CONTENTS

PART I **Getting Started with Device Configuration** 73

CHAPTER 1 **Device Registration** 1

About device registration 1

Firewall management center overview 1

Firewall Management Center and device management 2

Devices managed by a Secure Firewall Management Center 2

Management connection 3

Beyond policies and events 4

Device management interfaces 4

Management and event interfaces on the Firewall Threat Defense 4

Using the Firewall Threat Defense data interface for management 5

Management interface support per device model 6

Network routes on device management interfaces 7

NAT environments 8

Management and event traffic channel examples 10

Prerequisites for device registration 12

Log into the Command-Line Interface on the device 13

Complete the Firewall Threat Defense initial configuration for manual registration 15

Complete the Firewall Threat Defense Initial Configuration Using the Firewall Device Manager 15

Complete the Firewall Threat Defense Initial Configuration Using the CLI 21

Configure an event interface 28

Device registration management 30

About the device management page 30

Add a Device Group 31

Registration with the management center 32

Add a Device Using a Registration Key 32
Add a Device Using the Serial Number (Zero-Touch Provisioning) 36
Add a chassis 43
Register with a new management center 46
Resolve serial number (zero-touch provisioning) registration issues 47
Register with a new management center 53
Delete (Unregister) a Device from the Firewall Management Center 54
Shut down or restart the device 55
Download the managed device list 56
Migrate Firewall Threat Defense devices 56
Supported Devices for Migration 57
License for Firewall Threat Defense migration 57
Prerequisites for migration 57
Configurations that the wizard migrates 57
Guidelines and limitations for migration 59
Best practices for Threat Defense device migration 60
Switch managers 61
Switch from the Firewall Device Manager to the Firewall Management Center 61
Switch from Firewall Management Center to Firewall Device Manager 65
History for device registration 67

CHAPTER 2 **Transparent or Routed Firewall Mode** 71
Firewall mode 71
Routed firewall mode 71
Transparent firewall mode 72
Transparent firewall network usage 72
Passing traffic for routed-mode features 73
Bridge groups 73
Bridge virtual interfaces 73
Bridge groups in transparent firewall mode 74
Bridge groups in routed firewall mode 75
Allow layer 3 traffic 76
Allowed MAC addresses 76
BPDUs handling 76

MAC address and route lookups 77
Unsupported features for bridge groups in transparent mode 79
Unsupported features for bridge groups in routed mode 80
Default settings 81
Guidelines for firewall mode 81
Set the firewall mode 82

CHAPTER 3 CLI Users 85
CLI users 85
Internal and external users 85
CLI access 86
CLI user roles 86
Guidelines for CLI users 87
Add an internal user at the CLI 87
External authentication for the Firewall Threat Defense 90
External authentication for the Firewall Threat Defense 90
LDAP 91
RADIUS 91
Add an LDAP external authentication object for Firewall Threat Defense 92
Add a RADIUS external authentication object for Firewall Threat Defense 98
External authentication for users on Firewall Threat Defense devices 103
Troubleshoot LDAP authentication connections 103
History for CLI users 105

CHAPTER 4 Change Management 107
Change management 107
Make configuration changes in the change management workflow 107
Create separate approver and configuration roles 108
Policies and objects that support change management 109
Requirements and prerequisites for change management 111
Guidelines and limitations for change management 111
Enabling or disabling change management 112
Manage tickets 113
Create change management tickets 114

Opening a ticket for configuration changes 115
Preview a ticket 116
Submit a ticket 116
Discard a ticket 117
Approving or rejecting a ticket 117
History for change management 118

CHAPTER 5 **Configuration Deployment** 121
Configuration deployment 121
Configuration changes that require deployment 121
Deployment preview 122
Guidelines for selective policy deployment 123
System username 126
Auto-enabling of application detectors 126
Asset rediscovery with network discovery policy changes 127
Snort restart scenarios 127
Inspection interruption warnings during deployment 127
Inspect traffic during policy apply 128
Snort restart traffic behavior 129
Configurations that restart the snort process when deployed or activated 131
Actions that immediately restart the snort process 132
Requirements and prerequisites for deployment management 133
Best practices for deploying configuration changes 133
Configuration deployment 134
Deploy configuration changes 135
Redeploy existing configurations to a device 140
Deployment management 141
Deployment status 141
View deployment history 141
Set the number of configuration versions to retain 146
Deployment rollback 147
Perform a rollback 149
View the deployment rollback transcript 150
Download policy changes report for multiple devices 151

Compare policies 152
Generate current policy reports 153
History for configuration deployment 154

PART II **High Availability and Scalability** 157

CHAPTER 6 **Multi-Instance Mode** 159
Multi-instance mode 159
Multi-instance modes and appliance modes 159
Chassis management interface 160
Instance interfaces 161
Interface types 161
Chassis interfaces vs. instance interfaces 161
Shared interface scalability 163
Shared interface best practices 164
How the chassis classifies packets 166
Classification examples 167
Cascading container instances 167
Typical multi-instance deployments 168
Automatic MAC addresses for instance interfaces 169
Performance scaling factors for multi-instance modes 170
Instances and high availability 170
Licenses for instances 171
Requirements and prerequisites for instances 171
Guidelines and limitations for instances 172
Instance configuration 175
Enable multi-instance mode 175
Add a multi-instance chassis to the Firewall Management Center 177
Chassis interface configuration 180
Configure a physical interface 180
Configure an EtherChannel 183
Configure a subinterface 187
Add an instance 189
System configuration customization 195

Configure SNMP 196
Import or export the chassis configuration 196
Chassis platform settings 199
Create a chassis platform settings policy 199
Configure DNS 200
Configure SSH and SSH access list 201
Configure syslog 206
Configure time synchronization 211
Configure time zones 213
Multi-instance mode management 214
Change interfaces assigned to an instance 214
Change chassis management settings at the FXOS CLI 216
Multi-instance mode 219
Multi-instance setups 219
Instance interfaces 220
Multi-instance mode feature and version history 222

CHAPTER 7 **Logical Devices on the Firepower 4100/9300** 223
Supported interfaces 223
Chassis management interface 223
Interface types 224
FXOS interfaces and application interfaces 226
Shared interface scalability 228
Shared interface best practices 229
Shared Interface Usage Examples 231
View shared interface resources 237
Inline set link state propagation for the Firewall Threat Defense 238
Logical devices 238
Standalone and clustered logical devices 239
Logical device application instances 239
Container instance interfaces 239
How the chassis classifies packets 240
Classification examples 240
Cascading container instances 244

Typical multi-instance deployment 245
Automatic MAC Addresses for Container Instance Interfaces 246
Container instance resource management 247
Performance scaling factor for multi-instance capability 247
Container instances and high availability 247
Container instances and clustering 247
Licenses for container instances 247
Requirements and prerequisites for logical devices 248
Requirements and prerequisites for hardware and software combinations 248
Requirements and prerequisites for container instances 250
Requirements and prerequisites for high availability configuration 251
Requirements and prerequisites for clustering 251
Guidelines and limitations for logical devices 255
Guidelines and limitations for interface configuration 255
General guidelines for firewall mode, HA, and multi-instance configurations 258
Configure interfaces 259
Enable or disable an interface 259
Configure a physical interface 259
Add an EtherChannel (port channel) 261
Add a VLAN subinterface for container instances 263
Configure logical devices 264
Add a resource profile for container instances 264
Add a Standalone Firewall Threat Defense 265
Add a high availability pair 271
Change an Interface on a Firewall Threat Defense Logical Device 272
Connect to the Console of the Application 274
History for logical devices 276

CHAPTER 8 **High Availability for Devices** 283
Secure Firewall Threat Defense high availability 283
High availability system requirements 284
Hardware requirements 284
Software requirements 285
License requirements for Firewall Threat Defense devices in a high availability pair 285

Failover and stateful failover links 285
Failover link 286
Stateful failover links 288
Failover and data link interruption avoidance 288
MAC addresses and IP addresses in High availability 290
Stateful failover 292
Supported features 292
Unsupported features 294
Bridge group requirements for high availability 294
Failover health monitoring 295
Unit health monitoring 295
Heartbeat module redundancy 296
Interface monitoring 296
Failover triggers and detection timing 298
Active/standby failover 300
Primary/secondary roles and active/standby status 300
Active unit determination at startup 300
Failover events 301
Config-sync optimization 302
Requirements and prerequisites for high availability 303
Guidelines for High availability 303
Add a high availability pair 306
Configure optional high availability parameters 309
Configure standby IP addresses and interface monitoring 309
Edit high availability failover criteria 310
Configure virtual MAC addresses 310
Manage High availability 311
Switch the Active Peer in the Firewall Threat Defense High Availability Pair 312
Refresh node status for a single Firewall Threat Defense high availability pair 312
Suspend and resume high availability 313
Replace a unit in Firewall Threat Defense high availability pair 314
Replace a Primary Firewall Threat Defense HA Unit with no Backup 314
Replace a Secondary Firewall Threat Defense HA Unit with no Backup 315
Break a high availability pair 316

Delete (Unregister) a High Availability Pair and Register to a New Firewall Management Center 318
Monitoring High availability 319
View failover history 319
View stateful failover statistics 319
Troubleshoot configuration sync failure 320
History for high availability 320

CHAPTER 9 **Clustering: Secure Firewall 3100/4200 323**
Clustering for the Secure Firewall 3100/4200 323
How a cluster fits into your network 323
Control and data node roles 324
Cluster interfaces 324
Cluster control links 324
Configuration replication 324
Management network 325
Licenses for clustering 325
Prerequisites for clustering 325
Guidelines for clustering 326
Clustering configuration 331
Cluster interfaces 331
Cluster control link 331
Spanned EtherChannels 333
Cable and add devices to the Firewall Management Center 336
Create a Cluster 338
Configure interfaces 345
Configure cluster health monitor settings 346
Cluster node management 351
Add a new cluster node 351
Break a node 353
Break the cluster 354
Disable clustering 355
Rejoin the cluster 356
Change the control node 356
Edit the cluster configuration 357

Reconcile cluster nodes 358
Delete (Unregister) the Cluster or Nodes and Register to a New Firewall Management Center 360
Monitor the cluster 361
Cluster health monitor dashboard 363
View cluster health 363
Cluster metrics 365
Troubleshoot the cluster 365
Perform a ping on the cluster control link 367
Clustering examples 368
Firewall on a stick 368
Traffic segregation 369
Reference for Clustering 370
Firewall Threat Defense features and clustering 370
Unsupported features with clustering 370
Centralized features for clustering 371
Connection settings and clustering 372
FTP and Clustering 372
NAT and clustering 372
Dynamic routing 374
SIP inspection and clustering 374
SNMP and clustering 374
Syslog and clustering 375
Cisco TrustSec and clustering 375
VPN and clustering 375
Performance scaling factor 375
Control node election 376
High availability within clusters 376
Node health monitoring 377
Interface monitoring 377
Status after failure 377
Rejoin the cluster 378
Data path connection state replication 378
How the cluster manages connections 379
Connection roles 379

New connection ownership 380
Sample data flow for TCP 380
Sample data flows for ICMP and UDP 381
History for Clustering 382

CHAPTER 10 **Clustering: Private Cloud 385**
About clustering: private cloud 385
How the cluster fits into your network 385
Control and data node roles 386
Individual interfaces 386
Policy-based routing 387
Equal-cost multi-path routing 387
Cluster Control Link 388
Cluster control link traffic overview 388
Configuration replication 389
Management network 389
Licenses for clustering: Private cloud 389
Prerequisites for clustering: Private cloud 390
Guidelines for clustering: Private cloud 391
Configure clustering: private cloud 392
Add nodes to the Management Center 392
Create a cluster 392
Configure interfaces 400
Configure Cluster Health Monitor Settings 401
Manage cluster nodes 404
Add a new cluster node 404
Break a node 406
Break the cluster 407
Disable clustering 408
Rejoin the cluster 409
Change the control node 409
Edit the cluster configuration 410
Reconcile cluster nodes 411
Delete (Unregister) the cluster or nodes and register to a New Firewall Management Center 413

Monitor cluster status 414
Cluster health monitor 416
View the cluster health monitor 417
Troubleshoot the cluster 419
Perform a ping on the cluster control link 420
Reference for clustering 422
Threat Defense features and clustering 422
Unsupported features and clustering 422
Centralized features for clustering 422
Connection settings and clustering 423
Dynamic routing and clustering 423
FTP and clustering 424
NAT and clustering 424
SIP inspection and clustering 426
SNMP and clustering 426
Syslog and clustering 426
Cisco trustsec and clustering 426
VPN and clustering 426
Performance scaling factor 427
Control node election 427
High availability within the cluster 428
Node health monitoring 428
Interface monitoring 428
Status after failure 428
Rejoining the cluster 429
Data path connection state replication 429
How the cluster manages connections 430
Connection roles 430
New connection ownership 431
Sample data flow for TCP 431
Sample data flow for ICMP and UDP 432
History for clustering: private cloud 434

CHAPTER 11 **Clustering: Public Cloud** 437

About Threat Defense Virtual clustering in the public cloud 437
How the cluster fits into your network 438
Individual interfaces 438
Control and data node roles 439
Cluster Control Link 439
Cluster control link traffic overview 440
Configuration replication 440
Management network 440
Licenses for Threat Defense Virtual clustering 440
Requirements and prerequisites for Threat Defense Virtual clustering 441
Guidelines for Threat Defense Virtual clustering 443
Deploy the cluster in AWS 444
AWS gateway load balancer and Geneve single-arm proxy 444
Sample topology 445
End-to-end process for deploying Threat Defense Virtual cluster on AWS 446
Templates 448
Deploy the Stack in AWS Using a CloudFormation template 448
Manual cluster deployment in AWS 461
Create the Day0 configuration for AWS 461
Deploy cluster nodes 463
Target failover for Secure Firewall Threat Defense Virtual clustering with GWLB in AWS 464
Enable target failover for Secure Firewall Threat Defense Virtual clustering in AWS 465
Deploy the cluster in Azure 466
Sample topology for GWLB-based cluster deployment 466
Azure gateway load balancer and paired proxy 467
End-to-end process for deploying Threat Defense Virtual cluster in Azure with GWLB 468
Templates 470
Prerequisites for Azure GWLB cluster deployment 470
Deploy cluster on Azure with GWLB using an Azure resource manager template 471
Sample topology for NLB-based cluster deployment 473
End-to-end process for deploying Threat Defense Virtual cluster in Azure with NLB 474
Templates 476
Prerequisites for Azure NLB cluster deployment 476
Deploy cluster on Azure with NLB using an Azure resource manager template 478

Manual cluster deployment in Azure 479
Create the Day0 configuration for Azure 479
Deploy cluster nodes manually - GWLB-based deployment 481
Deploy cluster nodes manually - NLB-based deployment 483
Troubleshoot cluster deployment in Azure 484
Deploy the cluster in GCP 485
Sample topology for GCP clustering autoscale solution 485
End-to-end process for deploying Threat Defense Virtual cluster in GCP 486
Templates 488
Deploy the instance group in GCP using an instance template 488
Manual cluster deployment in GCP 490
Create the Day0 configuration with a fixed configuration for GCP 490
Deploy cluster nodes manually 491
Allow health checks for GCP network load balancers 491
Add the cluster to the Management Center (manual deployment) 493
Edit cluster health monitor settings 500
Manage cluster nodes 503
Disable clustering 503
Rejoin the cluster 504
Reconcile Cluster Nodes 504
Delete (Unregister) the cluster or nodes and register with a new Firewall Management Center 505
Monitor cluster status 506
Cluster health monitor 508
View the cluster health monitor 509
Troubleshoot the cluster 512
Perform a ping on the cluster control link 513
Upgrade the cluster 514
Reference for clustering 515
Threat Defense features and clustering 515
Unsupported features and clustering 515
Centralized features for clustering 515
Cisco Trustsec and clustering 516
Connection settings and clustering 516
Dynamic routing and clustering 516

FTP and clustering 517
NAT and clustering 517
SIP inspection and clustering 519
SNMP and clustering 519
Syslog and clustering 519
VPN and Clustering 519
Performance scaling factor 520
Control node election 520
High availability within the cluster 521
Node health monitoring 521
Interface monitoring 521
Status after failure 522
Rejoining the cluster 522
Data path connection state replication 522
How the cluster manages connections 523
Connection roles 523
New connection ownership 524
Sample data flow for TCP 524
Sample data flow for ICMP and UDP 525
History for Threat Defense Virtual clustering in the public cloud 527

CHAPTER 12 **Clustering: Firepower 4100/9300** 529
About clustering on the Firepower 4100/9300 chassis 529
Bootstrap configuration 530
Cluster members 530
Cluster control link 530
Size the cluster control link 531
Cluster control link redundancy 531
Cluster control link reliability for inter-chassis clustering 532
Cluster control link network 532
Management network 532
Management interface 532
Cluster interfaces 532
Spanned EtherChannels 533

Connecting to a redundant switch system 533
Configuration replication 533
Licenses for clustering 534
Requirements and prerequisites for clustering 534
Clustering guidelines and limitations 538
Configure clustering 541
FXOS: Add a Firewall Threat Defense cluster 541
Create a Firewall Threat Defense cluster 541
Add more cluster nodes 552
Firewall Management Center: Add a cluster 556
Firewall Management Center: Configure cluster, data interfaces 562
Firewall Management Center: Configure Cluster Health Monitor Settings 564
FXOS: Remove a cluster node 567
Firewall Management Center: Manage cluster members 569
Add a new cluster member 569
Replace a cluster member 570
Deactivate a member 571
Rejoin the cluster 572
Delete (Unregister) a data node 572
Change the control unit 573
Reconcile cluster members 574
Firewall Management Center: Monitor the cluster 574
Cluster Health Monitor Dashboard 577
Viewing cluster health 578
Cluster metrics 580
Troubleshoot the cluster 581
Perform a ping on the cluster control link 582
Examples for Clustering 583
Firewall on a stick 583
Traffic segregation 584
Reference for clustering 585
Firewall Threat Defense features and clustering 585
Unsupported features with clustering 585
Centralized features for clustering 586

Connection settings 586
Dynamic routing and clustering 587
FTP and clustering 587
Multicast routing and clustering 587
NAT and clustering 587
SIP inspection and clustering 589
SNMP and clustering 589
Syslog and clustering 589
TLS/SSL connections and clustering 589
Cisco TrustSec and clustering 589
VPN and clustering 589
Performance scaling factor 590
Control unit election 590
High availability within the cluster 591
Chassis-application monitoring 591
Unit health monitoring 591
Interface monitoring 591
Decorator application monitoring 592
Status after failure 592
Rejoining the cluster 592
Data path connection state replication 593
How the cluster manages connections 593
Connection roles 593
New connection ownership 595
Sample data flow for TCP 595
Sample data flow for ICMP and UDP 596
History for clustering 597

PART III **Interfaces and Device Settings** 603

CHAPTER 13 **Interface Overview** 605
Management interface 605
Management interface 605
Diagnostic interface 606

Interface Mode and Types 607
Security zones and interface groups 607
Auto-MDI/MDIX feature 609
Redundant interfaces (deprecated) 609
Default settings for interfaces 609
Create security zone and interface group objects 610
Enable the physical interface and configure Ethernet settings 611
Configure EtherChannel interfaces 614
About EtherChannels 614
EtherChannels 614
Guidelines for EtherChannels and redundant interfaces 617
Configure an EtherChannel 619
Sync Interface Changes with the Firewall Management Center 622
Network module management for Secure Firewall 3100/4200 625
Configure breakout ports 626
Add a network module 630
Hot swap the network module 632
Replace the network module with a different type 634
Remove the network module 638
Merge the management and diagnostic interfaces 640
Unmerge the management interface 644
History for interfaces 645

CHAPTER 14 **Regular Firewall Interfaces** 649
Requirements and prerequisites for regular firewall interfaces 649
Configure switch ports 650
About switch ports 650
Switch ports and interfaces 650
Auto-MDI/MDIX feature 651
Prerequisites for switch ports 651
Guidelines for switch ports 651
Configure switch ports and power over ethernet 653
Enable or disable switch port mode 653
Configure a VLAN interface 653

Configure switch ports as access ports 655
Configure switch ports as trunk ports 657
Configure Power over Ethernet 660
Loopback interfaces 661
Guidelines for Loopback Interfaces 662
Configure a loopback interface 662
Rate-Limit traffic to the loopback interface 663
VLAN subinterfaces and 802.1Q trunking 667
Guidelines for VLAN subinterfaces 667
Maximum number of VLAN subinterfaces by device model 668
Add a subinterface 669
Configure VXLAN Interfaces 671
VXLAN interfaces 671
encapsulation 671
VXLAN tunnel endpoints 671
VTEP source interface 672
VNI interfaces 672
How VXLAN and Geneve packets are processed 673
Peer VTEPs 674
VXLAN use cases 675
Requirements and prerequisites for VXLAN interfaces 679
Guidelines for VXLAN interfaces 679
Configure VXLAN or Geneve interfaces 680
Configure VXLAN interfaces 680
Configure geneve interfaces 683
Allow gateway load balancer health checks 685
Configure routed and transparent mode interfaces 686
Routed and transparent mode interfaces 686
Dual IP stack (IPv4 and IPv6) 686
31-bit subnet masks 686
Guidelines and limitations for routed and transparent mode interfaces 687
Configure routed mode interfaces 690
Bridge group interfaces 695
Configure general bridge group member interface parameters 695

Configure the bridge virtual interface (BVI) 698
Configure IPv6 addressing 699
About IPv6 699
IPv6 prefix delegation client configuration 700
Configure a global IPv6 address 704
Configure IPv6 neighbor discovery 709
Advanced interface settings 711
About advanced interface configuration 711
MAC addresses 711
MTU 712
TCP MSS 714
ARP inspection for bridge group traffic 715
MAC address tables 716
Default settings 716
Guidelines for ARP inspection and the MAC address table 716
Configure the MTU 717
Configure the MAC address 718
Add a static ARP entry 718
Add a static MAC address and disable MAC learning for a bridge group 720
Set security configuration parameters 720
History for Regular Firewall Interfaces 723

CHAPTER 15 **Inline Sets and Passive Interfaces** 727
IPS interfaces 727
Inline sets 727
Multiple inline pairs and asynchronous routing 728
Passive interfaces 729
Hardware Bypass for inline sets 730
Hardware Bypass triggers 730
Hardware bypass switchover 730
Snort Fail Open vs. Hardware Bypass 731
Hardware Bypass status 731
Requirements and prerequisites for inline sets 731
Guidelines for configuring inline sets and passive interfaces 733

Configure a passive interface 735
Configure Inline Sets 736
History for inline sets and passive interfaces 740

CHAPTER 16 Device Settings 743
Edit general settings 743
Generate troubleshooting files 745
View CLI output 747
Copy a configuration to another device 749
Export and import the device configuration 751
Edit license settings 755
View system information 756
View device inventory 756
View the inspection engine 757
Edit health settings 757
Edit management settings 757
Configure a redundant manager access data interface 758
Change manager access interface settings 763
Change the device IP address 763
Change the Firewall Management Center IP Address 774
Change both Firewall Management Center and Threat Defense IP addresses 776
Change the manager access interface 779
Troubleshoot the management connection 790
Manually Roll Back the configuration if the Firewall Management Center loses Connectivity 791
Troubleshoot Management Connectivity on a Data Interface 792
View inventory details 793
Edit applied policies 794
Edit advanced settings 796
Configure automatic application bypass 797
Configure object group search 798
Configure interface object optimization 799
Edit deployment settings 800
Edit cluster health monitor settings 802
Hot swap an SSD 805

Configure SNMP for FXOS 808
Enable SNMP for FXOS 808
Create an SNMP Trap for FXOS 809
Create an SNMP user for FXOS 811
Configure alarms for the ISA 3000 811
About alarms 812
Alarm input interfaces 812
Alarm output interface 813
Syslog alarms 813
SNMP Alarms 813
Defaults for alarms 813
Prerequisites for alarms 814
Configure alarms for the ISA 3000 814
Configure alarm input contacts 814
Configure power supply alarms 817
Configure temperature alarms 819
Turn off the external alarm 822
Monitoring alarms 822
Monitoring alarm status 822
Monitoring syslog messages for alarms 822
History for Device Settings 823

CHAPTER 17 DHCP and DDNS 827
About DHCP and DDNS services 827
DHCPv4 servers 827
DHCP options 828
DHCPv6 stateless server 828
DHCP relay agents 829
Requirements and prerequisites for DHCP and DDNS 829
Guidelines for DHCP and DDNS services 829
Configure the DHCPv4 server 831
DHCPv6 stateless server configuration 833
Create a DHCP IPv6 pool 833
Enable the DHCPv6 stateless server 836

Configure the DHCP relay agent 837
Configure Dynamic DNS 838
History for DHCP and DDNS 844

CHAPTER 18 Platform Settings 847
Platform settings policies 848
List requirements and prerequisites for platform settings policies 848
Manage platform settings policies 849
Chassis platform settings 850
Configure ARP inspection 850
Configure a banner 852
Configure DNS server settings 852
Configure external authentication 855
Configure an LDAP External Authentication Object 857
Configure a RADIUS Authentication Object 860
Configure fragment settings 861
Configure HTTP access 862
Configure ICMP access 864
Configure NetFlow 865
Add a collector in NetFlow 866
Add a traffic class to NetFlow 867
Configure Secure Shell (SSH) access 867
Configure an SMTP server 869
Configure SNMP for a security device 870
SNMP protocol 871
List SNMP terminology 871
Describe MIBs and traps 872
List of supported tables and objects in MIBs 873
Add SNMPv3 users 877
Add SNMP hosts 880
Configure SNMP traps 882
Configure SSL Settings 884
Configure SSL settings 885
Syslog 888

Syslog messages 889
Syslog message severity levels 889
Syslog message filters 890
Syslog message classes and associated message ID numbers 891
Guidelines for logging 894
Configure syslog logging for Firewall Threat Defense devices 895
Firewall Threat Defense platform settings that apply to security event syslog messages 896
Configure logging and basic settings 897
Enable logging destinations 898
Configure syslog messages to be sent to an e-mail address 900
Create a custom event list 900
Configure syslog rate limits 902
Configure syslog settings 903
Configure a syslog server 904
Configure timeouts 906
Synchronize time on FTD devices 908
Configure a time zone for a device 911
Configure UCAPL/CC compliance 911
Configure a performance profile 912
History for platform settings 913

CHAPTER 19 **FlexConfig policies 921**
FlexConfig policy overview 921
Recommended usage for FlexConfig policies 922
CLI commands in FlexConfig objects 922
Determine the ASA software version and current CLI configuration 923
Prohibited CLI commands 924
Template scripts 926
FlexConfig variables 926
Variable processing 927
Evaluate device variable results 930
FlexConfig policy object variables 932
FlexConfig system variables 933
Predefined FlexConfig objects 934

Predefined text objects 939
Requirements and prerequisites for FlexConfig policies 942
Guidelines and limitations for FlexConfig 943
Customize device configuration with FlexConfig policies 943
Configure FlexConfig objects 945
Add a policy object variable to a FlexConfig object 948
Configure secret keys 949
Configure FlexConfig text objects 950
Configure the FlexConfig policy 951
Set target devices for a FlexConfig policy 952
Preview the FlexConfig policy 953
Verify the deployed configuration 954
Remove features configured using FlexConfig 956
Convert from FlexConfig to managed feature 958
Examples for FlexConfig 958
Configure precision time protocol (ISA 3000) 958
Configure automatic hardware bypass for power failure (ISA 3000) 962
Migrate FlexConfig policies 964
History for FlexConfig 966

PART IV **Routing** 971

CHAPTER 20 **Static and Default Routes** 973
Static and default routes overview 973
Default routes 973
Static routes 974
Route to null0 interface to drop unwanted traffic 974
Route priorities 974
Transparent firewall mode and bridge group routes 975
Static route tracking 975
Requirements and prerequisites for static routes 976
Guidelines for static and default routes 976
Add a static route 977
Reference for routing 978

Path determination 978
Supported route types 979
Static versus dynamic routing algorithms 979
Single-path versus multipath 979
Flat versus hierarchical routing 979
Link-state versus distance vector 980
Supported internet protocols for routing 980
Routing tables 981
How the routing table is populated 981
How forwarding decisions are made 983
Dynamic routing and High availability 984
Dynamic routing in Clustering 984
Dynamic routing in individual interface mode 985
Routing table for management traffic 986
Equal-cost multi-path routing 987
Routing GRE traffic 988
About route maps 988
Permit and deny clauses 988
Match and set clause values 989

CHAPTER 21 **Virtual Routers** 991
Virtual routers and virtual routing and forwarding (VRF) 991
Virtual router applications 992
Global and user-defined virtual routers 992
Virtual-router-aware policies 993
Virtual router interconnection 994
Best practice for overlapping IP addresses 996
Configuring SNMP on user-defined virtual routers 997
Maximum number of virtual routers by device model 997
Requirements and prerequisites for virtual routers 999
Guidelines and limitations for virtual routers 999
Manage virtual routers 1001
Create a virtual router 1002
Configure a virtual router 1002

Modify a virtual router 1004
Remove Virtual Routers 1005
Monitor virtual routers 1006
Configuration examples for virtual routers 1006
Route to a distant server through virtual routers 1006
How to Provide Internet Access with Overlapping Address Spaces 1011
Allow RA VPN access to internal networks in virtual routing 1018
Secure traffic from networks in multiple virtual routers over a site-to-site VPN 1021
Secure traffic from networks with multiple virtual routers over a site-to-site VPN with dynamic VTI 1025
Route traffic between two overlapping network hosts in virtual routing 1027
Manage overlapping segments in routed firewall mode with BVI interfaces 1030
Configure user authentication with overlapping networks 1034
Interconnect virtual routers using BGP 1040
History for virtual routers 1045

CHAPTER 22 **ECMP** 1047
ECMP routing methods 1047
Guidelines and limitations for ECMP 1048
Manage ECMP zones for virtual routers 1049
Create an ECMP zone 1049
Configure an equal cost static route 1050
Modify an ECMP zone 1051
Remove an ECMP zone 1052
Configure ECMP zones on your device 1053
History for ECMP in Secure Firewall Threat Defense 1056

CHAPTER 23 **Bidirectional Forwarding Detection Routing** 1057
BFD routing protocol 1057
Guidelines for BFD routing 1057
Configure BFD 1059
Configure BFD policies 1059
Configure a single-hop BFD policy 1060
Configure a multi-hop BFD policy 1061

History for BFD routing 1062

CHAPTER 24 OSPF 1063

OSPF 1063

OSPF routing 1063

OSPF support for fast hello packets 1065

OSPF fast hello packets configuration prerequisites 1065

OSPF hello interval and dead interval 1065

OSPF fast hello packets 1065

Benefits of OSPF fast hello packets 1066

OSPFv2 and OSPFv3 implementation differences 1066

Requirements and prerequisites for OSPF 1067

Guidelines for OSPF 1067

OSPFv2 configuration 1070

Configure OSPF areas, ranges, and virtual links 1070

Configure OSPF redistribution 1073

Configure OSPF Inter-Area filtering 1075

Configure OSPF filter rules 1076

Configure OSPF summary addresses 1077

Configure OSPF interfaces and neighbors 1078

Configure OSPF Advanced Properties 1080

OSPFv3 configuration 1083

Configure OSPFv3 Areas, Route Summaries, and Virtual Links 1083

Configure OSPFv3 redistribution 1085

Configure OSPFv3 summary prefixes 1087

Configure OSPFv3 interfaces, authentication, and neighbors 1088

Configure OSPFv3 Advanced Properties 1090

History for OSPF 1093

CHAPTER 25 EIGRP 1095

EIGRP routing 1095

Requirements and prerequisites for EIGRP 1096

Guidelines and limitations for EIGRP routing 1097

Configure EIGRP routing on firewall devices 1098

Configure EIGRP settings 1099
Configure EIGRP neighbors settings 1099
Configure EIGRP filter rules 1100
Configure EIGRP redistribution settings 1101
Configure EIGRP summary address settings 1102
Configure EIGRP interfaces settings 1103
Configure EIGRP advanced settings 1104
History for EIGRP 1106

CHAPTER 26 BGP 1107
BGP 1107
Routing tables 1107
BGP usage scenarios 1108
BGP path selection 1109
BGP multipath 1109
Requirements and prerequisites for BGP 1111
Guidelines for BGP 1111
Configure BGP 1112
Configure basic BGP settings 1113
Configure BGP general settings 1115
Configure BGP Neighbor Settings 1117
Configure BGP aggregate address settings 1121
Configure BGPv4 filtering settings 1122
Configure BGP network settings 1123
Configure BGP redistribution settings 1123
Configure BGP route injection settings 1124
Configure BGP route import and export 1125
History for BGP 1127

CHAPTER 27 RIP 1129
RIP 1129
How RIP routing updates work 1130
RIP routing metric 1130
RIP stability features 1130

RIP timers 1131
Requirements and prerequisites for RIP 1132
Guidelines for RIP 1132
Configure RIP 1133

CHAPTER 28 **Multicast** 1137
Multicast routing 1137
IGMP Protocol 1138
Stub multicast routing 1138
PIM multicast routing 1139
PIM sparse mode 1139
PIM source specific multicast support 1139
Multicast Bidirectional PIM 1140
PIM bootstrap router (BSR) 1140
PIM bootstrap router (BSR) terminology 1141
Multicast group concept 1141
Multicast Addresses 1142
Clustering 1142
Prerequisites for Multicast Routing 1142
Guidelines for multicast routing 1142
Configure IGMP features 1143
Enable multicast routing 1144
Configure IGMP protocol 1145
Configure IGMP access groups 1146
Configure IGMP static groups 1147
Configure IGMP join groups 1148
Configure PIM features 1149
Configure PIM protocol 1149
Configure PIM neighbor filters 1150
Configure PIM bidirectional neighbor filters 1151
Configure PIM rendezvous points 1152
Configure PIM route trees 1153
Configure PIM request filters 1154
Configure the Firewall Threat Defense device as a candidate bootstrap router 1154

Configure multicast routes 1155
Configure multicast boundary filters 1156

CHAPTER 29 Policy-Based Routing 1159
About policy-based routing 1159
Licenses for policy-based routing 1161
Best practices for policy-based routing 1161
Path monitoring metrics for best path route determination 1163
Configure path monitoring settings 1165
Add path monitoring dashboard 1166
Configure policy-based routing policy 1166
Configure policy-based routing 1169
Configure PBR with path monitoring 1175
Useful CLIs for monitoring PBR 1177
Troubleshoot PBR 1179
History for policy-based routing 1182

PART V Network Policies 1185

CHAPTER 30 Network Address Translation 1187
NAT functions 1187
NAT basics 1188
NAT terminology 1188
NAT types 1188
NAT in routed and transparent mode 1189
NAT in routed mode 1189
NAT in transparent mode or within a bridge group 1190
Auto NAT and Manual NAT 1191
Auto NAT 1191
Manual NAT 1191
Comparing Auto NAT and Manual NAT 1192
NAT rule order 1192
NAT interfaces 1194
NAT exemption 1195

Configuring routing for NAT 1195
Addresses on the same network as the mapped interface 1196
Addresses on a unique network 1196
The same address as the real address (identity NAT) 1196
Requirements and prerequisites for NAT policies 1197
Guidelines for NAT 1197
Firewall mode guidelines for NAT 1197
IPv6 NAT guidelines 1198
IPv6 NAT best practices 1198
NAT support for inspected protocols 1198
FQDN destination guidelines 1200
Additional guidelines for NAT 1201
Manage NAT policies 1203
Create NAT policies 1204
Configure NAT policy targets 1204
Configure NAT for threat defense 1205
Customize NAT rules for multiple devices 1207
Search and filter the NAT rule table 1209
Enable, disable, or delete multiple rules 1210
Dynamic NAT 1210
About dynamic NAT 1211
Dynamic NAT disadvantages and advantages 1212
Configure dynamic auto NAT 1212
Configure dynamic manual NAT 1214
Dynamic PAT 1216
About dynamic PAT 1216
Dynamic PAT disadvantages and advantages 1217
PAT pool object guidelines 1217
Configure dynamic auto PAT 1218
Configure dynamic manual PAT 1220
Configure PAT with port block allocation 1223
Static NAT 1226
About static NAT 1226
Configure static auto NAT 1230

Configure static manual NAT 1232
Identity NAT 1235
Configure identity auto NAT 1236
Configure identity manual NAT 1237
NAT rule properties for Firewall Threat Defense 1239
Interface objects NAT properties 1240
Translation properties for auto NAT 1241
Translation properties for manual NAT 1242
PAT pool NAT properties 1243
Advanced NAT properties 1244
Translating IPv6 networks 1245
NAT64/46: translating IPv6 addresses to IPv4 1246
NAT64/46 example: inside IPv6 network with outside IPv4 internet 1246
NAT64/46 example: inside IPv6 network with outside IPv4 internet and DNS translation 1248
NAT66: translating IPv6 addresses to different IPv6 addresses 1252
NAT66 example, static translation between networks 1252
NAT66 example, simple IPv6 interface PAT 1255
Monitoring NAT 1258
Examples for NAT 1259
Providing access to an inside web server (static auto NAT) 1259
Dynamic auto NAT for inside hosts and static NAT for an outside web server 1261
Configure inside load balancer with multiple mapped addresses 1268
Single address for FTP, HTTP, and SMTP (static auto NAT with port translation) 1270
Different translation depending on the destination (dynamic manual PAT) 1278
Configure dynamic manual PAT with different destination ports 1285
NAT and site-to-site VPN 1291
DNS query and response rewriting using NAT 1296
DNS64 reply modification 1297
Create DNS reply modification with DNS server on outside 1304
Configure DNS reply modification with DNS server on host network 1307
History for Firewall Threat Defense NAT 1310

CHAPTER 31 **Quality of Service** 1313
QoS 1313

QoS policies 1314
Requirements and prerequisites for QoS 1314
Guidelines and limitations for QoS policies 1315
Rate limiting with QoS policies 1315
Create a QoS policy 1316
Set target devices for a QoS policy 1317
Filter QoS rules by device 1317
Configuring QoS rules 1318
QoS rule components 1319
QoS rule conditions 1320
Interface rule conditions 1320
Network rule conditions 1321
User rule conditions 1321
Application rule conditions 1322
Best practice: use application-based rules over port-based rules 1323
Recommendation: use URL conditions for website access control 1324
Custom SGT rule conditions 1325
ISE SGT versus custom SGT rule conditions 1325
Autotransition from custom Security Group Tags to ISE Security Group Tags 1325
History for QoS 1326

PART VI **Secure Connections** 1327

CHAPTER 32 **Secure Connections Overview** 1329
VPN types 1329
VPN basics 1330
Internet Key Exchange (IKE) 1331
IPsec 1332
VPN packet flow 1333
IPsec flow offload 1333
VPN licensing 1334
VPN encryption and performance 1334
Comply with security certification requirements 1334
Decide encryption algorithms for VPN policies 1334

Decide which hash algorithms to use 1335
Decide which Diffie-Hellman modulus group to use 1336
Decide VPN authentication methods 1336
Pre-shared keys 1337
PKI infrastructure and digital certificates 1337
Deprecated hash algorithms, encryption algorithms, and Diffie-Hellman modulus groups 1339
VPN topologies 1340
Point-to-point VPN topologies 1340
Hub and spoke VPN topology 1341
Full mesh VPN topology 1342
Implicit topologies 1343

CHAPTER 33 Site-to-Site VPN 1345
Site-to-site VPN 1345
Guidelines for configuring site-to-site VPN in Secure Firewall Threat Defense devices 1347
Limitations for configuring site-to-site VPN in Threat Defense devices 1347
Types of site-to-site VPN topologies 1348
License requirements for site-to-site VPN 1348
Prerequisites for site-to-site VPN 1349
Manage site-to-site VPNs 1349
Configure a policy-based site-to-site VPN 1351
Firewall Threat Defense VPN endpoint options 1352
Firewall Threat Defense VPN IKE options 1356
Firewall Threat Defense VPN IPsec options 1358
Firewall Threat Defense advanced site-to-site VPN deployment options 1360
Firewall Threat Defense VPN advanced IKE options 1361
Firewall Threat Defense VPN advanced IPsec options 1362
Firewall Threat Defense advanced site-to-site VPN tunnel options 1362
Configure virtual tunnel interfaces 1364
Virtual tunnel interfaces 1364
Static VTI 1365
Dynamic VTI 1366
Guidelines for virtual tunnel interfaces 1368
Limitations for Virtual Tunnel Interfaces 1370

