metrics to determine optimal routes, and these metrics differ depending on the design of the routing algorithm used.

Routers communicate with one another and maintain their routing tables through the transmission of a variety of messages. The routing update message is one such message that generally consists of all or a portion of a routing table. By analyzing routing updates from all other routers, a router can build a detailed picture of network topology. A link-state advertisement, another example of a message sent between routers, informs other routers of the state of the sender links. Link information also can be used to build a complete picture of network topology to enable routers to determine optimal routes to network destinations.

Supported route types

There are several route types that a router can use. The Firewall Threat Defense device uses the following route types:

- Static Versus Dynamic
- Single-Path Versus Multipath
- Flat Versus Hierarchical
- Link-State Versus Distance Vector

Static versus dynamic routing algorithms

Static routing algorithms are actually table mappings established by the network administrator. These mappings do not change unless the network administrator alters them. Algorithms that use static routes are simple to design and work well in environments where network traffic is relatively predictable and where network design is relatively simple.

Dynamic routing algorithms

Because static routing systems cannot react to network changes, they generally are considered unsuitable for large, constantly changing networks. Most of the dominant routing algorithms are dynamic routing algorithms, which adjust to changing network circumstances by analyzing incoming routing update messages. If the message indicates that a network change has occurred, the routing software recalculates routes and sends out new routing update messages. These messages permeate the network, stimulating routers to rerun their algorithms and change their routing tables accordingly.

Dynamic routing algorithms can be supplemented with static routes where appropriate. A router of last resort (a default route for a router to which all unrouteable packets are sent), for example, can be designated to act as a repository for all unrouteable packets, ensuring that all messages are at least handled in some way.

Single-path versus multipath

Some sophisticated routing protocols support multiple paths to the same destination. Unlike single-path algorithms, these multipath algorithms permit traffic multiplexing over multiple lines. The advantages of multipath algorithms are substantially better throughput and reliability, which is generally called load sharing.

Flat versus hierarchical routing

Some routing algorithms operate in a flat space, while others use routing hierarchies.

In a flat routing system, the routers are peers of all others. In a hierarchical routing system, some routers form what amounts to a routing backbone. Packets from non-backbone routers travel to the backbone routers, where they are sent through the backbone until they reach the general area of the destination. At this point, they travel from the last backbone router through one or more non-backbone routers to the final destination.

Routing systems often designate logical groups of nodes, called domains, autonomous systems, or areas.

In hierarchical systems, some routers in a domain can communicate with routers in other domains, while others can communicate only with routers within their domain. In very large networks, additional hierarchical levels may exist, with routers at the highest hierarchical level forming the routing backbone.

The primary advantage of hierarchical routing is that it mimics the organization of most companies and therefore supports their traffic patterns well. Most network communication occurs within small company groups (domains). Because intradomain routers need to know only about other routers within their domain, their routing algorithms can be simplified, and, depending on the routing algorithm being used, routing update traffic can be reduced accordingly.

Link-state versus distance vector

Link-state algorithms (also known as shortest path first algorithms) flood routing information to all nodes in the internetwork. Each router, however, sends only the portion of the routing table that describes the state of its own links. In link-state algorithms, each router builds a picture of the entire network in its routing tables.

Distance vector algorithms (also known as Bellman-Ford algorithms) call for each router to send all or some portion of its routing table, but only to its neighbors. In essence, link-state algorithms send small updates everywhere, while distance vector algorithms send larger updates only to neighboring routers. Distance vector algorithms know only about their neighbors. Typically, link-state algorithms are used in conjunction with OSPF routing protocols.

Supported internet protocols for routing

The Firewall Threat Defense device supports several internet protocols for routing. Each protocol is briefly described in this section.

The device supports these internet routing protocols:

- **Enhanced Interior Gateway Routing Protocol (EIGRP)**

  EIGRP is a Cisco proprietary protocol that provides compatibility and seamless interoperation with IGRP routers. An automatic-redistribution mechanism allows IGRP routes to be imported into Enhanced IGRP, and vice versa, so it is possible to add Enhanced IGRP gradually into an existing IGRP network.

- **Open Shortest Path First (OSPF)**

  OSPF is a routing protocol developed for Internet Protocol (IP) networks by the interior gateway protocol (IGP) working group of the Internet Engineering Task Force (IETF). OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area includes an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

- **Routing Information Protocol (RIP)**

  RIP is a distance-vector protocol that uses hop count as its metric. RIP is widely used for routing traffic in the global Internet and is an interior gateway protocol (IGP), which means that it performs routing within a single autonomous system.

- **Border Gateway Protocol (BGP)**

  BGP is an interautonomous system routing protocol. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP). Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

Routing tables

The Firewall Threat Defense uses separate routing tables for data traffic (through-the-device) and for management traffic (from-the-device). This section describes how the routing tables work. For information about the management routing table, see also Routing table for management traffic, on page 1148.

How the routing table is populated

The Firewall Threat Defense routing table can be populated by statically defined routes, directly connected routes, and routes discovered by the dynamic routing protocols. Because the Firewall Threat Defense device can run multiple routing protocols in addition to having static and connected routes in the routing table, it is possible that the same route is discovered or entered in more than one manner.

Route selection criteria

When two routes to the same destination are put into the routing table, the one that remains in the routing table is determined as follows:

- If the two routes have different network prefix lengths (network masks), then both routes are considered unique and are entered into the routing table. The packet forwarding logic then determines which of the two to use.

  For example, if the RIP and OSPF processes discovered the following routes:

  - RIP: 192.168.32.0/24
  - OSPF: 192.168.32.0/19

  Even though OSPF routes have the better administrative distance, both routes are installed in the routing table because each of these routes has a different prefix length (subnet mask). They are considered different destinations and the packet forwarding logic determines which route to use.

- If the Firewall Threat Defense device learns about multiple paths to the same destination from a single routing protocol, such as RIP, the route with the better metric (as determined by the routing protocol) is entered into the routing table.

  Metrics are values associated with specific routes, ranking them from most preferred to least preferred. The parameters used to determine the metrics differ for different routing protocols. The path with the lowest metric is selected as the optimal path and installed in the routing table. If there are multiple paths to the same destination with equal metrics, load balancing is done on these equal cost paths.

- If the Firewall Threat Defense device learns about a destination from more than one routing protocol, the administrative distances of the routes are compared, and the routes with lower administrative distance are entered into the routing table.

Administrative Distances for Routes

You can change the administrative distances for routes discovered by or redistributed into a routing protocol. If two routes from two different routing protocols have the same administrative distance, then the route with the lower *default* administrative distance is entered into the routing table. In the case of EIGRP and OSPF routes, if the EIGRP route and the OSPF route have the same administrative distance, then the EIGRP route is chosen by default.

Administrative distance is a route parameter that the Firewall Threat Defense uses to select the best path when there are two or more different routes to the same destination from two different routing protocols. Because the routing protocols have metrics based on algorithms that are different from the other protocols, it is not always possible to determine the best path for two routes to the same destination that were generated by different routing protocols.

Each routing protocol is prioritized using an administrative distance value. The following table shows the default administrative distance values for the routing protocols supported by the Firewall Threat Defense.

Table 80: Default Administrative Distance for Supported Routing Protocols

Route Source	Default Administrative Distance
Connected interface	0
VPN route	1
Static route	1
EIGRP Summary Route	5
External BGP	20
Internal EIGRP	90
OSPF	110
IS-IS	115
RIP	120
EIGRP external route	170
Internal and local BGP	200
Unknown	255

The smaller the administrative distance value, the more preference is given to the protocol. For example, if the Firewall Threat Defense receives a route to a certain network from both an OSPF routing process (default administrative distance - 110) and a RIP routing process (default administrative distance - 120), the Firewall Threat Defense chooses the OSPF route because OSPF has a higher preference. In this case, the router adds the OSPF version of the route to the routing table.

A VPN advertised route (V-Route/RRI)) is equivalent to a static route with the default administrative distance 1. But it has a higher preference as with the network mask 255.255.255.255.

In this example, if the source of the OSPF-derived route was lost (for example, due to a power shutdown), the Firewall Threat Defense would then use the RIP-derived route until the OSPF-derived route reappears.

The administrative distance is a local setting. For example, if you change the administrative distance of routes obtained through OSPF, that change would only affect the routing table for the Firewall Threat Defense on which the command was entered. The administrative distance is not advertised in routing updates.

Administrative distance does not affect the routing process. The routing processes only advertise the routes that have been discovered by the routing process or redistributed into the routing process. For example, the RIP routing process advertises RIP routes, even if routes discovered by the OSPF routing process are used in the routing table.

Backup Dynamic and Floating Static Routes

A backup route is registered when the initial attempt to install the route in the routing table fails because another route was installed instead. If the route that was installed in the routing table fails, the routing table maintenance process calls each routing protocol process that has registered a backup route and requests them to reinstall the route in the routing table. If there are multiple protocols with registered backup routes for the failed route, the preferred route is chosen based on administrative distance.

Because of this process, you can create floating static routes that are installed in the routing table when the route discovered by a dynamic routing protocol fails. A floating static route is simply a static route configured with a greater administrative distance than the dynamic routing protocols running on the Firewall Threat Defense. When the corresponding route discovered by a dynamic routing process fails, the static route is installed in the routing table.

How forwarding decisions are made

A forwarding decision is a network routing process that

- determines the appropriate interface for packet transmission based on destination address matching in the routing table
- prioritizes routes with longer network prefix lengths when multiple matches exist, and
- directs packets through default routes when no specific routing table entries match the destination.

Forwarding decision process

Forwarding decisions are made as follows:

- If the destination does not match an entry in the routing table, the packet is forwarded through the interface specified for the default route. If a default route has not been configured, the packet is discarded.
- If the destination matches a single entry in the routing table, the packet is forwarded through the interface associated with that route.
- If the destination matches more than one entry in the routing table, then the packet is forwarded out of the interface associated with the route that has the longer network prefix length.

Note When a route change occurs, the Threat Defense re-evaluates the forwarding decision of established connections the next time a packet is seen on the flow.

The resulting behavior is determined by your configuration:

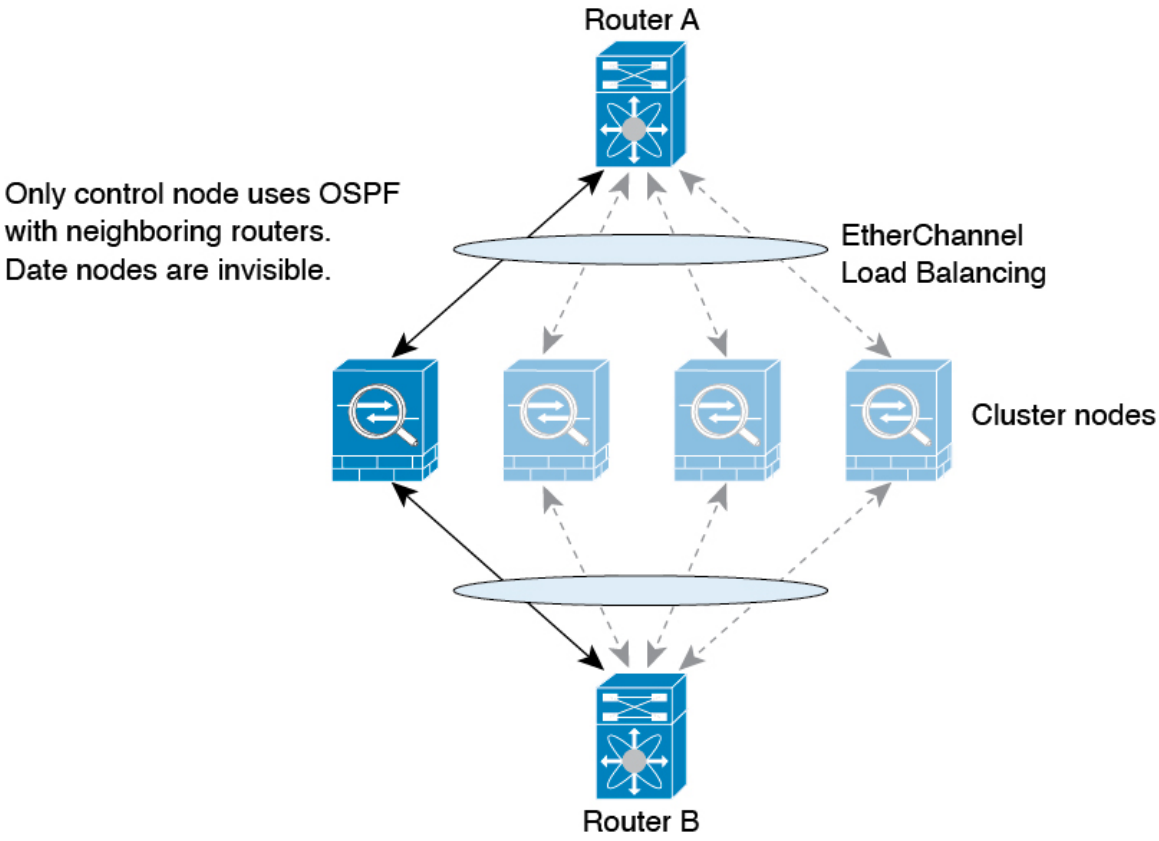
Configuration	Behavior	Outcome
Default (timeout floating-conn 0, no ECMP zone)	Retains the original egress path initially.	If that path can no longer resolve the destination, the flow is torn down after the conn-holddown period (default 15s) rather than waiting for an idle timeout.
Floating-Connection (timeout floating-conn configured)	Identifies a new optimal path on a different interface (outside the same ECMP zone).	The flow is torn down after the floating-conn timeout to allow for a fresh connection. Note: May trigger %FTD-6-110003 syslog messages.
ECMP Zone (Both interfaces in the same ECMP zone)	Dynamically updates the flow's egress interface.	The flow is switched to the new path atomically and non-disruptively.

Longest prefix match example

For example, a packet destined for 192.168.32.1 arrives on an interface with these routes in the routing table:

- 192.168.32.0/24 gateway 10.1.1.2
- 192.168.32.0/19 gateway 10.1.1.3

In this case, a packet destined to 192.168.32.1 is directed toward 10.1.1.2, because 192.168.32.1 falls within the 192.168.32.0/24 network. It also falls within the other route in the routing table, but 192.168.32.0/24 has the longest prefix within the routing table (24 bits verses 19 bits). Longer prefixes are always preferred over shorter ones when forwarding a packet.



Dynamic routing and High availability

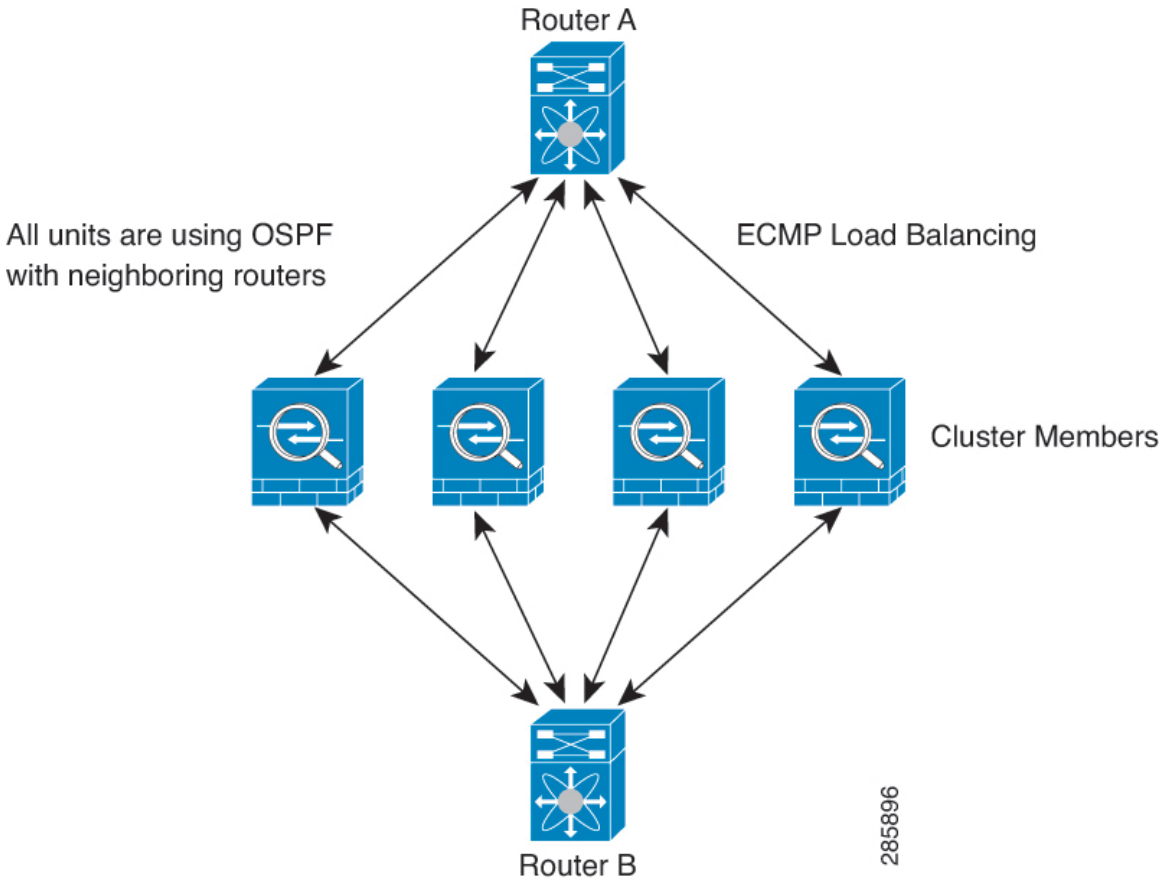
Dynamic routes are synchronized on the standby unit when the routing table changes on the active unit. This means that all additions, deletions, or changes on the active unit are immediately propagated to the standby unit. If the standby unit becomes active in an active/standby ready High availability pair, it will already have an identical routing table as that of the former active unit because routes are synchronized as a part of the High availability bulk synchronization and continuous replication processes.

Dynamic routing in Clustering

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.

Figure 379: Dynamic Routing in Spanned EtherChannel Mode

After the data node learn the routes from the control node, each node makes forwarding decisions independently.



The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

Dynamic routing in individual interface mode

Learn how dynamic routing functions in individual interface mode, where each cluster node operates as a standalone router. Understand how to configure unique router IDs and manage traffic zones to ensure effective load balancing and prevent asymmetric routing in your network environment.

In Individual interface mode, each node runs the routing protocol as a standalone router, and routes are learned by each node independently.

Figure 380: Dynamic Routing in Individual Interface Mode

In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

EIGRP does not form neighbor relationships with cluster peers in individual interface mode.

Note If the cluster has multiple adjacencies to the same router for redundancy purposes, asymmetric routing can lead to unacceptable traffic loss. To avoid asymmetric routing, group all of these node interfaces into the same traffic zone. See Create an ECMP zone, on page 1211.

Routing table for management traffic

The Firewall Threat Defense device includes the following routing tables for from-the-device management traffic:

- Linux Management routing table—Special management traffic sourced from the Management interface such as Firewall Management Center communication, licensing communication, and database updates always uses the Linux Management routing table.
- Data routing table—All from-the-device traffic (as well as all through traffic) uses the data routing table by default. All regular data interfaces are part of this routing table. Most services let you choose a specific interface, so only routes associated with that interface are used.
- Management-only routing table—The Management interface and all data interfaces that you set to management-only are part of this routing table. To send from-the-device traffic from any of these interfaces, you must choose a specific management-only interface when you configure the service. An exception is for DNS lookups and ICMP (ping and traceroute): in these cases, the Firewall Threat Defense will use data and then fall back to management automatically if a route is not found. You can add static routes for management-only interfaces, but not for the special Management interface. The Firewall Threat Defense device automatically adds a default route for Management that forwards traffic to Linux, where a separate route lookup occurs in the Linux routing table. You can add static routes to the Linux routing table that can be used by Management using the Firewall Threat Defense CLI **configure network static-routes** command.

Note The *default* Linux route is set with the **configure network ipv4** or **configure network ipv6** command.

Note For devices that have not yet merged the Management and legacy Diagnostic interfaces, see refer to pre-7.3 versions of this guide.

Equal-cost multi-path routing

The Firewall Threat Defense supports Equal-Cost Multi-Path (ECMP) routing.

ECMP routing implementation

You can have up to 8 equal cost static or dynamic routes per interface. For example, you can configure multiple default routes on the outside interface that specify different gateways.

```
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.3
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.4
```

In this case, traffic is load-balanced on the outside interface between 10.1.1.2, 10.1.1.3, and 10.1.1.4. Traffic is distributed among the specified gateways based on an algorithm that hashes the source and destination IP addresses, incoming interface, protocol, source and destination ports.

ECMP Across Multiple Interfaces Using Traffic Zones

If you configure traffic zones to contain a group of interfaces, you can have up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone. For example, you can configure multiple default routes across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2
route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

Similarly, your dynamic routing protocol can automatically configure equal cost routes. The Firewall Threat Defense load-balances traffic across the interfaces with a more robust load balancing mechanism.

When a route is lost, the device seamlessly moves the flow to a different route.

Routing GRE traffic

In Firewall Threat Defense, Generic Routing Encapsulation (GRE) traffic is managed using bi-directional flows. This means that each GRE session is represented by a single flow entry that handles both inbound and outbound traffic between endpoints. With bi-directional flows, only one route lookup is performed and both directions are mapped to the same interface. As a result, the system cannot make independent routing decisions for each direction, which may lead to sub-optimal routing in some scenarios.

About route maps

Route maps are used when redistributing routes into an OSPF, RIP, EIGRP or BGP routing process. They are also used when generating a default route into an OSPF routing process. A route map defines which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process.

Route map characteristics

Route maps have many features in common with widely known ACLs. These are some of the traits common to both:

- They are an ordered sequence of individual statements, and each has a permit or deny result. Evaluation of an ACL or a route map consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is aborted once the first statement match is found and an action associated with the statement match is performed.
- They are generic mechanisms. Criteria matches and match interpretation are dictated by the way that they are applied and the feature that uses them. The same route map applied to different features might be interpreted differently.

These are some of the differences between route maps and ACLs:

- Route maps are more flexible than ACLs and can verify routes based on criteria which ACLs can not verify. For example, a route map can verify if the type of route is internal.
- Each ACL ends with an implicit deny statement, by design convention. If the end of a route map is reached during matching attempts, the result depends on the specific application of the route map. Route maps that are applied to *redistribution* behave the same way as ACLs: if the route does not match any clause in a route map then the route redistribution is denied, as if the route map contained a deny statement at the end.

Permit and deny clauses

Route maps can have permit and deny clauses. The deny clause rejects route matches from redistribution. You can use an ACL as the matching criterion in the route map.

Route map and ACL clause interaction rules

Because ACLs also have permit and deny clauses, the following rules apply when a packet matches the ACL:

- ACL permit + route map permit: routes are redistributed.
- ACL permit + route map deny: routes are not redistributed.
- ACL deny + route map permit or deny: the route map clause is not matched, and the next route-map clause is evaluated.

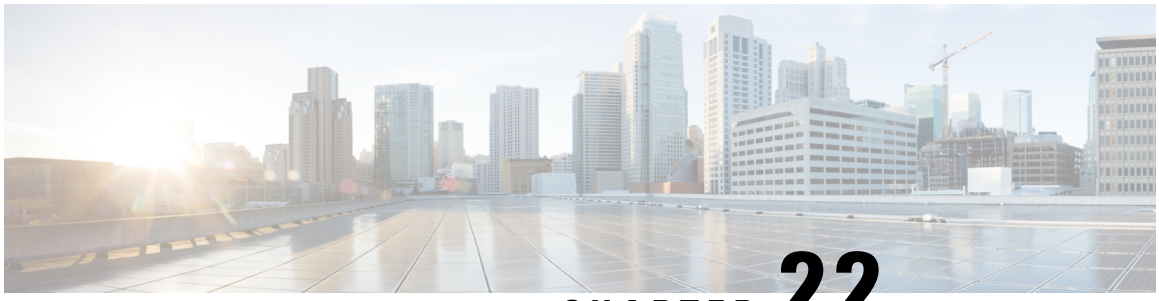
Match and set clause values

Each route map clause has two types of values:

- A match value selects routes to which this clause should be applied.
- A set value modifies information that will be redistributed into the target protocol.

Route map evaluation process

For each route that is being redistributed, the router first evaluates the match criteria of a clause in the route map. If the match criteria succeeds, then the route is redistributed or rejected as dictated by the permit or deny clause, and some of its attributes might be modified by the values set from the set commands. If the match criteria fail, then this clause is not applicable to the route, and the software proceeds to evaluate the route against the next clause in the route map. Scanning of the route map continues until a clause is found that matches the route or until the end of the route map is reached.



A match or set value in each clause can be missed or repeated several times, if one of these conditions exists:

- If several match entries are present in a clause, all must succeed for a given route in order for that route to match the clause (in other words, the logical AND algorithm is applied for multiple match commands).
- If a match entry refers to several objects in one entry, either of them should match (the logical OR algorithm is applied).
- If a match entry is not present, all routes match the clause.
- If a set entry is not present in a route map permit clause, then the route is redistributed without modification of its current attributes.

Note Do not configure a set entry in a route map deny clause because the deny clause prohibits route redistribution—there is no information to modify.

A route map clause without a match or set entry does perform an action. An empty permit clause allows a redistribution of the remaining routes without modification. An empty deny clause does not allow a redistribution of other routes (this is the default action if a route map is completely scanned, but no explicit match is found).

CHAPTER 22

Virtual Routers

This chapter describes underlying concepts about virtual routers and on how virtual routing behaves within the Secure Firewall Threat Defense.

- Virtual routers and virtual routing and forwarding (VRF), on page 1153
- Maximum number of virtual routers by device model, on page 1159
- Requirements and prerequisites for virtual routers, on page 1161
- Guidelines and limitations for virtual routers, on page 1161
- Manage virtual routers, on page 1164
- Create a virtual router, on page 1164
- Monitor virtual routers, on page 1168
- Configuration examples for virtual routers, on page 1168
- History for virtual routers, on page 1207

Virtual routers and virtual routing and forwarding (VRF)

A virtual router is a network virtualization feature that

- maintains separate routing tables for groups of interfaces
- provides clean separation in the traffic flowing through the device, and
- implements the "light" version of Virtual Routing and Forwarding, or VRF-Lite, which does not support Multiprotocol Extensions for BGP (MBGP).

Virtual router capabilities and configuration

Virtual routers provide support to two or more distinct customers over a common set of networking equipment. You can also use virtual routers to provide more separation for elements of your own network, for example, by isolating a development network from your general purpose corporate network.

When you create a virtual router, you assign interfaces to the router. You can assign a given interface to one, and only one, virtual router. You would then define static routes, and configure routing protocols such as OSPF or BGP, for each virtual router. You would also configure separate routing processes over your entire network, so that routing tables on all participating devices are using the same per-virtual-router routing process and tables. Using virtual routers, you create logically-separated networks over the same physical network to ensure the privacy of the traffic that runs through each virtual router.

Because the routing tables are separate, you can use the same, or overlapping, address spaces across the virtual routers. For example, you could use the 192.168.1.0/24 address space for two separate virtual routers, supported by two separate physical interfaces.

Note that there are separate management and data routing tables per virtual router. For example, if you assign a management-only interface to a virtual router, then the routing table for that interface is separate from the data interfaces assigned to the virtual router.

Virtual routers and dynamic VTI

You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. You can assign a dynamic VTI to only one virtual router. For more information, refer to Virtual Routers and Dynamic VTI, on page 1541.

Virtual router applications

Virtual router applications are network implementation scenarios that

- isolate networks on shared resources through dedicated routing tables
- enable common security policy management across different departments or networks, and
- provide shared internet access for different departments or networks.

Global and user-defined virtual routers

This reference provides information about global and user-defined virtual routers, including their characteristics and the features supported by each type.

Global virtual routers

For a device with virtual routing capability, system creates a global virtual router by default. The system assigns all interfaces in your network to the global virtual router. A routed interface can belong to either a user-defined virtual router or a global virtual router. When you upgrade Firewall Threat Defense to a version which has virtual router capability, all its existing routing configuration becomes part of the global virtual router.

User-Defined virtual routers

A user-defined virtual router is the one defined by you. You can create more than one virtual router on a device. However, anytime, an interface can be assigned to only one user-defined virtual router. While some of the device features are supported on user-defined virtual routers, few of the features are supported only on the global virtual routers. User-defined virtual routers support route-based site-to-site VPN (static VTI) (static and dynamic VTI).

Supported features and monitoring policies

You can configure these features on the global virtual router only:

- OSPFv3
- RIP

- EIGRP
- IS-IS
- Multicast Routing
- Policy Based Routing (PBR)

ISIS and PBR are supported through Flex Config in Firewall Management Center (see Predefined FlexConfig objects, on page 1096). Configure only global virtual router interfaces for these features.

DHCP server auto-configuration uses WINS/DNS server that is learned from an interface. This interface can only be a global virtual router interface.

You can configure these features separately for each user-defined virtual router:

- Static routes and their SLA monitors
- OSPFv2
- BGPv4/v6
- Integrated Routing and Bridging (IRB)
- SNMP

These features are used by the system when querying or communicating with the remote system (from-the-box traffic). These features use interfaces in the global virtual router only. That means, if you configure an interface for the feature, it must belong to the global virtual router. As a rule, anytime, if the system must look up a route to reach an external server for its own management purposes, it does the route lookup in the global virtual router.

- DNS server when used to resolve fully qualified names used in access control rules, or for resolving names for the **ping** command. If you specify **any** as the interface for a DNS server, the system considers interfaces in the global virtual router only.
- AAA server or identity realm when used with VPN. You can configure VPN on interfaces in the global virtual router only. Thus, the external AAA servers that are used for VPN, such as Active Directory, must be reachable through an interface in the global virtual router.

Virtual-router-aware policies

Virtual-router-aware policies are security policies that

- apply to interfaces from a single virtual router only
- use security zones whose memberships are constrained to interfaces assigned to a specific virtual router, and
- prevent policies from affecting all interfaces across all virtual routers when that is not desired.

Virtual router policy behavior

When you create a virtual router, the routing table for that virtual router is automatically separated from the global virtual router or any other virtual router. However, security policies are not automatically virtual-router-aware.

For example, if you write an access control rule that applies to "any" source or destination security zone, then the rule will apply to all interfaces across all virtual routers. This might in fact be exactly what you want. For example, all of your customers might want to block access to the same list of objectionable URL categories.

But, if you need to apply a policy to one of the virtual routers but not others, you need to create security zones that contain interfaces from that single virtual router only. Then, use the virtual-router-constrained security zones in the source and destination criteria of the security policy.

By using security zones whose memberships are constrained to the interfaces assigned to a single virtual router, you can write virtual-router-aware rules in these policies:

- Access control policy.
- Intrusion and file policies.
- SSL decryption policy.
- Identity policy and user-to-IP address mappings. If you use overlapping address spaces in virtual routers, ensure that you create separate realms for each virtual router and apply them correctly in the identity policy rules.

If you use overlapping address spaces in your virtual routers, you should use security zones to ensure that the right policies get applied. For example, if you use the 192.168.1.0/24 address space in two separate virtual routers, an access control rule that simply specifies the 192.168.1.0/24 network will apply to traffic in both virtual routers. If that is not the desired outcome, you can limit the application of the rule by also specifying the source/destination security zones for just one of the virtual routers.

Virtual router interconnection

Virtual router interconnection is a routing mechanism that

- enables traffic routing between virtual routers through route leaking,
- supports both manual static routes and dynamic BGP configurations, and
- allows network segmentation while maintaining controlled inter-segment communication.

Route leaking methods

You can configure the device to route traffic between virtual routers. This process of route leaking can be done manually by setting up static routes or dynamically through BGP settings.

Static route leaking involves manual configuration:

You can configure static routes to route traffic between virtual routers.

For example, if you have the outside interface in the global virtual router, you can set up static default routes in each of the other virtual routers to send traffic to the outside interface. Then, any traffic that cannot be routed within a given virtual router gets sent to the global router for subsequent routing.

Static routes between virtual routers are known as route leaks, because you are leaking traffic to a different virtual router. When you are leaking routes, say, VR1 routes to VR2, you can initiate connections from VR2 to VR1 only. For traffic to flow from VR1 to VR2, you must configure the reverse route. When you create a static route to an interface in another virtual router, you do not need to specify a gateway address. Simply select the destination interface.

For inter-virtual-router routes, the system does destination interface look-up in the source virtual router. Then, it looks up the MAC address of the next hop in the destination virtual router. Thus, the destination virtual router must have either a dynamic (learned) or static route for the selected interface for the destination address.

Configuring NAT rules that use source and destination interfaces in different virtual routers can also allow traffic to route between virtual routers. If you do not select the option for NAT to do a route lookup, the rule will simply send traffic out the destination interface with a NATed address whenever destination translation happens. However, the destination virtual router should have a route for the translated destination IP address so that next-hop lookup can succeed.

Though NAT rule leaks traffic from one virtual router to another, to ensure correct routing, we recommend that you configure a static route leak between these virtual routers for the translated traffic. Without the route leak, sometimes the rule may not match the traffic you expect it to match, and the translation may not be applied.

Virtual routing does not support a cascading or chain of route leaks. For example, assume that your Firewall Threat Defense has VR1, VR2, and VR3 virtual routers; VR3 is directly connected to a network - 10.1.1.0/24. Now, assume you configure a route leak in VR1 for network 10.1.1.0/24 through interface in VR2 and in VR2 define a route leak for 10.1.1.0/24 through VR3. This chain of route leaks will not allow traffic to hop from VR1 to VR2 and then exit from VR3. In case of route leaks, the route lookups first determine egress interface from input Virtual Router's routing table and then looks at the output of Virtual Router's routing table for next hop lookup. From both the lookups, egress interface should match. In our example, the egress interfaces will not be the same and hence the traffic does not pass through.

Use static inter VRF route with caution when the destination network is not a direct-connected subnet of the upstream (outgoing) VR. For example, assume two VRs - VR1 and VR2. While VR1 handles the outgoing traffic which gets the default route from its external peer through BGP or any dynamic routing protocol, and VR2 handles the incoming traffic which is configured with static inter VRF default route with VR1 as the next-hop. When VR1 loses the default route from its peer, VR2 will not able to detect that its upstream (outgoing) VR lost the default route and the traffic is still sent toward VR1 which will eventually get dropped without notifications. In this scenario, we recommend that you configure VR2 with dynamic route leak through BGP.

You can implement an inter-virtual-router route leak by exporting routes from a source virtual router (say VR1) to the source BGP table using route target extended community and then importing the same route target extended community from the source BGP table into the destination BGP table, which in turn is used by the destination virtual router (say, VR2). You can use the route maps for filtering the routes. The routes of global virtual router can also be leaked to user-defined virtual routers and vice versa. The BGP inter-virtual-router route leaking supports both ipv4 and ipv6 prefixes.

For details on configuring BGP route leaking, see Configure BGP route import and export, on page 1288.

BGP route leaking guidelines:

- Ensure that all the routes required for recursion are imported and present in the routing table of the ingress virtual router.
- ECMP is supported per virtual router. Hence, do not configure an ECMP across different virtual routers. The overlapping prefixes imported from different virtual routers cannot form an ECMP. That is, when you attempt to import routes with overlapping addresses from two different virtual routers to other virtual routers (a global virtual router or n user-defined virtual router), only one route (as per BGP best path algorithm, the first route that was advertised) is imported to the respective virtual routing table. For example, if a network 10.10.0.0/24, connected to VR1 is advertised through BGP to a global virtual router first, and later another network with the same address 10.10.0.0/24, connected to VR2 is also advertised through BGP to global virtual router, only the VR1 network route is imported to the global virtual routing table.

- OSPFv3 is not supported on user-defined virtual routers. Hence, do not configure BGPv6 to leak OSPFv3 user-defined virtual routers to global virtual router. However, you can configure BGPv6 to leak OSPFv3 global virtual router routes to user-defined virtual router through redistribution.
- It is recommended to keep VTI interface, protected internal interfaces (loopback interface if supported for VTI) to be part of same virtual router to prevent the need for route leak.

Best practice for overlapping IP addresses

Virtual router creates multiple instances of routing tables that are independent, thereby, the same or overlapping IP addresses can be used without conflicts. Firewall Threat Defense allows the same network to be part of two or more virtual routers. This involves multiple policies to be applied at the interface or at the virtual router level.

Limitations with overlapping IP addresses

When using an overlapping IP address in multiple virtual routers, to ensure proper application of the policy, you have to modify policies or rules for some of the features. Such features require you to use more specific interface either by splitting existing security zone or using new interface group as the need be.

- Network Map—Modify the network discovery policy to exclude some overlapping IP segments to ensure that there is no overlapping IP address being mapped.
- Identity Policy—The identity feed source cannot differentiate among virtual routers; to overcome this limitation, map overlapping address spaces or virtual routers in different realms.
- Access Policy—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.
- Prefilter Policy—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.
- QoS/Rate Limit—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.
- SSL Policy—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.

Unsupported features with overlapping IP addresses

These features are not supported with overlapping IP addresses:

- ISE SGT-based Rule in AC Policy—The static security group tag (SGT) to IP address mappings downloaded from Cisco Identity Services Engine (ISE) are not virtual-router-aware. Set up separate ISE systems per virtual router if you need to create different SGT mappings per virtual router. This is not necessary if you intend to map the same IP addresses to the same SGT number in each virtual router.
- Overlapping DHCP server pools are not supported across virtual routers.
- Events and Analytics—Many of the Firewall Management Center analytics are dependent on network map and identity mappings which cannot differentiate if the same IP address belongs to two different end hosts. Hence, these analytics are not accurate when there are overlapping IP segments existing in same device but different virtual routers.

Other than few exceptions, the routing functions and most of the NGFW and IPS capability does not get impacted by the overlapping IP addresses.

Configuring SNMP on user-defined virtual routers

In addition to supporting SNMP on the management interface and Global virtual router data interfaces, Secure Firewall Threat Defense now allows you to configure SNMP host on user-defined virtual routers.

Summary

The key components involved in configuring SNMP on user-defined virtual routers are:

- Device interfaces: Physical or logical interfaces that need to be configured and enabled
- Virtual router: User-defined virtual router configured on specific interfaces
- SNMP hosts: Network management stations that receive SNMP polling and traps
- Secure Firewall Threat Defense: The target device where configurations are deployed

Workflow

The SNMP configuration on user-defined virtual routers involves these stages:

1. Configure device interfaces.
2. Configure virtual router on an interface.
3. Configure SNMP hosts on a virtual router interface.

Note SNMP is not virtual router-aware. Hence, while configuring SNMP server on the user-defined virtual router, ensure that the network address is not an overlapping IP address.

4. Deploy configurations to Secure Firewall Threat Defense.

   On successful deployment, the SNMP polling and traps are sent to the Network Management Station through the virtual router interface.

Maximum number of virtual routers by device model

The maximum number of virtual routers you can create depends on the device model. The following table shows the maximum supported virtual routers per model. You can confirm the maximum for your system by entering the **show vrf counters** command, which displays the maximum number of user-defined virtual routers for your platform (not including the global virtual router). The numbers below include both user and global routers. For Firepower 4100/9300 devices, these values apply to native mode.

For platforms that support multi-instance capability, such as the Firepower 4100/9300, determine the maximum number of virtual routers per container instance by dividing the maximum virtual routers by the number of cores on the device, and then multiplying by the number of cores assigned to the instance, rounding down to the nearest whole number. For example, if the platform supports a maximum of 100 virtual routers, and it has

70 cores, then each core would support a maximum of 1.43 virtual routers (rounded). Thus, an instance assigned 6 cores would support 8.58 virtual routers, which rounds down to 8, and an instance assigned 10 cores would support 14.3 virtual routers (rounding down, 14).

Device Model	Maximum Virtual Routers
Secure Firewall 220	5
Firepower 1010	5
Firepower 1120	5
Firepower 1140	10
Firepower 1150	10
Secure Firewall 1210CE	5
Secure Firewall 1210CP	5
Secure Firewall 1220CX	10
Secure Firewall 1230	10
Secure Firewall 1240	10
Secure Firewall 1250	15
Secure Firewall 3105	10
Secure Firewall 3110	15
Secure Firewall 3120	25
Secure Firewall 3130	50
Secure Firewall 3140	100
Firepower 4112	60
Firepower 4115	80
Firepower 4125	100
Firepower 4145	100
Secure Firewall 4215	250
Secure Firewall 4225	250
Secure Firewall 4245	250
Secure Firewall 6160	250
Secure Firewall 6170	250

Device Model	Maximum Virtual Routers
Firepower 9300 appliance, all models	100
Firewall Threat Defense Virtual, all platforms	30
ISA 3000	10

Use virtual routers on routed firewall mode only.

Interface guidelines

Configure interfaces for virtual routers according to these guidelines:

- Assign an interface to only one virtual router.
- A virtual router can have any number of interfaces that are assigned to it.
- Assign only routed interfaces with logical names and VTIs to a user-defined virtual router.
- If you want to change a virtual router interface to a non-routed mode, remove the interface from the virtual router, and then change its mode.

- You can assign an interface to a virtual router, either from a global virtual router or from another user-defined virtual router.
- Do not assign these interfaces to a user-defined virtual router:
  - Members of EtherChannel.
  - Members of Redundant interfaces.
  - Members of BVI.
- VTI is a route-based VPN. When the tunnel is established, control the traffic that uses VTI for encryption through routing. Static routing, as well as dynamic routing with BGP, OSPFv2/v3, or EIGRP is supported.
- Do not use interfaces that belong to user-defined virtual routers in policy-based site-to-site or remote access VPNs.
- A dynamic VTI and its corresponding protected network interface must be part of the same virtual router.
- You must map the borrow IP interface and the dynamic VTI to the same virtual router.
- User-defined virtual routers support only BGPv4/v6 and OSPFv2 routing protocols.
- A tunnel source interface can be in a different user-defined virtual router than that associated with the dynamic VTI.

Follow these precautions when moving interfaces between virtual routers:

- If a route using the interface that is being moved or its virtual router is deleted, exist in source or destination virtual router table, remove the routes before the interface movement or virtual router deletion.
- As separate routing tables are maintained for each virtual router, when an interface is moved from one virtual router to another virtual router, be it global or user-defined, the system removes the IP address configured on the interface temporarily. All existing connections on the interface are terminated. Thus, moving interfaces between virtual routers have drastic effect on the network traffic. Hence take precautionary measures before you move interfaces.

Global virtual router guidelines

Consider these guidelines for global virtual routers:

- The interfaces which are named and not part of other virtual routers, are part of the global virtual router.
- Do not remove routed interfaces from global virtual router.
- Do not modify global virtual router.
- Generally, after configuring interfaces, if you un-register and register back to same or another Firewall Management Center, interface configuration is imported back from device. With virtual router support, there is a restriction—the IP address for only global virtual router interfaces is retained.

Clustering guidelines

Consider these limitations when using virtual routers with clustering:

- When the control unit link fails due to failure of its interfaces, the unit removes all leaked routes of its interfaces from the global routing table and propagates the inactive connected and static routes to other units of the cluster. This results in removal of those leaked routes from the routing table in other units.

These removal takes place prior to another unit becoming a new control unit, which takes approximately 500 ms. When another unit becomes the new control unit, these routes are learned and added back to the routing tables through BGP convergence. Thus, till the convergence time, approximately one minute, the leaked routes are not available for the routing events to take place.

- When a control role change occurs in a cluster, the leaked routes learnt through BGP is updated with the best ECMP path. However, the non-best ECMP path is removed from the cluster routing table only after the BGP reconvergence timer elapses, that is 210 seconds. Thus, till the BGP reconvergence timer elapse, the old, non-best ECMP path persist as preferred route for routing events.

Additional guidelines

Follow these additional guidelines when configuring virtual routers:

- While configuring BGP for virtual routers, you can redistribute the routes belonging to different protocols within the same virtual routers. For example, OSPF VR2 routes cannot be imported into BGP VR1. You can only redistribute OSPF VR2 into BGP VR2, and then configure a route leak between BGP VR2 and BGP VR1.
- Do not use IPv6 ACL for filtering the routes in the route map. Only prefix list is supported.
- Security Intelligence Policy—The Security Intelligence policy is not virtual-router-aware. If you add an IP address, URL, or DNS name to the block list, it is blocked for all virtual routers. This limitation is applicable on the interface having security zones.
- NAT Rules—Do not mix interfaces in NAT rules. In virtual routing, if the specified source and destination interface objects (interface groups or security zones) have interfaces that belong to different virtual routers, the NAT rule diverts traffic from one virtual router through another virtual router. The NAT does the route lookup in the virtual router table for the inbound interface only. If necessary, define static routes in the source virtual router for the destination interface. If you leave the interface as **any**, the rule applies to all interfaces regardless of virtual router membership.
- DHCP Relay—Interconnecting virtual routers for DHCP relay is not supported. For example, if DHCP relay client is enabled on VR1 interface and DHCP relay server is enabled on VR2 interface, the DHCP requests will not be forwarded outside of VR2 interface.
- Recreating a deleted virtual router—When you recreate a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to recreate a deleted virtual router successively, use a different name for the new virtual router.
- The Threat Defense Snort engine maintains state for each traffic flow and is designed to inspect each flow exactly once. Duplicate or double inspection is unsupported when repeated traffic maps to the same Snort flow key, because the subsequent instance is associated with the existing per-flow state and may be identified as an anomaly.

  This can occur when a flow re-enters the device through a different interface or VLAN, is rerouted by an ACI fabric with different VLAN tags, or traverses VRF cross-VLAN paths. The resulting drop may appear in packet-tracer or capture output as:

  ```
  Drop-reason: (stream) Blocked or blacklisted by the stream preprocessor.
  ```

  If a flow-identifying attribute differs such that the traffic maps to a different Snort flow key, Snort can process the flows independently. However, differences in fields that are not part of the flow key do not create a separate flow.

From an optimal network architecture perspective, each traffic flow, in both directions, should traverse the Snort engine only once. If duplicate inspection cannot be avoided, use a prefilter or fastpath rule to bypass Snort inspection for the affected flows.

Manage virtual routers

When you click **Manage Virtual Routers** on the Virtual Routers pane, the Manage Virtual Routers page appears. This page displays the existing virtual routers on the device and the associated interfaces. On this page, you can **Add Virtual Router** (+) to the device. You can also **Edit** (✎) and **Delete** (🗑) user-defined virtual routers. You cannot edit or remove a global virtual router. You can only **View** (🔍) the details of a global virtual router.

Create a virtual router

Create a virtual router to enable network segmentation and manage routing configurations independently within the firewall device.

Virtual routers allow you to segment network traffic and create separate routing domains within a single firewall device, providing enhanced network management and security isolation.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

Step 4 Click **Add Virtual Router** (+).

Step 5 In the Add Virtual Router box, enter a name and description for the virtual router.

Note If you are creating a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to create a deleted virtual router successively, use a different name for the new virtual router.

Step 6 Click **Ok**.

The Routing page appears, displaying the newly created virtual router page.

The virtual router is successfully created and appears in the routing configuration interface, ready for further configuration.

What to do next

- Configure a Virtual Router.

Configure a virtual router

Configure a virtual router to assign interfaces and set up routing policies for network traffic management and routing capabilities on your device.

You can assign interfaces to a user-defined virtual router and configure the routing policies for the device. Though you cannot manually add or remove interfaces for a global virtual router, you can configure the routing policies for the device interfaces.

Before you begin

- To configure routing policies for a user-defined virtual router, add a router. See Create a virtual router, on page 1164.
- All routing configuration settings of a non-virtual routing capable device are also available for a global virtual router. For information on the settings, see Routing Settings.
- Only limited routing protocols are supported for a user-defined virtual router.

Procedure

Step 1 From the **Devices** > **Device Management** page, edit the virtual-router supported device. Navigate to **Routing**.

For information on the modifications to the routing page, see Modifications to the Firewall Management Center web interface routing page.

Step 2 From the drop-down list, select the desired virtual router.

Step 3 In the **Virtual Router Properties** page, modify the description as needed.

Step 4 To add interfaces, select the interface under the **Available Interfaces** box, and then click **Add**.

Remember these guidelines:

- Only interfaces with a logical name are listed under the **Available Interfaces** box. You can edit the interface and provide a logical name in **Interfaces**. Remember to save the changes for the settings to take effect.
- Only interfaces of global virtual routers are available for assigning; the **Available Interfaces** box lists only interfaces that are not assigned to any other user-defined virtual routers. You can assign physical interfaces, subinterfaces, redundant interfaces, bridge groups, VTIs, and EtherChannels to a virtual router, but not their member interfaces. Because the member interfaces cannot be named, they cannot be used in virtual routing.

  You can assign the diagnostic interface to the global virtual router only.

Step 5 To save the interface settings, click **Save**.

Step 6 To configure the routing policy for the virtual router, click the respective names to open the corresponding settings page:

- **OSPF**—Only OSPFv2 is supported on the user-defined virtual router. All other settings for OSPFv2 are as applicable as for a non-virtual-router-aware interface, except that **Interface** allows you to select only the interfaces of the virtual router that you are configuring. You can define the OSPFv3 and OSPFv2 routing policies for a global virtual router. For information on the OSPF settings, see OSPF, on page 1225.
- **RIP**—You can configure RIP routing policies only for a global virtual router. For information on RIP settings, see RIP, on page 1293.
- **BGP**—This page displays the BGP general settings that you have configured in **Settings**:
  - You cannot modify any of those general settings on this page, except for the router ID settings. You can override the router ID settings that were defined in the **Settings** page by editing them on this page.
  - To configure other BGP IPv4 or IPv6 settings, you must enable the BGP option in **BGP** page under **General Settings**.
  - BGP configuration for both IPv4 and IPv6 address family are supported for global router and the user-defined virtual router.

  For information on configuring BGP settings, see BGP, on page 1269.
- **Static Route**—Use this setting to define where to send traffic for a specific destination network. You can also use this setting to create an inter-virtual-router static route. You can create a leak of connected or static route by using the interfaces of user-defined or global virtual routers. **FMC prefixes** to an interface to indicate that it is belonging to another virtual router and can be used for a route leak. For the route leak to be successful, do not specify next hop gateway.

  The Static Route table displays the virtual router whose interface is used for a route leak in the **Leaked from Virtual Router** column. If it is not a route leak, the column displays N/A.

  Irrespective of which virtual router the static route belongs, a Null0 interface is listed along with the interfaces of the same virtual router to which the static route belongs.

  For information on static route settings, see Static and Default Routes, on page 1135.
- **Multicast**—You can configure multicast routing policies only for a global virtual router. For information on multicast settings, see Multicast, on page 1301.

Step 7 To save the routing policy settings, click **Save**.

The virtual router is configured with the assigned interfaces and routing policies you specified.

What to do next

- Modify a virtual router.
- Remove a virtual router.

Modify a virtual router

This task allows you to update the configuration settings of virtual routers to meet changing network requirements.

You can modify the description and other routing policies of a virtual router.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

All virtual routers along with the assigned interfaces are displayed in the **Virtual Routers** page.

Step 4 To modify a virtual router, click **Edit** (✎) against the desired virtual router.

Note You cannot modify the general settings of the global virtual router. Hence, edit is not available for the global router; instead a **View** (🔍) is provided to view the settings.

Step 5 To save the changes, click **Save**.

The virtual router configuration is updated with your changes.

What to do next

- Remove a virtual router.

Remove Virtual Routers

Remove virtual routers when they are no longer needed or when consolidating routing configurations. This helps maintain a clean and efficient network routing structure.

Virtual routers provide network segmentation and routing isolation. When removing virtual routers, all associated interfaces automatically move to the global virtual router, and all routing policies are deleted.

Before you begin

- You cannot delete the Global virtual router. Hence, the delete option is not available for the Global virtual router.
- You can remove multiple virtual routers at a time.
- All the routing policies of the deleted virtual router are also deleted.
- All the interfaces of the deleted virtual router move to the global virtual router.
- If there are any restrictions on the movement of interfaces, such as overlapping IPs, route conflicts, and so on, you can remove the router only after resolving the conflicts.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

All virtual routers along with the mapped interfaces are displayed in the **Virtual Routers** page.

Step 4 To remove a virtual router, click **Delete** ( ) against the desired virtual router.

Step 5 To remove multiple routers, holding the CTRL key, click the virtual routers that you want to delete. Right-click, and then click **Delete**.

Step 6 To save the changes, click **Save**.

The selected virtual routers are removed from the device configuration. All interfaces from the deleted virtual routers are automatically moved to the global virtual router, and all associated routing policies are permanently deleted.

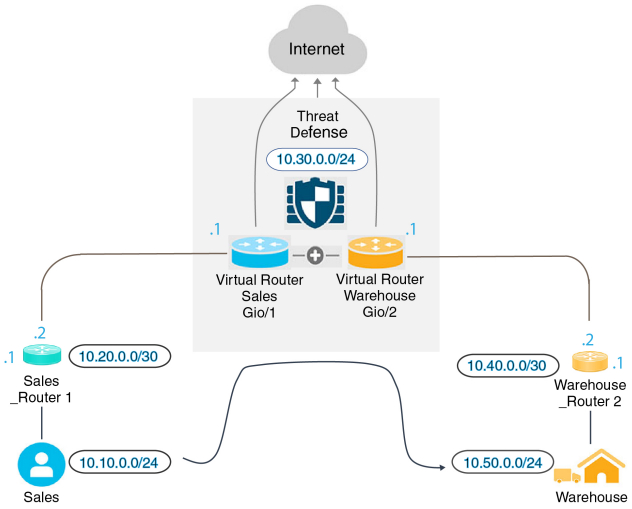
Monitor virtual routers

To monitor and troubleshoot virtual routers, log into the device CLI and use these commands:

- **show vrf**: Displays the details of the virtual routers and their associated interfaces.
- **show route vrf** <*vrf_name*>: Displays the routing details of a virtual router.
- **show run router BGP all**: Displays the BGP routing details of all virtual router.
- **show run router BGP vrf** <*vrf_name*>: Displays the BGP routing details of a virtual router.
- **show crypto ipsec sa/show crypto ikev2 sa**: Displays the details of the tunnel and the associated virtual router.
- You can monitor the tunnels in the Site-to site monitoring dashboard (**Overview > Site to Site VPN**).

  In the **Tunnel Status** widget, hover over a topology, click View and click **Packet Tracer** to view and troubleshoot the threat defense VPN tunnels.

Configuration examples for virtual routers



Route to a distant server through virtual routers

This task enables network separation while maintaining connectivity to servers across different virtual routing domains. You can create multiple virtual routers to maintain separate routing tables for groups of interfaces and interconnect them to reach hosts that are multiple hops away.

In virtual routing, you can create multiple virtual routers to maintain separate routing tables for groups of interfaces, thereby achieve network separation. In some scenarios, you may need to access a server that is reachable only through a separate virtual router. This example provides the procedure that interconnects virtual routers to reach to a host that is multiple hops away.

Consider an example, where a member of the sales department of a garment company wants to look up at the stock maintained by the warehousing department of its factory unit. In a virtual routing environment, you need to leak route between virtual routers where destination (warehousing department) is multiple hops away from sales department. This route leaking is done by adding multihop route leak, where, you configure a static route in Sales virtual router(source) to an interface in Warehouse virtual router (destination). As the destination network is multi-hop away, you also need to configure the Warehouse virtual router with the route to the destination network, namely 10.50.0.0/24.

Figure 381: Interconnecting two virtual routers - an example

Before you begin

This example assumes that you have already configured Sales_Router1 to route traffic from 10.20.0.1/30 interface to 10.50.0.5/24.

Follow these steps to route to a distant server through virtual routers:

Procedure

Step 1 Configure the inside interface (Gi0/1) of the device to be assigned to Sales virtual router.

a) Choose **Devices** > **Device Management**, click the device name, and click **Interfaces**.

b) Edit the Gi0/1 interface.

- **Name**—For this example, VR-Sales.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 10.30.0.1/24.

c) Click **Ok**.
d) Click **Save**.

Step 2 Configure the inside interface (Gi0/2) of the device to be assigned to Warehouse virtual router.

a) Choose **Devices** > **Device Management**, click the device name, and click **Interfaces**.
b) Edit the Gi0/2 interface.

- **Name**—For this example, VR-Warehouse.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave it blank. The system does not allow you to configure interfaces with same IP address (10.30.0.1/24), as you are yet to create user-defined virtual routers.

c) Click **Ok**.
d) Click **Save**.

Step 3 Create Sales and Warehouse virtual routers and assign their interfaces.

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**.
c) Click **Add Virtual Router** and create Sales.
d) Click **Add Virtual Router** and create Warehouse.
e) Select Sales from virtual router drop-down, in **Virtual Router Properties**, add VR-Sales as **Selected Interface** and save.
f) Select Warehouse from virtual router drop-down, in **Virtual Router Properties**, add VR-Warehouse as **Selected Interface** and save.

Step 4 Revisit the VR-Warehouse interface configuration.

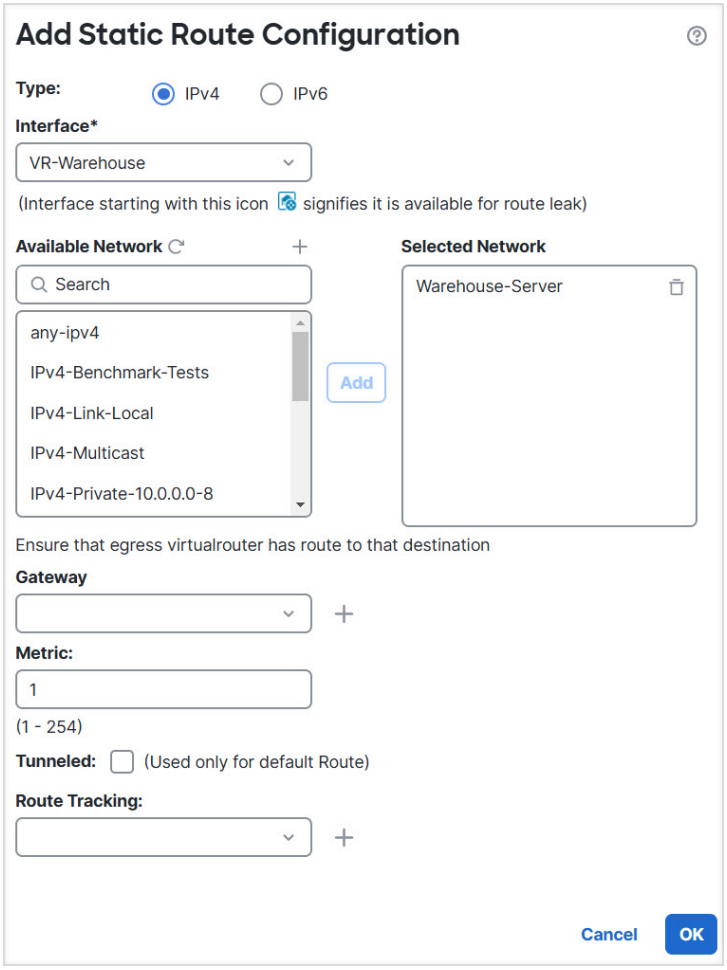
a) Choose **Devices** > **Device Management**, click the device name, and click **Interfaces**.
b) Click **Edit** against VR-Warehouse interface. Specify the IP Address as 10.30.0.1/24. The system now allows you to configure with same IP address of VR-Sales, because the interfaces are seperately assigned to two different virtual routers.
c) Click **Ok**.
d) Click **Save**.

Step 5 Create network objects for the warehouse server—10.50.0.0/24, and for the warehouse gateway— 10.40.0.2/30.

a) Choose **Objects**.
b) Choose **Add Network** > **Add Object**.

- **Name**—For this example, Warehouse-Server.
- **Network**—Click Network and enter 10.50.0.0/24.

c) Click **Save**.
d) Choose **Add Network** > **Add Object**.



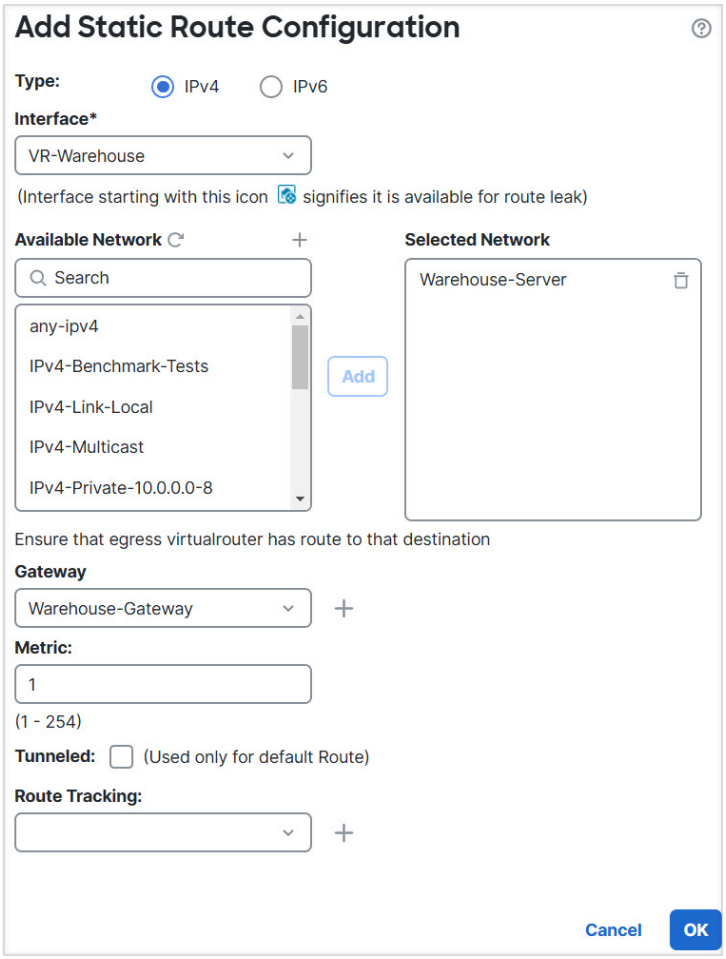
- **Name**—For this example, Warehouse-Gateway.
- **Network**—Click Host and enter 10.40.0.2.

e) Click **Save**.

Step 6 Define the route leak in Sales that points to the VR-Warehouse interface.

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing**.
c) Choose Sales virtual router from the drop-down, and then click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select VR-Warehouse.
- **Network**—Select the Warehouse-Server object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.



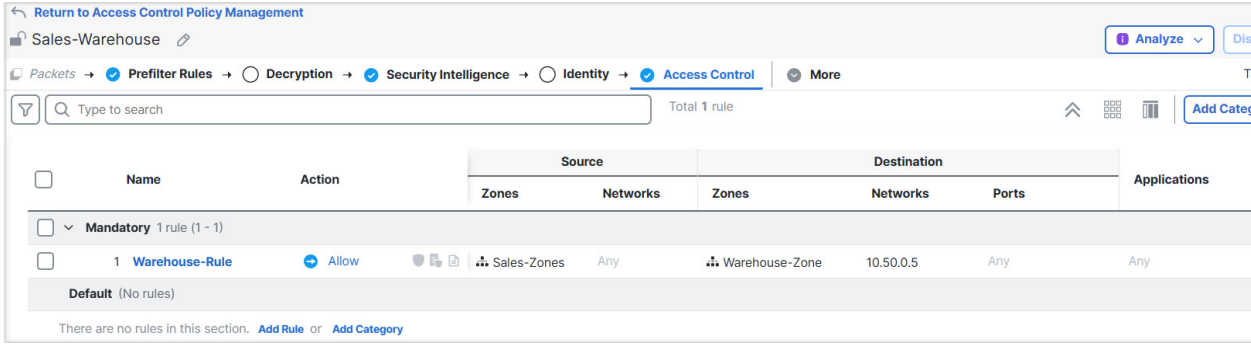
e) Click **Ok**.
f) Click **Save**.

Step 7 In the Warehouse virtual router, define the route that points to the Warehouse Router 2 gateway.

a) Choose Warehouse virtual router from the drop-down, and then click **Static Route**.
b) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select VR-Warehouse.
- **Network**—Select the Warehouse-Server object.

- **Gateway**—Select the Warehouse-Gateway object.



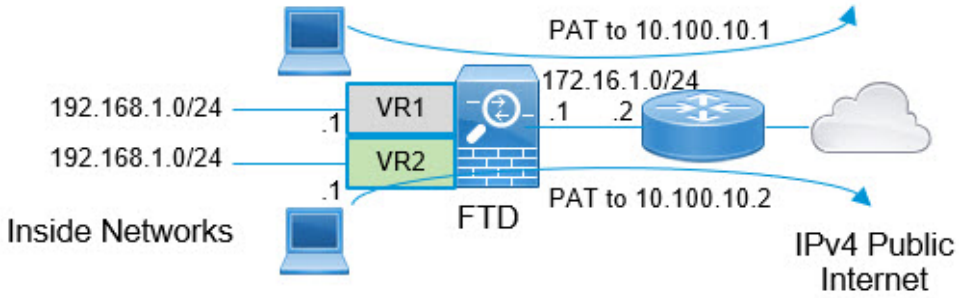
c) Click **Ok**.

d) Click **Save**.

Step 8 Configure access control rule that allows access to the warehouse server. For creating the access control rule, you need to create security zones. Use **Objects** > **Interface**. Choose **Add** > **Security Zone** and create security zones for VR-Sales and VR-Warehouse; for Warehouse-Server network object, create a Warehouse-Server interface group (Choose **Add** > **Interface Group**).

Step 9 Choose **Policies** > **Security policies** > **Access Control** and configure an access control rule to allow traffic from the source interfaces in the Sales virtual router to the destination interfaces in the Warehouse virtual router for the destination Warehouse-Server network object.

For example, if the interfaces in Sales are in the Sales-Zone security zone, and those in Warehouse are in the Warehouse-Zone security zone, the access control rule would look similar to this:



The route leak configuration enables traffic from the Sales virtual router to reach the warehouse server through the Warehouse virtual router. The access control rule allows the required traffic between the security zones.

How to Provide Internet Access with Overlapping Address Spaces

Ensure that endpoints using the same IP address space in different virtual routers can securely access the internet by implementing NAT/PAT policies

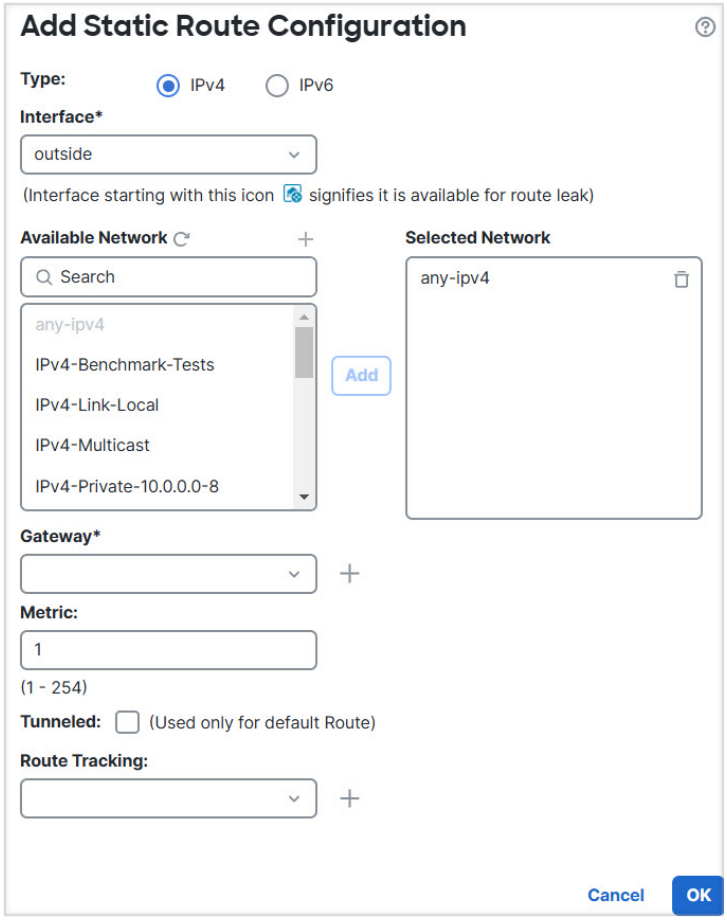
When using virtual routers, you can have the same network address for interfaces that reside in separate routers. However, because the IP addresses routed in these separate virtual routers are the same, apply NAT/PAT rules for each interface with separate NAT/PAT pools to ensure that return traffic goes to the correct destination. This example provides the procedure to configure the virtual routers and NAT/PAT rules to manage the overlapping address spaces.

For example, interfaces vr1-inside and vr2-inside on Firewall Threat Defense is defined to use the IP address 192.168.1.1/24, managing endpoints on their segment in the 192.168.1.0/24 network. To allow Internet access from two virtual routers that use the same address space, you need to apply NAT rules separately to the interfaces within each virtual router, ideally using separate NAT or PAT pools. You could use PAT to translate the source addresses in VR1 to 10.100.10.1, and for those in VR2, to 10.100.10.2. The following illustration shows this setup, where the Internet-facing outside interface is part of the global router. You must define the NAT/PAT rules with the source interface (vr1-inside and vr2-inside) explicitly selected—using “any” as the source interface makes it impossible for the system to identify the correct source because the same IP address could exist on two different interfaces.

Note Even if you have some interfaces within virtual routers that does not use overlapping address spaces, define the NAT rule with the source interface to make troubleshooting easier, and to ensure a cleaner separation between traffic from the virtual routers that is Internet-bound.

Procedure

Step 1 Configure the inside interface of the device for VR1:



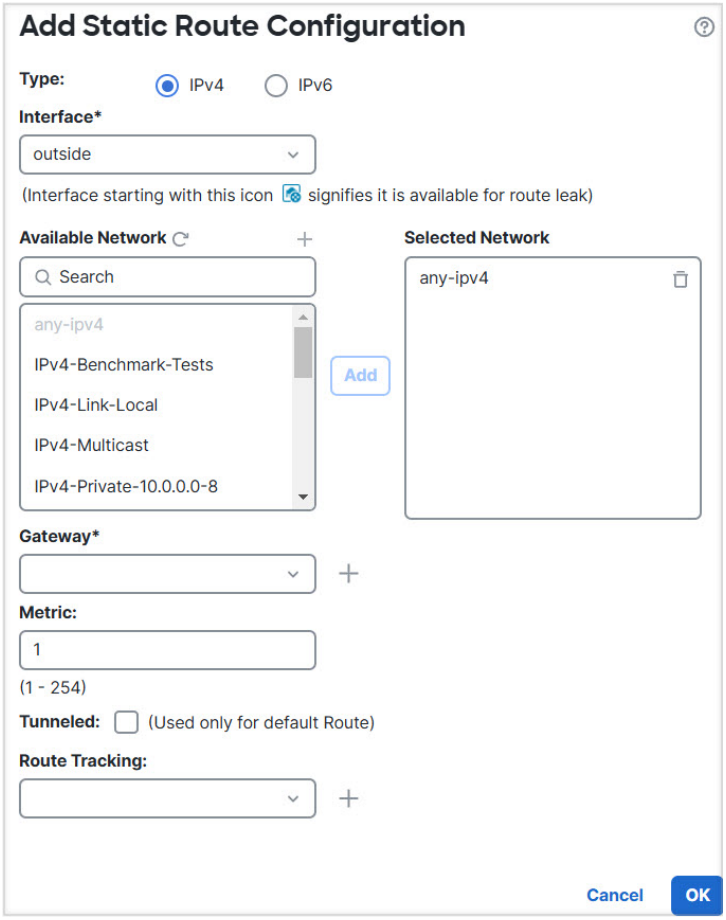
a) Choose **Devices** > **Device Management**, click the device name, and then click **Interfaces** .
b) Edit the interfaces that you want to assign to VR1:
   - **Name**—For this example, vr1-inside.
   - Select the **Enabled** checkbox.
   - In **IPV4**, for **IP Type**, choose **Use Static IP** .
   - **IP Address**—Enter 192.168.1.1/24.
c) Click **Ok** .
d) Click **Save** .

Step 2 Configure the inside interface of the device for VR2:

a) Choose **Devices** > **Device Management** , click the device name, and then click **Interfaces** .
b) Edit the interfaces that you want to assign to VR2:
   - **Name** —For this example, vr2-inside.
   - Select the **Enabled** checkbox.
   - In **IPV4** , for **IP Type** , choose **Use Static IP** .
   - **IP Address** —Leave it blank. The system does not allow you to configure interfaces with same IP address, as you are yet to create user-defined virtual routers.
c) Click **Ok** .
d) Click **Save** .

Step 3 Configure VR1 and the static default route leak to the outside interface:

a) Choose **Devices** > **Device Management** , and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers** . Click **Add Virtual Router** and create VR1.
c) For VR1, in **Virtual Router Properties** , assign vr1-inside and save.
d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration** , specify the following:
   - **Interface** —Select the outside interface of the global router.
   - **Network** —Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR1.
   - **Gateway** —Leave it blank. When leaking a route into another virtual router, do not provide a Gateway.



f) Click **Ok**.
g) Click **Save**.

Step 4 Configure VR2 and the static default route leak to the outside interface:

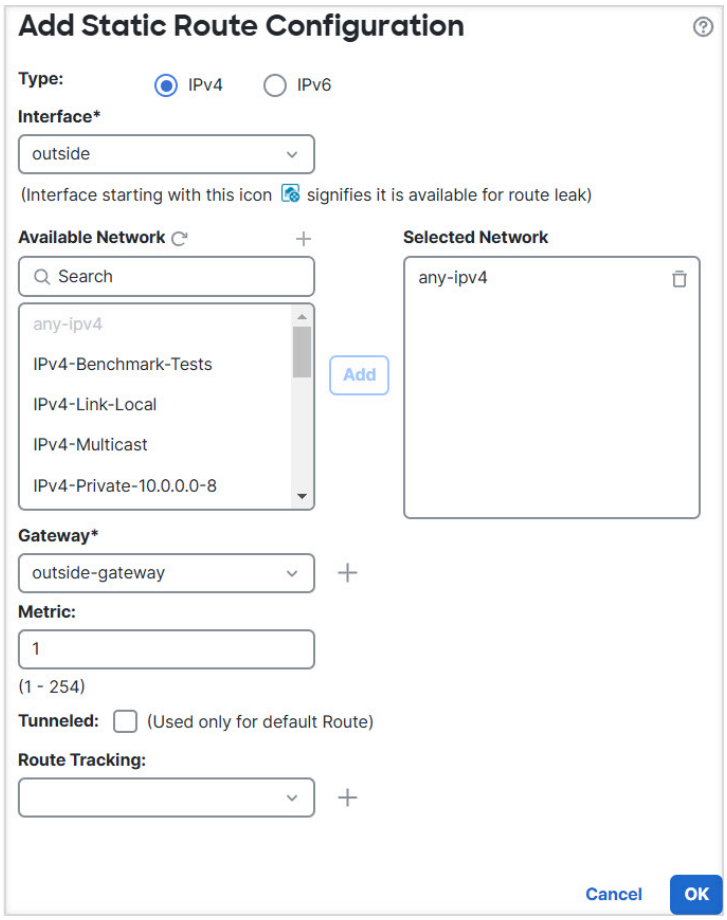
a) Choose **Devices** > **Device Management** , and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VR2.
c) For VR2, in **Virtual Router Properties**, assign vr2-inside and save.
d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration** , specify the following:

- **Interface** —Select the outside interface of the global router.
- **Network** —Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR2.
- **Gateway** —Leave it blank. When leaking a route into another virtual router, do not select the Gateway.

f) Click **Ok**.

g) Click **Save**.

Step 5 Configure IPv4 static default route, namely 172.16.1.2 on the outside interface of the global router:



a) Choose **Devices** > **Device Management** , and edit the Firewall Threat Defense device.

b) Choose **Routing** and edit global router properties.

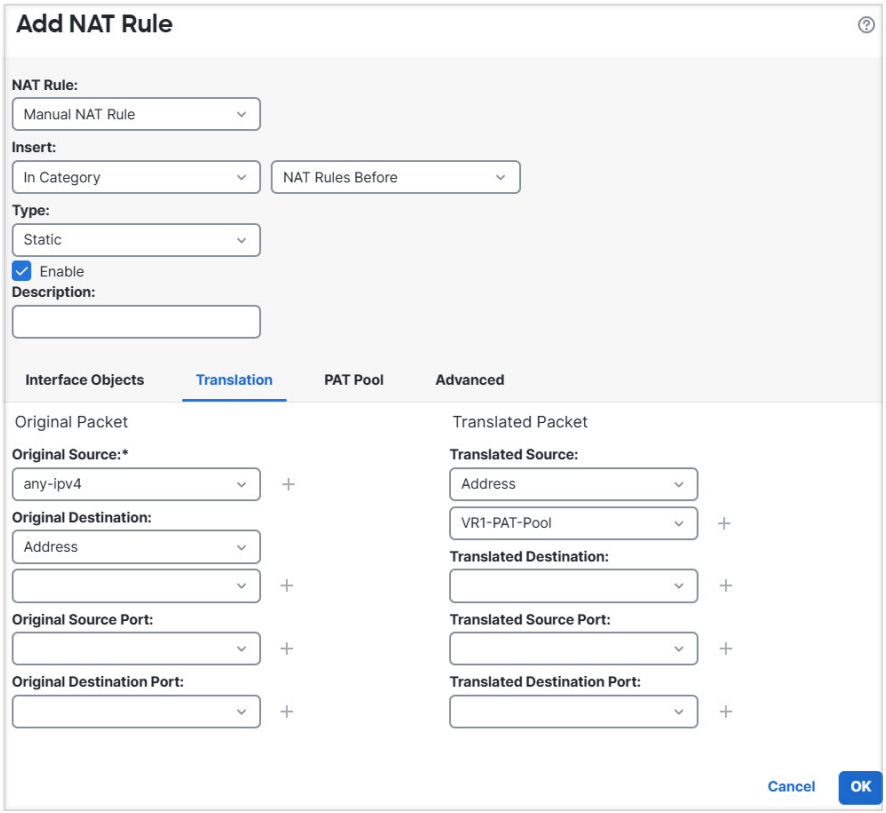
c) Click **Static Route** .

d) Click **Add Route** . In **Add Static Route Configuration** , specify the following:

- **Interface** —Select the outside interface of the global router.
- **Network** —Select the any-ipv4 object. This will be the default route for any IPv4 traffic.
- **Gateway** —If already created, select the host name from the drop-down. If the object is not yet created, click **Add** and define the host object for the IP address of the gateway at the other end of the network link on the outside interface, in this example, 172.16.1.2. After you create the object, select it in the Gateway field.

e) Click **Ok** .
f) Click **Save** .

Step 6 Revisit the vr2-inside interface configuration:



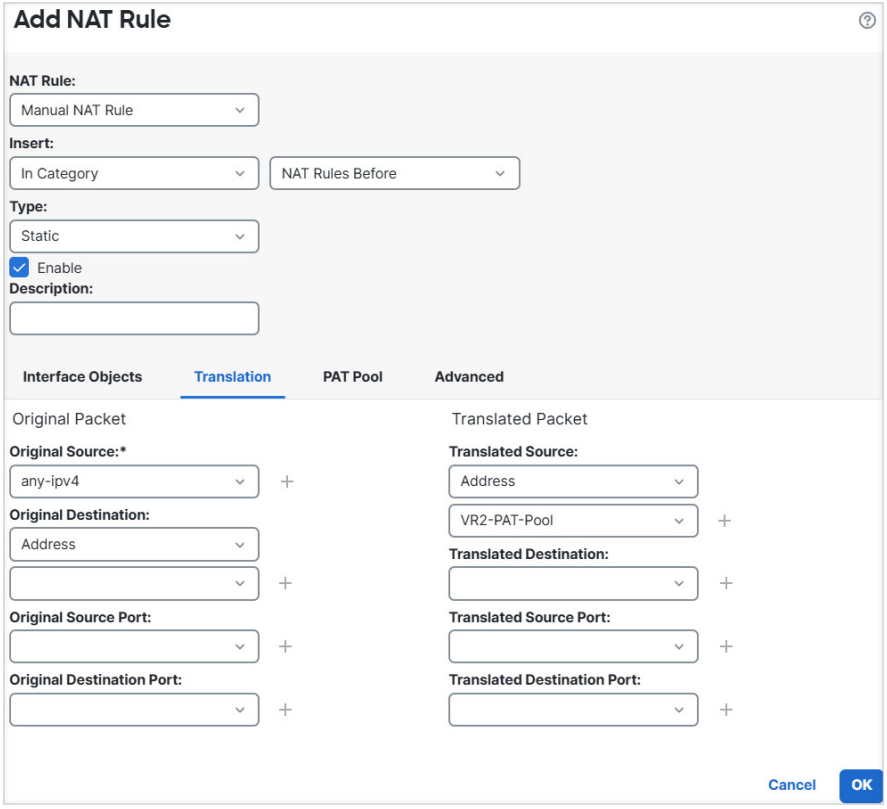
a) Choose **Devices** > **Device Management** , click the device name, and then click **Interfaces** .
b) Click **Edit** against vr2-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with same IP address of vr1-inside, because the interfaces are separately assigned to two different virtual routers.
c) Click **Ok** .
d) Click **Save** .

Step 7 Create the NAT rule to PAT inside to outside traffic of VR1 to 10.100.10.1.

a) Choose **Policies** > **Network policies** > **NAT**.
b) Click **New Policy**.
c) Enter InsideOutsideNATRule as the NAT policy name, and select the Firewall Threat Defense device. Click **Save** .
d) In InsideOutsideNATRule page, click **Add Rule** and define the following:

- **NAT Rule** —Select Manual NAT Rule.
- **Type** —Select Dynamic.
- **Insert** —Above, if any dynamic NAT rule exists.

- Click **Enabled** .
- In **Interface Objects** , select vr1-interface object and click **Add to Source** (If the object is not available, create one in **Objects** > **Interface**), and select outside as **Add to Destination** .
- In **Translation** , for **Original Source** , select any-ipv4. For **Translated Source** , click **Add** and define host object VR1-PAT-Pool with 10.100.10.1. Select VR1-PAT-Pool as shown in the figure below:



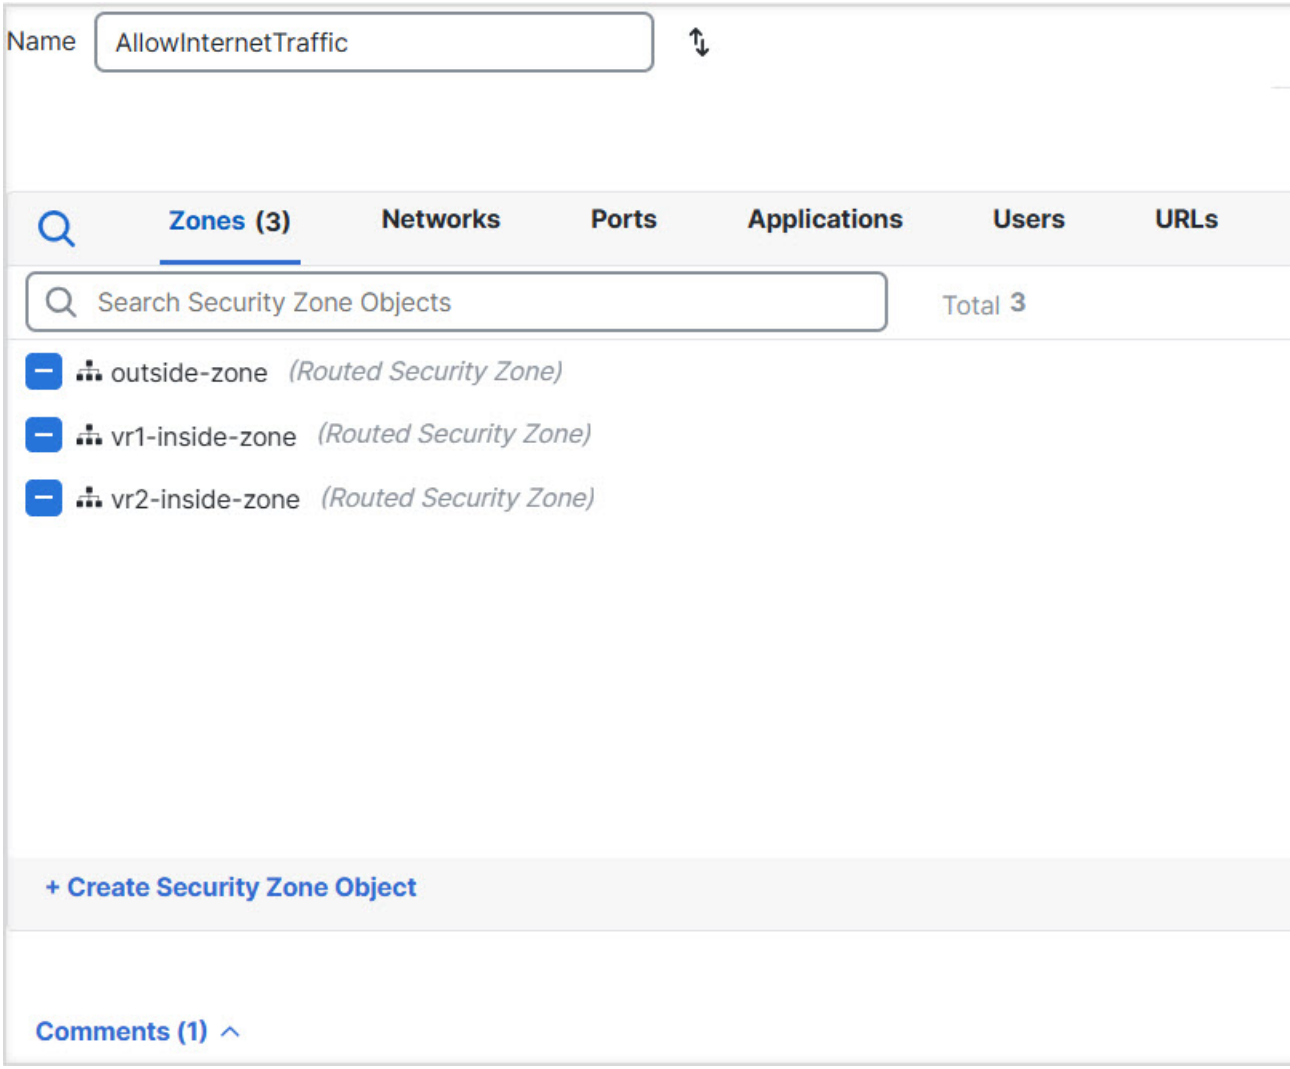
e) Click **Ok** .
f) Click **Save** .

Step 8 Add NAT rule to PAT inside to outside traffic of VR2 to 10.100.10.2.

a) Choose **Policies** > **Network policies** > **NAT** .
b) Edit InsideOutsideNATRule to define the VR2 NAT rule:

- **NAT Rule** —Select Manual NAT Rule.
- **Type** —Select Dynamic.
- **Insert** —Above, if any dynamic NAT rule exists.
- Click **Enabled** .
- In **Interface Objects** , select vr2-interface object and click **Add to Source** (If the object is not available, create one in **Administration** > **Configuration** > **Management Interfaces**), and select outside as **Add to Destination** .

- In **Translation** , for **Original Source** , select any-ipv4. For **Translated Source** , click **Add** and define host object VR2-PAT-Pool with 10.100.10.2. Select VR2-PAT-Pool as shown in the figure below:

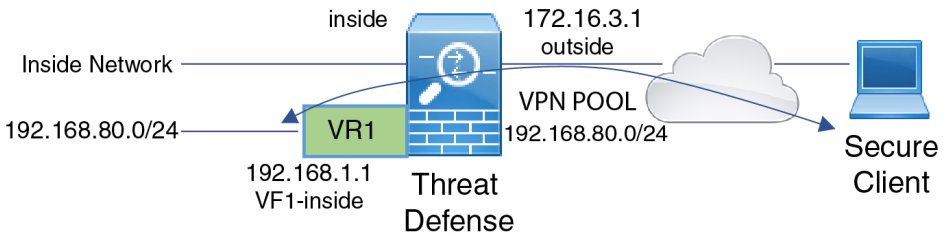


c) Click **Ok** .

d) Click **Save** .

Step 9 To configure the access control policy that allows traffic from the vr1-inside and vr2-inside interfaces to the outside interface, you need to create security zones. Use **Objects** > **Interface** . Choose **Add** > **Security Zone** and create security zones for vr1-inside, vr2-inside, and outside interfaces. Choose **Policies** > **Security policies** > **Access Control** and configure an access control rule to allow traffic from vr1-inside-zone and vr2-inside-zone to outside-zone.

Assuming that you create zones named after the interfaces, a basic rule that allows all traffic to flow to the Internet will look like the following. You can apply other parameters to this access control policy:



Allow RA VPN access to internal networks in virtual routing

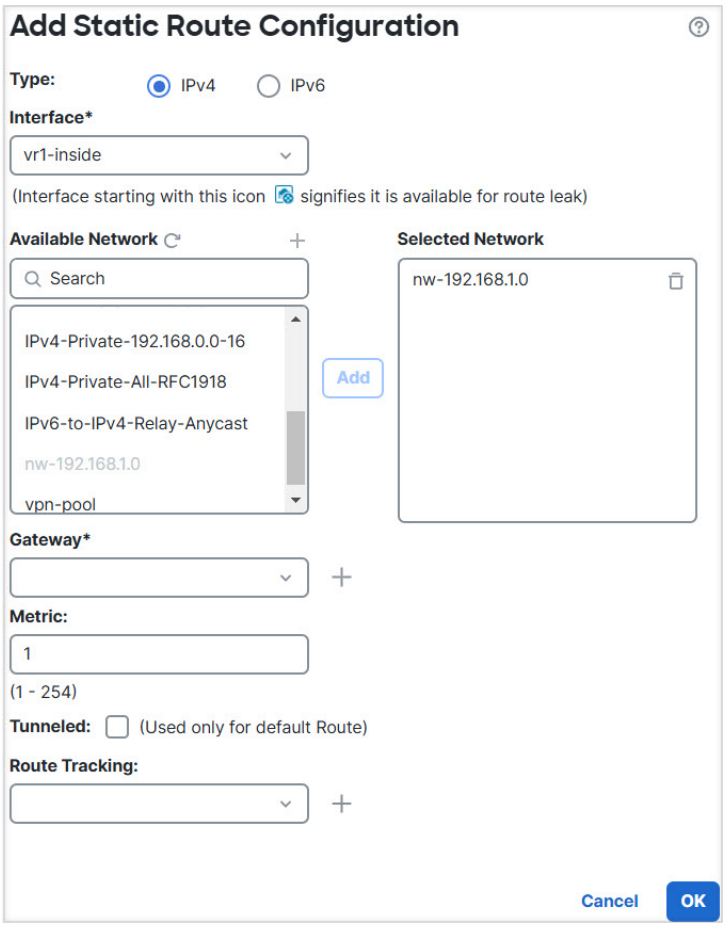
Allow Secure Client users to connect to user-defined virtual router networks by configuring route leaks between the global virtual router and user-defined virtual routers.

On virtual routing-enabled devices, RA VPN is supported only on global virtual router interfaces. This example provides the procedure that allows your Secure Client user to connect to user-defined virtual router networks.

In the following example, the RA VPN (Secure Client) user connects to the outside interface of Firewall Threat Defense at 172.16.3.1, and is given an IP address within the pool of 192.168.80.0/24. The user can access the inside network of only the global virtual router. To allow traffic flow through the network of the user-defined virtual router VR1, namely 192.168.1.0/24, leak the route by configuring the static routes on global and VR1.

Before you begin

This example assumes that you have already configured the RA VPN, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.



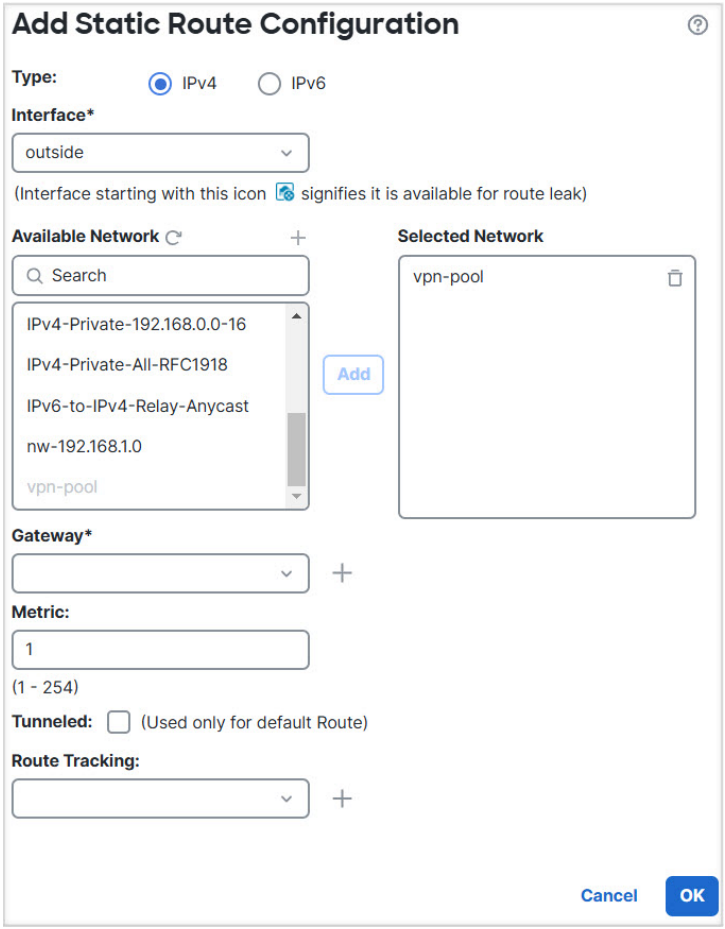
Follow these steps to allow RA VPN access to internal networks in virtual routing:

Procedure

Step 1 Configure route leak from Global virtual router to the user-defined VR1:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Click **Routing**. By default, the Global routing properties page appears.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the VR1 inside interface.
- **Network**—Select the VR1 virtual router network object. You can create one using the **Add Object** option.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.



The route leak allows Secure Client assigned IP addresses in the VPN pool to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click **Ok**.

Step 2 Configure the route leak from VR1 to the Global virtual router:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Click **Routing** and from the drop-down, select VR1.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

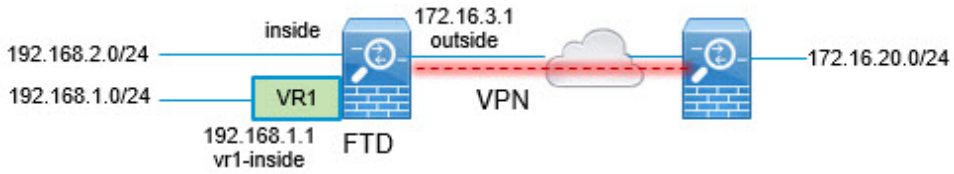
- **Interface**—Select the outside interface of the global router.
- **Network**—Select the global virtual router network object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.

The configured static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections to Secure Client assigned IP addresses in the VPN pool.

e) Click **Ok**.

Secure Client users can now access networks in both the global virtual router and the user-defined VR1 virtual router through the configured route leaks.

What to do next



If RA VPN address pool and the IP addresses in the user-defined virtual router overlap, you must also use static NAT rules on the IP addresses to enable proper routing. Alternatively, you can change your RA VPN address pool so that there is no overlap.

Secure traffic from networks in multiple virtual routers over a site-to-site VPN

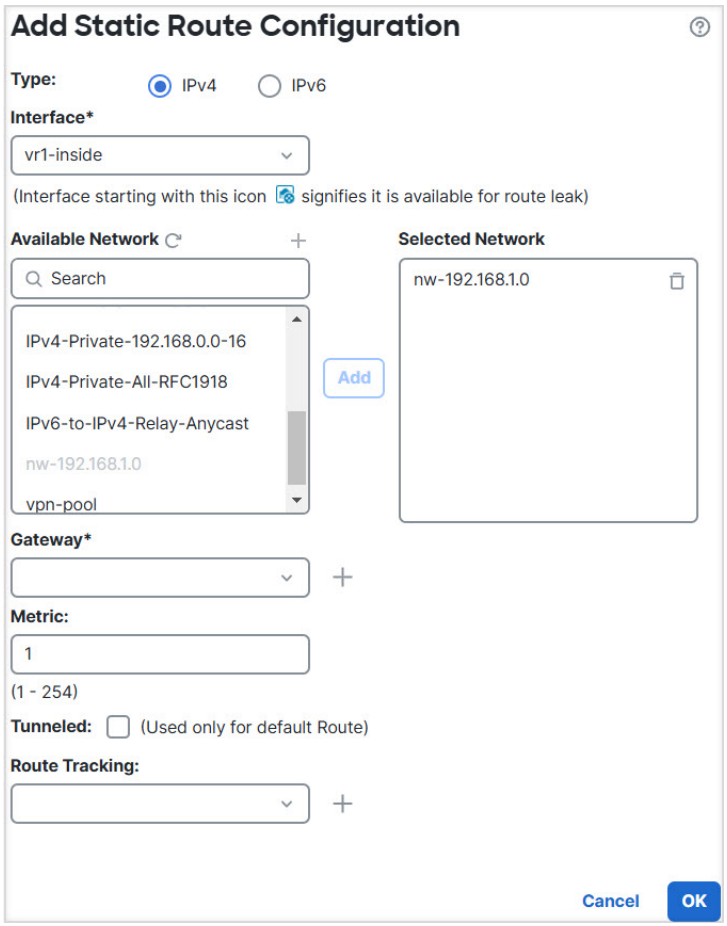
This task allows you to secure connections from or to networks hosted within user-defined virtual routers over the site-to-site VPN by configuring route leaking between virtual routers and updating the VPN connection profile.

On virtual routing-enabled devices, Site-to-Site VPN is supported only on global virtual router interfaces. You cannot configure it on an interface that belongs to a user-defined virtual router. This procedure allows you to secure the connections from or to networks hosted within user-defined virtual routers over the site-to-site VPN. You also need to update the site-to-site VPN connection to include the user-defined virtual routing networks.

Let us consider a scenario, where, a site-to-site VPN is configured between a branch office network to a company headquaters network; the Firewall Threat Defense in the branch office having virtual routers. In this case, the site-to-site VPN is defined on the outside interface of the branch office at 172.16.3.1. This VPN includes the inside network 192.168.2.0/24 without extra configuration, because the inside interface is also part of the global virtual router. But, to provide site-to-site VPN services to the 192.168.1.0/24 network, which is part of the VR1 virtual router, you must leak the route by configuring the static routes on global and VR1, and add the VR1 network to the site-to-site VPN configuration.

Before you begin

This example assumes that you have already configured the site-to-site VPN between the 192.168.2.0/24 local network and the 172.16.20.0/24 external network, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.



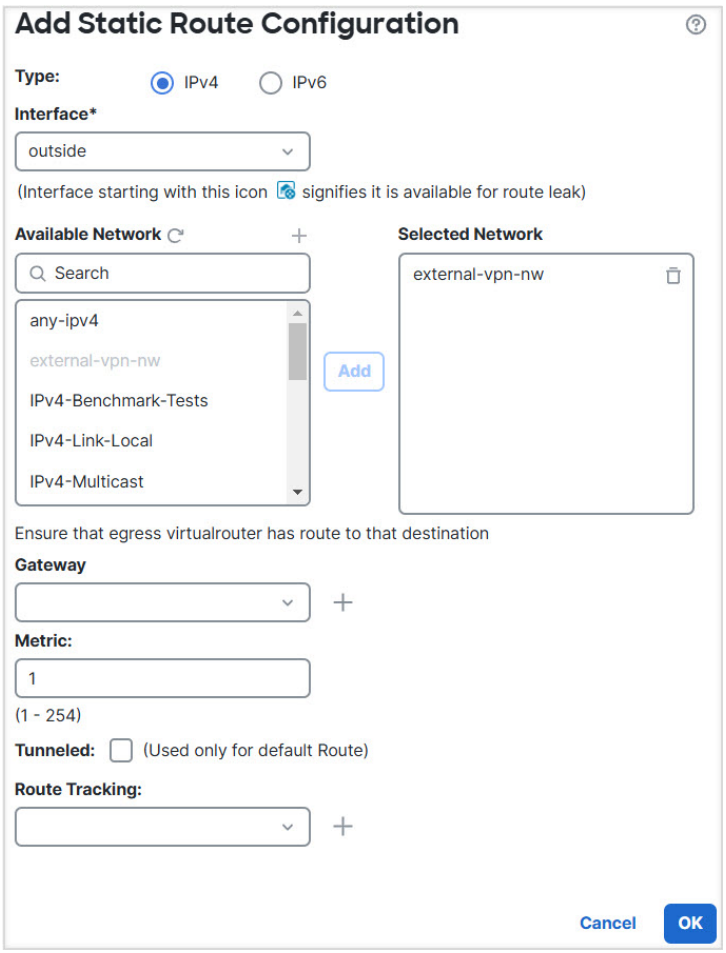
Follow these steps to secure traffic from networks in multiple virtual routers over a site-to-site VPN:

Procedure

Step 1 Configure route leak from the Global virtual router to the user-defined VR1:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Click **Routing**. By default, the Global routing properties page appears.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the VR1 inside interface.
- **Network**—Select the VR1 virtual router network object. You can create one using the **Add Object** option.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.



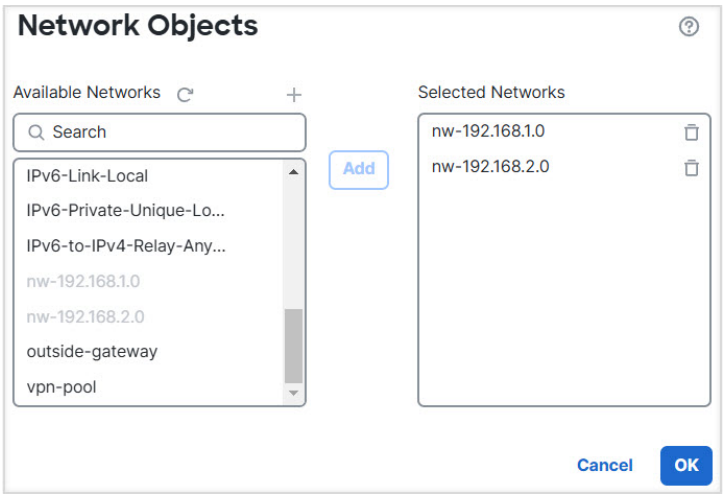
The route leak allows endpoints protected by the external (remote) end of the site-to-site VPN to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click **Ok**.

Step 2 Configure the route leak from VR1 to the Global virtual router:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Click **Routing** and from the drop-down, select VR1.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the outside interface of the global router.
- **Network**—Select the global virtual router network object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.



This static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections that will traverse the site-to-site VPN tunnel. For this example, the remote endpoint that is protecting the 172.16.20.0/24 network.

e) Click **Ok**.

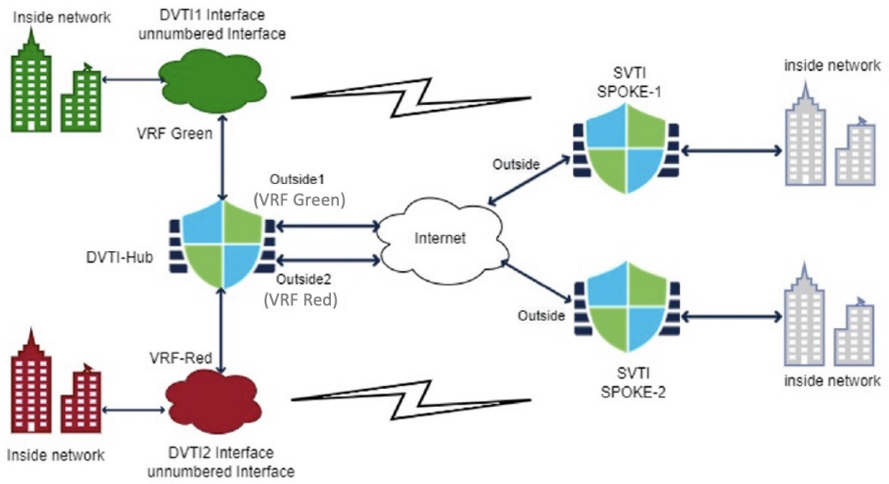
Step 3 Add the 192.168.1.0/24 network to the site-to-site VPN connection profile:

a) Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN**, and edit the VPN Topology.
b) In **Endpoints**, edit Node A endpoint.
c) In **Edit Endpoint**, in the **Protected Networks** field, click **Add New Network Object**.
d) Add the VR1 network object with 192.168.1.0 network:

e) Click **Ok** and save the configuration.

The route leaking configuration allows traffic from networks in user-defined virtual routers to traverse the site-to-site VPN tunnel securely, enabling connectivity between the VR1 network and remote networks protected by the VPN.

Secure traffic from networks with multiple virtual routers over a site-to-site VPN with dynamic VTI



This task enables ISPs to create virtual routers and associate dynamic VTIs with these virtual routers to extend the capabilities of dynamic VTIs in their network. You can associate dynamic VTIs either with global or user-defined virtual routers.

ISPs have different segmented networks for different customers. You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. A single threat defense device can act as a dynamic VTI hub with a global or one or more user-defined virtual routers. Each user-defined virtual router can be one customer network.

Let us consider an example where route-based site-to-site VPNs are configured between two company headquarter networks and their two branch office networks. The ISP's threat defense, a dynamic VTI hub, manages the two company headquarter networks with two user-defined virtual routers: VRF green and VRF red. The dynamic VTI hub establishes a site-to-site VPN between:

- Customer 1 (VRF green) and Branch 1 (SVTI spoke 1)
- Customer 2 (VRF red) and Branch 2 (SVT2 spoke 2)

Figure 382: Site-to-Site VPNs with multiple virtual routers and dynamic VTI

Procedure

Step 1 Configure a dynamic VTI interface on the hub.

a) Choose **Devices** > **Device Management** and edit the threat defense device.
b) Choose **Add Interfaces > Virtual Tunnel Interface**.
c) Select the **Tunnel Type** as **Dynamic**.
d) Specify the interface name as DVTI1 and configure all the parameters for the dynamic VTI.
e) Click **Save**
f) Repeat steps 1a - e to configure the second dynamic VTI on the hub, DVTI2.

Step 2 Configure static VTI on spoke 1.

a) Choose **Devices** > **Device Management** and edit the threat defense device.
b) Select **Add Interfaces > Virtual Tunnel Interface**.
c) Select the **Tunnel Type** as **Static**.
d) Specify the interface name as SVTI spoke-1 and configure all the parameters for the static VTI.
e) Click **Save**
f) Repeat steps 2a - e to configure the static VTI on spoke 2: SVTI spoke-2.

Step 3 Configure a route-based site-to-site VPN between hub and SVTI spoke 1.

a) Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN** and click **+ Site To Site VPN**.
b) Enter a name for the VPN topology in the **Topology Name** field.
c) Choose **Route Based (VTI)** and select **Hub and Spoke** as the network topology.
d) Click the **Endpoints** tab.
e) Configure the hub and the spoke (DVTI1 and SVTI spoke-1) and their routing policies.
f) Configure the **IKE**, **IPsec**, and **Advanced** options for the VPN, if required.
g) Click **Save**.
h) Repeat steps 3a - g to configure the second route-based site-to-site VPN topology between hub (DVTI2) and SVTI spoke 2.

Step 4 Configure the two virtual routers.

a) Choose **Devices** > **Device Management** and edit the threat defense device.
b) Click **Routing**.
c) Click **Manage Virtual Routers**.
d) Click **Add Virtual Router**.

Specify the name as VRF green and provide a description for the virtual router.

e) Repeat steps 4a - d to configure VRF red.

Step 5 Assign all the interfaces to the virtual routers.

a) From the drop-down list, select the virtual router.
b) In the **Virtual Router Properties** page, select the interfaces listed under the **Available Interfaces** box.

Assign the dynamic VTI interface along with the other interfaces.

c) Click **Add**.

Step 6 Repeat steps 5a - c for VRF red.

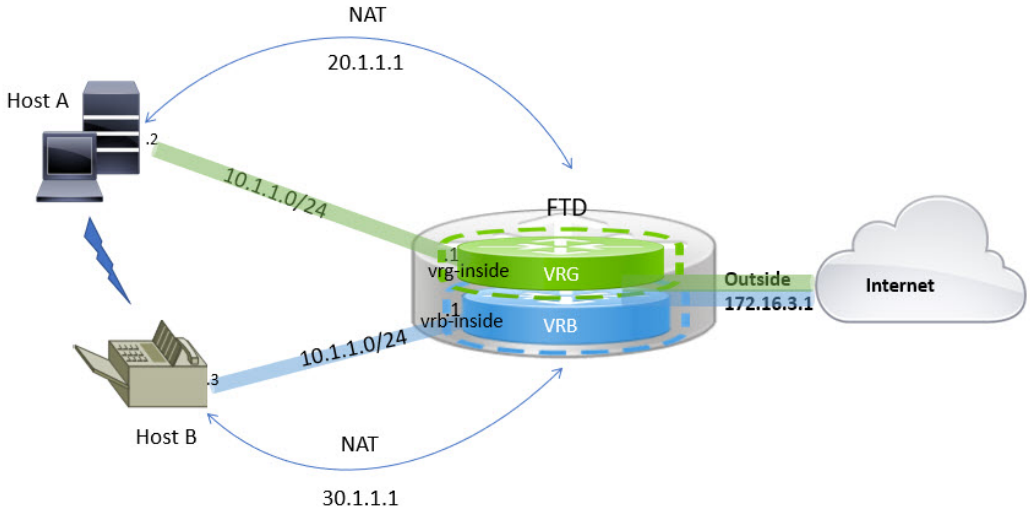
Step 7 Configure the routing policy for the virtual router.

a) From the drop-down list, select the virtual router.
b) Click **Static Route** or one of the dynamic routing protocols.
c) Configure the routing parameters.
d) Click **Save**.

You have successfully configured networks with multiple virtual routers over a site-to-site VPN with dynamic VTI, enabling ISPs to manage different segmented networks for different customers through virtual routers.

What to do next

Select the hub and spoke devices and click **Deploy**. After the deployment, you can monitor the VPN tunnels in the Site-to site monitoring dashboard (**Insights & Reports** > **VPN dashboards** > **Site-to-Site VPN**).



You can also use the commands listed in Monitor virtual routers, on page 1168 to view and troubleshoot the virtual router.

Route traffic between two overlapping network hosts in virtual routing

Configure NAT rules to manage overlapping network hosts and enable communication between hosts on different virtual routers that have the same network address.

You can configure hosts on the virtual routers that have same network address. If the hosts want to communicate, you can configure twice NAT. This example provides the procedure to configure the NAT rules to manage the overlapping network host.

In the following example, two hosts Host A and Host B belong to different virtual routers: VRG (interface VRG-inside), VRB (interface VRB-inside) respectively with the same subnet 10.1.1.0/24. For both the hosts to communicate, create a NAT policy where, VRG-Host interface object would use a mapped NAT address - 20.1.1.1, and VRB-Host interface object would use a mapped NAT address - 30.1.1.1. Thus, Host A uses 30.1.1.1 to communicate to Host B; Host B uses 20.1.1.1 to reach Host A.

Before you begin

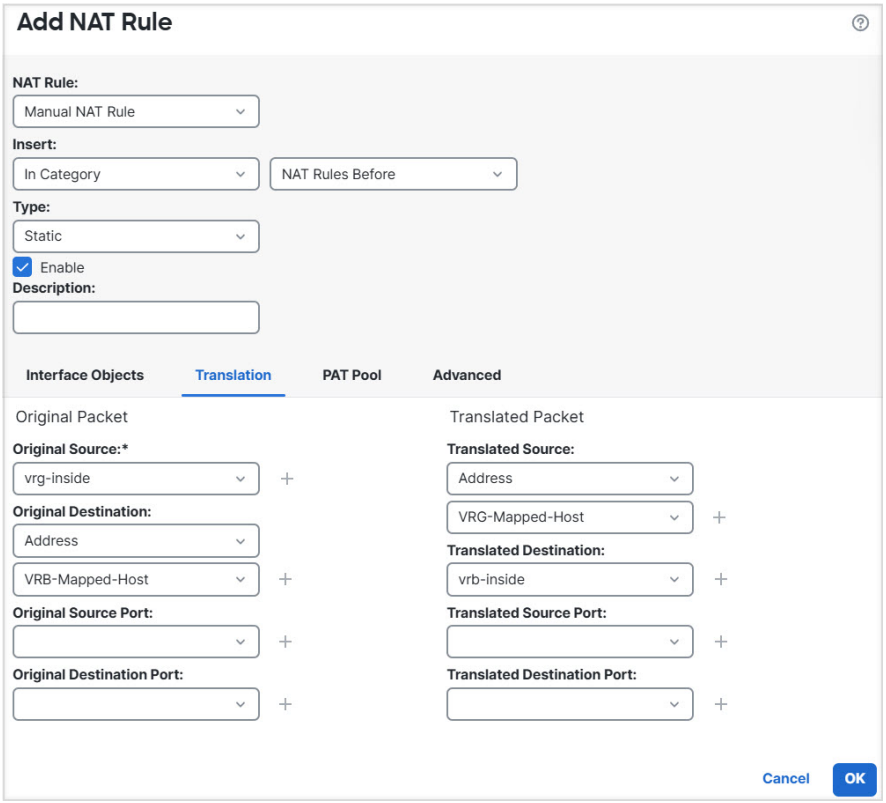
This example assumes that you have already configured:

- VRG-inside and VRB-inside interfaces are associated with virtual routers: VRG and VRB respectively and VRG-inside and VRB-inside interfaces configured with same subnet address (say, 10.1.1.0/24).
- Interfaces zones VRG-Inf, VRB-Inf created with VRG-inside and VRB-inside interfaces respectively.
- Host A in VRG with VRG-inside as default gateway; Host B in VRB with VRB-inside as default gateway.

Follow these steps to route traffic between two overlapping network hosts in virtual routing:

Procedure

Step 1 Create the NAT rule to handle traffic from Host A to Host B. Choose **Policies** > **Network policies** > **NAT**.



Step 2 Click **New Policy**.

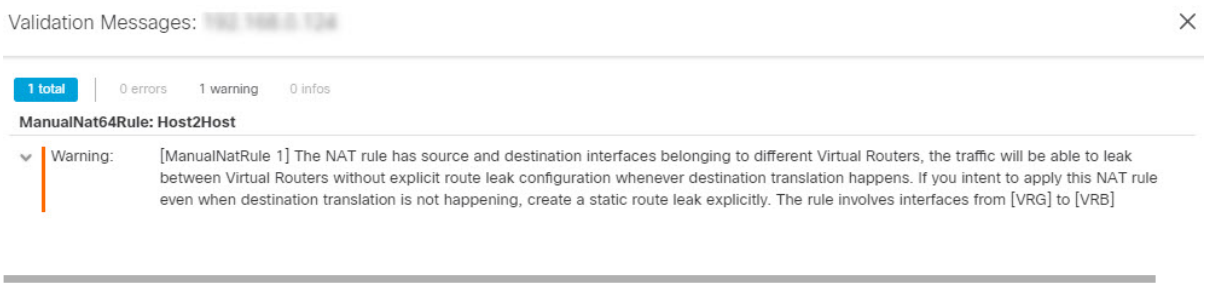
Step 3 Enter a NAT policy name, and select the Firewall Threat Defense device. Click **Save**.

Step 4 In the NAT page, click **Add Rule** and define the following:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRG-Inf object and click **Add to Source** (If the object isn't available, create one in **Objects** > **Interface**), and select VRB-Inf object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select VRG-inside.
  - **Original Destination**, click **Add** and define object VRB-Mapped-Host with 30.1.1.1. Select VRB-Mapped-Host.

- **Translated Source**, click **Add** and define object, VRG-Mapped-Host with 20.1.1.1. Select VRG-Mapped-Host.
- **Translated Destination**, select VRB-inside as shown in the following figure:

When you run the **show NAT detail** command on the Firewall Threat Defense device, you will see an output similar to this:



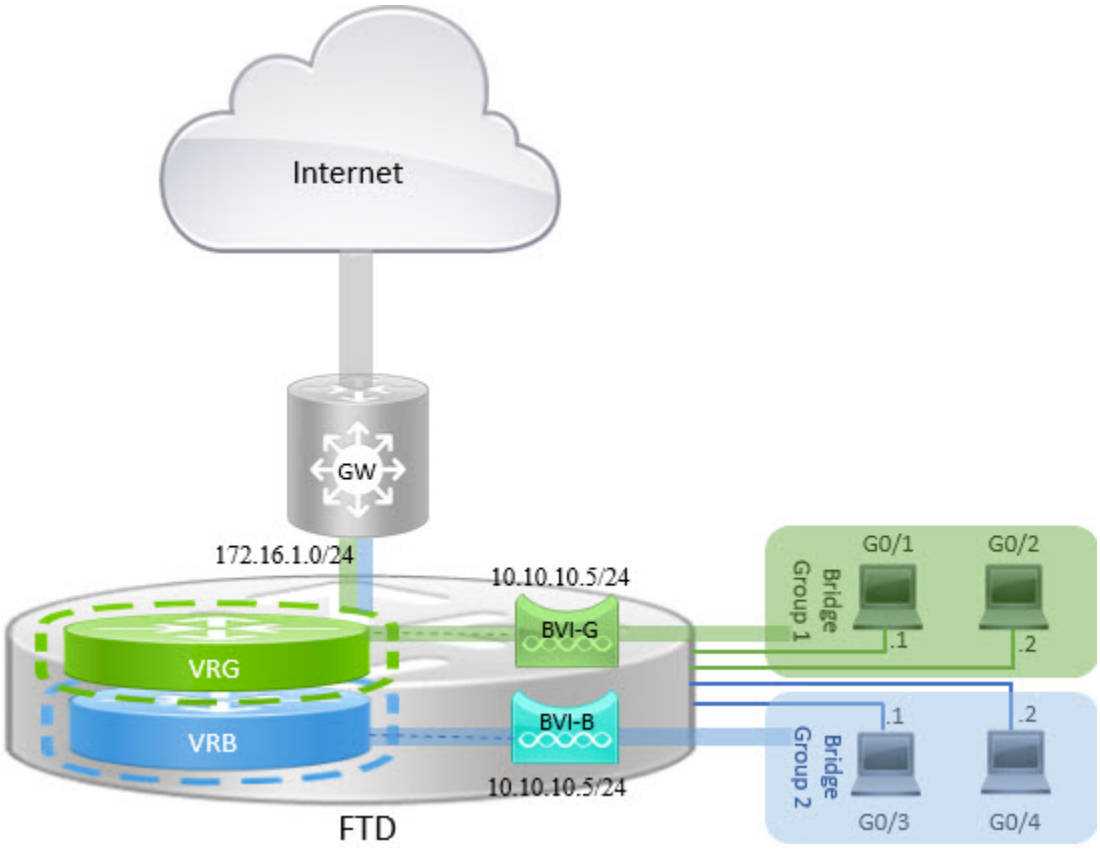
```
firepower(config-service-object-group)# show nat detail
Manual NAT Policies (Section 1)
1 (2001) to (3001) source static vrg-inside VRG-MAPPED-HOST destination static VRB-MAPPED-HOST
 vrb-inside
translate_hits = 0, untranslate_hits = 0
Source - Origin: 10.1.1.1/24, Translated: 20.1.1.1/24
Destination - Origin: 30.1.1.1/24, Translated: 10.1.1.1/24
```

Step 5 Click **Ok**.

Step 6 Click **Save**.

The NAT rule looks like this:

When you deploy the configuration, a warning message appears:



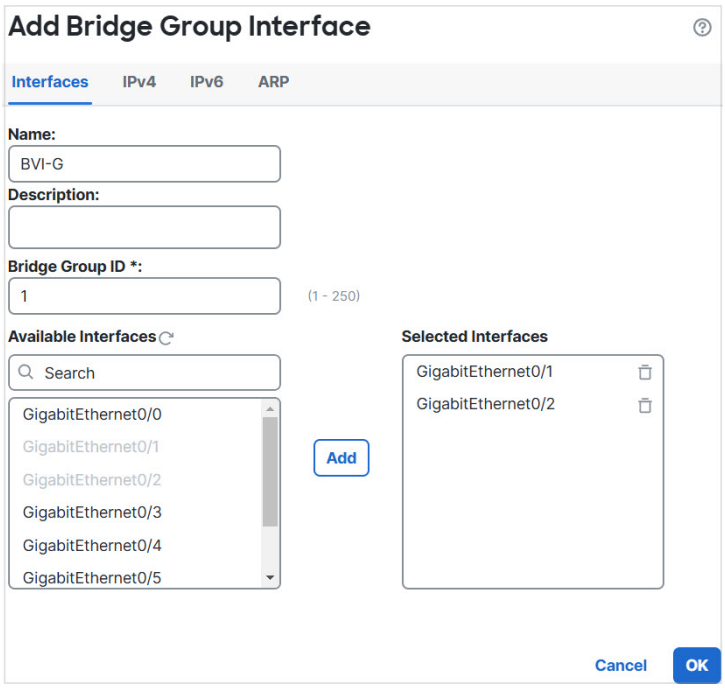
The NAT rule is configured to enable communication between Host A and Host B on overlapping network addresses. Host A uses 30.1.1.1 to communicate with Host B, and Host B uses 20.1.1.1 to reach Host A.

Manage overlapping segments in routed firewall mode with BVI interfaces

This task allows you to deploy single Firewall Threat Defense between multiple overlapping networks transparently and/or deploy the firewall between the hosts of same network by configuring BVI per virtual router.

BVI is a virtual interface within a router that acts like a normal routed interface. It does not support bridging, but represents the comparable bridge group to routed interfaces within the router. All the packets coming in or going out of these bridged interfaces, pass through the BVI interface. The interface number of the BVI is the number of the bridge group that the virtual interface represents.

In the following example, BVI-G is configured in VRG and Bridge Group 1 is the routed interface for interfaces G0/1 and G0/2. Similarly, BVI-B is configured in VRB and Bridge Group 2 is the routed interface for interfaces G0/3 and G0/4. Consider that both BVIs have the same IP subnet address, say 10.10.10.5/24. Because of virtual routers, the network is isolated on the shared resources.



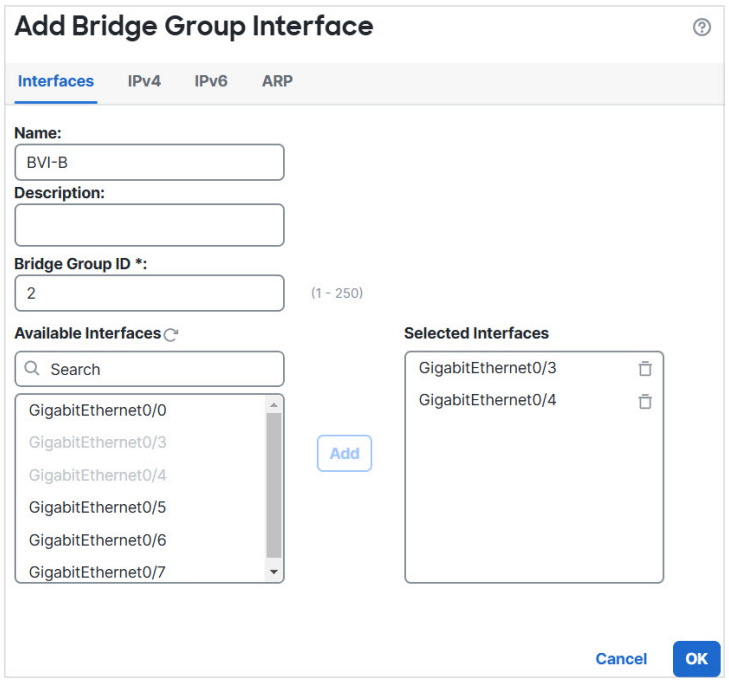
Procedure

Step 1 Choose **Devices** > **Device Management**. Edit the required device.

Step 2 In **Interfaces**, choose **Add Interfaces** > **Bridge Group Interface**.

a) Enter the following details for BVI-G:

- **Name**—For this example, BVI-G.
- **Bridge Group ID**—For this example, 1.
- **Available Interface**—Select the interfaces.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 10.10.10.5/24.



b) Click **Ok**.

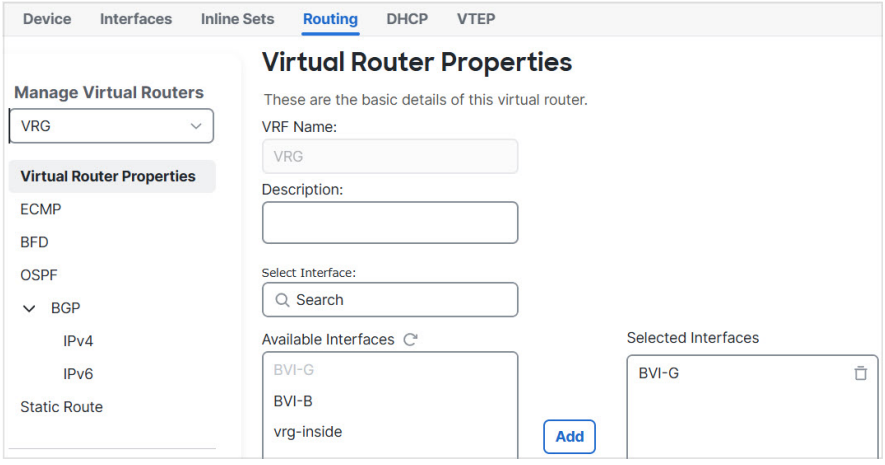
c) Click **Save**.

a) Enter the following details for BVI-B:

- **Name**—For this example, BVI-B.
- **Bridge Group ID**—For this example, 2.
- **Available Interface**—Select the sub interfaces.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave this field empty as the system does not allow two interfaces to have overlapping IP address. You can revisit the Bridge Group and provide the same IP address after aligning it under a virtual router.

b) Click **Ok**.

c) Click **Save**.



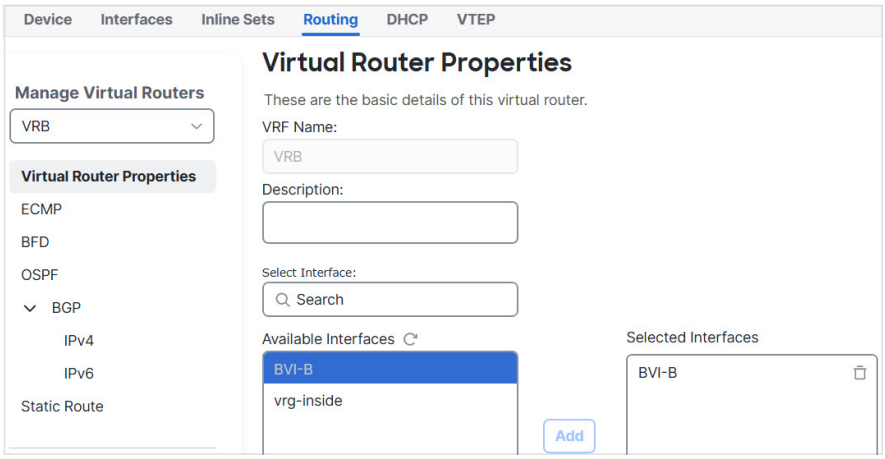
Step 3 Create virtual router, say VRG, and select BVI-G as its network:

a) Choose **Devices** > **Device Management**.

b) Edit the device, and choose **Routing** > **Manage Virtual Routers**.

c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.

d) In **Virtual Routing Properties**, select **BVI-G** and click **Add**.



e) Click **Save**.

Step 4 Create virtual router, say VRB, and select BVI-B as its network:

a) Choose **Devices** > **Device Management**.

b) Edit the device, and choose **Routing** > **Manage Virtual Routers**.

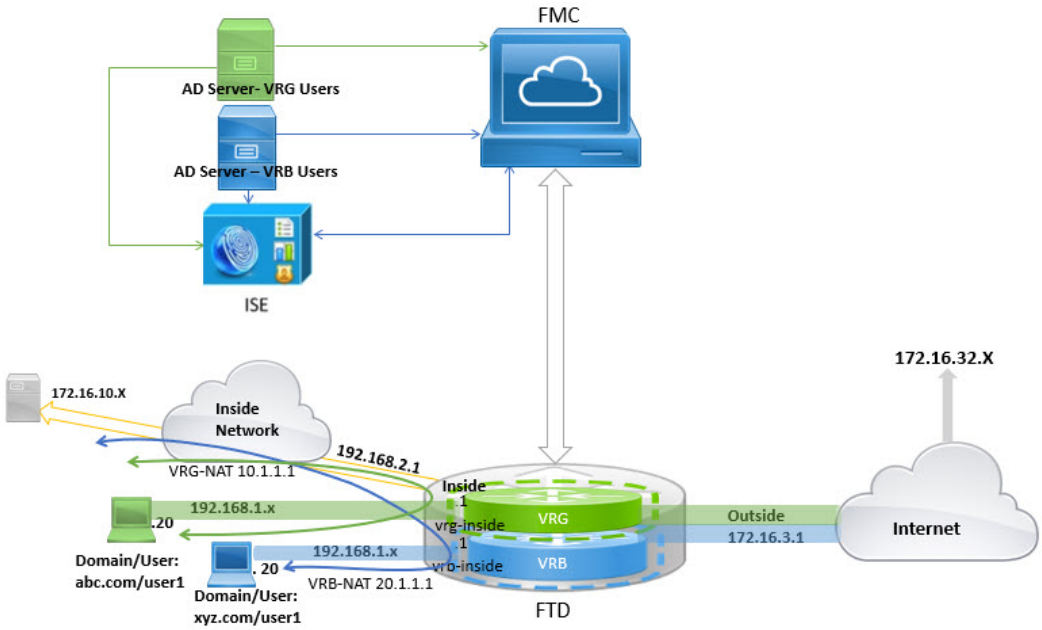
c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.
d) In **Virtual Routing Properties**, select **BVI-B** and click **Add**.

e) Click **Save**.

Step 5 Revisit the BVI-B configuration:

a) Choose **Devices** > **Device Management**, edit the device and click **Interfaces**.
b) Click **Edit** against BVI-B interface. Specify the IP Address as 10.10.10.5/24. The system now allows you to configure with same IP address of BVI-G, because the interfaces are seperately assigned to two different virtual routers.
c) Click **Ok**.
d) Click **Save**.

If you want to enable inter-BVI communication, use an external router as default gateway. In overlapping BVI scenarios, as in this example, use twice NAT external router as gateway to establish inter-BVI traffic. When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself. When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify "any" as the interface.



You have successfully configured BVI interfaces per virtual router to manage overlapping segments in routed firewall mode. The virtual routers isolate the network on shared resources, allowing the use of same IP subnet addresses for both BVIs.

Configure user authentication with overlapping networks

This task enables you to configure user authentication in virtual routing environments where multiple virtual routers share overlapping IP addresses and user networks. The configuration allows users from different domains to access shared resources while maintaining proper access control.

In virtual routing, you can configure multiple virtual routers with overlapping IP and overlapping users. In the example, VRG, and VRB are the virtual routers with overlapping IP - 192.168.1.1/24. The users on two different domains are also on overlapping network IP 192.168.1.20. For VRG and VRB users to access the shared server 172.16.10.X, leak routes to the global virtual router. Use source NAT to handle the overlapping IP. For controlling the access from VRG and VRB users, you must set user authentication in Firewall Management Center. Firewall Management Center uses realms, Active Directories, Identity source, and

Identity rules and policies for authenticating user identity. Because Firewall Threat Defense does not have direct role in authenticating users, user access is managed only through the access control policy. For controlling traffic from the overlapping users, use Identity policy and rules to create access control policy.

Before you begin

This example assumes that you have:

- Two AD servers for the VRG and VRB users.
- ISE with the two AD servers added.

Follow these steps to configure user authentication with overlapping networks:

Procedure

Step 1 Configure the inside interface of the device for VRG:

a) Choose **Devices** > **Device Management**, click the device name, and then click **Interfaces**.

b) Edit the interfaces that you want to assign to VRG:

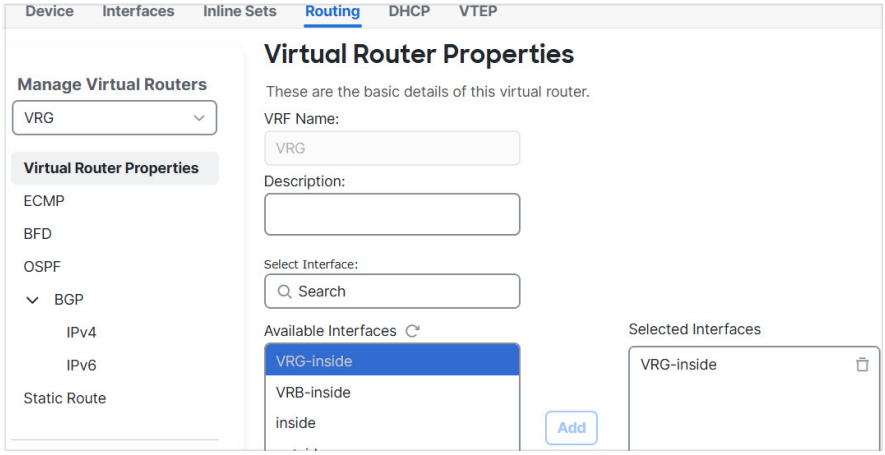
- **Name**—For this example, VRG-inside.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 192.168.1.1/24.

c) Click **Ok**.

d) Click **Save**.

Step 2 Configure the inside interface of the device for VRB:

a) Choose **Devices** > **Device Management** > **Interfaces**.



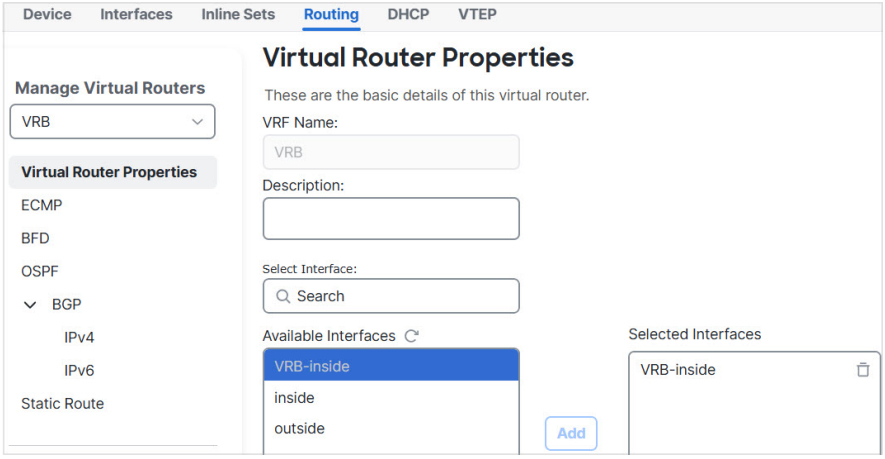
b) Edit the interfaces that you want to assign to VRB:

- **Name**—For this example, VRB-inside.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave it blank. The system doesn't allow you to configure interfaces with same IP address, as you're yet to create user-defined virtual routers.

c) Click **Ok**.
d) Click **Save**.

Step 3 Configure VRG and the static default route leak to the inside interface of the Global router for the VRG users to access the common server 172.16.10.1:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VRG.
c) For VRG, in **Virtual Router Properties**, assign VRG-inside and save.



d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the inside interface of the global router.
- **Network**—Select the any-ipv4 object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.

f) Click **Ok**.
g) Click **Save**.

Step 4 Configure VRB and the static default route leak to the inside interface of the Global router for the VRB users to access the shared server 172.16.10.x:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VRB.
c) For VRB, in **Virtual Router Properties**, assign VRB-inside and save.

d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

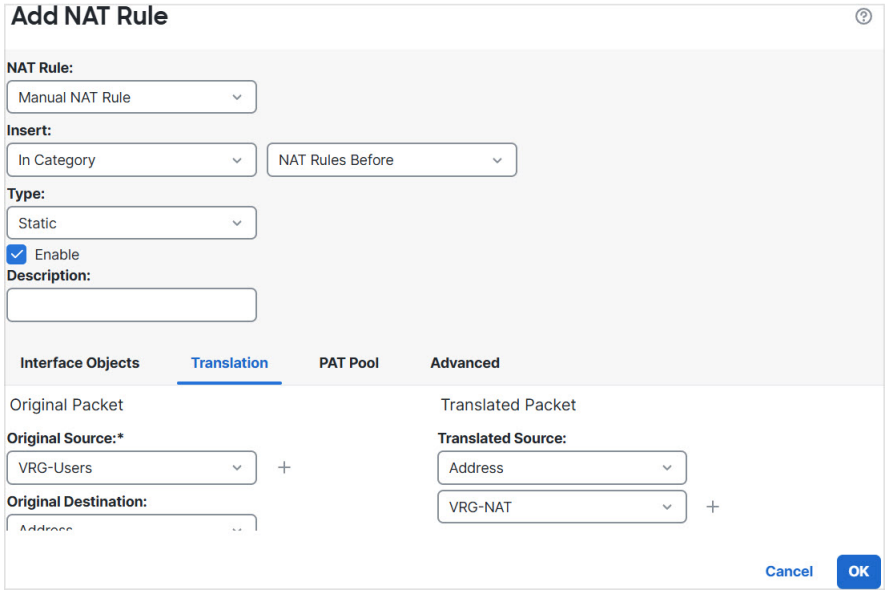
- **Interface**—Select the inside interface of the global router.
- **Network**—Select the any-ipv4 object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.

f) Click **Ok**.
g) Click **Save**.

Step 5 Revisit the VRB-inside interface configuration:

a) Choose **Devices** > **Device Management**, click the device name, and then click **Interfaces**.
b) Click **Edit** against VRB-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with the same IP address as that of VRG-inside, because the interfaces are seperately assigned to two different virtual routers.
c) Click **Ok**.
d) Click **Save**.

Step 6 Add NAT rules for the source objects VRG and VRB. Click **Policies** > **Network policies** > **NAT**.

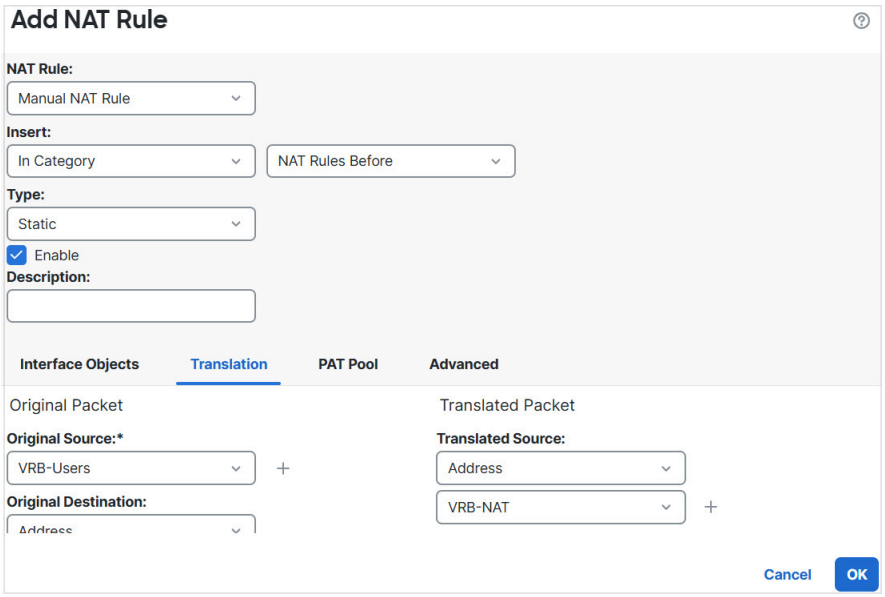


Step 7 Click **New Policy**.

Step 8 Enter a NAT policy name, and select the Firewall Threat Defense device. Click **Save**.

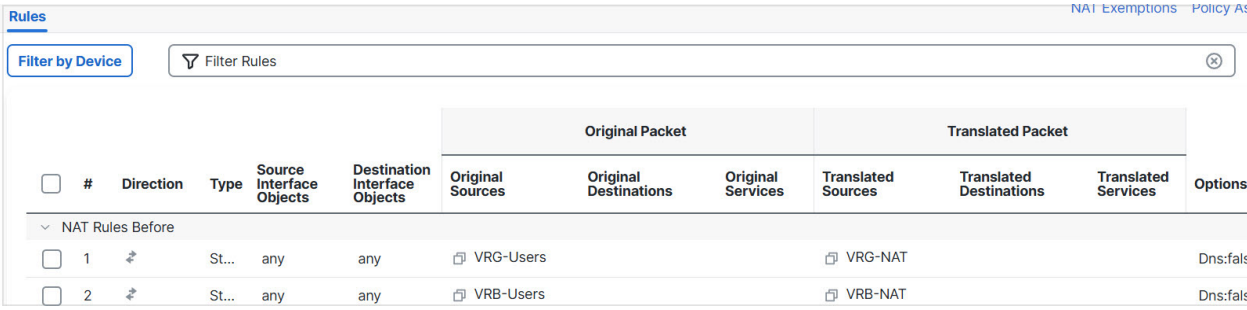
Step 9 In the NAT page, click **Add Rule** and define the following source NAT for VRG:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRG-Inside object and click **Add to Source** (If the object is not available, create one in **Objects** > **Interface**), and select Global-Inside object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select VRG-Users.



- **Translated Source**, click **Add** and define object, VRG-NAT with 10.1.1.1. Select VRG-NAT as shown in the figure:

Step 10 Click **Ok**.



Step 11 In the NAT page, click **Add Rule** and define the following source NAT for VRB:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRB-Inside object and click **Add to Source** (If the object is not available, create one in **Objects** > **Interface**), and select Global-Inside object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select VRB-Users.
  - **Translated Source**, click **Add** and define object, VRB-NAT with 20.1.1.1. Select VRB-NAT as shown in the figure:

Step 12 Click **Save**.

The NAT rule looks like this:

Step 13 Add the two unique AD servers in Firewall Management Center one for each VRG and VRB users—choose **System** > **Integration** > **Realms**.

Step 14 Click **New Realm** and complete the fields. For detailed information on the fields, see Realm fields, on page 2100.

Step 15 For controlling the access from VRG and VRB users, define 2 Active Directories, see Realm directory and synchronize fields, on page 2104see Create an LDAP realm or an Active Directory realm and realm directory, on page 2133

Step 16 Add ISE in Firewall Management Center—choose **System** > **Integration** > **Identity Sources**.

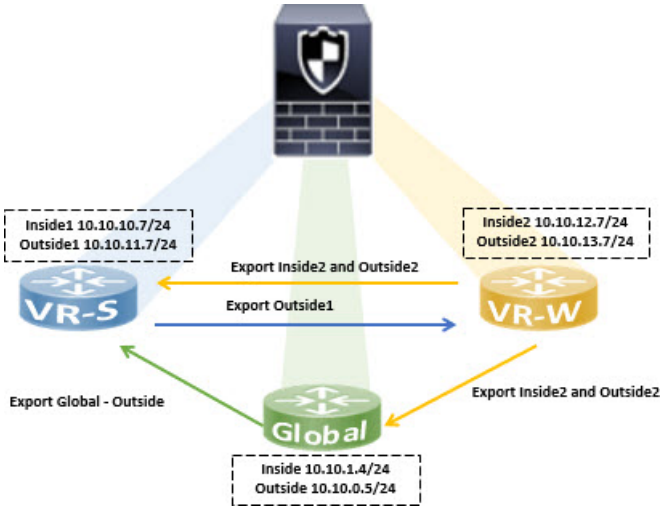
Step 17 Click **Identity Services Engine** and complete the fields. For detailed information on the fields, see Configure ISE/ISE-PIC for user control using a realm, on page 2189.

Step 18 Create Identity policy, rules, and then define access control policy for controlling access of overlapping users from VRG and VRB.

You have successfully configured user authentication for virtual routers with overlapping networks. VRG and VRB users can now access the shared server through proper NAT translation and authentication controls, with distinct identity policies managing access for each user group.

Interconnect virtual routers using BGP

This task enables you to configure BGP settings to leak routes among virtual routers (Global and user-defined virtual routers) by using route targets and route maps to share routes between different virtual routing instances.



You can now configure BGP settings on a device to leak the routes among virtual routers (Global and user-defined virtual routers). The route target of the source virtual router is exported to the BGP table, which, in turn is imported to the destination virtual router. The route map is used to share the Global virtual routes with the user-defined virtual routers and vice versa. Note that all import or export of the routes to the BGP table is configured at the user-defined virtual router, including the Global virtual routes.

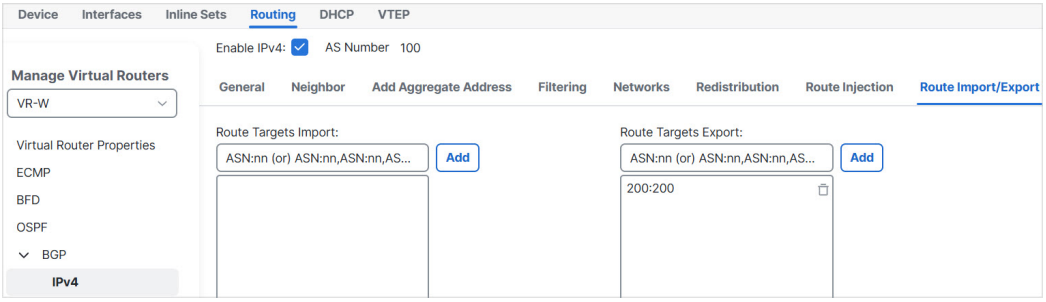
Consider the firewall device of a factory is configured with virtual routers and interfaces:

- Global virtual router is configured with Inside (10.10.1.4/24) and Outside (10.10.0.5/24)
- VR-S (Sales) virtual router is configured with Inside1 (10.10.10.7/24) and Outside1 (10.10.11.7/24)
- VR-W (Warehouse) virtual router is configured with Inside2 (10.10.12.7/24) and Outside2 (10.10.13.7/24)

Assume that you want the routes of warehouse (VR-W) to be leaked with sales (VR-S) and Global, and the outside interface routes of VR-S to VR-W. Similarly, you want the outside interface routes of the Global router to be leaked to sales (VR-S). This example demonstrates the BGP configuration procedure to achieve interconnecting the routers:

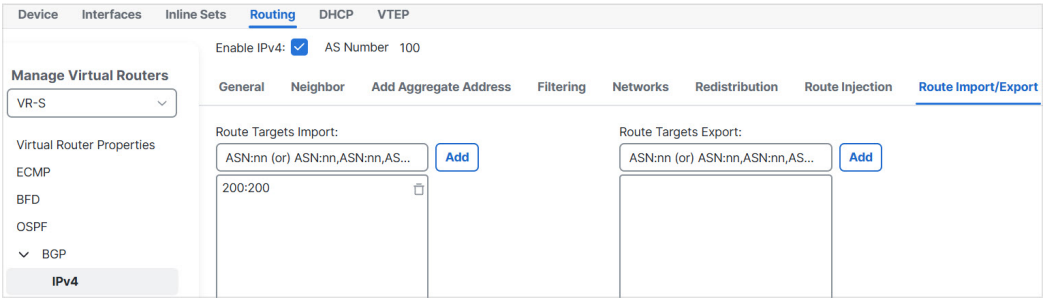
Figure 383: Interconnect virtual routers using BGP settings

Before you begin



- Create the virtual routers—VR-S and VR-W.
- Enable BGP and for each virtual router Configure BGP for redistribution of connected routes.

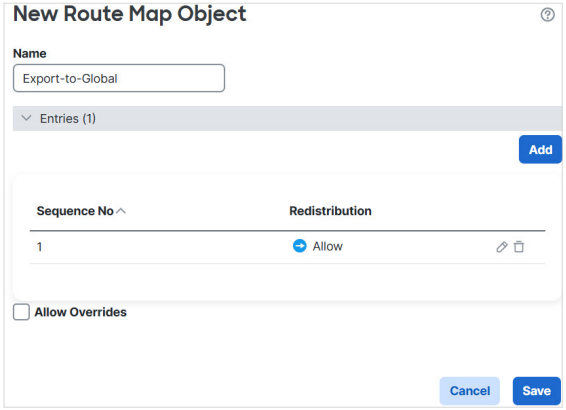
Follow these steps to interconnect virtual routers using BGP:



Procedure

Step 1 Configure VR-W to export its routes tagging them with a route target to VR-S:

a) Choose **Devices** > **Device Management**, edit device, and then click the **Routing** tab.
b) From the virtual router drop-down, select VR-W. Then click **BGP** > **IPv4** > **Route Import/Export**.
c) To leak the VR-W routes to VR-S, tag the routes with a route target, so that the VR-W routes are exported to its BGP table with the route target marked on them. In the **Route Targets Export** field, enter a value, say, *200:200*. Click **Add**:

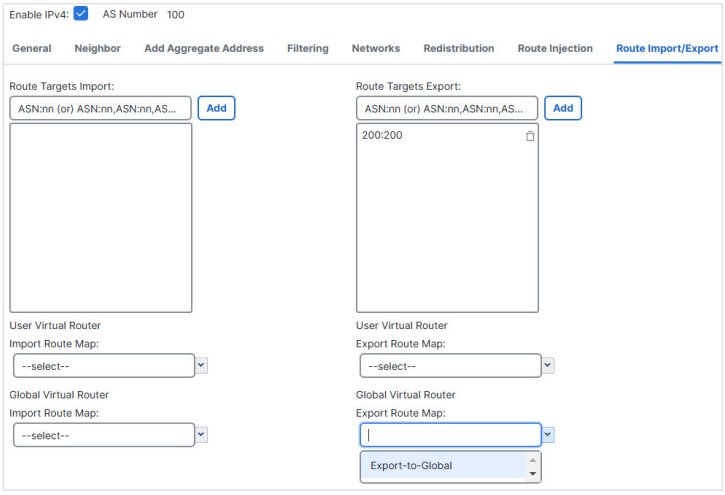


d) From the virtual router drop-down, select VR-S. Then click **BGP** > **IPv4** > **Route Import/Export**.
e) To receive the leaked routes from VR-W, configure the Import Route Target to import the VR-W routes that are marked with the route target from the (peer or redistributed) BGP table. In the **Route Targets Import** field, enter the same route target value that you had configured for VR-W, *200:200*. Click **Add**.

Note If you want to conditionalize routes to be leaked from VR-W, you can specify the match criteria in the route map object, and choose it in the **User Virtual Router Export Route Map**. Similarly, if you want to conditionalize the routes to be imported to VR-S from the BGP table, you can use the **User Virtual Router Import Route Map**. This procedure is explained in Step 3.

Step 2 Configure VR-W to export its routes to the Global virtual router:

a) You need to create a route map that would allow the VR-W routes to be exported to the Global routing table. Choose **Objects** > **Route Map**.
b) Click **Add Route Map**, give a name, say *Export-to-Global*, and then click **Add**.
c) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list:



d) Click **Save**.

In this example, all the VR-W routes are leaked to the Global routing table. Hence, no match criteria is configured for the route map.

e) Navigate to the **Routing** tab of the device, and select VR-W. Click **BGP** > **IPv4** > **Route Import/Export**.

f) From the **Global Virtual Router Export Route Map** drop-down list, choose Export-to-Global:

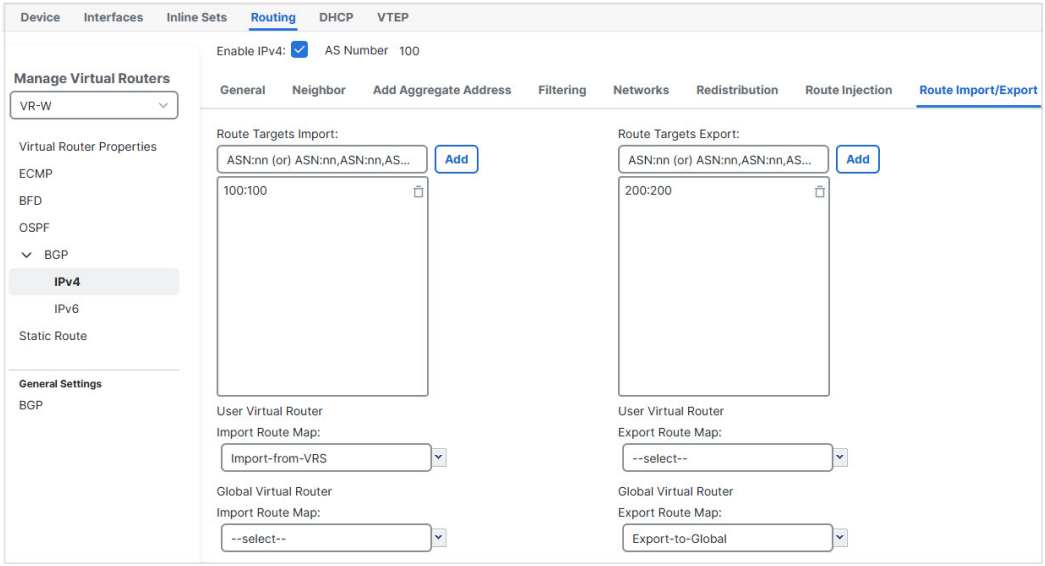
Step 3 To leak only the Outside1 routes of VR-S to VR-W:

a) From the virtual router drop-down, select VR-S and then click **BGP** > **IPv4** > **Route Import/Export**.

b) To leak the VR-S routes to VR-W, tag the routes with a route target, so that the VR-S routes are exported to its BGP table with the route target marked on them. In the **Route Targets Export** field, enter a value, say, *100:100*. Click **Add**.

c) From the virtual router drop-down, select VR-W, and choose **BGP** > **IPv4** > **Route Import/Export**. To receive the leaked routes from VR-S, configure the Import Route Target to import the VR-S routes that are marked with the route target from the (peer or redistributed) BGP table. In the **Route Targets Import** field, enter the VR-S route target value, *100:100*. Click **Add**.

d) Now, you need to conditionalize that only the Outside1 routes of VR-S to be leaked to VR-W. Choose **Objects** > **Prefix Lists** > **IPv4 Prefix List**. Click **Add IPv4 Prefix List**, give a name, say *VRS-Outside1-Only*, and then click **Add**.



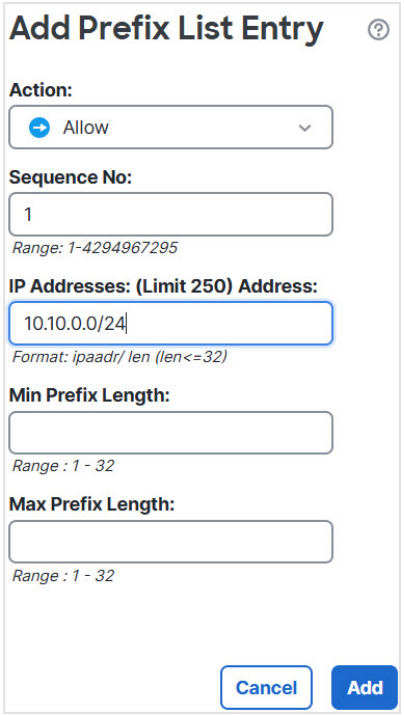
e) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list. Enter the IP Address (first two octets) of the VR-S Outside1 interface and then click **Save**.

f) Create a route map with the match clause with the prefix list. Click **Route Map**. Click **Add Route Map**, give a name, say *Import-from-VRS*, and then click **Add**.

g) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.

h) In the **Match Clause** tab, click **IPv4**. Under **Address** tab, click **Prefix List**. Under **Available IPv4 Prefix List**, select VRS-Outside1-Only, and then click **Add**.

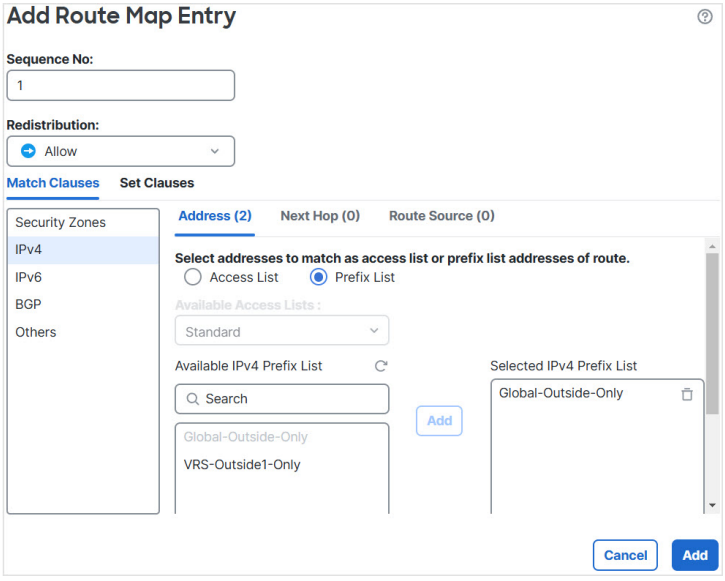
i) Navigate to the **Routing** tab of the device, and select VR-W. Click **BGP** > **IPv4** > **Route Import/Export**. From the **Global Virtual Router Import Route Map** drop-down list, choose Import-from-VRS:



Step 4 Configure VR-S to import the Outside routes of Global virtual router:

Note To leak routes to or from a Global virtual router, you must configure the source or destination user defined virtual router respectively. Thus, in this example, VR-S is the destination router that imports the routes from Outside interface of the Global virtual router.

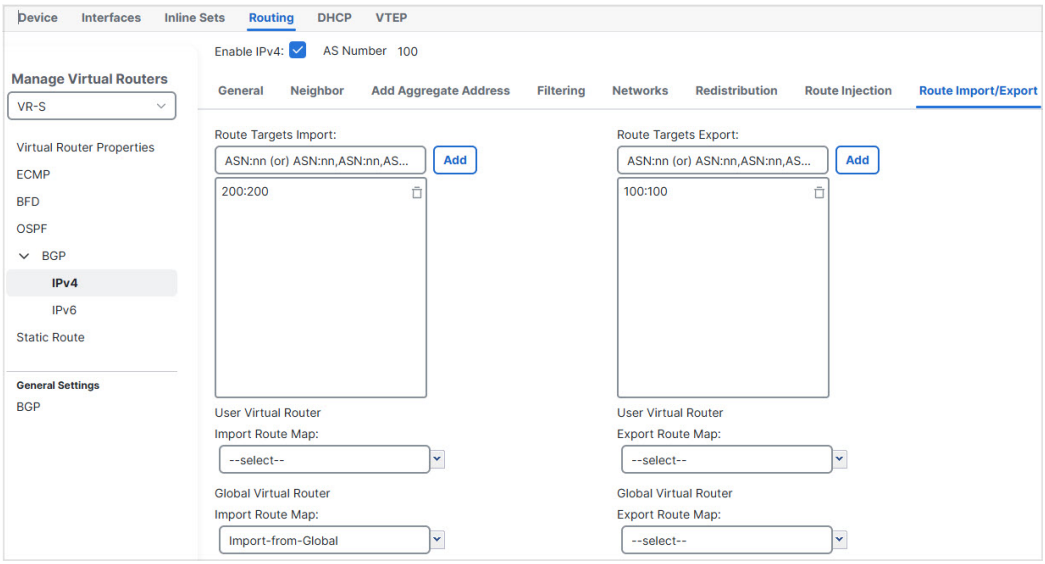
a) Choose **Objects** > **Prefix Lists** > **IPv4 Prefix List**.



b) Click **Add IPv4 Prefix List**, give a name, say *Global-Outside-Only*, and then click **Add**. Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.

c) Enter the IP Address (first two octets) of the Global Outside interface:

Then click **Save**.



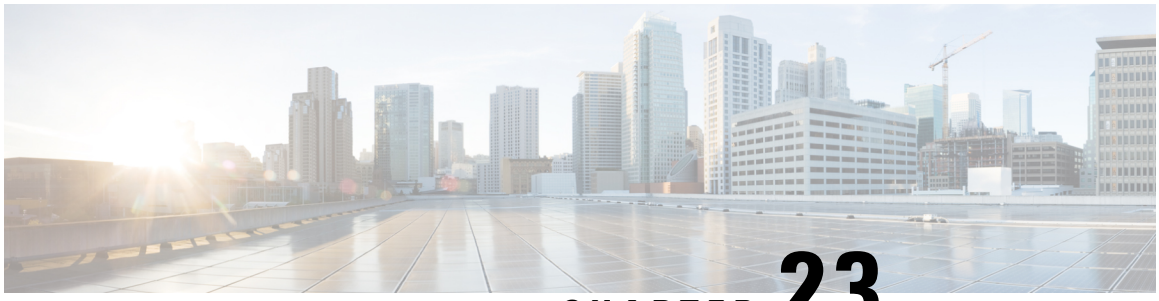
d) Click **Route Map**. Click **Add Route Map**, give a name, say *Import-from-Global*, and then click **Add**.
e) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.
f) In the **Match Clause** tab, click **IPv4**. Under **Address** tab, click **Prefix List**.
g) Under **Available IPv4 Prefix List**, select Global-Outside-Only, and then click **Add**:

Then click **Save**.

h) Navigate to the **Routing** tab of the device, and select VR-S. Click **BGP** > **IPv4** > **Route Import/Export**.

i) From the **Global Virtual Router Import Route Map** drop-down list, choose Import-from-Global:

Step 5 **Save** and **Deploy**.



The BGP configuration is complete and routes are now leaked among the virtual routers according to the configured route targets and route maps. VR-W routes are exported to VR-S and Global, VR-S Outside1 routes are exported to VR-W, and Global Outside routes are imported to VR-S.

History for virtual routers

This reference provides a comprehensive history of virtual router features introduced across different versions, including feature descriptions, minimum version requirements, and implementation details.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
AAA for user-defined VRF interfaces	7.6	7.6	A device's authentication, authorization, and accounting (AAA) is now supported on user-defined Virtual Routing and Forwarding (VRF) interfaces. The default is to use the management interface. In device platform settings, you can now associate a security zone or interface group having the VRF interface, with a configured external authentication server. New/modified screens: **Devices** > **Platform Settings** > **External Authentication**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Virtual routing with dynamic VTI	7.4	7.4	You can now configure a virtual router with a dynamic VTI for a route-based site-to-site VPN. New/modified screens: **Devices** > **Device management** > **Edit Device** > **Routing** > **Virtual Router Properties** > **Dynamic VTI interfaces under Available Interfaces** Platform restrictions: Supported only on native mode standalone or high availability devices. Not supported for container instances or clustered devices.
Virtual router support for the ISA 3000.	7.0	7.0	You can configure up to 10 virtual routers on the ISA 3000.
SNMP support on user-defined virtual routers	7.0	7.0	You can now configure SNMP on user-defined virtual routers.
Bulk removal of virtual routers.	6.7	6.6	You can remove multiple virtual routers from threat defense at a time. New/modified screens: **Devices** > **Device Management** > **Routing** > **Manage Virtual Routers**
Virtual routers and VRF-Lite for threat defense.	6.6	6.6	You can now create multiple virtual routers to maintain separate routing tables for groups of interfaces. Because each virtual router has its own routing table, you can provide clean separation in the traffic flowing through the device. Virtual routers implement the "light" version of Virtual Routing and Forwarding, or VRF-Lite, which does not support Multiprotocol Extensions for BGP (MBGP). The maximum number of virtual routers you can create ranges from five to 100, and depends on the device model.. New/modified screens: **Devices** > **Device Management** edit device **Routing** tab New/modified CLI commands: . • **show VRF** • Added the [**VRF** *name* | **all**] keyword set to these CLI commands, and changed the output to indicate virtual router information where applicable: **clear ospf**, **clear route**, **ping**, **show asp table routing**, **show BGP**, **show ipv6 route**, **show ospf**, **show route**, **show snort counters** Platform restrictions: Not supported on the Firepower 1010 and ISA 3000.

CHAPTER 23

ECMP

Equal Cost Multi-Path (ECMP) is a routing strategy that allows a router to forward packets along multiple paths of equal cost to a destination.

- Enables load balancing across multiple network paths.
- Utilizes routing protocols to determine path cost.
- Increases total available bandwidth for traffic flows.

- ECMP routing methods, on page 1209
- Guidelines and limitations for ECMP, on page 1210
- Manage ECMP zones for virtual routers, on page 1211
- Create an ECMP zone, on page 1211
- Configure an equal cost static route, on page 1212
- Configure ECMP zones on your device, on page 1213
- Modify an ECMP zone, on page 1216
- Remove an ECMP zone, on page 1217
- History for ECMP in Secure Firewall Threat Defense, on page 1217

ECMP routing methods

ECMP is a routing method that

- enables traffic distribution across multiple equal-cost paths,
- supports up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone, and
- uses traffic zones per virtual router to contain a group of interfaces.

Multiple default routes configuration

This example shows multiple default routes configured across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2

route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2

route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

Guidelines and limitations for ECMP

Follow these principles for effective ECMP zone configuration:

Firewall mode limitations

Use ECMP zones only in routed firewall mode.

Interface restrictions

Do not use dVTI or Loopback interfaces with ECMP zones.

ECMP zone configuration limits

Follow these limits when configuring ECMP zones:

- Devices can have a maximum of 256 ECMP zones.
- You can associate only 8 interfaces per ECMP zone.
- An interface can be a member of only one ECMP zone.

Interface management limitations

Do not remove interfaces or delete zones actively used for routing:

- You cannot remove an interface that is associated with an equal cost static route from the ECMP zone.
- You cannot delete an ECMP zone if its interface has equal cost static routes associated with it.

Supported interface types

Use only routed interfaces for ECMP zones. Do not associate these interface types with an ECMP zone:

- BVI interface.
- Member interfaces in an EtherChannel.
- Failover or state link interface.
- Management-only or management-access interfaces.
- Cluster control link interface.
- VNIs.
- VLAN interfaces.
- Interfaces in a remote access VPN configuration with SSL enabled.

Feature compatibility limitations

Consider these feature limitations when using ECMP zones:

- DHCP Relay is not supported on interfaces in an ECMP zone.
- Dual ISP/WAN Firewall Threat Defense Deployment—Create a single ECMP zone for the primary and secondary data interfaces, enabling static routes with identical metric values.

- The Firewall Threat Defense does not support ECMP with NAT in IPsec sessions—a standard IPsec virtual private network (VPN) tunnel does not work with NAT points in the delivery path of IPsec packets.

Manage ECMP zones for virtual routers

The ECMP page lets you manage existing ECMP zones linked with virtual routers. When you click **ECMP** on the **Routing** pane, the ECMP page displays the current ECMP zones, including the associated interfaces, for the selected virtual router. On this page, you can add new ECMP zones to the virtual router. You can also **Edit** (✎) and **Delete** (🗑) ECMP zones.

You can perform these actions:

- Create an ECMP zone, on page 1211
- Configure an equal cost static route, on page 1212
- Modify an ECMP zone, on page 1216
- Remove an ECMP zone, on page 1217

Create an ECMP zone

Create an ECMP zone to enable load balancing across multiple equal-cost paths in a virtual router configuration.

ECMP zones are created per virtual router. Only interfaces that belong to the virtual router where the ECMP is being created can be associated with the ECMP zone.

Procedure

Step 1 Navigate to **Devices** > **Device Management**, and edit the Firewall Threat Defense device. Click the **Routing** tab.

Step 2 From the virtual router drop-down, select the virtual router in which you want to create the ECMP zone.

You can create ECMP zones in the global virtual router and user-defined virtual routers. For information on creating virtual routers, refer to Create a virtual router, on page 1164.

Step 3 Click **ECMP**, and click **Add**.

Step 4 In the **Add ECMP** box, enter a name for the ECMP zone.

Note The ECMP name must be unique on the routed device.

Step 5 Under the **Available Interfaces** box, select the interface.

Step 6 Click **Add**.

- Only interfaces belonging to the virtual router where you are creating the ECMP can be associated with it. Interfaces must have a logical name to be displayed; edit the interface and save to set a logical name.

- From Version 10.0, ECMP is supported on dynamic VTIs (DVTIs) of hub devices in SD-WAN VPN topologies. When enabled on a DVTI, it is automatically added to a system-generated ECMP zone, so DVTIs do not appear under **Available Interfaces**.

Step 7 Click **OK**.

The ECMP page displays your newly created ECMP zone.

Step 8 Click **Save** and **Deploy** the configuration.

You can associate the ECMP zone interfaces with equal cost static route by defining them with same destination and metric value but with a different gateway.

What to do next

- Configure an equal cost static route, on page 1212
- Modify an ECMP zone, on page 1216
- Remove an ECMP zone, on page 1217

Configure an equal cost static route

Configure equal cost static routes to enable load balancing across multiple interfaces with the same destination and metric value within an ECMP zone.

Smart License	Classic License	Supported Devices	Supported Domains	Access
Any	N/A	Firewall Threat Defense and Firewall Threat Defense Virtual	Any	Admin/Network Admin/Security Approver

You can assign interfaces of a virtual router, both global and user-defined, to an ECMP zone for the device.

Before you begin

- To configure an equal cost static route for an interface, ensure that it is associated with an ECMP zone. For more information, refer to Create an ECMP zone, on page 1211.
- All routing configuration settings of a non-VRF-capable device are also available for a global virtual router.
- You cannot define a static route for interfaces with the same destination and metric without associating the interfaces with an ECMP zone.

Procedure

Step 1 From the **Devices** > **Device Management** page, edit the Firewall Threat Defense device. Click the **Routing** tab.

Step 2 From the drop-down list, select the virtual router whose interfaces are associated with an ECMP zone.

Step 3 To configure the equal cost static route for the interfaces, click **Static Route**.

Step 4 Either click **Add Route** to add a new route, or click **Edit** (✎) for an existing route.

Step 5 From the **Interface** drop-down, select the interface that belongs to the virtual router and is associated with an ECMP zone.

Step 6 Select the destination network from the **Available Networks** box and click **Add**.

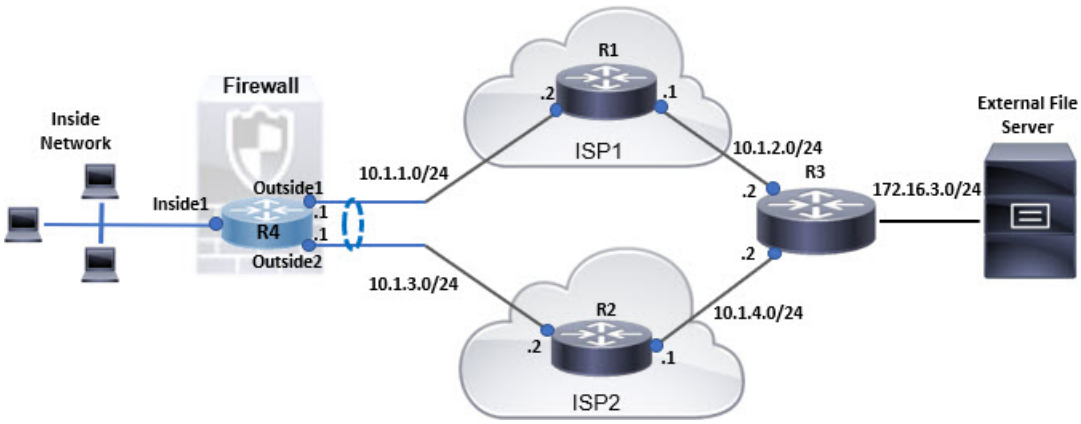
Step 7 Enter a gateway for the network.

Step 8 Enter a metric value. It can be a number that ranges between 1 and 254. Click **Save**.

To configure equal cost static routing, repeat these steps to configure the static route for another interface in the same ECMP zone with the same destination network and metric value. Remember to provide a different gateway.

The equal cost static routes are configured for the interfaces associated with the ECMP zone, enabling load balancing across multiple paths.

What to do next



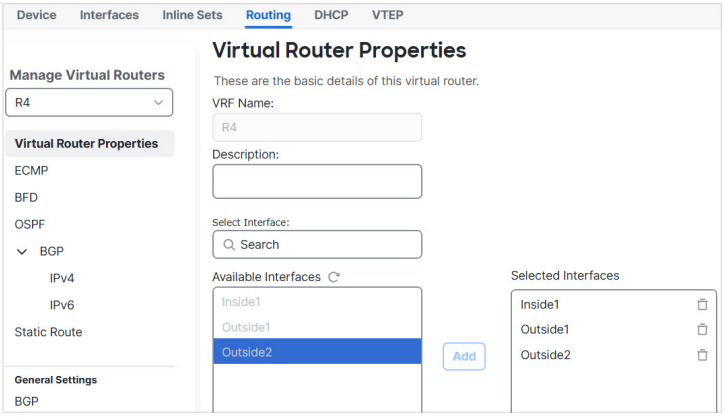
- Modify an ECMP zone, on page 1216
- Remove an ECMP zone, on page 1217

Configure ECMP zones on your device

Configure Equal-Cost MultiPath (ECMP) to enable efficient traffic handling through the device with support for asymmetric routing, load balancing, and traffic rerouting when a path becomes unavailable.

This example demonstrates how to use Firewall Management Center to configure ECMP zones on Firewall Threat Defense such that the traffic flowing through the device is handled efficiently. With ECMP configured, Firewall Threat Defense maintains the routing table on a per-zone basis, enabling efficient packet re-routing. Thus, ECMP supports asymmetric routing, load balancing, and traffic rerouting when a path becomes unavailable. In this example, R4 records the two paths to reach the external file server.

Figure 384: Configuration example for ECMP



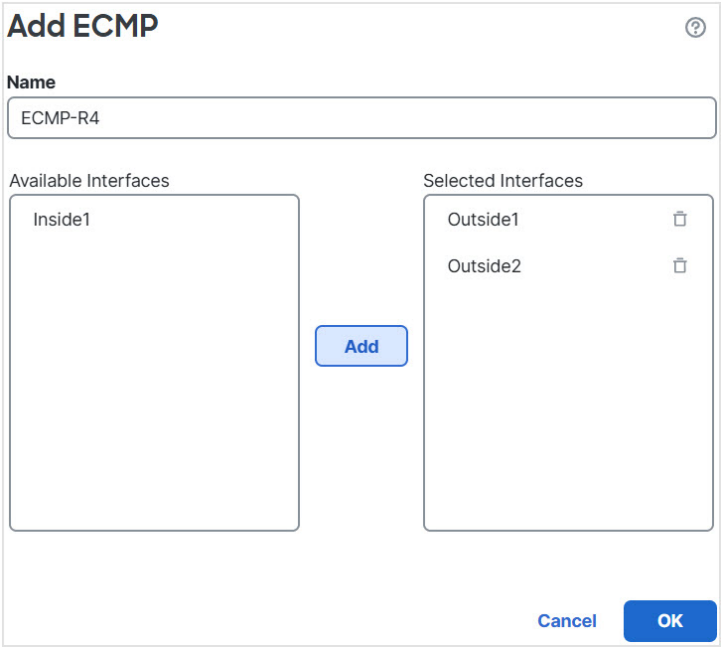
Follow these steps to configure ECMP on your device:

Procedure

Step 1 Create a virtual router.

Set up a new router on *R4* with interfaces: *Inside1*, *Outside1*, and *Outside2*. For more information, refer to Create virtual router.

Figure 385: Configuring R4 virtual router



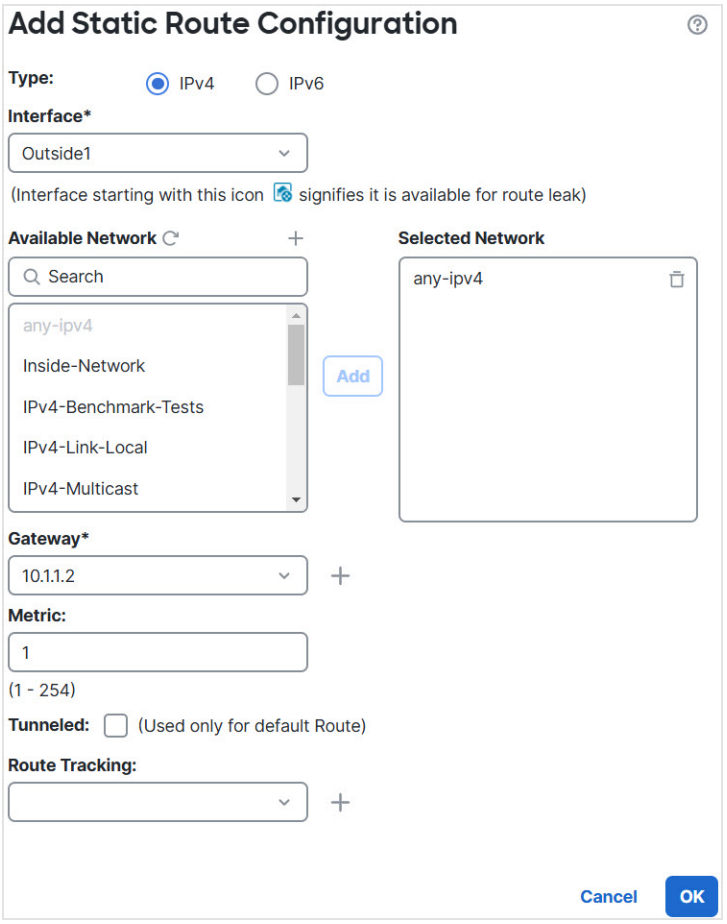
Step 2 Create ECMP zones:

a) In the **Routing** tab, choose R4 user-defined virtual router, and then click **ECMP**.

b) Click **Add**.

c) Enter an ECMP name and from the **Available Interfaces** list, choose *Outside1* and *Outside2*:

Figure 386: Creating ECMP zone



d) Click **OK**.
e) Click **Save**.

Step 3 Create static routes for the zone interfaces:

a) In the **Routing** tab, click **Static Route**.
b) From the **Interface** drop-down list, select Outside1.
c) Under **Available Network**, choose any-ipv4 and click **Add**.
d) Specify the next-hop address in the **Gateway** field, 10.1.1.2.

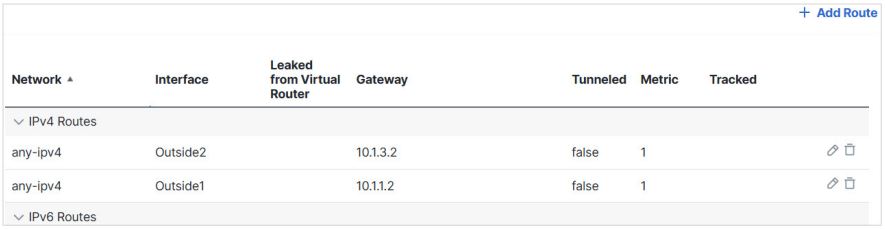


Figure 387: Configuring static route for Outside1

e) Configure the static route for Outside2 by repeating Step 3b through Step 3d.

Ensure that you specify the same metric but different gateways for the static routes:

Figure 388: Configured static routes of ECMP zone interfaces

Step 4 Save and deploy the changes to apply ECMP routing to your device.

Network packets will now utilize efficient routes to reach their destination R3, either through R4>R1>R3 or R4>R2>R3, according to the ECMP algorithm configuration. If the R1>R3 route becomes unavailable, traffic can be rerouted through R2, which helps reduce disruption during path failure. Additionally, return traffic from R3 can arrive on *Outside2* even if the original packet was sent through *Outside1*. When network traffic is heavy, R4 distributes the network load between two specified routes to maintain balanced traffic.

Modify an ECMP zone

Use this procedure when you need to make changes to an existing ECMP zone configuration on your device.

Follow these steps to modify an ECMP zone:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click the **Routing** tab.

Step 3 Click **ECMP**.

ECMP zones with their associated interfaces appear.

Step 4 To modify an ECMP zone, click **Edit** (✎) next to the desired ECMP zone. In the **Edit ECMP** dialog box, you can make changes to the ECMP name or associated interfaces.

- ECMP Name: Ensure that the ECMP name you enter is unique.
- Interfaces: Add or remove one or more interfaces as needed.

Note An interface must not belong to more than one ECMP zone, and it should not be linked to an equal-cost static route.

Step 5 Click **OK**.

Step 6 Click **Save**.

The ECMP zone shows your updated settings.

What to do next

- Configure an equal cost static route, on page 1212
- Remove an ECMP zone, on page 1217

Remove an ECMP zone

ECMP zones group interfaces for equal-cost multipath routing. You may need to remove an ECMP zone when reconfiguring your network topology or when the zone is no longer required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click the **Routing** tab.

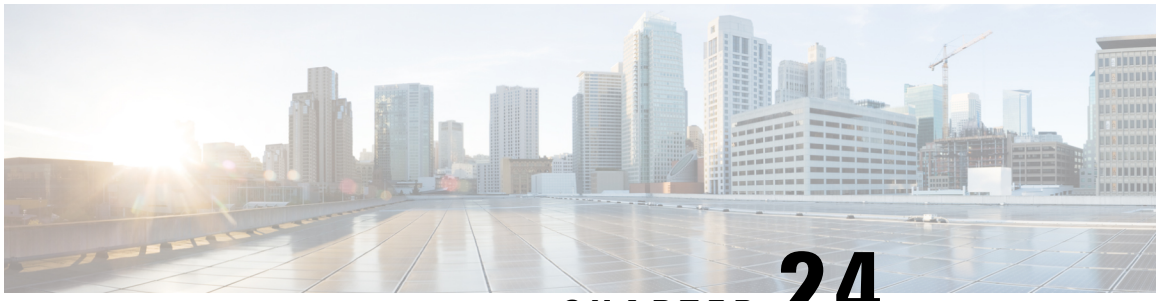
Step 3 Click **ECMP**.

The ECMP zones with associated interfaces appear.

Step 4 To remove an ECMP zone, click **Delete** ( ) next to the ECMP zone.

Note You cannot delete the ECMP zone if it has interfaces associated with equal-cost static routes.

Step 5 Click **Delete** in the confirmation message.



Step 6 Click **Save** to apply changes.

The ECMP zone is removed from the device configuration and is no longer available for routing operations.

History for ECMP in Secure Firewall Threat Defense

This reference provides the history of Equal-Cost Multi-Path (ECMP) features, focusing on key enhancements introduced in various releases and their implementation specifics.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
ECMP support as Routing Policy	7.1	Any	Secure Firewall Threat Defense supports ECMP routing through FlexConfig policies. Group interfaces into traffic zones to refine ECMP routing in Secure Firewall Management Center. New/modified screens: **Devices** > **Device Management** > **Routing** > **ECMP**

CHAPTER 24

Bidirectional Forwarding Detection Routing

This chapter describes how to configure Firewall Threat Defense to use the Bidirectional Forwarding Detection (BFD) routing protocol.

- BFD routing protocol, on page 1219
- Guidelines for BFD routing, on page 1219
- Configure BFD, on page 1221
- History for BFD routing, on page 1224

BFD routing protocol

A BFD routing protocol is a detection protocol that

- provides fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols
- operates in a unicast, point-to-point mode on top of any data protocol being forwarded between two systems, and
- carries packets in the payload of the encapsulating protocol appropriate for the media and the network.

Why BFD?

BFD provides a consistent failure detection method for network administrators in addition to fast forwarding path failure detection.

Network administrators can use BFD to detect forwarding path failures at a uniform rate, rather than the variable rates for different routing protocol hello mechanisms. This makes network profiling and planning easier, and reconvergence time is consistent and predictable.

Guidelines for BFD routing

Context mode guidelines

BFD is supported on all Firewall Threat Defense platforms and is available in multi-instance mode.

Firewall mode guidelines

BFD is supported in routed firewall mode and not in transparent mode.

Failover and cluster guidelines

- BFD is not supported on failover interfaces.
- In clustering, BFD is supported only on the control node.

Routing and protocol guidelines

- OSPFv2, OSPFv3, IS-IS, BGP IPv4, and BGP IPv6 protocol are supported.

  For BFD support on IS-IS, using FlexConfig CLI configure BFD on IS-IS interfaces (Physical Interfaces, Sub-Interfaces, Port-Channels only):

```
For IPv6
###Flex-config Appended CLI###

router isis
  net 11.1111.0000.0000.0001.00
exit
interface GigabitEthernet x/x
  ipv6 router isis
  isis ipv6 bfd
exit

For IPv4
###Flex-config Appended CLI###

router isis
  net 11.1111.0000.0000.0001.00
exit
interface GigabitEthernet x/x
  isis
  isis bfd
exit
```

  EIGRP protocol is not supported.
- BFD for static routes is not supported. You can configure BFD on interfaces that belong only to virtual routers.
- Only named interfaces are supported.
- BFD on BVI, VTI, and loopback interfaces are not supported.

Single-hop guidelines

- Echo mode is disabled by default. You can enable echo mode on single-hop only.
- Echo mode is not supported for IPv6.
- Use only a single-hop template to configure a single-hop policy.
- Authentication of the single-hop template is optional.
- You cannot configure multiple BFDs on the same interface.

Multi-hop guidelines

- Do not configure the source IP address also as the destination IP address.

- Source and destination address should have same IP type—IPV4 or IPV6.
- Only network objects of host or network type are allowed.
- Use only a multi-hop template to configure a multi-hop policy.
- Authentication is mandatory for the multi-hop template.

Upgrade guidelines

When you upgrade to version 7.3 and the previous version has any FlexConfig BFD policies, the management center displays a warning message during deployment. However, it does not stop the deployment process. After post-upgrade deployment, to manage the BFD policies from the UI (**Device (Edit)** > **Routing** > **BFD**), you must configure BFD policies in the **Device (Edit)** > **Routing** > **BFD** page and remove the configuration from the FlexConfig policy for the device.

Configure BFD

This task enables and configures the Bidirectional Forwarding Detection (BFD) routing policy on your system to provide rapid detection of faults in the forwarding path.

Before you begin

Ensure you have access to the system where you want to configure BFD.

Follow these steps to configure BFD:

Procedure

Step 1 Create Configure a BFD template, on page 2784.

Step 2 Configure BFD policies, on page 1221.

Step 3 Configure BFD support in the BGP neighbor settings; see, Configure BGP Neighbor Settings.

BFD is enabled and configured on your system.

Configure BFD policies

BFD policies are used to provide rapid failure detection for interfaces associated with virtual routers. Configuring BFD templates allows you to monitor connectivity and quickly identify link failures.

- Enable fast failure detection for routing interfaces.
- Support both single-hop and multi-hop BFD configurations.

You can bind a BFD template to an interface belonging to a virtual router, or to a source and destination address pair.

Before you begin

- BFD policy is configurable only on interfaces that belong to virtual routers. See Configure interfaces to a virtual router.

To configure BFD policies, complete these steps.

Procedure

Step 1 From the **Devices** > **Device Management** page, edit the virtual-router supported device. Navigate to **Routing**.

Step 2 From the drop-down list, select the desired virtual router, and then click **BFD**.

Step 3 To configure a BFD on the interface, click the **Single-Hop** tab or **Multi-Hop** tab.

Note For a single-hop policy, the BFD template is configured on an interface; for a multi-hop policy, the BFD template is configured on a source and destination address pair.

Step 4 Click **Add**. To modify the configured BFD policy, click **Edit** ( ).

Note When you edit the interface mapping with BFD template to replace it with a new BFD template, the Firewall Management Center uses a **no** command to remove the template mapping from interface and applies the new template to the interface which causes a BFD flap which may also lead to an OSPFv2, OSPFv3, or BGP flap. However, if the BFD intervals are higher, the BFD flap might not occur. Alternatively, to avoid the flapping, you can delete the existing BFD template mapping; deploy the interface, and then add the new BFD template to the interface and deploy the configuration.

- See Configure a single-hop BFD policy, on page 1222.
- See Configure a multi-hop BFD policy, on page 1223.

After completing this task, BFD policies are configured on the selected interfaces or address pairs.

Configure a single-hop BFD policy

You can configure a single-hop BFD policy only on an interface that belongs to a virtual router. This task is relevant when you need to apply BFD for rapid link failure detection on specific interfaces.

Before you begin

- Create single-hop BFD templates. You cannot configure single-hop BFD policy on interfaces that use a multi-hop template.

Follow these steps to configure a single-hop BFD policy:

Procedure

Step 1 In the **Single-Hop** tab, click **Add** or **Edit**.

Step 2 In the **Add BFD Single-Hop** dialog box, configure the following:

a) The **Interface** drop-down list displays interfaces belonging to virtual routers. Select the interface you want to configure with the BFD policy.

b) The **Template Name** drop-down list displays single-hop templates. Select the template that you want to apply.

If you have not created a single-hop template, use **Add** (+) and create a single-hop BFD template.

Step 3 Click **OK** and **Save** the configuration.

The single-hop BFD policy is applied to the selected interface. The interface will now use the specified BFD template for single-hop operations.

Configure a multi-hop BFD policy

Configure a multi-hop BFD policy to enable monitoring of connectivity between specific source and destination address pairs. This configuration helps to monitor links that traverse multiple hops in your network.

Before you begin

- Create multi-hop BFD templates. You cannot configure multi-hop BFD policy using a single-hop template.

Follow these steps to configure a multi-hop BFD policy:

Procedure

Step 1 In the **Add BFD Multi-Hop** dialog box, configure the following:

a) Click the BFD source address type:**IPv4** or **IPv6** radio button.

b) The **Source Address** drop-down list displays the network objects. Select the source address for the BFD policy; do not choose *any-ipv4* or *any-ipv6*.

If you have not created the required network object, use **Add** (+) and create a host/network object.

Note The created network object's IP type should match with the selected source IP type.

c) The **Destination Address** drop-down list displays network objects. Select the destination address for the BFD; do not choose *any-ipv4* or *any-ipv6*.

If you have not created the required network object, use **Add** (+) and create a host/network object.

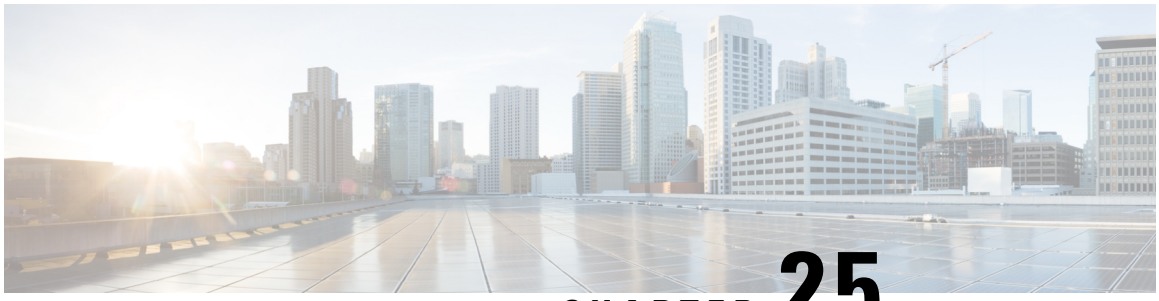
Note The created network object's IP type should match with the selected source IP type.

Attention Do not select the network object that has the same IP address as that of the source address.

d) The **Template Name** drop-down list displays multi-hop templates. Select the template to apply to the BFD policy.

If you have not created a multi-hop template, use **Add** (+) and create a multi-hop BFD template.

Step 2 Click **OK** and **Save** the configuration.



The multi-hop map (table view) is displayed on the **Multi-Hop** tab page.

History for BFD routing

The History table summarizes the introduction and evolution of the BFD routing in Cisco Firewall Management Center across releases, enabling quick tracking of feature availability and changes.

Table 81: Feature history for BFD routing

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
BFD support for IS-IS	7.4	7.4	You can configure BFD on IS-IS interfaces using FlexConfig CLI.
BFD support for OSPF	7.4	7.4	You can enable BFD on interfaces that use OSPF version 2 and OSPF version 3. New/modified screens: • **Configuration** > **Device Setup** > **Routing** > **OSPFv2** • **Configuration** > **Device Setup** > **Routing** > **OSPFv3**
BFD configuration	7.4	7.4	In the previous releases, BFD was configurable on threat defense only through FlexConfig. FlexConfig no longer supports BFD configuration. You can now configure BFD policies for threat defense in the management center UI. In threat defense, BFD is supported only on the BGP protocol. New/modified screens: **Devices** > **Device Management** > **Routing** > **BFD**.

CHAPTER 25

OSPF

This chapter describes how to configure the Firewall Threat Defense to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

- OSPF, on page 1225
- Requirements and prerequisites for OSPF, on page 1229
- Guidelines for OSPF, on page 1229
- OSPFv2 configuration, on page 1232
- OSPFv3 configuration, on page 1245
- History for OSPF, on page 1255

OSPF

This chapter describes how to configure the Firewall Threat Defense to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

OSPF routing

OSPF is an interior gateway routing protocol that

- uses link states rather than distance vectors for path selection,
- propagates link-state advertisements rather than routing table updates, and
- converges more quickly than RIP networks because only LSAs are exchanged instead of the entire routing tables.

OSPF characteristics and features

OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area contains an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

The advantages of OSPF over RIP include these characteristics:

- OSPF link-state database updates are sent less frequently than RIP updates, and the link-state database is updated instantly, rather than gradually, AS stale information is timed out.

- Routing decisions are based on cost, which is an indication of the overhead required to send packets across a certain interface. The Firewall Threat Defense device calculates the cost of an interface based on link bandwidth rather than the number of hops to the destination. The cost can be configured to specify preferred paths.

The disadvantage of shortest path first algorithms is that they require a lot of CPU cycles and memory.

The Firewall Threat Defense device can run two processes of OSPF protocol simultaneously on different sets of interfaces. You might want to run two processes if you have interfaces that use the same IP addresses (NAT allows these interfaces to coexist, but OSPF does not allow overlapping addresses). Or you might want to run one process on the inside and another on the outside, and redistribute a subset of routes between the two processes. Similarly, you might need to segregate private addresses from public addresses.

You can redistribute routes into an OSPF routing process from another OSPF routing process, a RIP routing process, or from static and connected routes configured on OSPF-enabled interfaces.

The Firewall Threat Defense device supports these OSPF features:

- Intra-area, inter-area, and external (Type I and Type II) routes.
- Virtual links.
- LSA flooding.
- Authentication to OSPF packets (both password and MD5 authentication).
- Configuring the Firewall Threat Defense device AS a designated router or a designated backup router. The Firewall Threat Defense device also can be set up AS an ABR.
- Stub areas and not-so-stubby areas.
- Area boundary router Type 3 LSA filtering.

OSPF supports both MD5 and clear text neighbor authentication. Authentication should be used with all routing protocols when possible because route redistribution between OSPF and other protocols (such AS RIP) can potentially be used by attackers to subvert routing information.

If NAT is used, if OSPF is operating on public and private areas, and if address filtering is required, then you need to run two OSPF processes—one process for the public areas and one for the private areas.

A router that has interfaces in multiple areas is called an Area Border Router (ABR). A router that acts AS a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR).

An ABR uses LSAs to send information about available routes to other OSPF routers. Using ABR Type 3 LSA filtering, you can have separate private and public areas with the ASA acting AS an ABR. Type 3 LSAs (inter-area routes) can be filtered from one area to other, which allows you to use NAT and OSPF together without advertising private networks.

Note Only Type 3 LSAs can be filtered. If you configure the Firewall Threat Defense device AS an ASBR in a private network, it will send Type 5 LSAs describing private networks, which will get flooded to the entire AS, including public areas.

If NAT is employed but OSPF is only running in public areas, then routes to public networks can be redistributed inside the private network, either AS default or Type 5 AS external LSAs. However, you need to configure

static routes for the private networks protected by the Firewall Threat Defense device. Also, you should not mix public and private networks on the same Firewall Threat Defense device interface.

You can have two OSPF routing processes, one RIP routing process, and one EIGRP routing process running on the Firewall Threat Defense device at the same time.

OSPF support for fast hello packets

OSPF support for fast hello packets is a feature that

- provides a way to configure the sending of hello packets in intervals less than one second, and
- results in faster convergence in an Open Shortest Path First (OSPF) network.

OSPF fast hello packets configuration prerequisites

OSPF must be configured in the network already or configured at the same time as the OSPF Support for Fast Hello Packets feature.

OSPF hello interval and dead interval

OSPF hello interval and dead interval are configurable time parameters that

- maintain connectivity between OSPF neighbors through regular hello packet exchanges,
- detect neighbor failures when hello packets are not received within the specified timeframes, and
- must be consistent across all routers within the same network to ensure proper operation.

Hello interval and dead interval configuration details

OSPF hello packets are packets that an OSPF process sends to its OSPF neighbors to maintain connectivity with those neighbors. The hello packets are sent at a configurable interval (in seconds). The defaults are 10 seconds for an Ethernet link and 30 seconds for a non broadcast link.

Hello packets include a list of all neighbors for which a hello packet has been received within the dead interval. The dead interval is also a configurable interval (in seconds), and defaults to four times the value of the hello interval. The value of all hello intervals must be the same within a network. Likewise, the value of all dead intervals must be the same within a network.

These two intervals work together to maintain connectivity by indicating that the link is operational. If a router does not receive a hello packet from a neighbor within the dead interval, it will declare that neighbor to be down.

OSPF fast hello packets

OSPF fast hello packets are hello packets that

- are sent at intervals of less than 1 second,
- are achieved by using the OSPF dead-interval command with a dead interval set to 1 second, and
- use a hello-multiplier value set to the number of hello packets sent during that 1 second.

Fast hello packet behavior

When fast hello packets are configured on the interface, these behaviors occur:

- The hello interval advertised in the hello packets that are sent out this interface is set to 0.
- The hello interval in the hello packets received over this interface is ignored.

The dead interval must be consistent on a segment, whether it is set to 1 second (for fast hello packets) or set to any other value. The hello multiplier need not be the same for the entire segment as long as at least one hello packet is sent within the dead interval.

To understand fast hello packets, you should already understand the relationship between OSPF hello packets and the dead interval. For more information, refer to OSPF hello interval and dead interval, on page 1227.

Benefits of OSPF fast hello packets

A fast hello packet is an OSPF protocol feature that

- reduces network convergence time by enabling routers to detect changes in the network faster,
- allows rapid detection of lost neighbors within one second, and
- enhances reliability in LAN environments where neighbor loss may not be detected at the Open Systems Interconnection (OSI) physical or data-link layer.

The benefit of OSPF Fast Hello Packets is that your OSPF network can react swiftly to changes, minimizing downtime and improving overall network stability. This feature is particularly useful in scenarios where routers may not detect lost neighbors via traditional methods, allowing OSPF to maintain accurate routing tables.

If a router on a LAN segment is powered off or disconnected and the physical and data-link layers do not signal neighbor loss, OSPF fast hello packets will detect the neighbor's disappearance within one second.