Add a VTI interface 1371
Create a route-based site-to-site VPN 1373
Configure endpoints for a point-to-point VPN topology 1374
Configure endpoints for a hub and spoke topology 1376
Configure multiple hubs in a route-based VPN 1380
Route traffic through a backup VTI tunnel 1383
Configure dynamic VTI for a route-based site-to-site VPN 1384
Configure a virtual router with dynamic VTI 1384
Configure routing and AC policies for VTI 1385
View virtual tunnel interface details 1388
Deploy a SASE tunnel on Umbrella 1388
Guidelines for configuring SASE tunnels on Umbrella 1388
Limitations for configuring SASE tunnels on Umbrella 1389
Deploy a SASE tunnel on Umbrella 1389
Prerequisites for configuring Umbrella SASE tunnels 1390
Map Management Center Umbrella parameters and Cisco Umbrella API keys 1390
Configure a SASE tunnel for Umbrella 1392
Monitor site-to-site topologies 1395
Monitor site-to-site VPNs using Site-to-Site VPN summary page 1395
Monitor site-to-site VPNs using Site-to-Site VPN dashboard 1395
Tunnel status widget 1396
Site-to-site VPN connection event monitoring 1399
View site-to-site VPN connection events 1400
History for site-to-site VPN 1400

CHAPTER 34 **SD-WAN** 1405
SD-WAN capabilities 1405
SD-WAN features 1406
Use cases for SD-WAN capabilities 1407
Monitor SD-WAN topologies 1408
SD-WAN summary dashboard 1408
Prerequisites for using SD-WAN summary dashboard 1408
Monitor WAN devices and interfaces using the SD-WAN summary dashboard 1411

Monitor application performance metrics of WAN interfaces using SD-WAN summary dashboard 1413

CHAPTER 35 **Remote Access VPN** 1415

Remote Access VPN Overview 1415
Remote Access VPN Features 1416
Secure Client Components 1418
Remote Access VPN Authentication 1418
Understanding Policy Enforcement of Permissions and Attributes 1420
Understanding AAA Server Connectivity 1420
License Requirements for Remote Access VPN 1421
Requirements and Prerequisites for Remote Access VPN 1421
Remote Access VPN Guidelines and Limitations 1422
Configuring a New Remote Access VPN Connection 1425
Prerequisites for Configuring Remote Access VPN 1426
Create a New Remote Access VPN Policy 1426
Update the Access Control Policy on the Secure Firewall Threat Defense Device 1429
(Optional) Configure NAT Exemption 1430
Configure DNS 1431
Add Secure Client Profile XML File 1431
(Optional) Configure Split Tunneling 1432
(Optional) Configure Dynamic Split Tunneling 1433
Verify Dynamic Split Tunneling Configuration 1434
Verify the Configuration 1434
Create a Copy of an Existing Remote Access VPN Policy 1435
Set Target Devices for a Remote Access VPN Policy 1435
Associate Local Realm with Remote Access VPN Policy 1436
Additional Remote Access VPN Configurations 1436
Configure Connection Profile Settings 1436
Configure IP Addresses for VPN Clients 1437
Configure AAA Settings for Remote Access VPN 1439
Create or Update Aliases for a Connection Profile 1454
Configure Access Interfaces for Remote Access VPN 1455
Configure Advanced Options for Remote Access VPN 1457

Cisco Secure Client Image 1457
Remote Access VPN Address Assignment Policy 1459
Configure Certificate to Connection Profile Mapping 1460
Configure Group Policies 1461
Configuring LDAP Attribute Mapping 1462
Configuring VPN Load Balancing 1463
Configure IPsec Settings 1467
Customize Cisco Secure Client 1472
Configure Secure Client Management VPN Tunnel 1485
Requirements and Prerequisites for Secure Client Management VPN Tunnel 1485
Limitations of Secure Client Management VPN Tunnel 1486
Configuring Secure Client Management VPN Tunnel on Firewall Threat Defense 1486
Multiple Certificate Authentication 1488
Guidelines and Limitations of Multiple Certificate Authentication 1488
Configuring Multiple Certificate Authentication 1489
Customizing Remote Access VPN AAA Settings 1490
Authenticate VPN Users via Client Certificates 1490
Configure VPN User Authentication via Client Certificate and AAA Server 1492
Manage Password Changes over VPN Sessions 1493
Send Accounting Records to the RADIUS Server 1494
Delegating Group Policy Selection to Authorization Server 1495
Override the Selection of Group Policy or Other Attributes by the Authorization Server 1496
Deny VPN Access to a User Group 1497
Restrict Connection Profile Selection for a User Group 1498
Update the Secure Client Profile for Remote Access VPN Clients 1498
RADIUS Dynamic Authorization 1499
Configuring RADIUS Dynamic Authorization 1500
Two-Factor Authentication 1501
Configuring RSA Two-Factor Authentication 1501
Configuring Duo Two-Factor Authentication 1502
Secondary Authentication 1504
Configure Remote Access VPN Secondary Authentication 1504
Single Sign-On Authentication with SAML 2.0 1506
Guidelines and Limitations for SAML 2.0 1507

Configuring a SAML Single Sign-On Authentication 1508
Configuring SAML Authorization 1509
Advanced Secure Client Configurations 1511
Configure Secure Client Modules on a Firewall Threat Defense 1511
Types of Secure Client Modules 1511
Prerequisites for Configuring Secure Client Modules 1512
Guidelines for Configuring Secure Client Modules 1513
Install Secure Client Modules using a Firewall Threat Defense 1514
Configure a Remote Access VPN Group Policy with Secure Client Modules 1515
Verify Secure Client Modules Configuration 1515
Configure Application-Based (Per App VPN) Remote Access VPN on Mobile Devices 1516
Prerequisites and Licensing for Configuring Per App VPN Tunnels 1516
Determine the Application IDs for Mobile Applications 1517
Configure Application-Based VPN Tunnels 1518
Verify Per App Configuration 1519
Remote Access VPN Examples 1519
How to Limit Secure Client Bandwidth Per User 1519
How to Use VPN Identity for User-Id Based Access Control Rules 1520
Configure Firewall Threat Defense Multiple Certificate Authentication 1520
Monitor Remote Access VPNs 1524
Remote Access VPN Dashboard 1524
VPN Session and User Information 1526
Viewing Remote Access VPN Active Sessions 1526
Viewing Remote Access VPN User Activity 1526
History for Remote Access VPNs 1526

CHAPTER 36 **Dynamic Access Policies** 1531
Firewall Threat Defense dynamic access policies 1531
Hierarchy of policy enforcement of permissions and attributes in a Firewall Threat Defense device 1532
Prerequisites for dynamic access policy 1533
Guidelines and limitations for dynamic access policies 1533
Configure a Dynamic Access Policy (DAP) 1534
Create a dynamic access policy 1534
Create a dynamic access policy record 1534

Configure AAA criteria settings for a DAP record 1535
Configure endpoint attribute selection criteria in DAP 1536
Add an anti-malware endpoint attribute to a DAP record 1536
Add a device endpoint attribute to a DAP record 1537
Add Secure Client endpoint attributes to a DAP record 1538
Add NAC endpoint attributes to a DAP record 1539
Add an application attribute to a DAP record 1539
Add a personal firewall endpoint attribute to a DAP record 1540
Add an operating system endpoint attribute to a DAP record 1541
Add a process endpoint attribute to a DAP 1541
Add a registry endpoint attribute to a DAP record 1542
Add a file endpoint attribute to a DAP record 1542
Add certificate authentication attributes to a DAP record 1543
Configure advanced settings for DAP 1543
Associate dynamic access policy with remote access VPN 1544
History for dynamic access policy 1544

PART VII **Zero Trust Network Access** 1547

CHAPTER 37 **Zero Trust Network Access Overview** 1549
Zero Trust Access 1549
How Threat Defense Works with Zero Trust Access 1550
Zero trust network access 1551
Components of a Clientless Zero Trust Network Access Configuration 1551
Clientless Zero Trust Network Access Workflow 1552
Limitations for Clientless Zero Trust Network Access 1553
Prerequisites for Zero Trust Application Policy 1554
Manage Zero Trust Application Policies 1555
Create a Zero Trust Application Policy 1555
Create an Application Group 1557
Create an Application 1558
Set Targeted Devices for Zero Trust Access Policy 1560
Edit a Zero Trust Application Policy 1560
Monitor Zero Trust Sessions 1562

History for zero trust network access 1564

PART VIII **Access Control Policy Basics** 1567

CHAPTER 38 **Access Control Policies** 1569

Access control policies 1569

Access control policy components 1570

Access control policy default actions 1570

Access control policy inheritance 1572

Rule and other policy warnings 1573

Requirements and prerequisites for access control policies 1574

Manage access control policies 1575

Creating a basic access control policy 1575

Editing an access control policy 1576

Lock an access control policy 1578

Configure the access control default action 1579

Manage access control policy inheritance 1580

Choose a base access control policy 1581

Lock settings in descendant access control policies 1581

Inherit access control policy settings from the base policy 1582

Enforce an access control policy in a domain 1583

Assign access control policy to devices 1583

Logging settings for access control policies 1584

Associate prefilter, decryption, and identity policies with an access control 1585

View rule hit counts 1586

Analyzing rule conflicts and warnings 1588

Search for rules 1589

History for access control policies 1591

CHAPTER 39 **Security Intelligence** 1595

Security intelligence 1595

License requirements for security intelligence 1596

Requirements and prerequisites for security intelligence 1596

Best practices for security intelligence 1596

Guidelines and limitations for security intelligence 1597
Security intelligence sources 1598
Configure security intelligence 1599
Security intelligence options 1601
Security intelligence categories 1602
Block list icons 1604
Configuration example: Security intelligence blocking 1605
Security intelligence monitoring 1606
Override security intelligence blocking 1606
Troubleshooting security intelligence 1607
Security intelligence categories missing from the Available Options List 1607
History for security intelligence block listing 1608

CHAPTER 40 Access Control Rules 1609
Access control rules 1609
Access control rule management 1611
Access control rule components 1611
Access control rule order 1613
Access control rule actions 1614
Access control rule monitor action 1614
Access control rule trust action 1614
Access control rule blocking actions 1615
Access control rule interactive blocking actions 1615
Access control rule allow action 1616
Deep inspection using file and intrusion policies 1617
File and intrusion inspection order 1618
How access control traffic handling works with intrusion and file policies 1619
Requirements and prerequisites for access control rules 1620
Guidelines and limitations for access control rules 1621
Best practices for application control 1622
Recommendations for application control 1622
Best practice for choosing between application matching and port matching 1624
Application-specific requirements for filtering 1625
Best practices for access control rules 1625

General best practice for access control 1626
Best practices for ordering rules 1627
Application rule order 1627
Rule preemption 1628
Best practice for rule actions and rule order 1628
Best practices for simplifying and focusing rules 1629
Maximum number of access control rules and intrusion policies 1630
Access control rule management 1630
Add an access control rule category 1630
Create and edit access control rules 1631
Access control rule conditions 1633
Enable and disable access control rules 1641
Copy access control rules from one access control policy to another 1641
Move access control rules to a prefilter policy 1642
Position an access control rule 1643
Add comments to an access control rule 1644
Examples for access control rules 1645
How to control access using security zones 1645
Control application usage 1645
Block threats 1646
History for access control rules 1649

CHAPTER 41 **URL Filtering Rules** 1651
URL filtering 1651
URL filtering with category and reputation 1652
URL category and reputation descriptions 1653
URL filtering data from the Cisco cloud 1653
Best practices for URL filtering 1654
HTTPS traffic filtering 1657
Use categories in URL filtering 1658
QUIC Fingerprinting 1659
License requirements for URL filtering 1659
Requirements and prerequisites for URL filtering 1660
Configure URL filtering with category and reputation 1660

Enable URL filtering using category and reputation 1662
URL filtering options 1662
Configure URL conditions 1663
Rules with URL conditions 1665
URL rule order 1665
DNS filtering 1665
Enable DNS filtering to identify URLs during domain lookup 1666
DNS filtering behavior for block actions 1667
DNS filtering and events 1667
Manual URL filtering 1667
Manual URL filtering options 1668
Supplement or selectively override category and reputation-based URL filtering 1668
HTTP response pages 1669
Limitations to HTTP response pages 1669
Requirements and prerequisites for HTTP response pages 1670
Choose HTTP response pages 1671
Interactive blocking with HTTP response pages 1671
Configure interactive blocking 1672
Set the user bypass timeout for a blocked website 1673
Configure URL filtering health monitors 1673
Dispute URL category and reputation 1673
Take action if the URL category set changes 1674
URL category and reputation changes 1675
Troubleshoot URL filtering 1676
History for URL filtering 1678

CHAPTER 42 **Content Restriction** 1681
About content restriction 1681
Requirements and prerequisites for content restriction 1682
Guidelines and limitations for content restriction 1683
Using access control rules to enforce content restriction 1683
Safe search options for access control rules 1684
Use a DNS sinkhole to enforce content restriction 1684

CHAPTER 43 **Intrusion Prevention Overview** 1687

Network Analysis and Intrusion Policy Basics 1687

How Policies Examine Traffic For Intrusions 1689

Decoding, Normalizing, and Preprocessing: Network Analysis Policies 1690

Access Control Rules: Intrusion Policy Selection 1691

Intrusion Inspection: Intrusion Policies, Rules, and Variable Sets 1692

Intrusion Event Generation 1693

System-Provided and Custom Network Analysis and Intrusion Policies 1694

System-Provided Network Analysis and Intrusion Policies 1694

Benefits of Custom Network Analysis and Intrusion Policies 1696

Benefits of Custom Network Analysis Policies 1696

Benefits of Custom Intrusion Policies 1697

Limitations of custom policies 1698

License Requirements for Network Analysis and Intrusion Policies 1700

Requirements and Prerequisites for Network Analysis and Intrusion Policies 1700

Guidelines and Limitations for Network Analysis and Intrusion Policies 1700

The Navigation Panel: Network Analysis and Intrusion Policies 1701

Conflicts and Changes: Network Analysis and Intrusion Policies 1702

Exiting a Network Analysis or Intrusion Policy 1704

PART IX **Decryption Policies and Encrypted Visibility for Access Control** 1705

CHAPTER 44 **Traffic Decryption Overview** 1707

Traffic decryption 1707

How TLS/SSL handshakes work 1708

ClientHello message handling 1709

How ServerHello and server certificate messages work 1712

Decryption rule and policy basics 1713

Guidelines for traffic decryption 1714

Best practice for deciding when to decrypt traffic 1714

Decrypt and re-sign (outgoing traffic) 1715

Known key decryption for incoming traffic 1716

Other decryption rule actions 1716

Decryption rule components 1716
Decryption Rule order evaluation 1717
Multi-rule example 1718
TLS crypto acceleration 1720
TLS crypto acceleration guidelines and limitations 1721
View the status of TLS crypto acceleration 1722
History for decryption policy 1723

CHAPTER 45 **Decryption Policies** 1727
About Decryption Policies 1727
Requirements and Prerequisites for Decryption Policies 1728
Create a decryption policy 1728
Create a decryption policy with outbound connection protection 1728
Create a decryption policy with inbound connection protection 1730
Configure Decryption policy exclusions 1731
Generate an internal CA for outbound protection 1735
Upload an internal CA for outbound protection 1736
Upload an internal certificate for inbound protection 1737
Create a decryption policy with other rule actions 1737
Decryption policy default actions 1739
Default handling options for undecryptable traffic 1739
Set default handling for undecryptable traffic 1741
Decryption policy advanced options 1742
TLS 1.3 decryption best practices 1743

CHAPTER 46 **Decryption Rules** 1745
Decryption Rule overview 1745
Requirements and prerequisites for Decryption Rules 1745
Decryption Rules guidelines and limitations 1746
Guidelines for using TLS/SSL decryption 1746
Decryption Rules unsupported features 1747
Guidelines for TLS/SSL Do Not Decrypt configuration 1748
TLS/SSL Decrypt - Resign guidelines 1749
TLS/SSL Decrypt - Known Key Guidelines 1751

TLS/SSL block guidelines 1752
TLS/SSL certificate pinning guidelines 1752
TLS/SSL heartbeat guidelines 1752
TLS/SSL anonymous cipher suite limitation 1753
TLS/SSL normalizer guidelines 1753
Other Decryption Rule guidelines 1753
Decryption Rule traffic handling 1754
Encrypted traffic inspection configuration 1756
Decryption Rule order evaluation 1757
Decryption Rule conditions 1758
Security zone rule conditions 1759
Security zone conditions in multidomain environments 1760
Network rule conditions 1760
VLAN tag rule conditions 1760
User rule conditions 1761
Application rule conditions 1761
Best practice: use application-based rules over port-based rules 1763
Category rule conditions 1763
Server certificate-based rule conditions 1764
Certificate rule conditions 1765
Conditions for distinguished name rules in decryption policies 1765
Trust external certificate authorities 1770
Certificate Status Decryption rule conditions 1771
Cipher suite rule conditions 1774
Encryption protocol version rule conditions 1777
Decryption Rule actions 1777
Decryption rule monitor action 1777
Decryption rule Do Not Decrypt action 1778
Decryption rule blocking actions 1779
Decryption rule decrypt actions 1779
Monitor TLS/SSL hardware acceleration 1780
Informational counters 1780
Alert counters 1781
Error counters 1781

Fatal counters 1781
Troubleshoot Decryption Rules 1782
TLS/SSL oversubscription 1782
Troubleshoot TLS/SSL oversubscription 1782
TLS heartbeat 1783
Troubleshoot TLS heartbeat 1784
TLS/SSL pinning 1784
Troubleshoot TLS/SSL pinning 1785
Troubleshoot unknown or bad certificates or certificate authorities 1787
Verify TLS/SSL cipher suites 1789
Troubleshoot using crypto archives 1790

CHAPTER 47 **Decryption rules and Policy Example** 1793
Decryption rule Examples 1793
1793
: Decrypt Specific Test Traffic 1794
Decryption rules: Block or Monitor Certificates and Protocol Versions 1794
Example: Decryption rule to Monitor or Block Certificate Status 1794
Example: Decryption rule to Monitor or Block Protocol Versions 1795
Optional Example: Manual Decryption rule to Monitor or Block Certificate Distinguished Name 1797
Associate the Decryption policy with an Access Control Policy and Advanced Settings 1798
Traffic to Prefilter 1800
Decryption rule Settings 1801

CHAPTER 48 **Encrypted Visibility Engine** 1803
Encrypted Visibility Engine 1803
How EVE works 1804
Indications of compromise events 1805
QUIC fingerprinting in EVE 1806
Configure EVE 1806
View Encrypted Visibility Engine events 1807
View EVE dashboard 1808
Configure EVE Exception Rules 1809
Add exception rule from unified events 1810

Use case - Block Traffic Based on the EVE Threat Confidence Score 1810
About Encrypted Visibility Engine 1810
Benefits 1811
Sample Business Scenario 1811
Prerequisites 1811
High-Level Workflow 1811
Configure Block Thresholds in EVE 1811
View EVE Events 1815
Additional References 1816

PART X **Identity Policies for Access Control** 1817

CHAPTER 49 **Identity Overview** 1819
User identity 1819
Identity terminology 1819
About user identity sources 1820
Best practices for user identity 1822
Identity deployments 1824
Set up an identity policy 1825
User activity database 1828
Users database 1828
Host and user limits 1830
Host limits 1830
User limits for microsoft active directory 1831
Recommendation: identity realm limit 1833
User limits for microsoft azure active directory realms 1833

CHAPTER 50 **Realms** 1835
Realms and realm sequences 1835
Realms and trusted domains 1837
Supported servers for realms 1841
Supported server object class and attribute names 1842
License requirements for realms 1843
Requirements and prerequisites for realms 1843

Prerequisites for kerberos authentication 1843
Realm fields 1844
Realm directory and synchronize fields 1848
Create a Microsoft Azure AD Realm 1850
How Entra ID and Cisco ISE authentication with resource owned password credentials works 1851
How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS 1852
Create a Microsoft Azure AD realm 1853
Configure Microsoft Entra ID 1854
Configure Cisco ISE for Microsoft Azure AD 1855
Get required information For Your Microsoft Azure AD realm 1855
Create an Azure AD realm 1858
Azure AD user session timeout 1860
Create an LDAP realm or an Active Directory realm and realm directory 1860
Configure the Realm 1862
Connect securely to Active Directory or LDAP 1862
Find the active directory server's name 1863
Export the active directory server's root certificate 1863
Synchronize users and groups 1865
Create a realm sequence 1867
Cross-domain trust setups with Firewall Management Center 1868
Configure Secure Firewall Management Center for cross-domain-trust step 1: Configure realms and directories 1869
Configure the Secure Firewall Management Center for cross-domain trust Step 2: Synchronize users and groups 1874
Configure the Secure Firewall Management Center for cross-domain trust step 3: Resolve issues 1875
Manage a realm 1876
Compare realms 1877
Troubleshoot realms and user downloads 1877
Detect realm or user mismatches 1881
Troubleshoot cross-domain trust 1882
History for realms 1885

CHAPTER 51 **Identity Source: Captive Portal** 1887
Captive portal identity source 1887

Hostname redirect 1888
License requirements for captive portal 1888
Requirements and prerequisites for captive portal 1888
Best practices for captive portal guidelines and limitations 1889
Configure the captive portal for user control 1891
Create a network object 1892
Create an identity policy and active authentication rule 1894
Update a custom authentication form 1896
Create a TCP port access control rule 1896
Create a user access control rule 1898
Create a decryption policy with an outbound rule 1899
Create A decryption policy with a Decrypt-Resign rule 1901
Associate Identity and decryption policies with the access control policy 1903
Captive portal fields 1903
Exclude applications from captive portal 1905
Troubleshoot the captive portal identity source 1906
History for captive portal 1907

CHAPTER 52 **Identity Source: ISE/ISE-PIC** 1911
The ISE/ISE-PIC identity source 1911
Source and destination security group tag (SGT) matching 1912
License requirements for ISE/ISE-PIC 1913
Requirements and prerequisites for ISE/ISE-PIC 1913
Best practices for ISE/ISE-PIC integration 1914
ISE/ISE-PIC configurations for user control 1916
Configure ISE/ISE-PIC without a realm 1916
Configure ISE/ISE-PIC for user control using a realm 1917
ISE/ISE-PIC configuration 1919
Configure security groups and SXP publishing in ISE 1919
Export certificates from the ISE/ISE-PIC server for use in the Secure Firewall Management Center 1921
Export a system certificate 1922
Generate a self-signed certificate 1923
Import ISE/ISE-PIC certificates 1924
Configure ISE for user control 1924

ISE/ISE-PIC configuration fields 1926
Troubleshoot Cisco ISE/ISE-PIC or Cisco TrustSec issues 1927
History for ISE/ISE-PIC 1929

CHAPTER 53 **Identity Source: Remote Access VPN** 1931
Remote access VPN identity sources 1931
Configure Remote Access VPN for AD-authenticated users 1932
Hybrid Entra ID and on-premises AD deployments 1933
Troubleshooting guidelines for remote access VPN identity source 1934
Not Observing Correct Settings for VPN Statistics 1934
History for RA VPN 1935

CHAPTER 54 **Identity source: TS agent** 1937
Terminal services agent identity source 1937
Best practices for TS agent configuration 1938
Identity source: TS agent 1938
Troubleshoot the TS agent identity source 1938
History for TS agent 1939

CHAPTER 55 **Identity Policies** 1941
Identity policies 1941
License requirements for identity policies 1942
Requirements and prerequisites for identity policies 1942
Create an identity policy 1943
Create an identity mapping filter 1944
Identity rule conditions 1945
Security zone rule conditions 1945
Security zone conditions in multidomain environments 1946
Network rule conditions 1946
Redirect to host name network rule conditions 1946
VLAN tag rule conditions 1947
Best practice: use application-based rules over port-based rules 1948
Port, protocol, and ICMP code rule conditions (concept) 1948
Realm & settings rule conditions 1949

Create an identity rule 1952
Identity rule fields 1953
Sample identity policies and rules 1954
Create an identity policy with a passive authentication rule 1955
Create a sample identity policy with an active authentication rule 1956
Active authentication using a realm 1958
Active authentication using a realm sequence 1959
Manage an identity policy 1961
Manage an identity rule 1961
Troubleshoot user control 1962

PART XI **Advanced Policies and Settings for Access Control** 1965

CHAPTER 56 **Prefilter Policies** 1967
Prefilter policies 1967
Default prefilter policy 1968
Prefilter policy rule order 1968
Tunnel vs prefilter rules 1969
How the system processes plain-text tunnels 1969
Using tunnel zones to apply access control at the tunnel level 1970
Large flow offloads 1971
Restrictions for flow offload implementation 1973
Prefilter vs access control policy 1974
Requirements and prerequisites for prefilter policies 1976
Guidelines and limitations for the prefilter policy 1976
Guidelines and limitations for encapsulated traffic handling 1977
Best practices for fastpath prefiltering 1978
Configure prefilter policies 1979
Configuring the default action 1981
Configure prefilter rules 1981
VLAN tags rule conditions 1983
Port rule conditions for prefilter rules 1983
Configure tunnel rules 1984
Creating tunnel zones 1986

Move prefilter rules to an access control policy 1987
Examples of prefilter policy 1988
Rezone tunnels for customized inspection 1988
Offload large flows 1991
History for the prefilter policy 1992

CHAPTER 57 **DNS Policies for Security Intelligence** 1993
DNS policies 1993
Cisco umbrella DNS policies 1994
DNS policy components 1995
License requirements for DNS policies 1996
Requirements and prerequisites for DNS policies 1996
Managing DNS and Umbrella DNS Policies 1996
Create basic DNS policies 1997
Edit DNS policies 1998
DNS rules 1998
Create and edit DNS rules 1999
DNS rule management 2000
Enable and disable DNS rules 2000
DNS rule order evaluation 2001
DNS rule actions 2001
DNS rule conditions 2002
Security zone rule conditions 2003
Network rule conditions 2003
VLAN tag rule conditions 2004
DNS policy rule conditions 2004
DNS rules 2005
Control traffic based on DNS and security zone 2005
Control traffic based on DNS and network 2006
Control traffic based on DNS and VLAN 2006
Control traffic based on DNS list or feed 2007
Requirement: deploy DNS policy configuration changes 2008
Cisco umbrella DNS policies 2008
Redirect DNS requests to Cisco umbrella 2009

Prerequisites for configure the umbrella DNS connector 2010
Configure Cisco umbrella connection settings 2011
Create an umbrella DNS policy 2012
Edit Umbrella DNS policies and rules 2012
Associate the umbrella DNS policy with an access control policy 2013

CHAPTER 58 **File Policies for Network Malware Protection** 2015
Network malware protection and file policies 2015
File policies 2015
Prerequisites for file policies 2016
License requirements for file and malware policies 2017
Best practices for file policies and malware detection 2017
File rule best practices 2017
File detection best practices 2018
File blocking best practices 2019
File policy best practices 2020
Configure malware protection 2021
Plan and prepare for malware protection 2022
Configure file policies 2023
Add file policies to your access control configuration 2023
Configure an access control rule to perform malware protection 2024
Verify and monitor malware protection 2025
Cloud connections for malware protection 2026
AMP cloud connection configurations 2027
Prerequisites and best practices for AMP cloud connections 2027
Choose an AMP cloud 2028
Cisco AMP private cloud 2028
Manage connections to the AMP cloud (public or private) 2030
Change AMP options 2031
Dynamic analysis connections 2031
Prerequisites for dynamic analysis 2031
View the default dynamic analysis connection 2032
Dynamic analysis on-premises appliance (Cisco Secure Malware Analytics) 2032
Enable access to dynamic analysis results in the public cloud 2034

Maintain your system: file types eligible for dynamic analysis 2034
File policies and file rules 2035
Create or edit a file policy 2035
Advanced and archive file inspection options 2036
Manage file policies 2039
File rules 2040
File rule components 2041
File rule actions 2042
Create file rules 2050
Access control rule logging for malware protection 2051
Retrospective disposition changes 2051
File and malware inspection performance and storage options 2052
Tune file and malware inspection performance and storage 2053
(Optional) Malware protection with Secure Endpoint 2054
Comparison of malware protection: Firepower vs. Secure Endpoint 2054
Integrate Secure Firewall with Secure Endpoint 2055
Benefits of integrating Firepower and Secure Endpoint 2055
Secure Endpoint and AMP private cloud 2056
Integrate Firepower and Secure Endpoint 2056
History for network malware protection and file policies 2058

CHAPTER 59 **Dynamic Attributes Connector** 2061
About the dynamic attributes connector 2061
How Cisco secure dynamic attributes connector works 2061
System requirements for the dynamic attributes connector 2063
Enable the dynamic attributes connector 2063
Configure networks and subnets for Docker containers 2064
Dashboard 2065
Dashboard of an unconfigured system 2066
Dashboard of a configured system 2067
Add, edit, or delete connectors 2069
Add, edit, or delete dynamic attributes filters 2070
Connectors 2072
Amazon Web Services connector user permissions and imported data 2072

Create an AWS user with minimal permissions for the dynamic attributes connector 2073
Create an AWS connector 2074
Azure connector—About user permissions and imported data 2075
Create an Azure user with minimal permissions for the dynamic attributes connector 2076
Create an Azure connector 2078
Create an Azure service tags connector 2079
Create a generic text connector 2080
Create a GitHub connector 2082
Google cloud connector user permissions and imported data 2082
Create a Google Cloud user with minimal permissions for the dynamic attributes connector 2083
Create a google cloud connector 2084
Create an office 365 connector 2085
vCenter connector—About user permissions and imported data 2086
Create a vCenter user with minimal permissions for the dynamic attributes connector 2086
Create a vCenter connector 2088
Create a Webex connector 2090
Create a Zoom connector 2091
Create dynamic attributes filters 2092
Dynamic attribute filter examples 2093
Manually get a certificate authority (CA) chain 2094
Dynamic objects in access control rules 2097
Create dynamic attributes filters 2098
Dynamic attributes rule conditions 2099
Create access control rules using dynamic attributes filters 2100
Dynamic Firewall 2101
Dynamic Firewall 2102
How to configure the dynamic firewall 2102
Enable the dynamic attributes connector 2104
Get required information for Identity Intelligence 2105
Create an identity source and realm for the dynamic firewall 2106
Create a dynamic firewall instance 2107
Associate an identity source with Identity Intelligence 2108
Configure Identity Intelligence 2109
View system-defined filters 2110

View system-defined access control rules 2111
Edit the user exclusion list 2113
View and edit the system-created access control policy 2114
Create dynamic attributes filters 2115
Disable the dynamic attributes connector 2116
Troubleshoot the Dynamic Attributes Connector 2117
Troubleshoot using the Secure Firewall Management Center 2117
Recommendation: security requirements for network deployment 2117
Internet access requirements 2117
History for the dynamic attributes connector 2119

CHAPTER 60 **Threat Intelligence Director** 2121
Secure Firewall Threat Intelligence Director 2121
Threat Intelligence Director and Security Intelligence 2123
Performance impact of Threat Intelligence Director 2123
Requirements and prerequisites for threat intelligence director 2124
Platform, element, and license requirements 2124
Source requirements 2125
Source content limitations 2126
Set up Threat Intelligence Director 2126
Configure policies to support Threat Intelligence Director 2127
Options for ingesting data sources 2128
Fetch TAXII feeds to use as sources 2129
Fetch sources from a URL 2130
Upload a local file to use as a source 2132
Handling of duplicate indicators 2133
Configure TLS/SSL settings for a Threat Intelligence Director source 2133
User roles with Threat Intelligence Director access 2135
About backing up and restoring Threat Intelligence Director data 2135
Analyze Threat Intelligence Director incident and observation data 2136
Observation and incident generation 2136
View and manage incidents 2138
Incident summary information 2139
Incident details 2139

View events for a Threat Intelligence Director observation 2143
Threat Intelligence Director observations in Secure Firewall Management Center events 2144
Factors that affect the action taken 2144
Threat Intelligence Director - Firewall Management Center action prioritization 2145
View and change Threat Intelligence Director configurations 2148
View Threat Intelligence Director status of elements (managed devices) 2149
View and manage sources 2149
Source summary information 2150
Source status details 2151
View and manage indicators 2152
Indicator summary information 2153
Indicator details 2154
View and manage observables 2155
Observable summary information 2156
Filter Threat Intelligence Director data in table views 2156
Inheritance in Threat Intelligence Director configurations 2157
Inheritance of TID settings from multiple parents 2158
Overriding inherited TID settings 2158
Edit Threat Intelligence Director actions at the source, indicator, or observable Level 2159
Pausing publishing 2160
Pause Threat Intelligence Director and purge Threat Intelligence Director data from elements 2161
Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level 2161
Modify the observable publication frequency 2162
Adding Threat Intelligence Director observables to the Do Not Block list 2163
Add Threat Intelligence Director observables to a Do Not Block list 2164
View a STIX source file 2164
Troubleshoot Threat Intelligence Director 2164
History for Threat Intelligence Director 2166

CHAPTER 61 **Advanced Settings for Access Control** 2169
Requirements and prerequisites for advanced settings 2169
Configure advanced settings for the access control policy 2170
General settings 2172
TLS server identity discovery 2173

Intelligent application bypass 2175
Configure intelligent application bypass 2176
IAB logging and analysis 2178
Transport/network layer preprocessor settings 2181
Detection enhancement settings 2182
Adaptive profile updates 2183
Adaptive profile updates and recommended rules 2184
Performance settings 2184
Latency-based performance settings 2186
History for advanced settings for the access control policy 2187

CHAPTER 62 **Service Policies** 2191
Threat defense service policies 2191
Service policy relationships with FlexConfig and other features 2192
Connection settings 2192
Requirements and prerequisites for service policies 2193
Guidelines and limitations for service policies 2193

PART I

Getting Started with Device Configuration

- Device Registration, on page 1
- Transparent or Routed Firewall Mode, on page 71
- CLI Users, on page 85
- Change Management, on page 107
- Configuration Deployment, on page 121

CHAPTER 1

Device Registration

You can add and manage devices in the Secure Firewall Management Center.

- About device registration, on page 1
- Prerequisites for device registration, on page 12
- Log into the Command-Line Interface on the device, on page 13
- Complete the Firewall Threat Defense initial configuration for manual registration, on page 15
- Device registration management, on page 30
- Switch managers, on page 61
- History for device registration, on page 67

About device registration

Register your devices to the Firewall Management Center.

Firewall management center overview

The Firewall Management Center is a powerful, web-based, multi-device manager that runs on its own server hardware, or as a virtual device on a hypervisor. You should use the Firewall Management Center if you want a multi-device manager, and you require all features on the Firewall Threat Defense. The Firewall Management Center also provides powerful analysis and monitoring of traffic and events.

This guide applies to an *on-premises* Firewall Management Center, either as your primary manager or as an analytics-only manager. When using the Security Cloud Control Cloud-Delivered Firewall Management Center as your primary manager, you can use an on-prem Firewall Management Center for analytics. Do not use this guide for the Cloud-Delivered Firewall Management Center; see *Cisco Security Cloud Control: Secure Firewall Threat Defense Management*.

Note If you have a Security Cloud Control-managed device and are using the on-prem Firewall Management Center for analytics only, then the on-prem Firewall Management Center does not support policy configuration or upgrading. Some chapters and procedures in this guide related might not apply to devices whose primary manager is Security Cloud Control.

For the Firewall Management Center used as the primary manager: The Firewall Management Center is not compatible with other managers because the Firewall Management Center owns the Firewall Threat Defense

configuration, and you are not allowed to configure the Firewall Threat Defense directly, bypassing the Firewall Management Center.

Firewall Management Center and device management

When the Firewall Management Center manages a device, it sets up a two-way, SSL-encrypted communication channel between itself and the device. The Firewall Management Center uses this channel to send information to the device about how you want to analyze and manage your network traffic to the device. As the device evaluates the traffic, it generates events and sends them to the Firewall Management Center using the same channel.

By using the Firewall Management Center to manage devices, you can:

- configure policies for all your devices from a single location, making it easier to change configurations
- install various types of software updates on devices
- push health policies to your managed devices and monitor their health status from the Firewall Management Center

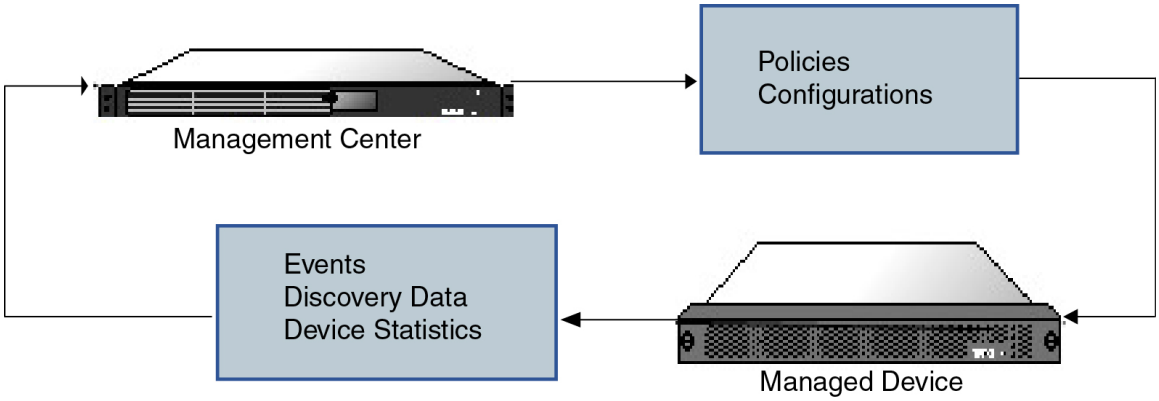
Note If you have a Security Cloud Control-managed device and are using the on-prem Firewall Management Center for analytics only, then the on-prem Firewall Management Center does not support policy configuration or upgrading. Chapters and procedures in this guide related to device configuration and other unsupported features do not apply to devices whose primary manager is Security Cloud Control.

The Firewall Management Center aggregates and correlates intrusion events, network discovery information, and device performance data, allowing you to monitor the information that your devices are reporting in relation to one another, and to assess the overall activity occurring on your network.

You can use the Firewall Management Center to manage nearly every aspect of a device's behavior.

Note Although the Firewall Management Center can manage devices running certain previous releases as specified in the compatibility matrix available at http://www.cisco.com/c/en/us/support/security/defense-center/products-device-support-tables-list.html, new features that require the latest version of Firewall Threat Defense software are not available to these previous-release devices. Some Firewall Management Center features may be available for earlier versions.

Devices managed by a Secure Firewall Management Center



You can use the Secure Firewall Management Center as a central management point to manage Firewall Threat Defense devices.

Communication channel security

When you manage a device, information is transmitted between the Firewall Management Center and the device over a secure, TLS-1.3-encrypted communication channel. You do not need to run this traffic over an

additional encrypted tunnel such as Site-to-Site VPN for security purposes. If the VPN goes down, for example, you will lose your management connection, so we recommend a simple management path.

This illustration lists what is transmitted between the Firewall Management Center and its managed devices. Note that the types of events and policies that are sent between the appliances are based on the device type.

Management connection

After you configure the device with the Firewall Management Center information and after you add the device to the Firewall Management Center, either the device or the Firewall Management Center can establish the management connection. Depending on initial setup:

- Either the device or the Firewall Management Center can initiate.
- Only the device can initiate.
- Only the Firewall Management Center can initiate.

Connection initiation behavior

Initiation always originates with eth0 on the Firewall Management Center or with the lowest-numbered management interface on the device. Additional management interfaces are tried if the connection is not established. Multiple management interfaces on the Firewall Management Center let you connect to discrete networks or to segregate management and event traffic. However, the initiator does not choose the best interface based on the routing table.

Make sure the management connection is stable, without excessive packet loss, with at least 5 Mbps throughput. By default, the management connection uses TCP port 8305 (this port is configurable). If you place another Firewall Threat Defense between devices and the Firewall Management Center, to prevent potential management disruption, be sure to exempt management traffic from deep inspection by applying a prefilter policy for it.

Note The management connection is a secure, TLS-1.3-encrypted communication channel between itself and the device. You do not need to run this traffic over an additional encrypted tunnel such as Site-to-Site VPN for security purposes. If the VPN goes down, for example, you will lose your management connection, so we recommend a simple management path.

Beyond policies and events

In addition to deploying policies to devices and receiving events from them, you can also perform other device-related tasks on the Firewall Management Center.

Device management tasks

These tasks provide essential functions for maintaining and updating your managed devices:

- **Backing up a device**:

  You cannot back up a physical managed device from its CLI. To back up configuration data, and, optionally, unified files, use the Firewall Management Center that manages the device.

  To back up event data, perform a backup of the Firewall Management Center that is managing the device.

- **Updating devices**:

  Cisco periodically releases updates to the Firepower System, including:

  - intrusion rule updates, which may contain new and updated intrusion rules
  - vulnerability database (VDB) updates
  - geolocation updates
  - software patches and updates

  You can use the Firewall Management Center to install updates on the managed devices.

Device management interfaces

A device management interface is a network connection that

- enables communication with the Firewall Management Center,
- supports initial device setup through the management interface or console port, and
- facilitates communication with the Smart Licensing server, update downloads, and other management functions.

Interface configuration options

Each device includes a single dedicated Management interface for management communication. You can optionally configure the device to use a data interface for management instead of the dedicated Management interface.

Management and event interfaces on the Firewall Threat Defense

Management and event interfaces on the Firewall Threat Defense are network connections that

- handle initial device registration and ongoing management communications between the Firewall Management Center and managed device
- transmit event data from the managed device to the Firewall Management Center, and

- can be configured as separate interfaces to isolate management and event traffic for enhanced performance and security.

Connection establishment behavior

When you set up your device, you specify the Firewall Management Center IP address or hostname that you want to connect to, if known. In this case, the device initiates the connection, and both management and event traffic go to this address at initial registration. If the Firewall Management Center is not known, then the Firewall Management Center establishes the initial connection. In this case, it might initially connect from a different Firewall Management Center management interface than specified on the Firewall Threat Defense. Subsequent connections should use the Firewall Management Center management interface with the specified IP address.

Separate event-only interface configuration requirements:

- Always enable an event interface on the Firewall Management Center before configuring a separate event-only interface on the managed device. If the Firewall Management Center has a separate event-only interface, the managed device sends subsequent event traffic to the Firewall Management Center event-only interface if the network allows. In addition, some managed-device models include an additional management interface that you can configure for event-only traffic.
- If the event network goes down, then event traffic reverts to the regular management interfaces on the Firewall Management Center and/or on the managed device. If the device management interface is down, the eventing interface will be used to establish the management connection, even if you disable management traffic for it.
- Ensure that the Firewall Management Center and managed devices have consistent configurations regarding management and event interfaces to avoid communication issues.

Using the Firewall Threat Defense data interface for management

Using the Firewall Threat Defense data interface for management is a configuration option that

- allows communication with the Firewall Management Center through a regular data interface instead of the dedicated Management interface
- enables remote management from the outside interface when a separate management network is not available, and
- provides redundant secondary interface configuration to take over management functions if the primary interface goes down.

Manager access requirements

Manager access from a data interface has the requirements listed in this table.

- You can only enable manager access on a physical, data interface. You cannot use a subinterface or EtherChannel, nor can you create a subinterface on the manager access interface. You can also use the Firewall Management Center to enable manager access on a single secondary interface for redundancy.
- This interface cannot be management-only.
- Routed firewall mode only, using a routed interface.

- PPPoE is not supported. If your ISP requires PPPoE, you will have to put a router with PPPoE support between the Firewall Threat Defense and the WAN modem.
- The interface must be in the global VRF only.
- SSH is not enabled by default for data interfaces, so you will have to enable SSH later using the Firewall Management Center. Because the Management interface gateway will be changed to be the data interfaces, you also cannot SSH to the Management interface from a remote network unless you add a static route for the Management interface using the **configure network static-routes** command. For Firewall Threat Defense Virtual on Amazon Web Services, a console port is not available, so you should maintain your SSH access to the Management interface: add a static route for Management before you continue with your configuration. Alternatively, be sure to finish all CLI configuration (including the **configure manager add** command) before you configure the data interface for manager access and you are disconnected.
- You cannot use separate management and event-only interfaces.
- Clustering is not supported. You must use the Management interface in this case.

When using a data interface with device high availability, see the requirements that are listed in this table.

- Use the same data interface on both devices for manager access.
- Redundant manager access data interface is not supported.
- You cannot use DHCP; only a static IP address is supported. Features that rely on DHCP cannot be used, including DDNS and zero-touch provisioning.

Note If you use zero-touch provisioning to register the device, when you use the outside interface for manager access, it uses DHCP by default. Before you can enable high availability, you need to change the IP address to a static address. See Change the device IP address, on page 763. Alternatively, you can use the Management interface instead; DHCP is supported on Management with high availability.

- Have different static IP addresses in the same subnet.
- Use the same manager configuration (**configure manager add** command) to ensure that the connectivity is the same.
- You cannot use the data interface as the failover or state link.

Management interface support per device model

This reference provides information about management interface support across different device models. See the hardware installation guide for your model for the management interface locations.

Note For the Firepower 4100/9300, the MGMT interface is for *chassis* management, not for Firewall Threat Defense logical device management. You must configure a separate interface to be of type MGMT (and/or firepower-eventing), and then assign it to the Firewall Threat Defense logical device.

For devices with Management and Eventing interfaces, if one interface is down, the other interface will be used as backup for management or eventing even if you disable that function for the interface.

Table 1: Management interface support on managed devices

Model	Management Interface	Optional Event Interface
Firepower 1000	management0 **Note** management0 is the internal name of the Management 1/1 interface.	No Support
Firepower 2100	management0 **Note** management0 is the internal name of the Management 1/1 interface.	No Support
Secure Firewall 3100	management0 **Note** management0 is the internal name of the Management 1/1 interface.	No Support
Secure Firewall 4200	management0 **Note** management0 is the internal name of the Management 1/1 interface.	management1 **Note** management1 is the internal name of the Management 1/2 interface.
Firepower 4100 and 9300	management0 **Note** management0 is the internal name of this interface, regardless of the physical interface ID.	management1 **Note** management1 is the internal name of this interface, regardless of the physical interface ID.
ISA 3000	br1 **Note** br1 is the internal name of the Management 1/1 interface.	No support
Secure Firewall Threat Defense Virtual	eth0	No support

Network routes on device management interfaces

Management interfaces (including event-only interfaces) support only static routes to reach remote networks. When you set up your managed device, the setup process creates a default route to the gateway IP address that you specify. You cannot delete this route; you can only modify the gateway address.

Note The routing for management interfaces is completely separate from routing that you configure for data interfaces. If you configure a data interface for management instead of using the dedicated Management interface, traffic is routed over the backplane to use the data routing table. The information in this section does not apply.

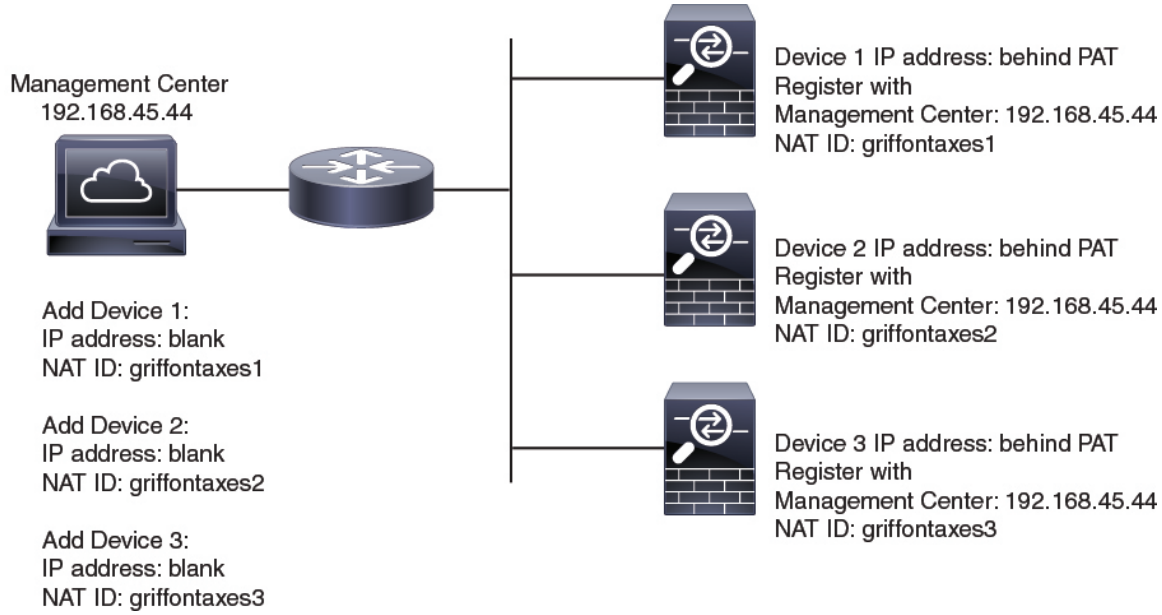
You can configure multiple management interfaces on some platforms (a management interface and an event-only interface). The default route does not include an egress interface, so the interface chosen depends on the gateway address you specify, and which interface's network the gateway belongs to. In the case of multiple interfaces on the default network, the device uses the lower-numbered interface as the egress interface.

At least one static route is recommended per management interface to access remote networks. We recommend placing each interface on a separate network to avoid potential routing problems, including routing problems from other devices to the Firewall Threat Defense.

Note The interface used for management connections is not determined by the routing table. Connections are always tried using the lowest-numbered interface first.

NAT environments

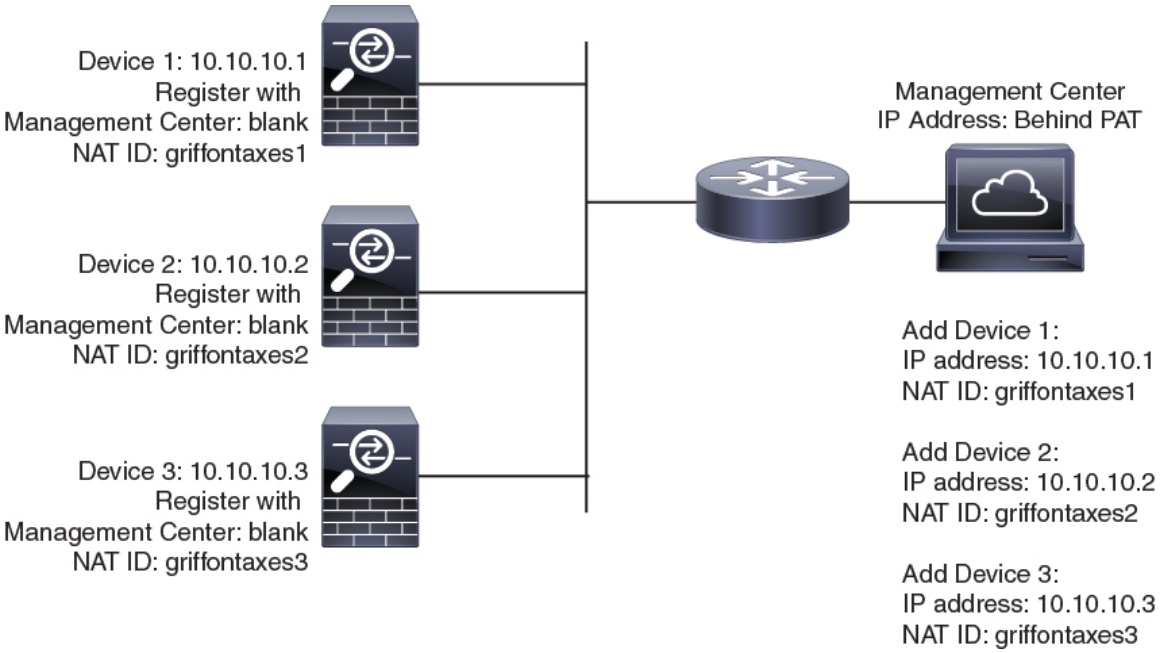
Network address translation (NAT) is a method of transmitting and receiving network traffic through a router that involves reassigning the source or destination IP address. The most common use for NAT is to allow private networks to communicate with the internet. Static NAT performs a 1:1 translation, which does not pose a problem for Firewall Management Center communication with devices, but port address translation (PAT) is more common. PAT lets you use a single public IP address and unique ports to access the public network; these ports are dynamically assigned as needed, so you cannot initiate a connection to a device behind a PAT router.



Normally, you need both IP addresses (along with a registration key) for both routing purposes and for authentication: the Firewall Management Center specifies the device IP address when you add a device, and the device specifies the Firewall Management Center IP address. However, if you only know one of the IP addresses, which is the minimum requirement for routing purposes, then you must also specify a unique NAT ID on both sides of the connection to establish trust for the initial communication and to look up the correct registration key. The Firewall Management Center and device use the registration key and NAT ID (instead of IP addresses) to authenticate and authorize for initial registration.

For example, you add a device to the Firewall Management Center, and you do not know the device IP address (for example, the device is behind a PAT router), so you specify only the NAT ID and the registration key on the Firewall Management Center; leave the IP address blank. On the device, you specify the Firewall Management Center IP address, the same NAT ID, and the same registration key. The device registers to the Firewall Management Center's IP address. At this point, the Firewall Management Center uses the NAT ID instead of IP address to authenticate the device.

Although the use of a NAT ID is most common for NAT environments, you might choose to use the NAT ID to simplify adding many devices to the Firewall Management Center. On the Firewall Management Center, specify a unique NAT ID for each device you want to add while leaving the IP address blank, and then on each device, specify both the Firewall Management Center IP address and the NAT ID. Note: The NAT ID must be unique per device.



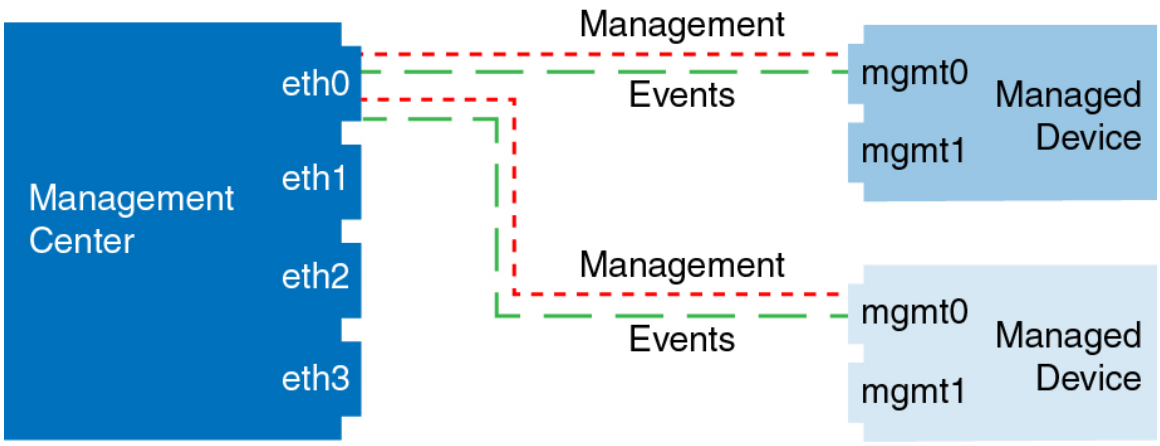
The following example shows three devices behind a PAT IP address. In this case, specify a unique NAT ID per device on both the Firewall Management Center and the devices, and specify the Firewall Management Center IP address on the devices.

Figure 1: NAT ID for Managed Devices Behind PAT

The following example shows the Firewall Management Center behind a PAT IP address. In this case, specify a unique NAT ID per device on both the Firewall Management Center and the devices, and specify the device IP addresses on the Firewall Management Center.

Figure 2: NAT ID for Firewall Management Center Behind PAT

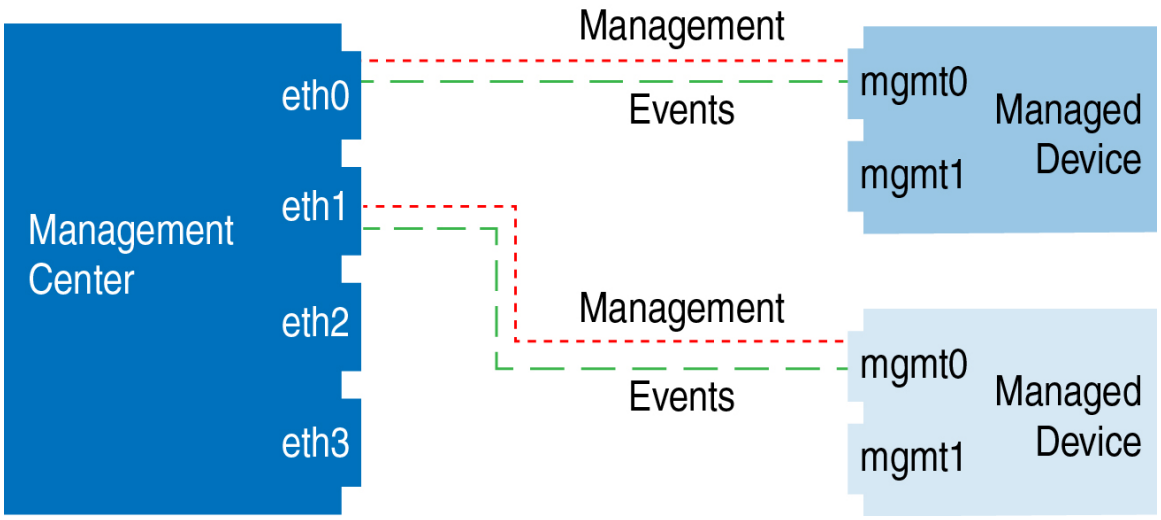
Management and event traffic channel examples



The management and event traffic channel examples illustrates the implementation and configuration of separate communication paths for network management and event reporting functions.

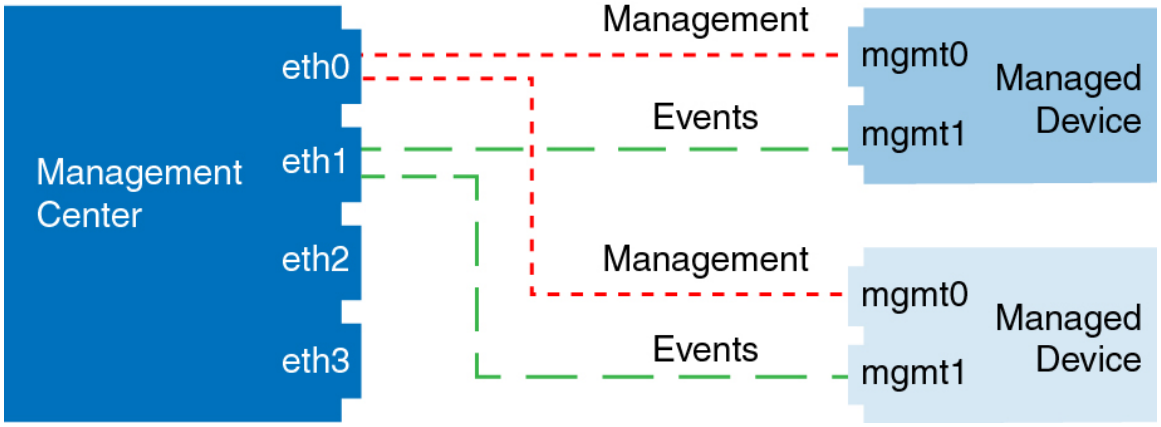
Note

- Configure a separate, dedicated event interface on both the Firewall Management Center and the managed device to segregate event traffic from management traffic. This separation improves performance and security by isolating event data flows.
- If Firewall Management Center uses a single interface for both management and event traffic, the managed device must send event traffic on that same interface. If the Firewall Management Center has a dedicated event interface, the managed device must also have a dedicated event interface configured.
- Mixing management and event channels on the same interface on the Firewall Management Center while the managed device uses a separate event interface can cause connectivity or event delivery issues. Ensure interface pairing is consistent between Firewall Management Center and managed devices.
- If you use a data interface for management on a Firewall Threat Defense, you cannot use separate management and event interfaces for that device.



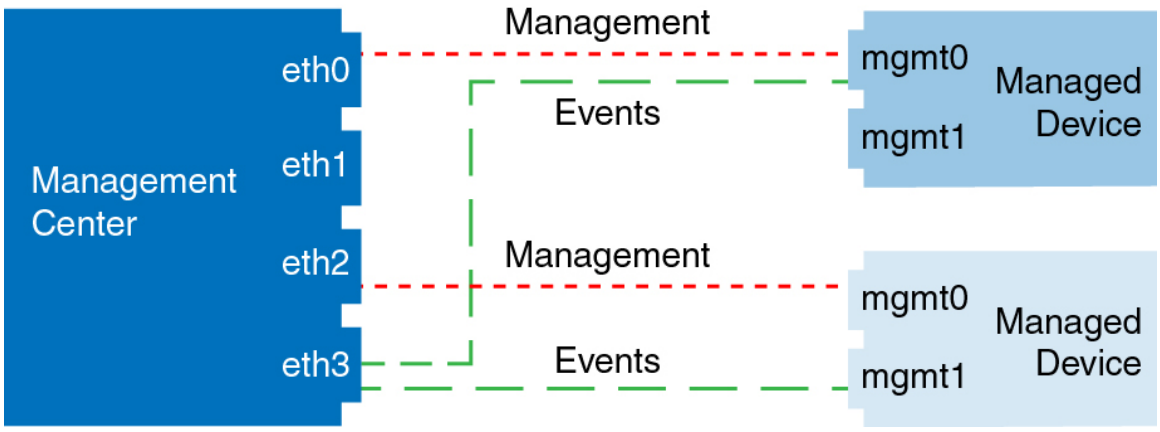
The following example shows the Firewall Management Center and managed devices using only the default management interfaces.

Figure 3: Single Management Interface on the Secure Firewall Management Center



The following example shows the Firewall Management Center using separate management interfaces for devices; and each managed device using 1 management interface.

Figure 4: Multiple Management Interfaces on the Secure Firewall Management Center



The following example shows the Firewall Management Center and managed devices using a separate event interface.

Figure 5: Separate Event Interface on the Secure Firewall Management Center and Managed Devices

The following example shows a mix of multiple management interfaces and a separate event interface on the Firewall Management Center and a mix of managed devices using a separate event interface, or using a single management interface.

Figure 6: Mixed Management and Event Interface Usage

Prerequisites for device registration

This reference provides the prerequisites and requirements that must be satisfied before registering a device with the management center, including domain requirements, user roles, connection specifications, and Zero-Touch Provisioning requirements.

Supported domains

The domain in which the device resides.

User roles

- Admin
- Network Admin

Management connection

Make sure the management connection is stable, without excessive packet loss, with at least 5Mbps throughput.

Zero-Touch Provisioning requirements

Zero-Touch Provisioning is not supported with clustering or multi-instance mode.

High availability is only supported when you use the Management interface because zero-touch provisioning uses DHCP, which is not supported for data interfaces and high availability.

Zero-Touch Provisioning is supported on these models using 7.4 or later:

- Firepower 1010
- Firepower 1100
- Secure Firewall 1200
- Firepower 2100 (on supported device versions)

- Secure Firewall 3100

Log into the Command-Line Interface on the device

You can log directly into the command-line interface on Firewall Threat Defense devices. If this is your first time logging in, complete the initial setup process using the default **admin** user; see Complete the Firewall Threat Defense Initial Configuration Using the CLI , on page 21 .

For zero-touch provisioning , if you must access the Firewall Threat Defense CLI and run through the setup script, answer **n** when prompted: `Do you want to configure IPv4? (y/n) [y]:` and `Do you want to configure IPv6? (y/n) [y]:` . You also must accept the default local manager: `Manage the device locally? (yes/no) [yes]:` . These settings will preserve zero-touch provisioning capability.

Note If a user makes three consecutive failed attempts to log in to the CLI via SSH, the system terminates the SSH connection.

Before you begin

- Create additional user accounts that can log in to the CLI using the **configure user add** command.
- If you get unreadable characters when connecting to the console port, verify the port settings. If they are correct, try the cable with another device using the same settings. If the cable is good, you might need to replace the hardware for the console port. Also consider trying a different workstation to make the connection.

Procedure

Step 1 Connect to the Firewall Threat Defense CLI, either from the console port or using SSH.

You can SSH to the management interface of the Firewall Threat Defense device. You can also connect to the address on a data interface if you open the interface for SSH connections. SSH access to data interfaces is disabled by default. See Configure Secure Shell (SSH) access, on page 867 to allow SSH connections to specific data interfaces.

For physical devices, you can directly connect to the console port on the device. See the hardware guide for your device for more information about the console cable. Use the following serial settings:

- 9600 baud
- 8 data bits
- No parity
- 1 stop bit

The CLI on the console port is FXOS (with the exception of the ISA 3000, where it is the regular Firewall Threat Defense CLI) . Use the Firewall Threat Defense CLI for basic configuration, monitoring, and normal system troubleshooting. See the FXOS documentation for information on FXOS commands.

For a chassis in multi-instance mode, you can connect to FXOS on the console port, or you can enable SSH for FXOS on the Management interface according to Configure SSH and SSH access list, on page 201 . SSH is disabled by default.

Step 2 Log in with the **admin** username and password.

Example:

```
firepower login: admin
Password:
Last login: Thu May 16 14:01:03 UTC 2019 on ttyS0
Successful login attempts for user 'admin' : 1
firepower#
```

Step 3 If you used the console port, access the Firewall Threat Defense CLI.

connect ftd

Multi-instance mode:

connect ftd *name*

To view the instance names, enter the command without a name.

Note This step does not apply to the ISA 3000.

Example:

```
firepower# connect ftd
>
```

Step 4 At the CLI prompt (>), use any of the commands allowed by your level of command line access.

To return to FXOS on the console port, enter **exit** .

Step 5 (Optional) If you used SSH, you can connect to FXOS.

connect fxos

To return to the Firewall Threat Defense CLI, enter **exit** .

Step 6 (Optional) Access the diagnostic CLI:

system support diagnostic-cli

Use this CLI for advanced troubleshooting. This CLI includes additional **show** and other commands.

This CLI has submodes: user EXEC mode, privileged EXEC mode . More commands are available in privileged EXEC mode than user EXEC mode. To enter privileged EXEC mode, enter the **enable** command; press enter without entering a password when prompted.

Example:

```
> system support diagnostic-cli
firepower> enable
Password:
firepower#
```

To return to the regular CLI, type **Ctrl-a** , **d** .

Complete the Firewall Threat Defense initial configuration for manual registration

You can complete the Firewall Threat Defense initial configuration using the CLI or the Firewall Device Manager for all models except for the Firepower 4100/9300.

Platform-specific configuration methods

For the Firepower 4100/9300, you complete initial configuration when you deploy the logical device. See Logical Devices on the Firepower 4100/9300, on page 223.

For zero-touch provisioning (serial number registration), you should not log in to the device or perform initial setup. See Add a Device Using the Serial Number (Zero-Touch Provisioning) , on page 36.

Note Devices registered to a Firewall Management Center (FMC) for analytics-only purposes count toward the FMC platform device capacity limit. As the number of devices increases, event processing requirements also increase. Properly size your virtual FMC (vFMC) tier when planning analytics-only deployments.

Complete the Firewall Threat Defense Initial Configuration Using the Firewall Device Manager

When you use the Firewall Device Manager for initial setup, the following interfaces are preconfigured in addition to the Management interface and manager access settings:

- Ethernet 1/1—"outside", IP address from DHCP, IPv6 autoconfiguration
- Ethernet 1/2 (or for the 1010), the VLAN1 interface)— "inside", 192.168.95.1/24
- Default route—Obtained through DHCP on the outside interface

Note that other settings, such as the DHCP server on inside, access control policy, or security zones, are not configured.

If you perform additional interface-specific configuration within Firewall Device Manager before registering with the Firewall Management Center , then that configuration is preserved.

When you use the CLI, only the Management interface and manager access settings are retained (for example, the default inside interface configuration is not retained).

- The Secure Firewall 4200 does not support the Firewall Device Manager . You need to use the CLI procedure: Complete the Firewall Threat Defense Initial Configuration Using the CLI , on page 21 .
- This procedure does not apply for Security Cloud Control -managed devices for which you want to use an on-prem Firewall Management Center *for analytics only*. The Firewall Device Manager configuration

is meant to configure the primary manager. See Complete the Firewall Threat Defense Initial Configuration Using the CLI , on page 21 for more information about configuring the device for analytics.

- This procedure applies to all other devices except for the Firepower 4100/9300 and the ISA 3000. You can use the Firewall Device Manager to onboard these devices to the Firewall Management Center , but because they have different default configurations than other platforms, the details in this procedure may not apply to these platforms.

Procedure

Step 1 Log into the Firewall Device Manager .

a) Enter the following URL in your browser.

- Inside— **https://192.168.95.1** .
- Management— **https://** *management_ip* . The Management interface is a DHCP client, so the IP address depends on your DHCP server. You will have to set the Management IP address to a static address as part of this procedure, so we recommend that you use the inside interface so you do not become disconnected.

b) Log in with the username **admin** , and the default password **Admin123** .

c) You are prompted to read and accept the End User License Agreement and change the admin password.

Step 2 Use the setup wizard when you first log into the Firewall Device Manager to complete the initial configuration. You can optionally skip the setup wizard by clicking **Skip device setup** at the bottom of the page.

After you complete the setup wizard, in addition to the default configuration for the inside interface, you will have configuration for an outside (Ethernet1/1) interface that will be maintained when you switch to the Firewall Management Center management.

a) Configure the following options for the outside and management interfaces, and click **Next** .

1. **Outside Interface Address** —This interface is typically the internet gateway, and might be used as your manager access interface. You cannot select an alternative outside interface during initial device setup. The first data interface is the default outside interface.

   If you want to use a different interface from outside (or inside) for manager access, you will have to configure it manually after completing the setup wizard.

   Configure IPv4 —The IPv4 address for the outside interface. You can use DHCP or manually enter a static IP address, subnet mask, and gateway. You can also select **Off** to not configure an IPv4 address. You cannot configure PPPoE using the setup wizard. PPPoE may be required if the interface is connected to a DSL modem, cable modem, or other connection to your ISP, and your ISP uses PPPoE to provide your IP address. You can configure PPPoE after you complete the wizard.

   Configure IPv6 —The IPv6 address for the outside interface. You can use DHCP or manually enter a static IP address, prefix, and gateway. You can also select **Off** to not configure an IPv6 address.

2. **Management Interface**

   You will not see Management Interface settings if you performed initial setup at the CLI.

   The Management interface settings are used even if you enable manager access on a data interface. For example, the management traffic that is routed over the backplane through the data interface will resolve FQDNs using the Management interface DNS servers, and not the data interface DNS servers.

DNS Servers —The DNS server for the system's management address. Enter one or more addresses of DNS servers for name resolution. The default is the OpenDNS public DNS servers. If you edit the fields and want to return to the default, click **Use OpenDNS** to reload the appropriate IP addresses into the fields.

Firewall Hostname —The hostname for the system's management address.

b) Configure the **Time Setting (NTP)** and click **Next** .

1. **Time Zone** —Select the time zone for the system.
2. **NTP Time Server** —Select whether to use the default NTP servers or to manually enter the addresses of your NTP servers. You can add multiple servers to provide backups.

c) Select **Start 90 day evaluation period without registration** .

Do not register the Firewall Threat Defense with the Smart Software Manager; all licensing is performed on the Firewall Management Center .

d) Click **Finish** .

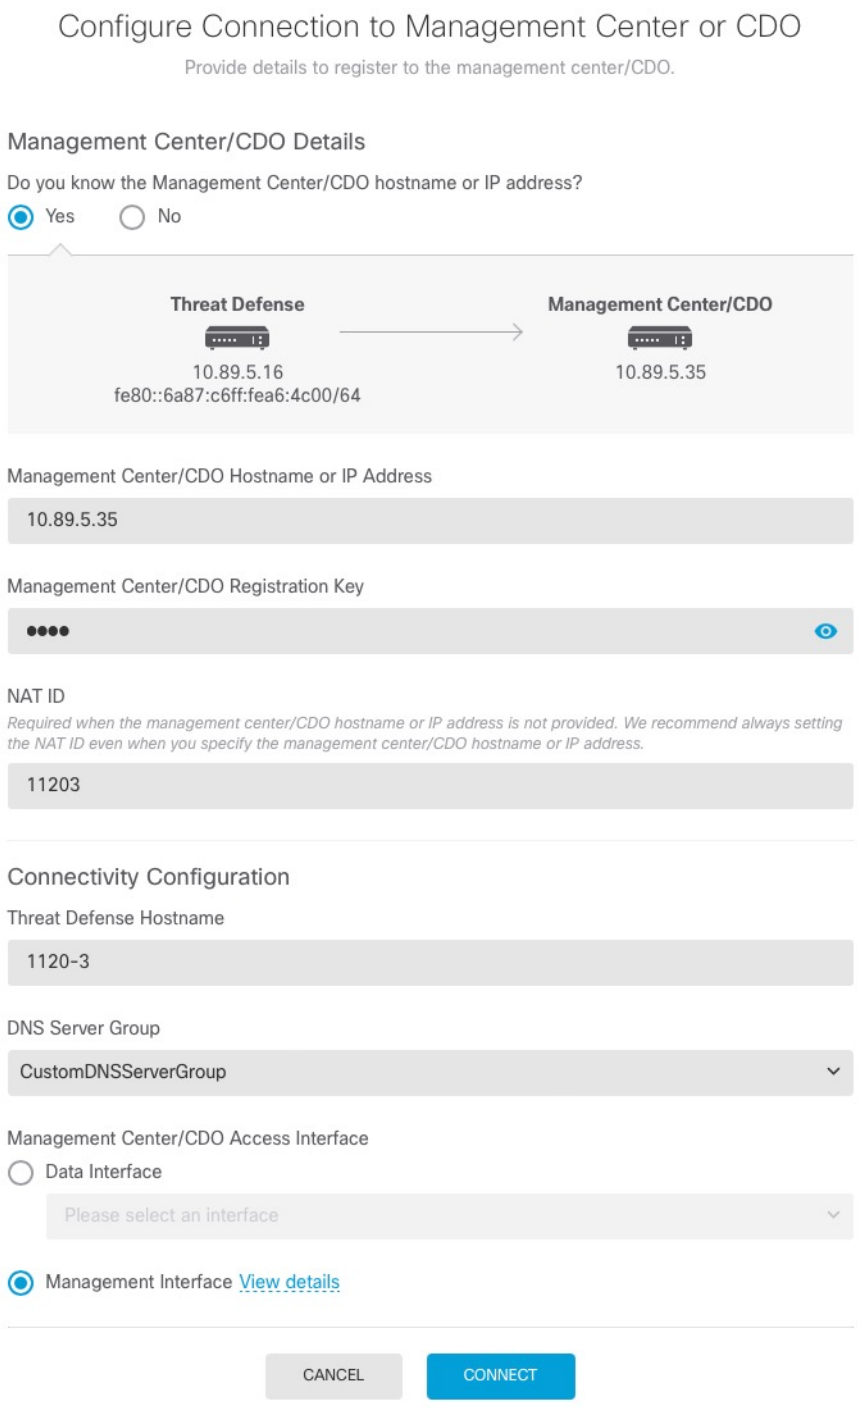
e) You are prompted to choose **Cloud Management** or **Standalone** . For Firewall Management Center management, choose **Standalone** , and then **Got It** .

Step 3 (Might be required) Configure the Management interface.

You may need to change the Management interface configuration, even if you intend to use a data interface for manager access. You will have to reconnect to the Firewall Device Manager if you were using the Management interface for the Firewall Device Manager connection.

- Data interface for manager access—The Management interface must have the gateway set to data interfaces. By default, the Management interface receives an IP address and gateway from DHCP. If you do not receive a gateway from DHCP (for example, you did not connect this interface to a network), then the gateway will default to data interfaces, and you do not need to configure anything. If you did receive a gateway from DHCP, then you need to instead configure this interface with a static IP address and set the gateway to data interfaces.
- Management interface for manager access—If you want to configure a static IP address, be sure to also set the default gateway to be a unique gateway instead of the data interfaces. If you use DHCP, then you do not need to configure anything assuming you successfully get the gateway from DHCP.

a) To configure additional interfaces, including an interface other than outside or inside that you want to use for manager access, choose **Device**



b) Click the link in the **Interfaces** summary.

Other Firewall Device Manager configuration will not be retained when you register the device to Firewall Management Center.

Step 4 Choose **Device** > **System Settings** > **Central Management**, and click **Proceed** to set up the Firewall Management Center management.

Step 5 Configure the **Management Center/CDO Details**.

Figure 7: Management Center/Security Cloud Control Details

a) For **Do you know the Management Center/CDO hostname or IP address?**, click **Yes** if you can reach the Firewall Management Center using an IP address or hostname, or **No** if the Firewall Management CenterSecurity Cloud Control is behind NAT or does not have a public IP address or hostname.

At least one of the devices, either the Firewall Management Center or the Firewall Threat Defense device, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices.

b) If you chose **Yes**, then enter the **Management Center/CDO Hostname or IP Address**.

c) Specify the **Management Center/CDO Registration Key**.

This key is a one-time registration key of your choice that you will also specify on the Firewall Management Center when you register the Firewall Threat Defense device. The registration key must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID can be used for multiple devices registering to the Firewall Management Center.

d) Specify a **NAT ID**.

This ID is a unique, one-time string of your choice that you will also specify on the Firewall Management Center. The NAT ID must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID *cannot* be used for any other devices registering to the Firewall Management Center. The NAT ID is used in combination with the IP address to verify that the connection is coming from the correct device; only after authentication of the IP address/NAT ID will the registration key be checked. We recommended that you always use the NAT ID even when it is optional, but it is required if:

- You set the Firewall Management Center IP address to **DONTRESOLVE**.
- When adding the device on the Firewall Management Center, you do not specify a reachable device IP address or hostname.
- You use the data interface for management, even if you specify IP addresses on both sides.
- The Firewall Management Center uses multiple management interfaces.

Step 6 Configure the **Connectivity Configuration**.

a) Specify the **FTD Hostname**.

If you use a data interface for the **Management Center/CDO Access Interface** access, then this FQDN will be used for this interface.

b) Specify the **DNS Server Group**.

Choose an existing group, or create a new one. The default DNS group is called **CiscoUmbrellaDNSServerGroup**, which includes the OpenDNS servers.

If you intend to choose a data interface for the **Management Center/CDO Access Interface**, then this setting sets the *data* interface DNS server. The Management DNS server that you set with the setup wizard is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface. You are likely to choose the same DNS server group that you used for Management, because both management and data traffic reach the DNS server through the outside interface.

On the Firewall Management Center, the data interface DNS servers are configured in the Platform Settings policy that you assign to this Firewall Threat Defense device. When you add the Firewall Threat Defense device to the Firewall Management Center, the local setting is maintained, and the DNS servers are *not* added to a Platform Settings policy. However, if you later assign a Platform Settings policy to the Firewall Threat Defense device that includes a DNS configuration, then that configuration will overwrite the local setting. We suggest that you actively configure the DNS Platform Settings to match this setting to bring the Firewall Management Center and the Firewall Threat Defense device into sync.