OSPFv2 and OSPFv3 implementation differences

A protocol distinction is a protocol category that

- prevents backward compatibility between OSPFv2 and OSPFv3,
- requires both OSPF versions to run simultaneously for IPv4 and IPv6 routing, and
- allows OSPFv2 and OSPFv3 to coexist without interacting with each other.

OSPFv3 additional features

OSPFv3 provides additional features that include:

- Protocol processing per link.
- Removal of addressing semantics.
- Addition of flooding scope.
- Support for multiple instances per link.
- Use of the IPv6 link-local address for neighbor discovery and other features.

- LSAs expressed as prefix and prefix length.
- Addition of two LSA types.
- Handling of unknown LSA types.
- Authentication support using the IPsec ESP standard for OSPFv3 routing protocol traffic, as specified by RFC-4552.

Requirements and prerequisites for OSPF

This reference provides the requirements and prerequisites that must be met before configuring OSPF on supported devices.

Model support

Firewall Threat Defense

Firewall Threat Defense Virtual

Supported domains

Any

User roles

Administrator

Network Admin

Guidelines for OSPF

Context mode guidelines

OSPFv2 supports single and multiple context mode.

- OSPFv2 instances cannot form adjacencies with each other across shared interfaces because, by default, inter-context exchange of multicast traffic is not supported across shared interfaces. However, you can use the static neighbor configuration under OSPFv2 process configuration under OSPFv2 process to bring up OSPFv2 neighbourship on a shared interface.
- Inter-context OSPFv2 on separate interfaces is supported.
- **(For point-to-point topology)** In a multiple context mode, you can configure static OSPFv2 neighbors to advertise OSPFv2 routes over a point-to-point, non-broadcast network. For a successful OSPF adjacency formation, when you remove and reconfigure OSPF on a shared interface, execute the commands in this order: Remove the OSPF configuration using **no router <OSPF name>**, and then remove the OSPF point-to-point non-broadcast configuration on the interface using **no OSPF network point-to-point non-broadcast**. When you reconfigure OSPF on the shared interface, configure the OSPF router using **router <OSPF name>**, and then configure the interface with **OSPF network point-to-point non-broadcast**.
- OSPFv3 supports single mode only.

Key chain authentication guidelines

OSPFv2 supports key chain authentication on both single and multiple mode, both in physical and virtual modes. However, in multiple mode, you can configure the key chain only in context mode.

- The rotating keys are applicable only for OSPFv2 protocol. OSPF area authentication with key chain is not supported.
- The existing MD5 authentication without time range in OSPFv2 is still supported along with new rotating keys.
- Though the platform supports SHA1 and MD5 cryptographic algorithms, only MD5 cryptographic algorithm is used for authentication.

Firewall mode guidelines

OSPF supports routed firewall mode only. OSPF does not support transparent firewall mode.

High availability Guidelines

OSPFv2 and OSPFv3 support Stateful High availability.

IPv6 guidelines

OSPFv2 does not support IPv6, while OSPFv3 provides IPv6 support with specific authentication and routing capabilities.

- OSPFv2 does not support IPv6.
- OSPFv3 supports IPv6.
- OSPFv3 uses IPv6 for authentication.
- The Firewall Threat Defense device installs OSPFv3 routes into the IPv6 RIB, provided it is the best route.

OSPFv3 hello packets and GRE

Typically, OSPF traffic does not pass through GRE tunnel. When OSPFv3 on IPv6 is encapsulated inside GRE, the IPv6 header validation for security check such as Multicast Destination fails. The packet is dropped due to the implicit security check validation, as this packet has destination IPv6 multicast.

- You may define a pre-filter rule to bypass GRE traffic. However, with pre-filter rule, inner packets would not be interrogated by the inspection engine.

Clustering guidelines

OSPFv2 and OSPFv3 have specific limitations and behaviors in clustering environments.

- OSPFv3 encryption is not supported. An error message appears if you try to configure OSPFv3 encryption in a clustering environment.
- In Spanned interface mode, dynamic routing is not supported on management-only interfaces.
- In Individual interface mode, make sure that you establish the control and data units as either OSPFv2 or OSPFv3 neighbors.

- In Individual interface mode, OSPFv2 adjacencies can only be established between two contexts on a shared interface on the control unit. Configuring static neighbors is supported only on point-to point-links; therefore, only one neighbor statement is allowed on an interface.
- When a control role change occurs in the cluster, specific behavior occurs based on interface mode. In spanned interface mode, the router process is active only on the control unit and is in a suspended state on the data units. Each cluster unit has the same router ID because the configuration has been synchronized from the control unit. As a result, a neighboring router does not notice any change in the router ID of the cluster during a role change. In individual interface mode, the router process is active on all the individual cluster units. Each cluster unit chooses its own distinct router ID from the configured cluster pool. A control role change in the cluster does not change the routing topology in any way.

Multiprotocol label switching (MPLS) and OSPF guidelines

When a MPLS-configured router sends Link State (LS) update packets containing opaque Type-10 link-state advertisements (LSAs) that include an MPLS header, authentication fails and the appliance silently drops the update packets, rather than acknowledging them. Eventually the peer router will terminate the neighbor relationship because it has not received any acknowledgments.

- Make sure that non-stop forwarding (NSF) is disabled on the appliance to ensure that the neighbor relationship remains stable. Navigate to the **Non Stop Forwarding** page in Firewall Management Center (**Devices** > **Device Management (select the desired device)** > **Routing** > **OSPF** > **Advanced** > **Non Stop Forwarding**). Ensure the **Non Stop Forwarding Capability** boxes are not checked.

These guidelines apply to MPLS environments where opaque LSAs might cause authentication failures.

Note The Firepower 4100/9300 models may have high latency when using MPLS because they lack load balancing across multiple receiving queues.

Bidirectional and forwarding detection (BFD) and OSPF guidelines

You can enable BFD on specific interface types with OSPFv2 and OSPFv3.

- You can enable BFD on OSPFv2 and OSPFv3 interfaces (Physical Interfaces, Sub-Interfaces, and Port-Channels).
- BFD is not supported on VTI Tunnels, DVTI Tunnels, Loopback, Switchport, VNI, VTEP, and IRB interfaces.

Route redistribution guidelines

Route redistribution with prefix lists and between routing domains requires specific configuration considerations.

- Redistribution of route maps with IPv4 prefix list on OSPFv2 is supported. However, redistribution of route maps with IPv6 prefix list on OSPFv3 is not supported. Use an access list in the route map on OSPF for redistribution.
- When OSPF is configured on a device that is a part of EIGRP network or vice versa, ensure that OSPF-router is configured to tag the route (EIGRP does not support route tag yet). When redistributing OSPF into EIGRP and EIGRP into OSPF, a routing loop occurs when there is an outage on one of the links, interfaces, or even when the route originator is down. To prevent the redistribution of routes from one domain back into the same domain, a router can tag a route that belongs to a domain while it is

redistributing, and those routes can be filtered on the remote router based on the same tag. Because the routes will not be installed into the routing table, they will not be redistributed back into the same domain.

Additional guidelines

OSPFv2 and OSPFv3 support various features and have specific limitations in different deployment scenarios.

- OSPFv2 and OSPFv3 support multiple instances on an interface.
- OSPFv3 supports encryption through ESP headers in a non-clustered environment.
- OSPFv3 supports Non-Payload Encryption.
- OSPFv2 supports Cisco NSF Graceful Restart and IETF NSF Graceful Restart mechanisms as defined in RFCs 4811, 4812 & 3623 respectively.
- OSPFv3 supports Graceful Restart mechanism as defined in RFC 5187.
- There is a limit to the number of intra area (type 1) routes that can be distributed. For these routes, a single type-1 LSA contains all prefixes. Because the system has a limit of 35 KB for packet size, 3000 routes result in a packet that exceeds the limit. Consider 2900 type 1 routes to be the maximum number supported.
- For a device using virtual routing, you can configure OSPFv2 and OSPFv3 for a global virtual router. However, you can configure only OSPFv2 for a user-defined virtual router.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.
- OSPFv3 drops the LS update if the packet size exceeds 8190. As a result, the neighbourship is terminated. Hence, configure the switch with the "ospfv3 MTU-ignore" command to avoid neighbourship termination.

OSPFv2 configuration

This section describes the tasks involved in configuring an OSPFv2 routing process. For a device using virtual routing, you can configure OSPFv2 for global as well as for user-defined virtual routers.

Configure OSPF areas, ranges, and virtual links

Complete the configuration of OSPF by defining areas, assigning route summarization ranges, and creating virtual links to connect discontiguous OSPF areas.

You can configure several OSPF area parameters, which include setting authentication, defining stub areas, and assigning specific costs to the default summary route. You can enable up to two OSPF process instances. Each OSPF process has its own associated areas and networks. Authentication provides password-based protection against unauthorized access to an area.

Stub areas are areas into which information on external routes is not sent. Instead, there is a default external route generated by the ABR into the stub area for destinations outside the autonomous system. To take advantage of the OSPF stub area support, default routing must be used in the stub area.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

For a virtual-router-aware device, choose the virtual router from the virtual routers drop-down list.

Step 3 Click **OSPF** and configure the following on the **OSPF** page:

- Check the check box of **Process 1**. You can enable up to two OSPF process instances for each context /virtual router. You must choose an OSPF process to be able to configure the Area parameters.

  If the device is using virtual routing, the ID fields display the unique process IDs generated for the chosen virtual router.

- Choose the **OSPF Role** from the drop-down list, and enter a description for it in the next field. The options are **Internal Router**, **ABR**, **ASBR**, and **ABR & ASBR**. For a description of the OSPF roles, refer to OSPF routing, on page 1225.

Step 4 Select **Area** > **Add**.

You can click **Edit** ( ) , or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 5 Configure the following area options for each OSPF process:

- **OSPF Process**: Choose the process ID. For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Area ID**: Designation of the area for which routes are to be summarized.
- **Area Type**: Choose one of the following:
  - **Normal**: (Default) Standard OSPF area.
  - **Stub**: A stub area does not have any routers or areas beyond it. Stub areas prevent Autonomous System (AS) External LSAs (Type 5 LSAs) from being flooded into the stub area. When you create a stub area, you can prevent summary LSAs (Types 3 and 4) from being flooded into the area by not checking the **Summary Stub** check box.
  - **NSSA**: Makes the area a not-so-stubby area (NSSA). NSSAs accept Type 7 LSAs. You can disable route redistribution by not checking the **Redistribute** check box and checking the **Default Information Originate** check box. You can prevent summary LSAs from being flooded into the area by not checking the **Summary NSSA** check box.
- **Metric Value**: The metric used for generating the default route. The default value is 10. Valid metric values range from 0 through 16777214.
- **Metric Type**: The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Available Network**: Choose one of the available networks and click **Add** , or click **Add** ( ) to add a new network object. For the procedure for adding networks, refer to Networks, on page 2813.

- **Authentication**: Choose the OSPF authentication:
  - **None**: (Default) Disables OSPF area authentication.
  - **Password**: Provides a clear text password for area authentication, which is not recommended where security is a concern.
  - **MD5**: Allows MD5 authentication.
- **Default Cost**: The default cost for the OSPF area, which is used to determine the shortest paths to the destination. Valid values range from 0 through 65535. The default value is 1.
- Click **OK** to save the area configuration.

Step 6 Select **Range** > **Add**.

- Choose one of the available networks and whether to advertise, or
- Click **Add** (+) to add a new network object. For the procedure for adding networks, refer to Networks, on page 2813.
- Click **OK** to save the range configuration.

Step 7 Select **Virtual Link**, click **Add** (+), and configure the following options for each OSPF process:

- **Peer Router**: Choose the IP address of the peer router. To add a new peer router, click **Add** (+). For the procedure for adding networks, refer to Networks, on page 2813.
- **Hello Interval**: The time in seconds between the hello packets sent on an interface. The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. Valid values range from 1 through 65535. The default is 10.

  The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.
- **Transmit Delay**: The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 through 8192. The default is 1.

  LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.
- **Retransmit Interval**: The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 through 65535. The default is 5.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.
- **Dead Interval**: The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The dead interval is an unsigned integer. The default is four times the hello interval, or

40 seconds. The value must be the same for all routers and access servers that are attached to a common network. Valid values range from 1 through 65535.

- **Authentication**: Choose the OSPF virtual link authentication from the following:
  - **None**: (Default) Disables virtual link area authentication.
  - **Area Authentication**: Enables area authentication using MD5. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.
  - **Password**: Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
  - **MD5**: Allows MD5 authentication. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.

Note Ensure to enter only numbers as the MD5 key ID.

  - **Key Chain**: Allows key chain authentication. Click **Add**, and create the key chain, and then click **Save**. For detailed procedure, refer to Create a key chain object, on page 2812. Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.
  - Click **OK** to save the virtual link configuration.

Step 8 Click **Save** on the **Routing** page to save your changes.

OSPF is configured with designated areas, summarized ranges, and any necessary virtual links. Routing updates are generated based on your configuration.

Configure OSPF redistribution

This task enables you to control the redistribution of routes between the OSPF routing processes on your Firewall Threat Defense device.

The Firewall Threat Defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by EIGRP, RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

Before you begin

Follow these steps to configure OSPF redistribution:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**, and from **OSPF Role** drop-down, choose role.

Step 5 Click **Redistribution** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 6 Configure the following redistribution options for each OSPF process:

- **OSPF Process**: Choose the process ID. For a device using virtual routing, this drop-down list displays the unique process IDs generated for the selected virtual router.
- **Route Type**: Choose one of the following types:
  - **Static**: Redistributes static routes to the OSPF routing process.
  - **Connected**: Redistributes connected routes (routes established automatically by virtue of having the IP address enabled on the interface) to the OSPF routing process. Connected routes are redistributed AS external to the device. You can select whether to use subnets under the Optional list.
  - **OSPF**: Redistributes routes from another OSPF routing process, for example, internal, external 1 and 2, NSSA external 1 and 2, or whether to use subnets. You can select these options under the Optional list.
  - **BGP**: Redistribute routes from the BGP routing process. Add the AS number and whether to use subnets.
  - **RIP**: Redistributes routes from the RIP routing process. You can select whether to use subnets under the Optional list.

Note As a user-defined virtual router does not support RIP, you cannot redistribute routes from RIP.

  - **EIGRP**: Redistribute routes from the EIGRP routing process. Add the AS number and whether to use subnets.

- **Metric Value**: Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

  When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.

- **Metric Type**: The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Tag Value**: Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.

- **RouteMap**: Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add** (+). To add a new route map, refer to Configure Route Map Entry.

Step 7 Click **OK** to save the redistribution configuration.

Step 8 Click **Save** on the **Routing** page to save your changes.

OSPF redistribution is now configured for the selected OSPF process with the specified route types and parameters.

Configure OSPF Inter-Area filtering

Configure ABR type 3 LSA filtering to control which prefixes are sent between different OSPF areas and restrict other prefixes to their local OSPF area.

ABR type 3 LSA filtering extends the capability of an ABR that is running OSPF to filter type 3 LSAs between different OSPF areas. Once a prefix list is configured, only the specified prefixes are sent from one OSPF area to another OSPF area. All other prefixes are restricted to their OSPF area. You can apply this type of area filtering to traffic going into or coming out of an OSPF area, or to both the incoming and outgoing traffic for that area.

When multiple entries of a prefix list match a given prefix, the entry with the lowest sequence number is used. For efficiency, you may want to put the most common matches or denials near the top of the list by manually assigning them a lower sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.

Before you begin

Follow these steps to configure OSPF inter-area filtering:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**, and select **InterArea** > **Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete inter-areas.

Step 5 Configure these inter-area filtering options for each OSPF process:

- **OSPF Process**: For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Area ID**: The area for which routes are to be summarized.
- **PrefixList**: The name of the prefix. To add a new prefix list object, see Step 5.

- **Traffic Direction**: Inbound or outbound. Choose Inbound to filter LSAs coming into an OSPF area, or Outbound to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.

Step 6 Click **Add** (+), and enter a name for the new prefix list, and whether to allow overrides.

You must configure a prefix list before you can configure a prefix rule.

Step 7 Click **Add** to configure prefix rules, and configure these parameters:

- **Action**: Select **Block** or **Allow** for the redistribution access.
- **Sequence No**: The routing sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.
- **IP Address**: Specify the prefix number in the format of IP address/mask length.
- **Min Prefix Length**: (Optional) The minimum prefix length.
- **Max Prefix Length**: (Optional) The maximum prefix length.
- Click **OK** to save the inter-area filtering configuration.

Step 8 Click **Save** on the Routing page to save your changes.

The OSPF inter-area filtering configuration is saved and applied to control LSA distribution between the specified OSPF areas according to the configured prefix lists and traffic direction settings.

Configure OSPF filter rules

Configure OSPF filter rules to improve control of route distribution between OSPF areas by allowing only specified prefixes to be sent from one area to another area while restricting all other prefixes.

You can configure ABR Type 3 LSA filters for each OSPF process. ABR Type 3 LSA filters allow only specified prefixes to be sent from one area to another area and restrict all other prefixes. You can apply this type of area filtering out of a specific OSPF area, into a specific OSPF area, or into and out of the same OSPF area at the same time. OSPF ABR Type 3 LSA filtering improves your control of route distribution between OSPF areas.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Filter Rule** > **Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete filter rules.

Step 6 Configure the following filter rule options for each OSPF process:

- **OSPF Process**: For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Access List**: The access list for this OSPF process. To add a new standard access list object, click **Add** (+) and refer to Configure a standard ACL object, on page 2780.
- **Traffic Direction**: Choose In or Out for the traffic direction being filtered. Choose In to filter LSAs coming into an OSPF area, or Out to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.
- **Interface**: The interface for this filter rule.

Step 7 Click **OK** to save the filter rule configuration.

Step 8 Click **Save** on the Routing page to save your changes.

The OSPF filter rules are configured and saved, enabling controlled route distribution between OSPF areas based on the specified access list and traffic direction settings.

Configure OSPF summary addresses

Configure OSPF summary addresses to decrease the size of the OSPF link-state database by advertising a single route for all redistributed routes that are included for a specified network address and mask.

When routes from other protocols are redistributed into OSPF, each route is advertised individually in an external LSA. However, you can configure the Firewall Threat Defense device to advertise a single route for all the redistributed routes that are included for a specified network address and mask. This configuration decreases the size of the OSPF link-state database. Routes that match the specified IP address mask pair can be suppressed. The tag value can be used as a match value for controlling redistribution through route maps.

Routes learned from other routing protocols can be summarized. The metric used to advertise the summary is the smallest metric of all the more specific routes. Summary routes help reduce the size of the routing table.

Using summary routes for OSPF causes an OSPF ASBR to advertise one external route as an aggregate for all redistributed routes that are covered by the address. Only routes from other routing protocols that are being redistributed into OSPF can be summarized.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Summary Address** > **Add**.

You can click **Edit** (✎) to edit, or use the right-click menu to cut, copy, past, insert, and delete summary addresses.

Step 6 Configure the following summary address options for each OSPF process:

- **OSPF Process**: For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Available Network**: The IP address of the summary address. Select one from the Available networks list and click **Add**, or to add a new network, click **Add** (+). See Networks, on page 2813 for the procedure for adding networks.
- **Tag**: A 32-bit decimal value that is attached to each external route. This value is not used by OSPF itself, but may be used to communicate information between ASBRs.
- **Advertise**: Advertises the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

Step 7 Click **OK** to save the summary address configuration.

Step 8 Click **Save** on the Routing page to save your changes.

The OSPF summary address configuration is saved and the device will advertise a single route for all redistributed routes that are included for the specified network address and mask.

Configure OSPF interfaces and neighbors

You can change some interface-specific OSPFv2 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval, the dead interval, and the authentication key. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

You need to define static OSPFv2 neighbors to advertise OSPFv2 routes over a point-to-point, non-broadcast network. This feature lets you broadcast OSPFv2 advertisements across an existing VPN connection without having to encapsulate the advertisements in a GRE tunnel.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**, and select **Interface** > **Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 5 Configure the following Interface options for each OSPF process:

- **Interface**: The interface you are configuring.

Note If the device is using virtual routing, this drop-down list displays only those interfaces that belong to the router.

- **Default Cost**: The cost of sending a packet through the interface. The default value is 10.
- **Priority**: The designated router for a network. Valid values range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router.

  When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router. This setting does not apply to interfaces that are configured as point-to-point interfaces.
- **MTU Ignore—OSPF** checks whether neighbors are using the same MTU on a common interface. This check is performed when neighbors exchange DBD packets. If the receiving MTU in the DBD packet is higher than the IP MTU configured on the incoming interface, OSPF adjacency is not established.
- **Database Filter**: Use this setting to filter the outgoing LSA interface during synchronization and flooding. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. In a fully meshed topology, this flooding can waste bandwidth and lead to excessive link and CPU usage. Checking this check box prevents OSPF flooding of the LSA on the selected interface.
- **Database Filter**: Use this setting to filter the outgoing LSA interface during synchronization and flooding. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. In a fully meshed topology, this flooding can waste bandwidth and lead to excessive link and CPU usage. Checking this check box prevents OSPF flooding of the LSA on the selected interface.
- **Hello Interval**: Specifies the interval, in seconds, between hello packets sent on an interface. Valid values range 1–8192 seconds. The default value is 10 seconds.

  The smaller the hello interval, the faster topological changes are detected, but more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface.
- **Transmit Delay**: Estimated time in seconds to send an LSA packet on the interface. Valid values range 1–65535 seconds. The default is 1 second.

  LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.
- **Retransmit Interval**: Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.
- **Dead Interval**: Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range 1–65535.
- **Hello Multiplier**: Specifies the number of Hello packets to be sent per second. Valid values are 3–20.
- **Point-to-Point**: Lets you transmit OSPF routes over VPN tunnels.

- **Authentication**: Choose the OSPF interface authentication from the following:
  - **None**: (Default) Disables interface authentication.
  - **Area Authentication**: Enables interface authentication using MD5. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.
  - **Password**: Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
  - **MD5**: Allows MD5 authentication. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.

Note Enter only letters, numbers, and special characters for the MD5 key ID. Do not enter spaces; spaces are truncated in management center.

  - **Key Chain**:Allows key chain authentication. Click **Add**, and create the key chain, and then click **Save**. For detailed procedure, refer to Create a key chain object, on page 2812. Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.

- **Enable BFD**: Allows you to enable BFD on this interface.
- **Enter Password**: The password you configure if you choose Password as the type of authentication.
- **Confirm Password**: Confirm the password that you chose.

Step 6 Select **Neighbor** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 7 Configure the following parameters for each OSPF process:

- **OSPF Process**: Choose 1 or 2.
- **Neighbor**: Choose one of the neighbors in the drop-down list, or click **Add** () to add a new neighbor; enter the name, description, network, whether to allow overrides, and then click **Save**.
- **Interface**: Choose the interface associated with the neighbor.

Step 8 Click **OK** and click **Save** to save the changes.

OSPF interface and neighbor configuration is completed. The configured parameters are applied to the selected interfaces and neighbors, enabling OSPF routing functionality on the specified network segments.

Configure OSPF Advanced Properties

Enable advanced OSPF features for optimized routing behavior and enhanced protocol reliability.

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, an LSA timer, and graceful restarts.

Graceful Restarts

The Firewall Threat Defense device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv2 by using either using NSF Cisco (RFC 4811 and RFC 4812) or NSF IETF (RFC 3623).

Note NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.
- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF** > **Advanced**.

Step 5 Select **General**, and configure the following:

- **Router ID**: Choose Automatic or IP Address (appears for non-cluster and a cluster in spanned etherchannel mode) or Cluster Pool (appears for a cluster in individual interface mode) for the router ID. If you choose IP address, enter the IP address in the adjacent field. If you choose Cluster Pool, choose the IPv4 cluster pool value in the adjacent drop-down field. For information on creating the cluster pool address, refer to Configure address pools, on page 2781.
- **Ignore LSA MOSPF**: Suppresses syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.
- **RFC 1583 Compatible**: Configures RFC 1583 compatibility as the method used to calculate summary route costs. Routing loops can occur with RFC 1583 compatibility enabled. Disable it to prevent routing loops. All OSPF routers in an OSPF routing domain should have RFC compatibility set identically.
- **Adjacency Changes**: Defines the adjacency changes that cause syslog messages to be sent.

By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.

- **Log Adjacency Changes**: Causes the Firewall Threat Defense device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.
- **Log Adjacency Change Details**: Causes the Firewall Threat Defense device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

- **Administrative Route Distance**: Allows you to modify the settings that were used to configure administrative route distances for **inter-area**, **intra-area**, and **external** IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.
- **LSA Group Pacing**: Specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- **Enable Default Information Originate**: Check the **Enable** check box to generate a default external route into an OSPF routing domain and configure the following options:
  - **Always advertise the default route**: Ensures that the default route is always advertised.
  - **Metric Value**: Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  - **Metric Type**: The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  - **RouteMap**: Choose the routing process that generates the default route if the route map is satisfied or click **Add** (+) to add a new one. See Configure Route Map Entry to add a new route map.

Step 6 Click **OK** to save the general configuration.

Step 7 Select **Non Stop Forwarding**, and configure Cisco NSF graceful restart for OSPFv2, for an NSF-capable or NSF-aware device.

Note There are two graceful restart mechanisms for OSPFv2, Cisco NSF and IETF NSF. Only one of these graceful restart mechanisms can be configured at a time for an OSPF instance. An NSF-aware device can be configured as both Cisco NSF helper and IETF NSF helper but a NSF-capable device can be configured in either Cisco NSF or IETF NSF mode at a time for an OSPF instance.

a) Check the **Enable Cisco Non Stop Forwarding Capability** check box.
b) (Optional) Check the **Cancel NSF restart when non-NSF-aware neighboring networking devices are detected** check box if required.
c) (Optional) Make sure the **Enable Cisco Non Stop Forwarding Helper** mode check box is unchecked to disable the helper mode on an NSF-aware device.

Step 8 Configure IETF NSF Graceful Restart for OSPFv2, for an NSF-capable or NSF-aware device:

a) Check the **Enable IETF Non Stop Forwarding Capability** check box.
b) In the **Length of graceful restart interval (seconds)** field, enter the restart interval in seconds. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.

c) (Optional) Make sure the **Enable IETF nonstop forwarding (NSF) for helper mode** check box is unchecked to disable the IETF NSF helper mode on an NSF-aware device.
d) **Enable Strict Link State advertisement checking**: When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.
e) **Enable IETF Non Stop Forwarding**: Enables non stop forwarding, which allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. OSPF uses extensions to the OSPF protocol to recover its state from neighboring OSPF devices. For the recovery to work, the neighbors must support the NSF protocol extensions and be willing to act as "helpers" to the device that is restarting. The neighbors must also continue forwarding data traffic to the device that is restarting while protocol state recovery takes place.

Advanced OSPF settings are applied. The device now uses customized OSPF general and graceful restart properties for improved routing behavior, syslog management, and protocol resilience.

OSPFv3 configuration

OSPFv3 configuration is a routing process setup that

- enables IPv6 routing functionality on network devices,
- involves multiple configuration tasks to establish the routing process, and
- supports configuration only for global virtual routers in virtual routing environments.

Virtual routing limitations

For a device using virtual routing, you can configure OSPFv3 only for its global virtual router and not for its user-defined virtual router.

Configure OSPFv3 Areas, Route Summaries, and Virtual Links

Use this task to enable OSPFv3, create routing areas, set up route summaries, and configure virtual links for advanced routing scenarios on the Cisco Secure Firewall Management Center (FMC). These steps allow for flexible IPv6 routing and help ensure optimal path calculation and efficient management.

Before you begin

Have admin access to Cisco Secure Firewall Management Center.

- Have admin access to Cisco Secure Firewall Management Center.
- Know the IP addresses and roles for devices to be configured.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Navigate to the **Routing** tab, and click **OSPFv3** in the left pane.

Step 3 You can enable up to two OSPF process instances:

- By default, **Process 1** is selected. To enable it, check **Enable Process 1**.
- To configure **Process 2**, select **Process 2** and then check **Enable Process 2**.

Note Assume that you have configured only process 2 and deployed the settings. Post the deployment, only **Process 1** check box is selected by default. You must click **Process 2** to view the configured settings.

Step 4 Choose the OSPFv3 role from the drop-down list, and enter a description for it. The options are **Internal**, **ABR**, **ASBR**, and **ABR and ASBR**. For descriptions of the OSPFv3 roles, refer to OSPF routing, on page 1225. Select **Area** > **Add**.

Click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Select **General**, and configure the following options for each OSPF process:

a) **Area ID**: The area for which routes are to be summarized.
b) **Cost**: The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.
c) **Type**: Specifies Normal, NSSA, or Stub. If you select Normal, there are no other parameters to configure. If you select Stub, you can choose to send summary LSAs in the area. If you select NSSA, you can configure the next three options:
   - **Allow Sending summary LSA into this area**: Allows the sending of summary LSAs into the area.
   - **Imports routes to normal and NSSA area**: Allows redistribution to import routes to normal and not to stubby areas.
   - **Defaults information originate**: Generates a default external route into an OSPFv3 routing domain.
d) **Metric**: Metric used for generating the default route. The default value is 10. Valid metric values range from 0 to 16777214.
e) **Metric Type**: The metric type is the external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route. Click **OK** to save the general configuration.

Step 5 (Not applicable for Internal OSPFv3 Role) Select **Route Summary** > **Add Route Summary**.

Click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete route summaries.

Configure the following route summary options for each OSPF process:

- **IPv6 Prefix/Length**: The IPv6 prefix. To add a new network object, click **Add** (). For the procedure for adding networks, refer to, Networks, on page 2813.
- **Cost**: The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.
- **Advertise**: Advertises the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

  Click **OK** to save the route summary configuration.

Step 6 (Not applicable for Internal OSPFv3 Role) Select **Virtual Link**, click **Add Virtual Link** , and configure the following options for each OSPF process:

- **Peer RouterID**: Choose the IP address of the peer router. To add a new network object, click **Add** (+). For the procedure to add networks, refer to Networks, on page 2813.
- **TTL Security**: Enables TTL security check. The value for the hop-count is a number from 1 to 254. The default is 1.

  OSPF sends outgoing packets with an IP header Time to Live (TTL) value of 255 and discards incoming packets that have TTL values less than a configurable threshold. Because each device that forwards an IP packet decrements the TTL, packets received via a direct (one-hop) connection have a value of 255. Packets that cross two hops have a value of 254, and so on. The receive threshold is configured in terms of the maximum number of hops that a packet may have traveled.
- **Dead Interval**: The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The default is four times the hello interval, or 40 seconds. Valid values range from 1 to 65535.

  The dead interval is an unsigned integer. The value must be the same for all routers and access servers that are attached to a common network.
- **Hello Interval**: The time in seconds between the hello packets sent on an interface. Valid values range from 1 to 65535. The default is 10.

  The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.
- **Retransmit Interval**: The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 to 65535. The default is 5.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.
- **Transmit Delay**: The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 to 8192. The default is 1.

  LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

  Click **OK** to save the virtual link configuration.

Step 7 Click **Save** on the **Router** page to save your changes.

Configure OSPFv3 redistribution

Configure OSPFv3 redistribution to control how routes are redistributed between OSPF routing processes and other routing protocols on the Secure Firewall Threat Defense device.

The Secure Firewall Threat Defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by EIGRP, RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

Before you begin

Follow these steps to configure OSPFv3 redistribution:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** > **OSPF**.

Step 3 Select **Redistribution**, and click **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 4 Configure the following redistribution options for each OSPF process:

- **Source Protocol**—The source protocol from which routes are being redistributed. The supported protocols are connected, OSPF, Static, EIGRP, and BGP. If you choose OSPF, you must enter the Process ID in the **Process ID** field. If you choose BGP, you must add the AS number in the **AS Number** field.
- **Metric**—Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

  When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.
- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Tag**—Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.
- **Route Map**—Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add** (). See Configure a route map, on page 2847 for the procedure to add a new route map.
- **Process ID**—The OSPF process ID, either 1 or 2.

Note The Process ID is enabled the OSPFv3 process is redistributing a route learned by another OSPFv3 process.

- **Match**—Enables OSPF routes to be redistributed into other routing domains:
  - **Internal** for routes that are internal to a specific autonomous system.
  - **External 1**for routes that are external to the autonomous system, but are imported into OSPFv3 AS Type 1 external routes.
  - **External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 AS Type 2 external routes.
  - **NSSA External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 AS Type 1 external routes.
  - **NSSA External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 AS Type 2 external routes.

Step 5 Click **OK** to save the redistribution configuration.

Step 6 Click **Save** on the Routing page to save your changes.

The OSPFv3 redistribution configuration is saved and routes are redistributed according to the specified parameters.

What to do next

Continue with Configure OSPFv3 summary prefixes, on page 1249.

Configure OSPFv3 summary prefixes

Configure OSPFv3 summary prefixes to control route advertisement and suppression based on IPv6 prefix and mask pairs.

You can configure the Firewall Threat Defense device to advertise routes that match a specified IPv6 prefix and mask pair.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** > **OSPFv3**.

Step 3 Select **Summary Prefix** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete summary prefixes.

Step 4 Configure the following summary prefix options for each OSPF process:

- **IPv6 Prefix/Length**: The IPv6 prefix and prefix length label. Select one from the list or click **Add** (+) to add a new network object. For the procedure to add networks, refer to Networks, on page 2813.
- **Advertise**: Advertises routes that match the specified prefix and mask pair. Uncheck this check box to suppress routes that match the specified prefix and mask pair.
- (Optional) **Tag**: A value that you can use as a match value for controlling redistribution through route maps.

Step 5 Click **OK** to save the summary prefix configuration.

Step 6 Click **Save** on the Routing page to save your changes.

The OSPFv3 summary prefix configuration is saved and will control route advertisement based on your specified settings.

Configure OSPFv3 interfaces, authentication, and neighbors

Set up OSPFv3 routing, authentication, and neighbor relationships to support IPv6 dynamic network routing.

You can change certain interface-specific OSPFv3 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval and the dead interval. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

For a successful implementation of OSPFv3 authentication with Nexus switches, ensure that you have the compatible version of the switch, for example, Nexus 3000, 7000, and 9000 series switches.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** > **OSPFv3**.

Step 3 Select **Interface** > **Add**.

You can click **Edit** to edit, or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 4 Configure the following interface options for each OSPFv3 process:

- **Interface**: The interface you are configuring.
- **Enable OSPFv3**: Enables OSPFv3.
- **OSPF Process**: Choose 1 or 2.
- **Area**: The area ID for this process.
- **Instance**: Specifies the area instance ID to be assigned to the interface. An interface can have only one OSPFv3 area. You can use the same area on multiple interfaces, and each interface can use a different area instance ID.

Step 5 Select **Properties**, and configuring the following options for each OSPFv3 process:

- **Filter Outgoing Link Status Advertisements**: Filters outgoing LSAs to an OSPFv3 interface. All outgoing LSAs are flooded to the interface by default.
- **Filter Outgoing Link Status Advertisements**: Filters outgoing LSAs to an OSPFv3 interface. All outgoing LSAs are flooded to the interface by default.
- **Disable MTU mismatch detection**: Disables the OSPF MTU mismatch detection when DBD packets are received. OSPF MTU mismatch detection is enabled by default.
- **Flood Reduction**: Changes normal LSAs into Do Not Age LSAs, so that they don't get flooded every 3600 seconds across areas.

  OSPF LSAs are refreshed every 3600 seconds. In large OSPF networks, this can lead to large amounts of unnecessary LSA flooding from area to area.
- **Point-to-Point Network**: Lets you transmit OSPF routes over VPN tunnels. When an interface is configured as point-to-point, non-broadcast, the following restrictions apply:
  - You can define only one neighbor for the interface.
  - You need to manually configure the neighbor.
  - You need to define a static route pointing to the crypto endpoint.
  - If OSPF over a tunnel is running on the interface, regular OSPF with an upstream router cannot be run on the same interface.
  - You should bind the crypto map to the interface before specifying the OSPF neighbor to ensure that the OSPF updates are passed through the VPN tunnel. If you bind the crypto map to the interface after specifying the OSPF neighbor, use the **clear local-host all** command to clear OSPF connections so that the OSPF adjacencies can be established over the VPN tunnel.
- **Broadcast**: Specifies that the interface is a broadcast interface. By default, this check box is checked for Ethernet interfaces. Uncheck this check box to designate the interface as a point-to-point, nonbroadcast interface. Specifying an interface as point-to-point, nonbroadcast lets you transmit OSPF routes over VPN tunnels.
- **Cost**: Specifies the cost of sending a packet on the interface. Valid values for this setting range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router. This setting does not apply to interfaces that are configured as point-to-point, nonbroadcast interfaces.

  When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router.
- **Priority**: Determines the designated router for a network. Valid values range from 0 to 255.
- **Dead Interval**: Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range from 1 to 65535.
- **Hello Interval**: Time period in seconds between OSPF packets that the router will send before adjacency is established with a neighbor. Once the routing device detects an active neighbor, the hello packet interval changes from the time specified in the poll interval to the time specified in the hello interval. Valid values range from 1 to 65535 seconds.

- **Retransmit Interval**: Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.
- **Transmit Delay**: Estimated time in seconds to send a link-state update packet on the interface. Valid values range from 1 to 65535 seconds. The default is 1 second.
- **Enable BFD**: Allows you to enable BFD on this interface.

Step 6 Select **Authentication**, and configure the following options for each OSPFv3 process:

- **Type**: Type of authentication. The available options are Area, Interface, and None. The None option indicates that no authentication is used.
- **Security Parameters Index**: A number from 256 to 4294967295. Configure this if you chose Interface as the type.
- **Authentication**: Type of authentication algorithm. Supported values are SHA-1 and MD5. Configure this if you chose Interface as the type.
- **Authentication Key**: When MD5 authentication is used, the key must be 32 hexadecimal digits (16 bytes) long. When SHA-1 authentication is used, the key must be 40 hexadecimal digits (20 bytes) long.
- **Encrypt Authentication Key**: Enables encryption of the authentication key.
- **Include Encryption**: Enables encryption.
- **Encryption Algorithm**: Type of encryption algorithm. Supported value is DES. The NULL entry indicates no encryption. Configure this if you chose **Include Encryption**.
- **Encryption Key**: Enter the encryption key. The key length must be a hexadecimal string. When AES-256-CBC authentication is used, the key must be 130 hexadecimal digits. Configure this if you chose **Include Encryption**.
- **Encrypt Key**: Enables the key to be encrypted.
- Click **OK** to save the authentication configuration.

Step 7 Select **Neighbor**, click **Add**, and configure the following options for each OSPFv3 process:

- **Link Local Address**: The IPv6 address of the static neighbor.
- **Cost**: Enables cost. Enter the cost in the **Cost** field, and check the **Filter Outgoing Link State Advertisements** if you want to advertise.
- (Optional) **Poll Interval**: Enables the poll interval. Enter the **Priority** level and the **Poll Interval** in seconds.
- Click **Add** to add the neighbor.

Step 8 Click **OK** to save the Interface configuration.

OSPFv3 interface, authentication, and neighbor settings are configured on the device. OSPFv3 processes will operate according to the specified parameters.

Configure OSPFv3 Advanced Properties

Enable and fine-tune OSPFv3 advanced properties to optimize routing, ensure stability, and automate operations for your device

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, passive OSPFv3 routing, LSA timers, and graceful restarts.

Graceful Restarts

The Firewall Threat Defense device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv3 using graceful-restart (RFC 5187).

Note NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.
- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **OSPFv3** > **Advanced**.

Step 3 For **Router ID**, choose **Automatic** or **IP Address** (appears for non-cluster and a cluster in spanned etherchannel mode) or **Cluster Pool** (appears for a cluster in individual interface mode). If you choose **IP Address**, enter the IPv6 address in the **IP Address** field. If you choose **Cluster Pool**, choose the IPv6 cluster pool value from the **Cluster Pool** down-down list. For information on creating the cluster pool address, refer to Configure address pools, on page 2781.

Check the **Ignore LSA MOSPF** check box if you want to suppress syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.

Step 4 Select **General**, and configure the following:

- **Adjacency Changes**: Defines the adjacency changes that cause syslog messages to be sent.

  By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.

- **Adjacency Changes**: Causes the Firewall Threat Defense device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.
- **Include Details**: Causes the Firewall Threat Defense device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

- **Administrative Route Distances**: Allows you to modify the settings that were used to configure administrative route distances for inter-area, intra-area, and external IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.
- **Default Information Originate**: Check the **Enable** check box to generate a default external route into an OSPFv3 routing domain and configure the following options:
  - **Always Advertise**: Will always advertise the default route whether or not one exists.
  - **Metric**: Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  - **Metric Type**: The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  - **Route Map**: Choose the routing process that generates the default route if the route map is satisfied or click **Add** (+) to add a new one. See Configure a route map, on page 2847 to add a new route map.

    Click **OK** to save the general configuration.

Step 5 Select **Passive Interface**, select the interfaces on which you want to enable passive OSPFv3 routing from the **Available Interfaces** list, and click **Add** to move them to the **Selected Interfaces** list.

Passive routing assists in controlling the advertisement of OSPFv3 routing information and disables the sending and receiving of OSPFv3 routing updates on an interface.

Click **OK** to save the passive interface configuration.

Step 6 Select **Timer**, and configure the following LSA pacing and SPF calculation timers:

- **Arrival**: Specifies the minimum delay in milliseconds that must pass between acceptance of the same LSA arriving from neighbors. The range is from 0 to 6000,000 milliseconds. The default is 1000 milliseconds.
- **Flood Pacing**: Specifies the time in milliseconds at which LSAs in the flooding queue are paced in between updates. The configurable range is from 5 to 100 milliseconds. The default value is 33 milliseconds.
- **Group Pacing**: Specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- **Retransmission Pacing**: Specifies the time in milliseconds at which LSAs in the retransmission queue are paced. The configurable range is from 5 to 200 milliseconds. The default value is 66 milliseconds.
- **LSA Throttle**: Specifics the delay in milliseconds to generate the first occurrence of the LSA. The default value is 0 millisecond. The minimum specifies the minimum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds. The maximum specifies the maximum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds.

Note For LSA throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

- **SPF Throttle**: Specifies the delay in milliseconds to receive a change to the SPF calculation. The default value is 5000 milliseconds. The minimum specifies the delay in milliseconds between the first and second SPF calculations. The default value is 10000 milliseconds. The maximum specifies the maximum wait time in milliseconds for SPF calculations. The default value is 10000 milliseconds.

Note For SPF throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

Click **OK** to save the LSA timer configuration.

Step 7 Select **Non Stop Forwarding ngf**, and check the **Enable graceful-restart helper** check box. This is checked by default. Uncheck this to disable the graceful-restart helper mode on an NSF-aware device.

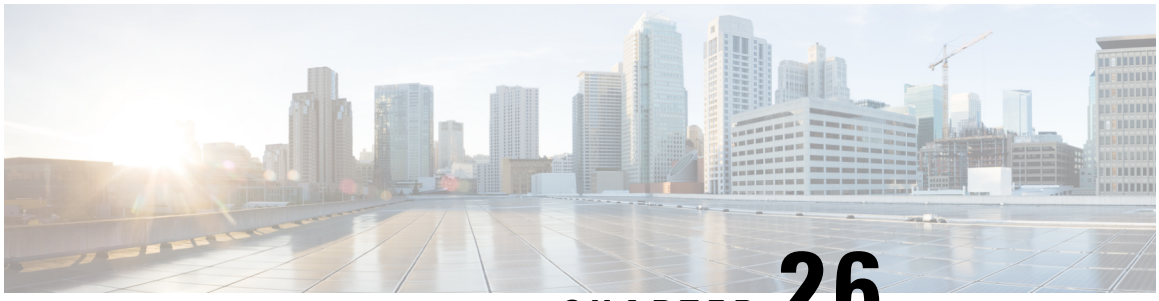
Check the **Enable link state advertisement** check box to enable strict link state advertisement checking.

When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.

Check the **Enable graceful-restart (Use when Spanned Cluster or Failover Configured)** check box and enter the graceful-restart interval in seconds. The range is 1-1800. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.

Click **OK** to save the graceful restart configuration.

Step 8 Click **Save** on the **Routing** page to save your changes.



The device is configured with your OSPFv3 advanced properties. All changes are applied, enhancing routing resilience, logging, and failover handling.

History for OSPF

This reference provides a summary of the key features introduced in OSPF and the versions in which they became available, along with details about their implementation.

Table 82: Feature history for OSPF

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
BFD Support for OSPF v2 and v3	7.4	7.4	You can enable BFD on OSPFv2 and OSPFv3 interfaces. New/modified screens: • **Configuration** > **Device Setup** > **Routing** > **OSPFv2** • **Configuration** > **Device Setup** > **Routing** > **OSPFv3**

CHAPTER 26

EIGRP

EIGRP is a routing protocol that

- enables routers to efficiently exchange information,
- maintain network topology tables, and
- ensures secure data path selection and communication across networks.

EIGRP Operational Overview

This section covers the configuration of the Firewall Threat Defense to perform these routing tasks:

- Route data traffic
- Perform authentication
- Redistribute routing information

- EIGRP routing, on page 1257
- Requirements and prerequisites for EIGRP, on page 1258
- Guidelines and limitations for EIGRP routing, on page 1259
- Configure EIGRP routing on firewall devices, on page 1260
- History for EIGRP, on page 1267

EIGRP routing

An Enhanced Interior Gateway Routing Protocol (EIGRP) is a routing protocol that

- sends updates only when network topology changes, not at regular intervals,
- offers rapid convergence and supports variable-length subnet masks, and
- supports partial updates and multiple network layer protocols.

EIGRP capabilities and operations

EIGRP stores all neighbor routing tables for quick adaptation to alternate routes. If a suitable route does not exist, EIGRP queries its neighbors to discover an alternate route. It propagates these queries through the network to locate a route. EIGRP's support for variable-length subnet masks allows routes to be automatically

summarized on a network boundary. Additionally, EIGRP can be configured to summarize any bit boundary at any interface.

EIGRP sends partial updates when route metrics change, limiting propagation to necessary routers, which minimizes bandwidth use compared to protocols that send periodic full updates.

To learn about routers on attached networks, EIGRP uses neighbor discovery through multicast hello packets to announce their presence on the network. When a new neighbor is detected through hello packets, a topology table exchange occurs.

EIGRP hello packets are normally sent as multicast messages and do not require explicit replies. For manually configured static neighbors, hello packets are sent as unicast messages to the specified neighbor.

Once this neighbor relationship is established, routing updates are exchanged only on topology changes. The relationship persists through regular multicast hello packets, with devices expected to respond within advertised hold times. Hold time is the time within which threat defense can expect to receive a hello packet from that neighbor. If the device does not receive a hello packet within the advertised hold time, it considers the neighbor unavailable.

EIGRP employs mechanisms like neighbor discovery/recovery, Reliable Transport Protocol (RTP), and Diffusing Update Algorithm (DUAL) for route computations. DUAL retains all routes to a destination, selecting the least-cost route for packet forwarding while retaining others in case of network changes. If the main route fails, another route is chosen from the feasible successors. A successor is a neighboring router that is used for packet forwarding that has a least-cost path to a destination. DUAL utilizes a feasibility condition to ensure that the path is not part of a routing loop.

If a feasible successor is not found in the topology table, a route recomputation takes place. During route recomputation, DUAL queries the EIGRP neighbors for a route. The query is propagated to successive neighbors. If a feasible successor is not found, an unreachable message is returned.

During route recomputation, DUAL marks the route as active. By default, threat defense waits for three minutes to receive a response from its neighbors. If the device does not receive a response from a neighbor, the route is marked as stuck-in-active. All routes in the topology table that point to the unresponsive neighbor as a feasible successor are removed.

Requirements and prerequisites for EIGRP

This topic provides the necessary prerequisites and requirements for deploying EIGRP within a Cisco network environment.

Model support

Firewall Threat Defense

Firewall Threat Defense Virtual

Supported domains

Any

User roles

Administrator

Network Admin

Guidelines and limitations for EIGRP routing

Firewall mode guidelines

Use routed firewall mode only for EIGRP routing.

Device guidelines

Configure only one EIGRP process per device.

- EIGRP can be configured through management center UI on Firewall Threat Defense version 6.6 and later.

Interface guidelines

Use only routed interfaces with logical names and IP addresses for EIGRP routing processes.

- EIGRP can only incorporate interfaces from the global virtual router. EIGRP can learn, filter, and redistribute routes across routing protocols in the global virtual router.
- Supports physical, EtherChannel, redundant, and subinterfaces only. However, the members of EtherChannel interfaces are not supported.
-
- Passive interfaces cannot be configured as neighbor interfaces.

IP address and network objects support

Use only IPv4 addresses and standard access list objects for EIGRP configuration.

- Ranges, FQDNs, and wildcard masks are not supported.

Redistribution guidelines

Configure route tagging to prevent routing loops when redistributing between EIGRP and OSPF.

- BGP, OSPF, and RIP in the global virtual router can redistribute routes toward EIGRP.
- EIGRP can redistribute to BGP, OSPF, RIP, Static, and Connected in the global virtual router.
- When EIGRP is configured on a device that is a part of an OSPF network or vice versa, ensure that the OSPF router is configured to tag the route (EIGRP does not support route tag).

  When redistributing EIGRP into OSPF and OSPF into EIGRP, a routing loop can occur when there is an outage on one of the links, interfaces, or even when the route originator is down. To prevent the redistribution of routes from one domain back into the same domain, a router can tag a route that belongs to a domain while it is redistributing, and those routes can be filtered on the remote router based on the same tag. Because the routes will not be installed into the routing table, they will not be redistributed back into the same domain.

Deployment process guidelines

Disable and redeploy EIGRP when changing the AS number to prevent deployment failures.

To effectively change the AS number of an existing EIGRP setup, you should disable and redeploy EIGRP configurations to avoid repeated deployments and ensure error-free deployment processes.

Upgrade guidelines

Migrate FlexConfig EIGRP policies to UI management after upgrading to version 7.2 and later.

When you upgrade to version 7.2 and later, and if the previous version includes any FlexConfig EIGRP policies, the management center displays a warning message during deployment. It does not stop the deployment process; a warning message is displayed. After deployment, to manage the EIGRP policies from the UI (**Devices** > **Device Management**, click the **Edit** (✎) icon. Then, click **Routing>EIGRP**), you must redo the configuration in the **EIGRP** page and remove the configuration from FlexConfig. To automate policy creation in the UI, Firewall Management Center provides an option to migrate the policies from FlexConfig to the UI. For more information, refer to Migrate FlexConfig policies, on page 1127.

Configure EIGRP routing on firewall devices

Enable EIGRP on a firewall device for efficient routing within an autonomous system.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click the **Routing** tab.

Step 3 Under Global, click **EIGRP**.

Step 4 Check the **Enable EIGRP** check box to enable the EIGRP routing process.

Step 5 In the **AS Number** field, enter the autonomous system (AS) number for the EIGRP process.

Valid values are from 1 to 65535. The AS number identifies the local EIGRP routing domain and must match on EIGRP neighbors.

Step 6 To configure other EIGRP properties, refer to these topics for detailed steps:

a. Configure EIGRP settings, on page 1261.

b. Configure EIGRP neighbors settings, on page 1261.

c. Configure EIGRP filter rules, on page 1262.

d. Configure EIGRP redistribution settings, on page 1263.

e. Configure EIGRP summary address settings, on page 1264.

f. Configure EIGRP interfaces settings, on page 1265.

g. Configure EIGRP advanced settings, on page 1266.

The firewall device is now configured with the base EIGRP process and the designated AS number. It can participate in EIGRP routing after the required interfaces, networks, and related settings are configured.

Configure EIGRP settings

Use this procedure when you need to set up EIGRP routing protocol parameters on your device. EIGRP configuration includes enabling automatic network summarization, selecting networks that participate in the routing process, and configuring passive interfaces that do not exchange routing updates.

Procedure

Step 1 On the **EIGRP** page, click the **Setup** tab.

Step 2 Check the **Auto Summary** check box to enable EIGRP to summarize at network boundaries.

Note Enabling Auto Summary can cause routing problems if you have noncontiguous networks.

Step 3 In the **Available Networks/Hosts** box, select the networks or hosts that should participate in the EIGRP routing process, and then click **Add**. To add a new network object, click **Add** (+). For detailed instructions on adding networks, refer to Networks, on page 2813.

Step 4 To configure passive interfaces, check the **Passive Interface** check box. In EIGRP, a passive interface does not send or receive routing updates.

a) To specify selective interfaces as passive, click the **Selected Interface** radio button. In the **Available Interfaces** box, select the interfaces, and click **Add**.

b) To specify all interfaces as passive, click the **All Interfaces** radio button.

Step 5 Click **Save**.

The EIGRP settings are configured and saved. The routing protocol will operate according to the specified configuration, including automatic summarization behavior, network participation, and passive interface settings.

Configure EIGRP neighbors settings

Define static neighbors for the EIGRP process. This results in unicast hello packets being sent to that neighbor.

Procedure

Step 1 On the **EIGRP** page, click the **Neighbors** tab.

Step 2 Click +**Add**.

Step 3 Select the interface through which the neighbor is available from the **Interface** drop-down list.

Step 4 Select the IP address of the static neighbor from the **Neighbor** drop-down list.

Step 5 To add a new network object, click +. For instructions on adding network objects, refer to Networks, on page 2813.

Step 6 Click **OK**.

Step 7 Click **Save**.

The EIGRP static neighbor is configured, and hello packets are sent as unicast to the specified neighbor through the designated interface.

Configure EIGRP filter rules

Filter rules provide granular control over EIGRP route advertisements and acceptances, allowing you to manage network traffic flow and routing table contents based on specific criteria such as interface or protocol type.

To configure EIGRP filter rules, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Filter Rules** tab.

Step 2 Click **Add**.

Step 3 In the **Add Filter Rules** dialog box, select the direction for the rule from the **Filter Direction** drop-down list:

- **Inbound**: The rule filters routes received in incoming EIGRP updates.
- **Outbound**: The rule filters routes advertised in outgoing EIGRP updates.

Step 4 Under **Type**, choose one of these options:

- To select the interface to which the filtering rule applies, click **Interface**, and then select the interface from the **Select Interface** drop-down list. Select the access list from the **Access List** drop-down list. The list defines the networks that are to be received and suppressed in routing updates. To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2780. Click **OK**.

Note You cannot apply EIGRP filtering rules on VTI interfaces.

- (This option is enabled only if you choose **Outbound** filter direction.) To select the protocol to which the filtering rule applies, click **Protocol** and then select BGP, RIP, Static, Connected, or OSPF from the **Select Protocol** drop-down list. You can specify the relevant **Process ID** for BGP and OSPF protocols. Select the access list from the **Access List** drop-down list. The list defines the networks that are to be received and suppressed in routing updates. To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2780. Click **OK**.

Step 5 Click **Save**.

The EIGRP filter rule is configured and applied to control route filtering based on the specified direction, interface, protocol, and access list criteria.

Configure EIGRP redistribution settings

Define rules to redistribute routes from other routing protocols to the EIGRP routing process to enable route sharing across different routing protocols.

To configure EIGRP redistribution settings, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Redistribution** tab.

Step 2 Click **Add**.

Step 3 In the **Add Redistribution** dialog box, from the **Protocol** drop-down list, select the source protocol from which the routes are being redistributed:

- **BGP**: Redistributes routes discovered by the BGP routing process to EIGRP. Specify the relevant **Process ID**.
- **RIP**: Redistributes routes discovered by the RIP routing process to EIGRP.
- **Static**: Redistributes static routes to the EIGRP routing process. Static routes within a network statement scope automatically redistribute to EIGRP, without additional rules. Specify the metric when redistributing static routes to VTI interfaces in EIGRP. You do not need to specify the metric for static routes pointing to other types of interfaces.
- **Connected**: Redistributes connected routes (routes established automatically by virtue of having IP address enabled on the interface) to the EIGRP routing process. Connected routes that fall within the scope of a network statement are automatically redistributed to EIGRP; you do not need to define a redistribution rule for them.
- **OSPF**: Redistributes routes discovered by the OSPF routing process to EIGRP. Specify the relevant **Process ID**. If you select this protocol, the Match options on this dialog box become available under **Optional OSPF Redistribution**:
  - **Internal**: Routes that are internal to a specific AS.
  - **External1**: Routes that are external to the AS and imported into OSPF as a Type 1 external route.
  - **External2**: Routes that are external to the AS and imported into the selected process as a Type 2 external route.
  - **Nsaa-External1**: Not-So-Stubby Area (NSSA) routes that are external to the AS and imported into the selected process as Type 1 external routes.
  - **Nsaa-External2**: (NSSA) routes that are external to the AS and imported into the selected process as Type 2 external routes.

Note These options are not available when redistributing static, connected, RIP, or BGP routes.

Step 4 Under **Optional Metrics**, enter the relevant values:

- **Bandwidth**: The minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295.
- **Delay Time**: The routing delay in tens of microseconds. Valid values range from 0 to 4294967295.
- **Reliability**: The likelihood of successful packet transmission is expressed as a number 0 through 255. The value 255 indicates 100 percent reliability; 0 means no reliability.
- **Loading**: The effective bandwidth of the route. Valid values range from 1 to 255. 255 indicates 100 percent loading.
- **MTU**: The smallest permissible value for the maximum transmission unit of the path. Valid values range from 1 to 65535.
- **Route Map**: Select the route map object to apply to the redistribution entry from the **Route Map** drop-down list. To create a new route map object, click +. For instructions on adding a new route map, refer to Configure Route Map Entry.

Step 5 Click **OK**.

Step 6 Click **Save**.

The EIGRP redistribution settings have been configured and saved. Routes from the selected source protocol will be redistributed to EIGRP according to the specified rules and metrics.

Configure EIGRP summary address settings

You can configure summary addresses for each interface. If you want to create summary addresses that do not occur at a network boundary, you should manually define them. Alternatively, you can use summary addresses with automatic route summarization disabled. If more specific routes are available in the routing table, EIGRP advertises the summary address with a metric equal to the minimum of all specific routes.

Procedure

Step 1 On the **EIGRP** page, click the **Summary Address** tab.

Step 2 Click +**Add**.

Step 3 From the **Interface** drop-down list, select the interface from which the summary address is advertised.

Step 4 From the **Network** drop-down list, select the network object with a specific IP address and network mask to be summarized. To add a new network, click +. For detailed instructions for adding networks, refer to Networks, on page 2813.

Step 5 In the **Administrative Distance** field, enter the administrative distance of the summary route. Valid values range from 1 to 255.

Step 6 Click **OK**.

Step 7 Click **Save**.

The EIGRP summary address settings are configured and saved. EIGRP will advertise the summary address from the specified interface with the configured administrative distance.

Configure EIGRP interfaces settings

Manage interface settings to optimize routing operations.

To configure EIGRP interface settings, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Interfaces** tab.

Step 2 Click **Add**.

Step 3 Select the appropriate interface from the **Interface** drop-down list.

Step 4 In the **Hello Interval** field, enter the hello interval in seconds for EIGRP packets on an interface. Valid values range from 1 to 65535. The default value is 5 seconds.

Step 5 In the **Hold Time** field, enter the hold time that is advertised by the device in EIGRP hello packets. Valid values range from 1 to 65535. The default value is 15 seconds.

To enable EIGRP split-horizon on the interface, check the **Split Horizon** check box.

Step 6 In the **Delay Time** field, enter the delay time in tens of microseconds. Valid values are from 1 to 16777215.

Note This option is not supported in multi-context mode devices.

Step 7 Specify authentication properties:

- **Enable MD5 Authentication**: Check the check box to use the MD5 hash algorithm for authentication of EIGRP packets.
- **Key Type**: Select one key type from the drop-down list:
  - **None**: Indicates that no authentication is required.
  - **Unencrypted**: Indicates that the key string is a clear text password for authentication.
  - **Encrypted**: Indicates that the key string is an encrypted password for authentication.
  - **Auth Key**: Indicates that the key string is an EIGRP authentication key.
- **Key ID**: The ID of the key that is used to authenticate EIGRP updates. Enter a numerical key identifier. Valid values range from 0 to 255.
- **Key**: An alphanumeric character string up to 17 characters. For an encrypted authentication type, this field should have a minimum of 17 characters.
- **Confirm Key**: Re-enter the key.

Step 8 Click **OK**.

Step 9 Click **Save**.

The EIGRP interface settings that you configured are saved. The interface uses the specified hello interval, hold time, split-horizon setting, delay time, and authentication parameters for EIGRP routing operations.

Configure EIGRP advanced settings

Configure EIGRP advanced settings to optimize routing behavior and performance in your network.

To configure EIGRP advanced settings, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Advanced** tab.

Step 2 Under **Default Route Information**, specify the sending and receiving of default route information in EIGRP updates.

- (Appears for non-cluster and cluster in spanned etherchannel mode)**Router ID (IP Address)**: Enter the ID used to identify the originating router for external routes. If an external route is received with the local router ID, the route is discarded. Specify a global address for the router ID to prevent this issue. Each EIGRP router requires a unique value.
- (Appears only for a cluster in individual interface mode)**IPv4 Address Pool**: Select the relevant cluster pool value (IPv4 address pool object). To create the address pool, refer to Configure address pools, on page 2781.
- **Accept Default Route Info**: Check the check box to configure EIGRP to accept default route information.
  - **Access List**: From the **Access List** drop-down list, specify a standard access list that defines the networks that are allowed and the networks that are not when receiving default route information.

    To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2780.
- **Send Default Route Info**: Check the check box to configure EIGRP to advertise exterior default routing information.
  - **Access List**: From the **Access List** drop-down list, specify a standard access list that defines the networks that are allowed and the networks that are not when sending default route information.

    To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2780.

Step 3 Under **Administrative Distance**, specify:

- **Internal Distance**: Administrative distance for EIGRP internal routes. Internal routes are those that are learned from another entity within the same autonomous system. Valid values range from 1 to 255. The default value is 90.
- **External Distance**: Administrative distance for EIGRP external routes. External routes are those for which the best path is learned from a neighbor external to the autonomous system. Valid values range from 1 to 255. The default value is 170.

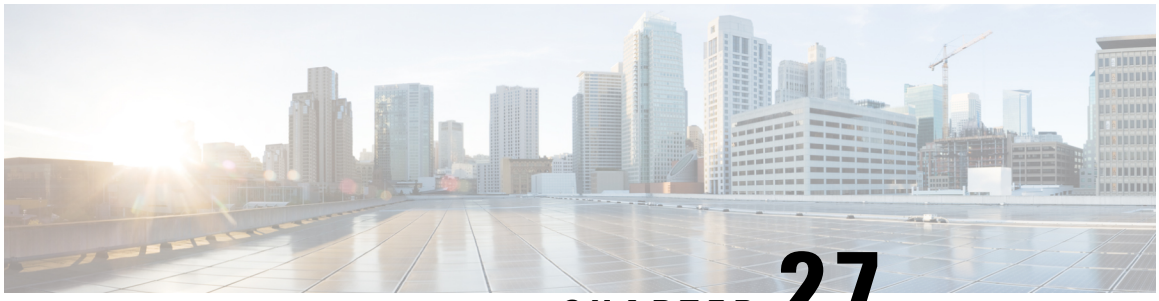
Step 4 Under **Adjacency Changes**, specify:

- **Log Neighbor Changes**: Check the check box to enable the logging of EIGRP neighbor adjacency changes.
- **Log Neighbor Warnings**: Check the check box to enable the logging of EIGRP neighbor warning messages.
- (Optional) Enter the time interval (in seconds) between repeated neighbor warning messages. Valid values range from 1 to 65535. Repeated warnings are not logged if they occur during this interval.

Step 5 Under **Stub**, to enable the device as an EIGRP stub routing process, click one or more of the EIGRP stub routing processes check boxes:

- **Receive only**: Configures the EIGRP stub routing process to receive route information from the neighbor routers but not send route information to the neighbors. If this option is selected, you cannot select any of the other stub routing options.
- **Connected**: Advertises connected routes.
- **Redistributed**: Advertises redistributed routes.
- **Static**: Advertises static routes.
- **Summary**: Advertises summary routes.

Step 6 Under **Default Metrics**, define the default metrics for routes redistributed to the EIGRP routing process:



- **Bandwidth**: The minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295.
- **Delay Time**: The route delay in tens of microseconds. Valid values range from 0 to 4294967295.
- **Reliability**: The likelihood of successful packet transmission expressed as a number from 0 to 255. The value 255 indicates 100 percent reliability; 0 means no reliability.
- **Loading**: The effective bandwidth of the route. Valid values range from 1 to 255; 255 indicates 100 percent loading.
- **MTU**: The smallest allowed value for the maximum transmission unit of the path. Valid values range from 1 to 65535.

EIGRP advanced settings are configured according to your specifications, optimizing routing behavior and performance.

History for EIGRP

This reference provides historical data about EIGRP version compatibility and configuration changes across various releases.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
EIGRP configuration	7.2	Any	In the previous releases, EIGRP was configured on threat defense only through FlexConfig. FlexConfig no longer supports EIGRP configuration. Configuration of EIGRP settings for threat defense is now available in the management center UI. New/modified screens: **Devices** > **Device Management** > **Routing** > **EIGRP**.

CHAPTER 27

BGP

This section describes how to configure the Firewall Threat Defense to route data, perform authentication, and redistribute routing information using the Border Gateway Protocol (BGP).

- BGP, on page 1269
- Requirements and prerequisites for BGP, on page 1273
- Guidelines for BGP, on page 1273
- Configure BGP, on page 1274
- History for BGP, on page 1290

BGP

Border Gateway Protocol (BGP) is an inter- and intra-autonomous system routing protocol that

- operates within and between autonomous systems (networks or groups of networks under common administration with common routing policies),
- exchanges routing information for the Internet, and
- serves as the protocol used between Internet service providers (ISPs).

BGP usage scenarios

BGP usage scenarios are network configurations that

- enable ISPs to exchange customer and ISP routes between autonomous systems using External BGP (EBGP),
- allow service providers to exchange routes within an autonomous system using Interior BGP (IBGP), and
- support IPv6 prefix routing over IPv6 networks.

BGP implementation contexts

Customer networks, such as universities and corporations, usually employ an Interior Gateway Protocol (IGP) such as OSPF for the exchange of routing information within their networks. Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS),

the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

BGP can also be used for carrying routing information for IPv6 prefix over IPv6 networks.

BGP path selection

BGP path selection is a routing process that selects only one path as the best path when BGP receives multiple advertisements for the same route from different sources, puts the selected path in the IP routing table, and propagates the path to its neighbors using specific criteria in order of precedence.

BGP path selection criteria

BGP uses these criteria, in the order presented, to select a path for a destination:

1. If the path specifies a next hop that is inaccessible, drop the update. Otherwise, prefer the path with the largest weight.
2. If the weights are the same, prefer the path with the largest local preference. If the local preferences are the same, prefer the path that was originated by BGP running on this router.
3. If no route was originated, prefer the route that has the shortest AS_PATH. If all paths have the same AS_PATH length, prefer the path with the lowest origin type (where IGP is lower than EGP, and EGP is lower than incomplete).
4. If the origin codes are the same, prefer the path with the lowest MED attribute. If the paths have the same MED, prefer the external path over the internal path.
5. If the paths are still the same, prefer the path through the closest IGP neighbor.
6. Determine if multiple paths require installation in the routing table for BGP multipath, on page 1270.
7. If both paths are external, prefer the path that was received first (the oldest one).
8. Prefer the path with the lowest IP address, as specified by the BGP router ID. If the originator or router ID is the same for multiple paths, prefer the path with the minimum cluster list length.
9. Prefer the path that comes from the lowest neighbor address.

BGP multipath

BGP multipath is a BGP feature that

- allows installation into the IP routing table of multiple equal-cost BGP paths to the same destination prefix,
- enables traffic to the destination prefix to be shared across all installed paths, and
- does not affect best path selection algorithm.

BGP multipath requirements

These paths are installed in the table together with the best path for load-sharing. BGP multipath does not affect best path selection. For example, a router still designates one of the paths as the best path, according to the algorithm, and advertises this best path to its BGP peers.

To be candidates for multipath, paths to the same destination need to have these characteristics equal to the best-path characteristics:

- Weight
- Local preference
- AS-PATH length
- Origin code
- Multi Exit Discriminator (MED)
- One of these:
  - Neighboring AS or sub-AS (before the addition of the BGP Multipaths)
  - AS-PATH (after the addition of the BGP multipaths)

Some BGP multipath features put additional requirements on multipath candidates:

- The path should be learned from an external or confederation-external neighbor (eBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric.

These are the additional requirements for internal BGP (iBGP) multipath candidates:

- The path should be learned from an internal neighbor (iBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric, unless the router is configured for unequal-cost iBGP multipath.

BGP inserts up to *n* most recently received paths from multipath candidates into the IP routing table, where *n* is the number of routes to install in the routing table, as specified when you configure BGP multipath. The default value, when multipath is disabled, is 1.

For unequal-cost load balancing, you can also use BGP Link Bandwidth.

Note The equivalent next-hop-self is performed on the best path that is selected among eBGP multipaths before it is forwarded to internal peers.

Routing tables

A routing table is a network database that

- records paths to destination networks based on exchanged routing information
- updates dynamically as neighbors share new or modified routing routes, and
- determines the optimal path to a destination without requiring periodic updates.

BGP attributes for route selection

Routes learned via BGP have several attributes that determine the best path when multiple routes to a destination exist. The most important BGP attributes include:

- Weight: A Cisco-defined attribute that is local to a router. It is not advertised to neighboring routers. Among multiple routes to the same destination, the route with the highest weight is preferred.
- Local preference: This attribute selects an exit point from the local autonomous system (AS) and is shared throughout the local AS. If multiple exit points exist, the one with the highest local preference attribute is chosen for a specific route.
- Multi-exit discriminator: The multi-exit discriminator (MED) or metric attribute is used as a suggestion to an external AS regarding the preferred route into the AS that is advertising the metric. It is referred to as a suggestion because the external AS that is receiving the MEDs may also be using other BGP attributes for route selection. The route with the lower MED metric is preferred.
- Origin: The origin attribute indicates how BGP learned about a particular route. The origin attribute can have one of three possible values and is used in route selection.
  - IGP: The route is interior to the originating AS. This value is set when the network router configuration command is used to inject the route into BGP.
  - EGP: The route is learned via the Exterior Border Gateway Protocol (EBGP).
  - Incomplete: The origin of the route is unknown or learned in some other way. An origin of incomplete occurs when a route is redistributed into BGP.
- AS_PATH: When a route advertisement passes through an autonomous system, the AS number is added to an ordered list of AS numbers that the route advertisement has traversed. Only the route with the shortest AS_PATH list is installed in the IP routing table.
- Next hop: The EBGP next-hop attribute is the IP address that is used to reach the advertising router. For EBGP peers, the next-hop address is the IP address of the connection between the peers. For IBGP, the EBGP next-hop address is carried into the local AS. However, when the next hop is in the same subnet the peering address of the EBGP peer, the next hop is not modified. This behavior is referred to as the third-party next hop.

  Use the **next-hop-self** command when redistributing VPN-advertised routes to IBGP as peers to ensure that the routes are redistributed with the correct next hop IP.
- Community: The community attribute provides a way of grouping destinations, called communities, to which routing decisions (such as acceptance, preference, and redistribution) can be applied. Route maps are used to set the community attribute. The predefined community attributes are as follows:
  - no-export: Do not advertise this route to EBGP peers.
  - no-advertise: Do not advertise this route to any peer.
  - internet: Advertise this route to the Internet community; all routers in the network belong to it.

Note As loop detection is done by scanning the full AS_PATH (as specified in the AS_PATH attribute), and checking that the AS number of the local system does not appear in the AS_PATH. By default, EBGP advertises the learned routes to the same peer to prevent additional CPU cycles on the device in performing loop checks and to avoid delays in the existing outgoing update tasks.

Requirements and prerequisites for BGP

This reference provides the requirements and prerequisites necessary for configuring BGP on supported devices.

Model support

Firewall Threat Defense

Firewall Threat Defense Virtual

Supported domains

Any

User roles

Administrator

Network Admin

Guidelines for BGP

Context mode guidelines

Consider these context mode requirements when implementing BGP.

- Supported in single and multiple context modes.
- Only one Autonomous System (AS) number is supported for all contexts.

Firewall mode guidelines

Does not support transparent firewall mode. BGP is supported only in routed mode.

IPv6 guidelines

Supports IPv6.

Additional guidelines

Consider these additional operational requirements and limitations.

- For BGP, the next hop IP address for the routes is the network IP address and not 0.0.0.0.

- The system does not add a route entry for the IP address received over PPPoE in the CP route table. BGP always looks into the CP route table for initiating the TCP session, hence BGP does not form TCP session.

  Thus, BGP over PPPoE is not supported.
- BGP is not supported on management-only or BVI interfaces.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.
- BGP with PATH MTU (PMTU) can cause adjacency flaps if MTU discovery fails, especially with ECMP routing. Hence, be cautious while using BGP, PMTU, and ECMP as packet drops can occur if MTU discovery fails due to any reason.
- The BGP table of the member unit is not synchronized with the control unit table. Only its routing table is synchronized with the control unit routing table.
- Enable the graceful timeout feature when you use BGP on Firewall Threat Defense devices that are configured in high availability mode. Enabling this feature reduces packet drops that occur due to issues related to BGP convergence.
- When you configure a route-based site-to-site VPN using static or dynamic VTI interfaces, ensure that the TTL hop count is greater than one if you use BGP as the routing protocol.
- On Firewall Threat Defense devices, changing a large number of BGP neighbors from iBGP to eBGP in a single deployment can fail. During deployment, Firewall Management Center can remove and re-create the same peer in immediate succession, and the deployment can fail if the previous peer deletion is still in progress. To avoid this issue, split the changes across multiple deployments. Remove or modify a subset of neighbors, deploy the configuration, and then apply additional neighbor changes in subsequent deployments.

Configure BGP

Configure BGP routing protocol to establish peering relationships and control route advertisement between autonomous systems.

BGP configuration involves multiple components including basic settings, neighbor relationships, route filtering, and redistribution policies.

Procedure

Step 1 Configure basic BGP settings, on page 1275

Step 2 Configure BGP general settings, on page 1278

Step 3 Configure BGP Neighbor Settings, on page 1279

Step 4 Configure BGP aggregate address settings, on page 1283

Step 5 Configure BGPv4 filtering settings, on page 1284

Note The Filtering section is applicable only to IPv4 settings

Step 6 Configure BGP network settings, on page 1285

Step 7 Configure BGP redistribution settings, on page 1286

Step 8 Configure BGP route injection settings, on page 1287

Step 9 Configure BGP route import and export, on page 1288

BGP is configured with all necessary settings, enabling dynamic routing and proper route exchange between autonomous systems.

Configure basic BGP settings

Enable and customize BGP settings to control routing behavior and improve network operations.

You can set many basic settings for BGP.

For a device using virtual routing, the basic settings described in this section must be configured in the **BGP** page under **General Settings**. For more information, refer to Modifications to the Firewall Management Center web interface routing page.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select the **Routing** tab and do the following:

a) (For a virtual-router-aware device) Under **General Settings**, click **BGP**.

b) Check the **Enable BGP** check box to enable the BGP routing process.

c) In the **AS Number** field, enter the autonomous system (AS) number for the local BGP process. The AS number internally includes multiple autonomous numbers. Valid values are from 1 to 4294967295 or from 1.0 to 65535.65535 when a dot notation is used. The AS number is a uniquely assigned value that identifies each network on the Internet.

d) In the **Router Id** drop-down list, choose **Automatic** or **Manual** (appears for non-cluster and a cluster in spanned etherchannel mode) or **Cluster Pool** (appears for a cluster in individual interface mode). If you choose **Automatic**, the highest-level IP address on the Firewall Threat Defense device is used as the router ID. If you choose **Manual**, enter the IP address in the **IP Address** field. If you choose **Cluster Pool**, enter the cluster pool value in the **Cluster Pool** field. For more information on creating the cluster pool address, refer to Configure address pools, on page 2781..

e) To use a fixed router ID, choose **Manual** and enter an IPv4 address in the **IP Address** field. The default value is **Automatic**. For a virtual router-aware device, you can override the router ID settings in the **Virtual Routers** > **BGP** page.

Step 3 (Optional) Edit the various BGP settings, starting with **General**. The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network. Click **Edit** (✎) to edit the settings in the group:

a) Enter a **Scanning Interval** for BGP routers for next-hop validation. Valid values are from 5 to 60 seconds. The default value is 60.
b) In the **Number of AS numbers in AS_PATH attribute of received routes** field, enter the maximum number of AS numbers allowed in the AS_PATH attribute of received routes. An AS_PATH attribute is a sequence of intermediate AS numbers between source and destination routers that form a directed route for packets to travel. Valid values are between 1 and 254. The default value is **None**.
c) Check the **Log Neighbor Changes** check box to enable logging of BGP neighbor changes (up or down) and resets. This helps in troubleshooting network connectivity problems and measuring network stability. This is enabled by default.
d) Check the **Use TCP path MTU discovery** check box to use the Path MTU determining technique to determine the maximum transmission unit (MTU) size on the network path between two IP hosts. This avoids IP fragmentation. This is enabled by default.
e) Check the **Reset session upon failover** check box to reset the external BGP session immediately upon link failure. This is enabled by default.
f) Check the **Enforce the first AS is peer's AS for EBGP routes** check box to discard incoming updates received from external BGP peers that do not list their AS number as the first segment in the AS_PATH attribute. This prevents a misconfigured or unauthorized peer from misdirecting traffic by advertising a route as if it was sourced from another autonomous system. This is enabled by default.
g) Check the **Use dot notation for AS number** check box to split the full binary 4-byte AS number into two words of 16 bits each, separated by a dot. AS numbers from 1 to 65535 are represented as decimal numbers, and AS numbers greater than 65535 are represented using dot notation. This is disabled by default.

   Enter a value for the aggregate timer (in seconds) in the **Aggregate Timer** field. Valid values are 0 or any value between 6 and 60. The default value is 30.

h) Check the **BGP community new format (AA:NN)** check box to configure BGP to display community values in the AA:NN format, where AA represents the autonomous system number, and NN represents the community number, each being 2 bytes long. This format conforms to RFC-1997. By default, BGP communities are displayed as a single 32-bit decimal number.
i) Click **OK**.

Step 4 (Optional) Edit the **Best Path Selection** section:

a) Enter a value for **Default local preference** between 0 and 4294967295. The default value is 100. Higher values indicate higher preference. This preference is sent to all routers and access servers in the local autonomous system.
b) Check the **Allow comparing MED from different neighbors** check box to allow the comparison of Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems. This is disabled by default.
c) Check the **Compare Router ID for identical EBGP paths** check box to compare similar paths received from external BGP peers during the best path selection process and switch the best path to the route with the lowest router ID. This is disabled by default.
d) Check the **Pick the best-MED path among paths advertised by neighbor AS** check box to enable MED comparison among paths learned from confederation peers. The comparison between MEDs is made only if no external autonomous systems are there in the path. This is disabled by default.
e) Check the **Treat missing MED as the least preferred path** check box to consider the missing MED attribute as having a value of infinity, making the path the least desirable; therefore, a path with a missing MED is least preferred. This is disabled by default.
f) Click **OK**.

Step 5 (Optional) Edit the **Neighbor Timers** section:

a) Enter the time interval for which the BGP neighbor remains active after not sending a keepalive message in the **Keepalive interval** field. At the end of this keepalive interval, the BGP peer is declared dead, if no messages are sent. The default value is 60 seconds.
b) Enter the time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Hold time** field. The default value is 180 seconds. Specify a value from 0 to 65535.
c) (Optional) Enter the minimum time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Min Hold time** field. Specify a value from 3 to 65535.

Note A hold time of less than 20 seconds increases the possibility of peer flapping.

d) Click **OK**.

Step 6 In the **Next Hop** section, optionally check the **Address tracking** check box to enable BGP next hop address tracking and enter the **Delay Interval** between checks on updated next-hop routes installed in the routing table. Click **OK**.

Note The **Next Hop** section is applicable only to IPv4 settings.

Step 7 (Optional) Edit the **Graceful Restart** section:

Note This section is available only when the Firewall Threat Defense device is in failover or spanned cluster mode. This is done so that there is no drop in packets in the traffic flow, when one of the devices in the failover setup fails.

a) Check the **Enable Graceful Restart** check box to enable Firewall Threat Defense peers to avoid a routing flap following a switchover.
b) Specify the time duration that Firewall Threat Defense peers will wait to delete stale routes before a BGP open message is received in the **Restart Time** field. The default value is 120 seconds. Valid values are between 1 and 3600 seconds.
c) Enter the time duration that the Firewall Threat Defense will wait before deleting stale routes after an end of record (EOR) message is received from the restarting Firewall Threat Defense in the **Stalepath Time** field. The default value is 360 seconds. Valid values are between 1 and 3600 seconds.
d) Click **OK** and then click **Save**.

Step 8 To view the BGP basic settings, from the virtual routers drop-down, select the desired router, and then click **BGP**.

This page displays the basic settings that are configured in the **Settings** page. You can edit the router ID settings on this page.

To edit the router ID settings, modify the IP address in the **IP Address** fields. The modified value overrides the router ID settings that were configured on the **BGP** page under **General Settings**.

The device is configured with basic BGP settings, enabling BGP routing, specifying the AS number, router ID, and any custom parameters you set.

Configure BGP general settings

Configure route maps, administrative route distances, synchronization, next-hop, and packet forwarding for BGP to optimize routing performance in your network.

The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select the **Routing** tab.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down, select the virtual router for which you are configuring BGP.

Step 4 Choose **BGP** > **IPv4** or **IPv6**.

Step 5 In the **General** tab, update the following sections:

a) In the **Setting** section, enter or select a **RouteMap** object and click **OK**.

Note The **RouteMap** field is applicable only to IPv4 settings.

b) In the **Administrative Route Distances** section, update the following as required, and click **OK**:

- **External**: Enter the administrative distance for external BGP routes. Routes are external when learned from an external autonomous system. The range of values for this argument are from 1 to 255. The default value is 20.
- **Internal**: Enter administrative distance for internal BGP routes. Routes are internal when learned from peer in the local autonomous system. The range of values for this argument are from 1 to 255. The default value is 200.
- **Local**: Enter administrative distance for local BGP routes. Local routes are routes originated by the local BGP process, such as networks specified with the network router configuration command or routes redistributed into BGP from another routing process. The range of values for this argument is from 1 to 255. The default value is 200.

c) In the **Routes and Synchronization** section, update the following as required, and click **OK**:

- (Optional) **Generate default route**s: Check the check box of this option to configure default-information originate.
- (Optional) **Summarize subnet routes into network level routes**: Check the check box of this to configure automatic summarization of subnet routes into network-level routes. This check box is applicable only to IPv4 settings.

- (Optional) **Advertise inactive routes**: Check the check box of this to advertise routes that are not installed in the routing information base (RIB).
- (Optional) **Synchronize between BGP and IGP systems**: Check the check box of this to enable synchronization between BGP and your Interior Gateway Protocol (IGP) system. Usually, a BGP speaker does not advertise a route to an external neighbor unless that route is local or exists in the IGP. This feature allows routers and access servers within an autonomous system to have the route before BGP makes it available to other autonomous systems.
- (Optional) **Redistribute IBGP into IGP**: Check the check box of this to configure IBGP redistribution into an interior gateway protocol (IGP), such as OSPF.

d) In the **Forward Packets Over Multiple Paths** section, update the following as required and click **OK**:

- (Optional) **Number of Paths**: Enter the maximum number of Border Gateway Protocol routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.
- (Optional) **IBGP Number of Paths**: Enter the maximum number of parallel internal Border Gateway Protocol (IBGP) routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.

Step 6 Click **Save**.

BGP general settings are configured with your specified route maps, administrative distances, synchronization options, and multi-path forwarding parameters.

Configure BGP Neighbor Settings

Define and customize BGP neighbor connections on your device for efficient routing and advanced peer management.

A BGP router must connect with each of its peers before exchanging updates. These peers are called BGP neighbors. Perform this procedure to define BGP IPv4 or IPv6 neighbors and neighbor settings.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device. Select the **Routing** tab.

(For a virtual router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring BGP.

Step 2 Choose **BGP** > **IPv4** or **IPv6**. Click **Neighbor**.

Step 3 Click **Add** to define BGP neighbors and neighbor settings.

a) Enter the BGP neighbor **IP address**. This IP address is added to the BGP neighbor table. When you are configuring BGP IPv6 on static VTI, enter the virtual tunnel IP address of the neighbor. Choose the BGP neighbor **Interface**.

Note The **Interface** field is only applicable to IPv6 settings.

b) Enter the autonomous system to which the BGP neighbor belongs, in the **Remote AS** field. Check the **Enabled address** check box to enable communication with this BGP neighbor. Further neighbor settings will be configured only if the **Enabled address** check box is selected.

c) (Use this option only when the routing does not result in a loop.) Check the **AS Override** check box to enable overriding of the AS number of the originating router with the AS number of the sending BGP router.

Note Loop prevention in BGP is achieved by verifying the AS number in the AS path. BGP rejects route updates when the AS path attribute contains its own AS number. However, in circumstances where the same ASN is used by discontiguous network segments, to establish end-to-end reachability, you can opt to override the AS number with that of the sending BGP router.

d) (Optional) Check the **Shutdown administratively** check box to disable a neighbor or peer group.

e) (Optional) Check the **Configure graceful restart (failover / spanned mode)** check box to enable configuration of the BGP graceful restart capability for this neighbor. After selecting this option, you must check the **Enable graceful restart** check box to specify whether graceful restart should be enabled or disabled for this neighbor.

Note

- The graceful restart is enabled only when the device is in HA mode or when L2 cluster (all nodes from the same network) is configured.
- The graceful restart option for BGPv6 is enabled only on Firewall Threat Defense Version 7.3+.
- If you configure graceful restart only at General Settings and not at BGP IPv6, the global General Settings configuration persists.
- If you configure graceful restart at General Settings and also at BGP IPv6, the global General Settings configuration is overridden by the BGP IPv6 configuration settings.

f) (Optional) To enable configuration of the BFD support for BGP, from the **BFD Fallover** drop-down list, choose the BFD type—single-hop, multi-hop, or auto-detect-hop. This selection registers the BGP neighbor to receive forwarding path detection failure messages from BFD. Choose None if you do not want to have BFD support.

g) (Optional) Enter a **Description** for the BGP neighbor.

h) (Optional) From the **Update Source** drop-down list, choose an interface to source the BGP packets.

You can choose a loopback address as this interface to overcome path failures. You can also choose any physical, port-channel, or a sub-interface.

Step 4 (Optional) In **Filtering Routes**, use access lists, route maps, prefix lists and AS path filters as required, to distribute BGP Neighbor information. Update the following sections:

a) Choose or select the appropriate incoming or outgoing **Access List** to distribute BGP neighbor information.

Note Access lists are only applicable to IPv4 settings.

b) Choose or select the appropriate incoming or outgoing **Route Maps** to apply a route map to incoming or outgoing routes.
c) Choose or select the appropriate incoming or outgoing **Prefix List** to distribute BGP neighbor information.
d) Choose or select the appropriate incoming or outgoing **AS path filter** to distribute BGP neighbor information.
e) Check the check box of **Limit the number of prefixes allowed from the neighbor** to control the number of prefixes that can be received from a neighbor.
   - Enter the maximum number of prefixes allowed from a specific neighbor in the **Maximum Prefixes** field.
   - Enter the percentage (of maximum) at which the router starts to generate a warning message in the **Threshold Level** field. Valid values are integers between 1 and 100. The default value is 75.

f) Check the **Control prefixes received from the peer** check box to specify additional controls for the prefixes received from a peer. Do one of the following:
   - Check the **Terminate peering when prefix limit is exceeded** check box to stop the BGP neighbor when the prefix limit is reached. Specify the interval after which the BGP neighbor will restart in the **Restart interval** field.
   - Check the **Give only warning message when prefix limit is exceeded** check box to generate a log message when the maximum prefix limit is exceeded. Here, the BGP neighbor will not be terminated.

g) Click **OK**.

Step 5 (Optional) In **Routes**, specify miscellaneous Neighbor route parameter. Proceed to update the following:
a) Enter the minimum interval (in seconds) between the sending of BGP routing updates in the **Advertisement Interval** field. Valid values are between 1 and 600.
b) Check the **Remove private AS numbers from outbound routing updates** check box to exclude the private AS numbers from being advertised on outbound routes.
c) Check the **Generate default routes** check box to allow the local router to send the default route 0.0.0.0 to a neighbor to use as a default route. Enter or Select the route map that allows the route 0.0.0.0 to be injected conditionally in the **Route map** field.
d) To add conditionally advertised routes, click Add Row +. In the Add Advertised Route dialog box, do the following:
   1. Add or choose a route map in the **Advertise Map** field, that will be advertised if the conditions of the exist map or the non-exist map are met.
   2. Click **Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.
   3. Click **Non-Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.
   4. Click **OK**.

Step 6 In **Timers**, check the **Set timers for the BGP peer** check box to set the keepalive frequency, hold time, and minimum hold time.

- **Keepalive interval**: Enter the frequency (in seconds) with which Firewall Threat Defense sends keepalive messages to the neighbor. Valid values are between 0 and 65535. The default value is 60 seconds.
- **Hold time**: Enter the interval (in seconds) after not receiving a keepalive message that Firewall Threat Defense declares a peer dead. Valid values are between 0 and 65535. The default value is 180 seconds.
- **Min hold time**: (Optional) Enter the minimum interval (in seconds) after not receiving a keepalive message that Firewall Threat Defense declares a peer dead. Valid values are between 3 and 65535. The default value is 3 seconds.

Note A hold time of less than 20 seconds increases the possibility of peer flapping.

Step 7 In **Advanced**, update the following:

a) (Optional) Check the **Enable Authentication** check box to enable MD5 authentication on a TCP connection between two BGP peers.

1. Choose an encryption type from the **Enable Encryption** drop-down list.
2. Enter a password in the **Password** field. Reenter the password in the **Confirm Password** field. The password is case-sensitive and can be up to 25 characters long when the service password-encryption command is enabled and up to 81 characters long when the service password-encryption command is not enabled. The string can contain any alphanumeric characters, including spaces.

Note You cannot specify a password in the format number-space-anything. The space after the number can cause authentication to fail.

b) (Optional) Select the **Send Community attribute to this neighbor** check box to specify that community attributes should be sent to the BGP neighbor

c) (Optional) Select the **Use FTD as next hop for this neighbor** check box to configure the router as the next-hop for a BGP speaking neighbor or peer group.

d) Select the **Disable Connection Verification** check box to disable the connection verification process for eBGP peering sessions that are reachable by a single hop but are configured on a loopback interface or otherwise configured with a non-directly connected IP address. When deselected (default), a BGP routing process will verify the connection of single-hop eBGP peering session (TTL=254) to determine if the eBGP peer is directly connected to the same network segment by default. If the peer is not directly connected to same network segment, connection verification will prevent the peering session from being established.

e) Select **Allow connections with neighbor that is not directly connected** to accept and attempt BGP connections to external peers residing on networks that are not directly connected. (Optional) Enter the time-to-live in the **TTL hops** field. Valid values are between 1 and 255. However, for eBGP multi-hop neighborship configuration, you must enter the **TTL hops** value. Alternatively, select **Limited number of TTL hops to neighbor**, to secure a BGP peering session. Enter the maximum number of hops that separate eBGP peers in the **TTL hops** field. Valid values are between 1 and 254.

f) (Optional) Select the **Use TCP MTU path discovery** check box to enable a TCP transport session for a BGP session.
g) Choose the TCP connection mode from the **TCP Transport Mode** drop-down list. Options are Default, Active, or Passive.
h) (Optional) Enter a **Weight** for the BGP neighbor connection.
i) Select the **BGP Version** that Firewall Threat Defense will accept from the drop-down list. The version can be set to 4-Only to force the software to use only Version 4 with the specified neighbor. The default is to use Version 4 and dynamically negotiate down to Version 2 if requested.

Step 8 Update **Migration**, only if AS migration is considered.

Note The AS migration customization should be removed after transition has been completed.

a) (Optional) Check the **Customize the AS number for routes received from the neighbor** check box to customize the AS_PATH attribute for routes received from an eBGP neighbor.
b) Enter the local autonomous system number in the **Local AS number** field. Valid values are any valid autonomous system number from 1 to 4294967295 or 1.0 to 65535.65535.
c) (Optional) Check the **Do not prepend local AS number to routes received from neighbor** check box to prevent the local AS number from being prepended to any routes received from eBGP peer.
d) (Optional) Check the **Replace real AS number with local AS number in routes received from neighbor** check box to replace the real autonomous system number with the local autonomous system number in the eBGP updates. The autonomous system number from the local BGP routing process is not prepended.
e) (Optional) Check the **Accept either real AS number or local AS number in routes received from neighbor** check box to configure the eBGP neighbor to establish a peering session using the real autonomous system number (from the local BGP routing process) or by using the local autonomous system number.

Step 9 Click **OK**, and then click **Save**.

The BGP neighbor and its associated advanced settings are configured. The device can now establish and manage BGP sessions as specified, ensuring effective routing and network reachability.

Configure BGP aggregate address settings

Route aggregation combines the attributes of several different routes so that only a single route is advertised, reducing the number of routes that need to be advertised.

BGP neighbors store and exchange routing information and the amount of routing information increases as more BGP speakers are configured. Route aggregation is the process of combining the attributes of several different routes so that only a single route is advertised. Aggregate prefixes use the classless interdomain routing (CIDR) principle to combine contiguous networks into one classless SET of IP addresses that can be summarized in routing tables. As a result fewer routes need to be advertised. Use the Add/Edit Aggregate Address dialog box to define the aggregation of specific routes into one route.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Add Aggregate Address**.

Step 5 Enter a value for the aggregate timer (in seconds) in the **Aggregate Timer** field. Valid values are 0 or any value between 6 and 60. The default value is 30.

Step 6 Click (+)**Add** and update the **Add Aggregate Address** dialog box:

a) **Network**: Enter an IPv4 address or select the desired network/hosts objects.
b) **Attribute Map**: (Optional) Enter or select the route map used to SET the attribute of the aggregate route.
c) **Advertise Map**: (Optional) Enter or select the route map used to select the routes to create AS_SET origin communities.
d) **Suppress Map**: (Optional) Enter or select the route map used to select the routes to be suppressed.
e) **Generate AS SET path Information**: (Optional) Check the check box to enable generation of autonomous system SET path information.
f) **Filter all routes from updates**: (Optional) Check the check box to filter all more-specific routes from updates.
g) Click **OK**.

The BGP aggregate address settings are configured and fewer routes need to be advertised due to route aggregation.

What to do next

- For BGPv4 settings, proceed to Configure BGPv4 filtering settings, on page 1284.
- For BGPv6 settings, proceed to Configure BGP network settings, on page 1285.

Configure BGPv4 filtering settings

Configure filtering settings to filter routes or networks received in incoming BGP updates and restrict routing information that the router learns or advertises.

Filtering settings are used to filter routes or networks received in incoming BGP updates. Filtering is used to restrict routing information that the router learns or advertises.

Before you begin

Filtering is only applicable for a BGP IPv4 routing policy.

Follow these steps to configure BGPv4 filtering settings:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select the **Routing** tab.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 4 Choose **BGP** > **IPv4**.

Step 5 Click **Filtering**.

Note The **Filtering** field is applicable only to IPv4 settings.

Step 6 Click (+)**Add** and update the **Add Filter** dialog box:

a) **Access List**: Choose an access control list that defines which networks are to be received and which are to be suppressed in routing updates.

b) **Direction**: (Optional) Choose a direction that specifies if the filter should be applied to inbound updates or outbound updates.

c) **Protocol**: (Optional) Choose the routing process for which you want to filter: None, BGP, Connected, OSPF, RIP, or Static.

d) **Process ID**: (Optional) Enter the process ID for the OSPF routing protocol.

e) Click **OK**.

Step 7 Click **Save**.

BGPv4 filtering settings are configured to filter routes or networks based on the specified access control list and filtering criteria.

Configure BGP network settings

Configure BGP network settings to control which networks are advertised by the BGP routing process and to apply route map filters for network advertisement.

Network settings are used to add networks that will be advertised by the BGP routing process and route maps that will be examined to filter the networks to be advertised.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select the **Routing** tab.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 4 Choose **BGP** > **IPv4** or **IPv6**.

Step 5 Click **Networks**.

Step 6 Click **Add** and update the **Add Networks** dialog box:

a) **Network**: Choose the network to be advertised by the BGP routing processes.

Note For a network prefix to be advertised, a route to the device must exist on the routing table.

To add a new network object, refer to Create a network object, on page 2815.

b) (Optional) **Route Map**: Enter or choose a route map that should be examined to filter the networks to be advertised. If not specified, all networks are redistributed. To add a new route map object, refer to Configure a route map, on page 2847.

c) Click **OK**.

Step 7 Click **Save**.

The BGP network settings are configured with the specified networks and route maps for advertisement filtering.

Configure BGP redistribution settings

Configure redistribution settings to define the conditions for redistributing routes from another routing domain into BGP.

Redistribution settings allow you to define the conditions for redistributing routes from another routing domain into BGP.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select the **Routing** tab.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 4 Choose **BGP** > **IPv4** or **IPv6**.

Step 5 Click **Redistribution**.

Step 6 Click **Add** and update the **Add Redistribution** dialog:

a) **Source Protocol**: Select the protocol from which you want to redistribute routes into the BGP domain from the Source Protocol drop-down list.

Note User-defined virtual routers do not support redistributing routes from RIP.

b) **Process ID**: Enter the identifier for the selected source protocol. Applies to the OSPF protocol. For devices using virtual routing, this drop-down lists the process ID assigned for the virtual router for which you are configuring the BGP settings.

c) **Metric**: (Optional) Enter a metric for the redistributed route.
d) **Route Map**: Enter or select a route map that should be examined to filter the networks to be redistributed.

If not specified, all networks are redistributed. To create a new route map object, click **Add** (+). For the procedure to add a new route map, see Configure Route Map Entry.

e) **Match**: The conditions used for redistributing routes from one routing protocol to another. The routes must match the selected condition to be redistributed. You can choose one or more conditions. These options are enabled only when OSPF is chosen as the Source Protocol.

- Internal
- External 1
- External 2
- NSSA External 1
- NSSA External 2

f) Click **OK**.

The BGP redistribution settings are configured and routes from the specified source protocol are redistributed into the BGP domain according to the defined conditions.

Configure BGP route injection settings

Configure BGP route injection settings to control which routes are conditionally injected into the BGP routing table based on defined criteria.

Route injection settings allow you to define the routes to be conditionally injected into the BGP routing table.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select the **Routing** tab.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 4 Choose **BGP** > **IPv4** or **IPv6**.

Step 5 Click **Route Injection**.

Step 6 Click **Add** and update the **Add Route Injection** dialog box:

a) **Inject Map**: Enter or select the route map that specifies the prefixes to inject into the local BGP routing table. To create a new route map object, click **Add** (+). For the procedure to add a new route map, see Configure Route Map Entry.
b) **Exist Map**: Enter or select the route map containing the prefixes that the BGP speaker will track.
c) **Injected routes will inherit the attributes of the aggregate route**: Check this box to configure the injected route to inherit attributes of the aggregate route.
d) Click **OK**.

Step 7 Click **Save**.

The BGP route injection settings are configured and the specified routes will be conditionally injected into the BGP routing table according to the defined route maps.

Configure BGP route import and export

This task enables you to implement inter-virtual-router route leaking in BGP by importing or exporting routes using route target extended communities, allowing controlled sharing of routes between virtual routers.

In BGP, you can implement an inter-virtual-router route leak by importing or exporting routes using the route target extended community of the destination and source virtual routers respectively. You can use a route map to filter the desired route targets instead of leaking the entire routing table. You can also leak the routes of global virtual router to user-defined virtual routers and vice versa.

- You can configure BGP to leak routes between two user-defined virtual routers using the route target extended communities:
  - Tag the routes with the route targets from the source virtual router using route target export.
  - Import the routes that are matching the route targets into the destination virtual router using route target import.
  - Optionally, you can filter routes from source virtual router or to destination virtual router using export or import route maps respectively. You can configure route map with match extended community list for filtering the routes. Similarly, you can configure route map with set extended community route targets to tag the routes with the route target extended community.
- To import routes from the global virtual router to a user-defined virtual router, specify the IPv4/IPv6 route map in Global Virtual Router Import Route Map to import to the user-defined virtual router.
- To export routes from a user-defined virtual router to the global virtual router, in addition to exporting the route targets, you can also specify the Global Virtual Router Export Route Map to export from the user-defined virtual router.

The BGP inter-virtual-router route leaking supports both IPv4 and IPv6 prefixes.

Before you begin

- Create virtual routers.
- Enable BGP on the virtual router.
- Configure BGP, on page 1274.

Follow these steps to configure BGP route import/export settings:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device. Select the **Routing** tab.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 (Supported for virtual routers only) Click **Route Import/Export**. In the **Route Targets Import** field, enter the route target extended community that you want to match for the routes to be imported. On deployment, the routes of the destination virtual router that match this value are imported to the source virtual router's BGP table.

Note
- The route target must be in **ASN:nn** format.
- You can enter multiple route targets as comma-separated values.
- This value can range from 0:1 to 65534:65535.

Step 5 In the **Route Targets Export** field, enter the route target extended community to tag the source virtual router's routes with the route target value. On deployment, the routes of the source virtual router are tagged with this value.

Note
- The route target must be in **ASN:nn** format.
- You can enter multiple route targets as comma separated values.
- This value can range from 0:1 to 65534:65535.

Step 6 Route maps help you to narrow down the routes to be shared instead of leaking the entire routing table. Route map filtering is applied on the list of routes that are obtained with the specified route target values:

a) (Optional) Under **User Virtual Router**, choose the route map from the **Import Route Map** drop-down list to filter the routes at the destination virtual router.

Note The user virtual router import route map is effective only when the route targets import is configured.

b) (Optional) Under **User Virtual Router**, choose the route map from the **Export Route Map** drop-down list to filter the routes at the source virtual router before the routes are exported to other virtual routers.

Note You can use the match and set clauses in the route map with the route target extended community lists for filtering based on other criteria or tagging the routes with the route target community values. For more information, refer to Configure a route map, on page 2847.

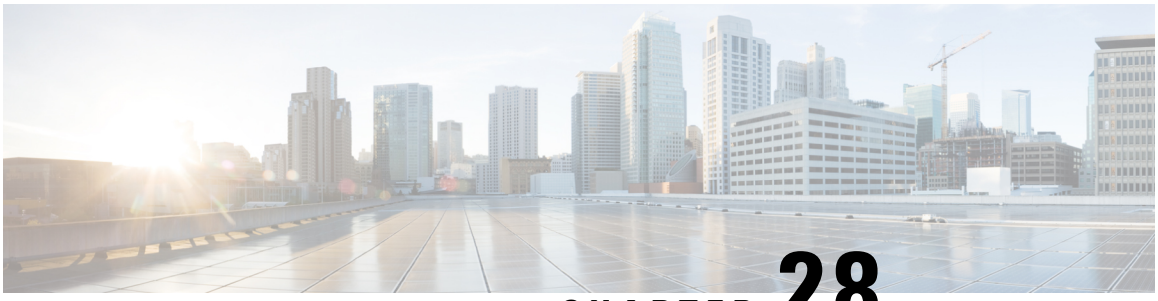
Step 7 To share the routes between a user-defined virtual router and global virtual router, specify the route map under the **Global Virtual Router**:

a) To leak the global virtual router routes to the user-defined virtual router, select the route map from the **Import Route Map** drop-down list. The IPv4 or IPv6 route map is imported to the user-defined virtual router.
b) To leak the user-defined virtual router routes to the global virtual router, select the route map from the **Export Route Map** drop-down list. The IPv4 or IPv6 route map is exported to the global virtual router.

Note You must specify the route targets for export apart from specifying the route map.

Note You can use the match clause of the route map object to filter the routes for leaking. For more information, refer to Configure a route map, on page 2847.

Step 8 Follow the procedure (Step 3 to Step 8) to configure relevant BGP route import and export settings for other virtual routers as well. Click **Save**, then **Deploy** to apply your import/export settings.



When the packets flow into the ingress virtual router, BGP imports the routes from the destination virtual routers that have the matching route target value and if a route map is also configured, the routes are further filtered and used to identify the best path routes for routing the packets.

History for BGP

This reference provides the history and version information for BGP features and enhancements, including minimum required versions and implementation details.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
BGP AS Override	7.77.6.1	7.77.6.1	You can enable the receiving BGP router to override the AS number of the originating router (that is the same as the receiving router) with the AS number of the sending BGP router if the same AS number is being used by discontiguous network segments. New/modified screens: **Routing** > **BGP** > **IPv4 or IPv6** > **Add/Edit Neighbor**.
Graceful restart support on BGPv6	7.4	Any	You can configure graceful restart on BGPv6 for Secure Firewall Threat Defense version 7.3 and later. New/modified screens: **Routing** > **BGP** > **IPv6** > **Add/Edit Neighbor**.
Loopback interface support for BGP	7.4	Any	You can use a loopback interface for BGP. New/modified screens: **Routing** > **BGP** > **IPv4 or IPv6** > **Add/Edit Neighbor**.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
BGP configuration to interconnect virtual routers	7.1	Any	You can configure BGP settings to dynamically leak routes among user-defined virtual routers, and between global virtual router and user-defined virtual routers. The import and export routes feature was introduced to exchange routes among the virtual routers by tagging them with route targets and optionally, filtering the matched routes with route maps. This BGP feature is accessible only when you select a user-defined virtual router. New/modified screens: For a selected user-defined virtual router, **Devices** > **Device Management** > **Routing** > **BGPv4/v6** > **Route Import/Export** tab.
BGPv6 support for user-defined virtual routers	7.1	Any	Secure Firewall Threat Defense now supports configuring BGPv6 on user-defined virtual routers. New/modified screens: For a selected user-defined virtual router, **Devices** > **Device Management** > **Routing** > **BGPv6** page.

CHAPTER 28

RIP

The Routing Information Protocol (RIP) is a distance-vector routing protocol that

- enables devices to exchange routing information,
- supports authentication mechanisms, and
- facilitates redistribution of routing information.

RIP Configuration Constraints

There are constraints when deploying RIP on the Firewall Threat Defense:

- RIP configuration is restricted to the global virtual router and is not supported for user-defined virtual routers.

- RIP, on page 1293
- Requirements and prerequisites for RIP, on page 1294
- Guidelines for RIP, on page 1294
- Configure RIP, on page 1295
- How RIP routing updates work, on page 1298
- RIP stability features, on page 1299
- RIP timers, on page 1299

RIP

Routing Information Protocol (RIP) is a distance-vector routing protocol that

- uses hop count as the metric for path selection,
- exchanges RIP broadcasts with neighboring devices to dynamically learn and advertise routes, and
- includes four basic components: routing update process, RIP routing metrics, routing stability, and routing timers.

RIP characteristics and versions

RIP is a widely used routing protocol. It sends routing updates at regular intervals and when the network topology changes. These updates provide information about network reachability and the number of hops to each destination.

You can configure RIP with less effort than OSPF, but it generates more network traffic. RIP supports both Version 1 and Version 2.

Secure Firewall Threat Defense device supports both RIP Version 1 and Version 2. RIP Version 1 does not send subnet masks with its updates; Version 2 supports variable-length subnet masks and neighbor authentication to ensure trusted routing information exchanges.

RIP offers simple configuration and adapts to topology changes. In contrast, static routes require manual updates for each change. RIP, however, incurs higher network and processing overhead compared to static routing.

RIP routing metric

A RIP routing metric is a network measurement that

- calculates the distance between a source and a destination network,
- assigns a hop count value, typically 1, to each hop in a network path from the source to the destination, and
- updates the routing table when new routing data is received, using the sender's IP address as the next hop.

Requirements and prerequisites for RIP

These requirements and prerequisites must be met for configuring RIP on supported firewall models.

Model support

Network Admin

Guidelines for RIP

IPv6 guidelines

RIP does not support IPv6.

RIP version 2 guidelines

Consider these guidelines for RIP Version 2 configuration:

- If using neighbor authentication, the authentication key and key ID must be the same on all neighbor devices that provide RIP Version 2 updates to the interface.
- With RIP Version 2, the Secure Firewall Threat Defense device transmits and receives default route updates using the multicast address 224.0.0.9. In passive mode, it receives route updates at that address.
- When RIP Version 2 is configured on an interface, the multicast address 224.0.0.9 is registered on that interface. When a RIP Version 2 configuration is removed from an interface, that multicast address is unregistered.

RIP limitations

These are the limitations of RIP:

- The Secure Firewall Threat Defense device cannot pass RIP updates between interfaces.
- RIP Version 1 does not support variable-length subnet masks.
- RIP has a maximum hop count of 15. A route with a hop count greater than 15 is considered unreachable.
- RIP convergence is relatively slow compared to other routing protocols.
- You can only enable a single RIP process on the Secure Firewall Threat Defense device.

Configure RIP

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection.

Use this procedure to define networks, manage redistribution, and apply interface-specific filtering or broadcast parameters.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select the **Routing** tab, and select **RIP** from the table of contents.

Check the **Enable RIP** check box to configure the RIP settings.

Choose the RIP versions for sending and receiving RIP updates from the **RIP Version** drop-down list:

- **Receive Version 1 & 2, Send Version 1**
- **Send & Receive Version 1**
- **Send & Receive Version 2**

Step 3 (Optional) Check the **Generate Default Route** check box to generate a default route for distribution, based on the route map that you specify.

a) Specify a route map name to use for generating default routes, in the **Route Map** field.

Generate the default route 0.0.0.0/0 for distribution when a route map is specified in the **Route Map** field.

Step 4 When you choose Send and Receive Version 2, the **Enable Auto Summary** option is available. When the **Enable Auto Summary** check box is checked, automatic route summarization is enabled. Disable automatic summarization if you must perform routing between disconnected subnets. When automatic summarization is disabled, subnets are advertised.

Note RIP Version 1 always uses automatic summarization—you cannot disable it.

Step 5 Click **Networks**. Define one or more networks for RIP routing. Enter IP address(es), or enter or select the desired Network/Hosts objects. There is no limit to the number of networks you can add to the security appliance configuration. Interfaces belonging to the defined network will participate in the RIP routing. The RIP routing updates will be sent and received only through interfaces on the specified networks. Also, if the network of an interface is not specified, the interface will not be advertised in any RIP updates.

Note RIP only supports IPv4 objects.

(Optional) Click **Passive Interface**. Use this option to specify passive interfaces on the appliance, and by extension the active interfaces. The device receives RIP routing broadcasts on passive interfaces, using that information to populate its routing tables, but does not broadcast routing updates on passive interfaces. Interfaces that are not designated as passive receive and send updates.

Step 6 Click **Redistribution** to manage redistribution routes. These are the routes that are being redistributed from other routing processes into the RIP routing process.

a) Click **Add** to specify redistribution routes.

b) Choose the routing protocol to redistribute into the RIP routing process, in the **Protocol** drop-down list. Available options are **Static**, **Connected**, **OSPF**, **BGP**, and **EIGRP**.

Note For OSPF, specify the process ID in the **Process ID** field. For BGP, specify the AS number in the **AS Number** field. When you choose the Connected option in the **Protocol** drop-down list, you can redistribute directly connected networks into the RIP routing process.

c) (Optional) If you are redistributing OSPF routes into the RIP routing process, you can select specific types of OSPF routes to redistribute in the **Match** drop-down list. Ctrl-click to select multiple types:

- **Internal**: Routes internal to the autonomous system (AS) are redistributed.
- **External 1**: Type 1 routes external to the AS are redistributed.
- **External 2**: Type 2 routes external to the AS are redistributed.
- **NSSA External 1**: Type 1 routes external to a not-so-stubby area (NSSA) are redistributed.
- **NSSA External 2**: Type 2 routes external to an NSSA are redistributed.

Note The default is match Internal, External 1, and External 2.

d) Select the RIP metric type to apply to the redistributed routes in the **Metric** drop-down list. The three choices are:

- **Transparent**: Use the current route metric.
- **Specified Value**: Assign a specific metric value from 0 to 16 in the **Metric Value** field.
- **None**: No metric is specified. Do not use any metric value, to apply to redistributed routes.

Note **None** option is applicable only for **Static** and **Connected** protocols.

e) (Optional) Enter the name of a route map that must be satisfied, in the **Route Map** field before the route can be redistributed into the RIP routing process. Routes are redistributed only if IP address matches an allow statement in the route map address list. To create a new route map object, click **Add** (+). See Configure Route Map Entry for the procedure to add a new route map.

f) Click **OK**.

Step 7 (Optional) Click **Filtering** to manage filters for the RIP policy. In this section, filters are used to prevent routing updates through an interface, control the advertising of routes in routing updates, control the processing of routing updates and filtering sources of routing updates.

a) Click **Add** to add RIP filters.

b) Select the type of traffic to be filtered - Inbound or Outbound in the **Traffic Direction** field.

Note If traffic direction is inbound, you can only define an Interface filter.

c) Specify whether the filter is based on an Interface or a Route, by selecting appropriate option in the **Filter On** field. If you click **Interface**, you can enter or choose the name of the interface on which routing updates are to be filtered. If you click **Route**, you can choose the route type:

- **Static**: Only static routes are filtered.
- **Connected**: Only connected routes are filtered.
- **OSPF**: Only OSPFv2 routes discovered by the specified OSPF process are filtered. Enter the Process ID of the OSPF process to be filtered.
- **BGP**: Only BGPv4 routes discovered by the specified BGP process are filtered. Enter the value in the **Process ID** field.
- **EIGRP**: Only EIGRP routes are filtered.

d) In the **Access List** field, enter or choose the name of one or more access control lists (ACLs) that define the networks to be allowed or removed from RIP route advertisements. To add a new standard access list object, click **Add** (+) and see Configure a standard ACL object, on page 2780.

e) Click **OK**.

Step 8 (Optional) Click **Broadcast** to add or edit interface configurations. Using Broadcast, you can override the global RIP versions to send or receive per interface. You can also define the authentication parameters per interface if you want to implement authentication to ensure valid RIP updates.

a) Click **Add** to add interface configurations.
b) Enter or choose an interface defined on this appliance in the **Interface** field.
c) In the Send option, select the appropriate boxes to specify sending updates using the RIP **Version 1**, **Version 2**, or both. These options let you override, for the specified interface, the global Send versions specified.
d) In the Receive option, select the appropriate boxes to specify accepting updates using the RIP **Version 1**, **Version 2**, or both. These options let you override, for the specified interface, the global Receive versions specified.
e) Select the **Authentication** used on this interface for RIP broadcasts.

- **None**: No authentication
- **MD5**: Employ MD5
- **Clear Text**: Employ clear-text authentication

If you choose MD5 or Clear Text, you must also provide the following authentication parameters.

- **Key ID**: The ID of the authentication key; valid values are from 0 to 255.
- **Key**: The key used by the chosen authentication method; can contain up to 16 characters.
- **Confirm**: Enter the authentication key again to confirm.

f) Click **OK**.

How RIP routing updates work

Summary

Key components in the RIP routing update process include:

- RIP routers: Send and receive routing update messages to maintain network topology information
- Routing tables: Store the best routes to destinations with associated metric values
- Routing update messages: Contain network topology changes and route information
- Metric values: Determine the best path, with routers maintaining only the lowest metric route

Workflow

The process involves these stages:

1. RIP routers send routing-update messages at regular intervals and when the network topology changes.

2. When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop.
3. RIP routers maintain only the best route to a destination, which is the route with the lowest metric value.
4. After updating its routing table, the router immediately begins transmitting routing updates to inform other network routers of the change. These updates occur independently from regularly scheduled RIP router updates.

RIP stability features

RIP stability features are routing mechanisms that

- prevent routing loops by setting a limit on the number of hops in a path from source to destination,
- provide stability despite potentially rapid changes in network topology, and
- include split horizon and hold-down mechanisms to prevent incorrect routing information propagation.

Additional stability mechanisms

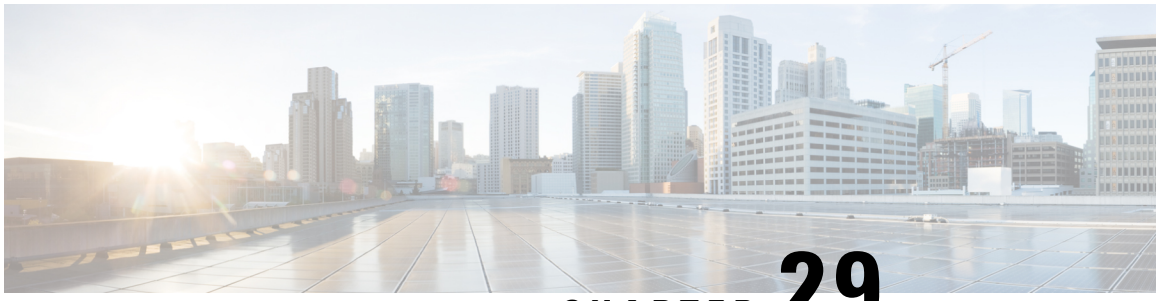
The maximum number of hops allowed in a path is 15. If a routing update shows a new or changed entry, the system increases the metric value to infinity (16), which makes the network destination unreachable. This stability mechanism limits the maximum diameter of a RIP network to fewer than 16 hops.

RIP timers

RIP timers are network protocol mechanisms that

- regulate RIP performance through timed intervals for routing updates and route management,
- control when routes are marked invalid, placed in holddown, or flushed from the routing table, and
- help prevent network congestion by managing the timing of routing updates across devices.

RIP timer stages



RIP uses numerous timers to regulate its performance. These are the timer stages for RIP:

- Update: The routing-update timer is the interval between periodic routing updates. This is how often the device sends routing updates. Generally, set to 30 seconds, a small random delay added to prevent simultaneous route updates.
- Invalid: Each routing table entry has a route-timeout timer for the last valid update. The route is marked invalid and moves to holddown once the timer expires. The default is 180 seconds (3 minutes).
- Holddown: The period the system waits before accepting any new updates for invalid routes. The default is 180 seconds (3 minutes).
- Flush: The route-flush timer marks the period from when the system receives the last valid update until the route is discarded and removed from the routing table. The default is 240 seconds (4 minutes).

RIP timer sequence when adjacent router interface goes down

When an adjacent router goes down, routing updates stop, and the Invalid and Flush timers start increasing. In the first 180 seconds, nothing will happen. After 180 seconds, the Invalid timer expires, marks the route invalid, and the Holddown timer begins, holding the route for 60 seconds.

If there is no routing update for the adjacent router's status (that is, it is still down), the route enters into the Flush state. In total, the system has waited for 240 seconds from the last update (180 seconds for the Invalid timer and 60 seconds for Holddown timer), and then the system flushes the route. Even if the adjacent router's interface comes up immediately, the system waits for the Holddown timer to complete the 120-second period before accepting updates.

CHAPTER 29

Multicast

This chapter describes how to configure the Secure Firewall Threat Defense device to use the multicast routing protocol.

- Multicast routing, on page 1301
- Prerequisites for Multicast Routing, on page 1306
- Guidelines for multicast routing, on page 1307
- Limitations for multicast routing over an SVTI tunnel, on page 1309
- Configure IGMP features, on page 1309
- Configure PIM features, on page 1315
- Configure multicast routes, on page 1321
- Configure multicast boundary filters, on page 1322
- Verify multicast routing over an SVTI tunnel, on page 1323
- Troubleshoot multicast routing over an SVTI tunnel, on page 1324

Multicast routing

Multicast routing is a bandwidth-conserving technology that reduces traffic by simultaneously delivering a single stream of information to thousands of corporate recipients and homes. Applications include videoconferencing, corporate communications, distance learning, and distributing software, stock quotes, and news.

Multicast routing applications and protocols

Multicast routing protocols send source traffic to multiple receivers efficiently, without adding extra load on the source or receivers, and use less network bandwidth than other technologies. Multicast packets are replicated in the network by Firewall Threat Defense device enabled with Protocol Independent Multicast (PIM) and other supporting multicast protocols, which results in the most efficient delivery of data to multiple receivers possible.

The Firewall Threat Defense device supports both stub multicast routing and PIM multicast routing. However, you cannot configure both concurrently on a single Firewall Threat Defense device.

Note The UDP and non-UDP transports are both supported for multicast routing. However, the non-UDP transport has no FastPath optimization.

IGMP Protocol

IP hosts use the Internet Group Management Protocol (IGMP) to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IGMP uses group addresses (Class D IP address) as group identifiers. Host group address can be in the range of 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is never assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

Note When you enable multicast routing on the Firewall Threat Defense device, IGMP Version 2 is automatically enabled on all interfaces.

Query Messages to Multicast Groups

The Firewall Threat Defense device sends query messages to discover which multicast groups have members on the networks attached to the interfaces. Members respond with IGMP report messages indicating that they want to receive multicast packets for specific groups. Query messages are addressed to the all-systems multicast group, which has an address of 224.0.0.1, with a time-to-live value of 1.

These messages are sent periodically to refresh the membership information stored on the Firewall Threat Defense device. If the Firewall Threat Defense device discovers that there are no local members of a multicast group still attached to an interface, it stops forwarding multicast packets for that group to the attached network, and it sends a prune message back to the source of the packets.

By default, the PIM designated router on the subnet is responsible for sending the query messages. By default, they are sent once every 125 seconds.

When changing the query response time, by default, the maximum query response time advertised in IGMP queries is 10 seconds. If the Firewall Threat Defense device does not receive a response to a host query within this amount of time, it deletes the group.

Stub multicast routing

Stub multicast routing provides dynamic host registration and facilitates multicast routing.

When configured for stub multicast routing, the Firewall Threat Defense device acts as an IGMP proxy agent. Instead of fully participating in multicast routing, the Firewall Threat Defense device forwards IGMP messages to an upstream multicast router, which sets up delivery of the multicast data. When configured for stub multicast routing, the Firewall Threat Defense device cannot be configured for PIM sparse or bidirectional mode. Enable PIM on the interfaces that participate in IGMP stub multicast routing.

The Firewall Threat Defense device supports both PIM-SM and bidirectional PIM. PIM-SM is a multicast routing protocol that uses the underlying unicast routing information base or a separate multicast-capable routing information base. It builds unidirectional shared trees, each rooted at a single Rendezvous Point (RP) per multicast group. Optionally, it creates shortest-path trees for each multicast source.

PIM multicast routing

Bidirectional PIM is a variant of PIM-SM that builds bidirectional shared trees connecting multicast sources and receivers.

DF election process

Bidirectional trees are built using a Designated Forwarder (DF) election process operating on each link of the multicast topology. With the assistance of the DF, multicast data is forwarded from sources to the Rendezvous Point (RP) and then along the shared tree to receivers. This process does not require source-specific state. The DF election takes place during RP discovery and provides a default route to the RP.

Note If the Firewall Threat Defense device is the PIM RP, use the untranslated outside address of the Firewall Threat Defense device as the RP address.

PIM sparse mode

PIM Sparse Mode (PIM-SM) is a PIM mode that forwards traffic only when specifically requested by receivers. It uses a central Rendezvous Point (RP) to coordinate the multicast traffic forwarding between the multicast source and the destination. RP is a router that serves as the meeting point for the source and the receivers. Multicast sources register with the RP through their first hop router. They send a copy of the multicast traffic to the receivers through the RP.

PIM source specific multicast support

Firewall Threat Defense device can forward source specific multicast traffic (e.g., for groups in the 232.x.x.x range) even though they do not support PIM-SSM configuration or Internet Group Management Protocol version 3 (IGMPv3).

SSM is classified as a data delivery mechanism for one-to-many applications such as IPTV. The SSM model uses a concept of "channels" denoted by an (S,G) pair, where S is a source address and G is an SSM destination address. Subscribing to a channel is achieved by using a group management protocol such as IGMPv3. SSM enables a receiving client, once it has learned about a particular multicast source, to receive multicast streams directly from the source rather than receiving it from a shared Rendezvous Point (RP). Access control mechanisms are introduced within SSM, providing a security enhancement that is not available with current sparse or sparse-dense mode implementations.

Limitation:

- Firewall Threat Defense device cannot act as the last-hop router for SSM multicast because it does not support IGMPv3 (which receivers use to join SSM groups).

  If the Firewall Threat Defense device is the last-hop, it will ignore IGMPv3 join messages from receivers for SSM groups, and SSM forwarding will not work.

- Static multicast routes on Firewall Threat Defense device do not work for SSM range (232.x.x.x).

Workaround:

For Cisco Firewall Threat Defense device firewall to forward SSM-related multicast traffic, you must add a multicast-capable layer 3 device (such as a router or switch) that supports PIM and IGMPv3 on the same network segment as the receivers.

How it Works:

- Receivers register their SSM group joins (IGMPv3) with this layer 3 device.
- This layer 3 device sends PIM join messages towards the Firewall Threat Defense device.
- The Firewall Threat Defense device receives these PIM messages and dynamically learns multicast routes.
- SSM multicast traffic is then properly forwarded by the Firewall Threat Defense device, since it is no longer the last-hop device.

Multicast Bidirectional PIM

Multicast bidirectional PIM is useful for networks that have many sources and receivers talking to each other simultaneously and where each participant can become both the source and receiver of multicast traffic, such as in videoconferencing, Webex meetings, and group chat. When PIM bidirectional mode is used, the RP only creates the (*,G) entry for the shared tree. There is no (S,G) entry. This conserves resources on the RP because state tables for each (S,G) entry are not maintained.

In PIM sparse mode, traffic only flows down the shared tree. In PIM bidirectional mode, traffic flows up and down the shared tree.

PIM bidirectional mode also does not use the PIM register/register-stop mechanism to register sources to the RP. Each source can begin sending to the source at any time. When the multicast packets arrive at the RP, they are forwarded down the shared tree (if there are receivers) or dropped (when there are no receivers). However, there is no way for the RP to tell the source to stop sending multicast traffic.

Design-wise you must think about where to place the RP in your network because it should be somewhere in the middle between the sources and receivers in the network.

PIM bidirectional mode has no Reverse Path Forwarding (RPF) check. Instead it uses the concept of a Designated Forwarder (DF) to prevent loops. This DF is the only router on the segment that is allowed to send multicast traffic to the RP. If there is only one router per segment that forwards multicast traffic, there will be no loops. The DF is chosen using the following mechanism:

- The router with the lowest metric to the RP is the DF.
- If the metric is equal, then the router with the highest IP address becomes the DF.

PIM bootstrap router (BSR)

PIM Bootstrap Router (BSR) is a dynamic Rendezvous Point (RP) selection model that uses candidate routers for RP function and for relaying the RP information for a group.

The RP function includes RP discovery and provides a default route to the RP. It does this by configuring a set of devices as candidate BSRs (C-BSR) which participate in a BSR election process to choose a BSR amongst themselves. Once the BSR is chosen, devices that are configured as candidate Rendezvous Points (C-RP) start sending their group mapping to the elected BSR. The BSR then distributes the group-to-RP mapping information to all the other devices down the multicast tree through BSR messages that travel from PIM router to PIM router on a per-hop basis.

This feature allows networks to learn RPs dynamically. Dynamic RP discovery is essential in large, complex networks where an RP may occasionally go down and come up.

PIM bootstrap router (BSR) terminology

This reference provides definitions for key terminology used in PIM Bootstrap Router (BSR) configurations to help understand the roles and functions of different components in the BSR election and RP advertisement process.

These terms are frequently referenced in the PIM BSR configuration:

- Bootstrap Router (BSR) — A BSR advertises Rendezvous Point (RP) information to other routers with PIM on a hop-by-hop basis. Among multiple Candidate-BSRs, a single BSR is chosen after an election process. The primary purpose of this Bootstrap router is to collect all Candidate-RP (C-RP) announcements in to a database called the RP-set and to periodically send this out to all other routers in the network as BSR messages (every 60 seconds).
- Bootstrap Router (BSR) messages — BSR messages are multicast to the All-PIM-Routers group with a TTL of 1. All PIM neighbors that receive these messages retransmit them (again with a TTL of 1) out of all interfaces except the one in which the messages were received. BSR messages contain the RP-set and the IP address of the currently active BSR. This is how C-RPs know where to unicast their C-RP messages.
- Candidate Bootstrap Router (C-BSR) — A device that is configured as a candidate-BSR participates in the BSR election mechanism. A C-BSR with highest priority is elected as the BSR. The highest IP address of the C-BSR is used as a tiebreaker. The BSR election process is preemptive, for example if a new C-BSR with a higher priority comes up, it triggers a new election process.
- Candidate Rendezvous Point (C-RP) — An RP acts as a meeting place for sources and receivers of multicast data. A device that is configured as a C-RP periodically advertises the multicast group mapping information directly to the elected BSR through unicast. These messages contain the Group-range, C-RP address, and a hold time. The IP address of the current BSR is learned from the periodic BSR messages that are received by all routers in the network. In this way, the BSR learns about possible RPs that are currently up and reachable.

Note The Firewall Threat Defense device does not act as a C-RP, even though the C-RP is a mandatory requirement for BSR traffic. Only routers can act as a C-RP. So, for BSR testing functionality, you must add routers to the topology.

- BSR Election Mechanism — Each C-BSR originates Bootstrap messages (BSMs) that contain a BSR Priority field. Routers within the domain flood the BSMs throughout the domain. A C-BSR that hears about a higher-priority C-BSR than itself suppresses its sending of further BSMs for some period of time. The single remaining C-BSR becomes the elected BSR, and its BSMs inform all the other routers in the domain that it is the elected BSR.

Multicast group concept

Multicast is based on the concept of a group. An arbitrary group of receivers expresses an interest in receiving a particular data stream. This group does not have any physical or geographical boundaries. Hosts can be

located anywhere on the Internet. Hosts that want to receive data sent to a group must join the group using IGMP.

Group membership requirements

Hosts must be a member of the group to receive the data stream.

Multicast Addresses

Multicast addresses specify an arbitrary group of IP hosts that have joined the group and want to receive traffic sent to this group.

Clustering

Multicast routing supports clustering. In Spanned EtherChannel clustering, the control unit sends all multicast routing packets and data packets until fast-path forwarding is established.

After fast-path forwarding is established, data units may forward multicast data packets. All data flows are full flows. Stub forwarding flows are also supported. Because only one unit receives multicast packets in Spanned EtherChannel clustering, redirection to the control unit is common.

Multicast routing over static virtual tunnel interface tunnel

You can securely deliver real-time multicast applications, such as video streaming, financial data feeds, and data replication over your VPN infrastructure by using IPsec tunnels configured with static VTI. Use this feature to ensure confidentiality, integrity, and compliance with security policies.

Key characteristics

Multicast routing over VPN supports PIM-SM, BSR-based RP discovery, and IGMP forward over encrypted tunnels. The source transmits multicast traffic through the static VTI tunnel.

Note We recommend that you configure the First Hop Router (FHR) as the RP.

Prerequisites for Multicast Routing

Model support

Firewall Threat Defense

Firewall Threat Defense Virtual

Supported domains

Any

User roles

- Administrator
- Network Admin

Prerequisites for multicast routing over static tunnel virtual interface

- Firewall Threat Defense device must be Version 10.1.
- Management Center Essentials (formerly Base) license must allow export-controlled functionality. Choose **Administration** > **Licenses** > **Smart Licenses** to verify this in Management Center.
- Ensure that you configure a Rendezvous Point (RP).

  RP IP address must be reachable throughout the multicast network.
- Create static tunnel virtual interfaces (SVTIs) on the Firewall Threat Defense devices and configure a route-based VPN topology using these interfaces.
- Configure basic routing and access control policies to route traffic between the SVTI tunnels.
  - Ensure that you have a multicast source sending traffic to the Firewall Threat Defense devices.
  - Ensure unicast routing is available between the multicast source and the receiver.
- You do not have to configure security levels on the interfaces of the Firewall Threat Defense devices.

Guidelines for multicast routing

Table 83: System requirements

Item	Description
Context mode	Supported in single context mode.
Firewall mode	Supported only in routed firewall mode. Transparent firewall mode is not supported.
IPv6	IPv6 is not supported.
Multicast group	The range of addresses from 224.0.0.0 to 224.0.0.255 is reserved for routing protocols and other topology discovery or maintenance protocols, such as gateway discovery and group membership reporting. Internet multicast routing from the 224.0.0/24 address range is not supported. When multicast routing is enabled for reserved addresses, an IGMP group is not created.
Clustering	In clustering, for IGMP and PIM, this feature is only supported on the primary unit.

Access control configuration

You must configure an access control or prefilter rule on the inbound security zone to allow traffic to the multicast host, such as 224.1.2.3. However, you cannot specify a destination security zone for the rule, or it cannot be applied to multicast connections during initial connection validation.

Interface and protocol management

Ensure proper configuration management when working with PIM-enabled interfaces and multicast routing protocols.

- You cannot disable an interface with PIM configured on it. If you have configured PIM on the interface (see Configure PIM protocol, on page 1315), disabling the multicast routing and PIM does not remove the PIM configuration. You must remove (delete) the PIM configuration to disable the interface.
- Multicast routing is not supported in ECMP.
- Do not configure Firewall Threat Defense to simultaneously be a Rendezvous Point (RP) and a First Hop Router.
- The HSRP standby IP address does not participate in PIM neighborship. If the RP router IP is routed through the HSRP standby IP address, multicast routing does not work in Firewall Threat Defense. To ensure multicast traffic passes through successfully, configure the route for the RP address to use an interface IP address rather than the HSRP standby IP address.
- For a device using virtual routing, you can configure multicast only for its global virtual router and not for its user-defined virtual router.

Guidelines for multicast routing over an SVTI tunnel

We recommend these configurations for multicast routing over an SVTI tunnel:

- Configure the first hop router as the Rendezvous Point (RP).
- Configure the Firewall Threat Defense device as an RP only when it operates as an first hop router.
- Use a loopback interface as the RP IP address. You can also use an SVTI IP address as an RP.

  Configure two loopback interfaces: one for the SVTI (IP unnumbered) and the other one for the PIM RP.

Ensure that you review these guidelines for multicast routing over an SVTI tunnel:

- For PIM-SM, ensure that you have configured an RP.
- Ensure that the RP is located near to the multicast source.
- For an external RP in a dynamic RP deployment, Bootstrap Router (BSR) is supported.
- Configure the IGMP forward interface on the ingress interface of the last hop router that points to the tunnel interface.

Note IGMP forwarding to tunnel interfaces is supported only on physical interfaces and subinterfaces.

Limitations for multicast routing over an SVTI tunnel

Protocol and addressing limitations

Review these protocol and addressing restrictions when implementing multicast routing over SVTI tunnels.

- IPv6 address in the overlay is not supported.

  An IPv6 address in the overlay is not supported. However, using an IPv6 address as the underlay in an SVTI tunnel with IPv4 multicast routing is supported.

- PIM Dense Mode (PIM-DM) is not supported.

Interface, clustering, and failover limitations

Review these interface, clustering, and failover restrictions for multicast routing over IPsec tunnels.

- Multicast routing over IPsec tunnels with dynamic VTI (DVTI) is not supported.
- Multicast routing over IPsec tunnels with static VTI does not support clustering.
- RP failover with a global RP is not supported. If multiple RPs are configured, RP does not failover to global RP.
- When using static VTIs, backup multicast path failover through the underlay is not supported.
- Switchover events may result in transient packet loss.

Routing limitations

Review these routing limitations that affect multicast routing over SVTI tunnels.

- ECMP, traffic-zone multicast routing, multicast boundary filtering, and Bidirectional Forwarding Detection (BFD) over static VTI are not supported.
- A static mroute does not support SVTI as next-hop or outgoing interface.
- You cannot advertise Threat Defense device as a Candidate Rendezvous Point (C-RP).
- Dynamic SLA-based multipath and fallback are not supported. IPSLA-based failover is supported with static route.

Configure IGMP features

Configure IGMP features to enable dynamic registration of individual hosts in multicast groups on a particular LAN and to manage multicast traffic efficiently.

IP hosts use IGMP to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IP hosts use IGMP to report their group memberships to directly connected multicast routers. IGMP dynamically registers individual hosts in a multicast group on a specific LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

This section describes how to configure optional IGMP settings on a per-interface basis.

Procedure

Step 1 Enable multicast routing, on page 1310.

Step 2 Configure IGMP protocol, on page 1311.

Step 3 Configure IGMP access groups, on page 1312.

Step 4 Configure IGMP static groups, on page 1313.

Step 5 Configure IGMP join groups, on page 1314.

Enable multicast routing

Enable multicast routing to allow the device to forward multicast traffic using Internet Group Management Protocol (IGMP) and Protocol Independent Multicast (PIM) protocols on all interfaces.

Enabling multicast routing on the Firewall Threat Defense device, enables IGMP and PIM on all interfaces by default. IGMP is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. PIM is used to maintain forwarding tables to forward multicast datagrams.

Note Only the UDP transport layer is supported for multicast routing.

These are the maximum number of entries for specific multicast tables. Any new entries are discarded when these limits are reached.

- Multicast Forwarding Information Base (MFIB): 30,000
- IGMP Groups: 30,000
- PIM Routes: 72,000

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 Check the **Enable Multicast Routing** check box.

Checking this check box enables IP multicast routing on the device. Unchecking it disables IP multicast routing. By default, multicast is disabled. Enabling multicast routing enables multicast on all interfaces.

You can disable multicast on a per-interface basis. This is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the Firewall Threat Defense device from sending host query messages on that interface.

Configure IGMP protocol

Use this task to configures IGMP parameters per-interface. These settings help manage multicast group membership on a Firewall Threat Defense device.

You can configure IGMP parameters per interface, such as the forward interface, query messages, and time intervals.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 Click the **Protocol** tab and click **Add**, or edit an interface.

In the **Add IGMP parameters** dialog box, configure new IGMP parameters to the Firewall Threat Defense device. Use the **Edit IGMP parameters** dialog box to modify the existing parameters.

Step 4 Configure these parameters:

- **Interface**: From the drop-down list, choose the interface for which you want to configure IGMP protocol.
- **Enable IGMP**: Check the check box to enable IGMP.

Note Disabling IGMP on specific interfaces is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the device from sending host query messages on that interface.

- **Forward Interface**: From the drop-down list, choose the specific interface from which you want to forward IGMP messages. You can choose a static virtual interface (SVTI) to enable secure delivery of multicast applications over your VPN infrastructure.

  This configures the Secure Firewall Threat Defense device to act as an IGMP proxy agent and forward IGMP messages from hosts connected on one interface to an upstream multicast router on another interface.

- **Version**: Choose IGMP Version 1 or 2.

  By default, the Firewall Threat Defense device runs IGMP Version 2, which enables several additional features.

Note All multicast routers on a subnet must support the same version of IGMP. The Firewall Threat Defense device does not automatically detect Version 1 routers and switch to Version 1. However, you can have a mix of IGMP Version 1 and 2 hosts on the subnet; the Firewall Threat Defense device running IGMP Version 2 works correctly when IGMP Version 1 hosts are present.

- **Query Interval**: The interval in seconds at which the designated router sends IGMP host-query messages. The range is 1 to 3600. The default is 125.

Note If the Firewall Threat Defense device does not hear a query message on an interface for the specified timeout value, then the device becomes the designated router and starts sending the query messages.

- **Response Time**: The interval in seconds before the Firewall Threat Defense device deletes the group. The range is 1 to 25. The default is 10.

  If the Firewall Threat Defense device does not receive a response to a host query within this amount of time, it deletes the group.

- **Group Limit**: Maximum number of hosts that can join on an interface. The range is 1 to 500. The default is 500.

  You can limit the number of IGMP states resulting from IGMP membership reports on a per-interface basis. Membership reports that exceed the configured limits are not entered in the IGMP cache, and their traffic is not forwarded.

- **Query Timeout**: The period of time in seconds before which the Firewall Threat Defense device takes over as the requester for the interface after the previous requester has stopped. The range is 60 to 300. The default is 255.

Step 5 Click **OK** to save the IGMP protocol configuration.

Configure IGMP access groups

You can control access to multicast groups by using access control lists.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **Access Group**.

Step 3 On **Access Group**, click **Add** or **Edit**.

Use the **Add IGMP Access Group parameters** dialog box to add new IGMP access groups to the Access Group table. Use the **Edit IGMP Access Group parameters** dialog box to change the parameters of an existing access group.

Step 4 Configure the access group options:

a) From the **Interface** drop-down list, choose the interface associated with the access group. You cannot change the associated interface when you are editing an existing access group.

b) Click one of the following:

- **Standard Access List**: From the **Standard Access List** drop-down list, choose the standard ACL or click **Add** (+) to create a new standard ACL. For more information, refer to Configure a standard ACL object, on page 2780.
- **Extended Access List**: From the **Extended Access List** drop-down list, choose the extended ACL or click **Add** (+) to create a new extended ACL. For more information, refer to Configure an extended ACL object, on page 2775.

Step 5 Click **OK** to save the access group configuration.

Configure IGMP static groups

Configure a statically joined IGMP group to enable multicast traffic for that group to be sent to a network segment even when group members cannot report membership or no members exist on the segment.

Sometimes a group member cannot report its membership in the group or there may be no members of a group on the network segment, but you still want multicast traffic for that group to be sent to that network segment. You can have multicast traffic for that group sent to the segment by configuring a statically joined IGMP group. With this method, the Firewall Threat Defense device does not accept the packets itself, but only forwards them. Therefore, this method allows fast switching. The outgoing interface appears in the IGMP cache, but this interface is not a member of the multicast group.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 On **Static Group**, click **Add** or **Edit**.

Use the **Add IGMP Static Group parameters** dialog box to statically assign a multicast group to an interface. Use the **Edit IGMP Static Group parameters** dialog box to change existing static group assignments.

Note The IGMP Static Group enables PIM to send *Join* requests towards the sources or towards the Rendezvous Point (RP), provided, the firewall with this command is the PIM Designated Router (DR) on that interface where the command is applied.

Step 4 Configure the following options:

- From the **Interface** drop-down list, choose the interface to which you want to statically assign a multicast group. If you are editing an existing entry, you cannot change the value.
- From the **Multicast Group** drop-down list, choose the multicast group to which you want to assign the interface, or click **Add** (+) to create a new multicast group. Refer to Creating Network Objects for the procedure.

Step 5 Click **OK** to save the static group configuration.

Configure IGMP join groups

You can configure an interface to be a member of a multicast group.

Configuring the Firewall Threat Defense device to join a multicast group, upstream routers maintain multicast routing table information for that group and keep the group's paths active.

Note Refer to Configure IGMP static groups, on page 1313 if you want to forward multicast packets for a specific group to an interface without the Firewall Threat Defense device accepting those packets as part of the group.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 On **Join Group**, click **Add** or **Edit**.

Use the **Add IGMP Join Group parameters** dialog box to configure the Firewall Threat Defense device to be a member of a multicast group. Use the **Edit IGMP Join Group parameters** dialog box to change existing parameters.

Note The IGMP Join Group enables PIM to send *Join* requests to sources or to the Rendezvous Point (RP) if the firewall with this command is the PIM Designated Router (DR) on that interface.

Step 4 Configure the following options:

- From the **Interface** drop-down list, choose the interface you want to be a member of a multicast group. If you are editing an existing entry, you cannot change the value.
- From the **Join Group** drop-down list, choose the multicast group to which you want to assign the interface, or click **Plus** to create a new multicast group. Refer to Creating Network Objects for the procedure.

Configure PIM features

This section describes how to configure optional PIM settings.

Routers use PIM to maintain forwarding tables to use for forwarding multicast diagrams. Enable multicast routing on the Secure Firewall Threat Defense device, to automatically enable IGMP and PIM on all interfaces.

Note PIM is not supported with PAT. The PIM protocol does not use ports, and PAT only works with protocols that use ports.

Procedure

Step 1 Configure PIM protocol, on page 1315.
Step 2 Configure PIM neighbor filters, on page 1316.
Step 3 Configure PIM bidirectional neighbor filters, on page 1317.
Step 4 Configure PIM rendezvous points, on page 1318.
Step 5 Configure PIM route trees, on page 1319.
Step 6 Configure PIM request filters, on page 1320.
Step 7 Configure multicast boundary filters, on page 1322.

Configure PIM protocol

You can enable or disable PIM on a specific interface.

You can also configure the Designated Router (DR) priority. The DR is responsible for sending PIM register, join, and prune messages to the RP. When there is more than one multicast router on a network segment, the DR is chosen based on DR priority. If multiple devices share the same DR priority, the device with the highest IP address becomes the DR. By default, the Firewall Threat Defense device has a DR priority of 1.

Router query messages are used to choose the PIM DR. The PIM DR is responsible for sending router query messages. By default, router query messages are sent every 30 seconds. Additionally, every 60 seconds, the Firewall Threat Defense device sends PIM join or prune messages.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.
Step 3 Click the **Protocol** tab and click **Add**, or edit an interface.

In the **Add PIM parameters** dialog box, add new PIM parameters for the interface. Use the **Edit PIM parameters** dialog box to change existing parameters.

Step 4 Configure these options:

- **Interface**: From the drop-down list, select the interface for which you want to configure PIM protocol. You can choose a static virtual interface (SVTI) to enable secure delivery of multicast applications over your VPN infrastructure.
- **Enable PIM**: Check the check box to enable PIM.
- **DR Priority**: Set the DR priority value for the selected interface. The router with the highest DR priority on the subnet becomes the designated router.
- **Hello Interval(seconds)**: The interval in seconds at which the interface sends PIM hello messages. The range is 1 to 3600. The default is 30.
- **Join Prune Interval(seconds)**: The interval in seconds at which the interface sends PIM join and prune advertisements. The range is 10 to 600. The default is 60.

Step 5 Click **OK** to save the PIM protocol configuration.

Configure PIM neighbor filters

You can define and filter the routers that become Protocol Independent Multicast (PIM) neighbors.

PIM neighbor filters allow you to define and filter the routers that become Protocol Independent Multicast (PIM) neighbors to:

- Prevent unauthorized routers from becoming PIM neighbors.
- Prevent attached stub routers from participating in PIM.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 Click the **Neighbor Filter** tab and click **Add**, or edit an interface.

In the **Add PIM Neighbor Filter** dialog box, add new PIM neighbor filters to the interface. Use the **Edit PIM Neighbor Filter** dialog box to change existing parameters.

Step 4 Configure these options:

- From the **Interface** drop-down list, choose the interface to which you want to add a PIM neighbor filter. You can choose a static virtual interface (SVTI) to enable secure delivery of multicast applications over your VPN infrastructure.
- From the **Standard Access List** drop-down list, choose a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2780 for the procedure.

Note Choosing **Allow** on the **Add Standard Access List Entry** dialog box lets the multicast group advertisements pass through the interface. Choosing **Block** prevents the specified multicast group advertisements from passing through the interface. When a multicast boundary is configured on an interface, all multicast traffic is prevented from passing through the interface unless permitted with a neighbor filter entry.

Step 5 Click **OK** to save the PIM neighbor filter configuration.

Configure PIM bidirectional neighbor filters

Configure PIM bidirectional neighbor filters to control which neighbor devices participate in the Designated Forwarder (DF) election for bidirectional multicast routing. This helps ensure proper multicast traffic forwarding in the network.

A PIM bidirectional neighbor filter is an ACL that defines the neighbor devices that can participate in the Designated Forwarder (DF) election. If you do not configure a PIM bidirectional neighbor filter for an interface, there are no restrictions. If you configure a PIM bidirectional neighbor filter, only neighbors permitted by the ACL can participate in the DF election process.

Bidirectional PIM allows multicast routers to keep reduced state information. All multicast routers in a segment must be bidirectionally enabled to elect a DF.

When a PIM bidirectional neighbor filter is enabled, the routers permitted by the ACL are considered to be bidirectionally capable. Therefore, the following is true:

- If a permitted neighbor does not support bidirectional mode, the DF election does not occur.
- If a denied neighbor supports bidirectional mode, the DF election does not occur.
- If a denied neighbor does not support bidirectional mode, the DF election can occur.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Multicast Routing** > **PIM**.

Step 3 On **Bidirectional Neighbor Filter**, click **Add** or **Edit**.

Use the **Add PIM Bidirectional Neighbor Filter** dialog box to create ACL entries for the PIM bidirectional neighbor filter ACL. Use the **Edit PIM Bidirectional Neighbor Filter** dialog box to change existing parameters.

Step 4 Configure these options:

- In the **Interface** drop-down list, select the interface for which you want to configure the PIM bidirectional neighbor filter ACL entry. You can choose a static virtual interface (SVTI) to enable secure delivery of multicast applications over your VPN infrastructure.

- From the **Standard Access List** drop-down list, select a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2780 for the procedure.

Note Choosing **Allow** in the **Add Standard Access List Entry** dialog box lets the specified devices participate in the DR election process. Choosing **Block** prevents the specified devices from participating in the DR election process.

Step 5 Click **OK** to save the PIM bidirectional neighbor filter configuration.

Configure PIM rendezvous points

You can configure the Firewall Threat Defense device to serve as a RP to more than one group.

The group range specified in the ACL determines the PIM RP group mapping. If an ACL is not specified, then the RP for the group is applied to the entire multicast group range (224.0.0.0/4). Refer to Multicast Bidirectional PIM, on page 1304 for more information about bidirectional PIM.

These restrictions apply to RPs:

- You cannot use the same RP address twice.
- You cannot specify **All Groups** for more than one RP.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Rendezvous Points**, click **Add** or **Edit**.

Use the **Add Rendezvous Point** dialog box to create a new entry in the Rendezvous Point table. Use the **Edit Rendezvous Point** dialog box to modify existing parameters.

Step 4 Configure these options:

- From the **Rendezvous Point IP address** drop-down list, choose the IP address that you want to add as an RP or click **Add** (+) to create a new network object. Refer to Creating Network Objects for the procedure.

  We recommend that you configure the IP address as the SVTI tunnel IP address of the FTD device. You can also use the IP address of a loopback interface.

- Check the **Use bi-directional forwarding** check box to enable bidirectional mode for the specified multicast groups. In this mode, if the Firewall Threat Defense device receives a multicast packet and has no directly connected members or PIM neighbors present, it sends a prune message back to the source.
- Click **Use this RP for all Multicast Groups** to use the specified RP for all multicast groups on the interface.

- Click **Use this RP for all Multicast Groups as specified below** to designate the multicast groups to use with the specified RP and then from the **Standard Access List** drop-down list, choose a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2780 for the procedure.

Step 5 Click **OK** to save the rendezvous point configuration.

Configure PIM route trees

Configure PIM route trees to control whether the Firewall Threat Defense device joins the shortest-path tree or uses the shared tree for multicast traffic routing.

By default, PIM leaf routers join the shortest-path tree immediately after the first packet arrives from a new source. This method reduces delay, but requires more memory than the shared tree. You can configure whether or not the Firewall Threat Defense device should join the shortest-path tree or use the shared tree, either for all multicast groups or only for specific multicast addresses.

The shortest-path tree is used for any group that is not specified in the Multicast Groups table. The Multicast Groups table displays the multicast groups to use with the shared tree. The table entries are processed from the top down. You can create an entry that includes a range of multicast groups, but excludes specific groups within that range by placing deny rules for the specific groups at the top of the table and the permit rule for the range of multicast groups below the deny statements.

Note This behavior is known as Shortest Path Switchover (SPT). We recommend that you always use the Shared Tree option.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Route Tree**, select the path for the route tree:

- Click **Shortest Path** to use the shortest-path tree for all multicast groups.
- Click **Shared Tree** to use the shared tree for all multicast groups.
- Click **Shared tree for below mentioned group** to designate the groups specified in the Multicast Groups table, and then from the **Standard Access List** drop-down list, select a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2780 for the procedure.

Step 4 Click **OK** to save the route tree configuration.

Configure PIM request filters

When the Firewall Threat Defense device is acting as an RP, you can restrict specific multicast sources from registering with it to prevent unauthorized sources from registering with the RP. You can define the multicast sources from which the Firewall Threat Defense device will accept PIM register messages.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Request Filter**, define the multicast sources that are allowed to register with the Firewall Threat Defense device when it acts as an RP:

- From the **Filter PIM register messages using:** drop-down list select **None**, **RouteMap**, or **Access List**.
- If you choose **Access List** from the drop-down list, select an extended ACL or click **Add** (+) to create a new extended ACL. Refer to Configure an extended ACL object, on page 2775 for the procedure.

Note In the **Add Extended Access List Entry** dialog box, select **Allow** from the drop-down list to create a rule that allows the specified source of the specified multicast traffic to register with the Firewall Threat Defense device, or select **Block** to create a rule that prevents the specified source of the specified multicast traffic from registering with the device.

- If you choose **RouteMap**, select a route map from the **Route Map** drop-down list, or click **Add** (+) to create a new route map. Refer to Creating Network Objects for the procedure.

Step 4 Click **OK** to save the request filter configuration.

Configure the Firewall Threat Defense device as a candidate bootstrap router

You can configure the Firewall Threat Defense device as a candidate BSR.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Bootstrap Router**, check the **Configure this FTD as a Candidate Bootstrap Router (C-BSR)** check box to perform the C-BSR setup.

a) From the **Interface** drop-down list, select the interface in the Firewall Threat Defense device from which the BSR address is derived to make it a candidate. You can choose a static virtual interface (SVTI) to enable secure delivery of multicast applications over your VPN infrastructure.

This interface must be enabled with PIM.

b) In the **Hashmask Length** field, enter the length of a mask (32 bits maximum) that is to be ANDed with the group address before the hash function is called. All groups with the same seed hash (correspond) to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. This allows you to configure one RP for multiple groups. The range is 0 to 32.

c) In the **Priority** field, enter the priority of the candidate BSR. The BSR with the larger priority is preferred. If the priority values are the same, the router with the larger IP address is the BSR. The range is 0 to 255. The default value is 0.

Step 4 (Optional) Click **Add** (+) to select an interface on which no PIM BSR messages will be sent or received in the **Configure this FTD as a Border Bootstrap Router (BSR)** section.

- From the **Interface** drop-down list, select the interface on which no PIM BSR messages will be sent or received. You can choose a static virtual interface (SVTI) to enable secure delivery of multicast applications over your VPN infrastructure.

  RP or BSR advertisements are filtered effectively isolating two domains of RP information exchange.

- Check the **Enable Border BSR** check box to enable BSR.

Step 5 Click **OK** to save the bootstrap router configuration.

Configure multicast routes

Configure static multicast routes to separate multicast traffic from unicast traffic. For example, when a path between a source and destination does not support multicast routing, the solution is to configure two multicast devices with a GRE tunnel between them and to send the multicast packets over the tunnel.

When using PIM, the Firewall Threat Defense device expects to receive packets on the same interface where it sends unicast packets back to the source. In some cases, such as bypassing a route that does not support multicast routing, you may want unicast packets to take one path and multicast packets to take another.

Static multicast routes are not advertised or redistributed.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **Multicast Routes** > **Add or Edit**.

Use the **Add Multicast Route Configuration** dialog box to add a new multicast route to the Firewall Threat Defense device. Use the **Edit Multicast Route Configuration** dialog box to change an existing multicast route.

Step 3 Choose an existing network from the **Source Network** drop-down, or click **Add** (+) to add a new network.

Refer to Creating Network Objects for the procedure.

Step 4 To configure an interface to forward the route, click **Interface** and configure the following options:

- From the **Source Interface** drop-down list, choose the incoming interface for the multicast route.
- From the **Output Interface/Dense** drop-down list, choose the destination interface that the route is forwarded through.
- In the **Distance** field, enter the distance of the multicast route. The range is 0 to 255.

Step 5 To configure an RPF address to forward the route, click **Address** and configure the following options:

- In the **RPF Address** field, enter the IP address for the multicast route.
- Enter the multicast route distance in the **Distance** field. The value must be between 0 and 255.

Step 6 Click **OK** to save the multicast routes configuration.

Configure multicast boundary filters

Address scoping defines domain boundary filters so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

You can set up an administratively scoped boundary filter on an interface for multicast group addresses. IANA has designated the multicast address range from 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. The addresses are considered local and are not globally unique.

A standard ACL defines the range of affected addresses. When a boundary filter is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary filter allows the same multicast group address to be reused in different administrative domains.

You can configure, examine, and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary ACL are removed. An Auto-RP group range announcement is permitted and passed by the boundary filter only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **Multicast Boundary Filter**, and then click **Add** or **Edit**.

Use the **Add Multicast Boundary Filter** dialog box to add new multicast boundary filters to the device. Use the **Edit Multicast Boundary Filter** dialog box to change existing parameters.

You can configure a multicast boundary for administratively scoped multicast addresses. A multicast boundary restricts multicast data packet flows and enables reuse of the same multicast group address in different administrative domains. When a multicast boundary is defined on an interface, only the multicast traffic permitted by the filter ACL passes through the interface.

Step 3 From the **Interface** drop-down list, choose the interface for which you are configuring the multicast boundary filter ACL.

Step 4 From the **Standard Access List** drop-down list, choose the standard ACL you want to use, or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2780 for the procedure.

Step 5 Check the **Remove any Auto-RP group range announcement from the Auto-RP packets that are denied by the boundary** check box to filter Auto-RP messages from sources denied by the boundary ACL. If this check box is not checked, all Auto-RP messages are passed.

Step 6 Click **OK** to save the multicast boundary filter configuration.

The multicast boundary filter is configured on the selected interface with the specified standard ACL, restricting multicast traffic according to the filter rules and enabling address reuse across administrative domains.

Verify multicast routing over an SVTI tunnel

The table lists the commands to verify multicast routing over an SVTI tunnel.

CLI Command	Description
show running-config pim	Displays all PIM configurations including IP address of the RP and BSR configurations.
show mroute	Displays the IPv4 multicast routing table to verify multicast traffic forwarding.
show pim neighbor	Displays details of the directly connected PIM neighbors.
show pim tunnel detail	Displays information about the PIM tunnel interfaces.
show pim group-map	Displays the mapping between RPs and multicast groups.
show pim topology	Displays details of the PIM topology.
show pim traffic	Displays PIM traffic counters.
show pim interface	Displays information about PIM interfaces.
show igmp interface	Displays multicast information for an interface.
show mfib count	Displays the Multicast Forwarding Information Base (MFIB) count and packet statistics.
show mfib route	Displays the MFIB routing table.
show pim group-map	Displays the multicast group to RP mapping.

Troubleshoot multicast routing over an SVTI tunnel

Provides troubleshooting guidance for multicast routing issues over SVTI tunnels in Secure Firewall environments, including symptoms, causes, and resolution steps.

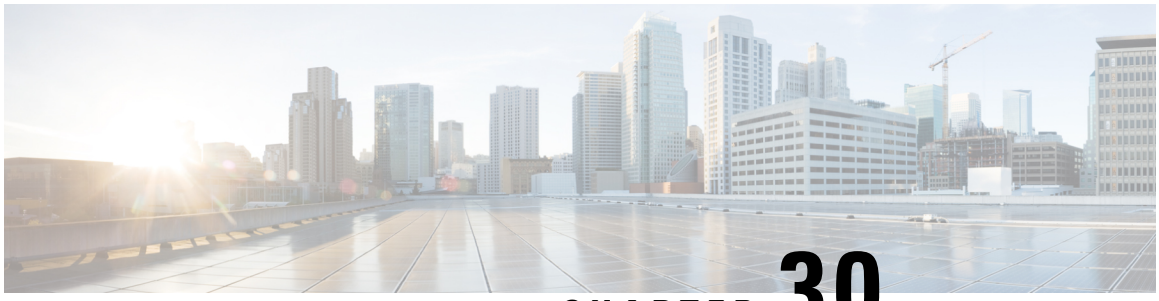
Troubleshoot multicast traffic issues

- **Symptoms**:
  - Unicast connectivity across VTI tunnel works fine.
  - Multicast stream never starts even when the receiver device sends an IGMP join.
  - LHR does not receive multicast traffic even though the source device is active.

  Possible cause: Reverse Path Forwarding (RPF) check failed because the return path to the source did not point to the VTI tunnel.

  Resolution:

  1. Perform a ping between tunnel endpoints to ensure basic connectivity and if SVTI is up.
  2. Run **show pim interface** to verify if PIM is enabled in the SVTI.
  3. Run **show pim neighbor** to ensure PIM adjacency is established across the tunnel.
  4. Run **show mroute** to verify the incoming and outgoing interfaces.
  5. Run **show route** <**source-ip**> to ensure that the RPF path points to the VTI.



Use clear commands

- **clear pim topology** and **clear igmp group**: Resets the multicast state for any recovery.
- **clear mroute <multicast_ipaddress>**: Clears entries for a specific multicast group.

Use debug commands

Note Use debug commands only during low network traffic periods and for specific troubleshooting or TAC sessions, as they increase CPU usage.

- **debug pim**: Debugs PIM configuration and events.
- **debug igmp**: Debugs IGMP configuration and events.
- **debug mfib**: Debugs MFIB configuration and events.

CHAPTER 30

Policy-Based Routing

This chapter describes how to configure Firewall Threat Defense to support policy-based routing (PBR) through Firewall Management Center's policy-based routing page. The following sections describe policy based routing, guidelines for PBR, and configuration for PBR.

- About policy-based routing, on page 1325
- Licenses for policy-based routing, on page 1327
- Best practices for policy-based routing, on page 1327
- Path monitoring metrics for best path route determination, on page 1329
- Configure policy-based routing policy, on page 1332
- Configure policy-based routing, on page 1345
- Configure PBR with path monitoring, on page 1350
- Useful CLIs for monitoring PBR, on page 1352
- Troubleshoot PBR, on page 1355
- History for policy-based routing, on page 1357

About policy-based routing

Policy-based routing (PBR) extends traditional routing protocols to provide greater control over traffic flow. It enables routing decisions based on criteria beyond destination IP, such as source and destination ports, protocols, and applications. Furthermore, PBR facilitates secure, application-specific traffic breakout in large-scale network deployments.

Policy-based routing characteristics

In traditional routing, packets are routed based on the destination IP address. Changing the routing of specific traffic in a destination-based routing system is difficult. PBR extends and complements the mechanisms provided by routing protocols.

PBR allows you to set the IP precedence. It also allows you to specify a path for certain traffic, such as priority traffic over a high-cost link. With PBR, you can define routing that is based on criteria other than destination network such as source port, destination address, destination port, protocol, applications, or a combination of these objects.

You can use PBR to classify the network traffic based on applications, username, group membership, and security group association. This routing method applies to scenarios involving numerous devices accessing applications and data in large network deployment. In large deployments, network traffic is typically backhauled to a hub as encrypted traffic in a route-based VPN. These topologies often result in issues such as packet

latency, reduced bandwidth, and packet drop. Resolving these issues requires costly, complex deployments and management.

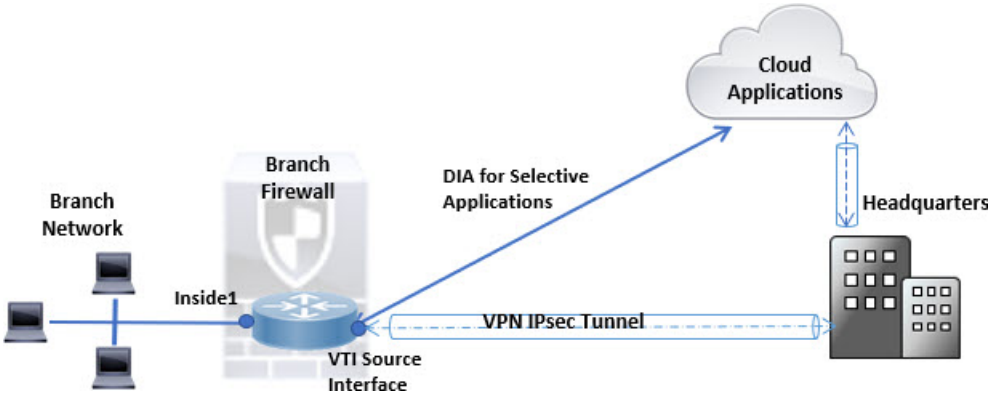
PBR policy enables you to securely break out traffic for specified applications. You can configure PBR policy in the Secure Firewall Management Center user interface to allow the applications to be directly accessed.

Consider a company that has two links between locations: one a high-bandwidth, low-delay expensive link, and the other a low-bandwidth, higher-delay, less-expensive link. While using traditional routing protocols, the higher-bandwidth link gets most, if not all, of the traffic sent across it based on the metric savings obtained by the bandwidth, delay, or both (using EIGRP or OSPF) characteristics of the link. With PBR, you can route higher priority traffic over the high-bandwidth/low-delay link, while sending all other traffic over the low-bandwidth/high-delay link.

These scenarios demonstrate policy-based routing applications:

- **Direct internet access**: In this topology, application traffic from the branch office can be routed directly to the internet instead of through the VPN tunnel connecting to the headquarters. The branch Firewall Threat Defense is configured with an internet exit point. The PBR policy is applied on the ingress interface (*Inside 1*) to identify the traffic based on the applications, user identity (username and group membership), and Security Group Tag (security group association) defined in the ACL. Correspondingly, the traffic is forwarded through the egress interfaces directly to the internet or to the IPsec VPN tunnel.
- **Equal-access and source-sensitive routing**: In this topology, traffic from the HR and Mgmt networks can be configured to go through ISP1 and traffic from Eng network can be configured to go through ISP2. Thus, policy-based routing enables the network administrators to provide equal-access and source-sensitive routing, in this example.
- **Load sharing**: In addition to the dynamic load-sharing capabilities offered by ECMP load balancing, network administrators can now implement policies to distribute traffic among multiple paths based on the traffic characteristics. As an example, in the topology depicted in the Equal-Access Source Sensitive Routing scenario, an administrator can configure policy-based routing to route the traffic from HR network through ISP1 and traffic from Eng network through ISP2 and thus share the load.

Figure 389: Direct internet access scenario



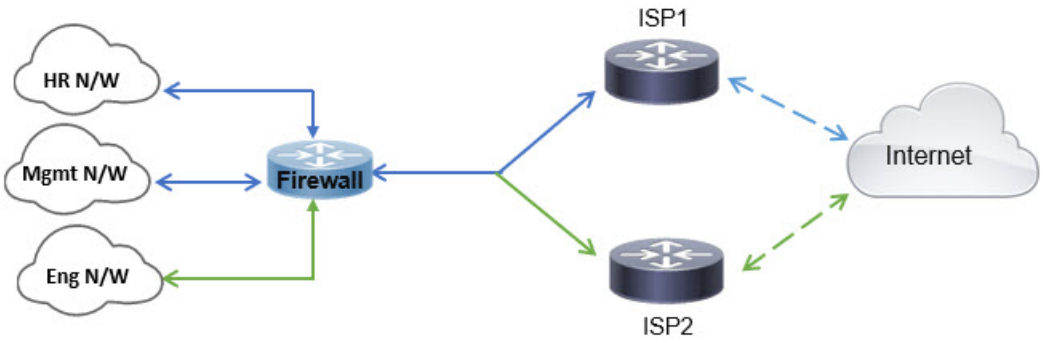


Figure 390: Equal access scenario

Licenses for policy-based routing

Policy-based routing (PBR) has specific licensing requirements depending on the features and services used in your configuration.

- All PBR policy features are supported with the Essentials Firewall Threat Defense smart license.
- Secure Client licensing is required if you are configuring PBR for routing traffic through RA VPN tunnel interface.
- Cisco ISE license is required for ISE usage in PBR policy.

Best practices for policy-based routing

Device guidelines

Ensure proper version compatibility and device-specific configurations when implementing PBR.

- PBR through Firewall Management Center's policy-based routing page is supported only from version 7.1 or later on both the Firewall Management Center and the Firewall Threat Defense device.
- When you upgrade Firewall Management Center or Firewall Threat Defense to version 7.1 or later, the PBR configuration in the device is removed. You must configure PBR again using the PBR page. If the managed device is earlier than version 7.1, you must configure PBR again using FlexConfig with deploy option set to "every time."
- On cluster devices, do not configure application, user identity, and Security Group Tag (SGT) based PBR policies, because they are not supported on cluster devices.
- On Secure Firewall 200 model devices, do not configure user identity- or Security Group Tag (SGT)-based PBR policies, because they are not supported on these devices.

Interface guidelines

Configure appropriate interface types and settings for PBR policies.

- Configure only routed-mode interfaces and non management-only interfaces in the Global virtual router as ingress or egress interfaces for the PBR policy. You cannot configure user-defined virtual router interfaces for the policy.
- The interfaces that you want to define in the policy must have a logical name.
- Configure Static VTIs only as egress interfaces.
- Do not choose Dynamic VTIs for configuring the PBR egress interfaces.

You can apply PBR for managing both IPv4 and IPv6 traffic.

Application-based PBR and DNS configuration

Ensure proper DNS configuration for application-based PBR functionality.

- Application-based PBR uses DNS snooping for application detection. Application detection succeeds only if the DNS requests pass through Firewall Threat Defense in a clear-text format; the DNS traffic is not encrypted.
- You must configure trusted DNS servers for the application detection to succeed.

For more information on configuring DNS servers, refer to Configure DNS server settings, on page 1010.

PBR policies not applied for output route look-up

PBR is an ingress-only feature; The system applies PBR only to the first packet of a new incoming connection, at which time the egress interface for the forward leg of the connection is selected. Note that PBR will not be triggered if the incoming packet belongs to an existing connection, or if NAT is applied and NAT chooses the egress interface.

PBR policies not applied for embryonic traffic

An embryonic connection is where the necessary handshake between source and destination has not been made. When a new internal interface is added and a new VPN policy is created using a unique address pool, PBR is applied to the outside interface matches the source of the new client pool. Thus, PBR sends traffic from the client to the next hop on the new interface. However, PBR does not process return traffic from a host until the new internal interface establishes a connection with the client. Thus, the return traffic from the host to the VPN client, specifically, the VPN client response is dropped as there is no valid route. To prevent the response from being dropped, configure a weighted static route with a higher metric on the internal interface.

HTTP-based path monitoring guidelines

Configure HTTP-based path monitoring with appropriate interface types and version considerations.

- Configure HTTP-based path monitoring only on physical, port-channel, subinterfaces, and static tunnel interfaces. Do not configure it on cluster devices.
- HTTP uses only IPv4 to ping applications. IPv4 metrics are applied for routing and forwarding both IPv4 and IPv6 traffic.
- HTTP-based application monitoring is enabled by default in Secure Firewall Management Center version 7.4 and higher. However, when you upgrade from previous versions, this option is not enabled by default. You must manually enable it.

Additional guidelines

Follow these additional configuration considerations for effective PBR implementation.

- All existing configuration restrictions and route map limitations remain in effect.
- When you define the ACL for the policy match criteria, you can select multiple predefined applications from a list to form an Access Control Entry (ACE). In Firewall Threat Defense, the predefined applications are stored as Network Service objects and the group of applications as Network Service Groups (NSG). You can create a maximum of 1024 such NSGs. The application or network service group is detected through first-packet classification. Currently, you cannot add to or modify the predefined applications list. However, you can create a custom application detector. See Create a custom application detector for PBR, on page 1336.
- Unicast Reverse Path Forwarding (uRPF) validates the source IP address of packets received on an interface against the routing table and not against the PBR route map. When uRPF is enabled, packets received on an interface through PBR are dropped as they are without the specific route entry. Therefore, when using PBR, ensure you disable uRPF.

Path monitoring metrics for best path route determination

Path monitoring metrics for best path route determination is a dynamic routing method that uses various monitoring approaches, such as ICMP and HTTP, to collect performance metrics and determine the best path.

Path monitoring methods and operation

PBR uses either static cost or path monitoring (dynamic metrics) to route its traffic.

Path monitoring, when configured on interfaces, derive metrics such as round trip time (RTT), jitter, mean opinion score (MOS), and packet loss per interface. These metrics are used to determine the best path for routing PBR traffic.

ICMP-based path monitoring method

The metrics on the interfaces are collected dynamically using ICMP probe messages to the interface's default gateway or a specified remote peer.

HTTP-based path monitoring method

Path monitoring calculates dynamic metrics for each remote peer associated with an interface. HTTP is preferred over ICMP when monitoring multiple applications and determining the best path through a policy on a branch firewall, because:

- HTTP-ping can derive the performance metrics of the path up to the application layer of the server, where the application is hosted.
- Because the application domain is tracked instead of the IP address, you do not need to change the firewall configuration when the application server IP address changes.

Note You can configure both ICMP and HTTP on the same interface. If the destination in the policy matches to any of the domain IP, the corresponding metrics are used. If the destination does not match to any of the configured domains, the metrics from the ICMP are used by PBR to select the outgoing interface.

Default monitoring timers for metric collection

For metric collection and monitoring, the following timers are used:

- The interface monitor average interval is 30 seconds. This interval indicates the frequency to which the probes average.
- The interface monitor update interval is 30 seconds. This interval indicates the frequency at which the average of the collected values are calculated and made available for PBR to determine the best routing path.
- The interface monitor probe interval by ICMP is one second. This interval indicates the frequency at which an ICMP ping is sent.
- The application monitor probe interval by HTTP is 10 seconds. This interval indicates the frequency at which an HTTP ping is sent. Path monitoring uses the last 30 samples of HTTP ping for calculating the average metrics.

Note You cannot configure or modify the interval for any of these timers.

PBR and path monitoring integration

Typically, in PBR, traffic is forwarded through egress interfaces based on the priority value (interface cost) configured on them. From management center version 7.2, PBR uses IP-based path monitoring to collect the performance metrics (RTT, jitter, packet-lost, and MOS) of the egress interfaces. PBR uses the metrics to determine the best path (egress interface) for forwarding the traffic. Path monitoring periodically notifies PBR about the monitored interface whose metric got changed. PBR retrieves the latest metric values for the monitored interfaces from the path monitoring database and updates the data path.

Path monitoring functions only with dynamic metrics, and only if the RTT, jitter, packet-lost, or MOS variables are set on the interfaces. Path monitoring does not function with static metrics—interface cost (cost set in interface).

You must enable path monitoring for the interface and configure the monitoring type. The PBR policy page allows you to specify the desired metric for path determination. See Configure policy-based routing policy, on page 1332.

PBR and HTTP-based path monitoring

From management center version 7.4, PBR can be configured to use HTTP-based path monitoring to collect the performance metrics of the application domains and not just one destination IP address. Path monitoring begins only after a DNS entry for a domain is detected; it does not start immediately when HTTP-based application monitoring is configured. After obtaining the resolved IP address for the domain, path monitoring sends an HTTP request and receives a response. If DNS resolves multiple IP addresses for a domain, path monitoring probes and monitors the application using the first resolved IP address. Path monitoring continues until the IP address changes or until HTTP-based monitoring is disabled.

Based on the HTTP request and response durations, path monitoring computes the performance metrics for the application. Path monitoring sends collected metrics to PBR at regular intervals so that PBR can make routing and forwarding decisions for traffic from the configured ingress interface. If traffic arrives before path monitoring sends metrics to PBR, the routing table determines the traffic flow. Once metrics are available, PBR uses them to make routing decisions for subsequent traffic.

Note Based on the Network Service Groups in the match ACL of the policy, you can apply PBR for multiple domains having multiple IP addresses.

The management center associates applications and NSGs with the egress interface only when the PBR configuration meets these criteria:

- The match ACL contains the monitored applications.
- The PBR policy is configured with any one of the interface ordering values (metric type):
  - Minimal Jitter
  - Maximum Mean Opinion Score
  - Minimal Round-Trip Time
  - Minimal Packet Loss

Configure path monitoring settings

Configure path monitoring to collect metrics such as RTT, jitter, MOS, and packet loss on specified interfaces for effective traffic management and routing optimization.

The PBR policy relies on flexible metrics, such as round-trip time (RTT), jitter, mean opinion score (MOS), and packet loss of the interfaces to identify the best routing path for its traffic. Path monitoring collects these metrics on the specified interfaces. On the **Interfaces** page, you can configure path monitoring settings on interfaces to send ICMP probes or HTTP pings to collect metrics.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Path Monitoring** tab.

Step 4 To configure ICMP based monitoring of the interface, click the **Enable IP based Monitoring** check box.

Step 5 From the **Monitoring Type** drop-down list, select the relevant option:

- **Next-hop of default route out of interface (Auto)**—Sends ICMP probes to the IPv4 default gateway of the interface. If the IPv4 gateway does not exist, path monitoring sends the probes to the IPv6 default gateway of the interface.
- **IPv4 address of the peer (Peer IPv4)**—Sends ICMP probes to the specified peer IPv4 address (next-hop IP) for monitoring. If you select this option, enter the IPv4 address in the **Peer IP To Monitor** field.
- **IPv6 address of the peer (Peer IPv6)**—Sends ICMP probes to the specified peer IPv6 address (next-hop IP) for monitoring. If you select this option, enter the IPv6 address in the **Peer IP To Monitor** field.
- **Next-hop of IPv4 default route (Auto IPv4)**—Sends ICMP probes to the default IPv4 gateway of the interface.

- **Next-hop of IPv6 default route (Auto IPv6)**—Send ICMP probes to the default IPv6 gateway of the interface.

Note

- The Auto options are not available for VTI interfaces. You must specify the peer address.
- Only one next-hop is monitored to a destination. That is, you cannot specify more than one peer address to monitor for an interface.

Step 6 By default, the **Enable HTTP based Application Monitoring** check box is selected. All applications selected for path monitoring in the match ACL of the PBR policy are listed, provided this interface is configured as the egress interface in the policy. To disable the HTTP-based monitoring of the interface, clear the check box.

Step 7 Click **Ok**.

Step 8 To save the settings, click **Save**.

Path monitoring is configured on the interface with the specified settings. The system will collect metrics using ICMP probes or HTTP pings based on your configuration to optimize routing paths.

Add path monitoring dashboard

Add the Path Monitoring Dashboard to enable viewing path monitoring metrics with customizable display options through predefined correlations and widget management.

Procedure

Step 1 Choose **Troubleshooting** > **Health** > **Monitor**.

Step 2 Select the device, and click **Add new dashboard** (+).

Step 3 Enter a name for the custom dashboard.

Step 4 In the **Metrics** area, click the **Add from predefined correlations** button.

Step 5 From the list, click **Interface - Path metrics**.

By default, all four metrics and an additional metric field are selected to display as widgets in the dashboard.

To exclude any, click **Delete** (🗑).

Step 6 Click **Add dashboard**.

Configure policy-based routing policy

This task enables you to configure Policy-Based Routing (PBR) to control traffic routing based on specific criteria rather than relying solely on the routing table.

You can configure the PBR policy on the Policy Based Routing page by specifying the ingress interfaces, match criteria (Extended Access Control List), and egress interfaces.

Before you begin

To use the path monitoring metrics for configuring the traffic forwarding priority over egress interfaces, you must configure the path monitoring settings for the interfaces. See Configure path monitoring settings, on page 1331.

Follow these steps to configure policy-based routing policy:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Policy Based Routing**.

On the Policy Based Routing page, you can view the configured policy. The grid shows ingress interfaces and the combination of the policy-based route access list and egress interfaces.

Step 4 To configure the policy, click **Add**.

Step 5 In the **Add Policy Based Route** dialog box, select the **Ingress Interface** from the drop-down list.

Note You can only select interfaces with logical names that belong to a global virtual router from the drop-down list. You cannot configure a VLAN interface with a logical name as the source (ingress) interface.

Step 6 To specify the match criteria and the forward action in the policy, click **Add**.

Step 7 In the **Add Forwarding Actions** dialog box, do the following:

a) From the **Match ACL** drop-down, choose the extended access control list object. You can predefine the ACL object (see Configure an extended ACL object, on page 2775) or click the **Add** (+) icon to create the object. In the **New Extended Access List Object** box, enter a name, click **Add** to open the **Add Extended Access List Entry** dialog box, where you can define the network, port, user identity, SGT, or application match criteria for the PBR policy. For information on creating custom domain to be synchronized with PBR, see Create a custom application detector for PBR, on page 1336.

Note You can either have destination address or application/user identity/SGT defined in an ACE.

To selectively apply PBR on the incoming interface, you can define *Block* criteria in the ACE. When the traffic matches the block rule of the ACE, the traffic is forwarded to the egress interface based on the routing table.

b) From the **Send To** drop-down list:

- To select the configured interfaces, choose **Egress Interfaces**.
- To specify the IPv4/IPv6 next hop addresses, choose **IP Address**. Proceed to Step 7.e, on page 1334

c) If you have selected **Egress Interfaces**, from the **Interface Ordering** drop-down, choose the relevant option:

- By **Interface Priority**—The traffic is forwarded based on the priority of the interfaces. Traffic is routed to the interface with the least priority value first. When the interface is not available, the traffic is then forwarded to the interface with the next lowest priority value. For example, let us assume that interface1, interface2, and interface3 are configured with priority values *0*,*1*, and *2*, respectively. The traffic is forwarded to interface1. If interface1 becomes unavailable, the traffic is then forwarded to interface2.

Note To configure the priority for the interfaces, click **Configure Interface Priority** on the Policy Based Routing page. In the dialog box, provide the priority number against the interfaces, and then click **Save**. You can also configure the priority for an interface in the Interface Settings.

When the priority value is the same for all the interfaces, the traffic is balanced among the interfaces. By default, the interface priority for PBR is set to 0. Interfaces with the lowest priority value are preferred for traffic forwarding.

- By **Order**—The traffic is forwarded based on the sequence of the interfaces specified here. For example, let us assume that interface1, interface2, and interface3 are selected in this order, interface2, interface3, interface1. The traffic is forwarded first to interface2, then to interface3, regardless of their priority values.
- By **Minimal Jitter**—The traffic is forwarded to the interface that has the lowest jitter value. You need to enable Path Monitoring on the interfaces for PBR to obtain the jitter values.
- By **Maximum Mean Opinion Score**—The traffic is forwarded to the interface that has the maximum mean opinion score (MOS). You need to enable Path Monitoring on the interfaces for PBR to obtain the MOS values.
- By **Minimal Round Trip Time**—The traffic is forwarded to the interface that has the minimal round trip time (RTT). You need to enable Path Monitoring on the interfaces for PBR to obtain the RTT values.
- By **Minimal Packet Loss**—The traffic is forwarded to the interface that has the minimal packet loss. You need to enable Path Monitoring on the interfaces for PBR to obtain the packet loss values.

d) In the **Available Interfaces** box, all the interfaces with their priority values are listed. From the list of interfaces, click the **Add** (+) button to add to the selected egress interfaces. Proceed to Step 8.

Note The selected interface route must be present in the routing table.

e) If you have selected **IP Address**, enter the IP addresses separated by commas in the **IPv4 Addresses** or **IPv6 Addresses** fields. The traffic is forwarded as per the sequence of the specified IP addresses.

Note When multiple next-hop IP addresses are provided, the traffic is forwarded as per the sequence of the specified IP addresses until a valid routable next-hop IP address is found. The configured next-hops should be directly connected.

f) From the **Don't Fragment** drop-down list, select Yes, No, or None. If the DF (Don't Fragment) flag is set to *Yes*, the intermediate routers never perform fragmentation of a packet.To specify the current interface as the default for forwarding, check the **Default Interface** check box.

g) The **IPv4 Settings** and **IPv6 Settings** tabs enable you to specify the recursive and default settings:

Note For a route-map, you can only specify either IPv4 or IPv6 next-hop settings.

- **Recursive**—The route map configuration is applied only when the specified next-hop address and the default next-hop address are found on a directly connected subnet. However, you could use the recursive option, where the next-hop address need not be directly connected. Here, a recursive lookup is performed on the next-hop address, and matching traffic is forwarded to the next-hop used by that route entry according to the current routing path of the router.
- **Default**—If the normal route lookup fails to match traffic, the traffic is forwarded to this specified next-hop IP address.

h) Check the **Peer Address** check box to use the next-hop address as the peer address.

Note You cannot configure a route map with both default next-hop address and peer address.

i) For IPv4 settings, you can check whether the next IPv4 hops of a route map are available under **Verify Availability**—click the **Add** (+) button and add the next-hop IP address entries:

- **IP Address**—Enter the next hop IP address.
- **Sequence**—Entries are assessed in order using the sequence number. Ensure that no duplicate sequence numbers are entered. The valid range is 1 to 65535.
- **Track**—Enter a valid ID. The valid range is 1 to 500.

Step 8 To save the policy, click **Save** and **Deploy**.

The Firewall Threat Defense uses ACLs to match traffic and perform routing actions on the traffic. Typically, you configure a route map that specifies an ACL against which traffic is matched, and then you specify one or more actions for that traffic. With the use of path monitoring, PBR can now select the best egress interface for routing the traffic. Finally, you associate the route map with an interface on which you want to apply PBR on all incoming traffic.

Create a custom application detector for PBR

This task enables you to create custom application detectors and configure application-based PBR policies for enhanced traffic control and routing decisions.

Custom application detectors allow you to identify specific applications that may not be covered by default detection methods. These detectors can then be used in PBR policies to make routing decisions based on application identification.

Procedure

Step 1 Create a custom detector for a user-defined application, as described in Create a user-defined application, on page 2718.

Note While creating a user-defined application, ensure that you select NSG from the **Tag** drop-down list.

Step 2 Define the detection pattern by selecting the appropriate detector type and configuration method.

To manually define the detection pattern, select **Basic** detector type and proceed to define them, as described in Specifying detection patterns in basic detectors, on page 2719. Alternatively, if you want to create the detection pattern using a .lua file, select **Advanced** detector type and follow the instructions provided in Specify detection criteria in advanced detectors, on page 2720.

Step 3 Activate the custom detector.

Step 4 Configure ACL policy (Extended) for PBR with the custom application ACE.

For procedure to create the ACL, see Configure an extended ACL object, on page 2775.

Step 5 In the PBR policy, select the ACL that matches the desired forwarding actions.

For detailed procedure to create PBR policy, see Configure policy-based routing policy, on page 1332.

You have successfully created a custom application detector and configured an application-based PBR policy. The system can now identify the custom application and apply the appropriate routing decisions based on your configuration.

Configure PBR with a custom application detector (Basic)

This task configures PBR policy with custom application detectors to enable routing decisions based on specific application traffic patterns using custom detectors for defined domains.

This example demonstrates configuring a Policy Based Routing (PBR) policy with custom application detectors for specific domains such as:

- amazon123.com
- flipkart.com
- hamleysonline.com

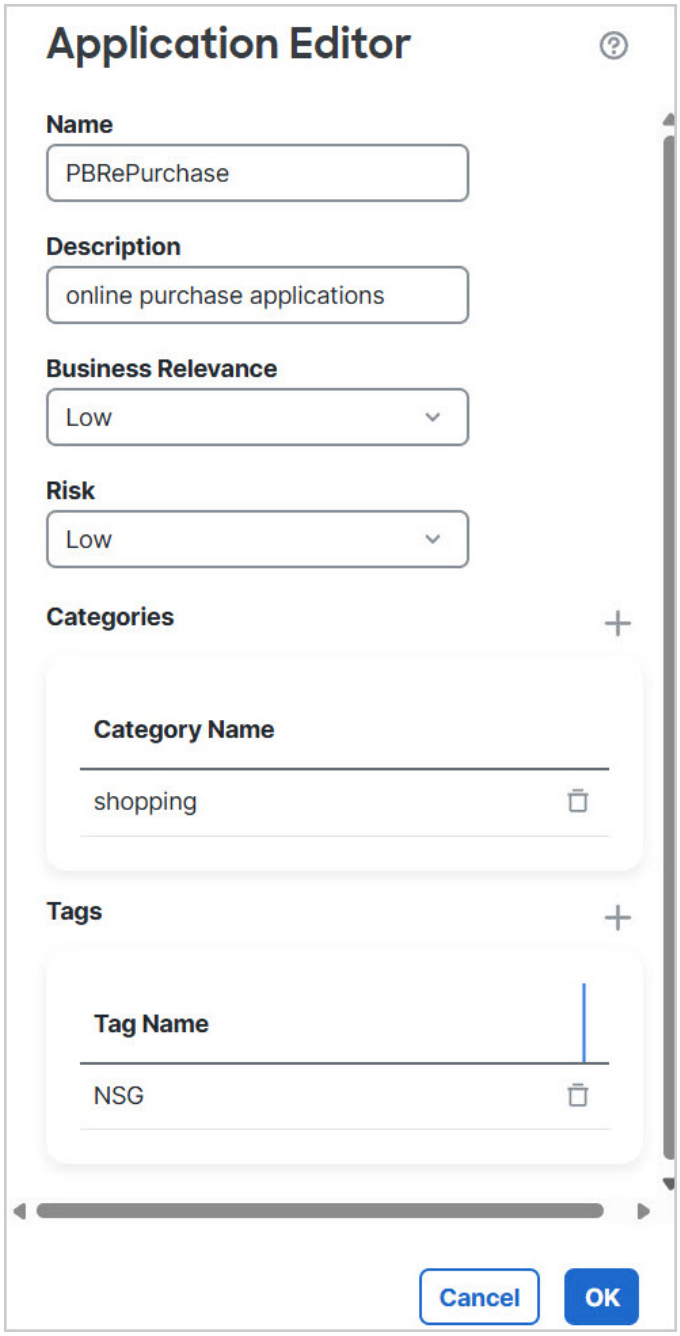
Before you begin

- This example assumes that you are aware of the basic steps to configure PBR policy and custom application detectors.
- You should have configured the ingress and egress interfaces with logical names. In this example, the ingress interface is named *Inside1*, and the egress interface is named *eBuy*.

Follow these steps to configure PBR with custom application detector:

Procedure

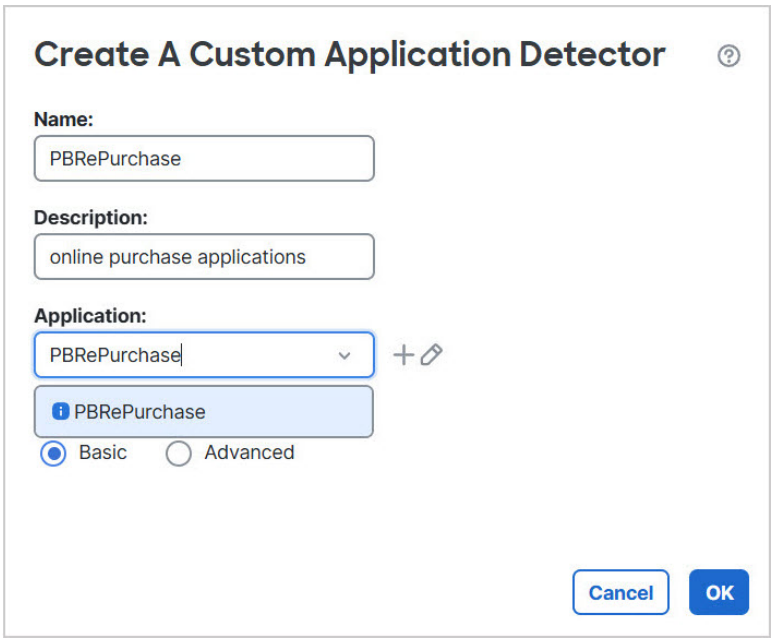
Step 1 Create a custom detector, *PBRePurchase*:



a) Choose **Policies** > **+ Show more** > **Advanced** > **Applications**, and click **Create Custom Detector**.

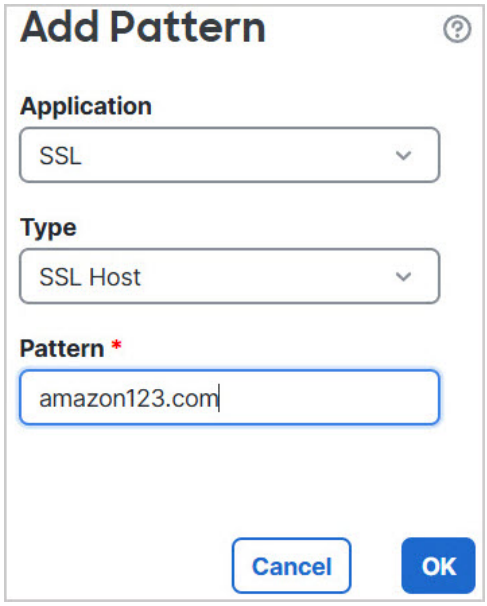
b) In the **Create A Custom Application Detector** field, enter a name (in this example, *PBRePurchase*) and a description.

c) To create a custom application, click (+).



d) In the **Application Editor** dialog box, enter the relevant values in the fields. See Create a user-defined application, on page 2718 for a detailed description of each field.

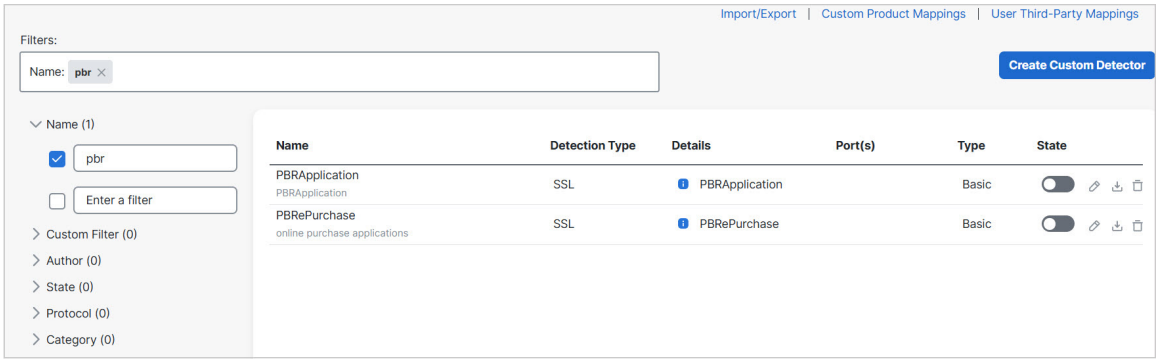
Note For the custom application to be detectable for PBR, choose **NSG** from the **Tag** drop-down list:



e) Click **Ok**.

f) From the **Application** drop-down list, choose *PBRePurchase*.

Note You can use the **Basic** or **Advanced** detector type in the PBR policy. This example uses the **Basic** detector type.

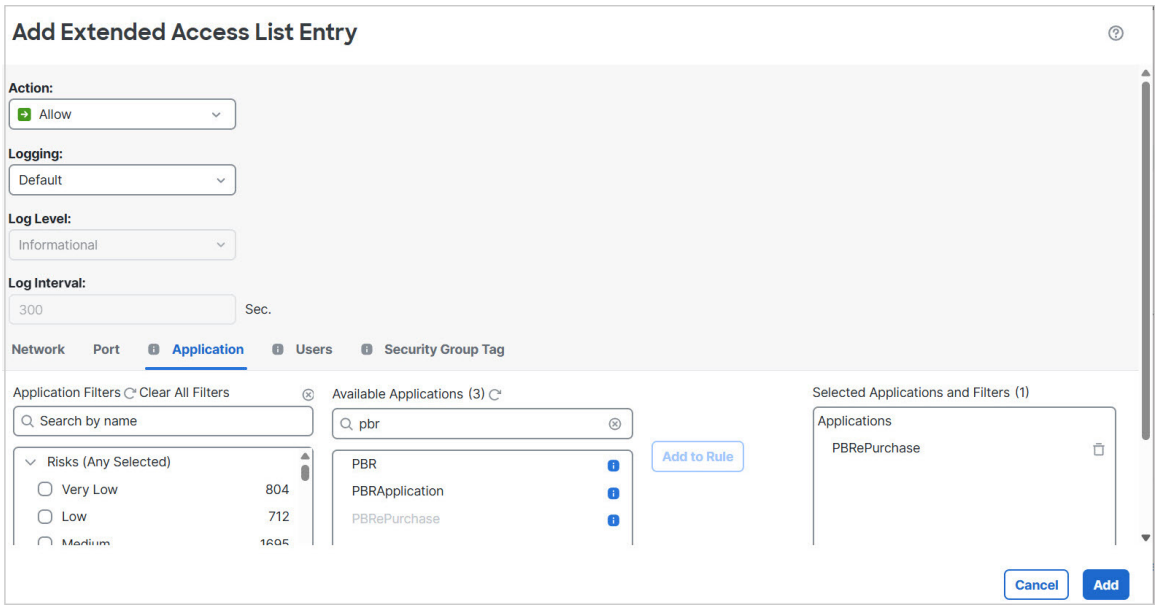


a) Click the **Basic** radio button, and then click **Ok**.
b) In the **Application Detector** page, click the **Add** button in the **Detection Patterns** area to add patterns.
c) From the **Application** drop-down list, choose **SSL** as the protocol, and select the appropriate pattern type. Enter a pattern string that matches the selected type (in this example, enter *amazon123.com*), and then click **Ok**.

d) Repeat the procedure and create two more patterns for the custom domains *flipkart.com* and *hamleysonline.com*.
e) Click **Save**.

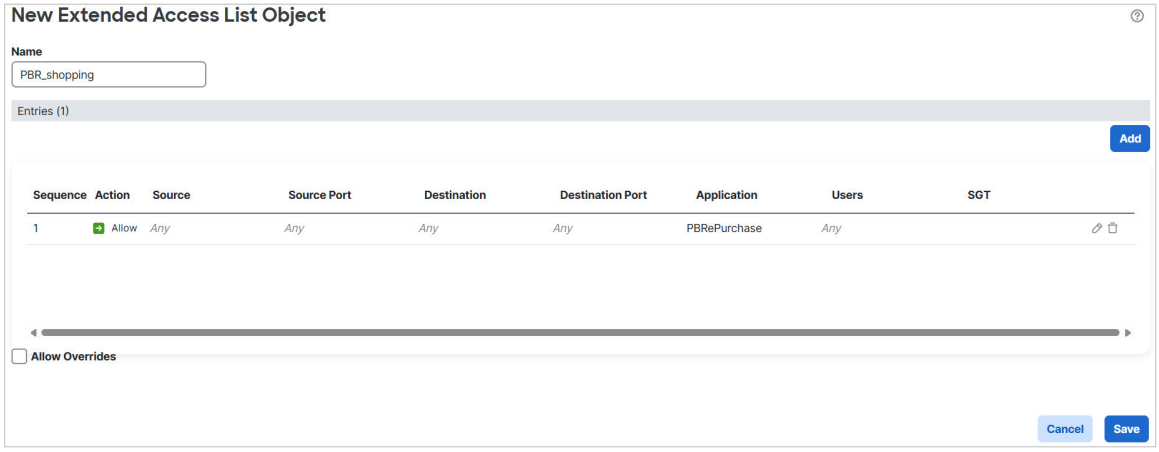
Step 2 In the application detector dashboard, use filters to search for the custom application detector that you have just created.

Step 3 To enable the custom detector, click the **State** toggle button ( ) adjacent to the corresponding application detector.