Also, local DNS servers are only retained by the Firewall Management Center if the DNS servers were discovered at initial registration.

If you intend to choose the Management interface for the **Management Center/CDO Access InterfaceFMC Access Interface**, then this setting configures the Management DNS server.

c) For the **Management Center/CDO Access Interface**, choose any configured interface.

You can change the manager interface after you register the Firewall Threat Defense device to the Firewall Management Center, to either the Management interface or another data interface.

Step 7 (Optional) If you chose a data interface, and it was not the outside interface, then add a default route.

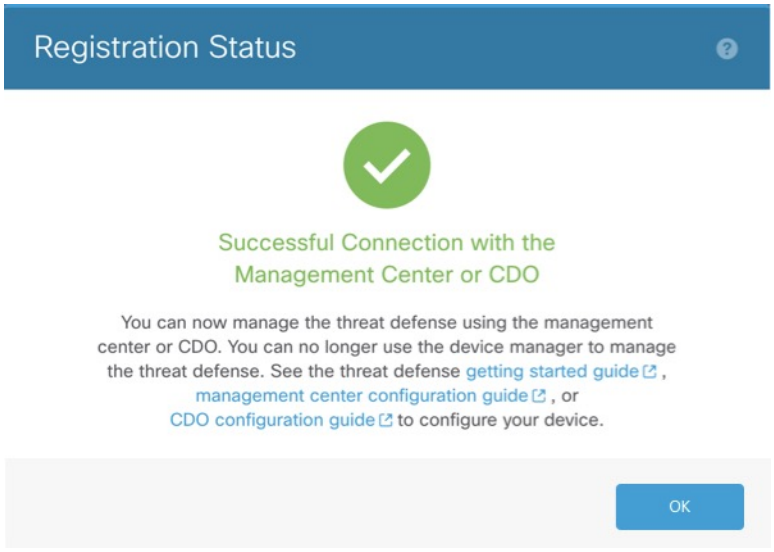
You will see a message telling you to check that you have a default route through the interface. If you chose outside, you already configured this route as part of the setup wizard. If you chose a different interface, then you need to manually configure a default route before you connect to the Firewall Management Center.

If you chose the Management interface, then you need to configure the gateway to be a unique gateway before you can proceed on this screen.

Step 8 (Optional) If you chose a data interface, click **Add a Dynamic DNS (DDNS) method**.

DDNS ensures the Firewall Management Center can reach the Firewall Threat Defense device at its Fully-Qualified Domain Name (FQDN) if the IP address changes. See **Device** > **System Settings** > **DDNS Service** to configure DDNS.

If you configure DDNS before you add the Firewall Threat Defense device to the Firewall Management Center, the Firewall Threat Defense device automatically adds certificates for all of the major CAs from the Cisco Trusted Root CA bundle so that the Firewall Threat Defense device can validate the DDNS server certificate for the HTTPS connection. Firewall Threat Defense supports any DDNS server that uses the DynDNS Remote API specification (https://help.dyn.com/remote-access-api/).



DDNS is not supported when using the Management interface for manager access.

Step 9 Click **Connect**. The **Registration Status** dialog box shows the current status of the switch to the Firewall Management Center. After the **Saving Management Center/CDO Registration Settings** step, go to the Firewall Management Center, and add the firewall.

If you want to cancel the switch to the Firewall Management Center, click **Cancel Registration**. Otherwise, do not close the Firewall Device Manager browser window until after the **Saving Management Center/CDO Registration Settings** step. If you do, the process will be paused, and will only resume when you reconnect to the Firewall Device Manager.

If you remain connected to the Firewall Device Manager after the **Saving Management Center/CDO Registration Settings** step, you will eventually see the **Successful Connection with Management Center/CDO** dialog box, after which you will be disconnected from the Firewall Device Manager.

Figure 8: Successful Connection

Complete the Firewall Threat Defense Initial Configuration Using the CLI

Connect to the Firewall Threat Defense CLI to perform initial setup, including setting the Management IP address, gateway, and other basic networking settings using the setup wizard. The dedicated Management interface is a special interface with its own network settings. If you do not want to use the Management interface for manager access, you can use the CLI to configure a data interface instead. You will also configure Firewall Management Center communication settings. When you perform initial setup using the Firewall Device Manager , *all* interface configuration completed in the Firewall Device Manager is retained when you switch to the Firewall Management Center for management, in addition to the Management interface and manager access interface settings. Note that other default configuration settings, such as the access control policy, are not retained.

This procedure applies to all models except for the Firepower 4100/9300 . To deploy a logical device and complete initial configuration on the Firepower 4100/9300 , see Logical Devices on the Firepower 4100/9300, on page 223 .

Procedure

Step 1 Connect to the Firewall Threat Defense CLI, either from the console port or using SSH to the Management interface, which obtains an IP address from a DHCP server by default. If you intend to change the network settings, we recommend using the console port so you do not get disconnected.

The console port connects to the FXOS CLI. The SSH session connects directly to the Firewall Threat Defense CLI. The exception is for the ISA 3000, where the console connection connects to the Firewall Threat Defense CLI.

Step 2 Log in with the username **admin** and the password **Admin123** .

At the console port, you connect to the FXOS CLI. The first time you log in to FXOS, you are prompted to change the password. This password is also used for the Firewall Threat Defense login for SSH.

Note If the password was already changed, and you do not know it, you must reimage the device to reset the password to the default.

For Firepower and Secure Firewall hardware, see the Reimage Procedures in the Cisco FXOS Troubleshooting Guide for the Firewall Threat Defense .

For the ISA 3000, see the Cisco Secure Firewall ASA and Threat Defense Reimage Guide .

Example:

```
firepower login:
                          admin
Password:
                          Admin123
Successful login attempts for user 'admin' : 1
[...]
Hello admin. You must change your password.
Enter new password:
                          ********
Confirm new password:
                          ********
Your password was updated successfully.
[...]
firepower#
```

Step 3 If you connected to FXOS on the console port, connect to the Firewall Threat Defense CLI.

connect ftd

Example:

```
firepower# connect ftd
>
```

Step 4 The first time you log in to the Firewall Threat Defense , you are prompted to accept the End User License Agreement (EULA) and, if using an SSH connection, to change the admin password. You are then presented with the CLI setup script.

Note You cannot repeat the CLI setup wizard unless you clear the configuration; for example, by reimaging. However, all of these settings can be changed later at the CLI using **configure network** commands. See the threat defense command reference .

Defaults or previously entered values appear in brackets. To accept previously entered values, press **Enter** .

Note The Management interface settings are used even when you enable manager access on a data interface. For example, the management traffic that is routed over the backplane through the data interface will resolve FQDNs using the Management interface DNS servers, and not the data interface DNS servers.

See the following guidelines:

- **Do you want to configure IPv4?** and/or **Do you want to configure IPv6?** —Enter **y** for at least one of these types of addresses.
- **Enter the IPv4 default gateway for the management interface** and/or **Enter the IPv6 gateway for the management interface** —If you want to use a data interface for manager access instead of the Management interface, choose **manual** . Although you do not plan to use the Management interface, you must set an IP address, for example, a private address. Make sure this interface is on a different subnet from the manager access interface to prevent routing issues. You cannot configure a data interface for management if the management interface is set to DHCP, because the default route, which must be **data-interfaces** (see the next bullet), might be overwritten with one received from the DHCP server.
- **Enter the IPv4 default gateway for the management interface** and/or **Configure IPv6 via DHCP, router, or manually?** — If you want to use a data interface for manager access instead of the management interface, set the gateway to be **data-interfaces** . This setting forwards management traffic over the backplane so it can be routed through the manager access data interface. If you want to use the Management interface for manager access, you should set a gateway IP address on the Management 1/1 network.
- **If your networking information has changed, you will need to reconnect** —If you are connected with SSH but you change the IP address at initial setup, you will be disconnected. Reconnect with the new IP address and password. Console connections are not affected.
- **Manage the device locally?** —Enter **no** to use the Firewall Management Center . A **yes** answer means you will use Secure Firewall Device Manager instead.
- **Configure firewall mode?** —We recommend that you set the firewall mode at initial configuration. Changing the firewall mode after initial setup erases your running configuration. Note that data interface manager access is only supported in routed firewall mode.

Example:

```
You must accept the EULA to continue.
Press <ENTER> to display the EULA:
Cisco General Terms
[...]
Please enter 'YES' or press <ENTER> to AGREE to the EULA:
System initialization in progress.  Please stand by.
You must configure the network to continue.
Configure at least one of IPv4 or IPv6 unless managing via data interfaces.
Do you want to configure IPv4? (y/n) [y]:
Do you want to configure IPv6? (y/n) [y]:
                        n
Configure IPv4 via DHCP or manually? (dhcp/manual) [manual]:
Enter an IPv4 address for the management interface [192.168.45.61]:
                        10.89.5.17
Enter an IPv4 netmask for the management interface [255.255.255.0]:
                        255.255.255.192
Enter the IPv4 default gateway for the management interface [data-interfaces]:
                        10.89.5.1
Enter a fully qualified hostname for this system [firepower]:
```

```
                        1010-3
Enter a comma-separated list of DNS servers or 'none'
[208.67.222.222,208.67.220.220,2620:119:35::35]:
Enter a comma-separated list of search domains or 'none' []:
                        cisco.com
If your networking information has changed, you will need to reconnect.
Disabling IPv6 configuration: management0
Setting DNS servers: 208.67.222.222,208.67.220.220,2620:119:35::35
Setting DNS domains:cisco.com
Setting hostname as 1010-3
Setting static IPv4: 10.89.5.17 netmask: 255.255.255.192 gateway: 10.89.5.1 on management0
Updating routing tables, please wait...
All configurations applied to the system. Took 3 Seconds.
Saving a copy of running network configuration to local disk.
For HTTP Proxy configuration, run 'configure network http-proxy'
Manage the device locally? (yes/no) [yes]:
                        no
DHCP server is already disabled
DHCP Server Disabled
Configure firewall mode? (routed/transparent) [routed]:
Configuring firewall mode ...
Device is in OffBox mode - disabling/removing port 443 from iptables.
Update policy deployment information
    - add device configuration
    - add network discovery
    - add system policy
You can register the sensor to a Firepower Management Center and use the
Firepower Management Center to manage it. Note that registering the sensor
to a Firepower Management Center disables on-sensor Firepower Services
management capabilities.
When registering the sensor to a Firepower Management Center, a unique
alphanumeric registration key is always required.  In most cases, to register
a sensor to a Firepower Management Center, you must provide the hostname or
the IP address along with the registration key.
'configure manager add [hostname | ip address ] [registration key ]'
However, if the sensor and the Firepower Management Center are separated by a
NAT device, you must enter a unique NAT ID, along with the unique registration
key.
'configure manager add DONTRESOLVE [registration key ] [ NAT ID ]'
Later, using the web interface on the Firepower Management Center, you must
use the same registration key and, if necessary, the same NAT ID when you add
this sensor to the Firepower Management Center.
>
```

Step 5 Identify the Firewall Management Center that will manage this Firewall Threat Defense .

configure manager add { *hostname* | *IPv4_address* | *IPv6_address* | **DONTRESOLVE** } *reg_key* [*nat_id*] [*display_name*]

Note If you are using Security Cloud Control for management, use the Security Cloud Control -generated **configure manager add** command for this step.

- { *hostname* | *IPv4_address* | *IPv6_address* | **DONTRESOLVE** }—Specifies either the FQDN or IP address of the Firewall Management Center . If the Firewall Management Center is not directly addressable, use **DONTRESOLVE** and also specify the *nat_id* . At least one of the devices, either the Firewall Management Center or the Firewall Threat Defense , must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices. If you specify

DONTRESOLVE in this command, then the Firewall Threat Defense must have a reachable IP address or hostname.

- *reg_key* —Specifies a one-time registration key of your choice that you will also specify on the Firewall Management Center when you register the Firewall Threat Defense . The registration key must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).
- *nat_id* —Specifies a unique, one-time string of your choice that you will also specify on the Firewall Management Center when you register the Firewall Threat Defense . The NAT ID must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the Firewall Management Center . The NAT ID is used in combination with the IP address to verify that the connection is coming from the correct device; only after authentication of the IP address/NAT ID will the registration key be checked. We recommended that you always use the NAT ID even when it is optional, but it is required if:
  - You set the Firewall Management Center IP address to **DONTRESOLVE** .
  - When adding the device on the Firewall Management Center , you do not specify a reachable device IP address or hostname.
  - You use the data interface for management, even if you specify IP addresses on both sides.
  - The Firewall Management Center uses multiple management interfaces.
- *display_name* —Provide a display name for showing this manager with the **show managers** command. This option is useful if you are identifying Security Cloud Control as the primary manager and an on-prem Firewall Management Center for analytics only. If you don't specify this argument, the firewall auto-generates a display name using one of the following methods:
  - *hostname* | *IP_address* (if you don't use the **DONTRESOLVE** keyword)
  - **manager-** *timestamp*

Example:

```
>
                        configure manager add MC.example.com 123456
Manager successfully configured.
```

Example:

If the Firewall Management Center is behind a NAT device, enter a unique NAT ID along with the registration key, and specify DONTRESOLVE instead of the hostname, for example:

```
>
                        configure manager add DONTRESOLVE regk3y78 natid90
Manager successfully configured.
```

Example:

If the Firewall Threat Defense is behind a NAT device, enter a unique NAT ID along with the Firewall Management Center IP address or hostname, for example:

```
>
```

```
                        configure manager add 10.70.45.5 regk3y78 natid56
Manager successfully configured.
```

Step 6 If you are using Security Cloud Control as your primary manager and want to use an on-prem Firewall Management Center for analytics only, identify the on-prem Firewall Management Center .

configure manager add { *hostname* | *IPv4_address* | *IPv6_address* | **DONTRESOLVE** } *reg_key* [*nat_id*] [*display_name*]

Example:

The following example uses the generated command for Security Cloud Control with a Security Cloud Control -generated display name and then specifies an on-prem Firewall Management Center for analytics only with the "analytics-FMC" display name.

```
> configure manager add account1.app.us.cdo.cisco.com KPOOP0rgWzaHrnj1V5ha2q5Rf8pKFX9E
Lzm1HOynhVUWhXYWz2swmkj2ZWsN3Lb account1.app.us.cdo.cisco.com
Manager successfully configured.
> configure manager add 10.70.45.5 regk3y78 natid56 analytics-FMC
Manager successfully configured.
```

Step 7 (Optional) Configure a data interface for manager access.

configure network management-data-interface

After pressing **Enter**, you are prompted to configure basic network settings for the data interface.

Note You should use the console port when using this command. If you use SSH to the Management interface, you might get disconnected and have to reconnect to the console port. See below for more information about SSH usage.

See the following details for using this command. See also Using the Firewall Threat Defense data interface for management, on page 5 .

- The original Management interface cannot use DHCP if you want to use a data interface for management. If you did not set the IP address manually during initial setup, you can set it now using the **configure network** { **ipv4** | **ipv6** } **manual** command. Make sure this interface is on a different subnet from the manager access interface to prevent routing issues. If you did not already set the Management interface gateway to **data-interfaces** , this command will set it now.
- When you add the Firewall Threat Defense to the Firewall Management Center , the Firewall Management Center discovers and maintains the interface configuration, including the following settings: interface name and IP address, static route to the gateway, DNS servers, and DDNS server. For more information about the DNS server configuration, see below. In the Firewall Management Center , you can later make changes to the manager access interface configuration, but make sure you don't make changes that can prevent the Firewall Threat Defense or Firewall Management Center from re-establishing the management connection. If the management connection is disrupted, the Firewall Threat Defense includes the **configure policy rollback** command to restore the previous deployment.
- DDNS ensures the Firewall Management Center can reach the Firewall Threat Defense at its Fully-Qualified Domain Name (FQDN) if the IP address changes. If you configure a DDNS server update URL, the Firewall Threat Defense automatically adds certificates for all of the major CAs from the Cisco Trusted Root CA bundle so that the Firewall Threat Defense can validate the DDNS server certificate

for the HTTPS connection. The Firewall Threat Defense supports any DDNS server that uses the DynDNS Remote API specification (https://help.dyn.com/remote-access-api/).

- This command sets the *data* interface DNS server. The Management DNS server that you set with the setup script (or using the **configure network dns servers** command) is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface.

  On the Firewall Management Center , the data interface DNS servers are configured in the Platform Settings policy that you assign to this Firewall Threat Defense . When you add the Firewall Threat Defense to the Firewall Management Center , the local setting is maintained, and the DNS servers are *not* added to a Platform Settings policy. However, if you later assign a Platform Settings policy to the Firewall Threat Defense that includes a DNS configuration, then that configuration will overwrite the local setting. We suggest that you actively configure the DNS Platform Settings to match this setting to bring the Firewall Management Center and the Firewall Threat Defense into sync.

  Also, local DNS servers are only retained by the Firewall Management Center if the DNS servers were discovered at initial registration. For example, if you registered the device using the Management interface, but then later configure a data interface using the **configure network management-data-interface** command, then you must manually configure all of these settings in the Firewall Management Center , including the DNS servers, to match the FTD configuration.

- You can change the management interface after you register the Firewall Threat Defense to the Firewall Management Center , to either the Management interface or another data interface.
- The FQDN that you set in the setup wizard will be used for this interface.
- You can clear the entire device configuration as part of the command; you might use this option in a recovery scenario, but we do not suggest you use it for initial setup or normal operation.
- To disable data management, enter the **configure network management-data-interface disable** command.

Example:

```
>
                        configure network management-data-interface
Data interface to use for management:
                        ethernet1/1
Specify a name for the interface [outside]:
IP address (manual / dhcp) [dhcp]:
DDNS server update URL [none]:

https://dwinchester:pa$$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>
Do you wish to clear all the device configuration before applying ? (y/n) [n]:
Configuration done with option to allow manager access from any network,
if you wish to change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.
Setting IPv4 network configuration.
Network settings changed.
>
```

Example:

```
>
                        configure network management-data-interface
Data interface to use for management:
                        ethernet1/1
Specify a name for the interface [outside]:
```

```
                        internet
IP address (manual / dhcp) [dhcp]:
                        manual
IPv4/IPv6 address:
                        10.10.6.7
Netmask/IPv6 Prefix:
                        255.255.255.0
Default Gateway:
                        10.10.6.1
Comma-separated list of DNS servers [none]:
                        208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]:
Configuration done with option to allow manager access from any network,
if you wish to change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.
Setting IPv4 network configuration.
Network settings changed.
>
```

Step 8 (Optional) Limit data interface access to a manager on a specific network.

configure network management-data-interface client *ip_address netmask*

By default, all networks are allowed.

Register your device to a Firewall Management Center .

Configure an event interface

You always need a management interface for management traffic. If your device has a second management interface, for example, the Firepower 4100/9300 and Secure Firewall 4200 , you can enable it for event-only traffic.

You can configure a separate event-only interface on both the Firewall Management Center and the managed device to isolate event traffic. This setup enhances performance and security by segregating event data from management operations.

If the event interface is unreachable, event traffic falls back to the management interface.

Before you begin

Ensure that you enable an event interface on the Firewall Management Center before configuring a separate event-only interface on the managed device. For more information, refer to *Cisco Secure Firewall Management Center Administration Guide* .

If you use a data interface for management on the managed device, you cannot configure separate management and event interfaces.

Procedure

Step 1 Enable the second management interface as an event-only interface.

configure network management-interface enable management1

configure network management-interface disable-management-channel management1

You can optionally disable events for the main management interface using the **configure network management-interface disable-events-channel** command. In either case, the device will try to send events on the event-only interface, and if that interface is down, it will send events on the management interface even if you disable the event channel.

You cannot disable both event and management channels on an interface.

Example:

```
> configure network management-interface enable management1
Configuration updated successfully
> configure network management-interface disable-management-channel management1
Configuration updated successfully
>
```

Step 2 Configure the IP address of the event interface.

The event interface can be on a separate network from the management interface, or on the same network.

a) Configure the IPv4 address:

configure network ipv4 manual *ip_address netmask gateway_ip* **management1**

Note that the *gateway_ip* in this command is used to create the default route for the device, so you should enter the value you already set for the management0 interface. It does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you create a static route separately for the event-only interface.

Example:

```
> configure network ipv4 manual 10.10.10.45 255.255.255.0 10.10.10.1 management1
Setting IPv4 network configuration.
Network settings changed.
>
```

b) Configure the IPv6 address:

- Stateless autoconfiguration:

  configure network ipv6 router management1

  Example:

  ```
  > configure network ipv6 router management1
  Setting IPv6 network configuration.
  Network settings changed.
  >
  ```

- Manual configuration:

  configure network ipv6 manual *ip6_address ip6_prefix_length* **management1**

  Example:

  ```
  > configure network ipv6 manual 2001:0DB8:BA98::3210 64 management1
  Setting IPv6 network configuration.
  ```

```
Network settings changed.
>
```

Step 3 Add a static route for the event-only interface if the Firewall Management Center is on a remote network; otherwise, all traffic will match the default route through the management interface.

configure network static-routes { **ipv4** | **ipv6** } **add management1** *destination_ip netmask_or_prefix gateway_ip*

For the *default* route, do not use this command; you can only change the default route gateway IP address when you use the **configure network ipv4** or **ipv6** commands (see, Step 2, on page 29).

Example:

```
> configure network static-routes ipv4 add management1 192.168.6.0 255.255.255.0 10.10.10.1
Configuration updated successfully
> configure network static-routes ipv6 add management1 2001:0DB8:AA89::5110 64
2001:0DB8:BA98::3211
Configuration updated successfully
>
```

To display static routes, enter **show network-static-routes** (the default route is not shown):

```
> show network-static-routes

                        ---------------[ IPv4 Static Routes ]---------------
Interface                 : management1
Destination               : 192.168.6.0
Gateway                   : 10.10.10.1
Netmask                   : 255.255.255.0
[…]
```

Device registration management

Register and unregister devices to the Firewall Management Center.

About the device management page

The **Devices** > **Device Management** page provides you with range of information and options.

- **View By**—View devices based on group, licenses, model, version, or access control policy.
- **Device State**—View devices based on state (**Error**, **Warning**, etc.). You can click on a state icon to view the devices belonging to it. The number of devices belonging to the states are provided within brackets.
- **Search Device**—Search for a device by device name, host name, or IP address.
- **Add**—Add devices and other manageable components.
- Columns—Click the column head to sort by that column.

- **Name**
- **Model**
- **Version**
- **Chassis**—For supported models, click **Manage** to bring up the integrated Chassis Manager. For the Firepower 4100/9300, the link cross-launches the Firewall Chassis Manager.
- **Licenses**
- **Access Control Policy**—Click on the link in the Access Control Policy column to view the policy that is deployed to the device.
- **Auto-Rollback**—Shows whether auto-rollback of the configuration is enabled ( ) or disabled) if the deployment causes the management connection to go down. See Edit deployment settings, on page 800.

- **Edit**—For each device, use the **Edit** ( ) icon to edit the device settings.

  You can also just click on the device name or IP address.

- **More**—For each device, click the **More** ( ) icon to execute other actions:
  - **Delete**—To unregister the device.
  - **Packet Tracer**—To navigate to the packet tracer page for examining policy configuration on the device by injecting a model packet into the system.
  - **Packet Capture**—To navigate to the packet capture page, where, you can view the verdicts and actions the system takes while processing a packet.
  - **Revert Upgrade**—To revert the upgrade and configuration changes that were made after the last upgrade. This action results in restoring the device to the version that was before the upgrade.
  - **Health Monitor**—To navigate to the device's health monitoring page.
  - **Troubleshoot Files**—Generate troubleshooting files, where you can choose the type of data to be included in the report.

Add a Device Group

The Firewall Management Center allows you to group devices so you can easily deploy policies and install updates on multiple devices. You can expand and collapse the list of devices in the group.

If you add the primary device in a high-availability pair to a group, both devices are added to the group. If you break the high-availability pair, both devices remain in that group.

Groups are not supported in a multidomain environment.

Procedure

Step 1 Choose **Devices** > **Device Management** .

Step 2 From the **Add** drop-down menu, choose **Add Group** .

To edit an existing group, click **Edit** ( ) for the group you want to edit.

Step 3 Enter a **Name** .

Step 4 Under **Available Devices** , choose one or more devices to add to the device group. Use Ctrl or Shift while clicking to choose multiple devices.

Step 5 Click **Add** to include the devices you chose in the device group.

Step 6 Optionally, to remove a device from the device group, click **Delete** ( ) next to the device you want to remove.

Step 7 Click **OK** to add the device group.

Registration with the management center

Registration with the Firewall Management Center is a process that establishes communication and management between devices and the central management platform.

Available registration methods

The Firewall Management Center offers multiple methods to register your devices.

Add a Device Using a Registration Key

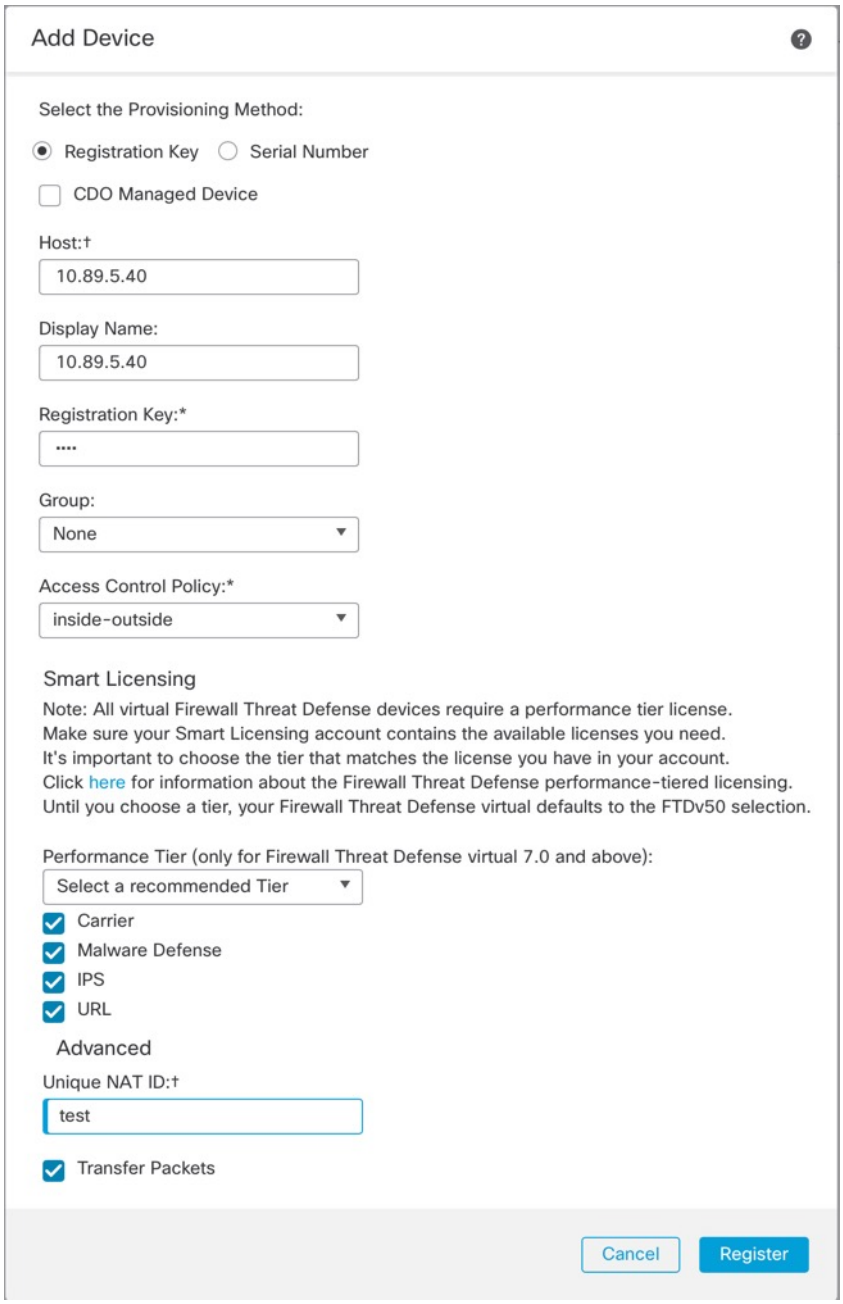
Use this procedure to add a single device to the Firewall Management Center using a registration key . If you plan to link devices for high availability, you must still use this procedure ; see Add a high availability pair, on page 306 . For clustering, see the clustering chapter for your model.

You can also use this procedure to add a device that is managed by a Cloud-Delivered Firewall Management Center , and you want to use the on-prem Firewall Management Center for event logging and analytics purposes only.

If you use Firewall Management Center high availability, add devices *only* to the active Firewall Management Center. Devices registered to the active Firewall Management Center are automatically registered to the standby.

Before you begin

- Set up the device to be managed by the Firewall Management Center. See:
  - Complete the Firewall Threat Defense initial configuration for manual registration, on page 15
  - The getting started guide for your model
- The Firewall Management Center must be registered to the Smart Software Manager. A valid evaluation license is sufficient, but if it expires, you will not be able to add new devices until you successfully register.
- If you registered a device using IPv4 and want to convert it to IPv6, you must delete and reregister the device.



Procedure

Step 1 Choose **Devices** > **Device Management** .

Step 2 From the **Add** drop-down menu, choose **Device** .

The **Registration Key** method is selected by default.

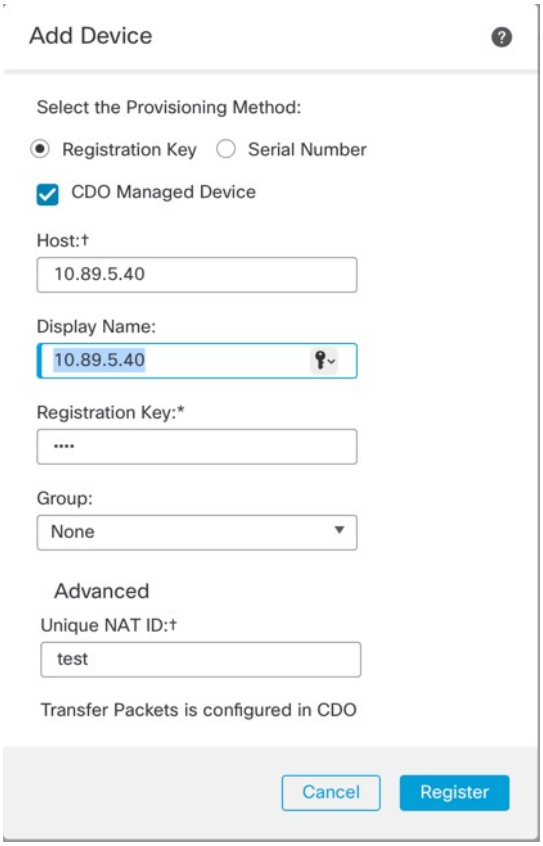


Figure 9: Add Device Using a Registration Key

Step 3 If you want to add a cloud-managed device to your on-prem Firewall Management Center for analytics only, check **CDO Managed Device** .

The system hides licensing and packet transfer settings because they are managed by Security Cloud Control (formerly CDO). You can skip those steps.

Figure 10: Add Device for Security Cloud Control

Step 4 For the **Host** , enter the IP address or the hostname of the device you want to add. Leave this field blank if you don't know the device IP address (for example, it's behind NAT).

If you leave this field blank, the initial configuration on the device needs to include a reachable Firewall Management Center IP address or hostname plus the NAT ID. For more information, see NAT environments, on page 8 .

Step 5 For the **Display Name** , enter a name for the device as you want it to display in the Firewall Management Center . You cannot change this name later.

Step 6 For the **Registration Key** , enter the same registration key in your initial configuration. The registration key is a one-time-use shared secret. The key can be up to 37-characters in length and include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). The registration key does not need to be unique per device. Add the device to a device **Group**.

Step 7 Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If the device is incompatible with the policy you choose, deploying will fail. This incompatibility could occur for multiple reasons, including licensing mismatches, model restrictions, passive vs inline issues, and other

misconfigurations. After you resolve the issue that caused the failure, manually deploy configurations to the device.

Step 8 Choose licenses to apply to the device.

You can also apply licenses after you add the device, from the **System** (⚙) > **Licenses** > **Smart Licenses** page.

For Firewall Threat Defense Virtual , you must also select the **Performance Tier** . It's important to choose the tier that matches the license you have in your account. Until you choose a tier, your device defaults to the FTDv50 selection. For more information about the performance-tiered license entitlements available for Firewall Threat Defense Virtual , see *FTDv Licenses* in the *Cisco Secure Firewall Management Center Administration Guide* .

Note If you are upgrading your Firewall Threat Defense Virtual to Version 7.0+, you can choose **FTDv - Variable** to maintain your current license compliance.

If you specified a NAT ID during initial configuration, in the **Advanced** section enter the same NAT ID for the **Unique NAT ID**.

The **Unique NAT ID** specifies a unique, one-time string of your choice that you will also specify on the device during initial configuration. It is required when one side does not specify a reachable IP address or hostname, for example if you left the **Host** field blank. Although technically optional, we recommend always specifying the NAT ID even when you know the IP addresses of both sides because it is required in certain situations. The ID can be up to 37-characters in length and include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the Firewall Management Center .

Step 9 Select the **Transfer Packets** check box to allow the device to transfer event metadata and packet data associated with intrusion events to the Firewall Management Center.

This option is enabled by default. The transferred packet data is used for intrusion-event analysis. It does not necessarily contain the complete original packet as transmitted on the wire or the complete traffic session. For intrusion events generated by Snort inspection, the device can transfer only the Protocol Data Unit (PDU) or packet content associated with the intrusion-rule match.

If you disable this option, the device sends only event information to the Firewall Management Center; packet data is not sent. Click **Register**.

It may take up to two minutes for the Firewall Management Center to verify the device's heartbeat and establish communication. If the registration succeeds, the device is added to the list. If it fails, you will see an error message. If the device fails to register, check the following items:

- Ping—Access the device CLI, and ping the Firewall Management Center IP address using the following command:

  ping system *ip_address*

  If the ping is not successful, check your network settings using the **show network** command. If you need to change the device IP address, use the **configure network** { **ipv4** | **ipv6** } **manual** command.

- Registration key, NAT ID, and Firewall Management Center IP address—Make sure you are using the same registration key, and if used, NAT ID, on both devices. You can set the registration key and NAT ID on the device using the **configure manager add** command.

For more troubleshooting information, see https://cisco.com/go/fmc-reg-error .

What to do next

Add a Device Using the Serial Number (Zero-Touch Provisioning)

Zero-Touch Provisioning lets you register devices to the Firewall Management Center by serial number without having to perform any initial setup on the device. The Firewall Management Center integrates with Security Cloud Control for this functionality.

When you use zero-touch provisioning , the following interfaces are preconfigured. Note that other settings, such as the DHCP server on inside, access control policy, or security zones, are not configured.

- Ethernet 1/1—"outside", IP address from DHCP, IPv6 autoconfiguration
- Ethernet 1/2 (or for the Firepower 1010, the VLAN1 interface) — "inside", 192.168.95.1/24
- Default route—Obtained through DHCP on the outside interface

Zero-Touch Provisioning is not supported with clustering or multi-instance mode.

High availability is only supported when you use the Management interface because zero-touch provisioning uses DHCP, which is not supported for data interfaces and high availability.

Zero-Touch Provisioning is only supported on the following models using 7.2, 7.4 or later (prior to 7.2.4, the Firewall Management Center must be publicly reachable):

- Firepower 1010
- Firepower 1100
- Firepower 2100
- Secure Firewall 3100

Before you begin

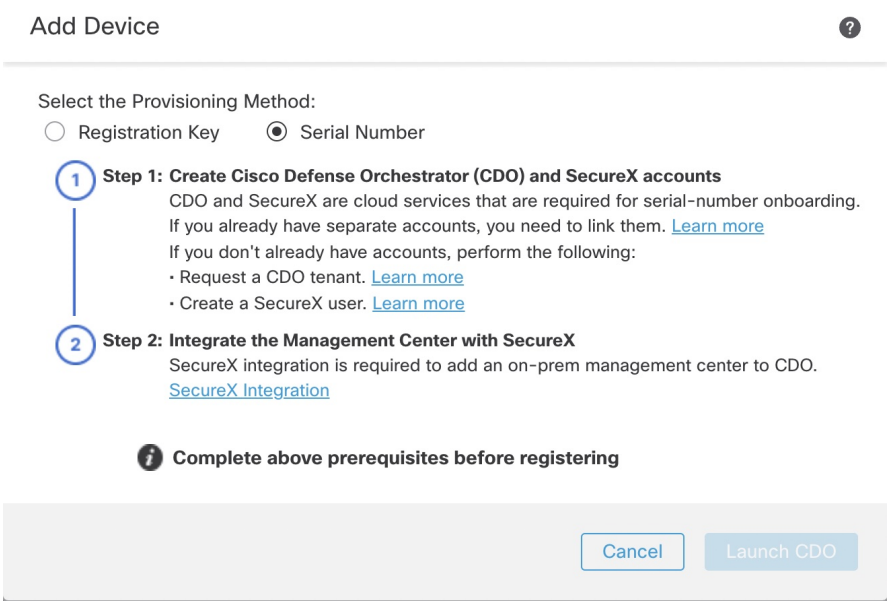
- Make sure the device is unconfigured or a fresh install. Zero-Touch Provisioning is meant for new devices only. Pre-configuration can disable zero-touch provisioning , depending on your settings.
- Cable the outside interface or Management interface so it can reach the internet. If you use the outside interface for zero-touch provisioning , do not also cable the Management interface; if the Management interface gets an IP address from DHCP, the routing will be incorrect for the outside interface.
- Make sure you have at least one access control policy configured on the Firewall Management Center so you can assign it to new devices. You cannot add a policy using Security Cloud Control .
- If the device does not have a public IP address or FQDN, or you use the Management interface, set a public IP address/FQDN for the Firewall Management Center (if different from the Firewall Management Center management interface IP address; for example, it is behind NAT) so the device can initiate the management connection. See **System** > **Configuration** > **Manager Remote Access** . You can also configure the public IP address/FQDN in Security Cloud Control during this procedure.
- DHCP server for either Management or Ethernet 1/1 that provides an IP address and default gateway.

- Network access to the OpenDNS public DNS servers. IPv4: 208.67.220.220 and 208.67.222.222; IPv6: 2620:119:35::35. DNS servers obtained from DHCP are never used.

  The following names need to be resolved:

  Table 2: FQDNs for zero-touch provisioning

FQDNs
*.cisco.com (many FQDNs)
*.defenseorchestrator.com (many FQDNs)
*.defenseorchestrator.eu (for the EU, many FQDNs)
0.sourcefire.pool.ntp.org, 1.sourcefire.pool.ntp.org, 2.sourcefire.pool.ntp.org
1.200.159.162.in-addr.arpa
60.19.239.178.in-addr.arpa
connected.by.freedominter.net
time.cloudflare.com
udc.neo4j.org



- The Firewall Management Center must be registered to the Smart Software Manager. A valid evaluation license is sufficient, but if it expires, you will not be able to add new devices until you successfully register.
- If you registered a device using IPv4 and want to convert it to IPv6, you must delete and reregister the device.

Procedure

Step 1 The first time you add a device using a serial number, you need to complete the following prerequisites. After the first time, you can skip to adding the devices directly in Security Cloud Control .

a) In the Firewall Management Center , choose **Devices** > **Device Management** .
b) From the **Add** drop-down menu, choose **Device** .
c) Click **Serial Number** for the provisioning method.

Figure 11: Add Device by Serial Number

d) Create a Security Cloud Control account.

Note If you already have preexisting but separate SecureX and Security Cloud Control accounts, you need to link them. See https://cisco.com/go/cdo-securex-link for more information about linking accounts.

If you don't already have accounts, perform the following:

- Create a Cisco Security Cloud (formerly SecureX) account. See the Security Cloud Control documentation for information about how to create one.
- Request a Security Cloud Control tenant. See the Security Cloud Control documentation for information about requesting a new Security Cloud Control tenant.

e) Integrate the Firewall Management Center with Cisco Security Cloud (formerly SecureX). Click the link to open the **SecureX Integration** page in the Firewall Management Center .

Click the **Enable SecureX** to open a separate browser tab to log you into your Cisco Security Cloud account and confirm the displayed code. Make sure this page is not blocked by a pop-up blocker.

For detailed information, see the "Enable SecureX Integration " section in the *Cisco Secure Firewall Management Center Administration Guide* .

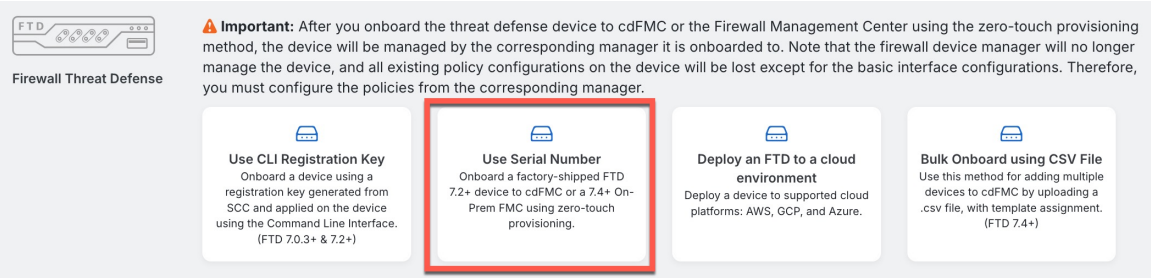
Security Cloud Control onboards the on-prem Firewall Management Center after you integrate the Firewall Management Center with Cisco Security Cloud. Security Cloud Control needs the Firewall Management Center in its inventory for zero-touch provisioning to operate. Security Cloud Control 's Firewall Management Center support is limited to device onboarding, viewing its managed devices, viewing objects associated with the Firewall Management Center , and cross-launching the Firewall Management Center .

Note For a Firewall Management Center high-availability pair, you also need to integrate the secondary Firewall Management Center with Cisco Security Cloud.

f) Click **Launch** Security Cloud Control if you do not already have it open, or log in here: https://www.defenseorchestrator.com/ .

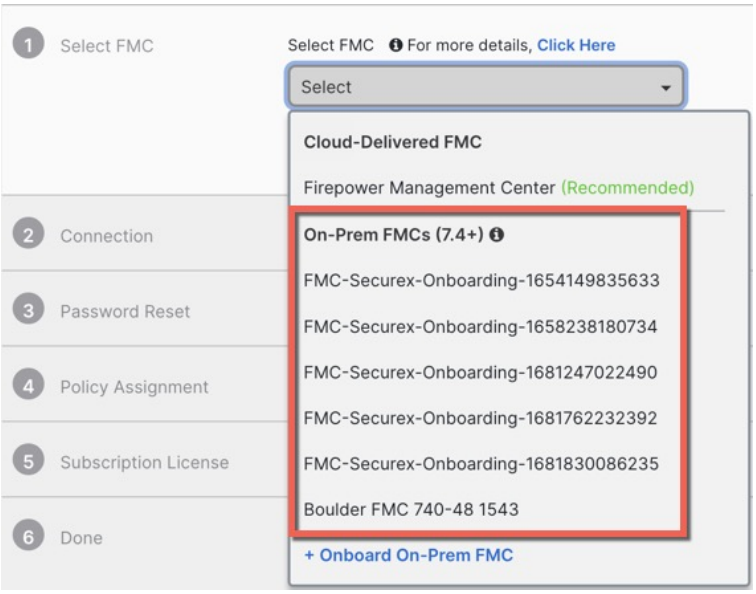
Make sure Security Cloud Control is not blocked by a pop-up blocker.

Step 2 On the Security Cloud Control **Dashboard** (https://www.defenseorchestrator.com/), click **Onboard** (+ Onboard).



Click the **FTD** tile.

Figure 12: FTD Tile



Step 3 On the **Onboard FTD Device** screen, click **Use Serial Number** .

Figure 13: Use Serial Number

Step 4 In **Select FMC** , choose an **On-Prem FMC** from the list, and click **Next** .

Figure 14: Select FMC

If the Firewall Management Center has a public IP address or FQDN set, it will show after you choose it.

Figure 15: Public IP Address/FQDN

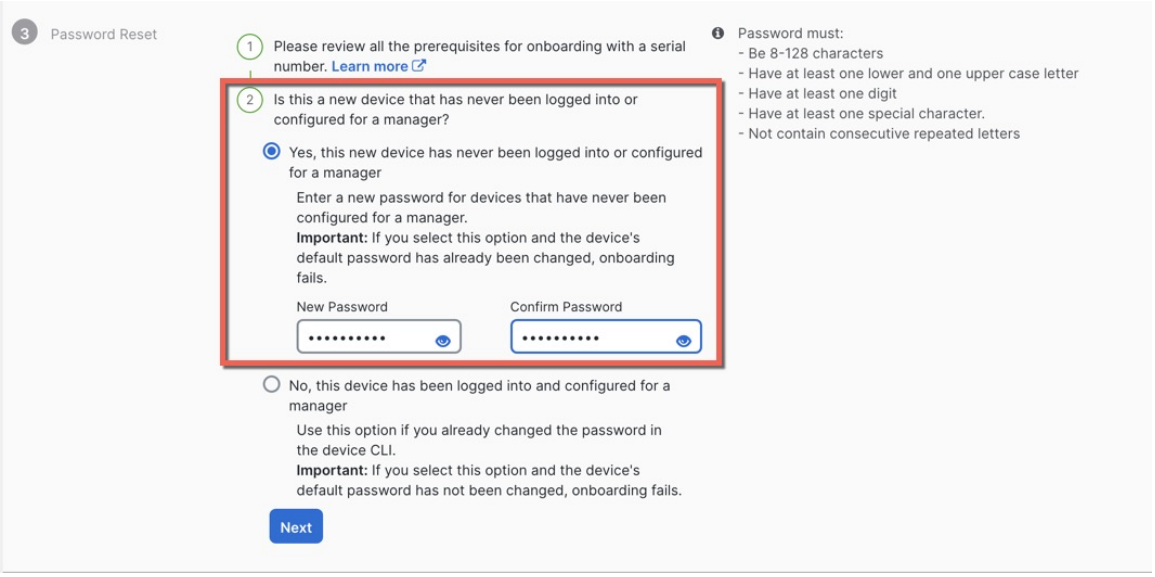
The Firewall Management Center needs a public IP address/FQDN if the device does not have a public IP address/FQDN or if you use the Management interface for zero-touch provisioning . You can set the Firewall Management Center public IP address/FQDN by clicking the **FMC Public IP** link. You see the following dialog box.

Figure 16: Configure FMC Public IP/FQDN

Note For a Firewall Management Center high-availability pair, you also need to set the public IP address/FQDN on the secondary Firewall Management Center . You can't set value this using Security Cloud Control ; you need to set it in the secondary Firewall Management Center . See **System** > > **Configuration** > **Manager Remote Access** .

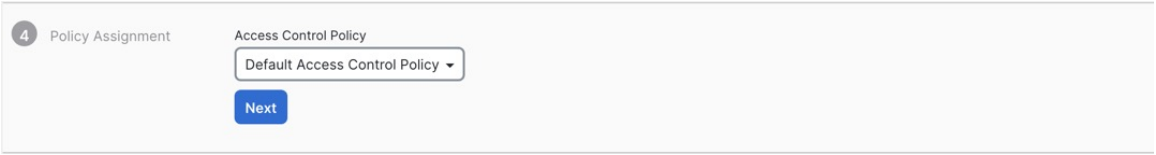
Step 5 In **Connection** , enter the device's serial number and device name. Click **Next** .

Figure 17: Connection



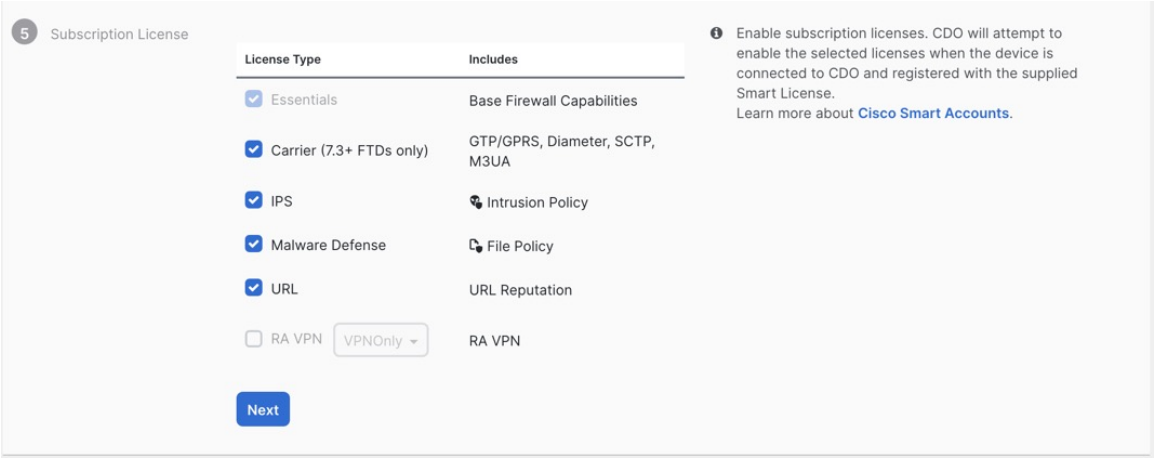
Step 6 In **Password Reset** , click **Yes...** . Enter a new password and confirm the new password for the device, then click **Next** .

For zero-touch provisioning , the device must be brand new or has been reimaged.



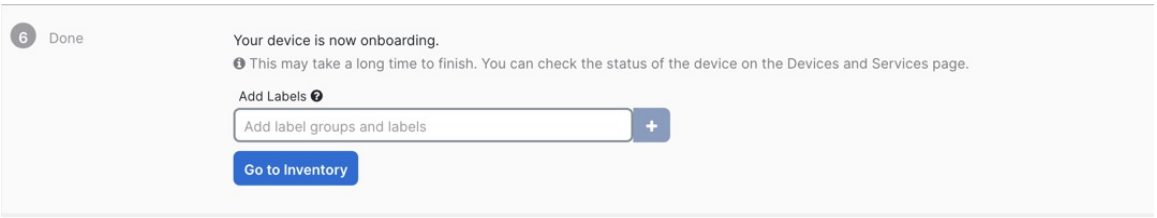
Note If you did log into the device and reset the password, and you did not change the configuration in a way that would disable zero-touch provisioning , then you should choose the **No...** option. There are a number of configurations that disable zero-touch provisioning , so we don't recommend logging into the device unless you need to, for example, to perform a reimage.

Figure 18: Password Reset



Step 7 In **Policy Assignment** , use the drop-down menu to select an access control policy for the device. If you have not added a policy on the Firewall Management Center , you should go to the Firewall Management Center and add one now. Click **Next** .

Figure 19: Policy Assignment



Step 8 In **Subscription License** , select the licenses for the device. Click **Next** .

Figure 20: Subscription License

Step 9 In **Done** , you can add labels to the device that show in Security Cloud Control ; they are not used on the Firewall Management Center .

Figure 21: Done

In the Firewall Management Center , the device is added to the **Device Management** page. You can also click **Go to Inventory** to see the devices in Security Cloud Control . On-prem Firewall Management Center devices are viewable in Security Cloud Control inventory for information purposes.

When using zero-touch provisioning on the outside interface, Security Cloud Control acts as a DDNS provider and does the following:

- Enables DDNS on outside using the "fmcOnly" method. This method is only supported for zero-touch provisioning devices.
- Maps the outside IP address with the following hostname: *serial-number* **.local** .

- Provides the IP address/hostname mapping to the Firewall Management Center so it can resolve the hostname to the correct IP address.
- Informs the Firewall Management Center if the IP address ever changes, for example, if the DHCP lease renews.

If you use zero-touch provisioning on the Management interface, DDNS is not supported. The Firewall Management Center must be publicly reachable so the device can initiate the management connection.

You can continue to use Security Cloud Control as the DDNS provider, or you can later change the DDNS configuration in the Firewall Management Center to a different method. See Configure Dynamic DNS, on page 838 for more information.

If the device fails to register, see Resolve serial number (zero-touch provisioning) registration issues, on page 47 .

Add a chassis

This task allows you to add a Firepower 4100/9300 chassis to the Firewall Management Center for chassis-level health monitoring and management.

You can add a Firepower 4100/9300 chassis to the Firewall Management Center. The management center and the chassis share a separate management connection using the chassis MGMT interface. The Firewall Management Center offers chassis-level health alerts. For configuration, you still need to use the Secure Firewall Chassis Manager or FXOS CLI.

Note For other models that support multi-instance mode, the manager configuration is completed as part of the conversion to multi-instance mode. See Enable multi-instance mode, on page 175. After you enable multi-instance mode, see Add a multi-instance chassis to the Firewall Management Center, on page 177.

Procedure

Step 1 Connect to the chassis FXOS CLI, either using the console port or SSH.

Step 2 Configure the Firewall Management Center.

create device-manager *manager_name* [**hostname** {*hostname* | *ipv4_address* | *ipv6_address*}] [**NAT-ID** *nat_id*]

You are prompted for the registration key.

You can enter this command from any scope. This command is accepted immediately without using **commit-buffer**.

- **hostname** {*hostname* | *ipv4_address* | *ipv6_address*}—Specifies either the FQDN or IP address of the Firewall Management Center. At least one of the devices, either the Firewall Management Center or the chassis, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices. If you do not specify a **hostname**, then the chassis must have a reachable IP address or hostname and you must specify the **NAT-ID**.

- **NAT-ID** *nat_id*—Specifies a unique, one-time string of your choice that you will also specify on the Firewall Management Center when you register the chassis when one side does not specify a reachable IP address or hostname. It is required if you do not specify a **hostname**, however we recommend that you always set the NAT ID even when you specify a hostname or IP address. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the Firewall Management Center.
- **Registration Key:** *reg_key*—You will be prompted for a one-time registration key of your choice that you will also specify on the Firewall Management Center when you register the chassis. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).

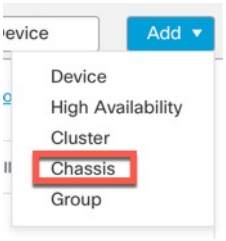
Example:

```
firepower# create device-manager boulder_fmc hostname 10.89.5.35 nat-id 93002
(Valid registration key characters: [a-z],[A-Z],[0-9],[-]. Length: [2-36])
Registration Key: Impala67
```

Step 3 In the Firewall Management Center, add the chassis using the chassis management IP address or hostname.

a) Choose **Devices** > **Device Management**, and then from **Add** drop-down list, choose **Chassis**.

Figure 22: Add chassis



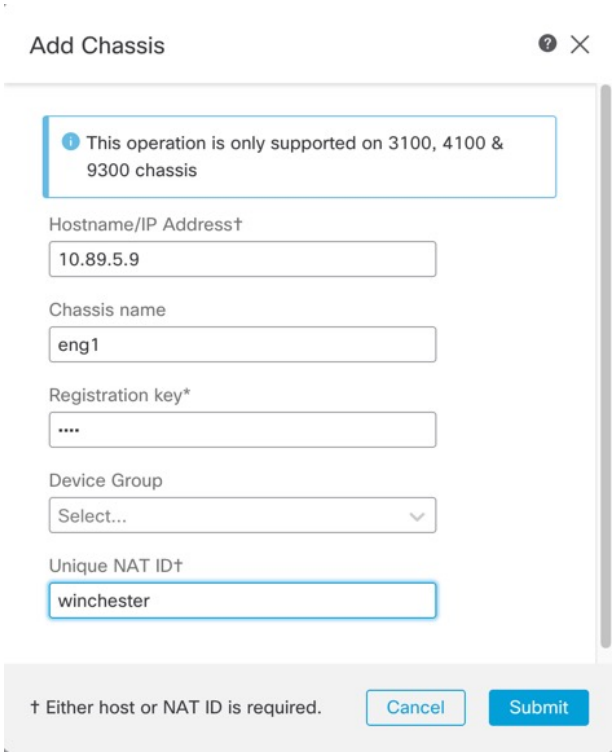


Figure 23: Add chassis

b) In the **Hostname/IP Address** field, enter the IP address or the hostname of the chassis you want to add.

If you don't know the hostname or IP address, you can leave this field blank specify the **Unique NAT ID**.

c) In the **Chassis Name** field, enter a name for the chassis as you want it to display in the Firewall Management Center.

d) In the **Registration Key** field, enter the same registration key that you used when you configured the chassis to be managed by the Firewall Management Center.

The registration key is a one-time-use shared secret. The key can include alphanumeric characters and hyphens (-).

e) In a multidomain deployment, regardless of your current domain, assign the chassis to a leaf **Domain**.

If your current domain is a leaf domain, the chassis is automatically added to the current domain. If your current domain is not a leaf domain, post-registration, you must switch to the leaf domain to configure the chassis. A chassis can only belong to one domain.

f) (Optional) Add the chassis to a **Device Group**.

g) If you used a NAT ID during chassis setup, expand enter the same NAT ID in the **Unique NAT ID** field.

The NAT ID can include alphanumeric characters and hyphens (-).

h) Click **Submit**.

The chassis is added to the **Devices** > **Device Management** page.

The chassis is successfully registered with the Firewall Management Center and appears in the device management interface for monitoring and management.

Register with a new management center

This procedure shows how to register with a new Firewall Management Center . You should perform these steps even if the new Firewall Management Center uses the old Firewall Management Center 's IP address.

Procedure

Step 1 On the old Firewall Management Center , if present, delete the managed device. See Delete (Unregister) a Device from the Firewall Management Center , on page 54 .

You cannot change the Firewall Management Center IP address if you have an active connection with the Firewall Management Center .

Step 2 Connect to the device CLI, for example using SSH.

Step 3 Configure the new Firewall Management Center .

configure manager add { *hostname* | *IPv4_address* | *IPv6_address* | **DONTRESOLVE** } *regkey* [*nat_id*] [*display_name*]

- { *hostname* | *IPv4_address* | *IPv6_address* }—Sets the Firewall Management Center hostname, IPv4 address, or IPv6 address.
- **DONTRESOLVE** —If the Firewall Management Center is not directly addressable, use **DONTRESOLVE** instead of a hostname or IP address. If you use **DONTRESOLVE** , then a *nat_id* is required. When you add this device to the Firewall Management Center , make sure that you specify both the device IP address and the *nat_id* ; one side of the connection needs to specify an IP address, and both sides need to specify the same, unique NAT ID.
- *regkey* —Make up a registration key to be shared between the Firewall Management Center and the device during registration. You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the Firewall Management Center when you add the Firewall Threat Defense .
- *nat_id* —Make up an alphanumeric string from 1 to 37 characters used only during the registration process between the Firewall Management Center and the device when one side does not specify an IP address. This NAT ID is a one-time password used only during registration. Make sure the NAT ID is unique, and not used by any other devices awaiting registration. Specify the same NAT ID on the Firewall Management Center when you add the Firewall Threat Defense .
- *display_name* —Provide a display name for showing this manager with the **show managers** command. This option is useful if you are identifying Security Cloud Control as the primary manager and an on-prem Firewall Management Center for analytics only. If you don't specify this argument, the firewall auto-generates a display name using one of the following methods:
  - *hostname* | *IP_address* (if you don't use the **DONTRESOLVE** keyword)
  - **manager-** *timestamp*

Example:

```
> configure manager add DONTRESOLVE abc123 efg456
Manager successfully configured.
Please make note of reg_key as this will be required while adding Device in FMC.
>
```

Step 4 Add the device to the Firewall Management Center.

Resolve serial number (zero-touch provisioning) registration issues

If the device fails to register using the serial number after 2-3 minutes, see the common causes for failure. If you have physical access to the device, Check the LED status, on page 48

If you want to bypass any serial number troubleshooting, you can always use Add a Device Using a Registration Key , on page 32.

For other requirements for serial number registration, see Add a Device Using the Serial Number (Zero-Touch Provisioning) , on page 36.

"Waiting for Device to come Online" in Firewall Management Center

- **Cause**: You performed initial configuration at the CLI and unintentionally disabled zero-touch provisioning.

  Workaround: See Delete the Configured Manager at the CLI to Re-Enable Zero-Touch Provisioning, on page 50.

- **Cause**: You performed initial configuration in the Firewall Device Manager and disabled zero-touch provisioning.

  Workaround: See Restart Zero-Touch Provisioning Using the Firewall Device Manager, on page 50.

- **Cause**: Zero-Touch Provisioning is disabled, and you don't have access to the CLI.

  Workaround: See Reset the Device, on page 52.

"A device with serial number <serial-number> already exists in the Security Cloud Control tenant" in Firewall Management Center

Cause: The serial number was already claimed by another manager in your tenant.

Workaround: If you already unregistered the device or you're unsure which Firewall Management Center has claimed it, then see Check for Changes in Security Cloud Control, on page 51. If the Firewall Management Center is offline, and you need to remove its claim, see Remove a Serial-Number Claim at the CLI, on page 48.

Note If there is an active Firewall Management Center management connection, you cannot remove the claim from the current manager.

"A device with serial number <serial-number> already exists in another Security Cloud Control tenant" in Firewall Management Center

Cause: The serial number was already claimed by another manager in another tenant.

Workaround: See Remove a Serial-Number Claim at the CLI, on page 48.

Note If there is an active Firewall Management Center management connection, you cannot remove the claim from the current manager.

Check the LED status

The LED status tells you about zero-touch provisioning readiness.

Firepower 1010, 1100

Table 3: Zero-Touch Provisioning: System (S) LED behavior

S LED	Description	Time after firewall powered on (minutes:seconds)
Slow flashing green	Connected to the Cisco cloud and ready for onboarding	15:00 - 30:00
Alternating green and amber (error condition)	Failed to connect to the Cisco cloud	15:00 - 30:00

Secure Firewall 1200, 3100

Table 4: Zero-Touch Provisioning: Managed (M) LED behavior

M LED	Description	Time after firewall powered on (minutes:seconds)
Slow flashing green	Connected to the Cisco cloud and ready for onboarding	15:00 - 30:00
Alternating green and amber (error condition)	Failed to connect to the Cisco cloud	15:00 - 30:00
Solid green	Onboarded	20:00 - 45:00

Remove a Serial-Number Claim at the CLI

If the device was claimed previously, but the management connection is not active, you can clear the claim. In the Firewall Management Center , you will see an error message such as **A device with serial number <serial-number> already exists in the Security Cloud Control tenant**.

Note If there is an active Firewall Management Center management connection, you cannot remove the claim from the current manager.

Procedure

Step 1 Connect to the FXOS CLI using SSH or the console port. See Log into the Command-Line Interface on the device, on page 13 for more information.

If you used SSH, you connect to the Firewall Threat Defense CLI. In this case, enter **connect fxos** .

Note If you are accessing the Firewall Threat Defense CLI for the first time and have to run through the setup script, answer **n** when prompted: `Do you want to configure IPv4? (y/n) [y]:` and `Do you want to configure IPv6? (y/n) [y]:` . You also must accept the default local manager: `Manage the device locally? (yes/no) [yes]:` . These settings will preserve zero-touch provisioning capability.

If you used the console port, you connect directly to FXOS.

If this is the first time you connect to the CLI using either SSH or the console, you are prompted to change the password. For zero-touch provisioning when you onboard the device, for the **Password Reset** area, be sure to choose **No** because you already set the password.

```
> connect fxos
firepower#
```

Step 2 Enter local management.

connect local-mgmt

```
firepower# connect local-mgmt
firepower(local-mgmt)#
```

Step 3 Deregister the device from the Cisco cloud.

cloud deregister

```
firepower(local-mgmt)# cloud deregister
Release Image Detected RESULT=success MESSAGE=SUCCESS 10, X-Flow-Id:
2b3c9e8b-76c3-4764-91e4-cfd9828e73f9
```

Step 4 Erase the configuration to restore cloud connectivity.

erase configuration

```
firepower(local-mgmt)# erase configuration
All configurations will be erased and system will reboot. Are you sure? (yes/no):yes
Removing all the configuration. Please wait....
Configurations are cleaned up. Rebooting....
```

What to do next

-

Delete the Configured Manager at the CLI to Re-Enable Zero-Touch Provisioning

-

If you performed initial CLI setup and set the device to remote management, you can re-enable zero-touch provisioning by deleting the manager and re-adding the local manager. This setting doesn't mean you are intending to use the local manager; it just restores functionality required for zero-touch provisioning . Even if you set the manager to local, if you logged into Firewall Device Manager and completed initial setup, you may have disabled zero-touch provisioning . Deleting and re-adding the local manager will restore zero-touch provisioning .

Note You can only delete the manager if there is no current Firewall Management Center management connection.

Before you begin

-

Procedure

Step 1 Check the management status.

show managers

```
> show managers
No managers configured.
```

In this case, you opted for remote management but did not configure a Firewall Management Center . You need to set the manager to local.

```
> show managers
Managed locally.
```

This output shows you are already running the local manager. Even in this case, deleting the manager restores necessary services for zero-touch provisioning .

Step 2 Delete the manager.

configure manager delete

Step 3 Add the local manager.

configure manager local

What to do next

-

Restart Zero-Touch Provisioning Using the Firewall Device Manager

You can unintentionally disable low-touch provisioning if you log into the Firewall Device Manager and complete the initial setup in Firewall Device Manager . In this case, you can restart zero-touch provisioning

within the Firewall Device Manager . If you have access to the CLI, you can alternatively Delete the Configured Manager at the CLI to Re-Enable Zero-Touch Provisioning, on page 50 .

Procedure

Step 1 In the Firewall Device Manager , click **Device** , then click the **System Settings** > **Cloud Services** .

Step 2 Check **Auto-enroll with** Security Cloud Control **or Secure Firewall Management Center** .

Step 3 Click **Register** .

Check for Changes in Security Cloud Control

If you unregister the device from a Firewall Management Center , the claim on the serial number should be removed automatically. However, in rare cases if the claim is still active, you can force Security Cloud Control to remove the device from your inventory.

Before you begin

-

Procedure

Step 1 Log into Security Cloud Control at https://security.cisco.com.

Step 2 Choose **Security Devices** , and then search for your serial number.

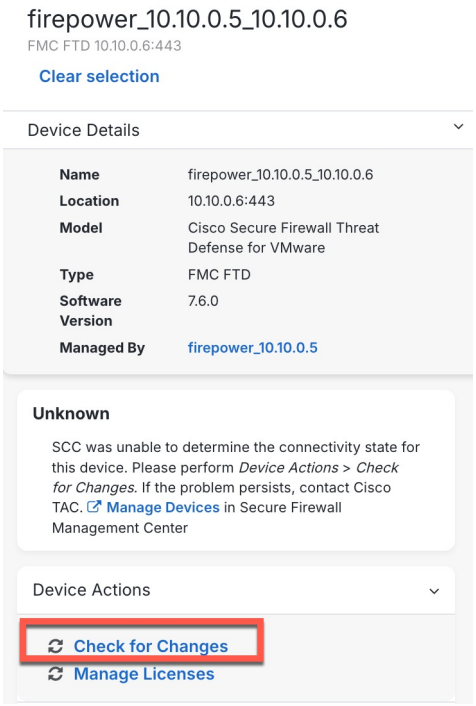

Figure 24: Search by Serial Number

If the device did not appear in the search results, it may be registered to a different tenant. In this case, see Remove a Serial-Number Claim at the CLI, on page 48.

Step 3 Select the device and click **Check for Changes** on the right.

Figure 25: Check for Changes

If the device was unregistered, it will disappear from the list and the device will attempt to connect to the cloud again.

If the device does not disappear, that means it's registered to another manager in the tenant. The name of the device includes the manager it is registered to, for example, **firepower_10.89.5.36**_1010-1. If you still want to register the device to a different manager, and you don't have access to the Firewall Management Center to unregister it, you can Remove a Serial-Number Claim at the CLI, on page 48 , but only if there is not an active management connection.

Reset the Device

Supported for the following models:

- Firepower 1010
- Firepower 1100
- Secure Firewall 3100

If you do not have access to the CLI and want to make sure your device is unconfigured and ready for zero-touch provisioning , reset the device to its default state.

Procedure

Step 1 Press the small, recessed Reset button for longer than five seconds.

See your hardware installation guide for more information. It can take a long time to start Firewall Threat Defense for the first time after a reset.

Step 2 Check the LED status, on page 48 to monitor when the device is zero-touch provisioning -ready.

Register with a new management center

This procedure shows how to register with a new Firewall Management Center . You should perform these steps even if the new Firewall Management Center uses the old Firewall Management Center 's IP address.

Procedure

Step 1 On the old Firewall Management Center , if present, delete the managed device. See Delete (Unregister) a Device from the Firewall Management Center , on page 54 .

You cannot change the Firewall Management Center IP address if you have an active connection with the Firewall Management Center .

Step 2 Connect to the device CLI, for example using SSH.

Step 3 Configure the new Firewall Management Center .

configure manager add { *hostname* | *IPv4_address* | *IPv6_address* | **DONTRESOLVE** } *regkey* [*nat_id*] [*display_name*]

- { *hostname* | *IPv4_address* | *IPv6_address* }—Sets the Firewall Management Center hostname, IPv4 address, or IPv6 address.
- **DONTRESOLVE** —If the Firewall Management Center is not directly addressable, use **DONTRESOLVE** instead of a hostname or IP address. If you use **DONTRESOLVE** , then a *nat_id* is required. When you add this device to the Firewall Management Center , make sure that you specify both the device IP address and the *nat_id* ; one side of the connection needs to specify an IP address, and both sides need to specify the same, unique NAT ID.
- *regkey* —Make up a registration key to be shared between the Firewall Management Center and the device during registration. You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the Firewall Management Center when you add the Firewall Threat Defense .
- *nat_id* —Make up an alphanumeric string from 1 to 37 characters used only during the registration process between the Firewall Management Center and the device when one side does not specify an IP address. This NAT ID is a one-time password used only during registration. Make sure the NAT ID is unique, and not used by any other devices awaiting registration. Specify the same NAT ID on the Firewall Management Center when you add the Firewall Threat Defense .
- *display_name* —Provide a display name for showing this manager with the **show managers** command. This option is useful if you are identifying Security Cloud Control as the primary manager and an on-prem Firewall Management Center for analytics only. If you don't specify this argument, the firewall auto-generates a display name using one of the following methods:
  - *hostname* | *IP_address* (if you don't use the **DONTRESOLVE** keyword)

- **manager-** *timestamp*

Example:

```
> configure manager add DONTRESOLVE abc123 efg456
Manager successfully configured.
Please make note of reg_key as this will be required while adding Device in FMC.
>
```

Step 4 Add the device to the Firewall Management Center.

Delete (Unregister) a Device from the Firewall Management Center

If you no longer want to manage a device, you can unregister it from the Firewall Management Center .

To unregister a cluster, cluster node, or high availability pair, see the chapters for those deployments.

Unregistering a device:

- Severs all communication between the Firewall Management Center and the device.
- Removes the device from the **Device Management** page.
- Returns the device to local time management if the device's platform settings policy is configured to receive time from the Firewall Management Center using NTP.
- Leaves the configuration intact, so the device continues to process traffic.

  Policies, such as NAT and VPN, ACLs , and the interface configurations remain intact.

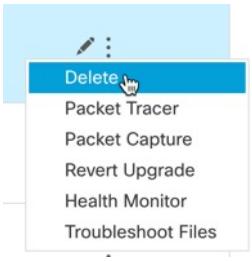
Registering the device again to the same or a different Firewall Management Center causes the configuration to be removed, so the device will stop processing traffic at that point.

Before you delete the device, be sure to export the configuration so you can re-apply the device-level configuration (interfaces, routing, and so on) when you re-register it. If you do not have a saved configuration , you will have to re-configure device settings.

After you re-add the device and either import a saved configuration or re-configure your settings, you need to deploy the configuration before it starts passing traffic again.

Before you begin

To re-apply the device-level configuration if you re-add it to the Firewall Management Center :



- Export the device configuration. See Export and import the device configuration, on page 751 .

Procedure

Step 1 Choose **Devices** > **Device Management** .

Step 2 Next to the device you want to unregister, click **More** (⋮) , and then click **Delete** .

Figure 26: Delete

Step 3 Confirm that you want to unregister the device.

Step 4 You can now change your manager.

- Re-register the device to this Firewall Management Center —If you know the registration key and NAT ID, refer to Add a Device Using a Registration Key , on page 32 . If you need to reset them, you can reconfigure the manager as though it's new. See Register with a new management center, on page 46 .
- Register to a new Firewall Management Center — Register with a new management center, on page 46 .
- Change to the Firewall Device Manager — Switch from Firewall Management Center to Firewall Device Manager , on page 65 .
- Delete the manager without specifying a new one—To sever the management connection on the Firewall Threat Defense without identifying a new manager (no manager mode), from the Firewall Threat Defense CLI use the **configure manager delete** command.

Shut down or restart the device

It's important that you shut down your system properly. Simply unplugging the power or pressing the power switch can cause serious file system damage. Remember that there are many processes running in the background all the time, and unplugging or shutting off the power does not allow the graceful shutdown of your firewall.

See the following task to shut down or restart your system properly.

Note After restarting your device, you may see an error that the management connection could not be reestablished. In some cases, the connection is attempted before the Management interface on the device is ready. The connection will be retried automatically and should come up within 15 minutes.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device that you want to restart, click **Edit** ( ) .

Step 3 Click **Device**.

Step 4 To restart the device:

a) Under **System**, click **Restart Device** ( ) .
b) When prompted, confirm that you want to restart the device.

Step 5 To shut down the device:

a) Under **System**, click **Shut Down Device** ( ) in the **System** section.
b) When prompted, confirm that you want to shut down the device.
c) If you have a console connection to the firewall, monitor the system prompts as the firewall shuts down. You will see the following prompt:

```
System is stopped.
It is safe to power off now.
Do you want to reboot instead? [y/N]
```

If you do not have a console connection, wait approximately 3 minutes to ensure the system has shut down.

For the ISA 3000, when shutdown is complete, the System LED will turn off. Wait at least 10 seconds before you remove the power.

Download the managed device list

You can download a report of all the managed devices.

Before you begin

To perform the following task, you must be an Admin user.

Procedure

Step 1 Choose **Devices** > **Device Management** .

Step 2 Click the **Download Device List Report** link.

Step 3 You can download the device list in CSV or PDF format. Choose **Download CSV** or **Download PDF** to download the report.

Migrate Firewall Threat Defense devices

The Secure Firewall Threat Defense model migration wizard enables you to migrate configurations from an earlier Firewall Threat Defense model. After the migration, all routing and interface configurations from the source Firewall Threat Defense device are available in the target Firewall Threat Defense.

Supported devices and capabilities

The wizard supports multiple models as source and target devices, for more information see Supported Devices for Migration, on page 57.

Supported Devices for Migration

Documents the supported migration paths and device compatibility for Cisco Firepower and Secure Firewall models.

License for Firewall Threat Defense migration

You must meet licensing requirements for Firewall Threat Defense migration.

- Your Smart Licensing account must have the license entitlements for the target device.
- You must register and enroll the device with the Smart Licensing account. The migration copies the source device licenses to the target device.

Prerequisites for migration

This reference provides comprehensive prerequisites that must be satisfied to successfully migrate configurations from a source device to a target device in Secure Firewall Management Center environments.

General device prerequisites

- Register the source and the target devices to the Firewall Management Center.
- Ensure that the target device is a newly registered device without any configurations.
- Source and target devices must be in the same state and modes:
  - Domain
  - Firewall mode: Routed or Transparent
  - Compliance mode (CC or UCAPL)
- Ensure that you have permission for modifications on the devices.
- Ensure that the configurations on the source device are valid and have no errors.
- Deployment, import, or export tasks must not run on either of the devices during the migration. The source device can have pending deployments.

Prerequisites for HA devices

Configurations that the wizard migrates

The migration wizard copies configurations from the source device to the target device, including licenses, interfaces, policies, routing settings, and other essential device configurations.

General configurations

The migration wizard copies these configurations from the source device to the target device:

- Licenses
- Interface configurations
- Inline sets configurations
- Routing configurations
- DHCP and DDNS configurations
- Policies
- Associated objects and object overrides
- Platform settings
- Remote branch deployment configurations

Policy configurations

The migration wizard copies these policy configurations from the source device to the target device:

- Health policy
- NAT and QoS policy
- Remote access VPN policy
- FlexConfig policy
- Access control and prefilter policy
- IPS and DNS policy
- Malware and File policy
- SSL and Identity policy

Routing configurations

The migration wizard copies these routing configurations from the source device to the target device:

- ECMP
- BFD
- OSPFv2/v3
- EIGRP
- RIP
- BGP
- Policy Based Routing
- Static and Multicast Route
- Virtual Router

Interface configurations

The migration wizard copies these interfaces from the source device to the target device:

- Physical interfaces
- Sub-interfaces
- EtherChannel interfaces
- Bridge group interfaces
- VTI interfaces
- VNI interfaces
- Loopback interfaces

The migration wizard retains the device group of the target device.

Guidelines and limitations for migration

Follow these guidelines to ensure successful migration of secure firewall threat defense models:

- **For devices in multi-instance mode**:

  During migration, ensure that you map the interfaces according to the table below:

Source Device	Target Device
Physical interface	Physical interface
EtherChannel interface	EtherChannel interface
Supervisor-provisioned subinterface	Supervisor-provisioned subinterface
Tagged interface	Tagged interface
Untagged interface	Untagged interface
Shared interface	Shared and dedicated interface
Dedicated interface	Dedicated interface

  You cannot map a supervisor-provisioned subinterface to a subinterface created by an instance.

- **For HA devices**, you can migrate:
  - Source HA device to target HA device.
  - Source HA device to target standalone device.

- **For devices in remote branch deployment**:
  - Map the source manager access interface to the target manager access interface.
  - Ensure that the manager access interfaces of the source and target Firewall Management Centers are of the same IP address type (static or DHCP).
  - Both manager access interfaces must have IPv4 or IPv6 addresses.

    - If the manager access interfaces have static IP addresses, ensure that they are in the same subnet.

- **For Snort**:
- **For devices using diagnostic interfaces**:

  Only merged management interfaces are available on the target devices after migration.

Limitations

Be aware of these limitations when using the migration wizard:

- The migration wizard does not migrate:
    - Site-to-site VPN policies
- You can perform only one migration at a time.
- Remote access VPN trustpoint certificates are not enrolled after migration.
- For HA devices:
    - Target device: You cannot migrate a standalone device to an HA device.

Best practices for Threat Defense device migration

After a successful migration, perform these actions before deployment to ensure proper device configuration and functionality.

- IP addresses of the interfaces are copied to the target device from the source device. Change the IP addresses of the target device interfaces if the source device is live
- Ensure that you update your NAT policies with the modified IP addresses.
- Configure the interface speeds if they are set to default values after migration.
- Re-enroll the device certificates, if any, on the target device.
- (Optional) Configure SNMP for Firepower 1100 and 2100 using the platform settings for the device.
- (Optional) Configure remote branch deployments.

  If the source or target device had manager access through a data interface, after the migration, the manager access will be lost. Update the manager access configuration on the target device. For more information, see the *Change the Manager Access Interface from Management to Data* topic in the Cisco Secure Firewall Management Center Device Configuration Guide or the Online Help.
- Configure site-to-site VPN, if required. These configurations are not migrated from the source device.
- View the deployment preview before the deployment. From the **Deploy** drop-down menu, click **Advanced Deploy**, and then click the **Preview** ( ) icon for the device.
- Monitor the health of the device in the health monitor (choose **System** ( ) > **Health** > **Monitor**). After migration, the health policy of the source device becomes the health policy of the target device. You can also configure a new health policy for the device.