Step 4 In the dialog box that is displayed, click **Yes**.

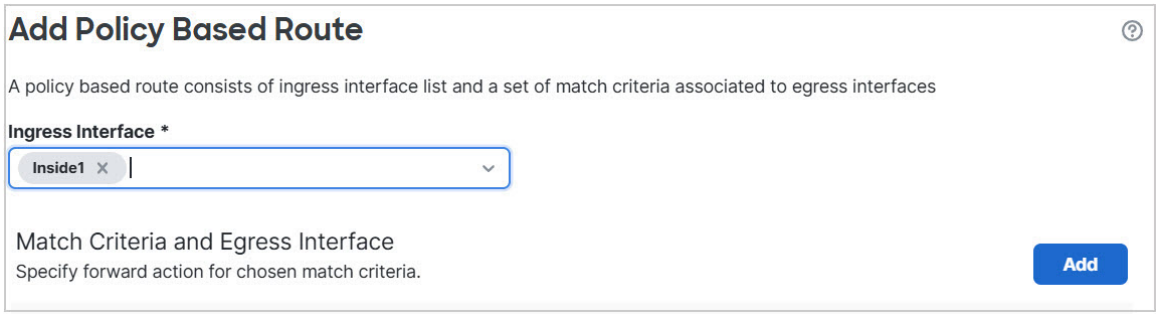
When the application detector is activated, a success message appears:



Step 5 To create an ACL using the custom application detector for synchronizing with the PBR policy:

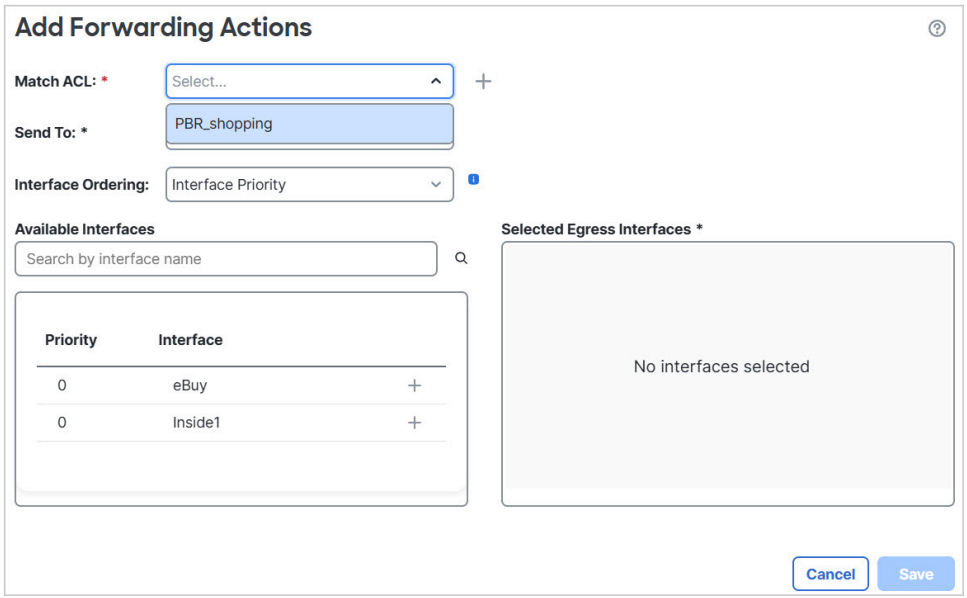
a) Choose **Objects** > **Access List** > **Extended**.
b) Click **Add Extended Access List**.
c) Enter a name (for example, *PBR_shopping*) to the list and click **Add** to create an ACE for the list.
d) In the **Add Extended Access List Entry** dialog box, click the **Application** tab, select the application name *PBRePurchase*, and then click **Add to Rule**.

e) Click **Add**.



f) Click **Save**.

Step 6 Choose **Routing** > **Policy Based Routing**.

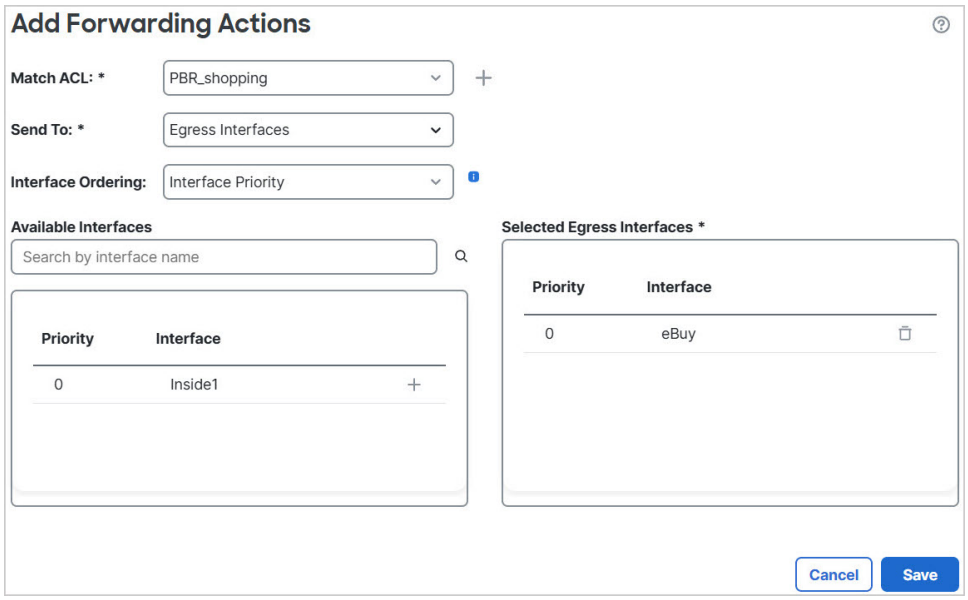


Step 7 On the **Policy Based Routing** page that is displayed, click **Add**.

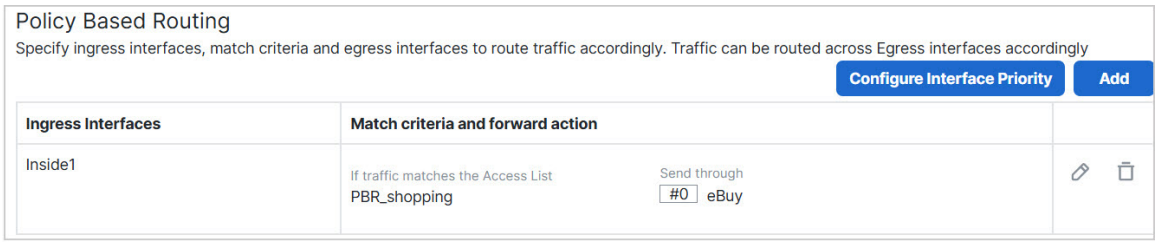
Step 8 In the **Add Policy Based Route** dialog box, choose *Inside 1* from the **Ingress Interface** drop-down list.

Step 9 From the **Match ACL** drop-down list, choose the ACL that you have created, which, in this example is *PBR_shopping*.

Note In a Firewall Threat Defense, the application group in an ACL is configured as a network service group. That is why we tag the custom application with **NSG**.



Step 10 Specify the egress interfaces:



a) From the **Send To** drop-down list, choose **Egress Interfaces**.

b) From the **Interface Ordering** drop-down list, choose the appropriate order.

c) Under **Available Interfaces**, click (+) adjacent to the corresponding interface, namely, *eBuy*.

d) Click **Save**.

Step 11 **Save** and **Deploy**.

The PBR policy is configured and deployed with the custom application detector. Traffic matching the specified domains will be routed through the defined egress interface.

Example for configuring PBR with a custom application detector using lua script

This task configures PBR policy with custom application detectors to enable routing decisions based on specific application traffic patterns using custom detectors for defined domains.

This example demonstrates configuring a Policy Based Routing (PBR) policy with custom application detectors for multiple domains such as:

- domain1.com
- domain2.net
- domain3.org

Before you begin

- This example assumes that you are aware of the basic steps to configure PBR policy and custom application detectors.

- You should have configured the ingress and egress interfaces with logical names. In this example, the ingress interface is named *Inside1*, and the egress interface is named *eBuy*.

Follow these steps to configure PBR with custom application detector:

Procedure

Step 1 Create a custom detector, *PBRcustom_domains*:

a) Choose **Policies** > **+ Show more** > **Advanced** > **Applications**, and click **Create Custom Detector**.

b) In the **Create A Custom Application Detector** dialog box, enter a name (in this example, *PBRcustom_domains*) and a description.

c) To create a custom application, click (+).

d) In the **Application Editor** dialog box, enter the relevant values in the fields. See Create a user-defined application, on page 2718 for a detailed description of each field.

Note For the custom application to be detectable for PBR, choose **NSG** from the **Tag** drop-down list.

e) Click **Ok**.

f) From the **Application** drop-down list, choose *PBRcustom_domains*.

g) Click the **Advanced** radio button, and then click **Ok**.

h) In the application detector page, click the **Add** button in the **Detection Criteria** area and upload the .lua file.

i) Click **OK**.

Step 2 In the application detector dashboard, use filters to search for the custom application detector that you have just created.

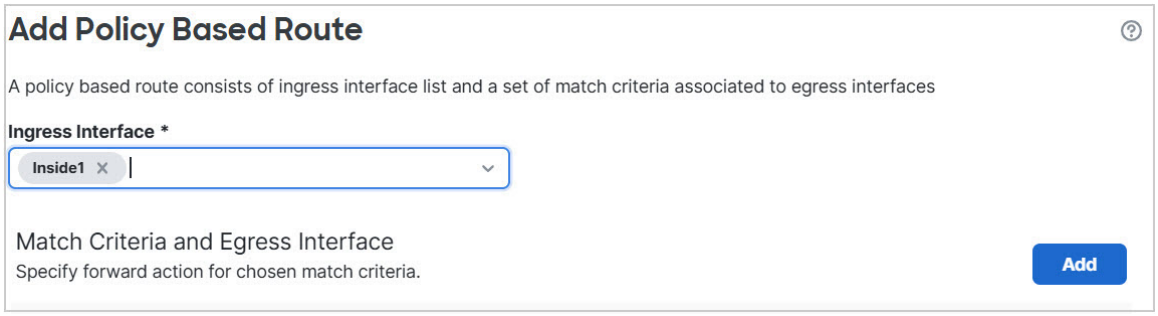
Step 3 To enable the custom detector, click the **State** toggle button () adjacent to the corresponding application detector and click **Yes**..

Step 4 To create an ACL using the custom application detector for synchronizing with the PBR policy:

a) Choose **Objects** > **Access List** > **Extended**.

b) Click **Add Extended Access List**.

c) Enter a name (for example, *PBR_multidomain*) to the list and click **Add** to create an ACE for the list.



d) In the **Add Extended Access List Entry** dialog box, click the **Application** tab, select the application name *PBRcustom_domains*, and then click **Add to Rule**.

e) Click **Add**.

f) Click **Save**.

Step 5 Choose **Routing** > **Policy Based Routing**, and then click **Add**.

Step 6 In the **Add Policy Based Route** dialog box, choose *Inside 1* from the **Ingress Interface** drop-down list.

Step 7 From the **Match ACL** drop-down list, choose the ACL that you have created, which, in this example is *PBR_multidomain*.

Note In a Firewall Threat Defense, the application group in an ACL is configured as a network service group. That is why we tag the custom application with **NSG**.

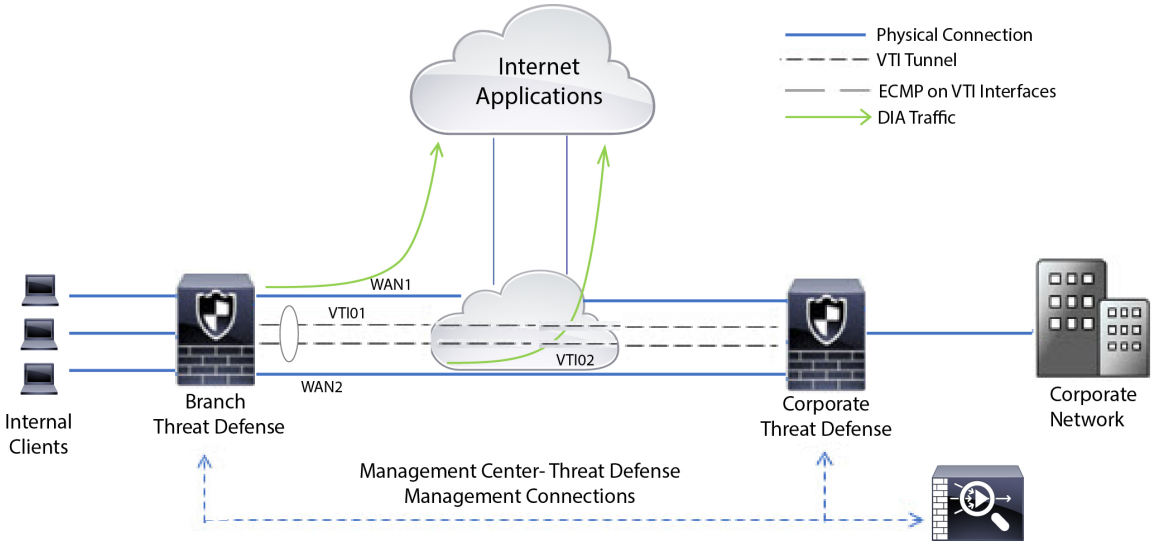
Step 8 Specify the egress interfaces:

a) From the **Send To** drop-down list, choose **Egress Interfaces**.
b) From the **Interface Ordering** drop-down list, choose the appropriate order.
c) Under **Available Interfaces**, click (+) adjacent to the corresponding interface, namely, *eBuy*.
d) Click **Save**.

Step 9 **Save** and **Deploy**.

The PBR policy is configured and deployed with the custom application detector. Traffic matching the specified domains will be routed through the defined egress interface.

Configure policy-based routing



Configure PBR to enable direct internet access for specific web-based applications, optimize traffic flow, and achieve load balancing between WAN and VTI interfaces.

Consider a typical corporate network scenario where all the branch network traffic passes through a route-based VPN of the corporate network and diverges to the extranet, when required. Accessing web-based applications through the corporate network to support daily operations may increase network size and maintenance costs. This example illustrates how to configure PBR for direct internet access.

The following figure depicts the topology of a corporate network. The branch network is connected to the corporate network through a route-based VPN. Traditionally, the corporate Firewall Threat Defense is configured to handle both the internal and external traffic of the branch office. With the PBR policy, the branch Firewall Threat Defense is configured with a policy that routes specific traffic to the WAN network instead of the virtual tunnels. The rest of the traffic flows through the route-based VPN, as usual.

This example also illustrates how to configure the WAN and VTI interfaces with ECMP zones to achieve load balancing.

Figure 391: Configuring policy-based routing on Branch Firewall Threat Defense in Firewall Management Center

Before you begin

This example assumes that you have already configured WAN and VTI interfaces for the branch Firewall Threat Defense in Firewall Management Center.

Procedure

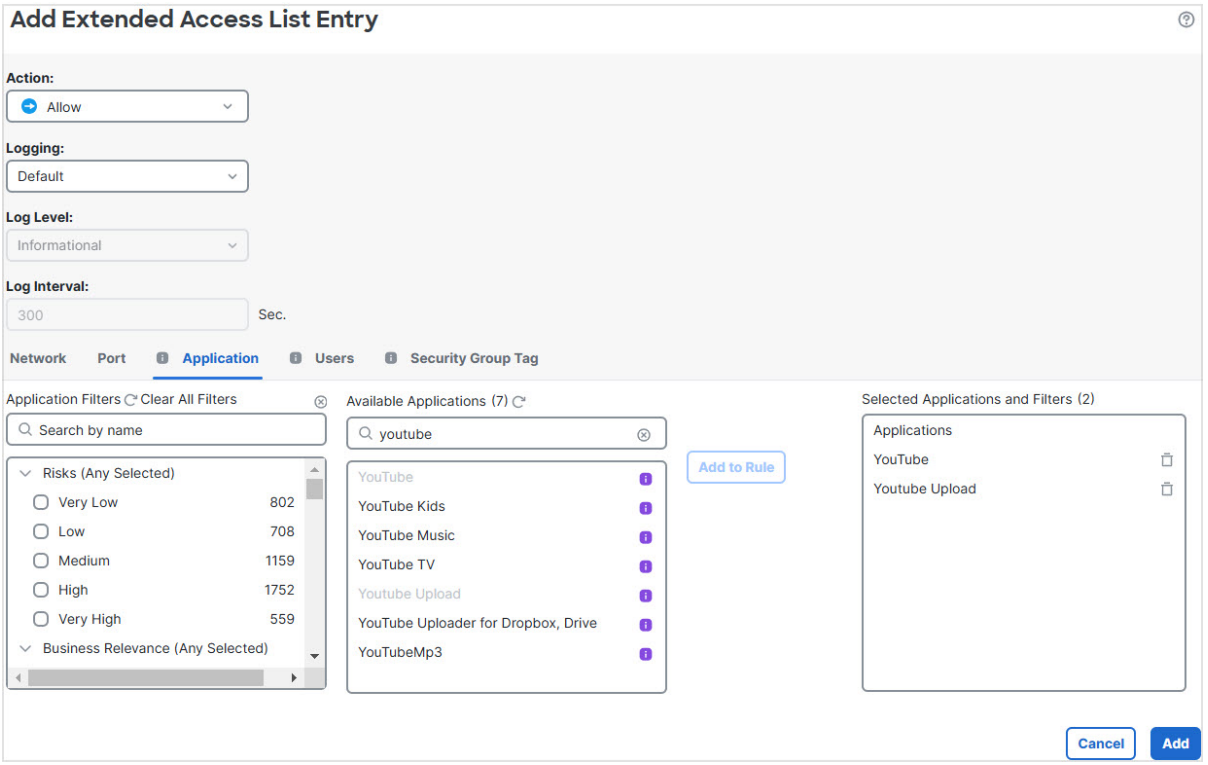
Step 1 Configure policy-based routing for the branch Firewall Threat Defense, select the ingress interfaces:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b) Choose **Routing** > **Policy Based Routing**, and on the **Policy Based Routing** page, click **Add**.

c) In the **Add Policy Based Route** dialog box, select the interfaces (say, *Inside 1*, and *Inside 2*) from the **Ingress Interface** drop-down list.

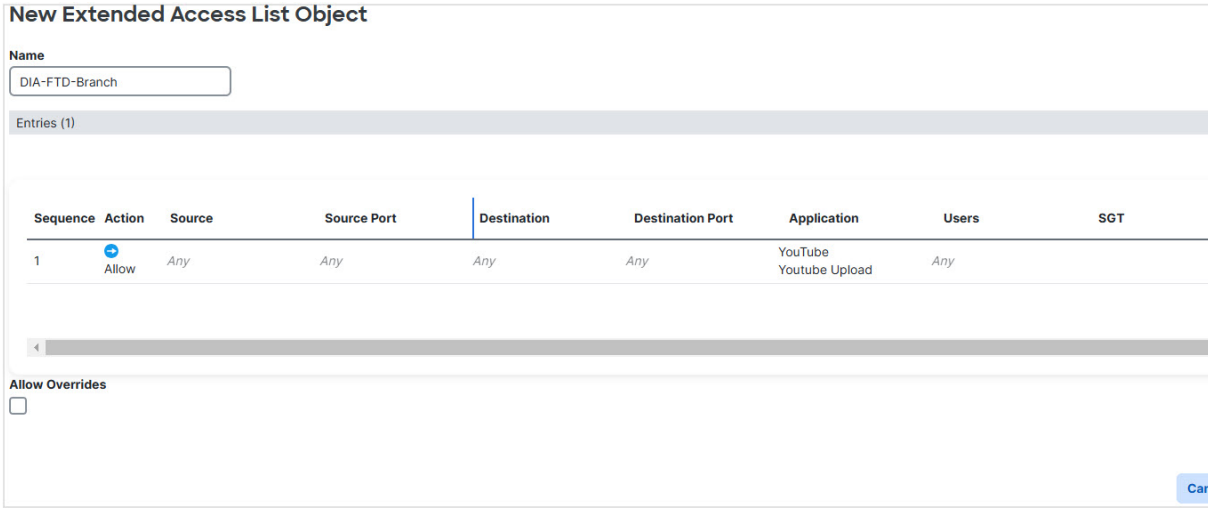
Step 2 Specify the match criteria:



a) Click **Add**.

b) To define the match criteria, click the **Add** (+) button.

c) In **New Extended Access List Object**, enter the name for the ACL (say, *DIA-FTD-Branch*), and click **Add**.



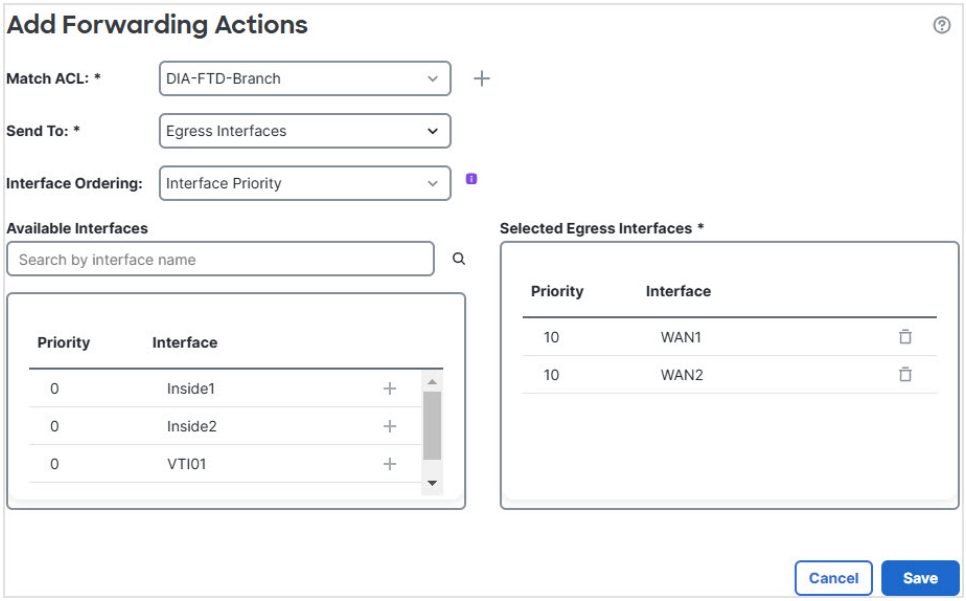
d) In the **Add Extended Access List Entry** dialog box, choose the required web-based applications from the **Application** tab:

Figure 392: Applications tab

On the Firewall Threat Defense, the application group in an ACL is configured as a network service group and each of the applications as a network service object.

Figure 393: Extended ACL

e) Click **Save**.



f) Select *DIA-FTD-Branch* from the **Match ACL** drop-down list.

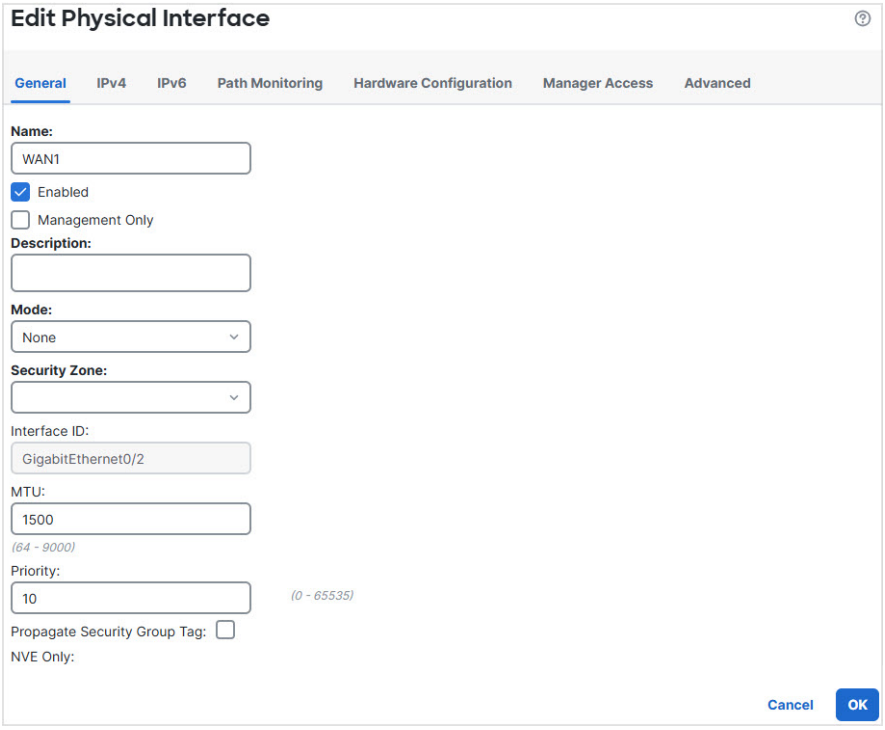
Step 3 Specify the egress interfaces:

a) From the **Send To** and **Interface Ordering** drop-down lists, choose Egress Interfaces, and Interface Priority respectively.

b) Under **Available Interfaces**, click the ⊕ button against the respective interface names to add *WAN1* and *WAN2*:

Figure 394: Configuring policy-based routing

c) Click **Save**.



Step 4 Configure interface priority:

You can set the priority value for the interfaces either in the **Edit Physical Interface** page, or in the **Policy Based Routing** page (**Configure Interface Priority**). In this example, the Edit Physical Interface method is described.

a) Choose **Devices** > **Device Management**, and edit the branch Firewall Threat Defense.

b) Set the priority for the interfaces. Click **Edit** against the interface and enter the priority value:

Figure 395: Setting interface priority

c) Click **Ok** and **Save**.

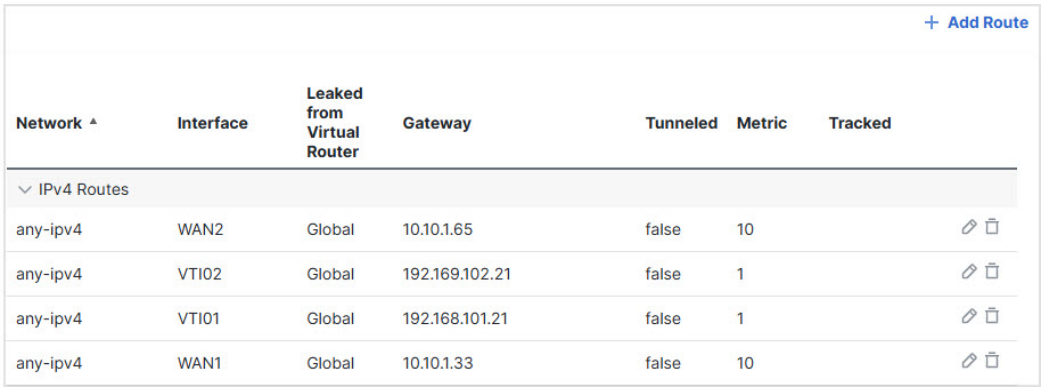
Step 5 Create ECMP zones for load balancing:

a) In the **Routing** page, click **ECMP**.

b) To associate interfaces to the ECMP zone, click **Add**.

c) Select *WAN1* and *WAN 2* and create an ECMP zone—*ECMP-WAN*. Similarly, add *VTI01* and *VTI02* and create an ECMP zone—*ECMP-VTI*:

Figure 396: Associating interfaces with ECMP zone



Step 6 Configure static routes for the zone interfaces for load balancing:

a) In the **Routing** page, click **Static Route**.

b) Click **Add** and specify the static routes for *WAN1*, *WAN2*, *VTI01*, and *VTI02*. Ensure that you specify the same metric value for the interfaces belonging to the same ECMP zones (Step 5):

Figure 397: Configuring static routes for ECMP zone interfaces

Note Ensure that the zone interfaces have the same destination address and metric, but different gateway addresses.

Step 7 Configure trusted DNS on the WAN objects of the branch Firewall Threat Defense to ensure secure flow of traffic to the internet:

a) Choose **Devices** > **Platform Settings**, and create a DNS policy on the branch Firewall Threat Defense.
b) To specify the trusted DNS, edit the policy and click **DNS**.
c) To specify the DNS servers for the DNS resolution to be used by WAN objects, in the **DNS Settings** tab, provide the DNS server group details and select WAN from the interface objects.
d) Use the **Trusted DNS Servers** tab to provide specific DNS servers that you trust for the DNS resolution.

Step 8 Click **Save**, and then click **Deploy**.

Any *YouTube* related access requests from the branch inside network *INSIDE1* or *INSIDE2* are routed to *WAN1* or *WAN2* as they would match the *DIA-FTD-Branch* ACL. Any other request, say *google.com*, are routed through *VTI01* or *VTI02* as configured in the Site to Site VPN Settings.

With the ECMP configured, the network traffic is seamlessly balanced.

Configure PBR with path monitoring

Configure PBR with path monitoring to optimize application traffic routing by dynamically selecting the best egress interface based on performance metrics such as jitter, round-trip time, and packet loss.

This example describes how to configure PBR with path monitoring for the following applications with flexible metrics:

- Audio or video sensitive applications (example, WebEx Meetings) with Jitter.
- Cloud-based application (example, Office365) with RTT.
- Network-based access control (with a specific source and destination) with packet loss.

Before you begin

1. This example assumes that you are aware of the basic configuration steps for PBR.
2. You have configured ingress and egress interfaces with logical names. In this example, the ingress interface is named *Inside1*, and egress interfaces are named *ISP01*, *ISP02*, and *ISP03*.

Follow these steps to configure PBR with path monitoring:

Procedure

Step 1 Path monitoring configuration on interfaces *ISP01*, *ISP02*, and *ISP03*:

For the metrics collection on the egress interfaces, you must enable and configure path monitoring on them.

a) Choose **Devices** > **Device Management**, and edit Firewall Threat Defense.
b) Under the **Interfaces** tab, edit the interface (in our example, *ISP01*)
c) Click the **Path Monitoring** tab, select the **Enable Path Monitoring** check box, and then specify the monitoring type (see Configure path monitoring settings, on page 1331).
d) Click **Ok** and **Save**.
e) Repeat these steps to configure the path monitoring settings for *ISP02* and *ISP03*.

Step 2 Configure policy-based routing for a branch in an organization Firewall Threat Defense, select the ingress interfaces:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Policy Based Routing**, and on the **Policy Based Routing** page, click **Add**.
c) In the **Add Policy Based Route** dialog box, select *Inside 1* from the **Ingress Interface** drop-down list.

Step 3 Specify the match criteria:

a) Click **Add**.
b) To define the match criteria, click the **Add** (+) button.
c) In **New Extended Access List Object**, enter the name for the ACL (example, *PBR-WebEx*), and click **Add**.
d) In the **Add Extended Access List Entry** dialog box, choose the necessary web-based applications, such as WebEx Meetings) from the **Application** tab.

Remember On Firewall Threat Defense, the application group in an ACL is configured as a network service group and each of the applications as a network service object.

e) Click **Save**.
f) Select *PBR-WebEx* from the **Match ACL** drop-down list.

Step 4 Specify the egress interfaces:

a) From the **Send To** drop-down list, choose Egress Interfaces.
b) From the **Interface Ordering** drop-down list, choose By Minimal Jitter.
c) Under **Available Interfaces**, click the **Right Arrow** (>)button against the respective interface names to add *ISP01*, *ISP02*, and *ISP03*.
d) Click **Save**.

Step 5 Repeat Step 2 and Step 3 to create PBRs for the *Inside1* interface to route Office365 and network-based access control traffic:

a) Create a match criteria object, example *PBR-Office365*, and select the Office365 application from the **Application** tab.
b) From the **Interface Ordering** drop-down list, choose By Minimal Round Trip Time.
c) Specify the egress interfaces *ISP01*, *ISP02*, and *ISP03*, and click **Save**.
d) Now, create a match criteria object, example *PBR-networks*, and specify the source and destination interface in the **Network** tab.
e) From the **Interface Ordering** drop-down list, choose By Minimal Packet Loss.
f) Specify the egress interfaces *ISP01*, *ISP02*, and *ISP03*, and click **Save**.

Step 6 Click **Save**, and then click **Deploy**.

Step 7 To view path monitoring metrics, Choose **Devices** > **Device Management**, and from **More** (⋮) click **Health Monitor**. To view the metric details for the interfaces of the device, you must add the path metrics dashboard. For details, see Add path monitoring dashboard, on page 1332.

The WebEx, Office365, and networks-based ACL traffic are forwarded through the best route derived from the metrics value collected on *ISP01*, *ISP02*, and *ISP03*.

Useful CLIs for monitoring PBR

Run the monitoring commands described in this topic from the Firewall Threat Defense device CLI.

Interface configurations

To view the interface configurations of the device, run the `show run interface` command:

```
> show run interface
!
interface Ethernetl/l
 description Outside ispl handoff
 nameif outside1
 security-level 0
 zone-member ECMP-WAN
 ip address dhcp setroute
 policy-route cost 10
 policy-route path-monitoring 8.8.8.8
 policy-route path-monitoring object-group network-service FMC_NSG_4295470581 policy-route
 path-monitoring object-group network-service FMC_NSG_4295470600
!
interface Ethernet1/2
 description Outside isp2 handoff
 nameif outside2
 security-level 0
 zone-member ECMP-WAN
 ip address 192.133.243.240 255.255.255.192
 policy-route cost 20
 policy-route path-monitoring 8.8.8.8
 policy-route path-monitoring object-group network-service FMC_NSG_4295470581 policy-route
 path-monitoring object-group network-service FMC_NSG_4295470600
!
```

DNS configurations

Application-based routing only uses trusted DNS servers to resolve domains. To view the DNS configurations of the device, run the `show run DNS` command:

```
> show run dns
DNS server-group DefaultDNS
dns trusted-source 10.100.0.5
dns trusted-source 10.200.0.5
```

Route map configurations

When you configure PBR on the device, the Management Center auto-generates the route-map and applies it to the specified ingress interface. To view the route maps of the device, run the `show run route-map` command:

```
> show run route-map
!
route-map FMC_VPN_CONNECTED_DIST_RMAP_1000 permit 10
 match interface inside-employee
 set community 1000
!
route-map FMC GENERATED PBR 1729024850865 permit 5
 match ip address Cloud-storage-apps-acl
  set adaptive-intertace cost outside1 outside2

!
route-map FMC_GENERATED PBR 1729024850865 permit 10
match ip address Social-media-apps-acl
set adaptive-interface rtt outside1 outside2

!
route-map FMC GENERATED PBR 1729024850865 permit 15
match ip address Conferencing-apps-acl
set adaptive-interface jitter outside1 outside2

!
route-map FMC_GENERATED_PBR_1729024850865 permit 20
match ip address Corp-internal-apps-acl
set adaptive-interface cost outside1_static_vti_1 outside2_static_vti_4
```

Access lists and network service groups configurations

The route-map applied to the ingress interface can reference an extended access control list. To view the details of an access list for PBR, run the `show run access list <access list_name>` command:

```
> show run access-list Cloud-storage-apps-acl
access-list Cloud-storage-apps-acl extended permit ip any object-group-network-service
FMC_NSG_4295470562
```

The network-service objects and object-groups are configured in extended access control lists and referenced in policy-based routing route maps and access control groups. To view the NSG configurations, run the `show object-group network-service <network-service-groups-name>` command. The *network-service-groups-name* is derived from the above show command for an access list.

```
> show object-group network-service FMC_NSG_4295470562
 object-group network-servire FMC_NSG_4295470562 (id=@xfdff0000)
 network-service-member "Box" dynamic
 description File storage and transfer site.
 app-id 1326

```

Troubleshoot PBR

This task helps you debug PBR configuration when packets get dropped by verifying routes, monitoring metrics, and validating interface selection.

When PBR is not working as intended, you need to systematically verify the configuration components including route maps, path monitoring, and interface selection to identify the root cause of packet drops.

Before you begin

Follow these steps to troubleshoot PBR configuration when packets get dropped:

Procedure

Step 1 Check that all essential routes for recursive resolution are present by using the show route or show ipv6 route commands in the appropriate tables.

Unless the route map for the interfaces participating in PBR is updated with correct routes, PBR will not work as intended.

Step 2 Display the remote address that path-monitoring uses to monitor metrics by using the **show running-config interface** command.

Example:

```
interface GigabitEthernet0/0
nameif outside_0
security-level 0
zone-member ecmp-zone
ip address 20.0.0.3 255.255.255.0 -> This is egress interface "show running-config" output,
 the monitored address and cost metric value is determined in this output.
policy-route cost 1
policy-route path-monitoring
20.0.0.4
!
int GigabitEthernet 0/3
!
interface GigabitEthernet0/3
nameif outside_3
security-level 0
ip address 11.1.1.2 255.255.255.0 -> This is ingress interface "show running-config" output,
 the specific route-map will be used by PBR to determine the next route.
policy-route route-map rtt-tes
```

This command shows the monitored address and cost metric values for path monitoring by sending ICMP packets or HTTP pings.

Step 3 Examine the **show path-monitoring** and **show run route-map** outputs for packet loss.

Example:

```
ciscoasa(config)# show path-monitoring
Interface: outside_0  -> The remote address used for ICMP monitoring
Remote peer: 20.0.0.4
Version: 6223
Remote peer reachable: Yes -> If this value turns "No", then the ICMPv4/v6 packet is not
reaching the required remote address.
RTT average: 1920 microsecond(s)
Jitter: 394 microsecond(s)
Packet loss: 0%
MOS: 4.40
Last updated: 17 second(s) ago -> The data should be updated by path monitoring after every
 30 seconds. The 'show route-map' would show the
updated metric values.
Interface: outside_2
Remote peer: 40.0.0.4
Version: 6223
Remote peer reachable: Yes
RTT average: 1935 microsecond(s)
Jitter: 433 microsecond(s)
Packet loss: 0%
MOS: 4.40
Last updated: 17 second(s) ago
```

Example:

```
ciscoasa(config)# show route-map
route-map rtt-test, permit, sequence 10
Match clauses:
Set clauses:
adaptive-interface rtt outside_0 (1920) outside_2 (1935) outside_1 (1971) -> Displays the
metric type (rtt) that is used by the policy route to select the adequate interface to send
 the packet. The interface list where cost of each interface is given. As the metric type
is "rtt" and considering the minimum rtt value, the "outside_0" interface route will be
selected by PBR.
route-map mos-test, permit, sequence 10
Match clauses:
Set clauses:
adaptive-interface mos outside_0 (378) outside_1 (390) outside_2 (440) - > As the metric
type is "mos", considering the maximum value of mos, the "outside_2" interface will be
selected by PBR.
```

The metric types (lost, rtt, jitter, cost) should select the interface with the minimum metric value for routing.

The metric type "mos" should select the interface with the maximum metric value for routing.

Step 4 Use **packet-tracer** command to validate the interface selection based on the metric type defined in the PBR.

Example:

```
packet-tracer input <interface> icmp <src ip address> 8 0 <dst ip
address> detailed
Phase: 3
Type: PBR-LOOKUP
Subtype: policy-route
Result: ALLOW
Elapsed time: 60656 ns
Config:
route-map rtt-test permit 10
match ip address allow_101_1_1_2
set adaptive-interface rtt outside_0 outside_2
Additional Information:
Matched route-map rtt-test, sequence 10, permit
Found next-hop 40.0.0.4 using egress ifc outside_2 -> PBR selects the adequate interface
from adaptiveinterface list given in "rtt-test" route-map.
```

Step 5 Use the **packet-tracer** command similar to the **debug policy-route** command.

When PBR successfully selects the route, the packet tracer output looks like this:

```
pbr: policy based route lookup called for 101.1.1.1/0 to 101.1.1.2/0 proto 1 sub_proto 8
received on
interface outside_3, NSGs, nsg_id=none
pbr: First matching rule from ACL(-1)
pbr: route map rtt-test, sequence 10, permit; proceed with policy routing
pbr: policy based routing applied; egress_ifc = outside_2 : next_hop = 20.0.0.4
```

When PBR is not able to find the adequate route, it falls back to normal route lookup, and the packet tracer output looks like this:

```
pbr: policy based route lookup called for 100.1.1.1/0 to 100.1.1.2/0 proto 1 sub_proto 8
received on interface outside_3, NSGs, nsg_id=none
pbr: First matching rule from ACL(-1)
pbr: route map mos-test, sequence 10, permit; proceed with policy routing
pbr: no route to 100.1.1.2 on adaptive-interface outside_2
pbr: no route to 100.1.1.2 on adaptive-interface outside_1
pbr: no route to 100.1.1.2 on adaptive-interface outside_0
pbr: policy based routing could not be applied; proceeding with normal route lookup
```

When a monitored remote address goes down, and path monitoring marks **Remote peer reachable** as **No** for that address, the PBR displays the a log that excludes the interface from adaptive-interface list.

```
pbr: policy based route lookup called for 100.1.1.1/0 to 101.1.1.2/0 proto 1 sub_proto 8
received on
interface outside_3, NSGs, nsg_id=none
pbr: First matching rule from ACL(-1)
pbr: route map rtt-test, sequence 10, permit; proceed with policy routing
pbr: Path Monitoring Ifc Down : adaptive-interface outside_1 Excluded from PBR routing
pbr: policy based routing applied; egress_ifc = outside_2 : next_hop = 40.0.0.4
```

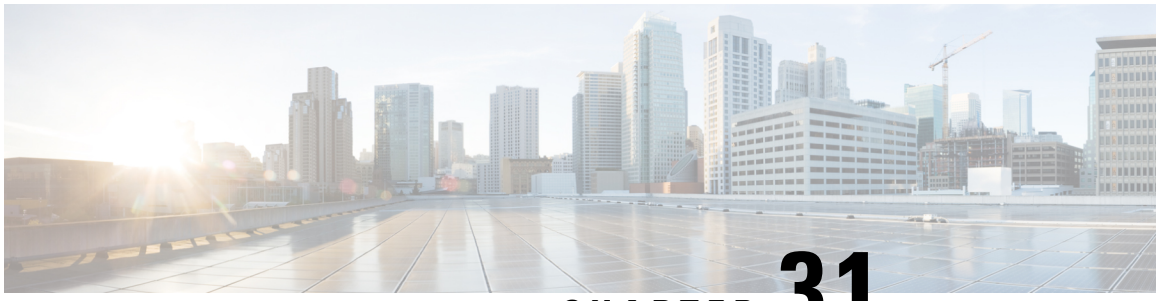
Note The interface becomes eligible for adaptive PBR routing when the interface is reported as reachable in the path monitoring module.

History for policy-based routing

This reference provides a comprehensive history table that summarizes the introduction and evolution of policy-based routing features in Cisco Secure Firewall Management Center across releases, enabling quick tracking of feature availability and changes.

Table 84: History table

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Custom Application Detector support in PBR	10.0.0	10.0.0	Using the Advanced detector type option, a .lua file containing the detector pattern can be used to create a custom detector. The created custom detector patterns can then be used in the Extended ACL for the application-based PBR policy. New/modified screens: No new or modified screens were added.
Custom Application Detector support in PBR	7.7	7.7	You can now create PBR policies with custom application domains. User-defined domains are created as custom detector patterns and can be used in Extended ACL for the application-based PBR policies. New/modified screens: No new or modified screens were added.
Identity and SGT based PBR Policy	7.4.0	7.4.0	You can now classify the network traffic based on users and user groups, and SGTs in PBR policies. You can select the identity and SGT objects while defining the extended ACLs for the PBR policies. New/modified screens: New tabs added in the extended access list object for configuring the policy-based routing policy: **Objects** > **Object Management** > **Access Control Lists** > **Add Extended** page, **Users** and **Security Group Tag**.
HTTP based Path Monitoring	7.4.0	7.2.0	PBR can now use the performance metrics (RTT, jitter, packet-lost, and MOS) collected by path monitoring through HTTP client on the application domain rather than the metrics on a specific destination IP. HTTP-based application monitoring option is enabled by default for the interface. You can configure a PBR policy with match ACL having the monitored applications and desired metric type for path determination. New/modified screens: New option in Interfaces page for enabling path monitoring: **Devices** > **Device Management** > **Edit Interfaces** > **Path Monitoring** > **Enable HTTP based Application Monitoring** check box.
Dual WAN/ISP Threat Defense Management Support	7.3.0	7.3.0	On a dual WAN-enabled threat defense, a single data interface was configured to communicate with the management center. Now, support to configure a secondary data interface is provided so that the communication channel is sustained when the primary data interface fails. The management center automatically configures PBR to route the SF-Tunnel traffic from the *tapnlp* (internal) interface to one of the available data interfaces based on the priority and SLA metric.
Next-hop settings for PBR route map	7.3.0	7.1.0	You can configure the next-hops for the PBR route-map while enabling packet forwarding actions. New/modified screens: New fields in Add/Edit Forwarding Actions page for configuring egress interfaces: **Device Management** > **Routing** > **Policy Based Routing** > **Add Forwarding Actions** page.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
PBR and Path Monitoring	7.2.0	7.2.0	PBR uses path monitoring to collect the performance metrics (RTT, jitter, packet-lost, and MOS) of the egress interfaces. You must enable path monitoring for the interface and configure the monitoring type. You can configure a PBR policy with the desired metric for path determination. New/modified screens: New tab in Interfaces page for enabling path monitoring: **Devices** > **Device Management** > **Edit Interfaces** > **Path Monitoring** tab.
Configure policy-based routing from the FMC web interface	7.1.0	7.1.0	**Upgrade impact. Redo FlexConfigs after upgrade.** You can now configure policy based routing (PBR) from the FMC web interface. This allows you to classify network traffic based on applications and to implement direct internet access (DIA) to send traffic to the internet from a branch deployment. You can define a PBR policy and configure it on ingress interfaces, specifying match criteria and egress interfaces. Network traffic that matches the access control policy is forwarded through the egress interface based on priority or the order as configured in the policy. This feature requires Version 7.1+ on both the FMC and the device. When you upgrade the FMC to Version 7.1+, existing policy based routing FlexConfigs are removed. After you upgrade your devices to Version 7.1+, redo your policy based routing configurations in the FMC web interface. For devices that you do not upgrade to Version 7.1+, redo the FlexConfigs and configure them to deploy "every time." New/modified screens: **Devices** > **Device Management** > **Routing** > **Policy Based Routing**

- Quality of Service, on page 1485

CHAPTER 31

Network Address Translation

The following topics explain Network Address Translation (NAT) and how to configure it on Firewall Threat Defense devices.

- NAT functions, on page 1363
- NAT basics, on page 1364
- Requirements and prerequisites for NAT policies, on page 1373
- Guidelines for NAT, on page 1373
- Manage NAT policies, on page 1379
- Configure NAT for threat defense, on page 1381
- Translating IPv6 networks, on page 1421
- Monitoring NAT, on page 1434
- Examples for NAT, on page 1435
- History for Firewall Threat Defense NAT, on page 1482

NAT functions

NAT enables private IP networks to connect to the Internet by replacing private IP addresses with public IP addresses. It conserves public addresses by advertising at minimum only one public address for the entire network to the outside world.

Private IP address ranges

Most devices within an IP network are assigned private IP addresses, which are not routable outside the company network due to the shortage of public IPv4 addresses. RFC 1918 defines the private IP address ranges that should not be advertised externally:

- 10.0.0.0 through 10.255.255.255
- 172.16.0.0 through 172.31.255.255
- 192.168.0.0 through 192.168.255.255

One of the primary functions of NAT is to enable private IP networks to access the Internet by translating private IP addresses into legal, routable public addresses. This approach conserves public IP addresses since NAT can be configured to advertise only a single public address for the entire network.

Other functions of NAT include:

- Security: Hides internal IP addresses, discouraging direct attacks.
- IP routing solutions: Handles overlapping IP addresses without conflict.
- Flexibility: Allows internal IP addressing schemes to change without affecting externally visible public addresses.
- Translating between IPv4 and IPv6 (Routed mode only): Supports translating between IPv4 and IPv6, enabling interoperability between different network types.

Note NAT is optional. If NAT is not configured for specific traffic, that traffic will not be translated but will still be subject to normal security policies.

NAT basics

The following topics explain some of the basics of NAT.

NAT terminology

This document uses the following terminology:

- Real address/host/network/interface—The real address is the address that is defined on the host, before it is translated. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the inside network would be the “real” network. Note that you can translate any network connected to the device, not just an inside network. Therefore if you configure NAT to translate outside addresses, “real” can refer to the outside network when it accesses the inside network.
- Mapped address/host/network/interface—The mapped address is the address that the real address is translated to. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the outside network would be the “mapped” network.

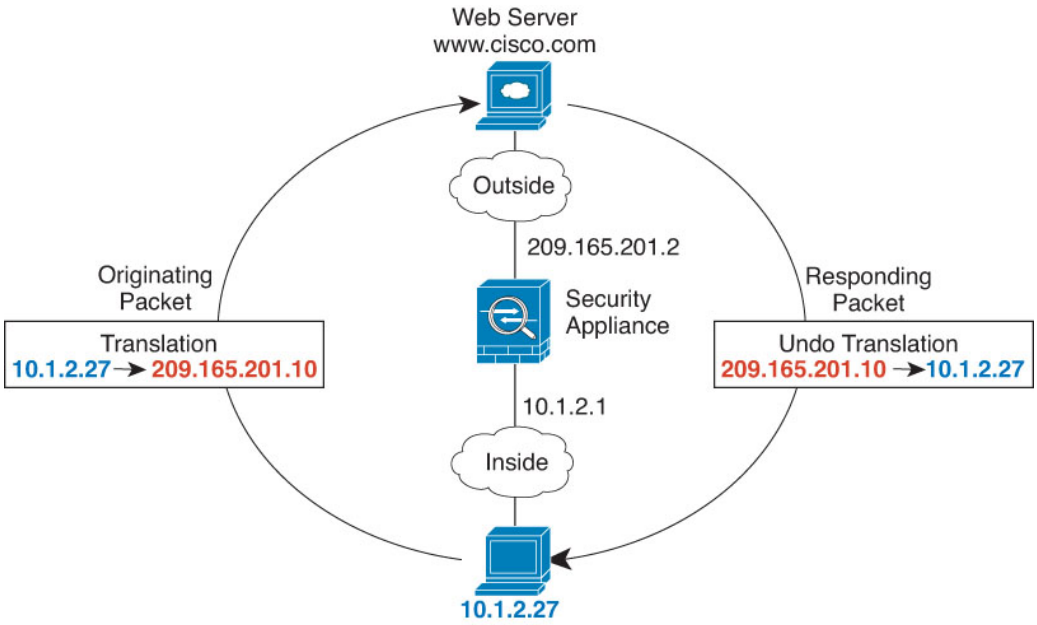
Note During address translation, IP addresses configured for the device interfaces are not translated.

- Bidirectional initiation—Static NAT allows connections to be initiated *bidirectionally*, meaning both to the host and from the host.
- Source and destination NAT—For any given packet, both the source and destination IP addresses are compared to the NAT rules, and one or both can be translated/untranslated. For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address.

NAT types

You can implement NAT using the following methods:

- Dynamic NAT—A group of real IP addresses are mapped to a (usually smaller) group of mapped IP addresses, on a first come, first served basis. Only the real host can initiate traffic. See Dynamic NAT, on page 1387.
- Dynamic Port Address Translation (PAT)—A group of real IP addresses are mapped to a single IP address using a unique source port of that IP address. See Dynamic PAT, on page 1392.
- Static NAT—A consistent mapping between a real and mapped IP address. Allows bidirectional traffic initiation. See Static NAT, on page 1402.
- Identity NAT—A real address is statically translated to itself, essentially bypassing NAT. You might want to configure NAT this way when you want to translate a large group of addresses, but then want to exempt a smaller subset of addresses. See Identity NAT, on page 1411.



NAT in routed and transparent mode

You can configure NAT in both routed and transparent firewall mode. You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. The following sections describe typical usage for each firewall mode.

NAT in routed mode

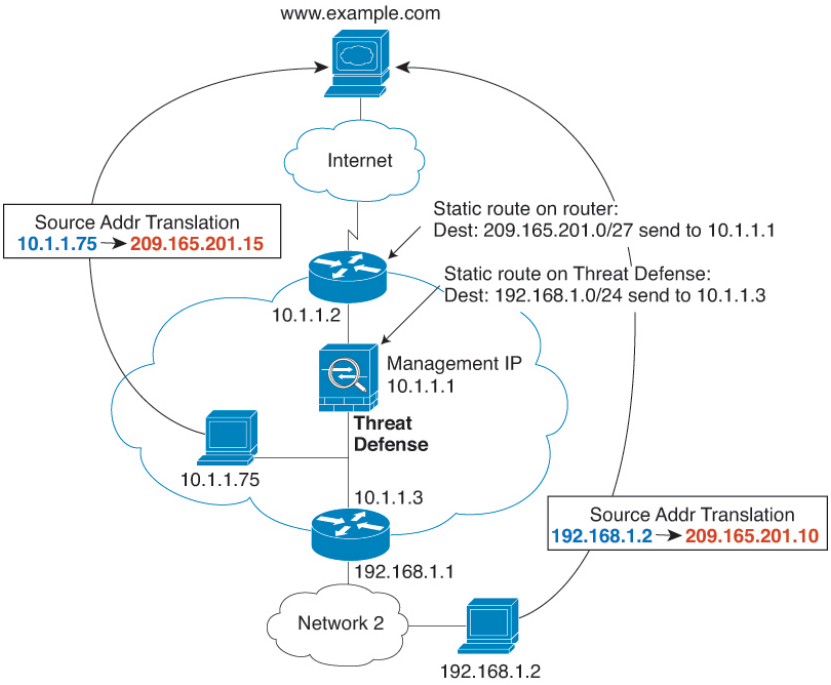
The following figure shows a typical NAT example in routed mode, with a private network on the inside.

Figure 398: NAT Example: Routed Mode

1. When the inside host at 10.1.2.27 sends a packet to a web server, the real source address of the packet, 10.1.2.27, is translated to a mapped address, 209.165.201.10.
2. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the Firewall Threat Defense receives the packet because the Firewall Threat Defense performs proxy ARP to claim the packet.

3. The Firewall Threat Defense then changes the translation of the mapped address, 209.165.201.10, back to the real address, 10.1.2.27, before sending it to the host.

NAT in transparent mode or within a bridge group



Using NAT in transparent mode eliminates the need for the upstream or downstream routers to perform NAT for their networks. It can perform a similar function within a bridge group in routed mode.

NAT in transparent mode, or in routed mode between members of the same bridge group, has the following requirements and limitations:

- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- ARP inspection is not supported. Moreover, if for some reason a host on one side of the Firewall Threat Defense sends an ARP request to a host on the other side of the Firewall Threat Defense, and the initiating host real address is mapped to a different address on the same subnet, then the real address remains visible in the ARP request.
- Translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.

The following figure shows a typical NAT scenario in transparent mode, with the same network on the inside and outside interfaces. The transparent firewall in this scenario is performing the NAT service so that the upstream router does not have to perform NAT.

Figure 399: NAT Example: Transparent Mode

1. When the inside host at 10.1.1.75 sends a packet to a web server, the real source address of the packet, 10.1.1.75, is changed to a mapped address, 209.165.201.15.

2. When the server responds, it sends the response to the mapped address, 209.165.201.15, and the Firewall Threat Defense receives the packet because the upstream router includes this mapped network in a static route directed to the Firewall Threat Defense management IP address.
3. The Firewall Threat Defense then undoes the translation of the mapped address, 209.165.201.15, back to the real address, 10.1.1.1.75. Because the real address is directly-connected, the Firewall Threat Defense sends it directly to the host.
4. For host 192.168.1.2, the same process occurs, except for returning traffic, the Firewall Threat Defense looks up the route in its routing table and sends the packet to the downstream router at 10.1.1.3 based on the Firewall Threat Defense static route for 192.168.1.0/24.

Auto NAT and Manual NAT

You can implement address translation in two ways: *auto NAT* and *manual NAT*.

We recommend using auto NAT unless you need the extra features that manual NAT provides. It is easier to configure auto NAT, and it might be more reliable for applications such as Voice over IP (VoIP). (For VoIP, you might see a failure in the translation of indirect addresses that do not belong to either of the objects used in the rule.)

Auto NAT

All NAT rules that are configured as a parameter of a network object are considered to be *auto NAT* rules. This is a quick and easy way to configure NAT for a network object. You cannot create these rules for a group object, however.

Although these rules are configured as part of the object itself, you cannot see the NAT configuration in the object definition through the object manager.

When a packet enters an interface, both the source and destination IP addresses are checked against the auto NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that sourceA/destinationA should have a different translation than sourceA/destinationB. Use manual NAT for that kind of functionality, where you can identify the source and destination address in a single rule.

Manual NAT

Manual NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that sourceA/destinationA can have a different translation than sourceA/destinationB.

Note For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address. For example, if you configure static NAT with port address translation, and specify the source address as a Telnet server, and you want all traffic going to that Telnet server to have the port translated from 2323 to 23, then you must specify the *source* ports to be translated (real: 23, mapped: 2323). You specify the source ports because you specified the Telnet server address as the source address.

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

Comparing Auto NAT and Manual NAT

The main differences between these two NAT types are:

- How you define the real address.
  - Auto NAT—The NAT rule becomes a parameter for a network object. The network object IP address serves as the original (real) address.
  - Manual NAT—You identify a network object or network object group for both the real and mapped addresses. In this case, NAT is not a parameter of the network object; the network object or group is a parameter of the NAT configuration. The ability to use a network object *group* for the real address means that manual NAT is more scalable.
- How source and destination NAT is implemented.
  - Auto NAT— Each rule can apply to either the source or destination of a packet. So two rules might be used, one for the source IP address, and one for the destination IP address. These two rules cannot be tied together to enforce a specific translation for a source/destination combination.
  - Manual NAT—A single rule translates both the source and destination. A packet matches one rule only, and further rules are not checked. Even if you do not configure the optional destination address, a matching packet still matches one manual NAT rule only. The source and destination are tied together, so you can enforce different translations depending on the source/destination combination. For example, sourceA/destinationA can have a different translation than sourceA/destinationB.
- Order of NAT Rules.
  - Auto NAT—Automatically ordered in the NAT table.
  - Manual NAT—Manually ordered in the NAT table (before or after auto NAT rules).

NAT rule order

Auto NAT and manual NAT rules are stored in a single table that is divided into three sections. Section 1 rules are applied first, then section 2, and finally section 3, until a match is found. For example, if a match is found in section 1, sections 2 and 3 are not evaluated. The following table shows the order of rules within each section.

Note There is also a Section 0, which contains any NAT rules that the system creates for its own use. These rules have priority over all others. The system automatically creates these rules and clears xlates as needed. You cannot add, edit, or modify rules in Section 0.

Table 85: NAT Rule Table

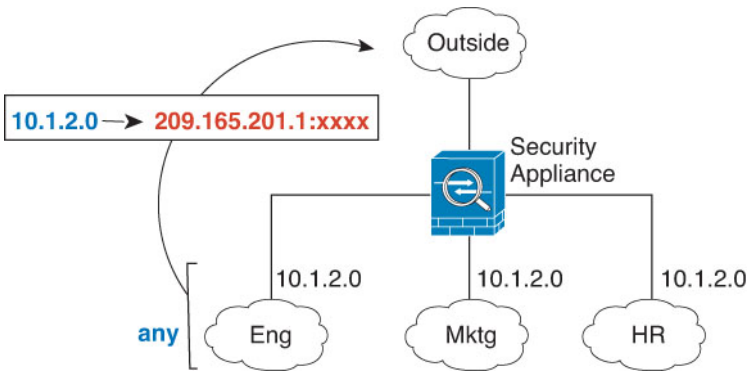
Table Section	Rule Type	Order of Rules within the Section
Section 1	Manual NAT	Applied on a first match basis, in the order they appear in the configuration. Because the first match is applied, you must ensure that specific rules come before more general rules, or the specific rules might not be applied as desired. By default, manual NAT rules are added to section 1. By "specific rules first," we mean: • Static rules should come before dynamic rules. • Rules that include destination translation should come before rules with source translation only. If you cannot eliminate overlapping rules, where more than one rule might apply based on the source or destination address, be especially careful to follow these recommendations. If you do not follow the above recommendation, ensure that accurate routes are configured for the mapped addresses to match the correct NAT rule.
Section 2	Auto NAT	If a match in section 1 is not found, section 2 rules are applied in the following order: **1.** Static rules. **2.** Dynamic rules. **Within each rule type, the following ordering guidelines are used:** **1.** Quantity of real IP addresses—From smallest to largest. For example, an object with one address will be assessed before an object with 10 addresses. **2.** For quantities that are the same, then the IP address number is used, from lowest to highest. For example, 10.1.1.0 is assessed before 11.1.1.0. **3.** If the same IP address is used, then the name of the network object is used, in alphabetical order. For example, abracadabra is assessed before catwoman.
Section 3	Manual NAT	If a match is still not found, section 3 rules are applied on a first match basis, in the order they appear in the configuration. This section should contain your most general rules. You must also ensure that any specific rules in this section come before general rules that would otherwise apply.

For section 2 rules, for example, you have the following IP addresses defined within network objects:

- 192.168.1.0/24 (static)

- 192.168.1.0/24 (dynamic)
- 10.1.1.0/24 (static)
- 192.168.1.1/32 (static)
- 172.16.1.0/24 (dynamic) (object def)
- 172.16.1.0/24 (dynamic) (object abc)

The resultant ordering would be:



- 192.168.1.1/32 (static)
- 10.1.1.0/24 (static)
- 192.168.1.0/24 (static)
- 172.16.1.0/24 (dynamic) (object abc)
- 172.16.1.0/24 (dynamic) (object def)
- 192.168.1.0/24 (dynamic)

NAT interfaces

Except for bridge group member interfaces, you can configure a NAT rule to apply to any interface (in other words, all interfaces), or you can identify specific real and mapped interfaces. You can also specify any interface for the real address, and a specific interface for the mapped address, or vice versa.

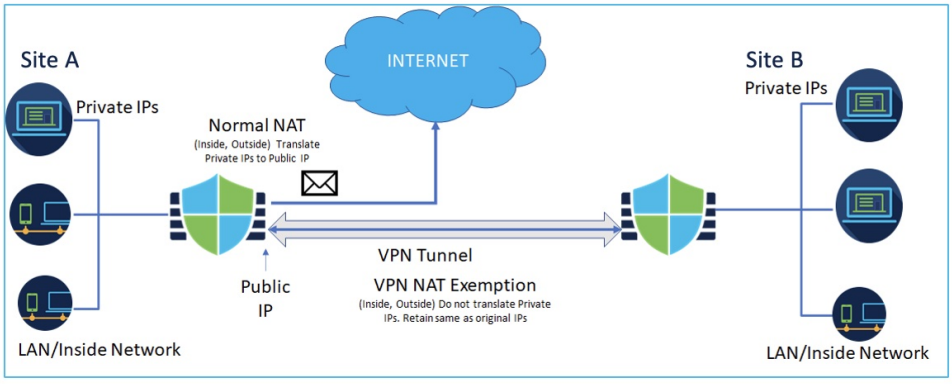
For example, you might want to specify any interface for the real address and specify the outside interface for the mapped address if you use the same private addresses on multiple interfaces, and you want to translate them all to the same global pool when accessing the outside.

Figure 400: Specifying Any Interface

However, the concept of "any" interface does not apply to bridge group member interfaces. When you specify "any" interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. This could result in many similar rules where only one interface is different. You cannot configure NAT for the Bridge Virtual Interface (BVI) itself, you can configure NAT for member interfaces only.

Note You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. When specifying interfaces, you do so indirectly by selecting the interface object that contains the interface.

NAT exemption



When internet edge devices have a site-to-site VPN configured on an interface and also have NAT rules for that interface, you must exempt the VPN traffic from the NAT rules. If you do not exempt the VPN traffic from NAT translation, the traffic gets dropped or is not routed through the VPN tunnel to the remote peer.

NAT exemption allows you to exclude traffic from being translated by NAT rules. When you create a policy-based site-to-site VPN using the Firewall Management Center VPN wizard, you can select the **NAT Exempt** option to create the rules automatically (**Secure Connections** > **Site-to-Site VPN & SD-WAN**). By default, this option is enabled. You can view the NAT exemptions for a device in the NAT policy page (**Policies** > **Network policies** > **NAT**, and then click **NAT Exemptions**).

The Firewall Management Center supports NAT exemption for all policy-based site-to-site VPN topology types. For more information, see Configure a policy-based site-to-site VPN, on page 1523.

Consider the following example, which shows a site-to-site VPN tunnel connecting Site A and Site B. For traffic that must go to the Internet, NAT translates the private IPs to a public IP address to access the Internet. For traffic that must go over the VPN tunnel, you must configure NAT exemption for the device in the VPN wizard.

Figure 401: Site-to-site VPN Topology with NAT Exemption

Note that when you upgrade from versions earlier than 7.4, if you have enabled NAT exemption, Firewall Management Center will disable this option. You must enable this option in the policy-based site-to-site VPN wizard.

Configuring routing for NAT

The Firewall Threat Defense device needs to be the destination for any packets sent to the translated (mapped) address.

When sending packets, the device uses the destination interface if you specify one, or a routing table lookup if you do not, to determine the egress interface. For identity NAT, you have the option to use a route lookup even if you specify a destination interface.

The type of routing configuration needed depends on the type of mapped address, as explained in the following topics.

Addresses on the same network as the mapped interface

If you use addresses on the same network as the destination (mapped) interface, the Firewall Threat Defense uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the Firewall Threat Defense does not have to be the gateway for any additional networks. This solution is ideal if the outside network contains an adequate number of free addresses, a consideration if you are using a 1:1 translation like dynamic NAT or static NAT. Dynamic PAT greatly extends the number of translations you can use with a small number of addresses, so even if the available addresses on the outside network is small, this method can be used. For PAT, you can even use the IP address of the mapped interface.

Note If you configure the mapped interface to be any interface, and you specify a mapped address on the same network as one of the mapped interfaces, then if an ARP request for that mapped address comes in on a *different* interface, then you need to manually configure an ARP entry for that network on the ingress interface, specifying its MAC address. Typically, if you specify any interface for the mapped interface, then you use a unique network for the mapped addresses, so this situation would not occur. Configure the ARP table in the ingress interface's **Advanced** settings.

Addresses on a unique network

If you need more addresses than are available on the destination (mapped) interface network, you can identify addresses on a different subnet. The upstream router needs a static route for the mapped addresses that points to the Firewall Threat Defense.

Alternatively for routed mode, you can configure a static route on the Firewall Threat Defense for the mapped addresses using any IP address on the destination network as the gateway, and then redistribute the route using your routing protocol. For example, if you use NAT for the inside network (10.1.1.0/24) and use the mapped IP address 209.165.201.5, then you can configure a static route for 209.165.201.5 255.255.255.255 (host address) to the 10.1.1.99 gateway that can be redistributed.

For transparent mode, if the real host is directly-connected, configure the static route on the upstream router to point to the Firewall Threat Defense: specify the bridge group IP address. For remote hosts in transparent mode, in the static route on the upstream router, you can alternatively specify the downstream router IP address.

The same address as the real address (identity NAT)

The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired. You can also disable proxy ARP for regular static NAT if desired, in which case you need to be sure to have proper routes on the upstream router.

Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues. For example, if you configure a broad identity NAT rule for “any” IP address, then leaving proxy ARP enabled can cause problems for hosts on the network directly connected to the mapped interface. In this case, when a host on the mapped network wants to communicate with another host on the same network, then the address in the ARP request matches the NAT rule (which matches “any” address). The Firewall Threat Defense will then proxy ARP for the address, even though the packet is not actually destined for the Firewall Threat Defense. (Note that this problem occurs even if you have a manual NAT rule; although the NAT rule must match both the source and destination addresses, the proxy ARP decision is made only on the “source” address). If the

Firewall Threat Defense ARP response is received before the actual host ARP response, then traffic will be mistakenly sent to the Firewall Threat Defense.

Requirements and prerequisites for NAT policies

Ensure you meet these requirements for configuring NAT policies:

Supported domains

Any

User roles

You must have one of these user privileges to configure and use NAT policies:

- Administrator
- Access Admin
- Network Admin

Guidelines for NAT

The following topics provide detailed guidelines for implementing NAT.

Firewall mode guidelines for NAT

NAT is supported in routed and transparent firewall mode.

However, configuring NAT on bridge group member interfaces (interfaces that are part of a Bridge Group Virtual Interface, or BVI) has the following restrictions:

- When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself.
- When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify “any” as the interface.
- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- You cannot translate between IPv4 and IPv6 networks (NAT64/46) when the source and destination interfaces are members of the same bridge group. Static NAT/PAT 44/66, dynamic NAT44/66, and dynamic PAT44 are the only allowed methods; dynamic PAT66 is not supported. However, you can do NAT64/46 between members of different bridge groups, or between a bridge group member (source) and standard routed interface (destination).

Note You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes.

IPv6 NAT guidelines

NAT supports IPv6 with the following guidelines and restrictions.

- For standard routed mode interfaces, you can also translate between IPv4 and IPv6.
- You cannot translate between IPv4 and IPv6 for interfaces that are members of the same bridge group. You can translate between two IPv6 or two IPv4 networks only. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.
- You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.
- For static NAT, you can specify an IPv6 subnet up to /64. Larger subnets are not supported.
- When using FTP with NAT46, when an IPv4 FTP client connects to an IPv6 FTP server, the client must use either the extended passive mode (EPSV) or extended port mode (EPRT); PASV and PORT commands are not supported with IPv6.

IPv6 NAT best practices

You can use NAT to translate between IPv6 networks, and also to translate between IPv4 and IPv6 networks (routed mode only). We recommend the following best practices:

- NAT66 (IPv6-to-IPv6)—We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only).
- NAT46 (IPv4-to-IPv6)—We recommend using static NAT. Because the IPv6 address space is so much larger than the IPv4 address space, you can easily accommodate a static translation. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only). When translating to an IPv6 subnet (/96 or lower), the resulting mapped address is by default an IPv4-embedded IPv6 address, where the 32-bits of the IPv4 address is embedded after the IPv6 prefix. For example, if the IPv6 prefix is a /96 prefix, then the IPv4 address is appended in the last 32-bits of the address. For example, if you map 192.168.1.0/24 to 201b::0/96, then 192.168.1.4 will be mapped to 201b::0.192.168.1.4 (shown with mixed notation). If the prefix is smaller, such as /64, then the IPv4 address is appended after the prefix, and a suffix of 0s is appended after the IPv4 address. You can also optionally translate the addresses net-to-net, where the first IPv4 address maps to the first IPv6 address, the second to the second, and so on.
- NAT64 (IPv6-to-IPv4)—You may not have enough IPv4 addresses to accommodate the number of IPv6 addresses. We recommend using a dynamic PAT pool to provide a large number of IPv4 translations.

NAT support for inspected protocols

Some application layer protocols that open secondary connections, or that embedded IP addresses in packets, are inspected to provide the following services:

- Pinhole creation—Some application protocols open secondary TCP or UDP connections either on standard or negotiated ports. Inspection opens pinholes for these secondary ports so that you do not need to create access control rules to allow them.

- NAT rewrite— Protocols such as FTP embed IP addresses and ports for the secondary connections in packet data as part of the protocol. If there is NAT translation involved for either of the endpoints, the inspection engines rewrite the packet data to reflect the NAT translation of the embedded addresses and ports. The secondary connections would not work without NAT rewrite.
- Protocol enforcement—Some inspections enforce some degree of conformance to the RFCs for the inspected protocol.

The following table lists the inspected protocols that apply NAT rewrite and their NAT limitations. Keep these limitations in mind when writing NAT rules that include these protocols. Inspected protocols not listed here do not apply NAT rewrite. These inspections include GTP, HTTP, IMAP, POP, SMTP, SSH, and SSL.

Note NAT rewrite is supported on the listed ports only. For some of these protocols, you can extend inspection to other ports using Network Analysis Policies, but NAT rewrite is not extended to those ports. This includes DCERPC, DNS, FTP, and Sun RPC inspection. If you use these protocols on non-standard ports, do not use NAT on the connections.

Table 86: NAT Supported Application Inspection

Application	Inspected Protocol, Port	NAT Limitations	Pinholes Created
DCERPC	TCP/135	No NAT64.	Yes
DNS over UDP	UDP/53	No NAT support is available for name resolution through WINS.	No
ESMTP	TCP/25	No NAT64.	No
FTP	TCP/21	(Clustering) No static PAT.	Yes
H.323 H.225 (Call signaling) H.323 RAS	TCP/1720 UDP/1718 For RAS, UDP/1718-1719	(Clustering) No static PAT. No extended PAT. No NAT64.	Yes
ICMP ICMP Error	ICMP (ICMP traffic directed to a device interface is never inspected.)	No limitations.	No
IP Options	RSVP	No NAT64.	No
NetBIOS Name Server over IP	UDP/137, 138 (Source ports)	No extended PAT. No NAT64.	No
RSH	TCP/514	No PAT. No NAT64. (Clustering) No static PAT.	Yes

Application	Inspected Protocol, Port	NAT Limitations	Pinholes Created
RTSP	TCP/554 (No handling for HTTP cloaking.)	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes
SIP	TCP/5060 UDP/5060	No extended PAT. No NAT64 or NAT46. (Clustering) No static PAT.	Yes
Skinny (SCCP)	TCP/2000	No extended PAT. No NAT64, NAT46, or NAT66. (Clustering) No static PAT.	Yes
SQL*Net (versions 1, 2)	TCP/1521	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes
Sun RPC	TCP/111 UDP/111	No extended PAT. No NAT64.	Yes
TFTP	UDP/69	No NAT64. (Clustering) No static PAT. Payload IP addresses are not translated.	Yes
XDMCP	UDP/177	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes

FQDN destination guidelines

You can specify the translated (mapped) destination in a manual NAT rule using a fully-qualified domain name (FQDN) network object instead of an IP address. For example, you can create a rule based on traffic that is destined for the www.example.com web server.

When using an FQDN, the system obtains the DNS resolution and writes the NAT rule based on the returned address. If you are using multiple DNS server groups, the filter domains are honored and the address is requested from the appropriate group based on the filters. If more than one address is obtained from the DNS server, the address used is based on the following:

- If there is an address on the same subnet as the specified interface, that address is used. If there isn't one on the same subnet, the first address returned is used.
- The IP type for the translated source and translated destination must match. For example, if the translated source address is IPv6, the FQDN object must specify IPv6 as the address type. If the translated source is IPv4, the FQDN object can specify IPv4 or both IPv4 and IPv6. In this case, an IPv4 address is selected.

You cannot include an FQDN object in a network group that is used for manual NAT destination. In NAT, an FQDN object must be used alone, as only a single destination host makes sense for this type of NAT rule.

If the FQDN cannot be resolved to an IP address, the rule is not functional until a DNS resolution is obtained.

Additional guidelines for NAT

- NAT rules apply to through the device traffic only, they do not apply to traffic initiated by the device, such as a RADIUS authentication.
- For interfaces that are members of a bridge group, you write NAT rules for the member interfaces. You cannot write NAT rules for the Bridge Virtual Interface (BVI) itself.
- You cannot write NAT rules for a Virtual Tunnel Interface (VTI), which are used in site-to-site VPN. Writing rules for the VTI's source interface will not apply NAT to the VPN tunnel. To write NAT rules that will apply to VPN traffic tunneled on a VTI, you must use "any" as the interface; you cannot explicitly specify interface names.
- (Auto NAT only.) You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules for an object, you need to create multiple objects with different names that specify the same IP address.
- If a VPN is defined on an interface, inbound ESP traffic on the interface is not subject to the NAT rules. The system allows the ESP traffic for established VPN tunnels only, dropping traffic not associated with an existing tunnel. This restriction applies to ESP and UDP ports 500 and 4500.
- If you define a site-to-site VPN on a device that is behind a device that is applying dynamic PAT, so that UDP ports 500 and 4500 are not the ones actually used, you must initiate the connection from the device that is behind the PAT device. The responder cannot initiate the security association (SA) because it does not know the correct port numbers.
- If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT configuration is used, you can clear the translation table using the **clear xlate** command in the device CLI. However, clearing the translation table disconnects all current connections that use translations.

  If you create a new NAT rule that should apply to an existing connection (such as a VPN tunnel), you need to use **clear conn** to end the connection. Then, the attempt to re-establish the connection should hit the NAT rule and the connection should be NAT'ed correctly.

Note If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the **clear xlate** or **clear conn** commands. This safeguard ensures that the same address is not assigned to multiple hosts.

- You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.
- A network object used in NAT cannot include more than 131,838 IP addresses, either explicitly or implied in a range of addresses or a subnet. Break up the address space into smaller ranges and write separate rules for the smaller objects.

- (Manual NAT only.) When using **any** as the source address in a NAT rule, the definition of "any" traffic (IPv4 vs. IPv6) depends on the rule. Before the Firewall Threat Defense performs NAT on a packet, the packet must be IPv6-to-IPv6 or IPv4-to-IPv4; with this prerequisite, the Firewall Threat Defense can determine the value of **any** in a NAT rule. For example, if you configure a rule from "any" to an IPv6 server, and that server was mapped from an IPv4 address, then **any** means "any IPv6 traffic." If you configure a rule from "any" to "any," and you map the source to the interface IPv4 address, then **any** means "any IPv4 traffic" because the mapped interface address implies that the destination is also IPv4.
- You can use the same mapped object or group in multiple NAT rules.
- The mapped IP address pool cannot include:
  - The mapped interface IP address. If you specify "any" interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), specify the interface name instead of the interface address.
  - The failover interface IP address.
  - (Transparent mode.) The management IP address.
  - (Dynamic NAT.) The standby interface IP address when VPN is enabled.
- Avoid using overlapping addresses in static and dynamic NAT policies. For example, with overlapping addresses, a PPTP connection can fail to get established if the secondary connection for PPTP hits the static instead of dynamic xlate.
- You cannot use overlapping addresses in the source address of a NAT rule and a remote access VPN address pool.
- If you specify a destination interface in a rule, then that interface is used as the egress interface rather than looking up the route in the routing table. However, for identity NAT, you have the option to use a route lookup instead.
- If you use PAT on Sun RPC traffic, which is used to connect to NFS servers, be aware that the NFS server might reject connections if the PAT'ed port is above 1024. The default configuration of NFS servers is to reject connections from ports higher than 1024. The error is typically "Permission Denied." Mapping ports above 1024 happens if you do not select the option to include the reserved ports (1-1023) in the port range of a PAT pool. You can avoid this problem by changing the NFS server configuration to allow all port numbers.
- NAT applies to through traffic only. Traffic generated by the system is not subject to NAT.
- Do not name a network object or group pat-pool, using any combination of upper- or lower-case letters.
- The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.
- You cannot use NAT on the internal payload of Protocol Independent Multicast (PIM) registers.
- (Manual NAT) When writing NAT rules for a dual ISP interface setup (primary and backup interfaces using service level agreements in the routing configuration), do not specify destination criteria in the rule. Ensure the rule for the primary interface comes before the rule for the backup interface. This allows the device to choose the correct NAT destination interface based on the current routing state when the primary ISP is unavailable. If you specify destination objects, the NAT rule will always select the primary interface for the otherwise duplicate rules.

- If you get the ASP drop reason nat-no-xlate-to-pat-pool for traffic that should not match the NAT rules defined for the interface, configure identity NAT rules for the affected traffic so the traffic can pass untranslated.
- If you configure NAT for GRE tunnel endpoints, you must disable keepalives on the endpoints or the tunnel cannot be established. The endpoints send keepalives to the original addresses.
- DHCP and BOOTP share ports UDP/67-68. Because BOOTP is obsolete, writing NAT rules for the bootps port can cause port allocation problems when also running DHCP. Consider using DHCP relay instead for transmitting DHCP requests between network segments.
- (Secure Firewall 200) If you use PAT with SIP sessions, and you send thousands of SIP connections through the device, reduce the SIP invite timeout to the minimum of 1 minute. This can avoid problems with free memory consumption by xlates related to the SIP sessions. Configure the timeout on the **Timeout** page in the Platform Settings policy.
- In rare cases, return traffic (server to client) with an existing translation (xlate) might be logged as a new flow in Connection Events. This can occur when the client has already terminated the connection and the server sends another packet that reaches the device during the brief interval between connection closure and xlate removal, often due to application behavior or TCP stack cleanup. Because the device removes the xlate only after deleting the connection, a server packet can arrive while the xlate still exists. If no valid connection entry is found, the device logs a separate connection event based on the matched Access Control Policy rule.

Manage NAT policies

NAT converts the IP address of an incoming packet to a different address in the outgoing packet. One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into routable addresses that can be used on the public Internet. NAT keeps track of the translations, also known as xlates, to ensure that return traffic is directed to the correct untranslated host address.

Procedure

Step 1 Choose **Policies** > **Network policies** > **NAT**.

Step 2 Manage your NAT policies:

- Create—Click **New Policy**. Refer to Create NAT policies, on page 1380.
- Copy—Click **Copy** ( ) next to the policy you want to copy. You are prompted to give the copy a new, unique name. The copy includes all policy rules and configurations, but does not include device assignments.
- Report—Click **Report** ( ) for the policy. You are prompted to save the PDF report, which includes policy attributes, device assignments, rules, and object usage information.
- Edit—Click **Edit** ( ) next to the policy you want to edit. Refer to Configure NAT for threat defense, on page 1381.

- Delete—Click **Delete** ( ) next to the policy you want to delete, then click **OK**. When prompted whether to continue, you are also informed if another user has unsaved changes in the policy.

Caution After you have deployed a NAT policy to a managed device, you cannot delete the policy from the device. Instead, you must deploy a NAT policy with no rules to remove the NAT rules already present on the managed device. You also cannot delete a policy that is the last deployed policy on any of its target devices, even if it is out of date. Before you can delete the policy completely, you must deploy a different policy to those targets.

Create NAT policies

Create a NAT policy to define how network addresses are translated between different network segments.

When you create a new NAT policy you must, at minimum, give it a unique name. Although you are not required to identify policy targets at policy creation time, you must perform this step before you can deploy the policy. If you apply a NAT policy with no rules to a device, the system removes all NAT rules from that device.

Procedure

Step 1 Choose **Policies** > **Network policies** > **NAT**.

Step 2 Click **New Policy** and from the drop-down list, choose **Threat Defense NAT** for Firewall Threat Defense devices.

Step 3 Enter a unique **Name**.

Step 4 (Optional) Enter a **Description**.

Step 5 Choose the devices where you want to deploy the policy:

- Choose a device in the **Available Devices and Templates** list, and then click **Add to Policy**.

  Alternatively, click and drag a device from the **Available Devices and Templates** list to the **Selected Devices and Templates** list.

- Remove a device from the **Selected Devices and Templates** list by clicking **Delete** ( ) next to the device.

Step 6 Click **Save**.

Configure NAT policy targets

Identify the managed devices that you want to target with your policy while creating or editing a policy and assign NAT policies to identified devices to control NAT behavior. You can search a list of available devices and high-availability pairs, and add them to a list of selected devices.

Procedure

Step 1 Choose **Policies** > **Network policies** > **NAT**.

Step 2 Click **Edit** (✎) next to the NAT policy you want to modify.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Click **Policy Assignments**.

Step 4 Do any of the following:

- To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices and Templates** list and click **Add to Policy**. Alternatively, you can also drag and drop selected devices.
- To remove a device assignment, click **Delete** (🗑) next to a device, high-availability pair, or device group in the **Selected Devices and Templates** list.

Step 5 Click **OK**.

Configure NAT for threat defense

The NAT policy is a shared policy. Assign it to devices that need similar NAT rules.

Each rule applies to a device if its interface objects (security zones or interface groups) include an interface for that device. When the interface objects include one or more interface for the device, the rule is deployed to the device. You can target subsets of devices within a shared policy by designing interface objects accordingly. Rules using the "any" interface object apply to all devices.

If you change an interface type to one not valid for NAT on an assigned device, the policy marks the interface as deleted. Click **Save** in the NAT policy to automatically remove the interface from the policy.

You can configure multiple NAT policies if groups of your devices require significantly different rules.

Procedure

Step 1 Select **Policies** > **Network policies** > **NAT**.

- Click **New Policy** to create a new policy. Give the policy a name, optionally assign devices to it, and click **Save**.

  You can change device assignments later by editing the policy and clicking **Policy Assignments**.

- Click **Edit** (✎) to edit an existing threat defense NAT policy.

  If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Decide what kinds of rules you need.

You can create dynamic NAT, dynamic PAT, static NAT, and identity NAT rules. For an overview, refer to NAT types, on page 1364.

Step 3 Decide which rules should be implemented as manual or auto NAT.

For a comparison of these two implementation options, refer to Auto NAT and Manual NAT, on page 1367.

Step 4 Decide which rules should be custom per device.

Because you can assign a NAT policy to multiple devices, you can configure a single rule on many devices. However, you might have rules that should be interpreted differently by each device, or some rules that should apply to a subset of devices only.

Use interface objects to control on which devices a rule is configured. Then, use object overrides on network objects to customize the addresses used per device.

For detailed information, refer to Customize NAT rules for multiple devices, on page 1383.

Step 5 Create the rules as explained in these sections.

- Dynamic NAT, on page 1387
- Dynamic PAT, on page 1392
- Static NAT, on page 1402
- Identity NAT, on page 1411

Step 6 Do these to manage your NAT policy:

- To edit the policy name or description, click in those fields, type in your changes, and click outside the fields.
- To view only those rules that apply to a specific device, click **Filter by Device** and select the desired device. A rule applies to a device if it uses an interface object that includes an interface on the device.
- To view any warnings or errors in the policy, click **Show Warnings**, then choose a **Device**. Warnings and errors mark configurations that could adversely affect traffic flow or prevent the policy from deploying.
- To change the devices to which the policy is assigned, click the **Policy Assignments** link and modify the selected devices list as desired.
- To change the number of rules displayed on the page, use the **Rows Per Page** drop-down list.

Step 7 Do these to manage your NAT rules:

- To add a rule, click the **Add Rule** button.
- To edit a rule, click the **Edit** (✎) icon next to the rule.
- To delete a rule, click the **Delete** (🗑) icon next to the rule.

- To enable or disable a rule, right-click the rule and choose **Enable** or **Disable** from the **State** menu. You can temporarily disable a rule without deleting it using these controls.
- To select more than one rule to enable, disable, or delete, click the checkbox for the rules, or the checkbox in the header, then perform the action.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Customize NAT rules for multiple devices

Because the NAT policy is shared, you can assign a given policy to more than one device. However, you can configure at most one auto NAT rule for a given object. Thus, if you want to configure different translations for an object based on the specific device doing the translation, you need to carefully configure the interface objects (security zones or interface groups) and define network object overrides for the translated address. The interface objects determine on which devices a rule gets configured. The network object overrides determine what IP addresses are used by a given device for that object.

Consider the following scenario:

- FTD-A and FTD-B have inside networks 192.168.1.0/24 attached to the interface named “inside.”
- On FTD-A, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.100.10.10 - 10.100.10.200 range when going to the “outside” interface.
- On FTD-B, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.200.10.10 - 10.200.10.200 range when going to the “outside” interface.

Do these steps to accomplish the above scenario. Although this example rule is for dynamic auto NAT, you can generalize the technique for any type of NAT rule.

Procedure

Step 1 Create the security zones for the inside and outside interfaces.

a) Choose **Objects**.
b) Select **Interface** from the table of contents and click **Add** > **Security Zone**.

You can use interface groups instead of zones.

c) Configure the inside zone properties.

- **Name**—Enter a name, for example, **inside-zone**.
- **Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
- **Selected Interfaces**—Add the FTD-A/inside and FTD-B/inside interfaces to the selected list.

d) Click **Save**.
e) Click **Add** > **Security Zone** and define the outside zone properties.

- **Name**—Enter a name, for example, **outside-zone**.
- **Interface Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
- **Selected Interfaces**—Add the FTD-A/outside and FTD-B/outside interfaces to the selected list.

f) Click **Save**.

Step 2 Create the network object for the original inside network on the Object Management page.

a) Select **Network** from the table of contents and click **Add Network** > **Add Object**.
b) Configure the inside network properties.

- **Name**—Enter a name, for example, **inside-network**.
- **Network**—Enter the network address, for example, **192.168.1.0/24**.

c) Click **Save**.

Step 3 Create the network object for the translated NAT pool and define overrides.

a) Click **Add Network** > **Add Object**.
b) Configure the NAT pool properties for FTD-A.

- **Name**—Enter a name, for example, **NAT-pool**.
- **Network**—Enter the range of addresses to include in the pool for FTD-A, for example, **10.100.10.10-10.100.10.200**.

c) Select **Allow Overrides**.
d) Click the **Overrides** heading to open the list of object overrides.
e) Click **Add** to open the Add Object Override dialog box.
f) Select FTD-B and **Add** it to the **Selected Devices** list.
g) Click **Override** and change **Network** to **10.200.10.10-10.200.10.200**.
h) Click **Add** to add the override to the device.

By defining an override for FTD-B, whenever the system configures this object on FTD-B, it will use the override value instead of the value defined in the original object.

i) Click **Save**.

Step 4 Configure the NAT rule.

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside-zone.
- **Destination Interface Objects** = outside-zone.

Note The interface objects control on which devices the rule is configured. Because in this example the zones contain interfaces for FTD-A and FTD-B only, even if the NAT policy were assigned to additional devices, the rule would be deployed to those 2 devices only.

e) On **Translation**, configure the following:

- **Original Source** = inside-network object.
- **Translated Source** > **Address**= NAT-pool object.

f) Click **Save**.

You now have a single rule that will be interpreted differently for FTD-A and FTD-B, providing unique translations for the inside networks protected by each firewall.

Search and filter the NAT rule table

You can search and filter the NAT rule table to help you find rules that you need to modify or view. When you filter the table, only matching rules are shown. Note that although the rule numbers change to be sequentially 1, 2, and so forth, filtering does not change the actual rule number or the rule's location in the table relative to hidden rules. Filtering simply changes what you can see to help you locate rules that interest you.

When editing the NAT policy, you can use the fields above the table to do these types of search or filter:

- **Filter by Device**—Click **Filter by Device**, then select the devices whose rules you want to see and click **OK**. Whether a rule applies to a device is determined by the rule's interface constraints. If you specify a security zone or interface group for either the source or destination interface, the rule applies to a device if at least one interface for the device is in the zone or group. If a NAT rule applies to any source and any destination interface, then it applies to all devices.

  If you also do a text or multiple-attribute search, the results are constrained to the selected devices.

  To remove this filter, click **Filter by Device** and deselect the devices, or select **All**, and click **OK**.

- **Simple Text Search**—In the **Filter** box, type a string and press Enter. The string is compared to all values in the rules. For example, if you enter "network-object-1," which is the name of a network object, you would get rules that use the object in source, destination, and PAT pool attributes.

  For network and port objects, the string is also compared to the contents of the objects used in the rule. For example, if a PAT pool object includes the range 10.100.10.3-10.100.10.100, searching on either 10.100.10.3 or 10.100.10.100 (or a partial 10.100.10) will include rules that use that PAT pool object. However, the match must be exact: searching on 10.100.10.5 will not match this PAT pool object, even though the IP address is within the object's IP address range.

  To remove the filter, click the **x** on the right side of the Filter box.

- **Multiple-Attribute Search**—If a simple text search gives you too many hits, you can configure multiple values for the search. Click in the **Filter** box to open the list of attributes, then select or enter strings for the attributes you intend to search and click the **Filter** button. These attributes are the same as the ones

you would configure within a NAT rule. The attributes are and'ed, so filtered results include only those rules that match all attributes you configured.

- For binary attributes, such as the rule state (enabled/disabled), whether a PAT pool is configured (enabled/disabled), the direction of the rule (uni/bi), or rule type (static/dynamic), simply check or uncheck the boxes as appropriate. Select both boxes if you do not care about the attribute value. If you deselect both boxes, no rules will match the filter.
- For string attributes, type a full or partial string relevant to that attribute. These will be object names, either for security zones/interface groups, network objects, or port objects. It can also be the network or port object contents, which are matched the same way they are for simple text searches.

To remove the filter, click the **x** on the right side of the Filter box, or click in the Filter box to open the drop-down list, and click the Clear button.

Enable, disable, or delete multiple rules

You can enable or disable manual NAT rules, or delete any NAT rule, one by one. You can also select multiple rules and apply changes to all of them at once. Because enable/disable applies to manual NAT only, if you select a mix of rule types, you can delete them only. Note that when you enable or disable rules, it does not matter if you select some rules that were already enabled or disabled. For example, enabling an already enabled rule simply leaves the rule enabled.

Procedure

Step 1 Select **Policies** > **Network policies** > **NAT**, and edit a threat defense NAT policy.

Step 2 (Optional) Filter the NAT rules to locate the ones you want to change.

Filtering is especially useful if you have a large NAT policy. For example, you could search on disabled rules to find ones that need to be enabled.

Step 3 Select the rules you want to change.

- Click the checkbox in the left column of the rule to select (or deselect) individual rules.
- Click the checkbox in the table header to select all the rules on the currently displayed page.

Your selection is preserved as you go from page to page. However, in practice, it makes most sense to perform your actions on the rules selected on a page before going to the next page.

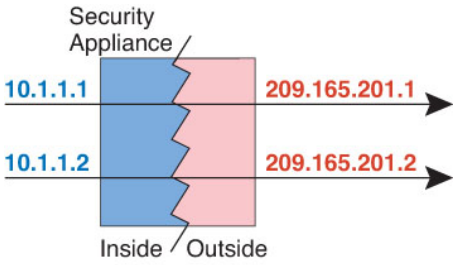
Step 4 Perform the desired action. When selecting multiple rules, you are asked to confirm the action.

Note that these actions are also available on the right-click menu.

- To enable all rules, click **Select Bulk Action** > **Enable**.
- To disable all rules, click **Select Bulk Action** > **Disable**.
- To delete all rules, click **Select Bulk Action** > **Delete**.

Dynamic NAT

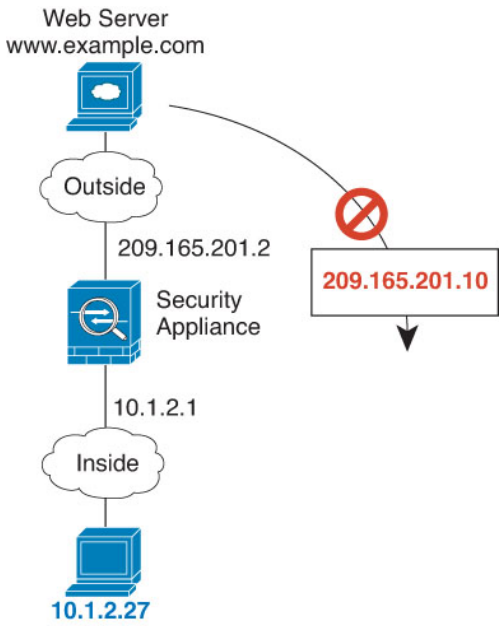
The following topics explain dynamic NAT and how to configure it.



About dynamic NAT

Dynamic NAT translates a group of real addresses to a pool of mapped addresses that are routable on the destination network. The mapped pool typically includes fewer addresses than the real group. When a host you want to translate accesses the destination network, NAT assigns the host an IP address from the mapped pool. The translation is created only when the real host initiates the connection. The translation is in place only for the duration of the connection, and a given user does not keep the same IP address after the translation times out. Users on the destination network, therefore, cannot initiate a reliable connection to a host that uses dynamic NAT, even if the connection is allowed by an access rule.

Note For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the address is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule. A successful connection from a remote host can reset the idle timer for the connection.



The following figure shows a typical dynamic NAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back.

Figure 402: Dynamic NAT

The following figure shows a remote host attempting to initiate a connection to a mapped address. This address is not currently in the translation table; therefore, the packet is dropped.

Figure 403: Remote Host Attempts to Initiate a Connection to a Mapped Address

Dynamic NAT disadvantages and advantages

Dynamic NAT has these disadvantages:

- If the mapped pool has fewer addresses than the real group, you could run out of addresses if the amount of traffic is more than expected.

  Use PAT or a PAT fall-back method if this event occurs often because PAT provides over 64,000 translations using ports of a single address.

- You have to use a large number of routable addresses in the mapped pool, and routable addresses may not be available in large quantities.

The advantage of dynamic NAT is that some protocols cannot use PAT. PAT does not work with the following:

- IP protocols that do not have a port to overload, such as GRE version 0.
- Some multimedia applications that have a data stream on one port, the control path on another port, and are not open standard.

Configure dynamic auto NAT

Use dynamic auto NAT rules to translate addresses to different IP addresses that are routable on the destination network.

Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.

- **Translated Source**—This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.

Procedure

Step 1 Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Dynamic**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The network object or group that contains the mapped addresses.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1467.
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure dynamic manual NAT

Use dynamic manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic NAT translates addresses to different IP addresses that are routable on the destination network.

Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—This can be a network object or group, but it cannot include a subnet. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

Procedure

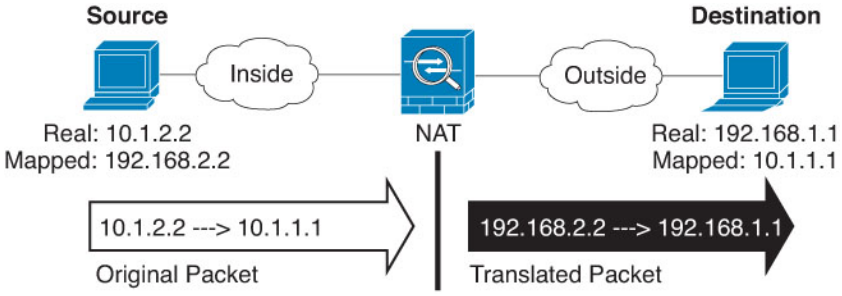
Step 1 Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The network object or group that contains the mapped addresses.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the destination service ports for service translation: **Original Destination Port**, **Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

Step 8 (Optional.) On **Advanced**, select the desired options:

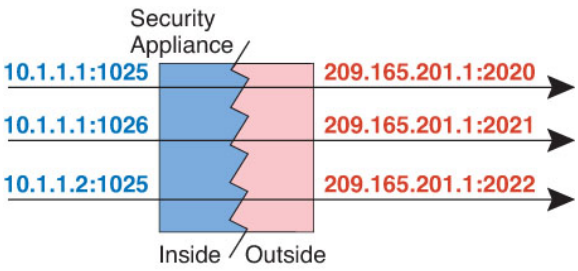
- (For source translation only.) **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1467.
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 9 Click **Save** to add the rule.

Step 10 Click **Save** on the NAT page to save your changes.

Dynamic PAT

The following topics describe dynamic PAT.



About dynamic PAT

Dynamic PAT translates multiple real addresses to a single mapped IP address by translating the real address and source port to the mapped address and a unique port.

Each connection requires a separate translation session because the source port differs for each connection. For example, 10.1.1.1:1025 requires a separate translation from 10.1.1.1:1026.

The following figure shows a typical dynamic PAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back. The mapped address is the same for each translation, but the port is dynamically assigned.

Figure 404: Dynamic PAT

For the duration of the translation, a remote host on the destination network can initiate a connection to the translated host if an access rule allows it. Because the port address (both real and mapped) is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

After the connection expires, the port translation also expires.

Note We recommend that you use different PAT pools for each interface. If you use the same pool for multiple interfaces, especially if you use it for "any" interface, the pool can be quickly exhausted, with no ports available for new translations.

Dynamic PAT disadvantages and advantages

Dynamic PAT lets you use a single mapped address, thus conserving routable addresses. You can even use the Firewall Threat Defense interface IP address as the PAT address.

You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.

Dynamic PAT does not work with some multimedia applications that have a data stream that is different from the control path. For more information, see NAT support for inspected protocols, on page 1374.

Dynamic PAT might also create a large number of connections appearing to come from a single IP address, and servers might interpret the traffic as a DoS attack. You can configure a PAT pool of addresses and use a round-robin assignment of PAT addresses to mitigate this situation.

PAT pool object guidelines

When creating network objects for a PAT pool, follow these guidelines.

For a PAT pool

- Ports are mapped to an available port in the 1024 to 65535 range. You can optionally include the reserved ports, those below 1024, to make the entire port range available for translations.

  When operating in a cluster, blocks of 512 ports per address are allocated to the members of the cluster, and mappings are made within these port blocks. If you also enable block allocation, the ports are distributed according to the block allocation size, whose default is also 512. If you change the cluster unit limit (the size of the cluster), ensure that you clear xlates or reboot the devices so that PAT pools can be appropriately reallocated to the cluster units.

- If you enable block allocation for a PAT pool, port blocks are allocated in the 1024-65535 range only. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host.

- If you use the same PAT pool object in two separate rules, then be sure to specify the same options for each rule. For example, if one rule specifies extended PAT, then the other rule must also specify extended PAT.

- If a host has an existing connection, then subsequent connections from that host use the same PAT IP address. If no ports are available, this can prevent the connection. Use the round robin option to avoid this problem.

- For best performance, limit the number of IP addresses within a PAT pool to 10,000.

For extended PAT for a PAT pool

- Many application inspections do not support extended PAT.
- If you enable extended PAT for a dynamic PAT rule, then you cannot also use an address in the PAT pool as the PAT address in a separate static NAT with port translation rule. For example, if the PAT pool includes 10.1.1.1, then you cannot create a static NAT-with-port-translation rule using 10.1.1.1 as the PAT address.
- If you use a PAT pool and specify an interface for fallback, you cannot specify extended PAT.
- For VoIP deployments that use ICE or TURN, do not use extended PAT. ICE and TURN rely on the PAT binding to be the same for all destinations.
- You cannot use extended PAT on units in a cluster.
- Extended PAT increases memory usage on the device.

For round robin for a PAT pool

- If a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. However, this “stickiness” does not survive a failover. If the device fails over, then subsequent connections from a host might not use the initial IP address.
- IP address “stickiness” is also impacted if you mix PAT pool/round robin rules with interface PAT rules on the same interface. For any given interface, choose either a PAT pool or interface PAT; do not create competing PAT rules.
- Round robin, especially when combined with extended PAT, can consume a large amount of memory. Because NAT pools are created for every mapped protocol/IP address/port range, round robin results in a large number of concurrent NAT pools, which use memory. Extended PAT results in an even larger number of concurrent NAT pools.

Configure dynamic auto PAT

Use dynamic auto PAT rules to translate addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object.
  - **Single PAT address**—Create a network object containing a single host.
  - **PAT pool**—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

Procedure

Step 1 Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Dynamic**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Do not select the destination interface IP or a single address as the **Translated Source**.

Step 6 If you are using a PAT pool, select the **PAT Pool** page and do the following:

a) Select **Enable PAT pool**.

b) Select the network object group that contains the addresses for the pool in the **PAT** > **Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.
- **Flat Port Range**, **Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the Firewall Threat Defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.
- **Block Allocation**—To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Step 7 (Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address or PAT pool.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 8 Click **Save** to add the rule.

Step 9 Click **Save** on the NAT page to save your changes.

Configure dynamic manual PAT

Use dynamic manual PAT rules when auto PAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic PAT translates addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object.
  - **Single PAT address**—Create a network object containing a single host.
  - **PAT pool**—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

Procedure

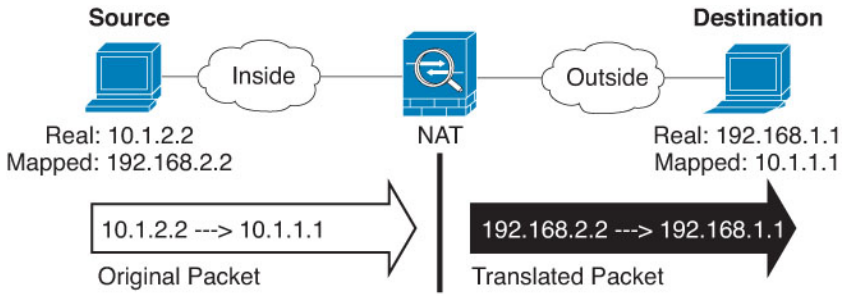
Step 1 Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Do not select the destination interface IP or a single address as the **Translated Source**.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the destination service ports for service translation: **Original Destination Port**, **Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

Step 8 If you are using a PAT pool, select the **PAT Pool** page and do the following:

a) Select **Enable PAT pool**.

b) Select the network object group that contains the addresses for the pool in the **PAT** > **Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.
- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.
- **Flat Port Range**, **Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the Firewall Threat Defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.
- **Block Allocation**—To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Step 9 (Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 10 Click **Save** to add the rule.

Step 11 Click **Save** on the NAT page to save your changes.

Configure PAT with port block allocation

For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time (see RFC 6888). If you allocate a block of ports, subsequent connections from the host use new randomly-selected ports within the block. If necessary, additional blocks are allocated

if the host has active connections for all ports in the original block. Blocks are freed when the last xlate that uses a port in the block is removed.

The main reason for allocating port blocks is reduced logging. The port block allocation is logged, connections are logged, but xlates created within the port block are not logged. On the other hand, this makes log analysis more difficult.

Port blocks are allocated in the 1024-65535 range only. There are separate blocks for TCP, UDP, and ICMP connections, and these blocks can overlap. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host. You can create a separate NAT rule that does not use block allocation for applications that use low port numbers; for twice NAT, ensure the rule comes before the block allocation rule.

Before you begin

Usage notes for NAT rules:

- You can include the **Use Round Robin Allocation** option, but you cannot include the options for extending PAT uniqueness, using a flat range, including the reserved ports, or falling through to interface PAT. Other source/destination address and port information is also allowed.
- As with all NAT changes, if you replace an existing rule, you must clear xlates related to the replaced rule to have the new rule take effect. You can clear them explicitly or simply wait for them to time out. However, when operating in a cluster, you must reload the cluster so that the units can distribute blocks correctly.

Note If you are switching between a regular PAT and block allocation PAT rule, for object NAT, you must first delete the rule, then clear xlates. You can then create the new object NAT rule. Otherwise, you will see pat-port-block-state-mismatch drops in the **show asp drop** output.

- When you form a cluster while the device that will become the control node has an existing NAT policy that uses PAT pools, PAT port block distribution might not initialize correctly. The control node does not own or distribute the port blocks, and the **show nat pool cluster summary** command might show all port blocks as *RESERVED* on every cluster node.
  - Before forming a cluster, remove any existing NAT policy that uses PAT pools from the device that will become the control node. After cluster formation is complete, reconfigure and deploy the NAT policy.
  - If the cluster is already formed and all port blocks appear as *RESERVED*, delete the affected NAT policy and deploy the change. Then re-create and deploy the policy. Use the **show nat pool cluster summary** command to verify that the port blocks are distributed correctly across the cluster nodes.
- For a given PAT pool, you must specify (or not specify) block allocation for all rules that use the pool. You cannot allocate blocks in one rule and not in another. PAT pools that overlap also cannot mix block allocation settings. You also cannot overlap static NAT with port translation rules with the pool.

Procedure

Step 1 (Optional.) Configure global PAT port block allocation settings.

There are a few global settings that control port block allocation. If you want to change the defaults for these options, you must configure a FlexConfig object and add it to your FlexConfig policy.

a) Select **Objects** > **FlexConfig** > **FlexConfig Object** and create a new object.

b) Configure the block allocation size, which is the number of ports in each block.

xlate block-allocation size *value*

The range is 32-4096. The default is 512. Use the "no" form to return to the default.

If you do not use the default, ensure that the size you choose divides evenly into 64,512 (the number of ports in the 1024-65535 range). Otherwise, there will be ports that cannot be used. For example, if you specify 100, there will be 12 unused ports.

Using the default block-allocation size, a single PAT IP can serve 126 unique, simultaneous users (number of ports 64,512 divided by 512).

c) Configure the maximum blocks that can be allocated per host.

xlate block-allocation maximum-per-host *number*

The limit is per protocol, so a limit of 4 means at most 4 UDP blocks, 4 TCP blocks, and 4 ICMP blocks per host. The range is 1-8, the default is 4. Use the "no" form to return to the default.

d) (Optional.) Enable interim syslog generation.

xlate block-allocation pba-interim-logging *seconds*

By default, the system generates syslog messages during port block creation and deletion. If you enable interim logging, the system generates the following message at the interval you specify. The messages report all active port blocks allocated at that time, including the protocol (ICMP, TCP, UDP) and source and destination interface and IP address, and the port block. You can specify an interval from 21600-604800 seconds (6 hours to 7 days).

%ASA-6-305017: Pba-interim-logging: Active *protocol* block of ports for translation from *real_interface*:*real_host_ip* to *mapped_interface*:*mapped_ip_address*/*start_port_num*-*end_port_num*

Example:

The following example sets the block allocation size to 64, the per-host maximum to 8, and enables interim logging every 6 hours.

```
xlate block-allocation size 64
xlate block-allocation maximum-per-host 8
xlate block-allocation pba-interim-logging 21600
```

e) Select the following options in the FlexConfig object:

- **Deployment** = **Everytime**
- **Type** = **Append**

f) Click **Save** to create the FlexConfig object.

g) Select **Devices** > **+ Show more** > **FlexConfig**, and create or edit the FlexConfig policy that is assigned to the devices that need to have these settings adjusted.
h) Select your object in the available objects list and click **>** to move it to the selected objects list.
i) Click **Save**.

You can click **Preview Config**, select one of the target devices, and verify that the xlate commands appear correctly.

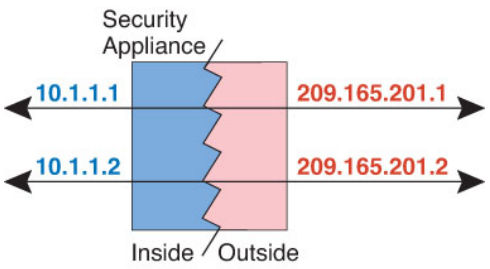
Step 2 Add NAT rules that use PAT pool port block allocation.

a) Select **Policies** > **Network policies** > **NAT** and add or edit the threat defense NAT policy.
b) Add or edit a NAT rule and configure at least the following options.

- **Type** = **Dynamic**
- In **Translation** > **Original Source**, select the object that defines the source address.
- On **PAT Pool**, configure the following options:
  - Select **Enable PAT Pool**
  - In **PAT** > **Address**, select a network object or group that defines the pat pool.
  - Select the **Block Allocation** option.

c) Save your changes to the rule and to the NAT policy.

Static NAT



The following topics explain static NAT and how to implement it.

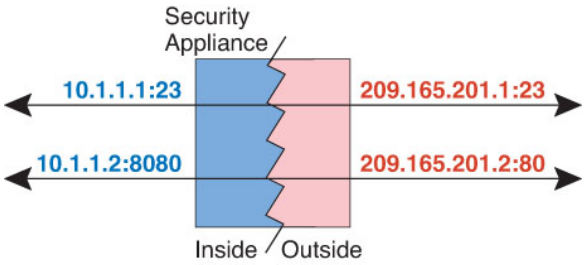
About static NAT

Static NAT creates a fixed translation of a real address to a mapped address. Because the mapped address is the same for each consecutive connection, static NAT allows bidirectional connection initiation, both to and from the host (if an access rule exists that allows it). With dynamic NAT and PAT, on the other hand, each host uses a different address or port for each subsequent translation, so bidirectional initiation is not supported.

The following figure shows a typical static NAT scenario. The translation is always active so both real and remote hosts can initiate connections.

Figure 405: Static NAT

Note You can disable bidirectionality if desired.



Static NAT with port translation

Static NAT with port translation lets you specify a real and mapped protocol and port.

When you specify the port with static NAT, you can choose to map the port and/or the IP address to the same value or to a different value.

The following figure shows a typical static NAT with port translation scenario showing both a port that is mapped to itself and a port that is mapped to a different value; the IP address is mapped to a different value in both cases. The translation is always active so both translated and remote hosts can initiate connections.

Figure 406: Typical Static NAT with Port Translation Scenario

Static NAT-with-port-translation rules limit access to the destination IP address for the specified port only. If you try to access the destination IP address on a different port not covered by a NAT rule, then the connection is blocked. In addition, for manual NAT, traffic that does not match the source IP address of the NAT rule will be dropped if it matches the destination IP address, regardless of the destination port. Therefore, you must add additional rules for all other traffic allowed to the destination IP address. For example, you can configure a static NAT rule for the IP address, without port specification, and place it after the port translation rule.

Note For applications that require application inspection for secondary channels (for example, FTP and VoIP), NAT automatically translates the secondary ports.

Following are some other uses of static NAT with port translation.

Static NAT with Identity Port Translation

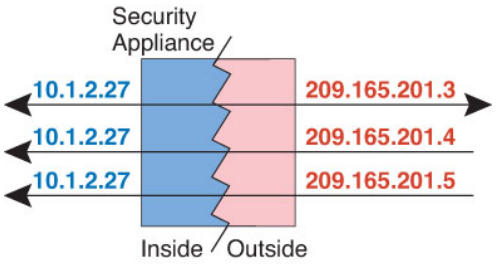
You can simplify external access to internal resources. For example, if you have three separate servers that provide services on different ports (such as FTP, HTTP, and SMTP), you can give external users a single IP address to access those services. You can then configure static NAT with identity port translation to map the single external IP address to the correct IP addresses of the real servers based on the port they are trying to access. You do not need to change the port, because the servers are using the standard ones (21, 80, and 25 respectively).

Static NAT with Port Translation for Non-Standard Ports

You can also use static NAT with port translation to translate a well-known port to a non-standard port or vice versa. For example, if inside web servers use port 8080, you can allow outside users to connect

to port 80, and then undo translation to the original port 8080. Similarly, to provide extra security, you can tell web users to connect to non-standard port 6785, and then undo translation to port 80.

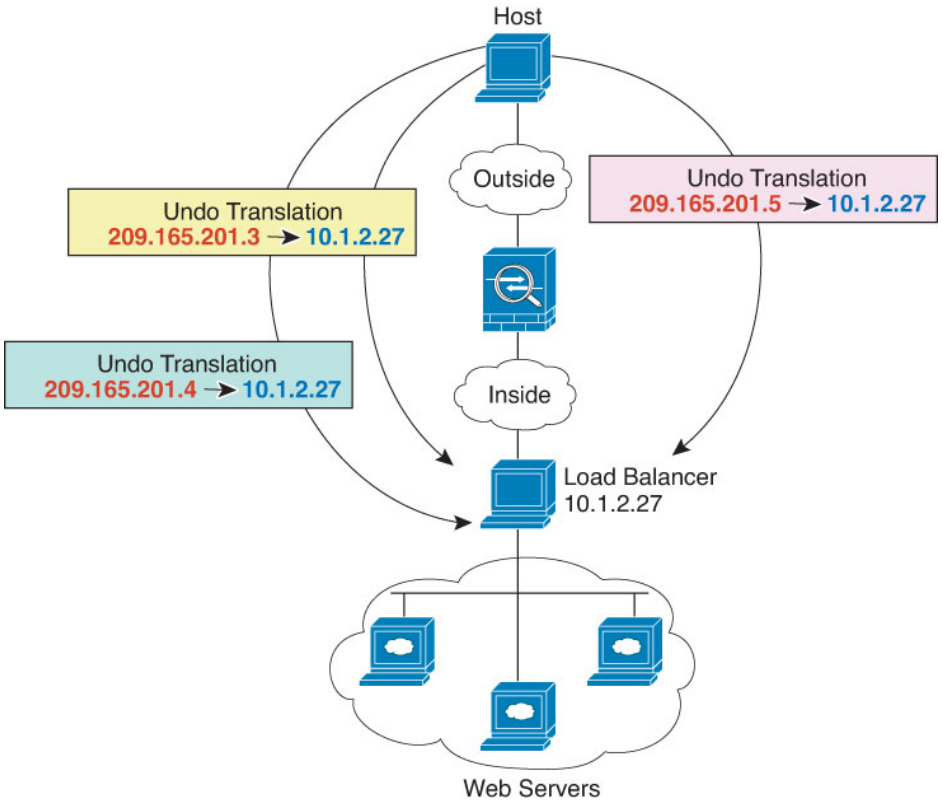
Static Interface NAT with Port Translation



You can configure static NAT to map a real address to an interface address/port combination. For example, if you want to redirect Telnet access for the device's outside interface to an inside host, then you can map the inside host IP address/port 23 to the outside interface address/port 23.

One-to-many static NAT

Typically, you configure static NAT with a one-to-one mapping. However, in some cases, you might want to configure a single real address to several mapped addresses (one-to-many). When you configure one-to-many static NAT, when the real host initiates traffic, it always uses the first mapped address. However, for traffic initiated to the host, you can initiate traffic to any of the mapped addresses, and they will be untranslated to the single real address.

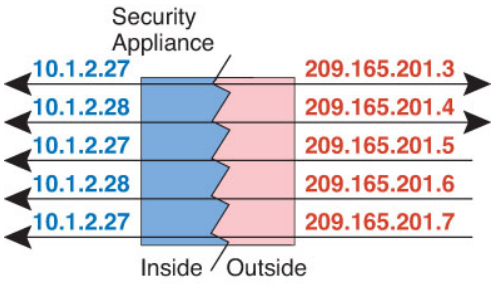


The following figure shows a typical one-to-many static NAT scenario. Because initiation by the real host always uses the first mapped address, the translation of real host IP/first mapped IP is technically the only bidirectional translation.

Figure 407: One-to-Many Static NAT

For example, you have a load balancer at 10.1.2.27. Depending on the URL requested, it redirects traffic to the correct web server.

Figure 408: One-to-Many Static NAT Example



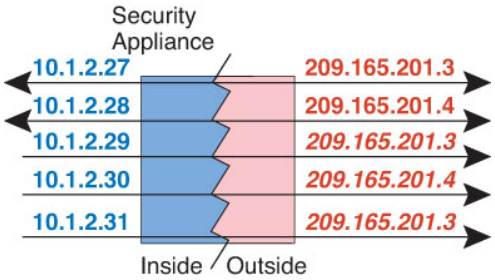
Other mapping scenarios (not recommended)

NAT has the flexibility to allow any kind of static mapping scenario: one-to-one, one-to-many, but also few-to-many, many-to-few, and many-to-one mappings. We recommend using only one-to-one or one-to-many mappings. These other mapping options might result in unintended consequences.

Functionally, few-to-many is the same as one-to-many; but because the configuration is more complicated and the actual mappings may not be obvious at a glance, we recommend creating a one-to-many configuration for each real address that requires it. For example, for a few-to-many scenario, the few real addresses are mapped to the many mapped addresses in order (A to 1, B to 2, C to 3). When all real addresses are mapped, the next mapped address is mapped to the first real address, and so on until all mapped addresses are mapped (A to 4, B to 5, C to 6). This results in multiple mapped addresses for each real address. Just like a one-to-many configuration, only the first mappings are bidirectional; subsequent mappings allow traffic to be initiated *to* the real host, but all traffic *from* the real host uses only the first mapped address for the source.

The following figure shows a typical few-to-many static NAT scenario.

Figure 409: Few-to-Many Static NAT



For a many-to-few or many-to-one configuration, where you have more real addresses than mapped addresses, you run out of mapped addresses before you run out of real addresses. Only the mappings between the lowest real IP addresses and the mapped pool result in bidirectional initiation. The remaining higher real addresses can initiate traffic, but traffic cannot be initiated to them (returning traffic for a connection is directed to the correct real address because of the unique 5-tuple (source IP, destination IP, source port, destination port, protocol) for the connection).

Note Many-to-few or many-to-one NAT is not PAT. If two real hosts use the same source port number and go to the same outside server and the same TCP destination port, and both hosts are translated to the same IP address, then both connections will be reset because of an address conflict (the 5-tuple is not unique).

The following figure shows a typical many-to-few static NAT scenario.

Figure 410: Many-to-Few Static NAT

Instead of using a static rule this way, we suggest that you create a one-to-one rule for the traffic that needs bidirectional initiation, and then create a dynamic rule for the rest of your addresses.

Configure static auto NAT

Use static auto NAT rules to translate addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.

- **Translated Source**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
  - **Address**—Create a network object or group containing hosts, ranges, or subnets. A group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

Procedure

Step 1 Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Static**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- (Optional.) **Original Port**, **Translated Port**—If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1467. This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure static manual NAT

Use static manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Static NAT translates addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
  - **Address**—Create a network object or group containing hosts, range, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination

static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports.

Procedure

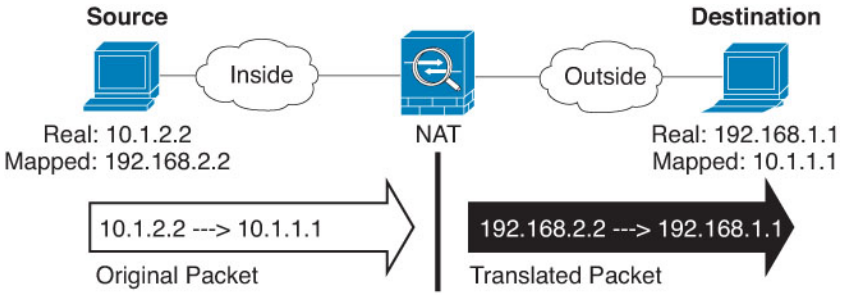
Step 1 Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Static**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.

- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

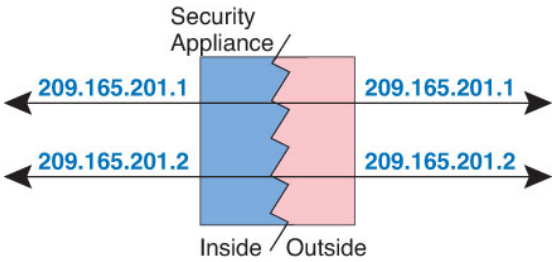
- **Original Source Port**, **Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port**, **Translated Destination Port**—Defines a port translation for the destination address.

Step 8 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1467. This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Step 9 Click **Save** to add the rule.



Step 10 Click **Save** on the NAT page to save your changes.

Identity NAT

You might have a NAT configuration in which you need to translate an IP address to itself. For example, if you create a broad rule that applies NAT to every network, but want to exclude one network from NAT, you can create a static NAT rule to translate that network to itself.

The following figure shows a typical identity NAT scenario.

Figure 411: Identity NAT

The following topics explain how to configure identity NAT.

Configure identity auto NAT

Use static identity auto NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.

- **Translated Source**—A network object or group with the exact same contents as the original source object. You can use the same object.

Procedure

Step 1 Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Static**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Do not configure the **Original Port** and **Translated Port** options for identity NAT.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Do not configure this option for identity NAT.
- **Net to Net Mapping**—Do not configure this option for identity NAT.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**— If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure identity manual NAT

Use static identity manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Use static identity NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—The same object or group as the original source. Optionally, you can select a different object that has the exact same contents.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports. You can use the same object for identity NAT.

Procedure

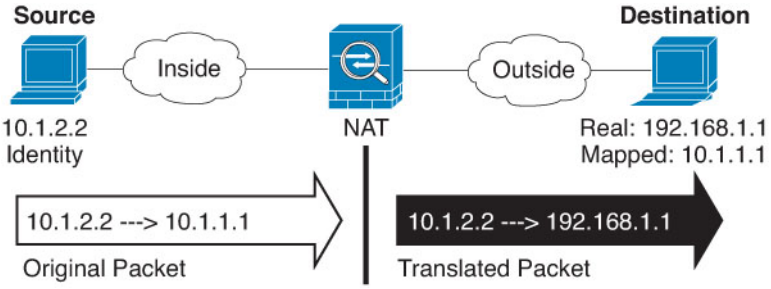
Step 1 Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Static**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet where you perform identity NAT on the inside host but translate the outside host.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Interface Object** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The same object or group as the original source. Optionally, you can select a different object that has the exact same contents.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port**, **Translated Source Port**—Defines a port translation for the source address.

- **Original Destination Port**, **Translated Destination Port**—Defines a port translation for the destination address.

Step 8 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**— If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.
- **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Step 9 Click **Save** to add the rule.

Step 10 Click **Save** on the NAT page to save your changes.

NAT rule properties for Firewall Threat Defense

Use network address translation (NAT) rules to translate IP addresses to other IP addresses. You would typically use NAT rules to convert private addresses to publicly routable addresses. The translation can be from one address to another, or you can use port address translation (PAT) to translate many addresses to one or a few addresses, using port numbers to distinguish among the source addresses.

NAT rules include the following basic properties. The properties are the same for auto NAT and manual NAT rules except where indicated.

NAT Type

Whether you want to configure a **Manual NAT Rule** or an **Auto NAT Rule**. Auto NAT translates the source address only, and you cannot make different translations based on the destination address. Because auto NAT is more simple to configure, use it unless you need the added features of manual NAT. For more information on the differences, see Auto NAT and Manual NAT, on page 1367.

Type

Whether the translation rule is **Dynamic** or **Static**. Dynamic translation automatically chooses the mapped address from a pool of addresses, or an address/port combination when implementing PAT. Use static translation if you want to precisely define the mapped address/port.

Enable (Manual NAT only.)

Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page. You cannot disable auto NAT rules.

Insert (Manual NAT only.)

Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Description (Optional. Manual NAT only.)

A description of the purpose of the rule.

The following topics describe the tabs for the NAT rules properties.

Interface objects NAT properties

Interface objects (security zones or interface groups) define the interfaces to which a NAT rule applies. In routed mode, you can use the default "any" for both source and destination to apply to all interfaces of all assigned devices. However, you typically want to select specific source and destination interfaces.

Notes

- The concept of “any” interface does not apply to bridge group member interfaces. When you specify “any” interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. You cannot configure NAT for the bridge virtual interface (BVI) itself, you can configure NAT for member interfaces only.

  If you select interface objects, a NAT rule will be configured on an assigned device only if the device has interfaces included in all selected objects. For example, if you select both source and destination security zones, both zones must contain one or more interface for a given device.

- If more than one interface in an interface object exists on a given device, identical rules are created for each interface. This can become an issue for static NAT rules that include destination translation. Because NAT rules are applied based on first hit rule, only the rule created for the first interface configured for the object matches traffic. When configuring static NAT with destination translation, use interface objects that include at most one interface per device assigned to the NAT policy to ensure you are getting the desired results.

Source Interface Objects, Destination Interface Objects

(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Translation properties for auto NAT

Use the **Translation** options to define the source addresses and the mapped translated addresses. The following properties apply to auto NAT only.

Original Source (Always required.)

The network object that contains the addresses you are translating. This must be a network object (not a group), and it can be a host, range, or subnet.

You cannot create auto NAT rules for the system-defined any-ipv4 or any-ipv6 objects.

Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.
- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Do not configure a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.
- **Static NAT**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Port, Translated Port (Static NAT only.)

If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary. Do not configure these options for identity NAT.

Translation properties for manual NAT

Use the **Translation** options to define the source addresses and the mapped translated addresses. The following properties apply to manual NAT only. All are optional except as indicated.

Original Source (Always required.)

The network object or group that contains the addresses you are translating. This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can specify **Any** in the rule.

Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.
- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Do not configure a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.
- **Static NAT**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Destination

The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Translated Destination

The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

You can use a network object that specifies a fully-qualified domain name as the translated destination; for more information, see FQDN destination guidelines, on page 1376.

Original Source Port, Translated Source Port, Original Destination Port, Translated Destination Port

The port objects that define the source and destination services for the original and translated packets. You can translate the ports, or select the same object to make the rule sensitive to the service without translating the ports. Keep the following rules in mind when configuring services:

- (Dynamic NAT or PAT.) You cannot do translation on the **Original Source Port** and **Translated Source Port**. You can do translation on the destination port only.
- NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

PAT pool NAT properties

When you configure dynamic NAT, you can define a pool of addresses to use for port address translation using the properties on the **PAT Pool** tab.

Enable PAT Pool

Select this option to configure a pool of addresses for PAT.

PAT

The addresses to use for the PAT pool, one of the following:

- **Address**—The object that defines the PAT pool addresses, either a network object that includes a range, or a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.
- **Destination Interface IP**—Indicates that you want to use the destination interface as the PAT address. For this option, you must select a specific **Destination Interface Object**; you cannot use **Any** as the destination interface. This is another way to implement interface PAT.

Round Robin

To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

Extended PAT Table

To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.

Flat Port Range; Include Reserved Ports

To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the Firewall Threat Defense devices running

version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.

Block Allocation

To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Advanced NAT properties

When you configure NAT, you can configure properties that provide specialized services in the **Advanced** options. All of these properties are optional: configure them only if you need the service.

Translate DNS replies that match this rule

Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1467. This option is not available if you are doing port translation in a static NAT rule.

Fallthrough to Interface PAT (Destination Interface) (Dynamic NAT only.)

Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address. You also cannot select the option if you configure a PAT pool.

IPv6

Whether to use the IPv6 address of the destination interface for interface PAT.

Net to Net Mapping (Static NAT only.)

For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.

Do not proxy ARP on Destination Interface (Static NAT only.)

Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

Perform Route Lookup for Destination Interface (Static Identity NAT only. Routed mode only.)

If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

Unidirectional (Manual NAT only, static NAT only.)

Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Translating IPv6 networks

In cases where you need to pass traffic between IPv6-only and IPv4-only networks, you need to use NAT to convert between the address types. Even with two IPv6 networks, you might want to hide internal addresses from the outside network.

You can use the following translation types with IPv6 networks:

- NAT64, NAT46—Translates IPv6 packets into IPv4 and vice versa. You need to define two policies, one for the IPv6 to IPv4 translation, and one for the IPv4 to IPv6 translation. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

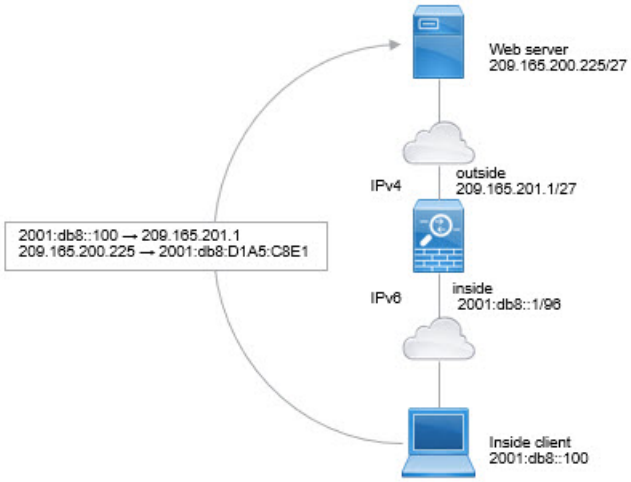
Note NAT46 supports static mappings only.

- NAT66—Translates IPv6 packets to a different IPv6 address. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

Note NAT64 and NAT 46 are possible on standard routed interfaces only. NAT66 is possible on both routed and bridge group member interfaces.

NAT64/46: translating IPv6 addresses to IPv4

When traffic goes from an IPv6 network to an IPv4-only network, you need to convert the IPv6 address to IPv4, and return traffic from IPv4 to IPv6. You need to define two address pools, an IPv4 address pool to bind IPv6 addresses in the IPv4 network, and an IPv6 address pool to bind IPv4 addresses in the IPv6 network.



- The IPv4 address pool for the NAT64 rule is normally small and typically might not have enough addresses to map one-to-one with the IPv6 client addresses. Dynamic PAT might more easily meet the possible large number of IPv6 client addresses compared to dynamic or static NAT.

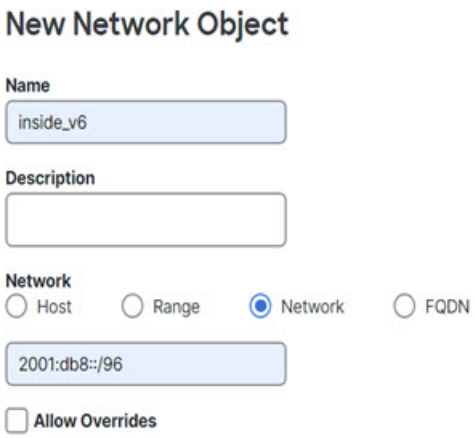
- The IPv6 address pool for the NAT46 rule can be equal to or larger than the number of IPv4 addresses to be mapped. This allows each IPv4 address to be mapped to a different IPv6 address. NAT46 supports static mappings only, so you cannot use dynamic PAT.

You need to define two policies, one for the source IPv6 network, and one for the destination IPv4 network. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

NAT64/46 example: inside IPv6 network with outside IPv4 internet

Following is a straight-forward example where you have an inside IPv6-only network, and you want to convert to IPv4 for traffic sent to the Internet. This example assumes you do not need DNS translation, so you can perform both the NAT64 and NAT46 translations in a single manual NAT rule.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network.



Procedure

Step 1 Create the network object that defines the inside IPv6 network.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

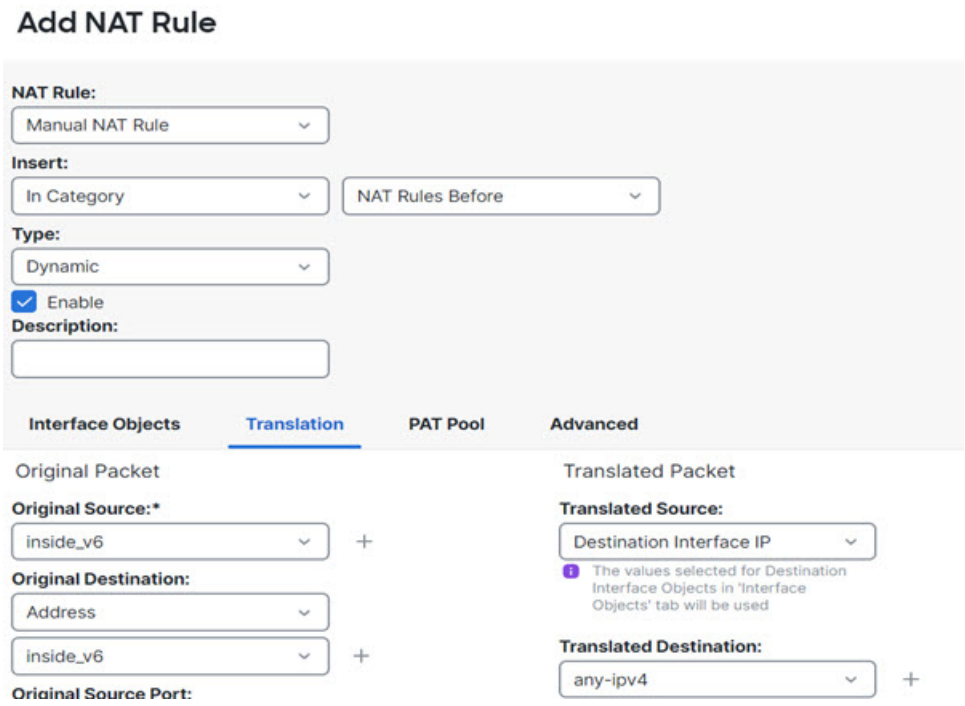
b) Define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:db8::/96.

c) Click **Save**.

Step 2 Create the manual NAT rule to translate the IPv6 network to IPv4 and back again.

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:



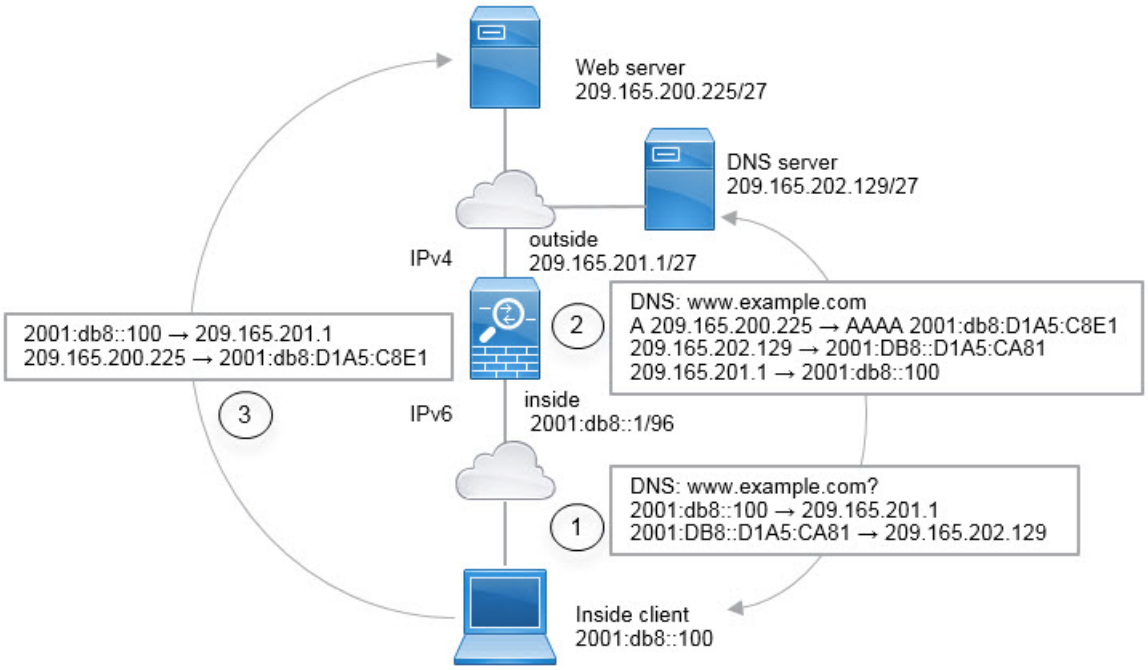
- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** = **Destination Interface IP**.
- **Original Destination** = inside_v6 network object.
- **Translated Destination** = any-ipv4 network object.



f) Click **OK**.

With this rule, any traffic from the 2001:db8::/96 subnet on the inside interface going to the outside interface gets a NAT64 PAT translation using the IPv4 address of the outside interface. Conversely, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method.

g) Click **Save** on the NAT rules page.

NAT64/46 example: inside IPv6 network with outside IPv4 internet and DNS translation

Following is a typical example where you have an inside IPv6-only network, but there are some IPv4-only services on the outside Internet that internal users need.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network. You enable DNS rewrite on the NAT46 rule, so that replies from the external DNS server can be converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.

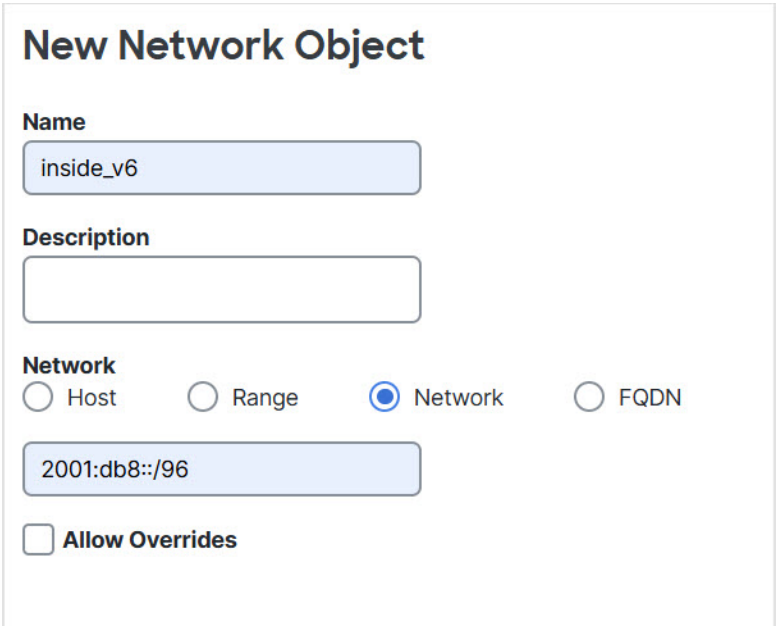
Following is a typical sequence for a web request where a client at 2001:DB8::100 on the internal IPv6 network tries to open www.example.com.

1. The client's computer sends a DNS request to the DNS server at 2001:DB8::D1A5:CA81. The NAT rules make the following translations to the source and destination in the DNS request:
   - 2001:DB8::100 to a unique port on 209.165.201.1 (The NAT64 interface PAT rule.)
   - 2001:DB8::D1A5:CA81 to 209.165.202.129 (The NAT46 rule. D1A5:CA81 is the IPv6 equivalent of 209.165.202.129.)
2. The DNS server responds with an A record indicating that www.example.com is at 209.165.200.225. The NAT46 rule, with DNS rewrite enabled, converts the A record to the IPv6-equivalent AAAA record, and translates 209.165.200.225 to 2001:db8:D1A5:C8E1in the AAAA record. In addition, the source and destination addresses in the DNS response are untranslated:
   - 209.165.202.129 to 2001:DB8::D1A5:CA81
   - 209.165.201.1 to 2001:db8::100
3. The IPv6 client now has the IP address of the web server, and makes an HTTP request to www.example.com at 2001:db8:D1A5:C8E1. (D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225.) The source and destination of the HTTP request are translated:
   - 2001:DB8::100 to a unique port on 209.156.101.54 (The NAT64 interface PAT rule.)
   - 2001:db8:D1A5:C8E1 to 209.165.200.225 (The NAT46 rule.)

The following procedure explains how to configure this example.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Interface**.

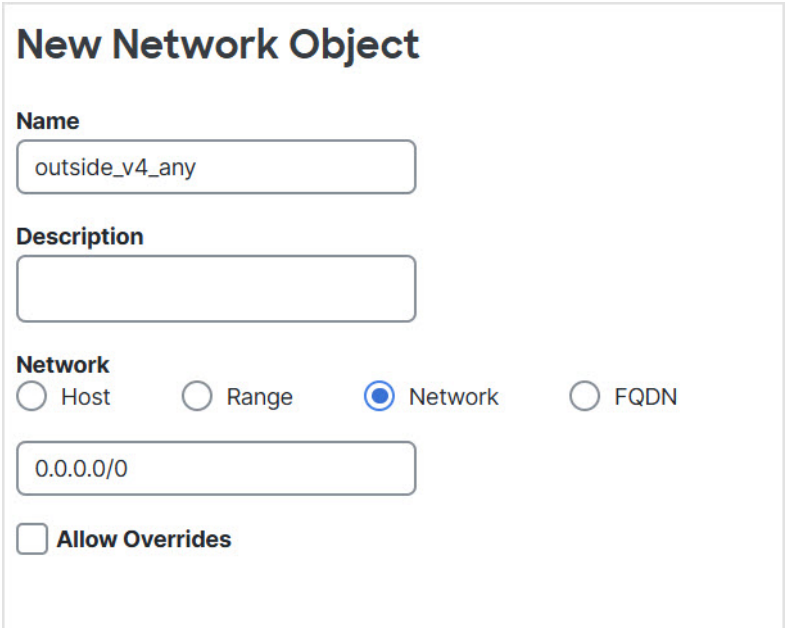


Procedure

Step 1 Create the network objects that define the inside IPv6 and outside IPv4 networks.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.



Name the network object (for example, inside_v6) and enter the network address, 2001:db8::/96.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the outside IPv4 network.

Name the network object (for example, outside_v4_any) and enter the network address 0.0.0.0/0.

e) Click **Save**.

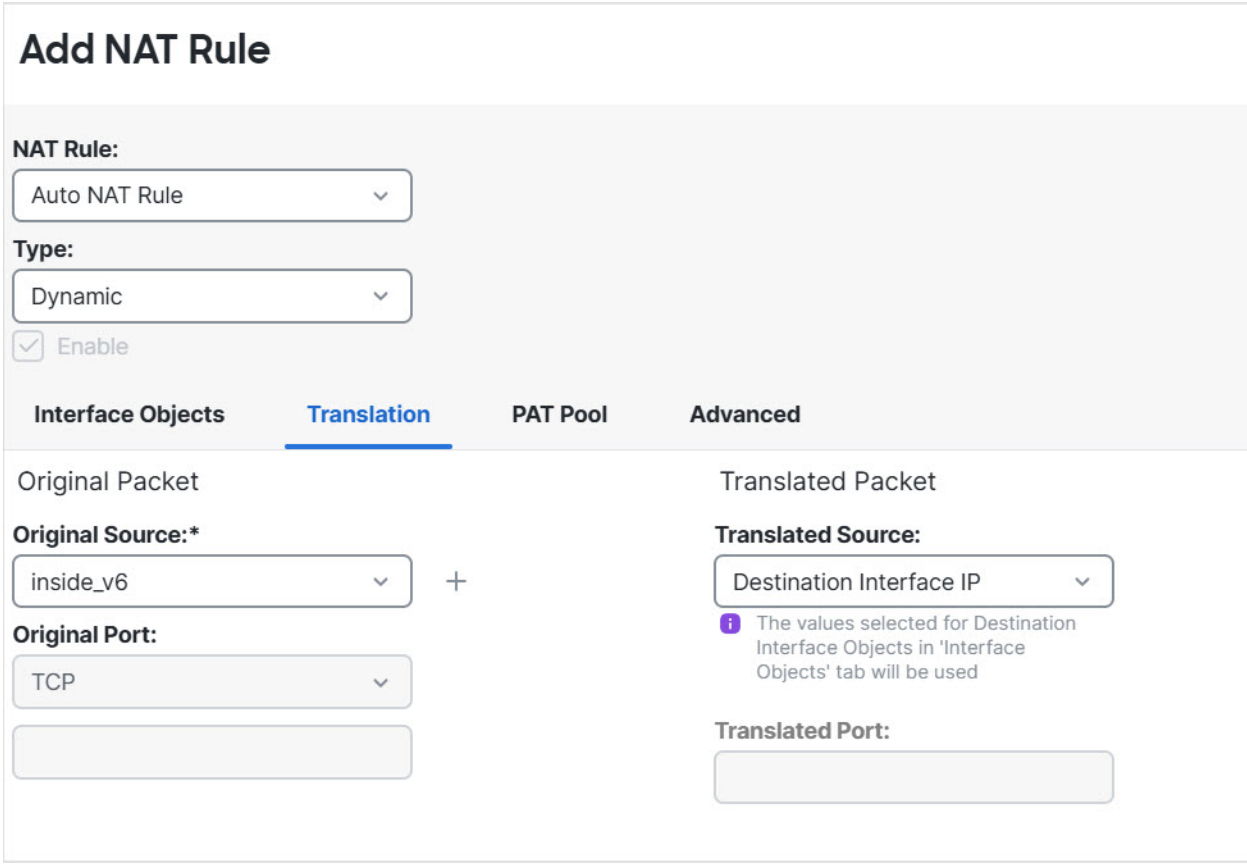
Step 2 Configure the NAT64 dynamic PAT rule for the inside IPv6 network.

Step 3 Configure the static NAT46 rule for the outside IPv4 network.

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

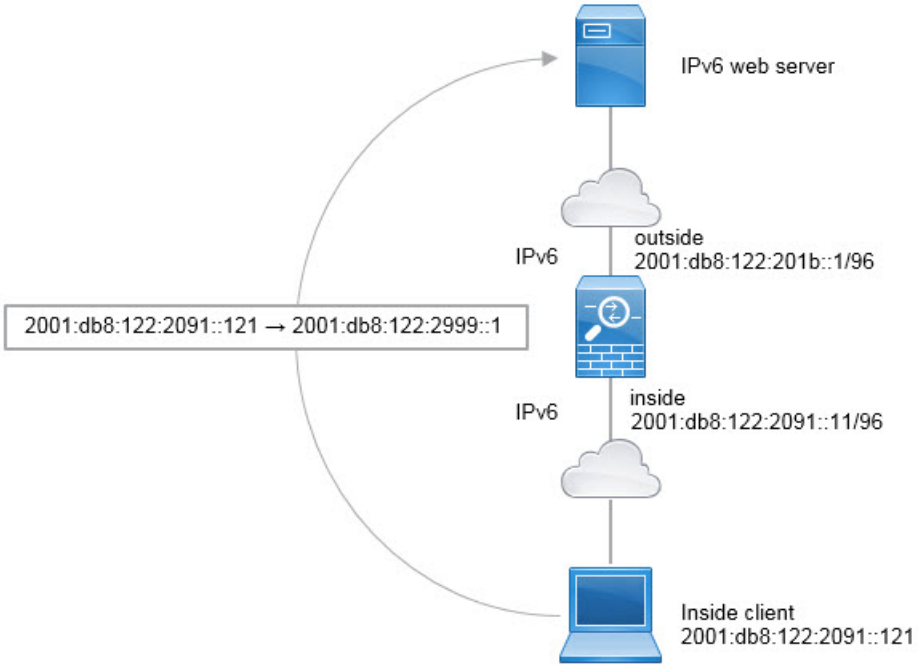
d) On **Translation**, configure the following:

- **Original Source** = outside_v4_any network object.
- **Translated Source** > **Address** = inside_v6 network object.

e) On **Advanced**, select **Translate DNS replies that match this rule**.

f) Click **OK**.

With this rule, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method. In addition, DNS responses are converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.



NAT66: translating IPv6 addresses to different IPv6 addresses

When going from an IPv6 network to another IPv6 network, you can translate the addresses to different IPv6 addresses on the outside network. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

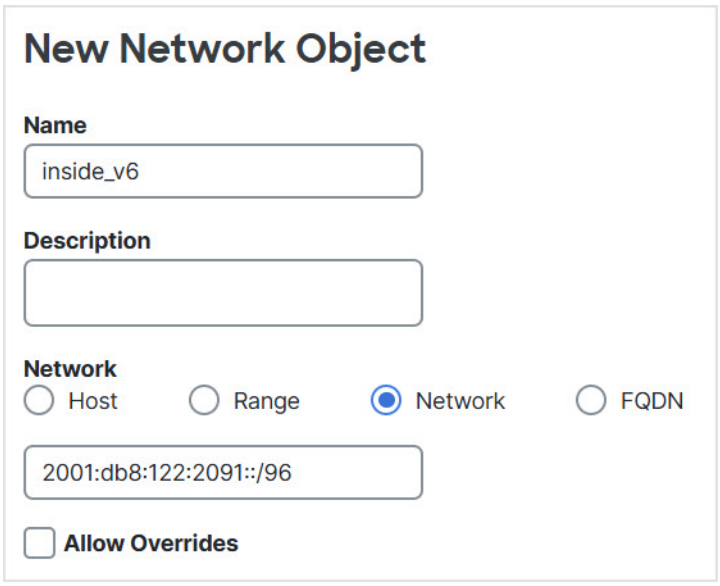
Because you are not translating between different address types, you need a single rule for NAT66 translations. You can easily model these rules using auto NAT. However, if you do not want to allow returning traffic, you can make the static NAT rule unidirectional using manual NAT only.

NAT66 example, static translation between networks

You can configure a static translation between IPv6 address pools using auto NAT. The following example explains how to convert inside addresses on the 2001:db8:122:2091::/96 network to outside addresses on the 2001:db8:122:2999::/96 network.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Interface**.

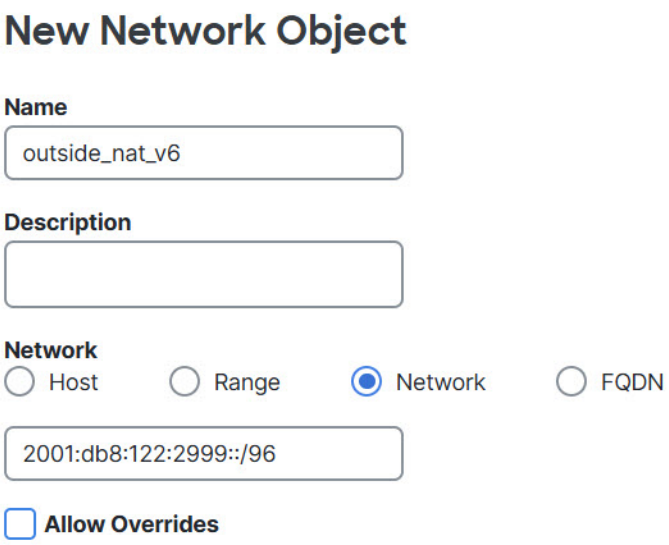


Procedure

Step 1 Create the network objects that define the inside IPv6 and outside IPv6 NAT networks.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.



Name the network object (for example, inside_v6) and enter the network address, 2001:db8:122:2091::/96.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the outside IPv6 NAT network.

Name the network object (for example, outside_nat_v6) and enter the network address 2001:db8:122:2999::/96.

e) Click **Save**.

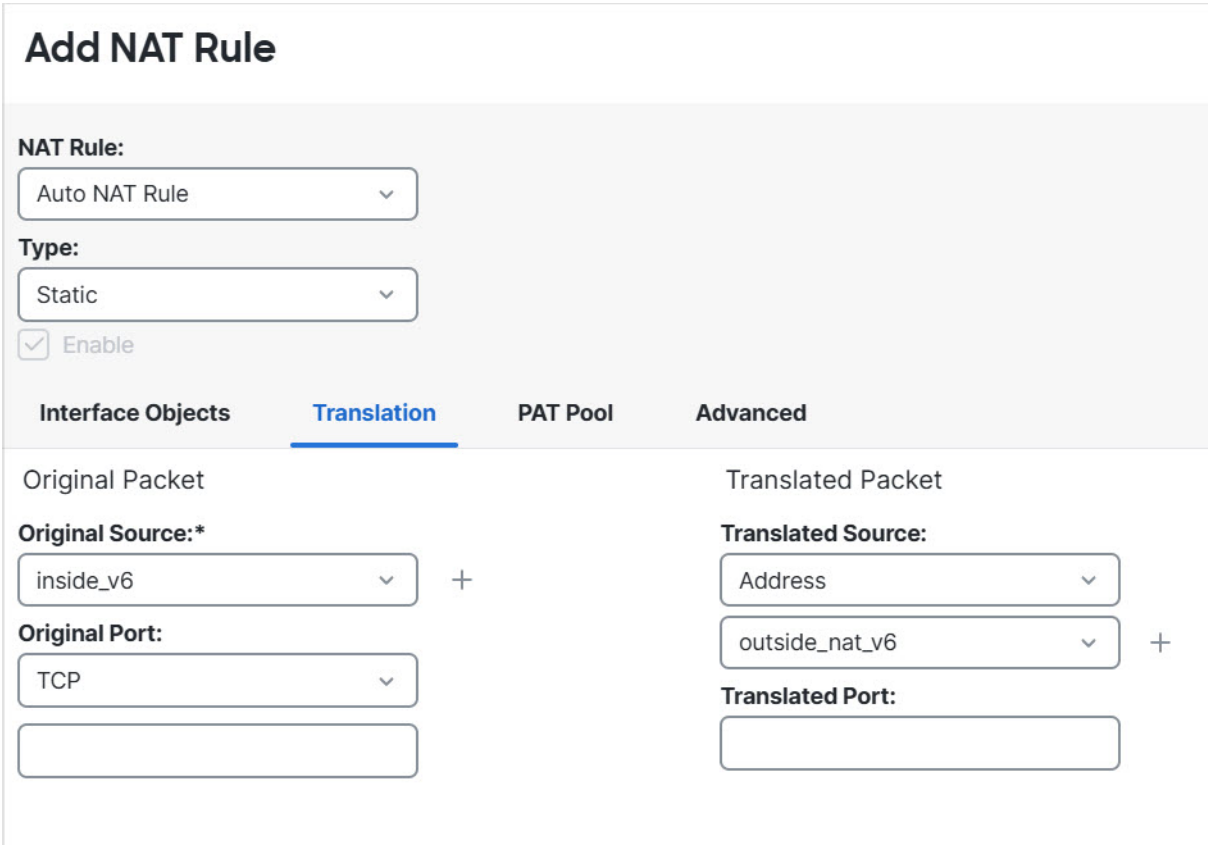
Step 2 Configure the static NAT rule for the inside IPv6 network.

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.



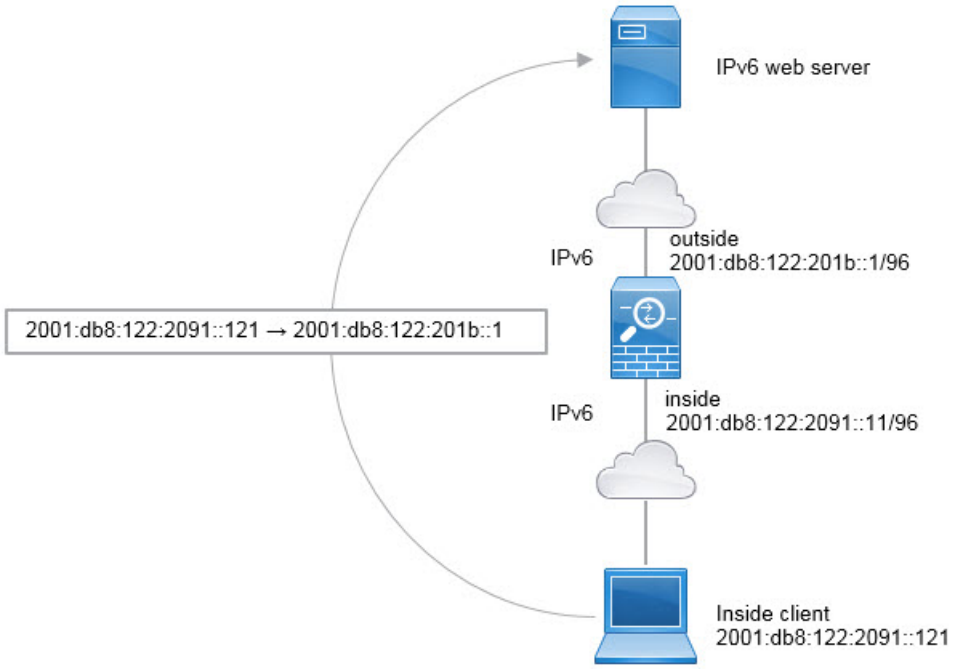
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** > **Address** = outside_nat_v6 network object.



f) Click **OK**.

With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a static NAT66 translation to an address on the 2001:db8:122:2999::/96 network.

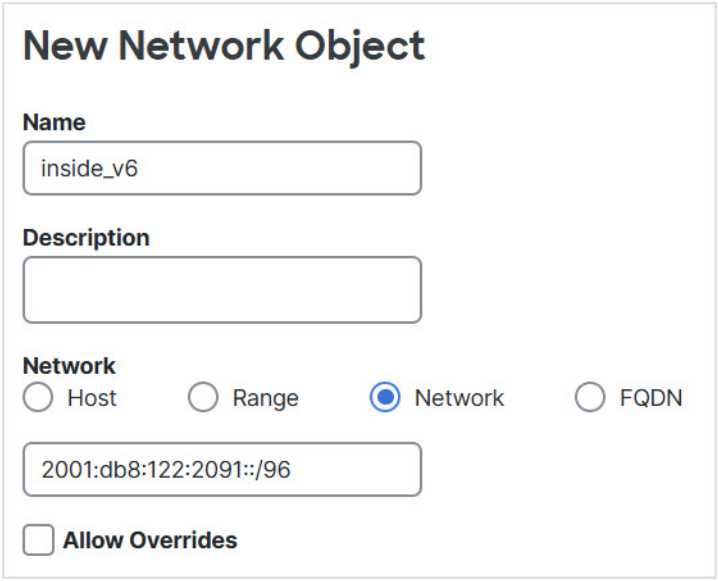
NAT66 example, simple IPv6 interface PAT

A simple approach for implementing NAT66 is to dynamically assign internal addresses to different ports on the outside interface IPv6 address.

When you configure an interface PAT rule for NAT66, all the global addresses that are configured on that interface are used for PAT mapping. Link-local or site-local addresses for the interface are not used for PAT.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Interface**.

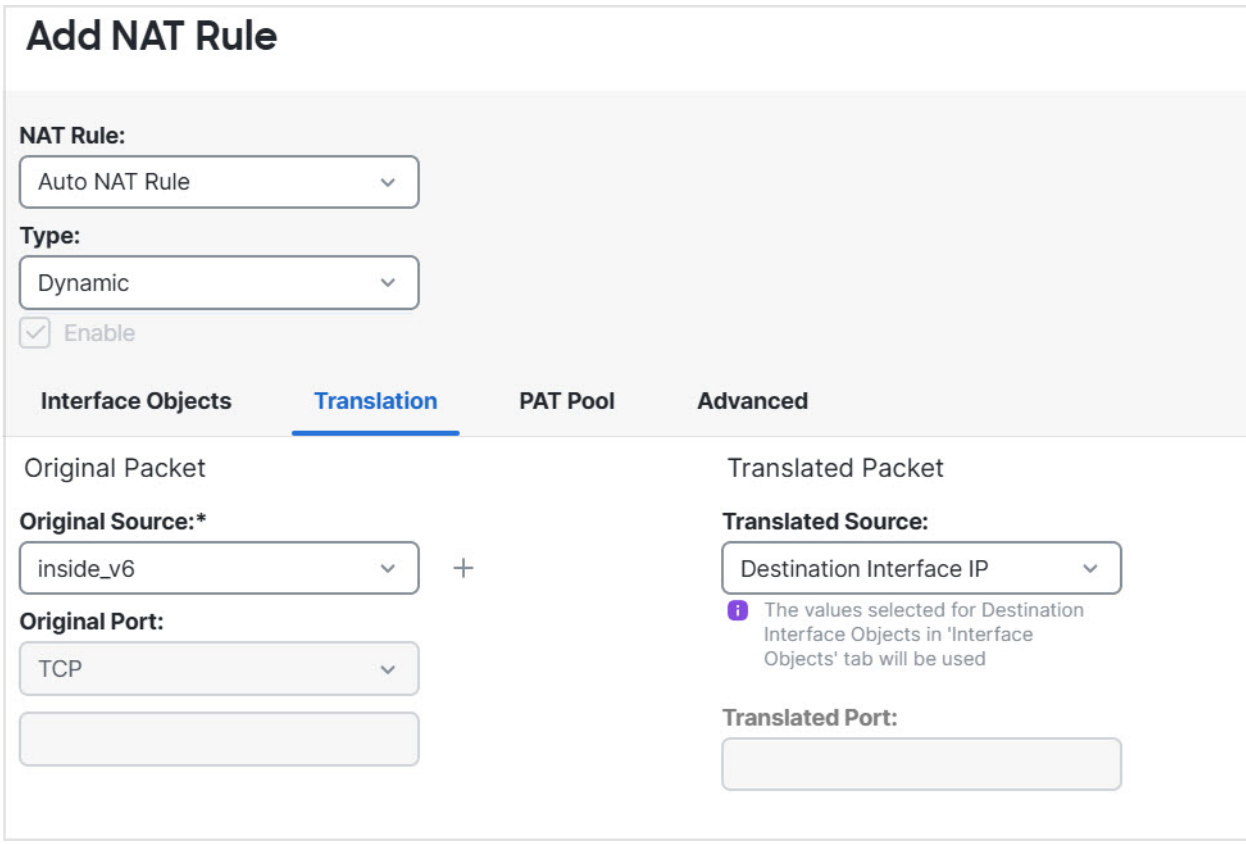


Procedure

Step 1 Create the network object that defines the inside IPv6 network.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.



Name the network object (for example, inside_v6) and enter the network address, 2001:db8:122:2091::/96.

c) Click **Save**.

Step 2 Configure the dynamic PAT rule for the inside IPv6 network.

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Dynamic.
d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = outside.
e) On **Translation**, configure the following:
   - **Original Source** = inside_v6 network object.
   - **Translated Source** = **Destination Interface IP**.
f) On **Advanced**, select **IPv6**, which indicates that the IPv6 address of the destination interface should be used.

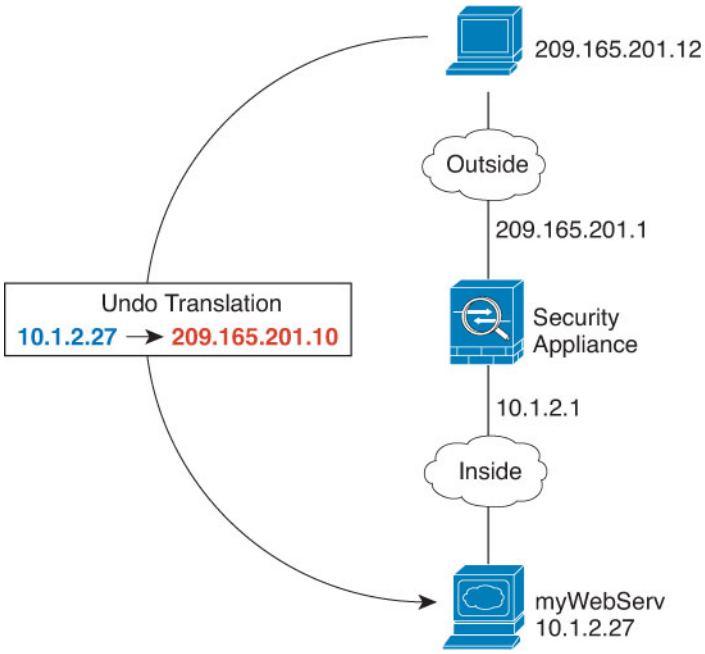
g) Click **OK**.

With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a NAT66 PAT translation to one of the IPv6 global addresses configured for the outside interface.

Monitoring NAT

To monitor and troubleshoot NAT connections, log into the device CLI and use the following commands.

- **show nat** displays the NAT rules and per-rule hit counts. There are additional keywords to show other aspects of NAT.
- **show xlate** displays the actual NAT translations that are currently active.
- **clear xlate** lets you remove an active NAT translation. You might need to remove active translations if you alter NAT rules, because existing connections continue to use the old translation slot until the connection ends. Clearing a translation allows the system to build a new translation for a client on the client's next connection attempt based on your new rules.



Examples for NAT

The following topics provide examples for configuring NAT.

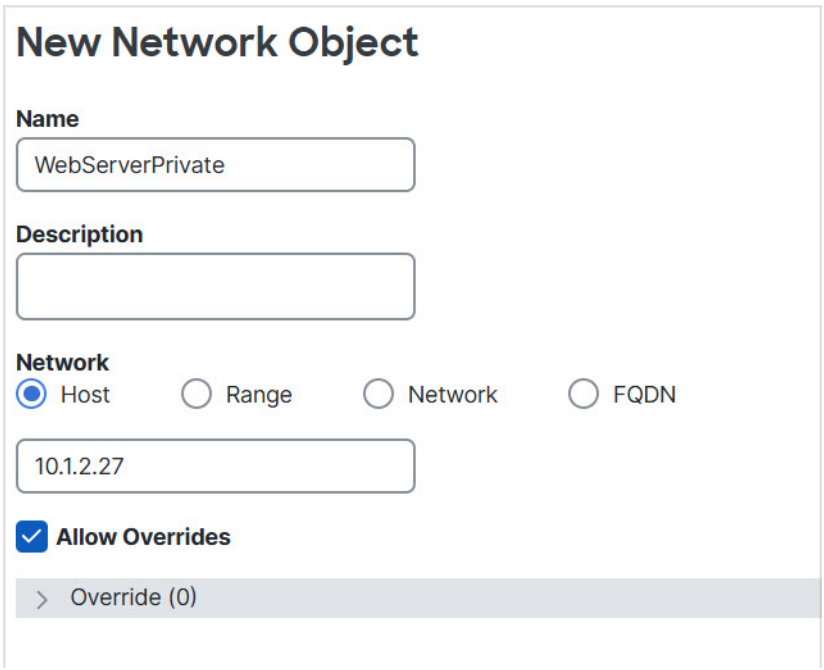
Providing access to an inside web server (static auto NAT)

This example performs static NAT for an inside web server. The real address is on a private network, so a public address is required. Static NAT is necessary so hosts can initiate traffic to the web server at a fixed address.

Figure 412: Static NAT for an inside web server

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Interface**.

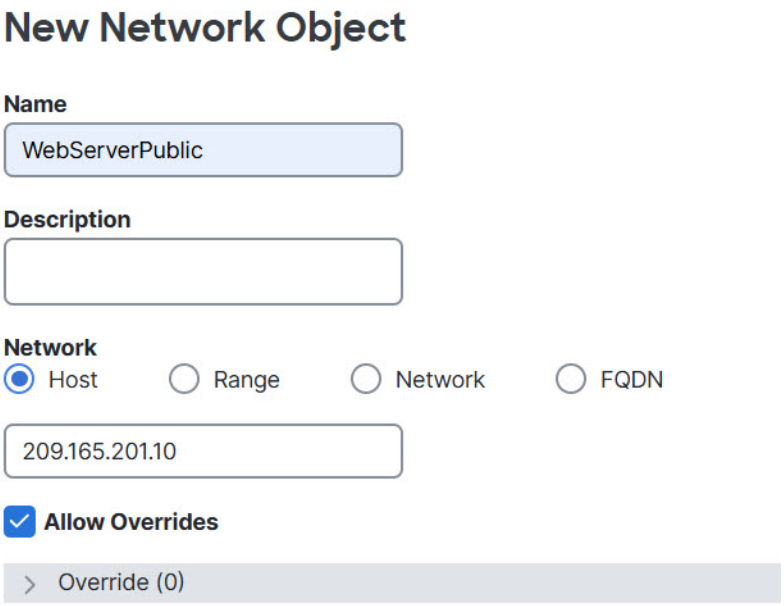


Procedure

Step 1 Create the network objects that define the server's private and public host addresses.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Define the web server's private address.

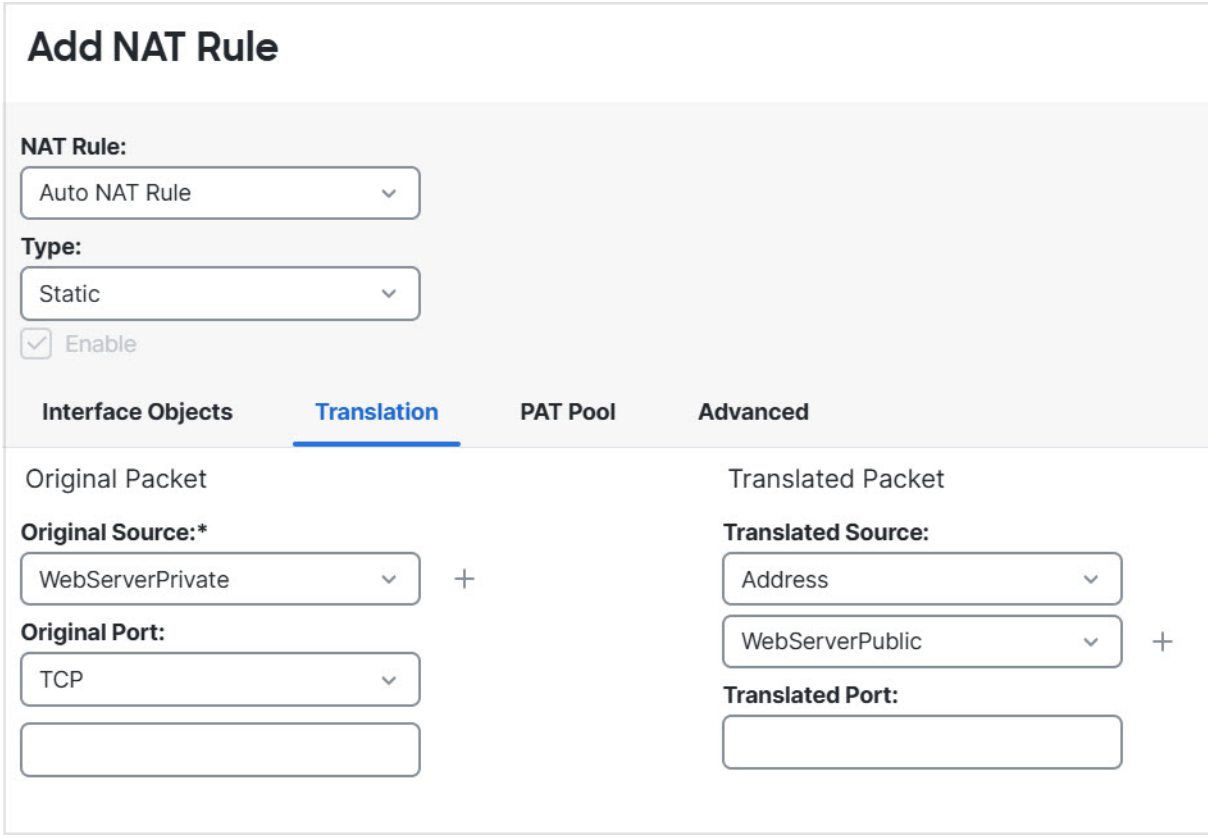


Name the network object (for example, WebServerPrivate) and enter the real host IP address, 10.1.2.27.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the public address.

Name the network object (for example, WebServerPublic) and enter the host address 209.165.201.10.

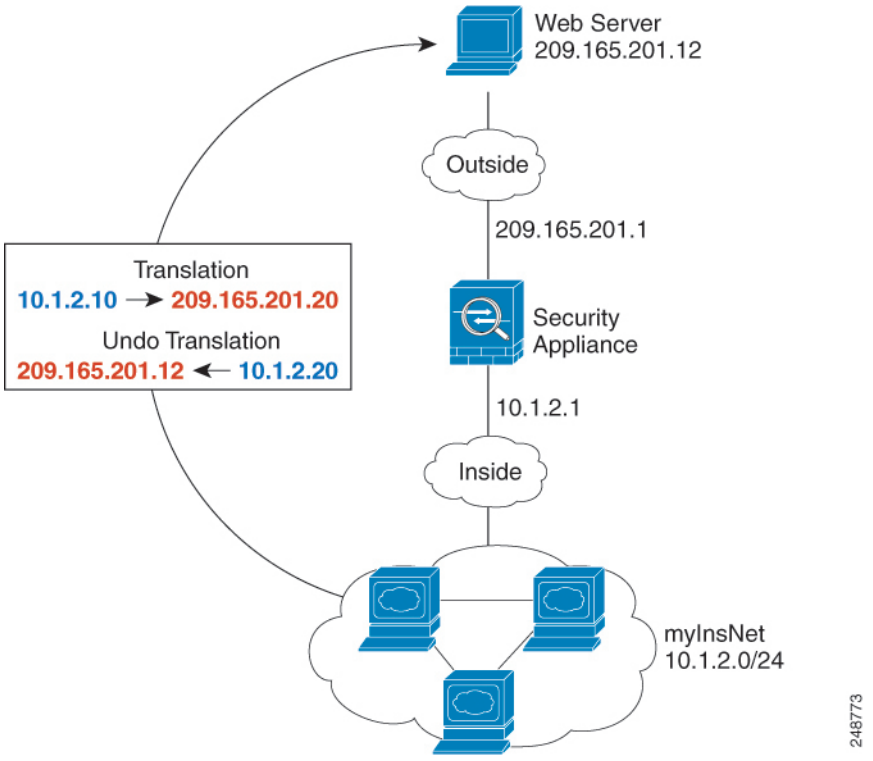


e) Click **Save**.

Step 2 Configure static NAT for the object.

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.
c) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Static.
d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = outside.
e) On **Translation**, configure the following:
   - **Original Source** = WebServerPrivate network object.
   - **Translated Source** > **Address** = WebServerPublic network object.



f) Click **Save**.

Step 3 Click **Save** on the NAT rule page.

Dynamic auto NAT for inside hosts and static NAT for an outside web server

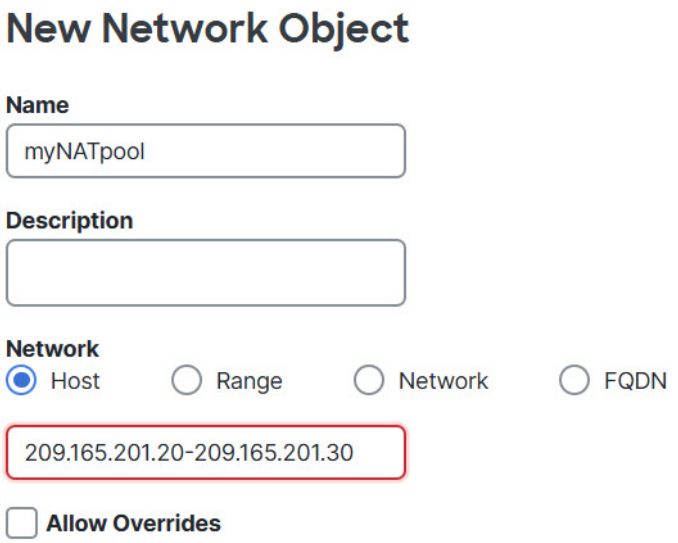
The following example configures dynamic NAT for inside users on a private network when they access the outside. Also, when inside users connect to an outside web server, that web server address is translated to an address that appears to be on the inside network.

Figure 413: Dynamic NAT for Inside, Static NAT for Outside Web Server

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select and click **Add Network** > **Add ObjectObjects** > **Interface**.

Procedure



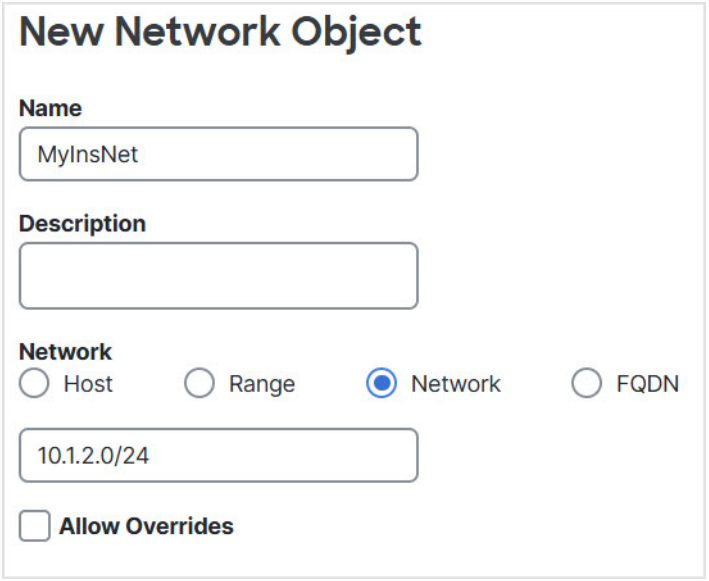
Step 1 Create a network object for the dynamic NAT pool to which you want to translate the inside addresses.

a) Choose **Objects**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the dynamic NAT pool.

Name the network object (for example, myNATpool) and enter the network range 209.165.201.20-209.165.201.30.

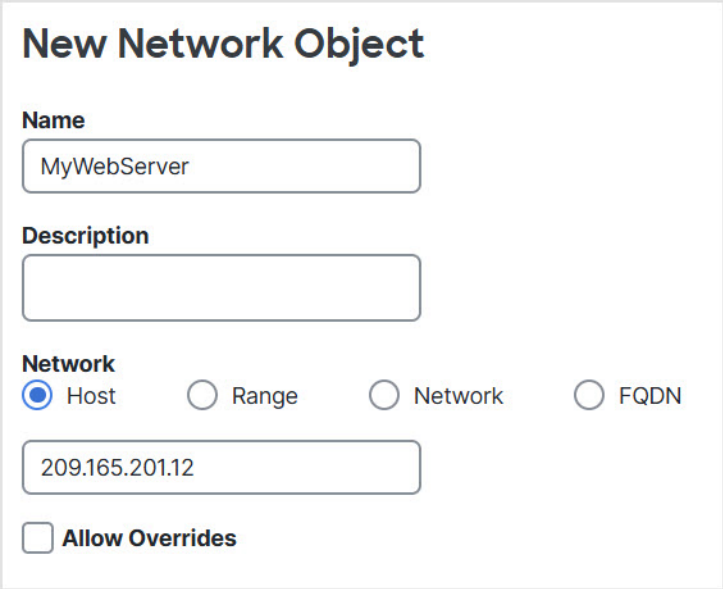


d) Click **Save**.

Step 2 Create a network object for the inside network.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, MyInsNet) and enter the network address 10.1.2.0/24.

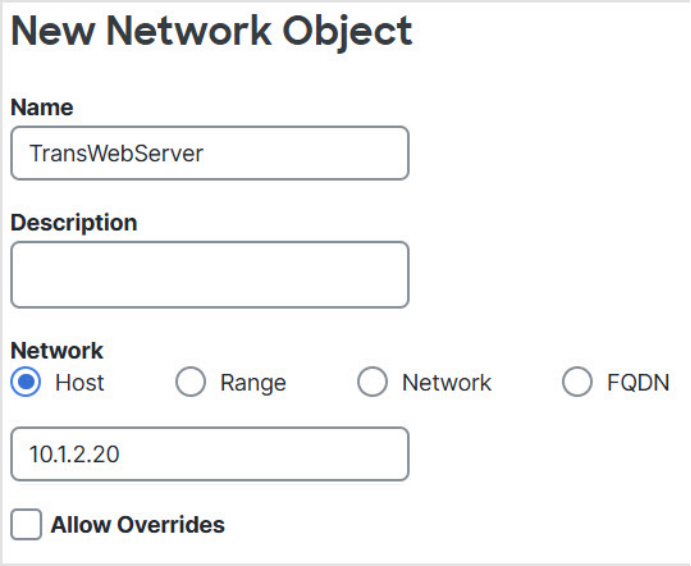


c) Click **Save**.

Step 3 Create a network object for the outside web server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, MyWebServer) and enter the host address 209.165.201.12.



c) Click **Save**.

Step 4 Create a network object for the translated web server address.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, TransWebServer) and enter the host address 10.1.2.20.

c) Click **Save**.

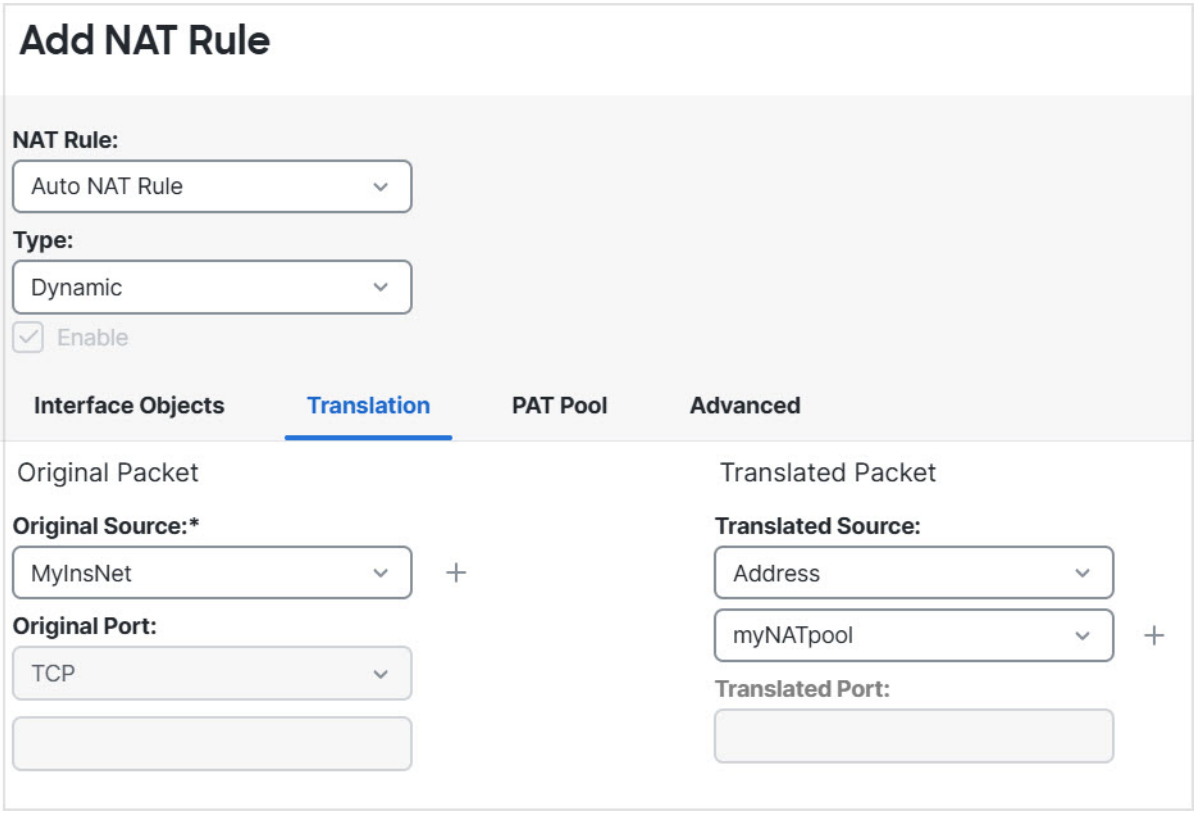
Step 5 Configure dynamic NAT for the inside network using the dynamic NAT pool object.

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.



- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = myInsNet network object.
- **Translated Source** > **Address**= myNATpool network group.

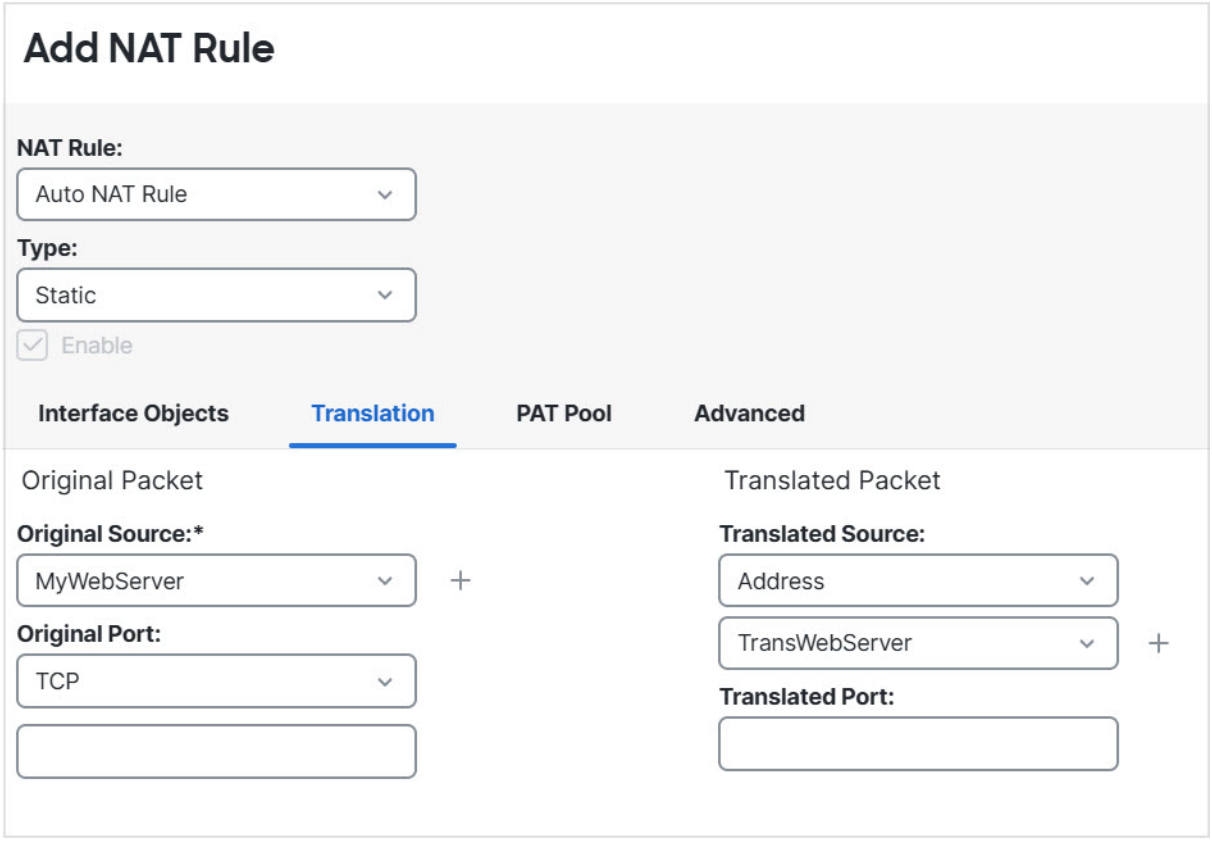
f) Click **Save**.

Step 6 Configure static NAT for the web server.

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



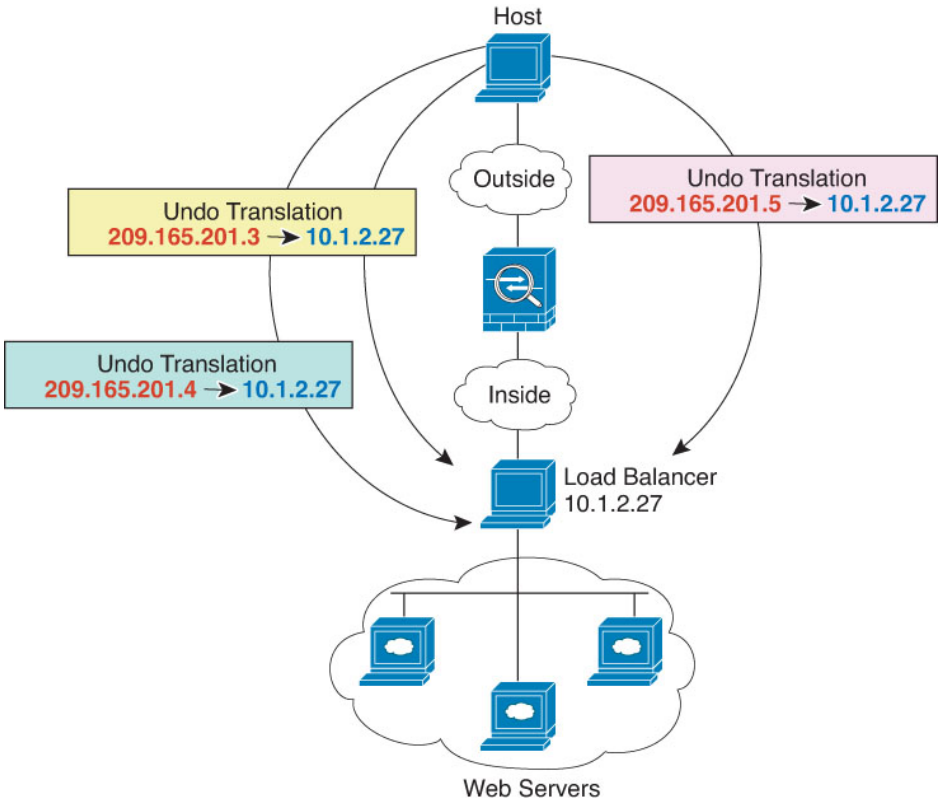
c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.

- **Destination Interface Objects** = inside.

d) On **Translation**, configure the following:

- **Original Source** = myWebServer network object.
- **Translated Source** > **Address**= TransWebServer network object.



e) Click **Save**.

Step 7 Click **Save** on the NAT rule page.

Configure inside load balancer with multiple mapped addresses

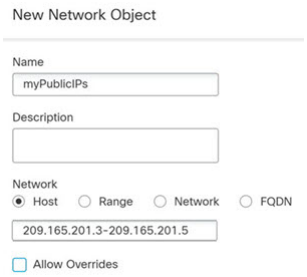
The following example shows an inside load balancer that is translated to multiple IP addresses. When an outside host accesses one of the mapped IP addresses, it is untranslated to the single load balancer address. Depending on the URL requested, it redirects traffic to the correct web server.

Figure 414: Static NAT with One-to-Many for an Inside Load Balancer

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Interface**.

Procedure



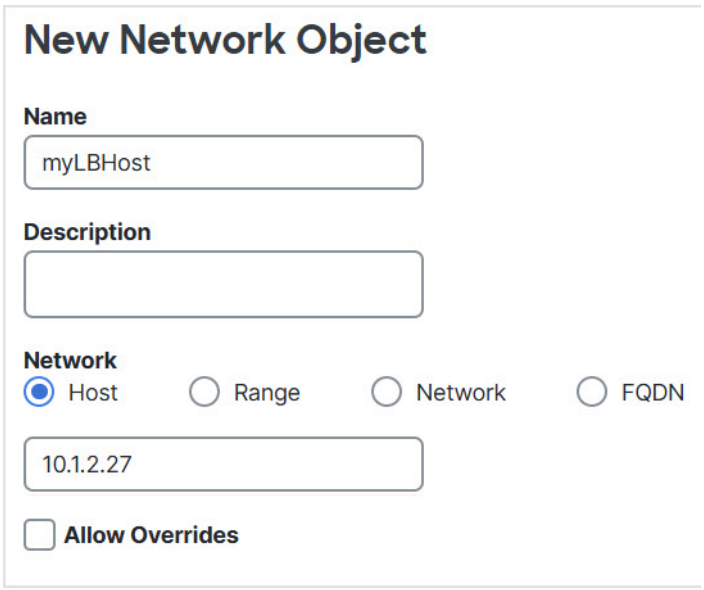
Step 1 Create a network object for the addresses to which you want to map the load balancer.

a) Choose **Objects**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the addresses.

Name the network object (for example, myPublicIPs) and enter the network range 209.165.201.3-209.165.201.5.



d) Click **Save**.

Step 2 Create a network object for the load balancer.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, myLBHost), enter the host address 10.1.2.27.

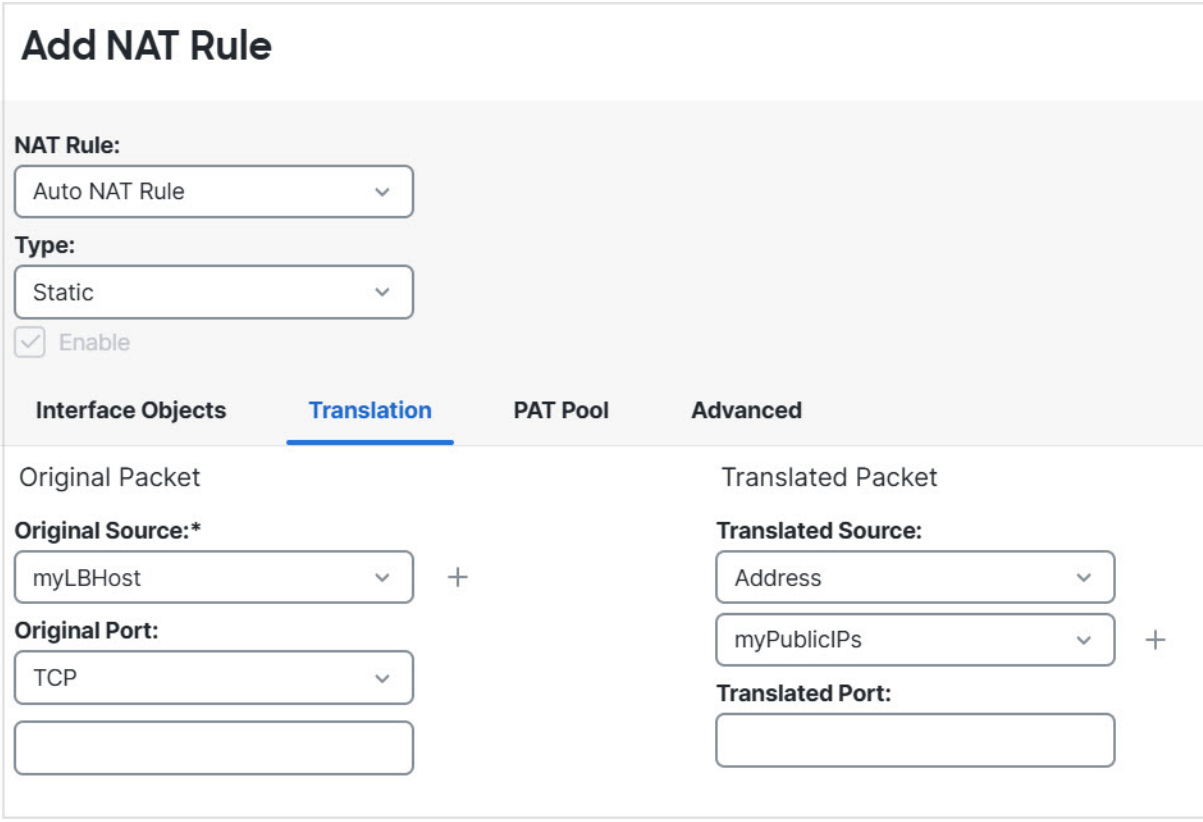
c) Click **Save**.

Step 3 Configure static NAT for the load balancer.

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



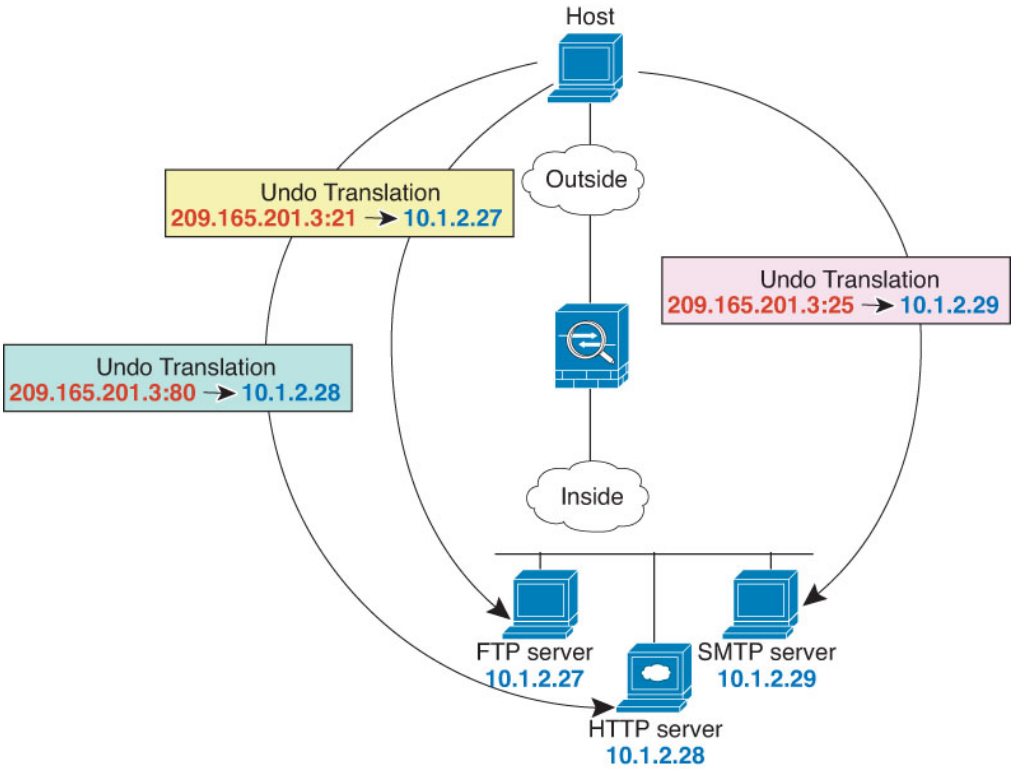
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = myLBHost network object.
- **Translated Source** > **Address** = myPublicIPs network group.



f) Click **Save**.

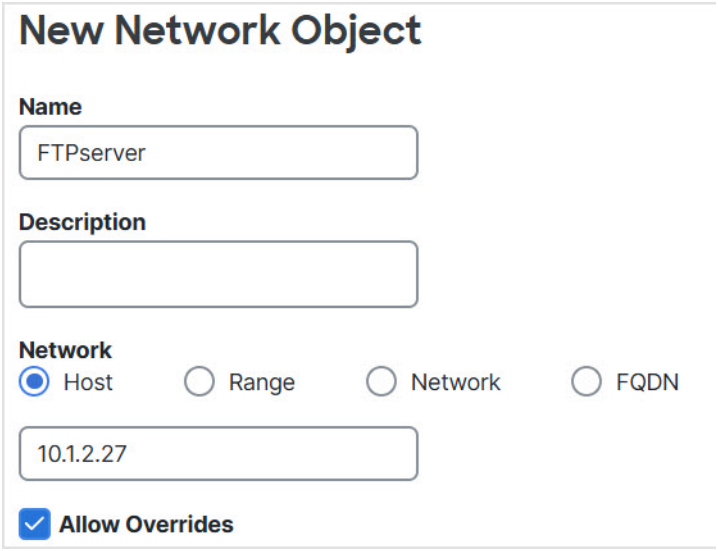
Step 4 Click **Save** on the NAT rule page.

Single address for FTP, HTTP, and SMTP (static auto NAT with port translation)

The following static NAT-with-port-translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT-with-port-translation rules that use the same mapped IP address, but different ports.

Figure 415: Static NAT-with-Port-Translation

Before you begin



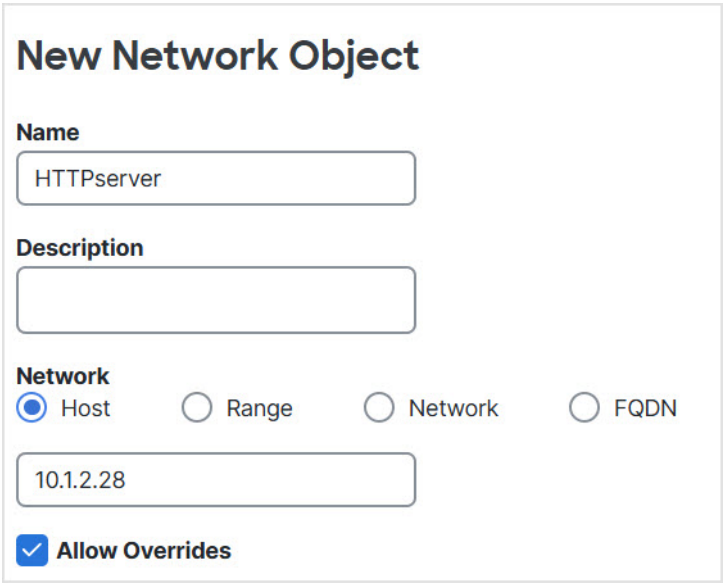
Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select and click **Add Network** > **Add GroupObjects** > **Interface**.

Procedure

Step 1 Create a network object for the FTP server.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Name the network object (for example, FTPserver), and enter the real IP address for the FTP server, 10.1.2.27.

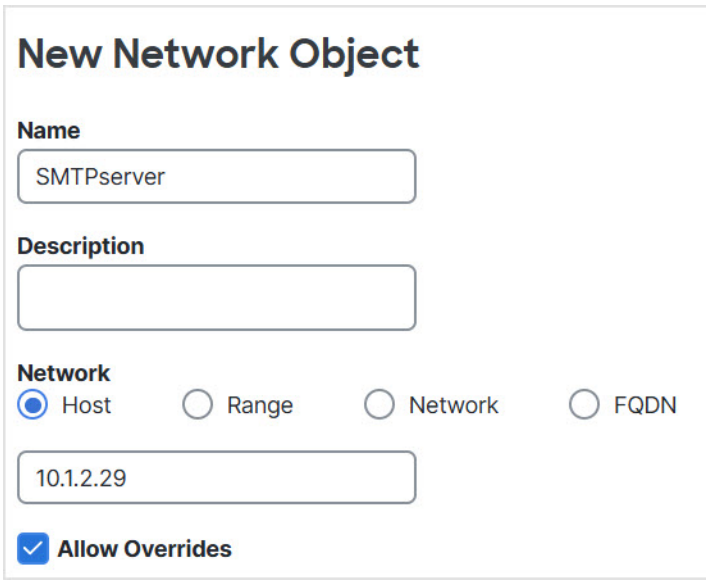


c) Click **Save**.

Step 2 Create a network object for the HTTP server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, HTTPserver), enter the host address 10.1.2.28.

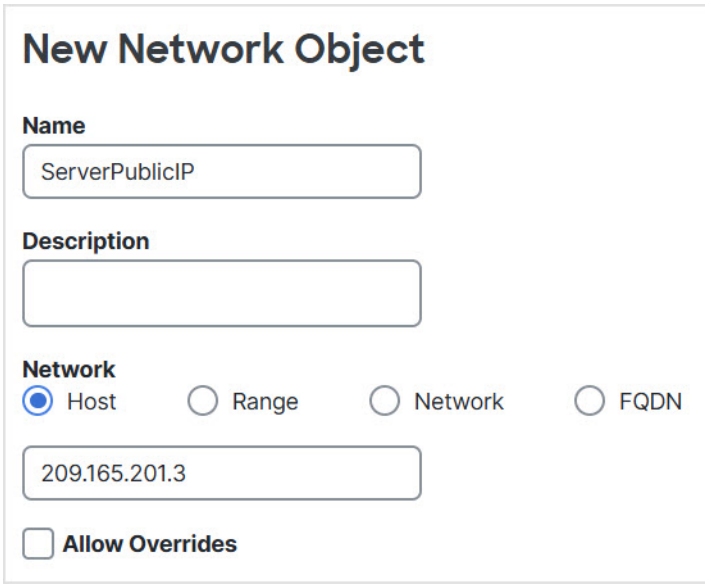


c) Click **Save**.

Step 3 Create a network object for the SMTP server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, SMTPserver), enter the host address 10.1.2.29.



c) Click **Save**.

Step 4 Create a network object for the public IP address used for the three servers.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, ServerPublicIP) and enter the host address 209.165.201.3.

c) Click **Save**.

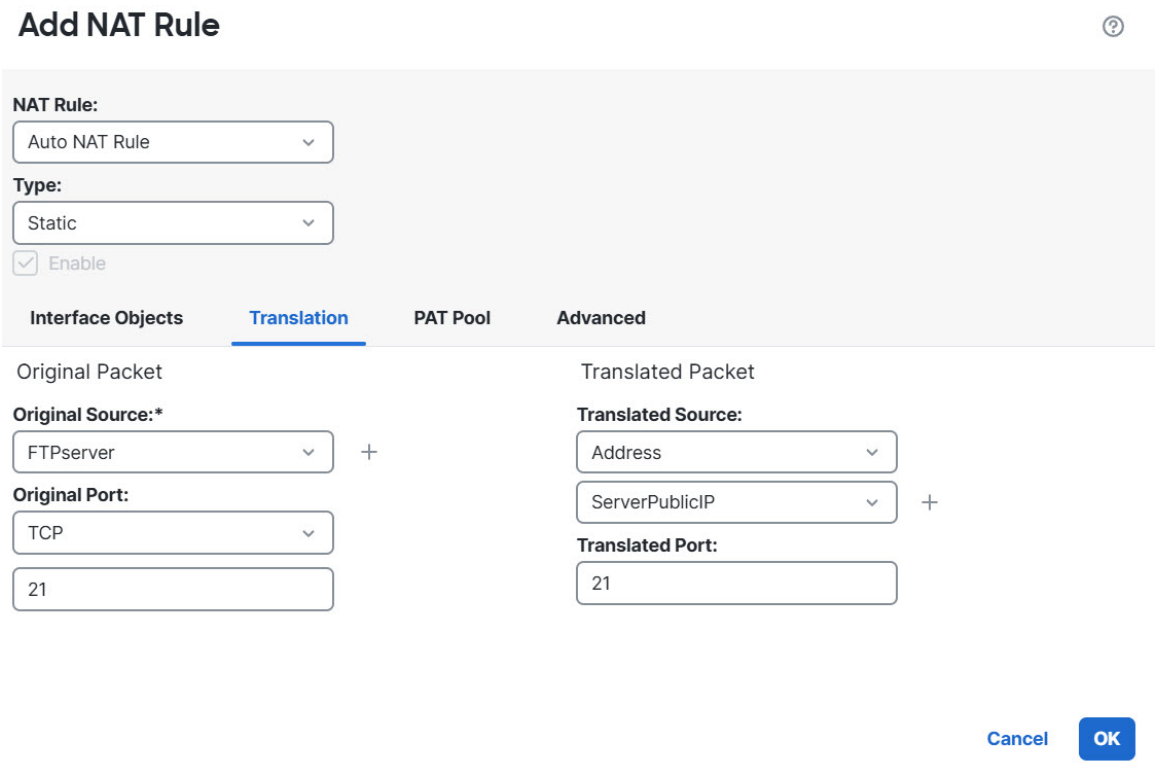
Step 5 Configure static NAT with port translation for the FTP server, mapping the FTP port to itself.

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.



- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

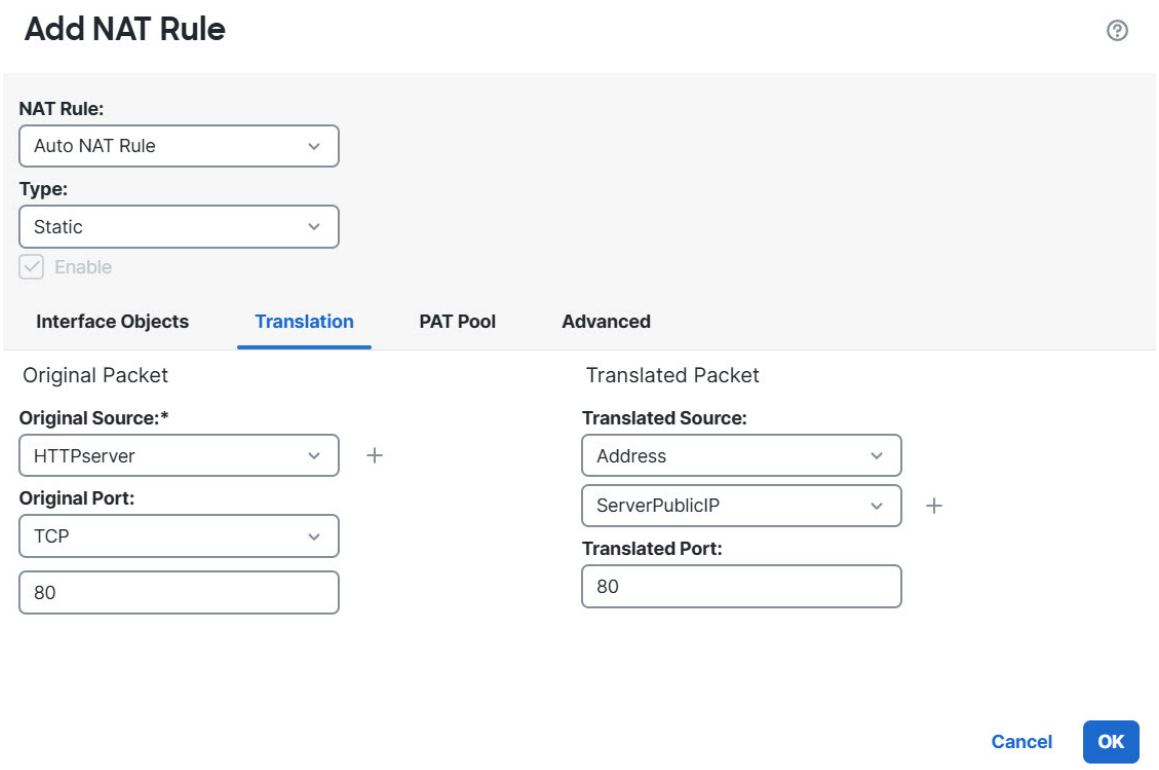
- **Original Source** = FTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 21.
- **Translated Port** = 21.

f) Click **Save**.

Step 6 Configure static NAT with port translation for the HTTP server, mapping the HTTP port to itself.

a) Click **Add Rule**.

b) Configure the following properties:



- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

d) On **Translation**, configure the following:

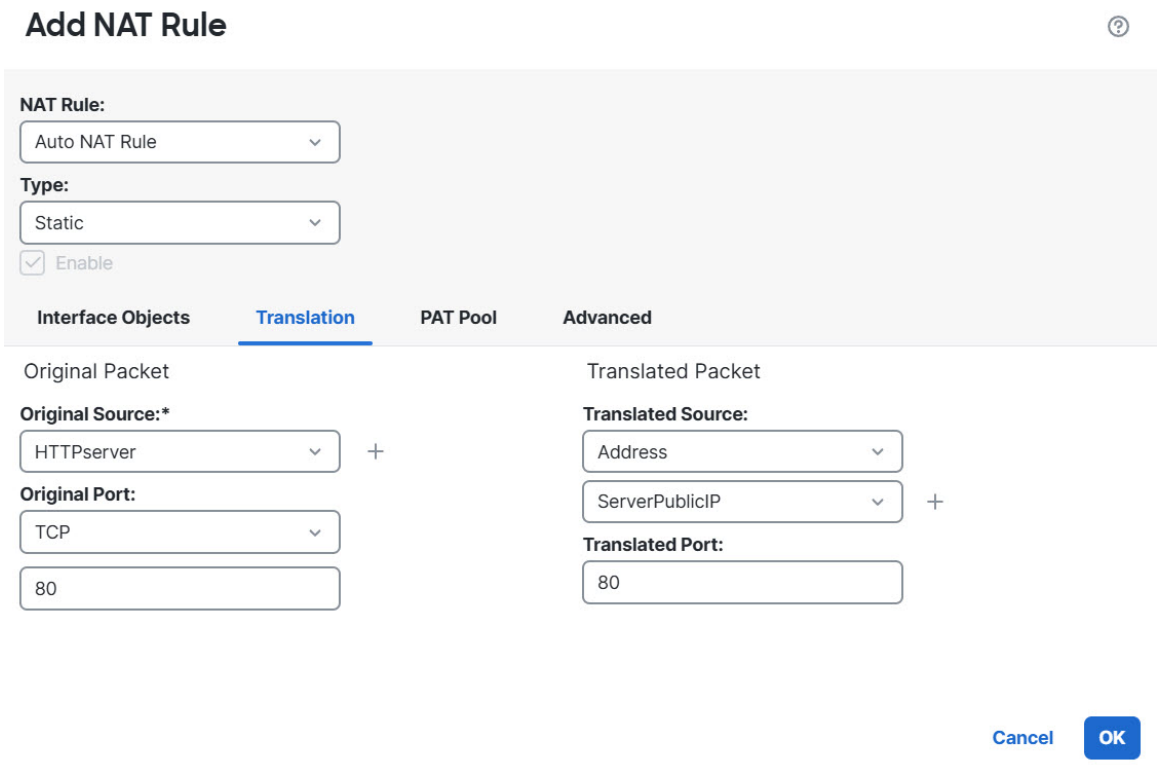
- **Original Source** = HTTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 80.
- **Translated Port** = 80.

e) Click **Save**.

Step 7 Configure static NAT with port translation for the SMTP server, mapping the SMTP port to itself.

a) Click **Add Rule**.

b) Configure the following properties:



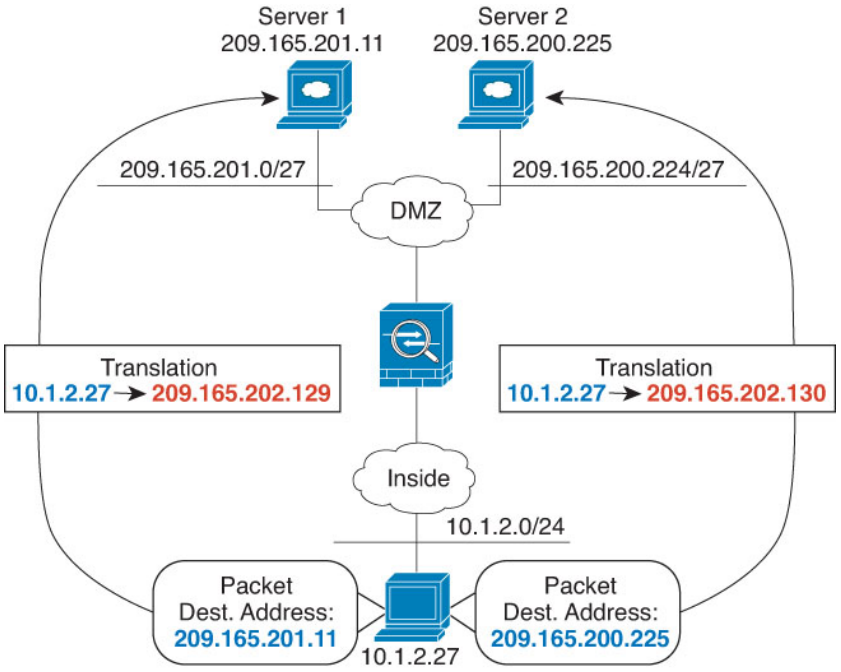
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

d) On **Translation**, configure the following:

- **Original Source** = SMTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 25.
- **Translated Port** = 25.



e) Click **Save**.

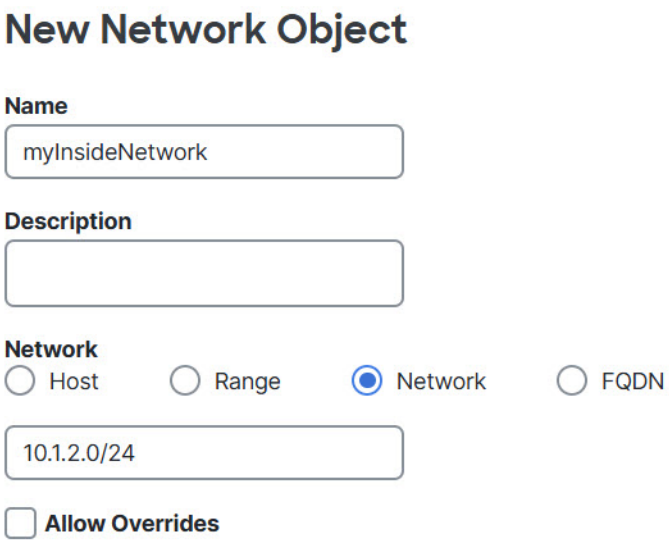
Step 8 Click **Save** on the NAT rule page.

Different translation depending on the destination (dynamic manual PAT)

The following figure shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129:*port*. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130:*port*.

Figure 416: Manual NAT with Different Destination Addresses

Before you begin



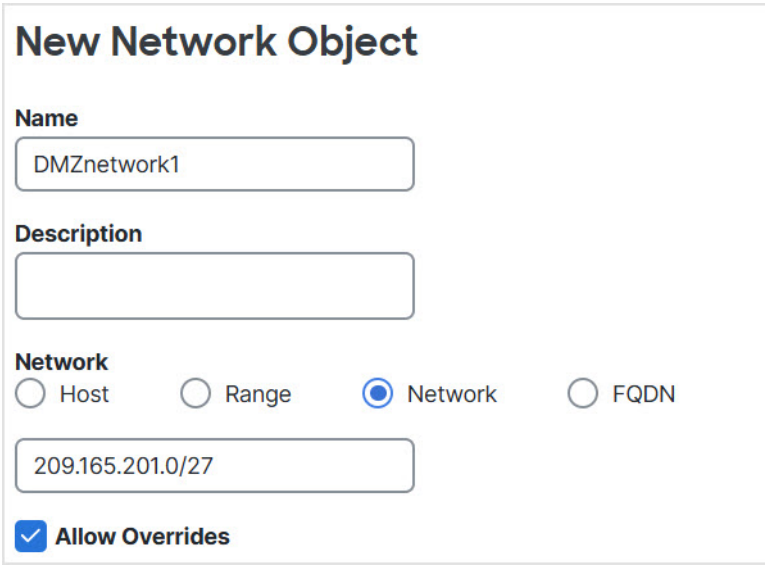
Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **dmz**. To configure interface objects, select **Objects** > **Interface**.

Procedure

Step 1 Create a network object for the inside network.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Name the network object (for example, myInsideNetwork), and enter the real network address, 10.1.2.0/24.

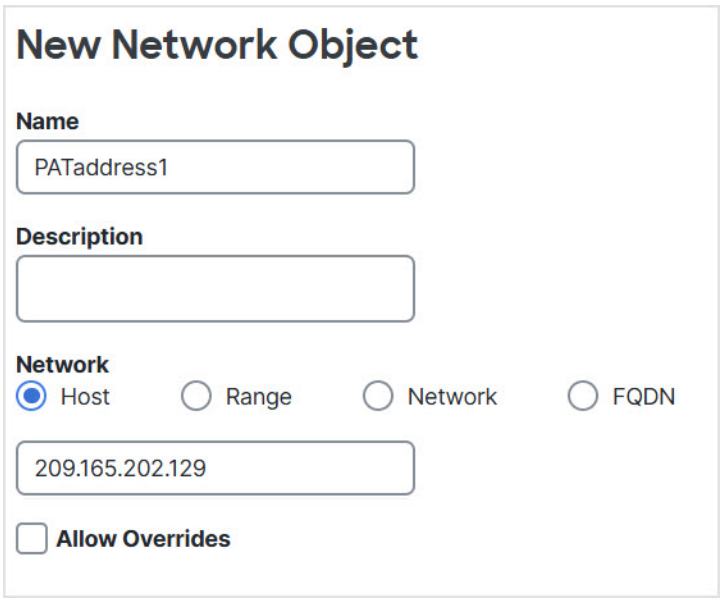


c) Click **Save**.

Step 2 Create a network object for the DMZ network 1.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, DMZnetwork1) and enter the network address 209.165.201.0/27 (subnet mask of 255.255.255.224).

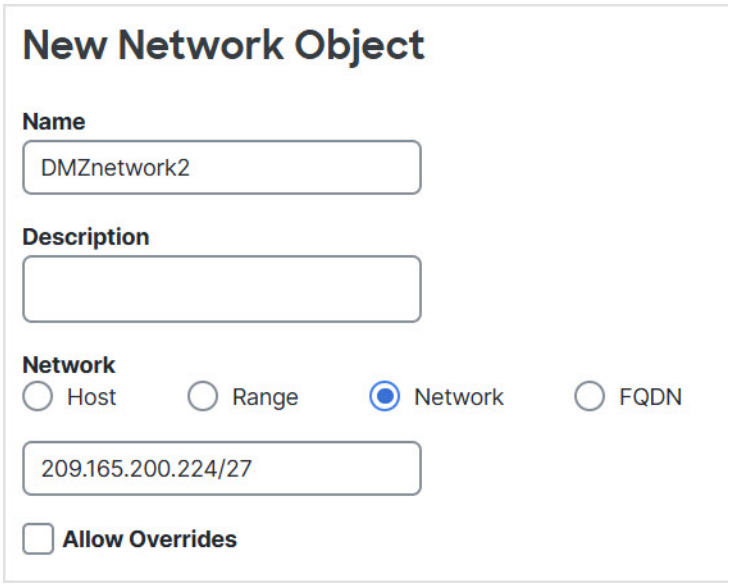


c) Click **Save**.

Step 3 Create a network object for the PAT address for DMZ network 1.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress1) and enter the host address 209.165.202.129.

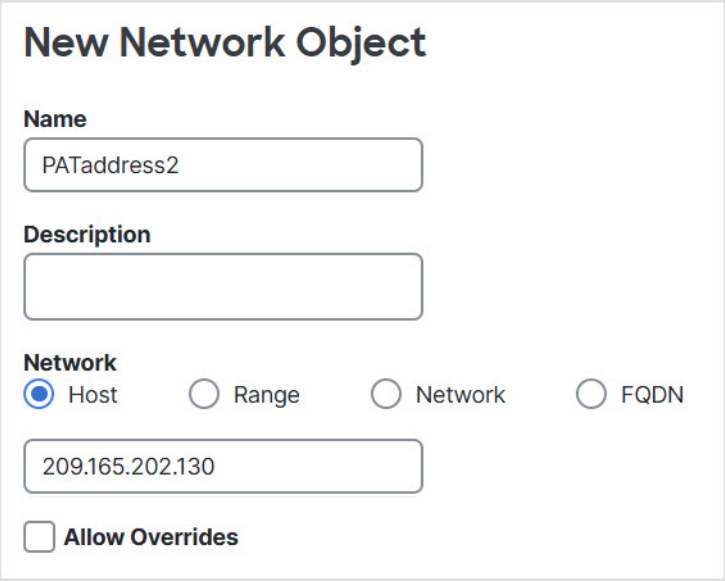


c) Click **Save**.

Step 4 Create a network object for the DMZ network 2.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, DMZnetwork2) and enter the network address 209.165.200.224/27 (subnet mask of 255.255.255.224).



c) Click **Save**.

Step 5 Create a network object for the PAT address for DMZ network 2.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.

c) Click **Save**.

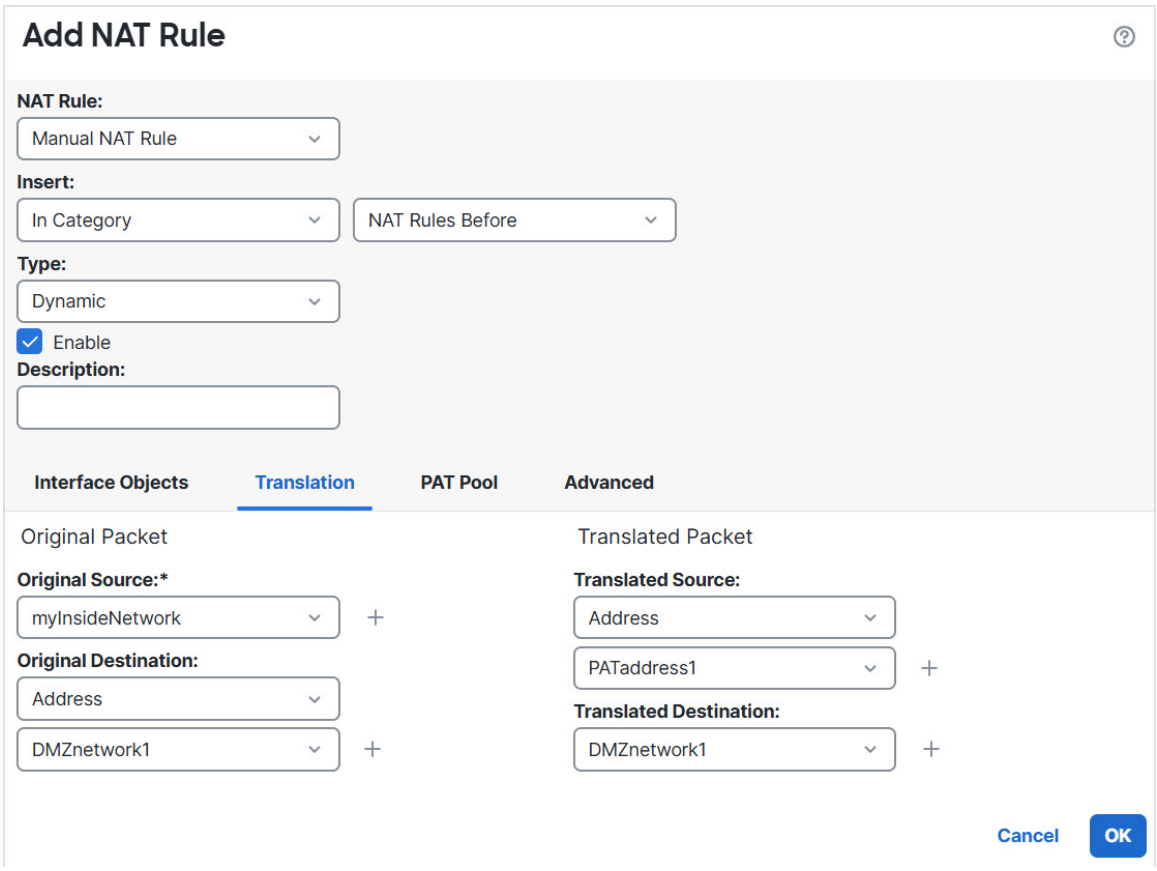
Step 6 Configure dynamic manual PAT for DMZ network 1.

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.



d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

e) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress1 network object.
- **Original Destination** > **Address** = DMZnetwork1 network object.
- **Translated Destination** = DMZnetwork1 network object.

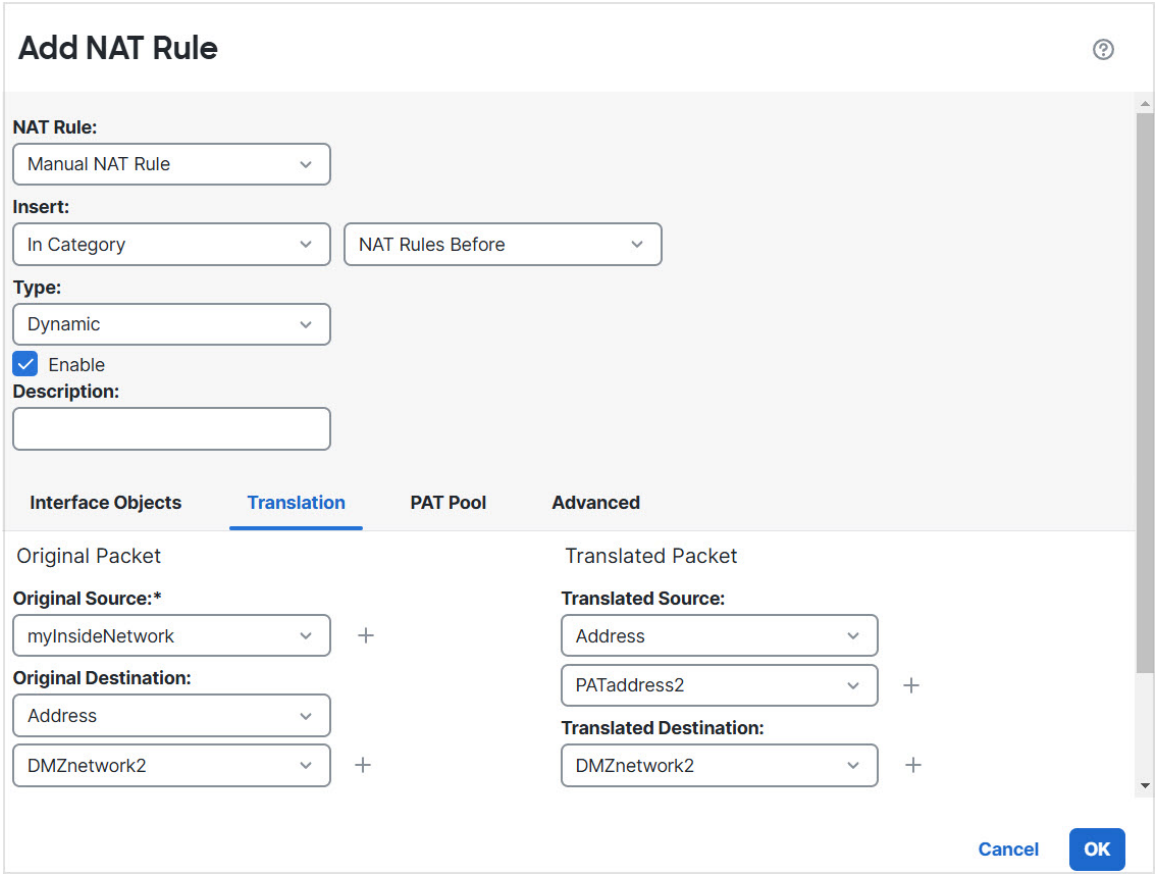
Note Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank.

f) Click **Save**.

Step 7 Configure dynamic manual PAT for DMZ network 2.

a) Click **Add Rule**.

b) Configure the following properties:



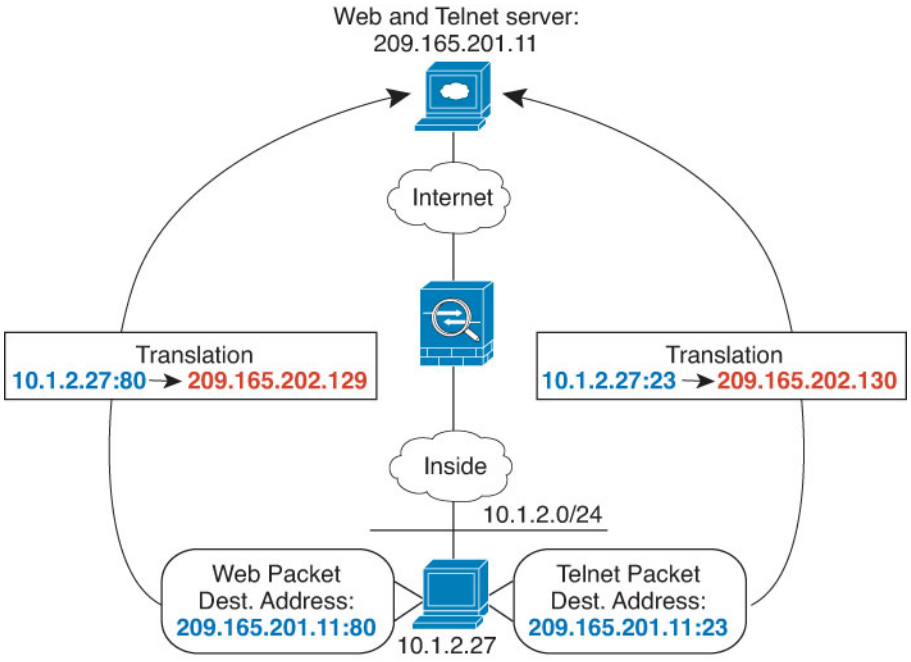
- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

d) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress2 network object.
- **Original Destination** > **Address** = DMZnetwork2 network object.
- **Translated Destination** = DMZnetwork2 network object.



e) Click **Save**.

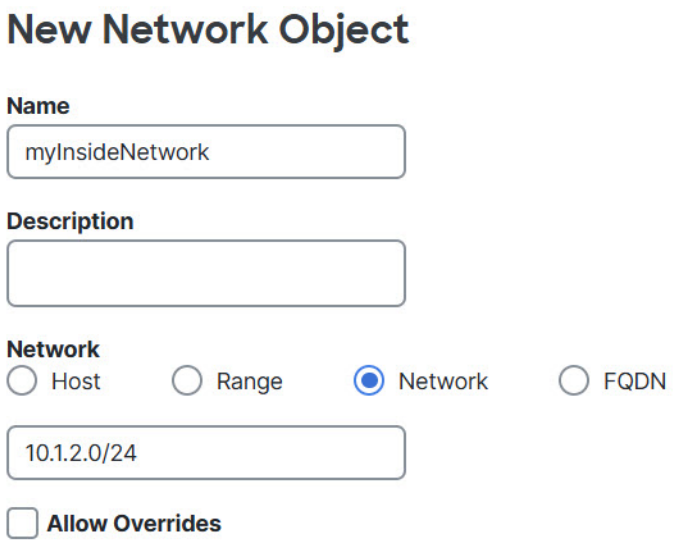
Step 8 Click **Save** on the NAT rule page.

Configure dynamic manual PAT with different destination ports

This illustration displays the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for Telnet services, the real address is translated to 209.165.202.129: *port*. When the host accesses the same server for web services, the real address is translated to 209.165.202.130: *port*.

Figure 417: Manual NAT with Different Destination Ports

Before you begin



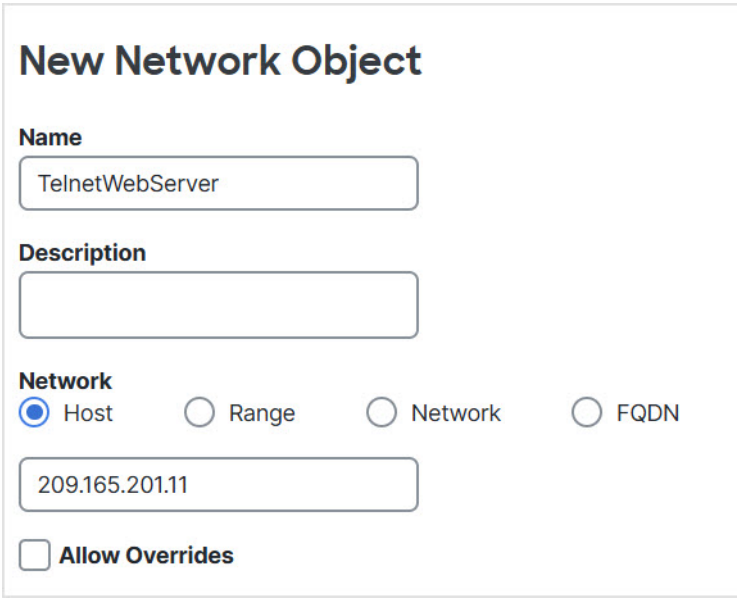
Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **dmz**. To configure interface objects, select **Objects** > **Interface**.

Procedure

Step 1 Create a network object for the inside network.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Name the network object (for example, myInsideNetwork) and enter the real network address, 10.1.2.0/24.

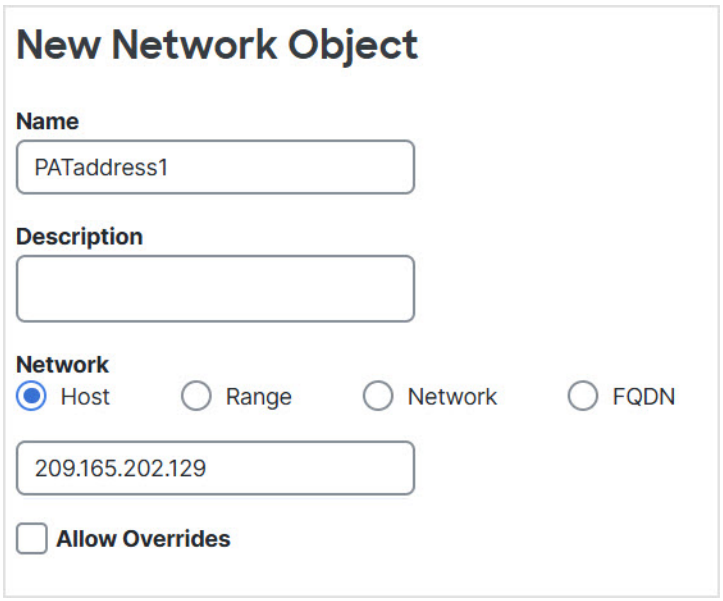


c) Click **Save**.

Step 2 Create a network object for the Telnet/Web server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, TelnetWebServer) and enter the host address 209.165.201.11.

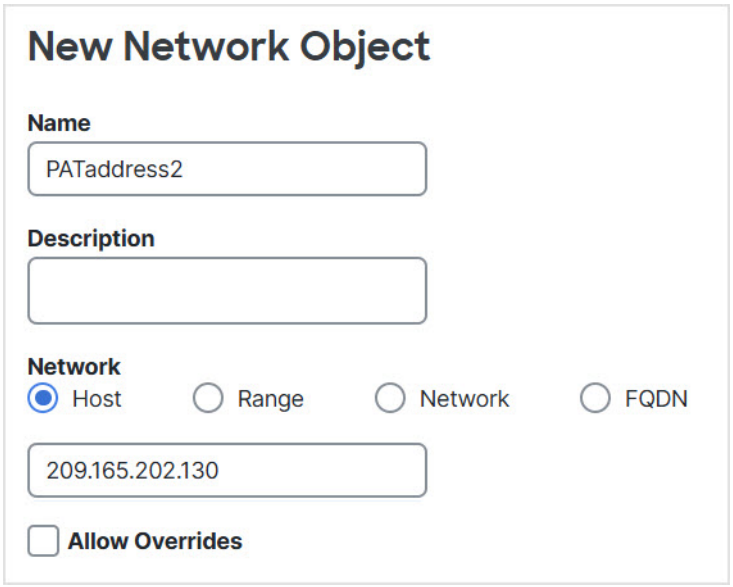


c) Click **Save**.

Step 3 Create a network object for the PAT address when using Telnet.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress1) and enter the host address 209.165.202.129.



c) Click **Save**.

Step 4 Create a network object for the PAT address when using HTTP.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.

c) Click **Save**.

Step 5 Configure dynamic manual PAT for Telnet access.

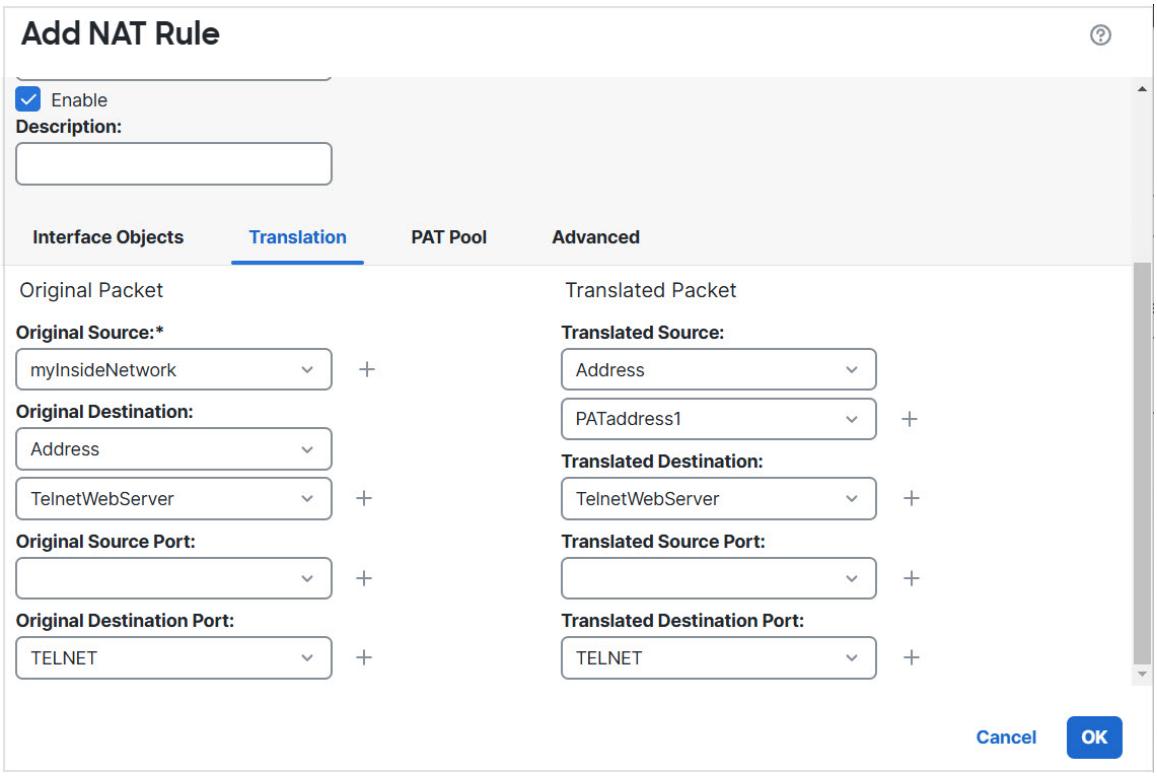
a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.

- **Type** = Dynamic.



d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

e) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address** = PATaddress1 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = TELNET port object (system-defined).
- **Translated Destination Port** = TELNET port object (system-defined).

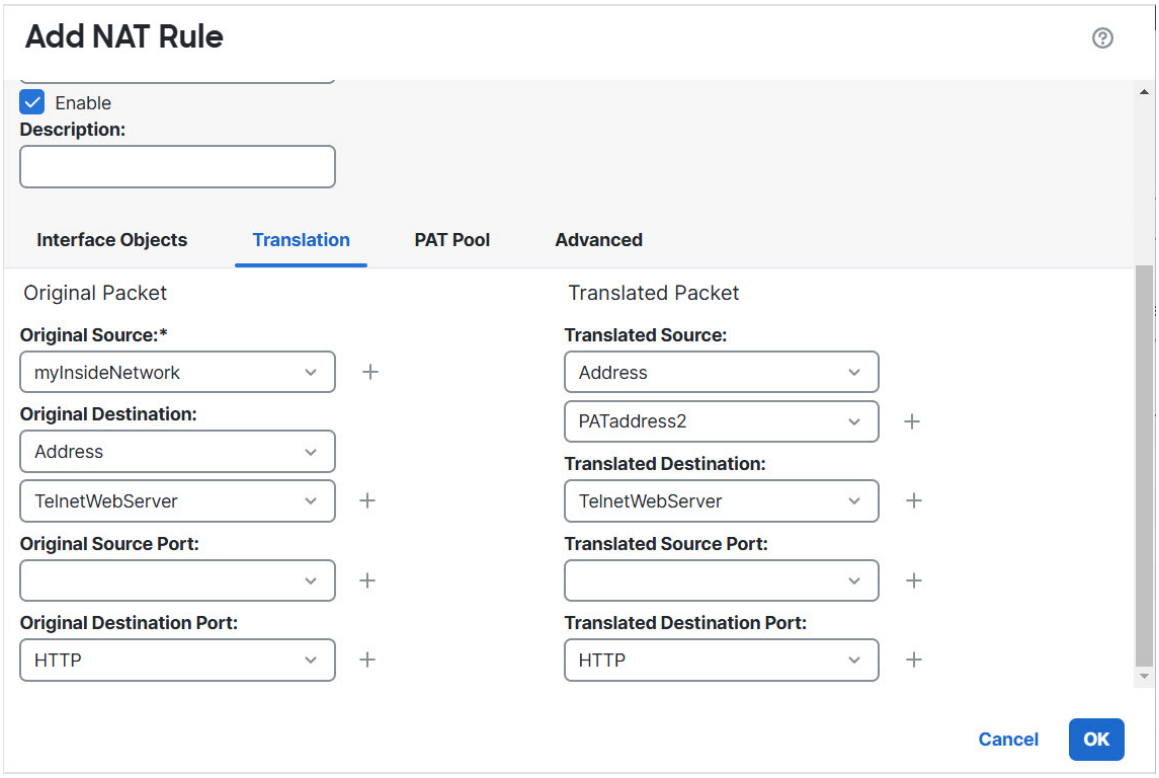
Note Because you do not want to translate the destination address or port, you need to configure identity NAT for them by specifying the same address for the original and translated destination addresses, and the same port for the original and translated port.

f) Click **Save**.

Step 6 Configure dynamic manual PAT for web access.

a) Click **Add Rule**.

b) Configure the following properties:



- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

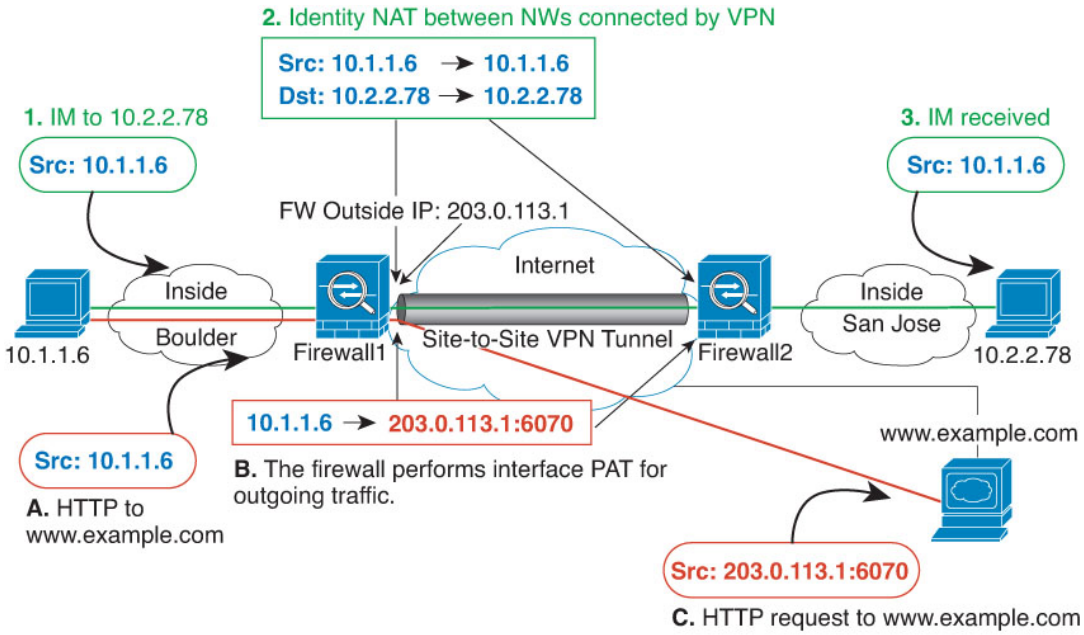
c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

d) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address** = PATaddress2 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = HTTP port object (system-defined).
- **Translated Destination Port** = HTTP port object (system-defined).

e) Click **Save**.



Step 7 Click **Save** on the NAT rule page.

NAT and site-to-site VPN

When you create a policy-based site-to-site VPN using the management center VPN wizard (**Device > Site To Site**), you can select the NAT Exempt option to create the rules automatically. You can view the NAT exemptions for a device in the NAT policy page (**Device > NAT > NAT Exemptions**). If you do not want to configure NAT Exempt in the VPN wizard, you can use the following procedure for NAT exemption.

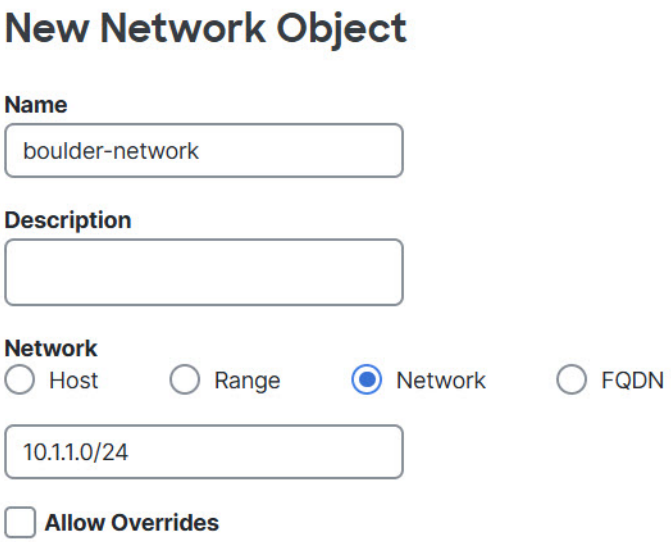
The following figure shows a site-to-site tunnel connecting the Boulder and San Jose offices. For traffic that you want to go to the Internet (for example from 10.1.1.6 in Boulder to www.example.com), you need a public IP address provided by NAT to access the Internet. The below example uses interface PAT rules. However, for traffic that you want to go over the VPN tunnel (for example from 10.1.1.6 in Boulder to 10.2.2.78 in San Jose), you do not want to perform NAT; you need to exempt that traffic by creating an identity NAT rule. Identity NAT simply translates an address to the same address.

Figure 418: Interface PAT and Identity NAT for Site-to-Site VPN

This example explains the configuration for Firewall1 (Boulder).

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the devices in the VPN. In this example, we will assume the interface objects are security zones named **inside-boulder** and **outside-boulder** for the Firewall1 (Boulder) interfaces. To configure interface objects, select **Objects** > **Interface**.

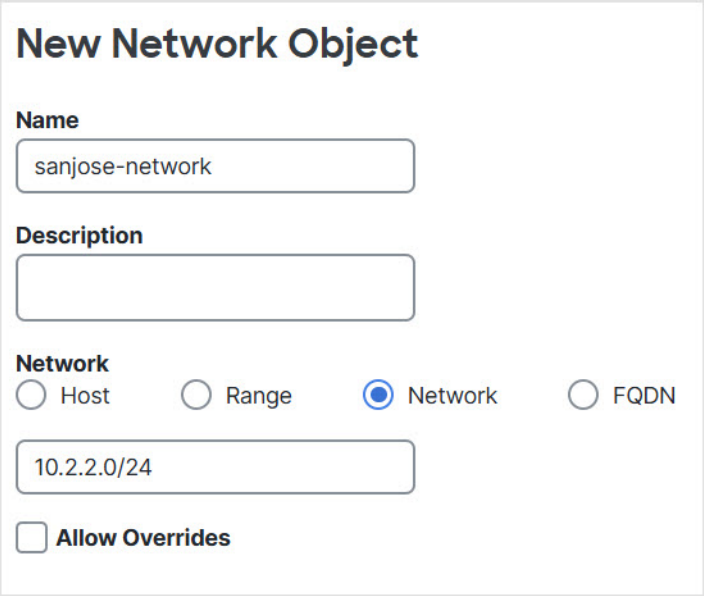


Procedure

Step 1 Create the objects to define the various networks.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Identify the Boulder inside network.



Name the network object (for example, boulder-network) and enter the network address, 10.1.1.0/24.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the inside San Jose network.

Name the network object (for example, sanjose-network) and enter the network address 10.2.2.0/24.

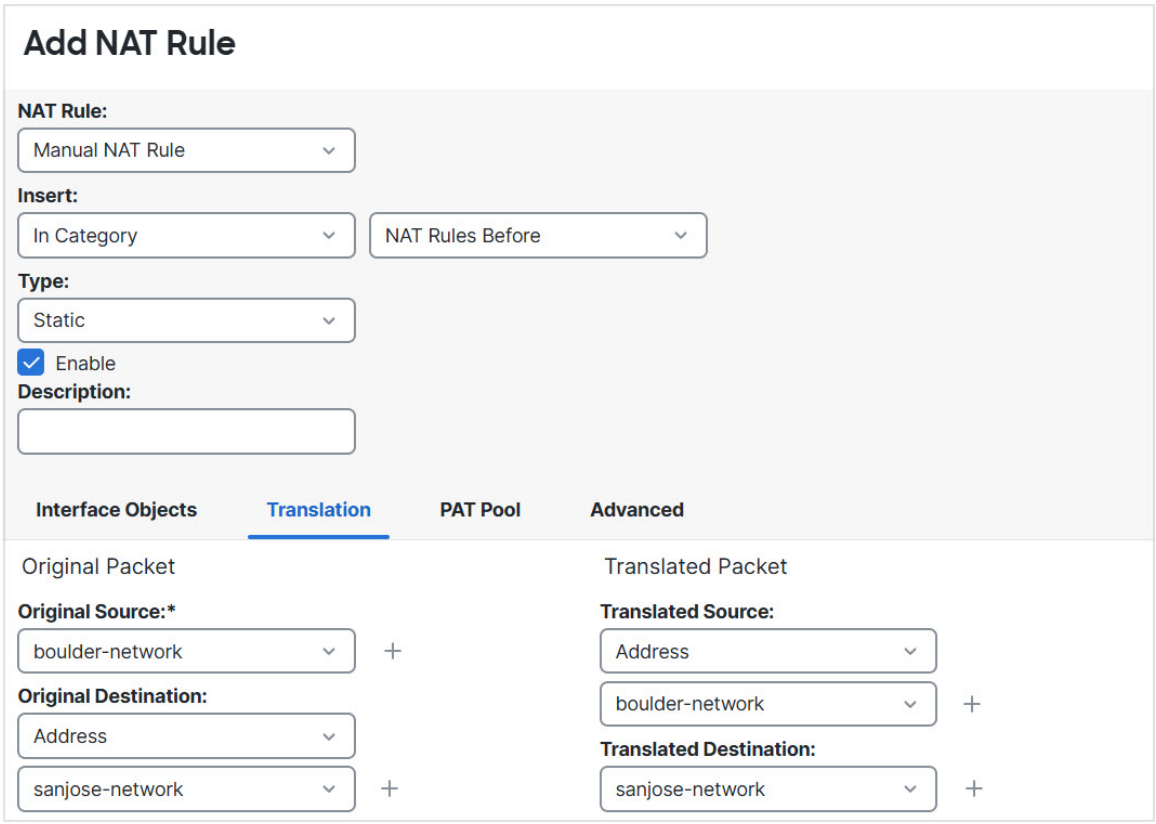
e) Click **Save**.

Step 2 Configure manual identity NAT for the Boulder network when going over the VPN to San Jose on Firewall1 (Boulder).

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:



- **Source Interface Objects** = inside-boulder.
- **Destination Interface Objects** = outside-boulder.

e) On **Translation**, configure the following:

- **Original Source** = boulder-network object.
- **Translated Source** > **Address** = boulder-network object.
- **Original Destination** > **Address** = sanjose-network object.
- **Translated Destination** = sanjose-network object.

Note Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank. This rule configures identity NAT for both source and destination.

f) On **Advanced**, select **Do not proxy ARP on Destination interface**.

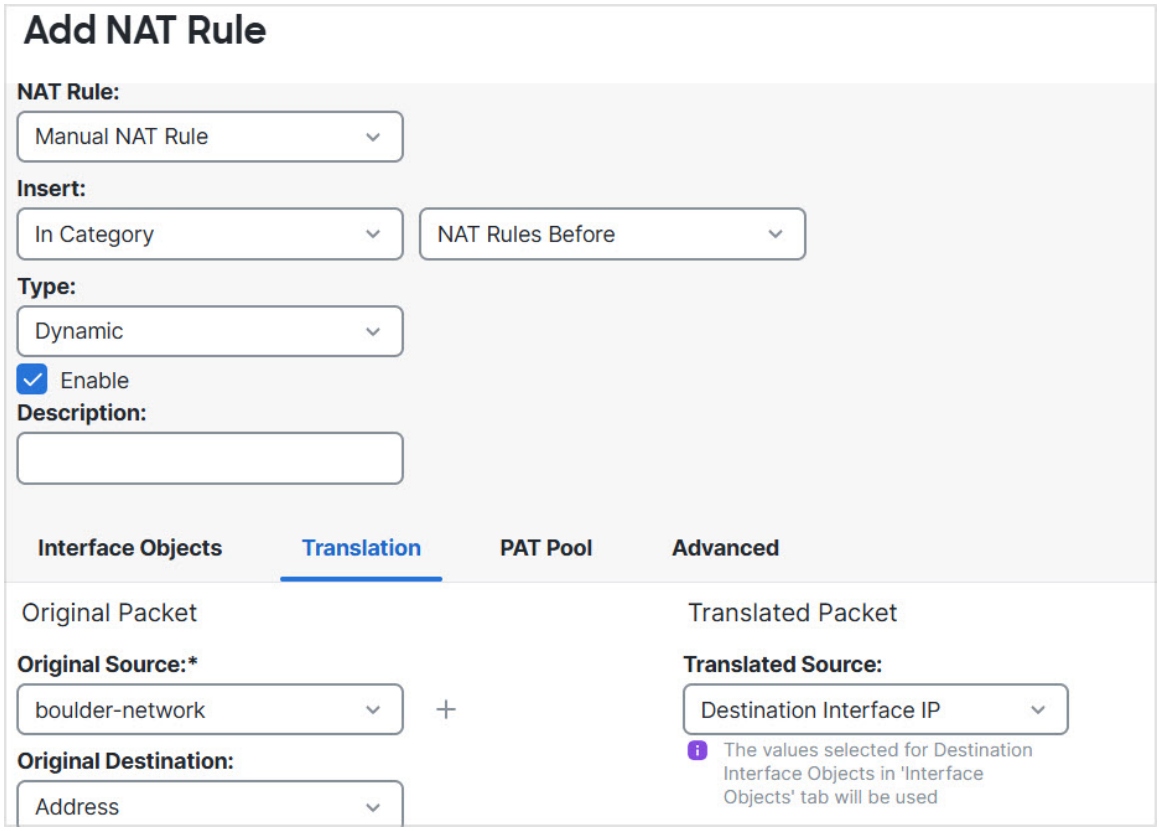
g) Click **Save**.

Step 3 Configure manual dynamic interface PAT when going to the Internet for the inside Boulder network on Firewall1 (Boulder).

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.
- **Insert Rule** = any position after the first rule. Because this rule will apply to any destination address, the rule that uses sanjose-network as the destination must come before this rule, or the sanjose-network rule will never be matched. The default is to place new manual NAT rules at the end of the "NAT Rules Before Auto NAT" section.



c) On **Interface Objects** , configure the following:

- **Source Interface Objects** = inside-boulder.
- **Destination Interface Objects** = outside-boulder.

d) On **Translation** , configure the following:

- **Original Source** = boulder-network object.

- **Translated Source** = **Destination Interface IP**. This option configures interface PAT using the interface contained in the destination interface object.
- **Original Destination** > **Address** = any (leave blank).
- **Translated Destination** = any (leave blank).

e) Click **Save**.

Step 4 If you are also managing Firewall2 (San Jose), you can configure similar rules for that device.

- The manual identity NAT rule would be for sanjose-network when the destination is boulder-network. Create new interface objects for the Firewall2 inside and outside networks.
- The manual dynamic interface PAT rule would be for sanjose-network when the destination is "any."

DNS query and response rewriting using NAT

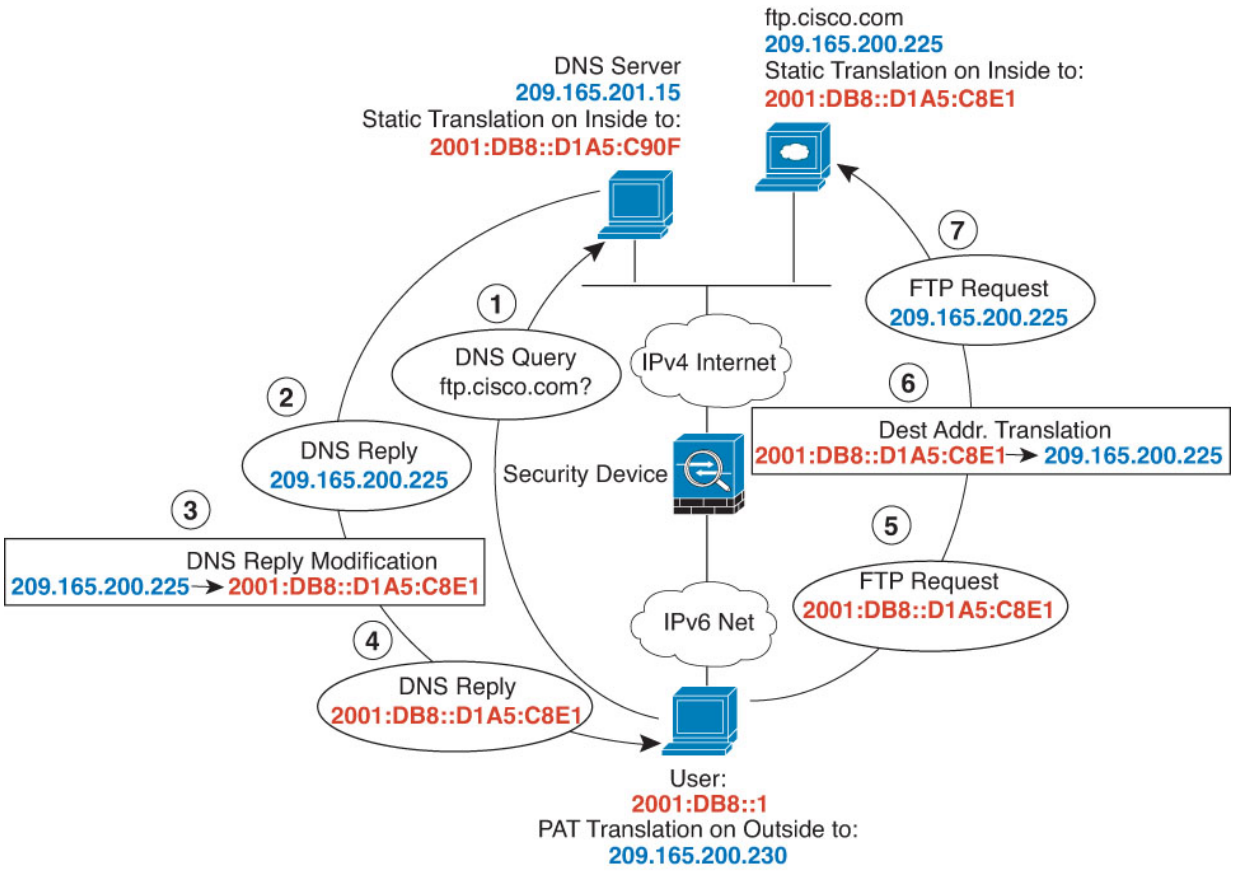
DNS rewrite is the process of modifying DNS replies so that the IP address returned in the DNS response is replaced with an address that matches the NAT configuration. It is used when a translated address must be returned to the requester instead of the original address in the DNS record. This function is also known as DNS doctoring.

This feature rewrites the address in DNS queries and replies that match a NAT rule (for example, the A record for IPv4, the AAAA record for IPv6, or the PTR record for reverse DNS queries). For DNS replies traversing from a mapped interface to any other interface, the record is rewritten from the mapped value to the real value. Inversely, for DNS replies traversing from any interface to a mapped interface, the record is rewritten from the real value to the mapped value. This feature works with NAT44,NAT 66, NAT46, and NAT64.

The main circumstances when you would need to configure DNS rewrite on a NAT rule are:

- The rule is NAT64 or NAT46, and the DNS server is on the outside network. You need DNS rewrite to convert between DNS A records (for IPv4) and AAAA records (for IPv6).
- The DNS server is on the outside, clients are on the inside, and some of the fully-qualified domain names that the clients use resolve to other inside hosts.
- The DNS server is on the inside and responds with private IP addresses, clients are on the outside, and the clients access fully-qualified domain names that point to servers that are hosted on the inside.

DNS rewrite has the following limitations:



- DNS rewrite is not applicable for PAT because multiple PAT rules are applicable for each A or AAAA record, and the PAT rule to use is ambiguous.
- If you configure a manual NAT rule, you cannot configure DNS modification if you specify the destination address as well as the source address. These kinds of rules can potentially have a different translation for a single address when going to A vs. B. Therefore, the can not accurately match the IP address inside the DNS reply to the correct twice NAT rule; the DNS reply does not contain information about which source/destination address combination was in the packet that prompted the DNS request.
- You must enable DNS application inspection with DNS NAT rewrite enabled for NAT rules to rewrite DNS queries and responses. By default, DNS inspection with DNS NAT rewrite enabled is globally applied, so you probably do not need to change the inspection configuration.
- DNS rewrite is actually done on the xlate entry, not the NAT rule. Thus, if there is no xlate for a dynamic rule, rewrite cannot be done correctly. The same problem does not occur for static NAT.
- DNS rewrite does not rewrite DNS Dynamic Update messages (opcode 5).

These topics provide examples of DNS rewrite in NAT rules.

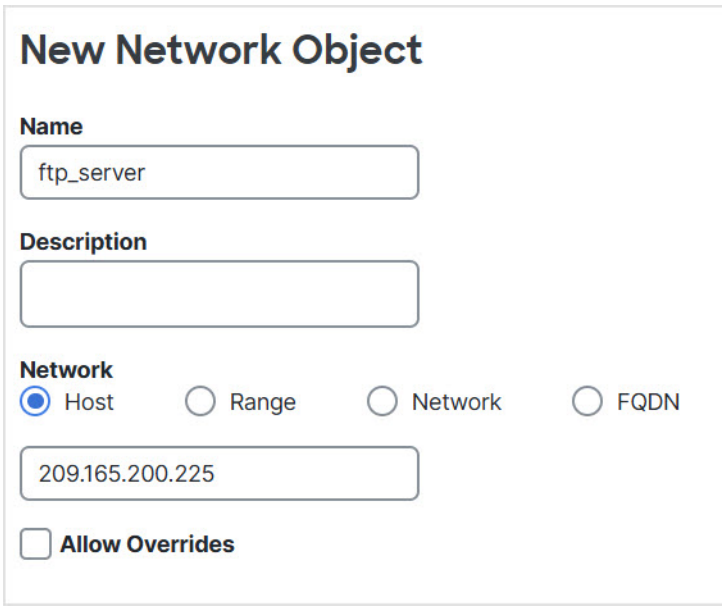
DNS64 reply modification

The following figure shows an FTP server and DNS server on the outside IPv4 network. The system has a static translation for the outside server. In this case, when an inside IPv6 user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.200.225.

Because you want inside users to use the mapped address for ftp.cisco.com (2001:DB8::D1A5:C8E1, where D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225) you need to configure DNS reply modification for the static translation. This example also includes a static NAT translation for the DNS server, and a PAT rule for the inside IPv6 hosts.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Interface**.

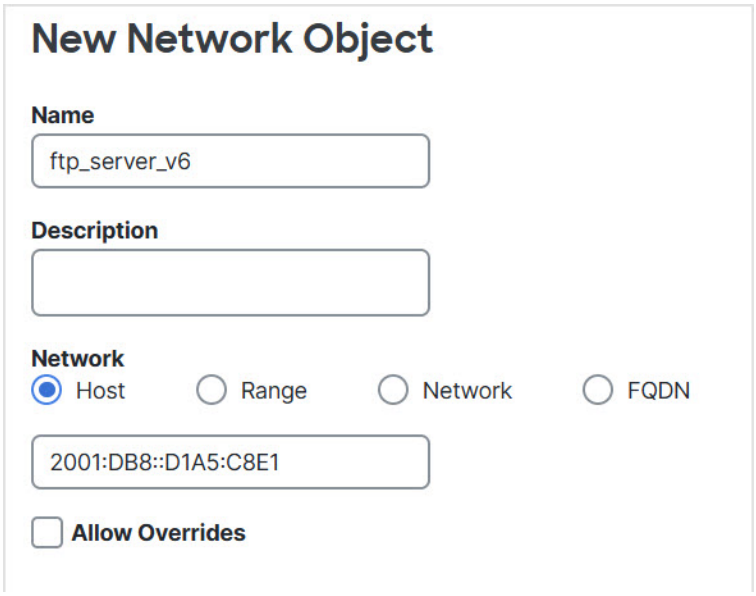


Procedure

Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Define the real FTP server address.

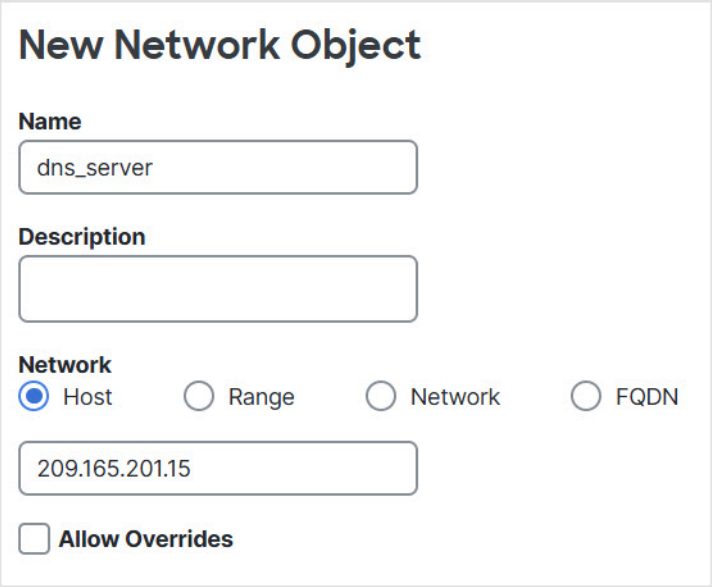


Name the network object (for example, ftp_server) and enter the host address, 209.165.200.225.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the FTP server's translated IPv6 address.

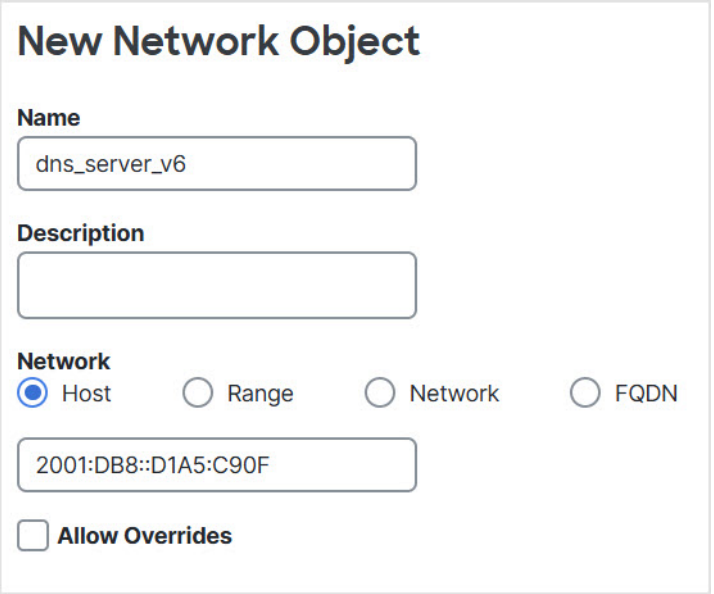
Name the network object (for example, ftp_server_v6) and enter the host address, 2001:DB8::D1A5:C8E1.



e) Click **Save**.

Step 2 Create the network objects for the DNS server.

a) Click **Add Network** > **Add Object** and define the DNS server's real address.

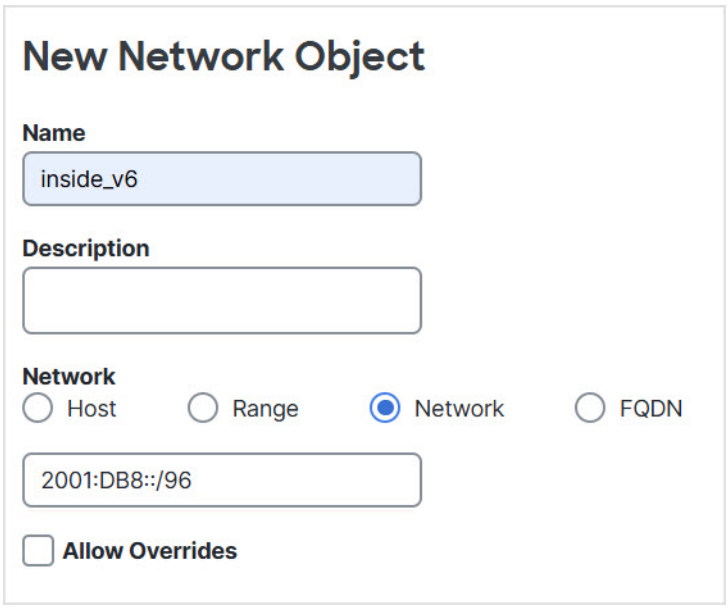


Name the network object (for example, dns_server) and enter the host address, 209.165.201.15.

b) Click **Save**.

c) Click **Add Network** > **Add Object** and define the DNS server's translated IPv6 address.

Name the network object (for example, dns_server_v6) and enter the host address, 2001:DB8::D1A5:C90F (where D1A5:C90F is the IPv6 equivalent of 209.165.201.15).

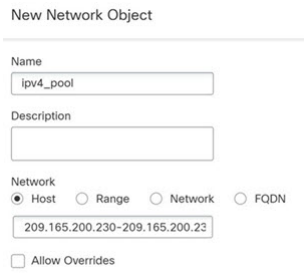


d) Click **Save**.

Step 3 Create the network objects for the inside network.

a) Click **Add Network** > **Add Object** and define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:DB8::/96.



b) Click **Save**.

Step 4 Create the network objects for the PAT pool.

a) Click **Add Network** > **Add Object** and define the IPv4 PAT pool for the inside IPv6 network.

Name the network object (for example, ipv4_pool) and enter the range 209.165.200.230-209.165.200.235.

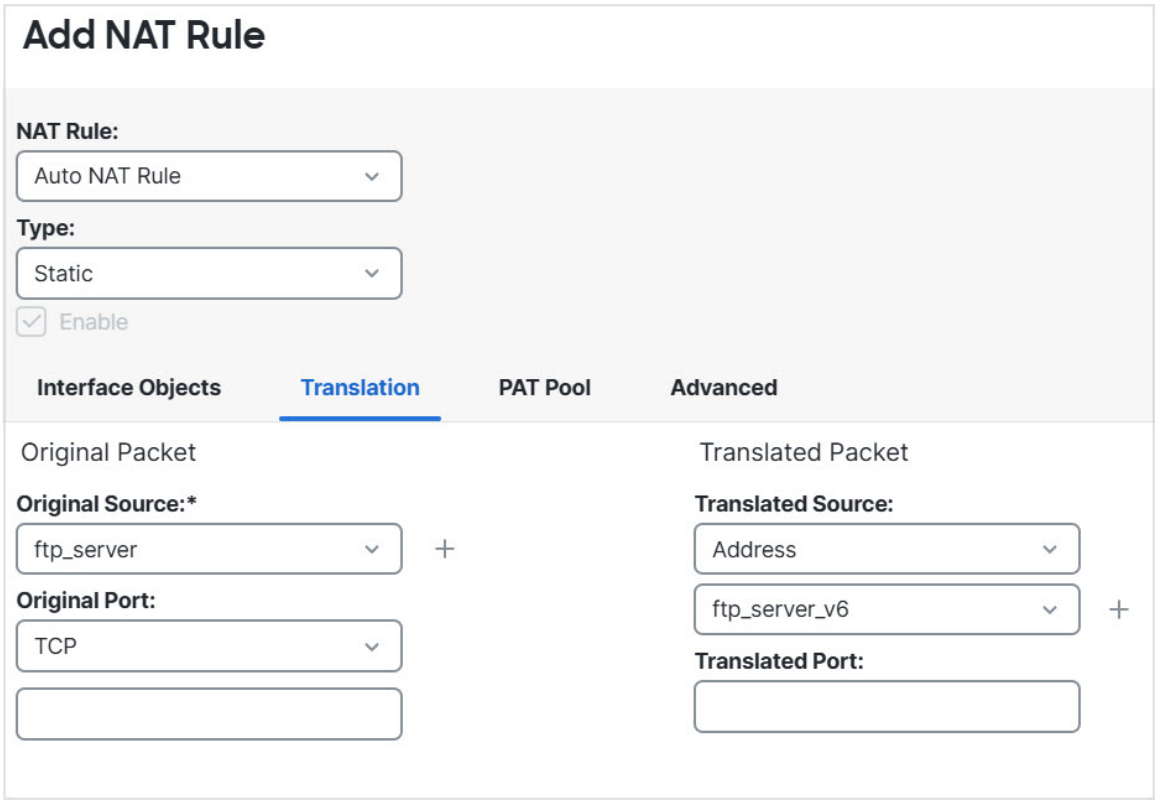
b) Click **Save**.

Step 5 Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_v6 network object.

f) On **Advanced**, select the following options:

- **Translate DNS replies that match this rule**.
- **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

g) Click **OK**.

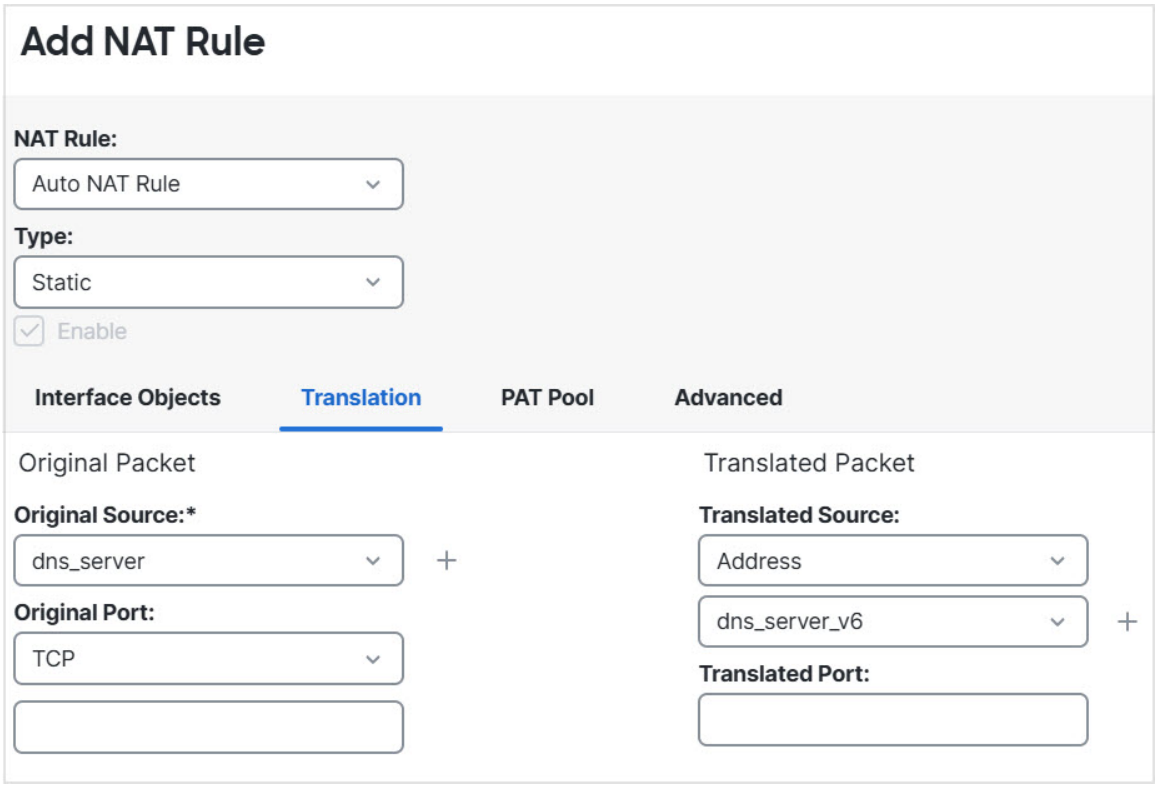
Step 6 Configure the static NAT rule for the DNS server.

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

c) On **Interface Objects**, configure the following:



- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

d) On **Translation**, configure the following:

- **Original Source** = dns_server network object.

- **Translated Source** > **Address** = dns_server_v6 network object.

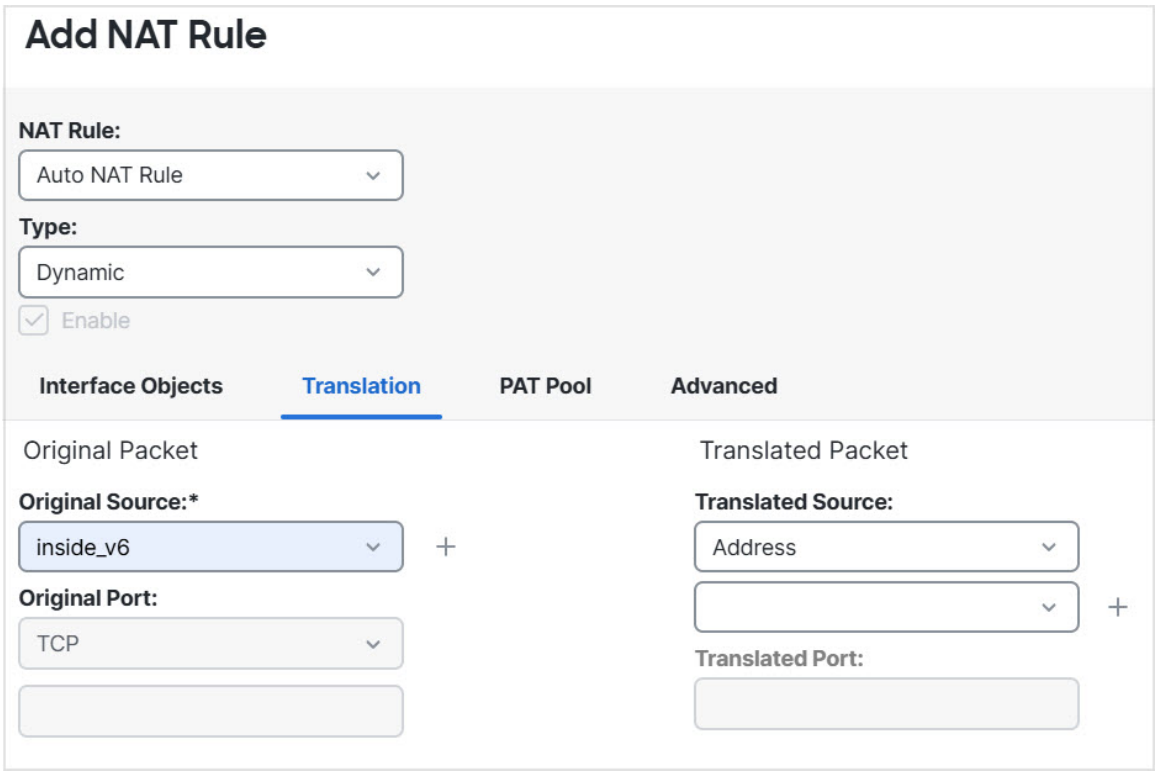
e) On **Advanced**, select **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

f) Click **OK**.

Step 7 Configure the dynamic NAT with a PAT pool rule for the inside IPv6 network.

a) Click **Add Rule**.

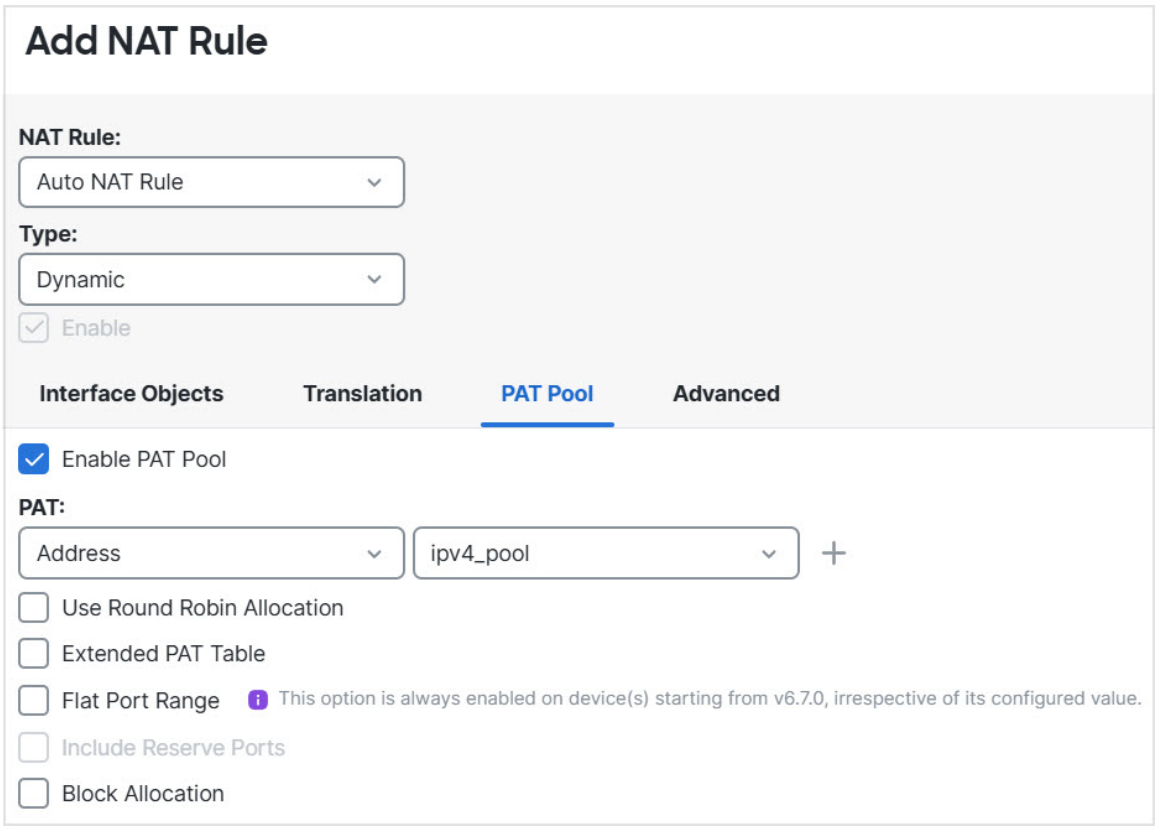
b) Configure the following properties:



- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

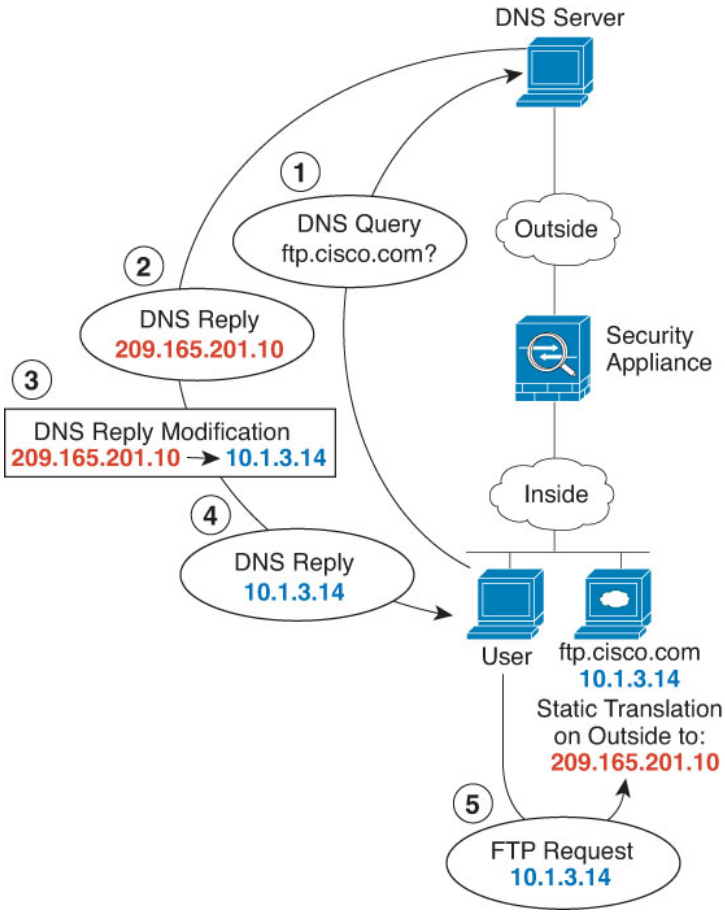


d) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** > **Address** = leave this field empty.

e) On **PAT Pool**, configure the following:

- **Enable PAT Pool** = select this option.
- **Translated Source** > **Address** = ipv4_pool network object.



f) Click **OK**.

Create DNS reply modification with DNS server on outside

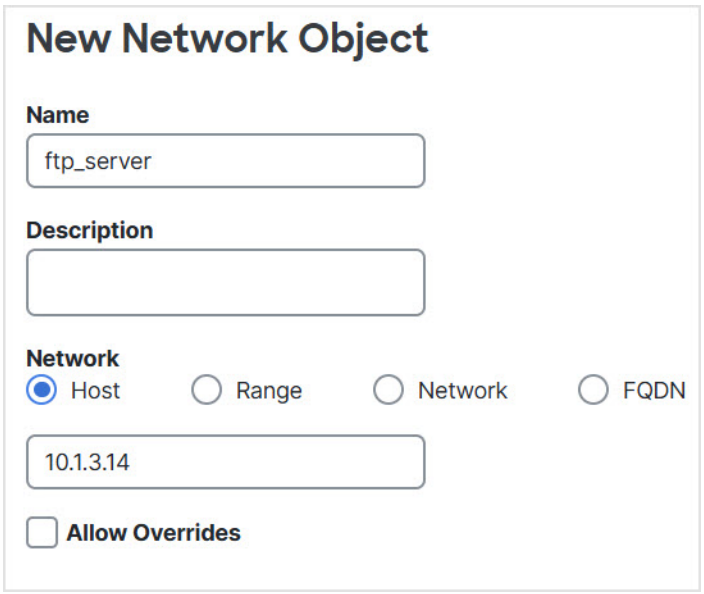
The following figure shows a DNS server that is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure NAT to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network.

In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The system refers to the static rule for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Interface**.

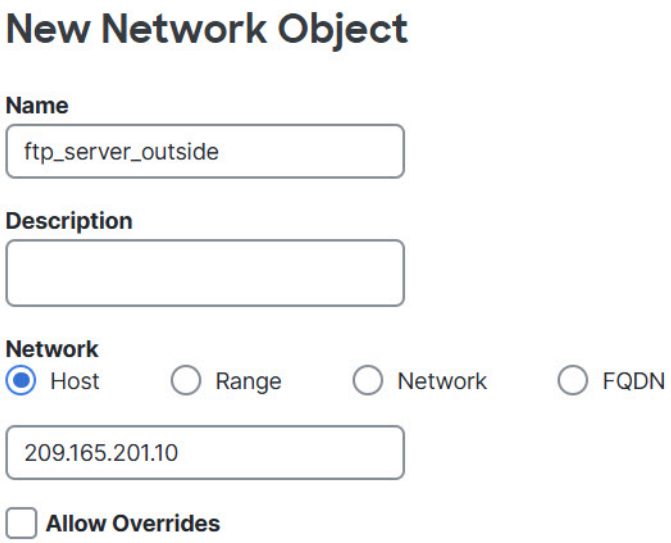


Procedure

Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Define the real FTP server address.



Name the network object (for example, ftp_server) and enter the host address, 10.1.3.14.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the FTP server's translated address.

Name the network object (for example, ftp_server_outside) and enter the host address, 209.165.201.10.

e) Click **Save**.

Step 2 Configure the static NAT rule with DNS modification for the FTP server.

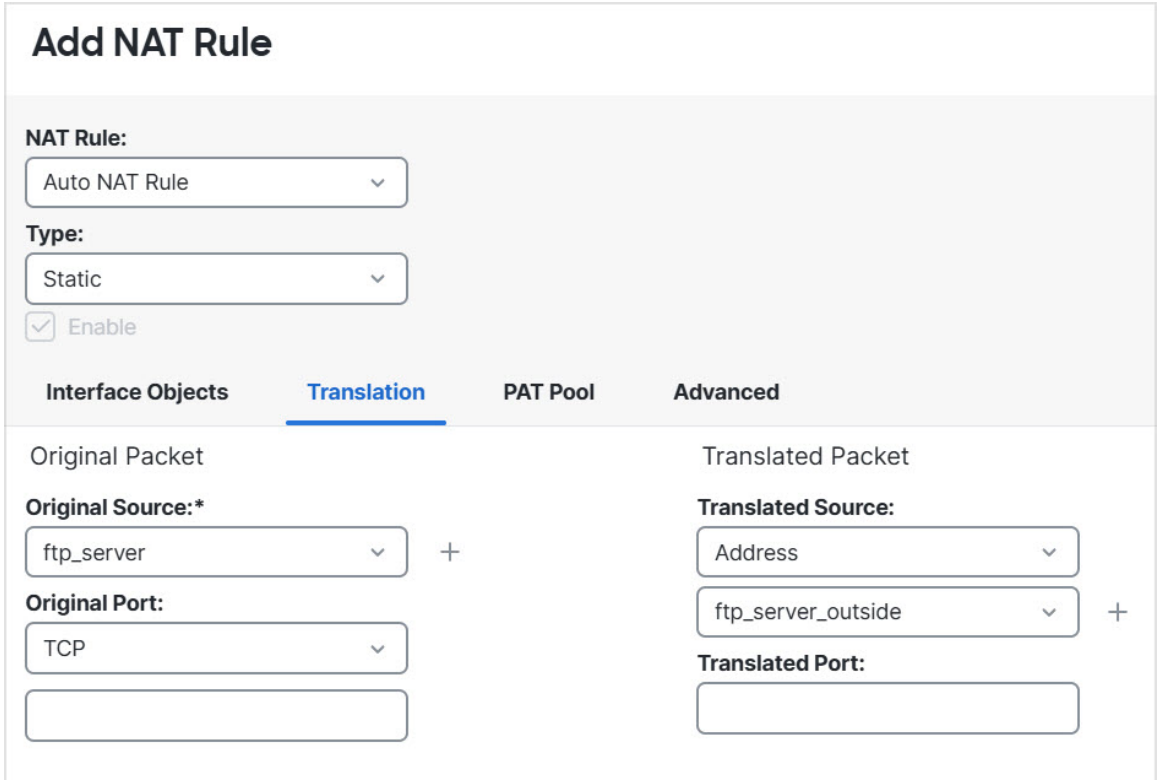
a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.

- **Type** = Static.

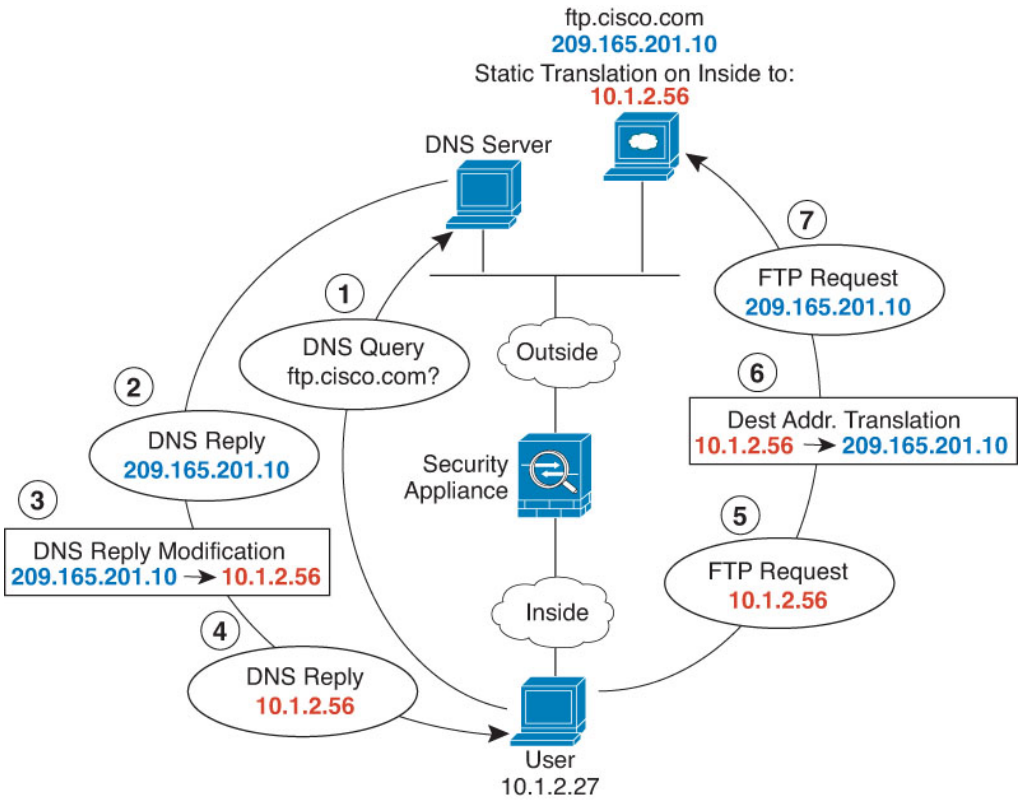


d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_outside network object.



f) On **Advanced**, select **Translate DNS replies that match this rule**.

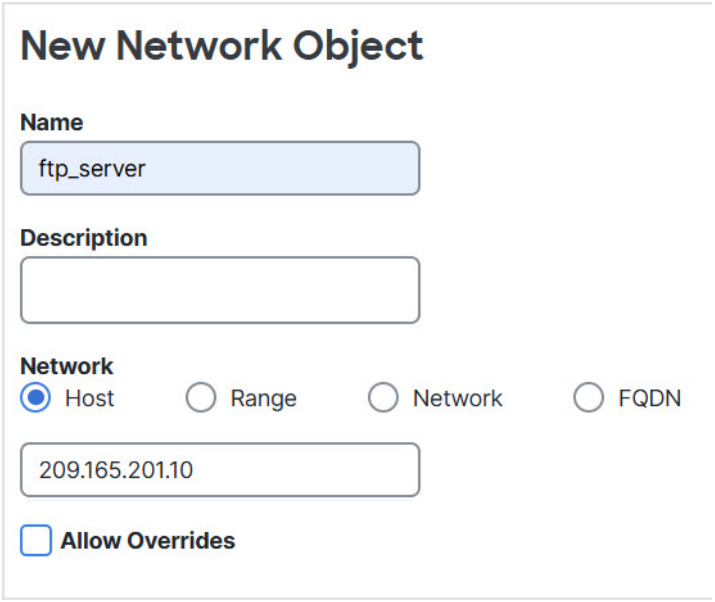
g) Click **OK**.

Configure DNS reply modification with DNS server on host network

The following figure shows an FTP server and DNS server on the outside. The system has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Interface**.

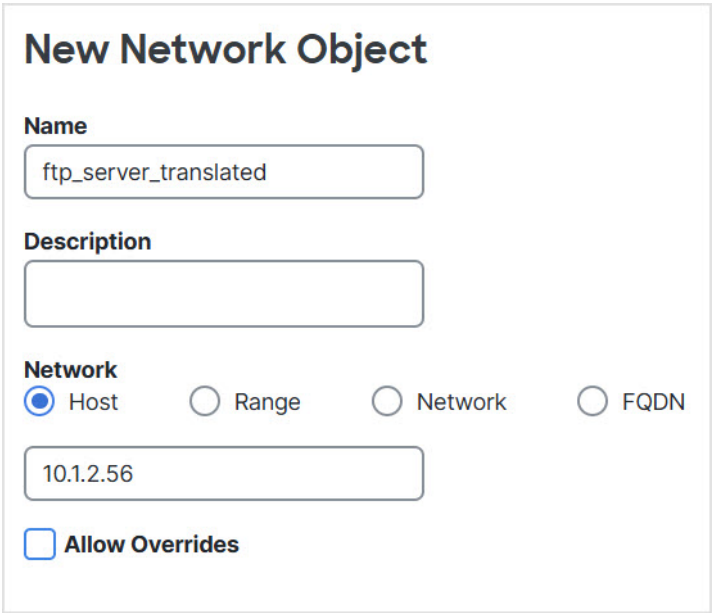


Procedure

Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Network** and click **Add Network** > **Add Object**.

b) Define the real FTP server address.



Name the network object (for example, ftp_server) and enter the host address, 209.165.201.10.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the FTP server's translated address.

Name the network object (for example, ftp_server_translated) and enter the host address, 10.1.2.56.

e) Click **Save**.

Step 2 Configure the static NAT rule with DNS modification for the FTP server.

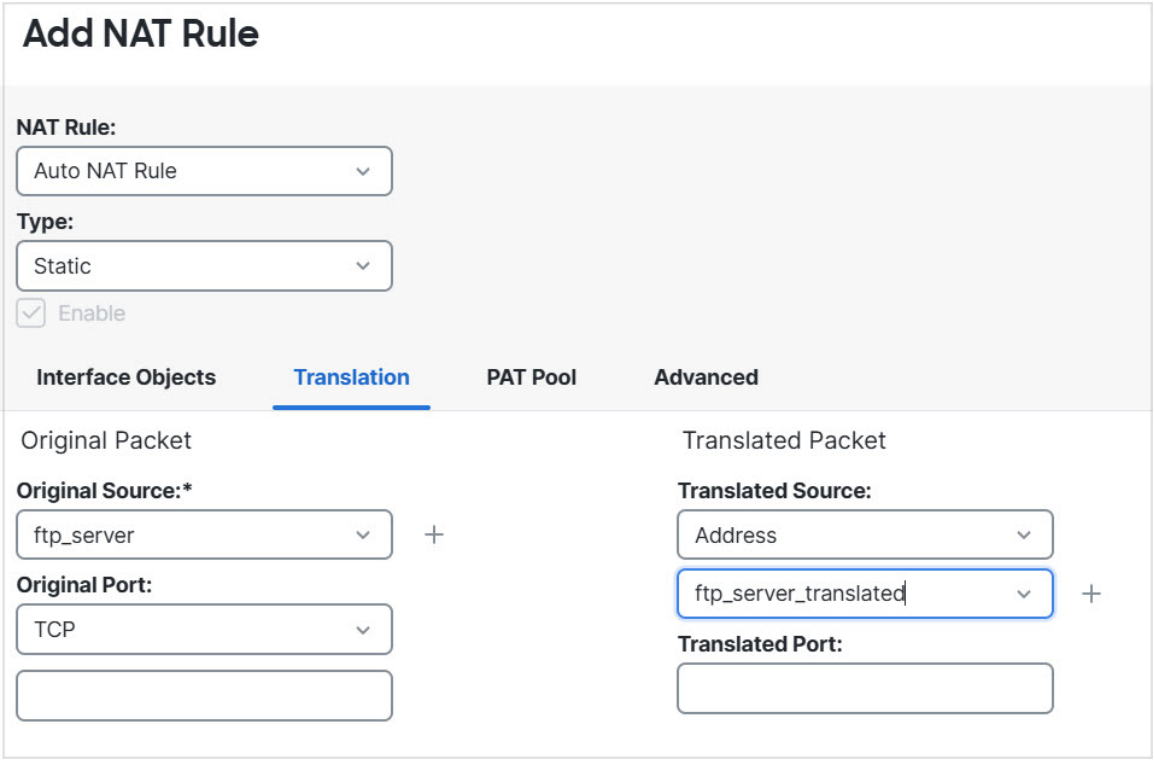
a) Select **Policies** > **Network policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.

- **Type** = Static.



d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_translated network object.

f) On **Advanced**, select **Translate DNS replies that match this rule**.

g) Click **OK**.

History for Firewall Threat Defense NAT

This table provides a chronological summary of feature changes and enhancements for the network address translation policy across different software releases.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Creation of network groups while editing NAT rules.	7.2.6 7.4.1	Any	You can create network groups in addition to network objects when you are editing a NAT rule. This feature is not supported in Version 7.3.x or 7.4.0.
Ability to enable, disable, or delete more than one NAT rule at a time.	7.2	Any	You can select multiple NAT rules and enable, disable, or delete them all at the same time. Enable and disable apply to manual NAT rules only, whereas delete applies to any NAT rule.
Manual NAT support for fully-qualified domain name (FQDN) objects as the translated destination.	7.1	Any	You can use an FQDN network object, such as one specifying www.example.com, as the translated destination address in manual NAT rules. The system configures the rule based on the IP address returned from the DNS server.
Changes to PAT address allocation in clustering. The PAT pool **Flat Port Range** option is now enabled by default and it is not configurable.	6.7	Any	The way PAT addresses are distributed to the members of a cluster is changed. Previously, addresses were distributed to the members of the cluster, so your PAT pool would need a minimum of one address per cluster member. Now, the control unit instead divides each PAT pool address into equal-sized port blocks and distributes them across cluster members. Each member has port blocks for the same PAT addresses. Thus, you can reduce the size of the PAT pool, even to as few as one IP address, depending on the amount of connections you typically need to PAT. Port blocks are allocated in 512-port blocks from the 1024-65535 range. You can optionally included the reserved ports, 1-1023, in this block allocation when you configure PAT pool rules. For example, in a 4-node cluster, each node gets 32 blocks with which it will be able to handle 16384 connections per PAT pool IP address compared to a single node handling all 65535 connections per PAT pool IP address. As part of this change, PAT pools for all systems, whether standalone or operating in a cluster, now use a flat port range of 1023 - 65535. Previously, you could optionally use a flat range by including the **Flat Port Range** option in a PAT pool rule. The **Flat Port Range** option is now ignored: the PAT pool is now always flat. You can optionally select the **Include Reserved Ports** option to include the 1 - 1023 port range within the PAT pool. Note that if you configure port block allocation (the **Block Allocation** PAT pool option), your block allocation size is used rather than the default 512-port block. In addition, you cannot configure extended PAT for a PAT pool for systems in a cluster.
Ability to search and filter the Firewall Threat Defense NAT rule table.	6.7	Any	You can now search for rules in Firewall Threat Defense NAT policies to help you find rules based on IP addresses, ports, object names, and so forth. Search results include partial matches. Searching on criteria filters the rule table so only matching rules are displayed. We added a search field above the rule table when you edit Firewall Threat Defense NAT policies.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Carrier grade NAT enhancements.	6.5	Any	For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time (see RFC 6888). New/modified screens: We added the **Block Allocation** option to the NAT PAT Pool tab for Firewall Threat Defense NAT rules.
Support for network range objects in NAT for Firewall Threat Defense.	6.1.0	Any	You can now use network range objects in Firewall Threat Defense NAT rules where appropriate.
Network Address Translation (NAT) for Firewall Threat Defense.	6.0.1	Any	The NAT policy for Firewall Threat Defense was added. New/modified screens: Threat Defense was added as a type of NAT policy to the **Devices** > **NAT** page.

CHAPTER 32

Quality of Service

Quality of Service is a network management feature that:

- enables the policing of network traffic on Firewall Threat Defense devices.
- assists administrators in managing network traffic,
- provides guidelines for rate limiting.

- QoS, on page 1485
- QoS policies, on page 1486
- Requirements and prerequisites for QoS, on page 1486
- Guidelines and limitations for QoS policies, on page 1487
- Rate limiting with QoS policies, on page 1487
- History for QoS, on page 1498

QoS

QoS is a traffic management mechanism that

- rate limits (polices) network traffic that is allowed or trusted by access control
- does not rate limit traffic that was fastpathed and
- is supported only on the routed interfaces of Firewall Threat Defense devices.

QoS interface limitations

QoS is supported only on the routed interfaces of Firewall Threat Defense devices. However, it does not support site-to-site VPN and VTI interfaces.

Logging Rate-Limited Connections

You cannot configure logging for QoS. A connection can be rate limited without being logged. Conversely, a logged connection may not be rate-limited. To view QoS details, you must separately log connection ends in your Firewall Management Center database. See *Other Connections You Can Log* in the *Cisco Secure Firewall Management Center Administration Guide* for more information.

Connection events for rate-limited connections show how much traffic was dropped and the specific QoS configurations that applied. You can view this information in event views (workflows), dashboards, and reports.

QoS policies

A QoS policy is a configuration mechanism that

- governs rate limiting on managed devices,
- can target multiple devices with each device having one deployed QoS policy at a time, and
- contains up to 63 QoS rules that handle network traffic in specified order.

QoS policy characteristics

QoS policies have these key characteristics:

-
- The system matches traffic to QoS rules in the order specified. The system rate limits traffic according to the first rule where all rule conditions match the traffic. Traffic not matching any of the rules is not rate limited.
- QoS rules can be limited by source or destination (routed) interfaces. The system enforces rate limiting *independently* on *each* of those interfaces and does not support an aggregate rate limit for a set of interfaces.
-
- You can independently rate limit download and upload traffic based on the connection initiator.

Note A device can have no more than 255 rules, including QoS rules. Exceeding this number causes a deployment warning necessitating a reduction in the number of rules.

Note QoS operates independently and is not subordinate to a main access control configuration. However, the access control and QoS policies deployed to the same device share identity configurations. For more information, refer to Associate prefilter, decryption, and identity policies with an access control, on page 1794.

Requirements and prerequisites for QoS

This reference provides the requirements and prerequisites for implementing QoS, including supported models, domains, and user roles.

Model support

Firewall Threat Defense

Supported domains

Any

User roles

Administrator

Access Admin

Network Admin

Guidelines and limitations for QoS policies

QoS rules and service policy rules (in the access control policy) are translated into firewall commands. There can be only one policy map per interface as the system combines QoS and service policy configurations automatically.

However, you can also create policy maps manually using FlexConfig. For lower-end firewalls, such as the Secure Firewall 3100, you can create up to 64 policy maps using FlexConfig. For more powerful firewalls, such as the Firepower 4100, you can create up to 128 policy maps. Ensure not to exceed this limit to prevent deployment failures. You can check the device configuration using the CLI or the deployment transcript to see how rules are translated into commands.

QoS cannot rate-limit traffic on interfaces participating in Equal-Cost Multipath (ECMP).

Rate limiting with QoS policies

To perform policy-based rate limiting, configure and deploy QoS policies to managed devices. Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Procedure

Step 1 Choose **Policies** > **Network policies** > **QoS**.

Step 2 Click **New Policy** to create a new QoS policy and, optionally assign target devices; for more information, refer to Create a QoS policy, on page 1488.

You can also **Copy** ( ) or **Edit** ( ) an existing policy.

Step 3 Configure QoS rules; for more information, refer to Configuring QoS rules, on page 1490 and QoS rule conditions, on page 1492.

The QoS policy editor lists each rule in evaluation order and displays a summary of the rule conditions and rate limiting configurations. Use the right-click menu to manage rules, including moving, enabling, and disabling them.

This feature is helpful in larger deployments. You can **Filter by Device** to display only the rules that affect a specific device or group of devices. You can also search for rules, and the system matches text entered in the **Search Rules** field to rule names and condition values, including objects and object groups.

Note Properly creating and ordering rules is a complex but essential to effective deployment. Careful planning is necessary to prevent rules from preempting each other, requiring additional licenses, or containing invalid configurations. Icons in the interface represent comments, warnings, and errors. If issues exist, click **Show Warnings** to display a list. For more information, refer to Best practices for access control rules, on page 1842.

Step 4 Click **Policy Assignments** to identify which managed devices the policy targets; for more information, refer to Set target devices for a QoS policy , on page 1489.

Verify your choices, if you identified target devices during policy creation.

Step 5 Save the QoS policy.

Step 6 Ensure that the relevant access control policy allows the traffic and that the inspection needed to evaluate the QoS rule conditions is configured. For application conditions, ensure that an application detector is enabled. Then deploy the applicable configuration changes.

Step 7 Deploy configuration changes; see Deploy configuration changes, on page 193.

The QoS policy is configured and deployed to the target devices, enabling policy-based rate limiting for network traffic.

Create a QoS policy

Create a QoS policy to establish the foundation for implementing rate limiting and traffic management rules on network devices.

The new QoS policy you create will not perform any rate limiting unless rules are added.

Procedure

Step 1 Choose **Policies** > **Network policies** > **QoS**.

Step 2 Click **New Policy**.

Step 3 Enter a **Name** and, optionally, a **Description**.

Step 4 (Optional) Choose the **Available Devices** where you want to deploy the policy, then click **Add to Policy**, or drag and drop to the **Selected Devices**. To narrow the devices that appear, type a search string in the **Search** field.

Devices must be assigned before policy deployment.

Step 5 Click **Save**.

A new QoS policy is created and ready for configuration with rate limiting rules.

What to do next

Configure and deploy the QoS policy; for more information, refer to Rate limiting with QoS policies, on page 1487.

Set target devices for a QoS policy

Before you begin

Ensure you are logged into the QoS policy editor and have the necessary access rights to configure system policies.

A QoS policy can target multiple devices, but each device can have one deployed QoS policy at a time.

Procedure

Step 1 In the QoS policy editor, click **Policy Assignments**.

Step 2 Build your target list:

- Add—Choose one or more **Available Devices**, then either click **Add to Policy** or drag and drop into the list of **Selected Devices**.
- Delete—Click **Delete** ( ) next to a single device, or choose multiple devices, right-click, then choose **Delete Selected**.
- Search—Enter a search string in the search field. Click **Clear** ( ) to clear the search.

Step 3 Click **OK** to save policy assignments.

Step 4 Click **Save** to save the policy.

The QoS policy is successfully configured with assigned target devices and is ready for deployment.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 193.

Filter QoS rules by device

You can filter the list of QoS policy rules based on the device to which the rules apply. A rule's interface constraints determine if the rule affects a device.

Tip Hover your pointer over a rule criterion to see its value. If the criterion represents an object with device-specific overrides, the system displays the override value when you filter the rules list by that device. If the criterion represents an object with domain-specific overrides, the system displays the override value when you filter the rules list by devices in that domain.

Procedure

Step 1 In the policy editor, click **Rules**, then click **Filter by Device**.
A list of targeted devices and device groups appears.

Step 2 Check one or more check boxes to display only the rules that apply to those devices or groups. Or, check **All** to reset and display all of the rules.

Step 3 Click **OK**.

A message appears next to the button showing the filter used. To remove the filter, click the X in the message. Alternatively, select **All** in the Filter by device dialog box.

The QoS rules list displays only the rules that apply to the selected devices or device groups. It simplifies the process of reviewing and managing device-specific QoS policies.

Configuring QoS rules

QoS rules enable you to control and rate limit network traffic on specific interfaces by configuring rule properties, conditions, and traffic limits.

When you create or edit a rule, use the upper portion of the rule editor to configure general rule properties. Use the lower portion of the rule editor to configure rule conditions and comments.

Procedure

Step 1 On Rules of the QoS policy editor:

- Add Rule—Click **Add Rule**.
- Edit Rule—Click **Edit** ( ).

Step 2 Enter a **Name**.

Step 3 Configure rule components:

- Enabled—Specify whether the rule is **Enabled**.
- Apply QoS On—Select the interfaces you want to rate limit, either **Interfaces in Destination Interface Objects** or **Interfaces in Source Interface Objects**. Your choice must correspond with a populated interface constraint (not **any**).
- Traffic Limit Per Interface—Enter a **Download Limit** and an **Upload Limit** in Mbits/sec. The default value of **Unlimited** prevent matching traffic from being rate limited in that direction.
- Conditions—Click the corresponding condition you want to add. You must configure a source or destination interface condition, corresponding to your choice for **Apply QoS On**.
- Comments—Click **Comments**. To add a comment click **New Comment**, enter a comment, and click **OK**. You can edit or delete this comment until you save the rule.

For detailed information on rule components, refer to QoS rule components, on page 1491.

Step 4 Save the rule.

Step 5 In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste.

Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

Step 6 Click **Save** to save the policy.

The QoS rule you created or modified is saved to the policy and configured with your set traffic limits and conditions.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 193.

Related Topics

Best practices for access control rules, on page 1842

QoS rule components

QoS rules consist of several key components that control traffic rate limiting and filtering behavior. Understanding these components helps you configure effective quality of service policies.

QoS rules include these main components:

- State (Enabled/Disabled): Controls whether the rule is active and enforced by the system.
- Interfaces (Apply QoS On): Specifies which interfaces the rate limiting applies to.
- Traffic Limit Per Interface: Sets the rate limiting values for matching traffic.
- Conditions: Defines the traffic criteria that must be matched for the rule to apply.
- Comments: Provides documentation and change tracking for the rule.

State (Enabled/Disabled)

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

Interfaces (apply QoS on)

You cannot save a QoS rule that rate limits all traffic. For each QoS rule, apply QoS on one of the options:

- Interfaces in Source Interface Objects—Rate limits traffic through the rule's source interfaces. If you choose this option, you must add at least one source interface constraint (cannot be **any**).
- Interfaces in Destination Interface Objects—Rate limits traffic through the rule's destination interfaces. If you choose this option, you must add at least one destination interface constraint (cannot be **any**).

Traffic limit per interface

A QoS rule enforces rate limiting *independently* on *each* interface specified with the Apply QoS On option. Aggregate rate limits cannot be applied to a group of interfaces.

You can rate limit traffic by Mbits per second. The default value of **Unlimited** prevents matching traffic from being rate limited.

You can independently rate limit download and upload traffic. The system determines download and upload directions based on the connection initiator.

If you specify a limit greater than the interface's maximum throughput, the system does not rate limit matching traffic. Maximum throughput may be affected by an interface's hardware configuration, which you specify in each device's properties (**Devices** > **Device Management**).

Conditions

Conditions specify the specific traffic that the rule handles. You can configure each rule with multiple conditions. Traffic must meet all conditions to match the rule. Each condition type has its own tab in the rule editor. For more information, refer to QoS rule conditions, on page 1492.

Comments

Each time you save changes to a rule, add comments. You might summarize the overall configuration for users, or note any changes made and the reasons.

In the policy editor, the system displays how many comments a rule has. In the rule editor, use the Comments tab to view existing comments and add new ones.

QoS rule conditions

Conditions specify the traffic the rule handles. You can configure each rule with multiple conditions. All conditions must be met for traffic to match the rule. Each condition type has its own tab in the rule editor. You can rate limit traffic using these conditions.

Custom SGT rule conditions, on page 1497

Interface rule conditions

An interface rule condition is a network traffic control that

- controls traffic by its source and destination interfaces,
- uses predefined interface objects called security zones or interface groups to build interface conditions, and
- improves system performance by constraining rules to specific interfaces.

Interface rule condition characteristics

Interface objects segment your network by grouping interfaces across multiple devices to manage and classify traffic flow. For more information, refer to Interfaces, on page 2810.

QoS rules can be applied only on routed interfaces.

Note Constraining rules by interface is one of the best ways to improve system performance. If a rule excludes all of a device's interfaces, that rule does not affect that device's performance.

Network rule conditions

A network condition is a traffic matching criterion that

- matches traffic for rate limiting based on source and destination IP addresses using inner packet headers,
- enables administrators to specify exact IP addresses or blocks for granular policy enforcement, and
- can be built using predefined network objects or by manually entering IP addresses or address blocks.

Network rule condition restrictions

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FQDN network objects in identity rules.

User rule conditions

A user rule condition is a traffic matching mechanism that

- matches traffic based on the user initiating the connection or the group to which they belong
- can be configured for users in Microsoft Active Directory realms only, and
- enables policy enforcement based on user identity and group membership.

Special identities users

In addition to configuring users and groups for configured realms, you can set policies for the special identities users:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1794.

Configure a QoS rule to rate-limit traffic initiated by users in the Finance group.

Application rule conditions

Application rule conditions are application awareness and control mechanisms that

- identify and classify applications through IP traffic analysis
- enable control with organized filters
- require one enabled detector for each condition.

Application filters and control benefits

System-provided *application filters* help perform control by organizing applications according to basic characteristics, such as type, risk, business relevance, category, and tags. You can also create reuseable, user-defined filters using combinations of system-provided filters, or custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled, the system automatically enables all available system-provided detectors, or the most recently modified user-defined detector. For more information about application detectors, see Application detectors, on page 2708.

You can utilize both application filters and individually specified applications to ensure complete coverage. Understand the application's requirements to effectively order access control rules.

Application filters help you to quickly configure application control effectively. For example, use a system-provided filter to create a QoS rule that identifies high-risk, low-business-relevance applications and rate-limits matching traffic.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can be sure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

The system characterizes detected applications using several criteria which form effective filters.

Table 87: Application characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email applications are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.

Characteristic	Description	Example
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged `high bandwidth` and `displays ads`.

Best practice: use application-based rules over port-based rules

Use application filtering criteria instead of port filtering to target traffic. Applications can be configured to use unique ports to bypass access control blocks.

Port conditions allow you to control traffic by its source and destination ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

The traditional method targets applications by using port specifications, but applications can manipulate unique ports to bypass these controls

Application filtering is recommended for applications to avoid blocking legitimate applications, like Firewall Threat Defense, that dynamically open separate channels for control and data flow. Port-based access control rules could block such applications, impacting desirable operations.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP).

- For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).
- If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

Port, protocol, and ICMP code rule conditions (concept)

A port, protocol, and ICMP code rule condition is a traffic matching criterion that

- matches traffic based on source and destination ports
- supports TCP, UDP, ICMP, and other protocols that do not use ports, and
- controls traffic flow in access control and other policy rules.

Port condition types

Port conditions match traffic based on the source and destination ports. Depending on the rule type, "port" can represent any of these types:

- TCP and UDP—Control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP (6) /22.
- ICMP—Control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—Control traffic using other protocols that do not use ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best practices for port-based rules

Specifying ports is the traditional method used to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Use application filtering criteria when possible; however, note that application filtering is unavailable in prefilter rules.

Use application filtering for FTP and similar applications that open separate channels for control and data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly and could result in blocking desirable connections.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching non-TCP traffic with port conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although configuring port conditions can match non-TCP traffic, restrictions apply:

- Access control rules—For Classic devices, match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, add only network-based conditions: zone, IP address, port, and VLAN tag. The system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For Firewall Threat Defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support only TCP port conditions.
- ICMP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies, sent in response to ICMP echo requests, are ignored. To match any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

Recommendation: use URL conditions for website access control

Use URL conditions to select website traffic that a QoS rule will rate-limit.

For more information, refer to URL filtering with category and reputation, on page 1870.

Custom SGT rule conditions

A custom SGT rule condition is a traffic filtering mechanism that

- Use manually created SGT objects to filter traffic. Do not rely on ISE SGTs from a server.
- Correspond to the SGT attributes on the traffic to be controlled.
- Exclude user control considerations when using custom SGT traffic.

SGT traffic control without ISE configuration

If you do not configure ISE or ISE-PIC as an identity source, you can control traffic using Security Group Tags (SGTs) that were **not** assigned by ISE. SGTs specify traffic source privileges in a trusted network.

ISE SGT versus custom SGT rule conditions

Certain rules allow you to control traffic based on assigned SGT. The rule type and identity source configuration determine whether ISE-assigned SGTs or custom SGTs are used to match traffic with assigned SGT attributes.

Condition Type	Requires	SGTs Listed in Rule Editor
ISE SGT	ISE identity source	SGTs obtained by querying the ISE server, automatically updated metadata
Custom SGT	No ISE or ISE-PIC identity source	Static SGT objects you create

Note If using ISE SGTs to match traffic, any packet will match an ISE SGT rule if the SGT associated with the packet source IP address is recognized in ISE, even without an assigned SGT attribute.

Autotransition from custom Security Group Tags to ISE Security Group Tags

An autotransition from custom Security Group Tags (SGTs) to ISE Security Group Tags is a system process that automatically adjusts rule configuration when you configure ISE/ISE-PIC as an identity source after creating rules with custom Security Group Tags.

System behavior during autotransition

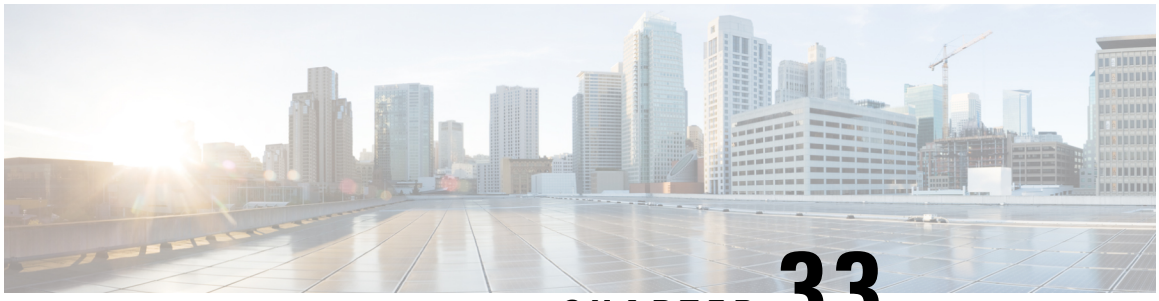
If you create rules that match custom SGTs, then configure ISE or ISE-PIC as an identity source, the system will:

- Disable **Security Group Tag** options: The system retains existing SGT objects, but you cannot modify them or add new ones.
- Retain existing rules: Existing rules with custom SGT conditions remain, but they do not match traffic, and you cannot add more custom SGT conditions.

If you configure ISE, it is recommended to delete or disable existing rules with custom Security Group Tag conditions and use ISE attribute conditions to match traffic with Security Group Tag attributes.

History for QoS

This reference provides a chronological history of QoS feature updates, including version information and implementation details.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Deprecated: priority-queue with FlexConfig.	7.2.5	7.2.5	FlexConfig was used to configurethe priority-queue in threat defense. This command was removed.
Ability to specify handling of URLs having unknown reputation.	6.7.0	Any	For details, see History for URL filtering, on page 1899. New/modified screens: QoS rule editor
Rate limit increased.	6.2.1	Any	Raised the maximum rate limit from 1,000 Mbps to 100,000 Mbps. New/modified screens: QoS rule editor
Custom SGT and original client network filtering.	6.2.1	Any	Rate limit traffic using custom Security Group Tags (SGTs) and original client network information (XFF, True-Client-IP, or custom-defined HTTP headers). New/modified screens: QoS Rule Editor
QoS (rate limiting) introduced.	6.1.0	Any	FTD can rate limit (police) network traffic that is either allowed or trusted by access control. New/modified screens: **Devices** > **QoS**

Secure Connections

- Secure Connections Overview, on page 1501
- Site-to-Site VPN, on page 1517
- SD-WAN, on page 1583
- Remote Access VPN, on page 1609
- Dynamic Access Policies , on page 1707

CHAPTER 33

Secure Connections Overview

A virtual private network (VPN) connection establishes a secure tunnel between endpoints over a public network such as the Internet.

This chapter applies to Remote Access and Site-to-site VPNs on Secure Firewall Threat Defense devices. It describes the Internet Protocol Security (IPsec), the Internet Security Association and Key Management Protocol (ISAKMP, or IKE) and SSL standards that are used to build site-to-site and remote access VPNs.

- VPN types, on page 1501
- VPN basics, on page 1502
- VPN packet flow, on page 1505
- IPsec flow offload, on page 1505
- VPN licensing, on page 1506
- VPN encryption and performance, on page 1506
- Deprecated hash algorithms, encryption algorithms, and Diffie-Hellman modulus groups, on page 1512
- VPN topologies, on page 1512

VPN types

VPN types are network connection categories that

- provide secure, encrypted connections between remote locations and private networks
- support deployment models including remote access and site-to-site configurations, and
- use various protocols including SSL and IPsec for establishing secure tunnels.

Supported VPN connection types

The Firewall Management Center supports these types of VPN connections:

- Remote Access VPNs in Firewall Threat Defense devices.

  Remote access VPNs provide secure, encrypted connections, or tunnels, between remote users and your company's private network. These connection use two devices: a VPN endpoint device, which is a workstation or mobile device with VPN client capabilities, and a VPN headend device, or secure gateway, at the edge of the corporate private network.

  Secure Firewall Threat Defense devices can be configured to support Remote Access VPNs over SSL or IPsec IKEv2 by the Firewall Management Center. When acting as secure gateways, these devices

authenticate remote users, authorize access, and encrypt data to provide secure connections to your network. Only these devices support remote access VPN connections, managed by the Firewall Management Center.

Secure Firewall Threat Defense secure gateways support the Secure Client full tunnel client. This client is required to provide secure SSL IPsec IKEv2 connections for remote users. This client automatically installs when a connection is established, so network administrators do not need to manually install or configure it on remote computers. It is the only client supported on endpoint devices.

- Site-to-site VPNs in Firewall Threat Defense devices.

  A site-to-site VPN connects networks in different geographic locations. You can create site-to-site IPsec connections between managed devices, and between managed devices and other Cisco or third-party peers. These peers can use either IPv4 and IPv6 addresses. Site-to-site tunnels are built using the Internet Protocol Security (IPsec) protocol suite and IKEv1 or IKEv2. After the VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel.

VPN basics

A VPN is a secure networking technology that

- uses tunneling to create secure connections between remote users and private corporate networks over public TCP/IP networks such as the Internet
- employs IPsec-based technologies with ISAKMP (IKE) and IPsec tunneling standards to build and manage tunnels, and
- enables bidirectional data transfer through tunnel endpoints that encapsulate and unencapsulate packets.

VPN tunnel management capabilities

ISAKMP and IPsec accomplish these tunnel management functions:

- Negotiate tunnel parameters.
- Establish tunnels.
- Authenticate users and data.
- Manage security keys.
- Encrypt and decrypt data.
- Manage data transfer across the tunnel.
- Manage data transfer inbound and outbound as a tunnel endpoint or router.

A device in a VPN functions as a bidirectional tunnel endpoint. It can receive plain packets from the private network, encapsulate them, create a tunnel, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets from the public network, unencapsulate them, and send them to their final destination on the private network.

After the site-to-site VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel. A connection consists of the IP addresses

and hostnames of the two gateways, the subnets behind them, and the method the two gateways use to authenticate to each other.

VPN deployments use two primary device types:

- Hubs: Devices that enable secure VPN connectivity to and from one or more remote branch devices or spokes. Hubs also act as a gateway for spokes to communicate with each other.
- Spokes: Devices that connect over VPN to a hub to securely access the corporate resources behind the hub. Spokes communicate with each other through the hub.

Internet Key Exchange (IKE)

Internet Key Exchange (IKE) is a key management protocol that

- authenticates IPsec peers
- negotiates and distributes IPsec encryption keys, and
- automatically establishes IPsec security associations (SAs).

IKE negotiation phases and policies

The IKE negotiation comprises two phases:

- Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2.
- During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec.

Each phase uses proposals to negotiate a connection.

An IKE policy is a set of algorithms that two peers use to secure the IKE negotiation between them. IKE negotiation begins when each peer agrees on a common IKE policy. This policy defines security parameters to protect subsequent IKE negotiations. IKEv1 policies contain a single set of algorithms and a modulus group. In an IKEv2 policy, you can select multiple algorithms and modulus groups for peers to choose from during the Phase 1 negotiation. You may create a single IKE policy, or create multiple policies to give higher priority to preferred options. For site-to-site VPNs, you can create an IKE policy. IKEv1 and IKEv2 each support a maximum of 20 IKE policies, each with a different set of values. Assign a unique priority to each policy that you create. A lower priority number indocates a higher priority for the policy.

To define an IKE policy, specify:

- A unique priority (1 to 65,543, with 1 being the highest priority).
- An encryption method for the IKE negotiation to protect the data and ensure privacy.
- A Hashed Message Authentication Codes (HMAC) method (called integrity algorithm in IKEv2) to verify the sender's identity, and to confirm that the message is unchanged during transit.
- For IKEv2, a separate pseudorandom function (PRF) used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption. The options are the same as those used for the hash algorithm.
- A Diffie-Hellman group to determine the strength of the encryption key determination algorithm. The device uses this algorithm to derive the encryption and hash keys.

- An authentication method, to ensure the identity of the peers.
- A limit to the time the device uses an encryption key before replacing it.

When IKE negotiation begins, the initiating peer sends all its policies to the remote peer. The remote peer searches for a match with its own policies, in priority order. IKE policies match if both peers use the same encryption, hash (integrity and PRF for IKEv2), authentication, and Diffie-Hellman values. The SA lifetime must be less than or equal to the lifetime in the policy sent. If the lifetimes are not identical, the shorter value from the remote peer policy applies. By default, the Secure Firewall Management Center deploys an IKEv1 policy with the lowest priority for all VPN endpoints to ensure a successful negotiation.

IPsec

IPsec is a secure method for setting up a VPN that:

- provides data encryption at the IP packet level,
- transmits data over a public network through tunnels, which are secure, logical communication paths between two peers, and
- secures traffic that enters an IPsec tunnel by a combination of security protocols and algorithms.

With IPsec, data is transmitted over a public network through tunnels.

IPsec proposal policy components

An IPsec proposal policy defines the settings for IPsec tunnels. An IPsec proposal includes one or more crypto maps that are applied to the VPN interfaces in the devices. A crypto map combines all the components required to set up IPsec security associations, including:

- A proposal (or transform set) combines security protocols and algorithms that secure traffic in an IPsec tunnel. During the IPsec security association (SA) negotiation, peers search for a matching proposal. Apply the selected proposal to create an SA that protects data flows in the crypto map's access list and secures VPN traffic. There are separate IPsec proposals for IKEv1 and IKEv2. In IKEv1 proposals (or transform sets), you set one value for each parameter. In IKEv2 proposals, you can configure multiple encryption and integration algorithms for a single proposal.
- A crypto map combines all components required to set up IPsec security associations (SA), including IPsec rules, proposals, remote peers, and other parameters that are necessary to define an IPsec SA. When two peers try to establish an SA, they must each have at least one compatible crypto map entry.

  Dynamic crypto map policies are used in site-to-site VPNs when an unknown remote peer tries to start an IPsec security association with the local hub. The hub does not initiate the security association negotiation. Dynamic crypto policies allow remote peers to exchange IPsec traffic with a local hub, even if the hub does not know the remote peer's identity. A dynamic crypto map policy creates a crypto map entry before configuring all parameters. IPsec negotiation then dynamically configures the missing parameters to match a remote peer's requirements.

  Dynamic crypto map policies are applicable to both hub-and-spoke and point-to-point VPN topologies. To apply dynamic crypto map policies, specify a dynamic IP address for one of the peers in the topology and ensure that the dynamic crypto-map is enabled on this topology. In a full mesh VPN topology, you can apply only static crypto map policies.

Note Simultaneous IKEv2 dynamic crypto map is not supported for the same interface for both remote access and site-to-site VPNs in a Firewall Threat Defense device.

VPN packet flow

VPN packet flow is a security process that

- requires explicit permission through access control before allowing traffic to pass through,
- decrypts incoming tunnel packets before sending them to the Snort process,
- processes outgoing packets through Snort before encryption, and
- blocks tunnel traffic to the public source when the tunnel is down.

Access control requirements

Access control identifies the protected networks for each endpoint node of a VPN tunnel and determines which traffic is allowed to pass through the Firewall Threat Defense device and reach the endpoints. For remote access VPN traffic, a group policy filter or an access control rule must be configured to permit VPN traffic flow.

IPsec flow offload

IPsec flow offload is a performance optimization feature that

- offloads IPsec connections to field-programmable gate array (FPGA) or specialized hardware components after initial setup
- improves device performance by handling pre-decryption, decryption, pre-encryption, and encryption processing in hardware, and
- is enabled by default on supporting device models while allowing system software to handle inner flow security policies.

IPsec flow offload characteristics

After the initial setup of an IPsec site-to-site VPN or remote access VPN security association (SA), IPsec connections are offloaded to the field-programmable gate array (FPGA) in the device. This process improves device performance.In the Secure Firewall 1200 series, IPsec connections are offloaded to the Marvell Cryptographic Accelerator (CPT) to improve device performance.In the Secure Firewall 6100 series, IPsec connections are offloaded to the Kintex 7 (KC400) FPGA. This FPGA contains a built-in crypto engine that is capable of handling AES-GCM-128 and AES-GCM-256 encryption and decryption.

Offloaded operations include pre-decryption and decryption processing on ingress and egress. The system software applies your security policies for traffic within the inner flow.

IPsec flow offload applies to these device types:

- Secure Firewall 1200
- Secure Firewall 3100
- Secure Firewall 4200
- Secure Firewall 6100

IPsec flow offload is also used when the device's VTI loopback interface is enabled.

For asymmetric flows in cluster distributed site-to-site VPN mode, IPsec flow offload lets the flow owner decrypt IPsec traffic in hardware that was forwarded over the cluster control link. This feature is not configurable and is always available with IPsec flow offload.

By default, the system enables IPsec flow offload on supported device models. To change the configuration, use FlexConfig to implement the **flow-offload-ipsec** command. For more information, refer to the ASA command reference.

VPN licensing

You do not need any specific license to enable VPN on a Firewall Threat Defense device, it is available by default.

The Firewall Management Center determines whether to allow or block the usage of strong encryption in the Firewall Threat Defense device based on the export-controlled functionality in the device. You can enable this functionality when you register with the Cisco Smart License Manager. If you are using the evaluation license, or you did not enable export-controlled functionality, you cannot use strong encryption. Choose **Administration** > **Licenses** > **Smart Licenses** to verify this functionality in Firewall Management Center.

If you created your VPN configurations with an evaluation license and later upgraded your license to a smart license with export-controlled functionality, check and update your encryption algorithms to use stronger encryption so that the VPNs function properly. Do not use DES-based encryption, as it is not supported.

VPN encryption and performance

When you configure VPN tunnel encryption, provide sufficient protection and maintain efficiency by balancing security and performance.

Because a VPN tunnel typically traverses a public network, most likely the Internet, you need to encrypt the connection to protect the traffic. You define the encryption and other security techniques with IKE policies and IPsec proposals. Using stronger tunnel encryption may lower system performance.

If your device license allows strong encryption, you can choose from a range of encryption and hash algorithms and Diffie-Hellman groups. This document does not provide specific guidance on which options you should choose. If you operate within a larger corporation or other organization, there might already be defined standards that you need to meet. If not, take the time to research the options.

Comply with security certification requirements

Review your certification requirements and the available options to plan your VPN configuration. Many VPN settings have options that allow you to comply with various security certification standards.

Decide encryption algorithms for VPN policies

When deciding which encryption algorithms to use for the IKE policy or IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN.

- For IKEv2, you can configure multiple encryption algorithms. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order.
- For IKEv1, you can select a single option only.
- For IPsec proposals, the algorithm is used by the Encapsulating Security Protocol (ESP), which provides authentication, encryption, and anti-replay services. ESP is IP protocol type 50. In IKEv1 IPsec proposals, the algorithm name is prefixed with ESP-.

If your device license qualifies for strong encryption, you can choose from the available encryption algorithms. If you are not qualified for strong encryption, you can select DES only.

Strong encryption license considerations

Note If you are qualified for strong encryption, before upgrading from the evaluation license to a smart license, check and update your encryption algorithms for stronger encryption so that the VPN configuration works properly. Choose AES-based algorithms. DES is not supported if you are registered using an account that supports strong encryption. After registration, you cannot deploy changes until you remove all uses of DES.

Available encryption algorithms

- AES-GCM—(IKEv2 only) Advanced Encryption Standard in Galois or Counter Mode is a block cipher mode that provides confidentiality and data-origin authentication. It offers greater security than AES.

  AES-GCM offers three different key strengths: 128-bit, 192-bit, and 256-bit keys. Longer keys increase security but reduce performance. NSA Suite B, a set of cryptographic algorithms that devices must support to meet federal cryptographic strength standards, requires GCM.
- AES—Advanced Encryption Standard is a symmetric cipher algorithm that provides greater security than DES and is computationally more efficient than 3DES. AES offers three different key strengths: 128-bit, 192-bit, and 256-bit keys. Longer keys increase security but reduce performance.
- DES—Data Encryption Standard, which encrypts using 56-bit keys, is a symmetric secret-key block algorithm. If your license account does not meet the requirements for export controls, this is your only option.
- Null, ESP-Null—A null encryption algorithm provides authentication without encryption. This method is not secure; use at your own discretion.

Decide which hash algorithms to use

In IKE policies, the hash algorithm creates a message digest to ensure your messages remain secure. In IKEv2, you can choose one hash algorithm for integrity and another for the pseudo-random function (PRF).

In IPsec proposals, the Encapsulating Security Protocol (ESP) uses the hash algorithm for authentication. In IKEv2 IPsec proposals, this is called the integrity hash. In IKEv1 IPsec proposals, the algorithm name has the ESP- prefix and an -HMAC suffix.

The system arranges your settings from the most secure to the least secure and negotiates with the peer in that order. For IKEv1, select only one option.

Select a hash algorithm that meets your security and performance needs:

- SHA (Secure Hash Algorithm)—The standard SHA (SHA1) produces a 160-bit digest.

  These SHA-2 options provide increased security and are available for IKEv2 configurations. Choose one if you require NSA Suite B cryptography compliance.

  - SHA256—Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.
  - SHA384—Specifies the Secure Hash Algorithm SHA 2 with the 384-bit digest.
  - SHA512—Specifies the Secure Hash Algorithm SHA 2 with the 512-bit digest.

- Null or None (NULL, ESP-NONE)—(IPsec Proposals only) AUse a null hash algorithm only for testing purposes. If you select one of the AES-GCM options as the encryption algorithm, choose the null integrity algorithm. For these encryption standards, the integrity hash is ignored even if you choose a non-null option.

Decide which Diffie-Hellman modulus group to use

You can use Diffie-Hellman key derivation algorithms to generate IPsec security association (SA) keys. Each group has a different size modulus. A larger modulus increases security but requires more processing time. You must have a matching modulus group on both peers.

For AES encryption, use Diffie-Hellman (DH) Group 5 or higher to support the large key sizes required by AES. IKEv1 policies do not support all of the groups.

To implement the NSA Suite B cryptography specification, use IKEv2 and select one of the elliptic curve Diffie-Hellman (ECDH) options: 19, 20, or 21. Elliptic curve options and groups that use a 2048-bit modulus reduce exposure to attacks such as Logjam.

For IKEv2, you can configure multiple groups. The system orders the settings from the most secure to the least secure, then negotiates with the peer using that order. For IKEv1, you can select only a single option.

- 14—Diffie-Hellman Group 14: 2048-bit modular exponential (MODP) group. Considered good protection for 192-bit keys.
- 15—Diffie-Hellman Group 15: 3072-bit MODP group.
- 16—Diffie-Hellman Group 16: 4096-bit MODP group.
- 19—Diffie-Hellman Group 19: National Institute of Standards and Technology (NIST) 256-bit elliptic curve modulo a prime (ECP) group.
- 20—Diffie-Hellman Group 20: NIST 384-bit ECP group.
- 21—Diffie-Hellman Group 21: NIST 521-bit ECP group.
- 31—Diffie-Hellman Group 31: Curve25519 256-bit EC Group.

Decide VPN authentication methods

A VPN authentication method is a security mechanism that

- validates the identity of peers in a VPN connection
- enables secure communication between network devices, and
- ensures that only authorized devices can establish VPN connections.

Available authentication methods

VPNs support two primary authentication methods:

- **Preshared keys**: A secret key shared between two peers and used by IKE during the authentication phase. The same shared key must be configured at each peer or the IKE SA cannot be established.
- **Digital certificates**: Use RSA key pairs to sign and encrypt IKE key management messages. Certificates provide proof of communication between two peers.

VPN type support varies by authentication method.

Table 88: VPN authentication method support

VPN Type	Preshared Keys	Digital Certificates
Site-to-site IKEv1 and IKEv2	Supported	Supported
Remote Access (SSL and IPsec IKEv2)	Not supported	Supported

When you use digital certificate authentication, you need a Public Key Infrastructure (PKI) defined for peers to obtain digital certificates from a Certification Authority (CA). CAs manage certificate requests and issue certificates to participating network devices, providing centralized key management for all participating devices.

Preshared keys are difficult to manage for large networks. CAs make it easier to manage and scale your IPsec network. With a CA, you do not need to configure keys between all encrypting devices. Register each device with the CA to request its certificate. Devices with their own certificates and the CA's public key can authenticate other devices within the CA's domain.

Pre-shared keys

A pre-shared key is a secret key that

- enables you to share authentication credentials between two peers
- is used by IKE in the authentication phase, and
- must be configured identically on each peer or the IKE SA cannot be established.

Key configuration options

To configure pre-shared keys, select either a manual key or an automatically generated key. Specify this key in the IKEv1 or IKEv2 options. When you deploy your configuration, the key is configured on all devices in the topology.

PKI infrastructure and digital certificates

A PKI infrastructure is a centralized key management system that

- provides defined policies, procedures, and roles supporting public key cryptography
- generates, verifies, and revokes public key certificates, commonly known as digital certificates, and
- manages key pairs consisting of public and private keys for VPN endpoints to sign and encrypt messages.

Public key cryptography and certificate components

In public key cryptography, each endpoint of a connection has a key pair consisting of both a public and a private key. The key pairs are used by the VPN endpoints to sign and encrypt messages. The keys act as complements, and anything encrypted with one of the keys can be decrypted with the other, securing the data flowing over the connection.

Generate a general-purpose RSA, ECDSA, or EDDSA key pair for signing and encryption. Alternatively, generate separate key pairs for each purpose. Separate signing and encryption keys help to reduce key exposure. SSL uses a key for encryption, while IKE uses a key for signing. Separate keys for each purpose minimize exposure.

Certificates also ensure non-repudiation by providing proof that communication between two peers occurred.

You can obtain CA certificates by:

- Using the Simple Certificate Enrollment Protocol (SCEP) or Enrollment over Secure Transport (EST) to retrieve the CA's certificate from the CA server
- Manually copying the CA's certificate from another participating device

Trustpoints represent the object representation of a CA and associated certificates. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

A PKCS#12, or PFX, file holds the server certificate, any intermediate certificates, and the private key in one encrypted file. This type of file may be imported directly into a device to create a trustpoint.

A CA may also revoke certificates for peers that no longer participate in your network. Revoked certificates are either managed by an Online Certificate Status Protocol (OCSP) server or are listed in a certificate revocation list (CRL) stored on an LDAP server. A peer may check these before accepting a certificate from another peer.

Digital certificates or identity certificates

When you use digital certificates as the authentication method for VPN connections, peers are configured to obtain digital certificates from a Certificate Authority (CA). CAs are trusted authorities that sign certificates to verify their authenticity, thereby guaranteeing the identity of the device or user.

Digital certificates contain these components:

- The digital identification of the owner for authentication, such as name, serial number, company, department, or IP address.

- A public key needed to send and receive encrypted data to the certificate owner.
- The secure digital signature of a CA.

The certificate enrollment process includes these steps:

1. CA servers manage public CA certificate requests and issue certificates to participating network devices as part of a PKI.
2. Each participating device enrolls individually with a CA server, which validates identities and creates an identity certificate.
3. Each participating peer sends their identity certificate to the other peer to validate their identities and establish encrypted sessions with the public keys contained in the certificates.

Certificate enrollment

Using a PKI improves the manageability and scalability of your VPN because you do not have to configure preshared keys between all encrypting devices. Instead, enroll each participating device with a CA server, which validates identities and creates an identity certificate for the device. After completing enrollment, each participating peer sends its identity certificate to the other peer to validate their identities and establish encrypted sessions with the public keys contained in the certificates. For more information about enrolling Firewall Threat Defense device certificates, refer to Certificate enrollment objects, on page 2827.

Certificate authority certificates

In order to validate a peer’s certificate, each participating device must retrieve the CA's certificate from the server. A CA certificate is used to sign other certificates. It is self-signed and called a root certificate. This certificate contains the CA's public key, which you use to decrypt and validate the CA's digital signature and the contents of the received peer's certificate.

To obtain the CA certificate:

- Use the Simple Certificate Enrollment Protocol (SCEP) or Enrollment over Secure Transport (EST) to retrieve the CA’s certificate from the CA server
- Manually copy the CA's certificate from another participating device

Trustpoints

Once enrollment is complete, a trustpoint is created in the managed device. It is the object representation of a CA and associated certificates. A trustpoint includes the identity of the CA, CA-specific parameters, and one enrolled identity certificate.

PKCS#12 file

A PKCS#12 file, or PFX file holds the server certificate, intermediate certificates, and the private key in one encrypted file. This type of file may be imported directly into a device to create a trustpoint.

Revocation checking

A CA may also revoke certificates for peers that no longer participate in your network. Revoked certificates are either managed by an Online Certificate Status Protocol (OCSP) server or are listed in a certificate revocation list (CRL) stored on an LDAP server. A peer may check these before accepting a certificate from another peer.

Deprecated hash algorithms, encryption algorithms, and Diffie-Hellman modulus groups

Update your VPN configuration to use supported DH and encryption algorithms before upgrading to Firewall Threat Defense 6.70 or later.

- Update your IKE proposals and IPSec policies to match the ones supported in Firewall Threat Defense 6.70 or later.
- Deploy the configuration changes after updating to supported algorithms.

Support has been removed for these less secure ciphers from Firewall Threat Defense Version 6.70:

- **Diffie-Hellman GROUP 5** is deprecated for IKEv1 and IKEv2.
- Diffie-Hellman groups 2 and 24 have been removed.
- **Encryption algorithms**: 3DES, AES-GMAC, AES-GMAC-192, and AES-GMAC-256 have been removed.

Note **DES** continues to be supported in evaluation mode or for users who do not satisfy export controls for strong encryption.

NULL is removed in IKEv2 policy, but supported in both IKEv1 and IKEv2 IPsec transform-sets.

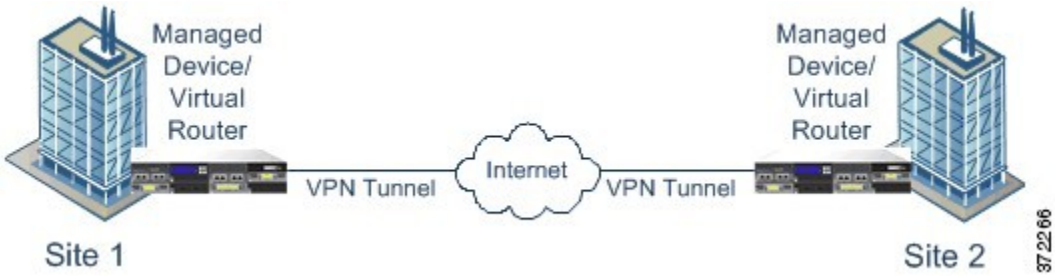
VPN topologies

When you create a new VPN topology you must give it a unique name, specify a topology type, and select the IKE version. You can select from three types of topologies, each containing a group of VPN tunnels:

- Point-to-point (PTP) topologies establish a VPN tunnel between two endpoints.
- Hub and spoke topologies establish a group of VPN tunnels connecting a hub endpoint to a group of spoke endpoints.
- Full mesh topologies establish a group of VPN tunnels among a set of endpoints.

There is no default pre-shared key for VPN authentication. You must define a pre-shared key manually or let the system generate it automatically. When choosing automatic, the Secure Firewall Management Center generates a pre-shared key and assigns it to all the nodes in the topology.

Point-to-point VPN topologies



A point-to-point VPN topology is a network configuration that

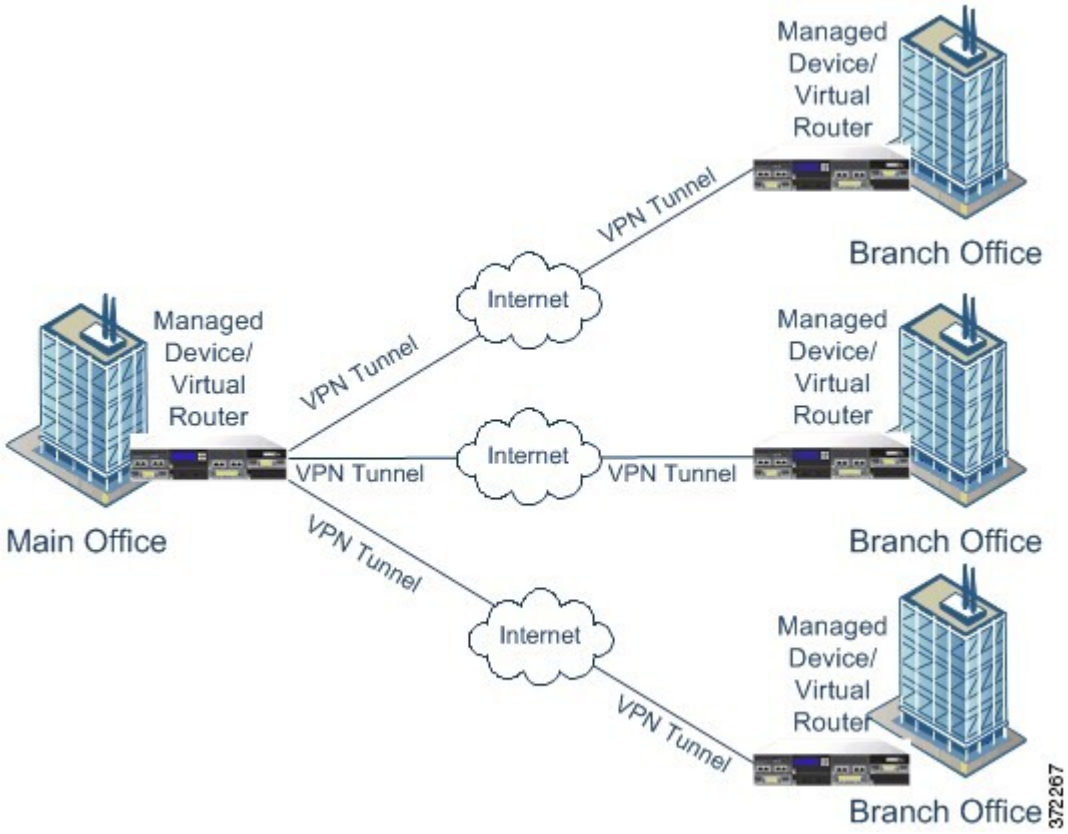
- enables two endpoints to communicate directly with each other

- allows you to configure the two endpoints as peer devices, and
- permits either device to start the secured connection.

This diagram displays a typical point-to-point VPN topology.

Figure 419: Point-to-point VPN topology

Hub and spoke VPN topology



A hub and spoke VPN topology is a network architecture that

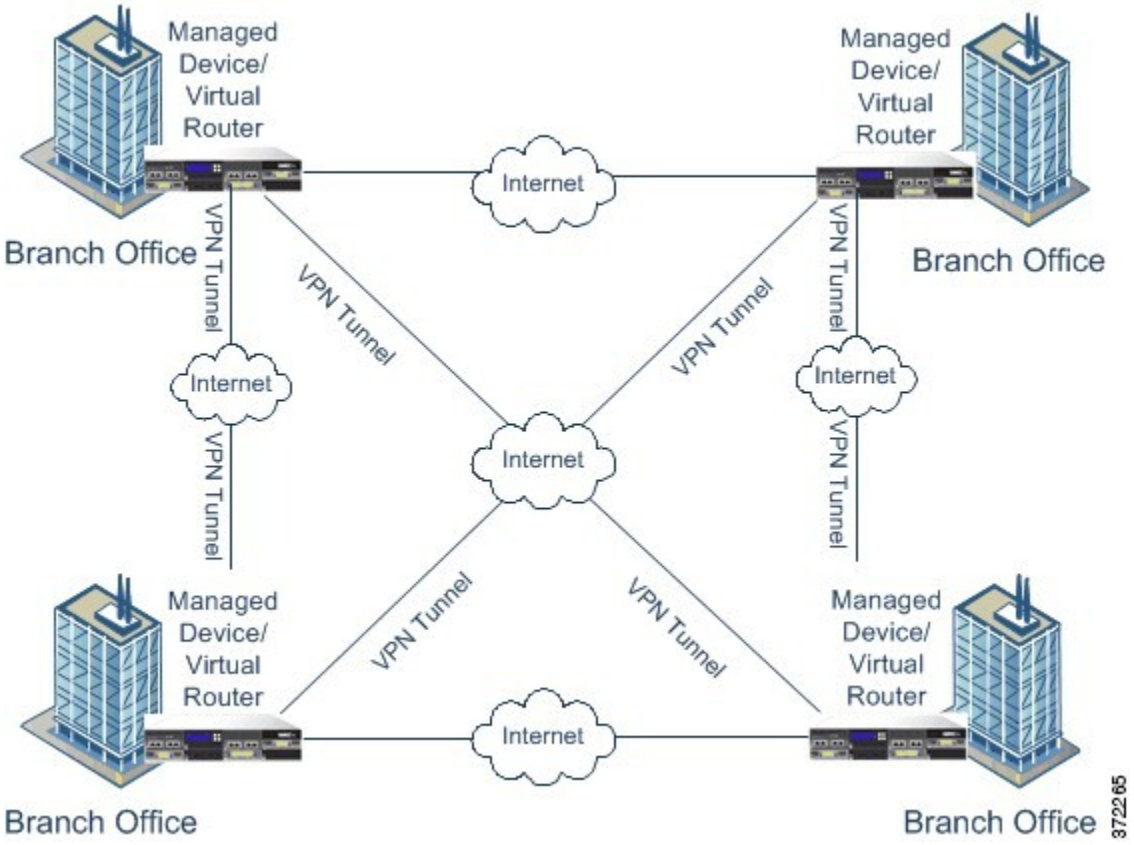
- connects a central endpoint (hub node) with multiple remote endpoints (spoke nodes)
- establishes each connection between the hub node and an individual spoke endpoint as a separate VPN tunnel, and
- enables hosts behind any of the spoke nodes to communicate with each other through the hub node.

The hub and spoke topology commonly represent a VPN that connects an organization's main and branch office locations using secure connections over the Internet or other third-party network. These deployments provide all employees with controlled access to the organization's network. Typically, the hub node is located at the main office. Spoke nodes are located at branch offices and start most of the traffic.

This diagram displays a typical hub and spoke VPN topology.

Figure 420: Hub and spoke VPN topology diagram

Full mesh VPN topology



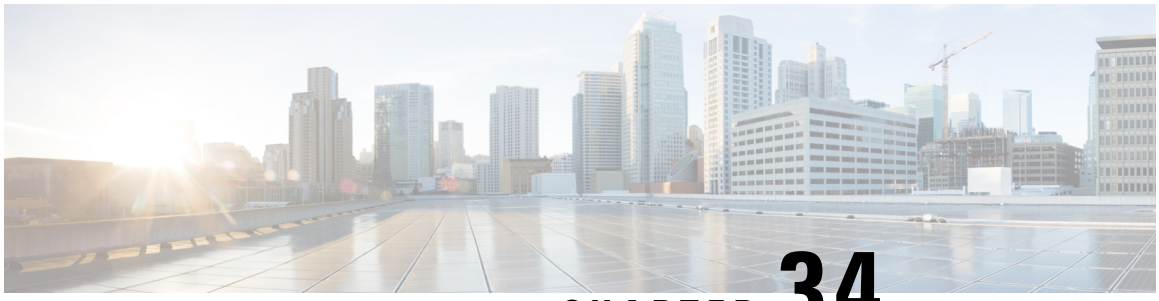
A full mesh VPN topology is a network configuration that

- allows all endpoints to communicate with every other endpoint by an individual VPN tunnel
- offers redundancy so that when one endpoint fails, the remaining endpoints can still communicate with each other, and
- commonly represents a VPN that connects a group of decentralized branch office locations.

The number of VPN-enabled managed devices you deploy in this configuration depends on the level of redundancy you require.

This diagram displays a typical full mesh VPN topology.

Figure 421: Full mesh VPN topology



Implicit topologies

Implicit topologies are complex VPN network configurations that

- combine elements from the three main VPN topologies (full mesh, hub-and-spoke, and point-to-point)
- create more advanced network architectures than individual topology types, and
- provide customized connectivity solutions for specific network requirements.

Types of implicit topologies

- **Partial mesh**: A network where some devices use a full mesh topology, while others form either hub-and-spoke or point-to-point connections with some fully meshed devices. The partial mesh does not offer the redundancy found in a full mesh but costs less to implement. Peripheral networks use partial mesh topologies to connect to a fully meshed backbone.
- **Tiered hub-and-spoke**: A network of hub-and-spoke topologies where devices act as a hub in some topologies and as a spoke in others. Spoke groups can send traffic to their closest hub.
- **Joined hub-and-spoke**: A combination of two topologies (hub-and-spoke, point-to-point, or full mesh) that connect to form a point-to-point tunnel. For example, a joined hub-and-spoke topology could comprise two hub-and-spoke topologies, with the hubs acting as peer devices in a point-to-point topology.

CHAPTER 34

Site-to-Site VPN

- Monitor site-to-site topologies, on page 1574
- History for site-to-site VPN, on page 1579

Site-to-site VPN

A site-to-site VPN is a secure, encrypted VPN tunnel between two networks in different geographic locations. After the VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel. You can create site-to-site IPsec connections between managed devices, and between managed devices and other Cisco or third-party peers.

Site-to-site VPN features

Secure Firewall Threat Defense site-to-site VPN supports these features:

- IPsec IKEv1 & IKEv2 protocols.
- Certificates and automatic or manual preshared keys for authentication.
- IPv4 & IPv6 addresses. All combinations of inside and outside are supported.
- Static and dynamic interfaces.
- HA environments for both Firewall Management Center and Firewall Threat Defense devices.
- VPN alerts when the tunnel goes down and tunnel statistics.
- IKEv1 and IKEv2 back-up peer configuration for point-to-point extranet and hub-and-spoke VPNs.
- Extranet device as hub in 'Hub and Spokes' deployments.

- Dynamic IP address for a managed endpoint pairing with extranet device in 'Point to Point' deployments and for extranet device as an endpoint.

VPN topologies

VPN topology configuration requires specifying a unique name, a topology type, IKE version selection, and authentication method. The Secure Firewall Management Center configures site-to-site VPNs on Firewall Threat Defense devices only.

You can select from three types of topologies, containing one or more VPN tunnels:

- Point-to-point (PTP) deployments establish a VPN tunnel between two endpoints.
- Hub and Spoke deployments establish a group of VPN tunnels connecting a hub endpoint to a group of spoke nodes.
- Full Mesh deployments establish a group of VPN tunnels among a set of endpoints.

In the Secure Firewall Management Center, site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. Policies and proposals are sets of parameters that define the characteristics of a site-to-site VPN, such as the security protocols and algorithms that are used to secure traffic in an IPsec tunnel. Several policy types may be required to define a full configuration image that can be assigned to a VPN topology.

For authentication of VPN connections, configure a preshared key in the topology, or a trustpoint on each device. Preshared keys allow for a secret key, used during the IKE authentication phase, to be shared between two peers. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

IPsec and IKE

In the Secure Firewall Management Center, site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. Policies and proposals are sets of parameters that define the characteristics of a site-to-site VPN, such as the security protocols and algorithms that are used to secure traffic in an IPsec tunnel. Several policy types may be required to define a full configuration image that can be assigned to a VPN topology.

Authentication

For authentication of VPN connections, configure a preshared key in the topology, or a trustpoint on each device. Preshared keys allow for a secret key, used during the IKE authentication phase, to be shared between two peers. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

Extranet Devices

Each topology type can include extranet devices, devices that you don't manage in Firewall Management Center. These include:

- Cisco devices that Secure Firewall Management Center supports, but for which your organization isn't responsible. Such as spokes in networks managed by other organizations within your company, or a connection to a service provider or partner's network.
- Non-Cisco devices. You can't use Secure Firewall Management Center to create and deploy configurations to non-Cisco devices.

Add non-Cisco devices, or Cisco devices not managed by the Secure Firewall Management Center, to a VPN topology as "Extranet" devices. Also specify the IP address of each remote device.

Guidelines for configuring site-to-site VPN in Secure Firewall Threat Defense devices

General guidelines

- Site-to-site VPN supports ECMP zone interfaces.
- Configure all nodes in a topology with either crypto ACL or a protected network. You cannot configure a topology with crypto ACL on one node and protected network on another.
- Configure a VPN connection across domains by using an extranet peer for the endpoint not in the current domain.
- You can backup Firewall Threat Defense VPNs using the Firewall Management Center backup.
- Configure unique local IKE identity for all tunnels across all your VPN topologies.
- Ensure that IKE ports 500 and 4500 are not already in use and that no active PAT translations exist on those ports before configuring a site-to-site VPN. Configuring a site-to-site VPN on ports that are already in use will cause the service to fail to start.
- When configuring a site-to-site VPN between two devices managed by the same Firewall Management Center, do not configure the devices as backup peers. Instead, configure one of the peer devices in the topology as an extranet device.
- If a spoke is part of multiple topologies with the same hub, for the Local Tunnel (IKE) Identity, we recommend that you use Key ID instead of an IP address.

  If the spoke uses an IP address as its local identity, the hub creates only one tunnel group. The spoke is then mapped to a specific virtual template interface, so the connection works with only one topology.

RBD with HA guidelines

In a remote branch deployment (RBD) with High Availability when you break a High Availability pair:

- For hub and spoke VPN:
  - If the Firewall Threat Defense HA is a hub, VPN configurations will be available in the active device and will be removed in the standby device.
  - If the Firewall Threat Defense HA is a spoke, VPN configurations will be available in the active and standby devices.
- For point-to-point VPN, if the endpoint has an RBD Firewall Threat Defense HA WAN interface, VPN configurations will be removed from the standby device.

Limitations for configuring site-to-site VPN in Threat Defense devices

General limitations

- IKEv1 does not support CC/UCAPL-compliant devices. IKEv2 is recommended for these devices.

- VPN does not support network objects with a 'range' option.
- Firewall Threat Defense VPNs do not support PDF export.
- Tunnel status is not updated realtime, but at an interval of five minutes in the Firewall Management Center.
- You cannot use the double quote character (") in pre-shared keys, replace it if already in use.

Crypto ACL limitations

- Firewall Management Center supports only point-to-point VPN with crypto ACL and does not support tunnel health events.
- Firewall Management Center does not verify the device interface address verification for transport mode when you select a crypto ACL.
- There is no support for automatic mirror ACE generation. Mirror ACE generation for the peer is a manual process on either side.

Topology management limitations

- You cannot move a VPN topology between domains.
- There is no per-tunnel or per-device edit option for Firewall Threat Defense VPNs, you can edit only the whole topology.

Types of site-to-site VPN topologies

This table provides an overview of the different site-to-site VPN topology options available for secure network connectivity configuration.

Site-to-Site VPN Topology	Description	More Information
SD-WAN Topology	Configure a secure branch network using the SD-WAN wizard. This wizard simplifies and automates VPN and routing configuration of your network using a hub and spoke topology, enabling SD-WAN capabilities.	SD-WAN wizard for secure branch network deployment, on page 1586
Route-Based VPN	Configure secure traffic dynamically between peers in a network based on routing over Virtual Tunnel Interfaces (VTIs).	Create a route-based site-to-site VPN, on page 1547
Policy-Based VPN	Configure secure traffic between peers in a network based on a static policy using protected networks.	Configure a policy-based site-to-site VPN, on page 1523

Site-to-Site VPN Topology	Description	More Information
SASE Topology	Configure an IPsec IKEv2 tunnel from a Firewall Threat Defense device to Secure Access or an Umbrella Secure Internet Gateway (SIG). This tunnel forwards all internet-bound traffic to Secure Access or Umbrella SIG for inspection and filtering.	Secure traffic using Cisco Secure Access and Firewall Threat Defense devices, on page 1569 Configure a SASE tunnel for Umbrella, on page 1566

License requirements for site-to-site VPN

This topic lists the license requirements for setting up various types of site-to-site VPN connections.

License requirements for policy-based and route-based VPN

With the Essentials license, you can set up policy-based and route-based VPNs on your Firewall Threat Defense devices.

Depending on whether export-controlled functionality is enabled in your Smart License account, Firewall Management Center determines whether to allow or block the usage of strong crypto on devices. To verify if export-controlled functionality is enabled for your Smart License account, choose **Administration** > **Licenses** > **Smart Licenses**.

Note If you use an evaluation license, or if you have not enabled the export-controlled functionality, you cannot use strong encryption for your VPN connections.

License requirements for deploying a SASE tunnel on Umbrella

To deploy SASE tunnels on Umbrella from Firewall Management Center, you must enable your Smart License account with the export-controlled functionality. If this functionality is not enabled, you can only create a SASE topology, you cannot deploy tunnels on Umbrella.

Licenses for automatic tunnel between Secure Accessand Firewall Threat Defense devices

- Firewall Management Center Essentials (formerly Base) license must allow export-controlled functionality. Choose **Administration** > **Licenses** > **Smart Licenses** to verify this in Firewall Management Center.

Note Evaluation license does not support this feature.

- Cisco Secure Access Essentials subscription license must be available.

Prerequisites for site-to-site VPN

Supported interfaces

Topology Type	Interface Type

Policy-Based and SD-WAN	• Physical interfaces
	  • Non-management
	  • Interface Mode must be either Routed or None
	• Subinterface interfaces
	• Redundant interfaces
	• Etherchannel interfaces
	• VLAN interfaces

Route-Based	Static Virtual Tunnel Interfaces

Note The maximum number of supported security associations (SA) depends on the maximum VPN peers for your platform. For more information about maximum VPN peers, refer the data sheet of the Secure Firewall Threat Defense device.

General prerequisites

- You must have administrator privileges.
- You must be in a leaf domain to perform the site-to-site VPN configurations.

Manage site-to-site VPNs

You can view, create, modify, and deploy site-to-site VPN configurations and manage their deployment status.

The **Site-to-Site VPN** page provides a snapshot of site-to-site VPN tunnels. You can view the status of the tunnels and filter the tunnels based on the device, topology, or tunnel type. The page lists 20 topologies per page and you can navigate between pages to view more topology details. You can click individual VPN topologies to expand and view details of the endpoints.

Before you begin

For certificate authentication of your site-to-site VPNs, you must prepare the devices by allocating trustpoints as described in Certificates, on page 2915.

Procedure

Select **Secure Connections** > **Site-to-Site VPN & SD-WAN** to manage your Firewall Threat Defense site-to-site VPN configurations and deployments.

The page lists the site-to-site VPNs topologies and indicates the status of tunnels using color codes:

- Active (Green)–There is an active IPsec Tunnel.
- Unknown (Amber)–No tunnel establishment event has been received from the device yet.
- Down (Red)–There are no active IPsec tunnels.
- Deployment Pending–Topology has not been deployed on the device yet.

Choose one of these actions:

- **Refresh**—View the updated status of the VPNs.
- **Add**—Create new policy based or route-based Site to Site VPNs.
- **Edit**—Modify the settings of an existing VPN topology.

Note You cannot edit the topology type after you initially save it. To change the topology type, delete the topology and create a new one.

Two users shouldn't edit the same topology simultaneously; however, the web interface doesn't prevent simultaneous editing.

- **Delete**—To delete a VPN deployment, click **Delete** ( ).
- Deploy—Choose **Deploy** > **Deploy**; see Deploy configuration changes, on page 193.

Note Some VPN settings are validated only during deployment. Be sure to verify that your deployment was successful.

Configure a policy-based site-to-site VPN

Configure a policy-based site-to-site VPN to establish secure communication channels between network endpoints using crypto maps and specified network topologies.

Procedure

Step 1 Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN**, click **Add**, and enter the topology name in the **Topology Name** field.

Step 2 Click the **Policy-Based VPN** radio button and select the VPN topology and click **Create**.

Step 3 Choose the IKE versions to use during IKE negotiations. Check the **IKEv1** or **IKEv2** check box.

Default is IKEv2. Select either or both options as appropriate; select IKEv1 if any device in the topology doesn't support IKEv2.

You can also configure a backup peer for point-to-point extranet VPNs. For more information, see Firewall Threat Defense VPN endpoint options, on page 1524.

Step 4 Required: Add Endpoints for this VPN deployment by clicking **Add** (+) for each node in the topology.

Configure each endpoint field as described in Firewall Threat Defense VPN endpoint options, on page 1524.

- For Point to point, configure **Node A** and **Node B**.
- For Hub and Spoke, configure a **Hub Node** and **Spoke Nodes**
- For Full Mesh, configure multiple **Nodes**

Step 5 (Optional) Specify non-default IKE options for this deployment as described in Firewall Threat Defense VPN IKE options, on page 1529

Step 6 (Optional) Specify non-default IPsec options for this deployment as described in Firewall Threat Defense VPN IPsec options, on page 1531

Step 7 (Optional) Specify non-default Advanced options for this deployment as described in Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1533 and click **Save**.

The policy-based site-to-site VPN is configured with the specified endpoints, IKE settings, and topology options.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 193.

Note Some VPN settings are validated only during deployment. Be sure to verify that your deployment was successful.

If you get an alert that your VPN tunnel is inactive even when the VPN session is up, follow the VPN troubleshooting instructions to verify and ensure that your VPN is active.

Firewall Threat Defense VPN endpoint options

Configure the basic parameters for a point-to-point topology in a policy-based VPN as described in Configure Endpoints for a Point to Point Topology and click the **Endpoints** tab.

Fields

Device

Choose an endpoint node for your deployment:

- A Firewall Threat Defense device managed by this Firewall Management Center
- A Firewall Threat Defense high availability container managed by this Firewall Management Center
- An **Extranet** device, any device (Cisco or third party) not managed by this Firewall Management Center .

Device Name

For extranet devices only, provide a name for this device. We recommend naming it such that it is identifiable as an unmanaged device.

Interface

If you chose a managed device as your endpoint, choose an interface on that managed device.

For 'Point to Point' deployments, you can also configure an endpoint with dynamic interface. An endpoint with a dynamic interface can pair only with an extranet device and can't pair with an endpoint, which has a managed device.

You can configure device interfaces at **Devices** > **Device Management Add/Edit device** > **Interfaces**.

IP Address

- If you choose an extranet device, a device not managed by the Firewall Management Center, specify an IP address for the endpoint.

  For an extranet device, select **Static** and specify an IP address or select **Dynamic** to allow dynamic extranet devices.

- If you chose a managed device as an endpoint, choose a single IPv4 address or multiple IPv6 addresses from the drop-down list. These IP addresses are already assigned to this interface on the managed device.
- All endpoints in a topology must have the same IP addressing scheme. IPv4 tunnels can carry IPv6 traffic and vice versa. The **Protected Networks** define which addressing scheme the tunneled traffic uses.
- If the managed device is a high-availability container, choose from a list of interfaces.

This IP is Private

Check the check box if the endpoint resides behind a firewall with network address translation (NAT).

Note Use this option only when the peer is managed by the same Firewall Management Center and don't use this option if the peer is an extranet device.

Public IP address

If you checked the **This IP is Private** check box, specify a public IP address for the firewall. If the endpoint is a responder, specify this value.

Connection Type

Specify the allowed negotiation as bidirectional, answer-only, or originate-only. Supported combinations for the connection type are:

Table 89: Connection Type Supported Combinations

Remote Node	Central Node
Originate-Only	Answer-Only
Bi-Directional	Answer-Only
Bi-Directional	Bi-Directional

Certificate Map

Choose a preconfigured certificate map object, or click **Add** (+) to add a certificate map object. The certificate map defines what information is necessary in the received client certificate to be valid for VPN connectivity. See Certificate map objects, on page 2889 for details.

Protected Networks

Caution Hub and Spoke topology—To avoid traffic drop for a dynamic crypto map, ensure that you don't select the protected network *any* for both the endpoints.

If the protected network is configured as *any*, on both the endpoints, the crypto ACL that works upon the tunnel is not generated.

Defines the networks that are protected by this VPN endpoint. Select the networks by selecting the list of Subnet/IP Address that define the networks that are protected by this endpoint. Click **Add** (+) to select from available Network Objects or add new Network Objects. See Create a network object, on page 2815 . Access control lists are generated from the choices made here.

- **Subnet/IP Address (Network)**—VPN endpoints can't have the same IP address and protected networks in a VPN endpoint pair cannot overlap. If protected networks for an endpoint contain IPv4 or IPv6 entries, the other endpoint's protected network must have at least one entry of the same type (IPv4 or IPv6). If it doesn't, the other endpoint's IP address must be of the same type and not overlap with the entries in the protected network. (Use /32 CIDR address blocks for IPv4 and /128 CIDR address blocks for IPv6.) If both of these checks fail, the endpoint pair is invalid.

  By default, **Reverse Route Injection is enabled** check box is enabled in Firewall Management Center.

  Subnet/IP Address (Network) remains the default selection.

  When you've selected Protected Networks as *Any* and observe default route traffic being dropped, disable the Reverse Route Injection.

  1. Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN**.
  2. Edit a VPN and then click **IPsec** > **Enable Reverse Route Injection** .

3. Deploy the configuration changes to remove set reverse-route (Reverse Route Injection) from the crypto map configuration and remove the VPN-advertised reverse route that causes the reverse tunnel traffic to be dropped.

- **Access List (Extended)** —An extended access list provides the capability to control the type of traffic that will be accepted by this endpoint, like GRE or OSPF traffic. Traffic may be restricted either by address or port. Click **Add** (+) to add access control list objects.

Note Access Control List is supported only in the point to point topology.

Enable NAT Traversal

Check this check box to allow seamless communication between the peer Firewall Threat Defense devices when there are NAT devices between these devices. For hub and spoke topologies, this option is available only for the spoke. You can uncheck this check box to disable this feature for an endpoint. This parameter is a per peer setting for an endpoint within a topology.

To view or configure the global NAT Traversal (NAT-T) setting, in the **Add/Edit VPN Topology** dialog box:

1. Click the **Advanced** tab.
2. In the left navigation pane, click **Tunnel** .
3. Under **NAT Settings**, the **Keepalive Messages Traversal** is a global setting that enables NAT-T for all endpoints within a topology.

Exempt VPN traffic from network address translation

Check this check box to exempt the VPN traffic from the Network Address Translation (NAT) rules.

If you do not exempt the VPN traffic from the NAT rules, the traffic gets dropped or is not routed through the VPN tunnel to the remote device. After you enable this option, you can view the NAT exemptions for the device in the NAT policy page (**Policies** > **Network policies** > **NAT** , and click **NAT Exemptions**).

Inside interfaces directly connected to the internal network

Specify the security zone or interface group for the inside interface(s) where the protected networks reside. By default, the inside interface is any.

Click + to configure one or more interfaces from a security zone or an interface group that can map to one or more inside interfaces. Ensure that the interface type of the security zone or an interface group is Routed.

Advanced Settings

Enable Dynamic Reverse Route Injection—Reverse Route Injection (RRI) enables routes to be automatically inserted into the routing process, for the networks and hosts protected by a remote tunnel endpoint. Dynamic RRI routes are created only upon the successful establishment of IPsec security associations (SA's).

Note

- Dynamic RRI is supported only on IKEv2, and not supported on IKEv1 or IKEv1 + IKEv2.
- Dynamic RRI isn't supported on originate-only peer, Full Mesh topology, and Extranet peer.
- In Point-to-Point, only one peer can have dynamic RRI enabled.
- Between Hub and Spoke, only one of the endpoints can have dynamic RRI enabled.
- Dynamic RRI cannot be combined with a dynamic crypto map.

Send Local Identity to Peers—Select this option to send local identity information to the peer device. Select one of the following **Local Identity Configuration** from the list and configure the local identity:

- **IP address**—Use the IP address of the interface for the identity.
- **Auto**—Use the IP address for pre-shared key and Cert DN for certificate-based connections.
- **Email ID**—Specify the email ID to use for the identity. The email address can be up to 127 characters.
- **Hostname**—Use the fully qualified hostname.
- **Key ID**—Specify the key-id to use for the identity. The key ID must be fewer than 65 characters.

The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows Firewall Threat Defense to have multiple IPsec tunnels behind a NAT to connect to the Cisco Umbrella Secure Internet Gateway (SIG).

For information about configuring a unique tunnel ID on Umbrella, refer to Cisco Umbrella SIG User Guide.

VPN Filter—Select an extended access list from the list or click **Add** to create a new extended access list object to filter the site-to-site VPN traffic.

The VPN filter provides more security and filters site-to-site VPN data using an extended access list. The extended access list object selected for the VPN filter lets you filter pre-encrypted traffic before entering the VPN tunnel and decrypted traffic that exits a VPN tunnel. The **sysopt permit-vpn** option, when enabled, would bypass the access control policy rules for the traffic coming from the VPN tunnel. When the **sysopt permit-vpn** option is enabled, the VPN filter helps in identifying and filtering the site-to-site VPN traffic.

Note The VPN filter is supported only on point to point, and hub and spoke topologies. It isn't supported on mesh topology.

For hub and spoke topology, you can choose to override the hub VPN filter on the spoke endpoints in case a different VPN filter needs to enabled on a specific tunnel.

Select the **Override VPN Filter on the Hub** option to override the hub VPN filter on the spokes. Select the **Remote VPN Filter** extended access list object or create an access list to override.

Note For an extranet device as a spoke, only the **Override VPN filter on the Hub** option is available.

For more information about sysopt permit-VPN, see Firewall Threat Defense advanced site-to-site VPN tunnel options , on page 1535 .

Firewall Threat Defense VPN IKE options

For the versions of IKE you have chosen for this topology, specify the **IKEv1/IKEv2 Settings**.

Note Settings in this dialog apply to the entire topology, all tunnels, and all managed devices.

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in Configure Endpoints for a Point to Point Topology and click the **IKE** tab.

Fields

Policy

Choose the required IKEv1 or IKEv2 policy objects from the predefined list or create new objects to use. You can choose multiple IKEv1 and IKEv2 policies. IKEv1 and IKEv2 support a maximum of 20 IKE policies, each with a different set of values. Assign a unique priority to each policy that you create. The lower the priority number, the higher the priority.
We recommend that you do NOT use values such as 10, 20 and so on because the default IKEv2 policy for remote access VPN can have these values as its priority value. Before deployment, verify that the priority values of the IKE policies (site-to-site and remote access VPN) do NOT conflict.

Note When upgrading from Version 7.4.x or earlier—where the IKEv2 policy priority field is optional—to Version 7.6.x or later—where it is mandatory—leaving the priority field blank may lead to IKEv2 policy configuration issues and affect network traffic. To avoid these problems, ensure that a priority value is set for all IKEv2 policies either before or after the upgrade.

For details, see IKE policies, on page 2903

Authentication Type

Site-to-site VPN supports two authentication methods, pre-shared key and certificate. For an explanation of the two methods, see Decide VPN authentication methods, on page 1509.

Note In a VPN topology that supports IKEv1, the **Authentication Method** specified in the chosen IKEv1 Policy object becomes the default in the IKEv1 **Authentication Type** setting. These values must match, otherwise, your configuration will error.

- **Pre-shared Automatic Key**—The Firewall Management Center automatically defines the pre-shared key for this VPN. Specify the **Pre-shared Key Length**, the number of characters in the key. The range is 1 to 27.

  The character " (double quote) isn't supported as part of pre-shared keys.

- **Pre-shared Manual Key**—Manually assign the pre-shared key for this VPN. Specify the **Key** and then reenter the same to **Confirm Key**.

  When you choose this option for IKEv2, the **Enforce hex-based pre-shared key only** check box appears, check if desired. If enforced, you must enter a valid hex value for the key, an even number of 2-256 characters, using numerals 0-9, or A-F.

- **Certificate**—When you use certificates as the authentication method for VPN connections, peers obtain digital certificates from a CA server in your PKI infrastructure, and trade them to authenticate each other.

  In the **Certificate** field, select a preconfigured certificate enrollment object. This enrollment object generates a trustpoint with the same name on the managed device. The certificate enrollment object should be associated with and installed on the device, post which the enrollment process is complete, and then a trustpoint is created.

  A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one enrolled identity certificate.

  Before you select this option, note these requirements:

  - Ensure you've enrolled a certificate enrollment object on all the endpoints in the topology—A certificate enrollment object contains the Certification Authority (CA) server information and enrollment parameters that are required for creating Certificate Signing Requests (CSRs) and obtaining Identity Certificates from the specified CA. Certificate Enrollment Objects are used to enroll your managed devices into your PKI infrastructure, and create trustpoints (CA objects) on devices that support VPN connections. For instructions on creating a certificate enrollment object, see Add certificate enrollment objects, on page 2829, and for instructions on enrolling the object on the endpoints see one of these as applicable:

    - Install a certificate using self-signed enrollment, on page 2920
    - Install a certificate using EST enrollment, on page 2921
    - Install a certificate using SCEP enrollment, on page 2921
    - Install a certificate using manual enrollment, on page 2922
    - Install a certificate using a PKCS12 file, on page 2923

Note For a site-to-site VPN topology, ensure that the same certificate enrollment object is enrolled in all the endpoints in the topology. For further details, see the table below.

  - Refer to this table to understand the enrollment requirement for different scenarios. Some of the scenarios require you to override the certificate enrollment object for specific devices. See Manage object overrides, on page 2767 to understand how to override objects.

Certificate Enrollment Types	Device identity certificate for all endpoints is from the same CA		Device identity certificate for all endpoints is from different CAs
	Device-specific parameters are NOT specified in the certificate enrollment object	Device-specific parameters are specified in the certificate enrollment object	
Manual	No override required	Override required	Override required
EST	No override required	Override required	Override required
SCEP	No override required	Override required	Override required
PKCS	Override required	Override required	Override required
Self-signed	NOT applicable	NOT applicable	NOT applicable

- Understand the VPN certificate limitations mentioned in Secure Firewall Threat Defense VPN certificate guidelines and limitations, on page 2915.

Note If you use a Windows Certificate Authority (CA), the default application policies extension is **IP security IKE intermediate**. If you use this default setting, you must select the **Ignore IPsec Key Usage** option in the Advanced Settings section on the **Key** tab in the **PKI Certificate Enrollment** dialog box for the object you select. Otherwise, the endpoints can't complete the site-to-site VPN connection.

Firewall Threat Defense VPN IPsec options

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in Configure Endpoints for a Point to Point Topology and click the **IPsec** tab.

Note Settings in this dialog apply to the entire topology, all tunnels, and all managed devices.

Crypto-Map Type

A crypto map combines all the components required to set up IPsec security associations (SA). When two peers try to establish an SA, they must each have at least one compatible crypto map entry. IPsec security negotiation uses the proposals defined in the crypto map entry to protect the data flows specified by that crypto map's IPsec rules. Choose static or dynamic for this deployment's crypto-map:

- **Static**—Use a static crypto map in a point-to-point or full mesh VPN topology.
- **Dynamic**—Dynamic crypto-maps essentially create a crypto map entry without all the parameters configured. The missing parameters are later dynamically configured (as the result of an IPsec negotiation) to match a remote peer's requirements.

Dynamic crypto map policies are applicable to both hub-and-spoke and point-to-point VPN topologies. To apply these policies, specify a dynamic IP address for one of the peers in the topology and ensure that the dynamic crypto-map is enabled on this topology. In a full mesh VPN topology, you can apply only static crypto map policies.

IKEv2 Mode

For IPsec IKEv2 only, specify the encapsulation mode for applying ESP encryption and authentication to the tunnel. This determines what part of the original IP packet has ESP applied.

- **Tunnel mode**—(default) Encapsulation mode is set to tunnel mode. Tunnel mode applies ESP encryption and authentication to the entire original IP packet (IP header and data), hiding the ultimate source and destination addresses and becoming the payload in a new IP packet.

  The major advantage of tunnel mode is that you don't need to modify the end systems to receive the benefits of IPsec. This mode allows a network device, such as a router, to act as an IPsec proxy. That is, the router performs encryption on behalf of the hosts. The source router encrypts packets and forwards them along the IPsec tunnel. The destination router decrypts the original IP datagram and forwards it onto the destination system. Tunnel mode also protects against traffic analysis; with tunnel mode, an attacker can only determine the tunnel endpoints and not the true source and destination of the tunneled packets, even if they are the same as the tunnel endpoints.

- **Transport preferred**—Encapsulation mode is set to transport mode with an option to fall back to tunnel mode if the peer doesn't support it. In transport mode only the IP payload is encrypted, and the original IP headers are left intact. Therefore, the admin must select a protected network that matches the VPN interface IP address.

  This mode has the advantages of adding only a few bytes to each packet and allowing devices on the public network to see the final source and destination of the packet. With transport mode, you can enable special processing (for example, QoS) on the intermediate network based on the information in the IP header. However, the layer 4 header is encrypted, which limits examination of the packet.

- **Transport required**— Encapsulation mode is set to transport mode only, falling back to tunnel mode is allowed. If the endpoints can't successfully negotiate transport mode, due to one endpoint not supporting it, the VPN connection is not made.

Proposals

Click **Edit** (✎) to specify the proposals for your chosen IKEv1 or IKEv2 method. Select from the available **IKEv1 IPsec Proposals** or **IKEv2 IPsec Proposals** objects, or create and then select a new one. See Configure an IKEv1 IPsec proposal object, on page 2902 and Configure an IKEv2 IPsec proposal object, on page 2902 for details.

Enable Security Association (SA) Strength Enforcement

Enabling this option ensures that the encryption algorithm used by the child IPsec SA isn't stronger (in terms of the number of bits in the key) than the parent IKE SA.

Enable Reverse Route Injection

Reverse Route Injection (RRI) enables static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint.

Enable Perfect Forward Secrecy

Whether to use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint

devices. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the Modulus Group list.

Modulus Group

The Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. For a full explanation of the options, see Decide which Diffie-Hellman modulus group to use, on page 1508.

Lifetime Duration

The number of seconds a security association exists before expiring. The default is 28,800 seconds.

Lifetime Size

The volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before it expires. The default is 4,608,000 kilobytes. Infinite data isn't allowed.

ESPv3 Settings

Validate incoming ICMP error messages

Choose whether to validate ICMP error messages received through an IPsec tunnel and destined for an interior host on the private network.

Enable 'Do Not Fragment' Policy

Define how the IPsec subsystem handles large packets that have the do-not-fragment (DF) bit set in the IP header.

Policy

- Copy DF bit—Maintains the DF bit.
- Clear DF bit—Ignores the DF bit.
- Set DF bit—Sets and uses the DF bit.

Enable Traffic Flow Confidentiality (TFC) Packets

Enable dummy TFC packets that mask the traffic profile which traverses the tunnel. Use the **Burst**, **Payload Size**, and **Timeout** parameters to generate random length packets at random intervals across the specified SA.

Note You can enable dummy Traffic Flow Confidentiality (TFC) packets at random lengths and intervals on an IPsec security association (SA). You must have an IKEv2 IPsec proposal set before enabling TFC.

Enabling TFC packets prevents the VPN tunnel from being idle. Thus the VPN idle timeout configured in the group policy doesn't work as expected when you enable the TFC packets.

Firewall Threat Defense advanced site-to-site VPN deployment options

The sections describe the advanced options you can specify in your site-to-site VPN deployment. These settings apply to the entire topology, all tunnels, and all managed devices.

Firewall Threat Defense VPN advanced IKE options

Advanced > IKE > ISAKAMP settings

IKE Keepalive

Enable or disables IKE Keepalives. You can set this option to EnableInfinite so that the device never starts the keepalive monitoring itself.

Threshold
Specifies the IKE keep alive confidence interval. This interval is the number of seconds allowing a peer to idle before beginning keepalive monitoring. The minimum and default interval is 10 seconds; the maximum interval is 3600 seconds.

Retry Interval
Specifies number of seconds to wait between IKE keep alive retries. The default is 2 seconds, the maximum is 10 seconds.

Identity Sent to Peers:
Choose the identity that the peers will use to identify themselves during IKE negotiations:

- **autoOrDN**(default)—Determines IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication (not supported).
- **ipAddress**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
- **hostname**—Uses the fully qualified domain name of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.

Note Enable or disable this option for all your VPN connections.

Peer Identity Validation
During IKE tunnel establishment, the peer provides its identity: either an IP address, a Fully Qualified Domain Name (FQDN), or a Distinguished Name (DN). It also presents a certificate, which contains none, some, or all of these fields.

If IKE peer identity validation is enabled, the Firewall Threat Defense compares the peer's identity to the respective field in the certificate to see if the information matches. If the information matches, then the peer's identity is validated and the Firewall Threat Defense establishes the tunnel. If the information does not match, the tunnel is not established.

- **Do not check**—Firewall Threat Defense does not validate the peer identity.
- **Required**—Firewall Threat Defense validates the peer identity.
- **If supported by cert**—Firewall Threat Defense validates the peer identity only if the peer provides a certificate.

Enable Aggressive Mode
Select this negotiation method for exchanging key information if the IP address isn't known and DNS resolution might not be available on the devices. Negotiation is based on hostname and domain name.

Enable Notification on Tunnel Disconnect
Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA does not match the traffic selectors for that SA. This notification is disabled by default.

Advanced > IKE > IKEv2 security association (SA) settings

More session controls are available for IKE v2 that limit the number of open SAs. By default, there's no limit to the number of open SAs.

Cookie Challenge
Whether to send cookie challenges to peer devices in response to SA initiate packets, which can help thwart denial of service (DoS) attacks. The default is to use cookie challenges when 50% of the available SAs are in negotiation. Select one of these options:

- Custom
- Never (default)
- Always

Threshold to Challenge Incoming Cookies
The percentage of the total allowed SAs that are in-negotiation. This triggers cookie challenges for any future SA negotiations. The range is zero to 100%.

Number of SAs Allowed in Negotiation
Limits the maximum number of SAs that can be in negotiation at any time. If used with Cookie Challenge, configure the cookie challenge threshold lower than this limit for an effective cross-check.

Maximum number of SAs Allowed
Limits the number of allowed IKEv2 connections. Default is unlimited.

Enable Notification on Tunnel Disconnect
Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA doesn't match the traffic selectors for that SA. Sending this notification is disabled by default.

Firewall Threat Defense VPN advanced IPsec options

Advanced > IPsec > IPsec Settings

The advanced IPsec settings include these configuration options:

- **Enable Fragmentation Before Encryption**: This option lets traffic travel across NAT devices that don't support IP fragmentation. It doesn't impede the operation of NAT devices that do support IP fragmentation.
- **Path Maximum Transmission Unit Aging**: Check to enable Path Maximum Transmission Unit (PMTU) Aging, the interval to reset the PMTU of a Security Association (SA).
- **Value Reset Interval**: Enter the number of minutes at which the PMTU value of an SA is reset to its original value. The range is 10 to 30 minutes, default is unlimited.

Firewall Threat Defense advanced site-to-site VPN tunnel options

This topic lists the advanced site-to-site VPN tunnel options.

Navigation path

1. Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN**, click **Add**, and enter the topology name in the **Topology Name** field.
2. Click the **Policy-Based VPN** or **Route-Based VPN** radio button and select the VPN topology and click **Create**.
3. Click the **Advanced** tab, and select **Tunnel** in the left pane.

Tunnel options

Only available for Hub and Spoke, and Full Mesh topologies. This section doesn't appear for Point to Point configurations.

- **Enable Spoke to Spoke Connectivity through Hub**—Disabled by default. Choosing this field enables the devices on each end of the spokes to extend their connection through the hub node to the other device.

NAT settings

- **Keepalive Messages Traversal**—Enabled by default. This parameter is a global setting that enables NAT-T for all endpoints within a topology. Check this check box to enable keepalive messages for NAT traversal. NAT traversal keepalive is used for the transmission of keepalive messages when there's a device (middle device) located between a VPN-connected hub and spoke, and that device performs NAT on the IPsec flow.

  NAT traversal allows seamless communication between the peer Firewall Threat Defense devices when there are NAT devices between these devices. For hub and spoke topologies, this option is available only for the spoke.

  If you select this option, configure the **Interval**, in seconds, between the keepalive signals sent between the spoke and the middle device to indicate that the session is active. The value can be from 5 to 3600 seconds. The default is 20 seconds. You can disable this feature for an endpoint in a topology when you add it using the VPN wizard (**Enable NAT Traversal** check box in the **Add Endpoint** dialog box).

Session settings

- **Enable VPN Idle Timeout**—Enabled by default. This timeout is the amount of time that the VPN connection can be idle, without any activity in the tunnel, before it is disconnected. The default timeout is 30 minutes.

Bidirectional Forwarding Detection (BFD) settings

- **Enable Bidirectional Forwarding Detection Routing**—BFD is a failure detection protocol to detect forwarding path failures. This option enables BFD routing protocol on the SVTIs and DVTIs. When BFD detects a path failure, traffic is rerouted over the newly identified path.

  1. From the **Interval** drop-down list, choose the unit of interval, microseconds or milliseconds, at which BFD control packets are sent.
  2. In the **Multiplier** field, enter the number of consecutive missed BFD control packets allowed before declaring that the peer is unavailable. The range is 3 to 50 packets.

3. In the **Minimum Transmit and Receive Interval** field, enter the minimum transmit and receive interval of the BFD control packets. The range is 50 to 999 milliseconds or 50000 to 999000 microseconds.

Note BFD over VTI is supported only with Firewall Threat Defense or ASA devices as it requires the peer to advertise its tunnel IP address using the IKEv2 CFG_SET payload.

TrustSec (SGT) settings

- **Enable SGT propagation over Virtual Tunnel Interfaces**—Cisco TrustSec uses Security Group Tags (SGTs) to control access and enforce traffic on a network. This option enables SGT propagation over SVTIs and DVTIs of the VPN topology. To enable SGT propagation on a specific SVTI or DVTI, configure it in individual devices. Note that the Firewall Threat Defense device must be Version 10.0.0 and later.

Access control for VPN traffic

Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)—By default, the Firewall Threat Defense applies access control policy inspection on the decrypted traffic. Enable this option to bypass the ACL inspection. The Firewall Threat Defense still applies the VPN Filter ACL and authorization ACL downloaded from the AAA server to the VPN traffic.

Enable or disable the option for all your VPN connections. If you disable this option, ensure that the traffic is allowed by the access control policy or prefilter policy.

Note For route-based VPNs, **sysopt permit-vpn** does not work. You must always create access control rules to allow route-based VPN traffic.