After migration, the device monitoring dashboard may temporarily display redundant colored lines because the device has different UUIDs before and after migration. This redundancy appears only during the migration time. An hour after migration, the dashboard will show a single line per metric.

Switch managers

You can change between managers as needed.

Switch from the Firewall Device Manager to the Firewall Management Center

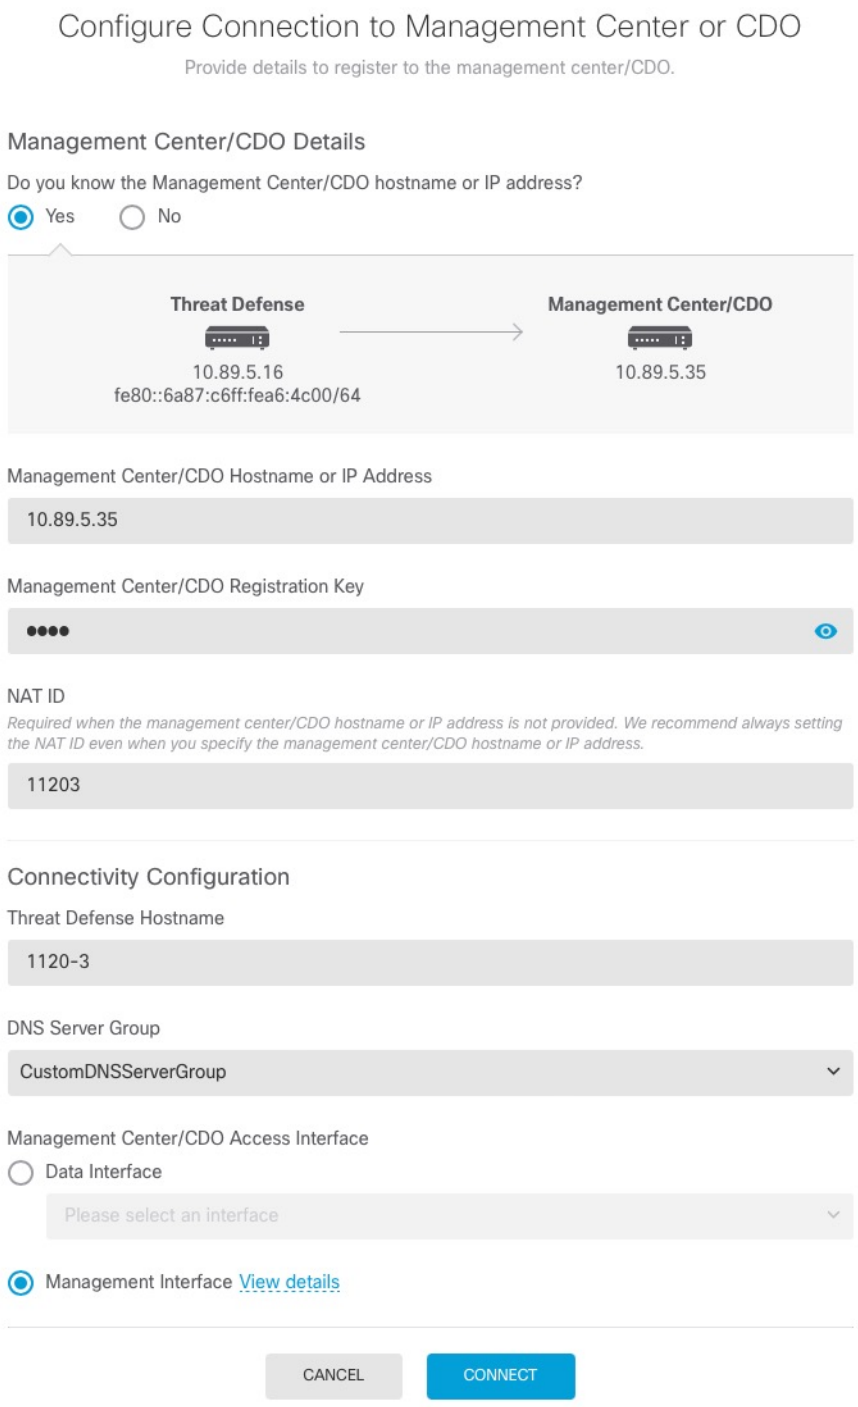
When you switch from the Firewall Device Manager to the Firewall Management Center, all interface configuration is retained, in addition to the Management interface and the manager access settings. Note that other configuration settings, such as the access control policy or security zones, are not retained.

After you switch to the Firewall Management Center , you can no longer use the Firewall Device Manager to manage the Firewall Threat Defense device.

Procedure

Step 1 In the Firewall Device Manager, unregister the device from the Cisco Smart Software Manager.

Step 2 (Might be required) Configure the Management interface.



You may need to change the Management interface configuration, even if you intend to use a data interface for manager access. You will have to reconnect to the Firewall Device Manager if you were using the Management interface for the Firewall Device Manager connection.

- Data interface for manager access—The Management interface must have the gateway set to data interfaces. By default, the Management interface receives an IP address and gateway from DHCP. If you do not receive a gateway from DHCP (for example, you did not connect this interface to a network), then the gateway will default to data interfaces, and you do not need to configure anything. If you did receive a gateway from DHCP, then you need to instead configure this interface with a static IP address and set the gateway to data interfaces.
- Management interface for manager access—If you want to configure a static IP address, be sure to also set the default gateway to be a unique gateway instead of the data interfaces. If you use DHCP, then you do not need to configure anything assuming you successfully get the gateway from DHCP.

Step 3 Choose **Device** > **System Settings** > **Central Management**, and click **Proceed** to set up the Firewall Management Center management.

Step 4 Configure the **Management Center/CDO Details**.

Figure 27: Management Center/Security Cloud Control Details

a) For **Do you know the Management Center/CDO hostname or IP address?**, click **Yes** if you can reach the Firewall Management Center using an IP address or hostname, or **No** if the Firewall Management CenterSecurity Cloud Control is behind NAT or does not have a public IP address or hostname.

At least one of the devices, either the Firewall Management Center or the Firewall Threat Defense device, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices.

b) If you chose **Yes**, then enter the **Management Center/CDO Hostname or IP Address**.

c) Specify the **Management Center/CDO Registration Key**.

This key is a one-time registration key of your choice that you will also specify on the Firewall Management Center when you register the Firewall Threat Defense device. The registration key must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID can be used for multiple devices registering to the Firewall Management Center.

d) Specify a **NAT ID**.

This ID is a unique, one-time string of your choice that you will also specify on the Firewall Management Center. The NAT ID must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID *cannot* be used for any other devices registering to the Firewall Management Center. The NAT ID is used in combination with the IP address to verify that the connection is coming from the correct device; only after authentication of the IP address/NAT ID will the registration key be checked. We recommended that you always use the NAT ID even when it is optional, but it is required if:

- You set the Firewall Management Center IP address to **DONTRESOLVE**.
- When adding the device on the Firewall Management Center, you do not specify a reachable device IP address or hostname.
- You use the data interface for management, even if you specify IP addresses on both sides.
- The Firewall Management Center uses multiple management interfaces.

Step 5 Configure the **Connectivity Configuration**.

a) Specify the **FTD Hostname**.

If you use a data interface for the **Management Center/CDO Access Interface** access, then this FQDN will be used for this interface.

b) Specify the **DNS Server Group**.

Choose an existing group, or create a new one. The default DNS group is called **CiscoUmbrellaDNSServerGroup**, which includes the OpenDNS servers.

If you intend to choose a data interface for the **Management Center/CDO Access Interface**, then this setting sets the *data* interface DNS server. The Management DNS server that you set with the setup wizard is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface. You are likely to choose the same DNS server group that you used for Management, because both management and data traffic reach the DNS server through the outside interface.

On the Firewall Management Center, the data interface DNS servers are configured in the Platform Settings policy that you assign to this Firewall Threat Defense device. When you add the Firewall Threat Defense device to the Firewall Management Center, the local setting is maintained, and the DNS servers are *not* added to a Platform Settings policy. However, if you later assign a Platform Settings policy to the Firewall Threat Defense device that includes a DNS configuration, then that configuration will overwrite the local setting. We suggest that you actively configure the DNS Platform Settings to match this setting to bring the Firewall Management Center and the Firewall Threat Defense device into sync.

Also, local DNS servers are only retained by the Firewall Management Center if the DNS servers were discovered at initial registration.

If you intend to choose the Management interface for the **Management Center/CDO Access InterfaceFMC Access Interface**, then this setting configures the Management DNS server.

c) For the **Management Center/CDO Access Interface**, choose any configured interface.

You can change the manager interface after you register the Firewall Threat Defense device to the Firewall Management Center, to either the Management interface or another data interface.

Step 6 (Optional) If you chose a data interface, and it was not the outside interface, then add a default route.

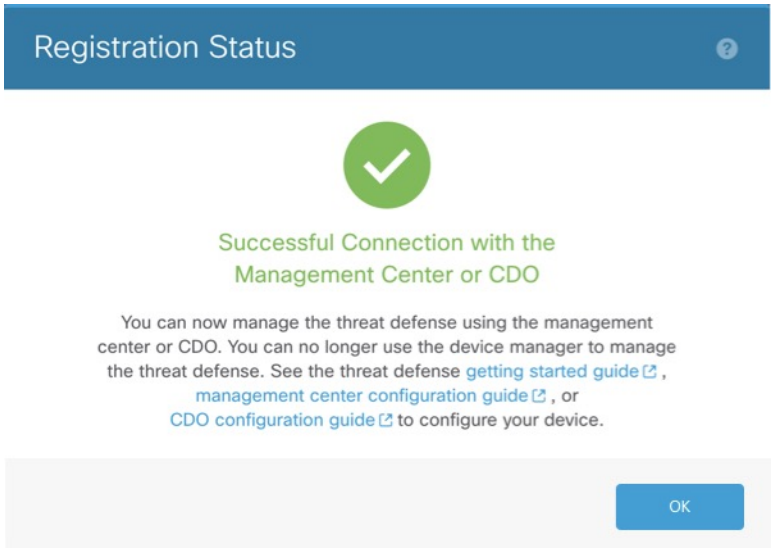
You will see a message telling you to check that you have a default route through the interface. If you chose outside, you already configured this route as part of the setup wizard. If you chose a different interface, then you need to manually configure a default route before you connect to the Firewall Management Center.

If you chose the Management interface, then you need to configure the gateway to be a unique gateway before you can proceed on this screen.

Step 7 (Optional) If you chose a data interface, click **Add a Dynamic DNS (DDNS) method**.

DDNS ensures the Firewall Management Center can reach the Firewall Threat Defense device at its Fully-Qualified Domain Name (FQDN) if the IP address changes. See **Device** > **System Settings** > **DDNS Service** to configure DDNS.

If you configure DDNS before you add the Firewall Threat Defense device to the Firewall Management Center, the Firewall Threat Defense device automatically adds certificates for all of the major CAs from the Cisco Trusted Root CA bundle so that the Firewall Threat Defense device can validate the DDNS server certificate for the HTTPS connection. Firewall Threat Defense supports any DDNS server that uses the DynDNS Remote API specification (https://help.dyn.com/remote-access-api/).



DDNS is not supported when using the Management interface for manager access.

Step 8 Click **Connect**. The **Registration Status** dialog box shows the current status of the switch to the Firewall Management Center. After the **Saving Management Center/CDO Registration Settings** step, go to the Firewall Management Center, and add the firewall.

If you want to cancel the switch to the Firewall Management Center, click **Cancel Registration**. Otherwise, do not close the Firewall Device Manager browser window until after the **Saving Management Center/CDO Registration Settings** step. If you do, the process will be paused, and will only resume when you reconnect to the Firewall Device Manager.

If you remain connected to the Firewall Device Manager after the **Saving Management Center/CDO Registration Settings** step, you will eventually see the **Successful Connection with Management Center/CDO** dialog box, after which you will be disconnected from the Firewall Device Manager.

Figure 28: Successful Connection

Switch from Firewall Management Center to Firewall Device Manager

You can configure the Firewall Threat Defense device currently being managed by the on-premises or cloud-delivered Firewall Management Center to use the Firewall Device Manager instead.

You can switch from the Firewall Management Center to the Firewall Device Manager without reinstalling the software. Before switching from the Firewall Management Center to the Firewall Device Manager, verify that the Firewall Device Manager meets all of your configuration requirements. If you want to switch from the Firewall Device Manager to the Firewall Management Center, see Switch from the Firewall Device Manager to the Firewall Management Center , on page 61.

Caution Switching to the Firewall Device Manager erases the device configuration and returns the system to the default configuration. However, the Management IP address and hostname are preserved.

Procedure

Step 1 In the Firewall Management Center, delete the firewall from the **Devices** > **Device Management** page.

Step 2 Connect to the Firewall Threat Defense CLI using SSH or the console port. For SSH, open a connection to the **management IP address**, and log in to the Firewall Threat Defense CLI with the **admin** username (or any other user with admin privileges).

The console port defaults to the FXOS CLI. Connect to the Firewall Threat Defense CLI using the **connect ftd** command. The SSH session connects directly to the Firewall Threat Defense CLI.

If you cannot connect to the management IP address, do one of the following:

- Ensure that the management physical port is wired to a functioning network.
- Ensure that the management IP address and gateway are configured for the management network. Use the **configure network ipv4/ipv6 manual** command.

Step 3 Verify you are currently in remote management mode.

show managers

Example:

```
> show managers
Type                      : Manager
Host                      : 10.89.5.35
Display name              : 10.89.5.35
Identifier                : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration              : Completed
```

Step 4 Delete the remote manager and go into no manager mode.

configure manager delete *uuid*

You cannot go directly from remote management to local management. If you have more than one manager defined, you need to specify the identifier (also known as the UUID; see the **show managers** command). Delete each manager entry separately.

Example:

```
> configure manager delete
Deleting task list
Manager successfully deleted.

>
> show managers
No managers configured.
```

Step 5 Configure the local manager.

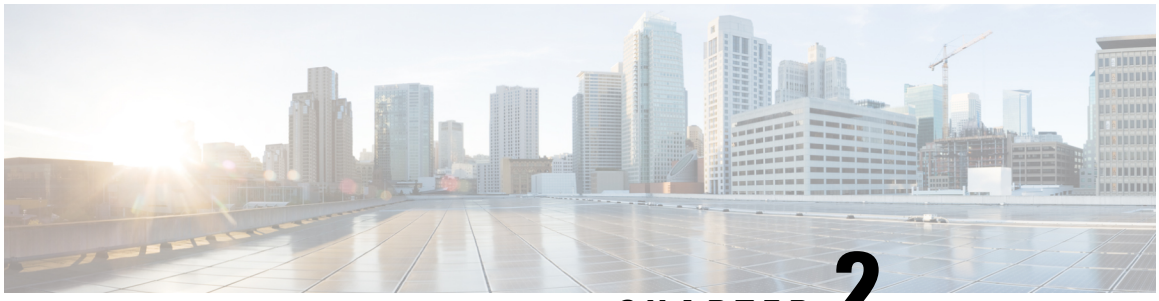
configure manager local

You can now use a web browser to open the local manager at *https://management-IP-address*.

Example:

```
> configure manager local
Deleting task list

> show managers
Managed locally.
```



History for device registration

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Chassis-level health alerts for the Firepower 4100/9300.	7.4.1	7.4.1	You can now view chassis-level health alerts for Firepower 4100/9300 by registering the chassis to the Firewall Management Center as a read-only device. You must also enable the Firewall Threat Defense Platform Faults health module and apply the health policy. The alerts appear in the Message Center, the health monitor (in the left pane, under Devices, select the chassis), and in the health events view. You can also add a chassis (and view health alerts for) the Secure Firewall 3100 in multi-instance mode. For those devices, you use the Firewall Management Center to manage the chassis. But for the Firepower 4100/9300 chassis, you still must use the chassis manager or the FXOS CLI. New/modified screens: **Devices** > **Device Management** > **Add** > **Chassis**
Zero-Touch Provisioning to register the Firepower 1000/2100 and Secure Firewall 3100 to the Firewall Management Center using a serial number.	7.4.0	Mgmt. center *is* publicly reachable: 7.2.0 Mgmt. center *is not* publicly reachable: 7.2.4/7.4.0	Zero-Touch Provisioning (also called low-touch provisioning) lets you register Firepower 1000/2100 and Secure Firewall 3100 devices to the Firewall Management Center by serial number without having to perform any initial setup on the device. The Firewall Management Center integrates with SecureX and Security Cloud Control for this functionality. New/modified screens: **Devices** > **Device Management** > **Add** > **Device** > **Serial Number**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Merged management and diagnostic interfaces.	7.4.0	7.4.0	**Upgrade impact. Merge interfaces after upgrade.** For new devices using 7.4 and later, you cannot use the legacy diagnostic interface. Only the merged management interface is available. If you upgraded to 7.4 or later and: • You did not have any configuration for the diagnostic interface, then the interfaces will merge automatically. • You have configuration for the diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate diagnostic interface. Note that support for the diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. Merged mode also changes the behavior of AAA traffic to use the data routing table by default. The management-only routing table can now only be used if you specify the management-only interface (including Management) in the configuration. For platform settings, this means: • You can no longer enable HTTP, ICMP, or SMTP for diagnostic. • For SNMP, you can allow hosts on management instead of diagnostic. • For Syslog servers, you can reach them on management instead of diagnostic. • If Platform Settings for syslog servers or SNMP hosts specify the diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices. • DNS lookups no longer fall back to the management-only routing table if you do not specify interfaces. New/modified screens: **Devices** > **Device Management** > **Interfaces** New/modified commands: **show management-interface convergence**
Migrate Firepower 1000/2100 to Secure Firewall 3100.	7.4.0	Any	You can now easily migrate configurations from the Firepower 1000/2100 to the Secure Firewall 3100. New/modified screens: **Devices** > **Device Management** > **Migrate** Platform restrictions: Migration not supported from the Firepower 1010 or 1010E.
Download a report of all registered devices.	7.4.0	Any	You can now download a report of all registered devices. On **Devices** > **Device Management** , click the new **Download Device List Report** link, at the top right of the page.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Manage Firewall Threat Defense high availability pairs using a data interface.	7.4.0	7.4.0	Firewall Threat Defense high availability now supports using a regular data interface for communication with the Firewall Management Center. Previously, only standalone devices supported this feature. See: Device Management
ISA 3000 System LED support for shutting down.	7.0.5/7.3.0	7.0.5/7.3.0	When you shut down the ISA 3000, the System LED will turn off. You should wait at least 10 seconds before removing the power.
ISA 3000 support for shutting down.	7.0.2/7.2.0	7.0.2/7.2.0	You can now shut down the ISA 3000; previously, you could only reboot the device.
Multi-manager support.	7.2.0	7.2.0	We introduced the cloud-delivered management center. The cloud-delivered management center uses the Security Cloud Control (Security Cloud Control) platform and unites management across multiple Cisco security solutions. We take care of manager updates. Hardware or virtual management centers running Version 7.2+ can "co-manage" cloud-managed devices, but for event logging and analytics purposes only. You cannot deploy policy to these devices from the hardware or virtual management center. New/modified commands: **configure manager add** , **configure manager delete** , **configure manager edit** , **show managers** New/modified screens: • When you add a cloud-managed device to a hardware or virtual management center, use the new Security Cloud Control Managed Device check box to specify that it is analytics-only. • View which devices are analytics-only on **Devices** > **Device Management** . For more information, see Security Cloud Control documentation.
RAID support for SSDs on the Secure Firewall 3100.	7.1.0	7.1.0	The SSDs are self-encrypting drives (SEDs), and if you have 2 SSDs, they form a software RAID. New/modified commands: **configure raid, show raid, show ssd**
Support for TLS 1.3 for the management connection.	7.1.0	7.1.0	The FMC-device management connection now uses TLS 1.3. Previously, TLS 1.2 was supported.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Use FDM to configure FTD for management by the FMC.	7.1.0	7.1.0	When you perform initial setup using FDM, all interface configuration completed in FDM is retained when you switch to FMC for management, in addition to the Management and manager access settings. Note that other default configuration settings, such as the access control policy or security zones, are not retained. When you use the FMC CLI, only the Management and manager access settings are retained (for example, the default inside interface configuration is not retained). After you switch to FMC, you can no longer use FDM to manage FTD. New/modified FDM screens: **System Settings** > **Management Center**
Filter devices by upgrade status.	6.7.0	6.7.0	The **Device Management** page now provides upgrade information about your managed devices, including whether a device is upgrading (and what its upgrade path is), and whether its last upgrade succeeded or failed. New/modified screens: **Devices** > **Device Management**
One-click access to the Firepower Chassis Manager.	6.4.0	6.4.0	For Firepower 4100/9300 series devices, the Device Management page provides a link to the Firepower Chassis Manager web interface. New/modified screens: **Devices** > **Device Management**
Filter devices by health and deployment status; view version information.	6.2.3	6.2.3	The Device Management page now provides version information for managed devices, as well as the ability to filter devices by health and deployment status. New/modified screens: **Devices** > **Device Management**

CHAPTER 2

Transparent or Routed Firewall Mode

This chapter describes how to set the firewall mode to routed or transparent, as well as how the firewall works in each firewall mode.

Note The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes. See Inline Sets and Passive Interfaces, on page 727 for more information about IPS-only interfaces. Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode described in this chapter or the firewall-type interfaces.

Caution

- Use FTD CLI commands to set "Firewall Mode."

- Firewall mode, on page 71
- Default settings, on page 81
- Guidelines for firewall mode, on page 81
- Set the firewall mode, on page 82

Firewall mode

A Firewall Threat Defense device supports two firewall modes for regular firewall interfaces:

- Routed Firewall mode
- Transparent Firewall mode

Routed firewall mode

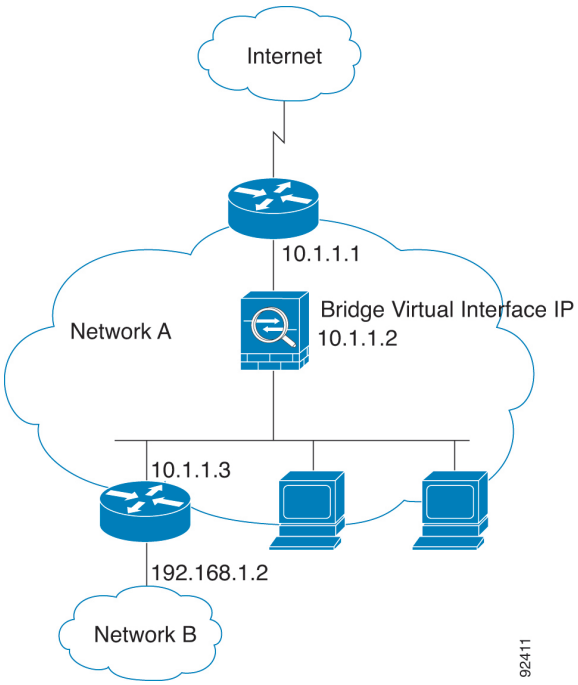
In routed mode, the Firewall Threat Defense device is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet.

Integrated routing and bridging features

With Integrated Routing and Bridging, you can use a "bridge group" where you group together multiple interfaces on a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. The Firewall Threat Defense device routes between BVIs and regular routed interfaces. If you do not need clustering or EtherChannel member interfaces, you might consider using routed mode instead of transparent mode. In routed mode, you can have one or more isolated bridge groups like in transparent mode, but also have normal routed interfaces as well for a mixed deployment.

Transparent firewall mode

Traditionally, a firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices. However, like any other firewall, access control between interfaces is controlled, and all of the usual firewall checks are in place.



Layer 2 connectivity is achieved by using a "bridge group" where you group together the inside and outside interfaces for a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. You can have multiple bridge groups for multiple networks. In transparent mode, these bridge groups cannot communicate with each other.

Transparent firewall network usage

The Firewall Threat Defense device connects the same network between its interfaces. Because the firewall is not a routed hop, you can easily introduce a transparent firewall into an existing network.

The figure shows a typical transparent firewall network where the outside devices are on the same subnet as the inside devices. The inside router and hosts appear to be directly connected to the outside router.

Figure 29: Transparent firewall network

Passing traffic for routed-mode features

For features that are not directly supported on the transparent firewall, you can allow traffic to pass through so that upstream and downstream routers can support the functionality.

Supported traffic types

For example, by using an access rule, you can allow DHCP traffic (instead of the unsupported DHCP relay feature) or multicast traffic such as that created by IP/TV. You can also establish routing protocol adjacencies through a transparent firewall; you can allow OSPF, RIP, EIGRP, or BGP traffic through based on an access rule. Likewise, protocols like HSRP or VRRP can pass through the Firewall Threat Defense device.

Bridge groups

A bridge group is a group of interfaces that the Firewall Threat Defense device bridges instead of routes. Bridge groups are supported in both transparent and routed firewall mode. Like any other firewall interfaces, access control between interfaces is controlled, and all of the usual firewall checks are in place.

Bridge virtual interfaces

Each bridge group includes a Bridge Virtual Interface (BVI). The Firewall Threat Defense device uses the BVI IP address as the source address for packets originating from the bridge group. The BVI IP address must be on the same subnet as the bridge group member interfaces. The BVI does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.

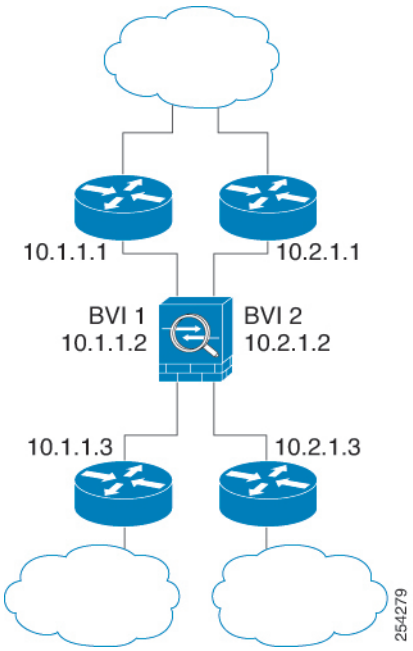
BVI functionality by mode

In transparent mode: Only bridge group member interfaces are named and can be used with interface-based features.

In routed mode: The BVI acts as the gateway between the bridge group and other routed interfaces. To route between bridge groups/routed interfaces, you must name the BVI. For some interface-based features, you can use the BVI itself:

- DHCPv4 server—Only the BVI supports the DHCPv4 server configuration.
- Static routes—You can configure static routes for the BVI; you cannot configure static routes for the member interfaces.
- Syslog server and other traffic sourced from the Firewall Threat Defense device—When specifying a syslog server (or SNMP server, or other service where the traffic is sourced from the Firewall Threat Defense device), you can specify either the BVI or a member interface.

If you do not name the BVI in routed mode, then the Firewall Threat Defense device does not route bridge group traffic. This configuration replicates transparent firewall mode for the bridge group. If you do not need clustering or EtherChannel member interfaces, you might consider using routed mode instead. In routed mode, you can have one or more isolated bridge groups like in transparent mode, but also have normal routed interfaces as well for a mixed deployment.



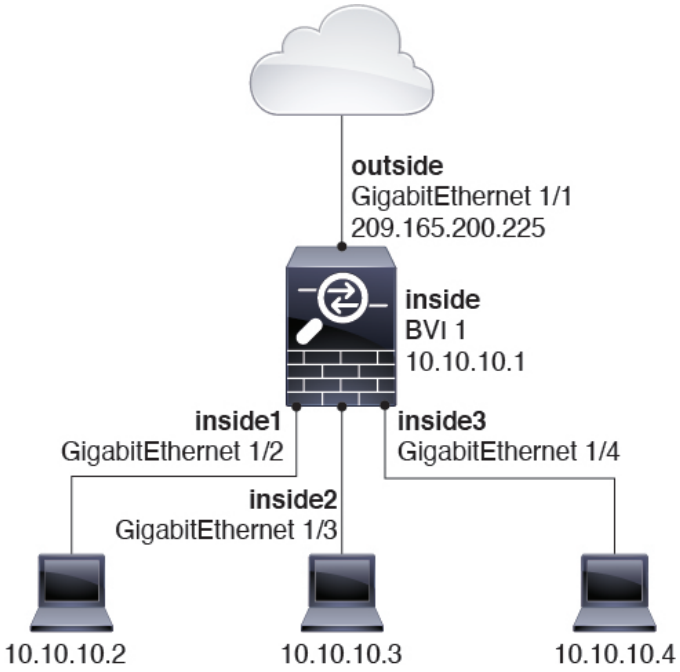
Bridge groups in transparent firewall mode

Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the Firewall Threat Defense device , and traffic must exit the Firewall Threat Defense device before it is routed by an external router back to another bridge group in the Firewall Threat Defense device. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration.

You can include multiple interfaces per bridge group. See Guidelines for firewall mode, on page 81 for the exact number of bridge groups and interfaces supported. If you use more than 2 interfaces per bridge group, you can control communication between multiple segments on the same network, and not just between inside and outside. For example, if you have three inside segments that you do not want to communicate with each other, you can put each segment on a separate interface, and only allow them to communicate with the outside interface. Or you can customize the access rules between interfaces to allow only as much access as desired.

This figure shows two networks connected to the Firewall Threat Defense device, which has two bridge groups.

Figure 30: Transparent firewall network with two bridge groups



Bridge groups in routed firewall mode

Bridge group traffic can be routed to other bridge groups or routed interfaces. You can choose to isolate bridge group traffic by not assigning a name to the BVI interface for the bridge group. If you name the BVI, then the BVI participates in routing like any other regular interface.

Bridge group usage and configuration

One use for a bridge group in routed mode is to use extra interfaces on the Firewall Threat Defense instead of an external switch. For example, the default configuration for some devices include an outside interface as a regular interface, and then all other interfaces assigned to the inside bridge group. Because the purpose of this bridge group is to replace an external switch, you need to configure an access policy so all bridge group interfaces can freely communicate.

Figure 31: Routed firewall network with an inside bridge group and an outside routed interface

Allow layer 3 traffic

This topic describes how different types of Layer 3 traffic are handled through bridge groups and the access rule requirements for each traffic type.

- Unicast IPv4 and IPv6 traffic requires an access rule to be allowed through the bridge group.
- ARPs are allowed through the bridge group in both directions without an access rule. ARP traffic can be controlled by ARP inspection.
- IPv6 neighbor discovery and router solicitation packets can be passed using access rules.
- Broadcast and multicast traffic can be passed using access rules.

Allowed MAC addresses

These destination MAC addresses are allowed through the bridge group if allowed by your access policy (For more information, refer to Allow layer 3 traffic, on page 76). Any MAC address not on this list is dropped.

- TRUE broadcast destination MAC address equal to FFFF.FFFF.FFFF
- IPv4 multicast MAC addresses from 0100.5E00.0000 to 0100.5EFE.FFFF
- IPv6 multicast MAC addresses from 3333.0000.0000 to 3333.FFFF.FFFF
- BPDU multicast address equal to 0100.0CCC.CCCD

BPDUs handling

To prevent loops using the Spanning Tree Protocol, BPDUs are passed by default.

By default BPDUs are also forwarded for advanced inspection, which is unnecessary for this type of packet, and which can cause problems if they are blocked due to an inspection restart, for example. We recommend that you always exempt BPDUs from advanced inspection. To do so, use FlexConfig to configure an EtherType ACL that trusts BPDUs and exempts them from advanced inspection on each member interface.

The FlexConfig object should deploy the following commands, where you replace <if-name> with an interface name. Add as many access-group commands as needed to cover each bridge group member interface on the device. You can also choose a different name for the ACL.

```
access-list permit-bpdu ethertype trust bpdu
access-group permit-bpdu in interface <if-name>
```

MAC address and route lookups

For traffic within a bridge group, the outgoing interface of a packet is determined by performing a destination MAC address lookup instead of a route lookup.

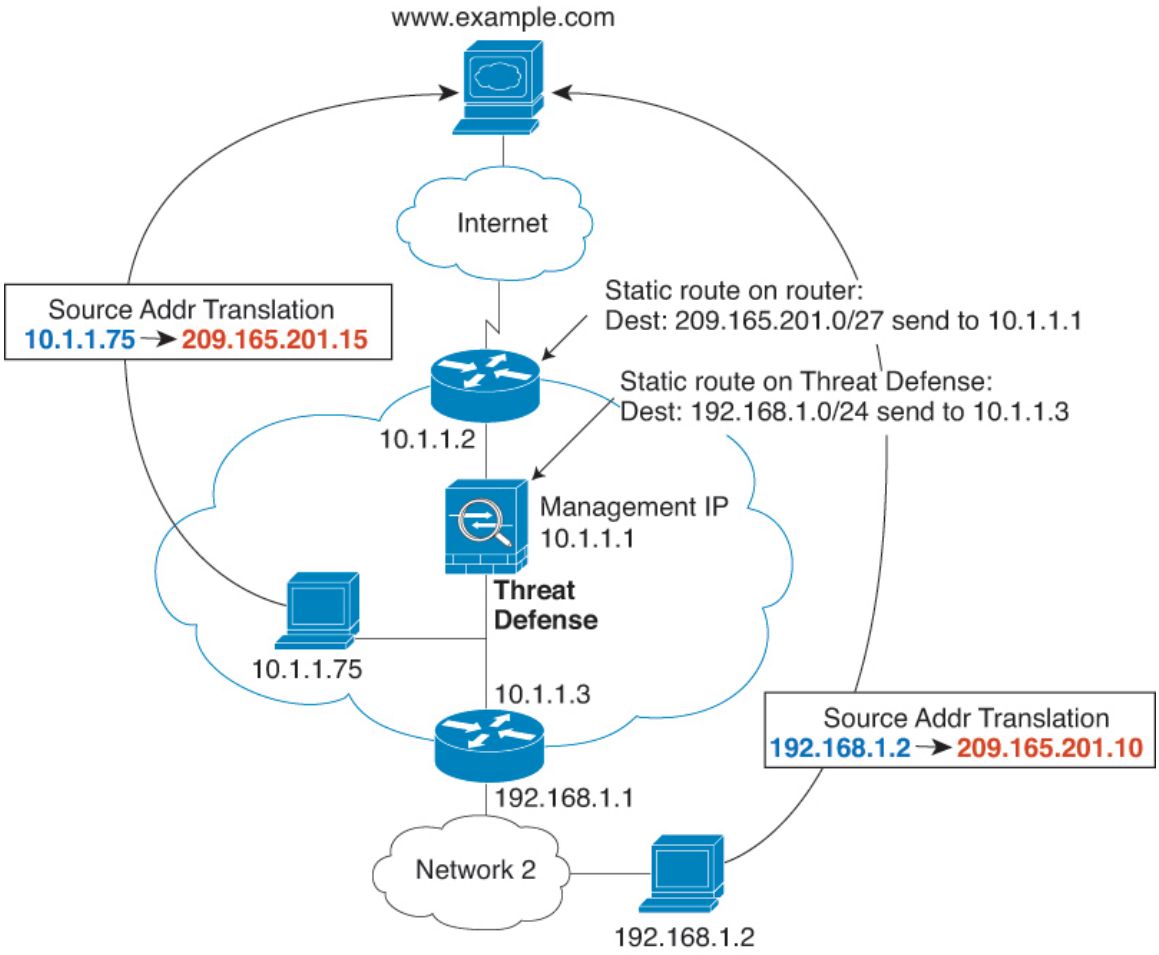
Route lookups, however, are necessary for these situations:

- Traffic originating on the Firewall Threat Defense device—Add a default/static route on the Firewall Threat Defense device for traffic destined for a remote network where a syslog server, for example, is located.
- SSL policy enabled in transparent firewall mode—
  - TLS 1.3 traffic passes through the Firewall Threat Defense device device.
  - Firewall Threat Defense device acts as a TCP proxy. It terminates the client-side TCP connection and initiates a separate server-side connection. The Firewall Threat Defense device TCP stack owns the session state.
  - For idle proxied sessions, Firewall Threat Defense device generates TCP ACK keepalive probes to preserve the connection state. These are not passthrough packets—the firewall originates them and sends them toward the client or server depending on the state of the TLS transit connection.
  - Because the Firewall Threat Defense device originates these keepalives, it must perform an adjacency table lookup (next-hop or egress MAC resolution) even in transparent mode.
  - If the adjacency lookup fails for one of these proxy-generated packets, the Firewall Threat Defense device logs syslog 110003.

    To prevent these syslog messages, configure routes on the Firewall Threat Defense device for the transit connection endpoints (client and server IP addresses). Proper routing enables successful adjacency lookups for keepalive packets.

    If the Firewall Threat Defense device successfully sends a TCP keepalive and receives a reply, it keeps the transit connection active. If the device cannot send the keepalives, or receives no reply, it removes the transit connection after approximately 240 seconds.
- Voice over IP (VoIP) and TFTP traffic, and the endpoint is at least one hop away—Add a static route on the Firewall Threat Defense device for traffic destined for the remote endpoint so that secondary connections are successful. The Firewall Threat Defense device creates a temporary "pinhole" in the access control policy to allow the secondary connection; and because the connection might use a different set of IP addresses than the primary connection, the Firewall Threat Defense device needs to perform a route lookup to install the pinhole on the correct interface.

Affected applications include:



- H.323
- RTSP
- SIP and Skinny (SCCP)
- SQL*Net
- SunRPC
- TFTP

- Traffic at least one hop away for which the Firewall Threat Defense device performs NAT—Configure a static route on the Firewall Threat Defense device for traffic destined for the remote network. You also need a static route on the upstream router for traffic destined for the mapped addresses to be sent to the Firewall Threat Defense device.

  This routing requirement is also true for embedded IP addresses for VoIP and DNS with NAT enabled, and the embedded IP addresses are at least one hop away. The Firewall Threat Defense device needs to identify the correct egress interface so it can perform the translation.

NAT within a bridge group

Figure 32: NAT example: NAT within a bridge group

Unsupported features for bridge groups in transparent mode

This table lists the features that are not supported in bridge groups in transparent mode.

Table 5: Unsupported features in transparent mode

Feature	Description
Dynamic DNS	—
DHCPv6 stateless server	Only the DHCPv4 server is supported on bridge group member interfaces.

Feature	Description
DHCP relay	The transparent firewall can act as a DHCPv4 server, but it does not support DHCP relay. DHCP relay is not required because you can allow DHCP traffic to pass through using two access rules: one that allows DCHP requests from the inside interface to the outside, and one that allows the replies from the server in the other direction.
Dynamic routing protocols	You can, however, add static routes for traffic originating on the Firewall Threat Defense device for bridge group member interfaces. You can also allow dynamic routing protocols through the Firewall Threat Defense device using an access rule.
Multicast IP routing	You can allow multicast traffic through the Firewall Threat Defense device by allowing it in an access rule.
QoS	—
VPN termination for through traffic	The transparent firewall supports site-to-site VPN tunnels for management connections only on bridge group member interfaces. It does not terminate VPN connections for traffic through the Firewall Threat Defense device. You can pass VPN traffic through the Firewall Threat Defense device using an access rule, but it does not terminate non-management connections.

Unsupported features for bridge groups in routed mode

This table lists the features are not supported in bridge groups in routed mode.

Table 6: Unsupported features in routed mode

Feature	Description
EtherChannel member interfaces	Only physical interfaces, redundant interfaces, and subinterfaces are supported as bridge group member interfaces. Management interfaces are also not supported.
Clustering	Bridge groups are not supported in clustering.
Dynamic DNS	—
DHCPv6 stateless server	Only the DHCPv4 server is supported on BVIs.
DHCP relay	The routed firewall can act as a DHCPv4 server, but it does not support DHCP relay on BVIs or bridge group member interfaces.
Dynamic routing protocols	You can, however, add static routes for BVIs. You can also allow dynamic routing protocols through the Firewall Threat Defense device using an access rule. Non-bridge group interfaces support dynamic routing.
Multicast IP routing	You can allow multicast traffic through the Firewall Threat Defense device by allowing it in an access rule. Non-bridge group interfaces support multicast routing.