Certificate map settings

- **Use the certificate map configured in the Endpoints to determine the tunnel**—If this option is enabled (checked), the tunnel is determined by matching the contents of the received certificate to the certificate map objects configured in the endpoint nodes.
- **Use the certificate OU field to determine the tunnel**—Indicates that if a node isn't determined based on the configured mapping (the above option) if selected, then use the value of the organizational unit (OU) in the subject distinguished name (DN) of the received certificate to determine the tunnel.
- **Use the IKE identity to determine the tunnel**—Indicates that if a node isn't determined based on a rule matching or taken from the OU (the above options) if selected, then the certificate-based IKE sessions are mapped to a tunnel based on the content of the phase1 IKE ID.
- **Use the peer IP address to determine the tunnel**—Indicates that if a tunnel isn't determined based on a rule matching or taken from the OU or IKE ID methods (the above options) if selected, then use the established peer IP address.

Configure virtual tunnel interfaces

Firewall Management Center supports a routable logical interface called the Virtual Tunnel Interface (VTI).

Virtual tunnel interfaces

A virtual tunnel interface is a routable logical interface that

- does not require static mapping of IPsec sessions to a physical interface
- associates the IPsec tunnel endpoint with a virtual interface, and
- supports static and dynamic routing policies.

Virtual tunnel interface capabilities

Firewall Management Center supports VTIs as an alternative to policy-based VPN. VTIs support route-based VPN with IPsec profiles attached to the end of each tunnel. VTIs use static or dynamic routes. The device encrypts or decrypts the traffic from or to the tunnel interface and forwards it according to the routing table. Deployments become easier, and having VTI which supports route-based VPN with dynamic routing protocol also satisfies many requirements of a virtual private cloud. Firewall Management Center enables you to easily migrate from crypto-map based VPN configuration to VTI-based VPN.

You can configure route-based VPN with static or dynamic VTI using the site-to-site VPN wizard. Traffic is encrypted using static route, BGP, OSPFv2/v3, or EIGRP.

You can create a routed security zone, add VTI interfaces to it, and define access control rules for the decrypted traffic control over the VTI tunnel.

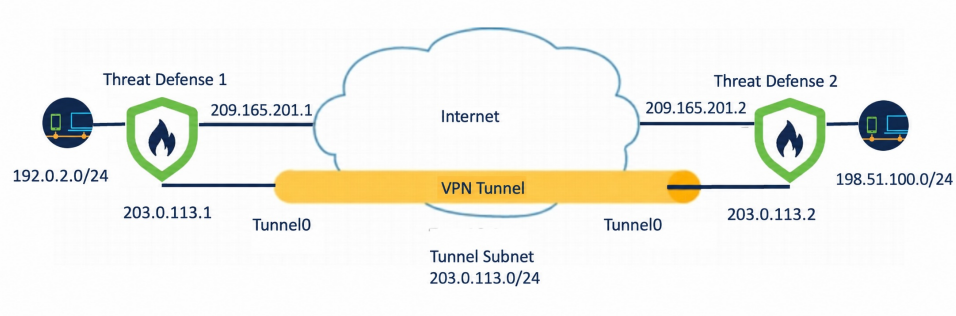
There are two types of VTI interfaces: static VTI and dynamic VTI.

You can create VTI-based VPNs between:

- Two Firewall Threat Defense devices.
- A Firewall Threat Defense and public cloud.
- One Firewall Threat Defense and another Firewall Threat Defense with service provider redundancy.
- A Firewall Threat Defense and any other device with VTI interfaces.
- A Firewall Threat Defense and another device with policy-based VPN configuration.

For more information, see Static VTI, on page 1538 and Dynamic VTI, on page 1540.

Static VTI



A static VTI is a virtual tunnel interface that

- uses tunnel interfaces to create a tunnel that is always-on between two sites
- requires defining a physical interface as a tunnel source, and
- supports a maximum of 1024 VTIs per device.

To create a static VTI interface in the Firewall Management Center, refer to Add a VTI interface, on page 1545.

The figure shows a VPN topology using static VTIs.

Figure 422: Static VTI VPN topology

On Threat Defense 1:

- Static VTI IP address is 203.0.113.1
- Tunnel source is 209.165.201.1
- Tunnel destination is 209.165.201.2

On Threat Defense 2:

- Static VTI IP address is 203.0.113.2
- Tunnel source is 209.165.201.2
- Tunnel destination is 209.165.201.1

Benefits of SVTI

Static VTI provides these benefits:

- Minimizes and simplifies configuration.

  You do not have to track all remote subnets for a crypto map access list, and configure complex access lists or crypto maps.

- Provides a routable interface.

  Supports IP routing protocols such as BGP, EIGRP, and OSPFv2/v3, and static routes.

- Supports backup VPN tunnels
- Supports load balancing using ECMP.
- Supports virtual routers.
- Provides differential access control for VPN traffic.

  You can configure a VTI with a security zone and use it in an AC policy. This configuration:

  - Allows you to classify and differentiate VPN traffic from clear-text traffic and permit VPN traffic selectively.

- Provides differential access-control for VPN traffic across different VPN tunnels.

Dynamic VTI

A dynamic VTI is a VPN interface that

- uses a virtual template for dynamic instantiation and management of IPsec interfaces
- dynamically generates a unique virtual access interface for each VPN session
- supports multiple IPsec security associations and accepts multiple IPsec selectors proposed by the spoke.

Benefits of dynamic VTI

- Minimizes and simplifies configuration.

  You do not have to configure complex access lists or crypto maps.

- Simplifies management.
  - Easily manage peer configuration for large enterprise hub and spoke deployments.
  - Use only one dynamic VTI for multiple spokes, instead of configuring one static VTI per spoke.
- Provides a routable interface.

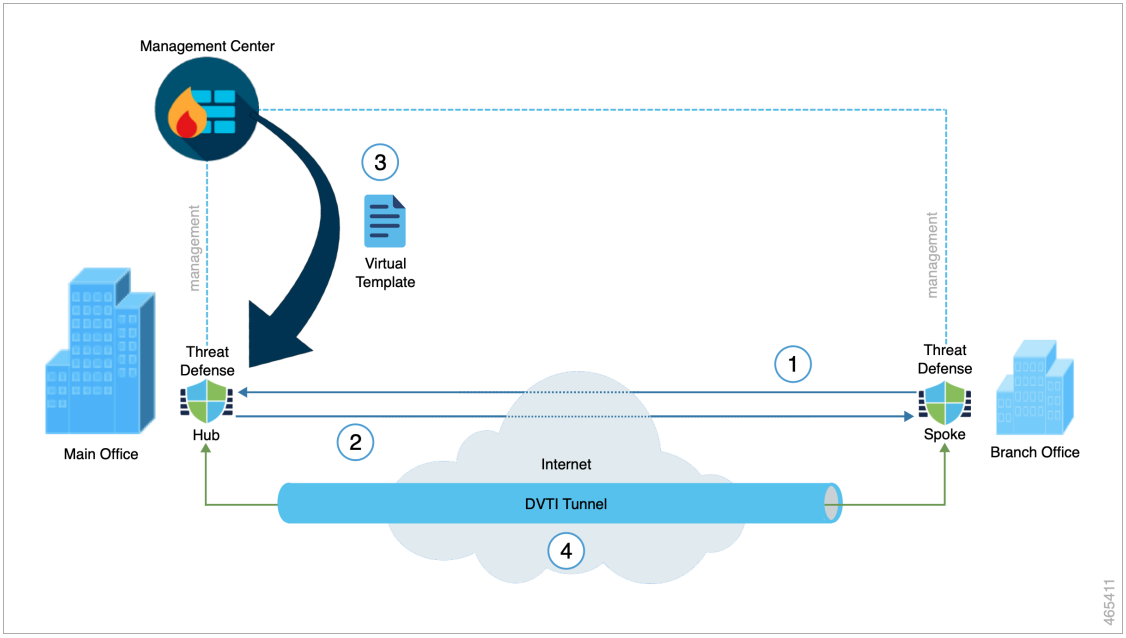
  Supports IP routing protocols such as BGP, EIGRP, and OSPFv2/v3.

- Simplifies scaling

  Addition of new spokes does not require any additional VPN configuration on the hub. You may need to update NAT and routing configurations depending upon the setup.

- Support for backup VPN tunnels.
- Supports dynamic spokes.

  You do not have to update the hub configuration for spoke's DHCP IP address changes.



- Conserves IP addresses.
  - Uses the IP unnumbered interface functionality to borrow the IP address from another physical or loopback interface.
  - All virtual access interfaces associated to a dynamic VTI use the same IP address.
- Supports virtual routers.
- Provides differential access control for VPN traffic.

  You can configure a VTI with a security zone and use it in an AC policy. This configuration:

  - Allows you to classify and differentiate VPN traffic from clear-text traffic and permit VPN traffic selectively.
  - Provides differential access-control for VPN traffic across different VPN tunnels.

How Does the Firewall Management Center Create a Dynamic VTI Tunnel for a VPN Session

When a spoke initiates a tunnel request with the hub:

1. The spoke initiates an IKE exchange with the hub for a VPN connection.
2. The hub authenticates the spoke.
3. The Firewall Management Center assigns a dynamic virtual template on the hub for the spoke.

   The virtual template dynamically generates a virtual access interface on the hub. This interface is unique for the VPN session with the spoke.
4. The hub establishes a dynamic VTI tunnel with the spoke using the virtual access interface.
   a. The hub and spoke exchange traffic over the tunnel using:
      - Specific traffic proposed by the spokes over IKE exchanges.
      - BGP/OSPF/EIRGP protocols over the IPsec tunnel.
   b. After the VPN session ends, the tunnel disconnects and the hub deletes the corresponding virtual access interface.

To create a dynamic VTI interface in the Firewall Management Center, see Add a VTI interface, on page 1545.

To configure a route-based site-to-site VPN using dynamic VTI, see Configure dynamic VTI for a route-based site-to-site VPN, on page 1558.

Virtual Routers and Dynamic VTI

You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. You can assign a dynamic VTI to only one virtual router.

A virtual router associated with:

- A dynamic VTI is called an Indoor VRF (IVRF).
- A tunnel source interface is known as Front Door VRF (FVRF).

A dynamic VTI and its corresponding protected network interface must be part of the same virtual router. You must map the borrow IP interface and the dynamic VTI to the same virtual router. A tunnel source interface can be part of multiple virtual routers.

To configure virtual routers using dynamic VTI for a route-based site-to-site VPN, refer to Configure a virtual router with dynamic VTI, on page 1558.

For more information about a configuration example, refer to Secure traffic from networks with multiple virtual routers over a site-to-site VPN with dynamic VTI, on page 1187

Guidelines for virtual tunnel interfaces

General configuration guidelines

- VTIs are only configurable in IPsec mode.
- Dynamic VTI supports only Firewall Threat Defense devices from Version 7.3.
- You can use static, BGP, EIGRP IPv4, OSPFv2/v3 routes for traffic using the tunnel interface.
- In an HA configuration with dynamic routing, the standby device cannot access the known subnets through the VTI tunnels as these tunnels are created with the active IP address.
- For static and dynamic VTI, ensure that you don't use the borrow IP interface as the tunnel source IP address for any VTI interface.
- When you configure a route-based site-to-site VPN using static or dynamic VTI interfaces, ensure that the value of the TTL hop is more than one if you use BGP.
- If NAT has to be applied, the IKE and ESP packets are encapsulated in the UDP header.
- Ensure that you remove unused transform sets from route-based IKE VPN configurations. If you have unused transform sets, the VPN tunnels may not come up and encapsulation and decapsulation will not happen. Use **show run crypto** and **show VPN-sessiondb detail l2l** commands to view the transform sets.

IPv6 address guidelines

- VTI supports IPv6 addresses.
- You can use an IPv6 address for the tunnel source interface and use the same address as the tunnel endpoint.
- The Firewall Management Center supports the following combinations of VTI IP (or internal networks IP version) over public IP versions: IPv6 over IPv6, IPv4 over IPv6, IPv4 over IPv4, and IPv6 over IPv4.
- VTI supports static and dynamic IPv6 addresses as the tunnel source and destination.
- The tunnel source interface can have IPv6 addresses and you can specify the tunnel endpoint address. If you don't specify the address, by default, the device uses the first IPv6 global address in the list as the tunnel endpoint.

IKE support and guidelines

- Static VTI supports IKE v1 and v2.
- Dynamic VTI supports only IKE version v2, and uses IPsec for sending and receiving data between the tunnel's source and destination.
- IKE and IPsec security associations are re-keyed continuously regardless of data traffic in the tunnel. This ensures that VTI tunnels are always up.
- Tunnel group name must match what the peer sends as its IKEv1 or IKEv2 identity.
- For IKEv1 in LAN-to-LAN tunnel groups, you can use names which aren't IP addresses, if the tunnel authentication method is digital certificates and/or the peer is configured to use aggressive mode.

MTU behavior

- MTU for VTIs is automatically set based on the underlying physical interface.
- For dynamic VTI, the virtual access interface inherits MTU from the configured tunnel source interface. If you don't specify the tunnel source interface, the virtual access interface inherits the MTU from the source interface from which the device accepts the VPN session request.

VTI scaling and guidelines

- Configure a maximum of 1024 static and dynamic VTIs in a device.

  While calculating the VTI count, consider nameif subinterfaces, portchannel configurations, and platform VLAN limitations.
- If you configure more than 400 VTIs in a device in a high-availability setup, configure 45 seconds as the unit holdtime.

Routing protocol support

VTI supports multiple routing protocols for different IP versions.

- VTI supports IPv6 BGP.
- VTI supports IPv4 EIGRP.
- VTI supports IPv4 and IPv6 OSPF.

ECMP configuration guidelines

- Configure spokes' static VTIs in an ECMP zone to load balance application traffic. If you do not configure the ECMP zone, the remaining paths act as backup paths when the primary path goes down.
- The VPN wizard allows you to enable ECMP on the virtual access interfaces associated with the hub's dynamic VTI. Hub device must be Version 10.0 and later for ECMP.
- You can associate VTI interfaces with ECMP zones and configure ECMP static routes to achieve these benefits:
  - Load balancing (Active/Active VTIs)—Connection can flow over any of the parallel VTI tunnels.
  - Seamless connection migration—When a VTI tunnel becomes unreachable, the flows are seamlessly migrated to another VTI interface that is configured in the same zone.

- Asymmetric routing—Forward traffic flow through one VTI interface and configure the reverse traffic flow through another VTI interface.

For information on configuring ECMP, see ECMP routing methods, on page 1209.

Access control rule guidelines

- By default, all traffic sent through a VTI is encrypted.
- Access control rules can be applied on a VTI interface to control traffic through VTI.
- For route-based VPNs, Bypass Access Control policy for decrypted traffic (**sysopt connection permit-VPN**) does not work. You must always create access control rules to allow route-based VPN traffic.

Crypto map guidelines

- If you use dynamic crypto maps and dynamic VTIs in your site-to-site VPNs, only the dynamic VTI tunnels will come up. This behaviour occurs because both the crypto maps and dynamic VTIs try to use the default tunnel group. We recommend that you migrate your site-to-site VPNs to dynamic VTIs or use static crypto maps with their own tunnel-groups.
- VTI and crypto map configurations can coexist on the same physical interface if the peer address configured in the crypto map and the tunnel destination for the VTI are different.

Topology guidelines

- Dynamic VTI supports only the hub and spoke topology in the Firewall Management Center.
- We recommend that you configure only a single hub for a route-based hub and spoke topology. To configure a topology with multiple hubs for a set of spokes, with one hub as the backup hub, configure multiple topologies with a single hub and the same set of spokes.

Dynamic VTI and virtual router guidelines

- A dynamic VTI and its corresponding protected network interface must be part of the same virtual router.
- You must map the borrow IP interface and the dynamic VTI to the same virtual router.
- User-defined virtual routers support only BGPv4/v6 and OSPFv2 routing protocols.
- A tunnel source interface can be in a different user-defined virtual router than that associated with the dynamic VTI.

Firewall mode guideline

Configure VTI only in routed mode.

Limitations for Virtual Tunnel Interfaces

This topic lists the limitations for configuring Virtual Tunnel Interfaces in Firewall Management Center.

General limitations

- VTIs do not support clustering.

- VTI tunnel interfaces are not supported for SNMP or Syslog in Platform Settings.

Static VTI limitations

- Only 20 unique IPSec profiles are supported.
- In policy-based routing, you can configure VTI only as an egress interface.
- You cannot configure a VTI interface as a network interface for a remote access VPN policy.

Dynamic VTI limitations

- Dynamic VTI does not support ECMP , VRF in multi-instance, Clustering, IKEv1, or QoS.
- If a spoke has a dynamic IP address and a hub has a dynamic VTI behind a NAT, the tunnel status will be unknown.
- For a dynamic extranet, when multiple spokes establish a connection, the site-to-site monitoring dashboard does not show the individual tunnels.
- If you configure a hub with dynamic VTI behind NAT with dynamic spokes, the VPN monitoring data will not be accurate.
- You cannot configure a VTI interface as a network interface for a remote access VPN policy.

Backup VTI limitations

- Flow resiliency across tunnel failovers isn't supported. For example, the clear text TCP connection gets lost after a tunnel failover, and you need to reinitiate any FTP transfer that took place during the failover.
- Certificate authentication isn't supported in backup VTI.

Add a VTI interface

For configuring a route-based site-to-site VPN, you must create a VTI interface on the devices at both the nodes of the VTI tunnel.

When you specify the tunnel type as dynamic and configure the related parameters, the Firewall Management Center generates a dynamic virtual template. The virtual template dynamically generates the virtual access interface that is unique for each VPN session.

Before you begin

Configure a loopback interface for redundancy of static and dynamic VTI VPN tunnels. For more information, see Configure a loopback interface, on page 795.

For a Secure Firewall 1200/3100/4200/6100 /200device, IPsec flow offload is also used when the device's VTI loopback interface is enabled.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click the **Edit** icon next to the device on which you want to create a VTI interface.

Step 3 Choose **Add Interfaces > Virtual Tunnel Interface**.

In the **Add Virtual Tunnel Interface** dialog box, configure these parameters:

a) Select the **Tunnel Type** as **Static** or **Dynamic**, and enter the name and description for the interface. By default, the interface is enabled.

b) (Optional) Choose a security zone from the **Security Zone** drop-down list to add the static VTI or dynamic VTI interface to that zone. In the **Priority** field, enter the priority to load balance the traffic across multiple VTIs.

If you want to perform traffic inspection based on a security zone, add the VTI interface to the security zone and configure an access control (AC) rule. To permit the VPN traffic over the tunnel, you need to add an AC rule with this security zone as the source zone.

The priority range is from 0 to 65535. The lowest number has the highest priority. This option is not applicable for dynamic VTI.

c) **Security Group Tag** configuration:

Check the **Propagate Security Group Tag** check box to enable Security Group Tag (SGT) propagation over the VTI.

TrustSec uses SGTs to control access and enforce traffic on a network. To enable SGT propagation over SVTIs and DVTIs of a VPN topology, check the **Enable SGT propagation over Virtual Tunnel Interfaces** check box in the **Advanced > Tunnel** tab of the VPN wizard.

Check the **Enforce Inline Security Group Tag** check box to enable inline SGT tagging over the static VTI interface. Use this option only when the tunnel peer cannot perform Cisco Vendor ID negotiation for SGT.

d) Depending on the tunnel type, do one of the following:

- For a dynamic VTI, enter a unique ID in the range of 1 to 10413 in the **Template ID** field.
- For a static VTI, enter a unique tunnel ID in the range of 0 to 10413 in the **Tunnel ID** field.

e) (Optional for dynamic VTI) Choose the tunnel source interface from the **Tunnel Source** drop-down list.

The VPN tunnel terminates at this interface, a physical or loopback interface. Choose the IP address of the interface from the drop-down list. You can select the IP address irrespective of the IPsec tunnel mode. In case of multiple IPv6 addresses, select the address that you want to use as the tunnel endpoint.

f) Under **IPSec Tunnel Mode**, click the **IPv4** or **IPv6** radio button to specify the traffic type over the IPsec tunnel.

g) Under **IP Address**:

- **Configure IP**: Enter the IPv4 or IPv6 address for the static VTI interface. You cannot configure an IP address for a dynamic VTI interface. Use the **Borrow IP** field for the dynamic VTI interface.
- **Borrow IP (IP unnumbered)**: Choose a physical or loopback interface from the drop-down list, the VTI interface inherits this IP address.

  Ensure that you use an IP address different from the tunnel source IP address. You can use this option for a static or dynamic VTI interface.

Click Add + to configure a loopback interface. The loopback interface helps to overcome path failures. If an interface goes down, you can access all interfaces through the IP address assigned to the loopback interface.

Step 4 Click **OK**.

Step 5 Click **Save**.

Create a route-based site-to-site VPN

You can configure a route-based site-to-site VPN for the following two topologies:

- **Point to Point**: Configure VTIs on both nodes of the tunnel and use the wizard to configure the VPN.
- **Hub and Spoke**: Configure VTIs on the hub and the spokes. Configure the hub with a dynamic VTI and spokes with static VTIs.

You can configure an extranet device as the hub and managed devices as spokes. You can configure multiple hubs and spokes, and also configure backup hubs and spokes.

- For extranet hubs and spokes, you can configure multiple IPs as backup.
- For managed spokes, you can configure a backup static VTI interface along with the primary VTI interface.

For more information on VTI, see Virtual tunnel interfaces, on page 1538.

Note All references to VTI stands for static VTI and dynamic VTI, unless mentioned.

Procedure

Step 1 Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN**, and click **Add**.

Step 2 Enter a name for the VPN topology in the **Topology Name** field.

Step 3 Choose **Route Based (VTI)** and do one of the following:

- Select **Point to Point** as the network topology. To configure endpoints for a route-based **Point to Point** topology, refer to Configure endpoints for a point-to-point route-based VPN topology, on page 1548.
- Select **Hub and Spoke** as the network topology. To configure endpoints for a route-based **Hub and Spoke** topology, refer to Configure endpoints for a hub and spoke route-based VPN topology, on page 1550.

Step 4 Click **Create**.

Step 5 (Optional) Specify the **IKE**, **IPsec**, and **Advanced** options and click **Save**.

For more information, refer to these topics:

- Firewall Threat Defense VPN IKE options, on page 1529

- Firewall Threat Defense VPN IPsec options, on page 1531
- Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1533

What to do next

After you configure VTI interfaces and VTI tunnel on both the devices, you must configure:

- A routing policy to route the VTI traffic between the devices over the VTI tunnel. For more information, refer to Configure routing and AC policies for VTI, on page 1559.
- An access control rule to allow encrypted traffic. Choose **Policies** > **Access Control**.

Configure endpoints for a point-to-point route-based VPN topology

Configure these parameters to configure endpoints for a route-based site-to-site VPN for the **Point to Point** topology nodes:

Before you begin

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in Create a route-based site-to-site VPN, on page 1547 and click the **Endpoints** tab.

Procedure

Step 1 Under **Node A**, in the **Device** drop-down menu, select the name of the registered device (Firewall Threat Defense) or extranet as the first endpoint of your VTI tunnel.

For an extranet peer, specify the following parameters:

a. Specify the name of the device.

b. Enter the primary IP address in the **Endpoint IP address** field. If you configure a backup VTI, add a comma and, specify the backup IP address.

c. Click **OK** .

After configuring the above parameters for the extranet hub, specify the pre-shared key for the extranet in the **IKE** tab.

Note The AWS VPC has **AES-GCM-NULL-SHA-LATEST** as the default policy. If the remote peer connects to AWS VPC, select **AES-GCM-NULL-SHA-LATEST** from the **Policy** drop-down list to establish the VPN connection without changing the default value in AWS.

Step 2 For a registered device, you can specify the VTI interface for Node A from the **Virtual Tunnel Interface** drop-down list.

The selected tunnel interface is the source interface for Node A and the tunnel destination for Node B.

If you want to create a new interface on Node A, click the Add + icon and configure the fields as described in Add a VTI interface, on page 1545 .

If you want to edit the configuration of an existing VTI, select the VTI in the **Virtual Tunnel Interface** drop-down field and click **Edit VTI**.

Step 3 If your Node A device is behind a NAT device, check the **Tunnel Source IP is Private** check box. In the **Tunnel Source Public IP Address** field, enter the tunnel source public IP address.

Step 4 **Send Local Identity to Peers**—Select this option to send local identity information to the peer device. Select one of the following **Local Identity Configuration** from the list and configure the local identity:

- **IP address**—Use the IP address of the interface for the identity.
- **Auto**—Use the IP address for pre-shared key and Cert DN for certificate-based connections.
- **Email ID**—Specify the email ID to use for the identity. The email ID can be up to 127 characters.
- **Hostname**—Use the fully qualified hostname.
- **Key ID**—Specify the key-id to use for the identity. The key ID must be fewer than 65 characters.

The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows Firewall Threat Defense to have multiple IPsec tunnels behind a NAT to connect to a Cisco Umbrella Secure Internet Gateway (SIG).

For information about configuring a unique tunnel ID on Umbrella, refer to Cisco Umbrella SIG User Guide.

Step 5 (Optional) Click **Add Backup VTI** to specify an extra VTI as the backup interface and configure the parameters.

Note Ensure that both peers of the topology do not have the same tunnel source for the backup VTI. A device cannot have two VTIs with the same tunnel source and tunnel destination; hence, configure a unique tunnel source and tunnel destination combination.

Though the virtual tunnel interface is specified under Backup VTI, the routing configuration determines which tunnel to be used as primary or backup.

Step 6 Expand **Advance Settings** to configure additional configurations for the device. For more information, see Configure advanced settings for a point-to-point topology in a route-based VPN, on page 1550.

Step 7 Repeat the above procedure for Node B and click **OK** .

What to do next

- (Optional) Specify the **IKE** options for the deployment as described in Firewall Threat Defense VPN IKE options, on page 1529.
- (Optional) Specify the **IPsec** options for the deployment as described in Firewall Threat Defense VPN IPsec options, on page 1531.
- (Optional) Specify the **Advanced** options for the deployment as described in Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1533.
- Click **Save**.

- To route traffic to the VTI, choose **Devices** > **Device Management** , edit the threat defense device and click the **Routing** tab.

  You can configure the static routes, or use BGP, OSPF v2/v3, or EIGRP for routing the VPN traffic.

- To permit VPN traffic, choose **Policies** > **Security policies** > **Access Control**. Add a rule specifying the security zone of the VTI. For a backup VTI, ensure that you include the backup VTI in the same security zone as that of the primary VTI.

Configure advanced settings for a point-to-point topology in a route-based VPN

Configure advanced settings to enhance the functionality and security of a point-to-point topology in a route-based VPN beyond the basic configuration parameters.

Before you begin

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in Configure endpoints for a point-to-point route-based VPN topology, on page 1548 and expand **Advance Settings**.

Procedure

Step 1 Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.

Step 2 Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the spokes and peers.

Step 3 Choose one of the following from the **Connection Type** drop-down list:

Answer Only: The device can only respond when a peer device initiates a connection, it can't initiate any connection.

Bidirectional: The device can initiate or respond to a connection. This is the default option.

Configure endpoints for a hub and spoke route-based VPN topology

You can create a route-based site-to-site VPN using dynamic VTI only for hub and spoke topologies. The hub can use only a dynamic VTI and the spokes can use only static VTI interfaces. You can also configure an extranet device as a hub.

Configure these parameters to configure endpoints for a route-based site-to-site VPN for the **Hub and Spoke** topology nodes:

Before you begin

Configure the basic parameters for a hub and spoke topology in a route-based VPN as described in Create a route-based site-to-site VPN, on page 1547 and click the **Endpoints** tab.

Procedure

Step 1 Under **Hub Nodes**:

a) Click Add + to configure the hub node in the **Add Endpoint** dialog box.
b) Choose a hub from the **Device** drop-down list.

For an extranet hub, configure these parameters:

1. Enter the name of the device.
2. Enter the primary IP address. If you configure a backup VTI, add a comma, and then specify the backup IP address.
3. Click **OK**.

After configuring the above parameters for the extranet hub, specify the pre-shared key for the extranet in the **IKE** tab.

Note The AWS VPC has **AES-GCM-NULL-SHA-LATEST** as the default policy. If the remote peer connects to AWS VPC, select **AES-GCM-NULL-SHA-LATEST** from the **Policy** drop-down list to establish the VPN connection without changing the default value in AWS.

c) Choose a dynamic VTI from the **Dynamic Virtual Tunnel Interface** drop-down list.

Tunnel source configuration is mandatory for a dynamic VTI as the management center needs this information to determine the tunnel destination of the spoke.

Click Add + to add a new dynamic VTI. We recommend that you configure the Borrow IP for the dynamic interface from a loopback interface.

If you want to edit an existing dynamic VTI, select the interface, and click **Edit VTI**.

d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box and configure the tunnel source IP address in the **Tunnel Source Public IP Address** field.
e) Click **Routing Policy** to configure the routing policy for the hub.
f) Click **AC Policy** to configure the access control policy.
g) Expand **Advance Settings** to configure additional configurations on the hub. For more information, see Configure advanced settings for hub and spokes in a route-based VPN, on page 1553 .
h) Click **OK**.
i) Check the **ECMP** check box to enable ECMP on the dynamic VTIs of hub devices with Version 10.0 or later. All virtual access interfaces on the hub connecting to the same spoke are grouped into an ECMP zone.

Note that this option does not enable ECMP on the spoke SVTIs. You must manually enable ECMP on the spoke SVTIs.

Step 2 Under **Spoke Nodes**:

a) Click Add + to configure the spoke in the **Add Endpoint** dialog box.
b) Choose a spoke from the **Device** drop-down list.

For an extranet spoke, configure these parameters:

1. Enter the name of the device.
2. In **Endpoint IP Address**, choose one of these options:
   - **Static**: Enter the IP address of the device, and the backup IP address, if required.

- **Dynamic**: Choose this option to dynamically assign the IP addresses for the extranet spokes.

3. Click **OK**.

c) Choose a static VTI from the **Static Virtual Tunnel Interface** drop-down list.

Click Add + to add a new static VTI. Tunnel IP of the static VTI is auto populated, ensure that this IP address is unique for the spoke.

If you want to edit an existing static VTI, select the interface, and click **Edit VTI**.

d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box. The Firewall Management Center needs the tunnel source interface address to configure the tunnel destination IP address on the spokes. In the **Tunnel Source Public IP Address** field, enter the tunnel source public IP address.

e) (Optional) **Send Local Identity to Peers**—Check this check box to send the local identity information to the peer device. Choose one of the following parameters from the **Local Identity Configuration** drop-down list and configure the local identity:

- **IP address**—Use the IP address of the interface for the identity.
- **Auto**—Use the IP address for pre-shared key and Cert DN for certificate-based connections.
- **Email ID**—Specify the email ID to use for the identity. The email ID can be up to 127 characters.
- **Hostname**—Use the fully qualified hostname.
- **Key ID**—Specify the key-id to use for the identity. The key ID must be less than 65 characters.

The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows Firewall Threat Defense to have multiple IPsec tunnels behind a NAT to connect to the Cisco Umbrella Secure internet Gateway (SIG).

For more information about configuring a unique tunnel ID on Umbrella, see Cisco Umbrella SIG User Guide.

f) (Optional) Click **Add Backup VTI** to specify an extra VTI interface as the backup interface.

Note Ensure that both peers of the topology do not have backup VTI configured on the same tunnel source. For instance, if Peer A is having two VTIs (primary and a backup) configured with a single tunnel source interface, say, 10.10.10.1/30, then Peer B also can't have its 2 VTIs with a single tunnel source IP, say 20.20.20.1/30.

Though the virtual tunnel interface is specified under backup VTI, the routing configuration determines which tunnel to be used as primary or backup.

g) Click **Routing Policy** to configure the routing policy for the spoke.

h) Click **AC Policy** to configure the access control policy.

i) Expand **Advance Settings** to configure additional configurations on the spoke and click **OK** . For more information, see Configure advanced settings for hub and spokes in a route-based VPN, on page 1553.

What to do next

1. (Optional) Specify the **IKE** options for the deployment as described in Firewall Threat Defense VPN IKE options, on page 1529.
2. (Optional) Specify the **IPsec** options for the deployment as described in Firewall Threat Defense VPN IPsec options, on page 1531.
3. (Optional) Specify the **Advanced** options for the deployment as described in Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1533.
4. Click **Save**.

Configure advanced settings for hub and spokes in a route-based VPN

After configuring basic parameters for a hub and spoke in a route-based VPN, you can configure additional advanced settings to optimize the VPN topology's functionality and performance.

Before you begin

Configure the basic parameters for a hub and spoke in a route-based VPN as described in Configure endpoints for a hub and spoke route-based VPN topology, on page 1550 and expand **Advance Settings**.

Procedure

Step 1 Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.

For a hub, you must check this check box if you use BGP as the routing protocol. This configuration ensures that the loopback IP address is shared in the BGP routing table.

For a spoke, this option is enabled by default.

Step 2 Add the **Protected Networks** to define the networks protected by the VPN endpoint. Click Add + to select a protected network.

For a hub, configure the protected networks behind the hub. This information and the spoke's protected network generate the spoke access list.

You cannot create a static route for a virtual access interface on a hub with dynamic VTI. The hub creates and deletes these interfaces dynamically during tunnel establishment and termination.

For a spoke, configure the spoke's protected network.

To enable static routing for the spokes, after you configure the endpoints for your topology, click the **IPsec** tab and check the **Enable Reverse Route Injection** check box.

You do not need this option if you use BGP, OSPF, or EIGRP.

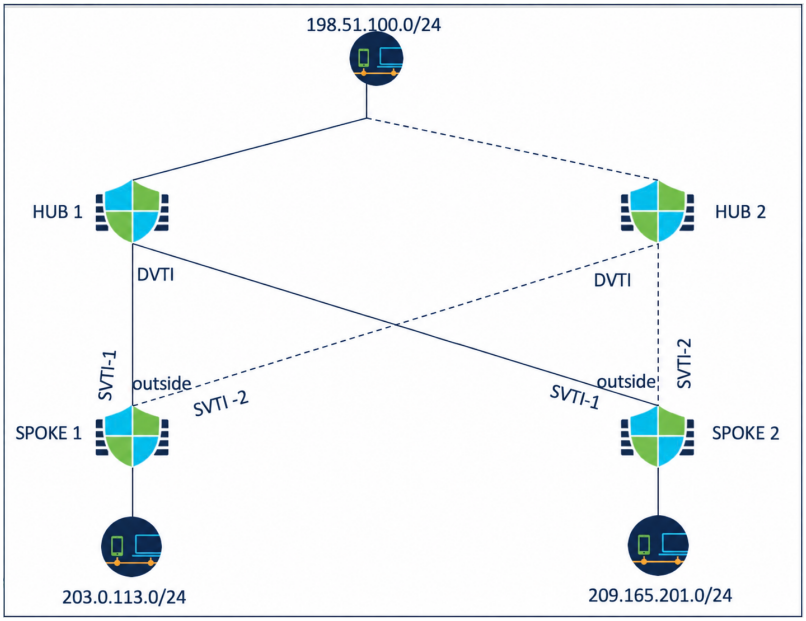
Step 3 Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the spokes and peers.

For a hub: During an IKE exchange, the hub advertises the dynamically created virtual access interfaces to the spokes, and the spokes advertise their VTI IP addresses to the hub.

For a spoke: By default, this option is enabled.

Step 4 In the **Connection Type** drop-down list, choose one of the following:

Answer Only: The device can only respond when a peer device initiates a connection, it can't initiate any connection.



Bidirectional: The device can initiate or respond to a connection. This is the default option.

Configure multiple hubs in a route-based VPN

You can configure a topology with multiple hubs for a set of spokes. With one hub as the backup hub, you can configure multiple topologies with a single hub and the same set of spokes.

In this example, there are two hubs connected to the same set of spokes. Hub 1 is the primary hub and Hub 2 is the secondary hub. To configure this network in the Firewall Management Center, you must configure two route-based hub and spoke topologies:

- Topology 1: Hub 1 connected to spoke 1 and spoke 2.
- Topology 2: Hub 2 connected to spoke 1 and spoke 2.

To configure topology 1:

Procedure

Step 1 Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN**, and click **Add**.

Step 2 Enter a name for the VPN topology in the **Topology Name** field.

Step 3 Choose **Route Based (VTI)** and do one of these topologies:

- Select **Point to Point** as the network topology. To configure endpoints for a route-based **Point to Point** topology, see Configure endpoints for a point-to-point route-based VPN topology, on page 1548.

- Select **Hub and Spoke** as the network topology. To configure endpoints for a route-based **Hub and Spoke** topology, see Configure endpoints for a hub and spoke route-based VPN topology, on page 1550.

Step 4 Click **Create**.

Step 5 Configure the IKE version and click the **Endpoints** tab.

Step 6 Under **Hub Nodes**:

a) Click Add + to add the hub.
b) Choose Hub 1 from the **Device** drop-down list.
c) Choose a dynamic VTI from the **Dynamic Virtual Tunnel Interface** drop-down list or click Add + to add a new dynamic VTI.

We recommend that you configure the Borrow IP for the dynamic interface from a loopback interface.

d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box and configure the tunnel source IP address in the **Tunnel Source Public IP Address** field.
e) Click **Routing Policy** to configure the routing policy for the hub. You can configure dynamic routing using BGP.
f) Expand **Advance Settings**. You can configure these advanced settings for the hub to enable IKEv2 routing, which can be used if you do not use dynamic routing.

- (Optional) Check the **Send Virtual Tunnel Interface IP to the peers** check box.
- Check the **Allow incoming IKEv2 routes from the peers** check box for the hub to accept routes from the spokes and update the routing table.
- Choose **Connection Type** as Bidirectional from the drop-down list.

g) Click **OK**.

Step 7 Under **Spoke Nodes**:

a) Click Add + to add a spoke.
b) Choose Spoke 1 from the **Device** drop-down list.
c) Choose SVTI-1 as the static VTI for the spoke from the **Static Virtual Tunnel Interface** drop-down list or click Add + to add a new static VTI.

Choose the outside interface as the tunnel source of SVTI-1. Tunnel IP of SVTI-1 is autopopulated, ensure that this IP address is unique for spoke 1 across peers in both the topologies.

d) Expand **Advance Settings**. If you do not use dynamic routing, you can configure these settings to enable IKEv2 routing for the spoke.

- Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.
- Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the peers.
- Choose **Connection Type** as Bidirectional from the drop-down list.

e) Click **OK**.
f) Repeat steps 5a to 5e to add spoke 2. Configure SVTI-1 as the static VTI of spoke 2.

Step 8 Configure the IKE and IPSec parameters as required or use the default values.

What to do next

1. Configure topology 2 with hub 2, spoke 1, and spoke 2.

   Configure SVTI-2 as the static VTI of spoke 1 and SVTI-2 as the static VTI of spoke 2 (refer the above illustration). Tunnel source for SVTI-2 should be the same outside interface.

2. For each spoke, configure the routing policy. For more information, see Configure routing for multiple hubs in a route-based VPN, on page 1556.

3. Verify the configuration and tunnel statuses. For more information, see Verify multiple hubs configuration in a route-based VPN, on page 1557.

Configure routing for multiple hubs in a route-based VPN

Configure dynamic routing using BGP on both hub and spoke devices, and implement Policy Based Routing on spokes to enable proper traffic routing in a route-based VPN topology with multiple hubs.

Before you begin

Configure topology 1 and 2 as explained in Configure multiple hubs in a route-based VPN, on page 1554.

Procedure

Step 1 Configure dynamic routing for the hub using BGP.

a) Choose **Devices** > **Device Management**, and click **Edit** (✎) then click the **Routing** tab.
b) In the left pane, choose **General Settings** > **BGP**.
c) Check the **Enable BGP** check box and enter the **AS number**.

   You can configure the other fields AS per your requirement.

d) Click **Save**.
e) On the left pane, choose **BGP** > **IPv4**.
f) Check the **Enable IPv4** check box.
g) Click the **Neighbor** tab, click **Add** and configure these parameters.

   1. **IP Address**: Enter the tunnel interface IP address of Spoke 1.
   2. **Remote AS**: AS number of Spoke 1.
   3. Check the **Enabled Address** check box.
   4. Click **OK**.

   Repeat the above steps to add Spoke 2 as a neighbor.

h) Click **Save**.
i) Click the **Networks** tab and click **Add** to advertise the network behind the hub to the peers.

Step 2 Configure dynamic routing for the spokes using BGP.

The BGP configuration for the spokes is similar to that of the hub except for these differences:

- Configure Hub 1 and Hub 2 AS the neighbors for both the spokes and use the tunnel interface IP address of the hubs.
- When you configure networks, use the network behind each spoke.

Step 3 Configure Policy Based Routing on the spokes.

a) In the left pane, choose **Policy Based Routing** and click **Add**.
b) Choose the **Ingress Interface** from the drop-down list.
c) Click **Add** to configure a Match ACL.

For example, for spoke 1, source network is 192.168.20.0/24 and destination network is 192.168.10.0/24.

d) Choose Egress Interfaces from the **Send to** drop-down list.
e) Choose Order from the **Interface Ordering** drop-down list.
f) Select the SVTI-1 and SVTI-2 interfaces AS the egress interfaces.
g) Click **Save**.

If you want to use the hubs as a load-balancing pair, you must configure ECMP.

Step 4 Deploy the configurations on the hub and spokes.

What to do next

Verify the configurations and tunnel statuses. For more information, see Verify multiple hubs configuration in a route-based VPN, on page 1557.

Verify multiple hubs configuration in a route-based VPN

To verify the multiple hub configurations and the tunnel statuses.

- After the deployment, check the tunnel status in the dashboards.
- Use **Packet Trace**r from the **Site-to-Site VPN dashboard** to verify the selected path of the traffic (hub 1 or hub 2).
- Use these show commands for each endpoint to verify the configurations:
  - **show run route-map**
  - **show run access-list**
  - **show route-map**
  - **show route**

Route traffic through a backup VTI tunnel

A backup VTI tunnel ensures traffic continuity by providing an alternative path when the primary VTI tunnel fails to route traffic in route-based VPN configurations.

You can deploy the backup VTI tunnel in these scenarios:

- Both peers having service provider redundancy backup.

  In this case, there are two physical interfaces, acting as the tunnel sources for the two VTIs of the peers.

- Only one of the peers has service provider redundancy backup.

  In this case, there's an interface backup on only one side of the peer and on the other end, there is only one tunnel source interface.

Before you begin

Ensure that you review the guidelines and limitations. For more information, refer to Guidelines for virtual tunnel interfaces, on page 1542.

Procedure

Step 1 Create the VTI interface.

For more information, refer to Add a VTI interface, on page 1545

Step 2 In the **Add Endpoint** dialog box of the **Create New VPN Topology** wizard, click **Add Backup VTI** to configure the respective backup interface for each peer.

For more information, refer to

- Configure endpoints for a point-to-point route-based VPN topology, on page 1548
- Configure endpoints for a hub and spoke route-based VPN topology, on page 1550

Step 3 Choose **Devices > Device Management**, and edit the threat defense device and click **Routing** to configure the routing policy.

Step 4 Choose **Policies > Access Control** to configure the access control policy.

Configure dynamic VTI for a route-based site-to-site VPN

To configure dynamic VTI for a route-based site-to-site VPN in the Management Center:

Step	Do This	More Information
1	Create a dynamic VTI interface on the hub.	Add a VTI interface, on page 1545
2	Create static VTI interfaces on the spokes.	Add a VTI interface, on page 1545
3	Create a route-based site-to-site VPN.	Create a route-based site-to-site VPN, on page 1547
4	Configure the routing policy and the access control policy.	Configure endpoints for a hub and spoke route-based VPN topology, on page 1550

Configure a virtual router with dynamic VTI

To configure a virtual router with dynamic VTI for a route-based site-to-site VPN in the Management Center:

Step	Do This	More Information
1	Create a route-based site-to-site VPN with a dynamic VTI interface on the hub and static VTI(s) on the spoke(s).	Create a route-based site-to-site VPN, on page 1547
2	Create a virtual router.	Create a virtual router, on page 1164
3	Assign the interfaces to the virtual router.	Configure a virtual router, on page 1165
4	Configure routing policies for the hub and spoke.	Configure endpoints for a hub and spoke route-based VPN topology, on page 1550
5	Configure access control policies for the hub and spoke.	Configure endpoints for a hub and spoke route-based VPN topology, on page 1550

Configure routing and AC policies for VTI

After you configure VTI interfaces and the VTI tunnel on both the devices, you must configure these parameters:

- A routing policy to route VTI traffic between the devices over the VTI tunnel.
- An access control rule to allow encrypted traffic.

Procedure

Step 1 Configure routing for VTI interfaces.

For the VTI interfaces, you can configure static route or routing protocols such AS BGP, EIGRP, OSPF/OSPFv3.

a. Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b. Click **Routing**.

c. Configure static route, or BGP, EIGRP, OSPF/OSPFv3.

Routing	Parameters	More Information
Static Route	• **Interface**—Select the VTI interface. For a backup tunnel, select the backup VTI interface. • **Selected Network**—Remote peer's protected network. • **Gateway**—Remote peer's tunnel interface IP address. For a backup tunnel, select the remote peer's backup tunnel interface IP address. • **Metric**—For a backup tunnel, configure a different metric to handle the failover of the traffic flow over the backup tunnel. **Note** DVTI does not support static routes.	Add a static route, on page 1139

BGP	• Under **General Settings** > **BGP**, enable BGP, provide the AS number of the local device, and add Router ID (if you choose Manual).
	• Under **BGP**, enable IPv4/IPv6 and click the **Neighbor** tab to configure the neighbors.
	  • **IP Address**—Remote peer's VTI interface IP address. For a backup tunnel, add a neighbor with the remote peer's backup VTI interface IP address.
	  • **Remote AS**—Remote peer's AS number.
	• Click the **Redistribution** tab, select the **Source Protocol** AS Connected to enable connected route redistribution.
		Configure BGP, on page 1274

Routing	Parameters	More Information
EIGRP	• Enable EIGRP, provide the AS number of the local device, and select the networks or hosts that participate in the EIGRP routing process. • Click the **Neighbors** tab and define the static neighbors for the EIGRP process. • To advertise summary addresses from a VTI interface, click the **Summary Address** tab, choose the VTI interface from the **Interface** drop-down. From the **Network** drop-down, choose the network to be summarized. • Click the **Interfaces** tab to configure the interface-specific EIGRP routing properties for the VTI interface. To enable EIGRP split-horizon on the interface, check the **Split Horizon** check box. You can also configure the **Hold Time** that is advertised by the device in the EIGRP hello packets.	Configure EIGRP routing on firewall devices, on page 1260
OSPF	• Check the **Process 1** check box, and choose the OSPF role. • Click the **Interface** tab and choose a VTI interface.	OSPFv2 configuration, on page 1232
OSPFv3	• Check the **Process 1** and **Enable Process 1** check boxes, and choose the OSPFv3 role. • Click the **Interface** tab and choose a VTI interface.	OSPFv3 configuration, on page 1245

Step 2 Add an access control rule to the access control policy on the device to allow encrypted traffic between the VTI tunnels with these settings:

a. Create the rule with the Allow action.

b. Select the VTI security zone of the local device AS the source zone and the VTI security zone of the remote peer AS the destination zone.

c. Select the VTI security zone of the remote peer AS the source zone and the VTI security zone of the local device AS the destination zone.

For more information about configuring an access control rule, see Create and edit access control rules, on page 1848.

View virtual tunnel interface details

You can view details of dynamic and static VTIs of route-based VPNs on the device. For every VPN topology, you can also view details of all the dynamically generated virtual access interfaces associated with each dynamic VTI.

Before you begin

- Supported device for static VTIs: Firewall Threat Defense Version 7.0 and later
- Supported device for dynamic VTIs: Firewall Threat Defense Version 7.3 and later

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click the **Virtual Tunnels** tab.

For each VTI, you can view details such as name, IP address, IPsec mode, tunnel source interface details, topology, and remote peer IP.

You can also view the ECMP zone for the interface.

Deploy a SASE tunnel on Umbrella

Guidelines for configuring SASE tunnels on Umbrella

SASE topology supports:

- Only PSK-based authentication
- IKEv2
- High availability

General configuration guidelines

- Firewall Management Center does not discover tunnels created directly on Umbrella or by other applications.

- You can add only devices managed by the Firewall Management Center as endpoints for the SASE topology. You cannot add extranet devices.

  For high availability pairs, the HA pair names appear in the endpoint list.

- If you check the **Deploy configuration on threat defense nodes** check box in the wizard, the Umbrella SASE topology configuration is deployed on the Firewall Threat Defense only after the tunnels are deployed on Umbrella.

  The Firewall Management Center requires the local tunnel ID to deploy the Umbrella configuration in Firewall Threat Defense. Umbrella generates the complete tunnel ID (*<prefix>@<umbrella generated ID>*-umbrella.com) only after the Firewall Management Center deploys the tunnel on Umbrella.

- After a Firewall Threat Defense HA switchover, the SASE topology will not appear in the site-to-site monitoring/VPN summary dashboard. We recommend that you bring the tunnel down using the **VPN-sessiondb logoff index** command and bring it up using packet tracer.

Version migration guideline (Pre-version 7.3)

You must create new SASE topologies in version 7.3 and delete the existing SASE topologies because Firewall Management Center does not recognize topologies using Umbrella data center as an extranet hub created before version 7.3 as SASE topologies.

Deployment status and monitoring guideline

You can track the tunnel deployment status in three places:

- Cisco Umbrella Configuration dialog box of the wizard
- Notifications page under the Deployments and Tasks tabs
- Site to Site VPN Monitoring dashboard

Tunnel deletion guidelines

- You cannot edit or delete a SASE topology while deployment to Umbrella is in progress.
- When you delete a tunnel from Firewall Management Center and if it is unable to delete the tunnel from Umbrella, you must manually delete it by logging into Umbrella.

Limitations for configuring SASE tunnels on Umbrella

SASE topology does not support these features:

- Clustering
- Certificate-based authentication
- IKEv1

Deploy a SASE tunnel on Umbrella

This section provides instructions to deploy a SASE tunnel on Umbrella from a Firewall Threat Defense device using the Firewall Management Center.

Step	Do This	More Info
1	Review the guidelines and limitations.	Guidelines for configuring SASE tunnels on Umbrella, on page 1562
2	Ensure that you meet the prerequisites.	Prerequisites for configuring Umbrella SASE tunnels, on page 1564
3	Configure Cisco Umbrella connection settings.	• Configure Cisco Umbrella Connection Settings • Map Management Center Umbrella parameters and Cisco Umbrella API keys, on page 1564
4	Configure a SASE tunnel on Umbrella.	Configure a SASE tunnel for Umbrella, on page 1566
5	View the status of the SASE tunnel.	View SASE tunnel status, on page 1568

Prerequisites for configuring Umbrella SASE tunnels

License prerequisites

- You must have a Cisco Umbrella Secure Internet Gateway (SIG) Essentials subscription.
- You must enable your Smart License account with the export-controlled features to deploy tunnels on Umbrella from the Firewall Management Center. If this license is not enabled, you can only create a SASE topology. You cannot deploy tunnels on Umbrella.

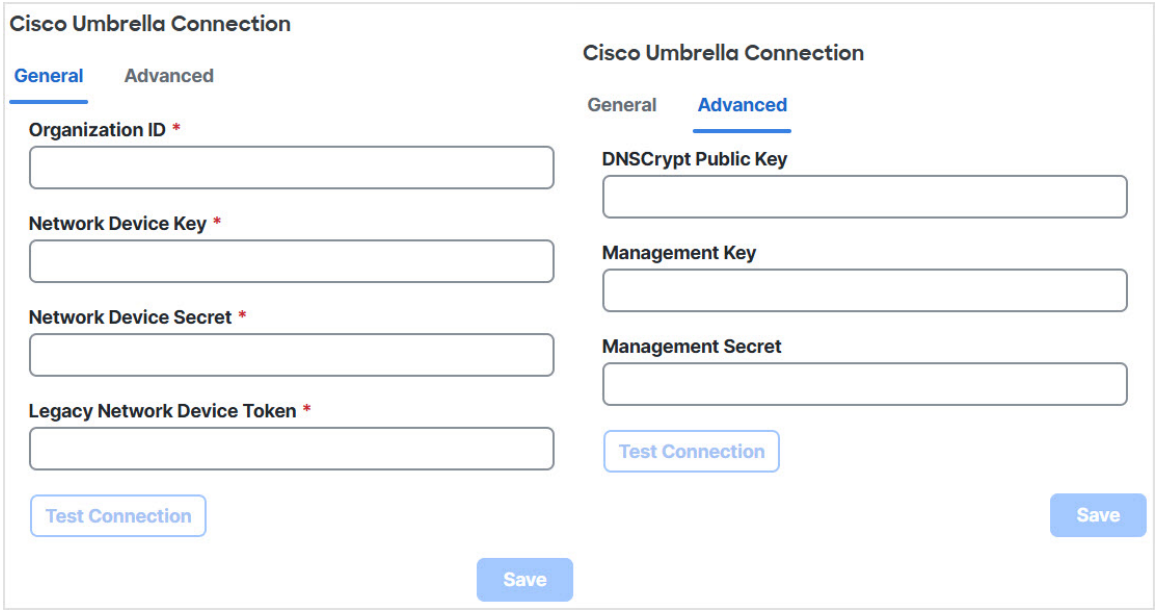
General prerequisites

- You must establish an account with Cisco Umbrella at https://umbrella.cisco.com, log into Umbrella at http://login.umbrella.com, and obtain the required information to establish connection to Cisco Umbrella.
- You must register Cisco Umbrella with the Firewall Management Center and configure the management key and the management secret in the Cisco Umbrella Connection Settings. The Firewall Management Center requires the management key and management secret to fetch the datacenter details from the Cisco Umbrella cloud. You must also configure the Organization ID, Network Device Key, Network Device Secret, and the Legacy Network Device Token in the Cisco Umbrella Connection Settings.

  For more information, refer to:

  - Configure Cisco Umbrella Connection Settings
  - Map Management Center Umbrella parameters and Cisco Umbrella API keys, on page 1564

- Ensure that Umbrella data center is reachable from the Firewall Threat Defense.



Map Management Center Umbrella parameters and Cisco Umbrella API keys

To register Cisco Umbrella with the Firewall Management Center and configure the Umbrella parameters in the Firewall Management Center, you must complete these steps:

1. Log in to Cisco Umbrella.
2. Choose **Admin > API Keys > Legacy Keys**.

3. Generate and copy the required API keys.
4. Use the API keys to configure the Cisco Umbrella connection parameters in the Firewall Management Center.

This figures show the parameters that you must configure in the Cisco Umbrella Connection in the Firewall Management Center. DNScrypt Public Key is an optional parameter.

This figure shows the Cisco Umbrella API keys that you must use to register the Cisco Umbrella with the Firewall Management Center.

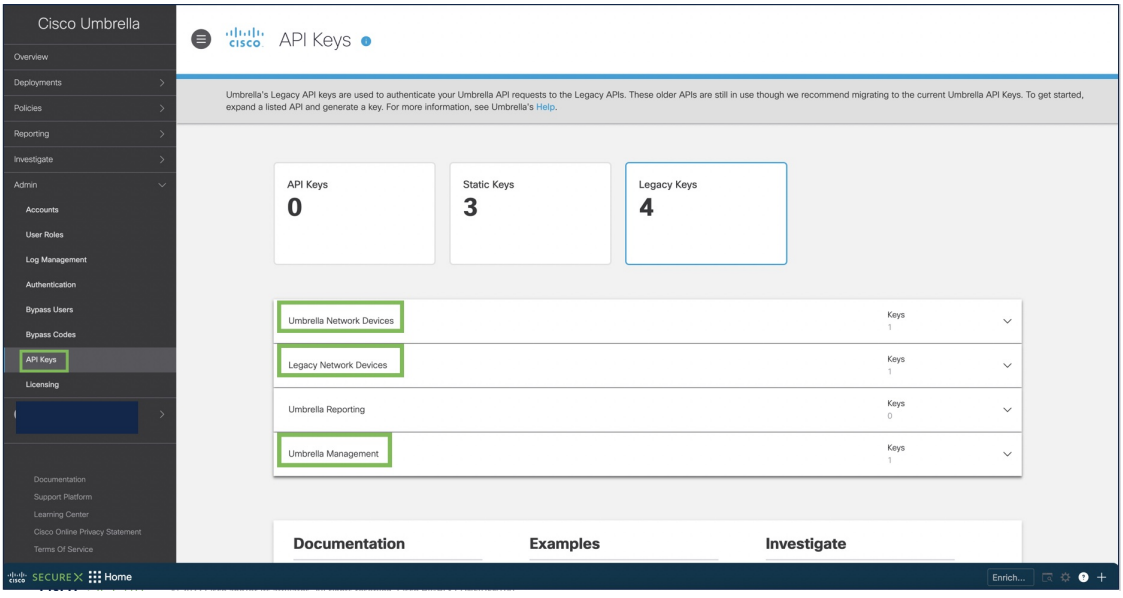


Table 90: Map Firewall Management Center Umbrella Parameters and Cisco Umbrella API Keys

Management Center Parameter	Cisco Umbrella API Keys
Network Device Key Network Device Secret	Umbrella Network Devices
Legacy Network Device Token	Legacy Network Devices
Management Key Management Secret	Umbrella Management

Configure a SASE tunnel for Umbrella

Configure a SASE tunnel to establish secure connectivity between threat defense devices and Cisco Umbrella data centers for cloud-delivered security services.

SASE (Secure Access Service Edge) tunnels provide secure connections to Umbrella data centers, enabling cloud-based security functions. These tunnels use IKEv2 with pre-shared keys for authentication and static VTI interfaces for routing traffic.

Before you begin

Ensure that you review the prerequisites and guidelines in Prerequisites for configuring Umbrella SASE tunnels, on page 1564 and Guidelines for configuring SASE tunnels on Umbrella, on page 1562.

Follow these steps to configure a SASE tunnel for Umbrella:

Procedure

Step 1 Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN**, and click **Add**.

Step 2 Enter a name for the topology in the **Topology Name** field, click the **SASE Topology** radio button and click **Create**.

Step 3 **Pre-shared Key**: This key is auto-generated according to the Umbrella PSK requirements. For a single topology, the pre-shared key is common for all threat defense spokes and Umbrella.

The device and Umbrella share this secret key, and IKEv2 uses it for authentication. If you want to configure this key, it must be between 16 and 64 characters in length, include at least one uppercase letter, one lowercase letter, one numeral, and have no special characters. Each topology must have a unique pre-shared key. If a topology has multiple tunnels, all the tunnels have the same pre-shared key.

Step 4 Choose a data center from the **Umbrella Data center** drop-down list. (Configure routing on the Firewall Threat Defense to ensure reachability of the umbrella data center from the Firewall Threat Defense.)

Step 5 Click **Add** to add a Firewall Threat Defense node.

a) Choose a Firewall Threat Defense from the **Device** drop-down list.

Only devices managed by the Firewall Management Center appear in the list. For high availability pairs, the HA pair names appear in the endpoint list.

b) Choose a static VTI interface from the **VPN Interface** drop-down list.

To create a new static VTI interface, click Add +. The **Add Virtual Tunnel Interface** dialog box appears with the following pre-populated default configurations.

- Tunnel Type is static.
- Name is <*tunnel_source interface logical name*>+ static_vti +<*tunnel ID*>. For example, outside_static_vti_2.
- Tunnel ID is auto-populated with a unique ID.
- Tunnel Source Interface is auto-populated with an interface with an 'outside' prefix.
- IPsec tunnel mode is IPv4.
- IP address is from the 169.254.x.x/30 private IP address range.

c) Enter a prefix for the local tunnel ID in the **Local Tunnel ID** field.

The prefix can have a minimum of eight characters and a maximum of 100 characters. Umbrella generates the complete tunnel ID (<*prefix*>@<*umbrella generated ID*>-umbrella.com) after the Firewall Management Center deploys the tunnel on Umbrella. The Firewall Management Center then retrieves and updates the complete tunnel ID and deploys it on the threat defense device. Each tunnel has a unique local tunnel ID.

d) Click **Save** to add the endpoint device to the topology.

You can add multiple endpoints in a SASE topology.

Step 6 Click **Next** to view the summary of the Umbrella SASE tunnel configuration.

- **Endpoints** pane: Displays the summary of the configured endpoints.
- **Encryption Settings** pane: Displays the default IKEv2 policies and IKEv2 IPsec transform sets for the topology.

Step 7 Check the **Deploy configuration on threat defense nodes** check box to trigger deployment of the network tunnels to the threat defense. This deployment occurs after the tunnels are deployed on Umbrella. Local tunnel ID is required for the threat defense deployment.

Step 8 Click **Save**.

This action:

a. Saves the topology in the Firewall Management Center.

b. Triggers deployment of the network tunnels to the Umbrella.

c. Triggers deployment of the network tunnels to the threat defense devices, if the option is enabled. This action commits and deploys all the updated configurations and policies, including non-VPN policies, since the last deployment on the device.

d. Opens the **Cisco Umbrella Configuration** window and displays the status of the tunnel deployment on Umbrella. For more details, see View SASE tunnel status, on page 1568.

What to do next

For the interesting traffic intended to flow through the SASE tunnel, configure a PBR policy with a specific match criteria to send the traffic through the VTI interface.

Ensure that you configure a PBR policy for each endpoint of the SASE topology.

View SASE tunnel status

After configuring Umbrella SASE topology, you need to monitor the tunnel deployment status and verify that the configuration has been successfully pushed to Umbrella.

Procedure

Step 1 Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN**, and click **Add**.

Step 2 Enter a name for the topology in the **Topology Name** field.

Step 3 Click the **SASE Topology** radio button and click **Create**.

Step 4 Enter a unique **Pre-shared Key**, choose a data center, add a device, and click **Next**.

Step 5 View the summary of the Umbrella SASE Tunnel configuration and click **Save**.

The **Cisco Umbrella Configuration** window appears.

You can view the topology details such as name, data center, data center IP address, start, and end time of the tunnel deployment.

You can view the deployment status of the tunnels on Umbrella. The different tunnel deployment statuses are:

- Pending: The Firewall Management Center hasn't pushed the configuration to Umbrella.
- Success: The Firewall Management Center successfully configured a tunnel on Umbrella.
- In Progress: The Firewall Management Center is deploying the tunnel on Umbrella.
- Failure: The Firewall Management Center couldn't configure a tunnel on Umbrella.

If the status appears as pending, or failure, use the transcript to troubleshoot the tunnel creation. Click the **Transcript** button to view the transcript details such as the APIs, request payload, and the response received from Umbrella.

Step 6 Click **Umbrella Dashboard** to view the network tunnels in Cisco Umbrella.

Step 7 View the Umbrella tunnel deployment status in:

- The **Notifications** page under the **Deployments** and **Tasks** tabs.
- The **Site to Site** VPN dashboard (**Insights & Reports** > **VPN dashboards** > **Site-to-Site VPN**).

  The dashboard provides a summary of the site to site VPN topologies including the Umbrella SASE topologies. You can view the tunnels between the peer devices and the status of each tunnel. You can also troubleshoot any problems with the tunnel deployment using CLI commands and packet tracer.

Secure traffic using Cisco Secure Access and Firewall Threat Defense devices

Cisco Secure Access is a cloud-based security service edge (SSE) solution that protects against internet threats and enables secure access to the internet, SaaS applications, and private resources from any location.

Benefits of using Secure Access

Secure Firewall seamlessly integrates with Secure Access for various use cases primarily for:

- **Enhanced visibility and control for remote users**: Secure Access extends security policies beyond the physical branch perimeter to protect users regardless of location, providing the same level of threat protection and access controls equivalent to on-premises, creating consistent security enforcement.
- **Simplified security architecture**: Secure Access integrates with a Firewall Threat Defense device to consolidate multiple security functions such as Secure Web Gateway, Cloud Access Security Broker (CASB), Data Loss Prevention (DLP), and cloud firewall. This consolidation provides a single-pane-of-glass experience for policy management across branch deployments and cloud-delivered security services.

Benefits of using SASE wizard to automate Secure Access tunnels from Firewall Threat Defense

You can automatically create secure tunnels between Firewall Threat Defense and Secure Access using Firewall Management Center. The SASE wizard provides a guided workflow to handle the tunnel setup across both the products, helping you avoid switching between consoles or manually matching tunnel parameters.

- Reduce tunnel setup time and configuration errors.
- Secure internet, cloud, and private application access through Secure Access.
- Simplify operations for distributed enterprise environments.

Licenses for automatic tunnel between Secure Access and Firewall Threat Defense devices

This topic lists the required licenses for using the SASE wizard to establish automatic tunnels between Threat Defense devices and Secure Access.

- Firewall Management Center Essentials (formerly Base) license must allow export-controlled functionality. Choose **Administration** > **Licenses** > **Smart Licenses** to verify this in Firewall Management Center.

Note Evaluation license does not support this feature.

- Cisco Secure Access Essentials subscription license must be available.

Prerequisites for an automatic tunnel between Secure Access and Firewall Threat Defense devices

This topic provides the prerequisites required to establish an automatic tunnel between Secure Access and Firewall Threat Defense devices for secure traffic integration.

- Integrate a Cisco Security Cloud Control tenant with a Secure Access organization.
- Configure basic routing and access control policies to route traffic between the Secure Access data center and the Firewall Threat Defense device.

Guidelines for an automatic tunnel between Secure Access and Firewall Threat Defense devices

General guidelines

- Set up routing in the Firewall Threat Defense device to route traffic over the tunnel.
- Delete the Firewall Threat Defense device from the topology and add it again with the required routing configuration to update routing settings in a SASE topology.
- When change management is enabled, tunnels are not deployed automatically to Secure Access. Manually deploy tunnels to Secure Access from the **Site-to-Site VPN** page after the change management ticket is approved.

Multi-ISP SASE topology guidelines

- To create a multi-ISP SASE topology, you must establish multiple tunnels from a Firewall Threat Defense device to the same Secure Access region using different interfaces. Since each SASE topology supports only one WAN interface, use the SASE wizard to create multiple topologies.
- When you configure multi-ISP SASE topologies that use the same region and device but different VPN interfaces, ensure that all topologies have identical settings. The tunnel ID prefix, passphrase, and routing configurations must match across all topologies.
- To update routing settings in a multi-ISP SASE topology, delete the Firewall Threat Defense device from each topology and add it again with the required configuration. Ensure that routing settings are consistent across all topologies.

Limitation for automatic tunnel between Secure Access and Firewall Threat Defense devices

Clustering is not supported.

Configure automatic tunnel between Secure Access and Firewall Threat Defense devices using SASE wizard

The SASE wizard simplifies tunnel creation from Firewall Threat Defense devices to Secure Access by automating multiple steps.

Before you begin

Ensure that you review Prerequisites for an automatic tunnel between Secure Access and Firewall Threat Defense devices, on page 1570 .

Procedure

Step 1 Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN** , and click **Add** .

Step 2 In the **Topology Name** field, enter a name for the SASE topology.

Step 3 Click the **SASE Topology** radio button and click **Create** .

Step 4 Configure a Secure Access region by choosing a region from the **Region** drop-down list:

A Secure Access region is a cluster of data centers in a specific geographic area.

Step 5 Configure Firewall Threat Defense nodes:

a) Click **Add** and configure the parameters in the **Add Threat Defense Node** dialog box.

b) From the **Device** drop-down list, choose a Firewall Threat Defense device.

Note Only Firewall Threat Defense devices managed by Firewall Management Center are displayed in this list. Extranet devices won't appear in the list.

c) From the **VPN Interface** drop-down list, choose a WAN-facing or internet-facing physical interface that establishes a VPN connection with Secure Access .

Step 6 Configure **Tunnel ID and passphrase** .

a) In the **Prefix for tunnel ID** field, enter a prefix containing 8 to 30 characters. The prefix can contain alphabets, numbers, period (.), underscore (_), and dash (-).

Secure Access uses this prefix to generate the complete tunnel ID after the Firewall Management Center deploys the tunnel in Secure Access . The tunnel ID format is < *prefix* >@< *org* >< *hub* >.sse.cisco.com.

b) The passphrase is auto generated. However, you can regenerate or enter a different passphrase. In the **Passphrase** field, enter a passphrase containing 16 to 64 characters. The passphrase must contain at least one upper-case alphabet, one lower-case alphabet, and one number, and cannot include special characters.

c) Confirm the passphrase.

d) Click **Next** .

Step 7 Configure **NAT or routing** :

a) Check the **Enable NAT/outbound only** check box to enable Network Address Translation (NAT) for correct routing and identification.

Use this option if the IP address of the subnet behind this tunnel group overlaps with the IP address in your network. When this option is selected, the tunnel group supports only outbound traffic and cannot provide access to private applications hosted at this site.

Note Routing options are unavailable when the network contains overlapping subnets.

b) Configure one of these options for **Routing** :

- Click the **Static routing** radio button.

  Use the **Network IP addresses** field to add the IP addresses of networks for this tunnel group. Add all the public and private addresses used internally by your organization.

- Click the **Dynamic routing** radio button.

  Use this option to advertise your internal networks over BGP.

  In the **AS number** field, enter the AS number of the device. This value must match the device's BGP AS number in the routing settings of the device.

c) Click **Next** .

Step 8 Check the **Deploy to Threat Defense devices** check box to trigger deployment of all the configurations besides the Secure Access auto tunnel configurations that are yet to be deployed on the device.

Step 9 Click **Finish** to save and validate the configurations, and create the SASE topology.

The wizard performs these actions:

- Saves all Firewall Threat Defense device configurations in Firewall Management Center .
- Pushes the configurations to Secure Access.
- Creates virtual tunnel interfaces (VTIs) on the device.
- Creates a SASE VPN topology.
- Triggers deployment of all the configurations besides the Secure Access auto tunnel configurations that are yet to be deployed in the device if the **Deploy to Threat Defense devices** option is enabled.
- Opens the **Configuration of Secure Access Tunnels** dialog box, which displays the status of the tunnel deployment in Secure Access .

  Click the **Transcript Details** ( ) button to view transcript details such as the APIs, request payload, and the responses received from Secure Access .

You can view the SASE topology in the **Site-to-Site VPN & SD-WAN** page (**Secure Connections** > **Site-to-Site VPN & SD-WAN**).

What to do next

1. Create an extended Access Control List (ACL).

   This ACL defines the specific DNS and web traffic intended for routing through the tunnel to Secure Access . For more information, refer to Configure an extended ACL object, on page 2775 .

2. Configure the static route to the next hop of the VTI interface.
3. Create a policy-based routing (PBR) policy.

   Use the newly created extended ACL within a policy-based routing policy to direct the defined DNS and web traffic through the tunnel to Secure Access for security inspection. For more information, refer to Configure policy-based routing policy, on page 1332 .

4. When you create multiple SASE topologies for a multi-ISP setup, configure ECMP zones with the VPN interfaces to balance the load of application traffic.
5. Perform validation. For more information, refer to Validate Secure Access integration with Firewall Threat Defense devices, on page 1573 .

Validate Secure Access integration with Firewall Threat Defense devices

You can validate the integration between Secure Access and Threat Defense devices by checking tunnel statuses and viewing transcript details.

Verify tunnel statuses in Firewall Management Center

To view the SASE topology tunnel details in the site-to-site VPN dashboard, choose **Insights & Reports** > **VPN dashboards** > **Site-to-Site VPN**.

To view more details about each tunnel:

1. For each tunnel, hover your cursor over a topology and click the **View** () icon.
2. Click the **CLI Details** tab.
3. Click **Maximize View**. You can view the output of these commands:
   - **show crypto ipsec sa peer**: Shows the number of packets that are transmitted through the tunnel.
   - **show VPN-sessiondb detail l2l filter ipaddress**: Shows detailed data for the VPN connection.

Verify tunnel statuses in Secure Access

1. In Secure Access, choose **Connect > Network Connections > Network Tunnel Groups**.
2. Click a network tunnel group to view details.

   In the **Network Tunnels** area, the primary and secondary tunnels will be displayed:
   - **Primary1** tunnel originates from the branch's outside interface and connects to the primary Secure Access data center.
   - **Secondary1** tunnel also originates from the branch's outside interface but connects to the secondary data center, serving as a standby for continuous connectivity.

View transcript details

In the **Configuration of Secure Access Tunnels** dialog box, click the **Transcript Details** () button to view the transcript details such as the APIs, request payload, and the responses received from Secure Access.

Transcript details are not available in these scenarios:

- When you delete a Network Tunnel Group (NTG) or an endpoint.
- When you configure any multi-ISP tunnel after configuring the primary tunnel.

Monitor site-to-site topologies

This section provides information about the different ways to monitor your site-to-site topologies.

Monitor site-to-site VPNs using Site-to-Site VPN summary page

You can view a summary of your site-to-site VPN topologies in the **Site-to-Site VPN Summary** page. For each topology, you can view details such as VPN type, network topology, VPN interfaces, VPN devices, and tunnel statuses.

You can edit or delete the topology using the edit and delete buttons. For SASE topology VPNs, you have options to deploy, edit and delete any topology.

Monitor site-to-site VPNs using Site-to-Site VPN dashboard

Choose **Insights & Reports** > **VPN dashboards** > **Site-to-Site VPN** to open the site to site dashboard.

The **Site-to-Site VPN** dashboard provides a snapshot and status of the site-to-site VPN tunnels. You can view the list of tunnels between peer devices and the status of each tunnel: Active, Inactive, or No Active Data. You can filter the data in the table according to the topology, device, and status. The dashboard shows live data and you can also configure the refresh interval.

Benefits of the dashboard

The dashboard provides these benefits:

- Identify problematic VPN tunnels and troubleshoot them.
- Verify connectivity between the site-to-site VPN peers devices.
- Monitor the health of the VPN tunnels to provide uninterrupted VPN connectivity between sites.
- Use Packet tracer to troubleshoot VPN tunnels.

Widgets of the dashboard

- **Tunnel Status**—A table listing the tunnel status of the site-to-site VPNs , including the SASE tunnels for Umbrella, configured using the Firewall Management Center. For more information, refer to Tunnel status widget, on page 1575.
- **Tunnel Summary**—Aggregated status of the tunnels in a donut graph.
- **Topology**—Status of tunnels summarized by topology.

Status of VPN tunnels

The different VPN tunnel statuses that you can view in the Site-to-Site dashboard are:

- **Inactive**—A policy-based (crypto map-based) VPN tunnel is inactive if all the IPSec tunnels are down. A VTI or and SASE topology VPN tunnel is down if the tunnel encounters any configuration or connectivity issues.

- **Active**—In the Firewall Management Center, policy-based site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. A policy-based VPN tunnel is in the Active state if the Firewall Management Center identifies interesting traffic through the tunnel after the deployment. An IKE tunnel is up only if a minimum of one IPsec tunnel is up.

  Route-based VPN (VTI) and SASE topology VPN tunnels do not require interesting traffic to be in the Active state. They are in the Active state if they are configured and deployed without errors.

- **No Active Data**—Policy-based and SASE topology VPN tunnels remain in the No Active Data state until there is a traffic flow event through the tunnel for the first time. The No Active Data state also lists the policy-based and route-based VPNs that have been deployed with errors.

Important notes about tunnel statuses in Firewall Management Center

- The VPN statuses in the Firewall Management Center are event-based. The Firewall Management Center does not initiate status updates. Hence, there might be mismatches between the tunnel statuses in the dashboard and the Firewall Threat Defense . You can view the correct status in the **CLI Details** tab of the **Tunnel Status** widget.
- When a Firewall Threat Defense switches over to a secondary Firewall Threat Defense , there is a mismatch between the status of the VPN tunnels in the Firewall Management Center and the Firewall Threat Defense . When the device switches back to the primary device, the correct tunnel status appears.
- The Firewall Management Center does not update the tunnel status of Firewall Threat Defense devices earlier than 7.3 after the devices reboot. We recommend that you bring the tunnel down using the command **vpn-sessiondb logoff index** and bring it up using the packet tracer.

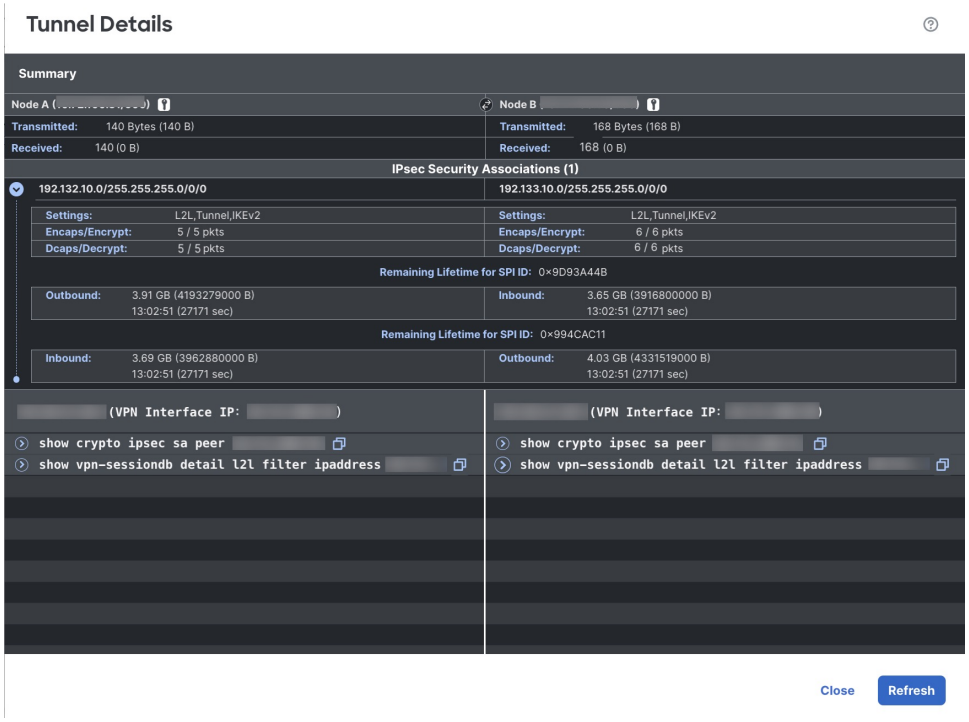
Limitations of the dashboard

- The table shows the list of site-to-site , including SASE topology, VPNs that are deployed. It does not show the tunnels that are created and not deployed.
- The table does not show the information about the backup tunnels of policy-based VPNs and backup VTIs.
- For cluster deployments, the table does not show director change in real-time data. It shows only the director information that existed when the VPN was deployed. The director change reflects in the table only after the tunnel AM redeployed after the change.

Tunnel status widget

This widget lists the site-to-site VPNs, including SASE topology VPN, configured using the Firewall Management Center and their tunnel statuses.

Features of the widget



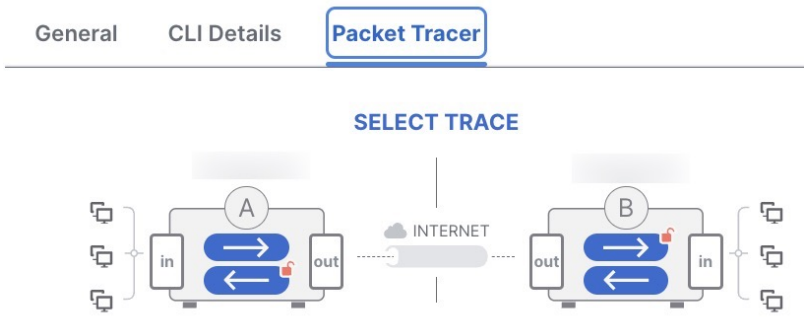
Hover over a topology and click **View** ( ) to view these details about the topology:

- **General**—Displays more information about the nodes such as IP address and interface name.
- **CLI Details**—Displays the CLI outputs for the following commands:
  - **show crypto ipsec sa peer**: Displays the IPsec SAs built between Node A and B.
  - **show vpn-sessiondb l2l filter ipaddress** : Displays information about VPN sessions.

For an extranet device, no command output appears.

Important details about the IKE and IPsec sessions, derived from the above command outputs, appear in a summarized, and user-friendly format. You can view the details of both nodes at a time. The icon next to the node name specifies the authentication type: preshared key or client certificate. The details include IKE statistics per tunnel and IPsec SA statistics as shown below:

Figure 423: Tunnel Status > View > CLI Details



- **Packet Tracer**—Use packet tracer to troubleshoot the VPN tunnels.

Packet Tracer

Packet tracer allows you to troubleshoot VPN tunnels between two threat defense devices. You can check if the VPN connection between device A and device B is up. This tool performs these actions:

- Injects a packet into the device and tracks the packet flow from the ingress to the egress ports.
- Simulates traffic after you configure the ingress interfaces of the devices along with the protected networks.
- Evaluates the packet against modules such as flow and route lookups, ACLs, protocol inspection, NAT, and QoS.

Figure 424: Packet Tracer

For each device, the tool runs an encrypted trace and a decrypted trace (packet is treated as decrypted VPN traffic). You can run four different traces between the ingress and egress ports of the devices. Click the individual encrypt and decrypt options to enable or disable the trace.

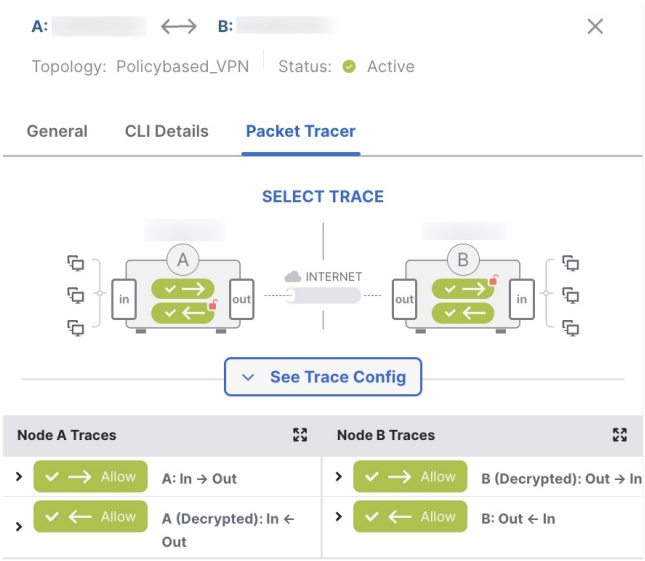
When you run the trace, the tool executes the trace sequentially in the following order:

1. Encrypted trace of A.
2. Decrypted trace of B.
3. Encrypted trace of B.
4. Decrypted trace of A.

After the trace completes, you can view the output of the trace with the results of each module.

Note You cannot run a decrypt trace for route-based (VTI-based) VPNs.

To run the Packet Tracer:



1. Click **See Detailed Config** to view the VPN interface name, VPN interface IP address, VTI interface name, and the VTI Interface IP address.
2. (Optional) Choose a protocol from the **Protocol** drop-down list. You can choose ICMP/8/0, TCP, or UDP.

   ICMP/8/0 is the default option. If you choose ICMP/8/0, 8 indicates the ICMP type as Echo Request and 0 indicates the ICMP code. If you choose TCP or UDP, choose the destination port from the **Destination Port** drop-down list. The range is from 0 to 65535.
3. Choose the ingress interface for both the devices on which to trace the packet from the **Ingress Interface** drop-down lists.
4. Enter an IP address from the same subnet as the ingress interface in the **Protected Network IP Address** fields.
5. Click **Trace Now**.

   After you initiate the trace, you can view if the trace is successful or not for each module. If the tunnel is down, the path appears in red. If the tunnel is up, the path appears in green. If a tunnel is down, click

Re-trace to run the tool again. For a crypto-map based VPN, when the tunnel is inactive with no interesting traffic, the initial trace can be red. Click **Re-trace** to run the trace again.

Figure 425: Packet Tracer after a Successful Trace

Extranet Nodes: You can initiate a packet trace for VPN tunnels with one node as an extranet. For an extranet node, you cannot choose the ingress interface. The remaining steps for the packet trace are the same. You can't run trace on the extranet side.

For example, if Node A is a managed threat defense and Node B is an extranet:

- Configure the ingress interface for node A.
- Configure the protected network for Node A and B.
- Click **Trace Now**. The traces appear for Node A and not for Node B.

Site-to-site VPN connection event monitoring

The site-to-site VPN connection event allows you to know if the VPN encrypts or do not encrypts the connection and helps you to troubleshoot connectivity issues, especially in multi-hop VPN deployments. The event dashboard of the Firewall Management Center displays the IP address of the VPN peer (peer's IKE address) which encrypts or decrypts the traffic and displays the VPN action.

The VPN actions displayed are:

- If the connection is decrypted by the VPN, the column **Decrypt Peer** displays the IP address of the peer's address from where the flow was received and displays **Decrypt** as the VPN action.
- If the connection is encrypted by the VPN, the column **Encrypt Peer** displays the IP address of the VPN peer to which the flow is sent and displays **Encrypt** as the VPN action.
- If the VPN server cascades the connection, it gets decrypted on one tunnel and gets re-encrypted on another tunnel. In this case, both **Encrypt Peer** and **Decrypt Peer** IP addresses get appears in the event. The column **VPN Action** displays **VPN Routing** as the action to indicate that the connection transit through the VPN server.

If you enable the **Bypass Access Control Policy for decrypted traffic (sysopt permit-VPN)** option, the system bypasses the access control policy and do not log events for decrypted traffic. This option is disabled by default and all decrypted traffic in the VPN tunnel undergoes ACL inspection.

View site-to-site VPN connection events

Access the connection event viewer of the Firewall Management Center to know if the VPN encrypts or do not encrypts the connection traffic and to retrieve the VPN peer details.

Before you begin

Ensure that you enable logging of connection events at the beginning of connection and at the end of connection in the access control rule.

Procedure

Step 1 Choose **Events & Logs** > **+ Show more** > **Connection** > **Events**.

Step 2 Click **Table View of Connection Events** tab.

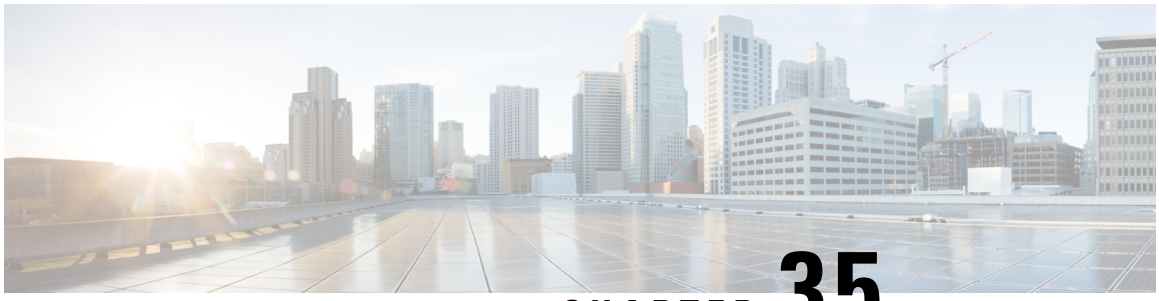
Step 3 In the table view of events, multiple fields are hidden by default. To change the fields that appear, click the **x** icon in any column name to display a field chooser.

Step 4 Choose these columns:

- Decrypt Peer
- Encrypt Peer
- VPN Action

Step 5 Click **Apply**.

See *Connection and Security-Related Connection Events* in the Secure Firewall Management Center Administration Guide for more information on the connection events.



History for site-to-site VPN

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Secure traffic using Secure Access and Firewall Threat Defense devices	10.1	7.2	Secure Access is a cloud-based SSE solution that delivers threat protection and secure connectivity to the internet, SaaS, and private resources from anywhere. With the new SASE wizard in Firewall Management Center, configuring IPsec IKEv2 tunnels from Firewall Management Center devices is now automated and streamlined. New/Modified screens: Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN** and click the **SASE Topology** radio button to launch the wizard.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
View Virtual Tunnel Information	7.4.1	Any	You can view details of dynamic and static VTIs of route-based VPNs on the device. For every VPN topology, you can also view details of all the virtual access interfaces of the dynamic VTIs. New/Modified screens: **Device** > **Device Management** > **Edit a device** > **Interfaces** and click the **Virtual Tunnels** tab.
IPsec flow offload	7.4	Any	IPsec flow offload is automatically enabled on the VTI loopback interface on Secure Firewall 3100 and Secure Firewall 4200 devices.
Umbrella SASE Topology	7.3	Any	You can configure an Umbrella SASE topology and deploy IPsec IKEv2 tunnels between a threat defense device and Umbrella. This tunnel forwards all internet-bound traffic to the Umbrella Secure Internet Gateway (SIG) for inspection and filtering.
Support for Dynamic Virtual Tunnel Interface	7.3	Any	You can create a dynamic VTI and use it to configure a route-based site-to-site VPN in a hub and spoke topology.
EIGRP IPv4 support for VTI	7.3	Any	Static and dynamic VTI interfaces support EIGRP IPv4 routing protocol.
OSPFv2/v3 IPv4/v6 support for VTI	7.3	Any	Static and dynamic VTI interfaces support OSPFv2/v3 IPv4/v6 routing protocol.
Packet Tracer in Site to Site VPN Monitoring Dashboard	7.3	Any	Use the packet tracer tool in the site-to-site VPN monitoring dashboard to troubleshoot the threat defense VPN tunnels. New/Modified screens: **Overview** > **Dashboards** > **Site to Site VPN**
Remote Access VPN Dashboard	7.3	Any	Use the Remote Access VPN dashboard to monitor real-time data from active remote access VPN sessions on the devices. New/Modified screens: **Overview** > **Dashboards> Remote Access VPN**
IPsec flow offload	7.2	Any	On the Secure Firewall 3100, IPsec flows are offloaded by default. After the initial setup of an IPsec site-to-site VPN or remote access VPN security association (SA), IPsec connections are offloaded to the field-programmable gate array (FPGA) in the device, which should improve device performance. You can change the configuration using FlexConfig and the **flow-offload-ipsec** command.
Site-to-Site VPN Filter	7.1	Any	You can control site-to-site VPN traffic by using an access control policy.
Local tunnel ID support	7.1	Any	For each endpoint on a site-to-site VPN, you can configure a unique tunnel ID to be shared with the peers.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Multiple IKE Policy Support	7.1	Any	You can add multiple IKEv1 and IKEv2 policy objects for each endpoint.
Site-to-Site VPN Monitoring Dashboard	7.1	Any	Use the Site-to-Site VPN Monitoring dashboard to view and monitor the status of site-to-site VPN tunnels.
Backup virtual tunnel interfaces (VTI) for route-based site-to-site VPN.	7.0	Any	When you configure a site-to-site VPN that uses virtual tunnel interfaces, you can select a backup VTI for the tunnel. Specifying a backup VTI provides resiliency, so that if the primary connection goes down, the backup connection might still be functional. For example, you could point the primary VTI to the endpoint of one service provider, and the backup VTI to the endpoint of a different service provider. You can add a backup VTI in the site-to-site VPN wizard by selecting route-based as the VPN type for a point-to-point connection.
Enhance the number of VTI from 100 per interface to 1024 per device	7.0	Any	Support for maximum number of VTIs is enhanced from 100 per physical interface to 1024 VTIs per device.
IPv6 Support	7.0	Any	You can configure IPv6 addressed VTIs. While only static IPv6 address is supported as the tunnel source and destination, IPv6 BGP isn't supported over VTI.
Removal and deprecation of weak ciphers	6.7	Any	Support has been removed for less secure ciphers. We recommend that you update your VPN configuration before you upgrade to Firewall Threat Defense 6.70 to supported DH and encryption algorithms to ensure the VPN works correctly. Update your IKE proposals and IPSec policies to match the ones supported in Firewall Threat Defense 6.70 and then deploy the configuration changes. These less secure ciphers have been removed or deprecated in Firewall Threat Defense 6.70 onwards: • **Diffie-Hellman Group 5** is deprecated for IKEv1 and removed for IKEv2 • Diffie-Hellman groups 2 and 24 have been removed. • **Encryption algorithms**: 3DES, AES-GMAC, AES-GMAC-192, AES-GMAC-256 have been removed. **Note** **DES** is supported in evaluation mode or for users who do not satisfy export controls for strong encryption. **NULL** is removed in IKEv2 policy, but supported in both IKEv1 and IKEv2 IPsec transform-sets.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Dynamic RRI support	6.7	Any	Dynamic Reverse Route Injection is supported with IKEv2 based static crypto maps.
Backup peer for site-to-site VPN	6.6	Any	You can use the Firewall Management Center to add a backup peer to a site-to-site VPN connection. For example, if you have two ISPs, you can configure the VPN connection to fail over to the backup ISP if the connection to the first ISP becomes unavailable. New/modified pages: **Devices** > **VPN** > **Site to Site**. When adding or editing a point to point or hub and spoke FTD VPN topology to add an endpoint, the **IP Address** field supports comma-separated backup peers.

CHAPTER 35

SD-WAN

This chapter describes the SD-WAN capabilities supported in Management Center.

- SD-WAN capabilities, on page 1583
- SD-WAN features, on page 1584
- SD-WAN wizard for secure branch network deployment, on page 1586
- Use cases for SD-WAN capabilities, on page 1602
- Monitor SD-WAN topologies, on page 1602

SD-WAN capabilities

SD-WAN capabilities are software-defined networking features that

- replace traditional WAN routers and are agnostic to WAN transport technologies
- provide dynamic, policy-based, application path selection across multiple WAN connections, and
- support service chaining for additional services such as WAN optimization and firewalls.

SD-WAN capabilities in Secure Firewall

As organizations expand their operations across multiple branch locations, ensuring secure and streamlined connectivity becomes paramount. Deploying a secure branch network infrastructure involves complex configurations, which can be time-consuming and prone to configuration errors if not handled properly. However, organizations can overcome these challenges by leveraging Management Center and Threat Defense devices for a simplified and secure branch deployment.

By integrating Secure Firewall as a foundational component of the branch network architecture, organizations can establish a strong security baseline while simplifying the deployment process. This approach enables organizations to enforce unified security policies, optimize traffic routing, and ensure resilient connectivity.

Some of the SD-WAN capabilities supported on the Cisco Secure Firewall include:

- **Simplified management:**
  - SD-WAN Wizard
  - SASE: Umbrella auto tunnel deployment
  - Dynamic VTI (DVTI) hub spoke topology simplification

- **Application awareness:**
  - Direct Internet Access (DIA) for public cloud and guest user
  - Policy based routing (PBR) using applications as a match criteria
  - Local tunnel ID support for Umbrella
- **Increased usable bandwidth:**
  - ECMP support for load balancing across multiple ISPs and VTIs
  - Application-based load balancing using PBR
- **High availability with near zero network downtime:**
  - Dual ISP configuration
  - Optimal path selection based on application-based interface monitoring.
- **Secure elastic connectivity:**
  - Route-based (VTI) VPN tunnels between headquarters (hub) and branches (spokes)
  - IPv4 and IPv6 BGP, IPv4 and IPv6 OSPF, and IPv4 EIGRP over VTI
  - DVTI hubs that support spokes with static or dynamic IP

SD-WAN features

This table lists the SD-WAN features of Management Center, including their introduction releases and links to detailed information.

Feature	Introduced in	More Information
Automated Secure Access tunnels from Management Center	Release 10.1	Secure traffic using Cisco Secure Access and Firewall Threat Defense devices, on page 1569
Configure settings to carry SGT over the SD-WAN tunnels using SD-WAN wizard.	Release 10.0	SD-WAN wizard for secure branch network deployment, on page 1586
Support for ECMP in hubs and BFD for SVTI and DVTI.	Release 10.0	SD-WAN wizard for secure branch network deployment, on page 1586
Use PBR to handle traffic based on advanced custom application detector.	Release 10.0	Policy-Based Routing, on page 1325
Management of Remote Branch (HA) with Dual WAN Support	Release 7.7	SD-WAN summary dashboard, on page 1602

Feature	Introduced in	More Information
PBR Support for Custom Applications	Release 7.7	Policy-Based Routing, on page 1325
SD-WAN Wizard	Release 7.6	SD-WAN wizard for secure branch network deployment, on page 1586
Application monitoring using SD-WAN Summary dashboard	Release 7.4.1	SD-WAN summary dashboard, on page 1602
SD-WAN Summary Dashboard	Release 7.4	SD-WAN summary dashboard, on page 1602
Policy-based routing with user identity and SGTs	Release 7.4	Policy-Based Routing, on page 1325
Policy-based routing using HTTP path monitoring	Release 7.4	Policy-Based Routing, on page 1325
Loopback interface support for VTIs	Release 7.3	Loopback interfaces, on page 794
Support for dynamic VTI (DVTI) with site-to-site VPN	Release 7.3	Dynamic VTI, on page 1540
Umbrella auto tunnel	Release 7.3	Deploy a SASE Tunnel on Umbrella
Support for IPv4 and IPv6 BGP, IPv4 and IPv6 OSPF, and IPv4 EIGRP for VTIs	Release 7.3	BGP, on page 1269 OSPF, on page 1225 EIGRP, on page 1257
Route-based site-to-site VPN with hub and spoke topology	Release 7.2	Create a route-based site-to-site VPN, on page 1547
Policy-based routing with path monitoring	Release 7.2	Policy-Based Routing, on page 1325
Site to Site VPN Monitoring Dashboard	Release 7.1	Monitor Site-to-Site VPNs Using Site-to-Site VPN Dashboard
Direct Internet Access/Policy Based Routing	Release 7.1	Policy-Based Routing, on page 1325
Equal-Cost-Multi-Path (ECMP) zone with WAN interfaces	Release 7.1	ECMP, on page 1209
ECMP zone with VTI interfaces	Release 7.1	ECMP, on page 1209
Backup VTI for route-based site-to-site VPN	Release 7.0	Route traffic through a backup VTI tunnel, on page 1557

Feature	Introduced in	More Information
Support for static VTI (SVTI) with site-to-site VPN	Release 6.7	Static VTI, on page 1538

SD-WAN wizard for secure branch network deployment

The SD-WAN wizard in Management Center

- simplifies and automates VPN tunnel and routing configuration between centralized headquarters (hubs) and remote branch sites (spokes)
- creates route-based VPN tunnels and automates tasks such as generating tunnel interfaces, assigning IP addresses, and configuring BGP for the SD-WAN overlay network
- provides seamless routing by enabling hubs to act as route reflectors that determine the best routing path based on spokes' active and backup tunnels.

Hub and spoke network components

The SD-WAN wizard configures two types of network components:

- Hubs: Devices that enable secure VPN connectivity to and from one or more remote branch devices or spokes. Hubs also act as a gateway for spokes to communicate with each other.
- Spokes: Devices in remote branches that connect over VPN to a hub to securely access the corporate resources behind the hub. Spokes communicate with each other through the hub.

The SD-WAN wizard provides these benefits:

- Simplifies and automates the VPN and routing configuration of your SD-WAN network.
- Requires minimal user input
- Easily adds multiple branches at a time
- Provides easy dual ISP configurations
- Enables network scaling

Guidelines for using SD-WAN wizard

General guidelines

- When you create security zones or interface groups, choose **Routed** as the **Interface Type**.
- Use the spoke security zone to configure an access control policy that allows tunnel traffic to and from the spokes.
- If a spoke is part of multiple SD-WAN topologies, ensure that you use the same local community tag and learned route community tag in each SD-WAN topology. Note that the local community tags and learned route community tags must be different from each other.
- Configure unique local IKE identity for all tunnels across all your SD-WAN VPN topologies.

- Ensure that the spokes in an SD-WAN topology do not have the same protected network.

IP address configuration guidelines

- When you configure IP address pools for spokes, ensure the following:
  - The **Allow Overrides** check box must be unchecked.
  - If you are using multiple pools, the IP addresses of the pools must not overlap.
  - IP addresses must not overlap with any of the interfaces on the spoke.
- If a device has only IPv6 address configurations, you must configure the BGP router ID with a loopback or physical interface that has an IPv4 address (**Devices** > **Device Management**, and click **Routing** > **General Settings** > **BGP**).

Dual-ISP topology guidelines

- In a dual-hub SD-WAN topology, the hubs can be in different geographic locations and have different protected networks behind them. To ensure direct communication between these networks, ensure that you configure the following:
  - A point-to-point route-based VPN topology between the two hubs (**Secure Connections** > **Site-to-Site VPN & SD-WAN**, and click **Add** > **Route-Based VPN**).
  - A dynamic routing protocol between the hubs (**Devices** > **Device Management**, click the device name and click **Routing**).
- In SD-WAN topologies with dual ISPs on spokes, the tunnel identity and the tunnel source of the spokes must be unique.

VTI guidelines

- When you configure the DVTIs of two hubs, ensure that they have the same IPsec tunnel mode (IPv4 or IPv6).
- Use distinct DVTIs for SD-WAN and route-based VPNs to avoid IPsec profile conflicts and errors.
- Configure the spokes' static VTIs in an ECMP zone to load balance the application traffic. If you do not configure the ECMP zone, the remaining paths act as backup paths when the primary path goes down. Note that you must configure the spokes' static VTIs and not the physical interfaces in the ECMP zone. This configuration is not part of the SD-WAN wizard.
- Ensure that you shutdown a DVTI virtual template before you change the IP address of a DVTI's numbered interface.

Limitations for using SD-WAN wizard

The SD-WAN wizard has these limitations and restrictions:

- You can configure a maximum of two hubs in an SD-WAN topology using the wizard.
- For each spoke, you can use only one WAN interface per topology. However, for dual-ISP setups, you can configure a second SD-WAN topology with the second WAN interface. For more information, see Sample configurations for dual-ISP deployment using SD-WAN wizard, on page 1594.

- SD-WAN wizard does not support the following:
  - IKEv1
  - Cluster devices are not supported on the hub and spoke because VTI is not supported on cluster devices.
  - Extranet hubs and spokes such as ASA, Cisco IOS, Cisco Viptela, Umbrella, Meraki, or vendor devices.

License requirements to use the SD-WAN wizard

Ensure that export-controlled features are enabled in your Smart License to configure an SD-WAN topology in Firewall Management Center.

To verify if export-controlled functionality is enabled for your Smart License account, choose **Administration** > **Licenses** > **Smart Licenses**.

Prerequisites for using SD-WAN wizard

Ensure that you review these prerequisites before you configure your SD-WAN topology using the SD-WAN wizard.

Device prerequisites

- Hub devices must be Version 7.6.0 and later.
- Spoke devices must be Version 7.3.0 and later.
- Hub devices must be Version 10.0 and later to enable ECMP on the virtual access interfaces associated with the hub's dynamic VTI.
- Firewall Threat Defense devices must be Version 10.0 and later to enable BFD routing protocol on SVTIs and DVTIs.

General prerequisites

- You must be an Admin user.
- The Firewall Threat Defense devices must have an internet-routable public IP address. The IP address can be static or dynamic.
- Assign appropriate logical names and IP addresses to the interfaces of the Firewall Threat Defense devices. For example, use *inside* for the interface connected to the LAN, and *outside* for the interface connected to the internet or WAN.
- If you are using certificate-based authentication, you must enroll the certificates in the hub and spokes.
- Configure routing, NAT, and AC policies to ensure underlay connectivity between the devices.

Configure an SD-WAN topology using the SD-WAN wizard

The SD-WAN wizard allows you to easily configure VPN tunnels between your centralized headquarters and remote branch sites.

Before you begin

Ensure that you review Prerequisites for using SD-WAN wizard, on page 1588 and Guidelines for using SD-WAN wizard, on page 1586.

Procedure

Step 1 Choose **Secure Connections** > **Site-to-Site VPN & SD-WAN** , and click **Add**.

Step 2 Enter a name for the SD-WAN VPN topology in the **Topology Name** field.

Step 3 Click the **SD-WAN Topology** radio button and click **Create**.

Step 4 Configure a hub:

a) Click **Add Hub**.

b) From the **Device** drop-down list, choose a hub.

c) Click **+** next to the **Dynamic Virtual Tunnel Interface (DVTI)** drop-down list to add a dynamic VTI for the hub.

The **Add Virtual Tunnel Interface** dialog box is prepopulated with default configurations. However, you must configure the **Tunnel Source**, and the **Borrow IP Address**. For more information, refer to Add a dynamic virtual tunnel interface for a hub, on page 1593.

d) In the **Hub Gateway IP Address** field, enter the public IP address of the hub's VPN interface or the tunnel source of the dynamic VTI to which the spokes connect.

This IP address is auto populated if the interface has a static IP address. If hub is behind a NAT device, you must manually configure the post-NAT IP address.

e) From the **Spoke Tunnel IP Address Pool** drop-down list, choose an IP address pool or click **+** to create an address pool.

When you add spokes, the wizard auto generates spoke tunnel interfaces, and assigns IP addresses to these spoke interfaces from this IP address pool.

f) Click **Add** to save the hub configuration.

g) (Optional) To add a secondary hub, repeat Step 4a to Step 4f.

h) Check the **ECMP** check box to enable Equal Cost Multi-Path (ECMP) on the dynamic VTIs of hub devices with Version 10.0 or later.

All virtual access interfaces on the hub connecting to the same spoke are grouped into an ECMP zone. This feature load balances traffic through multiple paths to a spoke.

Step 5 Configure spokes:

Click **Add Spoke** to add a single spoke device, or click **Add Spokes (Bulk Addition)** to add multiple spokes to your topology.

- Click **Add Spoke**. In the **Add Spoke** dialog box, configure the following parameters:

  a. From the **Device** drop-down list, choose a spoke.

b. From the **VPN Interface** drop-down list, choose a WAN-facing or internet-facing physical interface to establish a VPN connection with the hub.

c. Check the **Local Tunnel (IKE) Identity** check box to enable a unique and configurable identity for the VPN tunnel from this device to the remote peer. By default, this option is enabled.

d. Choose one of the following options from the **Identity Type** drop-down list:

- **Key ID**—(Default value) This value is auto populated as < sd-wan topologyname >_< device_IP_address >, for example, sdwantopo1_192.168.0.200. You can also specify a key ID of your choice.
- **Email ID**—Specify an email ID up to 127 characters.
- **IP Address**—IP address of the spoke's VPN interface.
- **Auto**—IP address of the spoke's VPN interface for pre-shared key authentication or the certificate Distinguished Name (DN) for certificate-based authentication.
- **Hostname**—Fully qualified hostname of the spoke.

e. Click **Save** to save the spoke configuration.

- Click **Add Spokes (Bulk Addition)**. In the **Add Bulk Spokes** dialog box, configure the following parameters:

a. Choose one or more devices from the **Available Devices** list and click **Add** to move the devices to **Selected Devices** .

b. Use one of the following methods to select the VPN interfaces of the spokes:

- Click the **Interface Name Pattern** radio button and specify a string to match the logical name of the internet or WAN interface of the spokes, for example, outside*, wan*.

  If the spoke has multiple interfaces with the same pattern, the first interface that matches the pattern is selected for the topology.
- Click the **Security Zone** radio button and choose a security zone with the VPN interfaces of the spokes from the drop-down list, or click + to create a security zone.

c. Click **Next**.

The wizard validates if the spokes have interfaces with the specified pattern. Only the validated devices are added to the topology.

d. Click **Add**.

e. Click **Next**.

For each spoke, the wizard automatically selects the hub's DVTI as the tunnel source IP address.

Note If the hub’s tunnel source IP address is an IPv6 address, the wizard automatically selects the first IPv6 address of the spokes' selected interface. To edit the IPv6 address of a spoke's tunnel source, click the edit icon next to a spoke, choose an IPv6 address from the **IP Address** drop-down list, and click **Save**.

Step 6 Configure authentication settings for the devices in the SD-WAN topology:

a) **Authentication Type**—For device authentication, you can use a manual pre-shared key, an auto-generated pre-shared key, or a certificate.

- **Pre-shared Manual Key**—Specify the pre-shared key for the VPN connection.
- **Pre-shared Automatic Key**—(Default value) The wizard automatically defines the pre-shared key for the VPN connection. Specify the key length in the **Pre-shared Key Length** field. The range is 1 to 127.
- **Certificate**—When you use certificates as the authentication method, the peers obtain digital certificates from a CA server in your PKI infrastructure, and use them to authenticate each other.

b) Choose one or more algorithms from the **Transform Sets** drop-down list.

c) Choose one or more algorithms from the **IKEv2 Policies** drop-down list.

Step 7 Configure the SD-WAN settings:

This step involves the auto generation of spoke tunnel interfaces, and BGP configuration of the overlay network.

a) From the **Spoke Tunnel Interface Security Zone** drop-down list, choose a security zone or click **+** to create a security zone to which the wizard automatically adds the spokes' auto-generated Static Virtual Tunnel Interfaces (SVTIs).

b) Check the **Enable BGP on the VPN Overlay Topology** check box to automate BGP configurations such as neighbor configurations between the overlay tunnel interfaces and basic route redistribution from the directly connected LAN interfaces of the hubs and spokes.

c) In the **Autonomous System Number** field, enter an Autonomous System (AS) number.

AS number is a unique number for a network with a single routing policy. BGP uses AS numbers to identify networks. The spoke's BGP neighbor configuration is generated based on the corresponding hub's AS number. Range is from 0 to 65536.

- If all the hubs and spokes are in the same region, by default, **64512** is the AS number.
- If the primary and secondary hubs are in different regions, the primary hub and the spokes are configured with **64512** as the AS number, and the secondary hub is configured with a different AS number.

d) In the **Community Tag for Local Routes** field, enter the BGP community attribute to tag connected and redistributed local routes. This attribute enables easy route filtering.

e) Check the **Redistribute Connected Interfaces** check box and choose an interface group from the drop-down list or click **+** to create an interface group with connected inside or LAN interfaces for BGP route redistribution in the overlay topology.

f) Check the **Enable Multiple Paths for BGP** check box to allow multiple BGP routes to be used at the same time to reach the same destination. This option enables BGP to load-balance traffic across multiple links.

Note that when you enable this option, BGP multipath is enabled only for spokes.

g) (Optional) Check the **Secondary Hub is in Different Autonomous System** check box. This check box appears only if you have a secondary hub in this topology.

h) In the **Autonomous System Number** field, enter the AS number for the secondary hub.

i) In the **Community Tag for Learned Routes** field, enter the BGP community attribute to tag routes learned from other SD-WAN peers over the VPN tunnel. This attribute is required only for eBGP

configuration when the secondary hub has a different AS number. This field appears only if you have configured two hubs in the SD-WAN topology.

Step 8 Configure **Advanced Settings**.

a) From the **Identity Sent to Peers** drop-down list, choose the identity that the peers will use to identify themselves during IKE negotiations.

- **autoOrDN**—(Default value) Determines IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication.
- **IP Address**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
- **Hostname**—Uses the fully qualified domain name of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.

b) Configure **TrustSec (SGT) Settings**.

Enable SGT propagation over Virtual Tunnel Interfaces—Cisco TrustSec uses Security Group Tags (SGTs) to control access and enforce traffic on a network. This option enables SGT propagation over SVTIs and DVTIs of the VPN topology. To enable SGT propagation on a specific SVTI or DVTI, configure it in individual devices. Note that the Firewall Threat Defense device must be Version 10.0.0 and later.

c) Configure **Bidirectional Forwarding Detection (BFD) Settings**.

Enable Bidirectional Forwarding Detection Routing—BFD is a protocol for detecting forwarding path failures. This option enables BFD routing protocol on the SVTIs and DVTIs. When BFD detects a path failure, traffic is rerouted over the newly identified path. Note that the Firewall Threat Defense device must be Version 10.0.0 and later.

1. From the **Interval** drop-down list, choose the unit of interval, microseconds or milliseconds, at which BFD control packets are sent.
2. In the **Multiplier** field, enter the number of consecutive missed BFD control packets allowed before declaring that the peer is unavailable. The range is 3 to 50 packets.
3. In the **Minimum Transmit and Receive Interval** field, enter the minimum transmit and receive interval of the BFD control packets. The range is 50 to 999 milliseconds or 50000 to 999000 microseconds.

Step 9 Click **Finish** to save and validate the SD-WAN topology.

You can view the topology in the **Site-to-Site VPN Summary** page (**Secure Connections** > **Site-to-Site VPN & SD-WAN**). After you deploy the configurations to all the devices, you can see the status of all the tunnels in this page.

What to do next

- View the auto-generated spoke SVTIs and their IP addresses—Click the edit icon next to the spoke configuration and click **View Generated Tunnel Interfaces** .
- We recommend that you enable ECMP on the spoke SVTIs. Choose **Devices** > **Device Management**, and click **Routing** > **ECMP**. Note that when you enable ECMP on the hubs, it is not enabled on the spoke SVTIs, you must manually enable ECMP on the SVTIs.

- Deploy the configurations on the hub and spokes. Choose **Deploy** . Select devices and click **Deploy** .
- Verify the SD-WAN topology tunnel statuses. For more information, see Verify tunnel statuses of an SD-WAN topology, on page 1599.
- Configure ACLs for the spokes' tunnel interface security zones. Choose **Policies** > **Security policies** > **Access Control**.
- We recommend that you enable BGP multipath on hubs. To enable BGP multipath on hubs:
  1. Choose ECMP **Devices** > **Device Management** , and click **Routing**.
  2. Under **General Settings**, click **BGP**.
  3. Check the **Enable BGP** check box to enable BGP.
  4. In the **AS Number** field, enter the AS number that you configured in the SD-WAN topology.
  5. Click **Save**.
  6. In the left pane, choose **BGP > IPv4 or IPv6**, and click the **General** tab.
  7. In the **Forward Packets over Multiple Paths** section, click the edit icon.
  8. Configure values for **Number of Paths** and **IBGP number of paths**. We recommend that you configure these values as 8.
- For more information about configuration examples using SD-WAN wizard, refer to Sample configurations for dual-ISP deployment using SD-WAN wizard, on page 1594.
- Configure a PBR policy on each spoke for application-aware routing based on the application performance metrics of the WAN interfaces. For more information, refer to Route Application Traffic from the Branch to the Internet Using Direct Internet Access (DIA).

Add a dynamic virtual tunnel interface for a hub

In the SD-WAN wizard, you must configure a DVTI for each hub. DVTI uses a virtual template to dynamically generate a unique virtual access interface for each VPN session.

Before you begin

In the SD-WAN wizard, click **Add Hub**, and choose a hub from the **Device** drop-down list.

Procedure

Step 1 Click + next to the **Dynamic Virtual Tunnel Interface (DVTI)** drop-down list to add a DVTI for the hub.

The **Add Virtual Tunnel Interface** dialog box appears with the following prepopulated default configurations.

a. **Tunnel Type**: Dynamic.

b. **Name**: <*tunnel_source_interface_logical name*>_dynamic_vti_<*tunnel_ID*>. For example, outside_dynamic_vti_1.

c. **Enabled** check box: Checked by default.

d. **Template ID**: Unique ID for the DVTI.

e. **Tunnel Source**: Physical interface that is the source of the DVTI and is auto populated by default.

f. **IPsec Tunnel Mode**: IPv4, by default.

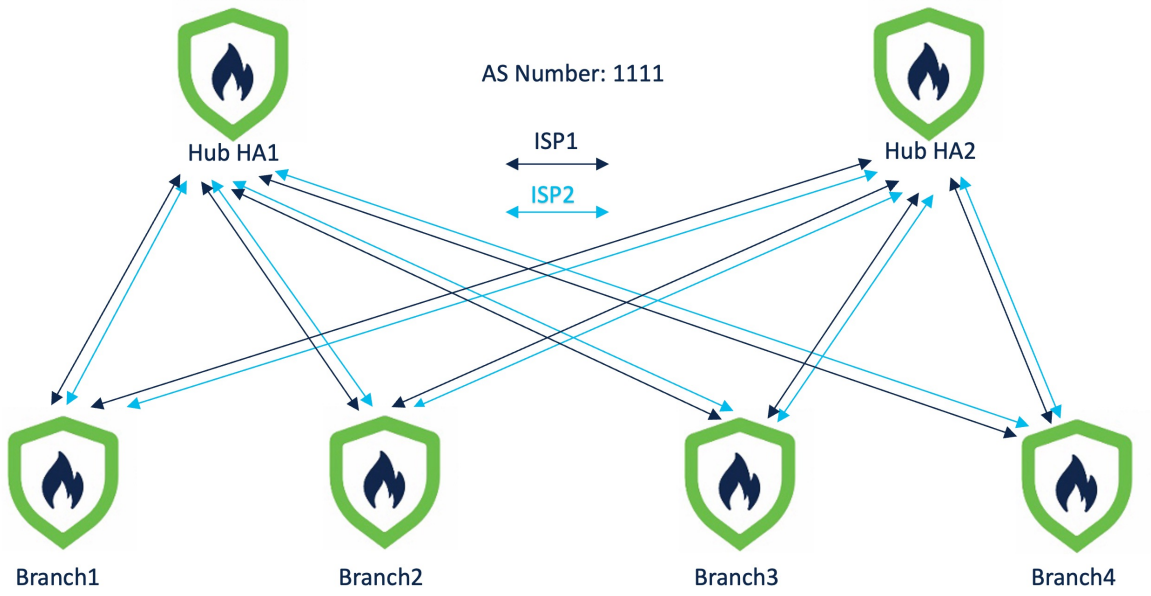
Step 2 Choose a security zone for the dynamic VTI from the **Security Zone** drop-down list.

Step 3 Choose a physical or loopback interface from the **Borrow IP** drop-down list, the dynamic VTI interface inherits this IP address.

Ensure that you use an IP address different from the tunnel source IP address. We recommend that you use a loopback IP address.

Step 4 Click **OK** to save the dynamic VTI.

Sample configurations for dual-ISP deployment using SD-WAN wizard



Here are some sample configurations that demonstrate how to implement dual-ISP deployment using the SD-WAN wizard for redundancy and load balancing across multiple internet service providers.

Dual ISP deployment: Two hubs and four spokes in the same region

In this dual ISP topology, the hubs and the spokes are in a single region, with AS number AS 1111. The hubs and spokes use Internal Border Gateway Protocol (iBGP) as the routing protocol to exchange routing information.

- Hub HA1 and Hub HA2 are hub Threat Defense devices at the headquarters.
- Branch1, Branch2, Branch3, and Branch4 are spoke Threat Defense devices at the branches.
- ISP1 is the VPN interface of each spoke to ISP1.
- ISP2 is the VPN interface of each spoke to ISP2.

Figure 426: Dual ISP topology with two hubs and four spokes in the same region

To configure this topology, you must create two SD-WAN topologies using the SD-WAN wizard.

SD-WAN topology 1

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2, Branch3, Branch4
AS Number	1111
VPN Interface (Spoke Tunnel Source)	ISP1
Number of Tunnels	8

The total number of tunnels in SD-WAN Topology 1 is 8.

SD-WAN topology 2

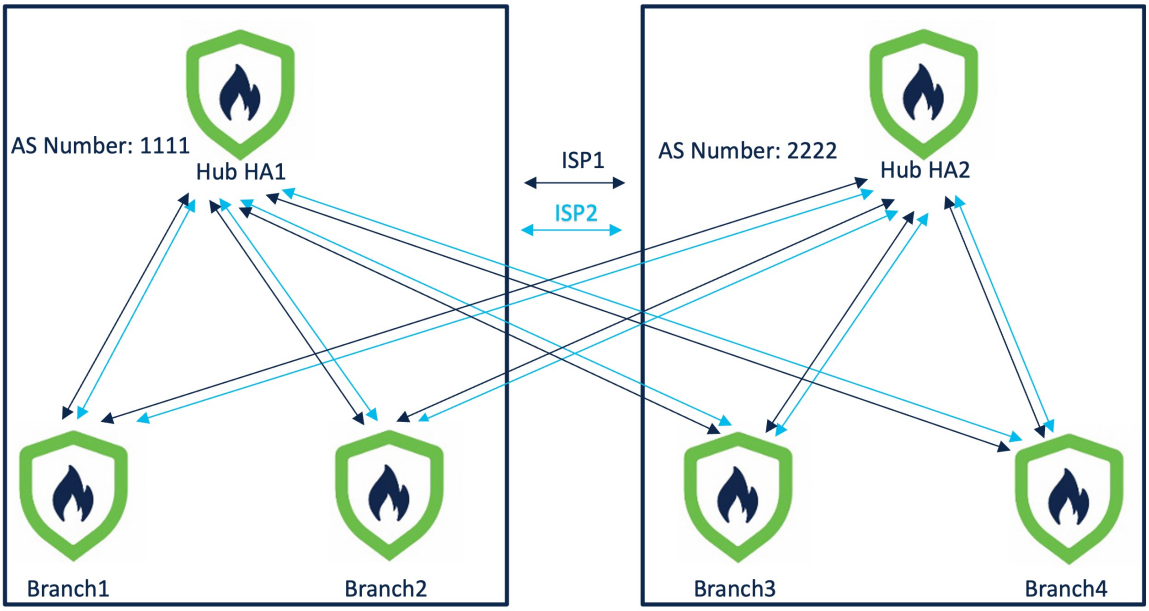
Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2, Branch3, Branch4
AS Number	1111

Parameter	Value
VPN Interface (Spoke Tunnel Source)	ISP2
Number of Tunnels	8

The total number of tunnels in SD-WAN Topology 2 is 8.

The total number of VPN tunnels for this dual ISP deployment is 16.

Note If the hubs are in different geographic locations and have different protected networks behind them, to ensure direct communication between these networks, configure a point-to-point route-based VPN topology between the two hubs using the route-based VPN wizard.



Dual ISP deployment: Two hubs and four spokes in different regions

In this dual ISP topology, the hubs are in different regions, and have two directly connected spokes each. The hubs and their directly connected spokes use Internal Border Gateway Protocol (iBGP) as the routing protocol, and the hubs use External Border Gateway Protocol (eBGP) to exchange routing information.

Topology components

- Hub HA1 and Hub HA2 are hub Threat Defense devices at the headquarters.
- Branch1, Branch2, Branch3, and Branch4 are spoke Threat Defense devices at the branches.
- HQ1, Branch1, and Branch2 are in a single region with AS number AS 1111.
- HQ2, Branch3, and Branch4 are in a single region with AS number AS 2222.
- ISP1 is the VPN interface of each spoke to ISP1.
- ISP2 is the VPN interface of each spoke to ISP2.

Figure 427: Dual ISP topology with two hubs and four spokes in different regions

To configure this topology, you must create the four SD-WAN topologies using the SD-WAN wizard:

SD-WAN topology 1

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2
AS Number	1111
Secondary AS Number	2222
VPN Interface (Spoke Tunnel Source)	ISP1

The number of tunnels in SD-WAN Topology 1 is 4.

SD-WAN topology 2

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2
AS Number	1111

Parameter	Value
Secondary AS Number	2222
VPN Interface (Spoke Tunnel Source)	ISP2

The number of tunnels in SD-WAN Topology 2 is 4.

SD-WAN topology 3

Parameter	Value
Primary Hub	Hub HA2
Secondary Hub	Hub HA1
Spokes	Branch3, Branch4
AS Number	2222
Secondary AS Number	1111
VPN Interface (Spoke Tunnel Source)	ISP1

The number of tunnels in SD-WAN Topology 3 is 4.

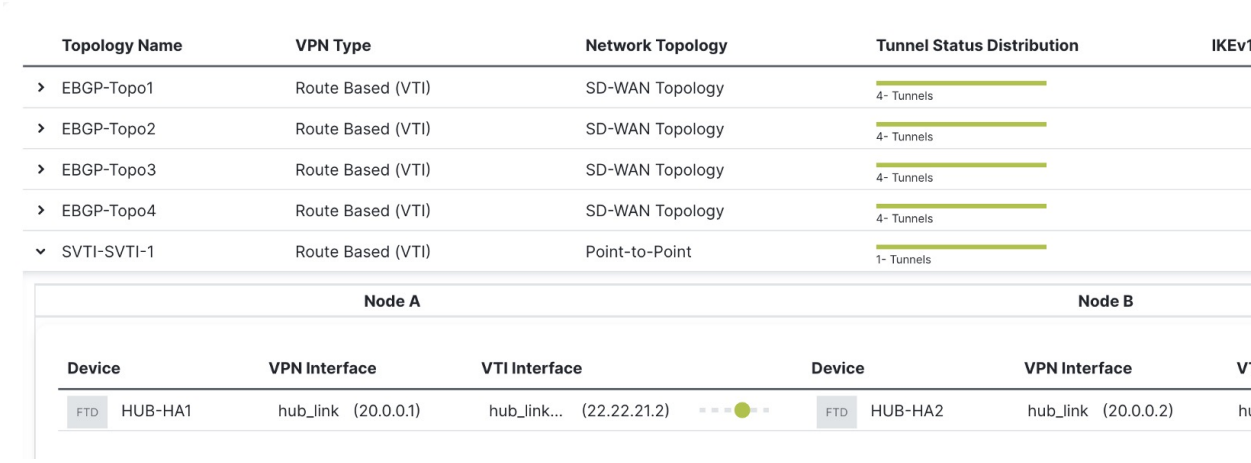
SD-WAN topology 4

Parameter	Value
Primary Hub	Hub HA2
Secondary Hub	Hub HA1
Spokes	Branch3, Branch4
AS Number	2222
Secondary AS Number	1111
VPN Interface (Spoke Tunnel Source)	ISP2

The number of tunnels in SD-WAN Topology 4 is 4.

The total number of VPN tunnels for this dual ISP deployment is 16.

Note If the hubs are in different geographic locations and have different protected networks behind them, to ensure direct communication between these networks, configure a point-to-point route-based VPN topology between the two hubs using the route-based VPN wizard.

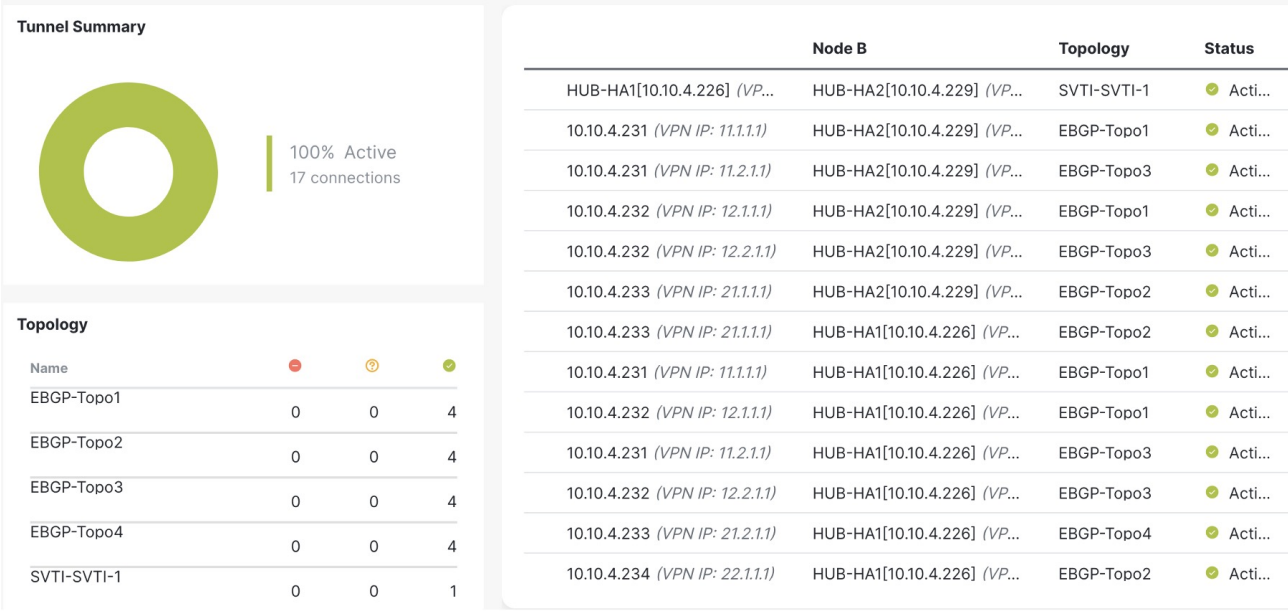


Verify tunnel statuses of an SD-WAN topology

You can verify the tunnel statuses of SD-WAN topologies, including checking VPN tunnel status in the Site-to-Site VPN Summary page and Dashboard, viewing virtual tunnel interfaces on devices, and verifying BGP routing configuration on hubs and branches.

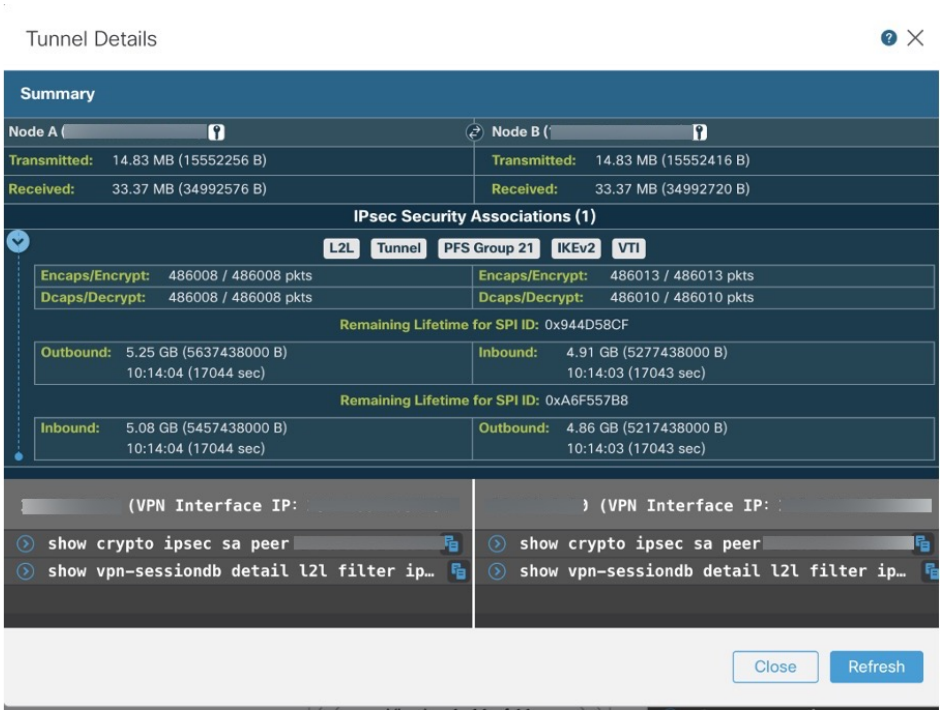
Verify tunnel statuses on the Site-to-Site VPN summary page

To verify if the VPN tunnels of the SD-WAN topologies are up, choose **Secure Connections** > **Site-to-Site VPN & SD-WAN**.



This example shows the five SD-WAN topologies with two hubs and four spokes in different regions that are connected to dual ISPs:

Verify tunnel statuses on the Site-to-Site VPN dashboard

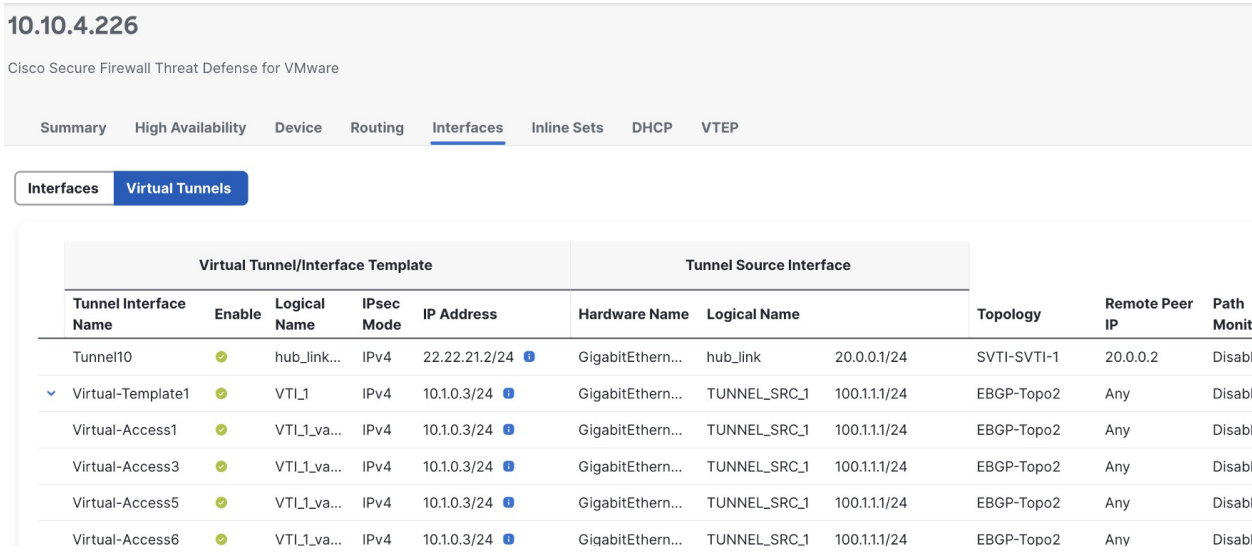


To view details of the SD-WAN VPN tunnels, choose **Insights & Reports** > **VPN dashboards** > **Site-to-Site VPN**.

This example shows the VPN tunnels for an SD-WAN topology with two hubs and four spokes in different regions that are connected to dual ISPs:

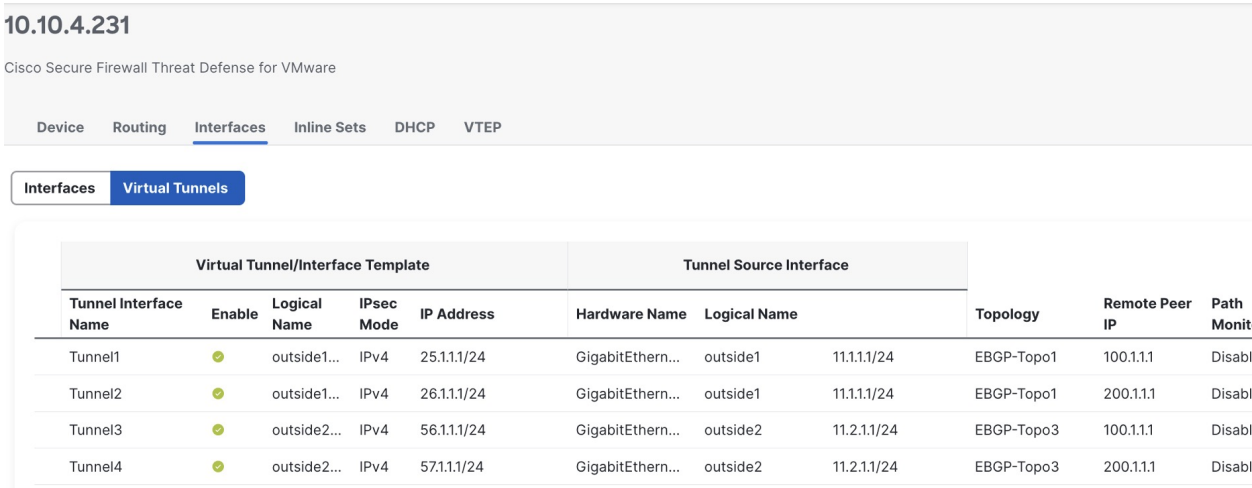
To view more details of each VPN tunnel:

1. Hover over a tunnel.
2. Click the **View Full Information** ( ) icon. A pane with tunnel details and more actions is displayed.
3. Click the **CLI Details** tab in the side pane to view the show commands and details of the IPsec security associations.



View virtual tunnel interfaces of the devices

To view the dynamic VTIs of hubs and static VTIs of spokes:



1. Choose **Devices** > **Device Management**.
2. Click the edit icon for a hub or a spoke device.
3. Click the **Interface** tab.
4. Click the **Virtual Tunnels** tab.

   For each VTI, you can view details such as name, IP address, IPsec mode, tunnel source interface details, topology, and remote peer IP.

This image shows an example of the virtual access interfaces created dynamically by a hub's DVTI:

This image shows an example of the static tunnel virtual interfaces (SVTIs) created on a spoke by the SD-WAN wizard:

The SD-WAN wizard assigns IP addresses to these tunnel interfaces from the IP address pool of the hub.

Verify routing in the hub and branch devices

To verify the BGP configuration of the hubs and spokes of the SD-WAN topologies:

1. Choose **Devices** > **Device Management**.
2. Click the edit icon for a hub or a spoke device.
3. Click the **Device** tab.
4. Click **CLI** in the **General** card. The **CLI Troubleshoot** window appears.
5. Enter one of these commands in the **Command** field and click **Execute**:
   - **show route**
   - **show BGP summary**

Use cases for SD-WAN capabilities

Use the Cisco Secure Firewall Threat Defense SD-WAN Design and Deployment Guide to design and deploy SD-WAN architectures using Firewall Threat Defense and Firewall Management Center. This guide explains design principles, configuration workflows, and best practices.

Use these guides for detailed instructions for the primary use cases leveraging the SD-WAN capabilities supported by Cisco Secure Firewall.

- Simplify Branch to Hub Communication using Dynamic Virtual Tunnel Interface (DVTI)
- Route Application Traffic from the Branch to the Internet Using Direct Internet Access (DIA)
- Secure Internet Traffic Using Umbrella Auto Tunnel
- Empower Remote Workers with Secure Connectivity: DIA, Umbrella Auto Tunnel, and DVTI in Action
- Set Up SD-WAN Branch Office with Dual ISPs Using Registration Key and Device Templates
- Set Up SD-WAN Branch Office with Dual ISPs Using Serial Numbers and Device Template

Monitor SD-WAN topologies

This section provides information about the different ways to monitor your SD-WAN topologies.

SD-WAN summary dashboard

The SD-WAN Summary dashboard (**Insights & Reports** > **VPN dashboards** > **SD-WAN Summary**) provides a snapshot of your WAN devices and their interfaces. This dashboard helps you to:

- Identify issues with the underlay and overlay (VPN) topologies.

- Troubleshoot VPN issues using the existing **Health Monitoring**, **Device Management**, and **Site-to-Site Monitoring** pages.
- Monitor application performance metrics of WAN interfaces. The threat defense steers application traffic based on these metrics.

For clusters, this dashboard displays application performance metrics of only the control node and not the data nodes.

WAN device criteria

A WAN device must meet one of these criteria:

- The device must be a VPN peer.
- The device must have WAN interface.

WAN interface criteria

A WAN interface must meet one of these criteria:

- The interface has IP address-based path monitoring enabled on it.
- The interface has a Policy Based Routing (PBR) policy with at least one application configured to monitor it.

For more information about PBR policy and path monitoring, see Policy-Based Routing, on page 1325.

Uplink decisions

Click **Uplink Decisions** to view the **VPN Troubleshooting** page. You can view syslogs with ID: 880001. These syslogs show the threat defense interfaces through which it steers traffic based on the configured PBR policy.

To view the above syslogs and to view the data on this dashboard, ensure that you review Prerequisites for using SD-WAN summary dashboard, on page 1603.

Prerequisites for using SD-WAN summary dashboard

Ensure that you review these prerequisites before using the SD-WAN summary dashboard.

General prerequisites

- You must be an Admin, Security Analyst, or Maintenance user to view this dashboard.
- Threat Defense devices must be Version 7.2 or later.
- Enable IP-based path monitoring and HTTP-based application monitoring on the WAN interfaces.

  To do this:

  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click the edit icon adjacent to the interface that you want to edit.

4. Click the **Path Monitoring** tab.
5. Check the **Enable IP based Monitoring** check box.
6. Check the **Enable HTTP based Application Monitoring** check box.
7. Click **OK**.

- Configure a PBR policy with at least one application configured to monitor it:
  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click **Routing**.
  4. In the left pane, click **Policy Based Routing**.
  5. Click **Add**.
  6. From the **Ingress Interface** drop-down list, choose an interface.
  7. Click **Add** to configure a forwarding action.
  8. Configure the parameters.
  9. Click **Save**.
- To view syslogs when you click **Uplink Decisions**, you must:
  - Choose **Devices** > **Platform Settings** and create or edit a threat defense policy.
  - In the left pane, click **Syslog**.
  - Click the **Logging Setup** tab.
  - Check the **Enable Logging** check box to turn on the data plane system logging for the threat defense device.
  - Click the **All Logs** radio button to enable logging of all the troubleshooting syslog messages.

    or

    Click the **VPN Logs** radio button to enable logging of only the VPN troubleshooting messages.
  - Click **Save**.

Prerequisites to view application performance metrics in the dashboard

- Threat Defense devices must be Version 7.4.1.
- Enable data collection from the SD-WAN module in the health policy.
  1. Choose **Troubleshooting** > **+ Show more** > **Health** > **Policies**.
  2. Click the **Edit health policy** icon.
  3. In the **Health Modules** tab, under **SD-WAN**, click the **SD-WAN Monitoring** toggle button.
- Configure applications for the PBR policies.

1. Choose **Objects** > **Access List** > **Extended**.
2. Click the edit icon adjacent to the access list and add the applications for the PBR policy.

- Configure the forwarding action for the policy with one of the four application metrics.
  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click **Routing**.
  4. In the left pane, click **Policy Based Routing**.
  5. Click the edit icon adjacent to the policy that you want to edit.
  6. In the **Edit Policy Based Route** dialog box, click the edit icon adjacent to the corresponding ACL.
  7. In the **Edit Forwarding Actions** dialog box, from the **Interface Ordering** drop-down list, choose one of these options:
     - **Minimal Jitter**
     - **Maximum Mean Opinion Score**
     - **Minimal Round-Trip Time**
     - **Minimal Packet Loss**

     If you choose **Interface Priority** or **Order**, application monitoring is not enabled on the interface.
- Configure ECMP on the WAN interfaces:
  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click **Routing**.
  4. In the left pane, click **ECMP**.
  5. Click **Add** and specify a name for the ECMP zone.
  6. Click **Add** to move interfaces from **Available Interfaces** to **Selected Interfaces**.
  7. Click **OK**.
- Ensure that traffic passes through the interface.
- Enable DNS inspection on each WAN device so that the Threat Defense device can do DNS snooping, and configure the trusted DNS servers:
  1. Choose **Devices** > **Platform Settings**.
  2. Click the edit icon adjacent to the threat defense policy that you want to edit.
  3. In the left pane, click **DNS**.
  4. Click the **DNS Settings** tab.
  5. Check the **Enable DNS name resolution by device** check box.

6. Click the **Trusted DNS Servers** tab.
7. Do one of these options:
   - Click the **Trust Any DNS server** toggle button.
   - Under **Specify DNS Servers**, click **Edit** to add trusted DNS servers.

Monitor WAN devices and interfaces using the SD-WAN summary dashboard

The SD-WAN Summary dashboard has these widgets under the **Overview** tab:

- Top applications, on page 1606
- WAN connectivity, on page 1606
- VPN topology, on page 1606
- WAN interface throughput, on page 1607
- Device inventory, on page 1607
- WAN device health, on page 1607

Top applications

This widget displays the top 10 applications ranked according to throughput.

You can choose a time range for the widget data from the **Show Last** drop-down list. The range is 15 minutes to two weeks.

WAN connectivity

This widget provides a summary of the WAN interfaces statuses. It shows the number of WAN interfaces that are in the **Online**, **Offline** or **No Data** states. Note that you cannot monitor subinterfaces using this widget.

Click **View All Interfaces** to view more details about the interfaces in the health monitor page.

If a WAN interface is in the **Offline** or **No Data** state, you can troubleshoot it from the health monitor page:

1. In the **Monitoring** pane, expand **Devices**.
2. Click the corresponding WAN device to view the device-specific health details.
3. Click the **Interface** tab to view the interface status and aggregate traffic statistics for a specific time.

   Alternatively, you can click **View System & Troubleshoot Details**. The health monitor page is displayed with all the necessary details.

VPN topology

This widget provides a summary of the site-to-site VPN tunnel statuses. It shows the number of **Active**, **Inactive**, and **No Active Data** VPN tunnels.

Click **View All Connections** to view the VPN tunnel details in the **Site-to-site VPN Monitoring** dashboard.

If the tunnels are in the **Inactive** or **No Active Data** state, you can troubleshoot using the **Site-to-site VPN Monitoring** dashboard. In the **Tunnel Status** widget, hover your cursor over a topology, click **View** ( ) and do one of these actions:

- Click the **CLI Details** tab to view the details of the VPN tunnels.
- Click the **Packet Tracer** tab to use the packet tracer tool for the topology.

WAN interface throughput

This widget monitors the average throughput of the WAN interfaces during the chosen time period.

The interface throughput is classified into four bands. These details aid in cost planning and resourcing. You can choose a time range for the widget data from the **Show Last** drop-down list. The range is from 15 minutes to two weeks.

Click **View Health Monitoring** to view more details about the interface in the health monitor page.

Device inventory

This widget lists all the managed WAN devices and groups them according to the model.

Click **View Device Management** to view more details about the device in the **Device Management** page.

WAN device health

This widget displays the device count according to the health of the WAN devices. You can view the number of devices with errors, warnings, or those that are in **Disabled** state.

Click **View Health Monitoring** to view the alarms, and quickly identify, isolate, and resolve issues.

If the health of a device is affected, you can troubleshoot it from the health monitor page.

1. In the **Monitoring** pane, expand **Devices**.
2. Click the corresponding WAN device to view the device-specific health details.
3. Click **View System & Troubleshoot Details**. The health monitor page is displayed with all the necessary details.

A device can be in **Disabled** state for multiple reasons, including these:

- Management interface is disabled.
- Device is powered off.
- Device is being upgraded.

Monitor application performance metrics of WAN interfaces using SD-WAN summary dashboard

You can monitor application performance metrics of WAN interfaces using the **Application Monitoring** tab of the SD-WAN Summary dashboard. These metrics include Jitter, Round Trip Time (RTT), Mean Opinion Score (MOS), and Packet Loss.

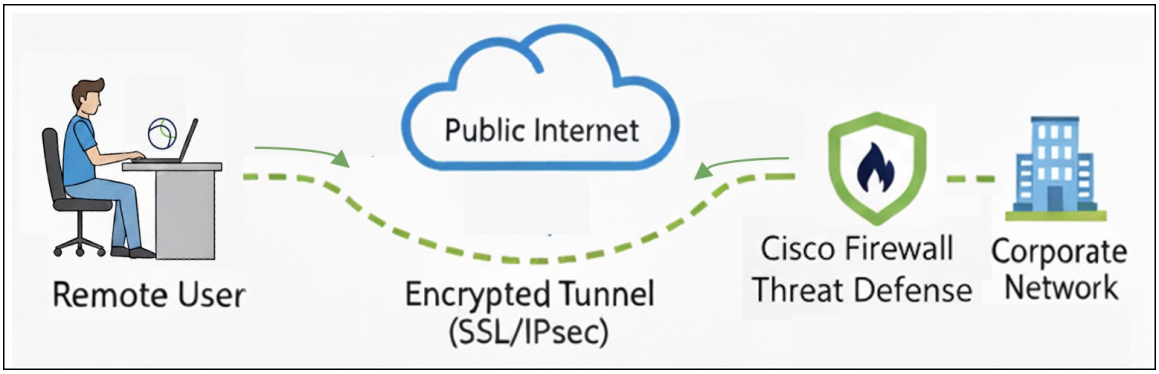
By default, the metrics data is refreshed every 5 minutes. You can change the refresh time; the range is from 5 to 30 minutes. You can view the metrics in tabular and graphical formats. For each WAN interface, the

latest metric value appears in the table. For graphical data, you can choose a time interval of up to 24 hours to view the metrics data for the corresponding WAN interfaces.

CHAPTER 36

Remote Access VPN

These topics explain how to configure remote access VPN for your network.



- Remote access VPN, on page 1609
- Plan your remote access VPN, on page 1610
- Configure a remote access VPN policy, on page 1613
- Postconfiguration tasks for a remote access VPN policy, on page 1631
- Configure advanced options for a remote access VPN policy, on page 1634
- Configure additional remote access VPN configurations, on page 1661
- Monitor remote access VPNs, on page 1688
- Troubleshoot remote access VPNs, on page 1690
- Appendix A: Concurrent VPN sessions of Firewall Threat Defense devices, on page 1692
- Appendix B: RADIUS server attributes for Firewall Threat Defense devices , on page 1694
- History for remote access VPN, on page 1704

Remote access VPN

Remote access VPN enables remote users to securely connect to a corporate network by using the Cisco Secure Client client on their laptops or desktops. All traffic between the remote device and the Firewall Threat Defense device is encrypted using SSL or IPsec-IKEv2 protocols, ensuring data protection across untrusted networks. After successful authentication using AAA servers, client certificates, or SAML identity providers, users can access internal corporate applications and services.

Firewall Management Center simplifies the configuration and management of remote access VPN policies through an intuitive, guided wizard. After you configure a remote access VPN policy, you can deploy it on your Firewall Threat Defense devices.

Figure 428: Remote access VPN using secure firewall

Plan your remote access VPN

Use these topics to prepare your remote access VPN before you configure it.

Licenses for remote access VPN

This topic lists the licensing requirements for configuring remote access VPN using Management Center.

- Ensure that export-controlled features are enabled in your Smart License.

  To verify if export-controlled functionality is enabled for your Smart License account, choose **Administration** > **Licenses** > **Smart Licenses**.

- Ensure that you have one of the following licenses for Secure Client:
  - Secure Client Advantage
  - Secure Client Premier
  - Secure Client VPN Only

Prerequisites for remote access VPN

Review these prerequisites for configuring a remote access VPN policy.

General prerequisites

- You must have an administrator role to configure a remote access VPN policy.
- Configure a certificate enrollment object to obtain the identity certificate for each Firewall Threat Defense device that acts as a remote access VPN gateway.
- Create a security zone or interface group so that remote users can access the network interfaces for VPN connections.
- Ensure IKE ports (500, 4500), and SSL port 443 are not in use by existing services, NAT, or PAT rules. The Firewall Threat Defense device cannot start VPN services on ports that are already active.

- Configure DNS on each device in a remote access VPN policy to resolve AAA server names, named URLs, and CA servers with FQDNs or hostnames.

  To configure DNS settings, choose **Devices** > **Platform Settings**, edit a policy. From the left pane, click **DNS**.

AAA server prerequisites

- Ensure that the AAA server is reachable from the Firewall Threat Defense device. Configure routing to ensure connectivity to the AAA servers (**Devices** > **Device Management**, click the **Edit** icon, and from the left pane, choose **Routing**).

  For remote access VPN double authentication, ensure that both the primary and secondary authentication servers are reachable from the Firewall Threat Defense device.

- Before using an AD or LDAP server as an authentication server for your remote access VPN policies, ensure that you configure these parameters:
  - AD or LDAP realms
  - LDAP attribute map

Secure Client prerequisites

- Download the latest Secure Client image files from Cisco Software Download Center.

  Choose **Objects** > **VPN** > **Secure Client File** to add the Secure Client image files.

- Download the Secure Client Profile Editor from Cisco Software Download Center to create the Secure Client profile. Use the standalone profile editor to create a new Secure Client profile or modify one.

Guidelines for remote access VPNs

Review these guidelines before configuring and managing remote access VPN policies.

General guidelines

- Ensure that only one administrator modifies the policy at a time. The web interface allows multiple concurrent sessions, but only the last saved configuration remains.
- Ensure that you unassign the remote access VPN policy associated with a Firewall Threat Defense device before moving it to a different domain.
- Verify the ciphers for the remote access VPN policy before deployment:
  - For SSL: Choose **Devices** > **Platform Settings**, edit a policy. From the left pane, click **SSL** > **RA-VPN**.
  - For IPsec-IKEv2: Choose **Secure Connections** > **Remote Access VPN**, edit a remote access policy. Click the **Advanced** tab and from the left pane, choose **IPsec**.
- Do not run **curl** commands, including HTTP HEAD requests, on the remote access VPN headend device because these commands are not supported.

- Ensure third-party clients provide a valid user agent because the Firewall Threat Defense device rejects VPN sessions with a null user agent.
- Configure browser proxy using FlexConfig.
- Breaking a remote branch deployment (RBD) high-availability pair automatically removes remote access VPN configurations from the standby unit's RBD WAN interface.
- Limit realms to 16 directories, as only the first 16 are deployed during a remote access VPN connection.
- When **Bypass Access Control policy for decrypted traffic** is disabled and a downloadable access control list (DACL) is applied, decrypted traffic is evaluated against the access control policy (ACP) first. Traffic permitted by the ACP is then evaluated against the DACL; traffic denied by the ACP is not evaluated further.

NAT guidelines

- Verify the NAT rules on the Firewall Threat Defense device to ensure that they do not disrupt the remote access VPN traffic.
- Enable route lookup for any NAT rule applied to a remote access VPN network that uses DHCP. This configuration ensures that the device identifies the correct egress interface for DHCP request forwarding.

Certificate guidelines

- Install the identity certificate on the device before deploying the remote access VPN policy to the device.
- Manually add client certificates to your clients. You cannot use SCEP or CA services to distribute certificates.

Secure Client guideline

Use only one Secure Client package on low-end Firewall Threat Defense devices to prevent memory exhaustion and continuous restarts.

Limitations for remote access VPN

Review these limitations before you configure a remote access VPN.

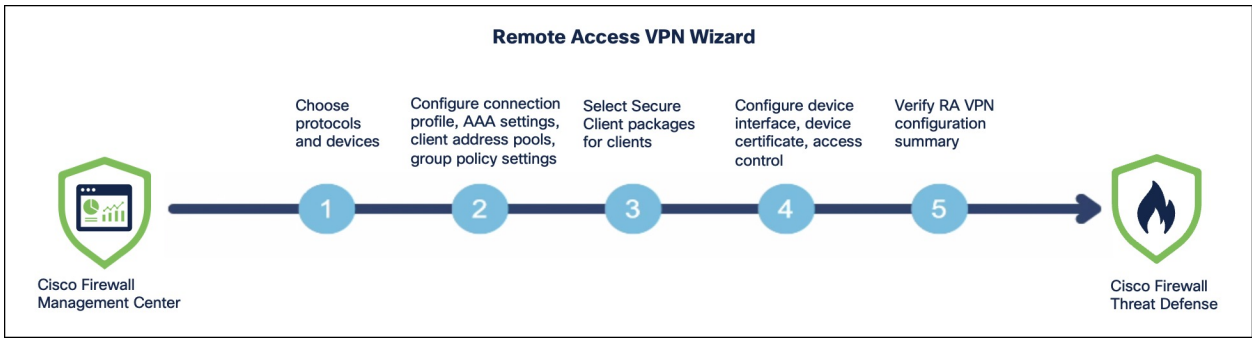
- Do not configure IPSec tunnels with null encryption on Firewall Threat Defense devices, as they are not supported.
- Use IPsec-IKEv2 instead of SSL when implementing remote access VPN with ECMP, as SSL is not supported in ECMP environments.
- Remote access VPN does not support clustering configurations.
- Secure Client does not support TACACS, Kerberos Constrained Delegation (KCD) and RSA SecurID (SDI), and SDI authentication methods when connecting to a Firewall Threat Defense device.

Manage user authorization attributes in remote access VPN policies

The Firewall Threat Defense device allows you to apply user authorization attributes, also called entitlements or permissions, to VPN connections. These attributes can come from an external AAA server (such as RADIUS) or through a group policy on the device, allowing precise control of user access during remote VPN sessions.

Authorization attribute order

Firewall Threat Defense applies user authorization attributes in this order:



- **User attributes in the external AAA server**—The server returns these attributes after a successful user authentication, authorization, or both.
- **User attributes in the device's group policy**—If a RADIUS server returns the RADIUS Class attribute IETF-Class-25 with the value `OU=group-policy` for a user, the Firewall Threat Defense device assigns the user to the group policy with the same name and enforces any attributes from that group policy which are not provided by the server.
- **User attributes in the device's group policy assigned by a connection profile**—The connection profile defines the initial settings for a remote access VPN connection and includes a default group policy that is applied to the user before authentication.

Note The Firewall Threat Defense device does not inherit system default attributes from the default group policy, `DfltGrpPolicy`. Instead, it uses the attributes from the group policy assigned to the connection profile for the user session, unless overridden by user attributes or a group policy from the AAA server.

Configure a remote access VPN policy

Use the **Remote Access VPN Policy Wizard** to quickly set up a basic remote access VPN policy. Enhance the configuration by adding optional attributes, then deploy the policy to your Firewall Threat Defense devices.

The wizard consists of five stages:

Before you begin

Ensure that you review Licenses for remote access VPN, on page 1610, Prerequisites for remote access VPN, on page 1610, and Guidelines for remote access VPNs, on page 1611.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN** and click **Add**.

In the **Name** field, enter the name for the remote access VPN policy.

Step 2 Select protocols and devices.

a) In **VPN Protocols**, select **SSL**, **IPSec-IKEv2**, or both. These protocols establish secure connections over a public network through VPN tunnels.

b) In **Targeted Devices**, select one or more devices as as your remote access VPN gateways.

Step 3 Configure connection profile.

In the **Connection Profile Name** field, enter the name for the VPN connection profile.

A connection profile includes settings and attributes for authentication, address assignments to VPN clients, and group policies. The default connection profile, *DefaultWEBVPNGroup*, is available when you configure a remote access VPN policy.

Step 4 Configure AAA settings.

For more information, see Configure AAA settings for a remote access VPN policy, on page 1617.

Step 5 Configure client address pool.

You can assign client IP address pools for your remote users from a AAA server, a DHCP server, and local IP address pools. If you select multiple options, the order of the IP address assignment is AAA server, DHCP server, and local IP address pools.

- **Use AAA Server**—Check this check box to assign client IP address pools from a AAA server. This option is supported only for realm and RADIUS authorization. Ensure that realm or RADIUS server is configured to provide client IP addresses.
- **Use DHCP Servers**—Check this check box to assign client IP address pools from a DHCP server.
- **Use IPv4 DHCP Servers**—Click the edit icon to add one or more DHCP servers.
- **Use IP Address Pools**—Check this check box to assign client IP address pools from the Firewall Management Center.
- **IPv4 Address Pools**—Click the edit icon to add one or more IPv4 address pools.
- **IPv6 Address Pools**—Click the edit icon to add one or more IPv6 address pools.

Step 6 Configure a group policy.

A group policy contains user-oriented attributes for remote access VPN connections. You can assign attributes to users or groups without configuring each attribute individually. The connection profile applies a group policy to define user access terms after the tunnel is established. When a user logs in, a group policy identified by the AAA server is applied. If no group policy has been identified for the user, the default group policy, `DfltGrpPolicy` is used. Click **+** to create group policies.

Step 7 Select the Secure Client image that the VPN users will use to connect to the remote access VPN.

When you deploy the remote access VPN policy on the Firewall Threat Defense device, and a client device initiates a VPN connection, the Secure Client package is automatically downloaded to the client device.

Click **Add new Secure Client Image** to add a new image, and select the required images.

Step 8 Configure VPN interfaces for the device and the identity certificate.

a) Configure the device interfaces that users will use to connect to the VPN.

From the **Interface group/Security Zone** drop-down list, choose a interface group or a security zone that contains device interfaces for the VPN connections.

Check the **Enable DTLS on member interfaces** check box, if required.

Note DTLS is applicable only for SSL protocol.

b) Configure the identity certificate of the Firewall Threat Defense device.

This certificate authenticates the VPN gateway to remote access clients.

From the **Certificate Enrollment** drop-down list, choose a device certificate or click **+** to add a certificate.

You can choose an ACME certificate for authenticating the VPN gateway. ACME certificates automate the lifecycle management of SSL and TLS certificates, including their auto-renewal.

Step 9 Configure access controls, including geolocation-based access control and access control for decrypted VPN traffic.

a) Configure geolocation-based access control for your clients.

With Version 7.7 or later, you can use a service access object on Firewall Threat Defense devices to control remote clients' VPN access based on geolocation before authentication. By default, there are no geolocation restrictions unless a service access object is specified. For more information, see **Manage VPN Access of Remote Users Based on Geolocation** and Configure a service access object, on page 2779.

b) Configure access control for VPN traffic.

By default, an access control policy inspects all decrypted VPN tunnel traffic. Check the **Bypass Access Control policy for decrypted traffic (sysopt permit-VPN)** check box to bypass this inspection. VPN filter ACLs and authorization ACLs from the AAA server still apply.

Note If you select this option, you do not need to update the access control policy for remote access VPN.

c) Verify the summary of the remote access VPN policy and click **Finish** to save the remote access VPN policy..

The summary page shows all configured remote access VPN settings and provides links to required additional configurations before policy deployment.

Click **Back** to make changes to the configuration, if required.

You can view the policy in the **Remote Access VPN** page.

What to do next

Complete these configurations to ensure the policy to work on all devices.

- Update access control policy in Firewall Threat Defense device, on page 1631
- Configure NAT exemption, on page 1632
- Configure DNS, on page 1633
- Add a Secure Client profile file, on page 1633
- Verify the status of the device certificate.

After you deploy the remote access policy on the devices, use the **Remote Access VPN** dashboard (**Insights & Reports** > **VPN dashboards** > **Remote Access VPN**) to monitor real-time data from active remote access VPN sessions on the devices. You can quickly determine problems related to user sessions and mitigate the problems for your network and users. For more information, see Remote Access VPN Dashboard.

Workflow to configure a remote access VPN connection

This workflow provides the necessary steps to successfully configure a remote access VPN connection on your device.

Table 91: Workflow to configure a remote access VPN connection

Step	Task	More Information
1	Review the licenses, prerequisites, and guidelines.	Licenses for remote access VPN, on page 1610 Prerequisites for remote access VPN, on page 1610 Guidelines for remote access VPNs, on page 1611
2	Create a new remote access VPN policy using the wizard.	Configure a remote access VPN policy, on page 1613
3	Update the access control policy deployed on the device.	Update access control policy in Firewall Threat Defense device, on page 1631
4	(Optional) Configure a NAT exemption rule if NAT is configured on the device.	Configure NAT exemption, on page 1632
5	Configure DNS.	Configure DNS, on page 1633
6	Add Secure Client profile.	Add a Secure Client profile file, on page 1633
7	Deploy the remote access VPN policy.	—

Step	Task	More Information
8	(Optional) Verify the remote access VPN policy configuration.	—

Configure AAA settings for a remote access VPN policy

In **Authentication, Authorization & Accounting (AAA)**, you can configure the AAA parameters for the remote access VPN policy. You can configure authentication alone, or with authorization and accounting.

Before you begin

Configure the protocols and devices, and the connection profile for a remote access VPN policy as described in Configure a remote access VPN policy, on page 1613.

Procedure

Step 1 From the **Authentication Method** drop-down list, choose an authentication method.

Authentication is the way a user is identified before being allowed access to the network and network resources. Authentication requires valid user credentials, a certificate, or both.

- **AAA Only**—Each user is authenticated using LOCAL authentication, RADIUS, AD, or LDAP servers.
- **SAML**—Each user is authenticated using a SAML single sign-on (SSO) server. For more information, see Authenticate remote access VPN users using SAML SSO, on page 1622.
- **Client Certificate Only**—Each user is authenticated using a client certificate. For more information, see Authenticate remote access VPN users using client certificates, on page 1618.
- **Client Certificate & AAA**—Each user is authenticated using client certificates and AAA methods such as LOCAL authentication, RADIUS, AD, and LDAP servers.
- **Client Certificate & SAML**—Each user is authenticated using client certificates and a SAML SSO server.

You can also configure secondary authentication in addition to primary authentication to provide more security for VPN sessions. It applies only to AAA-only and Client Certificate & AAA authentication methods. For more information, refer to Authenticate remote access VPN users using secondary authentication, on page 1620.

Step 2 From the **Authentication Server** drop-down list, choose an authentication server.

You can click + to configure a LOCAL realm, LDAP realm, AD realm, or a RADIUS server group.

- **LOCAL**—Configure LOCAL user settings using this realm.

  You can define users directly on the device and not use an external server. To configure LOCAL authentication, Firewall Threat Defense must be Version 7.0 and later.

- **Active Directory/LDAP**—Configure Microsoft Active Directory or LDAP server as an external authentication source using this realm.

For more information, refer to Create an LDAP realm or an Active Directory realm and realm directory, on page 2133.

- **RADIUS Server Group**—Add a RADIUS server group object with one or more RADIUS servers.

  For more information, refer to Add a RADIUS server group, on page 2770.

Step 3 (Optional) Check the **Fallback to LOCAL Authentication** check box to enable authentication of users using the LOCAL database if the AAA server group is unavailable, provided that the LOCAL database is configured.

When you check this option, choose a LOCAL realm from the **LOCAL Realm** drop-down list.

Step 4 From the **Authorization Server** drop-down list, choose an authorization server.

Once authentication is complete, authorization determines which services and commands each authenticated user can access. Authorization functions by gathering a set of attributes that define the user's permitted actions, capabilities, and any restrictions. Without authorization, all authenticated users have the same level of access. Authorization always requires authentication. For more information about authorization attributes, refer to Manage user authorization attributes in remote access VPN policies, on page 1613.

When you set up a RADIUS server for user authorization, you can define multiple authorization attributes on the server for individual users or user groups. After a successful authentication, the specific authorization attributes are pushed to the Firewall Threat Defense device. For more information about RADIUS authorization attributes, refer to Appendix B: RADIUS server attributes for Firewall Threat Defense devices , on page 1694.

Step 5 From the **Accounting Server** drop-down list, choose a RADIUS server group object as the accounting server.

Accounting tracks the services users access and the network resources they consume. When AAA accounting is enabled, the network access server sends user activity details such as session start and stop times, usernames, bytes transferred, services used, and session durations to the RADIUS server. You can use this data for network management, billing, and auditing. You can use same or different RADIUS servers for AAA.

Authenticate remote access VPN users using client certificates

Configure client certificate authentication to secure remote access VPN connections by verifying user identity through digital certificates.

Client certificate authentication provides enhanced security for remote access VPN users by utilizing digital certificates installed on client devices. You can configure this method for new or existing remote access VPN policies and supports both single certificate and multiple certificate authentication scenarios.

Before you begin

Ensure that client certificates are configured on the endpoints.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**

Step 2 To configure a client certificate for a new remote access VPN policy:

a) Click **Add** to create a remote access VPN policy.

b) Configure the protocols, devices, and connection profile for the policy.

c) From the **Authentication Method** drop-down list, choose **Client Certificate Only** to authenticate each user with a client certificate.

By default, user names are derived from CN and OU fields of the client certificates. To use different fields, configure the **Primary** and **Secondary** fields.

d) Select **Map specific field** to use certificate fields as the username, with the default **Primary** and **Secondary** fields set to **CN (Common Name)** and **OU (Organizational Unit)**.

e) Select **Use entire DN (Distinguished Name) as username** to automatically retrieve the user identity from the DN. It is a unique identifier used to match users to a connection profile and supports enhanced certificate authentication.

f) From the **Primary** and **Secondary** drop-down lists, choose these common values:

- C (Country), CN (Common Name)
- DNQ (DN Qualifier), EA (Email Address)
- GENQ (Generational Qualifier), GN (Given Name)
- I (Initial), L (Locality)
- N (Name)
- O (Organisation), OU (Organisational Unit)
- SER (Serial Number), SN (Surname)
- SP (State Province), T (Title)
- UID (User ID), UPN (User Principal Name)

g) Configure the required settings for the remote access VPN policy.

h) Click **Finish** to save the remote access VPN policy.

Step 3 To configure a client certificate for an existing remote access VPN policy:

a) Click the edit icon next to the remote access VPN policy.

b) Click the edit icon next to the connection profile that you want to modify.

c) Click the **AAA** tab.

d) From the **Authentication Method** drop-down list, choose **Client Certificate Only** to authenticate each user with a client certificate.

e) Repeat Step 2d to Step 2f.

f) (Optional) Check the **Enable multiple certificate authentication** check box to authenticate the client using machine and user certificates.

This option ensures that the device is corporate-issued and also authenticates the user's identity for VPN access. You can choose whether to derive the username from the machine or user certificate.

From the **Certificate to choose** drop-down list, choose these options:

- **First Certificate**—Maps the username from the machine certificate and authenticates the endpoint.
- **Second Certificate**—Maps the username from the user certificate and authenticates the VPN user.

Note If multiple certificate authentication is not enabled, by default, the user certificate (second certificate) is used for authentication.

g) Click **Save** to save the remote access VPN policy.

Limitations for multiple certificate-based authentication

Review these restrictions when implementing multiple certificate-based authentication:

- You can use a maximum of two certificates.
- You can use only RSA-based certificates.
- You can use only SHA256, SHA384, and SHA512 certificates during Secure Client aggregate authentication.
- You cannot combine multiple certificate authentication with SAML authentication.

Associate local realm with remote access VPN policy

You can associate a local realm with a remote access VPN policy to enable local user authentication. The configured local realm applies to all the connection profiles with local authentication enabled.

For more information about creating and managing realms, refer to Manage a realm, on page 2149.

For more information about configuring local user authentication for remote access VPNs, refer to Configure AAA settings for a remote access VPN policy, on page 1617.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the link next to **Local Realm**.

Step 4 From the **Local Realm Server** drop-down list, choose a realm, or click **+** to add a new realm.

Step 5 Click **OK**.

Step 6 Click **Save**.

Authenticate remote access VPN users using secondary authentication

Configure secondary authentication in addition to primary authentication to provide additional security for VPN sessions.

Secondary authentication applies only to AAA-only and Client Certificate & AAA authentication methods. Users gain access if both primary and secondary authentications succeed. If either authentication fails or a server is unreachable, users are denied access.

Secondary authentication requires VPN users to enter two sets of credentials in Secure Client. You can also configure the system to pre-fill the secondary username from the authentication server or client certificate.

Before you begin

Configure a AAA server to serve as the secondary authentication server.

For example, you can set the primary authentication server as an LDAP or Active Directory realm and the secondary authentication as a RADIUS server.

Follow these steps to authenticate remote access VPN users using secondary authentication:

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the edit icon next to the connection profile that you want to modify and click the **AAA** tab.

Step 4 From the **Authentication Method** drop-down list, choose **AAA-only** or **Client Certificate & AAA**.

Step 5 From the **Authentication Server** drop-down list, choose the primary AAA server.

Step 6 (Optional) Check the **Fallback to LOCAL Authentication** check box to enable user authentication using the LOCAL database if the AAA server group is unavailable.

Ensure that the LOCAL database is configured.

Step 7 Check the **Use secondary authentication** check box to configure a secondary AAA server and from the **Authentication Server** drop-down list, choose the secondary AAA server..

Step 8 In **Username for secondary authentication**, configure these parameters:

- **Prompt**—Prompts users to enter their username and password when logging in to the VPN gateway.
- **Use primary authentication username**—Uses the username of the primary authentication server for both primary and secondary authentication. Users must enter two passwords when they log in.
- **Prefill username from certificate on user login window**—Pre-fills the secondary username from the client certificate when the user connects through Secure Client.
  - Select **Map specific field** to use certificate fields as the username, with the default **Primary** and **Secondary** fields set to **CN (Common Name)** and **OU (Organizational Unit)**.
  - From the **Primary** and **Secondary** drop-down lists, choose the required certificate fields.
  - Select **Use entire DN (Distinguished Name) as username** to automatically retrieve the user identity from the DN. This unique identifier is used to match users to a connection profile and supports enhanced certificate authentication.
  - If you have enabled the **Enable multiple certificate authentication** option, from the **Certificate to choose** drop-down list, choose **First Certificate** or **Second Certificate**.
  - **Hide username in login window**—Pre-fills the secondary username from the client certificate. This username is hidden from the user, preventing modification of the pre-filled username.
  - **Use secondary username for VPN session**—Uses the secondary username for reporting user activity during a VPN session.

Step 9 Click **Save** to save the remote access VPN policy.

Authenticate remote access VPN users using SAML SSO

About SAML Single Sign-On authentication

Security Assertion Markup Language (SAML) is an open standard that enables single sign-on (SSO) across multiple applications by exchanging authentication and authorization data between an Identity Provider (IdP) and a Service Provider (SP).

When users authenticate with the IdP, it shares their identity with authorized applications (SPs). This action enables seamless access for users and permits centralized access control.

SAML SSO with Firewall Management Center

Firewall Threat Defense supports SAML 2.0 SSO for remote access VPN connections using Secure Client. With SAML IdP integration, users sign in to Firewall Management Center through the IdP and access resources based on their identity. The integration includes these components:

- Identity Provider (IdP)—Performs user authentication, authorization, and issues assertions. For example, Duo, Microsoft Entra ID, and Okta.
- Service Provider (SP)—Obtains the authentication assertion from IdP. A Firewall Threat Defense device acts as the SP.
- Secure Client—Performs SAML 2.0 authentication using the embedded browser.

Prerequisites for SAML SSO

Review these prerequisites before configuring SAML SSO authentication and authorization for remote access VPN.

- Create an account with your IdP.
- Obtain these from your IdP:
  - IdP Entity ID URL
  - Sign-in URL
  - Sign-out URL
  - IdP certificate
- If you use Duo, download and install Duo Access Gateway.
- Create a SAML single sign-on server object (**Objects** > **AAA Server** > **Single Sign-on Server**).

Note You can also create a single sign-on server object in the **Connection Profile** settings when you create a new remote access VPN policy using the wizard.

Guidelines for SAML SSO authentication

Follow these guidelines for authenticating users using SAML SSO and Firewall Threat Defense devices.

General guidelines

- A Firewall Threat Defense device can function only as a SAML SP. You cannot configure the device as an IdP in a gateway or peer mode.
- Ensure that you do not use multiple SAML objects with the same IdP entity ID on a single device.

  The device sets the IdP entity ID to the SAML object name from the SSO server object (**Objects** > **AAA Server** > **Single Sign-on Server**).
- Apply an access policy to a SAML-authenticated user by assigning an identity policy that uses an Active Directory (AD) realm matching the SAML domain. For Azure AD SAML, you must map the Azure AD tenant ID to a realm ID on the device.
- Synchronize the Network Time Protocol (NTP) servers of the Firewall Threat Defense device and the SAML IdP.
- Maintain valid signing certificates on the Firewall Threat Defense device and the IdP.

  The device does not perform a revocation check on the IdP's signing certificate.
- The `NameID` attribute of the SAML IdP determines the username for authorization, accounting, and VPN session database entries.

Secure Client guidelines

- Secure Client performs SAML 2.0 authentication through its embedded browser, and the authentication context is not shared with external web browsers.
- Secure Client can use various methods when connecting to a headend with the embedded browser.

  The client might connect using IPv4 address while the embedded browser uses IPv6 address, or vice versa. If a proxy failure occurs, the client switches to no proxy, and the embedded browser stops navigation.
- Ensure that you do not use untrusted server certificates in the embedded browser.

SAML assertion timing guidelines

The Firewall Threat Defense device's SAML timeout interacts with `NotBefore` and `NotOnOrAfter` conditions in SAML assertions for login requests.

- Timeout takes effect if the sum of `NotBefore` and timeout is less than `NotOnOrAfter`, then.
- `NotOnOrAfter` takes effect if the sum of `NotBefore` and timeout is more than `NotOnOrAfter`.
- The device denies the login request if `NotBefore` is not configured.
- The device denies the login request if `NotOnOrAfter` and SAML timeout are not configured.

Limitations for SAML SSO

Review these limitations when using SAML SSO authentication:

General limitations

- Do not provide SAML authentication attributes in a DAP evaluation similar to RADIUS attributes sent in a RADIUS authentication response from a AAA server. Although the Firewall Threat Defense device supports SAML-enabled group policy in a DAP policy, you cannot check the username attribute during SAML authentication because the SAML IdP masks it.
- Duo does not work with internal SAML deployments on the Firewall Threat Defense device if client authentication requires proxying due to FQDN changes during two-factor authentication challenges and responses.
- You cannot access internal servers with SSO after logging in using an internal IdP.
- Firewall Threat Defense device does not support receiving multiple attributes with a SAML assertion.

Secure Client limitations

- A Firewall Threat Defense device does not support embedded browser SAML integration in CLI or Start Before Logon (SBL) modes.
- SAML SSO in Firewall Management Center does not support Start Before Logon (SBL) mode.

Configure SAML SSO authentication

SAML SSO authentication allows users to authenticate once with their identity provider and access the VPN without requiring separate credentials. This method improves user experience while maintaining security standards.

Before you begin

Ensure that you review Prerequisites for SAML SSO, on page 1622, Guidelines for SAML SSO authentication, on page 1623, and Limitations for SAML SSO, on page 1623.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**

Step 2 To configure SAML SSO authentication for a new remote access VPN policy:

a) Click **Add** to create a remote access VPN policy.
b) Configure the protocols, devices, and connection profile for the policy.
c) From the **Authentication Method** drop-down list, choose **SAML**.
d) From the **Authentication Server** drop-down list, choose a SAML single sign-on server.
e) Configure the required settings for the remote access VPN policy.
f) Click **Finish** to save the remote access VPN policy.

Step 3 To configure SAML SSO authentication for an existing remote access VPN policy:

a) Click the edit icon next to the remote access VPN policy.
b) Click the edit icon next to the connection profile that you want to modify.
c) Click the **AAA** tab.
d) From the **Authentication Method** drop-down list, choose **SAML**.
e) From the **Authentication Server** drop-down list, choose a SAML single sign-on server.

f) Check the **Override Identity Provider Certificate** check box to override the primary SAML IdP certificate with a profile-specific certificate to support multiple SAML applications for an IdP.

The primary identity certificate is configured in the single sign-on server object.

g) From the drop-down list, choose the IdP certificate.

h) In **SAML Login Experience**, configure a browser for SAML web authentication:

- **VPN client embedded browser**—Select this option to use the embedded VPN client browser for VPN-only web authentication.
- **Default OS Browser**—Select this option to use the system's default browser for web authentication. You can use SSO and methods like biometric authentication that are not supported in the embedded browser. This option requires an external browser package which is by default `Default-External-Browser-Package`. To change this browser package, edit the remote access VPN policy, click the **Advanced** tab and choose a browser package from the **Package File** drop-down list.

i) Click **Save** to save the remote access VPN policy.

Configure SAML authorization

SAML authorization allows you to integrate your VPN solution with existing identity providers for centralized authentication and access control. This configuration involves setting up SAML authentication in connection profiles and creating DAP policies that match SAML criteria.

Before you begin

Ensure that you review Prerequisites for SAML SSO, on page 1622, Guidelines for SAML SSO authentication, on page 1623, and Limitations for SAML SSO, on page 1623.

Follow these steps to configure SAML authorization:

Procedure

Step 1 Configure SAML authentication in the remote access VPN connection profile.

For more information, see Configure SAML SSO authentication, on page 1624.

Step 2 Match a SAML criteria in a DAP policy.

a) Choose **Secure Connections** > **Dynamic Access Policy**.
b) Create a new DAP policy or edit an existing policy.
c) Create a DAP record or edit an existing record.
d) Click the **AAA Criteria** tab.
e) In **SAML Criteria**, click **+** to create SAML criteria based on the SAML assertions returned by the SSO server.

Step 3 Deploy the remote access VPN configuration.

Configure advanced AAA settings

Configure advanced AAA settings to customize authentication behavior and improve password management for remote access VPN users.

Before you begin

1. Configure the protocols and devices, and the connection profile for a remote access VPN policy as described in Configure a remote access VPN policy, on page 1613.
2. Configure the authentication method, and the AAA servers as described in Configure AAA settings for a remote access VPN policy, on page 1617.

Procedure

Step 1 Click the edit icon next to the remote access VPN policy.

Step 2 Click the edit icon next to the connection profile.

Step 3 Click the **AAA** tab.

Step 4 In **Advanced Settings**, configure these parameters:

- (Optional) Check the **Strip Realm from username** check box to remove the realm from the username before sending it to the AAA server for authentication. By default, this feature is disabled.

  If you select this option and provide a username in the `domain\username` format, the AAA server receives only the username.

- (Optional) Check the **Strip Group from username** check box to remove the group name from the username before sending it to the AAA server for authentication. By default, this feature is disabled.

Note A realm is an administrative domain used to manage authentication. When you enable these options, users can authenticate using only their username. You can select any of these options. If your server does not support delimiter parsing, enable both check boxes to ensure authentication.

- Check the **Enable Password Management** check box to configure the notification settings for the remote access VPN users about password expiry. Configure one of these options:
  - In the **Notify User – days ahead of password expiry** field, enter the number of days for password expiry notification.
  - Select **Notify user on the day of password expiration**.

Step 5 Click **Save**.

Configure connection profile settings

A connection profile defines authentication settings, VPN client address assignment, and associated group policies. A remote access VPN policy can include multiple connection profiles to support specific devices or distinct user groups with different access requirements.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 In the **Connection Profile** tab, click the edit icon next to a connection profile or click **+** to configure a new connection profile.

Step 4 Configure IP addresses for VPN clients.

Step 5 (Optional) Configure AAA settings for a remote access VPN policy, on page 1617.

Step 6 (Optional) Configure aliases for a connection profile, on page 1629.

Step 7 Click **Save**.

Configure IP addresses for VPN clients

You can assign IP addresses to remote access VPN users by using IP address pools. You can source these IP addresses from a AAA server, a DHCP server, or local IP address pools. If you select multiple sources, addresses are assigned in this order: AAA server, DHCP server, and then local IP address pools. IP address pools defined in a connection profile are used only when no pools are defined in the associated group policy or in the default group policy `DfltGrpPolicy`.

Before you begin

Note When you configure both a DHCP server and a local IP address pool for address assignment, automatic fallback to the local pool (if the DHCP server is unavailable) works only for SSL-based remote access VPN connections.

For IPsec-based remote access VPN connections, this fallback may not complete in time if the DHCP server is unreachable, which can cause the connection to fail.

To avoid connection issues with IPsec-based remote access VPN, do one of the following:

- Make sure the DHCP server is reachable, or
- Use only a local IP address pool for address assignment.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the edit icon next to the connection profile.

Step 4 Click the **Client Address Assignment** tab.

Step 5 Click + next to **Address Pools**:

a) Click **+** next to **Address Pools** to add IP address pools.

Note If you share a remote access VPN policy among multiple Firewall Threat Defense devices, the devices use the same address pool. Assign a unique address pool to each device using device-level object overrides. Unique address pools prevent overlapping IP addresses when devices do not use NAT.

b) Select **IPv4** or **IPv6**.

c) In the **Address Pools** dialog box, choose the IP address pools.

d) Click **+** next to **Available Pools** to add a new IPv4 or IPv6 address pool.

When you configure an IPv4 address pool, provide a starting and ending IP address. When you configure an IPv6 address pool, enter a number within the range 1 to 16384 in the **Number of Addresses** field.

e) Check the **Allow Overrides** check box to avoid conflicts with IP addresses when objects are shared across many devices. For more information, see Configure address pools, on page 2781.

f) Click **OK**.

If you plan to edit the IP address pools, perform these steps during a maintenance window:

1. Unassign the device from the remote access VPN policy.
2. Select the device and click **Deploy**.

   This deployment removes all the remote access VPN configurations from the device and ends the remote access VPN sessions. Users must reconnect because the sessions are not reestablished.
3. Click the edit icon next to the IP address pools. Update other remote access VPN configurations, if required, on the Firewall Management Center.
4. Assign the device to the updated remote access VPN policy.
5. Deploy the configurations on the device.

   The remote access VPN clients can connect to the device after the maintenance window.

Step 6 Click **+** next to **DHCP Servers** to add DHCP servers for address assignment.

Note You can use only IPv4 addresses for DHCP servers.

a) Choose the server from the object list.

b) Click **Add**

c) Click **+** to configure a DHCP server as a network object.

d) Click **OK**.

Step 7 Click **Save**.

What to do next

To define the IP address assignment policy, click the **Advanced** tab, and from the left pane, choose **Address Assignment Policy**.

Configure aliases for a connection profile

Aliases are alternate names or URLs for connection profiles. You can enable or disable these names and URLs that appear to VPN users during login. The Firewall Threat Defense device applies the matching connection profile when a user selects an alias name or connects using an alias URL.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the edit icon next to the connection profile.

Step 4 Click the **Aliases** tab.

Step 5 Click **+** next to **Alias Names**.

Step 6 In the **Add Alias Name** dialog box, enter an alias in the **Alias Name** field.

Step 7 Check the **Enabled** check box to enable the alias for the connection profile.

Step 8 Click **OK**.

Step 9 Click **Save**.

Configure access interfaces for a remote access VPN policy

The **Access Interface** table lists the interface groups and security zones that contain the device interfaces. These are configured for remote access SSL or IPsec IKEv2 VPN connections. The table displays the name of each interface group or security zone, the interface trustpoints used by the interface, and whether Datagram Transport Layer Security (DTLS) is enabled.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy and click the **Access Interface** tab.

Step 3 To add an access interface, click **+**.

In the **Add Access Interface** dialog box, configure these parameters:

a) **Access Interface**—Select the interface group or security zone to which the interface belongs.

The interface group or security zone must be a Routed type. Other interface types are not supported for remote access VPN connectivity.

b) Associate the **Protocol** object with the access interface by selecting these options:

- **Enable IPSet-IKEv2**—Select this option to enable **IKEv2** settings.

- **Enable SSL**—Select this option to enable **SSL** settings.
  - Select **Enable Datagram Transport Layer Security**.

    When selected, it enables Datagram Transport Layer Security (DTLS) on the interface and allows the AnyConnect VPN module of Cisco Secure Client to establish an SSL VPN connection using two simultaneous tunnels—an SSL tunnel and a DTLS tunnel.

    Enabling DTLS avoids the latency and bandwidth problems associated with certain SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

    To configure SSL settings, and TLS and DTLS versions, refer to Configure SSL settings, on page 1046 .

    To configure SSL settings for the AnyConnect VPN module of Cisco Secure Client , refer to Group policy options for Secure Client, on page 2897 .
  - Select the **Configure Interface Specific Identity Certificate** check box and select the Interface Identity Certificate from the drop-down list.

    If you do not select the Interface Identity Certificate or Trustpoint, the **SSL Global Identity Certificate** will be used by default.

c) Click **OK**.

Step 4 In **Access Settings**, configure these parameters:

- **Allow Users to select connection profile while logging in**—If you have multiple connection profiles, check this check box to allow user to select the correct connection profile during login. You must select this option for **IPsec-IKEv2** VPNs.
- **Enable HTTP-only VPN Cookies**—Check this check box to restrict cookie data access to the browser and its HTTP session, ensuring the data is only available to the server. This option helps protect against cross-site scripting attacks.

Step 5 In **SSL Settings**, configure these parameters:

- **Web Access Port Number**—The port to use for VPN sessions. The default port is 443.
- **DTLS Port Number**—The UDP port to use for DTLS connections. The default port is 443.
- **SSL Global Identity Certificate**— The selected **SSL Global Identity Certificate** will be used for all the associated interfaces if the **Interface Specific Identity Certificate** is not provided.

  You can choose an ACME certificate for authenticating the VPN gateway. ACME certificates automate the lifecycle management of SSL and TLS certificates, including their auto-renewal.

Step 6 In **IPsec-IKEv2 Settings**, choose an identity certificate from the **IKEv2 Identity Certificate** drop-down list.

Step 7 In **Service Access Control**, choose a service access object from the **Service Access Object** drop-down list or click + to create a new object.

You can use a service access object to control remote clients' access to VPN on Firewall Threat Defense devices with Version 7.7 or later. This object provides geolocation-based access control to clients before VPN authentication. By default, there is no access control for RA VPN, and remote clients can connect from any geolocation unless specified by a service access object. For more information, see Configure VPN access of remote users based on geolocation, on page 1668 and Configure a service access object, on page 2779.

Step 8 In **Access Control for VPN Traffic** section, select this option to bypass access control policy:

- **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** — Decrypted traffic is subjected to Access Control Policy inspection by default. Enabling the Bypass Access Control policy for decrypted traffic option bypasses the ACL inspection, but VPN Filter ACL and authorization ACL downloaded from AAA server are still applied to VPN traffic.

Note If you select this option, you need not update the access control policy for remote access VPN as specified in Update access control policy in Firewall Threat Defense device, on page 1631 .

Step 9 Click **Save**.

Postconfiguration tasks for a remote access VPN policy

Use these topics to understand and perform the postconfiguration tasks that must be completed after configuring a remote access VPN policy to ensure proper functionality and deployment.

Update access control policy in Firewall Threat Defense device

Before deploying a remote access VPN policy, update the access control policies on the devices with rules that permit all traffic from the outside interface, with the client networks as the source and the corporate network as the destination.

Note If you enable the **Bypass Access Control policy for decrypted traffic (sysopt permit-VPN)** option when configuring the remote access VPN policy, you do not have to update the access control policy.

Enable or disable the option for all your VPN connections. If you disable this option, ensure that the VPN traffic is allowed by the access control policy or pre-filter policy.

Before you begin

Configure remote access VPN policies using the **Remote Access VPN Policy Wizard**.

Procedure

Step 1 Choose **Policies** > **Security policies** > **Access Control**.

Step 2 Click the edit icon next to the access control policy that you want to update and click **Add Rule**.

Step 3 In the **Name** field, enter the name for the rule.

Step 4 Click the **Enable Rule** toggle button.

Step 5 From the **Action** drop-down list, choose **Allow** or **Trust**.

Step 6 Click the **Zones** tab.

a) Select the outside zone from the available zones and click **Add Source Zone**.

b) Select the inside zone from the available zones and click **Add Destination Zone**.

Step 7 Click the **Networks** tab.

a) Select the inside network, including the inside interface of the device and the corporate network, from the available networks and click **Add Destination Network**.

b) Select the VPN IP address pool network (client network) from **Available Networks** and click **Add Source Network**.

Step 8 Configure other required access control rule settings and click **Apply and Add New Rule**.

Step 9 Save the rule and access control policy.

Configure NAT exemption

NAT exemption allows certain addresses to bypass NAT translation, so both your internal and external hosts can initiate connections with protected hosts.

Unlike identity NAT, which does not restrict translation to specific interfaces, you must apply NAT exemption across all interfaces. NAT exemption lets you specify both real and destination addresses, similar to policy NAT. To control access by port, use static identity NAT with an access list.

For remote access VPN, configure static identity NAT with the route lookup option. Without this option, the Firewall Threat Defense device sends traffic through the interface defined in the NAT rule and ignores the routing table. Misrouting can cause problems, such as DHCP traffic not returning correctly. The route lookup option ensures that the device uses the proper interface based on the routing table, to maintain correct traffic flow for VPN and internal hosts.

Before you begin

Verify if NAT is enabled on the devices with remote access VPN policies. If NAT is enabled, create a NAT exemption policy for the VPN traffic.

Procedure

Step 1 Choose **Policies** > **Network policies** > **NAT**.

Step 2 Edit a NAT policy or click **New Policy** to create a NAT policy with a NAT rule to allow connections through all interfaces.

Step 3 Click **Add Rule** to add a NAT rule.

Step 4 In the **Add NAT Rule** dialog box, configure these parameters:

a) From the **NAT Rule** drop-down list, choose **Manual NAT Rule**.

b) From the **Type** drop-down list, choose **Static**.

c) Click the **Interface Objects** tab, and select the source and destination interface objects.

Note This interface object must match the interface specified in the remote access VPN policy.

a) Click the **Translation** tab.

- From the **Original Source** and **Translated Source** drop-down lists, choose the source networks.
- From the **Original Destination** and **Translated Destination** drop-down lists, choose the destination networks.

Step 5 Click the **Advanced** tab.

Step 6 Check the **Do not proxy ARP on Destination Interface** check box.

This option disables proxy ARP for incoming packets to mapped IP addresses. By default, the system uses proxy ARP to respond to ARP requests for mapped addresses on the same network, simplifying routing since no extra gateway is needed. If you disable proxy ARP, ensure the upstream router has correct routes to those addresses.

Step 7 Click **OK**.

Configure DNS

Configure DNS on each Firewall Threat Defense device to enable remote access VPN policies. Without DNS, the devices can resolve only IP addresses. They cannot resolve AAA server names, URLs, and CA servers with FQDN or hostnames.

Procedure

Step 1 Choose **Devices** > **Platform Settings**.

Step 2 Edit a Firewall Threat Defense policy or click **New Policy** to create a new platform settings policy.

Step 3 From the left pane, choose **DNS** to configure the DNS servers and domain-lookup interfaces.

For more information, see Configure DNS server settings, on page 1010 and DNS server groups, on page 2792.

Step 4 Configure split-tunnel in the group policy to allow DNS traffic through remote access VPN tunnel if the DNS server is reachable through the VPN network.

Add a Secure Client profile file

The Secure Client Profile is an XML file that contains configuration settings to control the client's operation and appearance, including host names, addresses, and feature options. You can create and manage this profile using the Secure Client Profile Editor, a standalone, GUI-based tool in the Secure Client software package. For more information about Secure Client Profile Editor, see Cisco Secure Client (including AnyConnect) Administrator Guide.

To use remote access VPN with Firewall Threat Defense devices, assign the Secure Client Profile to VPN clients by attaching it to a group policy. The Firewall Threat Defense device deploys the profiles during a Secure Client connection.

Before you begin

Download the Secure Client Profile Editor from Cisco Software Download Center.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Edit a remote access VPN policy.

Step 3 Click the edit icon next to the connection profile to which you want to add the Secure Client profile.

Step 4 Click **Edit Group Policy**. If you choose to add a new group policy, click **Add**.

Step 5 Click the tab.

Step 6 From the left pane, click **Profile**.

Step 7 From the **Client Profile** drop-down list, choose a Secure Client Profile or click **+** to add one.

Note For two-factor authentication, ensure that the timeout is set to 60 seconds or more in the Secure Client profile.

Step 8 Click **Save**.

Configure advanced options for a remote access VPN policy

This section provides information about configuring advanced settings for a remote access VPN policy.

Manage Secure Client images

Secure Client establishes secure SSL or IPsec IKEv2 connections to the Firewall Threat Defense device for remote users, providing full VPN access to corporate resources.

Client deployment and upgrade processes

The deployment process varies based on client installation status:

- **First-time installation**: Users without a pre-installed client can enter the IP address of a clientless VPN-enabled interface in their browser to automatically download and install the Secure Client. The Firewall Threat Defense device detects the remote computer's operating system and delivers the appropriate client package, which automatically installs and establishes a secure connection.
- **Existing client upgrades**: For users with a previously installed client, the Firewall Threat Defense device checks the client version upon authentication and upgrades it automatically if a newer version is available.

You can associate new or additional Secure Client images with the VPN policy. You can also remove packages that are unsupported or have reached end of life. Firewall Management Center determines the operating system from the client package filename. If the file has been renamed and lacks OS information, manually select the correct operating system from the available list.

Add a Secure Client image in Firewall Management Center

You can add and update the Secure Client images for a remote access VPN policy.

Before you begin

Download the Secure Client from Cisco Software Download Center.

Follow these steps to add a Secure Client image in Firewall Management Center:

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the **Advanced** tab.

Step 4 In the left pane, select **Secure Client Images**.

Step 5 Click + to add a Secure Client image.

Step 6 Click + in the **Secure Client Images** dialog box.

Step 7 In the **Add Secure Client Image** dialog box, configure these parameters:

a) In the **Name** and **Description** fields, enter the values for the Secure Client image.

b) Click **Browse**. Locate and select the client image that you want to upload.

When you upload the client image to the Secure Firewall Management Center, the operating system of the image is displayed automatically. You can also add the client image using an object (**Objects** > **VPN** > **Secure Client File**).

Step 8 Click **Show Re-order buttons** to change the order of the images.

Step 9 Click **Save**.

Add a Secure Client external browser package in Firewall Management Center

Use the external browser package to enable SAML-based authentication with an external web browser instead of the embedded browser. Download and associate the package with a connection profile to deploy it.

Before you begin

Download the Secure Client external browser package from Cisco Software Download Center.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the **Advanced** tab.

Step 4 In the left pane, select **Secure Client Images**.

Step 5 From the **Package File** drop-down list, choose an external browser package.

By default, **Default-External-Browser-package** is available. You can add only one package to the device. After you enable the external browser in the remote access VPN policy, the browser is pushed to the device. For more information, refer to Configure SAML SSO authentication, on page 1624

Step 6 Click **Save**.

Customize Cisco Secure Client

You can configure Secure Client customizations using the Firewall Management Center and deploy them to the Firewall Threat Defense device. The device distributes these customizations to the endpoint when a user connects from the Secure Client.

Table 92: Secure Client customizations available in Firewall Management Center

Customization	Description	More Info
GUI text and messages	Customize or localize Secure Client GUI text and informational or error messages	Customize and localize Secure Client GUI text and messages, on page 1640
Icons and images	Customize the logo, images, or icons of the Secure Client GUI	Customize Secure Client icons and images, on page 1641
Scripts	Deploy scripts on endpoint devices when a client establishes or disconnects a VPN session	Deploy scripts on endpoint devices using Secure Client, on page 1642
Binaries	Deploy custom applications using Secure Client APIs	Deploy custom applications using Secure Client APIs, on page 1644
Custom installer transforms	Customize the Secure Client installer	Customize the Secure Client installer, on page 1646
Localized installer transforms	Localize the Secure Client installer	Localize the Secure Client installer

Overview of the customization file

The customization file is an XML-based configuration object in the Threat Defense device that controls the visual appearance and layout of Secure Client to remote VPN users. It defines:

- Branding—logos and color schemes
- Page structure—logon page and portal layout
- Content elements—titles, banners, and button labels
- Messaging—error messages and other user-facing text

By default, a Threat Defense device has two customization objects:

- Template: A blank XML template file that you can update to add the required customizations. You cannot delete this file.

- DfltCustomization: An XML file with a set of URLs and basic customization to bring up the Secure Client. This is the default customization file.

  To view these customization files, run the **show import webvpn customization** command on the Threat Defense device:

```
FTD(config)# show import webvpn customization
Template
DfltCustomization
```

Customize the customization file

To update the **Template** XML file:

1. Export the file to disk0. You can rename the file, if required.

```
FTD(config)# export webvpn customization Template disk0:ABCTemplate
```

2. Copy the XML file to a remote PC.
3. Edit the XML file with the required customizations and copy it back to disk0.
4. Import the file to the Threat Defense device.

```
FTD(config)# import webvpn customization ABCTemplate disk0:ABCTemplate
```

5. Verify the customization files in the device.

```
FTD(config)# show import webvpn customization
Template
DfltCustomization
ABCTemplate
```

Note You can also update the **DfltCustomization** file using the same procedure as above. You can also rename this file.

Upload the customization file to Management Center

1. Choose **Objects** > **VPN** > **Secure Client File** and click **Add Secure Client File**.
2. In the **Add Secure Client File** dialog box, configure these parameters:
   a. In the **Name** file, enter the name of the customization file.
   b. From the **File Type** drop-down list, choose **Secure Client VPN Profile**.
   c. Click **Browse**, locate and select the customization file that you want to upload.
   d. Click **Save**.
3. Choose **Secure Connections** > **Remote Access VPN**.
4. Click the edit icon next to the remote access VPN policy.
5. Click the **Advanced** tab.
6. In the left pane, click **Group policies**.

7. Click + to add a group policy.
8. In the **Add Group Policy** dialog box, configure these parameters:
   a. Enter a **Name** and optionally a **Description** for this policy.
   b. Click the **Secure Client** tab, and from the **Client Profile** drop-down list, choose the customization file.
   c. Click **Save**.
9. Choose this group policy as the selected policy in the **Group Policy** dialog box, click **OK**, and click **Deploy**.

Guidelines for Secure Client customizations

Review these guidelines before you configure the Secure Client customizations.

General guidelines

- By default, the `DfltCustomization` customization object is available in a Firewall Threat Defense device. You can get this file when you run the **show run all tunnel-groups** command.

```
FTD# sh run all
tunnel-group tunnelgroup webvpn-attributes
 customization DfltCustomization
```

  Ensure that you import the Secure Client profile XML file to the `DfltCustomization` object. When you import the customization object, the Firewall Management Center checks the XML code for validity.

  For example:

```
hostname# import webvpn customization DfltCustomization
disk0:/csm/defaultcustomizationwebvpn.xml
```

- Add the Windows Secure Client headend deployment package to the remote access VPN policy before deploying customization commands. You must include this package to support Windows, MacOS, or Linux clients.

Guidelines for icon and image customizations

- Ensure customization object names match the Secure Client GUI filenames. File names are different for each operating system and are case-sensitive. For more information about the filenames, extensions, and sizes for each OS, see the Cisco Secure Client Administrator Guide.
- Verify that image sizes are correct before deployment. Images are not displayed properly if the size is incorrect, and neither the Firewall Management Center nor the Firewall Threat Defense validates image size.

Limitations for Secure Client customizations

Review these limitations when configuring Secure Client customizations.

General limitations

- Firewall Management Center removes all Secure Client customizations configured earlier than Version 7.4 directly on the device using CLI commands during deployment.
- You cannot apply customizations to clusters.

Limitations for GUI text and message customizations

- Restart Secure Client before you use this customization.
- Supports only left-to-right languages.
- Some strings may be truncated in the user interface because of fixed field lengths.
- Some client messages are hardcoded. For example:
  - Status messages (during an update)
  - Untrusted server messages
  - Deferred update messages
- Localization depends on the software version.

  If you created a translation table using a template of an earlier Secure Client version, new messages do not appear for remote users. You must merge the latest template with the translation table so that the table has the new messages. Use third-party tools like Gettext to perform the merge.

Limitations for icon and image customizations

- Restart Secure Client before you use this customization.
- You cannot apply this customization in macOS.

Limitations for deploying customized scripts

- Secure Client runs only one OnConnect and one OnDisconnect script; however, these scripts may launch other scripts.
- Scripts execute only functions that users have permissions to use.
- You cannot launch the OnConnect script from the Start Before Logon (SBL) user interface.

Limitation for deploying custom applications using Secure Client APIs (Binaries)

After you use this customization, if you deploy an updated version of the Secure Client on the Firewall Management Center, the client will download the update and replace your custom user interface.

Limitation for customizing the client installer

You can apply this customization only on Windows.

Customize and localize Secure Client GUI text and messages

You can customize and localize Secure Client GUI text and messages.

Customize GUI text and messages

To customize the GUI text or messages, you must edit the messages in the message file. You can update error messages to include additional details. For example:

- Change any label in the login dialog box such as **Password** to **Domain Password**.
- Add support contact details in error messages.

Localize GUI text and messages

Firewall Threat Defense devices use translation tables to translate the labels and user messages displayed in Secure Client. When a user connects to the remote access VPN, Secure Client identifies the locale set on the endpoint and downloads the translation file. Firewall Threat Defense supports 128 locales. By default, Secure Client is installed in English.

- For Secure Client Version 5.0, the default localization files for various languages are part of the application.
- For AnyConnect Client Version 4.x, you can download the localization files for a few languages from the Cisco website and upload them to the Firewall Management Center.

Customize Secure Client GUI text and messages

Customizing GUI text and messages helps provide a localized user experience or incorporate organization-specific branding in the Secure Client client. This customization is applied through translation files that contain message strings and their corresponding customized versions.

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Download the base template or translation file,such as AnyConnect.po, either from the Secure Client package or from the Cisco website.

Step 2 Use a text editor to add the translations or customize the labels or messages.

Step 3 Update the **msgstr** string corresponding to each **msgid**.

Step 4 Save the file.

Step 5 Create a Secure Client customization object.

a) Choose **Objects** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization object.
d) From the **Customization Type** drop-down list, choose **GUI Text and Messages**.
e) From the **Language** drop-down list, choose a language for which you are adding the translation.
f) Click **Browse** and select the translation file. Supported file extensions are .po, .mo, and .txt.

Step 6 Add the customization object to the remote access VPN policy.

a) Choose **Secure Connections** > **Remote Access VPN**.
b) Click the edit icon of the remote access VPN policy.
c) Click the **Advanced** tab.
d) In the left pane, click **Secure Client Customizations > GUI Text and Messages**.
e) Click **+** to select the customization object.
f) Click **OK**.

Step 7 Click **Save**.

Step 8 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes become active only when you deploy them.

What to do next

Verify the Secure Client customizations. For more information, refer to Verify Secure Client customizations, on page 1647.

Customize Secure Client icons and images

You can customize Secure Client icons and images.

Customization requirements

To customize the logo, images, and icons of the Secure Client GUI, you must create a Secure Client customization object in the Firewall Management Center. The name of this customization object must match the Secure Client GUI filename. File names are different for each operating system and are case-sensitive. For more information about the filenames, extensions, and sizes for each operating system, see the Cisco Secure Client Administrator Guide.

Image file locations by operating system:

- **Windows**: **%PROGRAMFILES%\Cisco\Cisco Secure Client\res**
- **Linux**: **/opt/cisco/secureclient/resources** or **/opt/cisco/anyconnect/resources**
- **macOS**: Not supported

Note When the remote access VPN connection is established, the logo or images are downloaded to the client directory. Ensure that you restart the client for the updated logo or images to appear in your client.

Customize Secure Client images and icons

Custom images and icons enhance the user experience by providing a personalized interface that aligns with your organization's visual identity. These customizations are applied through remote access VPN policies and deployed to connected clients.

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Create icons or images in the correct file format and size.

Note Verify that image sizes are correct before deployment. Images are not displayed properly if the size is incorrect, and neither the Firewall Management Center nor the Firewall Threat Defense validates image size.

For more information about the filenames, extensions, and sizes, see the Cisco Secure Client Administrator Guide.

Step 2 Create a new Secure Client customization object.

a) Choose **Objects** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization object.

Ensure that the customization object name matches the Secure Client GUI filenames. For more information about the filenames, see the Cisco Secure Client Administrator Guide.

d) From the **Customization Type** drop-down list, choose **Icon and Images**.
e) From the **Platform** drop-down list, choose a platform.
f) Click **Browse** and select the file. Supported file extensions are .png, .ico, and .jpeg.
g) Repeat Step 2a to Step 2f to add multiple icons and images.

Step 3 Add the customization object to the remote access VPN policy.

a) Choose **Secure Connections** > **Remote Access VPN**.
b) Click the edit icon of the remote access VPN policy.
c) Click the **Advanced** tab.
d) In the left pane, click **Secure Client Customizations** > **Icons and Images**.
e) Click **+** to select the file.
f) Click **Add**.
g) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Verify the Secure Client customizations. For more information, refer to Verify Secure Client customizations, on page 1647.

Deploy scripts on endpoint devices using Secure Client

Secure Client lets you download scripts and run them when these events occur:

- Establishment of a new client VPN session with a Firewall Threat Defense device. This event triggers an OnConnect script. Reconnection of the VPN session does not trigger this script.
- Disconnection of a client VPN session with a Firewall Threat Defense device. This event triggers an OnDisconnect script.

Secure Client identifies the OnConnect and OnDisconnect scripts by the filename. It looks for a file whose name begins with OnConnect or OnDisconnect regardless of the file extension.

Use cases

You can use this feature to perform these automated actions:

- Refresh the group policy upon VPN connection.
- Mount a network drive upon a VPN connection.
- Unmount a network drive upon a VPN disconnection.

Scripting behavior and requirements

- Secure Client launches scripts only after the user logs in and establishes a VPN session.
- The scripts run asynchronously and do not delay the connection establishment or disconnection.
- The scripts can have any file extension and must be executable in the endpoint.
- To enable scripts, select **Enable Scripting** in the VPN profile. By default, scripts do not launch automatically. They can be in any language. The endpoint must have an application that runs them from the command line.
- To trigger scripts after login, select **Enable Post SBL On Connect Script** in the VPN profile.
- You cannot launch the OnConnect script from the Start Before Logon (SBL) user interface.
- On 64-bit Windows systems, scripts run using the 32-bit version of cmd.exe, because Secure Client is a 32-bit application.

Add customized scripts for Secure Client

Add customized OnConnect and OnDisconnect scripts to enhance Secure Client functionality and automate endpoint operations during VPN connection events.

Customized scripts allow you to execute specific actions on endpoints when users connect to or disconnect from the VPN. These scripts can be used to configure network settings, install software, or perform other automated tasks.

Before you begin

1. Configure a remote access VPN.
2. Enable scripting in the VPN profile.
3. Add the VPN profile to the remote access VPN group policy.

Follow these steps to add customized scripts for Secure Client:

Procedure

Step 1 Create OnConnect and OnDisconnect scripts for a platform.

Step 2 Create a new Secure Client customization object.

a) Choose **Objects** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization object.
d) From the **Customization Type** drop-down list, choose **Scripts**.
e) From the **Platform** drop-down list, choose a platform.
f) Select one of these options:

- **On Connect**: To select an OnConnect script.
- **On Disconnect**: To select an OnDisconnect script.

g) Click **Browse** and select the script you want to execute on the endpoint.

Step 3 Add the customization object to the remote access VPN policy.

a) Choose **Secure Connections** > **Remote Access VPN**.
b) Click the edit icon of the remote access VPN policy.
c) Click the **Advanced** tab.
d) In the left pane, click **Secure Client Customizations** > **Scripts**.
e) Click **+** to select the customization object.
f) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes become active only when you deploy them.

What to do next

Verify the Secure Client customizations. For more information, refer to Verify Secure Client customizations, on page 1647.

Deploy custom applications using Secure Client APIs

For Windows, Linux, or macOS machines, create and deploy a custom client that uses Secure Client APIs. Use this client binary file to replace the Secure Client user interface or CLI binary files.

Executable file specifications

Your executable can use any resource files, such as logo images, that you import into the Firewall Management Center. When you deploy your own executable, use any filenames for your resource files.

The table lists the filenames of Secure Client executable files for different client operating systems.

Table 93: Filenames of Secure Client executable files

Client OS	Client GUI File	Client CLI File
Windows	vpnui.exe	vpncli.exe
Linux	vpnui	vpn
MacOS	Not supported by Firewall Management Center. However, you can deploy an executable for macOS that replaces the client GUI using other means, such as Altiris Agent.	vpn

Deploy custom applications using Secure Client API

Custom applications can be deployed to VPN clients through customization objects that are attached to remote access VPN policies. This allows organizations to distribute custom tools and applications to remote users.

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Create the custom application using the Secure Client APIs.

Step 2 Create a new Secure Client customization object.

a) Choose **Objects** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization object.
d) From the **Customization Type** drop-down list, choose **Binary**.
e) From the **Platform** drop-down list, choose a platform.
f) Click **Browse** and select the custom application.

Step 3 Add the customization object to the remote access VPN policy.

a) Choose **Secure Connections** > **Remote Access VPN**.
b) Click the edit icon of the remote access VPN policy.
c) Click the **Advanced** tab.
d) In the left pane, click **Secure Client Customizations > Binaries**.
e) Click **+** to select the customization object.
f) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Customize the Secure Client installer

Customize the Secure Client GUI by creating a custom transform that deploys with the client installer. Import the transform to the Firewall Management Center and deploy it to the Firewall Threat Defense device. The device then deploys this transform to the endpoint device using the client installer.

Note This customization is available only for Windows.

Customize or localize the client installer

Client installer customization enables you to modify the appearance, branding, or language of the VPN client installation process. This is useful for organizations that need to provide a localized experience or apply company-specific branding to their VPN deployments.

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Create a customized or localized transform.

Step 2 Create a new Secure Client customization object.

a) Choose **Objects** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization.
d) From the **Customization Type** drop-down list, choose **Customized Installer Transform** or **Localized Installer Transform**.
e) From the **Platform** drop-down list, choose an operating system.
f) Click **Browse** and select the transform file.

Step 3 Add the customization object to the remote access VPN policy.

a) Choose **Secure Connections** > **Remote Access VPN**.
b) Click the edit icon of the remote access VPN policy.
c) Click the **Advanced** tab.
d) In the left pane, click **Secure Client Customizations**.
e) Click **Custom Installer Transforms** or **Localized Installer Transforms**.
f) Click **+** to select the customization object.
g) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Verify Secure Client customizations

Use CLI commands and transcript details to verify Secure Client customizations after deployment in Firewall Management Center.

Validate the deployment

After the deployment is complete in Firewall Management Center, click the **Transcript Details** ( )) icon to view the customization commands.

Examples

1. The example displays transcript details of a GUI text and MESSAGES customization:

```
import webvpn translation-table AnyConnect language en-us disk0:/AnyConnect_en-us.po
```

2. The example displays the transcript details of customization of the Secure Client logo to ABC logo:

```
import webvpn AnyConnect-customization type resource platform win name company_logo.png
 disk0:/company_logo.png
```

3. The example displays the transcript details of customized OnConnect and OnDisconnect scripts. The OnConnect script mounts the network drive and the OnDisconnect script unmounts it.

```
import webvpn AnyConnect-customization type binary platform win name
  scripts_OnConnect_mount.bat disk0:/mount.bat
import webvpn AnyConnect-customization type binary platform win name
  scripts_OnDisconnect_unmount.bat disk0:/unmount.bat
```

Verify customizations using CLI commands

Run these commands on the Firewall Threat Defense device to verify the customizations:

- **show import webvpn translation-table detailed**: Displays the available translation tables.

```
HQ-FTD# show import webvpn translation-table detailed
 Translation Tables' Templates:
   AnyConnect           ia4DaAXNSvl5pZboQRGJcs9KMXY=
   customization
 Translation Tables:
   fr                   customization        BWWodsOt1PbvDvYOp8hLb3W7a64=
   ja                   customization        lNvUk1+qTLNZyNrBcApMQPHnm1M=
   ru                   customization        UqyKyUAcjR+xTGUtdiIFnoIiW5U=
```

- **show import webvpn AnyConnect-customization detailed**: Displays details about Secure Client customizations.

```
HQ-FTD# show import webvpn AnyConnect-customization detailed
OEM resources for AnyConnect client:
  linux-64/binary/scripts_OnConnect_conn.sh           w6+n7z80D/8AR+ul2f7DvTmcDTw=
  linux-64/binary/scripts_OnDisconnect_discon.sh      jx5LJC2XBEmEkGeww59CAkszvnI=
  linux-64/resource/company-logo.png                  GsfBDroqGSQEEwuBDS/3DJNVv88=
  win/binary/scripts_OnConnect_mount.bat              dzjfsLYYft/XMlPlzskKl+Wv1bw=
  win/binary/scripts_OnDisconnect_unmount.bat         k6xlKhF1l2IRyJu08+sdYXgKNgM=
  win/resource/company_logo.png                       cmEvxwqvtaS+Pz/6sb9n3NZudS4=
```

Verify customizations in Secure Client

- In Secure Client, click the **Message History** tab to verify if the customizations are downloaded.
- Use the DART tool to view the client-side diagnostics.

Table 94: Verify customizations in Secure Client

Customization type	Verification
GUI text and message customizations	• Verify if Secure Client has the localization or customized files in these locations: • Windows: %ProgramData%\Cisco\Cisco AnyConnect Secure Mobility Client\l10n\<LANGUAGE-CODE>\LC_MESSAGES (AnyConnect versions 4.9 and earlier) • Windows: %ProgramData%\Cisco\Cisco Secure Client\l10n\<LANGUAGE-CODE>\LC_MESSAGES (Secure Client versions 5.0 and later) • For macOS and Linux: /opt/cisco/anyconnect/l10n/<LANGUAGE-CODE>/LC_MESSAGES /opt/cisco/secureclient/l10n/<LANGUAGE-CODE>/LC_MESSAGES • Verify the contents of the localized or customized file and confirm if they have the customized or localized strings. For example: AnyConnect.mo
Image and icon customizations	• Verify if Secure Client has the customized files in these locations: • Windows: %PROGRAMFILES%\ Cisco\Cisco AnyConnect Secure Mobility Client\res\ (AnyConnect versions 4.10 and earlier) • Windows: %PROGRAMFILES%\ Cisco\Cisco Secure Client\UI\res (Cisco Secure Client 5.0 and above) • Linux: /opt/cisco/anyconnect/resources or /opt/cisco/secureclient/resources • Verify the content of the customized icon or image file.
Customized OnConnect and OnDisconnect scripts	• Verify if the customized scripts are in these locations: • Windows: %ProgramData%\Cisco\Cisco Secure Client\Script (Cisco Secure Client 5.0 and above) • Windows: %ProgramData%\Cisco\ Cisco AnyConnect Secure Mobility Client\Script (AnyConnect versions 4.9 and earlier) • macOS and Linux: /opt/cisco/anyconnect/script or /opt/cisco/secureclient/vpn/script • Verify the script.

Configure remote access VPN address assignment policy

Firewall Threat Defense devices support IPv4 and IPv6 address assignment policies for remote access VPN clients. This policy applies to all connection profiles of the remote access policy. If you configure multiple address assignment methods, the device attempts each method in sequence until it finds an IP address.

Before you begin

Ensure that you have configured a remote access VPN policy.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the **Advanced** tab.

Step 4 In the left pane, click **Address Assignment Policy**.

Step 5 In **IPv4 Policy**, configure these parameters:

a) Check the **Use authorization server** check box to retrieve IP addresses from an external authorization server on a per-user basis. Use this method when the authorization server has IP addresses configured. This address assignment policy supports only RADIUS servers, not AD or LDAP servers.

b) Check the **Use DHCP** check box to retrieve IP addresses from a DHCP server configured in a connection profile. You can also define the range of IP addresses by configuring the DHCP network scope in the group policy.

c) Check the **Use an internal address pool** check box to retrieve IP addresses from internally configured address pools.

Create IP address pools using objects, choose **Objects** > **Address Pools** and configure them in the connection profile.

d) In the **Allow reuse of IP address** field, enter the delay time (in minutes) before an IP address is reassigned to the pool after being released. A delay prevents issues that you could experience due to rapid IP address reassignment. The default delay is zero minutes, and the range is 0 to 480 minutes.

Step 6 In **IPv6 Policy**, check the **Use authorization server** and **Use an internal address pool** check boxes, as required.

Step 7 Click **Save**.

Configure certificate maps

Use certificate maps to define rules that match user certificates to connection profiles. These maps enable certificate authentication, prompting remote users for a client certificate regardless of the configured authentication method. If no certificate maps match, Firewall Management Center selects the default connection profile. You must define certificate map rules in certificate map objects. For more information about certificate map objects, refer to Certificate map objects, on page 2889.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the **Advanced** tab.

Step 4 In the left pane, click **Certificate Maps**.

Step 5 In **General Settings for Connection Profile Mapping** pane, configure these parameters:

Select one or both options to establish certificate authentication and map the client to a connection profile.

- Check the **Use Group URL if Group URL and Certificate Map match different Connection profiles** check box if required.
- Check the **Use the configured rules to match a certificate to a Connection Profile** check box to apply the rules defined in the connection profile maps.

Step 6 In **Certificate to Connection Profile Mapping**, click **Add Mapping** to create a certificate to connection profile mapping for this remote access VPN policy.

In the **Add Connection Profile to Certificate Map** dialog box, configure these parameters:

a) From the **Certificate Map Name** drop-down list, choose a certificate map for the connection profile.
b) From the **Connection Profile** drop-down list, choose a connection profile to use when the client certificate satisfies the rules of the map.
c) Click **OK** to create the mapping.

Step 7 Click **Save**.

Configure group policies

A group policy contains user-oriented attributes for remote access VPN connections. You can assign attributes to users or groups without configuring each attribute individually. After the tunnel is established, the connection profile applies a group policy to define user access terms. When a user logs in, the group policy identified by the AAA server is applied. If no group policy is identified for the user, the default group policy, `DfltGrpPolicy`, is used.

Before you begin

Ensure that you have configured a remote access VPN policy.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the **Advanced** tab.

Step 4 In the left pane, click **Group policies**.

The group policies associated with the remote access VPN policy are displayed.

Step 5 Click + to add a group policy.

Step 6 Select group policies from the **Available Group Policy** list and click **Add**. You can select one or more group policies for a remote access VPN policy.

Step 7 Click **OK**.

Step 8 Click **Save**.

Configure LDAP attribute maps for LDAP authorization

LDAP attribute maps are configuration elements that

- link LDAP user or group attribute names to Cisco-recognized attribute names
- equate attributes from AD or LDAP servers with Cisco attribute names, and
- can map one or more LDAP attributes to one or more Cisco LDAP attributes, or to a vendor-specific attribute (VSA).

Use LDAP attribute maps for VPN access control

To assign different VPN policies or access permissions to users based on their credentials, configure LDAP authorization with LDAP attribute maps. To accomplish this configuration, configure a map that links an LDAP attribute to a group policy. The Firewall Threat Defense device assigns this policy to the user during authentication.

How LDAP attribute maps work

During a remote access VPN connection, after the AD or LDAP server returns authentication to the Firewall Threat Defense device, it uses the mapped attributes to adjust how Secure Client completes the connection.

LDAP attribute map components

- **Realm**—Specifies the name of the LDAP realm. This name is used as the LDAP attribute map name.
- **Attribute Name Map**—Maps the LDAP user or group attribute name to a Cisco-understandable name.
- **Attribute Value Map**—Maps the value in the LDAP user or group attribute to the value of a Cisco attribute for the selected name mapping.

When a group policy is used in an LDAP attribute map, it is automatically added to the remote access VPN configuration. If you remove a group policy from the configuration, its associated LDAP attribute mapping is also removed.

Guidelines for LDAP attribute maps

Follow these guidelines when configuring LDAP attribute maps for LDAP authentication and authorization:

- Configure at least one map for each LDAP attribute. You cannot use duplicate LDAP attribute names.
- Configure a minimum of one name map for an LDAP attribute map.

- Use correct spelling and capitalization for both Cisco and LDAP attribute names and values.
- Remove an LDAP attribute map only if it is not associated with any connection profile in the remote access VPN configuration.

Configure LDAP attribute maps

LDAP attribute mapping allows you to map LDAP server attributes to Cisco attributes for authentication and authorization purposes in remote access VPN policies.

Before you begin

- Configure an LDAP realm and add the LDAP server as the authentication server for the remote access VPN policy.
- Review Guidelines for LDAP attribute maps, on page 1651.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the **Advanced** tab.

Step 4 In the left pane, click **LDAP Attribute Mapping**.

Step 5 Click **+** to configure an LDAP attribute map.

You can configure multiple attribute maps. Each attribute map must have a name map and one or more value maps.

Step 6 In the **Configure LDAP Attribute Map** dialog box, configure these parameters:

a) From the **LDAP Attribute Name** drop-down list, choose an attribute.
b) From the **Cisco Attribute Name** drop-down list, choose an attribute.
c) From the **LDAP Attribute Value** drop-down list, choose an attribute value.
d) From the **Cisco Attribute Value** drop-down list, choose an attribute value.
e) Click **Add Value Map** to add more value maps.
f) Click **OK**.

Step 7 Click **Save**.

Configure RA VPN with LDAP Authentication and Authorization for FTD

Configure VPN load balancing

VPN load balancing is a network distribution mechanism that groups two or more Firewall Threat Defense devices to distribute remote access VPN sessions evenly across the group.

How VPN load balancing works

- One device acts as the director and the remaining devices are members.

- The director routes incoming sessions to the least-loaded device, optimizing resource usage and improving performance and availability.
- VPN load balancing is based on session distribution, not throughput or other factors.

VPN load balancing group requirements

- Groups require two or more Firewall Threat Defense devices that support remote access VPN.
- Devices in a group do not need to be the same type or run identical software versions or configurations.
- Firewall Threat Defense devices support VPN load balancing with Secure Client SAML authentication.
- Devices behind NAT can be part of a load-balancing group.
- Devices in a high availabilty pair can be part of a load-balancing group.

Components of VPN load balancing

VPN load balancing consists of these components:

- **Load-Balancing Group**—A virtual group of two or more Firewall Threat Defense devices that share VPN sessions. Devices can run the same or mixed releases, provided they support remote access VPN configurations.
- **Director**—A Firewall Threat Defense device in the group that manages load distribution by monitoring all members, tracking their session loads, and routing new sessions to the least-loaded device. The director role is not tied to a specific device. If the current director fails, a member device automatically assumes the role.
- **Members**—All non-director Firewall Threat Defense devices in the group. Members participate in load balancing and share remote access VPN connections.

Prerequisites for VPN load balancing

Review these prerequisites before configuring VPN load balancing.

- Ensure the Firewall Threat Defense certificate includes the IP addresses or FQDNs of all directors and members to which connections are redirected. Use a Subject Alternative Name (SAN) or wildcard certificate to prevent the certificate from being flagged as untrusted.
- Add the group URL for the VPN load-balancing group IP address to the connection profiles. Specifying a group URL eliminates the need for users to select a group at login.
- Assign a unique IP address pool for member devices and override the IP address pool in Firewall Management Center for each member.

Guidelines and limitations for VPN load balancing

Review these guidelines and limitation before configuring VPN load balancing:

Guidelines

- Enable VPN load balancing explicitly, as it is disabled by default.

- Include a minimum of two Firewall Threat Defense devices in a load-balancing group.
- Add only co-located devices to a load-balancing group.
- Configure the identity certificate on each device with a SAN or wildcard.

Limitation

If a member or director device goes down, the device drops all VPN connections. Re-initiate your VPN connections to restore service.

Configure group settings for VPN load balancing

Enable VPN load balancing and configure group settings for all the members of the load-balancing group. You can also configure participation settings when you create the group.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the **Advanced** tab.

Step 4 In the left pane, click **Load Balancing**.

Step 5 Click the **Enable Load balancing between member devices** toggle button to activate load balancing.

Step 6 In the **Edit Group Configuration** dialog box, configure these parameters:

a) In the **Group IPv4 Address** and **Group IPv6 Address** fields, enter the IP address.

The IP address is for the entire load-balancing group and the director uses this IP address for incoming VPN connections.

b) In the **Communication Interface** drop-down list, choose the interface that the director and members use to share information about their load.

c) In the **UDP Port** field, enter the port of communication between the director and members.

The range is from 1 to 65535. The default port is 9023.

d) Click the **IPsec Encryption** toggle button to activate IPsec encryption for the communication between the director and members.

This setting establishes an IPsec tunnel between the director and members using a pre-shared key.

When you upgrade or downgrade Firewall Threat Defense devices with the **IPsec Encryption** option enabled, ensure there is no configuration mismatch between the Firewall Management Center and the Firewall Threat Defense to prevent deployment failures.

e) In the **Encryption Key** field, enter the key for IPsec encryption and confirm the key.

Encryption key must be 4–16 characters.

f) Click **OK**.

Step 7 Click **Save**.

Configure additional settings for VPN load balancing

These additional settings for VPN load balancing allow you to specify whether clients receive fully qualified domain names instead of IP addresses during redirection, and control when IKEv2 redirect occurs during the connection process.

Before you begin

VPN load balancing must already be configured for the remote access VPN policy.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the **Advanced** tab.

Step 4 In the left pane, click **Load Balancing**.

Step 5 Click the **Enable Load balancing between member devices** toggle button to activate load balancing.

Step 6 Configure the group settings for VPN load balancing.

For more information, see Configure group settings for VPN load balancing, on page 1654.

Step 7 Click **Settings**.

Step 8 In the **Configure Group Parameters** dialog box, configure these parameters:

a) Click the **Send FQDN to peer devices instead of IP** toggle button to enable redirection using a fully qualified domain name.

By default, a Firewall Threat Defense device sends only IP addresses to a client.

b) In **IKEv2 Redirect**, select one of these phases:

- **Redirect during SA authentication**
- **Redirect during SA initialization**

c) Click **OK**.

Step 9 Click **Save**.

Configure settings for participating devices

Configure device participation settings to determine how the devices share the load during VPN load balancing.

Device participation settings determine how the devices share the load during VPN load balancing.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy and click the **Advanced** tab.

Step 3 In the left pane, click **Load Balancing** and click the **Enable Load balancing between member devices** toggle button to activate load balancing.

Step 4 Configure the group settings for VPN load balancing.

For more information, see Configure group settings for VPN load balancing, on page 1654.

Step 5 In **Device Participation**, all the devices associated with the remote access VPN policy are displayed.

Step 6 Click the **Load Balancing** toggle button to enable load balancing for a device.

Step 7 Click the edit icon next to a device.

Step 8 In the **Edit Device Participation Attributes** dialog box, configure these parameters:

a) In the **Priority** field, enter a priority number for the device.

A higher priority number increases the chance that a device becomes a director. By default, the priority is 5. The range is 1 to 10.

b) In the **IPv4 NAT** and **IPv6 NAT** fields, enter the IP address for the VPN interface if the device is behind NAT.

c) Click **OK**.

Step 9 Click **Save**.

Configure IPsec settings for remote access VPNs

IPsec settings for remote access VPNs are security configuration parameters that

- define crypto maps for VPN tunnel establishment
- configure IKE policies for secure key exchange, and
- set IPsec and IKEv2 parameters for encryption and authentication.

IPsec configuration options

You can configure these IPsec settings for your remote access VPN policies:

- Crypto maps: For more information, see Configure remote access VPN crypto maps, on page 1656.
- IKE policy: For more information, see Configure remote access VPN IKE policies, on page 1659.
- IPsec and IKEv2 parameters: For more information, see Configure remote access VPN IPsec and IKEv2 parameters, on page 1659

Configure remote access VPN crypto maps

Firewall Threat Defense automatically generates crypto maps for interfaces with IPsec-IKEv2 protocol enabled. The **Crypto Maps** page lists these interface groups.

To add or remove interface groups of a remote access VPN policy, click the **Access Interface** tab.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the **Advanced** tab.

Step 4 In the left pane, click **IPsec > Crypto Maps**.

Step 5 Select a crypto map in the table and click the edit icon to update the crypto map parameters.

Step 6 In the **Edit Crypto Maps** dialog box, configure these parameters:

a) In **IKEv2 IPsec Proposals**, click **+** and choose the transform sets to define how to secure tunnel traffic with authentication and encryption.

b) Check the **Enable Reverse Route Injection** check box to automatically insert static routes into the routing process for networks and hosts protected by a remote endpoint.

c) Check the **Enable Client Services** check box and specify the port number.

The Client Services server provides HTTPS (SSL) access, enabling Secure Client Downloader to receive software upgrades, profiles, localization and customization files, and other required files. If you enable this option, specify the client services port number. If disabled, users cannot download any files required by Secure Client.

Note You can use the same port as SSL VPN running on the same device. Even if SSL VPN is configured, you must enable this option to allow file downloads over SSL for IPsec-IKEv2 clients.

d) Check the **Enable Perfect Forward Secrecy** check box.

Use Perfect Forward Secrecy (PFS) to generate a unique session key for each encrypted exchange, protecting recorded exchanges from decryption even if endpoint keys are compromised. If enabled, choose a Diffie-Hellman key derivation algorithm for generating the PFS session key from the **Modulus Group** list.

e) From the **Modulus group** drop-down list, choose a modulus group.

The modulus group specifies the Diffie-Hellman group used to derive a shared secret between two IPsec peers without transmitting it. A larger modulus provides stronger security but requires more processing time. Both peers must use a matching modulus group. Choose a modulus group to allow in the remote access VPN configuration:

- 1—Diffie-Hellman Group 1 (768-bit modulus)
- 2—Diffie-Hellman Group 2 (1024-bit modulus)
- 5—Diffie-Hellman Group 5 (1536-bit modulus, considered good protection for 128-bit keys, but group 14 is better). If you are using AES encryption, use this group (or higher)
- 14—Diffie-Hellman Group 14 (2048-bit modulus, considered good protection for 128-bit keys)
- 19—Diffie-Hellman Group 19 (256-bit elliptical curve field size)
- 20—Diffie-Hellman Group 20 (384-bit elliptical curve field size)
- 21—Diffie-Hellman Group 21 (521-bit elliptical curve field size)

- 24—Diffie-Hellman Group 24 (2048-bit modulus and 256-bit prime order subgroup)

f) In the **Lifetime Duration** field, enter the lifetime of the security association (SA), in seconds.

The range is 120 to 2147483647 seconds. The default is 28800 seconds.

When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Shorter lifetimes improve IKE negotiation security, while longer lifetimes allow future IPsec SAs to be established more quickly.

g) In the **Lifetime Size (kbytes)** field, enter the volume of traffic (in kilobytes) allowed between IPsec peers before the SA expires.

The range is 10 to 2147483647 kilobytes. The default is 4,608,000 kilobytes. If you do not specify a value, the SA allows unlimited data.

h) In **ESPv3 Settings**, configure these parameters:

- Check the **Validate incoming ICMP error messages** check box to validate ICMP error messages received through an IPsec tunnel and destined for a host in the private network.
- Check the **Enable 'Do Not Fragment' Policy** check box to define how the IPsec subsystem handles large packets with the do-not-fragment (DF) bit set in the IP header. From the **Policy** drop-down list, choose one of these options:
  - Set—Sets and uses the DF bit.
  - Copy—Maintains the DF bit.
  - Clear—Ignores the DF bit.
- Check the **Enable Traffic Flow Confidentiality (TFC) Packets** check box to send dummy TFC packets that mask the traffic profile traversing the tunnel. Configure the **Burst**, **Payload Size**, and **Timeout** parameters to generate random-length packets at random intervals across the specified SA.

Note Enabling TFC packets prevents the VPN tunnel from being idle, which may cause the VPN idle timeout configured in the group policy to not work as expected.

  - In the **Burst** field, enter the number of dummy packets to send in one burst. The range is 1 to 16 bytes.
  - In the **Payload Size** field, enter the size of the dummy packet payload. The range is from 64 to 1024 bytes.
  - In the **Timeout** field, enter the maximum time between bursts. The range is from 10 to 60 seconds.

i) Click **OK**.

Step 7 Click **Save**.

Configure remote access VPN IKE policies

Configure IKE policies to define the security parameters for IPsec negotiations in remote access VPN connections.

IKE is a key management protocol that authenticates IPsec peers, negotiates encryption keys, and automatically establishes IPsec SAs. IKE negotiation occurs in two phases:

- **Phase 1** — Establishes a secure security association between two IKE peers, enabling secure communication in Phase 2.
- **Phase 2** — Uses the Phase 1 SA to establish SAs for other applications, such as IPsec.

Both phases use proposals to negotiate a connection. An IKE proposal is a set of algorithms that two peers use to secure the negotiation. IKE negotiation begins with both peers agreeing on a common IKE policy that defines the security parameters for subsequent negotiations.

The IKE Policy table lists all the IKE policy objects applicable to the selected VPN configuration when Secure Client endpoints connect using the IPsec protocol.

Note Firewall Threat Defense supports only IKEv2 for remote access VPNs.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.
Step 2 Click the edit icon next to the remote access VPN policy.
Step 3 Click the **Advanced** tab.
Step 4 In the left pane, click **IPsec > IKE Policy**.
Step 5 Click **+** to select from the available IKEv2 policies, or add a new IKEv2 policy.
Step 6 Click **OK**.
Step 7 Click **Save**.

Configure remote access VPN IPsec and IKEv2 parameters

You can update the IKEv2 session settings, IKEv2 security association settings, IPsec settings, and NAT traversal settings.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.
Step 2 Click the edit icon next to the remote access VPN policy.
Step 3 Click the **Advanced** tab.
Step 4 In the left pane, click **IPsec > IPsec/IKEv2 Parameters**.

Step 5 In **IKEv2 Session Settings**, configure these parameters:

- From the **Identity Sent to Peers** drop-down list, choose how peers identify themselves during IKE negotiations. You can choose one of these options:
  - **Auto**—Determines the IKE negotiation by connection type.
  - **IP address**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
  - **Hostname**—Uses the fully qualified domain name (FQDN) of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.
- Check the **Enable Notification on Tunnel Disconnect** check box to enable the device to send an IKE notification to the peer when an inbound packet does not match the traffic selectors for its SA. By default, this option is disabled.
- Check the **Do not allow device reboot until all sessions are terminated** check box to ensure the device completes all active sessions before it restarts. By default, this option is disabled.

Step 6 In **IKEv2 Security Association (SA) Settings**, configure these parameters:

- From the **Cookie Challenge** drop-down list, choose when to send cookie challenges to peers in response to SA initiation packets. This feature prevents DoS attacks. By default, the system uses cookie challenges when 50% of the available SAs are in negotiation. Choose one of these options:
  - **Custom**—In the **Threshold to Challenge Incoming Cookies** field, enter the percentage of in-negotiation SAs that triggers cookie challenges for future negotiations. The range is zero to 100%. The default is 50%.
  - **Always**—Sends cookie challenges to peer devices always.
  - **Never**—Disables cookie challenges to peer devices.
- In the **Number of SAs Allowed in Negotiation** field, enter the maximum number of SAs permitted in negotiation at any time, in percentage. If you use this parameter with **Cookie Challenge**, configure the cookie challenge threshold lower than this limit. The default is 100%.
- In the **Maximum number of SAs Allowed** field, enter the maximum number of allowed IKEv2 connections.

Step 7 In **IPsec Settings**, configure these parameters:

- Check the **Enable Fragmentation Before Encryption** check box if your network includes NAT devices that do not support IP fragmentation.
- Check the **Path Maximum Transmission Unit Aging** check box to reset the PMTU of an SA at regular intervals.
- In the **Value Reset Interval** field, enter the interval, in minutes, at which the PMTU value of an SA is reset to its original value. The range is 10 to 30 minutes.

Step 8 In **NAT Transparency Settings**, configure these parameters:

- Check the **Enable IPsec over NAT-T** check box to allow seamless communication between the peer Firewall Threat Defense devices when there are NAT devices between these devices.

Note NAT-Traversal uses port 4500. Ensure that other services, such as NAT policy, do not use this port.

- In the **NAT Keepalive Interval** field, enter the interval, in seconds, between the keepalive signals sent between the devices to indicate that the session is active. The range is 10 to 3600 seconds. The default is 20 seconds.

  The Firewall Threat Defense device transmits NAT traversal keepalive messages when an intermediate NAT device exists between the Firewall Threat Defense device and the endpoint.

Step 9 Click **Save**.

Configure additional remote access VPN configurations

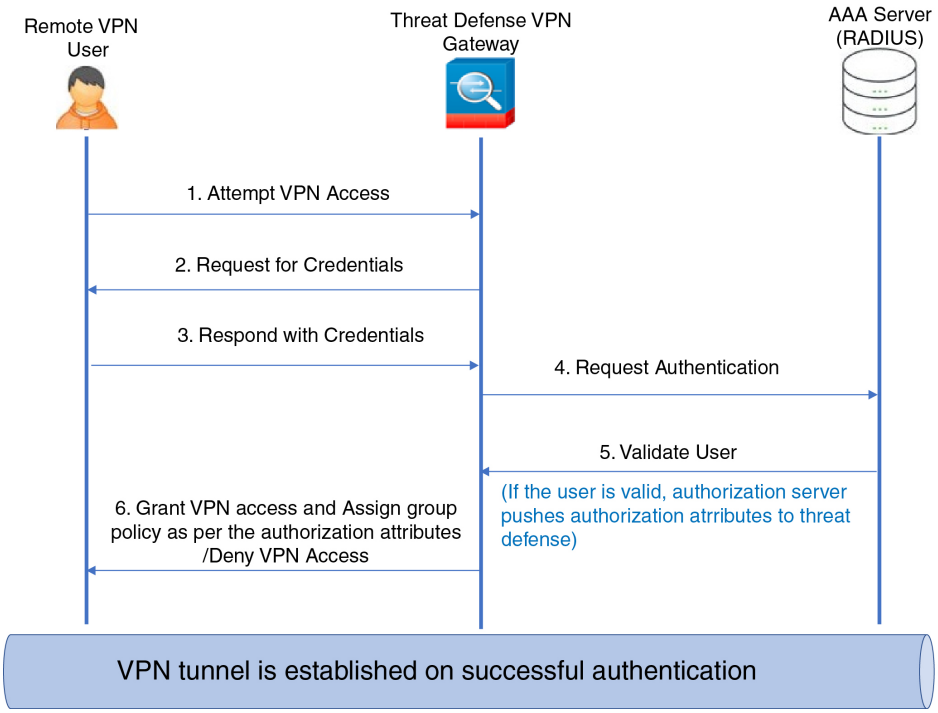
This topic provides supplementary configuration parameters and options that extend the basic remote access VPN setup to meet specific deployment requirements and enhance security policies.

Customize remote access VPN AAA settings

This section provides information about customizing your AAA preferences for a remote access VPN policy.

Delegate group policy selection to authorization server

Group policies are assigned to users during VPN tunnel establishment.



Group policy assignment for remote access VPN policies

Assign a group policy to a connection profile in two ways:

- Create a remote access VPN policy using the wizard.
- Update an existing connection profile.

You can source group policies from the connection profile, or an external AAA server. If the Firewall Threat Defense device receives conflicting attributes from an external AAA server and the connection profile, the AAA server attributes take precedence.

Figure 429: Selection of remote access VPN group policy by AAA server

For more information, see the Configure Standard Authorization Policies section of Cisco Identity Services Engine Administrator Guide and Appendix B: RADIUS server attributes for Firewall Threat Defense devices , on page 1694.

Assign group policies using ISE or RADIUS server

Configure an ISE or a RADIUS server to set the authorization profile for a user or user group. To do this, configure the server to send IETF RADIUS Attribute 25 and map it to the corresponding group policy name. With this approach, you can configure a group policy to perform these actions:

- Apply a downloadable ACL.
- Display a banner.
- Restrict VLAN access.
- Apply a Security Group Tag (SGT) to the session.

Assign group policy using the authorization server

Configure ISE or a RADIUS server to set the authorization profile for a user or user group and also select the group policy and other attributes. After users are authenticated, these authorization attributes are pushed to the Firewall Threat Defense device.

Before you begin

Ensure that you have a remote access VPN policy with RADIUS as the authentication server.

Procedure

Step 1 In Firewall Management Center, choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the **Advanced** tab.

Step 4 In the left pane, click **Group Policies** and add the required group policy.

You can map only one group policy to a connection profile. However, you can create multiple group policies within a remote access VPN policy and reference them in an ISE or a RADIUS server. After user authentication, the authorization server dynamically assigns one of these group policies using the authorization attributes, overriding the group policy configured in the connection profile.

Step 5 Deploy the configuration on the Firewall Threat Defense device.

Step 6 In the authorization server, create an authorization profile with RADIUS attributes for IP address and downloadable ACLs.

Deny VPN access to a user group

To block VPN access for a specific user or user group, create a group policy that denies VPN access and reference it in your ISE or RADIUS server authorization configuration.

Before you begin

Ensure that your remote access VPN policy includes authentication and authorization settings.

Procedure

Step 1 In Firewall Management Center, choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy and click the **Advanced** tab.

Step 3 In the left pane, click **Group Policies**.

Step 4 Click the edit icon next to a group policy or click **+** to add a new group policy.

Step 5 In the **Add Group Policy** or **Edit Group Policy** dialog box, click the **Advanced** tab.

Step 6 In the left pane, click **Session Settings**.

Step 7 In the **Simultaneous Login Per User** field, enter 0.

This configuration prevents the user or user group from connecting to the VPN even once.

Step 8 Click **Save** to save the group policy and then save the remote access VPN configuration.

What to do next

1. Configure ISE or the RADIUS server to send IETF RADIUS Attribute 25 for the specific user or user group, mapping the attribute value to the corresponding group policy name.

   Ensure that the ISE or RADIUS server is the authorization server in the remote access VPN policy.

2. Deploy the configuration on the Firewall Threat Defense device.

Enforce a connection profile for a user group

By default, Secure Client displays all connection profiles configured in the Firewall Management Center and deployed on the Firewall Threat Defense device, listed by connection profile name, alias, or alias URL. If no connection profiles are configured, Secure Client displays the `DefaultWEBVPNGroup` connection profile.

To enforce a specific connection profile for a user or user group, you can disable all other connection profiles so that their group aliases and URLs are hidden from users during login. This configuration ensures that users connect only through the connection profile meant for their group.

Use this approach to apply distinct VPN configurations for different user groups, such as mobile users, corporate-issued laptop users, or personal laptop users. Configure a dedicated connection profile for each group and disable the others to automatically apply the correct settings when users connect.

Before you begin

- In Firewall Management Center, configure a remote access VPN policy with the authentication method as **Client Certificate Only** or **Client Certificate & AAA**.
- Configure ISE or RADIUS server for authorization and associate the group policy with the server.

Procedure

Step 1 In Firewall Management Center, choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy and click the **Access Interfaces** tab.

Step 3 Uncheck the **Allow users to select connection profile while logging in** check box.

Step 4 Click the **Advanced** tab.

Step 5 In the left pane, click **Certificate Maps**.

Step 6 Check the **Use the configured rules to match a certificate to a Connection Profile** check box.

Step 7 Click **Add Mapping** to map the connection profile with a certificate rule.

Step 8 In the **Add Connection Profile to Certificate Map** dialog box, configure these parameters:

a) From the **Certificate Map Name** drop-down list, choose a certificate map, or click **+** to add a new map.
b) From the **Connection Profile** drop-down list, choose a connection profile.
c) Click **OK**.

Step 9 Click **Save**.

Configure RADIUS dynamic authorization

You can use RADIUS servers to authorize users in remote access VPN using dynamic access control lists (ACLs) or ACL names per user. When a user authenticates, the RADIUS server pushes a downloadable ACL or an ACL name directly to the device. This ACL determines the services the user can access. When the user's session expires, the device deletes the ACL. If a user's trust level or posture changes during an active session, the RADIUS server can update ACLs or disconnect the session in real time.

Before you begin

- Configure a RADIUS server as the authorization server for the remote access VPN policy.
- Configure a single interface in the security zone or interface group if the RADIUS server references it.
- Posture VPN in Threat Defense devices does not support group policy change through dynamic authorization or RADIUS change of authorization (CoA).

Procedure

Step 1 In Firewall Management Center, choose **Objects** > **AAA Server** > **RADIUS Server Group** to configure a RADIUS server object.

a) Configure the required parameters for the RADIUS server object.
b) Check the **Enable dynamic authorization** check box.
c) In the **Port** field, enter the port for RADIUS dynamic authorization requests.

The valid range is 1024 to 65535 and the default value is 1700. The RADIUS server group that is registered for dynamic authorization notification listens to the port for the dynamic authorization policy updates from the RADIUS server.

Step 2 Configure a route from the device to the RADIUS server, such as an ISE server, using the interface enabled for dynamic authorization.

For more information, refer to Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source, on page 2196.

Step 3 Configure the DNS server and domain-lookup interfaces using **Platform Settings**.

For more information, refer to Configure DNS, on page 1633 and DNS server groups, on page 2792.

Step 4 Configure split tunneling in the remote access VPN group policy to allow DNS traffic through the VPN tunnel.

For more information, refer to Configure a group policy object, on page 2894.

Step 5 Deploy the configuration on the device.

Configure two-factor authentication

Firewall Threat Defense devices support two-factor authentication that requires users to verify their identity through two separate steps before gaining access. With two-factor authentication enabled, a user must provide a username and static password, and an additional verification item, such as an RSA token or a passcode. Both factors are handled by a single authentication source. The two-factor authentication server connects directly to the primary authentication source. Two-factor authentication adds an extra layer of identity verification to your remote access VPN.

Firewall Threat Defense devices support these two factors for two-factor authentication:

- **RSA tokens**—A time-based one-time passcode generated by an RSA device or application.
- **Duo Push**—An authentication request pushed to the Duo Mobile application for user approval.

Prerequisites for configuring RSA two-factor authentication

Review these prerequisites for configuring RSA two-factor authentication in Secure Firewall, covering requirements for both RSA server and ISE server configurations.

Prerequisites for RSA server

- Configure RADIUS or AD server as an authentication agent. Add this server as the authentication server for the remote access VPN policy in Firewall Management Center.
- Generate and download the configuration file (`sdconf.rec`).
- Create a token profile and assign the token to the user.
- Give the token to the user after assigning it.
- Download and install the token in the remote access VPN client.

For more information, refer to RSA documentation.

Prerequisites for ISE server

- Import the configuration file (`sdconf.rec`) from the RSA server.
- Add the RSA server as the external identity source.
- Configure the shared secret.

Configure RSA two-factor authentication

You can configure your RADIUS or AD server as the authentication agent in the RSA server. Use it as the primary authentication source for your remote access VPN policy. Users authenticate with a username that exists in the RADIUS or AD server. In the password field, users must concatenate their password and the one-time RSA token, separated by a comma, in this format: `password,token`.

In this setup, it is common practice to use a dedicated RADIUS server, such as Cisco ISE, for authorization. You can configure this second RADIUS server as the accounting server too.

Before you begin

Ensure that you review Prerequisites for configuring RSA two-factor authentication, on page 1666.

Procedure

Step 1 In Firewall Management Center, choose **Objects** > **AAA Server** > **RADIUS Server Group** to configure a RADIUS server object.

Step 2 Configure the RADIUS server in the RADIUS server object with a timeout of 60 seconds or more.

Step 3 Configure a new remote access VPN policy or edit an existing policy.

Step 4 In **Authentication, Authorization & Accounting (AAA)**, from the **Authentication Method** drop-down list, choose **AAA** and add the RADIUS server as the authentication server.

For more information, see Configure AAA settings for a remote access VPN policy, on page 1617.

Step 5 Deploy the configuration on the device.

Prerequisites for configuring Duo two-factor authentication

Review these prerequisites before configuring Duo two-factor authentication for remote users in Secure Firewall.

- Configure a primary authentication RADIUS or AD server for your remote access VPN users.
- Create a Duo administrator account in Duo Admin Panel.
- Enroll users in Duo using the Duo Admin Panel.
- Create a Duo-protected application to integrate Duo with your Firewall Threat Defense device.

  This application generates an integration key, a secret key, and an API hostname. You need these parameters when you configure the `authproxy.cfg` file using Duo Authentication Proxy.
- Install Duo Authentication Proxy on a Windows or Linux machine in your network. The Duo proxy server also works as a RADIUS server.

  Download and install the most recent Duo Authentication Proxy.

  - **Windows**: https://dl.duosecurity.com/duoauthproxy-latest.exe
  - **Linux**: https://dl.duosecurity.com/duoauthproxy-latest-src.tgz

  To verify the checksum, refer to the Duo documentation at https://duo.com/docs/checksums#duo-authentication-proxy.
- Configure `authproxy.cfg`, the Duo authentication file.

  The `authproxy.cfg` file contains details of the RADIUS or ISE server, the Firewall Threat Defense device, the Duo proxy server details, the integration key, the secret key, and the API host details. For more information, refer to https://duo.com/docs/cisco-firepower#configure-the-proxy.

Configure two-factor authentication for remote access VPN users using Duo

Use Duo Multi-Factor Authentication (MFA) to add a second layer of security and protect your organization by verifying user identities. Remote users must authenticate using their credentials and then use a Duo passcode method such as push, phone call, passcode, or SMS.

Before you begin

Ensure that you review Prerequisites for configuring Duo two-factor authentication, on page 1667.

Procedure

Step 1 In Firewall Management Center, choose **Objects** > **AAA Server** > **RADIUS Server Group** to configure a RADIUS server object for Duo.

Add the Duo Authentication Proxy as the RADIUS server in the RADIUS server object, and set the timeout to more than 60 seconds. For more information, see RADIUS server group configuration options, on page 2770.

Step 2 Assign the RADIUS server as the authentication server for your remote access VPN policy.

For more information, see Configure AAA settings for a remote access VPN policy, on page 1617.

Step 3 Deploy the configuration on the device.

For detailed information about deploying Duo multi-factor authentication for remote access VPN, refer to Configure Duo Multi-Factor Authentication for Remote Workers using Cisco Secure Firewall Management Center.

Configure VPN access of remote users based on geolocation

Geolocation-based VPN access configuration is a security feature that

- manages remote access VPN connections of users based on their geolocations
- allows or denies VPN connections from specific countries or regions through configurable rules, and
- blocks connections that do not meet location-based criteria before authentication and logs the details.

By configuring geolocation-based rules, you can meet compliance requirements and enhance security. If a connection does not meet location-based criteria, Firewall Management Center blocks it before authentication and logs the details.

Requirements and compatibility

This feature supports all versions of Secure Client.

Note Firewall Threat Defense device must be Version 7.7.0 or later.

Workflow to manage VPN access of remote users based on geolocation

The table summarizes the workflow for managing VPN access of remote users based on geolocation.

Step	Task	More Information
1	Review guidelines and limitations for managing VPN access of remote users based on geolocation.	Guidelines for managing remote access VPN users based on geolocation, on page 1669 Limitations to manage VPN access of remote users based on geolocation, on page 1669
2	Define a policy to allow geolocation-based access control for your remote clients.	Configure a service access object, on page 2779
2	Update the remote access VPN configuration with the policy.	—
3	Deploy the configurations on the devices.	—

Step	Task	More Information
4	After clients connect to the Firewall Threat Defense device, complete these tasks: **1.** Verify active remote access VPN sessions in the **Remote Access VPN** dashboard. **2.** Verify logs for the denied remote access VPN sessions in Firewall Management Center. **3.** Troubleshoot service access policies.	Monitor and verify geolocation-based access control policies, on page 1669 Troubleshoot geolocation-based access control policies, on page 1672

Guidelines for managing remote access VPN users based on geolocation

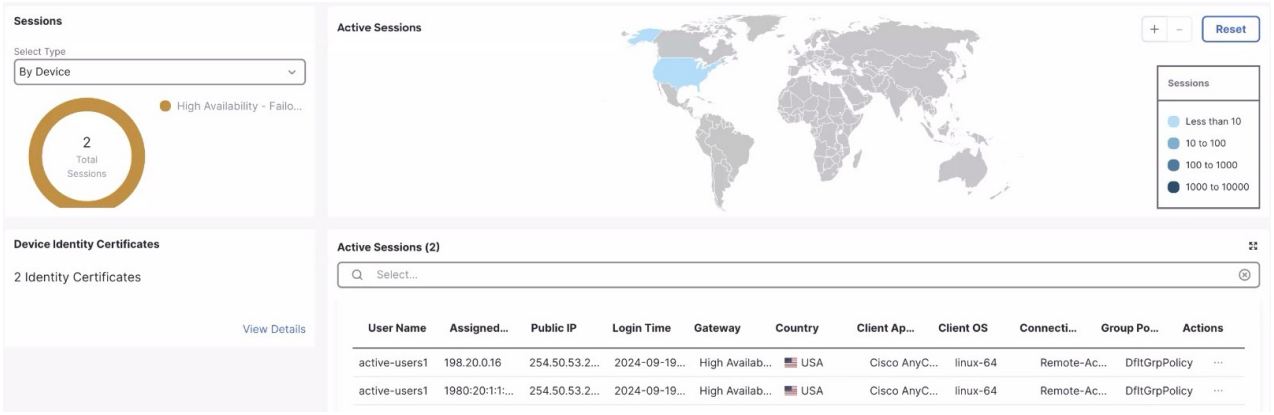
Review these guidelines when managing remote access VPN users based on geolocation:

- In a service access object, use a geolocation object (country, continent, or geolocation object) only in one rule.
- Configure the service access rules in the correct order because you cannot reorder these rules.

Limitations to manage VPN access of remote users based on geolocation

Review these limitations when managing VPN access of remote users based on geolocation:

- Clustering is not supported.
- Geolocation-based unclassified IP addresses are not categorized according to their geographic origin. For such unclassified IP addresses, the Firewall Management Center enforces the default service access policy action.
- Connections from IETF RFC1918 addresses are allowed for geolocation-based remote access VPN regardless of service-access policy settings.



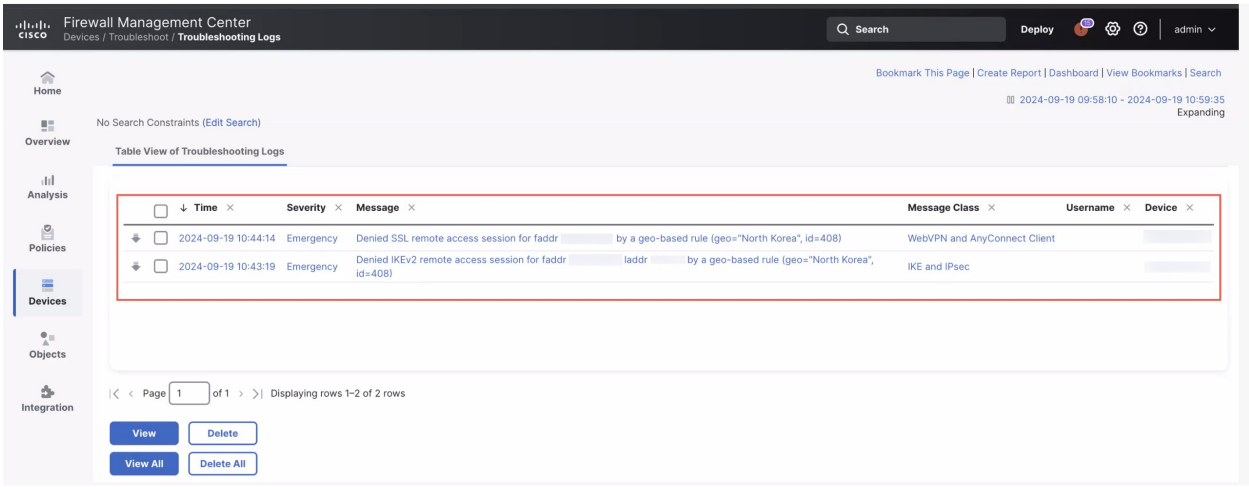
Monitor and verify geolocation-based access control policies

Use these monitoring and verification procedures to ensure that geolocation-based access control policies are working correctly for remote access VPN users. Monitor active sessions in the dashboard, review denied sessions through syslog, and verify policy configuration using CLI commands.

Monitor active remote access VPN sessions in remote access VPN dashboard

Choose **Insights & Reports** > **VPN dashboards** > **Remote Access VPN**.

Figure 430: Active remote access VPN sessions in the remote access VPN dashboard



Monitor denied remote access VPN sessions

Monitor denied remote access VPN sessions at **Troubleshooting** > **+ Show more** > **Advanced** > **Troubleshooting Logs**. To view these sessions, configure syslog settings in the Firewall Threat Defense device.

1. Choose **Devices** > **Platform Settings** and create or edit a threat defense policy.
2. In the left pane, click **Syslog**.
3. Click the **Logging Setup** tab.
4. Check the **Enable Logging** check box.
5. Click the **VPN Logs** radio button.
6. From the **Logging Level** drop-down list, choose **6 - informational**.
7. Click **Save**.

Note You cannot view the denied remote access VPN sessions if the **All Logs** option is configured with a **Logging Level** between 0 and 2.

Figure 431: Troubleshooting logs

Verify service access policies

From the Firewall Threat Defense device CLI, run these commands:

- **show running-config service-access**: Displays the user-defined service access policies.

```
firepower#show running-config service-access
   service-access deny geolocation OBJGRP_Asia1
   service-access permit interface outside ra-ssl-client geolocation OBJGRP_India
   service-access deny ra-ikev2 geolocation any
```

- **show service-access**: Displays details of the user-defined service access policies.

```
firepower# show service-access
1 outside          : ra-ikev2 ra-ssl-client (permit) hits = 8288
  Last hit time    : 10:58:10.038 IST Tue Jul 16 2024
  object-group     : FMC_INTERNAL_XXY
2 any              : ra-ikev2 ra-ssl-client (deny) hits = 123
  Last hit time    : 11:23:12.032 IST Tue Jul 17 2024
  object-group     : any

firepower# show service-access detail
1 outside          : ra-ikev2 ra-ssl-client (permit) hits = 8288
  Last hit time    : 10:58:10.038 IST Tue Jul 16 2024
  object-group     : FMC_INTERNAL_XXY
  geolocation      : Egypt(818) Jordan(400)
                     Iran (Islamic Republic of)(364)
                     Saudi Arabia(682)
```

- **show geodb**: Displays details of the geolocation table.

  show geodb {**ipv4** | **ipv6** | **counters** | **context**} [**location** *country_name* | **lookup** *ip_address*] [**detail**]

  - **show geodb** {**ipv4** | **ipv6**}: Displays the total number of IPv4 or IPv6 address mappings.

```
firepower# show geodb ipv4
 Geolocation Table - IPv4
 Total number of mappings available: 532507
```

```
Last geolocation data read time:  17:02:13.000 IST Thu Jul 18 2024
Running geolocation update version: 2024-02-15-019
```

- **show geodb** { **ipv4** | **ipv6** } **location** *country_name* **detail**: Displays the details of the IPv4 or IPv6 address mappings.

```
firepower# show geodb ipv4 location Antarctica detail
Geolocation Table - IPv4
id=0x00007fff82c284e0, geo_id=10, hits=0
        range_lower=77.70.176.176, range_upper=77.70.176.183
id=0x00007fff82cca360, geo_id:10, hits=0
     range_lower=79.110.169.69, range_upper=79.110.169.69
Total number of mappings available: 28
```

- **show geodb counters**: Displays the details of active, permitted, and denied sessions.

```
firepower# show geodb counters
current   - ongoing sessions
permitted - cumulative permitted sessions
denied    - cumulative denied sessions
Location                current          permitted      denied
Egypt                     0                  0             5
India                     45                 1345          45
```

- **show geodb** { **ipv4** | **ipv6lookup** *ip_address*: Displays the geolocation of a specific IPv4 or IPv6 address.

```
firepower# show geodb ipv4 lookup 223.223.128.24
Geolocation of 223.223.128.24 is "India" (356) with id=0x000015114d0aa330
Matching network range: 223.223.128.0 - 223.223.159.255
```

Troubleshoot geolocation-based access control policies

This topic provides syslogs and CLI commands to troubleshoot geolocation-based access control policies using Threat Defense devices.

Syslogs

To enable syslogs for remote access VPN service access policies, perform these steps:

1. Choose **Devices** > **Platform Settings**.
2. Create a platform settings policy, or edit an existing one.
3. In the left pane, click **Syslog**.
4. Click the **Logging Setup** tab and check the **Enable Logging** check box.
5. Click the **Syslog Settings** tab and enable the syslogs for service access syslog 751031 and 716166.

CLI commands

- Use the **show running-config service-access**, and **show service-access** commands to view details of user-defined service access policies.
- Use the **show geodb** command to view details of the geolocation table.
- Use the **debug geolocation <debug-level>** command to capture debug logs for geolocation. The debug levels are 1 (Error), 2 (Warning), 3 and 4 (Info), 5 (Debug), or 255 (Debug all).

- Use the **clear geodb counters** command to clear the geolocation table counters such as the hit counts of the service access policies. To clear the permitted and denied counters for locations, reboot the device. The command does not clear these counters.

Configure split tunneling

Split tunneling allows you to route selected traffic through an encrypted VPN while other applications can access the internet directly.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the edit icon next to the connection profile that you want to modify.

Step 4 Click **+** to add a group policy or click **Edit Group Policy**.

Step 5 In the **Add Group Policy** or **Edit Group Policy** dialog box, click the **General** tab.

a) From the left pane, click **Split Tunneling**.

b) From the **IPv4 Split Tunneling** or **IPv6 Split Tunneling** drop-down list, choose **Exclude networks specified below** and choose the networks to exclude from VPN traffic.

By default, all traffic routes through the VPN tunnel.

c) In **Split Tunnel Network List Type**, click **Standard Access List** or **Extended Access List**, and select an access list from the drop-down list or add a new one.

If you choose to add a new standard or extended access list, configure these parameters in the **New Access List Object** dialog box:

1. In the **Name** field, enter a name for the access list.
2. Click **Add** to match traffic based on a network.
3. From the **Action** drop-down list, choose **Allow**.
4. Click the **Network** tab and select the network whose traffic you want to route through the VPN tunnel.
5. Click **Add**.
6. Click **Save**.

Step 6 Click **Save**.

Configure dynamic split tunneling

Dynamic split tunneling allows you to fine-tune split tunneling based on DNS domain names. You can include or exclude specific DNS domains from your VPN tunnel. Excluded domains are not blocked, traffic to those domains is kept outside the VPN tunnel. For example, you can send Cisco WebEx traffic over the public internet, freeing up VPN bandwidth for traffic destined to your protected network.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the edit icon next to the connection profile that you want to modify.

Step 4 Click **+** to add a group policy or click **Edit Group Policy**.

Step 5 In the **Add Group Policy** or **Edit Group Policy** dialog box, click the **Secure Client** tab.

Step 6 From the left pane, click **Custom Attributes** and click **+**.

Step 7 In the **Add Custom Attribute** dialog box, configure these parameters:

a) From the **Secure Client Attribute** drop-down list, choose **Dynamic Split Tunneling**.

b) Click **+** next to the **Custom Attribute Object** drop-down list to create an object.

c) In the **Add Secure Client Custom Attribute** dialog box, configure these parameters:

1. In the **Name** field, enter the name for the custom attribute object.
2. In the **Include domains** field, enter the domain names to route through the VPN tunnel.

   You can include domains that would otherwise be excluded based on their IP addresses.
3. In the **Exclude domains** field, enter the domain names to route outside the VPN tunnel.

   Excluded domains are not blocked, their traffic simply routes outside the VPN tunnel.
4. Click **Save**.

d) Click **Add**.

Step 8 Click **Save**.

What to do next

1. Deploy the configuration on the Firewall Threat Defense device.
2. Verify the configured dynamic split tunnel configuration on the Firewall Threat Defense device and the Secure Client. For more information, refer to Verify dynamic split tunneling configuration, on page 1674.

anyconnect-custom dynamic-split-include-domains none
```

Verify dynamic split tunneling configuration on Secure Client

Click the Statistics () icon and choose **VPN > Statistics**. You can confirm the domains under the **Dynamic Split Exclusion or Inclusion** category.

Configure Secure Client management VPN tunnel

A Secure Client management VPN tunnel is a VPN connection that

- automatically connects to the corporate network as soon as the endpoint device powers up
- ensures that endpoints are up-to-date with software patches and updates, and
- disconnects once the user establishes their own VPN session.

Management VPN tunnel operation

When the endpoint device starts, Secure Client detects the management VPN feature and initiates a session using the host entry defined in the server list of the Secure Client management VPN profile.

To configure the Secure Client management VPN tunnel on a Firewall Threat Defense device, you need these components:

- A connection profile with certificate-based authentication and a group URL.
- A Secure Client management VPN profile file, with a server group URL and backup servers if required.
- A group policy associated with a remote access VPN policy that includes the management VPN profile, split tunneling with explicitly included networks, client bypass protocol, and no banner.

Prerequisites for Secure Client management VPN tunnel

Review these prerequisites before configuring and establishing a management VPN tunnel connection.

General prerequisites

- Ensure that Firewall Threat Defense and Firewall Management Center are versions 6.7.0 or later.
- Download the Secure ClientSecure Client Headend Deployment Package Version 4.7 or later and upload it to Firewall Threat Defense remote access VPN policy.
- Configure certificate authentication in the connection profile.
- Do not configure a banner in the group policy.
- Verify the split tunneling configuration in the management tunnel group policy.

Certificate prerequisites

- Ensure that the Firewall Threat Defense device has these certificates:
  - A valid identity certificate for remote access VPN.
  - A root certificate from the local Certificate Authority(CA).
- Install a valid identity certificate on the endpoints connecting to the management VPN tunnel.
- Install the endpoint identity certificate in the Machine Certificate Store (Windows) or System Keychain (macOS).
- Install the CA certificate for the Firewall Threat Defense device on all endpoints
- Install the CA certificate for all endpoints on the Firewall Threat Defense device.

Limitations of Secure Client management VPN tunnel

Review these limitations when using Secure Client management VPN tunnel:

- Supports only certificate authentication, it does not support AAA-based authentication.
- Public or private proxy settings are not supported.

- Secure Client upgrades and module downloads are not supported when the management VPN tunnel is connected.

Configure Secure Client management VPN tunnel on Firewall Threat Defense

The management VPN tunnel allows endpoints to automatically establish VPN connectivity at startup, ensuring immediate access to corporate resources. This configuration requires setting up a dedicated connection profile and management VPN profile specifically for the management tunnel.

Procedure

Step 1 Create a remote access VPN policy.

Choose **Secure Connections** > **Remote Access VPN**

For information, refer to Configure a remote access VPN policy, on page 1613.

Step 2 Configure the management VPN tunnel connection profile settings:

Note Create a dedicated connection profile for the Secure Client management VPN tunnel.

a) Click the edit icon next to the remote access VPN policy
b) Click the edit icon next to the connection profile that you want to modify.
c) Click the **AAA** tab.
d) From the **Authentication Method** drop-down list, choose **Client Certificate Only**
e) Configure the authorization and accounting settings.
f) Click the **Aliases** tab of the connection profile.
g) In **URL Alias**, click **+**.
h) In the **Add URL Alias** dialog box, configure these parameters:
   1. From the **URL Alias** drop-down list, choose a URL alias.
   2. Check the **Enabled** check box to enable the URL.
   3. Click **OK**.
i) Click **Save** to save the connection profile settings.

Step 3 Create a management VPN profile using the Secure Client profile editor:

a) Download the Secure Client Profile Editor from Cisco Software Download Center.
b) Create a Secure Client management VPN profile with the required settings for your VPN users and save the file.

   The management VPN profile stores all settings required to establish the VPN tunnel at endpoint startup.

c) In the management VPN profile server list, specify the server as the group URL from the connection profile (Step 2h).

Step 4 Create a VPN profile using the Secure Client profile editor.

Step 5 Upload the Secure Client management VPN profile and VPN profile to Firewall Management Center:

a) Choose **Objects** > **VPN** > **Secure Client File**
b) Click **Add Secure Client File**.
c) In the **Add Secure Client File** dialog box, configure these parameters:
   1. In the **Name** field, enter the name of the Secure Client management VPN profile file.
   2. From the **File Type** drop-down, choose **Secure Client Management VPN Profile**.
   3. Click **Browse** and select the management VPN profile file.
   4. Click **Save**.
d) Repeat Step 5b to Step 5c to upload the Secure Client VPN profile to Firewall Management Center.

Step 6 Associate the management VPN profile with a group policy and configure group policy settings:

Add the management VPN profile to the group policy associated with the management tunnel connection profile. When a user connects, Secure Client downloads both the management VPN profile and the user VPN profile. This action enables the management VPN tunnel.

a) Click the edit icon next to the connection profile that you want to modify.
b) Click **Edit Group Policy**. **Edit Group Policy** > **Secure Client** > **Management Profile Edit Group Policy** and choose **AnyConnect Secure Client**, then click **Management Profile**.
c) In the **Edit Group Policy** dialog box, click the **Secure Client** tab.
d) From the left pane, choose **Management Profile**.
e) From the **Management VPN Profile** drop-down list, choose the management profile file.
f) Click **Save**.

Note Ensure that the group policy does not have a banner. To check the banner settings, edit the connection profile. Click the **General** tab and select **Banner**.

Step 7 Configure split tunneling in the group policy.

For information, refer to Configure split tunneling, on page 1673.

Step 8 Deploy the configuration on the Firewall Threat Defense device.

What to do next

Verify Secure Client management VPN tunnel, on page 1678.

Related Topics

Configure Secure Client VPN Management Tunnel on Secure Firewall

Verify Secure Client management VPN tunnel

This topic provides instructions to verify Secure Client management VPN tunnel using Secure Firewall across different interfaces and devices.

Verify Secure Client management VPN tunnel using Secure Client

Click the Statistics () icon and choose **VPN > Statistics**.

Verify Secure Client management VPN tunnel in a Firewall Threat Defense device

From the Firewall Threat Defense device CLI, run the **show VPN-sessiondb anyconnect** command.

Verify Secure Client management VPN tunnel in Firewall Management Center

Choose **Events & Logs** > **Analysis** > **Audit Logs** to view details of the management tunnel session.

Configure Secure Client modules on Firewall Threat Defense devices

Secure Client can integrate with various Cisco endpoint security solutions using different Secure Client modules to offer enhanced security.

Secure Client module configuration on Firewall Threat Defense devices is a security management feature that

When a user connects to the Firewall Threat Defense headend device, it downloads and installs Secure Client and the required modules on the endpoint.

You can use Firewall Threat Defense devices to distribute, manage, and upgrade Secure Client modules and profiles on endpoints.

Types of Secure Client modules

This topic lists the different types of Secure Client modules and describes their functionality and deployment characteristics.

The Secure Client supports these modules:

- **AMP Enabler**: Deploys Cisco Secure Endpoint to endpoints from a locally hosted enterprise server, providing malware detection, removal, and protection. In Cisco Secure Client 5.0, this module is available only for macOS. Windows offers native Secure Endpoint integration.
- **DART**: Collects system logs and diagnostic information to troubleshoot Secure Client installation and connection issues. You can send this data to Cisco TAC to troubleshoot issues. By default, Diagnostics and Reporting Tool (DART) is not enabled in new remote access VPN group policies for version 6.7 and later.
- **Feedback**: Sends feature and module usage data to the Cisco Feedback Server to help improve Secure Client quality and performance. Secure Client does not download the Feedback module to the endpoint.
- **ISE Posture**: Performs client-side endpoint compliance checks, including antivirus, antispyware, and OS verification using Cisco Identity Services Engine (ISE). The client receives the posture policy from the headend, collects posture data, compares results against the policy, and reports back to the headend.
- **Network Access Manager**: Manages device authentication and user identity for secure access to wired and wireless networks at layer 2. This module is not supported on macOS and Linux.
- **Network Visibility**: Monitors endpoint application usage to identify behavior anomalies and support capacity planning, auditing, compliance, and security analytics. You can share the usage data with NetFlow tools such as Cisco Stealthwatch.

- **Umbrella Roaming Security**: Provides DNS-layer security using Cisco Umbrella, including content filtering, multiple policies, robust reporting, and Active Directory integration.
- **Start Before Login**: Establishes a VPN connection before Windows login, enabling domain authentication over VPN. You must enable SBL in the Secure Client VPN profile and add it to the remote access VPN group policy.
- **Web Security**: Protects endpoints by blocking risky sites and testing unknown sites using , powered by Cisco Talos. Supports on-premises and cloud-based deployments. This module is not available in AnyConnect version 4.5 and later or in Secure Client Version 5.0.

Prerequisites for configuring Secure Client modules

Review these prerequisites before configuring Secure Client Premier modules in Threat Defense devices.

License prerequisites

- Ensure that you have one of these Secure Client Premier licenses:
  - Secure Client Premier
  - Secure Client Advantage
  - Secure Client VPN Only
- Ensure that export-controlled features are enabled in your Smart License.

  To verify if export-controlled functionality is enabled in Firewall Management Center, choose **Administration** > **Licenses** > **Smart Licenses**.

General prerequisites

- Configure the products you plan to use with the modules.
- Download these Secure Client packages from Cisco Software Download Center to your local host:
  - Secure Client Headend Deployment Package for the required platforms: Contains all Secure Client modules.
  - Profile Editor: Creates profiles for modules that require them.

    To enable the module and connect to the corresponding security service, some modules require a Secure Client profile. The profile editor supports only Windows.

    See the table to determine which modules require a client profile.

Secure Client Module	Requires a Client Profile
AMP Enabler	Yes
ISE Posture	Yes
Network Access Manager	Yes
Network Visibility Module	Yes
Umbrella Roaming Secure Module	Yes

Secure Client Module	Requires a Client Profile
Feedback	Yes
Web Security	Yes
DART	No
Start Before Login	No

Guidelines for configuring Secure Client modules

This topic lists the guidelines for configuring Secure Client on Threat Defense devices.

- All Secure Client modules are supported from AnyConnect version 4.8 and later, and in Secure Client version 5.0.
- Each module supports profiles with specific file extensions. The table lists the modules and the supported file extensions of their profiles.

Table 95: Supported file extensions of profiles

Module	File extension
AMP Enabler	*.xml, *.asp
Feedback	*.xml
ISE Posture	*.xml, *.isp
Network Access Manager	*.xml, *.nsp
Network Visibility	*.xml, *.nvmsp
Umbrella Roaming Security	*.xml, *.json
Web Security	*.xml, *.wsp, *.wso

- Configure only one entry per client module.
- Install Network Access Manager before enabling ISE Posture for Windows systems.
- Disable the **Always send DNS requests over tunnel** option under split tunnelling in the remote access VPN group policy to use the Umbrella Roaming Security module.
- Enable SBL in the Secure Client VPN profile to use SBL.

Configure a remote access VPN group policy with Secure Client modules

To install and update Secure Client modules on endpoints, add the modules to the remote access VPN group policy.

Before you begin

Ensure that you have configured a remote access VPN policy in the Firewall Management Center.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click the edit icon next to the remote access VPN policy.

Step 3 Click the edit icon next to the connection profile that you want to modify.

Step 4 Click **Edit Group Policy**.

Step 5 In the **Edit Group Policy** dialog box, configure these parameters:

a) Click the **Secure Client** tab.

b) From the left pane, choose **Client Modules**.

c) Click **+**.

d) In the **Add Client Module** dialog box, configure these parameters:

1. From the **Client Module** drop-down list, choose a module.
2. From the **Profile to download** drop-down list, choose a profile, or click **+** to add a new profile file.
3. Check the **Enable module download** check box to download the module on the endpoint.
4. Click **Add**.

e) Repeat Step 5c to Step 5d to add more modules.

f) Click **Save** to save the group policy.

Step 6 Click **Save** to save the remote access VPN policy.

What to do next

1. Deploy the configuration on the Firewall Threat Defense device.
2. Launch Secure Client, select the VPN profile, and connect to the VPN. Secure Client installs the configured modules on the endpoint.
3. Verify the configuration. For more information, refer to Verify Secure Client module configuration, on page 1683.

Install Secure Client modules using a Firewall Threat Defense device

Use this procedure to deploy Secure Client modules to remote users connecting through VPN. The modules are automatically distributed when users establish VPN connections.

Before you begin

Ensure that you review Prerequisites for configuring Secure Client modules, on page 1680 and Guidelines for configuring Secure Client modules, on page 1681.

Procedure

Step 1 Create profiles for the required Secure Client modules.

Step 2 In Firewall Management Center, configure the modules and add the profiles to the remote access VPN group policy.

Step 3 Deploy the configuration on the Firewall Threat Defense device.

Step 4 From the endpoint, use Secure Client to initiate a VPN connection to the Firewall Threat Defense device.

Step 5 The Firewall Threat Defense device authenticates the user.

Step 6 Secure Client checks for updates.

Step 7 The Firewall Threat Defense device distributes the Secure Client modules and the profiles on the endpoint.

Verify Secure Client module configuration

This topic provides instructions to verify Secure Client modules configuration across the Firewall Threat Defense device, endpoint devices, and Firewall Management Center.

Verify configuration in the Firewall Threat Defense device

From the Firewall Threat Defense CLI, run these commands to view the profiles and the Secure Client module configuration:

- **show disk0**: View the profiles and their configuration.
- **show run webvpn**: View details of the Secure Client configurations.
- **show run group-policy <ravpn_group_policy_name>**: View details of the remote access VPN group policy.
- **show VPN-sessiondb anyconnect**: View details of the active Secure Client VPN sessions.

Verify configuration in the endpoint device

1. Use the Secure Client to establish a VPN connection to the Firewall Threat Defense device.
2. Verify if the configured modules are downloaded and installed as part of the Secure Client.
3. Verify if the configured profiles, if any, are available in the locations documented in Profile Locations for all Operating Systems.

Verify configuration in Firewall Management Center

You can monitor remote access VPN sessions and troubleshoot user session issues from the remote access VPN dashboard in Firewall Management Center. Choose **Insights & Reports** > **VPN dashboards** > **Remote Access VPN**.

Application-based (per app VPN) remote access VPN for mobile devices

When you use Secure Client to establish a VPN connection from a mobile device, all traffic, including personal application traffic, is routed through the VPN tunnel. Per App VPN allows only approved applications on your Android or iOS device to use the VPN.

To use Per App VPN, you must install and configure a third-party Mobile Device Manager (MDM), define the list of approved applications in the MDM, and enable Per App VPN in the Firewall Threat Defense headend device.

Benefits

Application-based remote access VPN provides these benefits:

- Performance: Reduce VPN traffic over the corporate network and free up headend device resources.
- Protection: Protect the corporate VPN tunnel from unapproved or malicious applications.

Prerequisites for configuring application-based VPN tunnels

Review these prerequisites before configuring application-based VPN tunnels.

Licensing prerequisites

- Secure Client Premier, or Secure Client Advantage.
- Essentials license must allow export-controlled functionality.

  To verify this functionality in Firewall Management Center, choose **Administration** > **Licenses** > **Specific Licenses**.

General prerequisites

- Configure a remote access VPN policy in Firewall Management Center.
- Install and configure a third-party Mobile Device Manager (MDM).

  You must configure the applications allowed over the VPN in the MDM and enroll each device to the MDM server.
- Download Cisco AnyConnect Enterprise Application Selector from Cisco Software Download Center.

  You need this tool to define the per-app VPN policy.

Determine application IDs for mobile applications

Before you configure per-application VPN in the Firewall Threat Defense headend device, find the application ID for each application you want to allow through the tunnel.

We recommend that you configure the per-application policy in MDM to simplify device configuration. If you configure the policy on the device, supply an application ID for each application on every endpoint.

Application IDs (bundle IDs in iOS) use the reverse DNS format. You can use an asterisk as a wildcard, for example, `*.*` allows all applications, and `com.cisco.*` allows all Cisco applications.

Procedure

Step 1 Determine application IDs for Android devices.

Open Google Play in your browser, search for the application, and check the URL. The application ID appears in the `ID=` parameter.

For example, `https://play.google.com/store/apps/details?ID=com.facebook.orca` is the Facebook Messenger URL and the app ID is `com.facebook.orca`.

For applications not available in Google Play, use a third-party package name viewer to extract the app ID.

Step 2 Search for the application in your browser for iOS devices.

Step 3 Find the Apple App Store download link.

Example:

For example, `https://apps.apple.com/us/app/messenger/id454638411` is the Facebook Messenger URL.

Step 4 Copy the number after `ID`.

Example:

In this example, it is `454638411`.

Step 5 Add the number to this URL and open it in a new browser window:
`https://itunes.apple.com/lookup?ID=454638411`

Step 6 Download the text file and open it in a text editor.

Step 7 Search for `bundleId`.

Example:

For example: `"bundleId":"com.facebook.Messenger"`.

In this example, the bundle ID is `com.facebook.Messenger`. Use this as the app ID.

What to do next

After you prepare your list of application IDs, see Configure application-based VPN tunnels in mobile devices, on page 1685 to configure the policy.

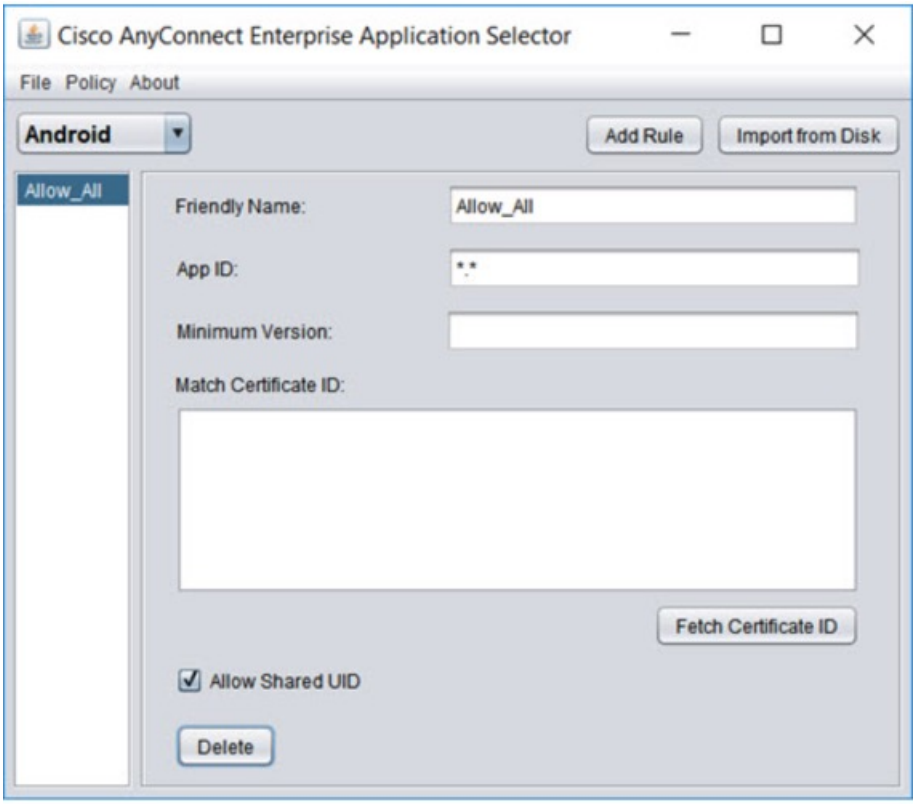
Configure application-based VPN tunnels in mobile devices

After you install and configure your MDM software, you can enable per-application VPN in the Firewall Threat Defense headend device. MDM controls which applications use the VPN tunnel.

Before you begin

Ensure that you review Prerequisites for configuring application-based VPN tunnels, on page 1684.

Follow these steps to configure application-based VPN tunnels in mobile devices:



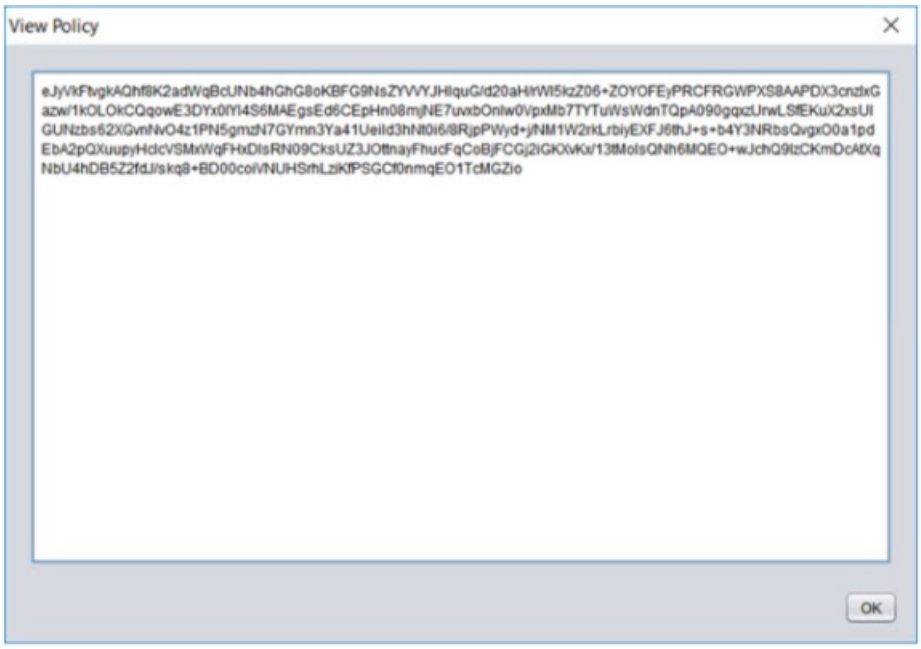
Procedure

Step 1 Define the per-application VPN policy using the Cisco AnyConnect Enterprise Application Selector.

You can manage allowed applications in two ways:

- Use MDM: Create a single **Allow All** policy and define allowed applications in MDM. This method is recommended.
- Use headend device: Create a separate rule for each application with a unique name and application ID. For more information about obtaining application IDs, see Determine the Application IDs for Mobile Apps.

To create an **Allow All** policy for both Android and iOS platforms using the AnyConnect Enterprise Application Selector:



a) From the drop-down list, choose **Android** or **iOS** as the platform type.
b) In the **Friendly Name** field, enter a name for the policy, for example, Allow_All.
c) In the **App ID** field, enter the application ID or *.* to match all applications.

   You can skip the other options.

d) Click **Add Rule**.
e) Choose **Policy > View Policy** to get the base64-encoded string for the policy.

   Copy the encrypted XML string. Use it during per-application VPN configuration.

Step 2 In Firewall Management Center, enable per-application VPN in the Firewall Threat Defense headend device.

a) Choose **Secure Connections** > **Remote Access VPN**.
b) Click the edit icon next to the remote access VPN policy.
c) Click the edit icon next to the connection profile.
d) Click **Edit Group Policy**.
e) In the **Edit Group Policy** dialog box, click the **Secure Client** tab.
f) From the left pane, click **Custom Attributes** and click **+**.
g) In the **Add Custom Attribute** dialog box, configure these parameters:

1. From the **Secure Client Attribute** drop-down list, choose **Per App VPN**.
2. Click **+** next to **Custom Attribute Object** drop-down list.
3. In the **AddSecure Client Custom Attribute** dialog box, configure these parameters:
   a. In the **Name** field, enter the name that you used in Step 1b for the per-application VPN custom attribute object.
   b. In the **Attribute Value** field, enter the base64 encoded string from the Cisco AnyConnect Enterprise Application Selector (Step 1e).
   c. Click **Save**.
4. Click **Add** and click **Save**.

Step 3 Deploy your changes on Firewall Management Center.

What to do next

1. In the endpoint device, open Secure Client, choose the VPN profile, then connect to the VPN.
2. Verify the configuration. For more information, refer to Verify per-application configuration, on page 1688.

Related Topics

Configure Application-Based Remote Access VPN (Per App VPN) on Mobile Devices Using Cisco Secure Firewall Management Center

Verify per-application configuration

This topic provides instructions to verify Per App configuration on Firewall Threat Defense and Secure Client.

Verify per-application configuration in a Firewall Threat Defense device

Run these commands in the Firewall Threat Defense CLI:

- **show run webvpn**: View details of the remote access VPN policy.
- **show run group-policy <ravpn_group_policy_name>**: View details of the group policy of the remote access VPN policy.
- **show run anyconnect-custom-data**: View the custom attributes and their associated values.

Verify per-application configuration in the endpoint device

After the endpoint establishes VPN connection with the Firewall Threat Defense., perform these steps:

1. Click the **Statistics** icon of the Secure Client.
2. Verify that **Tunnel Mode** is **Application Tunnel** instead of **Tunnel All Traffic**.
3. Verify that **Tunneled Apps** lists the applications that you enabled in the MDM.

Monitor remote access VPNs

Monitor remote access VPN connections and AAA server connectivity using the remote access VPN dashboard and CLI commands.

Remote access VPN dashboard

The Remote Access VPN dashboard provides real-time monitoring of active VPN sessions across your devices, enabling you to quickly identify and resolve remote user session issues. Choose **Insights & Reports** > **VPN dashboards** > **Remote Access VPN** to access the dashboard.

Benefits of using the dashboard

- Visualize active user sessions based on their location.
- View detailed information about active user sessions.

- Mitigate user session problems by terminating sessions if required.
- Distribute active user sessions per device, encryption type, Secure Client version, operating system, and connection profile.
- View expiration details for device identity certificates.

Dashboard widgets

- Active Sessions (Tabular View)
- Active Sessions (Map view)
- Sessions
- Device Identity Certificates

Active sessions (table view)

This widget displays a table of all connected remote access VPN users. For each session, you can view:

- Username, assigned IP address, and public IP address
- Login time, VPN gateway, and connection profile
- Client application, client operating system, and group policy

Use the filter to narrow results by any of these criteria.

For any individual session, you can terminate:

- A specific user session
- All sessions for a specific user on a specific VPN gateway
- All sessions on a specific VPN gateway

Dual address stack sessions—If a client device supports dual address stack (IPv4 and IPv6 addresses) and the remote access VPN configuration includes both IPv4 and IPv6 address pools, the device assigns both address types to the client's tunnel interface. Firewall Management Center displays two sessions for the same user, one per address, even though only a single VPN session exists on the device. If you run the **show VPN-sessiondb l2l filter ipaddress** command on the device, you can see only a single remote access VPN session.

Active sessions (map view)

This widget displays an interactive heat map of active remote access VPN user locations. The map displays countries with active sessions using shades of blue. Darker shades indicate higher session counts. Hover over any country to see its name and total active session count. You can use zoom in, zoom out, and reset controls.

Sessions

This widget provides real-time monitoring of active remote access VPN sessions in the devices. You can filter sessions by:

- Device: Displays the number of sessions per device.

- Encryption Type: Displays the number of Secure Client SSL or IPsec sessions.
- Secure Client Version: Displays the sessions per Secure Client version.
- Operating System: Displays the sessions for each operating systems (Windows, Linux, macOS, Mobile OS).
- Connection Profile: Displays the sessions per connection profile.

Device identity certificates

This widget displays identity certificate expiration details for your remote access VPN gateways. You can view expired certificates and those expiring within the next 30 days. To view certificates in the **Devices** > **Certificates** page, click **View Details**.

Monitor remote access VPN user activity

Monitor remote access VPN user activity to track user connections, analyze network usage patterns, analyze user behavior, and maintain network security oversight.

Procedure

Choose **Events & Logs** > **Users** > **User Activity**.

You can view historical events such as:

- Connection profile and IP address
- Geolocation data and connection duration
- Throughput and device information

Remote access VPN user activity data is displayed, showing connection profiles, geolocation information, and throughput details for analysis.

Troubleshoot remote access VPNs

This topic provides troubleshooting methods for remote access VPNs using logs, debug commands, DART diagnostics, and AAA server connectivity commands.

Use troubleshooting logs

To view remote access VPN logs, choose **Troubleshooting** > **+ Show more** > **Advanced** > **Troubleshooting Logs**. To view these logs, you must configure the syslog settings in the Firewall Threat Defense device. For more information about configuring syslog settings in the device, refer to Monitor denied remote access VPN sessions, on page 1670.

Use debug commands

Caution Debug output is CPU-intensive and can make the system unusable. Follow these guidelines when using debug commands:

- Use these commands only when troubleshooting specific problems or working with Cisco TAC.
- Run debug commands during periods of low network traffic and minimal user activity to reduce processing overhead.

The table lists debug commands for remote access VPN.

CLI Command	Description
system support diagnostic-CLI	Log in to Firewall Threat Defense Lina CLI.
debug webvpn	Debugs WebVPN configurations.
debug SSL	Debugs SSL sessions.
debug crypto ipsec	Debugs IPsec configurations.
debug crypto ikev2	Debugs IKEv2 configurations.
debug crypto ikev1	Debugs IKEv1 configurations.
debug crypto CA	Debugs CA operations.

Use DART to troubleshoot Secure Client issues

Use the Secure Client Diagnostics and Reporting Tool (DART) to collect diagnostic data for troubleshooting Secure Client installation and connection issues.

Use commands to troubleshoot AAA server connectivity

The table lists debug commands to troubleshoot AAA server connectivity in remote access VPN connections.

CLI Command	Description
show AAA-server	Displays AAA server statistics.
show network	Displays IP address settings, DNS, and management details.
show network-static-routes	Displays the management interface default route and static routes.
show route	Displays data traffic routing table entries.
ping system and **traceroute system**	Verifies the path to the AAA server through the management interface.

CLI Command	Description
ping interface and **traceroute**	Verifies the path to the AAA server through the data interfaces.
test AAA-server authentication and **test AAA-server authorization**	Tests authentication and authorization on the AAA server.
clear AAA-server statistics or **clear AAA-server statistics protocol**	Clears AAA server statistics by group or protocol.
AAA-server *groupname* **activehost***hostname*	Activates a failed AAA server.
AAA-server*groupname***failhost***hostname*	Marks a AAA server as failed.
debug LDAP	Debugs LDAP issues.
debug AAA authentication	Debugs AAA authentication.
debug AAA authorization	Debugs AAA authorization.
debug AAA accounting	Debugs AAA accounting.

Appendix A: Concurrent VPN sessions of Firewall Threat Defense devices

This topic provides maximum concurrent remote access VPN session limits for different Firewall Threat Defense device models to support capacity planning and system performance optimization.

Concurrent VPN sessions (Firewall Threat Defense Virtual models)

The number of concurrent remote access VPN sessions on a Firewall Threat Defense Virtual device is governed by the smart-licensed entitlement tier and enforced by a rate limiter. Each device model has a maximum session limit to maintain acceptable system performance. Use these limits when planning capacity.

Device Model	Maximum Concurrent Remote Access VPN Sessions
Firewall Threat Defense Virtual5	50
Firewall Threat Defense Virtual10	250
Firewall Threat Defense Virtual20	250
Firewall Threat Defense Virtual30	250
Firewall Threat Defense Virtual50	750
Firewall Threat Defense Virtual100	10,000

Concurrent VPN sessions (hardware models)

The maximum concurrent VPN sessions are governed by platform-specific limits and are not dependent on the license. There is a maximum limit to the number of concurrent remote access VPN sessions allowed on a device based on the device model. This limit is designed so that system performance does not degrade to unacceptable levels. Use these limits for capacity planning.

Device Model	Maximum Concurrent Remote Access VPN Sessions
Secure Firewall 220	50
Firepower 1010	75
Firepower 1120	150
Firepower 1140	400
Firepower 2110	1500
Firepower 2120	3500
Firepower 2130	7500
Firepower 2140	10,000
Secure Firewall 1210	200
Secure Firewall 1220	300
Secure Firewall 1230	500
Secure Firewall 1240	1000
Secure Firewall 1250	1500
Secure Firewall 3110	3000
Secure Firewall 3120	6000
Secure Firewall 3130	15,000
Secure Firewall 3140	20,000
Secure Firewall 6100	60,000
Secure Firewall 4215	20,000
Secure Firewall 4225	25,000
Secure Firewall 4245	30,000
Firepower 4100, all models	10,000
Firepower 9300 appliance, all models	20,000
ISA 3000	25

For capacity of other hardware models, check the data sheets.

Note Once the maximum session limit is reached, the Firewall Threat Defense device denies incoming VPN connections and generates a syslog message. Refer to the syslog messages **%FTD-4-113029** and **%FT-4-113038** in the syslog messaging guide. For more information, refer to Cisco Secure Firewall Threat Defense Syslog Messages.

Appendix B: RADIUS server attributes for Firewall Threat Defense devices

Lists the RADIUS attributes used for user authorization between the specified device and the RADIUS server.

You can apply user authorization attributes (user entitlements or permissions) to VPN connections using Firewall Threat Defense devices. These attributes come from the external RADIUS server configured for authentication, authorization, or both in the remote access VPN policy.

Note Firewall Threat Defense devices support attributes with vendor ID 3076.

These user authorization attributes are sent from the Firewall Threat Defense device to the RADIUS server.

- Attributes 146 and 150 for authentication and authorization requests.
- Attributes 146, 150, and 151 for accounting start, interim-update, and stop requests.

Table 96: RADIUS attributes sent from Firewall Threat Defense to RADIUS server

Attribute	Attribute Number	Syntax, Type	Single or Multi-valued	Description or Value
Connection Profile Name or Tunnel Group Name	146	String	Single	1-253 characters
Client Type	150	Integer	Single	2= Secure Client SSL VPN, 6= Secure Client IPsec VPN (IKEv2)
Session Type	151	Integer	Single	1= Secure Client SSL VPN, 2= Secure Client IPsec VPN (IKEv2)

Table 97: RADIUS attributes sent to Secure Firewall Threat Defense

Attribute	Attribute Number	Syntax, Type	Single or Multi-valued	Description or Value
Address-Pools	217	String	Single	The network object defined in the Firewall Threat Defense device that will be used as the address pool for clients connecting to the remote access VPN connection. Define the network object in the **Objects** page.
Banner1	15	String	Single	The banner to display when the user logs in.
Banner2	36	String	Single	The second part of the banner to display when the user logs in. Banner2 is appended to Banner1.
Downloadable ACLs	Cisco-AV-Pair	merge-dacl {before-avpair | after-avpair}		Supported through Cisco-AV-Pair configuration.
Filter ACLs	86, 87	String	Single	Filter ACLs are referred by ACL name in the RADIUS server. The ACL configuration must be present on the Firewall Threat Defense device, to be used during RADIUS authorization. 86=Access-List-Inbound 87=Access-List-Outbound
Group-Policy	25	String	Single	The group policy for the connection. You must create the group policy in the remote access VPN **Group Policy** page. You can use one of the following formats: • *group policy name* • OU= *group policy name* • OU= *group policy name* ;
Simultaneous-Logins	2	Integer	Single	The number of separate simultaneous connections the user is allowed to establish. The range is 0 to 2147483647.
VLAN	140	Integer	Single	The VLAN in which to confine the user's connection. The range is 0 to 4094. You must also configure this VLAN on a subinterface on the Firewall Threat Defense device.

You must set the values of the IE-Proxy-Server-Method attribute returned from ISE to one of the following:

- IE_PROXY_METHOD_PACFILE: 8
- IE_PROXY_METHOD_PACFILE_AND_AUTODETECT: 11
- IE_PROXY_METHOD_PACFILE_AND_USE_SERVER: 12

• IE_PROXY_METHOD_PACFILE_AND_AUTODETECT_AND_USE_SERVER: 15

Firewall Threat Defense will deliver a proxy setting only if one of the above values is used for the IE-Proxy-Server-Method attribute.

Table 98: Supported RADIUS Authorization Attributes

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
Access-Hours	Y	1	String	Single	Name of the time range, for example, Business-h
Access-List-Inbound	Y	86	String	Single	Both Access-List attributes take the name of an A is configured on the Firewall Threat Defense de Create these ACLs using the Extended Access Li type. These ACLs control traffic flow in the inbound (entering the Firewall Threat Defense device) or o (traffic leaving the Firewall Threat Defense devi direction.
Access-List-Outbound	Y	87	String	Single	
Address-Pools	Y	217	String	Single	The network object defined in the Firewall Threat device that identifies a subnet, which will be use address pool for clients connecting to the remote VPN. Define the network object in the **Objects** p then associate the network object with a group p a connection profile.
Allow-Network-Extension-Mode	Y	64	Boolean	Single	0=Disabled 1=Enabled
Authenticated-User-Idle-Timeout	Y	50	Integer	Single	1-35791394 minutes
Authorization-DN-Field	Y	67	String	Single	Possible values: UID, OU, O, CN, L, SP, C, EA, GN, SN, I, GENQ, DNQ, SER, use-entire-name
Authorization-Required		66	Integer	Single	0 = No 1 = Yes
Authorization-Type	Y	65	Integer	Single	0 = None 1 = RADIUS 2 = LDAP
Banner1	Y	15	String	Single	Banner string to display for Cisco VPN remote a sessions: IPsec IKEv1, Secure Client SSL-TLS/DTLS/IKEv2, and Clientless SSL
Banner2	Y	36	String	Single	Banner string to display for Cisco VPN remote a sessions: IPsec IKEv1, Secure Client SSL-TLS/DTLS/IKEv2, and Clientless SSL. The string is concatenated to the Banner1 string , if con
Cisco-IP-Phone-Bypass	Y	51	Integer	Single	0=Disabled 1=Enabled
Cisco-LEAP-Bypass	Y	75	Integer	Single	0=Disabled 1=Enabled

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
Client Type	Y	150	Integer	Single	1=Cisco VPN Client (IKEv1) 2= Secure Clie 3=Clientless SSL VPN 4=Cut-Through-Prox 5=L2TP/IPsec SSL VPN 6= Secure Client I (IKEv2)
Client-Type-Version-Limiting	Y	77	String	Single	IPsec VPN version number string
DHCP-Network-Scope	Y	61	String	Single	IP Address
Extended-Authentication-On-Rekey	Y	122	Integer	Single	0=Disabled 1=Enabled
Framed-Interface-Id	Y	96	String	Single	Assigned IPv6 interface ID. Combines with Framed-IPv6-Prefix to create a complete ass address. For example, Framed-Interface-ID=1:1:1:1 c with Framed-IPv6-Prefix=2001:0db8::/64 gi assigned IP address 2001:0db8::1:1:1:1.
Framed-IPv6-Prefix	Y	97	String	Single	Assigned IPv6 prefix and length. Combines Framed-Interface-Id to create a complete ass address. For example, prefix 2001:0db8::/64 combine Framed-Interface-Id=1:1:1:1 gives the IP ad 2001:0db8::1:1:1:1. You can use this attribut an IP address without using Framed-Interfac assigning the full IPv6 address with prefix le for example, Framed-IPv6-Prefix=2001:0db
Group-Policy	Y	25	String	Single	Sets the group policy for the remote access V You can use one of these formats: • *group policy name* • OU= *group policy name* • OU= *group policy name* ;
IE-Proxy-Bypass-Local		83	Integer	Single	0=None 1=Local
IE-Proxy-Exception-List		82	String	Single	New line (\n) separated list of DNS domains
IE-Proxy-PAC-URL	Y	133	String	Single	PAC address string
IE-Proxy-Server		80	String	Single	IP address
IE-Proxy-Server-Policy		81	Integer	Single	1=No Modify 2=No Proxy 3=Auto detect 4= Concentrator Setting
IKE-KeepAlive-Confidence-Interval	Y	68	Integer	Single	10-300 seconds

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
IKE-Keepalive-Retry-Interval	Y	84	Integer	Single	2-10 seconds
IKE-Keep-Alives	Y	41	Boolean	Single	0 = Disabled 1 = Enabled
Intercept-DHCP-Configure-Msg	Y	62	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Allow-Passwd-Store	Y	16	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Authentication		13	Integer	Single	0 = None 1 = RADIUS 2 = LDAP (authorization = NT Domain 4 = SDI 5 = Internal 6 = RADIUS Expiry 7 = Kerberos/Active Directory
IPsec-Auth-On-Rekey	Y	42	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Backup-Server-List	Y	60	String	Single	Server Addresses (space delimited)
IPsec-Backup-Servers	Y	59	String	Single	1 = Use Client-Configured list 2 = Disable and cle list 3 = Use Backup Server list
IPsec-Client-Firewall-Filter-Name		57	String	Single	Specifies the name of the filter to be pushed to th as firewall policy
IPsec-Client-Firewall-Filter-Optional	Y	58	Integer	Single	0 = Required 1 = Optional
IPsec-Default-Domain	Y	28	String	Single	Specifies the single default domain name to send client (1-255 characters).
IPsec-IKE-Peer-ID-Check	Y	40	Integer	Single	1 = Required 2 = If supported by peer certificate not check
IPsec-IP-Compression	Y	39	Integer	Single	0 = Disabled 1 = Enabled
IPsec-Mode-Config	Y	31	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Over-UDP	Y	34	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Over-UDP-Port	Y	35	Integer	Single	4001- 49151. The default is 10000.
IPsec-Required-Client-Firewall-Capability	Y	56	Integer	Single	0 = None 1 = Policy defined by remote FW Are-You-There 2 = Policy pushed CPP 4 = Policy from server
IPsec-Sec-Association		12	String	Single	Name of the security association
IPsec-Split-DNS-Names	Y	29	String	Single	Specifies the list of secondary domain names to the client (1-255 characters).
IPsec-Split-Tunneling-Policy	Y	55	Integer	Single	0 = No split tunneling 1 = Split tunneling 2 = Loc permitted

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
IPsec-Split-Tunnel-List	Y	27	String	Single	Specifies the name of the network or ACL th the split tunnel inclusion list.
IPsec-Tunnel-Type	Y	30	Integer	Single	1 = LAN-to-LAN 2 = Remote access
IPsec-User-Group-Lock		33	Boolean	Single	0 = Disabled 1 = Enabled
IPv6-Address-Pools	Y	218	String	Single	Name of IP local pool-IPv6
IPv6-VPN-Filter	Y	219	String	Single	ACL value
L2TP-Encryption		21	Integer	Single	Bitmap: 1 = Encryption required 2 = 40 bits 8 = Stateless-Req 15= 40/128-Encr/Stateless
L2TP-MPPC-Compression		38	Integer	Single	0 = Disabled 1 = Enabled
Member-Of	Y	145	String	Single	Comma-delimited string, for example: `Sales` An administrative attribute that can be used access policies. It does not set a group policy
MS-Client-Subnet-Mask	Y	63	Boolean	Single	An IP address
NAC-Default-ACL		92	String		ACL
NAC-Enable		89	Integer	Single	0 = No 1 = Yes
NAC-Revalidation-Timer		91	Integer	Single	300-86400 seconds
NAC-Settings	Y	141	String	Single	Name of the NAC policy
NAC-Status-Query-Timer		90	Integer	Single	30-1800 seconds
Perfect-Forward-Secrecy-Enable	Y	88	Boolean	Single	0 = No 1 = Yes
PPTP-Encryption		20	Integer	Single	Bitmap: 1 = Encryption required 2 = 40 bits 8 = Stateless-Required 15= 40/128-Encr/Sta
PPTP-MPPC-Compression		37	Integer	Single	0 = Disabled 1 = Enabled
Primary-DNS	Y	5	String	Single	An IP address
Primary-WINS	Y	7	String	Single	An IP address
Privilege-Level	Y	220	Integer	Single	An integer between 0 and 15.

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value

Require-HW-Client-Auth	Y	48	Boolean	Single	0 = Disabled 1 = Enabled
Secondary-DNS	Y	6	String	Single	An IP address
Secondary-WINS	Y	8	String	Single	An IP address
SEP-Card-Assignment		9	Integer	Single	Not used
Session Subtype	Y	152	Integer	Single	0 = None 1 = Clientless 2 = Client 3 = Client Or Session Subtype applies only when the Session (151) attribute has the following values: 1, 2, 3,
Session Type	Y	151	Integer	Single	0 = None 1 = Secure Client SSL VPN 2 = Secur IPSec VPN (IKEv2) 3 = Clientless SSL VPN 4 = Clientless Email Proxy 5 = Cisco VPN Client (I = IKEv1 LAN-LAN 7 = IKEv2 LAN-LAN 8 = VI Balancing
Simultaneous-Logins	Y	2	Integer	Single	0-2147483647
Smart-Tunnel	Y	136	String	Single	Name of a Smart Tunnel
Smart-Tunnel-Auto	Y	138	Integer	Single	0 = Disabled 1 = Enabled 2 = AutoStart
Smart-Tunnel-Auto-Signon-Enable	Y	139	String	Single	Name of a smart tunnel auto sign-on list appende domain name.
Strip-Realm	Y	135	Boolean	Single	0 = Disabled 1 = Enabled
SVC-Ask	Y	131	String	Single	0 = Disabled 1 = Enabled 3 = Enable default ser Enable default clientless (2 and 4 not used)

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
SVC-Ask-Timeout	Y	132	Integer	Single	5-120 seconds
SVC-DPD-Interval-Client	Y	108	Integer	Single	0 = Off 5-3600 seconds
SVC-DPD-Interval-Gateway	Y	109	Integer	Single	0 = Off) 5-3600 seconds
SVC-DTLS	Y	123	Integer	Single	0 = False 1 = True
SVC-Keepalive	Y	107	Integer	Single	0 = Off 15-600 seconds
SVC-Modules	Y	127	String	Single	String (name of a module)
SVC-MTU	Y	125	Integer	Single	MTU value 256-1406 in bytes
SVC-Profiles	Y	128	String	Single	String (name of a profile)
SVC-Rekey-Time	Y	110	Integer	Single	0 = Disabled 1-10080 minutes
Tunnel Group Name	Y	146	String	Single	1-253 characters
Tunnel-Group-Lock	Y	85	String	Single	Name of the tunnel group or “none”.
Tunneling-Protocols	Y	11	Integer	Single	1 = PPTP 2 = L2TP 4 = IPSec (IKEv1) 8 = I 16 = WebVPN 32 = SVC 64 = IPsec (IKEv2) mutually exclusive. 0 - 11, 16 - 27, 32 - 43, 4 legal values.
Use-Client-Address		17	Boolean	Single	0 = Disabled 1 = Enabled
VLAN	Y	140	Integer	Single	0-4094
WebVPN-Access-List	Y	73	String	Single	Access-List name
WebVPN ACL	Y	73	String	Single	Name of a WebVPN ACL in the device.
WebVPN-ActiveX-Relay	Y	137	Integer	Single	0 = Disabled Otherwise = Enabled
WebVPN-Apply-ACL	Y	102	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Auto-HTTP-Signon	Y	124	String	Single	Reserved
WebVPN-Citrix-Metaframe-Enable	Y	101	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Content-Filter-Parameters	Y	69	Integer	Single	1 = Java ActiveX 2 = Java Script 4 = Image 8 in images
WebVPN-Customization	Y	113	String	Single	Name of the customization
WebVPN-Default-Homepage	Y	76	String	Single	A URL such as http://example-example.com
WebVPN-Deny-Message	Y	116	String	Single	Valid string (up to 500 characters)

History for remote access VPN

This topic provides the feature history for remote access VPN functionality in Secure Firewall.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Geolocation-based RA VPN	7.7	7.7	You can now allow or block remote access VPN connections by country or region. If a connection does not meet your location-based criteria, the device blocks the connection before authentication and records it for auditing.
Secure Client Customizations	7.4	Any	You can configure Secure Client customizations and deploy them to the VPN headend. The Threat Defense device distributes these customizations to the endpoint when a user connects to the VPN. • GUI text and messages • Icons and images • Scripts • Binaries • Customized Installer Transforms • Localized Installer Transforms
Remote Access VPN dashboard	7.3	Any	Use the Remote Access VPN dashboard to monitor active VPN sessions in real time, quickly identify session issues, and take corrective action. New/Modified Screen: **Insights & Reports** > **VPN dashboards** > **Remote Access VPN**
SAML with Certificate Support	7.2	Any	Use the remote access VPN wizard to configure certificate and SAML-based machine user authentication.
Multiple IDP trustpoint support	7.1	Any	Firewall Management Center supports multiple identity provider trustpoints with Microsoft Azure, allowing multiple applications to share the same Entity ID with unique identity certificates.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
AnyConnect VPN SAML External Browser	7.1	Any	You can now configure Secure Client VPN SAML external browser to use the client's local browser for web authentication. This feature enables SSO, passwordless authentication, and advanced methods such as biometrics, web authentication, Fast IDentity Online (FIDO), Universal 2nd Factor (U2F), and YubiKeys. The embedded browser does not support these options. The remote access VPN wizard includes the SAML login experience configuration.
Multi-Certificate Authentication	7.0	Any	Firewall Management Center supports multiple certificate-based authentication for Firewall Threat Defense devices. It validates the machine certificate to confirm the device is corporate-issued and validates the user's identity certificate to grant Secure Client VPN access.
VPN Load balancing	7.0	Any	Use VPN load balancing to distribute remote access VPN sessions equally across two or more devices.
AnyConnect Custom Attributes	7.0	Any	Firewall Management Center supports Secure Client custom attributes, enabling you to configure Secure Client features such as per-application VPN in mobile devices, dynamic split tunneling in Firewall Threat Defense devices.
Local User Authentication	7.0	Any	Use Firewall Management Center to configure and manage local users on Firewall Threat Defense devices. Assign them for primary or secondary remote access VPN authentication.
Selective Policy Deployment	7.0	Any	You can include or exclude remote access VPN configuration changes during deployment.
Support for AnyConnect Modules Configuration	6.7	Any	Use Firewall Management Center to configure Secure Client modules and profiles for additional security.
Support for LDAP Authorization	6.7	Any	Use Firewall Management Center to configure LDAP authorization for remote access VPN.
SAML single sign-on support for remote access VPN	6.7	Any	Configure a SAML 2.0 server as the single sign-on authentication server for remote access VPNs.
Secure Client Management VPN tunnel support	6.7	Any	Firewall Threat Defense remote access VPN supports Secure Client management VPN tunnel, which automatically establishes VPN connectivity to endpoints at power-on, without any user intervention.
Support for Datagram Transport Layer Security (DTLS) 1.2	6.6	Any	DTLS 1.2 is now part of the default SSL cipher group and can be configured along with TLS 1.2.

CHAPTER 37

Dynamic Access Policies

Dynamic access policies (DAP) enable you to configure authorization that addresses the dynamics of VPN environments. You create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. These attributes address issues of multiple group membership and endpoint security.

- Firewall Threat Defense dynamic access policies, on page 1707
- Prerequisites for dynamic access policy, on page 1709
- Guidelines and limitations for dynamic access policies, on page 1709
- Configure a Dynamic Access Policy (DAP), on page 1710
- Associate dynamic access policy with remote access VPN, on page 1721
- History for dynamic access policy, on page 1722

Firewall Threat Defense dynamic access policies

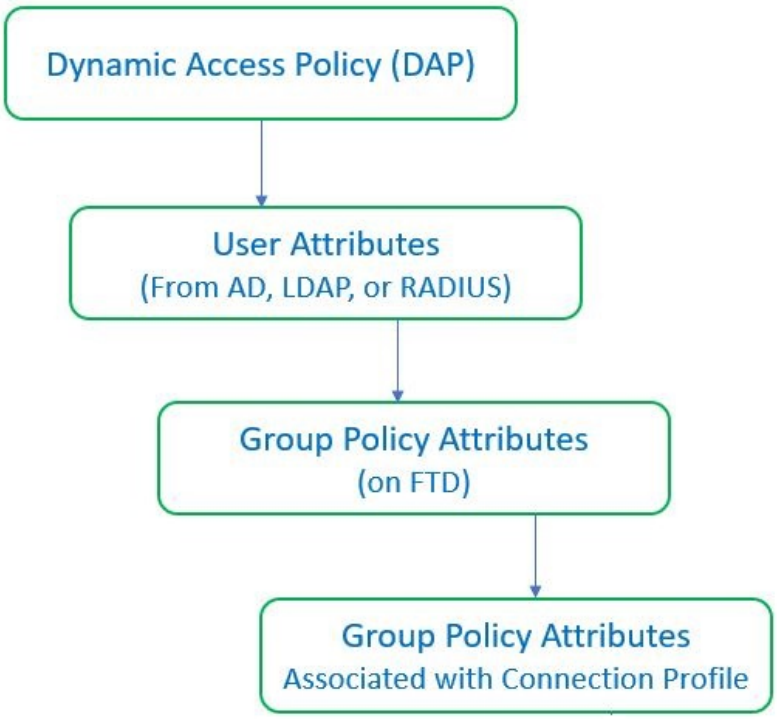
A Secure Firewall Threat Defense dynamic access policy is a collection of access control attributes that

- addresses issues of multiple group memberships and endpoint security in VPN environments
- grants access to particular users for particular sessions according to defined policies, and
- adapts to dynamic environments with multiple variables affecting each VPN connection.

Dynamic access policy operation

VPN gateways operate in dynamic environments. Multiple variables can affect each VPN connection. For example, intranet configurations that frequently change, the various roles each user inhabits within an organization, and log in attempts from remote access sites with different configurations and levels of security. The task of authorizing users is much more complicated in a VPN environment than it is in a network with a static configuration.

You can create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. The Firewall Threat Defense device generates a DAP during user authentication by selecting or aggregating attributes from one or more DAP records. The device then selects these DAP records based on the endpoint security information of the remote device and AAA authorization information for the authenticated user. Then the device applies the DAP record to the user tunnel or session.



Hierarchy of policy enforcement of permissions and attributes in a Firewall Threat Defense device

The Firewall Threat Defense device supports applying user authorization attributes, also called user entitlements or permissions, to VPN connections. The attributes are applied from a DAP on the Firewall Threat Defense, external authentication server and/or authorization AAA server (RADIUS) or from a group policy on the Firewall Threat Defense device.

If the Firewall Threat Defense device receives attributes from all sources, the device evaluates, merges, and applies the attributes to the user policy. If there are conflicts between attributes coming from the DAP, the AAA server, or the group policy, the attributes from the DAP always take precedence.

The Firewall Threat Defense device applies attributes in this order:

Figure 432: Policy enforcement flow

1. **DAP attributes on the FTD**—The DAP attributes take precedence over all others.
2. **User attributes on the external AAA server**—The server returns these attributes after successful user authentication and/or authorization.
3. **Group policy configured on the FTD**—If a RADIUS server returns the value of the RADIUS Class attribute IETF-Class-25 (OU= group-policy) for the user, the Firewall Threat Defense device places the user in the group policy of the same name and enforces any attributes in the group policy that are not returned by the server.

4. **Group policy assigned by the Connection Profile (also known as Tunnel Group)**—The Connection Profile has the preliminary settings for the connection, and includes a default group policy that is applied to the user before authentication.

Note The Firewall Threat Defense device does not support inheriting system default attributes from the default group policy, *DfltGrpPolicy*. For the user session, the device uses the attributes on the group policy that you assign to the connection profile, unless the user attributes or the group policy from the AAA server overrides them.

Prerequisites for dynamic access policy

This reference provides the licensing prerequisites that must be met before configuring Dynamic Access Policy features.

Licensing prerequisites

- Firewall Threat Defense must have at least one of these Secure Client licenses:
  - Secure Client Premier
  - Secure Client Advantage
  - Secure Client VPN Only
- The Firewall Threat Defense Essentials license must allow export-controlled functionality.

General prerequisite

Ensure that you have the Secure Firewall Posture package before you configure the dynamic access policy. You can add the Secure Firewall Posture file at **Objects** > **VPN** > **Secure Client File**.

Guidelines and limitations for dynamic access policies

Consider these guidelines and limitations when implementing Dynamic Access Policies:

- Matching of AAA attributes in a DAP will work only if a AAA server is configured to return the correct attributes when authenticating or authorizing a remote access VPN session.
- Minimum Secure Client and Secure Firewall Posture package version supported for DAP is 4.6. But it is highly recommended to use the latest version of Secure Client.
- DAP does not support clustering or multi-instance mode.
- DAP condition with an assigned IPv4 or IPv6 address does not work for local authentication.

Configure a Dynamic Access Policy (DAP)

Create a dynamic access policy

Create a dynamic access policy to enable conditional access control for VPN users based on their endpoint security posture and compliance status.

Dynamic access policies evaluate endpoint attributes and security posture to determine appropriate access permissions for VPN users. These policies work in conjunction with posture assessment packages to enforce security compliance.

Before you begin

Ensure that you have the Secure Firewall Posture package before you configure the dynamic access policy. You can add the Secure Firewall Posture file at **Objects** > **VPN** > **Secure Client File**.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**, and click **Create Dynamic Access Policy**.

Step 2 Specify the **Name** for the DAP policy and an optional **Description**.

Step 3 Choose the **Secure Firewall Posture Package** from the drop-down list.

Step 4 Click **Save**.

What to do next

To configure DAP record, see Create Dynamic Access Policy Record

Create a dynamic access policy record

A dynamic access policy (DAP) can contain multiple DAP records, where you configure user and endpoint attributes. You can prioritize the DAP records within a DAP so that the Firewall Threat Defense device can select and sequence the required criteria when a user attempts VPN connection.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Edit an existing dynamic access policy or click **Create Dynamic Access Policy** to create a new one and then edit the policy.

Step 3 Click **Create DAP Record**.

Step 4 Click the **General** tab.

Step 5 Specify the **Name** for the DAP record.

Step 6 Enter the **Priority** for the DAP record.

The lower the number, the higher the priority.

Step 7 Select one of these actions to take when a DAP record matches:

- **Continue**—Applies access policy attributes to the session. If any, the next DAP record (next policy line with less priority) is then evaluated.
- **Terminate**—Terminates the session.
- **Quarantine**—Quarantines the connection.

Step 8 Check the **Display User Message on Criterion Match** check-box and add the user message.

The Firewall Threat Defense displays this message to the user when the DAP record matches.

Step 9 Check the **Apply a Network ACL on Traffic** check box and select the access control list from the drop-down.

Step 10 Check the **Apply one or more Secure Client Custom Attributes** check box and select the custom attributes object from the drop-down.

Step 11 Click **Save**.

Configure posture assessment criteria

For a DAP policy, you can configure file, process, or registry endpoint attributes with unique endpoint IDs. These IDs can be used as endpoint criteria in Lua scripts to configure a DAP record.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Click **Create Dynamic Access Policy** to create a new DAP policy. and then edit the policy.

Step 3 Click the edit icon adjacent to the DAP policy.

Step 4 Click **Add Posture Assessment Criteria**.

Step 5 Do one of these:

- Configure a file endpoint attribute:
  1. **a.** Click the **File** radio button.
  2. **b.** In the **Endpoint ID** field, enter a unique ID for the file. It can be a string or a number.
  3. **c.** In the **File Path** field, specify the file path.
- Configure a registry endpoint attribute:
  1. **a.** Click the **Registry** radio button.
  2. **b.** In the **Endpoint ID** field, enter a unique ID for the registry. It can be a string or a number.
  3. **c.** In the **Entry Path** field, specify the file path.
- Configure a process endpoint attribute:

a. Click the **Process** radio button.

b. In the **Endpoint ID** field, enter a unique ID for the process. It can be a string or a number.

c. In the **Process Name** field, specify the process name.

Note You cannot edit an Endpoint ID once it is saved.

Step 6 Click **Save**.

What to do next

You can use the endpoint IDs to configure advanced posture assessment criteria using Lua scripts. For more information, see Configure advanced settings for DAP, on page 1721.

Configure AAA criteria settings for a DAP record

Configure AAA criteria settings to specify the conditions under which DAP records are selected and applied to user sessions based on AAA authorization and posture assessment information.

DAP complements AAA services by providing a limited set of authorization attributes that can override the attributes that AAA provides. The Firewall Threat Defense device selects DAP records based on the AAA authorization information for the user and posture assessment information for the session. The Firewall Threat Defense device can choose multiple DAP records depending on this information, which it then aggregates to create DAP authorization attributes.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Edit an existing DAP policy or create a new one and then edit the policy.

Step 3 Select a DAP record or create a new one, and edit the DAP record.

Step 4 Click **AAA Criteria**.

Step 5 Select one of the **Match criteria between sections**.

- Any—Matches any of the criteria.
- All—Matches all the criteria.
- None—Matches none of the set criteria.

Step 6 Click **Add** to add the required **Cisco VPN Criteria**.

Cisco VPN criteria include attributes for group policy, assigned IPv4 address, assigned IPv6 address, connection profile, username, username 2, and SCEP required.

a) Select an attribute and specify the **Value**.

b) Click **Add another criteria** to add more criteria.
c) Click **Save**.

Step 7 Select **LDAP Criteria**, **RADIUS Criteria**, or **SAML Criteria** and specify the **Attribute ID** and **Value**.

Step 8 Click **Save**.

Configure endpoint attribute selection criteria in DAP

Endpoint attributes contain information about the endpoint system environment, posture assessment results, and applications. A Firewall Threat Defense device dynamically generates a collection of endpoint attributes during session establishment and stores these attributes in a database that is associated with the session. Each DAP record specifies the endpoint selection attributes that must be satisfied for the Firewall Threat Defense device to choose it for a session. The Firewall Threat Defense device selects only DAP records that satisfy every condition configured.

Note When using remote Access VPN with DAP or Secure Firewall Posture (formerly HostScan) and change of authorization (CoA), endpoint attribute checks differ between initial authentication and CoA-triggered authorization.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**, and click **Create Dynamic Access Policy**.

Step 2 Create or edit a DAP record.

Step 3 Click **Endpoint Criteria** and configure attributes such as anti-malware, device, Secure Client, NAC, application, personal firewall, operating system, process, registry, file, and certificate authentication.

Note You can create multiple instances of each type of endpoint attribute. There is no limit for the number of endpoint attributes for each DAP record.

Step 4 Click **Save**.

Add an anti-malware endpoint attribute to a DAP record

Add anti-malware endpoint attributes to a DAP to control access based on the presence and configuration of anti-malware software on client devices.

Anti-malware endpoint attributes allow you to create access policies that verify client devices have appropriate anti-malware protection before granting network access.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Anti-Malware**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add the anti-malware attributes.

In the **Anti-Malware** dialog box, configure these parameters:

a) Check the **Installed** check box to indicate whether the selected endpoint attribute and its accompanying qualifiers are installed or not installed.
b) In **Real Time Scanning**, choose **Enabled** or **Disabled** to activate or deactivate real-time malware scanning.
c) Choose the anti-malware vendor from the **Vendor** drop-down list.
d) Choose the anti-malware description from the **Product Description** drop-down list.
e) Choose the **Version** of the anti-malware product.
f) Specify the number of days since the **Last Update**.

You can indicate that an anti-malware update must occur in less than (<) or more than (>) the number of days you specify.

g) Click **Save**.

Add a device endpoint attribute to a DAP record

Add device endpoint attributes to a DAP to control access based on specific device characteristics such as hostname, MAC address, BIOS serial number, or port configuration.

Device endpoint attributes allow you to create policies that evaluate device-specific criteria to determine access permissions. These attributes help enforce security policies based on device identity and configuration.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Device**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add application attributes.

In the **Device** dialog box, configure these parameters:

Select the **=** or **≠** operator to check the attribute to be equal to or not equal to the value you enter for these attributes:

- **Host Name**—Hostname of the device. Use the computer's host name only, not the fully qualified domain name (FQDN).

- **MAC Address**—MAC address of the network interface card you are testing for. The address must be in the format xxxx.xxxx.xxxx where x is a hexadecimal character.
- **BIOS Serial Number**—BIOS serial number value of the device you are testing for. The number format is manufacturer-specific.
- **Port Number**—Listening port number of the device.
- **Secure Desktop Version**—Version of the Secure Firewall Posture image running on the endpoint.
- **OPSWAT Version**—The OPSWAT client version.
- **Privacy Protection**—None, Cache cleaner, Secure Desktop.
- **TCP/UDP Port Number**—TCP or UDP port in the listening state.

Step 6 Click **Save**.

Add Secure Client endpoint attributes to a DAP record

Add specific endpoint attributes to a Dynamic Access Policy (DAP) record to control client access based on Secure Client characteristics such as client version, platform, and device identifiers.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Secure Client**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add the attributes.

In the **Secure Client** dialog box, configure these parameters:

Select the = or ≠ operator to check the attribute to be equal to or not equal to the value you enter.

a) Specify the **Client Version**.
b) Choose the platform from the **Platform** drop-down list.
c) Choose the platform version from the **Platform Version** drop-down list.
d) Specify the **Device Type** and **Device Unique ID**.
e) Add the **MAC Addresses**.

Note The MAC Address must be in the format XX-XX-XX-XX-XX-XX, where each X is a hexadecimal character. You can click **Add another MAC Address** to add more addresses.

f) Click **Save**.

Add NAC endpoint attributes to a DAP record

You can configure Network Access Control (NAC) endpoint attributes within a DAP (Dynamic Access Policy) record to evaluate endpoint posture status based on a defined criteria.

NAC endpoint attributes in DAP records help determine access permissions based on endpoint posture compliance. You can specify whether endpoints must match all criteria or any criteria, and define specific posture token strings for evaluation.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **NAC**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add NAC attributes.

Step 6 In the **NAC** dialog box, set the operator to be equal to = or not equal to ≠ the posture status.

Step 7 Choose one of these options from the **Posture Status** drop-down list:

- Compliant
- Non-Compliant
- Unknown

Step 8 Click **Save**.

Add an application attribute to a DAP record

This task allows you to define application-specific criteria within a DAP record to control access based on the type of remote access client.

Application attributes in DAP records help determine access policies by evaluating the client application type used for remote connections. You can configure these attributes to match all or any specified criteria.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Application**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add application attributes.

Step 6 In the **Application** dialog box, choose equals (=) or does not equal (≠) and specify the **Client Type** to indicate the type of remote access connection. Choose from one of these options:

- Clientless

- Cut-Through-Proxy
- Secure Client
- IPsec
- L2TP
- IPsec-IKEv2-Generic-RA

Step 7 Click **Save**.

Add a personal firewall endpoint attribute to a DAP record

Adding personal firewall endpoint attributes to a DAP allows you to control network access based on whether client devices have specific firewall software installed, enabled, and meeting version requirements.

Personal firewall endpoint attributes help enforce security policies by ensuring that connecting devices meet firewall protection standards before granting network access.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Personal Firewall**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add personal firewall attributes.

In the **Personal Firewall** dialog box, configure these parameters:

a) Click **Installed** to indicate whether the personal firewall endpoint attribute and its accompanying qualifiers (fields below the Name/Operation/Value column) are installed or not installed.
b) Select **Enabled** or **Disabled** to activate or deactivate firewall protection.
c) Choose the name of the firewall vendor from the **Vendor** drop-down list.
d) Choose the firewall description from the **Product Description** drop-down list.
e) Select the equals (**=**) or does not equal (**≠**) operator and choose the **Version** of the personal firewall product.
f) Click **Save**.

Add an operating system endpoint attribute to a DAP record

Operating system endpoint attributes help create granular access policies by identifying and filtering client devices based on their operating system characteristics. This is useful for implementing different access levels or restrictions based on device types.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Operating System**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add endpoint attributes.

In the **Operating System** dialog box, configure these parameters:

a) Select the equals (=) or does not equal (≠) operator and then choose the operating system from the **Operating System** drop-down list.
b) Select the equals (=) or does not equal (≠) operator and then specify the operating system version in the **Version** field.
c) Click **Save**.

Add a process endpoint attribute to a DAP

Configure process endpoint attributes to define specific criteria for device access policy enforcement based on running processes.

Process endpoint attributes allow you to create device access policies based on specific processes running on endpoints. This helps ensure that only devices with approved processes can access network resources.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Process**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add process attributes.

In the **Process** dialog box, configure these parameters:

a) Select **Exists** or **Does not exist**.
b) Specify the **Process Name**.
c) From the **Endpoint ID** drop-down list, choose the process ID or click + to configure a posture assessment criteria for the process. For more information, see Configure posture assessment criteria, on page 1711.
d) For **Process Name**, click **Exists** or **Does not exist** and specify the process name.
e) Click **Save**.

Add a registry endpoint attribute to a DAP record

Registry endpoint attributes allow you to define specific registry keys that the system scans during posture assessment to determine endpoint compliance status.

Scanning for registry endpoint attributes applies to Windows operating systems only.

Before you begin

Before configuring a registry endpoint attribute, define the registry key for which you want to scan in the Secure Firewall Posture window for Cisco Secure Desktop.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Registry**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add registry attributes.

In the **Registry** dialog box, configure these parameters:

a) Select the **Entry Path** for the registry and specify the path.
b) From the **Endpoint ID** drop-down list, choose the ID for the registry or click + to configure a posture assessment criteria for the registry. For more information, see Configure posture assessment criteria, on page 1711.
c) Choose the existence of the registry, **Exists** or **Does not exist**.
d) Select the registry **Type** from the list.
e) Select the equals (=) or does not equal (≠) operator and enter the **Value** of the registry key.
f) Select **Case insensitive** to disregard the case of the registry entry while scanning.
g) Click **Save**.

Add a file endpoint attribute to a DAP record

You can configure file endpoint criteria within a DAP (Device Access Policy) record to specify file attributes used for posture assessment and device authorization.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **File**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add file attributes.

In the **File** dialog box, configure these parameters:

a) From the **Endpoint ID** drop-down list, choose the ID for the file or click **+** to configure a posture assessment criteria for the file. For more information, see Configure posture assessment criteria, on page 1711.
b) Specify the **File Path**.
c) Select **Exists** or **Does not exist** to indicate the presence of the file.
d) Select less than (<) or greater than (>) and specify the **Last Modified** days for the file.
e) Select the equal to (=) or not equal to ≠ operator and enter the **Checksum**.
f) Click **Save**.

Add certificate authentication attributes to a DAP record

Adding certificate authentication attributes to a DAP allows you to control access based on specific certificate fields such as subject, issuer, and serial number.

You can index each certificate to allow referencing to any of the received certificates, by the configured rules. Based on these certificate fields, you can configure DAP rules to allow or disallow connection attempts.

Note This configuration is applicable only for certificates used with multiple certificate authentication. It does not apply for single client certificate authentication.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.
Step 2 Create or edit a DAP record.
Step 3 Click the **Endpoint Criteria** tab and click **Multiple Certificate Authentication**.
Step 4 Select the **Match criteria** as **All** or **Any**.
Step 5 Click **+** to add certification authentication criteria.

In the **Multiple Certificate Authentication Criteria** dialog box, configure these parameters:

a) Select **Cert1** or **Cert2** certificate.
b) Select the **Subject** and specify the subject value.
c) Select the **Issuer** and specify the issuer value.
d) Select the **Subject Alternate Name** and specify the subject value.
e) Specify the **Serial Number**.
f) Choose the **Certificate Store** as **None**, **Machine**, or **User**.

The VPN client sends the certificate store information.

g) Click **Save**.

Configure advanced settings for DAP

This task allows you to configure selection criteria for DAP records using Lua scripts when the standard AAA AND endpoint attribute areas are insufficient for your requirements.

You can use the **Advanced** tab for adding selection criteria other than what is possible in the AAA AND endpoint attribute areas. For example, while you can configure the Firewall Threat Defense to use AAA attributes that satisfy any, all, OR none of the specified criteria, the endpoint attributes are cumulative, AND must satisfy all. To let the security appliance employ one endpoint attribute OR another, you must create appropriate logical expressions in Lua AND enter them here.

Procedure

Step 1 Choose **Secure Connections** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP record.

Step 3 Click the **Advanced** tab.

Step 4 Select **AND** OR **OR** as the match criteria to use in the DAP configuration.

Step 5 Add the Lua script in the **Lua script for advanced attribute matching** field.

Step 6 To use the endpoint criteria ID in your Lua script:

a. Place the cursor at the point where you want to insert the endpoint criteria ID.

b. From the **Endpoint Criteria** drop-down list, choose the criteria a

c. Choose the corresponding ID from the adjacent drop-down list.

Example:

In this example, DAPTESTFILE, LIBAGENT, vpnagent, AND DUOAGENT were inserted in the Lua script:

```
EVAL(endpoint.file["DAPTESTFILE"].exists,"EQ","true") or
EVAL(endpoint.file["LIBAGENT"].exists,"EQ","true") and
EVAL(endpoint.process[""vpnagent""].exists,"EQ","true") and
EVAL(endpoint.registry[""DUOAGENT""].exists,"EQ","true")
```

Step 7 Click **Save**.

Associate dynamic access policy with remote access VPN

You can associate Dynamic Access Policy (DAP) with remote access VPN policy for the dynamic access policy attributes to match during VPN session authentication and authorization. You can then deploy the remote access VPN on the Firewall Threat Defense.

Procedure

Step 1 Choose **Secure Connections** > **Remote Access VPN**.

Step 2 Click **Edit** next to the remote access VPN policy to which you want to associate dynamic access policy.

Step 3 Click the link in remote access VPN to select the dynamic access policy.

Step 4 Select the policy from the **Dynamic Access Policy** drop-down or click **Create a new Dynamic Access Policy** to configure a new dynamic access policy.

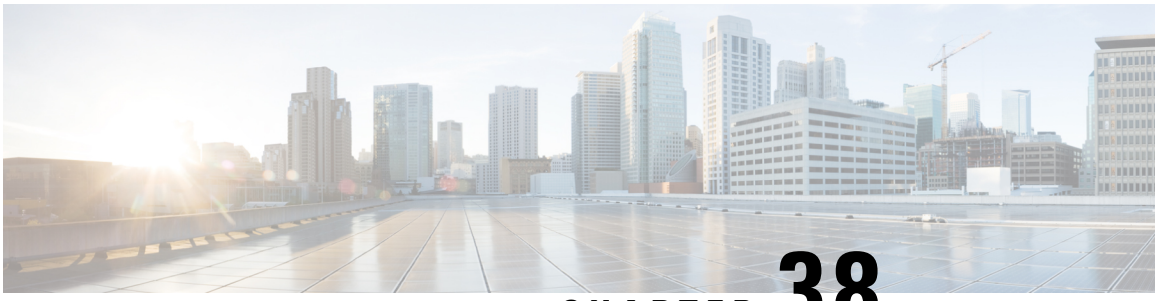
Step 5 Click **OK**.

Step 6 Click **Save** to save the remote access VPN policy.

When the remote access VPN user tries to connect, the VPN checks the configured dynamic access policy records and attributes. VPN creates a dynamic access policy based on the matching dynamic access policy records and takes appropriate action on the VPN session.

History for dynamic access policy

This reference provides the version history for dynamic access policy features, including when they were introduced and what changes were made in each release.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Easily configure posture assessment criteria for dynamic access policies	7.7	Any	For a DAP policy, you can configure file, process, or registry endpoint attributes with unique endpoint IDs. These IDs can be used as endpoint criteria in Lua scripts to configure a DAP record. New/Modified Screens: • **Devices** > **Dynamic Access Policy** > **Add/Edit Policy** > **Add Posture Assessment Criteria** • **Devices** > **Dynamic Access Policy** > **Add/Edit Policy** > **Add/Edit DAP Record** > **Advanced** > **Endpoint Criteria**
Dynamic Access Policy	7.0	Any	The feature was introduced.

PART VII

Zero Trust Network Access

- Zero Trust Network Access Overview, on page 1725
- Clientless Zero Trust Network Access, on page 1731
- Universal Zero Trust Network Access, on page 1751

CHAPTER 38

Zero Trust Network Access Overview

Zero Trust Network Access (ZTNA) secures internal resources by verifying user identity and device posture to grant least-privilege access. Organizations implement either browser-based Clientless ZTNA for web applications or agent-based Universal ZTNA for comprehensive, protocol-wide support using existing threat defense infrastructure.

- Clientless and universal zero trust network access, on page 1725
- Zero trust network access, on page 1726
- Comparison of clientless and universal ZTNA, on page 1726
- History for zero trust network access, on page 1727

Clientless and universal zero trust network access

Zero Trust Access or Zero Trust Network Access (ZTNA) is a security process that protects internal resources using identity-based access, including user trust and posture. The process verifies the user, device, and request context before allowing access to internal resources and applications. It grants the least privilege access only after verifying the user, understanding the request context, and assessing any risks.

ZTNA deployment models

You can choose between two ZTNA deployment models.

- Clientless Zero Trust Network Access
- Universal Zero Trust Network Access

Clientless zero trust network access

Clientless Zero Trust Network Access (Clientless ZTNA) authenticates and authorizes access to protected web-based resources and applications from inside (on-premises) or outside (remote) the network. Clientless ZTNA accomplishes this authentication using an external identity provider (IdP) with Security Assertion Markup Language (SAML) authentication. No client software is needed on the user's device.

Clientless ZTNA is ideal for remote users accessing web applications and unmanaged devices.

Universal zero trust network access

Universal Zero Trust Network Access (Universal ZTNA) is a client-based solution that provides identity-based access to all internal resources regardless of user location. It enforces strong authentication, posture validation, and traffic inspection for each application and user.

Universal ZTNA supports both remote and on-premises users. On-premises users access a trusted network using a Secure Firewall Threat Defense device. Remote users access a trusted network through the cloud-based Secure Access service, which evaluates policies and proxies the user traffic securely in the cloud.

Zero trust network access

Zero Trust Network Access (ZTNA) provides secure, segmented application access by requiring explicit authorization for every connection. This approach reduces the attack surface and simplifies secure migrations without adding devices.

Key characteristics

ZTNA uses your existing Threat Defense deployment as an enforcement point for application access, enabling segmented and per-application authorization. ZTNA establishes individual tunnels for both remote and on-premises users.

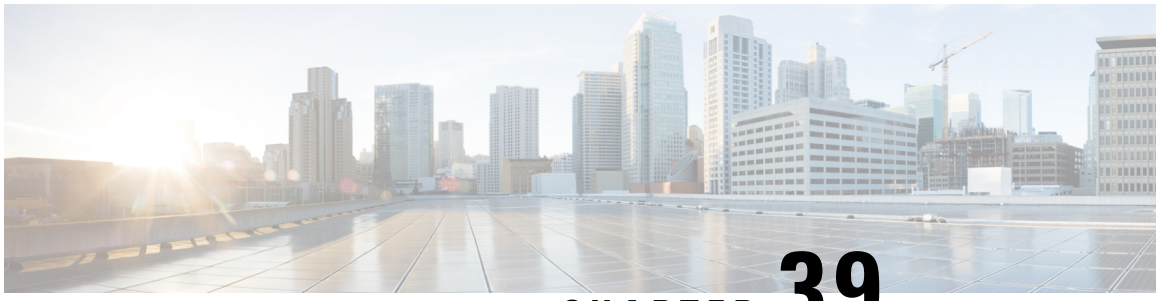
ZTNA hides the network from users and ensures that they can only access applications for which they have been explicitly authorized. Authorization for one application does not provide implicit access to other applications, which significantly reduces the attack surface. In other words, every access to an application or a resource must be explicitly authorized.

You can adopt a more secure access model by adding zero trust access functionality to Threat Defense. This eliminates the need to install or manage additional devices in the network.

Comparison of clientless and universal ZTNA

This comparison outlines the key technical and operational differences between clientless ZTNA and universal ZTNA deployment models. Clientless ZTNA uses a browser-based approach, which is ideal for guest users or unmanaged devices that require access to web applications. Universal ZTNA uses an agent-based solution that supports all protocols. It continuously monitors device posture in managed corporate environments. Consider factors such as application support, security inspection capabilities, and licensing requirements to choose the best strategy for securing your remote and on-premises workforce.

Factor	Clientless ZTNA	Universal ZTNA
Client required	No client is required(browser-based)	Yes, Secure Client is required
Application support	Supports HTTPS web applications only	Supports all protocols and applications
Device posture	Device posture monitoring is limited (available through agents such as Duo Desktop)	Provides comprehensive and continuous device posture monitoring



Factor	Clientless ZTNA	Universal ZTNA
Best for	Guest users, contractors, unmanaged devices	Employees, managed devices
Components involved	Third-party identity provider (IdP) configured with application access using Security Assertion Markup Language (SAML) authentication	• Secure Access • Secure Client software • Identity provider (depending on users' location)
Security policies	Deep inspection (Snort, IPS, File)	Deep inspection (Snort, IPS, File)
User location	Remote and on-premises	Remote and on-premises
Licenses	Export-controlled license for Firewall Management Center	Licenses for Secure Access, Secure Client software, and Security Cloud Control Firewall Management (formerly Cisco Defense Orchestrator)

History for zero trust network access

This reference provides the minimum Firewall Management Center and Threat Defense versions needed to support zero trust application policies and monitoring.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Universal Zero Trust Network Access (universal ZTNA).	10.1.0	10.1.0	Universal ZTNA integrates with the Lina datapath, improving performance, scalability, and serviceability without requiring dedicated CPU cores or device reboots. This release supports mixed-mode IPv4 and IPv6 combinations for outer and inner connections, along with IPv6 Source NAT and hardware acceleration for outer tunnels. The system automatically enrolls Secure Access certificates as trustpoints, simplifying deployment. Upgrade Impact: Following a Threat Defense device upgrade, the system automatically reverts the core profile, clears stale certificates, and disables the universal ZTNA feature in the LINA configuration. You must perform a mandatory deployment from the Firewall Management Center to push new trustpoints, re-enable the feature, and restore universal ZTNA traffic handling. Deployment restrictions: Not supported with clustered devices, container instances, or transparent mode. Supported platforms: Secure Firewall 1000 Series, 1100 Series, 1200 Series, 200 Series, 2100 Series, 3100 Series, 4100 Series, 4200 Series, 6100 Series, and 9300 Series and Firewall Threat Defense Virtual.
Universal Zero Trust Network Access (universal ZTNA).	7.7.10	7.7.10	Universal Zero Trust Network Access (universal ZTNA) is a comprehensive solution that provides secure access to internal network resources based on user identity, trust, and posture. It ensures that access to one application does not implicitly grant access to the entire network, as with remote access VPN. New/modified screens: **Policies** > **Security policies** > **Zero Trust Application** Requires Cisco Secure Access and Security Cloud Control. **Note** Due to framework changes, upgrading a universal ZTNA device to Version 10.1+ from older versions disables the feature. Traffic is interrupted until you deploy from the Firewall Management Center. Deployment restrictions: Not supported with clustered devices, container instances, or transparent mode. Supported platforms: Secure Firewall 1150, 3100, 4100, 4200, and Firewall Threat Defense Virtual.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Zero trust access enhancements	7.4.1	7.4.1 with Snort 3	Firewall Management Center now includes the following zero trust access enhancements: • You can configure source NAT for an application. The configured network object or object group translates the incoming request's public network source IP address to a routable IP address inside the application network. • You can troubleshoot the zero trust configuration issues using the diagnostics tool. New/modified screens: **Policies** > **Access Control** > **Zero Trust Application** New/modified CLI commands: **show running-config zero-trust**, **show zero-trust statistics**
Clientless zero-trust access	7.4.0	7.4.0 with Snort 3	Zero Trust Access allows you to authenticate and authorize access to protected web based resources, applications, or data from inside (on-premises) or outside (remote) the network using an external SAML Identity Provider (IdP) policy. The configuration consists of a Zero Trust Application Policy (ZTAP), Application Group, and Applications. New/modified screens: • **Policies** > **Zero Trust Application** • **Analysis** > **Connections** > **Events** • **Overview** > **Dashboard** > **Zero Trust** New/modified CLI commands: • **show running-config zero-trust application** • **show running-config zero-trust application-group** • **show zero-trust sessions** • **show zero-trust statistics** • **show cluster zero-trust statistics** • **clear zero-trust sessions application** • **clear zero-trust sessions user** • **clear zero-trust statistics**

CHAPTER 39

Clientless Zero Trust Network Access

Clientless Zero Trust Network Access enables users to access protected TLS web applications through their browser using SAML identity providers, eliminating the need to install a client on the endpoint. This solution leverages Zero Trust Application Policies, Application Groups, and applications. This document describes how to configure these features, outlines their limitations, and provides information on deployment, monitoring, and troubleshooting.

- Clientless Zero Trust Network Access, on page 1731
- Components of a Clientless Zero Trust Network Access configuration, on page 1732

- Set targeted devices for zero trust access policy, on page 1745
- Edit a zero trust application policy, on page 1746
- Manage zero trust application policies, on page 1747
- Monitor zero trust sessions, on page 1748

Clientless Zero Trust Network Access

Clientless Zero Trust Network Access is based on Zero Trust Access principles. Zero Trust Access is a zero trust security model that eliminates implicit trust. The model grants the least privilege access after verifying the user, the context of the request, and after analyzing the risk if access is granted.

Clientless Zero Trust Network Access enables you to authenticate and authorize access to protected web-based resources and applications from inside (on-premises) or outside (remote) the network using an external Security Assertion Markup Language (SAML) identity provider (IdP) policy.

Key features

The solution includes these capabilities.

- Supports multiple SAML-based identity providers such as Duo, Azure Active Directory (Azure AD), Okta, and other identity providers.
- Client applications such as Cisco Secure Client are not required on the endpoint (client devices) for secure access.
- Access and authentication are performed through the browser.
- Supports only TLS web applications.
- Agents such as Duo Health support client device posture. These agents evaluate the posture against a policy in Duo and provide access based on this evaluation. Third-party identity providers such as Okta or PingID perform this same functionality with their agents that support posture evaluation.
- Supports HTTP-Redirect SAML binding.
- Supports application groups that make it easier to enable clientless zero trust network access protection on a set of applications.
- Leverages threat defense intrusion and malware protection on zero trust application traffic.

You can use the Secure Firewall Management Center web interface to create a Zero Trust Application Policy that allows you to define private applications and assign threat policies to them. The policy is application specific where the administrator decides the inspection levels based on the threat perception for that application.

Components of a Clientless Zero Trust Network Access configuration

A new configuration of Clientless Zero Trust Network Access consists of a Zero Trust Application Policy, Application Group, and Applications.

Configuration components

The configuration includes these main components:

- **Zero Trust Application Policy**— consists of application groups, and grouped or ungrouped applications. Settings for Security Zones and Security Controls associate at a global level with all ungrouped applications and application groups.

  A global port pool is assigned to the policy, by default. A unique port is automatically assigned from this pool to each private application that is configured.

  Zero Trust Application policy consists of application groups, and grouped or ungrouped applications.

- **Application Groups**—Consists of a logical group of applications that share SAML authentication settings and can optionally share Security Zones and Security Controls settings.

  Application Groups inherit the Security Zones and Security Controls settings from the global policy and can override the values.

  When you create an Application Group, you can use the same SAML IDP configuration to authenticate multiple applications. Applications that are part of an Application Group inherit the Application Group's SAML configuration. This eliminates the need to configure the SAML settings for each application. After the Application Group is created, new applications can be added to it without configuring the IDP for it.

When an end user tries to access an Application that is part of group, the user is authenticated to the Application Group for the first time. When the user tries to access other applications that are part of the same Application Group, the user is provided access without being redirected again to the IDP for authentication. This prevents overloading the IDP with requests for application access and optimizes the usage of the IDP if a limit is enabled.

- **Applications**—There are two types:
  - **Ungrouped Applications**— Are standalone applications. SAML settings must be configured for every application. The applications inherit the Security Zones and Security Controls settings from the global policy and can be overridden by the application.
  - **Grouped Applications**— Are multiple applications that are grouped under an Application Group. The SAML settings are inherited from the Application Group and cannot be overridden. However, the Security Zones and Security Controls settings can be overridden for each application.

These certificates are required for the configuration.

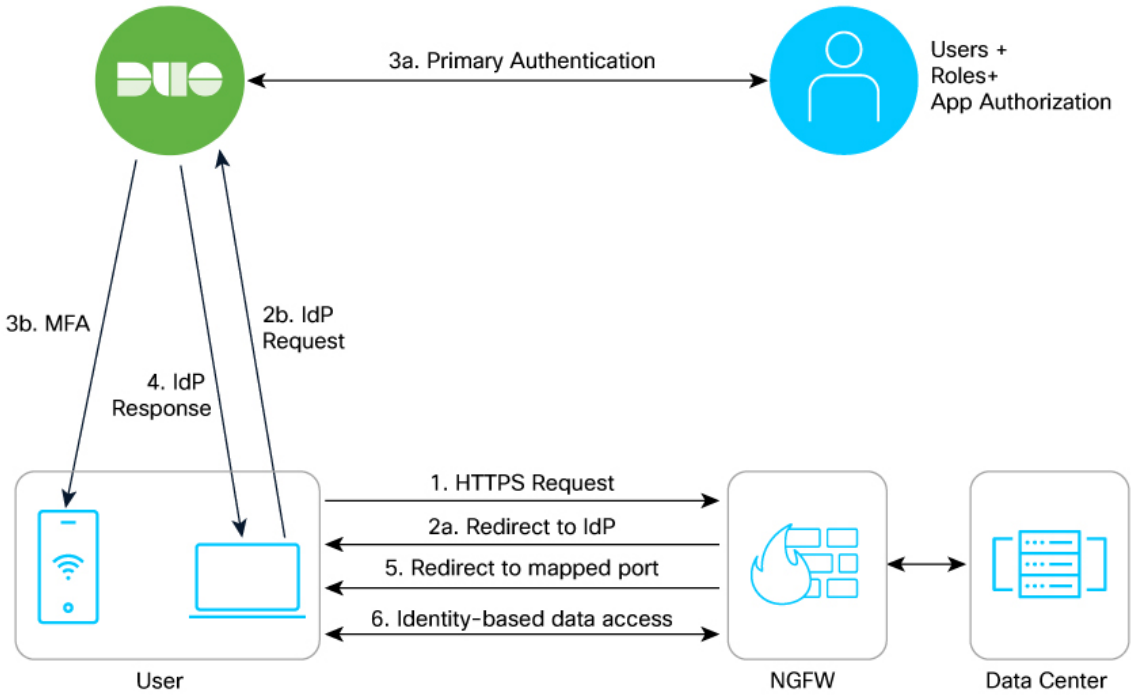
- **Identity Certificate**—This certificate is used by Firewall Threat Defense to masquerade as the applications. Firewall Threat Defense behaves as a SAML Service Provider (SP). This certificate must be a wildcard or Subject Alternative Name (SAN) certificate that matches the FQDN of the private applications. It acts as a common certificate for all applications protected by Firewall Threat Defense. Upload the public key from the same certificate to the identity provider (IDP), designating it as the SP certificate. The identity provider uses this certificate to verify the authentication request it receives. By default, Firewall Threat Defense signs the SAML authentication request before sending it to IDP. You cannot disable authentication request signing, and it is not configurable.
- **IDP Certificate**—The identity provider (IDP) provides a certificate for each defined Application or Application Group. This certificate must be configured so that Firewall Threat Defense can verify the IDP's signature on incoming SAML assertions.

Note IDP certificates are commonly included within the metadata file; otherwise, users are required to have the IDP certificate readily available during the configuration of applications.

- **Application Certificate**—The encrypted traffic from user to the application is decrypted by Firewall Threat Defense using this certificate for the purpose of inspection.

Note This certificate is required to verify the cookies in the header to authorize connections, even if you are not conducting an IPS or Malware inspection.

How Clientless Zero Trust Network Access works



Summary

The key components involved in the Zero Trust Access clientless workflow are:

- User: Initiates access requests through a browser and provides authentication credentials.
- Identity Provider (IdP): Handles user authentication including primary and multi-factor authentication challenges.
- Threat Defense: Validates HTTPS requests, processes SAML responses, and controls application access.
- Application: The target resource that users access after successful authentication and authorization.

Workflow

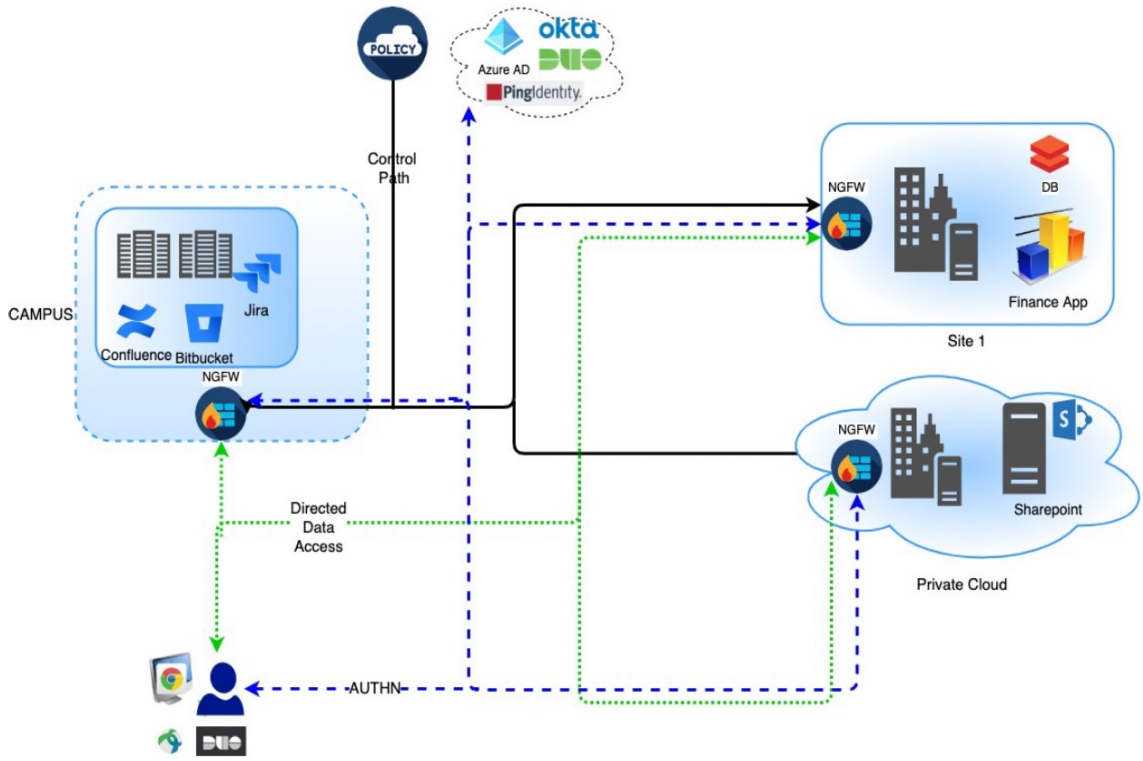
Figure 433: Clientless zero trust network access workflow

These stages describe how the clientless zero trust network access workflow processes user requests:

1. User types the application URL in the browser and threat defense validates the HTTPS request.
   - If the HTTPS request is authenticated and the session is valid, the user is redirected to the mapped port and granted access to the application. The workflow stops here.
   - If the HTTPS request is not authenticated, the user is sent for authentication per application. The workflow continues.
2. The user is redirected to the configured identity provider (IdP).
3. The IdP performs authentication challenges for the user.
   - The user is redirected to the configured primary authentication source.
   - The user is challenged with the configured secondary multi-factor authentication, if any.

4. After authentication, the IdP sends a SAML response. The user ID and other necessary parameters are retrieved from the SAML response through the browser.
5. The user is redirected to the application mapped port.
6. The user is allowed access to the application after session validation is successful.

How threat defense works with zero trust access



Summary

The key components involved in the Threat Defense Zero Trust Access process are:

- Remote or on-premises user: Initiates HTTPS requests from an endpoint using a browser to connect to applications.
- Threat Defense firewall: Intercepts user requests and redirects them to the identity provider for authentication and authorization.
- Identity Provider (IdP): Handles the authentication and authorization process for users attempting to access protected applications.
- Protected web applications: Applications secured behind the firewall that users can access after successful authentication.

Workflow

Figure 434: Threat defense deployment

These stages describe how Threat Defense works with Zero Trust Access:

1. Using a browser, a remote or on-prem user sends a HTTPS request to connect to an application from an endpoint.
2. The HTTPS request is intercepted by the firewall that protects the application.
3. The firewall redirects the user to application's configured IdP for authentication.

Note In the figure, each firewall protects a set of web applications. The user can directly access the applications behind the firewall after authentication and authorization.

4. After the authentication and authorization process is complete, the firewall allows the user to access the application.

Prerequisites for zero trust application policy

Licensing requirements

Ensure you have the necessary licensing before configuring Zero Trust Application Policy.

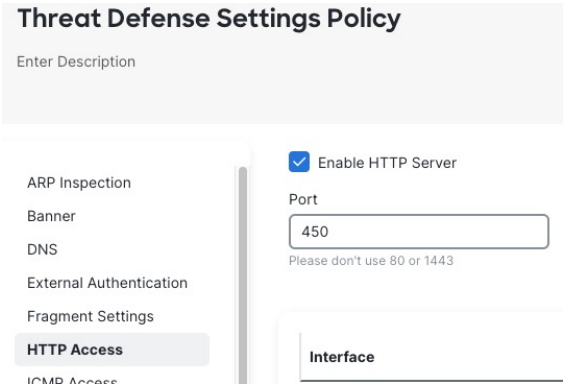
- Smart license account with export-controlled features
- (Optional) IPS and Threat licenses—You need these licenses if you use security controls.

Configuration requirements

Complete the required configurations for Zero Trust Application Policy implementation.

- Create a wildcard or Subject Alternative Name (SAN) certificate that matches the FQDN of private applications. For more information, see Add certificate enrollment objects, on page 2829.
- Create a security zone through which you can regulate access to private applications. For more information, see Create security zone and interface group objects, on page 744.

Limitations for Clientless Zero Trust Network Access



Be aware of the following limitations when using Clientless Zero Trust Network Access:

- Supports only TLS-enabled web applications. All traffic must be decrypted.
- Supports only SAML identity providers.
- Supports IPv6; however, you can use only homogeneous network address translations (NAT) scenarios such as NAT66 and NAT44.

  NAT64, and NAT46 scenarios are not supported.
- Clientless zero trust network access is available on Firewall Threat Defense only if Snort 3 is enabled.
- By default, the Firewall Threat Defense device uses port 443 for secure communications. Because this is the same port used by TLS-enabled applications likely to be configured for zero trust network access, you must change the device's HTTP server port.

  Go to **Devices** > **Platform Settings**, then edit the Threat Defense Settings policy for the device, click **HTTP Access**, select the **Enable HTTP Server** check box, and enter a port other than 443 in the field. When you're finished, click **Save** in the upper right corner of the page.

  The following figure shows an example.

- All hyperlinks in protected web applications must have a relative path and are not supported on individual mode clusters.
- Protected web applications running on a virtual host or behind internal load balancers must use the same external and internal URL.
- Not supported on applications with strict HTTP Host Header validation enabled.
- If the application server hosts multiple applications and serves content based on the Server Name Indication (SNI) header in the TLS Client Hello, the external URL of the zero trust application configuration must match the SNI of that specific application.

Create a zero trust application policy

This task creates a Zero Trust Application Policy that enables secure access to private applications through authentication and authorization controls.

Before you begin

Ensure that you complete all the prerequisites listed in Prerequisites for zero trust application policy, on page 1736.

Procedure

Step 1 Choose **Policies** > **Security policies** > **Zero Trust Application**.

Step 2 Click **Add Policy**.

Step 3 In the **General** section, enter the policy name in the **Name** field. The description field is optional.

Step 4 Enter a domain name in the **Domain Name** field.

Ensure that the domain name is added to the DNS. The domain name resolves to the Firewall Threat Defense gateway interface from where the application is accessed. The domain name is used to generate the ACS URL for all private applications in an Application Group.

If you select an ACME certificate as the policy's identity certificate in the next step, the domain name must match the common name (CN) of the ACME certificate.

Note When you change the domain name, the SAML Service Provider (SP) metadata gets updated. You must reconfigure these settings:

- IdP with the new SAML SP metadata
- DNS server with new domain name

When a deployment takes place after the domain name change, all the applications will be removed and readded, interrupting application access.

Step 5 Choose an existing certificate from the **Identity Certificate** drop-down list.

Click the **Add** (+) icon to configure a certificate enrollment object. For more information, see Add certificate enrollment objects, on page 2829.

You can choose an ACME certificate for authenticating the Firewall Threat Defense device as a SAML SP for a Zero Trust Application policy. ACME certificates automate the lifecycle management of SSL and TLS certificates, including their auto-renewal.

Step 6 Choose a security zone from the **Security Zones** drop-down list.

Click the **Add** (+) icon to add a new security zone.

To add security zones, see Create security zone and interface group objects, on page 744.

Step 7 The **Global Port Pool** section sisplays a default port range. Modify it, if required. Port values range from 1024 to 65535. A unique port from this pool is assigned to each private application.

Note

- This port range should not conflict with the existing NAT range.
- Ensure that any intermediary or third-party firewall devices in your network are configured to allow traffic across the entire range defined in the **Global Port Pool**. Blocking these ports prevents application access after SAML authentication and authorization.

Step 8 (Optional) In the **Security Controls** section, you can add an Intrusion or Malware and File policy:

- **Intrusion Policy**—Choose a default policy from the drop-down list or click the **Add** (+) icon to create a new custom intrusion policy. For more information, see Creating a Custom Snort 3 Intrusion Policy topic in the latest version of the Cisco Secure Firewall Management Center Snort 3 Configuration Guide.
- **Variable Set**—Choose a default variable set from the drop-down list or click the **Add** (+) icon to create a new variable set. For more information, see Create a variable set, on page 2885.

Note To use variable sets, you must have the Secure Firewall Threat Defense IPS license for your managed devices.

- **Malware and File Policy**—Choose an existing policy from the drop-down list. Click the **Add** (+) icon to create a new malware and file policy. For more information, see Manage file policies, on page 2425.

Step 9 Click **Save** to save the policy.

What to do next

1. Create an Application Group. See Create an application group, on page 1740.
2. Create an Application. See Create an application, on page 1741.
3. Associate a Zero Trust Application Policy with a device. See Set targeted devices for zero trust access policy, on page 1745

4. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Create an application group

Create an application group to enable SAML-based authentication and manage zero trust network access applications with centralized security controls.

Application groups allow you to organize and manage multiple applications under a single SAML configuration, providing centralized authentication and security policy enforcement for zero trust network access.

Before you begin

Create a zero trust application policy, on page 1738

Procedure

Step 1 Click **Add Application Group**.

Step 2 In the **Application Group** section, type the name in the **Name** field and click **Next**.

Step 3 In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the values of the **Entity ID** and **Assertion Consumer Service (ACS) URL** fields or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

Step 4 In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using any one of the methods:

- **XML File Upload**—Choose a file or drag and drop the XML file.

  The details of the **Entity ID**, **Single Sign-On URL**, and **IdP Certificate** are displayed.

- **Manual Configuration**—Perform these steps:
  - **Entity ID**—Enter the URL that is defined in the SAML IdP to identify a service provider uniquely.
  - **Single Sign-On URL**—Enter the URL for signing into the SAML identity provider server.
  - **IdP Certificate**—Choose the certificate of the IdP enrolled in threat defense to verify the messages signed by the IdP.

    Click the **Add** (+) icon to configure a new certificate enrollment object. For more information, see Add certificate enrollment, on page 1741.

- **Configure Later**—In the event you do not have the IdP metadata, you can configure it later.

Click **Next**.

Step 5 In the **Re-authentication Interval** section, enter the value in the **Timeout Interval** field and click **Next**.

The re-authentication interval allows you to provide a value that determines when a user must authenticate again.

Step 6 In the **Security Zones and Security Controls** section, the security zones and threat settings are inherited from the parent policy. You can override these settings. Click **Next**.

Step 7 Review the configuration summary. Click **Edit** to modify the details in any of the sections. Click **Finish**.

Step 8 Click **Save**.

The Application Group is created and is displayed on the Zero Trust Application page.

What to do next

1. Create an application, on page 1741.
2. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Add certificate enrollment

This task allows you to add certificate enrollment by configuring the certificate name and installing the IdP certificate in PEM format.

Certificate enrollment is required to establish secure authentication. You need to provide certificate information in the correct format to ensure proper system configuration.

Procedure

Step 1 Enter the **Name**.

Step 2 Paste the certificate information in the **IdP Certificate** field in PEM format.

Note If the certificate is dependent on a root or intermediate certificate, you must install the dependant certificates. See Certificates, on page 2915.

Step 3 Click **Save**.

Create an application

This task creates a Grouped or Ungrouped Application to establish secure access controls for private applications within your Zero Trust Access policy framework.

Before you begin

1. Create a zero trust application policy, on page 1738.
2. Create an application group, on page 1740 (required only for Grouped Applications).

Procedure

Step 1 Choose **Policies** > **Security policies** > **Zero Trust Application**

Step 2 Choose the policy.

Step 3 Click **Add Application**.

Step 4 In the **Application Settings** section, complete the following fields.

- **Application Name**—Enter the application name.
- **External URL**—Enter the URL that is used by the user to access the application.
- **Application URL**—By default, the external URL is used as the Application URL. Uncheck the **Use External URL as Application URL** check box to specify a different URL.

  If Threat Defense uses an internal DNS, the Application URL must match an entry within that DNS to ensure it resolves to the application. In addition, if you enter a fully qualified domain name (FQDN) that could have either an IPv4 or IPv6 address, the FQDN must resolve to both IPv4 and IPv6. Threat Defense does not translate between these types of addresses.

- **Application Certificate**—Choose the certificate for the private application. Click the **Add** (+) icon to configure an internal certificate object. For more information, see Add internal certificate objects, on page 2827.
- **Source Network Address Translation**—Source Network Address Translation (source NAT) translates the source IP address in a packet to an address from a specified range.

  Enable **Source Network Address Translation** to specify an IP address range. The source IP address of an incoming request is translated to an IP address from the specified range. Source NAT works for both IPv4 and IPv6 addresses.

  - **IPv4**—Choose the source network for NAT from the list. Click **Add** (+) to create a network object. For more information, see Networks, on page 2813.
  - **IPv6**—Choose the source network for NAT from the list. Click **Add** (+) to create a network object. For more information, see Networks, on page 2813.

  Source NAT translates the source IP address of an incoming request to a routable IP address specified in the network object or the object group.

Note Only object or object groups of type Host or Range are supported.

- **Application Group**—Choose the Application Group from the drop-down list. See Create an application group, on page 1740.

Note This field is not applicable for an ungrouped application.

Step 5 Click **Next**.

Step 6 Depending on the type of application:

- For a Grouped Application, the **SAML Service Provider (SP) Metadata**, **SAML Identity Provider (IdP) Metadata**, and **Re-authentication Interval** are inherited from the Application Group and do not need to be configured by the user.
- For an Ungrouped Application, perform these steps:

  a. In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the **Entity ID**, **Assertion Consumer Service (ACS) URL** of the IdP, or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

  b. In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using any one of the methods:

  - **XML File Upload**—Choose a file or drag and drop the XML file.

    The details of the **Entity ID**, **Single Sign-On URL**, and **IdP Certificate** are displayed.

  - **Manual Configuration**—Perform these steps:

    - **Entity ID**—Enter the URL that is defined in the SAML IdP to identify a service provider uniquely.
    - **Single Sign-On URL**—Enter the URL for signing into the SAML identity provider server.
    - **IdP Certificate**—Choose the certificate of the IdP enrolled in threat defense to verify the messages signed by the IdP.

      Click the **Add** (+) icon to configure a new certificate enrollment object. For more information, see Add certificate enrollment, on page 1741.

  - **Configure Later**—If you do not have the IdP metadata, you can configure it later.

  Click **Next**.

  c. In the **Re-authentication Interval** section, enter the value in the **Timeout Interval** field and click **Next**. The reauthentication interval allows you to provide a value that determines when a user must authenticate again.

Step 7 In the **Security Zones and Security Controls** section, the security zones and threat settings are inherited from the parent policy or application group. You can override these settings. Click **Next**.

Step 8 Review the configuration summary. Click **Edit** to modify the details in any of the sections. Click **Finish**.

Step 9 Click **Save**.

The application is listed on the Zero Trust Application page and enabled by default.

What to do next

1. Set targeted devices for zero trust access policy, on page 1745.
2. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Create an ungrouped application

This task creates a standalone application for zero trust application access.

Before you begin

Create a zero trust application policy, on page 1738

Procedure

Step 1 Choose **Policies** > **Access Control** > **Zero Trust Application**

Step 2 Select the policy and click **Add Application**.

Step 3 In the **Application Settings** section, complete the following fields.

- **Application Name**—Enter the application name.
- **Application Group**—This field is not applicable for a standalone application.
- **External URL**—Enter the URL that is used by the user to access the application.
- **Internal URL (FQDN or Network IP)**—Enter the URL where the application is hosted on the internal server.
- **Application Certificate**—Enter the certificate for the private application.

Click **Next**.

Step 4 In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the Entity ID or ACS URL of the IdP or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

Step 5 In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using either one of the methods:

- **XML File Upload**—Select a file or drag and drop the XML file.
- **Manual Configuration**—Complete the following fields:
  - **Entitv ID**—The URL that is defined in the SAML IdP to identify a service provider uniquely.
  - **Single Sign-On URL**—The URL for signing into the SAML identity provider server.
  - **Certificate**—Certificate of the IdP enrolled into the threat defense to verify the messages signed by the IdP.
- **Configure Later**—In the event you do not have the IdP metadata, you can configure it later.

Click **Next**.

Step 6 In the **Re-authentication Interval** section, enter the value in the **Interval** field and click **Next**.

Step 7 In the **Interface Access and Security Controls** section, the interface objects and threat settings are inherited from the parent policy. You can override these settings.

Step 8 Review the settings and click **Finish**.

Step 9 Click **Save**.

The Application is displayed on the policy page under **Ungrouped Applications**.

What to do next

Set targeted devices for zero trust access policy, on page 1745

Set targeted devices for zero trust access policy

Set the specific devices where a Zero Trust Application policy will be deployed to control application access and enforce security policies.

Each Zero Trust Application policy can target multiple devices; each device can have one deployed policy at a time.

Before you begin

1. Create a zero trust application policy, on page 1738.
2. Create an application group, on page 1740.
3. Create an application, on page 1741.

Follow these steps to set targeted devices for Zero Trust Access Policy:

Procedure

Step 1 Choose **Policies** > **Security policies** > **Zero Trust Application**

Step 2 Choose the policy.

Step 3 Click **Targeted Devices**.

Step 4 Choose the devices where you want to deploy the policy using any one of the methods:

- Choose a device in the **Available Devices** list and click >> or the **Add** ( ) icon.
- To remove a device from the **Selected Devices** list, choose a device and click << or the **Delete** ( ) icon.

Step 5 Click **Apply** to save policy assignments.

Step 6 Click **Save** to save the policy.

What to do next

Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Edit a zero trust application policy

Edit the settings of a Zero Trust Application Policy to modify policy configurations, application groups, or individual applications according to your security requirements.

Follow these steps to edit the settings of a Zero Trust Application Policy.

Procedure

Step 1 Choose **Policies** > **Security policies** > **Zero Trust Application**

Step 2 Click **Edit** (✎) next to the Zero Trust Application Policy you want to edit.

Step 3 Edit your Zero Trust Application Policy.

You can change these settings or perform these actions:

- Name and Description—Click **Edit** (✎) next to the policy name, make your changes, and click **Apply**.
- To modify the policy settings:
  - Click **Settings**
  - Modify the settings as required.

Important Editing the domain name for the SAML ACS URL interrupts application access.

  - Click **Save**.
- To modify the Application Group settings:
  - Click **Applications**.
  - Click **Edit** (✎) next to the Application Group you want to edit.
  - In each section, click **Edit** to modify the settings, as required

Important Editing the Application Group name interrupts application access.

  - Click **Apply** after you modify the settings in a section.
  - Click **Finish**.
  - Click **Save**.
- To modify the Application settings:
  - Click **Applications**.
  - Click **Edit** (✎) next to the Application you want to edit.

- In each section, click **Edit** to modify the settings, as required.

Important Editing the Application name interrupts application access.

- Click **Apply** after you modify the settings in a section.
- Click **Finish**.
- Click **Save**.

- To enable, disable, or delete multiple Applications, choose the Applications, click the required bulk action, and click **Save**.

Note These actions are also available in the right-click menu.

- To enable all Applications, click **Bulk Actions** > **Enable**.
- To disable all Applications, click **Bulk Actions** > **Disable**.
- To delete all Applications, click **Bulk Actions** > **Delete**.

- Click **Return to Zero Trust Application** to return to the policy page.

The Zero Trust Application Policy settings are updated with your changes.

What to do next

Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Manage zero trust application policies

This task allows you to manage zero trust application policies to control access and security for applications in your network.

Procedure

Step 1 Choose **Policies** > **Security policies** > **Zero Trust Application**

Step 2 Choose the appropriate action for the zero trust application policies.

- Create—Click **New Policy**. See Create a zero trust application policy, on page 1738
- Edit—Click **Edit** (). See Edit a zero trust application policy, on page 1746

- Report—Click **Report** ( ).
- Delete—Click **Delete** ( ).

Step 3 Click **Save**.

What to do next

Ensure that there are no warnings before you deploy the configuration to threat defense. To deploy configuration changes, see Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Monitor zero trust sessions

This task enables administrators to effectively monitor Zero Trust Application Policy sessions through multiple methods including connection events, dashboard visualization, CLI commands, and diagnostic troubleshooting tools.

After a Zero Trust Application Policy is deployed, additional monitoring capabilities become available to track session activity, user behavior, and system performance. To monitor the zero trust sessions, do these steps.

Procedure

Step 1 Add Zero Trust fields to the connection events table view.

a. Choose **Events & Logs** > **+ Show more** > **Connection** > **Events**.

b. Click the **Table View of Connection Events** tab.

c. In the table view of events, multiple fields are hidden by default. To change the fields that are displayed, click the **x** icon in any column name to display a field selector.

d. Select these fields:

- **Authentication Source**
- **Zero Trust Application**
- **Zero Trust Application Group**
- **Zero Trust Application Policy**
- **Zero Trust Application Host**
- **Zero Trust Origin User**
- **Zero Trust Proxy**
- **Zero Trust Rule**

- **Zero Trust Status**
- **Zero Trust Tunnel ID**

e. Click **Apply**.

See Connection and Security-Related Connection Events in the Secure Firewall Management Center Administration Guide for more information on the connection events.

Step 2 Access the Zero Trust dashboard to monitor real-time session data.

The Zero Trust dashboard provides a summary of the top zero trust applications and zero trust users that are managed by the management center.

Choose **Insights & Reports** > **Dashboard**, and click the **Zero Trust** tab to access the dashboard.

The dashboard has the following widgets:

- Top Zero Trust Applications
- Top Zero Trust Users

Step 3 Use CLI commands to monitor and troubleshoot Zero Trust configurations.

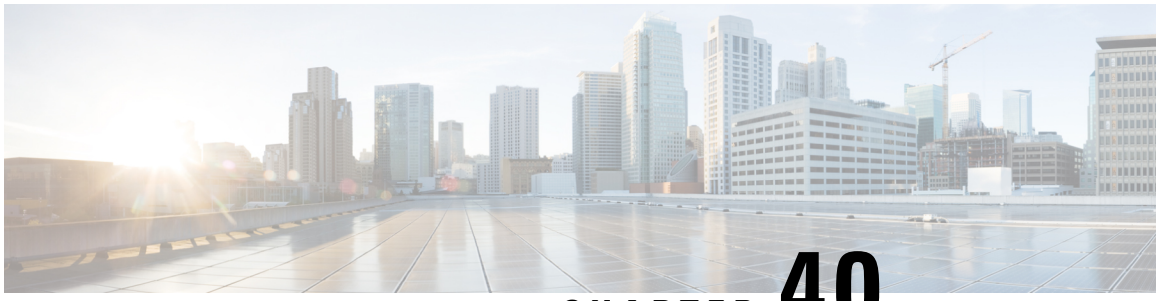
Log in to the device CLI and use the following commands:

CLI Command	Description
show running-config zero-trust	View the running configuration for a zero trust configuration.
show running-config zero-trust-hybrid	View the running configuration for a universal zero trust configuration.
show zero-trust	Display the run-time zero trust statistics and session information.
show cluster zero-trust	Display the summary of zero trust statistics across nodes in a cluster.
clear zero-trust	Clear zero trust sessions and statistics.
show counters protocol zero_trust	View the counters that are hit for zero trust flow.

Step 4 Run diagnostic tools to troubleshoot Zero Trust configuration issues.

The diagnostics tool facilitates the troubleshooting process by detecting possible issues with zero trust configurations. The diagnostics can be classified into two types:

- **Application-specific diagnostics** are used to detect issues such as:
  - DNS-related issues
  - Misconfigurations such as socket not open, and issues with classification and NAT rules.
  - Issues with deployment of zero trust policy or SSL rules
  - Issues with source NAT issues and exhaustion of PAT pool



- **General diagnostics** are used to detect issues such as:
  - Strong cipher license not enabled
  - Invalid application certificate
  - SAML-related issues
  - Home agent and cluster bulk sync issues

a. Click Diagnostics ( ) next to the zero trust application that you want to troubleshoot. The **Diagnostics** dialog box appears.

b. Choose the device from the **Select Device** drop-down list and click **Run**. A report is generated in the **Reports** tab after the diagnostic process is complete.

c. To view, copy, or download the logs, click the **Logs** tab.

You have successfully configured comprehensive monitoring for Zero Trust sessions. The connection events table now displays Zero Trust-specific fields, the dashboard provides real-time visualization of top applications and users, CLI commands are available for detailed system monitoring, and diagnostic tools can identify and troubleshoot configuration issues.

CHAPTER 40

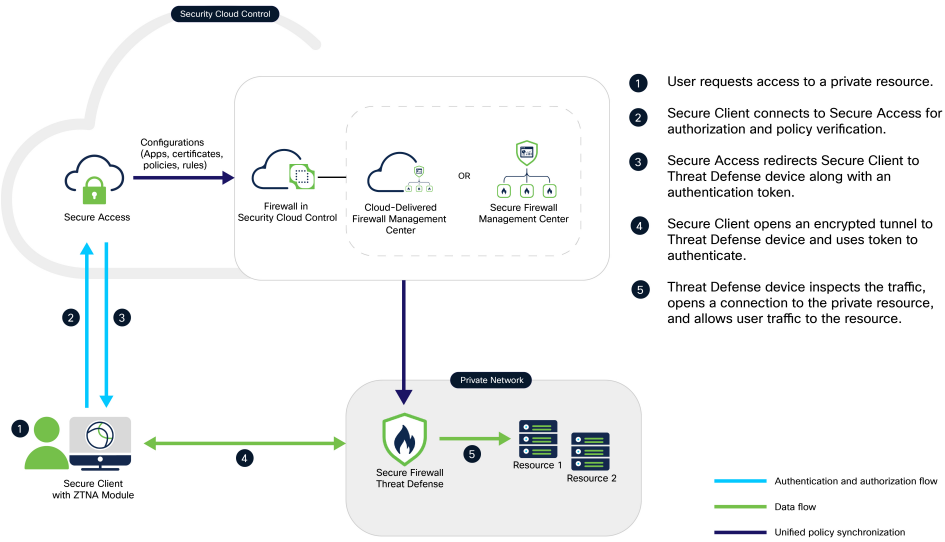
Universal Zero Trust Network Access

Universal Zero Trust Network Access (ZTNA) secures internal resources by validating user identity and device posture instead of granting full network access. The solution integrates Security Cloud Control, Secure Access, and Firewall Threat Defense devices to enforce granular, context-aware security policies. Administrators configure these components within the Security Cloud Control platform to protect applications and prevent lateral movement across hybrid environments.

- Universal Zero Trust Network Access, on page 1751
- Threat Defense with Universal Zero Trust Network Access, on page 1752
- Prerequisites for Universal Zero Trust Network Access, on page 1753
- Restrictions for Universal Zero Trust Network Access, on page 1754
- Integrate Firewall Management Center with Security Cloud Control, on page 1754
- Configure Security Devices, on page 1758
- Configure network connections, on page 1764
- Related documentation, on page 1772

Universal Zero Trust Network Access

Universal Zero Trust Network Access (universal ZTNA) is a client-based ZTNA solution that enables users to securely access internal resources and applications regardless of their location, whether remote or on-premises. It enables administrators to specifically allow access to internal network resources according to user identity including user trust and posture, without granting access to the entire network as with Remote Access VPN.



Because universal ZTNA does not assume that access granted to one application implicitly authorizes access to other applications, the network attack surface is reduced.

Universal ZTNA ensures least-privileged, per-application, per-user access with strong authentication, posture validation, and comprehensive traffic inspection. It secures applications effectively across hybrid environments.

Components of Universal ZTNA

A new configuration of universal ZTNA consists of Security Cloud Control Firewall Management (formerly called Cisco Defense Orchestrator), and Secure Access, both provisioned on the Security Cloud Control platform. Security Cloud Control Firewall Management manages the Firewall Threat Defense devices through the Secure Firewall Management Center.

Figure 435: Components of universal ZTNA

- **Security Cloud Control Firewall Management**: Manages the configuration and deployment of universal ZTNA policies to the Firewall Threat Defense devices. The Threat Defense devices protect on-premises resources by enforcing universal ZTNA policies. Threat Defense inspects traffic and enforces intrusion prevention system (IPS), file, and malware policies on the traffic.
- **Secure Access**: Secure Access defines the access policies, posture, and security profiles for the user. It enforces the policies for user traffic through the cloud.
- **Security Cloud Control platform**: Security Cloud Control provides a unified secure management plane for both Secure Access and Firewall, simplifying the administration of universal ZTNA policies across them.
- **Secure Client**: The Secure Client is installed on the end user's device. It acts as the enforcement point that intercepts connection requests to protected internal resources, enabling secure, identity-based access.

The following sections describe how to enable universal ZTNA on a Threat Defense device. For the complete configuration of universal ZTNA, refer to the *Universal Zero Trust Network Access Configuration Guide*.

Threat Defense with Universal Zero Trust Network Access

A universal ZTNA-enabled Firewall Threat Defense device is a critical enforcement point that protects private resources by integrating zero trust principles with firewall capabilities. Here's how it operates to secure private resources:

- Enforces access and validates policy: A Threat Defense device intercepts all access requests to private resources. It enforces granular, context-aware access policies that verify user identity, device posture, and contextual factors before granting access. Only requests that meet the least-privilege criteria are allowed, blocking the unauthorized attempts to access resources.
- Establishes a secure connection to the resource: After validating the access policy, the Threat Defense device enables the user to securely access the private resource.

- Inspects traffic: Threat Defense device continuously inspects the traffic and blocks threats before they reach the resources. The device applies the intrusion prevention system, file, and malware detection capabilities to detect and block the threats.
- Microsegments and prevents lateral movement: The device enforces microsegmentation by restricting traffic flows to only the authorized resources. This containment prevents lateral movement within the network, limiting the impact of any potential breach.

Prerequisites for Universal Zero Trust Network Access

This topic discusses requirements and guidelines for universal ZTNA.

Licensing requirements

- Secure Firewall Management Center requires a smart license account with export-controlled features. It does not function in evaluation mode for universal ZTNA.

  Secure Firewall Threat Defense devices require an IPS license if Intrusion policy is configured. If Malware policies are configured, the devices require IPS and Malware Defense licenses. For more information, refer to the "Licenses" section in the *Cisco Secure Firewall Management Center Administration Guide*.
- Secure Access requires a subscription of Cisco Secure Private Access Essentials or Advantage.

Device requirements

- All Secure Firewall Management Center and Secure Firewall Threat Defense devices must be running Version 7.7.10 or later.
- All Secure Firewall Threat Defense devices must be configured for routed mode; transparent mode is not supported.
- In Security Cloud Control, when you are configuring universal zero trust access for a device, ensure that the Enrollment Type for the device identity certificate is an object that is created using the PKCS12 file format. No other certificate type is supported. If necessary, you can also create a new certificate object from Security Cloud Control, which supports the PKCS12 format. See Configure Security Devices.
- Configure the Domain Name System (DNS) to resolve Fully Qualified Domain Name (FQDN) of private resources. Use the Platform Settings menu on the Secure Firewall to configure the DNS. See Interface and Device Settings.
- High Availability (HA) devices *are* supported; they are displayed as one entity.
- Secure Client (with ZTNA module enabled) Version 5.1.10 and later is supported.

  The client must be running in a platform that supports Trusted Platform Module (TPM), such as Windows 11.

Guidelines on certificate types

- **User Identity Certificate**: Secure Client, which is zero trust access enabled, presents the user identity certificate during the Mutual Transport Layer Security (mTLS) session with Secure Access and Firewall Threat Defense to request access to private resources.

- **Firewall Threat Defense Device Certificate**: Threat Defense devices that are universal ZTNA-enabled use device certificates to establish secure mTLS connections with the Secure Client and Secure Access. Ensure that the device identity certificate is of type PKCS12.

  If you have already enrolled a manual certificate for the device, first export it to the PKCS12 format using the **Devices** > **Certificates** > **Export Certificate** menu on Firewall Management Center. Use the exported PKCS12 file to create a new PKCS12 certificate enrollment object.

- **Decryption Certificate**: (Optional) To decrypt the traffic that is sent to private resources, enable **Decryption** for the resources in Secure Access and provide the server certificate and key. We recommend that you use a certificate that is signed by a publicly recognized certificate authority (CA).

Supported devices

Starting 10.1 release, universal ZTNA works with a default core profile and is supported on most of the Threat Defense platforms—Secure Firewall 1000 Series, 1100 Series, 1200 Series, 200 Series, 2100 Series, 3100 Series, 4100 Series, 4200 Series, 6100 Series, 9300 Series, and Firewall Threat Defense Virtual.

Restrictions for Universal Zero Trust Network Access

Be aware that Universal ZTNA has several operational limitations that may affect deployment and functionality.

- Universal ZTNA-enabled devices do not enforce policies for traffic over a site-to-site tunnel.
- Universal ZTNA does not support clustered devices.
- Universal ZTNA does not support devices in multi-instance mode.
- Universal ZTNA sessions do not support jumbo frames.
- Universal ZTNA supports only global VRF.
- Universal ZTNA does not support protocols such as active FTP or active TFTP, where the data or secondary connection originates from a server.

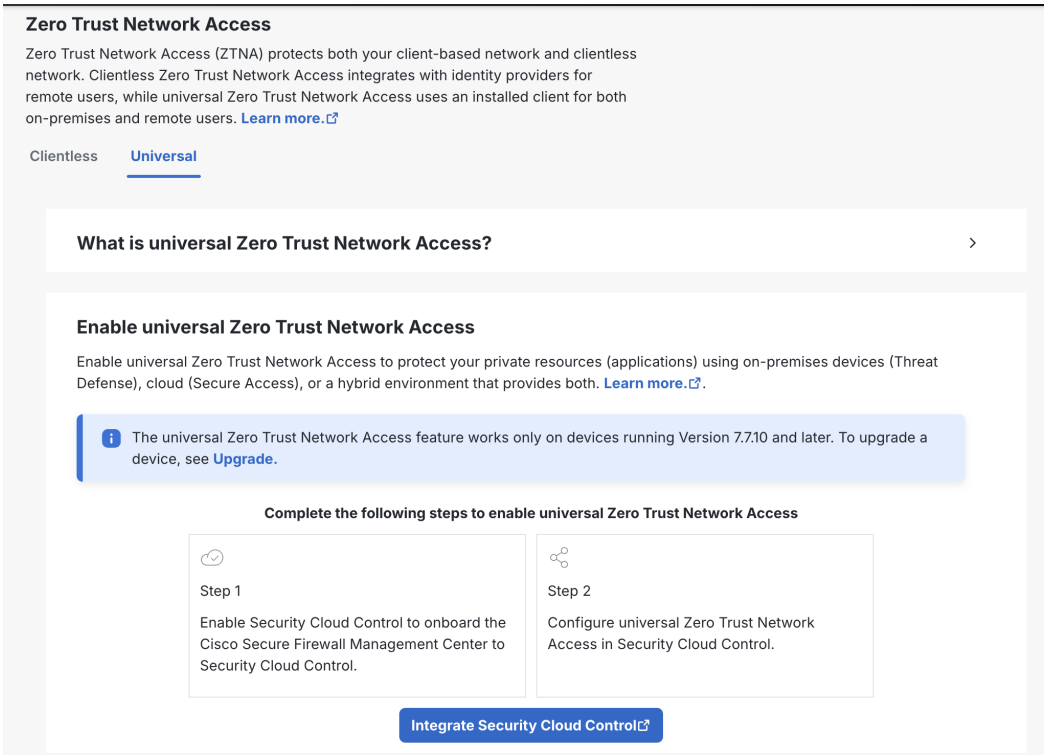
  For example, an active FTP connection uses a persistent control connection for commands and creates temporary data connections for file transfers. Universal ZTNA does not support such data connections that originate from the server.

Integrate Firewall Management Center with Security Cloud Control

Note This task is applicable only to on-premises Firewall Management Center.

Integrating the on-premises Secure Firewall Management Center with Security Cloud Control enables you to configure your Secure Firewall Management Center and its associated Secure Firewall Threat Defense devices. These devices can then use the networks, private resources, and policies necessary to configure and manage universal ZTNA .

Note Universal ZTNA uses *only* the access policies that are defined by Secure Access . Any other access control policies and rules deployed to the Threat Defense devices from the Secure Firewall Management Center are ignored for universal ZTNA .

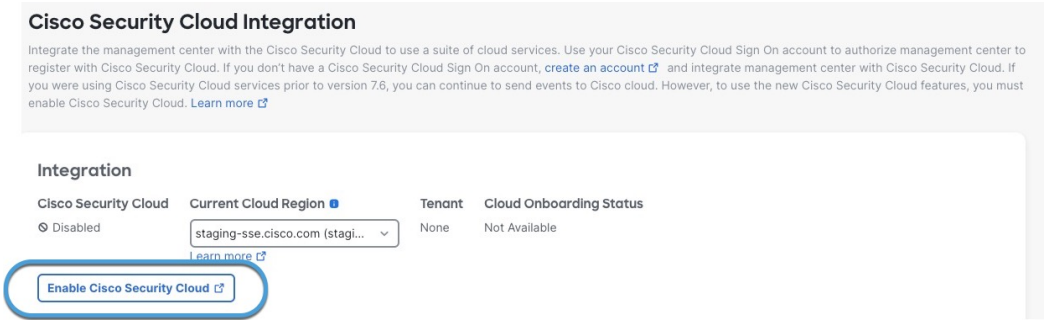


Before you begin

Your Cisco contact must onboard your Security Cloud Control and Secure Access systems, and create users and tenants.

Procedure

Step 1 Log in to the Secure Firewall Management Center and click **Policies** > **Security policies** > **Zero Trust Application**.

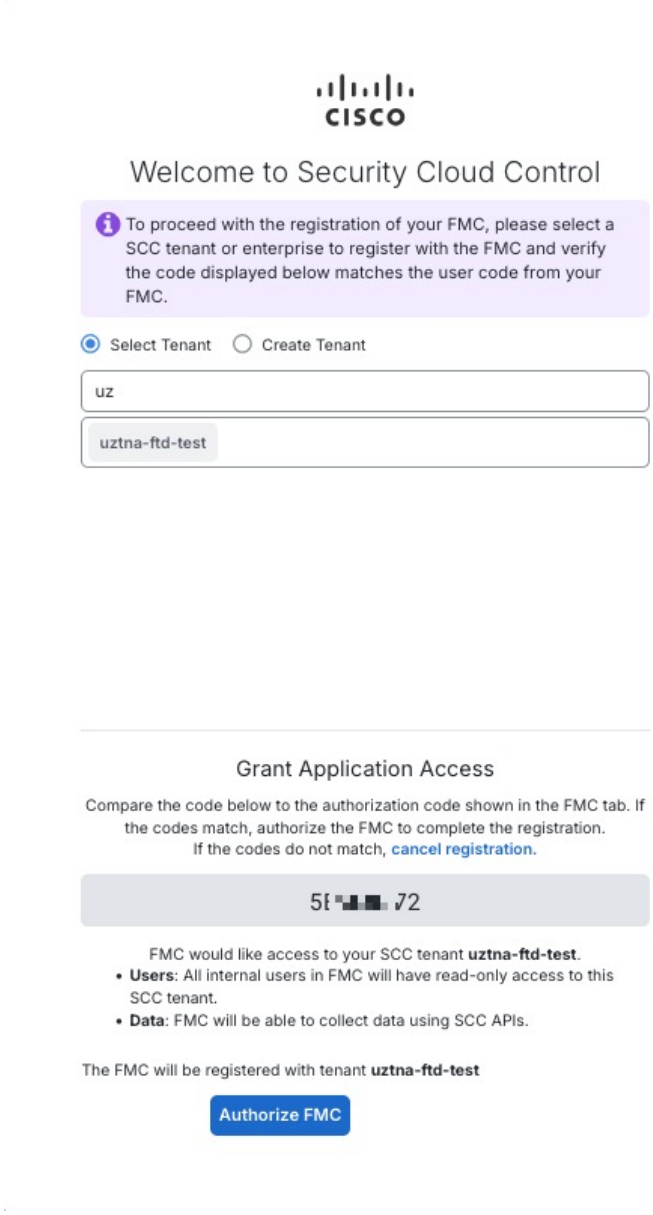


Step 2 In the Zero Trust Network Access page, under the **Universal** tab, click **Integrate Security Cloud Control**.

Step 3 In the Cisco Security Cloud Integration page:

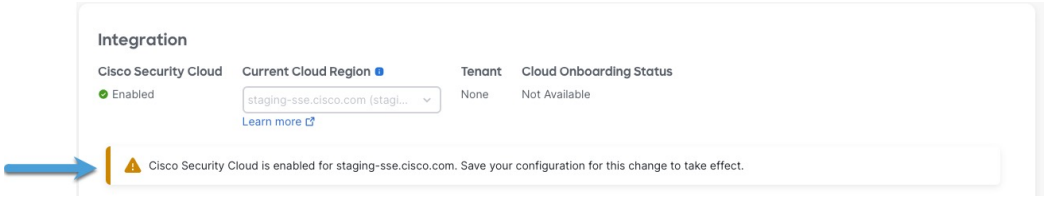
a) From the **Current Cloud Region** list, select your Security Cloud Control region.

b) Click **Enable Cisco Security Cloud**.



c) When prompted, click **Continue to Cisco SSO** .

Step 4 Log in to Security Cloud Control.



Step 5 From the **Select Tenant** list, click the name of your tenant.

Step 6 At the following page, click **Authorize FMC** .

Step 7 When prompted, close the tab page.

Step 8 A confirmation message appears to indicate that the onboarding was successful.

Step 9 Click **Save** at the bottom of the page.

It can take several minutes to save the configuration. After the configuration is saved, the page displays the onboarding status and the tenant name.

For more information about other options on this page, see Security Cloud Control Settings .

Configure Security Devices

All Firewall Threat Defense devices associated with the Secure Firewall Management Center that you onboarded to Security Cloud Control are *security devices* to which you can:

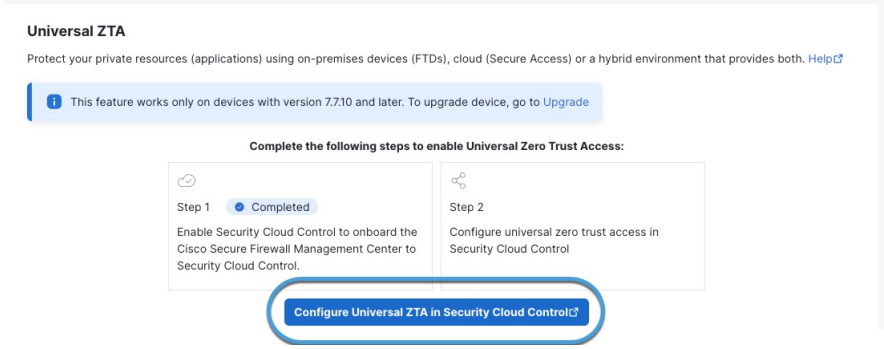
- Associate private resources, which are internal applications you want to protect with identity-based access control, IPS, malware, and other protections.
- Deploy Secure Access access rules. Security devices are responsible for enforcing access rules for on-premises users, remote users, or both.

Perform these steps to enable **universal zero trust network access settings** on the Threat Defense devices. These steps include configuring the device FQDN, inside interface, outside interface, and PKCS12 certificate to enable universal ZTNA on the devices.

Before you begin

You must know the name of each device's internal and external network interfaces:

- The internal interface (also referred to as the *DMZ* interface) is used to apply access rules to on-premises users.
- The external interface is used to apply access rules to remote users.



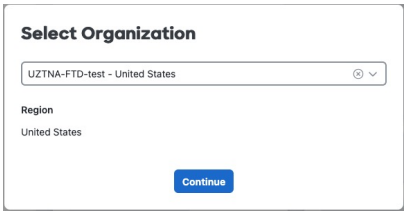
You can choose internal, external, or both types of interfaces for each security device.

Procedure

Step 1 In the Secure Firewall Management Center, click **Policies** > **Security policies** > **Zero Trust Application**.

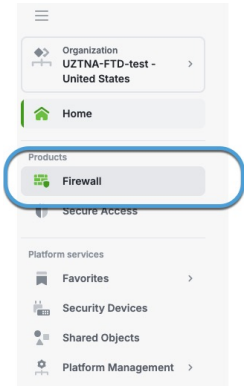
Step 2 Click **Configure Universal ZTA in Security Cloud Control**.

This figure shows an example.



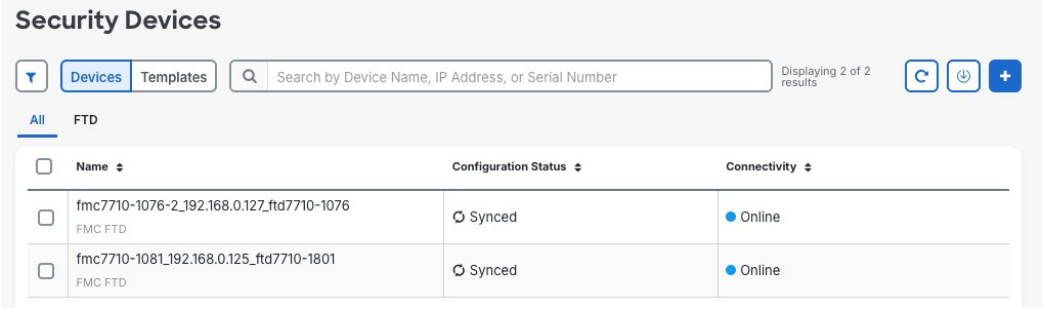
Step 3 When prompted, log in to Security Cloud Control.

Step 4 When prompted, select your organization from the drop-down list and click **Continue**.



Select an organization that has both Secure Access and Secure Firewall micro applications configured.

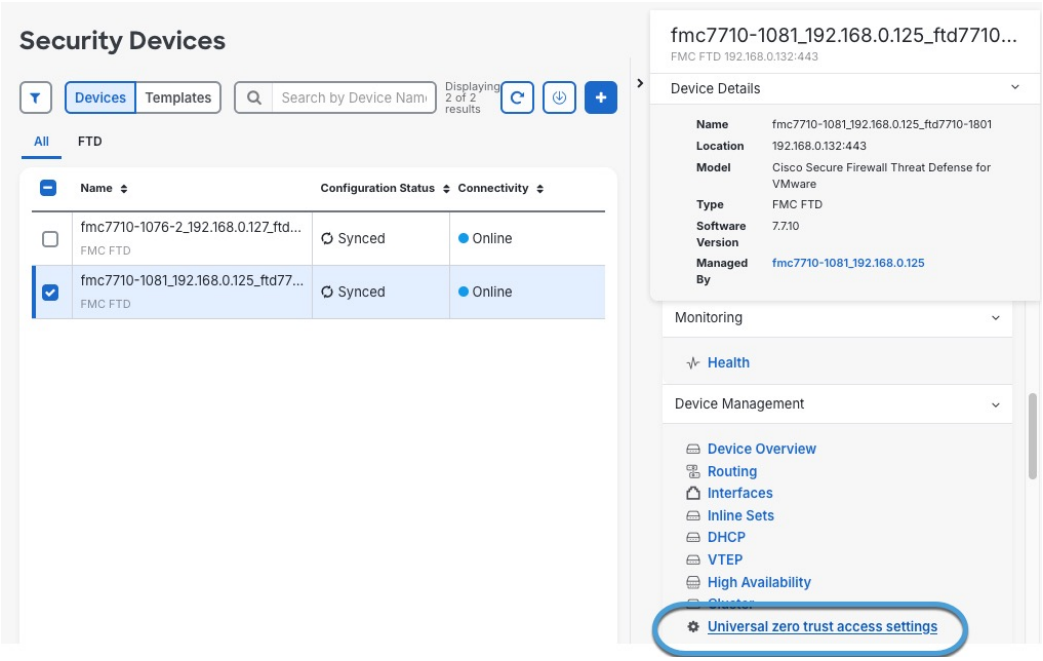
This figure shows an example.



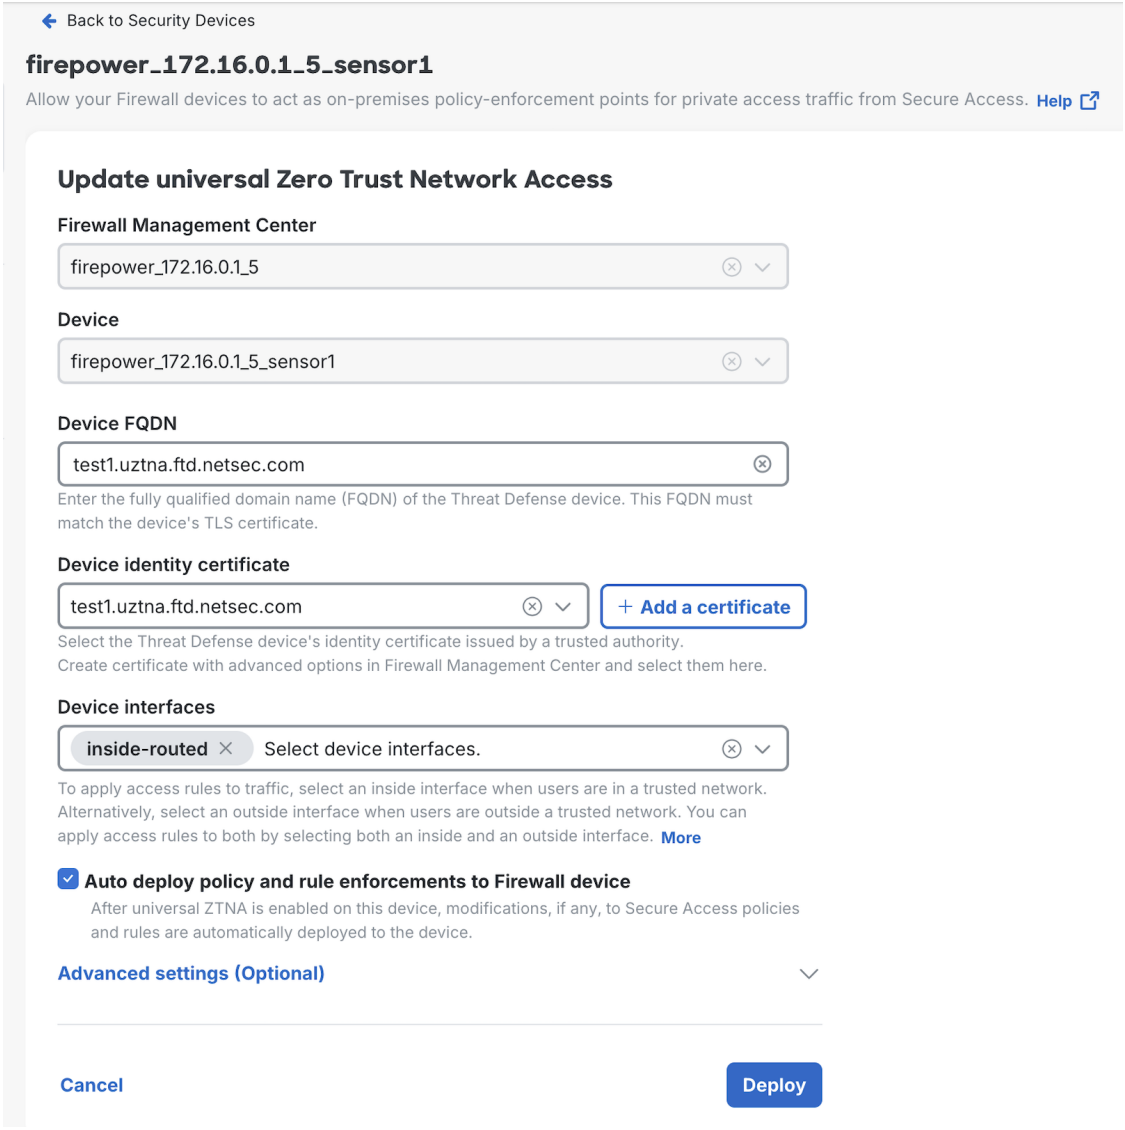
Step 5 In Security Cloud Control, in the Products section, click **Firewall**.

This figure shows an example.

Step 6 In the Manage section, click **Security Devices**.



The **Security Devices** page displays the available security devices.



Step 7 Select the check box next to a device to add to the universal zero trust network access configuration.

Step 8 In the right pane, click **Device Management** > **Universal zero trust access settings**.

This figure shows an example.

Step 9 Enter or edit the following information on the **Configure device for Universal Zero Trust Access** page.

This table describes the configurations to enable universal ZTNA on the device.

Item	Description
Firewall management center	From the drop-down list, click the name of a Secure Firewall Management Center to use for policy deployment, monitoring, and other tasks.
Device	From the drop-down list, click the name of a device to use for rule deployment and enforcement.

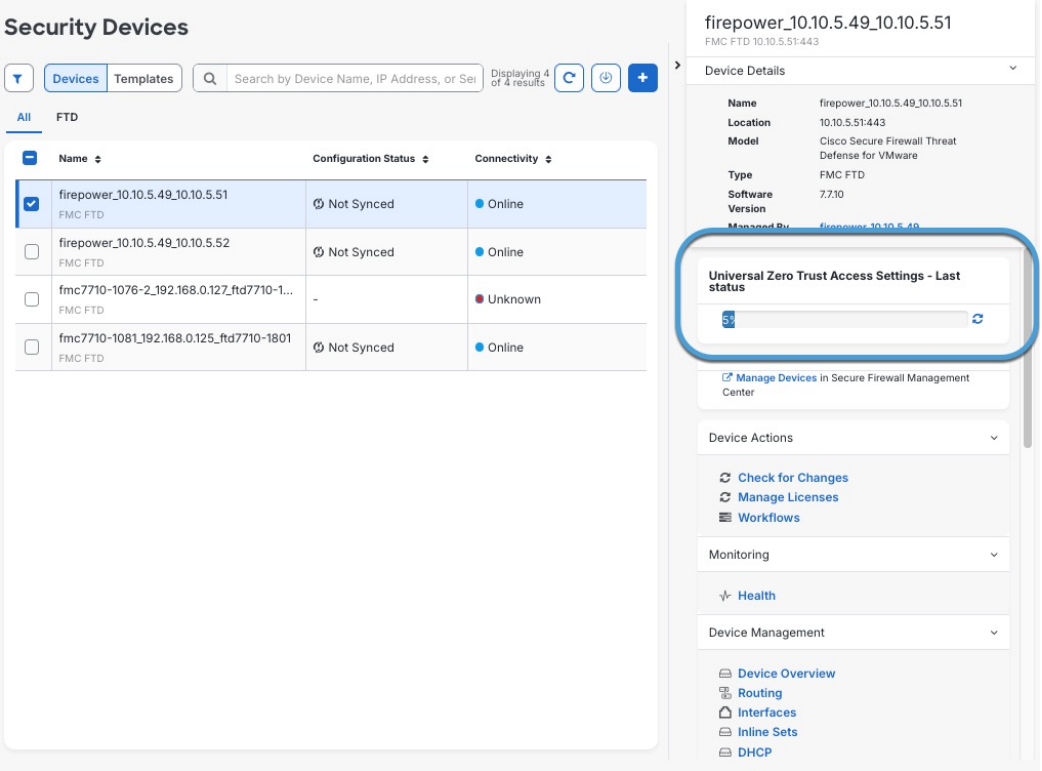
Item	Description
Device FQDN	Enter the security device's fully qualified domain name (FQDN). The FQDN is also referred to as the TLS/SSL certificate's Common Name. Secure Access redirects the clients to the resource that is represented by this FQDN. Ensure that the device FQDN *exactly matches* the Common Name (CN) of the device identity certificate and must also match a Subject Alternative Name (SAN) in the certificate.
Device identity certificate	The **Device identity certificate** must have a Common Name that: • *Exactly matches* the value you enter in the **Device FQDN** field. • Matches a Subject Alternative Name (SAN) in the certificate. From the drop-down list, click the name of an existing identity certificate from the list. Click **Add certificate** and add an identity certificate in **.p12** format (also referred to as PKCS#12; see this article on ssl.com). **Note** Universal ZTNA supports only the PKCS#12 format of certificate enrollment. In the provided fields, enter a **Name** to identify the certificate. Then copy/paste, drag/drop, or upload the certificate and private key. If the certificate is encrypted, enter its password in the provided field. You can optionally use a wildcard certificate as discussed in What is a Wildcard Certificate? on ssl.com.
Device Interface(s)	From the drop-down list, select the check box next to any of the following types of interfaces. • Internal network interface (or DMZ): deploys access rules for on-premises users only. • External network interface: deploys access rules for remote users only. • Both types of interfaces: deploys access rules for either on-premises or remote users.
Auto deploy policy and rule enforcements to firewall device	Select the check box to automatically deploy access rules to the device after they are updated on Secure Access. On the device, the Auto deploy feature selectively deploys only the Universal ZTNA access policy. It does not impact other changes or configurations on the Firewall Management Center. **Note** If there are other interdependent policies on the device (which are interlinked with the Universal ZTNA access policy), the Firewall configuration status displays an error message. The deployment then stops. In such cases, you should manually deploy the Universal ZTNA access policy from the Firewall Management Center.

Step 10 (**Applicable to only 10.0 and earlier versions**) Click **Deploy and Reboot**.

The device reboots to reallocate the system resources for universal ZTNA components.

Note The device takes several minutes to reboot, during which time all traffic handled by the device is disrupted.

If you deploy a High Availability (HA) pair of devices, both devices reboot simultaneously.



This behavior is applicable to only 10.0 version.

Step 11 Click **Deploy**.

universal ZTNA is enabled on the device.

Step 12 On the **Security Devices** page, select the check box next to the device to which you just deployed the Universal ZTNA configuration.

The right pane displays the deployment status, as shown in the figure.

For additional information, click **Device Actions** > **Workflows** in the right pane.

After the deployment completes, you can view the completion status in the **Universal Zero trust Access Settings - Last status** tab for the device.

Universal ZTNA-enabled Firewall Threat Defense device is connected to Secure Access.

What to do next:

Check the availability of the Threat Defense device under Secure Access by clicking **Security Cloud Control** > **Secure Access** > **Connect** > **Network Connections** > **FTD**.

Configure network connections

Configure private resources and the devices that protect these resources to complete the Universal ZTNA configuration.

The final step in configuring Universal ZTNA is to configure private resources and the devices that are responsible for protecting the resources.

Before you begin

Complete the tasks discussed in Configure Security Devices, on page 1758.

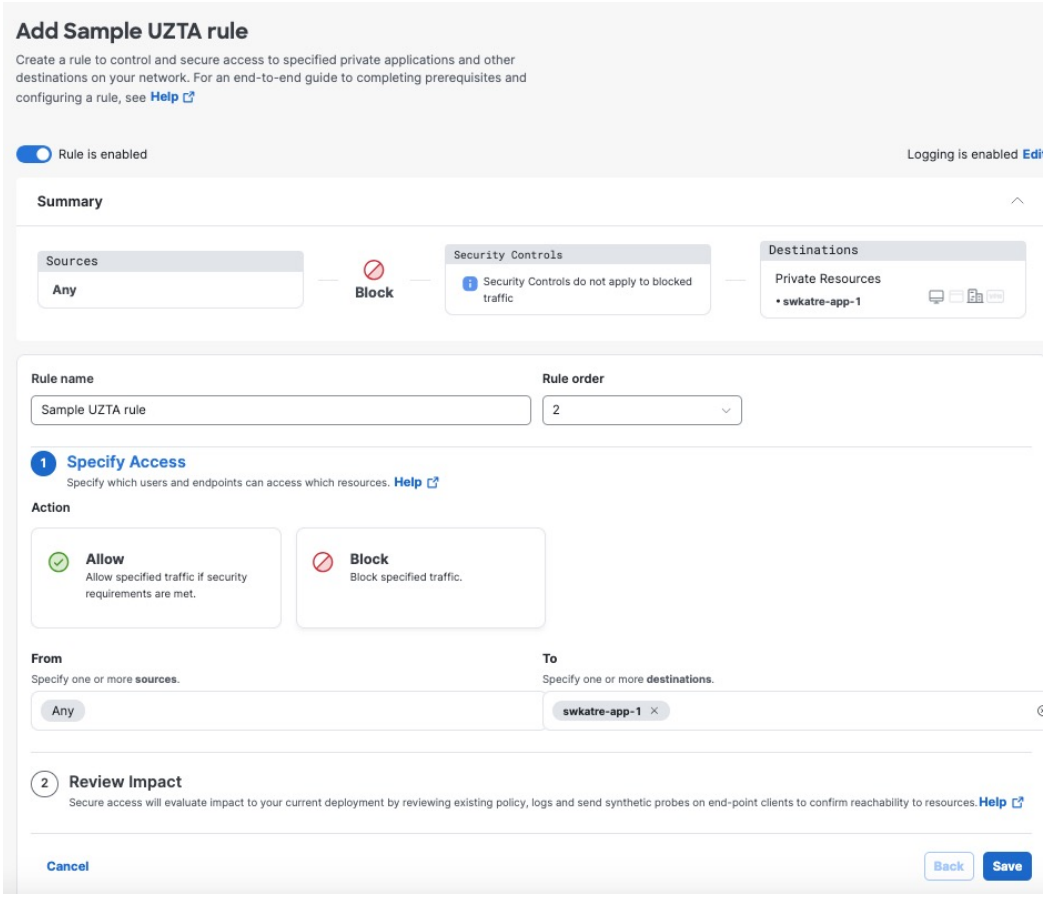
Procedure

Step 1 In Security Cloud Control, click **Products** > **Secure Access**.

The Secure Access product menu appears in the left navigation bar.

Step 2 Click **Resources** > **Destinations** > **Private Resources**.

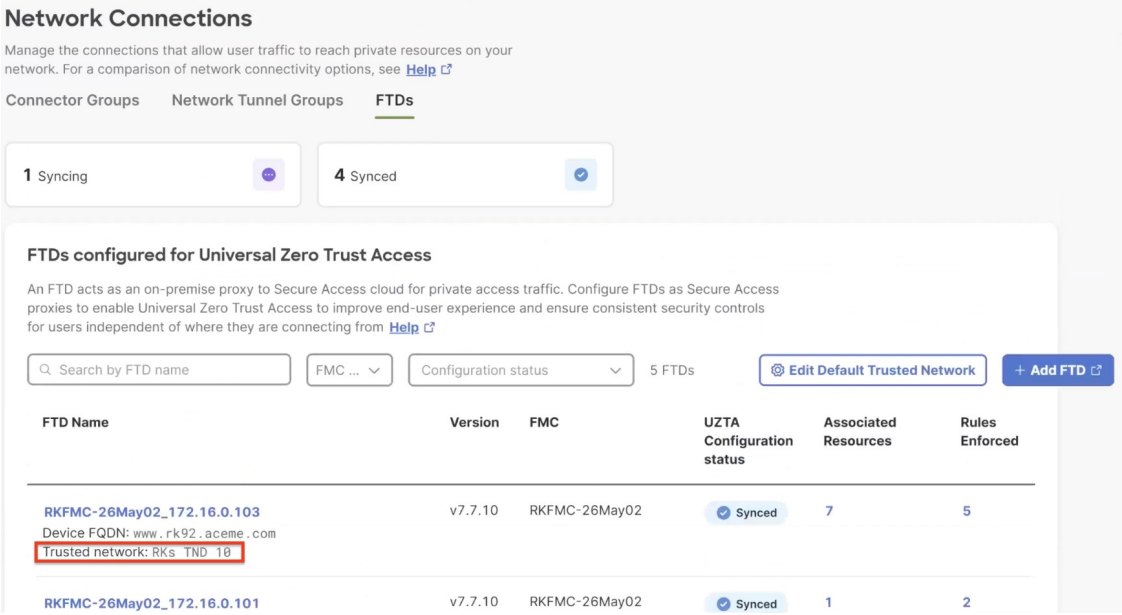
Add private resources. For guidance, refer to Manage Private Resources.



Note When you add a private resource, select the zero-trust connections method of endpoint connections. This selection enables client-based zero trust access for the private resource.

Step 3 Click **Secure** > **Access Policy**.

Add or edit access rules. For more information, refer to Manage the Access Policy.



This sample access rule blocks access to a destination named **swatw-app-1**:

Step 4 Click **Connect** > **Network Connections**.

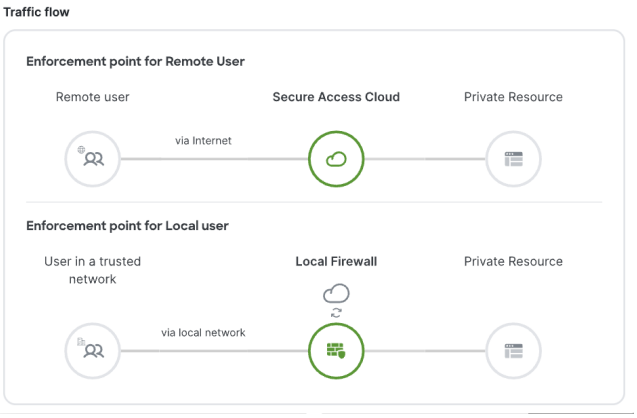
Step 5 Click the **FTDs** tab.

The page displays the available Secure Firewall Threat Defense devices configured for universal zero trust network access.

Before proceeding to the next step, ensure that the device is associated with a trusted network. This association enforces policies on traffic originating from the trusted network.

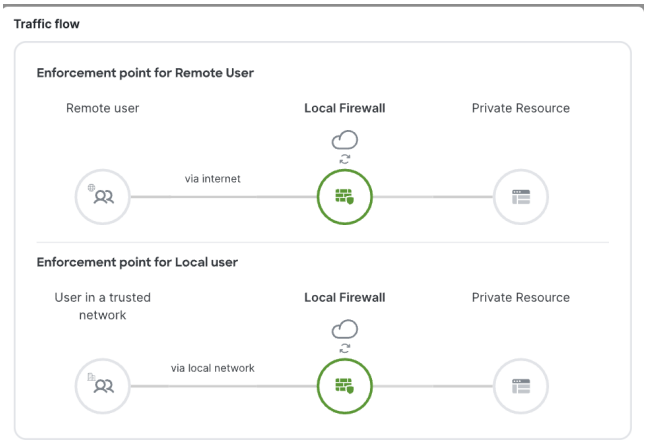
After onboarding a Threat Defense device, it is automatically associated with a default trusted network if one exists. If not, you must create a trusted network and associate it with the Threat Defense device.

Step 6 Click the name of a Threat Defense device to configure.



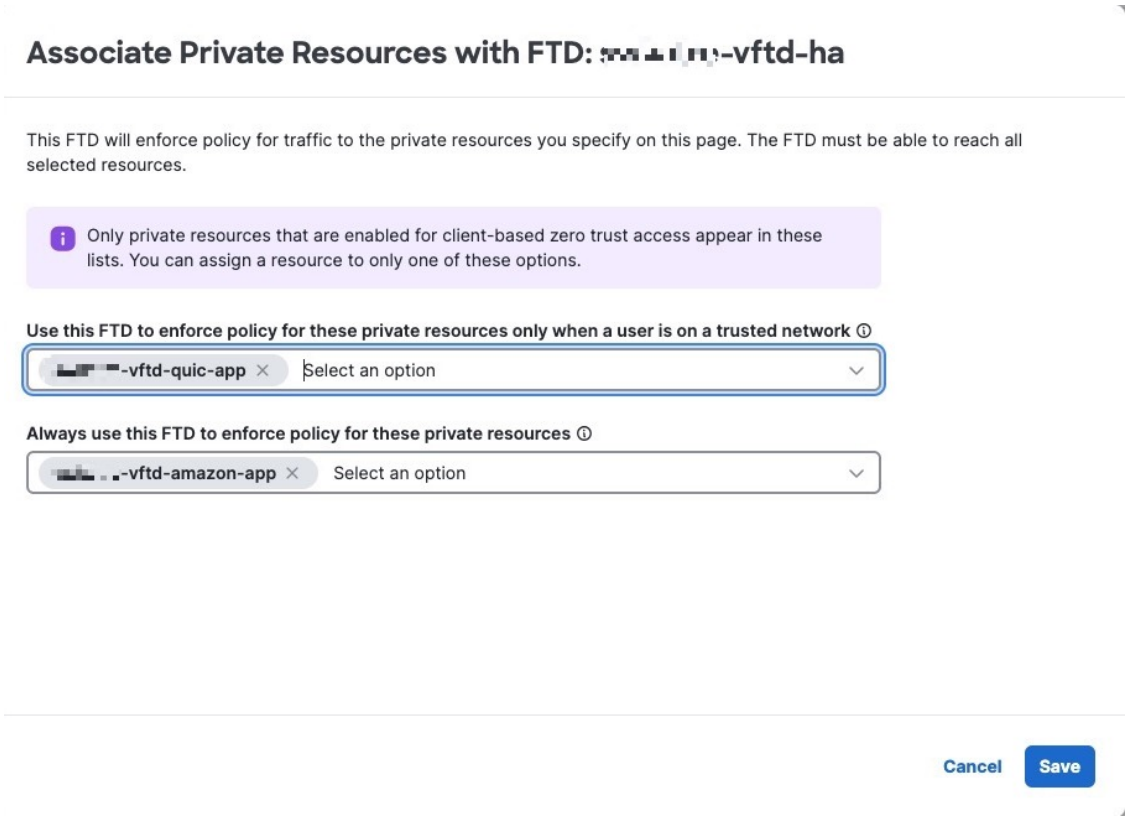
Step 7 In the right pane, click **Associate Resources**.

Note



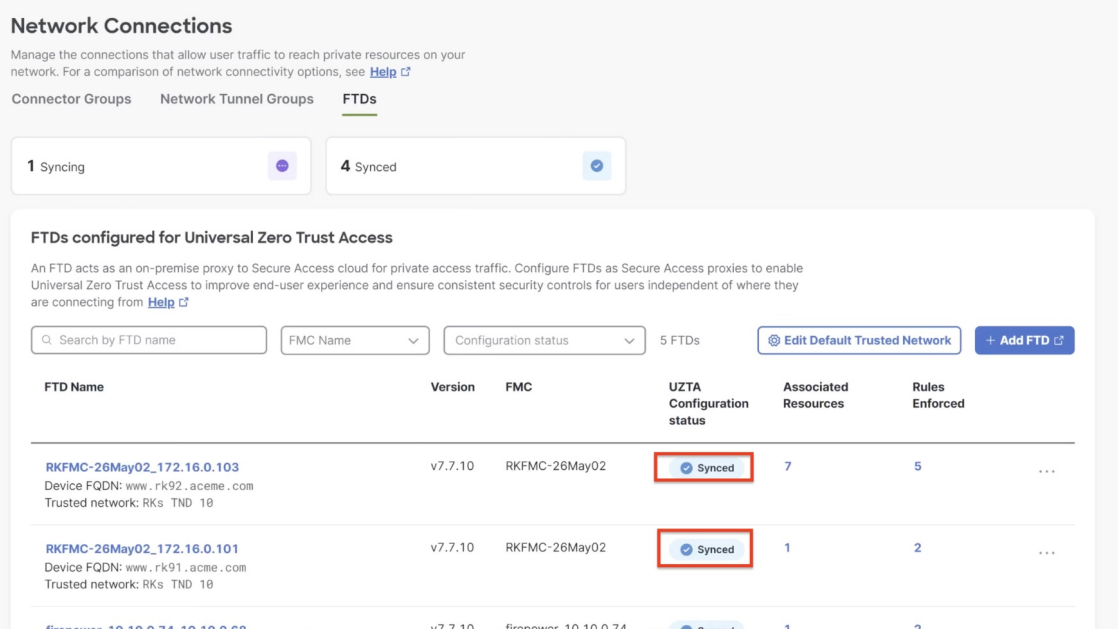
- Only those resources that are enabled for zero trust access can be associated with a Threat Defense device.
- A Threat Defense device must have connectivity to the associated private resources.
- Resources associated with a Threat Defense device are shared with other devices that have the same FQDN.

Step 8 In the **Associate Private Resources** dialog box, make the following selections to specify the access policy enforcement and traffic flow for a user:



- **Use Threat Defense device to enforce policy only for on-premises users**: From the **Use this FTD to enforce policy** drop-down list, select the private resources that a user should access only from an on-premises location.

- **Use Threat Defense device to enforce policy for both on-premises and remote users**: From the **Always use this FTD to enforce policy** drop-down list, select the private resources for which the selected Threat Defense device always enforces policy, regardless of whether the user is on-premises or remote.

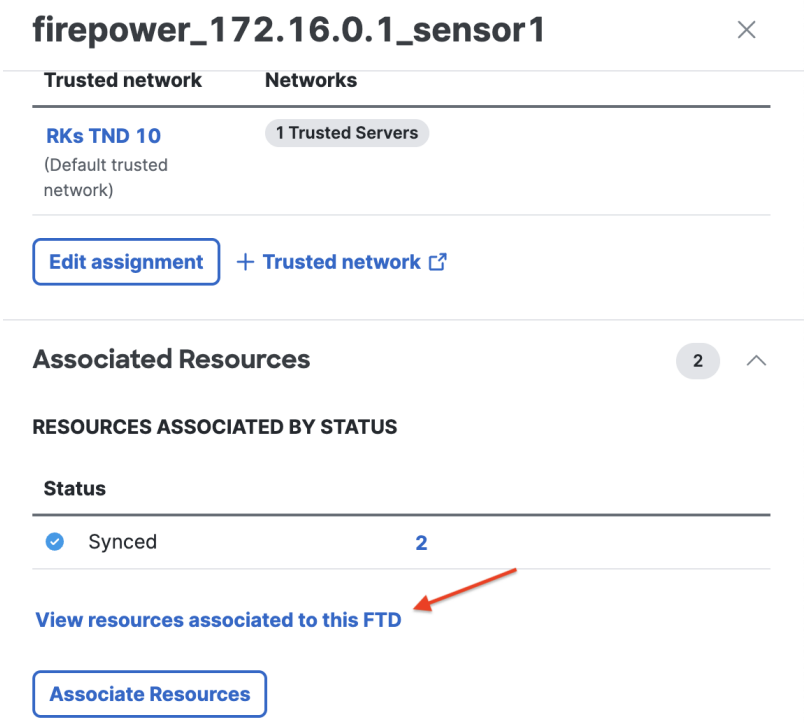


The following figure shows an example of using a Threat Defense device to enforce access rules for the **vftd-quic-app** for on-premises users and **vftd-amazon-app** for all users, whether on-premises or remote.

Step 9 Click **Save**.

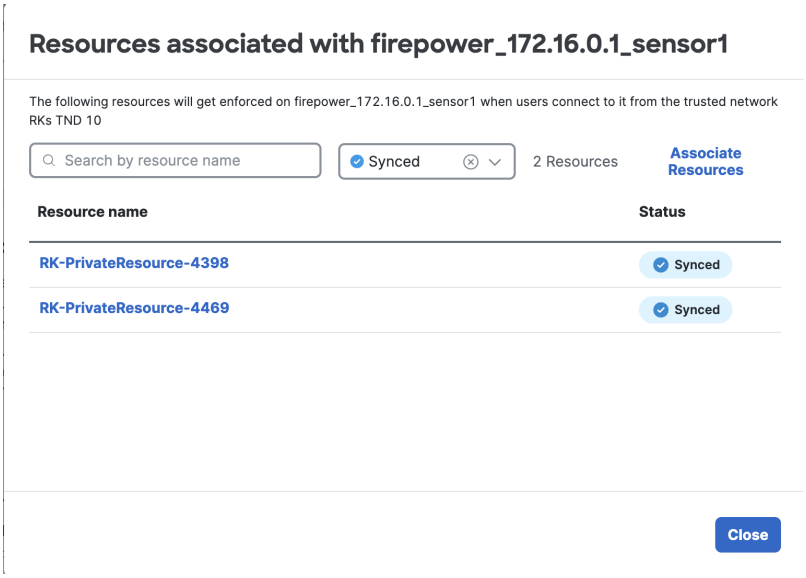
The configurations are applied to the device, and the **UZTA Configuration status** column for the device displays **Synced**.

The following figure shows an example.



Configuration status can also be:

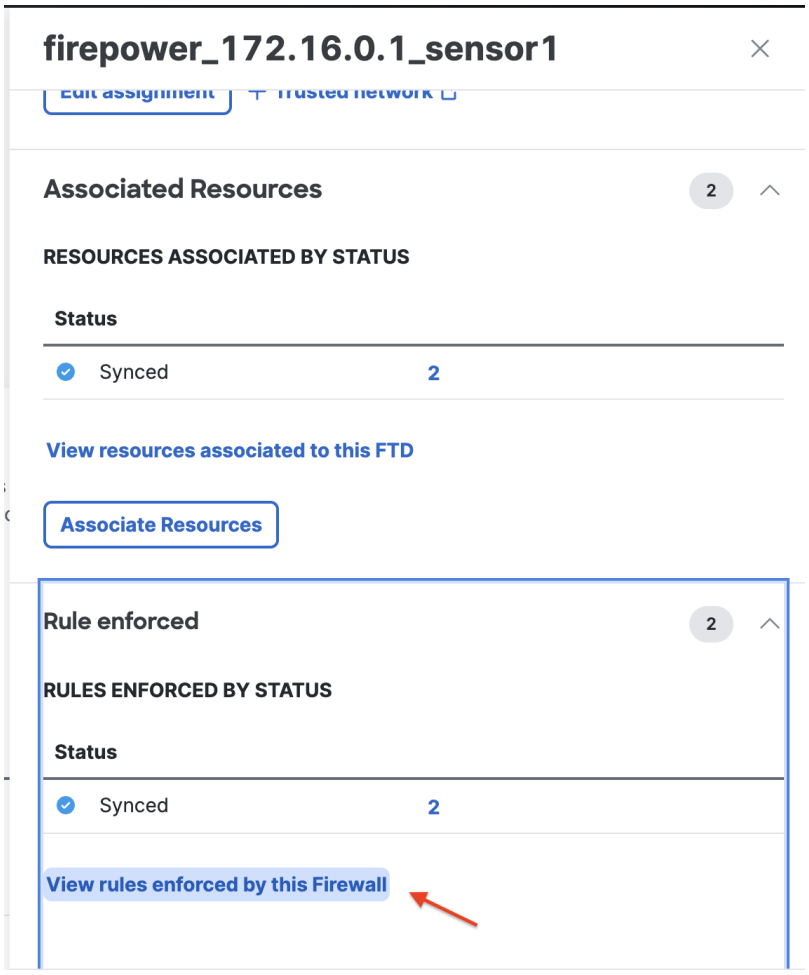
- Syncing—updates to the Threat Defense device are ongoing.
- Out of sync—modifications to Secure Access configurations are pending update to the Threat Defense device.
- Failed to sync—configurations were not updated on the Threat Defense device.



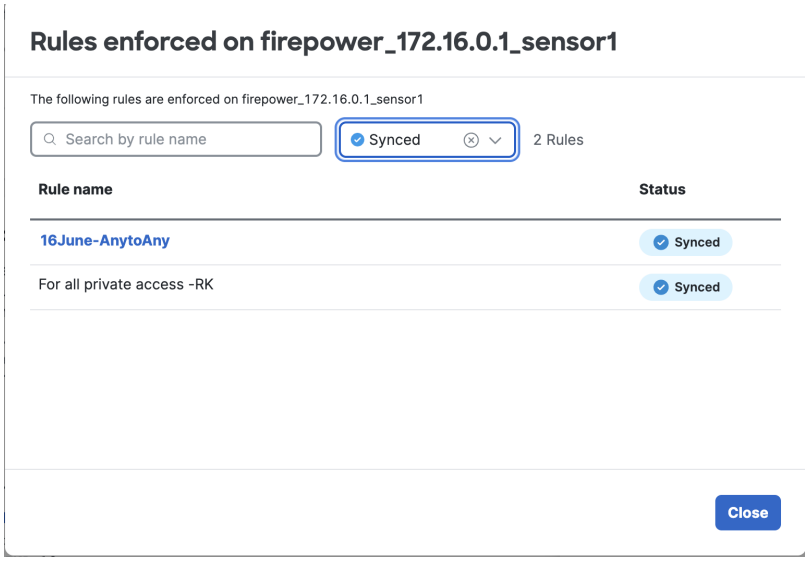
To view a detailed status for each resource and rule associated with a Threat Defense device, complete these actions:

a) Click the numeral in the **Associated Resources** column.

In the slide-in pane, under the **Associated Resources** section, click **View resources associated with this FTD**.



The configuration status of each resource is displayed.



b) To check the configuration status of each rule enforced by the Threat Defense device, click the numeral in the **Rules Enforced** column.

In the slide-in pane, under the **Rules Enforced** section, click **View rules enforced by this Firewall**.

The configuration status of each rule that is enforced is displayed.

Universal ZTNA is now set up, allowing your clients to access private resources in your network securely.

Network connections are configured, and Universal ZTNA is set up to allow secure access to private resources.

Access Control Policies

These topics describe how to work with access control policies:

- Access control policies, on page 1775
- Requirements and prerequisites for access control policies, on page 1780
- Manage access control policies, on page 1781
- Access control rule expansion, on page 1802
- History for access control policies, on page 1807

Access control policies

An access control policy is a hierarchical policy that allows you to specify, inspect, and log network traffic. You can use the characteristics of each connection to allow, trust, block, or monitor the connection.

Each managed device can be assigned to one access control policy. The data that the policy's assigned (also known as targeted) devices collect about your network traffic can be used to filter and control that traffic based on:

- simple, easily determined transport and network layer characteristics: source and destination, port, protocol, and so on
- the latest contextual information on the traffic, including characteristics such as reputation, risk, business relevance, application used, or URL visited
- realm, user, user group, or ISE attribute
- custom Security Group Tag (SGT)
- characteristics of encrypted traffic; you can also decrypt this traffic for further analysis
- whether unencrypted or decrypted traffic contains a prohibited file, detected malware, or intrusion attempt
- time and day (on supported devices)

Each type of traffic inspection and control occurs where it makes the most sense for maximum flexibility and performance. For example, reputation-based blocking uses simple source and destination data, so it can block prohibited traffic early in the process. In contrast, detecting and blocking intrusions and exploits is a last-line of defense.

Access control policy components

This list describes the main components of an access control policy.

- Name and description: Each access control policy must have a unique name. A description is optional.
- Inheritance settings: Policy inheritance allows you to create a hierarchy of access control policies. A parent (or base) policy defines and enforces default settings for its descendants. A policy's inheritance settings allow you to select its base policy. You can also lock settings in the current policy to force any descendants to inherit them. Descendant policies can override unlocked settings.
- Policy assignment: Every access control policy identifies which devices use it. Each device can use only one access control policy. You can also assign the policy to device templates.
- Rules: Access control rules provide a granular method of handling network traffic. Rules are numbered, starting at 1, including rules inherited from ancestor policies. The system matches traffic to rules from the top down, ascending by rule number.

  Traffic is handled by the first rule for which all conditions match. Conditions can be simple or complex, and often depend on licensing.
- Default action: The default action determines how the system handles and logs traffic that is not handled by any other access control configuration. It can block or trust all traffic without further inspection, or inspect traffic for intrusions and discovery data. Although an access control policy can inherit its default action from an ancestor policy, you cannot enforce this inheritance.
- Security Intelligence: This feature acts as the first line of defense against malicious internet content. It enables blocking of connections based on IP address, URL, and domain name reputation intelligence. To ensure continual access to vital resources, you can override block list entries with custom do not block list entries.
- HTTP responses: When a user's website request is blocked, you can display either a generic response page or a custom page. Alternatively, you can warn users but allow them to proceed to the requested site.
- Logging: Logging settings enable configuration of default syslog destinations for the policy. These settings apply to the policy and all included decryption, prefilter, and intrusion policies unless overridden in individual rules or policies.
- Advanced access control options: Advanced policy settings typically require little modification, and defaults are often suitable. Modifiable options include traffic preprocessing, decryption, identity, and various performance configurations.

Access control policy default actions

The default action is the access control policy configuration that determines how the system handles and logs traffic that is not handled by any other access control configuration. The default action can block or trust all traffic without further inspection, or inspect traffic for intrusions and discovery data.

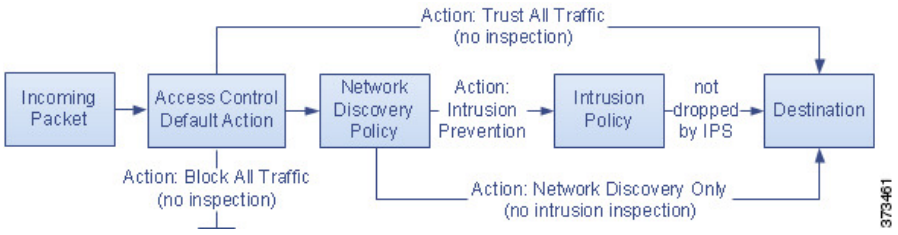
In a simple access control policy, the default action specifies how a device handles all traffic. In a more complex policy, the default action handles traffic that:

- is not fast pathed by the prefilter policy
- is not on a Security Intelligence block list

- is not blocked by the decryption policy (encrypted traffic only)
- matches none of the rules in the policy (except monitor rules, which match and log—but do not handle or inspect—traffic)

Note You cannot perform file or malware inspection on traffic handled by the default action. Logging of connections handled by the default action is initially disabled but can be enabled.

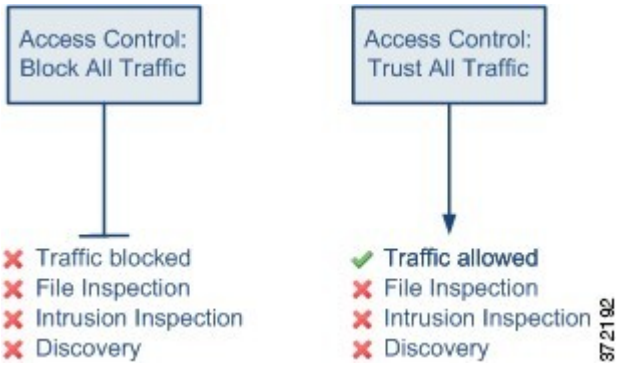
If you are using policy inheritance, the default action for the lowest-level descendant determines how traffic is handled. An access control policy can inherit its default action from the base policy, but this inheritance is not enforced.



This table describes the types of inspection you can perform on traffic handled by each default action.

Table 99: Types of default actions and inspection options

Default action	Effect on traffic	Inspection type and policy
Access Control: Block All Traffic	Block without further inspection.	None.
Access Control: Trust All Traffic	Trust (allow to its final destination without further inspection).	None.
Intrusion Prevention	Allow, as long as it is passed by the intrusion policy you specify.	Intrusion, using the specified intrusion policy and associated variable set. Discovery, using the network discovery policy.
Network Discovery Only	Allow.	Discovery only, using the network discovery policy.
Inherit from base policy	Defined in base policy.	Defined in base policy.



This diagram illustrates the table.

Figure 436: Default action configuration options

This diagram illustrates the **Block All Traffic** and **Trust All Traffic** default actions.

Figure 437: Block all traffic and trust all traffic default actions

This diagram illustrates the **Intrusion Prevention** and **Network Discovery Only** default actions.

Figure 438: Intrusion prevention and network discovery only default actions

Note The purpose of **Network Discovery Only** is to improve performance in a discovery-only deployment. Different configurations can disable discovery if you are only interested in intrusion detection and prevention.

Access control policy inheritance

Access control policy inheritance is a hierarchical policy-based implementation that allows child policies to inherit rules and settings from ancestor or base policies. This structure ensures that mandatory rules defined in parent policies are consistently enforced, while providing the flexibility for child policies to selectively override default configurations.

Access control policy hierarchy structure

You can nest access control policies, where each policy inherits the rules and settings from an ancestor policy. You can enforce this inheritance, or allow lower-level policies to override their ancestors.

Just as you create a domain hierarchy, you can create a corresponding hierarchy of access control policies. A descendant, or child, access control policy inherits rules and settings from its direct parent, or base, policy. That base policy may have its own parent policy from which it inherits rules and settings, and so on.

An access control policy's rules are nested between its parent policy's Mandatory and Default rule sections. This implementation enforces Mandatory rules from ancestor policies, but allows the current policy to write rules that preempt Default rules from ancestor policies.

You can lock these settings to enforce them in all descendant policies:

- Security Intelligence—Connections that are allowed or blocked based on the latest reputation intelligence for IP addresses, URLs, and domain names.
- HTTP response pages—Displaying a custom or system-provided response page when you block a user's website request.
- Advanced settings—Specifying associated subpolicies, network analysis settings, performance settings, and other general options.

When using policy inheritance, the default action for the lowest-level descendant determines final traffic handling. Although an access control policy can inherit its default action from an ancestor policy, you cannot enforce this inheritance.

Policy inheritance and multitenancy

Access control's hierarchical policy-based implementation complements multitenancy.

In a typical multidomain deployment, access control policy hierarchy corresponds to domain structure, and you apply the lowest-level access control policy to managed devices. This implementation allows selective access control enforcement at a higher domain level, while lower-level domain administrators can tailor deployment-specific settings. (You must use roles, not policy inheritance and enforcement alone, to restrict administrators in descendant domains.)

For example, as a Global domain administrator for your organization, you can create an access control policy at the Global level. You can then require that all your devices, which are divided into subdomain by function, use that Global-level policy as a base policy.

When subdomain administrators log into the Secure Firewall Management Center to configure access control, they can deploy the Global-level policy as-is. Or, they can create and deploy a descendant access control policy within the boundaries of the Global-level policy.

Note Although the most useful implementation of access control inheritance and enforcement complements multitenancy, you can create a hierarchy of access control policies within a single domain. You can also assign and deploy access control policies at any level.

Rule and other policy warnings

Policy and rule editors use icons to mark configurations that could adversely affect traffic analysis and flow. Depending on the issue, the system may warn you when you deploy or prevent you from deploying entirely.

Note Move your pointer over an icon to read the warning, error, or informational text.

Table 100: Policy error icons

Icon	Description	Example
Errors ()	If a rule or configuration has an error, you cannot deploy until you correct the issue, even if you disable any affected rules.	A rule that performs category and reputation-based URL filtering is valid until you assign a device that does not have a URL Filtering license. At that point, an error icon appears next to the rule, and you cannot deploy until you edit or delete the rule, unassign the device, or enable the license.
Warning ()	You can deploy a policy that displays rule or other warnings. However, misconfigurations marked with warnings have no effect. If you disable a rule with a warning, the warning icon disappears. It reappears if you enable the rule without correcting the underlying issue.	Preempted rules or rules that cannot match traffic due to misconfiguration have no effect. This includes conditions using empty object groups, application filters that match no applications, excluded LDAP users, invalid ports, and so on. However, if a warning icon marks a licensing error or model mismatch, you cannot deploy until you correct the issue.
Information ()	Information icons convey helpful information about configurations that may affect the flow of traffic. These issues do not prevent you from deploying.	The system might skip matching the first few packets of a connection against some rules, until the system identifies the application or web traffic in that connection. This allows connections to be established so that applications and HTTP requests can be identified.
Rule Conflict ()	When you enable rule conflict analysis, this icon appears in the rule table for rules that have conflicts.	Conflicts include redundant rules, redundant objects, and shadowed rules. Redundant and shadowed rules do not match traffic because previous rules would already match the criteria. Redundant objects make your rules unnecessarily complex.

Requirements and prerequisites for access control policies

Ensure that your environment meets these requirements before configuring access control policies.

- You must have **Administrator**, **Network Admin**, or **Access Admin** privileges to configure access control policies.
- Custom roles: You can define custom user roles to differentiate between the intrusion configuration in access control policy and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. The existing pre-defined user roles that included the Modify Access Control Policy permission support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions.
  - **Policies** > **Security policies** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** allows the selection of intrusion policy,

variable set, and file policy in a rule, the configuration of the advanced options for network analysis and intrusion policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. If a user has this option only, the user can modify no other part of the policy or rule.

- **Modify Remaining Access Control Policy Configuration** controls the ability to edit all other aspects of the policy.

Manage access control policies

Configure and manage access control policies by editing system-provided policies and creating custom access control policies.

Procedure

Step 1 Choose **Policies** > **Security policies** > **Access Control**.

At the top of the page, there are convenient links to some related features: Object management, Intrusion policies, Network Analysis policies, DNS policies, and policy Import/Export.

Step 2 These actions help you to manage your policy:

- Create—Click **Create Policy**; see Creating a basic access control policy, on page 1782.
- Edit—Click **Edit** (); see Editing an access control policy, on page 1783
- Delete—Click **Delete** (). You must remove any device assignments before deleting a policy.

  To delete more than one policy at a time, select the check boxes for the policies, then select **Delete Policies** above the table.
- Copy—Select **Clone** from the **More** () menu. Device assignments are not retained in the copy.
- Lock or unlock a policy—See Lock an access control policy, on page 1785.

Step 3 These options help you to analyze, monitor, and customize your policies:

- Analyze policy—Select one or more policy and then click **Analyze Policies** to evaluate access control policies for anomalies such as redundant or shadowed rules, and take action to fix discovered anomalies. The analysis job is sent to the cloud and takes time to complete. See Identify and fix anomalies with policy analyzer & optimizer, on page 1795.

  The Anomalies column shows the results of the analysis. Click the **% Optimizable** link to see the anomalies, or **Re-Analyze** to run the analysis again. The Last Analyzed column shows when Policy Analyzer & Optimizer was last run.

  After completing analysis and optimization, you can download the reports by selecting the following options from the **More** () menu: **Download Last Policy Analysis**, **Remediation History**.

Note To use the policy analysis feature, you must be using a Cloud-Delivered Firewall Management Center or an connected to Security Cloud Control (Security Cloud Control). If your setup does not meet requirements, the explanatory dialog that opens when you click this button includes an **Integrate** button to help get you started. Policy Analyzer & Optimizer operates in the cloud only.

- Columns—Click the **Show/Hide Columns** icon above the list of rules to select which information to show in the table. Click **Show All/Hide All** to quickly add or remove all listed columns, excepting name and actions. Click **Default** to undo all of your customizations.
- Inheritance—Vertical lines indicate inheritance relationships between policies.
- Report—Select **Generate Report** from the **More** (⋮) menu.. The report is generated as a background process. Go to the message/notifications center and look in the tasks list. When the report is finished, you can download it from the notification.
- View the audit log—Click **View Audit Log** from the **More** (⋮).

Creating a basic access control policy

When you create a new access control policy, it contains default actions and settings. After creating the policy, you are immediately placed in an edit session so that you can adjust the policy to suit your requirements.

Procedure

Step 1 Choose **Policies** > **Security policies** > **Access Control**.

Step 2 Click **Create Policy**.

Step 3 Enter a unique **Name** and, optionally, a **Description**.

Accented and other non-ASCII characters are not recommended in access control policy names.

Step 4 Optionally, choose a base policy.

If an access control policy is enforced on your domain, this step is not optional. You must choose the enforced policy or one of its descendants as the base policy.

If you select a base policy, the base policy defines the default action and you cannot select a new one in this dialog box. Logging for connections handled by the default action depends on the base policy.

Step 5 When you do not select a base policy, specify the initial **Default Action**:

- **Block all traffic** creates a policy with the **Access Control: Block All Traffic** default action.
- **Intrusion Prevention** creates a policy with the **Intrusion Prevention: Balanced Security and Connectivity** default action, associated with the default intrusion variable set.
- **Network Discovery** creates a policy with the **Network Discovery Only** default action.

When you select a default action, logging of connections handled by the default action is initially disabled. You can enable it later when you edit the policy.

Note If you want to trust all traffic by default, or if you chose a base policy and do not want to inherit the default action, you can change the default action later.

Step 6 Optionally, choose the devices to assign to the policy. To narrow the devices that appear, enter a search string. The list includes both devices and device templates.

If you want to deploy this policy immediately, you must perform this step.

Step 7 Click **Save**.

The new policy opens for edit. You can add rules to it and make other changes as needed. See Editing an access control policy, on page 1783.

Editing an access control policy

When you edit an access control policy, you should lock it to ensure that your changes do not get overridden by another person who might edit it simultaneously.

You can only edit access control policies that were created in the current domain. Also, you cannot edit settings that are locked by an ancestor access control policy.

To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Note When you edit a policy and do not lock it, a banner message might indicate that other users are currently editing the policy. When one of these users saves changes, you will be prompted to either merge or discard your changes. You should immediately decide what to do. For more information, see Merge concurrent edits to an access control policy, on page 1786 .

Procedure

Step 1 Choose **Policies** > **Security policies** > **Access Control** .

Step 2 Click **Edit** (✎) next to the access control policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Edit your access control policy.

Note You can operate on multiple rules at one time by selecting their checkboxes in the left column, then selecting the action you want to perform from the **Select Bulk Rule Actions** drop-down list next to the search box. Bulk editing is available for enabling and disabling, copying, moving, deleting, and editing rules, or viewing hit counts or related events. You can also remove object overlaps in the selected rules.

You can change the following settings or perform these actions:

- Name and description—Click **Edit** () next to the name, make your changes, and click **Save** .
- Default action and settings—Choose a value from the **Default Action** drop-down list, then click **Cog** () , make your changes to the settings, and click **OK** . For detailed information, see Configure the access control default action, on page 1788 .
- Associated policies—To edit or change policies in the packet flow, click the policy type in the packet flow representation below the policy name. You can select the **Prefilter Rules** , **Decryption** , **Security Intelligence** , and **Identity** policies. When necessary, click **Access Control** to return to the access control rules.
- Policy assignment—To identify the managed devices targeted by this policy, or enforce this policy in a subdomain, click the **Assigned: x devices** link. You can assign the policy to devices or device templates.
- Rules—To manage access control rules, and to inspect and block malicious traffic using intrusion and file policies, click **Add Rule** , or right-click an existing rule and select **Edit** or another appropriate action. The actions are also available from the **More** () button for each rule. See Create and edit access control rules, on page 1848 .
- Layout—Use the **Grid/Table View** icon above the list of rules to change the layout. Grid view provides color-coded objects in an easy-to-see layout. Table view provides a summary list so that you can see more rules at once. You can freely switch views without impacting the rules.
- Columns (table view only)—Click the **Show/Hide Columns** icon above the list of rules to select which information to show in the table. Click **Show/Hide Empty Columns** to quickly add, or remove, all columns that have no information, that is, you are not using those conditions in any rule. Click **Revert to Default** to undo all of your customizations.
- Analyze rule logic—You can select the following options from the **Analyze** menu to examine the logic of your rules:
  - **Manage Rule Hit Counts** —To view statistics on how many connections matched each rule. See View rule hit counts, on page 1797 .
  - **Enable/Disable Rule Conflicts** —Select whether you want to see information on whether rules interfere with each other. You can then view the results using the following commands. See Analyzing rule conflicts and warnings, on page 1799
    - **Show Warnings and Errors** —See whether there are rules with configuration issues that you need to address.
    - **Show Policy Warnings** —See whether there are configuration issues with the policy.
    - **Show Rule Conflicts** —See whether you have redundant or shadowed rules. These conflicts could prevent certain rules from ever being matched by connections, meaning either that you need to fix the match criteria, move the rule, or simply delete the rule.

Step 4 To change additional settings for the policy, select one of these options from the **More** drop-down arrow at the end of the packet flow line.

- **Encrypted Visibility Engine** —Whether to enable and configure the encrypted visibility engine. See Configure EVE, on page 2060 .
- **Advanced Settings** —To set preprocessing, decryption, identity, performance, and other advanced options. See Configure advanced settings for the access control policy, on page 2588 .
- **HTTP Responses** —To specify what the user sees in a browser when the system blocks a website request. See Choose HTTP response pages, on page 1889 .
- **Inheritance Settings** —To change the base access control policy for this policy, and to enforce this policy's settings in its descendant policies. See Choose a base access control policy, on page 1790 and Lock settings in descendant access control policies, on page 1790 .
- **Logging** —To set the default logging options for the policy.

Step 5 Click **Save** .

Lock an access control policy

Lock an access control policy to prevent other administrators from editing it, ensuring that your changes will not be invalidated if another administrator edits the policy and saves changes before you save your changes.

If you do not lock a policy, you might have to merge your changes if another user edits the policy simultaneously and saves changes first. For more information, see Merge concurrent edits to an access control policy, on page 1786.

The lock is for the access control policy itself. The lock does not apply to objects used in the policy. For example, another user can edit a network object that is used in a locked access control policy. Your lock remains in place until you explicitly unlock the policy, so you can log out and come back to your edits later.

When locked, other administrators have read-only access to the policy. However, other administrators can assign a locked policy to a managed device.

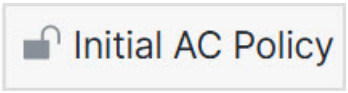
Before you begin

Any user role that has permission to modify the access control policy has permission to lock it, and to unlock a policy that was locked by another user.

However, the ability to unlock a policy that was locked by another administrator is controlled by the following permission: **Policies** > **Security policies** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Override Access Control Policy Lock**.

If you are using custom roles, your organization might have limited your unlocking abilities by not assigning this permission. Without this permission, only the administrator who locks a policy can unlock it.

Procedure



Step 1 Choose **Policies** > **Security policies** > **Access Control**.

Step 2 Click **Edit** (✎) next to the access control policy you want to lock or unlock.

In the access control policy list:

- A lock icon next to a policy name indicates that the policy is locked. Hover over the icon to see which user locked the policy.
- If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration. Or, it is locked by another user.

Step 3 Click the lock icon next to the policy name to lock or unlock the policy.

If the policy inherits settings from a parent policy, you must choose one of these options when you click the lock icon.

- **Lock/Unlock this policy**—The locking or unlocking is for this policy only.
- **Lock/Unlock all policies in hierarchy**—This policy and all parent policies are locked or unlocked. If a parent policy is already locked by another administrator, you will see a message and you will not be able to lock that parent policy. When unlocking policies, if you have the Override Access Control Policy Lock permission, all parent policies are unlocked even if they were locked by other users.

Merge concurrent edits to an access control policy

Handle conflicts when multiple users make changes to the same access control policy simultaneously, ensuring no critical changes are lost while maintaining policy integrity.

When you allow multiple users to edit an access control policy, you have two choices:

- Have users lock the policy when editing it. This ensures that a single user at a time can make changes. Using locking, you never have to worry about lost or conflicting changes. However, it limits your ability to respond quickly to unexpected events, especially if a user leaves the policy locked while out of the office. For more information about locking policies, see Lock an access control policy, on page 1785.
- Allow users to simultaneously edit the policy. If more than one user has made unsaved edits at a given time, the first user who saves the policy gets all of their changes saved. Other users are immediately notified of the save, and must then merge their changes. The rest of this topic explains this approach.

Note If you are using change management, where edits are done within the scope of a ticket, the ticket locks the policy and concurrent editing is not possible.

Before you begin

To limit the amount of merging you have to do, save the policy early and often.

Procedure

Step 1 Determine if other users are also editing the policy.

When you edit an access control policy, look for this message banner at the top of the page:

```
User name is currently editing this policy.
```

This message indicates that the named user (there might be more than one) currently have the policy open for edit.

Step 2 Watch for notifications that another user saved changes and take action.

This banner message indicates another user saved changes and you need to take immediate action:

```
User name modified this policy and saved changes. Merge Discard.
```

Click one of these links:

- **Merge**—Open a merge window where you can make decisions about which of your changes to keep or to discard, and to identify changes that cannot be merged. See the next step when taking this option.
- **Discard**—Discard all of your changes immediately and start over. If you select this option, the page is refreshed with the latest changes from the other user.

Step 3 Merge changes.

When you click the **Merge** option, a merge window opens with a summary of the total number of observed differences between your edits and the last user's saved edits. No other user's unsaved edits are included. Observations include direct conflicts and informational notifications.

Note You must complete all merge decisions before you close the window. You cannot wait until later once you click the **Merge** option.

a) Evaluate each conflict and make a decision for each.

When evaluating the change list, consider these points:

- Initially, all observations are shown, but you can select/deselect the filtering options for **Conflict** and **Info** to limit the displayed information. Conflicts arise when users edit the same rule or setting. Informational items are for edits to different rules or settings.
- If there are no conflicts, your cache is immediately updated with the last saved changes and you can proceed. For example, if you are editing rule 1, and the other user saved changes to rule 2, it is unlikely that there are any conflicts.
- For each conflict (other than rule name), the window shows the version of the element saved by the other user (**Version on Firewall Management Center**), and your changes (**Modified Version**). Changes are color-coded for new (e.g. an option that was not previously defined), edited, or deleted policy elements. You must select either to **Discard** your change, or to **Accept Mine** and overwrite the other user's change. When discarding a change, the rule is refreshed with the other user's saved change and yours is removed.

- Rule conflicts are considered at the rule level, not per element within the rule. For example, if you edit destination networks, and the saved changes are for source networks, either your changes or the other user's changes are retained, not both.
- If the conflict involves the name of a rule, the system tries to create a unique name by adding an underscore and number to the name, such as Rule_1. You can alternatively enter a new name in the edit box provided and click **Save**. If you click **Discard**, the generated rule name is used.
- You cannot skip any conflict. For each conflict, you must make a decision to discard or keep your change.
- If the user who saved changes deleted a rule that you edited, the rule is deleted and you do not have the option to keep the rule.
- If the user who saved changes updated a rule, and your change is to delete the rule, the rule is retained: you cannot merge your deletion.
- For these options, if your change conflicts with the saved changes, your change is discarded and merging the change is not an option:
  - Other policy assignments: prefilter, Security Intelligence, identity, decryption
  - Changes to advanced settings, policy logging, EVE, HTTP response pages.
  - Policy default action.
  - Inheritance settings.

b) Click **Close**.

Step 4 Once the merger is complete, you can either save the policy immediately or continue editing it. Saving the policy might reduce the impact of future merges.

Configure the access control default action

Configure the default action for an access control policy when connections do not match specific access control rules.

The default action for an access control policy is applied to any connection that:

- is not fast pathed by the prefilter policy
- is not on a Security Intelligence block list
- is not blocked by the decryption policy (encrypted traffic only)
- matches none of the rules in the policy (except monitor rules, which match and log—but do not handle or inspect—traffic)

Procedure

Step 1 Edit the access control policy whose inheritance settings you want to change; see Editing an access control policy, on page 1783.

Step 2 Select the **Default Action** at the bottom of the rules list.

For detailed information on what each option does, see Access control policy default actions, on page 1776.

Step 3 Click **Cog** ( ) to configure the default action settings.

You can configure the following options. Click **OK** when finished.

- Logging options—Whether to log the connection. You can **Log at beginning of connection**, **Log at end of connection**, or both. If you select block as the default action, you can log at the beginning of the connection only.
- **Send connection events to**—If you select one of the logging options, select whether to send events to any combination of the following:
  - **Firewall Management Center**—Send events to the manager.
  - **Syslog server**—Send events to the default syslog server configured for the policy. You can configure overrides to specify a different severity level or syslog server destination.

  (Splunk or SIEM syslog server integration) If you have configured Firewall Management Center as the source of connection events in Splunk configuration, choose **Firewall Management Center** under **Send Connection Events to** options. If you have configured Firewall Threat Defense as the connection event source, select at least one syslog destination. For Splunk or any SIEM syslog configuration procedure, see the *Cisco Secure Firewall Management Center Administration Guide*.
- **SNMP trap**—If you enable logging, you can send SNMP traps to an SNMP server. Select an SNMP configuration, or click **+** to configure a new one.
- **Default action variable set**—If you selected one of the intrusion prevention default actions, select the variable set that should be used with the intrusion policy you selected.

Step 4 Click **Save**.

Manage access control policy inheritance

Inheritance relates to using another policy as a base policy for an access control policy. This allows you to use one policy to define some baseline characteristics that can be applied to multiple policies. To understand how inheritance works, refer to Access control policy inheritance, on page 1778.

Procedure

Step 1 Edit the access control policy whose inheritance settings you want to change; see Editing an access control policy, on page 1783.

Step 2 Manage policy inheritance:

- Change base policy — To change the base access control policy for this policy, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line and proceed as described in Choose a base access control policy, on page 1790.
- Lock settings in descendants — To enforce this policy's settings in its descendant policies, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line and proceed as described in Lock settings in descendant access control policies, on page 1790.
- Inherit settings from base policy — To inherit settings from a base access control policy, proceed as directed in Inherit access control policy settings from the base policy, on page 1791.
- Required in domains — To enforce this policy in a subdomain, click the **Assigned: x devices** link and proceed as described in Enforce an access control policy in a domain, on page 1792.

Choose a base access control policy

Choose a base access control policy to establish policy inheritance, allowing a child policy to inherit rules and settings from its parent while maintaining the ability to modify unlocked configurations.

When you change the base policy for the current access control policy, the system updates the current policy with any locked settings from the new base policy.

Procedure

Step 1 In the access control policy editor, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 2 Choose a policy from the **Select Base Policy** drop-down list.

To remove inheritance, select **None**.

Step 3 Click **OK**.

Step 4 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Lock settings in descendant access control policies

Lock a setting in an access control policy to enforce the setting in all descendant policies.

Descendant policies can override unlocked settings. When you lock settings, the system saves overrides already made in descendant polices so that the overrides can be restored if you unlock settings again.

Procedure

Step 1 In the access control policy editor, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 2 In the Child Policy Inheritance Settings area, check the settings you want to lock.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration.

Step 3 Click **OK** to save the inheritance settings.

Step 4 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Inherit access control policy settings from the base policy

Configure a child access control policy to inherit settings from a base policy or override them with custom configurations.

Child access control policies inherit many settings from their base policy by default. If these settings are unlocked in the base policy, you can override them.

If you later reinherit the settings from the base policy, the Firewall Management Center displays the base policy's settings and dims the controls. However, it saves the overrides you made and restores them if you disable inheritance again.

Procedure

Step 1 In the access control policy editor, click **Security Intelligence**, or select **HTTP Responses**, **Logging**, **Encrypted Visibility Engine**, or **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line

Step 2 Check the **Inherit from (*base policy*)** check box for each setting you want to inherit.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration.

Step 3 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Enforce an access control policy in a domain

Require that every device in a domain use the same base access control policy or one of its descendant policies.

This procedure is relevant in a multi-domain deployment only.

Procedure

Step 1 In the access control policy editor, click the **Assigned: x devices** link.

Step 2 Click **Required on Domains**.

Step 3 Build your domain list:

- Add — Select the domains where you want to enforce the current access control policy, then click **Add** or drag and drop into the list of selected domains.
- Delete — Click **Delete** ( ) next to a leaf domain, or right-click an ancestor domain and choose **Delete Selected**.
- Search — Type a search string in the search field. Click **Clear** ( ) to clear the search.

Step 4 Click **OK** to save the domain enforcement settings.

Step 5 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Assign access control policy to devices

An access control policy specifies the devices that use it. Each device can be assigned to only one access control policy. You can also assign the policy to device templates. Templates are included in the list of available and selected devices.

Procedure

Step 1 In the access control policy editor, click the **Assigned to x devices** link.

Step 2 Build your target list:

- Add — Select one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**.
- Delete — Click **Delete** ( ) next to a single device, or select multiple devices, right-click, then choose **Delete Selection**.
- Search — Type a search string in the search field. Click **Clear** ( ) to clear the search.

Under **Impacted Devices**, the system lists the devices whose assigned access control policies are children of the current policy. Any change to the current policy affects these devices.

Step 3 Assign the access control policy to devices:

- Add — Select one or more **available devices**, then click the **Right Arrow** () icon or drag and drop into the list of **assigned devices**.
- Delete — Click the **Delete** () next to a device, or select multiple devices, and then click the Left Arrow .
- Search — Type a search string in the search field. Click **Clear** () to clear the search.

Step 4 Click **OKApply** to save your assigned device settings.

Step 5 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Logging settings for access control policies

Logging settings for access control policies are configuration option that allow you to configure default syslog destinations for the current access control policy. The settings are applicable to the access control policy and all the included decryption, prefilter, and intrusion policies unless the syslog destination settings are explicitly overridden with custom settings in included rules and policies.

To configure logging settings for an access control policy, select **Logging** from the **More** drop-down arrow at the end of the packet flow line.

You can configure default syslog destinations and syslog alert for the access control policy. The settings are applicable to the access control policy and all the included decryption, prefilter, and intrusion policies unless the syslog destination settings are explicitly overridden with custom settings in included rules and policies.

Logging for connections handled by the default action is initially disabled.

Intrusion settings and file and malware settings are effective only after you have selected an option at the top of the page for sending syslog messages generally.

Default logging settings

Default logging settings displays the defaul logging preferences configured for the new access control rules. When enabled, new rules in all access control policies use the default settings automatically. You can override the settings for individual rules.

This section is view-only. To change the default logging preference, refer to *Access Control Preferences* in the *Cisco Secure Firewall Management Center Administration Guide*.

Default syslog settingsEvent log destination

Default syslog settingsEvent log destination provide two destination options:

- **Destination** > ***Specific Syslog alert object***: Events are sent based on the selected syslog alert as configured using the instructions in *Creating a Syslog alert Response* in the *Cisco Secure Firewall Management Center Administration Guide*. You can select the syslog alert from the list or add one by specifying the name, logging host, port, facility, and severity.

When using this option, the system sends syslog messages to the server using the Management interface. Ensure there is a route from the Management interface to the syslog server, or messages will not arrive at the server.

- **Destination** > **Use FTD Platform Settings**: Connection or intrusion events are sent with the selected severity to syslog collectors configured in Platform Settings. Using this option, you can unify the syslog configuration by configuring it in platform settings and reusing the settings in access control policy. Severity selected in this section is applied to all connection and intrusion events. The default severity is alert.

Intrusion settings

Intrusion settings include these options:

- **Send syslog messages for intrusion events**: Send intrusion events as syslog messages. The defaults set above are used unless you override them.
- **Show overrides** or **Hide overrides**: If you want to use the default syslog destination and severity, leave these options empty. Otherwise, you can set a different syslog server destination for intrusion events, and change the severity of the events.

File and malware settings

File and malware settings include these options:

- **Send syslog messages for file and malware events**: Send file and malware events as syslog messages. The defaults set above are used unless you override them.
- **Show overrides** or **Hide overrides**: If you want to use the default syslog destination and severity, leave these options empty. Otherwise, you can set a different syslog server destination for file and malware events, and change the severity of the events.

AI defense settings

Associate prefilter, decryption, and identity policies with an access control

Associate subpolicies with an access control policy to create a comprehensive security framework that handles different aspects of network traffic processing.

The easiest way to associate subpolicies to an access control policy is by clicking the policy's link in the packet flow shown at the top of an access control policy. Alternatively, you can use the policy's advanced settings to associate the subpolicy, as described in this topic. The subpolicies that you can associate with access control policy are:

- Prefilter policy—Performs early traffic handling using limited network (layer 4) outer-header criteria.
- Decryption policy—Monitors, decrypts, blocks, or allows application layer protocol traffic encrypted with Secure Socket Layer (SSL) or Transport Layer Security (TLS).
- Identity policy—Performs user identification based on the realm and authentication method associated with the traffic.

Before you begin

Before associating a decryption policy with an access control policy, review the information about TLS server identity discovery in TLS server identity discovery, on page 2592.

Procedure

Step 1 In the access control policy editor, select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 2 Locate the policy settings area for prefilter, decryption, or identity policies.

Step 3 Click **Edit** (✎) in the corresponding policy settings area.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 Choose a policy from the drop-down list.

If you choose a user-created policy, you can click the edit icon that appears to edit the policy.

Step 5 Click **OK**.

Step 6 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Identify and fix anomalies with policy analyzer & optimizer

Use the Policy Analyzer & Optimizer to evaluate access control policies for anomalies such as redundant or shadowed rules, and take action to fix discovered anomalies.

The Policy Analyzer & Optimizer is hosted in the cloud and is different from the rule analysis available when you are not integrated with the cloud. The non-cloud policy analysis is not available once you integrate with the cloud.

The system automatically performs policy analysis on a daily basis (every 24 hours). You can also manually start an analysis. When you initially enable the service, the system starts an analysis of all existing access control policies.

Note Before optimizing a policy, create a copy of the policy. If you are then dissatisfied with the results of optimization, you can easily reassign the managed devices to the copy and return the system to its starting state.

Before you begin

- You can use Policy Analyzer & Optimizer directly from Security Cloud Control with Firewall Management Center 7.2+, but you can cross-launch the feature starting with 7.6 only. The software version running on the managed devices assigned to the access control policies does not matter. Policy Analyzer &

Optimizer is hosted in the cloud only, so whether you run the analysis from within the Firewall Management Center or directly from Security Cloud Control does not make a difference.

- To use the feature, you must select **Enable Policy Analysis & Optimization** when you integrate with the Cisco Security cloud, under **Integrations** > **Security Cloud Control**.
- If you have enabled change management, Policy Analyzer & Optimizer automatically creates a ticket for the changes, and submits the ticket. The approver must approve the ticket before the changes can be deployed.
- If you are using domains, you cannot click the link in the Anomaly column to see the report. Instead, log into Security Cloud Control and use the feature from that application.
- Policy Analyzer & Optimizer adds rule comments on rules that are updated, disabled, or merged. You can later search on these comments to find optimized rules.
- Changes implemented by Policy Analyzer & Optimizer are reflected in the audit log as API calls under the default name internaladmin.
- After enabling Policy Analyzer & Optimizer, the system evaluates changes every time a rule is added or edited. Users are notified when applying a rule edit if the change will create anomalies such as redundant or shadowed rules.

Procedure

Step 1 Choose **Policies** > **Security policies** > **Access Control**.

If you have already run an analysis, the Anomaly column shows the number of issues with the policy and the percentage the policy can be optimized, and the state of the policy analysis, such as Error or Completed. Last Analyzed shows the date/time when the analysis was run.

Step 2 Select one or more policy, then click **Analyze Policy**.

The analysis runs as a background process in the cloud. When the analysis is complete, the results appear in the Anomaly column.

Notes:

- You can also start an analysis when editing the policy by selecting **Analyze** > **Policy**. Other options from that menu allow you to show hit counts and warnings.
- If you have not connected to the cloud yet, the explanatory dialog that opens when you click this button includes an **Integrate** button to help get you started. Policy Analyzer & Optimizer operates in the cloud only.

Step 3 When the analysis is complete, click the **% Optimizable** link in the Anomaly column to launch Policy Analyzer & Optimizer in the cloud.

When you have done all the actions you want to take, click **Apply Remediations** (in the cloud). You are shown a confirmation of what will be done. Click **Proceed** to implement the changes.

If the initial analysis ended in an error, you could instead click **Re-analyze** to restart the process.

Step 4 Deploy the policy to complete the changes.

If you have change management enabled, the approver must first approved the ticket that contains the remediations before you can deploy them.

View rule hit counts

Hit count indicates the number of times a policy rule or default action has been matched to a connection. The hit count is incremented only for the first packet of a connection that matches a rule. You can use this information to identify the efficacy of your rules. Hit count information is available only for access control and prefilter rules applied to Firewall Threat Defense devices.

Note

- The count persists through reboots and upgrades.
- Counts are maintained by each unit in an HA pair or cluster separately.
- You will not be able to derive the hit count information from a device when deployment or a task is in progress on the device.
- You can also see rule hit count information in the device CLI using the **show rule hits** command.
- If you have accessed the Hit Count page from the Access Control Policy page, you will not be able to view or edit prefilter rules and vice-versa.
- Hit counts are not available for rules that use the Monitor action.

Before you begin

If you use custom user roles, ensure that the roles include these privileges:

- View Device, to see the hit counts.
- Modify Device, to refresh the hit counts.

Follow these steps to view rule hit counts:

Procedure

Step 1 In the access control policy or prefilter policy editor, click **Analyze** > **Manage Rule Hit Counts** on the top-right of the page.

Step 2 On the Hit Count page, select the device from the **Select a device** drop-down list.

If it is not the first time that you are generating hit counts for this device, the last fetched hit count information appears next to the drop-down box. Also, verify the **Last Deployed** time to confirm recent policy changes.

Select **All** to see an aggregate of hit counts across all devices assigned to the policy.

Step 3 If necessary, click **Refresh** ( ) to obtain current hit count data from the selected device.

In the prefilter policy, you might need to click **Fetch Current Hit Count** to get initial hit count data.

You cannot refresh the hit count while deployment to the device is in progress.

Step 4 View and analyze the data.

You can do these actions:

- Click **Prefilter** or **Access Control** to switch between the hit counts for these policies.
- Search for a specific rule by entering a search string in the **Filter** box.
- Broadly limit the list to **Hit Rules** or **Never Hit Rules** by selecting these options in the **Filter by** field. When viewing hit rules, you can further limit the list by selecting a time range in the **In Last** field (for example, in the last 1 day).
- (When viewed from the access control policy.) Clear the hit counts for one or more rule by selecting the checkbox for the rule, then clicking **Clear Hit Counts**. When confirming the action, choose **Clear and Reload** to refresh the hit count data. You can clear hit counts for up to 500 rules at a time. You cannot undo clearing hit counts.

Note Click the checkbox in the table header to select all rules visible in the list. To select a range of rules, select the first rule's checkbox, then **`Shift+click`** the last rule's checkbox; all rules in between are also selected.

- (When viewed from the access control policy.) You can do these actions with individual rules:
  - Edit the rule by clicking **Edit** from the **More** (⋮) menu.
  - Delete the rule from the policy by clicking **Delete** from the **More** (⋮) menu.
  - Enable or disable the rule by clicking **Enable Rule** or **Disable Rule** from the **More** (⋮) menu.
  - Clear the hit count (reset it to zero) for the rule by clicking **Clear Hit Count** from the **More** (⋮) menu. You cannot undo this action.
- (When viewed from the access control policy.) You can do these actions with individual rules:
  - Edit the rule by clicking **Edit** (✎).
  - Delete the rule from the policy by clicking **Delete** (🗑).
  - Enable or disable the rule by clicking the **Slider** (⬭).
  - Clear the hit count (reset it to zero) for the rule by clicking the **X** for the rule. You cannot undo this action.
- Change the displayed columns by clicking ▥ and selecting the columns to show. When viewed from the prefilter policy, use the **Cog** (⚙) to select the columns to display.
- (When viewed from the prefilter policy.) Click on a rule name to edit it, or click **View** (👁) in the last column to view the rule details. Clicking on the rule name highlights it in the policy page where you can edit it.

- (When viewed from the prefilter policy.) Clear the hit count information (reset it to zero) for a rule by right-clicking the rule and selecting **Clear Hit Count**. You can select multiple rules by using Ctrl+click. You cannot undo this action.

Step 5 Optionally, you can generate a comma-separated values report of the details on the page by clicking **Generate CSV** on the bottom-left of the page.

Step 6 Click **Close** to return to the policy page.

Analyzing rule conflicts and warnings

View warnings and information about rule conflicts to examine the logic of your access control policy and to identify rules that need changes.

Note The feature described in this topic is available only if you do not integrate with the Security Cloud Control. When you integrate with the cloud, the more powerful Policy Analyzer & Optimizer replaces this feature. See Identify and fix anomalies with policy analyzer & optimizer, on page 1795.

When rules overlap, you can end up with unnecessary rules in the policy, and these rules will never be matched to traffic. The analysis can help you delete unnecessary rules, or identify rules that should be moved or modified so they enforce the desired policy.

Policy warnings and errors point out things that you should understand and perhaps address to ensure that your rules provide the desired services.

Rule conflict analysis identifies these problems:

- Object overlap—An element in a field of a rule is a subset of one or more elements in the same field of the rule. For example, the source field might include a network object for 10.1.1.0/24, and another object for the host 10.1.1.1. Because 10.1.1.1 is within the network covered by 10.1.1.0/24, the object for 10.1.1.1 is redundant and can be deleted, simplifying the rule and saving device memory.
- Redundant rule—Two rules apply the same action to the same type of traffic and removing the base rule would not change the ultimate result. For example, if a rule permitting FTP traffic for a particular network were followed by a rule allowing IP traffic for that same network, and there were no rules in between denying access, then the first rule is redundant and you can delete it.
- Shadowed rule—This is the reverse of a redundant rule. In this case, one rule will match the same traffic as another rule such that the second rule will never be applied to any traffic because it comes later in the access list. If the action for both rules is the same, you can delete the shadowed rule. If the two rules specify different actions for traffic, you might need to move the shadowed rule or edit one of the two rules to implement your desired policy. For example, the base rule might deny IP traffic, and the shadowed rule might permit FTP traffic, for a given source or destination.

Before you begin

When doing the analysis:

- Only the first conflict for a given rule is identified. Once you fix the problem, the rule might be identified as having a conflict with another rule in the table. However, a rule might have multiple warnings or errors.

- Rule conflict analysis considers source/destination security zone, network, VLAN, and service/port match conditions and action only. It does not consider other match criteria, so an apparently redundant rule might not be completely redundant.
- FQDN network objects cannot be analyzed for conflict, because the IP address of an FQDN cannot be known prior to DNS lookup.
- Disabled rules are ignored.
- Time range attributes are ignored. Rules for different time periods might be marked as redundant when they are not actually redundant for the time ranges.
- Icons for warnings and errors, and rule conflicts when you enable the feature, are shown in the rules table. For a reference to the icons, see Rule and other policy warnings, on page 1779.

Procedure

Step 1 Choose **Policies** > **Security policies** > **Access Control** and edit an access control policy.

Step 2 Do one of these to open the rule conflicts and warnings dialog box:

- To view rule conflicts, click the **Analyze** drop-down and click **Enable Rule Conflicts**. When the analysis completes, you see a summary of the conflicts at the top of the page. Then, click **Show Rule Conflicts** from the same menu to see the specific results.

  You must re-enable rule conflict detection each time you open the policy or make a change and save the policy.
- To view rule warnings and errors, click **Analyze** > **Show Rule Warnings and Errors**.

  After you make a change to the policy, you can refresh the results by clicking the reload icon next to the **Analyze** button.
- To view policy warnings, click **Analyze** > **Show Policy Warnings**.
- If you are finished viewing rule conflicts, click **Analyze** > **Disable Rule Conflicts**.

Step 3 In the rule conflicts and warnings dialog box:

- Rule warnings and errors are shown on a separate tab from rule conflicts. There is also a separate tab for policy warnings.
- Each tab contains sub-tabs to let you examine individual types of problems, such as redundant vs. shadowed or warnings vs. errors. You can also search for an item.
- **More** (⋮) next to each rule name provides shortcuts to edit, disable, or delete the rule.

Step 4 Click **Close** when finished.

Search for rules

Use search to help you find rules, especially when you have a large number of them.

Procedure

Step 1 When editing an access control policy, build the search string by clicking in the **Search** box.

- For a simple text string search, type the string. The search returns rules that have that string in any column. You cannot do a string search in conjunction with a tag search, such as combining a string search with a source networks search.
- To search on a specific column, start typing the name of the column until the system prompts you with the full name, such as Source Networks, or select the name from the list of searchable fields. When you select the search tag, you can then enter the search string for that tag. For example, **Source Networks 10.1.1.1**.
- When searching for IP addresses within the source/destination columns (but not as a simple text search), you can use the **Seach Inside Subnets and Ranges** option to control whether you eactly match the IP address (unchecked) or match any subnet or range that includes the searched address (checked). For example, with the option checked, searching for 10.1.1.1 will include rules for 10.1.1.0/24.
- Searches in the port field return exact match only.
- When entering mulitple values, separate the values with commas.
- When building a search string with multiple tags, do not include spaces between the tags.
- When you select a tag, you are prompted with values that appear in those columns. Select the values you want to search for.
- You can quickly filter based on some common features by clicking the filter icon to the left of the search box and selecting to show rules with any combination of the following: Allow, Block, Monitor, Intrusion Policy, Time Range, Conflicts, Warnings, Errors, Disabled rules, expired rules, High expansion rules, rules that include objects whose definitions overlap..
- To see the rules that apply to a specific device or set of devices, click the filter icon and select the devices. Rules apply to a device if they use security zones that contain at least one interface on the device, or if they do not include security zones.

Step 2 With your cursor at the end of the search string in the search box, press Enter.

The rules that satisfy the search string are highlighted and non-matching rules are hidden. You can deselect **Show Only Matching Rules** to see the entire table, with the highlighted rules within the table. This lets you see the surrounding rules.

Beside the Show Only Matching Rules checkbox is a summary of the total number of rules in the policy compared to the number that match the search string.

Step 3 After your first search, clicking in the search box prompts you with recent searches and tags. You can quickly repeat a search by selecting it, or build similar searches by selecting previous searches or tags and building on them.

Step 4 To close the search and return to the unfiltered and unhighlighted table, click the **X** at the right of the search box. You can also put your cursor at the end of the search string and press the Esc key.

Access control rule expansion

A single access control rule can expand into many Access Control Entries (ACEs) on a device. Expansion increases when a rule contains nested source networks, destination networks, source ports, destination ports, virtual LAN tags, source security zones, destination security zones, inline values, objects, and object groups.

Object Group Search, Interface Object Optimization, and Object Group Optimization affect the memory calculation.

- Object Group Search groups network objects efficiently and changes the memory model used for validation. When Object Group Search is enabled, Firewall Management Center skips descriptor-limit validation for the Object Group Search path.
- Interface Object Optimization controls whether Firewall Management Center keeps zones grouped or expands zones into individual interfaces for access control list combinations. When Interface Object Optimization is disabled, source and destination security-zone interface combinations can multiply the access control list footprint.
- Object Group Optimization merges overlapping inline networks into fewer network entries when possible. When Object Group Optimization is disabled, Firewall Management Center counts inline literals and ranges directly. This approach can increase the projected footprint.

Rule expansion and memory calculation inputs

This table describes the factors considered for memory calculation and how they affect rule expansion.

Input	How it affects expansion	Where administrators review it
Virtual LAN tags	Virtual LAN tag combinations contribute to rule expansion.	Access control rule conditions
Networks and ports	Large inline lists, objects, object groups, and nested groups can multiply Access Control Entry counts.	Access control rule conditions
Security zones	Zone-to-interface expansion can increase access control list combinations when Interface Object Optimization is disabled.	Access control rule conditions and device settings
Object Group Optimization	Optimization can reduce overlapping inline network entries.	**Administration** > **Configuration** > **Access Control Preferences** > >
Object Group Search	When enabled, Object Group Search affects memory modeling and bypasses descriptor-limit validation.	Device settings
Device capacity data	Live memory and object counts determine deployment warning or block decisions.	Device command outputs collected during deployment validation

Access control rule capacity validation

You can enable access control rule capacity validation to detect policies that expand into high Access Control Entry (ACE) counts before deployment. Firewall Management Center calculates expansion when you open or edit an access control policy. It shows policy-level and rule-level warnings, and provides a High expansion rules filter.

Firewall Management Center warns when available memory approaches the configured limit. It blocks deployment if the projected policy can exceed safe memory or descriptor limits. A new "Heavy Rule" filter allows you to identify and optimize the high memory consumption rules.

Policy-level and rule-level warnings

Firewall Management Center shows a policy-level warning when a managed device reaches its policy expansion threshold or is projected to be at a risk of warning or blocking. From the warning message, you can select the impacted device and view the high expansion rules that contribute to the risk.

Firewall Management Center also displays rule-level warnings during rule creation or editing when a rule exceeds expansion limits for the selected policy or device scope. Rule-level warnings help administrators identify the rule conditions to optimize before deployment. These conditions include networks, ports, virtual LAN tags, security zones, inline values, objects, and nested object groups.

Deployment validation

When you deploy an access control policy, Firewall Management Center first recomputes policy impact using live device data, enabled access control rules, and enabled prefilter rules associated with the access control policy. The validation results in an allow, warning, or block decision based on several conditions.

- Firewall Management Center checks the memory utilization—available memory is below 5 percent, required memory exceeds available memory, projected post-deployment utilization reaches 95 percent, or descriptor limits are exceeded on the non-Object Group Search path.
- For devices that do not support the required device commands, are offline, or are unreachable, Firewall Management Center skips deployment validation for that device.
- Policy-level warnings, rule-level warnings, and high expansion rule filtering continue to use predicted ACE counts and cached device metadata.

Note When you change an access control policy, a memory-related warning can appear for an assigned device if used device memory exceeds 80 percent, even when the policy is below the Heavy Rule threshold and the Heavy Rule filter displays no rules. The memory warning reflects the device's current memory utilization, while the Heavy Rule filter evaluates policy expansion against the configured threshold. Review the warning details and the device memory condition before optimizing access control rules.

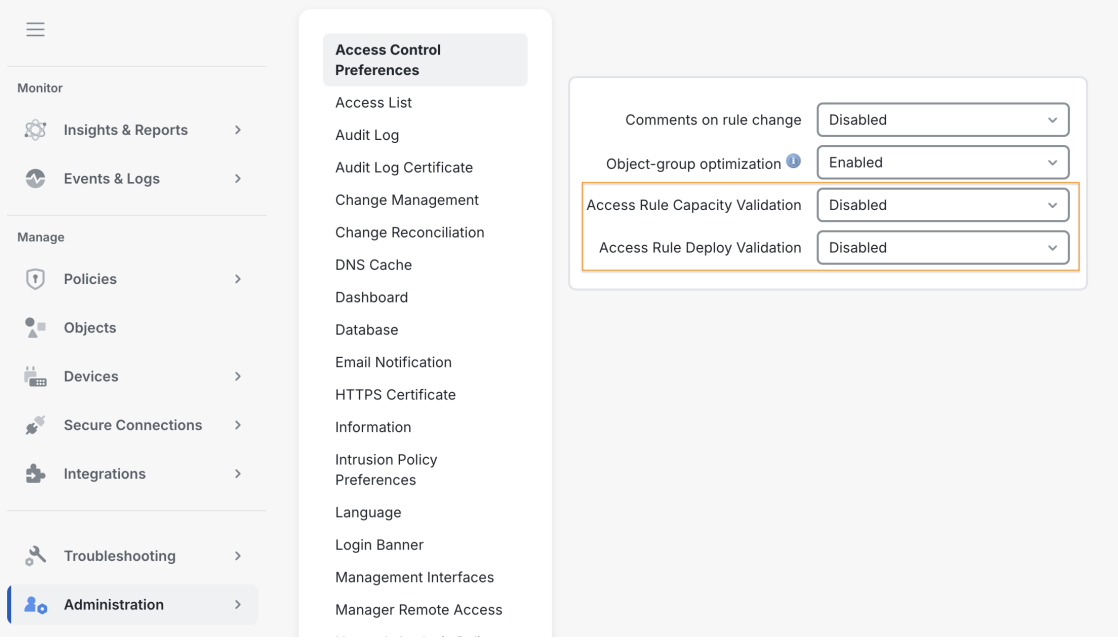
Pre-deployment validations run when the access control policy has changed and is not synchronized to the managed device. This table provides methods and results of access control policy validation performed before deployment.

Outcome	Condition
BLOCK	Required memory exceeds free memory on the device.

Outcome	Condition
BLOCK	Projected utilization of memory ((Used + Required) / Total) crosses the 95 percent ceiling.
BLOCK	Object or descriptor limit is exceeded. (Object Group Search disabled only)
WARN	Available memory on the device is between 5 percent and 20 percent, and no block condition is present
SKIP	Capacity data is unavailable or the command-line interface is unsupported. No block and no warning. Deployment proceeds.

Configure access control rule validataion

Configure and verify that Firewall Management Center can show policy warnings, rule warnings, high expansion rule filters, and deployment validation results.



Access rule capacity validation is enabled by default. Use these tasks to verify the setting, find high expansion rules, optimize rules, and respond to deployment validation.

Procedure

Step 1 In the Firewall Management Center menu, choose **Administration** > **Configuration** > **Access Control Preferences**.

Step 2 Confirm that **Access Rule Capacity Validation** and **Access Rule Deploy Validation** are enabled. These settings are enabled by default.

Step 3 To disable the feature, turn off these two options in the **Access Control Preferences** page.

Step 4 Click **Save**.

View high expansion rules for a policy

Use the High expansion rules filter to identify rules that contribute the most to policy expansion.

Procedure

Step 1 In the Firewall Management Center menu, choose **Policies** > **Security policies** > **Access Control**.

Step 2 Edit the access control policy.

Step 3 Click Filter presets (**Filter**( ) in the access policy search panel.

Step 4 In the **Show** options, select **High expansion rules**.

Step 5 Click **Apply**.

Firewall Management Center lists the high expansion rules for the policy scope. In this mode, the calculation uses domain-level object overrides and does not use device-specific security-zone calculations.

View high expansion rules for an impacted device

Examine rules with high expansion in the access control policy to identify those affecting a particular device.

Procedure

Step 1 In the Firewall Management Center menu, choose **Policies** > **Security policies** > **Access Control**.

Step 2 Edit the access control policy.

Step 3 Click Filter presets (**Filter**( ) in the access policy search panel.

Step 4 In the **Show** options, select **High expansion rules**.

Step 5 Select a managed device from the **Device** drop-down list.

Step 6 Click **Apply**.

Firewall Management Center lists high expansion rules for the selected device. The calculation includes device overrides and security zones for that device.

Optimize a high expansion rule

Reduce the rule contribution to the Access Control Entry count before deployment.

1. Open the rule that shows a rule-level warning or appears in the high expansion rule list.
2. Apply the high expansion rules filter again to confirm that the rule no longer drives excessive expansion.
3. Review source networks, destination networks, source ports, destination ports, virtual LAN tags, source security zones, destination security zones, inline values, objects, and nested object groups.
4. Remove unnecessary objects or inline values, reduce overly broad nested object groups, or adjust optimization settings when the change matches the policy intent.
5. Remove overlapping rules.
6. Save the rule.

Deploy Policy Analyzer and Optimizer

If the high expansion rules filter does not help reduce the number of access control entries (ACE), use the Policy Analyzer and Optimizer feature to detect common design anomalies, including duplicate rules, overlapping objects, expired rules, and mergeable rules.

As a cloud-delivered feature, Policy Analyzer and Optimizer is available in Security Cloud Control. You can access the feature directly in Security Cloud Control or by using a cross-launch from Firewall Management Center.

To learn more, refer to Policy Analyzer and Optimizer.

Deployment validation status outcomes

Review the deployment validation results to decide whether to proceed, optimize configurations, or retry deployment.

1. Start deployment for the access control policy.

2. Review the validation message.
3. If the system shows a memory warning, review and optimize high expansion rules before the next deployment cycle.
4. If the system blocks deployment, return to the access control policy. Apply the High expansion rules filter. Optimize the heavy rules. Retry deployment.
5. If validation is skipped for an unsupported, offline, or unreachable device, use policy-level and rule-level warnings to reduce risk before deployment.

Deployment proceeds only when the policy remains within the supported memory and descriptor conditions for the device.

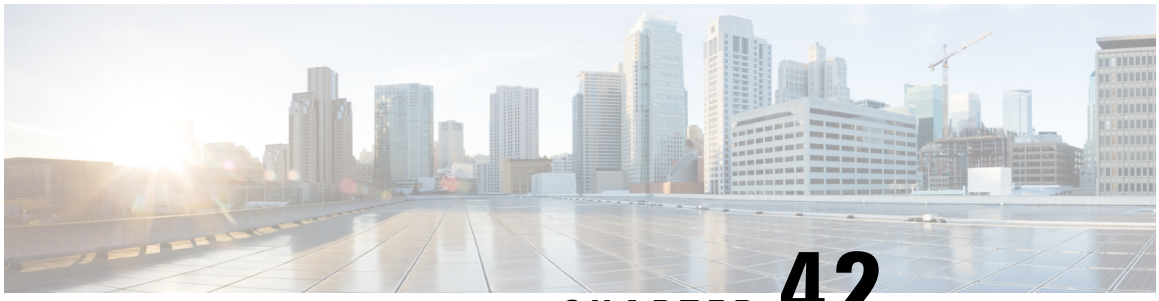
Troubleshooting commands

Lists the key troubleshooting commands with their purpose for analyzing access rule expansion issues.

Run these commands in the appropriate diagnostic or privileged execution mode on the device.

Command	Purpose
show memory	Provides available, used, and total memory and the free-memory percentage. Run the command from system support diagnostic-cli mode on the device.
show access-list element-count	Provides current Access Control Entry and access control list counts. Collect this information when the validation issue occurs.
show object-group count	Provides object-group usage, including IPv4 and IPv6 object counts. Collect this information along with policy and device details.
show asp table network-object count	Provides source and destination network-object counts. Use this command for Object Group Search-related sizing.
show dns fqdn-stats	Provides fully qualified domain name distribution and names in the training troubleshooting flow.

History for access control policies



This history table provides a comprehensive history of feature changes for access control policies in Cisco Secure Firewall Management Center across releases.

Table 101: Access control policy feature history by release

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Access control rule validation	10.1	10.1	Access control rule validation prevents device crashes by verifying that configurations remain within memory and capacity limits before deployment. The system displays warnings when access control policies approach device thresholds or when individual rules consume 10% or more of the total access control entries (ACE) limit. A new "Heavy Rule" filter allows administrators to identify and optimize these high-consumption rules. Additionally, the system blocks deployments that exceed memory or configuration limits to protect device stability. These controls proactively prevent performance issues and reduce the need for troubleshooting.
Simultaneous editing of access control policies by multiple users.	10.0.0	Any	In previous releases, if two or more users simultaneously edited an access control policy, the first user who saved would retain their changes, and all other users would immediately lose all of their edits. Now, these users have the ability to selectively merge their changes, and changes that do not conflict with the first user's saved changes will automatically be accepted. This improves collaboration between users and reduces the need to lock the policy during edits.
Object group search performance enhancements	7.6.0	7.6.0	Object group search is now faster and uses fewer CPU resources. New CLI commands: **clear asp table network-object**, **show asp table network-object**, **debug acl ogs** Modified CLI comments (enhanced output): , **packet-tracer**, **show access-list**, **show object-group**
Policy Analyzer & Optimizer for access control	From mgmt. center: 7.6.0 From Security Cloud Control: 7.2.0	Any	The Policy Analyzer & Optimizer evaluates access control policies for anomalies such as redundant or shadowed rules, and can take action to fix discovered anomalies. You can launch the access control Policy Analyzer & Optimizer directly from a Version 7.6+ Firewall Management Center; this requires Security Cloud Control. For Versions 7.2–7.4 Firewall Management Centers, use Security Cloud Control. New/modified screens: • To enable: **Integration** > **Cisco Security Cloud** > **Enable Policy Analyzer & Optimizer** • To analyze policies: **Policies** > **Access Control**, select policies, click **Analyze Policies**.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Granular permissions for modifying access control policies and rules.	7.4.0	Any	You can define custom user roles to differentiate between the intrusion configuration in access control policies and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. When defining user roles, you can select the **Policies** > **Access Control** > **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** option to allow the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for Network Analysis and Intrusion Policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. You can use the **Modify Remaining Access Control Policy Configuration** to control the ability to edit all other aspects of the policy. The existing pre-defined user roles that included the Modify Access Control Policy permission continue to support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions.
New access control policy user interface and rule conflict analysis.	7.3.0	Any	The access control policy user interface introduced in 7.2 is now the default interface. You can also enable rule conflict analysis to help identify redundant rules and objects, and shadowed rules that cannot be matched due to previous rules in the policy.
Access control policy locking.	7.2.0	Any	You can lock an access control policy to prevent other administrators from editing it. Locking the policy ensures that your changes will not be invalidated if another administrator edits the policy and saves changes before you save your changes. Any user who has permission to modify the access control policy has permission to lock it. We added an icon to lock or unlock a policy next to the policy name while editing the policy. In addition, there is a new permission to allow users to unlock policies locked by other administrators: Override Access Control Policy Lock. This permission is enabled by default in the Administrator, Access Admin, and Network Admin roles.
Rule hit counts persist over reboot.	7.2.0	Any	Rebooting a managed device no longer resets access control rule hit counts to zero. Hit counts are reset only if you actively clear the counters. In addition, counts are maintained by each unit in an HA pair or cluster separately. You can use the **show rule hits** command to see cumulative counters across the HA pair or cluster, or see the counts per node. We modified the device CLI command: **show rule hits**.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Usability improvements for the access control policy.	7.2.0	Any	There is a new user interface available for the access control policy. You can continue to use the legacy user interface, or you can try out the new user interface. The new interface has both a table and a grid view for the rules list, the ability to show or hide columns, enhanced search, infinite scroll, a clearer view of the packet flow related to policies associated with the access control policy, and a simplified add/edit dialog box for creating rules. You can freely switch back and forth between the legacy and new user interfaces while editing an access control policy.
DNS filtering	7.0.0 6.7.0 (experimental)	Any	If URL filtering is enabled and configured, a new option to enhance category and reputation filtering efficacy is enabled by default for each new access control policy. For more information, see DNS filtering, on page 1884 and subtopics. The Advanced tab of access control policy has a new option under General Settings: **Enable reputation enforcement on DNS traffic**.
TLS server identity discovery	6.7.0	Any	Enable access control policies to evaluate URL and application conditions when a client connects to a TLS 1.3-enabled server. TLS server identity discovery enables these conditions to be evaluated without decrypting traffic. Enabling this feature can impact device performance, depending on model. The Advanced tab page of access control policy has new options: • Warning is displayed on the Advanced tab; moving the slider to the right enables TLS server identity discovery. • New option on the Advanced tab page: **TLS Server Identity Discovery**.
New Security Intelligence categories	—	Any	These categories were introduced at about the time of the 6.6 release, but are not specific to 6.6: • banking_fraud • high_risk • ioc • link_sharing • malicious • newly_seen • spyware

CHAPTER 42

Security Intelligence

The following topics provide an overview of Security Intelligence, including use of lists for blocking and allowing traffic and basic configuration.

- Security intelligence, on page 1811
- License requirements for security intelligence, on page 1812
- Requirements and prerequisites for security intelligence, on page 1812
- Best practices for security intelligence, on page 1812
- Guidelines and limitations for security intelligence, on page 1813
- Security intelligence sources, on page 1813
- Configure security intelligence, on page 1814
- Security intelligence monitoring, on page 1822
- Override security intelligence blocking, on page 1822
- Troubleshooting security intelligence, on page 1823
- History for security intelligence block listing, on page 1824

Security intelligence

Security Intelligence is an early line of defense mechanism that

- uses reputation intelligence to quickly block connections to or from IP addresses, URLs, and domain names
- operates as the first phase of access control, before the system performs more resource-intensive evaluation, and
- improves performance by quickly excluding traffic that does not require inspection through Security Intelligence block listing.

Security intelligence features and limitations

Security Intelligence provides access to regularly updated intelligence feeds from Cisco. Sites representing security threats such as malware, spam, botnets, and phishing appear and disappear faster than you can update and deploy custom configurations.

You can refine Security Intelligence Block listing with Do Not Block lists and monitor-only Block lists. These mechanisms exempt traffic from being blocked by a Block list, but do **not** automatically trust or fastpath

matching traffic. Traffic added to a Do Not Block list or monitored at the Security Intelligence stage is intentionally subject to further analysis with the rest of access control.

Note You cannot use a Block list to block fastpathed traffic. Prefilter evaluation occurs before Security Intelligence filtering. Fastpathed traffic bypasses all further evaluation, including Security Intelligence.

Important You must apply the Network Discovery policy on the device for a successful application of the SI policy.

Best practices for security intelligence

Configure your access control policies to block threats detected by Cisco-provided Security Intelligence feeds. See Configuration example: Security intelligence blocking, on page 1820.

If you want to supplement the Cisco-provided Security Intelligence feeds with custom threat data, or manually block emerging threats:

- For IP addresses, use custom Security Intelligence lists and feeds, or Network objects. To create these, see Security intelligence, on page 2851 and Networks, on page 2813, and their subtopics. To use them for Security Intelligence, see Configure security intelligence, on page 1814. Network objects used in Security Intelligence policy require an IPS license.
- For URLs and domains, use custom Security Intelligence lists and feeds, *not* objects or groups. See details at Manual URL filtering options, on page 1886.
- You can also add entries to a Block list from events. See Global and domain security intelligence lists, on page 2853.

To test new feeds, or for passive deployments, set the action from block to monitor only. See Security intelligence monitoring, on page 1822.

If you need to exclude specific sites or addresses from Security Intelligence blocking, see Override security intelligence blocking, on page 1822.

If your Secure Firewall deployment is integrated with Cisco security cloud and Cisco XDR and you use custom Security Intelligence lists and feeds, ensure that you update security services exchange with these lists and feeds. For details, see instructions for configuring auto-promotion of events in the Security Services Exchange online help. For general information about this integration, see *Integrate with Cisco Security Cloud* in the *Cisco Secure Firewall Management Center Administration Guide*.

System-provided Security Intelligence categories may change over time and without notification; you should plan to check periodically for changes, and modify your policies accordingly.

You should also configure URL filtering, a separate feature with separate licensing requirements, for further protection against malicious sites. See URL Filtering Rules, on page 1869.

To reduce latency and CPU overhead, avoid referencing a single, massive SI feed object across your entire security policy. Instead, utilize customized objects to create smaller, targeted subsets of your intelligence data.

Using URL/Domain feeds instead of IP blocklists can reduce CPU overhead because domain filtering is generally more efficient and less resource-intensive than managing massive IP blocklists.

Excluding trusted IPs by adding known good or essential partner IP addresses to an "Do Not Block" list in Security Intelligence (SI) feeds helps reduce CPU overhead as the firewall or security device bypasses unnecessary scanning and deeper inspection for these IPs.

Guidelines and limitations for security intelligence

Be aware of these limitations when configuring and using Security Intelligence:

- The Security Intelligence configuration that includes detection signatures or malware URLs might lead to false threat alerts when the Firewall Threat Defense troubleshoot files are scanned.
- If a TCP connection attempt is initiated from an IP address that is blocked due to its poor reputation, a TCP reset (RST) packet is sent. This causes the connection to be terminated instantly, preventing the establishment of the TCP session and signalling the rejection to the sender.

Security intelligence sources

Security Intelligence sources are data providers that

- supply regularly updated intelligence feeds for domains, URLs and IP addresses
- enable custom blocking and allow lists for specific sites or addresses, and
- provide global lists for immediate event-based blocking and allowing.

Types of security intelligence sources

Security Intelligence uses these source types:

- **System-provided feeds**: Cisco provides access to regularly updated intelligence feeds for domains, URLs and IP addresses. For more information, see Security intelligence, on page 2851.

  If you see a feed with "TID" in the name, this feed is *not* used by Security Intelligence. Instead, this feed is used by the feature described in Threat Intelligence Director, on page 2539.

- **Third-party feeds**: Optionally, supplement Cisco-provided feeds with third-party reputation feeds, which are dynamic lists that the Secure Firewall Management Center downloads from the internet on a regular basis. See Custom security intelligence feeds, on page 2860.

- **Custom Block lists or feeds (or objects)**: Block specific IP addresses, URLs, or domain names using a manually-created list or feed (for IP addresses, you can also use network objects.)

  For example, if you become aware of malicious sites or addresses that are not yet blocked by a feed, add these sites to a custom Security Intelligence list and add this custom list to the Block list in the Security Intelligence tab of your access control policy, as described in Custom Security Intelligence lists, on page 2862 and Configure security intelligence, on page 1814.

  For IP addresses, you can optionally use network objects rather than lists or feeds for this purpose; for information, see Networks, on page 2813. (For URLs, using lists and feeds is strongly recommended over other methods.)

- **Custom Do Not Block lists or feeds**: Override Security Intelligence blocking for specific sites or addresses. See Override security intelligence blocking, on page 1822.

- **Global Block lists (one each for Network, URL and DNS)**: While reviewing events, you can immediately add an event's IP address, URL, or domain to the applicable Global Block List so that Security Intelligence will handle future traffic from that source. See Global and domain security intelligence lists, on page 2853.

- **Global Do Not Block lists (one each for Network, URL and DNS)**: While reviewing events, you can immediately add an event's IP address, URL, or domain to the applicable Global Do Not Block List if you do not want Security Intelligence to block future traffic from that source. See Global and domain security intelligence lists, on page 2853.

Configure security intelligence

Configure Security Intelligence filtering to automatically block or monitor traffic based on threat intelligence feeds and custom block or allow lists. This provides an additional layer of security by filtering known malicious IP addresses, URLs, and domains before they reach your network resources.

Each access control policy has Security Intelligence options. You can add network objects, URL objects and lists, and Security Intelligence feeds and lists to a Block list or Do Not Block list, and constrain any of these

by security zone. You can also associate a DNS policy with your access control policy, and add domain names to a Block or Do Not Block list.

The number of objects in the Do Not Block lists plus the number in the Block lists cannot exceed 125 network objects, or 32767 URL objects and lists.

Before you begin

- Tip: For guidance on minimum configuration recommendations, see also Configuration example: Security intelligence blocking, on page 1820.
- To ensure that ALL options are available to select, add at least one managed device to your management center.
- In passive deployments, or if you want to set Security Intelligence filtering to monitor-only, enable logging; see *Logging Connections with Security Intelligence* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Configure a DNS policy to take Security Intelligence action for domains. For more information, see DNS Policies for Security Intelligence, on page 2373.

Follow these steps to configure Security Intelligence filtering in an access control policy:

Procedure

Step 1 In the access control policy editor, click **Security Intelligence**.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Choose the type of objects to configure.

- Click **Networks** to add network objects (IP addresses).

Note Network objects used in a Security Intelligence policy require a IPS license.

- Click **URLs** to add URL objects.

Step 3 Find the **Available Objects** you want to add to the Block or Do Not Block list.

- Search the available objects by typing in the **Search by name or value** field. Clear the search string by clicking **Reload** ( ) or **Clear** ( ).
- If no existing list or feed meets your needs, click **Add** ( ), select **New Network List** or **New URL List**, and proceed as described in Create custom security intelligence feeds, on page 2861 or Upload new custom security intelligence lists to the Secure Firewall Management Center, on page 2863.
- If no existing object meets your needs, click **Add** ( ), select **New Network Object** or **New URL Object**, and proceed as described in Create a network object, on page 2815.

Security Intelligence ignores IP address blocks using a `/0` netmask.

Step 4 Choose one or more **Available Objects** to add.

Step 5 (Optional) Choose an **Available Zone** to constrain the selected objects by zone.

You cannot constrain system-provided Security Intelligence lists by zone.

Note The **Any** zone for an SI list applies only to interfaces that are part of a security zone. However, an exception is that if a device does not have any interfaces associated with a security zone, then the **Any** zone will match any interface.

For example, if you have five interfaces on a device and none of them are associated with a security zone, any SI list that is assigned to the **Any** zone will be inspected against traffic on ALL interfaces on the device. If you add one interface to a security zone on that device, it effectively would remove SI inspection on the other four interfaces, where the zone is set to **Any** for an SI list. If you add the other four interfaces to a security zone, they will be evaluated by the SI list attached to the **Any** zone.

Step 6 Click **Add to Do Not Block list** or **Add to Block list**, or click and drag the selected objects to either list.

To remove an object from a Block or Do Not Block list, click **Delete** ( ) To remove multiple objects, choose the objects and right-click to **Delete Selected**.

Step 7 (Optional) Set objects on the Block list to monitor-only by right-clicking the object under **Block List**, then choosing **Monitor-only (do not block)**.

You cannot set system-provided global Security Intelligence lists to monitor only.

Step 8 Choose a DNS policy from the **DNS Policy** drop-down list.

Step 9 Click **Save**.

Security Intelligence filtering is now configured for your access control policy. The system will automatically block or monitor traffic based on the configured Block and Do Not Block lists, providing enhanced protection against known threats.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Related Topics

Security intelligence, on page 2851
Snort restart scenarios, on page 185

Security intelligence options

Use the Security Intelligence tab in the access control policy editor to configure network (IP address) and URL Security Intelligence, and to associate the access control policy with a DNS policy in which you have configured Security Intelligence for domains.

Available objects

Available objects include:

- Security Intelligence categories populated by the system-provided feed.

  For details, see Security intelligence categories, on page 1818.

- System-provided Global Block and Do Not Block lists.

  For descriptions, see Security intelligence sources, on page 1813.

- Security Intelligence lists and feeds that you create under Object > Object Management > Security Intelligence.

  For descriptions, see Security intelligence sources, on page 1813.

- Network and URL objects that are configured on the respective pages under Object > Object Management. These are different from the Security Intelligence objects in the previous bullet.

  For details about network objects, see Networks, on page 2813. (For URLs, use Security Intelligence lists or feeds rather than objects.)

  Note that range and group network object types are not supported in Security Intelligence policy.

Available zones

Except for the system-provided Global lists, you can constrain Security Intelligence filtering by zone.

For example, to improve performance, you might want to target enforcement to specific zones rather than all interfaces. As a more specific example, you can block spam only for a security zone that handles email traffic.

To enforce Security Intelligence filtering for an object on multiple zones, you must add the object to the Block or Do Not Block list separately for each zone.

Note that range and group network object types are not supported in Security Intelligence policy.

DNS policy

In order to match DNS traffic using Security Intelligence, you must select a DNS policy for your Security Intelligence configuration.

Using Block or Do Not Block lists, or monitoring traffic based on a DNS list or feed, also requires that you:

- Configure DNS Security Intelligence lists and feeds. See Security intelligence, on page 2851.
- Create a DNS policy. See Create basic DNS policies, on page 2377 for more information.
- Configure DNS rules that reference your DNS lists or feeds. See Create and edit DNS rules, on page 2379 for more information.
- Because you deploy the DNS policy as part of your access control policy, you must associate both policies. See Requirement: deploy DNS policy configuration changes, on page 2391 for more information.

Do not block list

See Override security intelligence blocking, on page 1822.

To select all objects in the list, right-click an object.

Block list

See Configuration example: Security intelligence blocking, on page 1820 and other topics in this chapter.

For explanations of the visual indicators in the Block list, see Block list icons, on page 1820.

To select all objects in the list, right-click an object.

Logging

Security Intelligence logging, enabled by default, logs all blocked and monitored connections handled by an access control policy's assigned devices. However, the system does not log Do Not Block list matches; logging of connections on the Do Not Block list depends on their eventual disposition. Logging must be enabled for connections on the Block list before you can set objects on that list to monitor-only.

To enable, disable, or view logging settings, right-click an object in the Block list.

Related Topics

Global and domain security intelligence lists, on page 2853
Security intelligence lists and multitenancy, on page 2854

Security intelligence categories

Security Intelligence categories are determined by the system-provided feeds described in Security intelligence, on page 2851.

These categories are used in the following locations:

- The Networks sub-tab on the Security Intelligence tab of an access control policy
- The URLs sub-tab beside the Networks tab on the Security Intelligence tab of an access control policy
- In a DNS policy on the DNS tab in the DNS rule configuration page
- In events generated when traffic matches Block or Monitor configurations in the above locations

Note If your organization is using Secure Firewall Threat Intelligence Director: When viewing events, you may see categories that indicate that the action was taken by TID, such as `TID URL Block`.

Categories are updated by Talos from the cloud, and this list may change independently of Firepower releases.

Table 102:

Security Intelligence Category	Description
Attackers	Active scanners and hosts known for outbound malicious activity
Banking_fraud	Sites that engage in fraudulent activities that relate to electronic banking

Security Intelligence Category	Description
Bogon	Bogon networks and unallocated IP addresses The Security Intelligence Bogon feed is designed to provide threat-specific intelligence. It is not intended to function as a comprehensive filtering list for all bogon traffic. Bogon traffic, including private, multicast, and unallocated address space is generally expected to be filtered by upstream network providers or through standard network security controls. Key aspects of Bogon: • **Active threat indicators**: The feed is populated only when the security intelligence identifies active threat indicators associated with bogon address space. • **Empty feed status**: An empty feed does not indicate a system malfunction or an error. It simply signifies that no active threats have been identified in the monitored bogon space at this time.
Bots	Sites that host binary malware droppers
CnC	Sites that host command-and-control servers for botnets
Cryptomining	Hosts providing remote access to pools and wallets for the purpose of mining cryptocurrency
Dga	Malware algorithms used to generate a large number of domain names acting as rendezvous points with their command-and-control servers
Exploitkit	Software kits designed to identify software vulnerabilities in clients
High_risk	Domains and hostnames that match against the OpenDNS predictive security algorithms from security graph
Ioc	Hosts that have been observed to engage in Indicators of Compromise (IOC)
Link_sharing	Websites that share copyrighted files without permission
Malicious	Sites exhibiting malicious behavior that do not necessarily fit into another, more granular, threat category
Malware	Sites that host malware binaries or exploit kits

Security Intelligence Category	Description
Newly_seen	Domains that have recently been registered, or not yet seen via telemetry. **Attention** Currently, this category does not have any active feed and is reserved for future use.
Open_proxy	Open proxies that allow anonymous web browsing
Open_relay	Open mail relays that are known to be used for spam
Phishing	Sites that host phishing pages
Response	IP addresses and URLs that are actively participating in malicious or suspicious activity
Spam	Mail hosts that are known for sending spam
Spyware	Sites that are known to contain, serve, or support spyware and adware activities
Suspicious	Files that appear to be suspicious and have characteristics that resemble known malware
Tor_exit_node	Hosts known to offer exit node services for the Tor Anonymizer network

Block list icons

The visual indicators may appear in the Block list on the Security Intelligence tab in an access control policy.

Icon or Visual Indicator	Description
Block ()	The object is set to block.
Monitor ()	The object is set to monitor-only. See Security intelligence monitoring, on page 1822
An object is displayed in strikethrough text	The same object is also on the Do Not Block list, which overrides the block.

Configuration example: Security intelligence blocking

Configure Security Intelligence blocking to protect your network from known malicious IP addresses, URLs, and domains using regularly updated threat intelligence feeds.

Configure your access control policy to block all threats detectable by the system's regularly updated Security Intelligence feeds.

The number of objects in the Block lists plus the number in the Do Not Block lists cannot exceed 125 network objects, or 32767 URL objects and lists.

Before you begin

- To ensure that all options are available to select, add at least one managed device to your management center.
- Configure a DNS policy to block all Security Intelligence threat categories for domains. For more information, see DNS Policies for Security Intelligence, on page 2373.
- If you have, or will have, custom lists of entities to block, create a Security Intelligence object of each type (URLs, DNS, Networks.) See Security intelligence, on page 2851.

Procedure

Step 1 Click **Policies** > **Security policies** > **Access Control**.

Step 2 Create a new access control policy or edit an existing policy.

Step 3 In the access control policy editor, click **Security Intelligence**.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 Click **Networks** to add blocking criteria for IP addresses.

a) Scroll down in the Networks list and select all of the threat categories listed below the Global lists.
b) If applicable, select the security zones for which you want to block these threats.
c) Click **Add to Block List**.
d) If you have created custom lists or feeds with addresses to block, add those to the Block List using the same steps as above.

Step 5 Click **URLs** to add blocking criteria for URLs, and repeat the steps you followed for Networks.

Step 6 Choose a DNS policy from the **DNS Policy** drop-down list; see DNS policies, on page 2373.

Step 7 Click **Save**.

Your access control policy now blocks malicious IP addresses, URLs, and domains based on Security Intelligence threat feeds, providing enhanced protection against known threats.

What to do next

- Enable logging for these connections; see *Logging Connections with Security Intelligence* in the *Cisco Secure Firewall Management Center Administration Guide* .
- Deploy configuration changes; see Deploy configuration changes, on page 193.
- For additional protection, configure URL filtering to block malicious URLs. See URL Filtering Rules, on page 1869.

Security intelligence monitoring

Security Intelligence monitoring is a security feature that

- logs connection events for traffic that would have been blocked by Security Intelligence, but does not block the traffic,
- enables testing of feeds before implementation, and
- optimizes performance in passive deployments.

Use cases for security intelligence monitoring

Monitoring is especially useful for:

- Testing feeds before you implement them.

  Consider a scenario where you want to test a third-party feed before you implement blocking using that feed. When you set the feed to monitor-only, the system allows connections that would have been blocked to be further analyzed by the system, but also logs a record of each of those connections for your evaluation.

- Passive deployments, to optimize performance.

  Managed devices that are deployed passively cannot affect traffic flow; there is no advantage to configuring the system to block traffic. Additionally, because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

Note If configured, Secure Firewall Threat Intelligence Director may impact the action taken (Monitor or Block.) For more information, see Threat Intelligence Director - Firewall Management Center action prioritization , on page 2563.

To configure Security Intelligence monitoring:

After you configure Security Intelligence blocking following the instructions in Configuration example: Security intelligence blocking, on page 1820, right-click each applicable object in the Block list and choose **Monitor-only**. You cannot set system-provided Security Intelligence lists to monitor only.

Override security intelligence blocking

Use Do Not Block lists to exempt specific domains, URLs, or IP addresses from being blocked by Security Intelligence lists or feeds.

You can use Do Not Block lists for various purposes:

- Override the occasional false-positive block in a reputable Security Intelligence feed
- Inspect specific traffic in depth instead of blocking it early based on reputation
- Exempt otherwise-restricted transactions based on zone from Security Intelligence blocking

For example, you can add an improperly classified URL to a Do Not Block list, but then restrict the Do Not Block list object using a security zone used by those in your organization who need to access those URLs. That way, only those with a business need can access the URLs on the Do Not Block list.

Note Entries on a Do Not Block list are simply exemptions from the block list. Any connection that passes the Security Intelligence policy is subject to the access control rules. Thus, an entry in the Do Not Block list can subsequently be blocked by an access control rule or intrusion policy. Your Do Not Block entries should always be exemptions from your block lists.

Procedure

Step 1 Option 1: Add an IP address, URL, or domain from an event to the Global Do Not Block List. See Global and domain security intelligence lists, on page 2853.

Step 2 Option 2: Use a custom Security Intelligence list or feed.

a) Create the custom Security Intelligence list or feed. See Custom Security Intelligence lists, on page 2862 or Create custom security intelligence feeds, on page 2861.

b) For IP addresses (Networks) and URLs: Edit your access control policy, click the Security Intelligence tab, then click the custom list or feed in the Networks or URLs sub-tab, then click **Add to Do Not Block List**.

c) Save your changes.

d) For domains (DNS): See the "DNS Policy" section in the Security intelligence options, on page 1816 topic.

e) Deploy your changes.

The specified domains, URLs, or IP addresses are now exempted from Security Intelligence blocking and will be subject to access control rules instead.

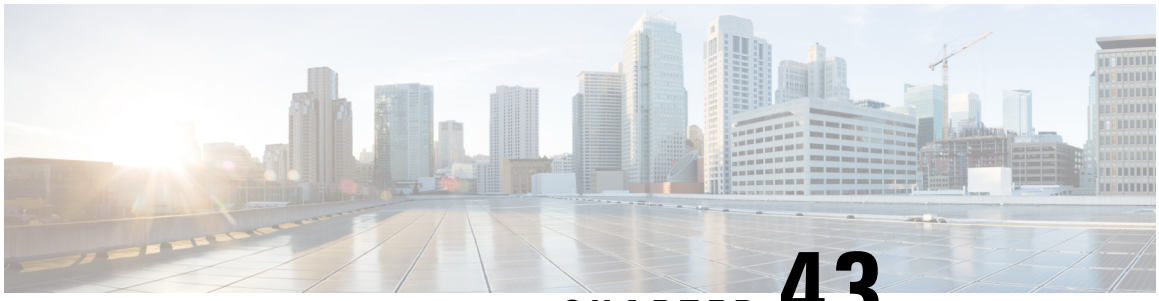
Troubleshooting security intelligence

See the following topics for troubleshooting Security Intelligence.

Security intelligence categories missing from the Available Options List

Security Intelligence categories (such as CnC or Exploitkit) display in the Networks tab under Available Options only after you add at least one managed device to your management center.

You must add a device in order to pull all TALOS feeds that provide the Security Intelligence categories.



If the expected category does not appear in Security Intelligence, verify that it is not a URL filtering category, which uses a different set of categories.

To see URL filtering categories, look at the **URLs** tab in an access control rule.

History for security intelligence block listing

This reference provides a chronological history of changes and updates to Security Intelligence Block Listing features, including terminology changes and new category additions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
New Security Intelligence categories	All	Any	Talos has added the new Security Intelligence categories: • banking_fraud • ioc • high_risk • link_sharing • malicious • newly_seen • spyware You should update your access control and DNS policies to address the new categories, and check periodically for future changes. New/modified pages: Security Intelligence tab, Networks and URLs sub-tabs; DNS rules in DNS policies Supported platforms: Firewall Management Center

CHAPTER 43

Access Control Rules

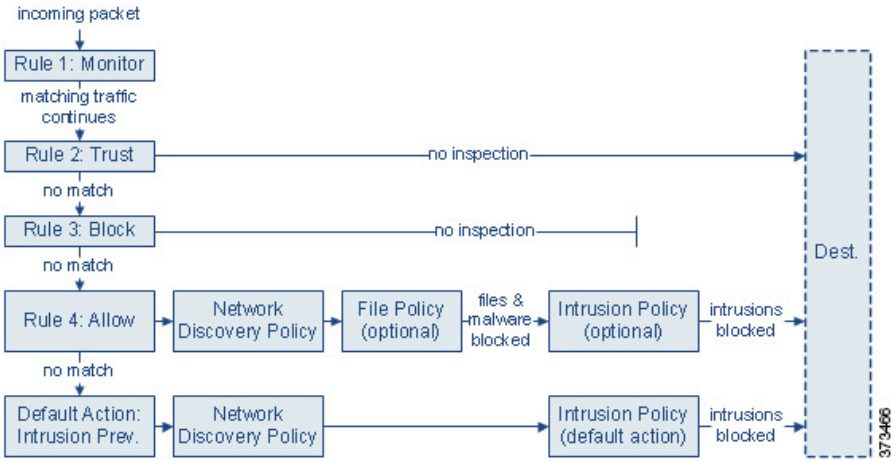
The following topics describe how to configure access control rules.

- Access control rules, on page 1825
- Requirements and prerequisites for access control rules, on page 1836
- Guidelines and limitations for access control rules, on page 1837
- Best practices for application control, on page 1838
- Best practices for access control rules, on page 1842
- Access control rule management, on page 1847
- Examples for access control rules, on page 1862
- History for access control rules, on page 1867

Access control rules

Within an access control policy, access control rules provide a granular method that

- handles network traffic across multiple managed devices within an access control policy
- provides conditions that match traffic in a specified order, and
- determines actions to monitor, trust, block, or allow matching traffic.



Rule evaluation and traffic handling

The system matches traffic to access control rules in the order you specify. In most cases, the system handles network traffic according to the first access control rule where all the rule's conditions match the traffic.

Each rule also has an action, which determines whether you monitor, trust, block, or allow matching traffic. When you allow traffic, you can specify that the system first inspect it with intrusion or file policies to block any exploits, malware, or prohibited files before they reach your assets or exit your network.

Note Security Intelligence filtering, decryption, user identification, and some decoding and preprocessing occur before access control rules evaluate network traffic.

This scenario summarizes the ways that traffic can be evaluated by access control rules in an inline, intrusion prevention deployment.

In this scenario, traffic is evaluated as follows:

- **Rule 1: Monitor** evaluates traffic first. Monitor rules track and log network traffic. The system continues to match traffic against additional rules to determine whether to permit or deny it. (However, see an important exception and caveat at Access control rule monitor action, on page 1830.)
- **Rule 2: Trust** evaluates traffic next. Matching traffic is allowed to pass to its destination without further inspection, though it is still subject to identity requirements and rate limiting. Traffic that does not match continues to the next rule.
- **Rule 3: Block** evaluates traffic third. Matching traffic is blocked without further inspection. Traffic that does not match continues to the final rule.
- **Rule 4: Allow** is the final rule. For this rule, matching traffic is allowed; however, prohibited files, malware, intrusions, and exploits within that traffic are detected and blocked. Remaining non-prohibited, non-malicious traffic is allowed to its destination, though it is still subject to identity requirements and rate limiting. You can configure Allow rules that perform only file inspection, or only intrusion inspection, or neither.
- **Default Action** handles all traffic that does not match any of the rules. In this scenario, the default action performs intrusion prevention before allowing non-malicious traffic to pass. In a different deployment, you might have a default action that trusts or blocks all traffic, without further inspection. (You cannot perform file or malware inspection on traffic handled by the default action.)

Traffic you allow, whether with an access control rule or the default action, is automatically eligible for inspection for host, application, and user data by the network discovery policy. You do not explicitly enable discovery, although you can enhance or disable it. However, allowing traffic does not automatically guarantee discovery data collection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy; additionally, application discovery is limited for encrypted sessions.

Note that access control rules handle encrypted traffic when your decryption configuration allows it to pass, or if you do not configure decryption. However, some access control rule conditions require unencrypted traffic, so encrypted traffic may match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Access control rule management

The rules table of the access control policy editor allows you to add, edit, categorize, search, filter, move, enable, disable, delete, and otherwise manage access control rules in the current policy.

Properly creating and ordering access control rules is a complex task, but one that is essential to building an effective deployment. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations.

Use the search bar to filter the list of access control policy rules. You can deselect the **Show Only Matching Rules** option to see all rules. Matched rules are highlighted.

For each access control rule, the policy editor displays its name, a summary of its conditions, the rule action, and icons that communicate the rule's inspection options or status.

The system provides specific icons to communicate the inspection options or status of each rule:

- **Time Range Option** ()
- **Intrusion policy** ()
- **File policy** ()
- **Logging** ()
- **Warning** ()
- **Errors** ()
- **Rule Conflict** ()

Disabled rules are dimmed and marked (disabled) after the rule name.

To create or edit a rule, refer to Create and edit access control rules, on page 1848 .

Tip A right-click menu provides shortcuts to many rule management options, including editing, deleting, moving, enabling, and disabling.

Access control rule components

In addition to its unique name, each access control rule has basic components that determine how the system processes and handles network traffic.

State

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

Position

Rules in an access control policy are numbered, starting at 1. If you are using policy inheritance, rule 1 is the first rule in the outermost policy. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.

Rules can also belong to a section and a category, which are organizational only and do not affect rule position. Rule position goes across sections and categories.

Section and category

To help you organize access control rules, every access control policy has two system-provided rule sections, Mandatory and Default. To further organize access control rules, you can create custom rule categories inside the Mandatory and Default sections.

If you are using policy inheritance, the current policy's rules are nested between its parent policy's Mandatory and Default sections.

Conditions

Conditions specify the specific traffic the rule handles. Conditions can be simple or complex; their use often depends on license.

Traffic must meet all of the conditions specified in a rule. For example, if the Application condition specifies HTTP but not HTTPS, the URL category and reputation conditions will not apply to HTTPS traffic.

Applicable time

You can set rules to operate during specified days and times

Action

A rule's action determines how the system handles matching traffic. You can monitor, trust, block, or allow (with or without further inspection) matching traffic. The system does not perform deep inspection on trusted, blocked, or encrypted traffic.

Inspection

Deep inspection options govern how the system inspects and blocks malicious traffic you would otherwise allow. When you allow traffic with a rule, you can specify that the system first inspect it with intrusion or file policies to block any exploits, malware, or prohibited files before they reach your assets or exit your network.

Logging

Logging settings govern records that the system keeps for handled traffic. You can log sessions at connection start, end, or both; log connections to databases, syslog, or SNMP trap servers. You can log connections to the database, as well as to a syslog or an SNMP trap server. You can log sessions by application and protocol, then forward these logs to event management solutions for further analysis.

Comments

Each time you save changes to an access control rule, you can add comments.

Access control rule order

Access control rule order is a traffic processing method that

- numbers rules in an access control policy starting at 1
- matches traffic to access control rules in top-down order by ascending rule number, and
- handles network traffic according to the first access control rule where all the rule's conditions match the traffic.

In most cases, except for Monitor rules, the system does not continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule.

To help you organize access control rules, every access control policy has two system-provided rule sections, Mandatory and Default. To further organize, you can create custom rule categories inside the Mandatory or Default sections. After you create a category, you cannot move it, although you can delete it, rename it, and move rules into, out of, within, and around it. The system assigns rule numbers across sections and categories.

If you use policy inheritance, the current policy's rules are nested between its parent policy's Mandatory and Default rule sections. Rule 1 is the first rule in the outermost policy, not the current policy, and the system assigns rule numbers across policies, sections, and categories.

Any predefined user role that allows you to modify access control policies also allows you to move and modify access control rules within and among rules categories. You can, however, create custom roles that restrict users from moving and modifying rules. Any user who is allowed to modify access control policies can add rules to custom categories and modify rules in them without restriction.

Caution Failure to set up your access control rules properly can have unexpected results, including traffic being allowed that should be blocked. In general, application control rules should be lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example.

Access control rules that use *specific* conditions (such as networks and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your access control rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your access control rules. For more information about the OSI model, see this Wikipedia article.

Note Proper access control rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs. For more information, refer to Best practices for ordering rules, on page 1843.

Access control rule actions

An access control rule action is a configuration setting that determines how the system handles and logs matching traffic, with options to monitor, trust, block, or allow traffic with or without further inspection.

Default action behavior

The access control policy's *default action* handles traffic that does not meet the conditions of any access control rule with an action other than Monitor.

Access control rule monitor action

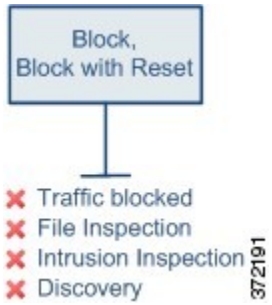
The **Monitor** action is an access control rule action that forces connection logging regardless of how matching traffic is eventually handled. It does not affect traffic flow by permitting or denying traffic immediately, and allows traffic to be matched against additional rules to determine the final action.

When a connection matches a monitor rule, the next non-monitor rule that the connection matches determines traffic handling and any further inspection. If there are no additional matching rules, the Firewall Threat Defense device uses the default action.

There is an exception: If a monitor rule contains layer 7 conditions, such as an application condition, the system allows early packets to pass and the connection to be established (or the SSL handshake to complete), even if a subsequent rule would block the connection. Early packets are not evaluated against subsequent rules, so to prevent uninspected traffic, you can specify an intrusion policy for these packets in the access control policy's advanced settings. For more information, refer to Inspection of packets that pass before traffic is identified. After the system completes its layer 7 identification, it applies the appropriate action to the remaining session traffic.

Access control rule trust action

The **Trust** action is the access control rule action that allows traffic to pass without deep inspection or network discovery, still subjects trusted traffic to identity requirements and rate limiting, and bypasses additional inspection services while maintaining basic security controls.



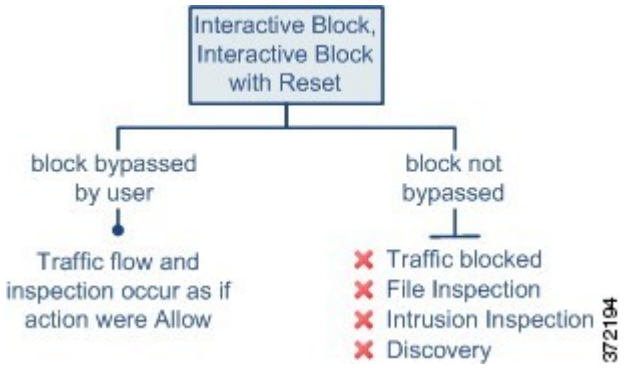
Note

- Some protocols, such as FTP and SIP, use secondary channels, which the system opens through the process of inspection. In some cases, trusted traffic can bypass all inspection, and these secondary channels cannot be opened properly. If you run into this problem, change the trust rule to **Allow**.
- For trust rules with logging options disabled, end-of-flow events are still generated in the system. However, the events are not visible on the event pages.
- Because access control rules are evaluated after other policies, such as decryption, trusting a connection does not necessarily mean it will be fast-pathed with no inspection. For example, if a connection matches both a decryption rule that requires decryption, and a trust access control rule, the connection is decrypted and inspected as needed, prior to being allowed by the trust rule. Trust simply means no additional inspection, such as intrusion inspection, will be applied. If your intention is to allow a connection uninspected, either use the prefilter policy to fast path the connection, or ensure that no other policy applies inspection services to the connection.

Access control rule blocking actions

A block action is an access control rule action that denies network traffic without further inspection and prevents the use of file, intrusion, or network discovery policies for blocked traffic.

Block and **Block with reset** actions immediately stop traffic from entering the network. Block with reset rules reset the connection except for web requests met with an HTTP response page. The HTTP response page is used to notify users when their web request is blocked, but it cannot be displayed if the connection is immediately reset.



For more information, refer to HTTP response pages, on page 1887.

Related Topics

HTTP response pages, on page 1887

Access control rule interactive blocking actions

The **Interactive Block** and **Interactive Block with reset** actions are access control rule actions that give web users a choice to continue to their intended destinations.

If a user bypasses the block, the rule mimics an allow rule. Therefore, you can associate interactive block rules with file and intrusion policies, and matching traffic is also eligible for network discovery.

If a user does not (or cannot) bypass the block, the rule mimics a block rule. Matching traffic is denied without further inspection.

Note If you enable interactive blocking, you cannot reset all blocked connections. This is because the response page cannot display if the connection is immediately reset. Use the **Interactive Block with reset** action to (non-interactively) block-with-reset all non-web traffic, while still enabling interactive blocking for web requests.

For more information, refer to HTTP response pages, on page 1887.

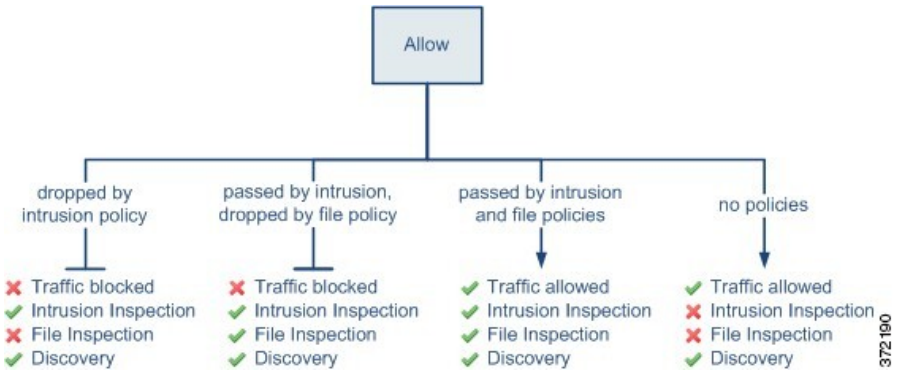
Rule-based decryption rule blocking actions, on page 2039



Access control rule allow action

An access control rule allow action is a rule action that allows matching traffic to pass. However, traffic is still subject to identity requirements and rate limiting.

Optionally, you can use deep inspection to further inspect and block unencrypted or decrypted traffic before it reaches its destination:

- You can use an intrusion policy to analyze network traffic according to intrusion detection and prevention configurations, and drop offending packets depending on the configuration.
- You can perform file control using a file policy. File control allows you to detect and block your users from uploading (sending) or downloading (receiving) files of specific types over specific application protocols.
- You can perform network-based advanced malware protection (AMP), also using a file policy. malware defense can inspect files for malware, and block detected malware depending on the configuration.

This diagram illustrates the types of inspection performed on traffic that meets the conditions of an Allow rule (or a user-bypassed Interactive Block rule). Notice that file inspection occurs before intrusion inspection; blocked files are not inspected for intrusion-related exploits.

For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with an access control rule. You can, however, configure one without the other. Without a file policy, traffic flow is determined by the intrusion policy; without an intrusion policy, traffic flow is determined by the file policy.

Regardless of whether the traffic is inspected or dropped by an intrusion or file policy, the system can inspect it using network discovery. However, permitting traffic does not guarantee that discovery inspection occurs. The system only performs discovery for connections involving IP addresses explicitly monitored by your network discovery policy. Also, application discovery is limited for encrypted sessions.

Deep inspection using file and intrusion policies

Deep inspection is a security mechanism that uses intrusion and file policies as the last line of defense before traffic is allowed to its destination.

Policy types and capabilities

Deep inspection uses two types of policies to analyze traffic:

- *Intrusion policies* govern the system's intrusion prevention capabilities.
- *File policies* govern the system's file control and malware defense capabilities.

Access control occurs before deep inspection; access control rules and the access control default action determine which traffic is inspected by intrusion and file policies.

By associating an intrusion or file policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect the traffic with an intrusion policy, a file policy, or both.

In an access control policy, you can associate one intrusion policy with each Allow and Interactive Block rule, as well as with the default action. Every unique **pair** of intrusion policy and variable set counts as one policy.

Note By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

To associate intrusion and file policies with an access control rule, see:

- Access control rules: Intrusion policy selection, on page 1915
- Configure an access control rule to perform malware protection, on page 2410

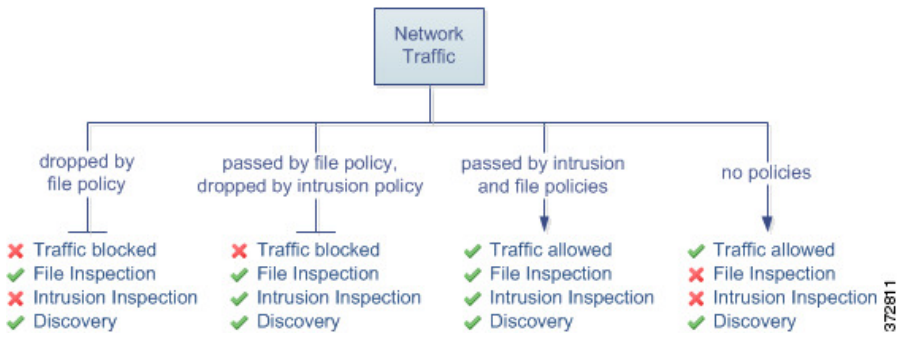
For more information about intrusion policies, refer to Intrusion prevention, on page 1903.

For more information about file policies, refer to File Policies for Network Malware Protection, on page 2401.

File and intrusion inspection order

File and intrusion inspection order defines the traffic processing sequence that performs file inspection before intrusion inspection for any single connection handled by an access control rule, preventing files blocked by a file policy from being inspected for intrusions while prioritizing simple file blocking by type over malware inspection.

For a connection matching an Allow or Interactive Block rule, the system determines traffic flow based on the following configurations:



- Without a file policy, traffic flow is determined by the intrusion policy.
- Without an intrusion policy, traffic flow is determined by the file policy.
- Without either, allowed traffic is inspected by network discovery only.

In your access control policy, you can associate multiple Allow and Interactive Block rules with different intrusion and file policies to match inspection profiles to various types of traffic.

Note The system does not perform any kind of inspection on trusted traffic. Although configuring an Allow rule with neither an intrusion nor file policy passes traffic like a Trust rule, Allow rules let you perform discovery on matching traffic.

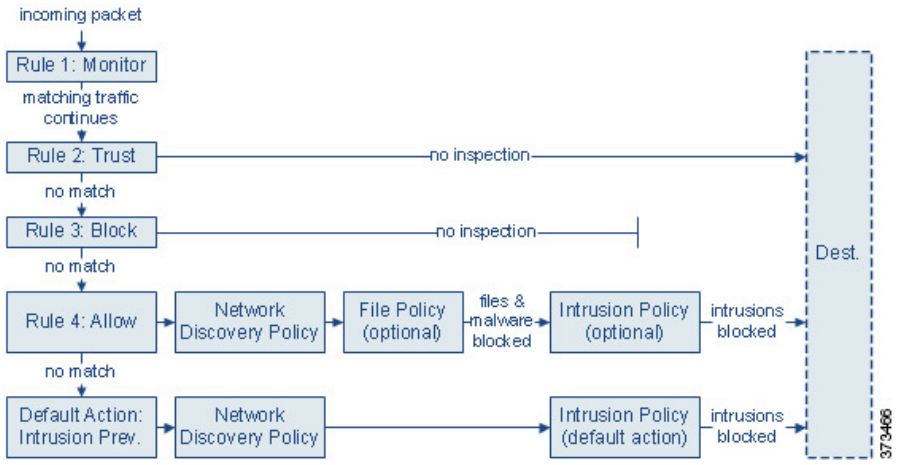
The diagram below illustrates the types of inspection you can perform on traffic that meets the conditions of either an Allow or user-bypassed Interactive Block access control rule. For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with a single access control rule.

Figure 439: Traffic inspection flowchart

For any single connection handled by an access control rule, file inspection occurs before intrusion inspection. That is, the system does not inspect files blocked by a file policy for intrusions. Within file inspection, simple blocking by type takes precedence over malware inspection and blocking.

For example, consider a scenario where you normally want to allow certain network traffic as defined in an access control rule. However, as a precaution, you want to block the download of executable files, examine downloaded PDFs for malware and block any instances you find, and perform intrusion inspection on the traffic.

You create an access control policy with a rule that matches the characteristics of the traffic you want to provisionally allow, and associate it with both an intrusion policy and a file policy. The file policy blocks the download of all executables, and also inspects and blocks PDFs containing malware:



- First, the system blocks the download of all executables, based on simple type matching specified in the file policy. Because they are immediately blocked, these files are subject to neither malware nor intrusion inspection.
- Next, the system performs malware cloud lookups for PDFs downloaded to a host on your network. Any PDFs with a malware disposition are blocked, and are not subject to intrusion inspection.
- Finally, the system uses the intrusion policy associated with the access control rule to inspect any remaining traffic, including files not blocked by the file policy.

Note Until a file is detected and blocked in a session, packets from the session might be subject to intrusion inspection.

How access control traffic handling works with intrusion and file policies

Summary

This diagram shows the flow of traffic in an inline intrusion prevention and malware defense deployment, as governed by an access control policy that contains four different types of access control rules and a default action.

Workflow

In the scenario above, the first three access control rules in the policy—Monitor, Trust, and Block—cannot inspect matching traffic. Monitor rules track and log but do not inspect network traffic, so the system continues to match traffic against additional rules to determine whether to permit or deny it. (However, see an important

exception and caveat at Access control rule monitor action, on page 1830.) Trust and Block rules handle matching traffic without further inspection of any kind, while traffic that does not match continues to the next access control rule.

The fourth and final rule in the policy, an Allow rule, invokes various other policies to inspect and handle matching traffic, in the following order:

1. Discovery: Network Discovery Policy—First, the network discovery policy inspects traffic for discovery data. Discovery is passive analysis and does not affect the flow of traffic. Although you do not explicitly enable discovery, you can enhance or disable it. However, allowing traffic does not automatically guarantee discovery data collection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy.
2. malware defense and File Control: File Policy—After traffic is inspected by discovery, the system can inspect it for prohibited files and malware. malware defense detects and optionally blocks malware in many types of files, including PDFs, Microsoft Office documents, and others. If your organization wants to block not only the transmission of malware files, but all files of a specific type (regardless of whether the files contain malware), file control allows you to monitor network traffic for transmissions of specific file types, then either block or allow the file.
3. Intrusion Prevention: Intrusion Policy—After file inspection, the system can inspect traffic for intrusions and exploits. An intrusion policy examines decoded packets for attacks based on patterns, and can block or alter malicious traffic. Intrusion policies are paired with variable sets, which allow you to use named values to accurately reflect your network environment.
4. Destination—Traffic that passes all the checks described above passes to its destination.

An Interactive Block rule (not shown in the diagram) has the same inspection options as an Allow rule. This is so you can inspect traffic for malicious content when a user bypasses a blocked website by clicking through a warning page.

Traffic that does not match any access control rules in the policy with an action other than Monitor is handled by the default action. In this scenario, the default action is an Intrusion Prevention action, which allows traffic to its final destination as long as it is passed by the intrusion policy you specify. In a different deployment, you might have a default action that trusts or blocks all traffic without further inspection. Note that the system can inspect traffic allowed by the default action for discovery data and intrusions, but not prohibited files or malware. You cannot associate a file policy with the access control default action.

Note Sometimes, when a connection is analyzed by an access control policy, the system must process the first few packets in that connection, allowing them to pass, before it can decide which access control rule (if any) will handle the traffic. However, so these packets do not reach their destination uninspected, you can specify an intrusion policy (in the advanced settings for the access control policy) to inspect these packets and generate intrusion events.

Requirements and prerequisites for access control rules

Ensure that your deployment meets these requirements before you configure access control rules.

Model support

Any

Supported domains

Any

User roles

- Administrator
- Access Admin
- Network Admin
- You can define custom user roles to differentiate between the intrusion configuration in access control policy and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. The existing pre-defined user roles that included the Modify Access Control Policy permission support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions. The granular permissions are:
  - **Policies** > **Security policies** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** allows the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for Network Analysis and Intrusion Policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. If a user has this option only, the user can modify no other part of the policy or rule.
  - **Modify Remaining Access Control Policy Configuration** controls the ability to edit all other aspects of the policy.

Guidelines and limitations for access control rules

Consider these limitations when you configure rules in the access control policy:

- There is a limit of 1000 rules that can be shown at a time on the current page. Thus, if you have a very large number of rules, such as 3000 rules within a single category, actions like selecting all rules in a category and deleting them does not delete all of the rules. You might need to select/delete rules again to delete all the rules that you are targeting.
- If you edit an access control rule that is actively in use, the changes do not apply to established connections at deploy-time. The updated rule is used to match against future connections. However, if the system is actively inspecting a connection (for example, with an intrusion policy), it will apply changed matching or action criteria to existing connections.

  For Firewall Threat Defense, you can ensure that your changes apply to all current connections by using the Firewall Threat Defense **clear conn** CLI command to end established connections. Note that you should only do this if it is acceptable to end those connections, on the assumption that the sources for the connections will then attempt to reestablish the connection and thus be matched appropriately against the new rule.

- VLAN tags in access rules only apply to inline sets; they cannot be used in access rules applied to firewall interfaces.
- To use fully-qualified domain name (FQDN) network objects as source or destination criteria, you must also configure DNS for the data interfaces in the platform settings policy. The system does not use the management DNS server setting to do lookups for FQDN objects used in access control rules.

  Note that controlling access by FQDN is a best-effort mechanism. Consider the following points:

  - Whenever possible, use Security Intelligence or URL filtering instead of FQDN rules.
  - Because DNS replies can be spoofed, only use fully trusted DNS servers.
  - Some FQDNs, especially for very popular servers, can have hundreds if not thousands of IP addresses, and these can frequently change. Because the system uses cached DNS lookup results, users might get addresses that are not yet in the cache, and their connections will not match the FQDN rule. Rules that use FQDN network objects function effectively only for names that resolve to fewer than 100 addresses.

    We recommend that you do not create network object rules for an FQDN that resolves to more than 100 addresses, as the likelihood of the address in a connection being one that has been resolved and available in the DNS cache on the device is low. For these cases, use a URL-based rule instead of an FQDN network object rule.
  - For popular FQDNs, different DNS servers can return a different set of IP addresses. Thus, if your users use a different DNS server than the one you configure, FQDN-based access control rules might not apply to all IP addresses for the site that are used by your clients, and you will not get the intended results for your rules.
  - Some FQDN DNS entries have very short time to live (TTL) values. This can result in frequent recompilation of the lookup table, which can impact overall system performance.
  - If more than 8 FQDNs resolve to the same IP address, the system cannot reliably match traffic to the rules for those FQDN. At most 8 FQDNs per IP address can be handled.
- The maximum objects per match criteria per access control rule is 200. For example, you can have up to 200 network objects in a single access control rule.
- Block with reset can be CPU-intensive for rules that drop a high rate of TCP traffic. When the system drops TCP traffic with this action, it also generates TCP reset packets, which can affect device performance during high-volume drops. For access control rules that are expected to drop large amounts of TCP traffic, use **Block** instead of **Block with reset**, unless TCP reset behavior is required.

  If TCP reset behavior is required for denied inbound TCP traffic, you can also evaluate using a regular **Block** rule with the **service resetinbound** command through FlexConfig for the applicable interface.

Best practices for application control

These topics discuss our recommended best practices for controlling applications with access control rules.

Recommendations for application control

Ensure that adaptive profiling is enabled

If adaptive profiling is not enabled (its default state), access control rules cannot perform application control.

Enable application detectors automatically

If no detector is enabled for an application you want to detect, the system automatically enables all system-provided detectors for the application. If none exist, the system enables the most recently modified user-defined detector for the application.

Configure your policy to examine the packets that must pass before an application is identified

The system cannot perform application control before *both* of these conditions occur:

- A monitored connection is established between a client and server
- The system identifies the application in the session

This identification should occur in 3 to 5 packets, or after the server certificate exchange in the SSL handshake if the traffic is encrypted. If you configure the access control rule to use application default ports, the application rule can be enforced without allowing initial packets to pass.

If early traffic matches all other criteria but application identification is incomplete, the system allows the packet to pass and the connection to be established (or the SSL handshake to complete). After the system completes its identification, the system applies the appropriate action to the remaining session traffic.

To ensure that your system examines these initial packets, select an intrusion policy in the **Intrusion Policy used before Access Control rule is determined** options in the access control policy advanced settings.

Understand limitations to identifying applications

A server must adhere to the protocol requirements of an application for the system to be able to recognize it. For example, if you have a server that sends a keep-alive packet rather than an ACK when an ACK is expected, that application might not be identified, and the connection will not match the application-based rule. Instead, it will be handled by another matching rule or the default action. This might mean that connections you want to allow can be denied instead. If you run into this problem, and you cannot fix the server to follow the protocol standards, you need to write a non-application-based rule to cover traffic for that server, for example, by matching the IP address and port number.

Create separate rules for URL and application filtering

Create separate rules for URL and application filtering whenever possible, because combining application and URL criteria can lead to unexpected results, especially for encrypted traffic.

Rules that include both application and URL criteria should come after application-only or URL-only rules, unless the application+URL rule is acting as an exception to a more general application-only or URL-only rule.

Place URL rules before application and other rules

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of these criteria:

- They include application conditions.
- The traffic to be inspected is encrypted.

Handling application traffic packets without payloads

When performing access control, the system applies the default policy action to packets that do not have a payload in a connection where an application is identified.

Handling referred application traffic

To handle traffic referred by a web server, such as advertisement traffic, match the referred application rather than the referring application.

Controlling application traffic that uses multiple protocols

Some applications use multiple protocols. To control their traffic, make sure your access control policy covers all relevant options. These applications typically include the application name in each aspect that you can control. Also see Application-specific requirements for filtering, on page 1841.

Controlling evasive application traffic

See Application-specific requirements for filtering, on page 1841.

Best practice for choosing between application matching and port matching

In traditional firewalls, you can match traffic based on OSI layers 3 (protocol) and 4 (transport), such as IP or TCP/80. All traffic on a given port (or a whole protocol) is then either allowed or blocked based on that rule's action.

Application criteria, on the other hand, are OSI layer 7. Different applications can use the same TCP/UDP port. By using application criteria, you can selectively allow or block different applications on the same port without allowing or blocking all applications on that port.

Whether you use port-based or application-based criteria in your rule can impact rule performance. Because TCP/UDP ports are quickly identifiable in packets, the system can match the correct rule on the first packet. With application-layer criteria, it can take 3-5 packets to identify the specific application (if you do not also specify ports).

Consider these best practices:

- If you want to handle all of the traffic on a given TCP/UDP port in the same way for the specified interfaces and networks, use port-based matching. For example, to handle all SSH traffic the same way, select the SSH port (TCP/22) on the Ports tab.
- If you want to narrowly match a specific application that uses the same port as other applications, select the application on the Applications tab. This is how you can handle web applications, which all use TCP/80 or 443, so that you can selectively block or allow certain web applications without blocking or allowing all web applications.
- If you want to control application use by a user group, select the user group on the Users tab and the application on the Application tab. For example, you could block the Gaming applications category for members of the Contractor user group.
- For rules that go from a less secure network (such as the internet) to a more secure network (such as an internal protected network), use the Ports tab whenever possible. For example, you can allow/block ICMP traffic from the internet to an internal network.
- Avoid mixing Port tab and Applications tab specifications in a single rule. Instead, when you select an application, leave the Port tab empty, and instead specify the port as **Application Default** on the Applications tab. This will target the rule to the right ports (per application) and enhance how quickly the right application can be matched to the rule.

- If you do have a mix of port-based and application-based rules, place the port-based rules higher in the rules list, so that connections can be matched to those rules first. Protocol and port can be more quickly identified than applications.

Application-specific requirements for filtering

Office 365 admin portal

If the access policy has logging enabled at the beginning as well as at the end of a connection, the first packet will be detected as Office 365 and the end of connection will be detected as Office 365 Admin Portal. This should not affect blocking.

Skype

To control Skype traffic, choose the **Skype** tag from the **Application Filters** list rather than selecting individual applications. This ensures that the system can detect and control all Skype traffic the same way.

GoToMeeting

In order to fully detect GoToMeeting, your rule must include all of these applications:

- GoToMeeting
- Citrix Online

Zoho mail

To control Zoho mail, choose *both* **Zoho** and **Zoho mail** from the Available Application list.

Evasive application detection considerations

For evasive applications such as Bittorrent, Tor, Psiphon, and Ultrasurf, only the highest-confidence scenarios are detected by default. If you need to take action on this traffic (such as block or implement QoS), it may be necessary to configure more aggressive detection with better effectiveness. To do this, contact TAC to review your configurations as these changes may result in false positives.

WeChat

It is not possible to selectively block WeChat Media if you allow WeChat.

RDP file transfer

If allowing the RDP (Remote Desktop Protocol) application does not allow file transfers, ensure that the rule for RDP includes both the TCP and UDP port 3389. RDP file transfer uses UDP.

Best practices for access control rules

Configuring and ordering access control rules properly is essential to protect your network. Consider these best practices to achieve optimal results:

- Always evaluate device compatibility of access control rules before deployment.
- Ensure resources, such as physical memory and processors, can handle expanded rule criteria.

Note Ensure the system evaluates all rules together and creates a set of criteria for devices when you deploy configuration changes. You cannot deploy to a device if these criteria exceed its resources.

General best practice for access control

General best practices

- Use a prefilter policy to provide early blocking for unwanted traffic, and to fastpath traffic that does not benefit from access control inspection. For more information, refer to Best practices for fastpath prefiltering, on page 2356.
- Access control rules are deployed as access control entries (ACE) on the device. To minimize the number of access control entries created per access control rule, and improve overall performance, enable object group search for each device. Object group search is a device setting, not an access control policy setting, so you must edit each device to ensure the feature is enabled. For more information, refer to Configure object group search, on page 953.
- The number of Access Control Entries (ACEs) can expand significantly based on network objects, zones, and interface configurations. The **High Expansion rules** option (under **Filter presets**) display rules contributing to 10 percent or more of the total ACE count. This allows you to optimize them proactively. Using high expansion rules, you can:
  - predict memory usage for your policy,
  - identify heavy rules, and
  - prevent unstable deployments if the configuration exceeds device memory thresholds or capacity limits.

  The system displays warnings for configurations approaching device thresholds. You must review these warnings before proceeding with deployment.
- Whenever possible, combine multiple network objects into a single object group. The system automatically creates an object group (during deployment) when you select more than one object (for source or destination separately). Selecting existing groups can avoid object group duplication and reduce the potential impact on CPU usage when there are a large number of duplicate objects.
- Certain features, including URL filtering, application detection, and rate limiting, must allow some packets to pass in order for the system to identify the traffic.

- If you will use syslog or store events externally, avoid special characters in object names such as policy and rule names. Object names should not contain special characters, such as commas, that the receiving application may use as separators.

Licensing and feature support

- Although you can configure the system without licensing your deployment, many features require that you enable the appropriate licenses before you deploy.
- Some features are only available on certain device models. Warning icons and confirmation dialog boxes designate unsupported features.

Deployment considerations

- When you deploy an access control policy, its rules are not applied to existing connections. Traffic on an existing connection is not bound by the new policy that is deployed. In addition, the policy hit count is incremented only for the first packet of a connection that matches a policy. Thus, the traffic on an existing connection that could match a policy is omitted from the hit count. To have the policy rules effectively applied, clear the existing connection sessions, and then deploy the policy.
- For the system to affect traffic, you must deploy relevant configurations to managed devices using routed, switched, or transparent interfaces, or inline interface pairs.
- The system might prevent you from deploying inline configurations to passively deployed devices, including inline devices in tap mode. In other cases, the policy might deploy successfully, but attempts to block or alter traffic can produce unexpected results because passive devices do not enforce traffic actions. For example, the system might report multiple beginning-of-connection events for a connection that the policy attempts to block.

Best practices for creating, ordering, and implementing access control rules are detailed in Best practices for access control rules, on page 1842 and subtopics.

Best practices for ordering rules

Access control rules are matched top down, first match wins. Thus, to get the results you expect, you must pay careful attention to proper sequencing.

- In general, place top-priority rules that must apply to all traffic near the top of the policy. Always order rules to suit your organization's needs.
- Specific rules should come before general rules, especially when the specific rules are exceptions to general rules. Otherwise, traffic will match the general rule first and never hit the applicable specific rule.
- Rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number) should come as early as possible. Rules based on these criteria do not require inspection to identify matching connections.
- Whenever possible, put specific drop rules near the top of the policy. This ensures the earliest possible decision on undesirable traffic.
- URL filtering, application-based, and geolocation-based rules and others that require inspection should come after rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number), but before rules that specify file and intrusion policies.

- For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:
  - They include application conditions.
  - The traffic to be inspected is encrypted.
- Put URL filtering rules above application rules, and follow application rules with micro-application rules and Common Industrial Protocol (CIP) sub-classification application filtering rules.
- In general, rules with application conditions should be lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example. For more information, see Best practice for choosing between application matching and port matching, on page 1840 and Recommendations for application control, on page 1838.
- Rules that specify file policies and intrusion policies should come at the bottom of the rule order. These rules require resource-intensive deep inspection, and you should eliminate as many threats as possible using less-intensive methods first, for performance reasons, in order to minimize the number of potential threats that require deep inspection.

Application rule order

Place rules with application conditions lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example.

Access control rules that use *specific* conditions (such as networks and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your access control rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your access control rules. For more information about the OSI model, see this Wikipedia article.

For more information, refer to Best practice for choosing between application matching and port matching, on page 1840 and Recommendations for application control, on page 1838.

Rule preemption

Rule preemption is a policy evaluation condition that occurs when a rule will never match traffic because a rule earlier in the evaluation order matches the traffic first. A rule's conditions govern whether it preempts other rules.

Rule preemption scenarios

Any type of rule condition can preempt a subsequent rule. This table shows common preemption scenarios:

Table 103: Rule preemption examples

Rule 1 (preempting)	Rule 2 (preempted)	Rule preemption scenario
Allow Admin users	Block Admin users	The second rule cannot block Admin traffic because the first rule allows it.

Rule 1 (preempting)	Rule 2 (preempted)	Rule preemption scenario
Allow Source Network VLAN 22-33	Block Source Network VLAN 27	The VLAN range in the first rule includes the VLAN in the second rule, so the first rule preempts the second. To block VLAN 27, you must move that rule above the one that allows VLAN 22-33.
Allow Source Network 10.4.0.0/16	Allow Source Network 10.4.0.0/16, VLAN 2	The VLAN range in the first rule includes the VLAN in the second rule, so the first rule preempts the second. To block VLAN 27, you must move that rule above the one that allows VLAN 22-33.
Allow Source Network 10.10.10.0/24 to URL www.netflix.com	Allow Source Network 10.10.10.0/24 to URL www.netflix.com	A rule also preempts an identical subsequent rule where all configured conditions are the same.

Best practice for rule actions and rule order

A rule's action determines how the system handles matching traffic. Improve performance by placing rules that do not perform or ensure further traffic handling before the resource-intensive rules that do. Then, the system can divert traffic that it might otherwise have inspected.

The following examples show how you might order rules in various policies, given a set of rules where none is more critical and preemption is not an issue.

If your rules include application conditions, also refer to Best practice for choosing between application matching and port matching, on page 1840.

Optimum order for access control rules

Intrusion, file, and malware inspection requires resources, especially if you use multiple custom intrusion policies and variable sets. Place access control rules that invoke deep inspection last.

1. Monitor—Rules that log matching connections, but take no other action on traffic. (However, see the important exception and caveat at Access control rule monitor action, on page 1830.)
2. Trust, Block, Block with reset—Rules that handle traffic without further inspection.
3. Allow, Interactive Block (no deep inspection)—Rules that do not inspect traffic further, but allow discovery.
4. Allow, Interactive Block (deep inspection)—Rules associated with file or intrusion policies that perform deep inspection for prohibited files, malware, and exploits.

Best practices for simplifying and focusing rules

Follow these best practices to simplify configuration and ensure optimal device performance and rule clarity:

Simplify rule conditions

Minimize individual rule criteria. Use as few elements in rule conditions as possible. For example, use IP address blocks rather than individual IP addresses when defining network conditions.

Avoid redundant conditions

If a single condition is enough to match the traffic you want to handle, do not add more. Redundant conditions can make configuration unnecessarily complex and may negatively impact device performance, especially during cluster or high-availability unit re-join.

For example:

- Use security zones that represent multiple interfaces carefully. If you specify source and destination networks as conditions, and these are enough to match the traffic you are targeting, then specifying a security zone is not required.
- If you want to match a set of internal interfaces to any destination on the Internet (for example), then simply use a source security zone that includes your internal interfaces. No network or destination interface criteria are needed.

Combine elements for organization, not performance

The use of network objects containing many individual IP addresses offers organizational benefits only. It does not improve device performance compared to listing those IP addresses individually.

For recommendations related to application detection, refer to Best practice for choosing between application matching and port matching, on page 1840.

Narrowly constrain resource-intensive rules, especially by interface

As much as possible, use rule conditions to narrowly define the traffic handled by resource-intensive rules. Focused rules are also important because rules with broad conditions can match many different types of traffic, and can preempt later, more specific rules. Examples of resource-intensive rules include:

- TLS/SSL rules that decrypt traffic—Not only the decryption, but further analysis of the decrypted traffic, requires resources. Narrow focus, and where possible, block or choose not to decrypt encrypted traffic.

  Certain Firewall Threat Defense models perform TLS/SSL encryption and decryption in hardware, which improves performance significantly. For more information, refer to TLS crypto acceleration, on page 1944.

- Access control rules that invoke deep inspection—Intrusion, file, and malware inspection requires resources, especially if you use multiple custom intrusion policies and variable sets. Make sure you only invoke deep inspection where required.
- If you specify security zones in a rule, the rule is deployed only to devices that have interfaces in the specified zone. So, if you want to focus a rule on only some devices that are assigned to the policy, ensure that you select a security zone that applies to the appropriate subset of devices. This ensures that unnecessary rules are not deployed to a device.

Maximum number of access control rules and intrusion policies

The maximum number of access control rules or intrusion policies that are supported by a device depends on many factors, including policy complexity, physical memory, and the number of processors on the device.

If you exceed the maximum supported by a device, you cannot deploy the access control policy and you must reevaluate.

Guidelines for intrusion policies

Consider these guidelines when configuring intrusion policies:

- In an access control policy, you can associate one intrusion policy with each Allow and Interactive Block rule, as well as with the default action. Every unique **pair** of intrusion policy and variable set counts as one policy.
- You may want to consolidate intrusion policies or variable sets so you can associate a single intrusion policy-variable set pair with multiple access control rules. On some devices you may find you can use only a single variable set for all your intrusion policies, or even a single intrusion policy-variable set pair for the whole device.

Access control rule management

Access control rule management is a security administration process that involves procedures for creating, modifying, and maintaining access control rules.

These topics explain how to manage access control rules.

Add an access control rule category

Categories help organize rules into logical groups so you can understand and manage your policy more easily.

You can divide an access control policy's **Mandatory** and **Default** rule sections into custom categories. After you create a category, you cannot move it, although you can delete it, rename it, and move rules into, out of, within, and around it. The Firewall Management Center assigns rule numbers across sections and categories.

Procedure

Step 1 In the access control policy editor, click **Add Category**.

If your policy already contains rules, you can click a blank area in the row for an existing rule to set the position of the new category before you add it. You can also right-click an existing rule and select **Insert new category**.

Step 2 Enter a **Name**.

Step 3 From the **Insert** drop-down list, choose where you want to add the category:

- To insert a category below all existing categories in a section, choose **into Mandatory** or **into Default**.
- To insert a category above an existing category, choose **above category**, then choose a category.
- To insert a category above or below an access control rule, choose **above rule** or **below rule**, then enter an existing rule number.

Step 4 Click **Apply**.

Step 5 Click **Save** to save the policy.

What to do next

You can now:

- Drag and drop rules into, or out of, the category.
- When creating a rule, select a category it should be part of.
- When editing a rule, reposition the rule to be in the category, or to move it out of the category.

Create and edit access control rules

Use access control rules to apply actions to specific traffic classes. Rules allow you to selectively allow desirable traffic and drop unwanted traffic.

Before you begin

If you have enabled the Policy Analyzer & Optimizer tool, your edits are evaluated as you make them. If anomalies are detected, you are notified during the edit and prompted to make changes when you click **Apply** to save the rule. You can view the anomalies, such as redundant and shadowed rules, and choose to edit or delete the rule. You can also proceed with saving the rule as is, to deal with the issue later.

Procedure

Step 1 In the access control policy editor, you have the following options:

- To add a new rule, click **Add Rule**.
- To edit an existing rule, click **Edit** ( ).
- To start with a copy of an existing rule, choose one of the following commands from the **More** ( ) menu.
  - **Copy Rule**, to copy the rule to the clipboard, so you can use the **Paste Above/Below** commands to place it anywhere in the same policy.
  - **Copy Rule to Different Policy**, to copy the rule to another access control policy. A dialog box opens so that you can select the policy and chose the rule placement.
  - **Clone Rule**, to create the copy immediately below the duplicated rule.
- To edit multiple rules, use the checkboxes to select multiple rules, then select **Edit** or another action from the **Select Action/Bulk Rule Actions** list next to the search box.
- To do inline editing, where you change the configuration of an object in a rule condition, right-click the value and choose **Edit**. You can also use the right-click menu to remove a item, add it to the filter, or copy the text or value.

If **View** ( ) appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.

Step 2 If this is a new rule, enter a **Name**.

Step 3 Configure the rule components.

If you are bulk-editing multiple rules, only a subset of options are available.

Table 104: Access control rule components

Rule component	Configuration description
Position	Specify the rule position (**Insert** for new rules, the **Reposition** icon next to the rule name for existing rules); see Access control rule order, on page 1829.
Action	Choose a rule **Action**; see Access control rule actions, on page 1830.
Advanced Logging	Click **Advanced Logging** and choose the protocols for application-aware and protocol-aware event logs. See *About Application-Aware Event Logging* in the *Cisco Secure Firewall Management Center Administration Guide* for more information. **Note** The **Advanced Logging** option is available when the feature is enabled in the access control policy's advanced settings. See *Enable Application-Aware Event Logging* in the *Cisco Secure Firewall Management Center Administration Guide*.
Logging	Click **Logging** to specify options for connection logging and SNMP traps. For new rules, the initial logging configuration depends on the global default logging settings in the **Administration** > **Configuration** > **Access Control Preferences** page. When **Enable logging by default for new rules** is enabled on the **Access Control Preferences** page: • Logging is automatically enabled for new rules and configured based on the rule action. • You can change the logging settings for an individual rule. Rule-level settings override the global default logging setting for that rule. • If you change the action of a rule, Firewall Management Center reapplies the default logging settings for the new action. This replaces the rule's current logging settings, even if you previously disabled logging for the rule. Review the logging settings after changing the rule action and reapply any required rule-level settings. For information about configuring the default logging settings, refer to *Configure access control preferences* in the *Cisco Secure Firewall Management Center Administration Guide*. See *Best Practices for Connection Logging* in the *Cisco Secure Firewall Management Center Administration Guide* for more information. **Note** You can integrate Splunk or any SIEM syslog server to directly receive connection events from the Firewall Management Center or from its managed devices. If you have configured Firewall Management Center as the source of connection events in Splunk configuration, under **Send Connection Events to**, choose **Firewall Management Center**. If you have configured Firewall Threat Defense as the connection event source, select at least one destination. For the Splunk configuration procedure, see the *Cisco Secure Firewall Management Center Administration Guide*.
Time Range	(Optional.) For Firewall Threat Defense devices, choose the days and times when the rule is applicable. If you do not choose an option, the rule is always active. For details, see Create a time range object, on page 2868.

Rule component	Configuration description
Enable Rule	Whether the rule is active. Disabled rules are not applied to connections. You can disable rules to temporarily turn them off, for example, during troubleshooting.
Security Protections (Deep inspection)	(Optional.) For Allow and Interactive Block rules, select options for **Intrusion Policy**, **Variable Set**, and **File Policy**. You can apply intrusion and file policies independently; you do not need to configure both.
Conditions	Select the objects you want to add to either source or destination, then click either **Add to Sources** or **Add to Destinations and Applications** to add matching conditions for connections. You can click a tab to restrict the list of available objects, for example, to Networks, Security Zones, Applications, and so forth. However, the sources and destination column always show all selected objects regardless of the tab you are on. See Access control rule conditions, on page 1850 for more information.
Comments	Open the comments list at the bottom of the dialog box, enter your comment, and click **Add Comment/Post** to add a comment.

Step 4 Click **Add** or **Apply** to save the rule. Click **Apply and Add New Rule** to leave the dialog box open so you can create a new rule.

Step 5 Click **Save** to save the policy.

What to do next

If you will deploy time-based rules, specify the time zone of the device to which the policy is assigned. See Configure a time zone for a device, on page 1073.

Deploy configuration changes; see Deploy configuration changes, on page 193.

Related Topics

Best practices for access control rules, on page 1842

Access control rule conditions

Access control rule conditions are traffic matching criteria that define the characteristics of the connections you want to target with each rule. Use the conditions precisely to fine-tune the rule to apply to all, and only, the traffic that should be handled by the rule. The following topics explain the match conditions that you can use.

Security/tunnel zone rule conditions

Security/tunnel zone rule conditions are traffic matching mechanisms that

- use security zones and tunnel zones to select traffic for a rule
- segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices
- allow you to identify tunneled traffic, such as GRE, that should be handled as a tunnel rather than apply access control rules to the encapsulated connections within the tunnel.

You can use security zones to control traffic by its source and destination interfaces. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones for it to match the rule. Just as all interfaces in a security zone must be of the same type (all inline, passive, switched, or routed), all zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

When using tunnel zones, ensure that you have matching rules in the prefilter policy to associate tunneled traffic with the zone. Then, you can select the tunnel zone as a source zone in a rule; tunnel zones cannot be destinations. If you do not have prefilter rules to rezone the tunnels into the tunnel zone, an access control rule for the tunnel will never apply to any connections. You can specify destination security zones to target tunnels that leave the device through specific interfaces.

Security zone considerations

Consider the following when deciding on security zone criteria:

- Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.
- Access control rules generate ACL entries (ACEs) in the device configuration to provide early processing and drops whenever possible. If you specify security zones in rules, ACEs are created for each interface in the zone, which can greatly increase the size of the ACL. Excessively large ACLs generated from access control rules can impact system performance.

Network rule conditions

Network rule conditions are the network objects or geographical locations that define the network addresses or locations of the traffic.

Network criteria selection

- To match traffic from an IP address or geographical location, add the criteria to the Sources list.
- To match traffic to an IP address or geographical location, add the criteria to the Destinations list.
- If you add both source and destination network conditions to a rule, matching traffic must originate from one of the specified IP addresses and be destined for one of the destination IP addresses.

When you add this criteria, you select from these tabs:

- **Network**—Select the network objects or groups that define the source or destination IP addresses for the traffic you want to control.

  Whenever possible, combine multiple network objects into a single object group. The system automatically creates an object group (during deployment) when you select more than one object (for source or destination separately). Selecting existing groups can avoid object group duplication and reduce the potential impact on CPU usage when there are a large number of duplicate objects.

  You can use objects that define the address using the fully-qualified domain name (FQDN); the address is determined through a DNS lookup. However, FQDN objects are not supported in these sections in access control policies: original client networks, SGT/ISE attributes, network analysis and intrusion policy, Security Intelligence, threat detection, elephant flow settings.

- **Geolocation**—Select the geographical location to control traffic based on its source or destination country or continent. Selecting a continent selects all countries within the continent. Besides selecting geographical location directly in the rule, you can also select a geolocation object that you created to define the location. Using geographical location, you could easily restrict access to a particular country without needing to know all of the potential IP addresses used there.

Note To ensure that you are using up-to-date geographical location data to filter your traffic, Cisco strongly recommends that you regularly update the geolocation database (GeoDB).

Traffic matching configuration:

- To match traffic from an IP address or geographical location, add the criteria to the Sources list.
- To match traffic to an IP address or geographical location, add the criteria to the Destinations list.
- If you add both source and destination network conditions to a rule, matching traffic must originate from one of the specified IP addresses and be destined for one of the destination IP addresses.

Original client in network conditions (filtering proxied traffic)

For some rules, you can handle proxied traffic based on the originating client. Use a source network condition to specify proxy servers, then add an original client constraint to specify original client IP addresses. The system uses a packet's X-Forwarded-For (XFF), True-Client-IP, or custom-defined HTTP header field to determine original client IP.

Traffic matches the rule if the proxy's IP address matches the rule's source network constraint, and the original client's IP address matches the rule's original client constraint. For example, to allow traffic from a specific original client address, but only if it uses a specific proxy, create three access control rules:

Access Control Rule 1: Blocks proxied traffic from a specific IP address (209.165.201.1)

Source Networks: 209.165.201.1
Original Client Networks: none/any
Action: Block

Access Control Rule 2: Allows proxied traffic from the same IP address, but only if the proxy server for that traffic is one you choose (209.165.200.225 or 209.165.200.238)

Source Networks: 209.165.200.225 and 209.165.200.238
Original Client Networks: 209.165.201.1
Action: Allow

Access Control Rule 3: Blocks proxied traffic from the same IP address if it uses any other proxy server.

Source Networks: any
Original Client Networks: 209.165.201.1
Action: Block

VLAN tag rule conditions

VLAN tags rule conditions are filtering mechanisms that

- control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic

- use the innermost VLAN tag to filter VLAN traffic, with the exception of prefilter policy which uses the outermost VLAN tag, and
- apply only to inline sets and do not match traffic on firewall interfaces.

VLAN tag rule conditions configuration details

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

User rule conditions

A user rule condition is a traffic matching mechanism that

- matches traffic based on the user initiating the connection or the group to which they belong
- can be configured for users in Microsoft Active Directory realms only, and
- enables policy enforcement based on user identity and group membership.

Special identities users

In addition to configuring users and groups for configured realms, you can set policies for the special identities users:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1794.

Configure a QoS rule to rate-limit traffic initiated by users in the Finance group.

Application rule conditions

Application rule conditions are application awareness and control mechanisms that

- identify and classify applications through IP traffic analysis
- enable control with organized filters
- require one enabled detector for each condition.

Application filters and control benefits

System-provided *application filters* help perform control by organizing applications according to basic characteristics, such as type, risk, business relevance, category, and tags. You can also create reuseable, user-defined filters using combinations of system-provided filters, or custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled, the system automatically enables all available system-provided detectors, or the most recently modified user-defined detector. For more information about application detectors, see Application detectors, on page 2708.

You can utilize both application filters and individually specified applications to ensure complete coverage. Understand the application's requirements to effectively order access control rules.

Application filters help you to quickly configure application control effectively. For example, use a system-provided filter to create a QoS rule that identifies high-risk, low-business-relevance applications and rate-limits matching traffic.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can be sure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

The system characterizes detected applications using several criteria which form effective filters.

Table 105: Application characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email applications are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.

Characteristic	Description	Example
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged `high bandwidth` and `displays ads`.

Configure application conditions and filters

To build an application condition or filter, choose the applications whose traffic you want to control from a list of available applications. It is recommended that you constrain the available applications using filters. You can use filters and individually specified applications in the same condition.

Before you begin

- Adaptive profiling must be enabled (its default state) in the access control policy's advanced settings for access control rules to perform application control.

Follow these steps to configure application conditions and filters:

Procedure

Step 1 In the access policy rule editor, click **Applications**.

Step 2 Find and choose the applications you want to add from the **Available Applications** list.

To constrain the applications displayed in **Available Applications**, choose one or more **Application Filters** or search for individual applications.

Tip Click **Information**( ) next to an application to display summary information and internet search links. A **lock** icon marks applications that the system can identify only in decrypted traffic.

When you choose filters, singly or in combination, the Available Applications list updates to display only the applications that meet your criteria. You can choose system-provided filters in combination, but not user-defined filters.

- Multiple filters for the same characteristic (risk, business relevance, and so on)—Application traffic must match only one of the filters. For example, if you choose both the medium and high-risk filters, the Available Applications list displays all medium and high-risk applications.
- Filters for different application characteristics—Application traffic must match both filter types. For example, if you choose both the high-risk and low business relevance filters, the Available Applications list displays only applications that meet both criteria.

Step 3 Click **Add Application** or **Add to Rule**, or drag and drop.

Tip Before you add more filters and applications, click **Clear Filters/Selection** to clear your current choices.

Step 4 If destination ports are not specified on the Ports tab, select the **Port** for the applications.

The **Port** specification applies to all the applications in the list; it does not apply to any filters. You cannot specify different port options for each application. If you already specified destination ports on the Ports tab, that selection is reflected in the application list, and you cannot make the selection.

If you have not already specified destination ports for the rule, choose one of the following:

- **Application Default**—The system looks at the default port only when evaluating traffic for an application match. Click the info button (i) to see what is considered the default for each application.

  When editing a rule, if the rule already has source ports, and you add an application that has an incompatible port and select Application Default port, you are warned. If you elect to use the application default port, the incompatible source port is removed.

- **Any**—The system does not restrict the application identification based on the port used in the connection. If there are source ports specified on the Port tab, you might need to select this option to be able to save the rule.

Regardless of the option you select, if you subsequently configure any destination value on the Ports tab, the ports specified on the Ports tab override your selection here, and change the application port to Any. If you want to limit the rule to one, multiple, or a range of ports that are not the application default port, use the Ports tab.

This option does not apply to custom detectors.

Note If the access control policy is assigned to devices running 7.x versions, the rule is handled differently if you have included applications that have different default ports. When you select to apply the rule to the default ports only, then for 7.7 systems, the rule is split into separate rules, one per application. For systems running versions 7.3-7.6, the rule is kept as a single rule, but the ports page is updated with each of the default ports. If you are managing devices running down-level software versions, and you want to use default port matching, we recommend that you limit the application's list in each rule to applications that have the same default port.

Step 5 Save or continue editing the rule or configuration.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 193.

Port, protocol, and ICMP code rule conditions (concept)

A port, protocol, and ICMP code rule condition is a traffic matching criterion that

- matches traffic based on source and destination ports
- supports TCP, UDP, ICMP, and other protocols that do not use ports, and

- controls traffic flow in access control and other policy rules.

Port condition types

Port conditions match traffic based on the source and destination ports. Depending on the rule type, "port" can represent any of these types:

- TCP and UDP—Control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP (6) /22.
- ICMP—Control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—Control traffic using other protocols that do not use ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best practices for port-based rules

Specifying ports is the traditional method used to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Use application filtering criteria when possible; however, note that application filtering is unavailable in prefilter rules.

Use application filtering for FTP and similar applications that open separate channels for control and data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly and could result in blocking desirable connections.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching non-TCP traffic with port conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although configuring port conditions can match non-TCP traffic, restrictions apply:

- Access control rules—For Classic devices, match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, add only network-based conditions: zone, IP address, port, and VLAN tag. The system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For Firewall Threat Defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support only TCP port conditions.
- ICMP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies, sent in response to ICMP echo requests, are ignored. To match any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

Recommendation: use URL conditions for website access control

Use URL conditions to select website traffic that a QoS rule will rate-limit.

For more information, refer to URL filtering with category and reputation, on page 1870.

Dynamic attributes rule conditions

Dynamic attributes rule conditions allow you to specify access control rules based on real-time properties such as network objects, device types, locations, and security tags. Dynamic attributes can be used as source criteria and destination criteria in access control rules. These criteria help match traffic more flexibly and accurately.

Dynamic attributes configuration and behavior

You can use these types of dynamic attributes to match connections in DNS rules:

- Dynamic objects (Source or destination): The dynamic attributes connector collects data such as networks and IP addresses from cloud providers for use in access control rules. For more information, refer to About the dynamic attributes connector , on page 2447 .
- SGT objects (Source only): These contain tags defined manually or in Cisco ISE. For more information, refer to Source and destination security group tag (SGT) matching, on page 2184 and Security group tags, on page 2803 .
- Location IP objects (Source only): Defined by Cisco ISE.
- Device type objects (Source only): Defined by Cisco ISE, also referred to as endpoint profile objects.

When you configure dynamic attributes for a DNS rule, objects of the same type within a source or destination list use OR logic, while objects of different types use AND logic. For example, if you select both a security group tag, and a dynamic object that lists IP addresses, the rule matches if traffic with the tag originates from (or is destined to) one of those IP addresses.

When you open the **Dynamic Attributes** tab, all **Dynamic Objects** and **Security Group Tags** appear in the list. To remove objects from the list, deselect the options. To find an object, type in the search box.

Time and Day Rule Conditions

You can specify a continuous time range or a recurring time period.

For example, a rule can apply only during weekday working hours, or every weekend, or during a holiday shutdown period.

Time-based rules are applied based on the local time of the device that processes the traffic.

Time-based rules are supported only on Firewall Threat Defense devices. If you assign a policy with a time-based rule to a different type of device, the time restriction associated with the rule is ignored on that device. You will see warnings in this case.

Enable and disable access control rules

Enable or disable access control rules to control whether they are used to evaluate network traffic.

When you create an access control rule, it is enabled by default. If you disable a rule, the system does not use it to evaluate network traffic and stops generating warnings and errors for that rule. When viewing rules in

an access control policy, disabled rules are grayed out but can still be modified. You can also change a rule's status in the rule editor.

Procedure

Step 1 In the access control policy editor, right-click the rule you want to change and choose a rule state.

If **View** ( ) appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.

Step 2 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Copy access control rules from one access control policy to another

You can copy access control rules from one access control policy to another. You can copy the rules either to the **Default** section or the **Mandatory** section of the access control policy.

All the settings of the copied rules, except the comments, are retained in the pasted version

Procedure

Step 1 Do one of the following:

- To copy a single rule, right-click the rule and select **Copy Rule to Different Policy**.
- To copy multiple rules, select their checkboxes, then select **Copy Rules to Different Policy** from the **Select Bulk Action** menu.

Step 2 Select the destination access control policy from the **Access Policy** drop-down list.

Step 3 From the **Place Rules** drop-down list, choose where you want to position the copied rules. You can place them at the top or bottom of either the Mandatory or Default sections.

Step 4 Click **Copy**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Move access control rules to a prefilter policy

You can move access control rules from an access control policy to the associated non-default prefilter policy.

You must first apply a user-defined prefilter policy to the access control policy. The access control rules cannot be moved to the default prefilter policy because the default prefilter policy cannot have rules.

Before you begin

Note these conditions before you proceed:

- When moving an access control rule to a prefilter policy the layer 7 (L7) parameters, such as application or URL filterin, in the access control rule cannot be moved. The L7 parameters are dropped during the operation.
- The comments in the access control rule configuration are lost after moving the rule. However, a new comment is added in the moved rule mentioning the source access control policy.
- You cannot move access control rules with **Monitor** set as the **Action** parameter.
- The **Action** parameter in the access control rule is changed to a suitable action in the prefilter rule when moved. To know what each action in the access control rule maps to, see this table:

Action in the access control rule	Action in the prefilter rule
Allow	Analyze
Block	Block
Block with reset	Block
Interactive Block	Block
Interactive Block with reset	Block
Trust	Fastpath

- Similarly, based on the action configured in the access control rule, the logging configuration is set to an appropriate setting after the rule is moved, as mentioned in this table.

Action in the access control rule	Enabled logging configurations in the prefilter rule
Allow	None of the check boxes are checked.
Block Block with reset Interactive Block Interactive Block with reset	• Log at Beginning of Connection • Event Viewer • Syslog Server • SNMP Trap
Trust	• Log at Beginning of Connection • Log at End of Connection • Event Viewer • Syslog Server • SNMP Trap

- While moving rules from the source policy, if another user modifies those rules, you will see get a message. You may continue with the process after refreshing the page.

Procedure

Step 1 Do one of the options:

- To move a single rule, right-click the rule and select **Move Rule to Prefilter Policy**.
- To move multiple rules, select their checkboxes, then select **Move Rules to Prefilter Policy** from the **Select Bulk Action** menu.

Step 2 From the **Place Rules** drop-down list, choose where you want to position the moved rules, either **At the bottom** or **At the top**.

Step 3 Click **Move**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Position an access control rule

Position rules correctly within an access control policy to ensure the first match wins behavior produces the intended security outcomes.

You can move an existing rule within an access control policy, or insert new rules in a desired location. When you add or move a rule to a category, the system places it last in the category.

Before you begin

Review rule order guidelines in Best practices for access control rules, on page 1842.

Procedure

Step 1 Do one of these:

- New rule—Insert a new rule by hovering over the line between the existing rules, and clicking **Add Rule**. The location is selected in the **Insert** box in the Add Rule dialog box; you can select a different rule to adjust the location. You can also select **Add Rule Above** or **Add Rule Below** from the right-click menu.
- Existing rules when viewing the rule table—Click and drag the rule to the new position. This action is final, you are not prompted to confirm it.
- Existing rules when viewing the rule table—Right-click a single rule and select **Reposition Rule**. To move multiple rules as a group, select their checkboxes, then select **Reposition Rules** from the **Select Bulk Action** menu. You are prompted for where you want the rule to go.
- Existing rule when editing the rule—Click the **Reposition Rule** icon next to the rule name.

Step 2 When editing or repositioning the rule, choose where you want to move or insert the rule, then click **Move**, **Confirm**, or **Reposition** (depending on what you are doing).

- Choose **into Mandatory** or **into Default**.
- Choose a **into Category**, then choose the category.
- Choose **above rule** or **below rule**, then select the rule.

Step 3 Save the rule if you are editing it.

Step 4 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Add comments to an access control rule

Adding comments to access control rules helps you keep track of the purpose of a rule, and changes made to the rule.

When you create or edit an access control rule, you can add a comment. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the change. You can display a list of all comments for a rule along with the user who added each comment and the date the comment was added.

When you save a rule, all comments made since the last save become read-only.

To search access control rule comments, use the **Search Rules** bar on the rule listing page.

Procedure

Step 1 In the access control rule editor, click **Comments**.

Step 2 Enter your comment and click **Add Comment**. You can edit or delete this comment until you save the rule.

Step 3 Save the rule.

Examples for access control rules

These topics provide examples of access control rules.

How to control access using security zones

Configure security zones and access control rules to inspect incoming traffic for intrusions and malware while allowing unrestricted internet access for internal hosts.

Consider a deployment where you want hosts to have unrestricted access to the internet, but you nevertheless want to protect them by inspecting incoming traffic for intrusions and malware.

First, create two security zones: Internal and External. Then, assign interface pairs on one or more devices to those zones, with one interface in each pair in the Internal zone and one in the External zone. Hosts connected to the network on the Internal side represent your protected assets.

Note You are not required to group all internal (or external) interfaces into a single zone. Choose the grouping that makes sense for your deployment and security policies.

Then, configure an access control rule with a destination zone condition set to Internal. This simple rule matches traffic that leaves the device from any interface in the Internal zone. To inspect matching traffic for intrusions and malware, choose a rule action of **Allow** , then associate the rule with an intrusion and a file policy.

Control application usage

Block web-based applications, particularly anonymizers or proxies, by creating access control rules that identify and restrict traffic based on application attributes

Enterprise networks increasingly rely on web-based delivery platforms and rich media applications, often using the same web protocols. Firewall Threat Defense inspects connections to determine the application, enabling access control rules targeting applications rather than just targeting specific TCP/UDP ports.

Although you can select specific applications to allow or block, you can also write rules based on type, category, tag, risk, or business relevance. For example, you could create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the session is blocked.

Cisco frequently updates and adds additional application detectors via system and vulnerability database (VDB) updates. Thus, a rule blocking high risk applications can automatically apply to new applications without you having to update the rule manually.

In this use case, we will block any application that belongs to the **anonymizer/proxy** category.

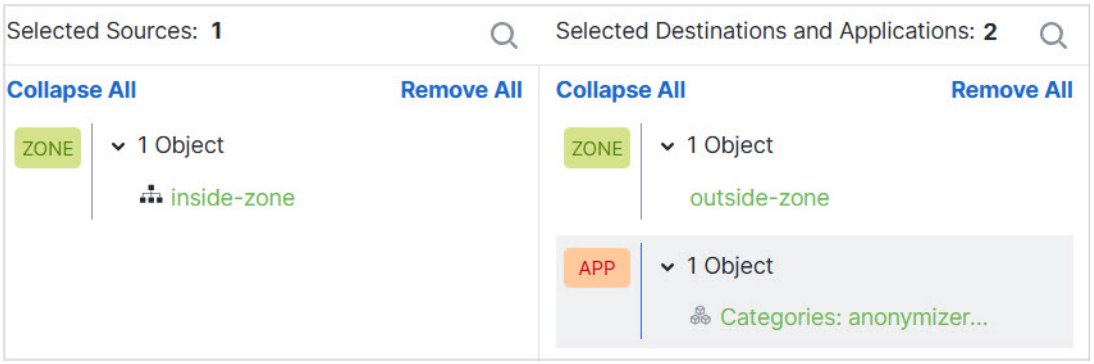
Procedure

Step 1 Choose **Policies** > **Security policies** > **Access Control** and edit the access control policy.

Step 2 Click **Add Rule** and configure the rule for application control.

a) Name the rule (for example, Block_Anonymizers).

b) For **Action**, select **Block**.



c) If you have configured security zones and want to restrict traffic from inside to outside, click the **Zones** tab, and choose your inside zone as the source zone, and the outside zone as the destination zone.

d) Click the **Applications** tab, select the applications to match, and click **Add Application**.

As you select criteria, such as category and risk level, the list to the right of the criteria updates to show exactly which applications match the criteria. The rule you are writing applies to these applications.

For purposes of this example, choose **anonymizers/proxy** from the **Categories** list and add it to **Destinations and Applications**. The match criteria should now look similar to the following graphic.

Note For **Port**, leave the default, Application Default. This ensures that the system looks only at the default ports used for a selected application, rather than all ports.

e) Click **Logging** next to the rule action, and enable logging at the start of the connection. You can select a syslog server if you use one.

You must enable logging to get information about any connections blocked by this rule.

Step 3 Move the rule so that it comes after any rules that use protocol and port criteria only, but that would not allow traffic that should be blocked by the application rule.

Matching applications requires Snort inspection. Because Snort inspection is not needed by rules that use protocol and port only, you can improve system performance by grouping these simple rules at the top of the access control policy as much as possible.

Step 4 Deploy the changes.

You can use the application rule hit counts and analysis dashboards to see how this rule is performing and how often users try these applications.

Block threats

You can implement next generation Intrusion Prevention System (IPS) filtering by adding intrusion policies to your access control rules. Intrusion policies analyze network traffic, comparing the traffic contents against known threats. If a connection matches a threat you are monitoring, the system drops the connection, thus preventing the attack.

All other traffic handling occurs before network traffic is examined for intrusions. By associating an intrusion policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect the traffic with an intrusion policy.

You can configure intrusion policies on rules that **allow** traffic only. Inspection is not performed on rules set to **trust** or **block** traffic. In addition, you can configure an intrusion policy as the default action if you do not want to use a simple block.

Security Intelligence policies allow you to preemptively block traffic to or from known bad IP addresses and URLs. This task demonstrates how to add an intrusion policy that allows traffic from the internal 192.168.1.0/24 network to external destinations, assuming block rules exist to eliminate unwanted connections, and adds Security Intelligence to block known threats.

Before you begin

- Apply the IPS license to any managed device that uses this rule.
- Ensure you have created security zones for inside and outside interfaces.
- Create the network object for the inside network.

Procedure

Step 1 Create the access control rule that applies the intrusion policy.

a) Edit the access control policy and add a new rule.

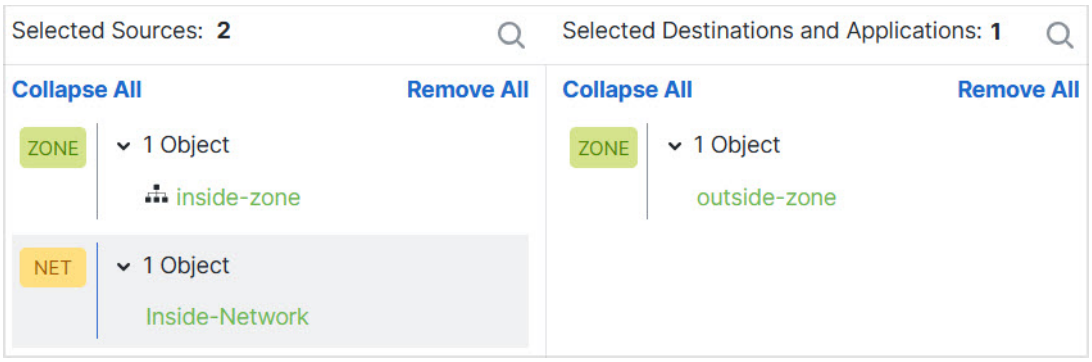
b) Name the rule (for example, Inside_Outside) and set the rule action to **Allow**.

c) Choose **Balanced Security and Connectivity** as the **Intrusion Policy**. You can either accept the default variable set or select your own if you want to customize it.

The **Balanced Security and Connectivity** policy is appropriate for most networks. It provides a good intrusion defense without being overly aggressive, which has the potential of dropping traffic that you might not want to be dropped. If you determine that too much traffic is getting dropped, you can ease up on intrusion inspection by selecting the **Connectivity over Security** policy.

If you need to be aggressive about security, try the **Security over Connectivity** policy. The **Maximum Detection** policy offers even more emphasis on network infrastructure security with the potential for even greater operational impact.

If you create your own custom policy, you can select that one instead.



A discussion of variable sets is beyond the scope of this example. Please read the chapters on intrusion policy for detailed information about variable sets and custom policies.

d) Select the **Zones** tab, and add your inside security zone to the source criteria, and outside zone to the destination criteria.

e) Select the **Networks** tab, and add the network object that defines your inside network to the source criteria.

The match criteria should look similar to the following:

f) Click **Logging** and enable logging at the beginning or end of the connection, or both, as desired.
g) Click **Apply** to save the rule, and then **Save** to save the updated policy.
h) Move the rule to the appropriate location in the access control policy.

Step 2 Configure the Security Intelligence policy to preemptively drop connections with known bad hosts and sites.

By using Security Intelligence to block connections with hosts or sites that are known to be threats, you save your system the time needed to do deep packet inspection to identify threats in each connection. Security Intelligence provides an early block of undesirable traffic, leaving more system time to handle the traffic you really care about.

a) While editing the access control policy, click the **Security Intelligence** link in the packet path.

The link includes two policies: the DNS policy at the top, and the Security Intelligence (Network and URL) at the bottom. In this example, we are configuring the Network and URL lists. By default, these lists already include the global block and do not block lists, but these lists are empty by default until you add items to them.

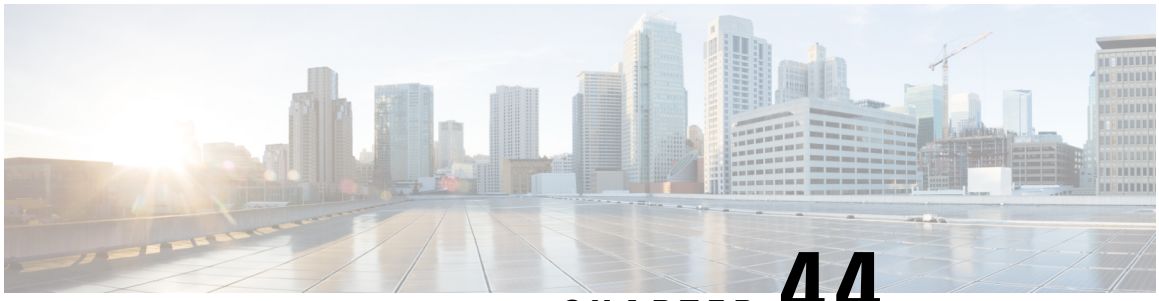
b) With **Networks** selected and the **Any** security zone selected, scroll down in the Networks list until you get to the global feeds, and the first Security Intelligence category (probably Attackers). Click Attackers, then scroll to the end of the categories (probably Tor_exit_node), and Shift+Click to select all of the categories. Click **Add To Block List**.
c) Select the **URL** tab, and **Any** security zone, and use Shift+Click to select URL versions of the same categories. Click **Add To Block List**.
d) Click **Save** to save the policy.
e) As necessary, you can add network and URL objects to the block or do not block lists.

The **Do Not Block** lists are not real "allow" lists. They are exception lists. If an address or URL in the exception list also appears in the blocked list, the connection for the address or URL is allowed to pass on to the access control policy.

This way, you can block a feed, but if you later find that a desirable address or site is being blocked, you can use the exception list to override that block without needing to remove the feed entirely.

Keep in mind that these connections are subsequently evaluated by access control, and if configured, an intrusion policy. Thus, if any connections do contain threats, they can be identified and blocked during intrusion inspection.

Use the events and dashboards to determine what traffic is actually being dropped by the policy, and whether you need to add addresses or URLs to the **Do Not Block** lists.



Step 3 Deploy your changes.

History for access control rules

This history table provides a summary of feature changes by release for the access control policy rules.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Default Port Specification for Application-based Access Control Rules.	10.0	10.0	When adding applications to access control rules, you can specify that the rule be limited to the default ports for the application. This is different from manually specifying ports on the Ports tab. You can alternatively specify that the application be identified on Any port, which is the behavior of the system prior to this enhancement. If you specify the default port and also make a specification on the Ports tab, the Ports tab overrides the application default port. You can use the Ports tab to limit the rule to one, multiple, or a range of ports. On upgrade, existing application-based rules continue to be applied to Any port. If you want to limit these rules to the default port, you must edit the rules, clear any specifications on the Ports tab, select Application Default port on the Applications tab, then save the rule. Deploy changes after editing all the rules you want to change. We added the ability to select Application Default or Any port when adding an application to an access control rule, so long as nothing is configured on the Ports tab. This option does not apply to application filters of any kind, nor does it apply to any other policy or object except access control rules.
Maximum objects per match criteria per access control rule is 200.	7.3	Any	Previously, you could have a maximum of 50 objects per match criteria in a single access control rule. For example, you could have up to 50 network objects in a single access control rule. The limit is now 200 objects per match criteria in a single rule. We updated the access control policy to allow the increased object limit.
Search for access control rule comments	6.7	Any	The **Search Rules** bar now offers the option to search for comments. New/modified pages: Access control rules page, **Search Rules** text entry field. Supported platforms: Firewall Management Center
Copy or move rules between access control and prefilter policies	6.7	Any	You can copy access control rules from one access control policy to another. You can also move access control rules from an access control policy to the associated prefilter policy. New/modified pages: Access control policy page; the right-click menu for the selected rules provides additional options to copy and move. Supported platforms: Firewall Management Center

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Bulk edit of certain settings in access control rules	6.6	Any	In the list of rules in a policy, shift-click or control-click to select multiple rules, then right-click and choose an option. Example bulk operations: You can enable or disable the rules, select a rule action, and edit most inspection and logging settings. New/modified pages: Access control rules page. Supported platforms: Firewall Management Center
Enhanced searching on configured rules	6.6	Any	Enhanced searching on configured rules. New/modified pages: Access control rules page. Supported platforms: Firewall Management Center
Time ranges for rule application	6.6	Any	Ability to specify an absolute or recurring time or time range for a rule to be applied. The rule is applied based on the time zone of the device that processes the traffic. New/modified pages: • A new option on the access control Add Rule page. • A related new option on the **Devices** > **Platform Settings** > **Threat Defense** page to specify time zones for managed devices. Supported platforms: Firewall Threat Defense devices only
View object details from access control rule pages	pre-6.6	Any	To see information about an object in a list of rules or from the rule configuration dialog, right-click the object. New/modified pages: **Policies** > **Access Control** > **Access control**, and **Add Rule** page. Supported platforms: Firewall Management Center

CHAPTER 44

URL Filtering Rules

You can implement URL filtering using access control rules.

- URL filtering, on page 1869
- Best practices for URL filtering, on page 1872
- License requirements for URL filtering, on page 1877
- Requirements and prerequisites for URL filtering, on page 1878
- Configure URL filtering with category and reputation, on page 1878
- Manual URL filtering, on page 1885
- HTTP response pages, on page 1887
- Configure URL filtering health monitors, on page 1894
- Dispute URL category and reputation, on page 1894
- Take action if the URL category set changes, on page 1895
- Troubleshoot URL filtering, on page 1896
- History for URL filtering, on page 1899

URL filtering

URL filtering is a security feature that

- controls the websites that users on your network can access,
- provides category and reputation-based filtering with a URL Filtering license, and
- enables manual specification of individual URLs, groups of URLs, and URL lists with any license.

URL filtering types

Use URL filtering to control website access through these methods:

- Category and reputation-based URL filtering—With a URL Filtering license, you can control access to websites based on the URL's general classification (category) and risk level (reputation). This is the recommended option.
- Manual URL filtering—With any license, you can manually specify individual URLs, groups of URLs, and URL lists and feeds to achieve granular, custom control over web traffic. For more information, see Manual URL filtering, on page 1885.

See also Security Intelligence, on page 1811, a similar but different feature for blocking malicious URLs, domains, and IP addresses.

The URL filtering feature is applicable only when you use a web browser to browse websites via the HTTP/HTTPS protocol. For other applications, you must use an FQDN-based access control rule instead of URL filtering. See Access Control Rules for more information.

URL filtering with category and reputation

URL filtering with category and reputation is a web security mechanism that

- controls access to websites based on the category and reputation of requested URLs,
- uses category classifications to group URLs by type (for example, ebay.com belongs to the Auctions category, and monster.com belongs to the Job Search category),
- assesses reputation levels from Unknown risk (level 0) or Untrusted (level 1) to Trusted (level 5) to determine how likely the URL is to be used for purposes that might be against the security policy for your organization, and
- allows URLs to belong to multiple categories simultaneously.

Reputation is determined per complete Uniform Resource Identifier (URI), e.g. different pages on www.cisco.com can have different reputations.

Benefits of category and reputation-based URL filtering

URL categories and reputations help you quickly configure URL filtering. For example, you can use access control to block untrusted URLs in the Hacking category. You can also use QoS to limit the rate of traffic from sites in the Streaming Video category. There are also categories for types of threats, such as a Spyware and Adware category.

Using category and reputation data simplifies policy creation and administration. It grants you assurance that the system controls web traffic as expected. Because Cisco continually updates its threat intelligence with new URLs, as well as new categories and risk levels for existing URLs, the system uses up-to-date information to filter requested URLs. Sites that (for example) represent security threats, or serve undesirable content may appear and disappear faster than you can update and deploy new policies.

These examples show how the system can adapt:

- If an access control rule blocks all gaming sites, as new domains are registered and classified as Games, the system can block those sites automatically. Similarly, if a QoS rule rate-limits traffic from all streaming video sites, the system can automatically limit traffic to new streaming video sites.
- If an access control rule blocks all malware sites and a shopping page gets infected with malware, the system can recategorize the URL from Shopping to Malware Sites and block that site.
- If an access control rule blocks untrusted social networking sites and somebody posts a link on their profile page that contains links to malicious payloads, the system can change the reputation of that page from Favorable to Untrusted and block it.

Limitations exist for category-based filtering in decryption policy Do Not Decrypt rules.

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from

its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security.

Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Recommendations for application control, on page 1838.

For more information, refer to Use categories in URL filtering, on page 1876.

URL category and reputation descriptions

This reference lists URL category and reputation level descriptions for security management.

Category descriptions

You can find a description of each URL category at https://www.talosintelligence.com/categories.

Click **Threat Categories** to view those categories.

Reputation level descriptions

Refer to Web reputation levels for information.

URL filtering data from the Cisco cloud

URL filtering data from the Cisco cloud is a threat intelligence dataset that

- allows traffic handling based on a website's general classification, or *category*, and risk level, or *reputation*,
- is automatically enabled when a URL Filtering license is added, and
- provides real-time threat intelligence evaluation for websites not found in local cache or datasets.

URL filtering data evaluation process

By default, when users browse to a URL whose category and reputation are not in a local cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache.

Optionally, you can use a local URL dataset of categories and reputations, which can make web browsing faster. When you enable or re-enable URL filtering, the Firewall Management Center automatically queries Cisco for URL data and pushes the dataset to managed devices. Then, when users browse to an URL, the system checks the local dataset and the cache for category and reputation information before submitting it to the cloud for threat intelligence evaluation. To see your options for using the local dataset, including how to disable individual cloud lookups altogether, see URL filtering options, on page 1880.

Automatic updates of URL data is enabled by default. We strongly recommend that you do not disable these updates.

Note The Secure Firewall Threat Defense 200 series device does not store URL category and reputation data locally. It relies entirely on browser cache and cloud-based lookups for URL filtering and reputation evaluation.

The set of URL categories may change periodically. When you receive a change notification, review your URL filtering configurations to make sure traffic is handled as expected. For more information, see Take action if the URL category set changes, on page 1895.

Best practices for URL filtering

Filter by category and reputation

Follow the instructions in Configure URL filtering with category and reputation, on page 1878.

Configure your policy to inspect packets that must pass before a URL can be identified

The system cannot filter URLs before:

- A monitored connection is established between a client and server.
- The system identifies the DNS, HTTP or HTTPS application in the session.
- The system identifies the requested domain or URL (for encrypted sessions, from a non-encrypted domain name, the ClientHello message or the server certificate).

This identification should occur within three to five packets, or after the server certificate exchange in the TLS/SSL handshake if the traffic is encrypted.

Important! To ensure that your system examines these initial packets that would otherwise pass, see Inspection of packets that pass before traffic is identified and subtopics.

If early traffic matches all other rule conditions but identification is incomplete, the system allows the packet to pass and the connection to be established (or the TLS/SSL handshake to complete). After the system completes its identification, the system applies the appropriate rule action to the remaining session traffic.

Block threat categories

Be sure that your policies specifically address Threat categories, which identify known malicious sites. Do this in addition to blocking sites with poor reputations.

For example, to protect your network from malicious sites, you must block all Threat categories. Additionally, Talos recommends that you block only sites with Poor category. You can block questionable reputations if you have an aggressive security posture, but this may result in a higher amount of false positives.

For specifics, see **Threat Categories** at the URL in URL category and reputation descriptions, on page 1871.

Position URL rules properly and consider rule order

Position URL rules after all other rules that *must* be hit.

URLs can belong to more than one category. It is possible to want to allow one category of websites and block another—whether explicitly or by relying on the default action. In this case, make sure you create and order URL rules so you get the desired effect, depending on whether the allow or the block should take precedence.

For additional guidelines for rules, see the following topics: Best practices for access control rules, on page 1842.

Handle uncategorized or reputationless URLs appropriately

When you build a URL rule, you first choose the category you want to match. If you explicitly choose **Uncategorized** URLs, you cannot further constrain by reputation.

Uncategorized URLs with Untrusted reputation are handled by the **Malicious Sites** category. If you want to block uncategorized sites with any other reputation level (such as Questionable), you must block all uncategorized sites.

After selecting a category and a reputation level, you can optionally select **Apply to unknown reputation**. For example, you can create a rule that applies to sites with Untrusted, Questionable, and unknown reputations.

You cannot manually assign categories and reputations to URLs, but in access control and QoS policies, you can manually block specific URLs. See Manual URL filtering, on page 1885. See also Dispute URL category and reputation, on page 1894.

URL filtering for encrypted web traffic

When performing URL filtering on encrypted web traffic, the system:

- (If DNS filtering is enabled) Checks to see if the system has previously seen the originating domain or the domain is in the local reputation database, and if so, takes action based on the reputation and category of the domain. Otherwise, the system processes the traffic based on your configurations for encrypted traffic, even if **Retry URL cache miss lookup** is enabled in the access control policy's advanced settings.
- Disregards the encryption protocol; a rule matches both HTTPS and HTTP traffic if the rule has a URL condition but not an application condition that specifies the protocol.
- Does not use URL lists. You must use URL objects and groups instead.
- Matches HTTPS traffic based on the subject common name in the public key certificate used to encrypt the traffic, and also evaluates the reputation of any other URLs presented at any time during the transaction, including the post-decryption HTTP URL.
- Disregards subdomains within the subject common name.
- Does not display an HTTP response page for encrypted connections blocked by access control rules (or any other configuration); see Limitations to HTTP response pages, on page 1888.

URL filtering and TLS server identity discovery considerations

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by RFC 8446, is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate *without* decrypting the entire packet.

Access control policy advanced settings offer an **Enhanced application and URL detection** option for TLS Server Identity Discovery.

We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. An decryption policy is not required because *traffic is not decrypted* in the process of extracting the server certificate.

Note

- TLS server identity discovery *cannot* be used with any of the following:
  - STARTTLS traffic
  - The HTTP CONNECT method
  - Traffic that is already being decrypted by another device on the network
- Because the certificate is decrypted, TLS server identity discovery can reduce performance depending on the hardware platform.
- TLS server identity discovery is not supported in inline tap mode or passive mode deployments.
- Enabling TLS server identity discovery is supported on any Secure Firewall Threat Defense Virtual version deployed in AWS. TLS server identity is incompatible with certain deployment scenarios that involve Gateway Load Balancer (GWLB). Whether the device initiates a server certificate probe depends on its deployment method with GWLB and the traffic direction.
  - Geneve single-arm flow: The probe *is not initiated* for either east–west or north–south traffic. A connection event **PROBE_FLOW_DROP_BYPASS_PROXY** increments every time the device attempts to extract the server certificate.
  - Geneve dual-arm flow: The probe *is initiated only* for north–south traffic.
- TLS Server Identity Discovery also operates on TLS 1.2 sessions.

For more information, see TLS server identity discovery, on page 2592.

HTTP/2 URL extraction limitations

The system can extract HTTP/2 URLs from TLS certificates, but not from a payload.

Use manual URL filtering effectively

- Specify URLs using a custom Security Intelligence list or feed object. Do not use a URL object or directly enter a URL into the rule. For details, see Manual URL filtering options, on page 1886.
- If you manually filter specific URLs using URL objects or by entering URLs directly into the rule, carefully consider other traffic that might be affected. To determine whether network traffic matches a URL condition, the system performs a simple substring match. If the requested URL matches any part of the string, the URLs are considered to match.
- If you use manual URL filtering to create exceptions to other rules, position the specific rule with the exceptions above the general rule that would otherwise apply.

Search query parameters in URLs are not used for matching

The system does not use search query parameters in the URL to match URL conditions. For example, consider a scenario where you block all shopping traffic. In that case, using a web search to search for amazon.com is not blocked, but browsing to amazon.com is.

Maintain default access control policy advanced settings

Unless you have good reason to change them, leave these settings on the Advanced tab of your access control policy at their defaults:

- **General Settings**:
  - **Retry URL cache miss lookup**
  - **Enable reputation enforcement on DNS traffic**

For descriptions of these settings, refer to General settings, on page 2591.

Reduce unnecessary usage of connection table space and NAT table slots

Consider a scenario in which URL filtering is enabled and any traffic that does not conform with the URL filtering rules is blocked. In such a scenario, the threat defence device analyses the initial packets in the traffic flow to extract URL information. After analysis, if the flow does not match any URL filtering rules, the flow is blocked. This means that the packets are dropped by the Threat Defense device. However, the associated connection remains in the connection table. This behaviour results in unnecessary use of connection table space and, if NAT is configured, NAT table slots, which can lead to increased consumption of network resources.

There are different ways to prevent this type of scenario. Since most of the traffic will be TCP, you can use the 'block with reset' option for TCP traffic instead of using 'block'. This approach reduces the usage of connection table space and NAT table slots.

URL filtering in high availability deployments

For guidelines for URL filtering with Firewall Management Centers in high availability, see *URL Filtering and Security Intelligence* in the *Cisco Secure Firewall Management Center Administration Guide* .

Memory limitations for selected device models

Device models with less memory store less URL data locally, and the system may therefore check the cloud more frequently to determine category and reputation for sites that are not in the local database.

Lower-memory devices include

- Firepower 1010
- Firewall Threat Defense Virtual with 8 GB of RAM

HTTPS traffic filtering

HTTPS traffic filtering is a security mechanism that

- determines the requested URL based on information passed during the TLS/SSL handshake using the subject common name in the public key certificate,
- disregards subdomains within the subject common name, requiring manual filtering to use top-level domains only, and
- does not support URL lists, requiring the use of URL objects and groups instead.

HTTPS filtering characteristics

There are several key differences between HTTPS filtering and HTTP filtering:

- Do not include subdomain information when manually filtering HTTPS URLs in access control or QoS policies. For example, use example.com instead of www.example.com.
-

Tip In an decryption policies, you can handle and decrypt traffic to specific URLs by defining a distinguished name decryption policy rule condition. The common name attribute in the subject distinguished name of a certificate contains the site's URL. Decrypting HTTPS traffic allows access control rules to evaluate the decrypted session, which improves URL filtering.

Traffic control by encryption protocol:

The system disregards the encryption protocol (HTTP vs HTTPS) when performing URL filtering in access control or QoS policies. This occurs for both manual and reputation-based URL conditions. In other words, URL filtering treats traffic to these websites identically:

- http://example.com/
- https://example.com/

To configure a rule that matches only HTTP or HTTPS traffic, add an application condition to the rule. For example, you could allow HTTPS access to a site while disallowing HTTP access by constructing two access control rules, each with an application and URL condition.

Application-specific URL filtering rules

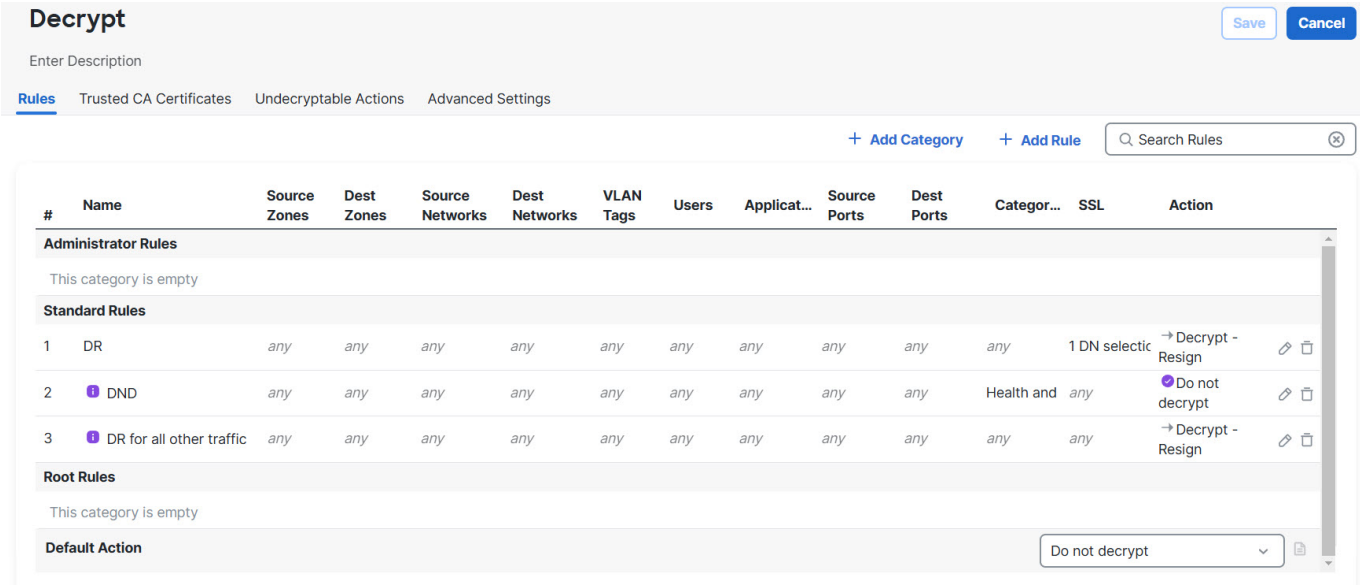
The first rule allows HTTPS traffic to the website:

- Action: Allow
- Application: HTTPS
- URL: example.com

The second rule blocks HTTP access to the same website:

- Action: Block
- Application: HTTP
- URL: example.com

Use categories in URL filtering



Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact

science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the WebMD website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for WebMD and everything else. General information about decryption rules can be found in Guidelines for using TLS/SSL decryption, on page 2004.

Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Recommendations for application control, on page 1838.

QUIC Fingerprinting

Snort can identify client applications in Quick UDP Internet Connections (QUIC sessions) based on EVE analysis. Refer to QUIC fingerprinting in EVE, on page 2060 for more information.

License requirements for URL filtering

This reference provides the license requirements for URL filtering functionality on Cisco Secure Firewall devices, covering both category and reputation filtering as well as manual filtering options.

Threat Defense License

- Category and reputation filtering—URL Filtering
- Manual filtering—No additional license.

URL filtering licenses for threat defense devices

Refer to *URL Licenses* in the *Licenses* chapter in the Cisco Secure Firewall Management Center Administration Guide.

Requirements and prerequisites for URL filtering

This reference provides the requirements and prerequisites necessary for implementing URL filtering, including model support, supported domains, and required user roles.

Model support

Any

Secure Firewall 200 does not maintain a local URL database. These options are not relevant for this device type and are automatically changed to Cloud Only lookup when deploying policies: **Enable Automatic Updates**, URL Query Source for the **Local Database Only** and the **Local Database and Cisco Cloud** options.

Supported domains

Any

User roles

- Administrator
- Access Admin
- Network Admin

Configure URL filtering with category and reputation

This task enables URL filtering with category and reputation to protect your network from malicious websites and to control user access to specific website categories.

URL filtering with category and reputation provides comprehensive web security by evaluating websites based on their content categories and reputation scores. This feature helps prevent access to malicious sites while allowing administrators to control access to specific types of content.

Before you begin

- Assign the URL Filtering license to each managed device that will filter URLs.
- Ensure that the Firewall Management Center can communicate with the cloud to obtain URL filtering data. Refer to *Communication Ports and Internet Access* in the *Cisco Secure Firewall Management Center Administration Guide*.

Follow these steps to configure URL filtering with category and reputation:

Procedure

Step 1 Review and understand limitations AND guidelines.

Best practices for URL filtering, on page 1872

Step 2 Enable the URL Filtering feature.

Enable URL filtering using category and reputation, on page 1880

Step 3 Configure rules to filter URLs by category and reputation.

Configure URL conditions, on page 1881

For the best protection against malicious sites, you must block sites by reputation and block URLs in all threat categories.

(Optional) Supplement or selectively override category and reputation-based URL filtering, on page 1886

Step 4 (Optional) Allow users to bypass a website block by clicking through a warning page.

This step is optional.

HTTP response pages, on page 1887

Step 5 Order your rules so that traffic hits the key rules first.

URL rule order, on page 1883

Step 6 (Optional) Modify advanced options related to URL filtering.

This step is optional. Generally, use the defaults unless you have a specific reason to change them.

For information about advanced options, refer to Advanced Settings for Access Control, on page 2587.

- **Maximum URL characters to store in connection events**
- **Allow an Interactive Block to bypass blocking for (seconds)**
- **Retry URL cache miss lookup**
- **Enable reputation enforcement on DNS traffic**

Step 7 Deploy your changes.

Deploy configuration changes, on page 193

Step 8 Ensure that your system receives future URL data updates as expected.

Configure URL filtering health monitors, on page 1894

Step 9 Enable other features to protect your network from malicious sites.

See Security Intelligence, on page 1811.

Enable URL filtering using category and reputation

Enable URL filtering to control and monitor web traffic based on website categories and reputation scores, providing enhanced security for your network.

You must be an Admin user to perform this task.

Before you begin

Complete prerequisites described in Configure URL filtering with category and reputation, on page 1878.

Follow these steps to enable URL filtering using category and reputation:

Procedure

Step 1 Choose **Integrations** > **Cloud Services**.

Step 2 Configure URL filtering options, on page 1880.

Step 3 Click **Save**.

URL filtering options

Adding a URL Filtering license automatically enables the URL filtering feature. With this feature, the system handles traffic based on a website's general classification (category) and risk level (reputation).

Although by default the system is configured to submit all URLs to the cloud for threat intelligence evaluation, using a local dataset of category and reputation data can make web browsing faster.When you enable or re-enable URL filtering, the Firewall Management Center automatically queries Cisco for URL data and pushes the dataset to managed devices. This process may take some time.

If you use SSL rules to handle encrypted traffic, also see Rule-based decryption rules guidelines and limitations, on page 2004.

Enable automatic updates

If you **Enable Automatic Updates** (the default), the Firewall Management Center checks the cloud every 30 minutes for updates. If you need strict control over when the system contacts external resources, disable automatic updates and instead create a recurring task using the scheduler. See the *Cisco Secure Firewall Management Center Administration Guide*.

Update now

Click **Update Now** to perform a one-time, on demand URL data update. You cannot start an on demand update if an update is already in progress. Although daily updates tend to be small, if it has been more than five days since your last update, new URL data may take as long as 20 minutes to download, depending on your bandwidth. The update itself may take up to 30 minutes to complete.

URL query source

You can choose how the system assigns a category and reputation to the URLs that your users browse to. You can choose:

- **Local Database Only**: Uses the local dataset only. Use this option if you do not want to submit your uncategorized URLs (category and reputation not in the local dataset) to Cisco, for example, for privacy reasons. However, note that connections to uncategorized URLs do *not* match rules with category or reputation-based URL conditions. You cannot assign categories or reputations to URLs manually.
- **Local Database and Cisco Cloud**: Uses the local dataset when possible, which can make web browsing faster. When users browse to an URL whose category and reputation is not in the local dataset or a cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache.
- **Cisco Cloud Only** (default): Does not use the local dataset. When users browse to an URL whose category and reputation is not in a local cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache. This option guarantees the most up-to-date category and reputation information.

  This option requires Version 7.3 on the device. If you enable this option, devices running earlier versions will use the **Local Database and Cisco Cloud** option.

Cached URLs expire

This setting is not relevant if you chose **Local Database Only** as your URL query source.

Caching category and reputation data makes web browsing faster. By default, cached data for URLs never expires, for fastest performance.

To minimize instances of URLs matching on stale data, you can set cached URLs to expire. For more accurate and current threat data, choose a shorter expiration time. A cached URL refreshes after the first time a user on the network visits it after the specified time passes. The first user does not see the refreshed result, but the next user who visits the URL does.

Configure URL conditions

Configure URL conditions to protect your network by controlling access to sites based on URL category and reputation.

URL conditions allow you to control network access based on website categories and reputations, providing protection against malicious sites and enabling security policy enforcement.

Before you begin

Attention As a prerequisite, ensure that you create at least a Monitor rule at the top of your access control policy, containing Category or Reputation parameters. This is essential to see ANY category or reputation data for ANY URLs that hit the particular access control policy.

If there is no rule in the access control policy with the category or reputation parameters configured, the **Connection Events** page in the management center shows no data for Category or Reputation for ANY URL traffic that hits the access control policy.

Follow these steps to configure URL conditions:

Procedure

Step 1 In the rule editor, click the following for URL conditions:

- Access control or QoS—Click **URLs**.
- SSL—Click **Category**.

Step 2 Find and choose the URL categories that you want to control:

In an access control or QoS rule, click **Category**.

For effective protection from malicious sites, you must block URLs in all Threat categories. Additionally, Talos recommends that you block only sites with Poor category. You can block questionable reputations if you have an aggressive security posture, but this may result in a higher amount of false positives. For a list of Threat categories, see URL category and reputation descriptions, on page 1871.

Be sure to click the arrows at the bottom of the list to see all available categories.

Step 3 (Optional) Constrain URL categories by choosing a **Reputation**.

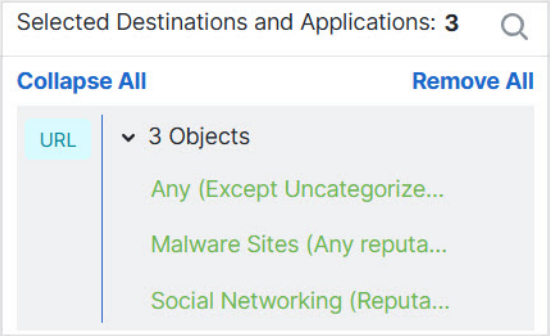
Note that if you explicitly match **Uncategorized** URLs, you cannot further constrain by reputation. Choosing a reputation level also includes other reputations either more or less severe than the level you choose, depending on the rule action:

- Includes less severe reputations—If the rule allows or trusts web traffic. For example, if you configure an access control rule to allow Favorable (level 4), it also automatically allows Trusted (level 5) sites.
- Includes more severe reputations—If the rule rate limits, decrypts, blocks, or monitors web traffic. For example, if you configure an access control rule to block Questionable sites (level 2), it also blocks Untrusted (level 1) sites.

If you change the rule action, the system automatically changes the reputation levels in URL conditions.

Optionally, select **Apply to unknown reputation**.

Step 4 Click **Add URL** or **Add to Rule**, or drag and drop.



Step 5 (Optional) To choose predefined URL objects, or URL lists and feeds in an access control or QoS rule, click **URL**, select the objects, and add them to the destination.

These objects implement manual URL filtering rather than category-based filtering.

Step 6 Save or continue editing the rule.

URL condition in an access control rule

The following graphic shows the URL condition for an access control rule that blocks all malware sites, all untrusted sites, and all social networking sites with a reputation level of Neutral or worse.

This table summarizes how you build the condition.

Blocked URL	Category	Reputation
Malware sites, regardless of reputation	Malware Sites	ANY
Any untrusted URL (level 1)	ANY	1 - Untrusted
Social networking sites with a reputation level of Neutral or worse (levels 1 through 3)	Social Network	3 - Neutral

Rules with URL conditions

This table lists rules that support URL conditions, and the types of filtering that each rule type supports.

Rule Type	Supports Category and Reputation Filtering?	Supports Manual Filtering?
Access control	Yes	Yes
Decryption policy	Yes	No. Use distinguished name conditions instead.
QoS	Yes	Yes

To use URL filtering in a decryption policy that has **Do Not Decrypt** rule conditions, refer to Use categories in URL filtering, on page 1876.

URL rule order

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:

- They include application conditions.
- The traffic to be inspected is encrypted.
- If you configure exceptions to a rule, place the exception above the other rule.

DNS filtering

DNS filtering is a URL filtering feature that

- evaluates domain category and reputation early in URL transactions, when the browser looks up the domain name to get the IP address,
- can often determine category and reputation of encrypted traffic without decryption, and
- is enabled by default through the **Enable reputation enforcement on DNS traffic** option on the **Advanced** tab of each new access control policy.

DNS filtering behavior

DNS filtering slightly modifies URL filtering behavior and is applicable only when URL filtering is enabled and configured.

If DNS filtering cannot determine the URL of encrypted traffic, that traffic is processed using your configurations for encrypted traffic.

Enable DNS filtering to identify URLs during domain lookup

DNS filtering allows you to identify and block URLs based on category and reputation during domain lookup, providing an additional layer of security by preventing access to malicious or unwanted domains before connections are established.

DNS filtering is enabled by default in new access control policies. However, additional configurations may be required in order for this setting to take effect.

Before you begin

- URL filtering using category and reputation must be licensed, enabled, and configured.

  DNS filtering does not use these settings in the URLs tab: URL groups, URL objects, URL lists and feeds, and URLs entered into the "Enter URL" text box.
- Refer to limitations at DNS filtering behavior for block actions, on page 1885.

Procedure

Step 1 In your access control policy's advanced settings, select **Enable reputation enforcement on DNS traffic**.

Step 2 In the same policy, for each access control rule that has URL category and reputation blocking configured:

- Application conditions—If the application condition is anything other than **any** (or empty), add **DNS** to that list. Other DNS-related options are not relevant for this purpose.
- Port condition—If the port/protocol condition is anything other than **any** (or empty), add **DNS_over_TCP** and **DNS_over_UDP**.

Step 3 Save your changes.

What to do next

If you are done making changes, Deploy configuration changes, on page 193.

DNS filtering behavior for block actions

Traffic that matches rules having action **Block with reset**, **Interactive Block**, or **Interactive Block with reset** will be treated as if the rule action were **Block**.

End users trying to access a blocked URL will experience this as an unexplained inability to connect to their page. The connection will spin and then time out.

DNS filtering and events

DNS filtering and events is a logging mechanism that

- generates connection events using specific fields such as DNS Query, URL Category, URL Reputation, and Destination Port,
- populates the DNS Query field with the domain name while leaving the URL field blank for DNS filtering matches, and
- sets the Destination Port to 53.

Event generation behavior

DNS filtering generates events based on the access control rule action:

- When the access control rule action is **Allow** or **Trust**, two connection events will be generated for the same traffic, one for DNS filtering (with the **DNS Query** field populated) and one for URL filtering (with the **URL** field populated).
- The first time the system encounters a particular URL, two events appear for that single session: one event showing uncategorized or reputationless for the DNS Query, and one event showing the actual category and reputation for the URL, which the system retrieves during the DNS Query and applies to the session while processing using standard URL filtering.

Manual URL filtering

Manual URL filtering is a URL filtering capability that

- supplements or selectively overrides category and reputation-based URL filtering by manually filtering individual URLs, groups of URLs, or URL lists and feeds in access control and QoS rules, and
- enables URL filtering without requiring a special license when manually permitting or blocking URLs through Allow or Block rules within an access control policy.

Manual URL filtering implementation examples

Examples:

- You might use access control to block a category of websites that are not appropriate for your organization. However, if the category contains a website that is appropriate, and to which you want to provide access, you can create a manual Allow rule for that site and place it before the Block rule for the category.

- If you prefer not to use category-based URL filtering, you can manually permit or block a URL or a group of URLs by creating an Allow or Block rule within an access control policy. You can perform this type of URL filtering without a special license.

Manual URL filtering is not supported in SSL rules. Use distinguished name conditions instead.

Caution Depending on how you implement manual URL filtering, URL matching may not be what you intend. Refer to Manual URL filtering options, on page 1886.

Manual URL filtering options

There are several ways to specify URLs for manual URL filtering.

Option	Description
(Best practice) Use custom Security Intelligence URL list or feed objects.	This is the recommended method for manual URL filtering. You can create a new list or feed, or choose an existing one in an access control or QoS rule. For more information, see Custom security intelligence lists and feeds, on page 2858 and subtopics.
Use URL objects, individually or as groups. URL objects are described at URLs, on page 2870. Or Enter URLs directly into the access control rule. (The **Enter URL** option on the rule page in the web interface.)	If you do not include a path (that is, there are no slash (/) characters in the URL), the match is based on the server's hostname only. If you include one or more / character, the entire URL string is used for a substring match. Then, a URL is considered a match if any of these are true: • The string is at the beginning of the URL. • The string follows a dot. • The string contains a dot in the beginning. • The string follows the :// characters. For example, ign.com matches ign.com or www.ign.com, but not versign.com. **Note** We recommend that you do not use manual URL filtering to block or allow individual web pages or parts of sites (that is, URL strings with / characters), as servers can be reorganized and pages moved to new paths. The **Enter URL** option does not support wildcards.

Supplement or selectively override category and reputation-based URL filtering

This task allows you to use Security Intelligence URL lists and feeds to supplement or create exceptions to your category and reputation-based URL filtering rules in access control or QoS policies.

In access control or QoS rules, you can use Security Intelligence URL lists and feeds to supplement, or to specify exceptions to, your category and reputation-based URL filtering rules.

Important! If the list or feed you are configuring in this procedure contains exceptions to category- or reputation-based rules, put this rule above those rules in the rule order.

In SSL rules, use distinguished name conditions to configure parallel behavior.

Before you begin

- Configure URL filtering using category and reputation. Refer to Configure URL conditions, on page 1881.
- Understand important best practices for manual URL filtering. Refer to Best practices for URL filtering, on page 1872 and Manual URL filtering options, on page 1886.
- Configure one or more Security Intelligence objects (lists or feeds) containing the URLs that you want to use for manual filtering. Refer to Custom security intelligence lists and feeds, on page 2858.

Follow these steps to supplement or selectively override category and reputation-based URL filtering:

Procedure

Step 1 Navigate to the access control or QoS policy in which you will define the rule.

Step 2 Create or edit the rule in which you will add the new condition:

- If you are supplementing a category- or reputation-based URL filtering rule, edit the existing rule.
- If you are overriding or creating exceptions to a category- or reputation-based URL filtering rule, create a new rule.

Step 3 Select the list or feed you created as the destination URL criteria.

Step 4 Save the rule.

HTTP response pages

An HTTP response page is a web page that displays when the system blocks web requests using either access control rules or the access control policy default action.

HTTP response page types

The response page displayed depends on how you block the session:

- **Block Response Page**: Overrides the default browser or server page that explains that the connection was denied.
- **Interactive Block Response Page**: Warns users, but also allows them to click a button (or refresh the page) to load the originally requested site. Users may have to refresh after bypassing the response page to load page elements that did not load.

If you do not choose a response page, the system blocks sessions without interaction or explanation.

Limitations to HTTP response pages

The system displays a response page only for unencrypted or decrypted HTTP/HTTPS connections blocked (or interactively blocked) either by access control rules or by the access control policy default action. The system does not display a response page for connections that are blocked by any other policy or mechanism.

The system cannot display a response page if the connection is reset (RST packet sent). If you enable response pages, the system prioritizes that configuration. Even if you choose **Block with reset** or **Interactive Block with reset** as the rule action, the system displays the response page and does not reset matching web connections. To ensure that blocked web connections are reset, you must disable response pages.

- Note that all non-web traffic that matches the rule *is* blocked with reset.

The system does not display a response page for encrypted connections that are blocked by access control rules (or any other configuration). Access control rules evaluate encrypted connections if you did not configure an SSL policy, or your SSL policy passes encrypted traffic.

-
- However, the system does display a response page for connections that are decrypted by the SSL policy, then blocked (or interactively blocked) either by access control rules or by the access control policy default action. In these cases, the system encrypts the response page and sends it at the end of the reencrypted SSL stream.

The system does not display a response page when web traffic is blocked because of a promoted access control rule (an early-placed blocking rule with only simple network conditions).

If a URL is entered without specifying "http" or "https", and the browser initiates the connection on port 80, and the user clicks through a response page, and the connection is subsequently redirected to port 443, the user will not see a second interactive response page because the response to this URL is already cached.

The system does not display a response page when web traffic is blocked before the system identifies the requested URL. Refer to Best practices for URL filtering, on page 1872.

The system does not display a response page if the block URL access control rule is configured after the allow application rule.

Requirements and prerequisites for HTTP response pages

Model support

Any

Supported domains

Any

User roles

- Administrator
- Access Admin
- Network Admin

Describe the necessary conditions, user roles, and supported domains required for setting up HTTP response pages.

Choose HTTP response pages

HTTP response pages provide feedback to users when their sessions are blocked by access control policies, allowing for better user experience and network transparency.

Reliable display of HTTP response pages depends on your network configuration, traffic loads, and size of the page. Smaller pages are more likely to display successfully.

Procedure

Step 1 In the access control policy editor, select **HTTP Responses** from the **More** drop-down arrow at the end of the packet flow line.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Choose the **Block Response Page** and **Interactive Block Response Page**:

- System-provided—Displays a generic response. Click **View** ( ) to view the code for this page.
- Custom—Create a custom response page. A pop-up window appears, prepopulated with system-provided code that you can replace or modify by clicking **Edit** ( ). A counter shows how many characters you have used.
- None—Disables the response page and blocks sessions without interaction or explanation. To quickly disable interactive blocking for the whole access control policy, choose this option.

Step 3 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Interactive blocking with HTTP response pages

Interactive blocking with HTTP response pages is a security mechanism that

- allows users to load an originally requested site after reading a warning page,
- provides user control over whether to proceed with potentially blocked traffic, and
- enables temporary bypass with configurable duration settings.

Configuration behavior and bypass settings

When you configure interactive blocking, users may have to refresh after bypassing the response page to load page elements that did not load.

Tip To quickly disable interactive blocking for the whole access control policy, display neither the system provided page nor a custom page. The system then blocks all connections without interaction.

If a user does not bypass an interactive block, matching traffic is denied without further inspection. If a user bypasses an interactive block, the access control rule allows the traffic, although the traffic may still be subject to deep inspection and blocking.

By default, a user bypass is in effect for 10 minutes (600 seconds) without displaying the warning page on subsequent visits. You can set the duration to as long as a year, or you can force the user to bypass the block every time. This limit applies to every Interactive Block rule in the policy. You cannot set the limit per rule.

Logging options for interactively blocked traffic are identical to those in allowed traffic. If a user does not bypass the interactive block, the system can log only beginning-of-connection events. When the system initially warns the user, it marks any logged beginning-of-connection event with the `Interactive Block` or `Interactive Block with reset` action. If the user bypasses the block, additional connection events logged for the session have an action of `Allow`.

Configure interactive blocking

Interactive blocking allows users to bypass URL filtering rules while maintaining security controls and logging capabilities.

This procedure describes how to allow users to bypass URL filtering rules.

Procedure

Step 1 As part of access control, configure an access control rule that matches web traffic; see Create and edit access control rules, on page 1848:

- Action—Set the rule action to **Interactive Block** or **Interactive Block with reset**; see Access control rule interactive blocking actions, on page 1831.
- Conditions—Use URL conditions to specify the web traffic to interactively block.
- Logging—Assume users will bypass the block and choose logging options accordingly; see *Logging for Allowed Connections* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Inspection—Assume users will bypass the block and choose deep inspection options accordingly; see Access control policies, on page 1775.

Step 2 (Optional) (Optional) In the access control policy **HTTP Responses**, choose a custom interactive-block HTTP response page; see Choose HTTP response pages, on page 1889.

Step 3 (Optional) (Optional) In the access control policy **Advanced** settings, change the user bypass timeout; see Set the user bypass timeout for a blocked website, on page 1891.

After a user bypasses a block, the system allows the user to browse to that page without warning until the timeout period elapses.

Step 4 Save the access control policy.

Step 5 Deploy configuration changes; see Deploy configuration changes, on page 193.

Set the user bypass timeout for a blocked website

Set the duration that users can browse after bypassing a URL filtering block before having to bypass the block again.

This procedure explains how to set the time allowed for browsing after the user bypasses a URL filtering block. When the timeout expires, the user must bypass the block again.

Procedure

Step 1 Click **Policies** > **Security policies** > **Access Control** and edit the policy.

Step 2 Select **Advanced Settings** from the **More** drop-down menu at the end of the packet flow line.

Step 3 Click **Edit** (✎) next to General Settings.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 In the **Allow an Interactive Block to bypass blocking for (seconds)** field, enter the number of seconds that must elapse before the user bypass expires.

Setting this value to 0 means the interactive block response is displayed once and the user bypass never expires.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 193.

Display contextual information on HTTP response pages

Configure the Firewall Management Center to dynamically display session-specific details on HTTP response pages when a Firewall Threat Defense device blocks traffic. This improves communication by providing the user with clear reasons for access denial, aiding troubleshooting.

- You can customize HTTP block pages with dynamic variables that reflect real-time session data.
- This configuration applies to HTTP block pages configured within Firewall Management Center access control policies, including Security Intelligence block rules.

Table 106: Dynamic variables and their descriptions

Dynamic variable	Description	Default value
`{{USER}}`	Username associated with the session.	(empty)
`{{URL}}`	URL requested by the user.	(empty)
`{{URL_ENCODED}}`	Requested URL in percent-encoded format.	(empty)

Dynamic variable	Description	Default value
`{{CATEGORY}}`	Primary category of the URL that triggered the matched rule.	"Unknown"
`{{CATEGORY_LIST}}`	All categories associated with the URL.	"Unknown"
`{{REPUTATION}}`	Reputation label of the URL. For more information about reputation, refer to Web Reputation Levels.	"Unknown"
`{{APPLICATION}}`	Combined client and web application names identified by AppID.	"Client: Unknown, Web app: Unknown"
`{{CLIENT_APP}}`	Client application name	"Unknown"
`{{WEB_APP}}`	Web application name	"Unknown"
`{{SRC_IP}}`	Source IP address	(empty)
`{{SRC_PORT}}`	Source port	"0"
`{{SRC_GEO}}`	Country name of the source IP address.	"Unknown"
`{{DST_IP}}`	Destination IP address	(empty)
`{{DST_PORT}}`	Destination port	"0"
`{{DST_GEO}}`	Country name of the destination IP address.	"Unknown"
`{{PROTOCOL}}`	Protocol used in the HTTP block session. Displays the protocol name for common protocols and numeric IP protocol number for uncommon protocols.	This variable always has a value in every HTTP block page served.
`{{VLAN}}`	VLAN identifier	"0"
`{{RULE_ID}}`	Access control rule ID	"0"
`{{RULE_REVISION}}`	Revision number of the access control rule.	"0"
`{{APPID_PRESENT}}`	Indicates whether the matched rule includes an application or protocol constraint. This flag is "true" if the rule specifies application identification (AppID) constraints, ensuring the block page reflects that the rule is application-aware.	"false"
`{{CATEGORY_PRESENT}}`	Indicates whether the matched rule includes a URL category constraint (`urlcat`). This flag is "true" only if the rule specifically constrains by URL category.	"false"
`{{URL_PRESENT}}`	Indicates whether the matched rule includes any URL constraint, such as custom URL, URL category, reputation, or reputation-unknown rules. This flag is "true" for any rule involving URL-based conditions beyond just category constraints.	"false"

If a variable has no value during a block event, the HTTP block page shows a preset default value. If there is no preset default value, the field appears empty.

Configure dynamic variables on HTTP response pages

Configure dynamic variables on HTTP block response pages so that the custom block page can display contextual information about blocked sessions.

Procedure

Step 1 In the access control policy editor, select **HTTP Responses** from the **More** drop-down arrow at the end of the packet flow line.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Locate the **Block Response Page** and **Interactive Block Response Page** settings.

Step 3 Select **Custom** from the drop-down menu for the **Block Response Page** or the **Interactive Block Response Page** option.

A pop-up window appears, prepopulated with system-provided code that you can replace or modify.

Step 4 Insert the desired dynamic variables into the HTML content using the prescribed syntax. For more information about the avialable dynamic variables, refer to Dynamic variables and their descriptions.

Step 5 Save the custom block page configuration.

Example configuration