Feature	Description
QoS	Non-bridge group interfaces support QoS.
VPN termination for through traffic	You cannot terminate a VPN connection on the BVI. Non-bridge group interfaces support VPN. Bridge group member interfaces support site-to-site VPN tunnels for management connections only. It does not terminate VPN connections for traffic through the Firewall Threat Defense device. You can pass VPN traffic through the bridge group using an access rule, but it does not terminate non-management connections.

Default settings

Lists the default settings for firewall mode.

Bridge group defaults

By default, all ARP packets are passed within the bridge group.

Guidelines for firewall mode

Review these guidelines for firewall mode.

Bridge group limits and network requirements

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The Firewall Threat Defense device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.

BVI IP address requirements

- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the Firewall Threat Defense device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).

Unsupported bridge group members

- Management interfaces are not supported as bridge group members.

- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the Firewall Threat Defense Virtual on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
- For the Firepower 2100 series, bridge groups are not supported in routed mode.
- For the / 1010/ , you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.

Transparent mode requirements and limitations

- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.
- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the Firewall Threat Defense as the default gateway.
- In transparent mode, the default route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.

Routed mode requirements and limitations

- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, Firewall Threat Defense-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.

Traffic handling limitation

- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the Firewall Threat Defense when using bridge group members. If there are two neighbors on either side of the Firewall Threat Defense running BFD, then the Firewall Threat Defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

Set the firewall mode

You can set the firewall mode when you perform the initial system setup at the CLI. We recommend setting the firewall mode during setup because changing the firewall mode erases your configuration to ensure you do not have incompatible settings. If you need to change the firewall mode later, you must do so from the CLI.

Procedure

Step 1 Unregister the Firewall Threat Defense device from the Firewall Management Center.

You cannot change the mode until you unregister the device.

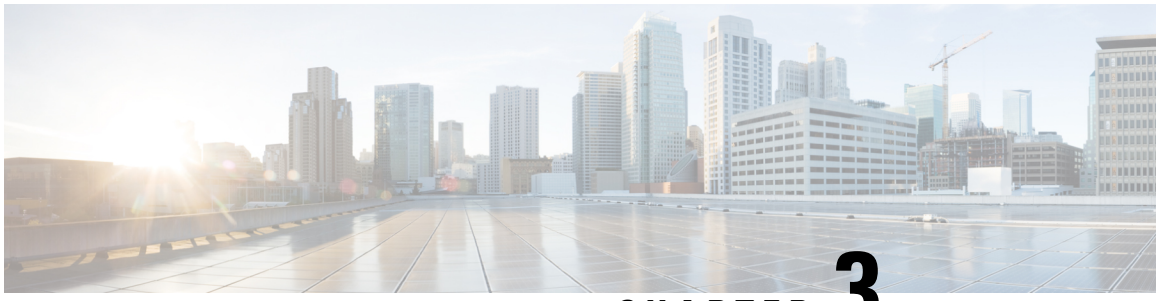
a) Performance profiles are retained across firewall mode changes and can't be changed after you re-register. You must set the performance profile to Default. See the **Performance Profile** page in your platform settings policy (choose **Devices** > **Platform Settings**, and then click **Edit** (✎) for your policy).

Deploy the configuration to make these changes.

b) Choose **Devices** > **Device Management**.

c) Next to the device you want to unregister, click **More** (⋮), and then click **Delete**.

Step 2 Access the Firewall Threat Defense device CLI, preferably from the console port.



Step 3 Change the firewall mode:

configure firewall [**routed** | **transparent**]

Example:

```
> configure firewall transparent
This will destroy the current interface configurations, are you sure that you want to
proceed? [y/N] y
The firewall mode was changed successfully.
```

Step 4 Re-register with the Firewall Management Center.

CHAPTER 3

CLI Users

Managed devices include a default **admin** account for CLI access. This chapter discusses how to create custom user accounts.

- CLI users, on page 85
- Guidelines for CLI users, on page 87
- Add an internal user at the CLI, on page 87
- External authentication for the Firewall Threat Defense, on page 90
- Troubleshoot LDAP authentication connections, on page 103
- History for CLI users, on page 105

CLI users

A CLI user is a user account that

- can be added as internal users or as external users on a LDAP or RADIUS server,
- is maintained separately on each managed device, and
- requires separate configuration for access to the Firewall Management Center versus managed devices.

User account separation

When you add a user to the Firewall Management Center, that user only has access to the Firewall Management Center; you cannot then use that username to log directly into a managed device. You must separately add a user on the managed device.

Internal and external users

Managed devices support two categories of users—internal and external—for user access control.

Internal users authenticate through a local database on the device. External users authenticate through LDAP or RADIUS servers when they are not found in the local database. Both user types enable secure access management for network devices.

User authentication types

Managed devices support these user authentication methods:

- Internal user: The device checks a local database for user authentication.
- External user: If the user is not present in the local database, the system queries an external LDAP or RADIUS authentication server.

CLI access

CLI access is a command-line interface capability that

- provides a Firepower CLI running on top of Linux for device administration
- enables creation of internal users on devices using the CLI, and
- supports establishment of external users on Firewall Threat Defense devices using the Firewall Management Center.

Security considerations for CLI access

Users with CLI Config level access can access the Linux shell using the **expert** command, and obtain `sudoers` privileges in the Linux shell, which can present a security risk.

Caution Users with CLI Config level access can access the Linux shell using the **expert** command, and obtain `sudoers` privileges in the Linux shell, which can present a security risk. For system security reasons, we strongly recommend:

- Only use the Linux shell under TAC supervision or when explicitly instructed by Firepower user documentation.
- Make sure that you restrict the list of users with CLI access appropriately.
- When granting CLI access privileges, restrict the list of users with Config level access.
- Do not add users directly in the Linux shell; only use the procedures in this chapter.
- Do not access Firepower devices using CLI expert mode unless directed by Cisco TAC or by explicit instructions in the Firepower user documentation.

CLI user roles

A CLI user role is an access control mechanism that

- determines the level of command access a user has on managed devices,
- controls whether users can execute configuration or non-configuration commands, and
- provides security by restricting unauthorized access to critical system functions.

Role types and permissions

On managed devices, user access to commands in the CLI depends on the role you assign.

- **None**: The user cannot log into the device on the command line.
- **Config**: The user can access all commands, including configuration commands. Exercise caution in assigning this level of access to users.
- **Basic**: The user can access non-configuration commands only. Only internal users and Firewall Threat Defense external RADIUS users support the Basic role.

Guidelines for CLI users

This reference provides essential guidelines for CLI users, including username requirements, default account information, and user account limits for different device models.

Usernames

- You cannot add the same username for both internal and external users. If the external server uses a duplicate username, the deployment to the device fails.
- The username must be Linux-valid:
  - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
  - All lowercase
  - Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Defaults

All devices include an **admin** user as a local user account; you cannot delete the **admin** user. The default initial password is **Admin123**; the system forces you to change this during the initialization process. The agent stores the modified credentials in the Windows registry and uses the same encryption as the Firewall Management Center, which is Cipher Block Chaining (CBC). See the getting started guide for your model for more information about system initialization.

Number of user accounts

You can create a maximum of 43 user accounts for the Firepower 1000 and 2100.

Add an internal user at the CLI

Create internal users to provide authorized access to the Firewall Threat Defense system with appropriate privilege levels.

Use the CLI to create internal users on the Firewall Threat Defense.

Procedure

Step 1 Log into the device CLI using an account with Config privileges.

The **admin** user account has the required privileges, but any account with Config privileges will work. You can use an SSH session or the Console port.

For certain Firewall Threat Defense models, the Console port puts you into the FXOS CLI. Use the **connect ftd** command to get to the Firewall Threat Defense CLI.

Step 2 Create the user account.

configure user add *username* {**basic** | **config**}

- *username*—Sets the username. The username must be Linux-valid:
  - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
  - All lowercase
  - Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)
- **basic**—Gives the user basic access. This role does not allow the user to enter configuration commands.
- **config**—Gives the user configuration access. This role gives the user full administrator rights to all commands.

Example:

This example adds a user account named johncrichton with Config access rights. The password is not shown as you type it.

```
> configure user add johncrichton config
Enter new password for user johncrichton: newpassword
Confirm new password for user johncrichton: newpassword
> show user
Login              UID   Auth Access  Enabled Reset    Exp Warn  Str Lock Max
admin             1000  Local Config  Enabled    No  Never  N/A  Dis   No N/A
johncrichton      1001  Local Config  Enabled    No  Never  N/A  Dis   No   5
```

Note Tell users they can change their own passwords using the **configure password** command.

Step 3 (Optional) Adjust the characteristics of the account to meet your security requirements.

You can use these commands to change the default account behavior.

- **configure user aging** *username max_days warn_days*

  Sets an expiration date for the user's password. Specify the maximum number of days for the password to be valid followed by the number of days before expiration the user will be warned about the upcoming expiration. Both values are 1 to 9999, but the warning days must be less than the maximum days. When you create the account, there is no expiration date for the password.

- **configure user forcereset** *username*

  Forces the user to change the password on the next login.

- **configure user maxfailedlogins** *username number*

Sets the maximum number of consecutive failed logins you will allow before locking the account, from 1 to 9999. Use the **configure user unlock** command to unlock accounts. The default for new accounts is 5 consecutive failed logins. The admin account is exempt from being locked out after a maximum number of failed logins unless you enable security certification compliance.

- **configure user minpasswdlen** *username number*

  Sets a minimum password length, which can be from 1 to 127.

- **configure user strengthcheck** *username* {**enable** | **disable**}

  Enables or disables password strength checking, which requires a user to meet specific password criteria when changing their password. When a user's password expires or if the **configure user forcereset** command is used, this requirement is automatically enabled the next time the user logs in.

Step 4 Manage user accounts as necessary.

Users can get locked out of their accounts, or you might need to remove accounts or fix other issues. Use these commands to manage the user accounts on the system.

- **configure user access** *username* {**basic** | **config**}

  Changes the privileges for a user account.

- **configure user delete** *username*

  Deletes the specified account.

- **configure user disable** *username*

  Disables the specified account without deleting it. The user cannot log in until you enable the account.

- **configure user enable** *username*

  Enables the specified account.

- **configure user password** *username*

  Changes the password for the specified user. Users should normally change their own password using the **configure password** command.

Caution Do not use the Linux **passwd** command in Expert Mode to change the admin user password. This command can cause file system corruption. Only use the regular Firewall Threat Defense CLI **configure user password admin** command (if you are not admin) or **configure password** command (if you are admin). If you do not know the password and can't log in at all, refer to the password recovery procedure.

- **configure user unlock** *username*

  Unlocks a user account that was locked due to exceeding the maximum number of consecutive failed login attempts.

Note Firewall Threat Defense uses the Pluggable Authentication Module (PAM) framework for user authentication. Within this framework, the pam_unix.so module handles password hashing and verification using the SHA-512 algorithm

Passwords are hashed using the SHA-512 algorithm.

External authentication for the Firewall Threat Defense

External authentication for the Firewall Threat Defense is a security configuration that enables Firewall Threat Defense devices to authenticate users through external authentication servers by adding one or more external authentication objects.

External authentication for the Firewall Threat Defense

External authentication for the Firewall Threat Defense is a security feature that

- verifies user credentials with an LDAP or RADIUS server as specified in an external authentication object
- can be used by both the Firewall Management Center and Firewall Threat Defense devices, and
- allows only one external authentication object to be activated in the platform settings for the Firewall Threat Defense.

Authentication object sharing and user privileges

You can share the same object between the different appliance/device types or create separate objects.

Note The timeout range is different for the Firewall Threat Defense and the Firewall Management Center, so if you share an object, be sure not to exceed the Firewall Threat Defense's smaller timeout range (1-30 seconds for LDAP, and 1-300 seconds for RADIUS). If you set the timeout to a higher value, the Firewall Threat Defense external authentication configuration will not work.

Only a subset of fields in the external authentication object are used for Firewall Threat Defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for other device types, those fields will be used.

User privilege levels:

- LDAP users always have Config privileges
- RADIUS users can be defined as either Config or Basic users

User definition options:

- For RADIUS: Define users on the RADIUS server (with the Service-Type attribute) or pre-define the user list in the external authentication object
- For LDAP: Specify a filter to match CLI users on the LDAP server

Note Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges, which can present a security risk. Make sure that you:

- Restrict the list of users with Linux shell access.
- Do not create Linux shell users.

LDAP

The Lightweight Directory Access Protocol (LDAP) is a directory service protocol that allows you to set up a directory on your network that organizes objects, such as user credentials, in a centralized location. Multiple applications can then access those credentials and the information used to describe them. If you ever need to change a user's credentials, you can change them in one place.

LDAP binding information

Microsoft has announced that Active Directory servers will start enforcing LDAP binding and LDAP signing in 2020. Microsoft is making these a requirement because when using default settings, an elevation of privilege vulnerability exists in Microsoft Windows that could allow a man-in-the-middle attacker to successfully forward an authentication request to a Windows LDAP server. For more information, refer to 2020 LDAP channel binding and LDAP signing requirement for Windows on the Microsoft support site.

If you have not done so already, we recommend you start using TLS/SSL encryption to authenticate with an Active Directory server.

RADIUS

RADIUS is a network authentication protocol that

- provides centralized authentication and authorization for network access,
- operates using client-server architecture for user credential verification, and
- supports accounting functions to track user sessions and network usage.

Remote Authentication Dial In User Service (RADIUS) is an authentication protocol used to authenticate, authorize, and account for user access to network resources. You can create an authentication object for any RADIUS server that conforms to RFC 2865.

Secure Firewall devices support the use of SecurID tokens. When you configure authentication by a server using SecurID, users authenticated against that server append the SecurID token to the end of their SecurID PIN and use that as their password when they log in. You do not need to configure anything extra on the Secure Firewall device to support SecurID.

By default, RADIUS uses port 1812 for authentication and port 1813 for accounting.

If you change the RADIUS authentication port, the RADIUS accounting port changes accordingly. Ensure that the Firewall Management Center can connect to the RADIUS server on the new accounting port; otherwise, authentication delays may occur.

Although you cannot configure RADIUS accounting parameters, the Firewall Threat Defense uses port 1813 for RADIUS accounting on the same server used for authentication. If the RADIUS server is unreachable on port 1813, it can cause delays in logging in.

Add an LDAP external authentication object for Firewall Threat Defense

Create external authentication object to provide authorized access to the Firewall Threat Defense system via LDAP, with appropriate privilege levels.

Add an LDAP server to support external users for Firewall Threat Defense management.

In a multidomain deployment, external authentication objects are only available in the domain in which they are created.

Sharing External Authentication

External LDAP objects can be used by the Firewall Management Center and Firewall Threat Defense devices. You can share the same object between the Firewall Management Center and devices or create separate objects. Be sure that both the Firewall Threat Defense and the Firewall Management Center can reach the LDAP server, even if you are not sharing the object. The Firewall Management Center is essential to retrieving the user list and downloading it to the device.

Note For LDAP, the timeout range is different for the Firewall Threat Defense and the Firewall Management Center , so if you share an object, be sure not to exceed the Firewall Threat Defense 's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the deployment to the Firewall Threat Defense will fail.

Supported Fields

Only a subset of fields in the LDAP object are used for Firewall Threat Defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for the Firewall Management Center , those fields will be used. This procedure only covers the supported fields for the Firewall Threat Defense. For other fields, refer to "Add an LDAP External Authentication Object for Firewall Management Center " in the *Cisco Secure Firewall Management Center Administration Guide* .

Usernames

Usernames must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

You cannot add the **admin** or **sshd** users for external authentication.

You can only add external users (as part of the External Authentication object) in the Firewall Management Center ; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the Firewall Management Center.

If you previously configured the same username for an internal user using the **configure user add** command, the Firewall Threat Defense first checks the password against the internal user, and if that fails, it checks the LDAP server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported.

Privilege Level

LDAP users always have Config privileges.

Before you begin

You must specify DNS server(s) for domain name lookup on your device. Even if you specify an IP address and not a hostname for the LDAP server on this procedure, the LDAP server may return a URI for authentication that can include a hostname. A DNS lookup is required to resolve the hostname. Refer to Modify Firewall Threat Defense management interface settings at the CLI , on page 763 to add DNS servers.

Procedure

Step 1 Choose **System** (⚙) > **Users**. Click the **External Authentication** tab.

Step 2 Click (+) **Add External Authentication Object**.

Step 3 Set the **Authentication Method** to **LDAP**.

a) Enter a **Name** and optional **Description**.

b) Choose a **Server Type** from the drop-down list.

Step 4 For the **Primary Server** , enter a **Host Name/IP Address**.

a) Change the **Port** from the default

If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

Step 5 (Optional) Enter the **Backup Server** parameters.

Step 6 Enter **LDAP-Specific Parameters**.

a) Enter the **Base DN** for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com`. Alternatively click **Fetch DNs** , and choose the appropriate base distinguished name from the drop-down list.

b) (Optional) Enter the **Base Filter**.

For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)`.

To retrieve all cn names, except for disallowed users admin and sshd, enter `(&(cn=*)(!(|(cn=sshd)(cn=admin))))`.

c) Enter a **User Name** for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at your example company has a `uid` value of `NetworkAdmin` , you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com`.

d) Enter the user password in the **Password** and the **Confirm Password** fields.

e) (Optional) Click **Show Advanced Options** to configure the following advanced options.

- **Encryption** —Click **None** , **TLS** , or **SSL**.

If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS** , the port resets to the default value of 389. If you choose SSL encryption, the port resets to 636.

- **SSL Certificate Upload Path** —For SSL or TLS encryption, you must choose a certificate by clicking **Choose File**.

  If you previously uploaded a certificate and want to replace it, upload the new certificate and redeploy the configuration to your devices to copy over the new certificate.

Note TLS encryption requires a certificate on all platforms. For SSL, the Firewall Threat Defense also requires a certificate. For other platforms, SSL does not require a certificate. However, we recommend that you *always* upload a certificate for SSL to prevent man-in-the-middle attacks.

- (Not Used) **User Name Template** —Not used by the Firewall Threat Defense.
- **Timeout (Seconds)** —Enter the number of seconds before rolling over to the backup connection, between 1 and 30. The default is 30.

Note The timeout range is different for the Firewall Threat Defense and the Firewall Management Center , so if you share an object, be sure not to exceed the Firewall Threat Defense 's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the Firewall Threat Defense LDAP configuration will not work.

Step 7 Configure **Attribute Mapping** to retrieve users based on an attribute.

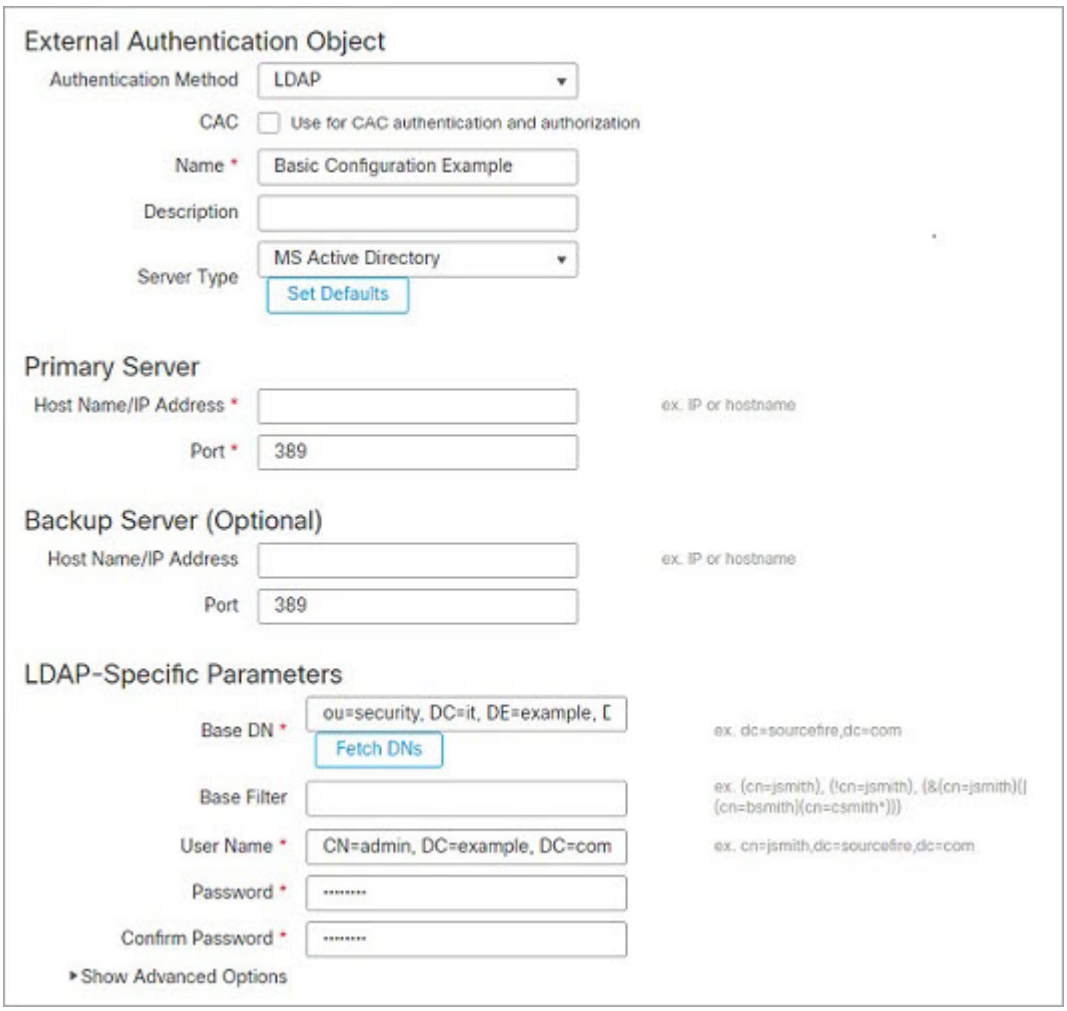
- Enter a **UI Access Attribute**.**Note** : This field is not used for device CLI access; however, it is a required field, so you need to enter a value. You can just enter the same value that you enter for the **CLI Access Attribute**.
- Set the **CLI Access Attribute** if you want to use a CLI access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` CLI access attribute to retrieve CLI access users by typing `sAMAccountName`.

Note Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges, which can present a security risk. Make sure that you restrict the list of users with CLI or Linux shell access.

Note Deploying an external authentication object that allows a large number of users with CLI access may cause deployments to time out and fail while waiting for the users to be created.

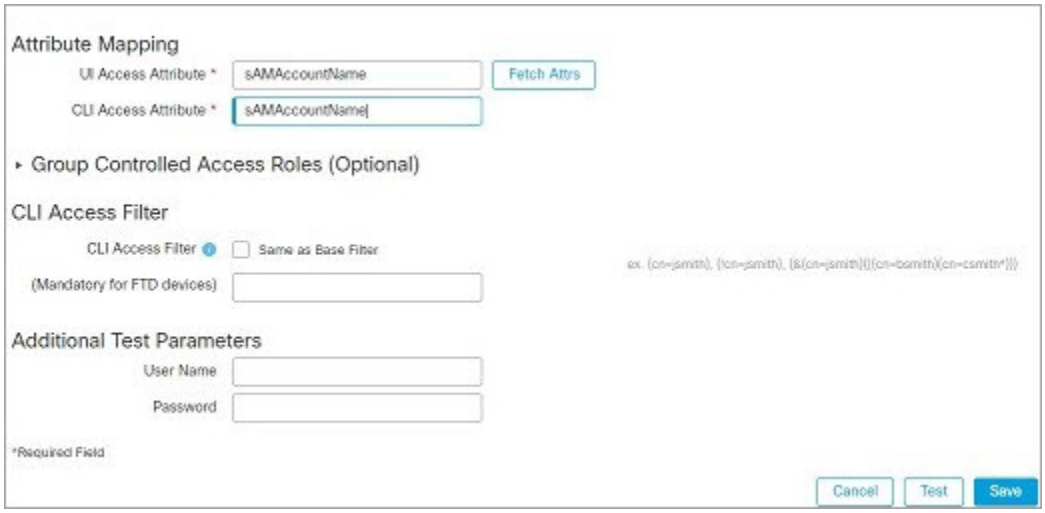
Step 8 Set the **CLI Access Filter**.

Choose one of the following methods:



- To use the same filter you specified when configuring authentication settings, check the check box of **Same as Base Filter**.
- To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell` , you can set a base filter of `(manager=shell)`.

For username guidelines, refer to Usernames at the start of this procedure.

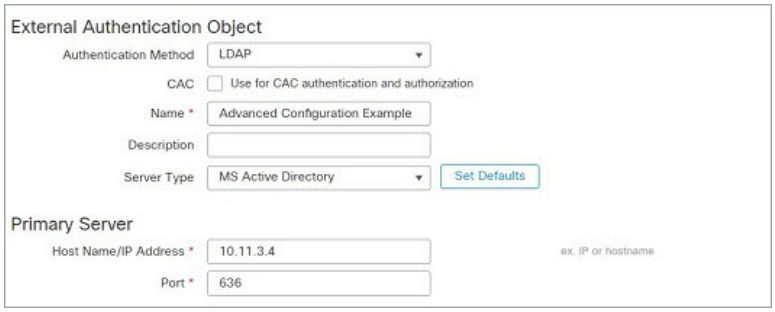


Step 9 Click **Save** and enable use of this server. For more information refer to Configure external authentication, on page 855.

Note If you later add or delete users on the LDAP server, you must redeploy the Platform Settings on managed devices. The Firewall Management Center redownloads the user list and deploys it to the device. For more information refer to Deploy configuration changes, on page 135.

The following figures illustrate a basic configuration of an LDAP login authentication object for a Microsoft Active Directory Server. The LDAP server in this example has an IP address of 10.11.3.4. The connection uses port 389 for access.

This example shows a connection using a base distinguished name of `OU=security,DC=it,DC=example,DC=com` for the security organization in the information technology domain of the Example company.



A **CLI Access Attribute** of `sAMAccountName` causes each `sAMAccountName` attribute to be checked for all objects in the directory for matches when a user logs into the Firewall Threat Defense.

Note that because no base filter is applied to this server, the Firewall Threat Defense checks attributes for all objects in the directory indicated by the base distinguished name. Connections to the server time out after the default time period (or the timeout period set on the LDAP server).

Advanced Example

This example illustrates an advanced configuration of an LDAP login authentication object for a Microsoft Active Directory Server. The LDAP server in this example has an IP address of 10.11.3.4. The connection uses port 636 for access.

This example shows a connection using a base distinguished name of `OU=security,DC=it,DC=example,DC=com` for the security organization in the information technology domain of the Example company. However, note that this server has a base filter of `(cn=*smith)`. The filter restricts the users retrieved from the server to those with a common name ending in `smith`.

The connection to the server is encrypted using SSL and a certificate named `certificate.pem` is used for the connection. In addition, connections to the server time out after 60 seconds because of the **Timeout (Seconds)** setting.

Because this server is a Microsoft Active Directory server, it uses the `sAMAccountName` attribute to store user names rather than the `uid` attribute.

The **CLI Access Attribute** of `sAMAccountName` causes each `sAMAccountName` attribute to be checked for all objects in the directory for matches when a user logs into the Firewall Threat Defense.

In the following example, the CLI access filter is set to be the same as the base filter.

Add a RADIUS external authentication object for Firewall Threat Defense

Configure a RADIUS server on the Firewall Threat Defense

Add a RADIUS server to support external users for the Firewall Threat Defense

Sharing External Authentication Objects

You can share the same object between the Firewall Management Center and devices or create separate objects. Note that the Firewall Threat Defense supports defining users on the RADIUS server, while the Firewall Management Center requires you to predefine the user list in the external authentication object. You can choose to use the predefined list method for the Firewall Threat Defense , but if you want to define users on the RADIUS server, you must create separate objects for the Firewall Threat Defense and the Firewall Management Center.

Note The timeout range is different for the Firewall Threat Defense and the Firewall Management Center , so if you share an object, be sure not to exceed the Firewall Threat Defense 's smaller timeout range (1-300 seconds). If you set the timeout to a higher value, the Firewall Threat Defense RADIUS configuration will not work.

Firewall Threat DefenseFirewall Threat Defense

Only a subset of fields in the RADIUS object are used for Firewall Threat Defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for the Firewall Management Center , those fields will be used. This procedure only covers the supported fields for the Firewall Threat Defense. For other fields, refer to Add a RADIUS External Authentication Object for Firewall Management Center in the *Cisco Secure Firewall Management Center Administration Guide*.

Firewall Threat Defense

You cannot add the **admin** user for external authentication. You can only add external users (as part of the External Authentication object) in the Firewall Management Center ; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the Firewall Management Center.

If you previously configured the same username for an internal user using the **configure user add** command, the Firewall Threat Defense first checks the password against the internal user, and if that fails, it checks the RADIUS server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported. For users defined on the RADIUS server, be sure to set the privilege level to be the same as any internal users; otherwise you cannot log in using the external user password.

Before you begin

Define users on the RADIUS server using the Service-Type attribute.

These are supported values for the Service-Type attribute:

- Administrator (6)—Provides Config access authorization to the CLI. These users can use all commands in the CLI.
- NAS Prompt (7) or any level other than 6—Provides Basic access authorization to the CLI. These users can use read-only commands, such as **show** commands, for monitoring and troubleshooting purposes.

The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a sign (@) or slash (/)

Alternatively, you can predefine users in the external authentication object (refer to Step 6, on page 100). To use the same RADIUS server for the Firewall Threat Defense and Firewall Management Center while using the Service-Type attribute method for the Firewall Threat Defense , create two external authentication objects that identify the same RADIUS server: one object includes the predefined **CLI Access Filter** users (for use with the Firewall Management Center), and the other object leaves the **CLI Access Filter** empty (for use with Firewall Threat Defense s).

Procedure

Step 1 In the Firewall Management Center , choose **System** (⚙) > **Users**.

Step 2 Click **External Authentication** and select (+) **Add External Authentication Object**.

a) Set the **Authentication Method** to **RADIUS**.

b) Enter a **Name** and optional **Description**.

Step 3 For the **Primary Server** , enter a **Host Name/IP Address**.

a) Change the **Port** from the default.

b) Enter the **RADIUS Secret Key**.

Only IPv4 is supported.

Note If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field.

Step 4 (Optional) Enter the **Backup Server** parameters.

Step 5 (Optional) Enter **RADIUS-Specific Parameters**.

a) Enter the **Timeout (Seconds)** in seconds before retrying the primary server, between 1 and 300. The default is 30.

Note The timeout range is different for the Firewall Threat Defense and the Firewall Management Center , so if you share an object, be sure not to exceed the Firewall Threat Defense 's smaller timeout range (1-300 seconds). If you set the timeout to a higher value, the Firewall Threat Defense RADIUS configuration will not work.

b) Enter the **Retries** before rolling over to the backup server. The default is 3.

Step 6 (Optional) Instead of using RADIUS-defined users, in the **CLI Access Filter** area **Administrator CLI Access User List** field, enter the user names that should have CLI access, separated by commas. For example, enter `jchrichton, aerynsun, rygel`.

You may want to use the **CLI Access Filter** method for Firewall Threat Defense so you can use the same external authentication object with Firewall Threat Defense and other platform types.

Note If you want to use RADIUS-defined users, you must leave the **CLI Access Filter** empty.

Make sure that these usernames match usernames on the RADIUS server. The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Note Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges, which can present a security risk. Make sure that you restrict the list of users with CLI or Linux shell access.

Note Deploying an external authentication object that allows a large number of users with CLI access may cause deployments to time out and fail while waiting for the users to be created.

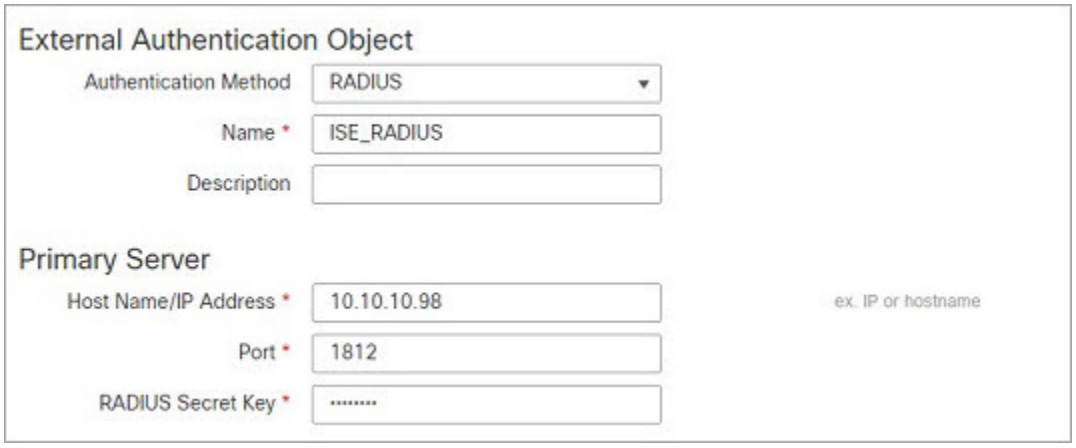
Step 7 (Optional) Click **Test** to test Firewall Management Center connectivity to the RADIUS server.

This function can only test Firewall Management Center connectivity to the RADIUS server; there is no test function for managed device connectivity to the RADIUS server.

Step 8 (Optional) You can also enter **Additional Test Parameters** to test user credentials for a user who should be able to authenticate: enter a **User Name** and **Password** , and then click **Test**.

Tip If you mistype the name or password of the test user, the test fails even if the server configuration is correct. To verify that the server configuration is correct, click **Test** without entering user information in the **Additional Test Parameters** field first. If that succeeds, supply a user name and password to test with the specific user.

Example:



To test if you can retrieve the `JSmith` user credentials at the Example company, enter `JSmith` and the correct password.

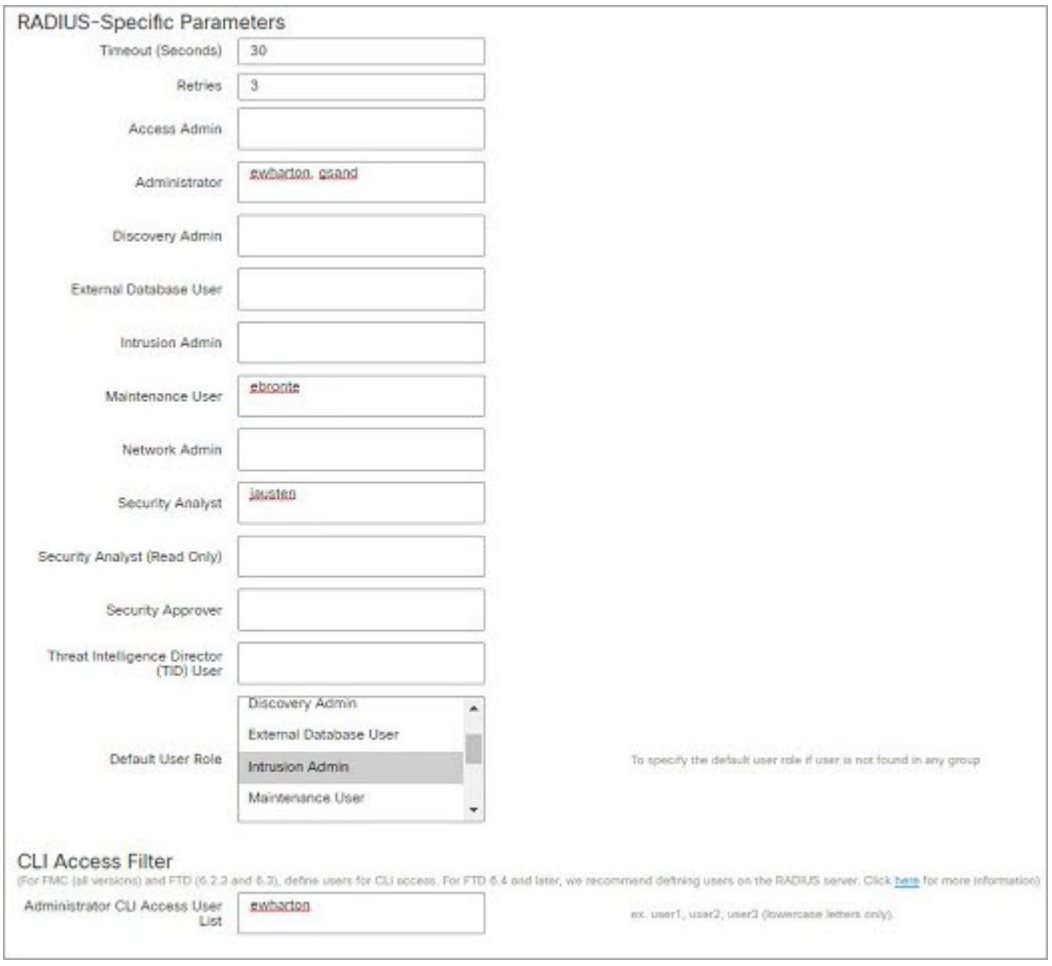
Step 9 Click **Save** and enable use of this server. For more information refer to Configure external authentication, on page 855

Examples

Simple User Role Assignments

This figure illustrates a sample RADIUS login authentication object for a server running Cisco Identity Services Engine (ISE) with an IP address of 10.10.10.98 on port 1812. No backup server is defined.

This example shows RADIUS-specific parameters, including the timeout (30 seconds) and number of failed retries before the system attempts to contact the backup server, if any.



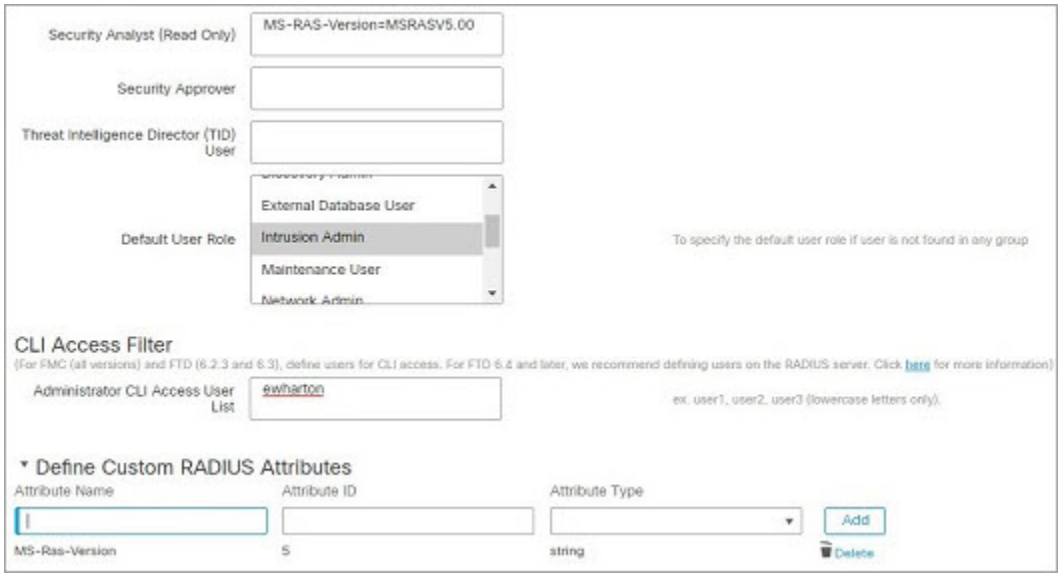
This example illustrates important aspects of RADIUS user role configuration:

Users `ewharton` and `gsand` are granted web interface Administrative access.

The user `cbronte` is granted web interface Maintenance User access.

The user `jausten` is granted web interface Security Analyst access.

The user `ewharton` can log into the device using a CLI account.



This graphic depicts the role configuration for the example:

Roles for Users Matching an Attribute-Value Pair

You can use an attribute-value pair to identify users who should receive a particular user role. If the attribute you use is a custom attribute, you must define the custom attribute.