```
<html>
<body>
  <h1>Access Blocked</h1>
  <p>User: {{USER}}</p>
  <p>URL: {{URL}}</p>
  <p>Category: {{CATEGORY}} (all: {{CATEGORY_LIST}})</p>
  <p>Reputation: {{REPUTATION}}</p>
  <p>Application: {{APPLICATION}}</p>
  <p>Source: {{SRC_IP}}:{{SRC_PORT}} ({{SRC_GEO}})</p>
  <p>Destination: {{DST_IP}}:{{DST_PORT}} ({{DST_GEO}})</p>
  <p>Protocol: {{PROTOCOL}} | VLAN: {{VLAN}}</p>
  <p>Rule: {{RULE_ID}} (rev {{RULE_REVISION}})</p>
  <p>Flags: appid={{APPID_PRESENT}} category={{CATEGORY_PRESENT}} url={{URL_PRESENT}}</p>
</body>
</html>
```

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 193.

Configure URL filtering health monitors

The following health policies alert if the system has problems obtaining or updating URL category and reputation data.

- URL Filtering Monitor
- Threat Data Updates on Device

To ensure that these are configured the way you want them, refer to *Health Modules* and *Configuring Health Monitoring* in the *Cisco Secure Firewall Management Center Administration Guide*.

Dispute URL category and reputation

This task allows you to challenge URL categorizations or reputation scores when you disagree with the assignments made by Talos Intelligence.

If you disagree with a category or reputation assigned by Talos, you can submit a request for re-evaluation.

Before you begin

You will need your Cisco account credentials.

Procedure

Step 1 In the Firewall Management Center web interface, do one of the following:

Location of dispute option	Path to dispute option
Cloud Services configuration page	a. Navigate to the **Integrations** > **Cloud Services** page. b. Select **Dispute URL categories and reputations**.
Manual URL Lookup page	a. Navigate to the manual URL Lookup page: **Events & Logs** > **+ Show more** > **Advanced** > **URL Lookup**. b. Look up the URL in question. c. To see **Dispute** at the end of the table row, hover over the relevant entry in the list of results, then click **Dispute**.
URL Connection Event	a. Navigate to any page under the **Events & Logs** > **+ Show more** > **Connection** > **Events** menu that has a table that includes URLs. b. Right-click an item in the **URL Category** or **URL Reputation** column (show hidden columns if needed) and select an option.

The Talos web site opens in a separate browser window.

Step 2 Sign in to the Talos site with your Cisco credentials.

Step 3 Review the information and follow the instructions on the Talos page.

Step 4 On the Talos site, review how submitted disputes are handled. Check what response you can expect, if any.

The dispute process is independent of Secure Firewall products.

Take action if the URL category set changes

URL filtering categories may occasionally change to accommodate new web trends and evolving usage patterns. Taking action when these changes occur ensures that your policies continue to function properly and can be deployed successfully.

The set of URL Filtering categories may occasionally change, in order to accommodate new web trends and evolving usage patterns.

These changes affect both policies and events.

Shortly before URL category changes are scheduled to occur, and after they occur, you will see alerts in the list of rules in any access control, SSL, and QoS policy that is affected by the changes, and on URL or Category in rules that you edit.

You should take action when you see these alerts.

Note Updates to the URL category set as described in this topic are distinct from the changes that simply add new URLs to existing categories or re-classify misclassified URLs. This topic does not apply to category changes for individual URLs.

Procedure

Step 1 If you see an alert beside a rule in an access control policy, hover over the alert to see details.

Step 2 If the alert mentions changes to URL categories, edit the rule to see further details.

Step 3 Hover over the URL or Category in the rule dialog to see general information about the type of changes.

Step 4 If you see an alert beside a category, click the alert to view details.

Step 5 If you see a "More information" link in the description of a change, click it to view information about the category on the Talos web site.

Alternatively, see a list and descriptions of all categories at the link in URL category and reputation descriptions, on page 1871.

Step 6 Depending on the type of change, take appropriate action:

Type of Category Change	What The System Will Do	What You Should Do
Existing category will soon be deprecated	Nothing yet. You have a few weeks to change affected rules. If you do not take action in that time, the system eventually will not be able to redeploy the policy.	Remove this category from all rules that include it. If there is a similar new category, consider using that category instead.
New category is added	By default, the system does not use newly added categories.	Consider creating new rules for the new category.
Existing category is deleted	The category will appear in the rule in strikethrough text (that is, with a line through the category name.)	You must delete the obsolete category from the rule before you can deploy the policy.

Step 7 Check your SSL rules (Category) for these changes and take action as needed.

Step 8 Check your QoS rules (URL) for these changes and take action as needed.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 193.

URL category and reputation changes

URL category and reputation changes are system modifications that

- affect how events are categorized and labeled in the system,
- result in different handling of events processed before and after the changes, and
- impact the display of URL reputation information in event viewers.

Effects on event processing

URL category and reputation changes affect events differently based on when they were processed:

- When URL categories change, events that the system processed before the category change will be associated with their original category names and will be labeled with **Legacy**. Events that the system processed after the category change will be associated with the new categories.

  Older, legacy events will age out of the system over time.

- If a URL does not have a reputation at the time it was processed, the URL Reputation column in the event viewer will be empty.

Troubleshoot URL filtering

This reference provides troubleshooting information for common URL filtering issues including missing categories, uninspected packets, registration failures, lookup errors, and performance problems.

Expected URL category is missing from the categories list

The URL filtering feature uses a different set of categories than the Security Intelligence feature. The category that you expect to see may be a Security Intelligence category. To see those categories, look at the **URLs** tab on the **Security Intelligence** tab in an access control policy.

Initial packets are passing uninspected

Refer to Inspection of packets that pass before traffic is identified and subtopics.

See also DNS filtering, on page 1884.

Health alert: "URL filtering registration failure"

Verify that the Firewall Management Center and any proxies can connect to the Cisco cloud. Refer to *Communication Ports and Internet Access* in the *Cisco Secure Firewall Management Center Administration Guide*.

How can I find the category and reputation of a particular URL?

Do a manual lookup. Refer to *Finding URL Category and Reputation* in the *Cisco Secure Firewall Management Center Administration Guide*.

Error when attempting a manual lookup: "cloud lookup failure for <URL>"

Make sure the feature is properly enabled. Refer to the prerequisites in *Finding URL Category and Reputation* in the *Cisco Secure Firewall Management Center Administration Guide*.

URL appears to be incorrectly handled based on its URL category and reputation

Problem: The system does not handle the URL correctly based on its URL category and reputation.

Solutions:

- Verify that the URL category and reputation associated with the URL are what you think they are. See *Finding URL Category and Reputation* in the *Cisco Secure Firewall Management Center Administration Guide*.
- These issues may be addressed by settings described in URL filtering options, on page 1880, accessible using Enable URL filtering using category and reputation, on page 1880.
  - The URL cache may hold stale information. See information about the **Cached URLs Expire** setting in URL filtering options, on page 1880.
  - The local data set may not be updated with current information from the cloud. See information about the **Enable Automatic Updates** setting in URL filtering options, on page 1880.
  - The system may be configured to *not* check the cloud for current data. See information about the **Query Cisco cloud for unknown URLs** setting in URL filtering options, on page 1880.
- Your access control policy may be configured to pass traffic to the URL without checking the cloud. See information about the **Retry URL cache miss lookup** setting in General settings, on page 2591.
- See also Best practices for URL filtering, on page 1872.
- If the URL is processed using an SSL rule, see Rule-based decryption rules guidelines and limitations, on page 2004 and Best practice for Decryption policy rule order, on page 2012

- Verify that the URL is being handled using the access control rule that you think it is being handled by, and that the rule does what you think it does. Consider rule order.
- Verify that the local URL category and reputation database on the Firewall Management Center is successfully being updated from the cloud and that managed devices are successfully being updated from the Firewall Management Center.

  Status of these processes are reported in the Health Monitor, in the **URL Filtering Monitor** module and the **Threat Data Updates on Devices** module. For details, see *Health* in the *Cisco Secure Firewall Management Center Administration Guide*.

If you want to immediately update the local URL category and reputation database, go to **Integrations** > **Cloud Services**, then click **Update Now** in the **URL Filtering** area. For more information, see URL filtering options, on page 1880.

A URL category or reputation is not correct

For access control or QoS rules: Use manual filtering, paying careful attention to rule order. See Manual URL filtering, on page 1885 and Configure URL conditions, on page 1881.

For SSL rules: Manual filtering is not supported. Instead, use distinguished name conditions.

See also Dispute URL category and reputation, on page 1894.

Web pages are slow to load

There is a tradeoff between security and performance. Some options:

- Consider modifying the **Cached URLs Expire** setting. Choose **Integrations** > **Cloud Services**. For information, see URL filtering options, on page 1880.
- Consider deselecting the **Retry URL cache miss lookup** setting in General settings, on page 2591.

Events do not include URL category and reputation

- Make sure you have included applicable URL rules in an access control policy, the rules are active, and the policies have been deployed to the relevant devices.
- URL category and reputation do not appear in an event if the connection is processed before it matches a URL rule.
- The rule that handles the connection must be configured for URL category and reputation.
- Even if you have configured URL categories in the Categories tab in an SSL rule, you must also configure the URLs tab in a rule in your access control policy.

DNS filtering is not working

Make sure you have completed all prerequisites and steps in Enable DNS filtering to identify URLs during domain lookup, on page 1884.

An end user tries to access a blocked URL and the page just spins and times out

When DNS Filtering is enabled and end users access a URL that is blocked, the page will spin but not load. End users are not notified that the page is blocked. This is currently a limitation when DNS filtering is enabled.

Refer to DNS filtering behavior for block actions, on page 1885.

Events include URL category and reputation but URL field is blank

If the DNS Query field is populated and the URL field is empty, this is expected when the DNS filtering feature is enabled.

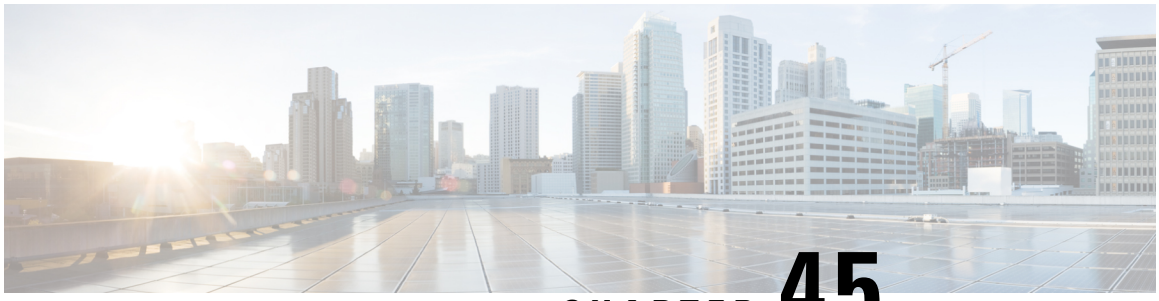
Refer to DNS filtering and events, on page 1885.

Multiple events are generated for a single transaction

A single web transaction sometimes generates two connection events, one for DNS filtering and one for URL filtering. This is expected when DNS filtering is enabled and:

- the access control rule action for the traffic is Allow or Trust.
- the system encounters a URL for the first time.

Refer to DNS filtering and events, on page 1885.



History for URL filtering

This reference provides a chronological history of URL filtering features, including release versions, supported platforms, and implementation details for each enhancement or change.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
New URL category	New in release 7.0, applies to all releases	Any	New URL category: Private IP address For details, see Talosintelligence.com
DNS filtering	7.0 6.7 (Beta)	Any	A new option in the advanced settings for each access control policy allows earlier filtering of web traffic by category and reputation. By default, this feature is enabled on new installations.
Ability to specify handling for sites with unknown reputation	6.7	Any	You can now specify handling for URLs with unknown reputation. Modified screens: URL rules in access control policies and QoS policies, and category rules in SSL policies, include a new checkbox for this purpose below the reputation selection area.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
New and changed URL categories New names for reputation levels	6.5	6.5	These changes apply to URL rules in access control and QoS policies and to Category rules in SSL policies: The set of URL categories has changed. There are now two pages of categories from which to select when you create a URL rule. The name associated with each reputation level has changed. For descriptions of the new categories and reputation names, see URL category and reputation descriptions, on page 1871. For complete details specific to upgrades, see also the Release Notes and upgrade instructions for version 6.5. If there are future category set changes, your rules will display icons to alert you. Modified screens: URL rules in access control policies, SSL policies, and QoS policies; event data related to URL categories.
Minor change to Classic device licensing	6.5	Any	For devices that use Classic licenses, URL filtering will not be enabled until the device is registered to the Firewall Management Center and a URL Filtering license is assigned to the device. Supported platforms: NGIPSv and ASA with FirePOWER Services devices.
Addresses for retrieving URL data from the Cisco cloud have changed	6.5	Any	Refer to *Communication Ports and Internet Access* in the *Cisco Secure Firewall Management Center Administration Guide*.
Opportunity to dispute an assigned URL category	6.5	Any	If you disagree with the category that the system assigns to a URL, you can submit a request to change the category. New and modified screens: • New menu option when right-clicking a URL category or reputation in tables of connection events under the **Analysis** menu. • New button on the URL Lookups page (**Analysis** > **Advanced** > **URL**). (Hover your pointer over the URL to display the button.) • New option on the **System** > **Integration** > **Cloud Services** page
The **Cisco CSI** tab is renamed to **Cloud Services**	6.4	Any	Modified screens and navigation: **System** > **Integration** > **Cisco CSI** is now **System** > **Integration** > **Cloud Services**
New option: Cached URLs Expire	6.3	Any	Use this new control to balance performance with freshness of URL category and reputation data in order to minimize instances of URLs matching on stale data. Modified screens: **System** > **Integration** > **Cisco CSI**.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Changed menu path	6.3	Any	The path to the manual URL Lookup page has changed from **Analysis** > **Lookup** > **URL** to **Analysis** > **Advanced** > **URL**.

CHAPTER 45

Intrusion Prevention

The Snort inspection engine is an integral part of the Firewall Threat Defense. In most cases, the system-provided policies are all you need. For advanced users with specific needs, you can create custom rules. To configure custom Snort 3 rules, see Custom Snort 3 Intrusion Policies for Access Control.

Note To configure custom Snort 2 rules, see Custom Snort 2 Intrusion Policies for Access Control.

- Intrusion prevention, on page 1903
- Snort inspection engine, on page 1905
- Snort 3, on page 1905
- Multi-layer inspection, on page 1909
- Guidelines and limitations for network analysis and intrusion policies, on page 1912
- Prerequisites for network analysis and intrusion policies, on page 1912
- How policies examine traffic for intrusions, on page 1913
- System-provided and custom network analysis and intrusion policies, on page 1919

Intrusion prevention

Network analysis and intrusion policies work together as part of the intrusion detection and prevention feature.

- The term 'intrusion detection' generally refers to the process of passively monitoring and analyzing network traffic for potential intrusions and storing attack data for security analysis. This is sometimes referred to as "Intrusion Detection System (IDS)."
- The term 'intrusion prevention' includes the concept of intrusion detection, but adds the ability to block or alter malicious traffic as it travels across your network. This is sometimes referred to as "Intrusion Prevention System (IPS)."
- uses network analysis and intrusion policies working together to provide comprehensive packet inspection and threat protection.

Intrusion prevention components and operation

In an intrusion prevention deployment, when the system examines packets:

- A **network analysis policy** governs how traffic is *decoded* and *preprocessed* so it can be further evaluated, especially for anomalous traffic that might signal an intrusion attempt.
- An **intrusion policy** uses *intrusion and preprocessor rules* (sometimes referred to collectively as *intrusion rules*) to examine the decoded packets for attacks based on patterns. Intrusion policies are paired with *variable sets*, which allow you to use named values to accurately reflect your network environment.

Both network analysis and intrusion policies are invoked by a parent access control policy, but at different times. As the system analyzes traffic, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (additional preprocessing and intrusion rules) phase. Together, network analysis and intrusion policies provide broad and deep packet inspection. They can help you detect, alert on, and protect against network traffic that could threaten the availability, integrity, and confidentiality of hosts and their data.

The system is delivered with several similarly named network analysis and intrusion policies (for example, Balanced Security and Connectivity) that complement and work with each other. By using system-provided policies, you can take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and inspector rule states, as well as provides the initial configurations for inspectors and other advanced settings.

You can also create custom network analysis and intrusion policies. You can tune settings in custom policies to inspect traffic in the way that matters most to you so that you can improve both the performance of your managed devices and your ability to respond effectively to the events they generate.

You create, edit, save, and manage network analysis and intrusion policies using similar policy editors in the web interface. When you are editing either type of policy, a navigation panel appears on the left side of the web interface; the right side displays various configuration pages.

Refer to the videos for additional support and information:

- Snort 3 Condensed Overview
- Snort 3 Extended Overview

Attention Detection mode deprecation: From management center Version 7.4.0, for a network analysis policy (NAP), the Detection inspection mode is deprecated and will be removed in an upcoming release.

The Detection mode was intended to be used as a test mode so that you can enable inspections and see how they behave in your network before setting it to drop traffic, that is, to show traffic that would be dropped.

This behavior is improved where all inspector drops are controlled by the rule state, and you can set each one to generate events. This is done to test them before configuring the rule state to drop traffic. As we now have granular control over traffic drops in Snort 3, the Detection mode only adds more complexity to the product and is not needed, so the detection mode is deprecated.

If you change a NAP in Detection mode to Prevention, the NAP that processes the traffic of intrusion events and have the result "will be dropped" will now be "dropped" and the corresponding traffic will drop the traffic from these events. This is applicable for rules whose GIDs are not 1 or 3. GIDs 1 and 3 are text/compiled rules (typically provided by Talos or from your custom/imported rules) and all other GIDs are inspections for anomalies. These are more uncommon rules to trigger in a network. Changing to Prevention mode is unlikely to have any impact on the traffic. You need to just disable the intrusion rule that is applicable for the dropped traffic and set it to just generate or disable.

We recommend you choose Prevention as the inspection mode, but if you choose Prevention, you cannot revert to Detection mode.

Snort inspection engine

A Snort inspection engine is an integral traffic analysis component that

- analyzes traffic in real time to provide deep packet inspection,
- operates as part of the Secure Firewall Threat Defense (formerly Firepower Threat Defense) device, and
- enables network analysis and intrusion policies to detect and protect against intrusions.

Snort 3

Snort 3 is a network inspection engine that

- provides vast improvements compared to the earlier version of Snort,
- offers more efficient operation with better performance and scalability, and
- is architecturally redesigned to inspect more traffic with equivalent resources when compared to Snort 2.

Snort 3 changes and improvements

The older version of Snort is Snort 2, which is no longer supported. Snort 3 provides simplified and flexible insertion of traffic parsers. Snort 3 also provides new rule syntax that makes rule writing easier and shared object rule equivalents visible.

The other significant changes with Snort 3 are:

- Unlike Snort 2, which uses multiple Snort instances, Snort 3 associates multiple threads with a single Snort instance. This uses less memory, improves Snort reload times, and supports more intrusion rules and a larger network map. The number of Snort threads varies by platform and is the same as the number of Snort 2 instances for each platform. Usage is virtually transparent. On Secure Firewall 6160 and 6170 devices, by default, Snort 3 associates multiple threads with two Snort processes. See Snort 3 Multi-Process Support for more information.
- Snort version per Firewall Threat Defense—The Snort inspection engine is Firewall Threat Defense specific and not Secure Firewall Management Center (formerly Firepower Management Center) specific. Firewall Management Center can manage several Firewall Threat Defenses, each with either versions of Snort (Snort 2 and Snort 3). Although the Firewall Management Center's intrusion policies are unique, the system applies Snort 2 or Snort 3 version of an intrusion policy for intrusion protection depending on the device's selected inspection engine.
- Decoder rules—Packet decoder rules fire only in the default intrusion policy. The system ignores decoder rules that you enable in other policies.
- Shared object rules—Snort 3 supports some, but not all, shared object (SO) intrusion rules (rules with a generator ID (GID) of 3). Enabled shared object rules that are not supported do not trigger.
- Multi-layer inspection for Security Intelligence—Snort 3 detects the innermost IP address regardless of the layer.
- Platform support—Snort 3 requires Firewall Threat Defense version 7.0 or later. It is not supported with ASA FirePOWER or NGIPSv.
- Managed Devices—An Firewall Management Center with version 7.0 can simultaneously support versions 6.4, 6.5, 6.6, 6.7, and 7.0 Snort 2 Firewall Threat Defenses, and version 7.0 Snort 3 Firewall Threat Defenses.
- Traffic interruption when switching Snort versions—Switching Snort versions interrupts traffic inspection and a few packets might drop during deployment.
- Unified policies—Irrespective of the underlying Snort engine version that is enabled in the managed Firewall Threat Defenses, the access control policies, intrusion policies, and network analysis policies configured in the Firewall Management Center work seamlessly in applying the policies. All intrusion policies in Firewall Management Center version 7.0 and above have two versions available, Snort 2 version and Snort 3 version. The intrusion policy is unified, which means that it has a common name, base policy, and inspection mode, although there are two versions of the policy (Snort 2 version and Snort 3 version). The Snort 2 and the Snort 3 versions of the intrusion policy can be different in terms of the rule settings. However, when the intrusion policy is applied on a device, the system automatically identifies the Snort version enabled on the device and applies the rule settings configured for that version.
- Lightweight Security Package (LSP)—Replaces the Snort Rule Updates (SRU) for Snort 3 next-generation intrusion rule and configuration updates. Downloading updates downloads both the Snort 3 LSP and the Snort 2 SRU.

  LSP updates provide new and updated intrusion rules and inspector rules, modified states for existing rules, and modified default intrusion policy settings for Firewall Management Center and Firewall Threat Defense versions 7.0 or above. When you upgrade an Firewall Management Center from version 6.7 or lower to 7.0, it supports both LSPs and SRUs. LSP updates may also delete system-provided rules, provide new rule categories and default variables, and modify default variable values. For more information on LSP updates, see the *Update Intrusion Rules* topic in the latest version of the *Firepower Management Center Configuration Guide*.

- Mapping of Snort 2 and Snort 3 rules and presets—Snort 2 and Snort 3 rules are mapped and the mapping is system-provided. However, it is not a one-to-one mapping. The system-provided intrusion base policies are pre-configured for both Snort 2 and Snort 3, and they provide the same intrusion prevention although with different rule sets. The system-provided base policies for Snort 2 and Snort 3 are mapped with each other for the same intrusion prevention settings.
- Synchronizing Snort 2 and Snort 3 rule override—When a Firewall Threat Defense is upgraded to 7.0, you can upgrade the inspection engine of the Firewall Threat Defense to the Snort 3 version. Firewall Management Center maps all the overrides in the existing rules of the Snort 2 version of the intrusion policies to the corresponding Snort 3 rules using the mapping provided by Talos. However, if there are additional overrides performed after the upgrade or if you have installed a new Firewall Threat Defense of version 7.0, they have to be manually synchronized.
- Custom intrusion rules—You can create custom intrusion rules in Snort 3. You can also import the custom intrusion rules that exist for Snort 2 to Snort 3.
- Rule groups—The Firewall Management Center groups all Snort 3 rules into rule groups. Rule groups are logical groups of rules that provide an easy management interface to enhance rule accessibility, rule navigation, and better control over the rule group security level.

  From Firewall Management Center 7.3.0, rule navigation for several levels of rule groups is supported that provides more flexibility and logical grouping of rules. The MITRE framework is added that enables you to navigate through rules using the MITRE framework. MITRE is just another category of rule groups and is a part of Talos rule groups.

Note See https://attack.mitre.org for information about MITRE.

  A rule can be part of multiple rule groups, such as multiple MITRE ATT&CK rule groups, a rule category rule group, multiple "asset type" rule groups, a malware campaign, and others. The available rule groups are listed in the intrusion policy editor and can be selected to enhance policies.

  With this multi-level hierarchical structure, you can traverse down to the last element, which is the "leaf rule group." These rule groups contain sets of rules that are related to each other, such as a specific type of vulnerability, a similar target system, or a similar threat category. Rule groups have four security levels associated with them. You can change the security level, add or remove rule groups, and you can change the rule action for rules that match traffic seen on the network. This is done to bring a satisfactory balance between security, performance, and false positive resistance.

- The Threat Defense Snort engine maintains state for each traffic flow and is designed to inspect each flow exactly once. Duplicate or double inspection is unsupported when repeated traffic maps to the same Snort flow key, because the subsequent instance is associated with the existing per-flow state and may be identified as an anomaly.

  This can occur when a flow re-enters the device through a different interface or VLAN, is rerouted by an ACI fabric with different VLAN tags, or traverses VRF cross-VLAN paths. The resulting drop may appear in packet-tracer or capture output as:

  ```
  Drop-reason: (stream) Blocked or blacklisted by the stream preprocessor.
  ```

  If a flow-identifying attribute differs such that the traffic maps to a different Snort flow key, Snort can process the flows independently. However, differences in fields that are not part of the flow key do not create a separate flow.

From an optimal network architecture perspective, each traffic flow, in both directions, should traverse the Snort engine only once. If duplicate inspection cannot be avoided, use a prefilter or fastpath rule to bypass Snort inspection for the affected flows.

Snort 3 multi-process support

Snort 3 multi-process support is a feature that:

- associates multiple threads with two Snort instances on Secure Firewall 6160 and 6170 devices running Secure Firewall version 10.0,
- automatically configures each Snort 3 instance with the threads as required during deployment, and
- results in reduced memory load, reduced lock contention, and shorter core generation times for improved resiliency, performance, and scalability.

Snort 3 multi-process architecture

Individual Snort 3 instances provide several advantages. Any Snort instance failure results in minimal traffic impact and you can also restart a single Snort process, if required.

Snort threads are distributed over NUMA nodes where each node is considered as an independent processor. This ensures that memory boundaries are maintained. For example, Snort instance 0 uses the memory of node 0, and instance 1 uses the memory of node 1.

The CLI outputs of commands such as **show coredump** and **show perfstats** have been enhanced to display information on both the Snort instances. On the Management Center, navigate to **Troubleshooting > Monitor > Devices** to view the **Overview > Critical Processes** and the **Memory** sections for information on both the Snort instances. If there are any rule profiling errors, the Snort instance number is displayed with the error.

Disable Snort 3 multi-process support

This task disables Snort 3 multi-process support.

Disabling multi-process support is intended for debugging purposes only and requires a manual deployment to take effect.

Procedure

Step 1 Use the **configure snort multi-process disable** command to disable Snort 3 multi-process support.

Example:

```
> configure snort multi-process disable
----------------------------------------------------------------------
Caution: this command is intended for debugging purposes only.
A deployment is required after enabling/disabling multi-process and will cause a Snort
restart and temporary traffic interruption.
----------------------------------------------------------------------
Do you still want to continue?
Please enter 'YES' or 'NO': YES
Please perform a manual deployment to disable multi-process.
```

Note This command causes the Snort engine to restart and will also lead to traffic interruption during the next deployment when Snort is changing from the multi-process state to a single-process state.

Step 2 Redeploy the configuration to ensure that the Snort 3 multi-process support is disabled.

Multi-layer inspection

The multi-layer inspection feature in Snort 3 enables you to inspect traffic across multiple protocol layers within the same session.

Snort 3 can simultaneously inspect the following layers:

- Network layer (L3): IP addresses, fragmentation
- Transport layer (L4): TCP or UDP ports, flags, session tracking
- Application layer (L7): HTTP, DNS, SMTP, TLS, SIP, and others.
- File and payload layer: File extraction, malware signatures, embedded content

Snort 3 supports decoding for a wide range of protocols. It inspects encapsulated protocols and evaluates packet headers to determine policy actions during advanced threat inspection.

Header inspection

On versions earlier than 7.6.4

For encapsulation protocols not supported by Lina, the system initially matches traffic based on the outer IP header. The subsequent evaluation depends on the rule criteria:

- Rules without Layer 7 (L7) criteria: If the matched rule does not include L7 criteria (such as URL, application ID, or user identity), the system applies the rule based on the outer IP header.
- Rules with Layer 7 (L7) criteria: If the rule includes L7 criteria, the system uses the outer-IP header match as a starting point and then performs an additional evaluation using the innermost header.

This behavior can lead to unexpected results, such as a non-L7 rule matching the outer-IP header taking precedence over a rule matching the inner-IP header located lower in the rule set.

On version 7.6.4 and later

- Snort 3 always inspects the innermost header for protocols not supported by Lina, regardless of the presence of Layer 7 rules.
- Outer header-based rules alone are not sufficient for policy enforcement for protocols such as VXLAN. Snort 3 disregards connection details for action in such cases, using the actual packet content instead.
- For protocols supported by Lina, policy action continues to be based on the innermost header.

- If you currently manage encapsulated traffic for protocols not supported by Lina (such as VXLAN) using only outer-IP rules, be aware that on version 7.6.4 or later, this traffic will be handled by the default access control rule. In such a scenario, if your default policy action is set to Block, this may result in the traffic being dropped. We recommend that you review and update access control policies to match the inner IP header for such protocols, in addition to any existing outer IP header configurations.

Layer 7 features

For encapsulated traffic in Layer 7 features, only the innermost IP header must be matched in rules. Outer header-only rules will not apply.

Example scenarios

The following table lists examples based on different parameters.

Protocol	Version	Outer IP rule	Inner IP rule	L7 rule needed	Result
VXLAN (not supported by LINA)	7.6.2	Yes	No	No	Traffic allowed if outer header matches
VXLAN (not supported by LINA)	7.6.4	No	Yes	No	Traffic allowed if inner header matches
GRE (supported by LINA)	7.6.2 and 7.6.4	No	Yes	No	Traffic allowed if inner header matches
VXLAN + L7 feature	7.6.2 and 7.6.4	No	Yes	Yes	Inner header rule required

Note An outer IP rule matches traffic based on the tunnel endpoints. It evaluates:

- Source IP address of the encapsulating device
- Destination IP address of the encapsulating device

An inner IP rule matches traffic based on the original IP packet inside the tunnel. It evaluates:

- The real client IP address
- The real destination server IP address

Encapsulation layer limits and inspection behavior

When managing encapsulated traffic, it is important to understand the processing limits of the system's two primary inspection engines, Lina and Snort.

- LINA: Supports decoding up to 2 layers of encapsulation.
- Snort: Supports decoding up to 255 layers of encapsulation (with a default limit of 40).

Supported protocols and inspection capabilities of LINA and Snort 3

LINA

LINA supports decoding for the following protocols across the Data Link (L2), Network (L3), and Transport (L4) layers.

Layer	Supported protocols and headers
Layer 2	Cisco MetaData (CMD), IEEE 802.1Q, IEEE 802.1ad (DOT1AD), and Q-in-Q (EtherTypes 0x9100 and 0x9200). Supports up to three levels of VLAN headers.
Layer 3	IPv4, IPv6
Layer 4	ICMP (v4/v6), ESP, VXLAN, Geneve, GRE, IP-in-IP, and IPv6-in-IPv6. Supports up to 1 level of encapsulation.

GRE-specific support

For GRE traffic, the system supports decoding for the following protocol types:

- Point-to-Point Tunneling Protocol (PPTP)
- Web Cache Communication Protocol (WCCP)

ERSPAN handling

The system decodes GRE and ERSPAN (types 1, 2, and 3). To facilitate dispatch layer load-balancing, the system internally skips to the inner headers. Consequently, other modules are unable to inspect ERSPAN headers.

Snort 3

While Snort 3 supports a vast array of protocols, the following list highlights common encapsulation and tunneling protocols supported for inspection:

- VXLAN
- GRE
- Teredo
- GTP
- MPLS
- Geneve
- IP-in-IP
    - IPv4-in-IPv4

- IPv6-in-IPv4
- IPv4-in-IPv6
- IPv6-in-IPv6

Note This list is not exhaustive. Snort 3 is designed to decode a wide range of industry-standard protocols.

Guidelines and limitations for network analysis and intrusion policies

Feature Limitations of Snort 3 for Firewall Management Center-Managed Firewall Threat Defense

The table lists the features that are supported on Snort 2 but not supported on Snort 3 for Firewall Management Center-managed Firewall Threat Defense devices.

Table 107: Feature Limitations of Snort 3

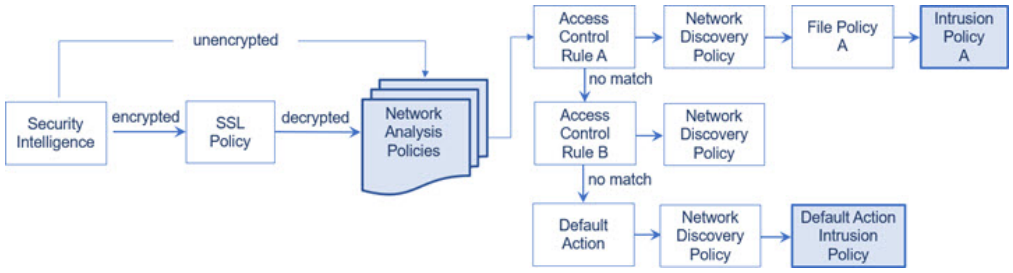
Policy/Area	Features not supported
Access Control Policy	The following application settings: • Safe Search • YouTube EDU
Intrusion Policy	• Global rule thresholding • Logging configuration: • SNMP • SRU rule updates as Snort 3 supports only LSP rule updates
Other features	Event logging with fully qualified domain name (FQDN).

Prerequisites for network analysis and intrusion policies

To allow the Snort inspection engine to process traffic for intrusion and malware analysis, you must have the Intrusion Prevention System (IPS) license enabled for the Firewall Threat Defense device.

You must be an Admin user to manage network analysis, intrusion policies, and perform migration tasks.

How policies examine traffic for intrusions



When the system analyzes traffic as part of your access control deployment, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (intrusion rules and advanced settings) phase.

Summary

The key components involved in examining traffic for intrusions are:

- Security Intelligence: Performs initial traffic filtering and blocking
- SSL policy: Handles encrypted traffic inspection and decryption
- Network analysis policies: Conduct decoding and preprocessing of traffic
- Access control rules: Determine which policies to apply to traffic
- Intrusion policies: Examine traffic for security threats and intrusions
- File policies: Analyze files for malware and threats
- Network discovery policy: Passively inspects packets for network mapping

Workflow

These stages describe how the system examines traffic for intrusions in an inline deployment:

1. The system processes traffic through multiple policy layers in a specific order, with network analysis and intrusion policy selection phases highlighted in the deployment.

   In an inline deployment (that is, where relevant configurations are deployed to devices using routed, switched, or transparent interfaces, or inline interface pairs), the system can block traffic without further inspection at almost any step in the illustrated process. Security Intelligence, the SSL policy, network analysis policies, file policies, and intrusion policies can all either drop or modify traffic. Only the network discovery policy, which passively inspects packets, cannot affect the flow of traffic.

2. At each step of the process, a packet could cause the system to generate an event. Intrusion and preprocessor events (sometimes referred to collectively as *intrusion events*) are indications that a packet or its contents may represent a security risk.

Tip The diagram does not reflect that access control rules handle encrypted traffic when your SSL inspection configuration allows it to pass, or if you do not configure SSL inspection. By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

3. Note that for a single connection, although the system selects a network analysis policy before an access control rule as shown in the diagram, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does **not** affect how you configure preprocessing in custom network analysis policies.

Decoding, normalizing, and preprocessing: Network analysis policies

Without decoding and preprocessing, the system cannot appropriately evaluate traffic for intrusions because protocol differences would make pattern matching impossible. Network analysis policies govern these traffic-handling tasks

- after traffic is filtered by Security Intelligence,
- after encrypted traffic is decrypted by an optional SSL policy, and
- before traffic can be inspected by file or intrusion policies

A network analysis policy governs packet processing in phases. First the system decodes packets through the first three TCP/IP layers, then continues with normalizing, preprocessing, and detecting protocol anomalies:

- The packet decoder converts packet headers and payloads into a format that can be easily used by the inspectors and later, intrusion rules. Each layer of the TCP/IP stack is decoded in turn, beginning with the data link layer and continuing through the network and transport layers. The packet decoder also detects various anomalous behaviors in packet headers.
- In inline deployments, the inline normalization preprocessor reformats (normalizes) traffic to minimize the chances of attackers evading detection. It prepares packets for examination by other inspectors and intrusion rules, and helps ensure that the packets the system processes are the same as the packets received by the hosts on your network.
- Various network and transport layers inspectors detect attacks that exploit IP fragmentation, perform checksum validation, and perform TCP and UDP session preprocessing.

  Note that some advanced transport and network inspector settings apply globally to all traffic handled by the target devices of an access control policy. You configure these in the access control policy rather than in a network analysis policy.
- Various application-layer protocol decoders normalize specific types of packet data into formats that the intrusion rules engine can analyze. Normalizing application-layer protocol encodings allows the system to effectively apply the same content-related intrusion rules to packets whose data is represented differently, and to obtain meaningful results.
- The Modbus, DNP3, CIP, and s7commplus SCADA inspectors detect traffic anomalies and provide data to intrusion rules. Supervisory Control and Data Acquisition (SCADA) protocols monitor, control, and acquire data from industrial, infrastructure, and facility processes such as manufacturing, production, water treatment, electric power distribution, airport, and shipping systems.

- Several inspectors allow you to detect specific threats, such as Back Orifice, portscans, SYN floods and other rate-based attacks.

  Note that you configure the sensitive data inspector, which detects sensitive data such as credit card numbers and Social Security numbers in ASCII text, in intrusion policies.

Note When TLS Server Identity is disabled, Snort 3 does not perform SNI mismatch detection. It only evaluates the SNI in the Client Hello packet and bypasses the validation of the certificate's Common Name (CN) in the Server Hello packet.

In a newly created access control policy, one default network analysis policy governs preprocessing for all traffic for all intrusion policies invoked by the same parent access control policy. Initially, the system uses the Balanced Security and Connectivity network analysis policy as the default, but you can change it to another system-provided or custom network analysis policy. In a more complex deployment, advanced users can tailor traffic preprocessing options to specific security zones, networks, and VLANs by assigning different custom network analysis policies to preprocess matching traffic.

Note For an access control policy with rule action as Trust and a prefilter rule with action as Fastpath with logging options disabled, you will observe that the end-of-flow events are still generated in the system. The events are not visible on the management center event pages.

Access control rules: Intrusion policy selection

Intrusion policy selection is a traffic evaluation process that—

- evaluates traffic after initial preprocessing using access control rules,
- applies matching access control rule to handle traffic through monitor, trust, block, or allow actions,
- inspects allowed traffic for discovery data, malware, prohibited files, and intrusions in that order, and
- handles non-matching traffic using the access control policy's default action.

In most cases, the first access control rule that a packet matches is the rule that handles that traffic; you can monitor, trust, block, or allow matching traffic.

Traffic evaluation process

When you allow traffic with an access control rule, the system can inspect the traffic for discovery data, malware, prohibited files, and intrusions, in that order. Traffic not matching any access control rule is handled by the access control policy's default action, which can also inspect for discovery data and intrusions.

Note All packets, **regardless** of which network analysis policy preprocesses them, are matched to configured access control rules, making them potentially subject to inspection by intrusion policies in top-down order.

The diagram in How policies examine traffic for intrusions, on page 1913 shows the flow of traffic through a device in an inline, intrusion prevention and AMP for Networks deployment—

- Access Control Rule A allows matching traffic to proceed. The traffic is then inspected for discovery data by the network discovery policy, for prohibited files and malware by File Policy A, and then for intrusions by Intrusion Policy A.
- Access Control Rule B also allows matching traffic. However, in this scenario, the traffic is not inspected for intrusions (or files or malware), so there are no intrusion or file policies associated with the rule. Note that by default, traffic that you allow to proceed is inspected by the network discovery policy; you do not need to configure this.
- In this scenario, the access control policy's default action allows matching traffic. The traffic is then inspected by the network discovery policy, and then by an intrusion policy. You can (but do not have to) use a different intrusion policy when you associate intrusion policies with access control rules or the default action.

The example in the diagram does not include any blocking or trusting rules because the system does not inspect blocked or trusted traffic.

Intrusion inspection: Intrusion policies, rules, and variable sets

Intrusion inspection is a security mechanism that

- uses intrusion policies to govern how the system inspects traffic for security violations and can block or alter malicious traffic in inline deployments
- employs intrusion and preprocessor rules to analyze network traffic against specified criteria and detect attempts to exploit vulnerabilities, and
- utilizes variable sets to define values commonly used in intrusion rules for identifying source and destination IP addresses and ports.

Intrusion and inspector rules

An intrusion rule is a specified set of keywords and arguments that detects attempts to exploit vulnerabilities on your network; the system uses an intrusion rule to analyze network traffic to check if it matches the criteria in the rule. The system compares packets against the conditions specified in each rule and, if the packet data matches all the conditions specified in a rule, the rule triggers.

The system includes these types of rules created by Cisco Talos Intelligence Group (Talos):

- *shared object intrusion rules*, which are compiled and cannot be modified, except for rule header information such as source and destination ports and IP addresses
- *standard text intrusion rules*, which can be saved and modified as new custom instances of the rule.
- *preprocessor rules*, which are rules associated with inspectors and packet decoder detection options in the network analysis policy. You cannot copy or edit inspector rules. Most inspector rules are disabled by default; you must enable them to use inspectors to generate events and, in an inline deployment, drop offending packets.

When the system processes packets according to an intrusion policy, first a rule optimizer classifies all activated rules in subsets based on criteria such as: transport layer, application protocol, direction to or from the protected network, and so on. Then, the intrusion rules engine selects the appropriate rule subsets to apply to each packet.

Finally, a multi-rule search engine performs three different types of searches to determine if the traffic matches the rule:

- The protocol field search looks for matches in particular fields in an application protocol.
- The generic content search looks for ASCII or binary byte matches in the packet payload.
- The packet anomaly search looks for packet headers and payloads that, rather than containing specific content, violate well-established protocols.

In a custom intrusion policy, you can tune detection by enabling and disabling rules, as well as by writing and adding your own standard text rules. You can also use Cisco recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.

Note When there are insufficient packets to process specific traffic against a block rule, the system continues to evaluate the remaining traffic against other rules. If any of the remaining traffic matches a rule which is set to block, then the session is blocked. However, if the system analyses the remaining traffic to be passed, then the traffic status shows pending on the rule which is stuck for want of complete packets.

Variable Sets

Whenever the system uses an intrusion policy to evaluate traffic, it uses an associated *variable set*. Most variables in a set represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions and dynamic rule states.

The system provides a single default variable set, which is comprised of predefined default variables. Most system-provided shared object rules and standard text rules use these predefined default variables to define networks and port numbers. For example, the majority of the rules use the variable `$HOME_NET` to specify the protected network and the variable `$EXTERNAL_NET` to specify the unprotected (or outside) network. In addition, specialized rules often use other predefined variables. For example, rules that detect exploits against web servers use the `$HTTP_SERVERS` and `$HTTP_PORTS` variables.

Tip Even if you use system-provided intrusion policies, Cisco **strongly** recommends that you modify key default variables in the default set. When you use variables that accurately reflect your network environment, processing is optimized and the system can monitor relevant systems for suspicious activity. Advanced users can create and use custom variable sets for pairing with one or more custom intrusion policies.

Important If you are creating a custom variable set, do not use a number as the first character in a custom variable set name (for example, 3Snort). This will cause Snort 3 validation to fail when you deploy a configuration to Firewall Threat Defense firewall on the Firewall Management Center.

Intrusion event generation

Intrusion event generation is a security mechanism that:

- identifies possible intrusions through packet decoding, preprocessing, and rules engine analysis,
- generates *intrusion or preprocessor events* (sometimes collectively called *intrusion events*) when threats are detected, and
- transmits events from managed devices to the Firewall Management Center for aggregated analysis and network asset protection.

Event composition and data collection

Each intrusion event in the database includes an event header and contains information about the event name and classification; the source and destination IP addresses; ports; the process that generated the event; and the date and time of the event, as well as contextual information about the source of the attack and the target. For packet-based events, the system also logs a copy of the decoded packet header and payload for the packet or packets that triggered the event.

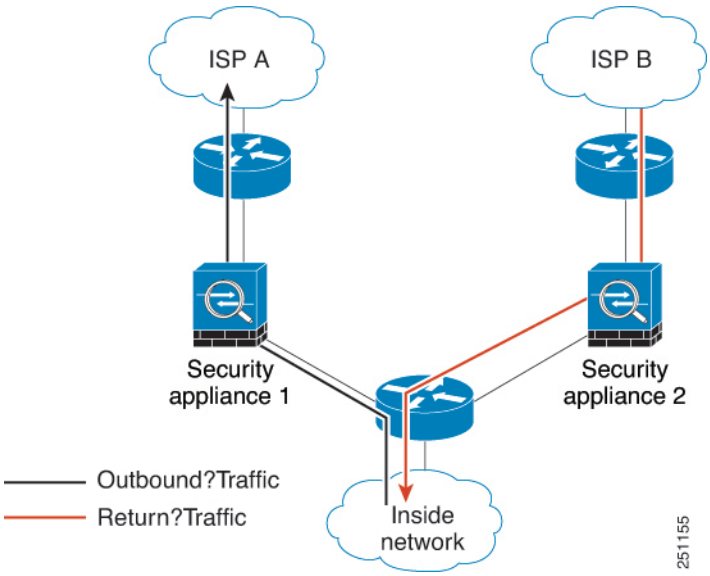
As the database accumulates intrusion events, you can begin your analysis of potential attacks. The system provides you with the tools you need to review intrusion events and evaluate whether they are important in the context of your network environment and your security policies.

Event generation scenarios

The packet decoder, the preprocessors, and the intrusion rules engine can all cause the system to generate an event. For example:

- If the packet decoder (configured in the network analysis policy) receives an IP packet that is less than 20 bytes, which is the size of an IP datagram without any options or payload, the decoder interprets this as anomalous traffic. If, later, the accompanying decoder rule in the intrusion policy that examines the packet is enabled, the system generates a inspector event.
- If the IP defragmentation preprocessor encounters a series of overlapping IP fragments, the inspector interprets this as a possible attack and, when the accompanying inspector rule is enabled, the system generates a inspector event.
- Within the intrusion rules engine, most standard text rules and shared object rules are written so that they generate intrusion events when triggered by packets.

Asymmetrical flow inspection in snort



Asymmetric flow inspection in Snort is a network security mechanism that

- operates in inline deployments where packet normalization is compromised due to Snort's limited visibility of unidirectional traffic,
- cannot account for TCP handshake parameters such as window scaling or maximum segment size (MSS) from the unseen flow direction, and
- dynamically adjusts operations based on flow patterns without requiring additional configuration.

Flow visibility and normalization

In the following illustration, both devices are running Snort engines. However, neither engine observes the complete traffic flow. The TCP three-way handshake of the flow is not fully captured, which limits the types of normalizations that can be applied. Other effective normalizations are carried out on the side of the flow that is visible to the Snort engine.

Figure 440: Asymmetric routing

Asymmetric traffic can potentially impact firewall effectiveness and may not be the optimal choice. However, Snort is designed to provide support for such deployments when necessary.

System-provided and custom network analysis and intrusion policies

Network analysis and intrusion policies are security mechanisms that

- examine traffic through preprocessing and intrusion prevention phases,
- provide system-provided default configurations for immediate deployment, and
- allow custom policy creation for tailored security requirements.

Default policy behavior in access control deployments

By default, a newly created access control policy invokes system-provided network analysis and intrusion policies to examine traffic.

This diagram shows how a newly created access control policy in an inline, intrusion-prevention deployment initially handles traffic:

The traffic flow demonstrates these characteristics:

- A default network analysis policy governs the preprocessing of *all* traffic handled by the access control policy. Initially, the system-provided *Balanced Security and Connectivity network analysis policy* is the default.
- The default action of the access control policy allows all non-malicious traffic, as determined by the system-provided *Balanced Security and Connectivity intrusion policy*. Because the default action allows traffic to pass, the discovery feature can examine it for host, application, and user data before the intrusion policy can examine and potentially block malicious traffic.
- The policy uses default Security Intelligence options (global Block and Do Not Block lists only), does not decrypt encrypted traffic with an SSL policy, and does not perform special handling and inspection of network traffic using access control rules.

A simple step you can take to tune your intrusion prevention deployment is to use a different set of system-provided network analysis and intrusion policies as your defaults. Cisco delivers several pairs of these policies with the system.

Or, you can tailor your intrusion prevention deployment by creating and using custom policies. You may find that the inspector options, intrusion rule, and other advanced settings configured in those policies do not address the security needs of your network. By tuning your network analysis and intrusion policies, you can control at a very granular level how the system processes and inspects traffic on your network for intrusions.

System-provided network analysis and intrusion policies

System-provided network analysis and intrusion policies are security configurations that

- leverage the experience of the Cisco Talos Intelligence Group (Talos) for intrusion and inspector rule states and advanced settings,
- provide starting points for well tuned defensive policies covering common network setups, and
- receive automatic updates through Lightweight Security Package (LSP) releases for new vulnerabilities.

Key characteristics and usage

No system-provided policy covers every network profile, traffic mix, or defensive posture. Each covers common cases and network setups that provide a starting point for a well-tuned defensive policy. Although you can use system-provided policies as-is, Cisco strongly recommends that you use them as the base for custom policies that you tune to suit your network.

Tip Even if you use system-provided network analysis and intrusion policies, you should configure the system's intrusion variables to accurately reflect your network environment. At a minimum, modify key default variables in the default set.

As new vulnerabilities become known, Talos releases intrusion rule updates, also known as *Lightweight Security Package* (LSP). These rule updates can modify any system-provided network analysis or intrusion policy, and can provide new and updated intrusion rules and inspector rules, modified states for existing rules, and modified default policy settings. Rule updates may also delete rules from system-provided policies and provide new rule categories, as well as modify the default variable set.

If a rule update affects your deployment, the web interface marks affected intrusion and network analysis policies as out of date, as well as their parent access control policies. You must re-deploy an updated policy for its changes to take effect.

For your convenience, you can configure rule updates to automatically re-deploy affected intrusion policies, either alone or in combination with affected access control policies. This allows you to easily and automatically keep your deployment up-to-date to protect against recently discovered exploits and intrusions.

To ensure up-to-date preprocessing settings, you **must** re-deploy access control policies, which also deploys any associated SSL, network analysis, and file policies that are different from those currently running, and can also update default values for advanced preprocessing and performance options.

Cisco delivers the system-provided network analysis and intrusion policies:

- Balanced Security and Connectivity network analysis and intrusion policies — These policies are built for both speed and detection. Used together, they serve as a good starting point for most organizations and deployment types. The system uses the Balanced Security and Connectivity policies and settings as defaults in most cases.
- Connectivity Over Security network analysis and intrusion policies — These policies are built for organizations where connectivity (being able to get to all resources) takes precedence over network infrastructure security. The intrusion policy enables far fewer rules than those enabled in the Security over Connectivity policy. Only the most critical rules that block traffic are enabled.
- Security Over Connectivity network analysis and intrusion policies — These policies are built for organizations where network infrastructure security takes precedence over user convenience. The intrusion policy enables numerous network anomaly intrusion rules that could alert on or drop legitimate traffic.
- Maximum Detection network analysis and intrusion policies — These policies are built for organizations where network infrastructure security is given even more emphasis than is given by the Security Over Connectivity policies, with the potential for even greater operational impact. For example, the intrusion policy enables rules in a large number of threat categories including malware, exploit kit, old and common vulnerabilities, and known in-the-wild exploits.
- No Rules Active intrusion policy — In the No Rules Active intrusion policy, all intrusion rules, and all advanced settings except intrusion rule thresholds, are disabled. This policy provides a starting point if you want to create your own intrusion policy instead of basing it on the enabled rules in one of the other system-provided policies.

Note Depending on the system-provided base policy that is selected, the settings of the policy vary. To view the policy settings, click the **Edit** icon next to the policy and then click the **Base Policy** drop-down menu.

Benefits of custom network analysis and intrusion policies

Custom network analysis and intrusion policies are security configurations that:

- improve system performance in your specific environment,
- provide a focused view of malicious traffic and policy violations occurring on your network, and
- allow granular configuration of how the system processes and inspects network traffic for intrusions.

Custom policy structure

You may find that the inspector options, intrusion rules, and other advanced settings configured in the system-provided network analysis and intrusion policies do not fully address the security needs of your organization.

All custom policies have a base policy, also called a base layer, which defines the default settings for all configurations in the policy. A layer is a building block that you can use to efficiently manage multiple network analysis or intrusion policies.

In most cases, you base custom policies on system-provided policies, but you can use another custom policy. However, all custom policies have a system-provided policy as the eventual base in a policy chain. Because rule updates can modify system-provided policies, importing a rule update may affect you even if you are using a custom policy as your base. If a rule update affects your deployment, the web interface marks affected policies as out of date.

Custom network analysis policy benefits

Custom network analysis policies:

- enable tuning preprocessing to match specific traffic characteristics and monitoring requirements,
- reduce system processing overhead by disabling unnecessary inspectors, and
- allow tailored preprocessing for different security zones, networks, or VLANs in complex deployments.

By default, one network analysis policy preprocesses all unencrypted traffic handled by the access control policy. That means that all packets are decoded and preprocessed according to the same settings, regardless of the intrusion policy (and therefore intrusion rule set) that later examines them.

Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default. A simple way to tune preprocessing is to create and use a custom network analysis policy as the default.

Tuning options available vary by inspector, but some of the ways you can tune inspectors and decoders include:

- You can disable inspectors that do not apply to the traffic you are monitoring. For example, the HTTP Inspect inspector normalizes HTTP traffic. If you are confident that your network does not include any web servers using Microsoft Internet Information Services (IIS), you can disable the inspector option that looks for IIS-specific traffic and thereby reduce system processing overhead.

Note If you disable an inspector in a custom network analysis policy, but the system needs to use that inspector to later evaluate packets against an enabled intrusion or inspector rule, the system automatically enables and uses the inspector although the inspector remains disabled in the network analysis policy web interface.

- Specify ports, where appropriate, to focus the activity of certain inspectors. For example, you can identify additional ports to monitor for DNS server responses, encrypted SSL sessions, or ports on which you decode telnet, HTTP, and RPC traffic.

If you are an advanced user with a complex deployment, you can create multiple network analysis policies, each tailored to preprocess traffic differently. Then, you can configure the system to use those policies to govern the preprocessing of traffic using different security zones, networks, or VLANs. (Note that ASA FirePOWER modules cannot restrict preprocessing by VLAN.)

Note Tailoring preprocessing using custom network analysis policies—especially multiple network analysis policies—is an advanced task. Because preprocessing and intrusion inspection are so closely related, you **must** be careful to allow the network analysis and intrusion policies examining a single packet to complement each other.

Benefits of custom intrusion policies

Custom intrusion policies are security configurations that

- enable tailored traffic inspection through multiple specialized intrusion policies
- manage which intrusion and inspector rules are enabled and how they are configured, and
- allow access control rules to specify which policy inspects which traffic based on multiple criteria.

In a newly created access control policy initially configured to perform intrusion prevention, the default action allows all traffic, but first inspects it with the system-provided Balanced Security and Connectivity intrusion policy. Unless you add access control rules or change the default action, all traffic is inspected by that intrusion policy.

To customize your intrusion prevention deployment, you can create multiple intrusion policies, each tailored to inspect traffic differently. Then, configure an access control policy with rules that specify which policy inspects which traffic. Access control rules can be simple or complex, matching and inspecting traffic using multiple criteria including security zone, network or geographical location, VLAN, port, application, requested URL, or user.

The main function of intrusion policies is to manage which intrusion and inspector rules are enabled and how they are configured, as follows:

- Within each intrusion policy, you should verify that all rules applicable to your environment are enabled, and improve performance by disabling rules that are not applicable to your environment. You can specify which rules should drop or modify malicious packets.
- Cisco recommendations allow you to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.
- You can modify existing rules and write new standard text rules as needed to catch new exploits or to enforce your security policies.

Other customizations you might make to an intrusion policy include:

- The sensitive data preprocessor detects sensitive data such as credit card numbers and Social Security numbers in ASCII text. Note that other inspectors that detect specific threats (back orifice attacks, several portscan types, and rate-based attacks that attempt to overwhelm your network with excessive traffic) are configured in network analysis policies.
- Global thresholds cause the system to generate events based on how many times traffic matching an intrusion rule originates from or is targeted to a specific address or address range within a specified time period. This helps prevent the system from being overwhelmed with a large number of events.
- Suppressing intrusion event notifications and setting thresholds for individual rules or entire intrusion policies can also prevent the system from being overwhelmed with a large number of events.

- In addition to the various views of intrusion events within the web interface, you can enable logging to syslog facilities or send event data to an SNMP trap server. For each policy, you can specify intrusion event notification limits, set up intrusion event notification to external logging facilities, and configure external responses to intrusion events. Note that in addition to these per-policy alerting configurations, you can globally enable or disable email alerting on intrusion events for each rule or rule group. Your email alert settings are used regardless of which intrusion policy processes a packet.

Limitations of custom policies

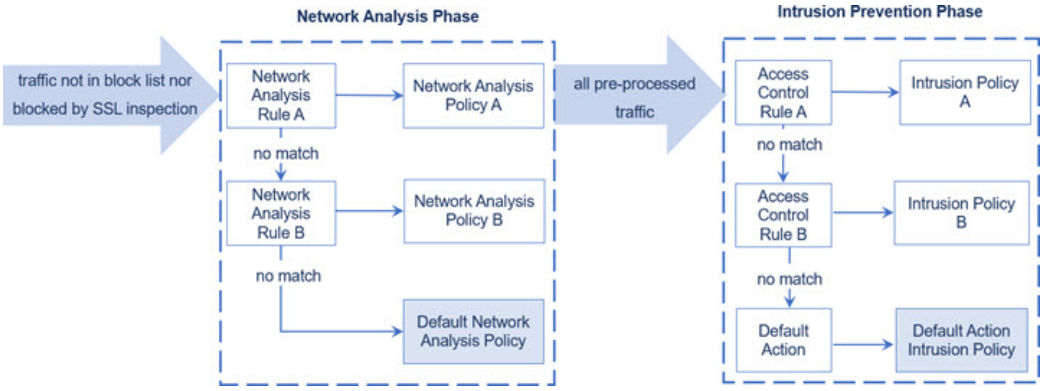
Because preprocessing and intrusion inspection are so closely related, you **must** be careful that your configuration allows the network analysis and intrusion policies processing and examining a single packet to complement each other.

By default, the system uses one network analysis policy to preprocess all traffic handled by managed devices using a single access control policy. This diagram shows how a newly created access control policy in an inline intrusion-prevention deployment initially handles traffic. The preprocessing and intrusion prevention phases are highlighted.

Notice how a default network analysis policy governs the preprocessing of *all* traffic handled by the access control policy. Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default.

You can tune preprocessing by creating and using a custom network analysis policy as the default. However, if you disable a inspector in a custom network analysis policy but the system needs to evaluate preprocessed packets against an enabled intrusion or inspector rule, the system automatically enables and uses the inspector although it remains disabled in the network analysis policy web interface.

Note In order to get the performance benefits of disabling an inspector, you **must** make sure that none of your intrusion policies have enabled rules that require that inspector.



An additional challenge arises if you use multiple custom network analysis policies. For advanced users with complex deployments, you can tailor preprocessing to specific security zones, networks, and VLANs by assigning custom network analysis policies to preprocess matching traffic. (Note that ASA FirePOWER cannot restrict preprocessing by VLAN.) To accomplish this, you add custom *network analysis rules* to your access control policy. Each rule has an associated network analysis policy that governs the preprocessing of traffic that matches the rule.

Tip You configure network analysis rules as an advanced setting in an access control policy. Unlike other types of rules, network analysis rules invoke network analysis policies, rather than being contained by them.

The system matches packets to any configured network analysis rules in top-down order by rule number. Traffic that does not match any network analysis rule is preprocessed by the default network analysis policy. While this allows you a great deal of flexibility in preprocessing traffic, keep in mind that all packets, **regardless** of which network analysis policy preprocessed them, are subsequently matched to access control rules—and

thus to potential inspection by intrusion policies—in their own process. In other words, preprocessing a packet with a particular network analysis policy does **not** guarantee that the packet will be examined with any particular intrusion policy. You **must** carefully configure your access control policy so it invokes the correct network analysis and intrusion policies to evaluate a particular packet.

The diagram shows in detail how the network analysis policy (preprocessing) selection phase occurs before and separately from the intrusion prevention (rules) phase. For simplicity, the diagram eliminates the discovery and file or malware inspection phases. It also highlights the default network analysis and default-action intrusion policies.

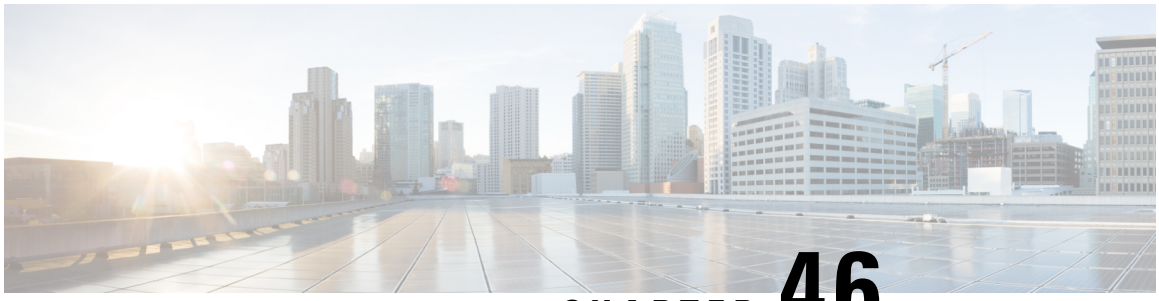
In this scenario, an access control policy is configured with two network analysis rules and a default network analysis policy:

- Network Analysis Rule A preprocesses matching traffic with Network Analysis Policy A. Later, you want this traffic to be inspected by Intrusion Policy A.
- Network Analysis Rule B preprocesses matching traffic with Network Analysis Policy B. Later, you want this traffic to be inspected by Intrusion Policy B.
- All remaining traffic is preprocessed with the default network analysis policy. Later, you want this traffic to be inspected by the intrusion policy associated with the default action of the access control policy.

After the system preprocesses traffic, it can examine the traffic for intrusions. The diagram shows an access control policy with two access control rules and a default action:

- Access Control Rule A allows matching traffic. The traffic is then inspected by Intrusion Policy A.
- Access Control Rule B allows matching traffic. The traffic is then inspected by Intrusion Policy B.
- The default action of the access control policy allows matching traffic. The traffic is then inspected by the default action's intrusion policy.

Each packet's handling is governed by a network analysis policy and intrusion policy pair, but the system does **not** coordinate the pair for you. Consider a scenario where you misconfigure your access control policy so that Network Analysis Rule A and Access Control Rule A do not process the same traffic. For example, you could intend the paired policies to govern the handling of traffic on a particular security zone, but you mistakenly use different zones in the two rules' conditions. This could cause traffic to be incorrectly preprocessed. For this reason, tailoring preprocessing using network analysis rules and custom policies is an **advanced** task.



Note that for a single connection, although the system selects a network analysis policy before an access control rule, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does **not** affect how you configure preprocessing in custom network analysis policies.

CHAPTER 46

Traffic Decryption Overview

These topics provide an overview of Transport Layer Security/Secure Sockets Layer (TLS/SSL) inspection, discuss the prerequisites for TLS/SSL inspection configuration, and detail deployment scenarios.

Note Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, see a resource such as SSL vs. TLS - What's the Difference?

- Traffic decryption, on page 1929
- How TLS/SSL handshakes work, on page 1931
- Decryption rule and policy basics, on page 1936
- TLS crypto acceleration, on page 1944
- DTLS crypto acceleration, on page 1947
- History for decryption policy , on page 1950

Traffic decryption

Traffic decryption enables deep inspection of traffic for analysis.

Traffic handling options

Most traffic on the internet is encrypted and in most cases, you might choose not to decrypt it. You can glean some information from encrypted traffic and you can also block it from your network if desired.

Your choices are:

- Decrypt the traffic and subject it to the full array of deep inspection:
  - Advanced Malware Protection
  - Security intelligence
  - Threat Intelligence Director
  - Application detectors

- URL and category filtering

- Leave the traffic encrypted and set up your access control and decryption policy to look for and potentially block:
  - Old protocol versions (such as Secure Sockets Layer)
  - Unsecure cipher suites
  - Applications with high risk and low business relevance
  - Untrusted issuer Distinguished Names

Access control policy integration

An access control policy is the main configuration that invokes subpolicies and other configurations, including a decryption policy. If you associate a decryption policy with access control, the system uses that decryption policy to handle encrypted sessions before it evaluates the sessions with access control rules. If you do not configure TLS/SSL inspection, or your devices do not support it, access control rules handle all encrypted traffic.

Access control rules also handle encrypted traffic when your TLS/SSL inspection configuration allows the traffic to pass. However, some access control rule conditions require unencrypted traffic, so encrypted traffic might match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improves performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Supported protocols for decryption:

- TLS versions up to 1.3 (if Snort 3 is enabled)
- DNS over HTTPS
- DNS over TLS (RFC 7858)
- FTPS, SMTPS, IMAPS, POP3S
- QUIC

Note As long as your managed devices have Snort 3 enabled, the system supports decrypting TLS 1.3 traffic. You can enable TLS 1.3 decryption in an decryption policy's advanced options; for more information, see Rule-based decryption policy advanced options, on page 1999.

Notes

Decryption rules require processing overhead that can impact performance. Before you decide to decrypt traffic, see Best practice for deciding when to decrypt traffic, on page 1937.

The system does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** decryption rule actions.

If you set the value of TCP maximum segment size (MSS) using FlexConfig, the observed MSS could be less than your setting. For more information, see TCP MSS, on page 851.

How TLS/SSL handshakes work

In this documentation, the term *TLS/SSL handshake* represents the two-way handshake that initiates encrypted sessions in both the SSL protocol and its successor protocol, TLS.

In an inline deployment, the system processes the TLS/SSL handshake, potentially modifying the ClientHello message and acting as a TCP proxy server for the session.

The figure shows an inline deployment.

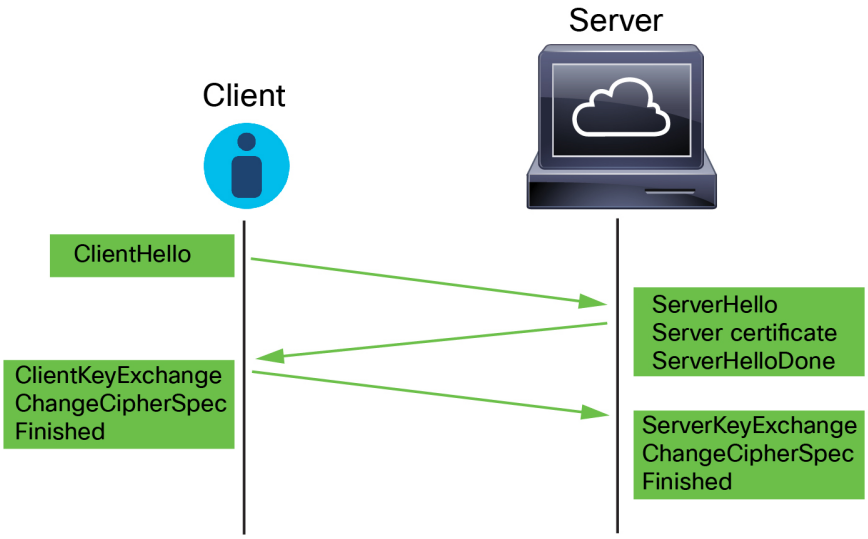
Summary

The key components involved in the TLS/SSL handshake process are:

- Client: Initiates the encrypted session by sending a ClientHello message specifying multiple supported values for each encryption attribute
- Server: Responds with a ServerHello message specifying a single supported value for each encryption attribute, determining the encryption method for the secure session
- Managed device: Monitors TCP sessions for encrypted session initiation attempts and can act as a TCP proxy server
- Handshake messages: Specialized packets that communicate encryption attributes between client and server

Workflow

These stages describe how TLS/SSL handshakes establish encrypted sessions:



1. The client establishes a TCP connection with the server after successfully completing the TCP three-way handshake.
2. The managed device monitors the TCP session for any attempt to initiate an encrypted session.
3. The client and server exchange specialized handshake messages to establish an encrypted session.
   - ClientHello—The client specifies multiple supported values for each encryption attribute.
   - ServerHello—The server specifies a single supported value for each encryption attribute, and the ServerHello response determines which encryption method the system uses during the secure session.
4. After the TLS/SSL handshake completes, the managed device caches encrypted session data and server certificate data.

   This caching allows session resumption without requiring the full handshake and enables faster handshake processing in subsequent sessions that use the same certificate.

ClientHello message handling

The client sends the ClientHello message to the server, which acts as the packet destination, when a secure connection can be established. The client uses this message to initiate the TLS/SSL handshake to respond to a ServerHello message from the destination server.

The following figure shows an example. Also see RFC 8446, sec. 4 . You can also consult a resource such as What Happens in a TLS Handshake? at cloudflare.com.

ClientHello message process

The process consists of these steps:

1. ClientHello initiates the process.

   The ClientHello message contains the Server Name Indication (SNI), which has the server's fully qualified domain name.

2. After a managed device processes a ClientHello message and transmits it to the destination server, the server determines whether it supports the decryption attributes the client specified in the message. If it does not support those attributes, the server sends a handshake failure alert to the client. If it supports those attributes, the server sends the ServerHello message. If the agreed-upon key exchange method uses certificates for authentication, the server certificate message immediately follows the ServerHello message.

   The server certificate contains the Subject Alternative Name (SAN), which can have fully qualified domain names and IP addresses. For more information about the SAN, see Distinguished names, on page 2790.

3. When the managed device receives these messages, it attempts to match them with decryption rules configured on the system. These messages contain information that was absent from either the ClientHello message or the session data cache. Specifically, the system can potentially match these messages on decryption rules' Distinguished Names, Certificate Status, Cipher Suites, and Versions conditions.

The entire process is encrypted.

Data exchange

If you configure TLS/SSL decryption, when a managed device receives a ClientHello message, the system attempts to match the message to decryption rules that have the **Decrypt - Resign** , **Decrypt - Replace Cert,** or **Decrypt - Known Key** action. The match relies on data from the ClientHello message and from cached server certificate data. The table lists the possible types of data available for matching conditions.

Table 108: Data Availability for Decryption rule Conditions

Decryption rule Condition	Data Present In
Zones	ClientHello
Networks	ClientHello
VLAN Tags	ClientHello
Ports	ClientHello
Users	ClientHello
Applications	ClientHello (Server Name Indicator extension)
Categories	ClientHello (Server Name Indicator extension)
Certificate	Server certificate (potentially cached)
Distinguished Names	Server certificate (potentially cached)
Certificate Status	Server certificate (potentially cached)
Cipher Suites	ServerHello
Versions	ServerHello

Important Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

ClientHello message modifications

If the ClientHello message matches a **Decrypt - Resign** , **Decrypt - Replace Cert** , or **Decrypt - Known Key** rule, the system modifies the ClientHello message.

- (TLS 1.2 only; TLS 1.3 does not support compression.) Compression methods—Strips the `compression_methods` element, which specifies the compression methods the client supports. The system cannot decrypt compressed sessions.
- Cipher suites—Strips cipher suites from the `cipher_suites` element if the system does not support them. If the system does not support any of the specified cipher suites, the system transmits the original, unmodified element. This modification reduces the Unknown Cipher Suite and Unsupported Cipher Suite types of undecryptable traffic.

- Session identifiers—Strips any value from the `Session Identifier` element and the SessionTicket extension (RFC 5077, sec 3.2) that does not match cached session data. If a ClientHello value matches cached data, an interrupted session can resume without the client and server performing the full TLS/SSL handshake. This modification improves the likelihood of session resumption and reduces the Session Not Cached incidents of undecryptable traffic..
- Elliptic curves—Strips elliptic curves from the Supported Elliptic Curves extension if the system does not support them. If the system does not support any of the specified elliptic curves, the managed device removes the extension and strips any related cipher suites from the `cipher_suites` element.
- ALPN extensions—Strips any value from the Application-Layer Protocol Negotiation (ALPN) extension that is unsupported in the system (for example, the HTTP/2 protocol).
- Other Extensions—Strips the Next Protocol Negotiation (NPN) and TLS Channel IDs extensions.

  Decryption rules with a **Decrypt - Resign** , **Decrypt - Replace Cert** , or **Decrypt - Known Key** action now natively support the Extended Master Secret (EMS) extension during ClientHello negotiation, enabling more secure communications. The EMS extension is defined by RFC 7627 .

After the system modifies the ClientHello message, it determines whether the message passes access control evaluation (which can include deep inspection). If the message passes, the system transmits it to the destination server.

If the ClientHello message does *not* match a **Decrypt - Resign** , **Decrypt - Replace Cert** or **Decrypt - Known Key** rule, the system does not modify the message. It then determines whether the message passes access control evaluation (which can include deep inspection). If the message passes inspection, the system transmits it to the destination server.

ClientHello is *not* modified if traffic matches a **Monitor** rule condition.

Man-in-the-middle

Direct communication between the client and server is not possible during the TLS/SSL handshake. After the message is modified, the Message Authentication Codes (MACs) computed by the client and server no longer match. For all subsequent handshake messages (and for the encrypted session once established), the managed device acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. Each session contains distinct cryptographic session details.

Note The cipher suites that the system can decrypt are frequently updated and do not correspond directly to the cipher suites you can use in decryption rule conditions. For the current list of decryptable cipher suites, contact Cisco TAC .

How ServerHello and server certificate messages work

Summary

The key components involved in ServerHello and server certificate message handling are:

- Managed device: Processes ServerHello and server certificate messages and performs rule matching
- decryption rules: Define actions to take when messages match specific criteria

- Server certificate data: Certificate information used for matching against internal certificate objects
- TLS/SSL handshake: The secure connection establishment process
- Certificate authority (CA): Used for re-signing certificates in decrypt-resign actions

Workflow

These stages describe how ServerHello and server certificate message handling works:

1. The managed device receives ServerHello and server certificate messages and checks for rule matches.

   If the messages do not match any decryption rules, the managed device performs the Rule-based decryption policy default actions, on page 1996.

2. When messages match a rule that belongs to a decryption policy associated with an access control policy, the managed device performs actions based on the rule configuration.
   - **Monitor**: The TLS/SSL handshake continues to completion. The managed device tracks and logs traffic but does not decrypt it.
   - **Block or Block with Reset**: The managed device blocks the TLS/SSL session and, if configured, resets the TCP connection.
   - **Do Not Decrypt**: The TLS/SSL handshake continues to completion. The managed device does not decrypt the application data exchanged during the TLS/SSL session.
   - **Decrypt - Replace Cert**: Decrypts incoming traffic and replaces the certificate with the internal certificate object configured in the decryption rule. The certificate configured in the decryption rule can be either the same as the internal server's certificate, or it can be different; in addition, you can replace this certificate at any time. To update the certificate, use either **Objects** > **PKI** > **Internal Certs** or the API.

3. For decrypt actions with known key or resign methods, the managed device performs certificate matching and processing.
   - **Decrypt - Known Key**: The managed device attempts to match the server certificate data to an Internal Certificate object previously imported into the Secure Firewall Management Center. Because you cannot generate an Internal Certificate object, and you must possess its private key, we assume you own the server on which you're using known key decryption.
   - **Decrypt - Resign**: The managed device processes the server certificate message and re-signs the server certificate with the previously imported or generated certificate authority (CA). The TLS/SSL handshake continues to completion. The managed device then uses the uploaded private key to decrypt and re-encrypt the application data exchanged during the TLS/SSL session.

   If the certificate matches a known certificate, the TLS/SSL handshake continues to completion. The managed device uses the uploaded private key to decrypt and re-encrypt the application data exchanged during the TLS/SSL session.

   If the server changes its certificate between the initial connection with the client and subsequent connections, you must import the new server certificate in the Secure Firewall Management Center for future connections to be decrypted.

Note The system does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** decryption rule actions.

Decryption rule and policy basics

This section discusses information you should keep in mind when creating your Decryption rules and policies.

Key information for decryption policy creation

Consider this information when creating your decryption policies and rules.

Note Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, refer to a resource such as SSL vs. TLS - What's the Difference?

Guidelines for traffic decryption

Traffic that is encrypted when it passes through the system can be allowed or blocked, but it *cannot* be subjected to deep inspection or the full range of policy enforcement (such as intrusion prevention).

All encrypted connections are sent through the decryption policy to determine if they should be decrypted or blocked.

You can also configure decryption rules to block encrypted traffic of types you know you do not want on your network, such as traffic that uses the nonsecure SSL protocol or traffic with an expired or invalid certificate.

If unblocked, whether or not decrypted, traffic goes through the access control policy for a final allow or block decision.

Only *decrypted* traffic takes advantage of the system's threat defense and policy enforcement features, including:

- Advanced Malware Protection
- Security intelligence
- Threat Intelligence Director
- Application detectors
- URL and category filtering
- QUIC

Keep in mind that decrypting and then re-encrypting traffic adds a processing load on the device, which can reduce overall system performance.

Encrypted traffic can be allowed or blocked by policy; encrypted traffic *cannot* be inspected.

Decrypted traffic is subject to threat defense and policy enforcement; decrypted traffic can be allowed or blocked by policy.

Detects encrypted application traffic using StartTLS (SMTPS, POPS, FTPS, TelnetS, IMAPS). Also identifies certain encrypted applications based on Server Name Indication in the TLS ClientHello message or subject distinguished name from the server certificate.

Best practice for deciding when to decrypt traffic

When not to decrypt traffic

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information
- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as *TLS/SSL pinning*) must remain encrypted to prevent breaking the connection

(Snort 3.) Decryption policy is *not* bypassed for any connections that match access control rules with actions of Trust, Block, or Block with Reset, unless the traffic is prefiltered. The encrypted traffic is first evaluated by decryption policy and then proceeds to the access control policy, where a final allow or block decision is made.

Encrypted traffic can be allowed or blocked on any decryption rule condition, including, but not limited to:

- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)
- URL category and reputation
- Port
- User group

Decryption rules provide a **Do Not Decrypt** action for traffic you do not want to decrypt; for more information, see Rule-based decryption rule Do Not Decrypt action, on page 2038.

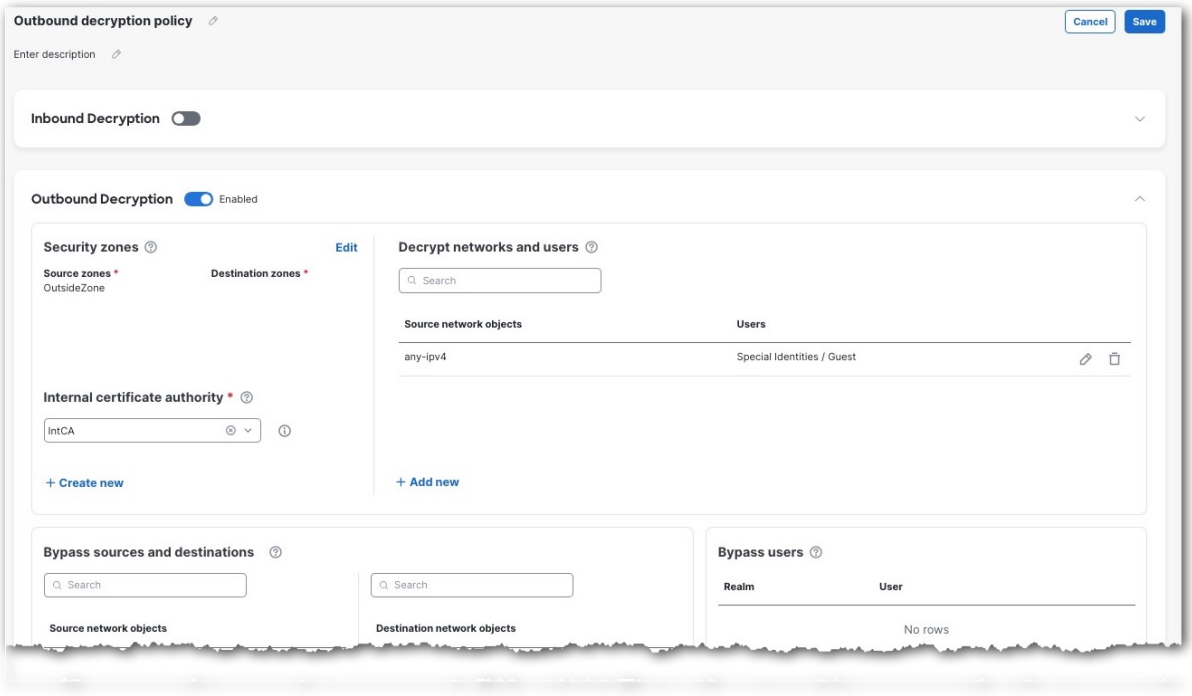
Note The related information links at the end of this topic explain how some aspects of rule evaluation work. Conditions such as URL and application filtering have limitations with respect to encrypted traffic. Make sure you understand those limitations.

For more information about using URL filtering in **Do Not Decrypt** rules, see Rule-based decryption rule Do Not Decrypt action, on page 2038.

When to decrypt traffic

All encrypted traffic must be decrypted to take advantage of the system's threat protection and policy enforcement features. If your managed device has sufficient memory and processing power to decrypt traffic, you should decrypt traffic that is not prohibited by law or regulation.

If you must decide what traffic to decrypt, base your decision on the risk of allowing the traffic on your network. The system provides a flexible framework for classifying traffic using rule conditions, which include URL reputation, cipher suite, protocol, and many other factors.



Decryption policy types

Decryption policy types include standard decryption policies and rule-based decryption policies.

Standard decryption policies

We recommend the standard decryption policy type because it's easy to set up with a wizard-like appearance, enabling you to easily pick security zones, users and networks, and other objects to use in your policy. A standard decryption policy is particularly suitable for users who are not familiar with the complexities of decryption policies.

This section provides an example of setting up a standard decryption policy.

This policy decrypts outbound traffic only. All traffic from the OutsideZone security zone on any IPv4 network is decrypted using an internal CA named `IntCA`.

Key points about decryption policies include:

- The rule is a partial example; more options are available.
- You can configure inbound criteria, outbound criteria, or both.

- In addition to objects, you can also optionally configure outbound decryption exclusions, such as:
  - Undecryptable applications (such as ones that use certificate pinning).
  - URL categories such as medical, trading, and finance.
- You can configure outbound block criteria for certificate status and TLS version.
- A standard policy has advanced policy options that are similar to rule-based policies.

Rule-based decryption policies

Rule-based decryption policies are created using a wizard that guides you through the available options for inbound decryption, outbound decryption, or both. After you create the rule-based decryption policy, you can add more rules to it, reorder rules, or make other changes to suit your needs.

A rule-based decryption policy is the most flexible but also the most potentially complicated. You can convert a standard decryption policy to a rule-based policy at any time.

Decrypt and re-sign (outgoing traffic)

Decrypt and re-sign of traffic enables the system to act as a man in the middle, intercepting, decrypting, and (if the traffic is allowed to pass) inspecting and re-encrypting traffic. It is used with outgoing traffic where the destination server is outside your protected network and requires the client to trust the firewall's certificate to complete the connection.

How decrypt and re-sign works

This information applies only to rule-based decryption policies and rules.

The Firewall Threat Defense device negotiates with the client using an internal Certificate Authority (CA) object specified in the rule and builds a TLS/SSL tunnel between the client and the Firewall Threat Defense device. At the same time, the device connects to the destination web site and creates a TLS/SSL tunnel between the server and the Firewall Threat Defense device.

Thus, the client sees the CA certificate configured for the decryption rule instead of the certificate from the destination server. The client must trust the firewall's certificate to complete the connection. The Firewall Threat Defense device then performs decryption/re-encryption in both directions for traffic between the client and the destination server.

Prerequisite

To use the **Decrypt - Resign** rule action, you must create an internal CA object using a CA file and paired private key file. You can generate a CA and private key in the system if you don't already have them.

We simplify the process of configuring the **Decrypt - Resign** rule by automatically adding **Do Not Decrypt** rules to the decryption policy based on your choices for types of traffic to exempt from encryption, such as undecryptable applications. (Typically, these applications use certificate pinning so that decrypting the connection breaks the connection.) For more information, see Create a rule-based decryption policy with outbound connection protection, on page 1983.

Note The system does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** decryption rule actions.

Incoming traffic decryption

Incoming traffic decryption protects internal servers from external attacks by intercepting and decrypting SSL/TLS encrypted traffic before it reaches the protected network.

Decryption policy requirements

This information applies only to rule-based decryption policies and rules

Note The Firepower System does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for either **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** decryption rule actions.

Inbound decryption types

There are two types of inbound decryption:

- Replace Cert (default): Uses a certificate and key defined in the decryption rule to decrypt traffic. This certificate and key can be the internal server's certificate or a different certificate. You can change the certificate and key at any time. You can replace the certificate in any of the these ways:
  - API as discussed in the *Cisco Secure Firewall Threat Defense REST API Guide*.
  - Automated Certificate Management Environment (ACME).
  - **Objects** > **PKI** > **Internal Certs** in the Secure Firewall Management Center.

  We recommend you include the certificate authority chain.
- Known Key: Use the internal server's certificate to decrypt incoming traffic. In the event the certificate changes, you must manually update it and consequently interrupt decryption until the new certificate is in place, both in the decryption policy and on the server.

Other decryption rule actions

This information applies only to rule-based decryption policies and rules.

These topics discuss other decryption rule actions.

Decryption rule components

This information applies only to rule-based decryption policies and rules.

Each decryption rule has the following components.

State

A rule can have either of two states: enabled or disabled. By default, rules are enabled. If you disable a rule, the system does not use it to evaluate network traffic, and stops generating warnings and errors for that rule.

Position

Rules in a decryption policy are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number.

Conditions

Conditions specify the specific traffic the rule handles. Conditions can match traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate subject or issuer, certificate status, cipher suite, or encryption protocol version. The use of conditions can depend on target device licenses.

Action

A rule's action determines how the system handles matching traffic. You can monitor, allow, block, or decrypt encrypted matching traffic. Decrypted traffic is subject to further inspection. Note that the system does *not* inspect blocked encrypted traffic.

Logging

A rule's logging settings govern the records the system keeps of the traffic it handles. You can keep a record of traffic that matches a rule. You can log a connection when the system blocks an encrypted session or allows it to pass without decryption, according to the settings in an decryption policy. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. You can log connections to the Secure Firewall Management Center database, as well as to the system log (syslog) or to an SNMP trap server.

For more information about logging, see Best Practices for Connection Logging in the *Cisco Secure Firewall Management Center Administration Guide*.

Tip Properly creating and ordering decryption rules is a complex task. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. To help ensure that the system handles traffic as you expect, the decryption policy interface has a robust warning and error feedback system for rules.

We recommend you create a standard decryption policy to avoid these complexities. A standard policy is easy to create and it avoids many of the issues experienced by our customers. For more information, see Decryption policy types, on page 1938

Categories

For information about using decryption rule categories (such as Applications, Category, and Cert Status), see Rule-based decryption rule conditions, on page 2017.

Rule-based decryption rule order evaluation

Rule-based decryption rule order evaluation determines the sequence in which the system evaluates decryption rules in a policy.

Rule evaluation process

This information applies only to rule-based decryption policies and rules.

When you create a rule-based decryption rule in a rule-based decryption policy , you specify its position using the **Insert** list in the rule editor. Decryption rules in an a decryption policy are numbered, starting at 1. The system matches traffic to decryption rules in top-down order by ascending rule number.

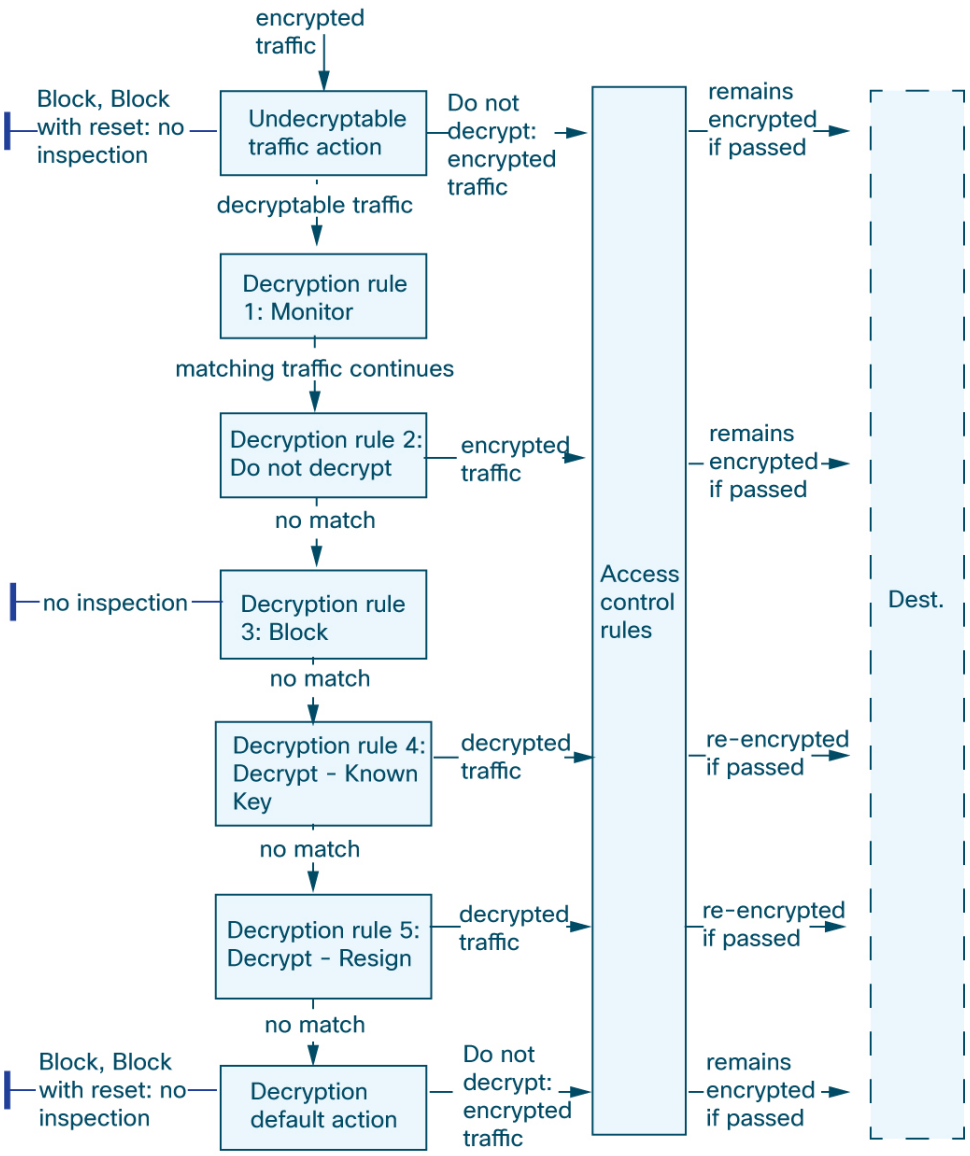
In most cases, the system handles network traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic flow), the system does *not* continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.

Rules that use *specific* conditions (such as network and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules.

Note Proper decryption rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.



Related Topics

Best practices for access control rules, on page 1842

Multi-rule example

This reference example demonstrates how the firewall handles traffic using a decryption policy that contains multiple rules.

The following scenario summarizes the ways that decryption rules handle traffic in an inline deployment.

In this scenario, traffic is evaluated as follows:

- **Undecryptable Traffic Action** evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.
- **Decryption rule 1: Monitor** evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.
- **Decryption rule 2: Do Not Decrypt** evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.

- **Decryption rule 3: Block** evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.
- **Decryption rule 4: Decrypt - Known Key** evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule continues to the next rule.
- **Decryption rule 5: Decrypt - Resign** is the final rule. If traffic matches, the system re-signs the server certificate with an uploaded CA certificate and decrypts traffic. The decrypted traffic is then evaluated against access control rules, which treat decrypted and unencrypted traffic the same. This additional inspection allows the system to block traffic. All remaining traffic is re-encrypted before being sent to its destination. Traffic that does not match the decryption rule rule continues to the next rule.
- **Decryption policy Default Action** handles all traffic that does not match any of the decryption rules. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

TLS crypto acceleration

TLS crypto acceleration accelerates the following:

- TLS/SSL encryption and decryption
- VPN, including TLS/SSL and IPsec

Supported hardware and acceleration details

The following hardware models support TLS crypto acceleration:

- Secure Firewall 3100
- Secure Firewall 4200
- Firepower 4100/9300

  For information about TLS crypto acceleration support on Firepower 4100/9300 Firewall Threat Defense container instances, see the *FXOS Configuration Guide*.

TLS crypto acceleration is *not* supported on any virtual appliances or on any hardware except for the preceding.

Note For more information about TLS crypto acceleration and the 4100/9300, see the *FXOS Configuration Guide*.

Features *not* supported by TLS crypto acceleration include:

- Managed devices where Firewall Threat Defense container instance is enabled.
- If the inspection engine is configured to preserve connections and the inspection engine fails unexpectedly, TLS/SSL traffic is dropped until the engine restarts.

This behavior is controlled by the **configure snort preserve-connection {enable | disable}** command.

TLS crypto acceleration guidelines and limitations

HTTP-only performance

Using TLS crypto acceleration on a managed device that is not decrypting traffic can affect performance.

Federal information processing standards (FIPS)

If TLS crypto acceleration and Federal Information Processing Standards (FIPS) are both enabled, connections with the following options fail:

- RSA keys less than 2048 bytes in size
- Rivest cipher 4 (RC4)
- Single Data Encryption Standard (single DES)
- Merkle–Damgard 5 (MD5)
- SSL v3

FIPS is enabled when you configure the Firewall Management Center and managed devices to operate in a security certifications compliance mode. To allow connections when operating in those modes, you can configure web browsers to accept more secure options.

For more information:

- Ciphers supported by FIPS: Configure SSL settings, on page 1046.
- Security certifications compliance modes.
- Common Criteria.

TLS heartbeat

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

When a managed device with TLS crypto acceleration enabled encounters a packet that uses the TLS heartbeat extension, the managed device takes the action specified by the setting for **Decryption Errors** in the decryption policy's **Undecryptable Actions**:

- Block
- Block with reset

For more information, see Default handling options for undecryptable traffic, on page 1997.

To determine whether applications are using TLS heartbeat, see Troubleshoot TLS heartbeat, on page 2047.

You can configure a **Max Heartbeat Length** in a Network Analysis Policy (NAP) to determine how to handle TLS heartbeats. For more information, refer to *The SSL Preprocessor* section in the "Custom Snort 2 Intrusion Policies for Access Control" document.

TLS/SSL oversubscription

TLS/SSL oversubscription is a state where a managed device is overloaded with TLS/SSL traffic. Any managed device can experience TLS/SSL oversubscription but only managed devices that support TLS crypto acceleration provide a configurable way to handle it.

When a managed device with TLS crypto acceleration enabled is oversubscribed, any packet received by the managed device is acted on according to the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions**:

- Inherit default action
- Do not decrypt
- Block
- Block with reset

If the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions** is **Do Not decrypt** and the associated access control policy is configured to inspect the traffic, inspection occurs; decryption does *not* occur.

If a significant amount of oversubscription is occurring, you have these options:

- Upgrade your managed devices to increase TLS/SSL processing capacity.
- Change your decryption policies to add **Do Not Decrypt** rules for traffic that is not a high priority to decrypt.

Keep these guidelines in mind if your managed device has TLS crypto acceleration enabled.

View the status of TLS crypto acceleration

This task allows you to determine if TLS crypto acceleration is enabled on your managed devices.

Perform this task in the Firewall Management Center to check the TLS crypto acceleration status for your managed devices.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Devices** > **Device Management**.

Step 3 Click **Edit** (✎) to edit a managed device.

Step 4 Click **Device** page.

TLS crypto acceleration status is displayed in the General section.

DTLS crypto acceleration

Firewall Threat Defense supports the Datagram Transport Layer Security (*DTLS*) cryptographic acceleration for specific firewall models. This feature improves the throughput of the DTLS-encrypted and DTLS-decrypted traffic for both IPv4 and IPv6 traffic. The Firewall Threat Defense also performs optimization of the egress-encrypted packets to improve latency. The data path is optimized to enhance performance for single tunnel flows. Both features are enabled by default and work only for DTLS 1.2.

Supported models

- Secure Firewall 3100
- Secure Firewall 4200
- Secure Firewall 6100

Crypto accelerator details

In Secure Firewall 3100 and 4200, FPGA and the Nitrox V crypto accelerator support DTLS cryptographic acceleration

In Secure Firewall 6100, two crypto accelerators replace the Nitrox V: one for Public Key Infrastructure (PKI) acceleration and another for IPsec and DTLS offload. Only AES-GCM 128 and 256 ciphers are supported.

Limitations

These features are not supported with:

- Flows that use DTLS 1.0 or packet compression
- Rekeyed DTLS keys
- Clustering or multi-instance mode

You can disable DTLS crypto acceleration using FlexConfig and the **no flow-offload-DTLS** and the **no flow-offload-DTLS egress-optimization** commands..

Prerequisites for DTLS crypto acceleration

Before you implement DTLS crypto acceleration, make sure you understand this information.

Supported license

- Management center Essentials (formerly Base) license must allow export-controlled functionality.

  Choose **Administration** > **Licenses** > **Smart Licenses** to verify this functionality in the management center.

Supported versions

- Firewall Management Center must be Version 7.6.0 and later.
- Cisco Secure Firewall 4200 and 3100 series devices must be Version 7.6.0 and later.

Supported devices

- Secure Firewall 3100
- Secure Firewall 4200
- Secure Firewall 6100

Monitor DTLS crypto acceleration

Use CLI commands on the threat defense device to verify and monitor DTLS crypto acceleration and optimization of egress-encrypted packets.

- To verify the status of DTLS crypto acceleration and optimization of egress-encrypted packets, use this command:

```
> show flow-offload-dtls info
  DTLS offload : Enabled
  Egress Optimization: Enabled
```

- To view the DTLS crypto acceleration statistics, use this command:

```
> show flow-offload-dtls statistics
  Packet stats of Pipe 0
  ----------------------
  Rx Packet count : 975638666
  Tx Packet count : 975638666
  Error Packet count : 0
  Drop Packet count : 0

  CAM stats of Pipe 0
  ----------------------
  Option ID Table CAM Hit Count : 1145314723
  Option ID Table CAM Miss Count : 0
  Tunnel Table CAM Hit Count : 0
  Tunnel Table CAM Miss Count : 0
  6-Tuple CAM Hit Count : 975638666
  6-Tuple CAM Miss Count : 169676057
   NOTE: The counters displayed are cumulative counters
   for all offload applications and indicates the total packets
  offloaded
```

- To view the device's Nitrox V crypto accelerator statistics for Secure Firewall 3100 and 4200, use this command:

```
> show crypto accelerator statistics

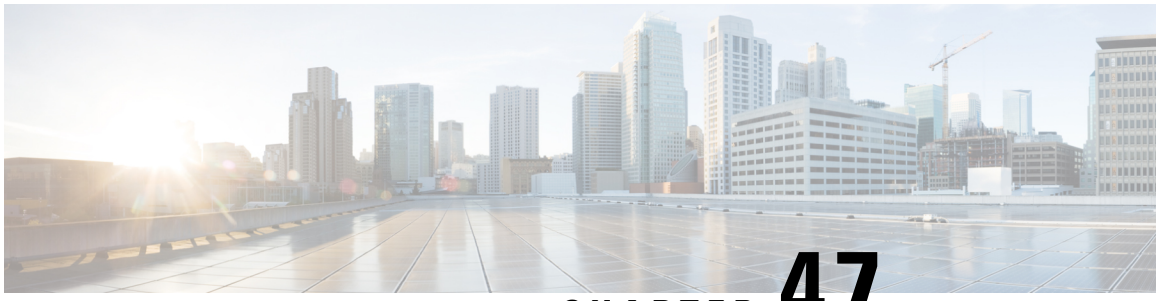
History for decryption policy



Provides a chronological overview of decryption policy features, including version support and configuration changes.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
New decryption policy user interface	10.0.0	Any	You have the choice of the following types of decryption policies: • Decryption policy: Also referred to as a standard decryption policy: We recommend the standard decryption policy type because it's easy to set up with a wizard-like appearance, enabling you to easily pick security zones, users and networks, and other objects to use in your policy. A standard decryption policy is particularly suited for anyone who is not proficient at understanding the ins and outs of decryption policies. • Rule-based decryption policy: Decryption policy you create using a wizard that steps you through the available options for inbound decryption, outbound decryption, or both. After you create the rule-based decryption policy, you can add more rules to it, reorder rules, or make other changes to suit your needs. A rule-based decryption policy is the most flexible but also the most potentially complicated. You can convert a standard decryption policy to a rule-based policy at any time. New/modified screens: **Policies** > **Decryption** > **Create New** > **Decryption Policy** **Policies** > **Decryption** > **Create New** > **Decryption Policy (Rule-Based)**
Hardware DTLS 1.2 crypto acceleration for the Secure Firewall 3100/4200	7.6.0	7.6.0	The Secure Firewall 3100/4200 now supports DTLS 1.2 cryptographic acceleration and egress optimization, which improves throughput of DTLS-encrypted and decrypted traffic. This is automatically enabled on new and upgraded devices. To disable, use FlexConfig. New/modified FlexConfig commands: **flow-offload-dtls**, **flow-offload-dtls egress-optimization**, **show flow-offload-dtls**
QUIC decryption	10.0.0 (beta) 7.7.0 (experimental) 7.6.0 (experimental)	7.6.0 with Snort 3	You can configure the decryption policy to apply to sessions running on the QUIC protocol. QUIC decryption is disabled by default. You can selectively enable QUIC decryption per decryption policy and write decryption rules to apply to QUIC traffic. By decrypting QUIC connections, the system can then inspect the connections for intrusion, malware, or other issues. You can also apply granular control and filtering of decrypted QUIC connections based on specific criteria in the access control policy. We modified the decryption policy Advanced Settings to include the option to enable QUIC decryption.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Easily bypass decryption for sensitive and undecryptable traffic	7.6.0	7.6.0	It is now easier to bypass decryption for sensitive and undecryptable traffic, which protects users and improves performance. New decryption policies now include predefined rules that, if enabled, can automatically bypass decryption for sensitive URL categories (such as finance or medical), undecryptable distinguished names, and undecryptable applications. Distinguished names and applications are undecryptable typically because they use TLS/SSL certificate pinning, which is itself not decryptable. For outbound decryption, you enable/disable these rules as part of creating the policy. For inbound decryption, the rules are disabled by default. After the policy is created, you can edit, reorder, or delete the rules entirely. New/modified screens: **Policies** > **Access Control** > **Decryption** > **Create Decryption Policy**
Decryption policy.	7.3.0	7.3.0	Feature renamed to *decryption policy* to better reflect what it does. We now enable you to configure a decryption policy with one or more **Decrypt - Resign** or **Decrypt - Known Key** rules at the same time. New/modified screens: • **Policies** > **Access Control heading** > **Decryption** (create new decryption policy) • The Create Decryption Policy dialog box now has two tab pages: **Outbound Connections** and **Inbound Connections** . • **Policies** > **Access Control heading** > **Decryption** (edit a decryption rule) **Advanced Settings** has new options discussed in TLS 1.3 decryption best practices, on page 2001 . • **Policies** > **Access Control Heading** > **Access Control** (edit an access control policy), click the word **Decryption** to associate a decryption policy with an access control policy.
TLS 1.3 decryption.	7.2.0	7.2.0	You can now enable TLS 1.3 decryption in an SSL policy's advanced actions. TLS 1.3 decryption requires the managed device run Snort 3. Other options are available as well; for more information, see TLS 1.3 decryption best practices, on page 2001 . New/modified screens: **SSL Policy** > **Advanced Settings**
SSL policy advanced settings.	7.2.0	7.1.0	SSL policy advanced settings New/modified screens: **SSL Policy** > **Advanced Settings**
Ability to specify handling of URLs having unknown reputation.	6.7.0	6.7.0	For details, see URL filtering with category and reputation, on page 1870 .

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
ClientHello modification for **Decrypt - Known** key rules.	6.7.0	6.7.0	For details, see ClientHello message handling, on page 1932 .
Ability to extract the certificate in TLS 1.3 traffic to enable traffic to match URL and application criteria in access control rules.	6.7.0	6.7.0	New/modified screens: **Policies** > **Access Control** > **(edit an access control policy)** > **Advanced** link. For details, see Rule-based decryption policy advanced options, on page 1999 .
Changes to category and reputation-based URL Filtering.	6.7.0	6.5.0	For details, see URL filtering with category and reputation, on page 1870 .
TLS crypto acceleration cannot be disabled.	6.4.0	6.4.0	TLS crypto acceleration is enabled on all supported devices. On a managed device with native interfaces, TLS crypto acceleration cannot be disabled. Removed commands: • **system support ssl-hw-accel enable** • **system support ssl-hw-accel disable** • **system support ssl-hw-status**
Support for TLS crypto acceleration on one container instance on a Firepower 4100/9300 module/security engine.	6.4.0	6.4.0	You can now enable TLS crypto acceleration for one container instance on a module/security engine. New/modified commands: • **config hwCrypto enable** • **show crypto accelerator status**
TLS/SSL hardware acceleration is now referred to as TLS crypto acceleration .	6.4.0	6.4.0	The name change reflects that TLS/SSL encryption and decryption acceleration is supported on more devices. New/modified screens: **Devices** > **Device Management** > **Edit** > **Device** > **General** > **TLS Crypto Acceleration**
Extended Master Secret extension supported (see RFC 7627).	6.3.0.1	6.3.0.1	The TLS Extended Master Secret extension is supported for SSL policies; specifically, policies with a rule action of **Decrypt - Resign** or **Decrypt - Known Key** .
Extended Master Secret extension not supported.	6.3.0	6.3.0	The extension is stripped during ClientHello modification for **Decrypt - Resign** rules.
TLS/SSL hardware acceleration enabled by default.	6.3.0	6.3.0	TLS/SSL hardware acceleration is enabled by default on all supported devices but can be disabled if desired.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Extended Master Secret extension supported (see RFC 7627).	6.2.3.9	6.2.3.9	The TLS Extended Master Secret extension is supported for SSL policies; specifically, policies with a rule action of **Decrypt - Resign** or **Decrypt - Known Key** .
Aggressive TLS 1.3 downgrade.	6.2.3.7	6.2.3.7	Using the **system support ssl-client-hello-enabled aggressive_tls13_downgrade {true|false}** CLI command, you can determine the behavior for downgrading TLS 1.3 traffic to TLS 1.2.
TLS/SSL hardware acceleration introduced.	6.2.3	6.2.3	Certain managed device models perform TLS/SSL encryption and decryption in hardware, improving performance. By default, the feature is enabled. Affected screen: To view the status of TLS/SSL hardware acceleration , **Devices** > **Device Management** > **Device** , General page.
Category and reputation conditions supported.	6.2.2	6.2.2	Access control rules or SSL rules with category/reputation conditions.
SafeSearch supported.	6.1.0	6.1.0	The system displays an HTTP response page for connections decrypted by the SSL policy, then blocked (or interactively blocked) either by access control rules or by the access control policy default action. SafeSearch filters objectionable content and stops people from searching adult sites.
TLS/SSL policy.	6.0.0	6.0.0	Feature introduced.

CHAPTER 47

Standard Decryption Policies

The following topics provide details about standard decryption policies.

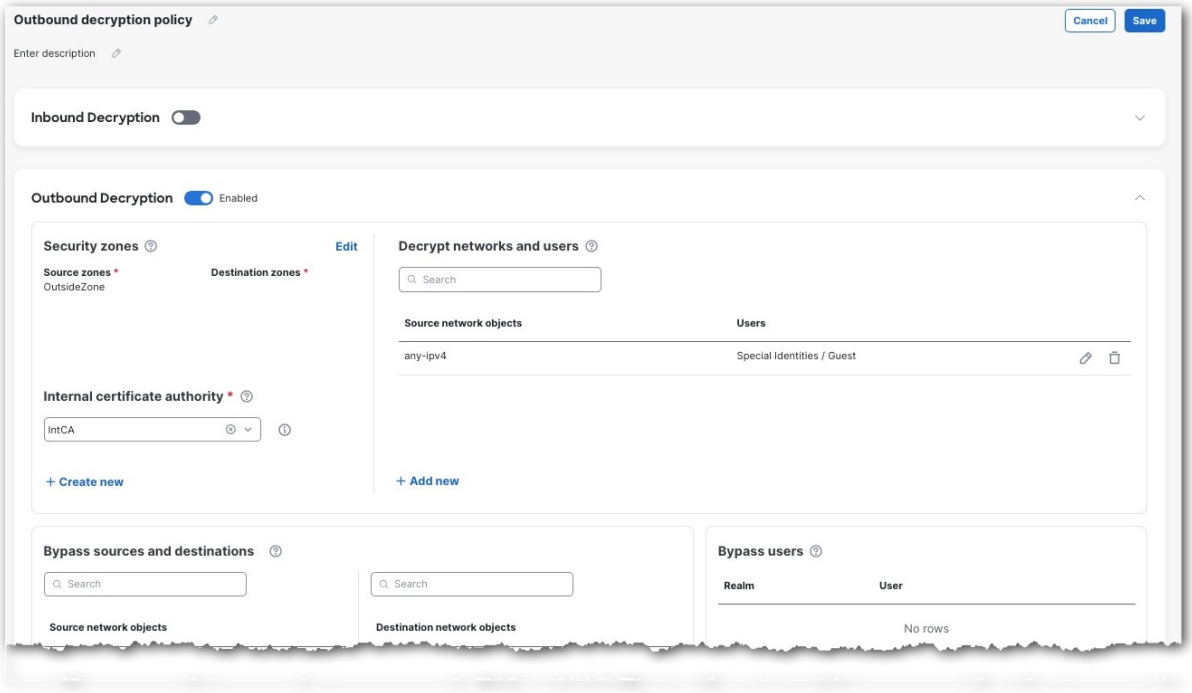
- Standard decryption policies, on page 1955
- Create a new standard decryption policy, on page 1957
- Standard decryption policy advanced options, on page 1975
- Decryption policy actions, on page 1978

Standard decryption policies

A standard decryption policy is a decryption policy type that is simpler to set up than other policy types and optimizes network performance by reducing processing load.

Benefits of standard decryption policies

Traffic decryption requires significant processing and decrypting too much traffic can slow down your system. The standard decryption policy type helps minimize issues commonly experienced by customers by preventing excessive traffic decryption.



Decryption policy types

Decryption policy types include standard decryption policies and rule-based decryption policies.

Standard decryption policies

We recommend the standard decryption policy type because it's easy to set up with a wizard-like appearance, enabling you to easily pick security zones, users and networks, and other objects to use in your policy. A standard decryption policy is particularly suitable for users who are not familiar with the complexities of decryption policies.

This section provides an example of setting up a standard decryption policy.

This policy decrypts outbound traffic only. All traffic from the OutsideZone security zone on any IPv4 network is decrypted using an internal CA named `IntCA`.

Key points about decryption policies include:

- The rule is a partial example; more options are available.
- You can configure inbound criteria, outbound criteria, or both.
- In addition to objects, you can also optionally configure outbound decryption exclusions, such as:
  - Undecryptable applications (such as ones that use certificate pinning).
  - URL categories such as medical, trading, and finance.
- You can configure outbound block criteria for certificate status and TLS version.
- A standard policy has advanced policy options that are similar to rule-based policies.

Rule-based decryption policies

Rule-based decryption policies are created using a wizard that guides you through the available options for inbound decryption, outbound decryption, or both. After you create the rule-based decryption policy, you can add more rules to it, reorder rules, or make other changes to suit your needs.

A rule-based decryption policy is the most flexible but also the most potentially complicated. You can convert a standard decryption policy to a rule-based policy at any time.

Standard decryption policy deployment issues to versions earlier than 10.0.0

If you deploy a standard decryption policy to a device that runs a version earlier than 10.0.0, you can encounter compatibility issues.

- If you configured any inbound decryption rules, the rule action is changed to **Decrypt - Known Key** on those devices. For more information about the kinds of incoming decryption actions, see Incoming traffic decryption, on page 1940.
- The advanced policy option **Intelligent Decryption Bypass** requires the device to run version 7.7 or later. By default, this advanced option is disabled. If enabled, policy deployment fails when the device runs a version earlier than 7.7.

Create a new standard decryption policy

A standard decryption policy decrypts and inspects encrypted network traffic.

Decryption policy types

You can create these types of decryption policies:

- Policy to protect *inbound* traffic: Decrypt network traffic coming *into* your network. You typically do this to decrypt and inspect traffic directed to an internal server.
- Policy to protect *outbound* traffic: Decrypt network traffic going *outside* of your network to external servers.

Related Topics

Create a standard decryption policy with inbound protection, on page 1957
Create a standard decryption policy with outbound protection, on page 1962

Create a standard decryption policy with inbound protection

Create a decryption policy to decrypt and inspect traffic directed to an internal server for enhanced network security monitoring.

This task creates a standard decryption policy to decrypt network traffic coming *into* your network. You typically do this to decrypt and inspect traffic directed to an internal server. All options on this page are required.

Before you begin

Review what an inbound protection decryption policy means in Incoming traffic decryption, on page 1940.

To create a decryption policy with outbound protection instead, see Create a standard decryption policy with outbound protection, on page 1962.

Follow these steps to create a standard decryption policy with inbound protection:

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Security policies** > **Decryption**.

Step 3 Click **Create New** > **Decryption Policy**.

Step 4 In the provided fields, enter a **Name** and optional **Description**.

The following characters are not supported in decryption policy names:

- `#,;,{,},=,$,<,>`

Step 5 Click **Create Policy**.

Step 6 Slide **Inbound Decryption** to **Enabled** as the following figure shows.

What to do next

Add these to your decryption policy:

- Security zones, on page 1958
- Internal server details (inbound decryption), on page 1960

Security zones

Security zones segment your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices. Security zones control or decrypt traffic based on its source and destination zone.

Zone configuration requirements

When configuring security zones, consider these requirements:

- If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.
- All zones used in a zone condition must be of the same type (all inline, passive, switched, or routed).
- You cannot use a zone with passive interfaces as a destination zone because devices deployed passively do not transmit traffic.
- Minimize the number of matching criteria whenever possible, especially for security zones, network objects, and port objects. If you specify multiple criteria, the system must match every combination of the criteria contents.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, the rule does not affect that device's performance.

For more information:

- Inbound decryption: Add security zones (inbound decryption), on page 1959
- Outbound decryption: Add security zones (outbound decryption), on page 1964

Add security zones (inbound decryption)

Add security zones to an inbound standard decryption policy to specify Firewall Threat Defense device interfaces that send traffic to the internal server.

A security zone specifies a Firewall Threat Defense device interface that sends traffic to the internal server. Typically, for inbound protection, this will be an internal (or *DMZ*) interface.

You must choose both a source and destination security zone.

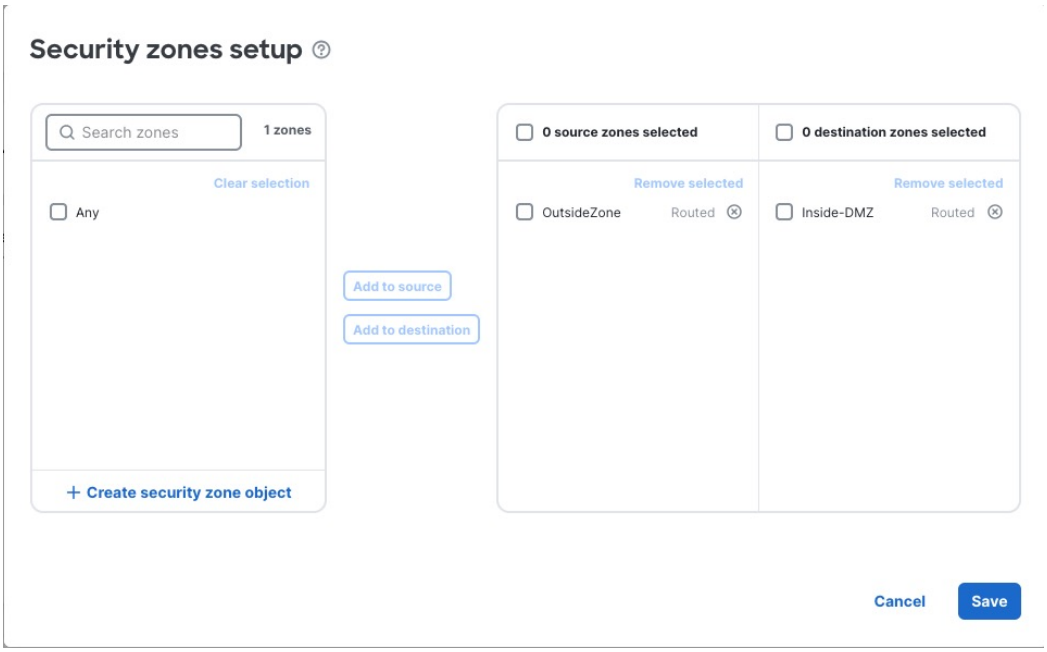
Before you begin

Complete the tasks discussed in Create a standard decryption policy with inbound protection, on page 1957.

Procedure

Step 1 Click **Edit zones** next to Security Zones.

Step 2 In the Security Zones dialog box, do any of the following:



- Select the check box next to a security zone to add to either the source or destination.
- To create a new security zone, click **Create security zone object**.
- Search for a security zone by entering text in the Search Zones field and pressing Enter.

Note Click **Help** (?) on any dialog box for more information.

Step 3 Click **Add to Source** to decrypt traffic that matches the source security zone or click **Add to Destination** to decrypt traffic that matches the destination security zone. If you select both source and destination zones, to be decrypted, traffic must match both zones.

Typically, your internal server should be the *destination* of an inbound decryption rule.

The following figure shows an example.

Step 4 Click **Save**.

Step 5 See Internal server details (inbound decryption), on page 1960.

Internal server details (inbound decryption)

Protect your internal servers by decrypting and optionally inspecting traffic directed to them. Add internal servers you wish to protect using network objects, and optionally, ports to specify these servers.

Network conditions and tunnel rules

Networks control or decrypt traffic based on its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions.

Minimize the number of matching criteria, particularly for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against each combination of the specified criteria.

For more information, see Add internal servers, on page 1961.

Default behaviour of inbound decryption

In an inbound decryption, by default, the firewall enforces strict validation of the internal server's certificate against the Trusted CA list defined within the policy. If the certificate fails validation, the firewall does not decrypt the traffic. Decryption fails if the certificate exhibits any of these conditions:

- Expired or Not-Yet-Valid: The current system time is outside the certificate's validity period.
- Untrusted: The signing Certificate Authority (CA) is not present in the Trusted CA list.
- Invalid Signature: The digital signature cannot be verified.

- Revoked or Invalid CRL: The certificate has been revoked, or the Certificate Revocation List (CRL) is invalid or unreachable.

Default handling of invalid certificates:

In a new standard decryption policy, the system generates an inbound decryption rule with the **Server Certificate Status** condition set to **Valid**.

If a server presents a certificate that does not meet these validation criteria, it fails to match the rule and is handled by the default Do Not Decrypt (DND) rule. This DND action is the default behavior for standard mode policies and is not configurable.

You can override the validation using the **Require exact certificate match** option. Refer to Override internal server validation.

Add internal servers

Add internal servers to specify certificates, networks, and ports for traffic decryption, which enables protection of internal servers and optimizes processing time.

This task discusses how to choose certificates to use to decrypt traffic coming to internal servers you want to protect. In addition to choosing a certificate, you can also specify the network and port on which the internal server is located, saving processing time.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with inbound protection, on page 1957.

Follow these steps to add internal servers:

Procedure

Step 1 Click **Add new** under Internal Server Details.

Step 2 In the Internal Servers dialog box, do any of the following:

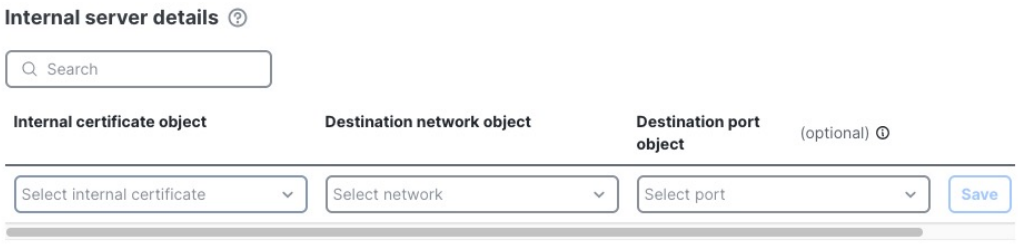
- Search for an internal certificate by entering text in the search field and pressing Enter.
- From the **Internal certificate object** list, choose an existing certificate or click **Add New** to create a new one.

Note The Secure Firewall Threat Defense device servicing the traffic must trust the certificate you upload to the rule. If you upload a self-signed certificate or a certificate not trusted by a certificate authority, and you want to replace the certificate later, you must update the policy's advanced settings in any of these ways:

- Add the certificate to the **Trusted CA certificates** list.
- Select the **Require exact certificate match for inbound decryption** check box.

For more information about advanced policy options, see Standard decryption policy advanced options, on page 1975.

For more information about replacing a certificate, see the discussion of Replace Cert in Incoming traffic decryption, on page 1940.



- From the **Destination network object** list, click the network on which the internal server is located or click **Add New** to create a new one.
- (Optional.) From the **Destination port** list, click the port on which to apply the decryption rule or click **Add New** to create a new one.

  For more information, see Upload an internal certificate for inbound protection, on page 1994.

Note Click **Help** (?) on any dialog box for more information.

Step 3 Click **Save**.

This figure shows an example.

Step 4 Save the decryption policy by clicking **Save** at the top of the page.

Step 5 If you're finished configuring your policy, see Decryption policy actions, on page 1978.

Create a standard decryption policy with outbound protection

This task enables you to create a standard decryption policy that protects servers outside your internal network by decrypting outbound connections.

Note For information about potential issues when deploying a standard decryption policy to a device that runs a version earlier than 10.0.0, see Standard decryption policy deployment issues to versions earlier than 10.0.0, on page 1957.

The following task discusses how to create a standard decryption policy to protect servers outside your internal network. To decrypt outbound connections, all options on this page are required except where noted. To bypass or block certain outbound connections, only security zones and bypass or block options are required.

Before you begin

Review what an outbound protection decryption policy means in Decrypt and re-sign (outgoing traffic), on page 1939.

To create a decryption policy with inbound protection instead, see Create a standard decryption policy with inbound protection, on page 1957.

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Security policies** > **Decryption**.

Step 3 Click **Create New** > **Decryption Policy**.

Step 4 In the provided fields, enter a **Name** and optional **Description**.

The following characters are not supported in decryption policy names:

- `#,;,{,},=,$,<,>`

Step 5 Click **Create Policy**.

Step 6 Slide **Outbound Decryption** to **Enabled** as the following figure shows.

Security zones

Security zones segment your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices. Security zones control or decrypt traffic based on its source and destination zone.

Zone configuration requirements

When configuring security zones, consider these requirements:

- If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.
- All zones used in a zone condition must be of the same type (all inline, passive, switched, or routed).

- You cannot use a zone with passive interfaces as a destination zone because devices deployed passively do not transmit traffic.
- Minimize the number of matching criteria whenever possible, especially for security zones, network objects, and port objects. If you specify multiple criteria, the system must match every combination of the criteria contents.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, the rule does not affect that device's performance.

For more information:

- Inbound decryption: Add security zones (inbound decryption), on page 1959
- Outbound decryption: Add security zones (outbound decryption), on page 1964

Add security zones (outbound decryption)

Add security zones to an outbound standard decryption policy to specify Firewall Threat Defense device interfaces that send traffic to the external server.

A security zone specifies a Firewall Threat Defense device interface that sends traffic to the external server. You can configure source zones, destination zones, or both to control which traffic gets decrypted.

Before you begin

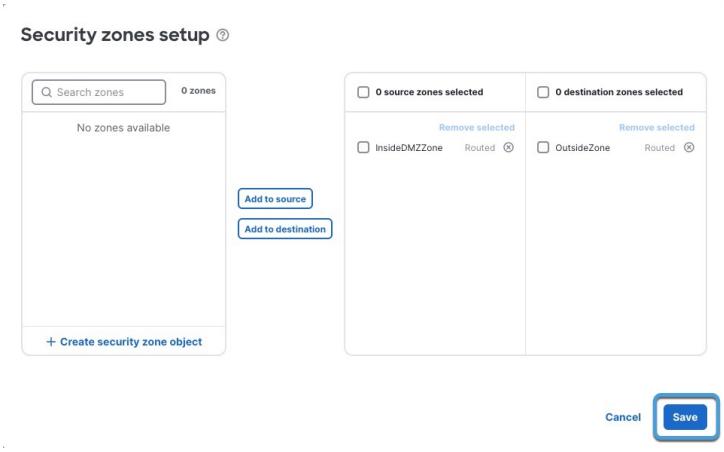
Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 1962.

Follow these steps to add security zones to an outbound decryption policy:

Procedure

Step 1 Click **Edit zones** next to Security Zones.

Step 2 In the Security Zones dialog box, do any of the following:



- Select the check box next to a security zone to add to either the source or destination.
- To create a new security zone, click **Create security zone object**.
- Search for a security zone by entering text in the Search Zones field and pressing Enter.

Note Click **Help** (?) on any dialog box for more information.

Step 3 Click **Add to Source** to decrypt traffic that matches the source network or click **Add to Destination** to decrypt traffic that matches the destination network. If you select both source and destination networks, to be decrypted, traffic must match both security zones.

Typically, the server for which you're decrypting traffic should be in the *destination* zone.

The following figure shows an example.

Step 4 Click **Save**.

Step 5 If you're finished configuring your policy, see Decryption policy actions, on page 1978.

Decrypt networks and users

This option enables you to enforce decryption and deep inspection for specific network objects and from specific users and groups in Microsoft AD, LDAP, or Local realms.

Network objects

Networks control or decrypt traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions.

Users and groups

You can choose to decrypt traffic from a subset of users and groups in your identity realms and you can also choose to decrypt traffic from special identities:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For more information, see Add networks and users, on page 1965.

Add networks and users

This task allows you to enforce decryption of outbound traffic from specific networks and from users and groups in Microsoft AD, LDAP, or Local realms.

Only traffic that matches all of the networks and users you select is decrypted.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 1962.

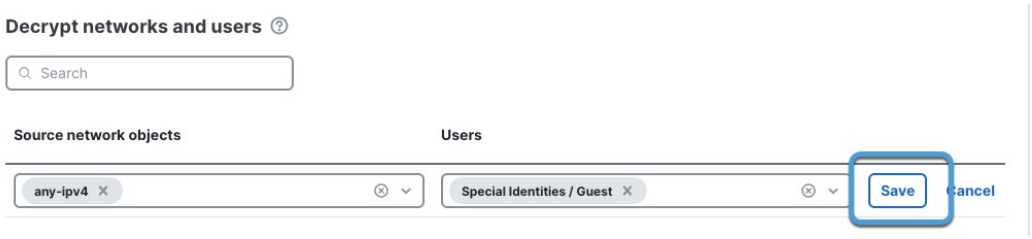
Follow these steps to add networks and users to your decryption policy:

Procedure

Step 1 Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 1962.

Step 2 Click **Add new** next to Decrypt Networks and Users.

Step 3 From the **Source Network Objects** list, do any of the following:



- In the provided field, enter all or part of an existing network object to filter for that object.
- Select the check box next to a network to decrypt. To decrypt traffic from all networks, click **Add New** and **Save** the row without selecting any networks.
- Click **Add new** to add another network to the list.

  For more information, see Create a network object, on page 2815.

Step 4 From the **Users** list, select the check box next to each user or group name to decrypt.

To decrypt traffic from all users, click **Add New** and **Save** the row without selecting any users.

This figure shows an example of selecting a network and users to decrypt.

Step 5 Click **Save**.

Step 6 If you're finished configuring your policy, see Decryption policy actions, on page 1978.

Internal certificate authority

A managed device uses the configured internal certificate authority to sign a replacement server certificate during the TLS handshake. It then decrypts and inspects the traffic.

This topic discusses how to add an internal certificate authority (CA) to an outbound section of a standard decryption policy. The internal CA must be trusted by users on your network to avoid seeing untrusted certificate errors in their web browser.

For more information, see Add an internal CA for outbound protection, on page 1967.

Add an internal CA for outbound protection

This task allows you to add an internal CA to resign outgoing traffic for enhanced security in outbound protection scenarios.

This task discusses how to add an internal CA to resign outgoing traffic.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 1962.

Follow these steps to add an internal CA for outbound protection:

Procedure

In the **Internal Certificate Authority** list, do any of the following:

- Click the name of an internal CA.
- Click **Create New** to create a new internal CA.

  Click **Help** for more information.

  If you do not already have an internal CA, see:

  - Generate an internal CA for outbound protection, on page 1967
  - Upload an internal CA for outbound protection, on page 1968

Generate an internal CA for outbound protection

This task allows you to generate an internal certificate authority object to protect outbound connections when creating a decryption rule.

This task discusses how you can optionally generate an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects** as discussed in Upload a signed certificate issued in response to a CSR, on page 2821.

Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in Internal certificate authority objects, on page 2817.

Procedure

Step 1 From the **Internal CA** list, click **Create New** > **Generate internal CA certificate**.

Step 2 Give the internal CA a **Name** and provide a two-letter **Country Name**.

Step 3 Click **Self-Signed** or **CSR**.

For more information about these options, see Internal certificate authority objects, on page 2817.

Step 4 Enter the requested information in the provided fields.

Step 5 Click **Save**.

Step 6 If you chose **CSR**, after the signing request has been completed, click **Install Certificate** as follows:

a) Repeat the preceding steps in this procedure.
b) Edit the CSR from the **Internal CA** list by clicking on the edit icon.
c) Click **Install Certificate**.
d) Follow the prompts on your screen to complete the task.

Step 7 Continue creating the policy as discussed in Create a standard decryption policy with outbound protection, on page 1962.

Upload an internal CA for outbound protection

Upload an internal certificate authority to create a decryption rule that protects outbound connections.

This task discusses how you can optionally upload an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects** as discussed in Upload a signed certificate issued in response to a CSR, on page 2821.

Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in Internal certificate authority objects, on page 2817.

Follow these steps to upload an internal CA for outbound protection:

Procedure

Step 1 From the **Internal CA** list, click **Create New** > **Upload internal CA certificate**.

Step 2 Give the internal CA a **Name**.

Step 3 Paste or browse to locate the certificate and its private key in the provided fields.

Step 4 If the CA has a password, select the **Encrypted** check box and enter the password in the adjacent field.

Step 5 Continue creating the policy as discussed in Create a standard decryption policy with outbound protection, on page 1962.

Bypass traffic when decrypting

You can optionally allow certain traffic to pass through the device encrypted without decryption. Bypassing certain traffic has the additional advantage that system resources are not consumed for decrypting it.

Traffic bypass methods

You can review some reasons to leave traffic encrypted here: Best practice for deciding when to decrypt traffic, on page 1937. The system provides these ways to bypass traffic when decrypting:

- Bypass source and destination networks: For example, traffic from internal servers located on an internal/DMZ network that you can trust doesn't need to be decrypted.
- Bypass users: You can bypass decryption for users and groups you trust.

- Bypass undecryptable applications: (Recommended) The typical reason to bypass outgoing traffic to applications is this traffic might use certificate pinning, which is not decryptable.

  For more information, see TLS/SSL pinning, on page 2048.

- Bypass categories: (Recommended) Bypass decrypting URL categories of sites for these reasons:
  - The categories represent applications (like personal finance or health) that might be illegal to decrypt and inspect.
  - Categories of websites Cisco has determined are low-risk.

- Intelligent decryption bypass: Bypass servers based on the threat confidence levels of clients which is determined by the Encrypted Visibility Engine (EVE) and the URL category reputation.

  All devices to which a standard decryption policy with this option enabled are deployed must run version 7.7 or later; otherwise, policy deployment fails.

Bypass sources and destinations

(Optional) Bypass traffic from source or destination network objects. For example, if traffic originates from an internal network that has trusted devices, you can opt not to decrypt that traffic. Networks control or decrypt traffic by its source and destination IP address, using inner headers.

For more information, see Add bypass sources and destinations, on page 1969.

Add bypass sources and destinations

Add bypass sources and destinations to optionally bypass outbound traffic originating from source networks or going to destination networks that you trust.

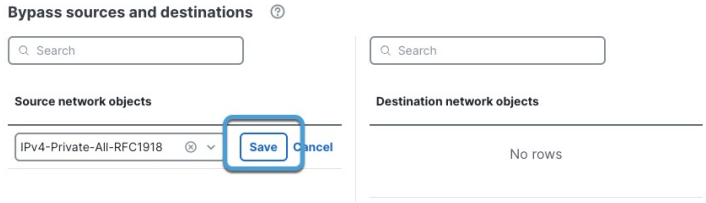
You should generally bypass traffic only if you trust the traffic from these networks.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 1962.

Follow these steps to add bypass sources and destinations:

Procedure



Step 1 Click **Add new** under Bypass sources and destinations for either source network objects or destination network objects.

Step 2 In the dialog box that is displayed, do any of the following:

- Search for a network object by entering text in the search field and pressing Enter.
- From the **Source network object** or **Destination network object** list, choose an existing network object or click **Add New** to create a new one.

Note Click **Help** (?) on any dialog box for more information.

The following figure shows an example.

Step 3 Click **Save**.

Step 4 If you're finished configuring your policy, see Decryption policy actions, on page 1978.

Bypass users

(Optional) You can choose to bypass decryption for users and groups in Microsoft Active Directory, LDAP, and Local realms. These users are typically ones you trust.

Bypass user configuration

You can choose to bypass a subset of users and groups in your identity realms and you can also choose to bypass from special identities:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For more information, see Add bypass users, on page 1970.

Add bypass users

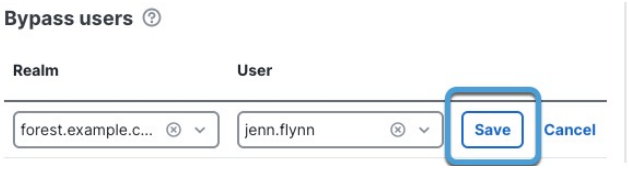
Bypass decryption for users and groups in selected Microsoft AD, LDAP, and Local realms.

This task allows you to exclude specific users and groups from decryption processing by adding them to a bypass list.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 1962.

Follow these steps to add bypass users:



Procedure

Step 1 Click **Add new** under Bypass users.

Step 2 In the dialog box that is displayed:

- From the **Realm** list, click the name of a realm.
- From the **User** list, select the check box next to one or more users or groups for which to bypass decryption.

The following figure shows an example.

Step 3 Click **Save**.

Step 4 Repeat the preceding steps as many times as necessary to bypass more users and groups.

Bypass applications

(Optional) You can bypass decryption for applications that cannot be decrypted.

Bypass application configuration

Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail.

Typically, this behavior is associated with *certificate pinning*, which is discussed in TLS/SSL certificate pinning guidelines, on page 2010.

Undecryptable applications are updated automatically in the Vulnerability Database (VDB). You can find a list of all applications on the Secure Firewall Application Detectors page; the **undecryptable** tag identifies applications Cisco determines are undecryptable.

The list of undecryptable applications is maintained by Cisco.

For more information, see Add bypass applications, on page 1971.

Add bypass applications

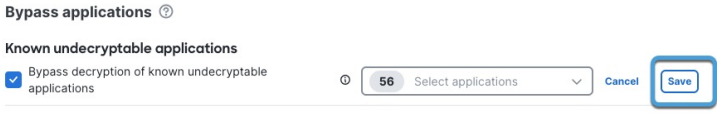
Bypass decryption for applications that are typically undecryptable due to their use of certificate pinning or other security mechanisms that prevent standard SSL/TLS decryption.

This task discusses how to bypass decryption for applications (typically because those applications are undecryptable due to their using certificate pinning as discussed in TLS/SSL pinning, on page 2048).

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 1962.

Procedure



Step 1 Select the **Bypass decryption of known undecryptable applications** check box.

Step 2 Click **Edit applications**.

Step 3 From the list, do any of the following:

- Click **Select All** to select all applications that Cisco has determined are undecryptable.
- Select the check box next to the name of an application for which to bypass decryption.
- Clear the check box next to the name of an application to decrypt connections to anyway.

The following figure shows an example.

Step 4 Under Selected applications and filters, click **Add New** to add applications or application filters to bypass. Click **Help** for more information.

Step 5 Click **Save**.

Step 6 If you're finished configuring your policy, see Decryption policy actions, on page 1978.

Bypass URL categories and reputations

(Optional) Select categories and reputations, such as personal finance or health, that you do not want to decrypt.

URL categories and reputations information

URL categories and reputations are maintained by Cisco Talos.

For more information about categories, see Intelligence Categories.

For more information about reputations, see Web reputation levels.

To add URL categories and reputations to your decryption policy, see Add bypass URL categories and reputations, on page 1972.

Note Depending on the laws in your area, decryption of such traffic might be prohibited. Consult an authority in your area for more information.

Add bypass URL categories and reputations

This task allows you to bypass decryption for specific URL categories and reputations to improve performance and reduce processing overhead for trusted or sensitive content.

This task is optional and discusses how to bypass decryption of categories and reputations, based on ratings provided by Cisco Talos.

The following figure shows the list of categories and reputations we recommend.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 1962.

Follow these steps to add bypass URL categories and reputations:

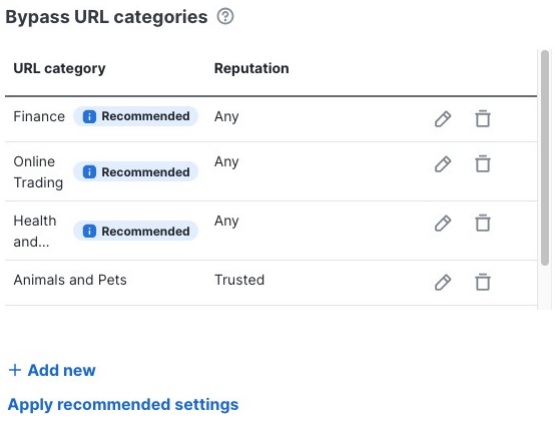
Procedure

Step 1 In the Bypass URL categories section, do any of the following:

- To edit an existing category/reputation, click **Edit** ( ).
- To delete an existing category/reputation, click **Delete** ( ).
- To add a new category/reputation, click **Add new**.
- To return the list of categories and reputations to the ones Cisco recommends, click **Apply recommended settings**.

Step 2 To add or edit a category/reputation, from the first list, click the name of a category.

For more information about categories, see Intelligence Categories.



Step 3 From the second list, click the name of a reputation.

For more information about reputations, see Web reputation levels.

The following figure shows an example of using Cisco's defaults and adding the Animals and Pets category with the Trusted reputation.

Step 4 Click **Save**.

This figure shows an example.

Step 5 If you're finished configuring your policy, see Decryption policy actions, on page 1978.

Intelligent decryption bypass

Intelligent decryption bypass allows very low-risk connections to dynamically bypass decryption. It leverages the power of the Encrypted Visibility Engine (EVE) and insights from Talos Server Reputation to assess both client and server risk in real-time.

Bypassing trusted connections reduces unnecessary decryption processing and conserves system resources. This also respects user privacy by not decrypting traffic that is classified as low-risk and trusted.

Classification and setup details

The bypass behavior applies broadly and covers many general browsing activities. For example, connections to www.CNN.com are not decrypted, but other connections that fetch assets from CNN's Content Delivery Networks (CDNs) may be decrypted if those URLs are not classified as Trusted.

Client classification is based on EVE's risk assessment which uses machine learning to identify traffic risk levels. URL classification is based on Talos URL reputation. Connections to trusted URLs from very-low risk clients are bypassed and not decrypted. All other connections, including connections to URLs that are not trusted or connections from clients classified at a higher risk level, are subject to decryption policies.

To set up Intelligent Decryption Bypass for an outbound decryption rule, locate **Intelligent Decryption Bypass** and set it to **Slider enabled** () to *not* decrypt traffic for very low-risk clients connecting to trusted servers, based on the threat confidence levels of clients which are determined by the Encrypted Visibility Engine (EVE) and the URL category reputation.

To view the current list of clients classified by trust level, visit Secure Firewall Application Detectors. For example, CNN.com is classified as Very Low. Make sure you understand what traffic you are choosing to *not* decrypt.

Block connections

You can choose to block any of these connection types:

- SSL and TLS versions because some are considered unsecure.
- Connections based on certificate status. For example, block outbound traffic to a server with an expired certificate because that server might not be trustworthy.

For more information, see Add block connections, on page 1974.

Add block connections

This task enables you to block outbound connections based on either old SSL or TLS versions or based on the server certificate status, enhancing security by preventing connections using insecure protocols or untrusted certificates.

This task discusses how to block connections based on either old SSL or TLS versions; or based on the server certificate status.

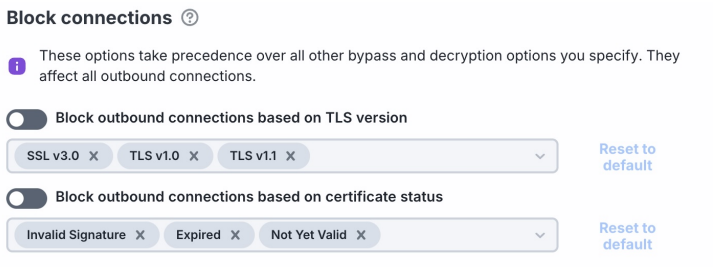
Note Blocking affects *all outbound connections* and takes precedence over all other bypass and decryption conditions you choose.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 1962.

Procedure

Step 1 Locate the Block connections section.



Step 2 To block outbound traffic based on its SSL or TLS protcol version, slide **Block outbound connections based on TLS version** to **Slider enabled** ( ).

Step 3 To block outbound traffic based on server certificate status, slide **Block outbound connections based on certificate status** to **Slider enabled** ( ).

Step 4 You have the following options:

- From the list, select the check box next to an option to add that protocol or status to the policy.
- Click **x** next to an item to remove it from the list.
- Click **Reset to default** to return the list entries to their original values.

The following figure shows an example of blocking traffic with both TLS versions and server certificate status. Self-signed was added to the list of server certificates to block.

Step 5 If you're finished configuring your policy, see Decryption policy actions, on page 1978.

Standard decryption policy advanced options

Advanced decryption policy options allow you to fine-tune SSL/TLS decryption behavior. These optional settings control certificate matching, legacy site bypassing, protocol handling, and logging configuration. We recommend setting all advanced options to their default values unless specific requirements dictate otherwise.

Bypass legacy Cisco undecryptable sites

Enable this option to bypass decryption for websites with Distinguished Names (DNs) that Cisco has determined are undecryptable. To view the list of DNs, go to **Objects** > **Distinguished Name** > **Object Groups**.

Require exact certificate match for inbound decryption

Enable this option to require the use of the internal server's certificate in the decryption policy (this option is referred to as *known key decryption*). The default is to use a different certificate, which is more convenient

for replacing the policy's certificate when needed. For more information, see Incoming traffic decryption actions, on page 2040.

Override internal server validation with Decrypt – Known key

To accommodate internal servers that do not meet standard validation requirements, you can modify the policy behavior by enabling **Require exact certificate match** under **Advanced Options**.

When this option is enabled, the decryption method shifts from **Decrypt – Replace Cert** to **Decrypt – Known Key**. In this mode, the system does not perform standard CA validation. Instead, it requires the certificate presented by the internal server to be an exact match for the certificate configured in the Secure Firewall Management Center.

Enable adaptive TLS server identity probe

Automatically enabled when TLS 1.3 decryption is enabled. A *probe* is a partial TLS connection with the server, the purpose of which is to obtain the server certificate and cache it. (If the certificate is already cached, the probe is never established.)

If TLS 1.3 Server Identity Discovery is disabled on the access control policy with which the decryption policy is associated, we attempt to use the Server Name Indication (SNI), which is not as reliable.

The adaptive TLS server identity probe occurs on any of the following conditions as opposed to on every connection as in earlier releases:

- Certificate Issuer—Matched when the value of **Issuer DNs** in a decryption rule's DN rule condition is matched.

  For more information, refer to Conditions for distinguished name rules in decryption policies, on page 2025.

- Certificate Status—Matched when any of the **Cert Status** conditions are matched in a decryption rule.

  For more information, refer to Certificate Status Decryption rule conditions, on page 2031.

- Internal/External Certificate—Internal certificates can be matched by the certificate used in **Decrypt - Known Key** rule actions; external certificates can be matched in **Certificates** rule conditions.

  For more information, refer to Incoming traffic decryption and Certificate rule conditions, on page 2024.

- Application ID—Can be matched by **Applications** rule conditions in either an access control policy or a decryption policy.

  For more information, refer to Application rule conditions, on page 1494.

- URL Category—Can be matched by **URLs** rule conditions in an access control policy.

  For more information, refer to Recommendation: use URL conditions for website access control , on page 1496.

Note **Enable adaptive TLS server discovery mode** is not supported on any Secure Firewall Threat Defense Virtual deployed to AWS. If you have any such managed devices managed by the Secure Firewall Management Center, the connection event **PROBE_FLOW_DROP_BYPASS_PROXY** increments every time the device attempts to extract the server certificate.

Decryption event logging options

To expedite troubleshooting and to inform yourself about how your decryption policies are working, we recommend you enable all logging options: bypassed traffic, decrypted traffic, and blocked traffic.

QUIC Decryption

Whether to apply decryption rules to connections that use the HTTP/3 over the QUIC protocol. When you decrypt QUIC connections, the system can inspect the contents of the sessions for intrusions, malware, or other issues. You can also apply granular control and filtering of decrypted QUIC connections based on specific criteria in the access control policy. QUIC support is in line with RFC 9000, 9001, 9002, 9114, 9204.

Consider the following when implementing QUIC decryption:

- On high availability or clustered devices, QUIC decryption works only if the connection remains on the same node. If the connection fails over, or is forwarded to another node, the connection drops and must be re-established. Multi-instance is supported without restrictions.
- Rules that apply to QUIC traffic would include the UDP protocol with destination port 443.
- Access control rules that apply to QUIC traffic would include the HTTP/3 or QUIC protocols, either explicitly or by implication.

The following limitations apply to QUIC decryption:

- QUIC decryption applies to Firewall Threat Defense 7.6+ only. Devices running a lower release cannot decrypt QUIC connections.
- Connections from browsers using the Chromium stack (Google Chrome, Opera, Edge) cannot be decrypted for outbound traffic. But inbound traffic from the same browsers can be decrypted.
- Connection Migration as described in RFC 9000 is not supported. The concept of Connection ID in QUIC allows endpoints to retain the same connection in the event of address change.
- Key update, session resumption, and QUIC version 2 are not supported.
- Interactive Block and Interactive Block with Reset (in access control rules) is not supported. These actions will work as Block and Block with Reset.