This figure illustrates the role configuration and custom attribute definition in a sample RADIUS login authentication object for the same ISE server as in the previous example.

In this example, however, the `MS-RAS-Version` custom attribute is returned for one or more of the users because a Microsoft remote access server is in use. Note the `MS-RAS-Version` custom attribute is a string. In this example, all users logging in to RADIUS through a Microsoft v. 5.00 remote access server should receive the Security Analyst (Read Only) role, so you enter the attribute-value pair of `MS-RAS-Version=MSRASV5.00` in the **Security Analyst (Read Only)** field.

External authentication for users on Firewall Threat Defense devices

External authentication for users on Firewall Threat Defense devices is a security configuration that enables authentication through external authentication servers rather than local device credentials.

Configuration process

Enable External Authentication in the Threat Defense Platform Settings, and then deploy the settings to the managed devices. Refer to Configure external authentication, on page 855 for more information.

Troubleshoot LDAP authentication connections

This reference provides troubleshooting information for resolving LDAP authentication connection problems in your system configuration.

If you create an LDAP authentication object and it either does not succeed in connecting to the server you select or does not retrieve the list of users you want, you can tune the settings in the object.

If the connection fails when you test it, try the following suggestions to troubleshoot your configuration:

- Use the messages displayed at the top of the web interface screen and in the test output to determine which areas of the object are causing the issue.
- Check that the user name and password you used for the object are valid:
  - Check that you have the rights to browse to the directory indicated in your base-distinguished name by connecting to the LDAP server using a third-party LDAP browser.
  - Check that the user name is unique to the directory information tree for the LDAP server.
  - If you see an LDAP bind error 49 in the test output, the user binding for the user failed. Try authenticating to the server through a third-party application to see if the binding fails through that connection as well.

- When configuring LDAP authentication, avoid using a backslash ("\") in the binding password. The presence of a backslash in the password causes the LDAP binding process to fail, resulting in unsuccessful external authentication.

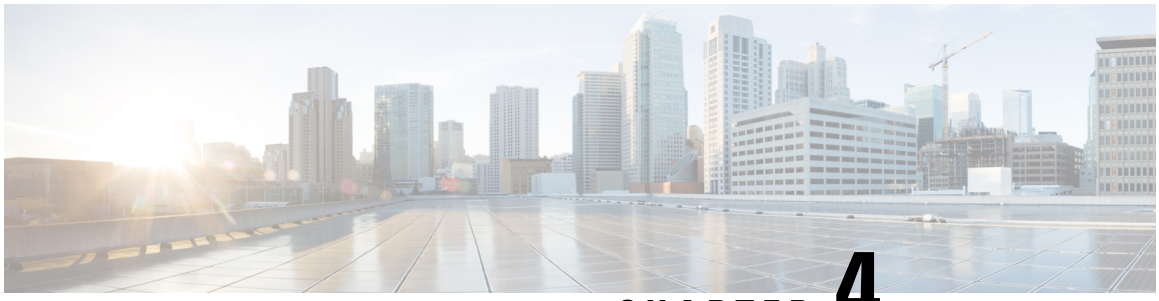
- Check that you have correctly identified the server:
  - Check that the server IP address or host name is correct.
  - Check that you have TCP/IP access from your local appliance to the authentication server where you want to connect.
  - Check that access to the server is not blocked by a firewall and that the port you have configured in the object is open.
  - If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used for the server.
  - Check that you have not used an IPv6 address for the server connection if you are authenticating CLI access.
  - If you used server type defaults, check that you have the correct server type and click **Set Defaults** again to reset the default values.
- If you typed in your base-distinguished name, click **Fetch DNs** to retrieve all the available base distinguished names on the server, and select the name from the list.
- If you are using any filters, access attributes, or advanced settings, check that each is valid and typed correctly.
- If you are using any filters, access attributes, or advanced settings, try removing each setting and testing the object without it.
- If you are using a base filter or a CLI access filter, make sure that the filter is enclosed in parentheses and that you are using a valid comparison operator (maximum 450 characters, including the enclosing parentheses).
- To test a more restricted base filter, try setting it to the base distinguished name for the user to retrieve just that user.
- If you are using an encrypted connection:
  - Check that the name of the LDAP server in the certificate matches the host name that you use to connect.
  - Check that you have not used an IPv6 address with an encrypted server connection.
- If you are using a test user, make sure that the user name and password are typed correctly.
- If you are using a test user, remove the user credentials and test the object.
- Test the query that you are using by connecting to the LDAP server and using this syntax:

```
ldapsearch -x -b 'base_distinguished_name'
-h LDAPserver_ip_address -p port -v -D
'user_distinguished_name' -W 'base_filter'
```

For example, if you are trying to connect to the security domain on `myrtle.example.com` using the `domainadmin@myrtle.example.com` user and a base filter of (`cn=*`), you could test the connection using this statement:

```
ldapsearch -x -b 'CN=security,DC=myrtle,DC=example,DC=com'
-h myrtle.example.com -p 389 -v -D
'domainadmin@myrtle.example.com' -W '(cn=*)'
```

If you can test your connection successfully but authentication does not work after you deploy a platform settings policy, check that authentication and the object you want to use are both enabled in the platform settings policy that is applied to the device.



If you connect successfully but want to adjust the list of users retrieved by your connection, you can add or change a base filter or CLI access filter or use a more restrictive or less restrictive base DN.

While authenticating a connection to Active Directory (AD) server, rarely the connection event log indicates blocked LDAP traffic although the connection to AD server is successful. This incorrect connection log occurs when the AD server sends a duplicate reset packet. The Firewall Threat Defense device identifies the second reset packet as part of a new connection request and logs the connection with Block action.

History for CLI users

This reference provides version history information for CLI user features, including authentication enhancements and external authentication support for SSH access.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Support for the Service-Type attribute for Firewall Threat Defense users defined on the RADIUS server.	6.4.0	Any	For RADIUS authentication of Firewall Threat Defense CLI users, you used to have to pre-define the usernames in the RADIUS external authentication object and manually make sure that the list matched usernames defined on the RADIUS server. You can now define CLI users on the RADIUS server using the Service-Type attribute and also define both Basic and Config user roles. To use this method, be sure to leave the shell access filter blank in the external authentication object. New/modified screens: **System** > **Users** > **External Authentication** > **Add External Authentication Object** > **Shell Access Filter**
External authentication for Firewall Threat Defense SSH access.	6.2.3	Any	You can now configure external authentication for SSH access to the Firewall Threat Defense using LDAP or RADIUS. New/modified screens: **Devices** > **Platform Settings** > **External Authentication**

CHAPTER 4

Change Management

You can enable change management if your organization needs to implement more formal processes for configuration changes, including audit tracking and official approval before changes are deployed.

- Change management, on page 107
- Requirements and prerequisites for change management, on page 111
- Guidelines and limitations for change management, on page 111
- Enabling or disabling change management, on page 112
- Manage tickets, on page 113
- History for change management, on page 118

Change management

Change management is a formal process that

- enforces an official approval process before configuration changes can be made to a device,
- requires administrators to open tickets before they can make configuration changes, and
- ensures that the right employees make the final decisions through submission and approval of tickets.

Change management characteristics

When using change management, the system implements these controls:

- Administrators can see their own changes within a ticket, but they cannot see changes anyone else has made within a ticket
- A policy is locked once a user makes a change within a ticket, preventing interfering changes
- Users cannot make changes while another user has made a change that is pending approval

Administrators can create multiple tickets so that a single ticket contains only logically-related policy changes. Tickets with a more limited scope are also easier to evaluate and approve quickly.

Make configuration changes in the change management workflow

This task enables configuration specialists to make configuration changes to supported policies and objects when change management is enabled.

When you enable change management, users who configure devices and shared policies need to change their approach slightly. Configuration specialists need to take the following approach when making configuration changes to supported policies and objects.

Procedure

Step 1 Create a ticket.

Step 2 Open the ticket.

Step 3 Make the configuration changes.

Note that the procedures explained in the online help and user guides assume that change management is not active, and omit any steps for creating, opening, or submitting tickets.

Step 4 Optionally, preview and validate the ticket to ensure the changes are complete and correct.

Step 5 Submit the ticket. At this point, the approver can either approve or reject the ticket.

- If the ticket is approved, deploy the changes.
- If the ticket is rejected, address the issues, and resubmit the ticket.

The configuration changes are successfully implemented through the change management workflow with proper approval and deployment processes.

Create separate approver and configuration roles

Separate approver and configuration roles are system-defined and custom roles that

- have permissions to modify (create/open/discard) and review (approve/reject) tickets,
- provide granular access control to separate ticket approval from configuration changes, and
- ensure that ticket approval is assigned only to users who have organizational authority to approve changes.

System-defined roles and permissions

Some system-defined roles have permissions to modify (create/open/discard) and review (approve/reject) tickets:

- To both modify and review tickets:
  - Admin
  - Network Admin
- To modify tickets only:
  - Access Admin
  - Intrusion Admin
- To review tickets only:

- Security Approver

If you need more granular roles to separate these activities due to your organizational requirements, you can create separate roles to ensure that ticket approval is assigned only to those users who have the organizational authority to approve changes. To create new user roles, go to **System** (⚙) > **Users** > **User Roles**.

These are the permissions, in the **System** (⚙) > **Configuration** > **Change Management** folder, relevant to ticket usage and approval. Note that these permissions are available only after you enable change management.

- Modify Tickets—To create tickets (for yourself), to use tickets for configuration changes, and to discard tickets.
- Review Tickets—To approve or reject tickets.
- Both Modify and Review Tickets—To create tickets for yourself and others, use tickets, and approve/reject tickets.

The approach you take depends on your precise requirements. For example:

- If your approvers should also be allowed to make configuration changes, you can simply assign them the system-defined roles, such as Administrator. Then, create custom configuration-only roles that include the same permissions but not the Review Tickets permission.
- If you need complete separation between approvers and those who make configuration changes, create custom roles for both, limiting the roles to either the Modify Tickets or the Review Tickets permission plus all other needed permissions for viewing or changing the supported policies and objects.

Policies and objects that support change management

If a policy or object supports the change management workflow, then creating, editing, or deleting the policy or object, including assigning a policy to a device, must be done in an open ticket.

Any action, policy, or object that does not support the change management workflow can be created, edited, or deleted, and so forth, without an open ticket. Even if a ticket is open, the changes made to unsupported policies are not included in the ticketed changes and are available for deployment immediately.

This information includes the policies and objects that are supported. Anything not listed is unsupported.

Supported policies

- Access control, including rules, references to other policies, and inheritance settings. Cloning access control policies is not included within a ticket. The clone is immediately accepted and available to all users.
- Device configuration policies:
  - Interfaces
  - Inline sets
  - DHCP
  - VTEP
  - All routing

- FlexConfig
- Intrusion policy and network analysis policy (NAP), Snort 3 only.
- Network address translation (NAT)
- Platform settings
- Prefilter policy
- QoS
- Umbrella SASE topology
- VPN policies, both site-to-site and remote access
- Zero trust access

Supported objects

- AAA server
- Access list
- Address pools
- AS path
- Community list
- DHCP IPv6 pools
- DNS server group
- FlexConfig objects
- Group policy
- Interface
- Key chain
- Network
- Policy list
- Port
- Prefix list
- Route map
- SLA monitor
- Time range
- Time zone
- Tunnel zone

- URL
- Variable set
- VLAN tag
- VPN objects (IKEv1, IKEv2 IPSec and policy, PKI enrollment, certificate map)

Requirements and prerequisites for change management

This reference provides the requirements and prerequisites necessary to configure change management functionality.

Model support

Management center

Supported domains

Any

User roles

- To enable or disable change management: Admin.
- To both modify and review tickets:
  - Admin
  - Network Admin
- To modify tickets only:
  - Access Admin
  - Intrusion Admin
- To review tickets only:
  - Security Approver

Guidelines and limitations for change management

When operating in change management mode, users can make changes to supported policies, but they cannot save the changes. For example, you could go through the dialog box to create a new platform settings policy without an open ticket, but when you click OK to actually create the policy, you will get an error and the policy will not be created.

The following activities require that all tickets be in a terminal state, that is, approved or discarded: backup/restore, moving a device between domains, upgrading Firewall Management Center.

Deleting a device from the inventory requires that all tickets involving that device be approved or discarded.

Some system processes prevent you from enabling or disabling change management. Wait until the following processes complete before you enable or disable change management:

- critical management center processes, including SRU updates, LSP updates, VDB updates, and management center upgrades
- pending or running background activities, including device registration; cluster auto-registration; Firewall Threat Defense high availability operations; high availability auto-registration; FlexConfig migration; cluster creation, break, edit, reconcile, or node changes; device-template creation or application; device-model migration; and EPM join or breakout
- system jobs, including backup or restore, device import or export, general import, and domain movement.

Your ability to create objects while configuring a feature is constrained based on whether the feature and objects are all supported by change management. For example, importing a configuration is not supported by change management. Therefore, you cannot create security zone objects, which are supported, during the import. On the other hand, you can create new objects while configuring access control rules, because both are supported.

When using Cloud-Delivered Firewall Management Center, a user defined in Security Cloud Control is available to be assigned tickets only after the user cross-launches cdFMC at least once. Until the first cross-launch, the user does not exist in cdFMC.

Enabling or disabling change management

Enable or disable change management to control whether users must open tickets and get approval when making configuration changes to the system.

The default is that the change management workflow is disabled. Users do not need to open tickets and get approval when making configuration changes. If you want to enforce the change management workflow, you must enable it globally for the system.

Before you begin

There are several system processes that prevent you from enabling/disabling change management. If any of the following are in process, you need to wait for them to complete before changing these settings: backup/restore; import/export; domain movement; upgrade; Flexconfig migration; device registration; high-availability registration, creation, break, or switch; cluster create, registration, break, edit, add or remove nodes; EPM break out or join.

An access control policy cannot be locked when you change these settings. If a policy is locked, you must wait for the lock to be released before enabling/disabling this feature.

Follow these steps to enable or disable change management:

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Change Management**.

Step 3 Select **Enable Change Management**.

To disable the feature, deselect the option. All tickets must be approved or discarded to disable change management. You cannot disable change management if any ticket is in the In Progress, On Hold, Rejected, or Pending Approval state.

Step 4 Select the **Number of approvals required**, which is how many administrators must approve the change for the ticket to be approved and deployable. The default is 1, but you can require up to 5 approvers per ticket. Users can override this number when creating tickets.

Step 5 Select the **Ticket Purge Duration**, which is the number of days to keep approved tickets, from 1-100 days. The default is 5 days.

Step 6 (Optional.) Enter the **Reply to Address** and the email addresses for the **List of Approver Addresses**. You must also configure the email notification system settings for email to work.

Step 7 Click **Save**.

The system adds the **Ticket** ( ) shortcut to the menu bar, and the **System** ( ) > **Change Management Workflow** command. Users can manage tickets using these methods.

Change management is enabled or disabled according to your configuration. If enabled, the system adds ticket management shortcuts to the interface, and users must follow the change management workflow when making configuration changes.

Manage tickets

This task enables you to manage change management tickets for configuration changes to supported policies that require approval workflow.

When you enable change management, configuration changes for supported policies must be done within the context of a ticket. You open a ticket, make your changes, then submit the ticket for approval.

You can see a list of tickets, and create new ones, either on the change management page or through the ticket quick-access menu. All ticket changes are synchronized in each menu, so you can switch back and forth at your convenience and use whichever method you prefer.

Note When you open a ticket and make a change to a supported policy, that policy is locked from changes by other users or through other tickets. The policy remains locked until the ticket is approved or discarded.

Procedure

Step 1 Do any of these actions:

- Choose **System** ( ) > **Change Management Workflow** to open a page showing existing tickets.
- Click the **Ticket** ( ) quick-access menu. The icon can either be named Select a Ticket (if no ticket is opened), the ticket name if a ticket is opened, or unnamed if no tickets exist.

Both pages are organized the same. The **Ticket** tab lists all tickets, whereas the **Review** tab lists tickets that have been submitted for approval. The default view shows your tickets only.

Step 2 On the **Ticket** tab, take any of these actions:

- To create a new ticket, click **Add Ticket**.
- To view the details of a ticket, click the > next to the ticket name. The Details page includes UUID, name, description, user, last modified date, and comments. The History page includes the status changes for the ticket. The image at the top shows where the ticket stands in the overall workflow.
- To preview the configuration changes for an open ticket, click **Preview** ( ).
- To validate the configuration changes in an open ticket, click **Validate** ( ) or **More** ( ) > **Validate**. A dialog box opens showing error, warning, and informational messages, if there are any validation errors.
- To open a ticket, click **Open** ( ) or **More** ( ) > **Open**. To close an open ticket, click **Put Ticket on Hold (X)** or **More** ( ) > **Put Ticket on Hold**. Closing a ticket does not submit it for review, nor does it release any locks placed on edited policies.
- To submit an open ticket for review and approval, click **Submit for Approval** ( ) or **More** ( ) > **Submit for Approval**. The ticket must be open to be submitted.
- To discard a ticket, click **Discard** ( ) or **More** ( ) > **Discard**.
- To search for a ticket, type a string in the search box. The search looks at ticket name, description, and responsible user. To filter the list by ticket status (on the change management workflow page), click the status above the list: **New**, **Open**, **On Hold** (ticket was closed), **Rejected**, **Pending Approval**, **Approved**. Each status has a count of the number of tickets in that state. Click **All** under **My Tickets** to return to the default of showing all of your tickets, or **All** under **Tickets in System** to see everyone's tickets.

Step 3 On the **Reviews** tab, take any of these actions on submitted tickets.

The list is empty if there are no submitted tickets. In addition, only users with Review Ticket permissions can see this tab.

- To preview the configuration changes for a ticket, click **Preview** ( ).
- To validate the configuration changes in an open ticket, click **Validate** ( ) or **More** ( ) > **Validate**.
- To approve the ticket, click **Approve** ( ) or **More** ( ) > **Approve**.
- To disapprove the ticket, click **Reject** ( ) or **More** ( ) > **Reject**.

You have successfully managed your change management tickets. Approved tickets can proceed with configuration changes, while rejected tickets require revision before resubmission.

Create change management tickets

Create change management tickets to ensure all configuration changes are performed within the context of an approved workflow ticket.

When using the change management workflow, you must do all configuration changes within the context of an open ticket. If you do not already have a ticket, you must create a new one.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.

Step 2 Click **Add Ticket**.

Step 3 Configure the ticket options:

- **Name**—The name of the ticket. The name can include letters, numbers, spaces, and the following special characters: #-_!
- **Description**—An optional description of what you intend to configure using this ticket. For example, if you have a case number related to what you intend to fix using this ticket, that would be useful information in a description.
- **Number of Approvers**—How many administrators must approve the change for the ticket to be approved and deployable. You can specify 1-5.
- **Assign to**—Select the user who will own the ticket and be responsible for implementing the changes. Choose **self** to assign it to yourself.

Step 4 Click one of the following:

- **Create**—The ticket is added to the list of tickets, but it is not opened. You need to open it before you can work within the context of the ticket.
- **Create and Open**—The ticket is added to the list of tickets and also opened.

The change management ticket is created and available for use in the workflow. If you selected Create and Open, the ticket is immediately opened for configuration changes.

Opening a ticket for configuration changes

Open a ticket to enable configuration changes within the ticket management system.

Before you can make changes within a ticket, you must open the ticket.

If you have another ticket open, the system puts it on hold (closes it) for you before opening the new one.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.

Step 2 On the **Tickets** tab, click **Open** (📂) or **More** (⋮) > **Open** for the ticket.

Step 3 Optionally, enter a comment for the action.

Step 4 Click **Open**.

You can now start your configuration changes. The name of the ticket icon changes to the name of the open ticket.

The ticket is now open and ready for configuration changes. The ticket icon displays the name of the open ticket.

Preview a ticket

Preview a ticket to view all configuration changes made within the context of the ticket.

You can preview a ticket while making your configuration changes, or before approving it. The preview shows all configuration changes made within the context of the ticket.

Procedure

Step 1 Choose **System** ( ) > **Change Management Workflow**, or click the **Ticket** ( ) shortcut menu.

Step 2 Click **Preview** ( ) for the ticket.

The Preview dialog box opens. Changes are color coded according to the legend at the top of the dialog box.

Step 3 Select the policy whose changes you want to view in the Changed Policies list.

You are shown both the current version of the policy as it is defined in Secure Firewall Management Center (on the left) and the proposed changes defined within the ticket.

For policies that contain pages, such as platform settings, you can select the overall policy to see all changes, or specific pages within the policy, in the Changed Policies list.

You cannot alter the changes from within the preview. If you need to change something, you must close the preview and return to the policy you want to change.

Step 4 Optionally, click **Download as PDF** to save the preview to a PDF file for offline viewing or archival purposes.

Step 5 Click **OK**.

The ticket preview displays all configuration changes, allowing you to review them before approval or while making modifications.

Submit a ticket

Submit a ticket to apply changes made within the ticket after validation and review.

After you have completed the changes needed for a ticket, you can preview and validate the changes. Then, when you are satisfied with the changes, submit the ticket for review and approval.

Changes made within the ticket are not applied until you submit the ticket and the ticket is approved. Until approval happens, all policies modified within a ticket are locked to that ticket and cannot be changed by anyone else.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📋) shortcut menu.

Step 2 Click **Submit for Approval** ( ) or **More** (⋮) > **Submit for Approval** for the open ticket.

Step 3 Optionally, enter a comment for your action.

Step 4 Click **Submit**.

The ticket is submitted for review and approval. Once approved, the changes made within the ticket are applied and the policies are unlocked.

Discard a ticket

Discard a ticket to remove any changes that were made within the ticket when you no longer need to proceed with those changes.

You cannot undo this action and retrieve a ticket with its changes. If you need them, you must create a new ticket and start over.

You cannot discard a ticket after you submit it. However, if the approver rejects the ticket, you can then discard it.

Note If you have permission to modify tickets, you can discard tickets that belong to another user. This makes it possible to deal with situations where an admin is on vacation or otherwise unavailable to manage an in-process ticket.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📋) shortcut menu.

Step 2 Click **Discard** ( ) or **More** (⋮) > **Discard** for the ticket.

Step 3 Optionally, enter a comment for your action.

Step 4 Click **Discard**.

The ticket is discarded and any changes made within the ticket are removed.

Approving or rejecting a ticket

Approve or reject tickets to control which configuration changes become active and available for deployment in your network.

When a user submits a ticket, it must be approved for the changes made within the ticket to become active and available for deployment.

Whether you can approve your own tickets, or there is a separate approver, depends on your workplace policies and how user roles are assigned, not on the management software.

The Details view includes a summary of how many approvers are required for the ticket, and who has approved the ticket.

If the changes are inadequate or undesirable, you can reject the ticket. Rejected tickets go back to the submitter, who can then make additional changes and resubmit the ticket, or simply discard the ticket and the configuration changes it contains.

Procedure

Step 1 Choose **System** ( ) > **Change Management Workflow**, or click the **Ticket** ( ) shortcut menu.

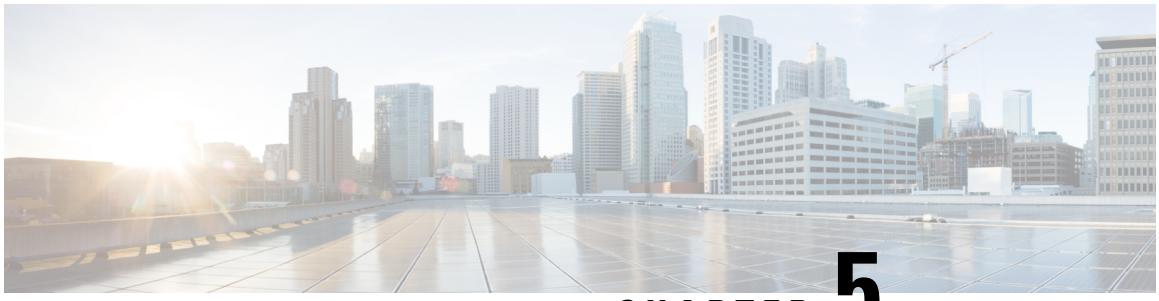
Step 2 On the **Review** tab, click **Preview** ( ) for the ticket and evaluate the proposed changes.

You can also click **Validate** ( ) or **More** ( ) > **Validate** to check for errors.

Step 3 After completing your evaluation, do one of the following:

- To approve the ticket, click **Approve** ( ) or **More** ( ) > **Approve**.
- To disapprove the ticket, click **Reject** ( ) or **More** ( ) > **Reject**.

Step 4 Optionally, enter a comment for your action.



Step 5 Click **Approve** or **Reject**, as appropriate.

The ticket is approved or rejected based on your selection. Approved tickets become active and available for deployment. Rejected tickets return to the submitter for revision or disposal.

History for change management

The following table summarizes the feature changes by release for change management functionality.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Change management.	7.4.1	Any	You can enable change management if your organization needs to implement more formal processes for configuration changes, including audit tracking and official approval before changes are deployed. We added the **System**(⚙) > **Configuration** > **Change Management** page to enable the feature. When enabled, there is a **System**(⚙) > **Change Management Workflow** page, and a new **Ticket**(📄) quick access icon in the menu.

CHAPTER 5

Configuration Deployment

This chapter describes how to download configuration changes to one or more managed devices.

- Configuration deployment, on page 121
- Requirements and prerequisites for deployment management, on page 133
- Best practices for deploying configuration changes, on page 133
- Configuration deployment, on page 134
- Deployment management, on page 141
- History for configuration deployment, on page 154

Configuration deployment

Configuration deployment is a management process that enables centralized control and distribution of device settings from Firewall Management Center to managed devices.

Configuration changes that require deployment

Firewall Management Center marks out-of-date policies with red status text that indicates how many of its targeted devices need a policy update. Redeploy the policy to the devices to clear this status.

Deployment required

You must deploy changes after these configuration updates:

- Modifying an access control policy: any changes to access control rules, the default action, policy targets, Security Intelligence filtering, advanced options including preprocessing, and so on.
- Modifying any of the policies that the access control policy invokes: the SSL policy, network analysis policies, intrusion policies, file policies, identity policies, or DNS policies.
- Changing any reusable object or configuration used in an access control policy or policies it invokes:
  - network, port, VLAN tag, URL, and geolocation objects
  - Security Intelligence lists and feeds
  - application filters or detectors
  - intrusion policy variable sets

  - file lists
  - decryption-related objects and security zones

- Updating intrusion rules (SRU/LSP) or the vulnerability database (VDB).
- Upgrading managed devices.
- Upgrading the Firewall Management Center.

You can change some of these configurations from multiple places in the web interface. For example, you can modify security zones using the object manager (**Objects** > **Object Management**), but modifying an interface type in a device configuration (**Devices** > **Device Management**) can also change a zone and require a deployment.

Deployment not required

These updates do not require a deployment:

- Security Intelligence updates to feeds and the global Block or Do Not Block lists.
- URL filtering data updates.
- Geolocation database (GeoDB) updates.

Deployment preview

A deployment preview is a snapshot that provides all the policy and object changes to be deployed on the device.

The policy changes include the new policies, changes in the existing policies, and the deleted policies. The object changes include the added and modified objects which are used in policies. The unused object changes are not displayed because they are not deployed on the device.

Click the **Preview** icon next to a deployment job to view the configuration change log for that are pending to be deployed on the device. The change log includes:

- **Comparison View**: Displays a side-by-side comparison of all the device configuration changes made since your last deployment.
- **Advanced View**: Displays the pending CLI commands to be applied to the device.

For more information about viewing the deployment preview, refer to Deploy configuration changes, on page 135.

The preview shows all the default values, even when they are not altered, along with the other configured settings when an interface or a platform settings policy is added for the first time. Similarly, the high availability-related policies and default values for settings are shown, even when they are not altered, in the first preview after a high availability pair is configured or disrupted.

To view changes due to an auto rollback, refer to Edit deployment settings, on page 800.

Unsupported features:

- Object additions and attribute changes are displayed in the preview only if the objects are associated with any device or interface. Object deletions are not displayed.

- Preview is not supported for the policies:
  - High availability
  - Network discovery
  - Network analysis
  - Device settings
- User information at the rule level is not available for intrusion policies.
- The preview does not show the reordering of rules across policies.

  For DNS policies, reordered rules appear in the preview list as rule additions and deletions. For example, moving a rule from position 1 to position 3 in the rule order is displayed as if the rule was deleted from position 1 and added as a new rule in position 3. Similarly, when a rule is deleted, the rules under it are listed as edited rules as they have changed their positions. The changes are displayed in the final order in which they appear in the policy.
- Preview is not supported in these HA scenarios:
  - If a device was in standalone mode and if a chain is made, then an auto-deployment is triggered.

    For that particular job, preview is not supported. On hover over the **Preview** (), a message is displayed that it is a HA bootstrap deployment, and no preview is supported.
  - **Configuration groups** - Consider a flow in which a device was initially standalone. Subsequently, three deployments took place. In the fourth deployment, the device was a HA bootstrap deployment. After these, the user deploys devices 5, 6, and 7. The deployment 7 is an HA break deployment, and the user deploys devices 8, 9, and 10.

    In this flow, the preview between 3 and 5 is not supported because 4 was a HA deployment. Similarly, the preview between 8 and 3 is also not supported. Preview is supported only from 3 to 1, 7,6, 5, 4, and 10, 9, and 8.
  - If a device is broken (HA is broken) then the new device is considered as a fresh device.

Guidelines for selective policy deployment

The Firewall Management Center allows you to select a specific policy within the list of all the changes on the device that are due for deployment and deploy only the selected policy.

This table describes the policies that suppot selective deployment.

Table 7: Policies that support selective deployment

Type	Policy
Access control	• Access control policies • Prefilter policies • QoS policies

Type	Policy
Threat prevention and inspection	• Intrusion policies • Malware and file policies • DNS policies
Identity and discovery	• SSL / decryption policies • Identity policies • Network discovery
Device or network connectivity	• NAT policies • Routing policies • VPN policies

Use the this table to understand the constraints and conditions for applying selective policy deployment.

Table 8: Limitations for selective deployment

Type	Description	Scenarios
Full deployment	Full deployment is necessary for specific deploy scenarios, and the Firewall Management Center does not support selective deployment in such scenarios. If you encounter an error in such scenarios, you may choose to proceed by selecting all the changes for deployment on the device.	Full deployment is required for: • The first deployment after you upgrade the Firewall Management Center or its devices. • The first deployment after you restore a device. • The first deployment after modifications to a device's interface settings. • The first deployment after modifications in the virtual router settings. • When a device moves to a new domain (global to sub-domain or sub-domain to global).

Type	Description	Scenarios
Associated policy deployment	The Firewall Management Center identifies interdependent policies which are interlinked. When one of the interlinked policies is selected, the remaining interlinked policies are automatically selected.	Scenarios wherein an associated policy is automatically selected: • When a new object is associated with an existing policy. • When an existing policy's object is modified. Scenarios wherein multiple policies are automatically selected: • When a new object is associated with an existing policy, and the same object is already associated with other policies, all the associated policies are automatically selected. • When a shared object is modified, all the associated policies are automatically selected.
Interdependent policy changes (shown using color-coded tags)	The Firewall Management Center dynamically detects dependencies in-between policies, and between the shared objects and the policies. The interdependency of the objects or policies is shown using color-coded tags.	Scenarios wherein color-coded interdependent policies or objects are automatically selected: • When all the out-of-date policies have interdependent changes. For example, when an access control policy, an intrusion policy, and a NAT policy are out-of-date. Since access control policy and NAT policy share an object, all policies are selected together for deployment. • When all out-of-date policies share an object, and the object is modified.

Type	Description	Scenarios
Access Policy Group specifications	Access Policy Group policies are listed together in the preview window under **Access Policy Group** when you click **View** ( ).	The scenarios and the expected behavior for Access Policy Group policies are: • If the access control policy is out-of-date, all other out-of-date policies under this group, except file policy and intrusion policy, are selected when the access control policy is selected for deployment. However, if the access control policy is out-of-date, intrusion and file policies can be individually selected or deselected irrespective of whether the access control policy is selected or not, unless there are any dependent changes. For example, if a new intrusion policy is assigned to an access control rule, it indicates that there are dependent changes, then both the access control policy and the intrusion policy will be automatically selected when either of them is selected. • If no access control policy is out-of-date, other out-of-date policies in this group can be selected and deployed individually.

System username

The Firewall Management Center displays the username as **system** for specific management operations. This allows administrators to distinguish system-initiated actions from those performed by users.

The **system** username is applied to these operations:

- Rollback
- Upgrade
- Firewall Threat Defense backup and restore
- SRU update
- LSP update
- VDB update

Auto-enabling of application detectors

When you perform application control but disable required detectors, the Firewall Management Center automatically enables the appropriate system-provided detectors upon policy deployment. If no system-provided detector exists for the application, the Firewall Management Center enables the most recently modified user-defined detector.

Asset rediscovery with network discovery policy changes

When you deploy changes to a network discovery policy, the system deletes and then rediscovers MAC address, TTL, and hops information from the network map for the hosts in your monitored networks. Also, the affected managed devices discard any discovery data that has not yet been sent to the Firewall Management Center.

Snort restart scenarios

A Snort restart scenario is a situation that

- causes the traffic inspection engine, referred to as the `Snort process`, on a managed device to restart,
- interrupts inspection until the process resumesWhether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129., and
- may result in resource demands that cause a small number of packets to drop without inspection when you deploy.

Common snort restart triggers

Any of these scenarios cause the Snort process to restart:

- You deploy a specific configuration that requires the Snort process to restart. For more information, refer to Configurations that restart the snort process when deployed or activated, on page 131.
- You make a change that immediately restarts the Snort process. For more information, refer to Actions that immediately restart the snort process, on page 132.
- Traffic activates the currently deployed Automatic Application Bypass (AAB) configuration. For more information, refer Configure automatic application bypass, on page 797.
- Enabling or disabling **Logging connection events to RAM disk** feature. For more information, refer the section **Log to Ramdisk** in Troubleshoot Drain of FMC Unprocessed Events.

Inspection interruption warnings during deployment

When you deploy configurations, the **Inspect Interruption** column in the deploy page indicates if a deployed configuration will restart the Snort process on the Firewall Threat Defense device. When the traffic inspection engine referred to as the `Snort process` restarts, inspection is interrupted until the process resumes. Whether traffic is interrupted or passes without inspection during the interruption depends on how the traffic is handled by the device. You can proceed with the deployment, cancel the deployment and modify the configuration, or delay the deployment until a time when deploying would have the least impact on your network.

During deployment, when the **Inspect Interruption** column indicates **Yes** and you expand the device configuration listing, an icon will highlight any configuration type that may restart the Snort process. Moving your pointer over the icon displays a message saying that deployment may interrupt traffic.

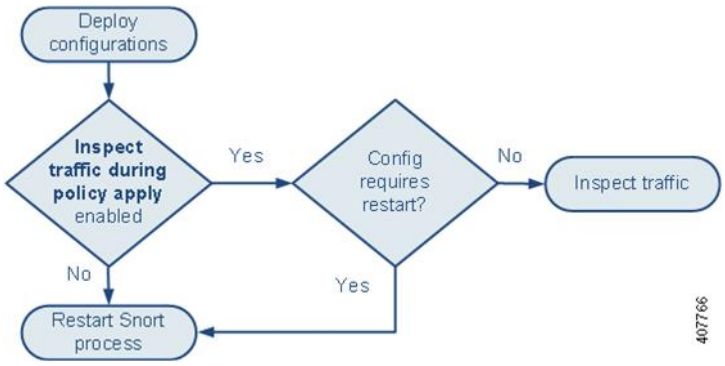
This table summarizes how the deploy page displays inspection interruption warnings.

Table 9: Inspection interruption indicators

Type	Inspect interruption	Description
Firewall Threat Defense	**Inspect Interruption** ( )Yes	At least one configuration would interrupt inspection on the device if deployed, and might interrupt traffic depending on how the device handles traffic. You can expand the device configuration listing for more information.
	--	Deployed configurations will not interrupt traffic on the device.
	Undetermined	The system cannot determine if a deployed configuration may interrupt traffic on the device. Undetermined status is displayed before the first deployment after a software upgrade, or in some cases during a Support call.
	Errors ( )	The system cannot determine the status due to an internal error. Cancel the operation and click **Deploy** again to allow the system to redetermine the **Inspect Interruption** status. If the problem persists, contact Support.
sensor	--	The device identified as *sensor* is not the Firewall Threat Defense device; the system does not determine if a deployed configuration may interrupt traffic on this device.

For information on all configurations that restart the Snort process for all device types, see Configurations that restart the snort process when deployed or activated, on page 131.

Inspect traffic during policy apply



Inspect traffic during policy apply is an advanced access control policy general setting that enables managed devices to inspect traffic while configuration changes are applied, and allows inspection unless a deployed configuration requires the Snort process to restart.

Configuration options

You can configure this setting as follows:

- Enabled — Traffic is inspected during the deployment unless certain configurations require the Snort process to restart. When a Snort restart is not needed, the system first uses the currently deployed access control policy to inspect traffic, then switches to the policy being deployed.
- Disabled — Traffic is not inspected during the deployment. The Snort process always restarts when you deploy.

This graphic illustrates how Snort restarts can occur when you enable or disable **Inspect traffic during policy apply**.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 129 and Configurations that restart the snort process when deployed or activated, on page 131.

Snort restart traffic behavior

This reference explains how different devices handle traffic when the Snort process restarts.

Table 10: The Firewall Threat Defense and the Firewall Threat Defense Virtual Restart Traffic Effects

Interface configuration	Restart traffic behavior
inline: **Snort Fail Open: Down**: disabled	dropped
inline: **Snort Fail Open: Down**: enabled	passed without inspection Some packets can be delayed in buffer for several seconds before the system recognizes that Snort is down. This delay can vary depending upon the load distribution. However, the buffered packets are eventually passed.

Interface configuration	Restart traffic behavior
routed, transparent (including EtherChannel, redundant, subinterface): **preserve-connection** enabled (**configure snort preserve-connection enable**; default) For more information, see *Cisco Secure Firewall Threat Defense Command Reference*.	existing TCP/UDP flows: passed without inspection so long as at least one packet arrives while Snort is down new TCP/UDP flows and all non-TCP/UDP flows: dropped Note that traffic drops even when **preserve-connection** is enabled for: • plaintext, passthrough prefilter tunnel traffic that matches an **Analyze** rule action or an **Analyze all tunnel traffic** default policy action • connections that do not match an access control rule and are instead handled by the default action • decrypted TLS/SSL traffic • a safe search flow • a captive portal flow
routed, transparent (including EtherChannel, redundant, subinterface): **preserve-connection** disabled (**configure snort preserve-connection disable**)	dropped
inline: tap mode	egress packet immediately, copy bypasses Snort
passive	uninterrupted, not inspected

Note In addition to traffic handling when the Snort process is down while it restarts, traffic can also pass without inspection or drop when the Snort process is busy, depending on the configuration of the Snort Fail Open **Busy** option (see Configure Inline Sets, on page 736). A device supports either the Failsafe option or the Snort Fail Open option, but not both.

Note When the Snort process is busy but not down during configuration deployment, some packets may drop on routed, switched, or transparent interfaces if the total CPU load exceeds 60 percent.

Warning Do not reboot the system while the Snort Rule Update is in progress.

Snort-busy drops happen when snort is not able to process the packets fast enough. Lina does not know whether Snort is busy due to processing delay, or if is stuck or due to call blocking. When transmission queue is full,

snort-busy drops occur. Based on Transmission queue utilization, Lina will try to access if the queue is being serviced smoothly.

Configurations that restart the snort process when deployed or activated

Deploying any of these configurations except AAB restarts the Snort process as described. Deploying AAB does not cause a restart, but excessive packet latency activates the currently deployed AAB configuration, causing a partial restart of the Snort process.

Access control policy advanced settings

- Deploy when **Inspect Traffic During Policy Apply** is disabled.
- Add or remove an SSL policy.

File policy

Deploy the first or last of any one of these configurations; note that while otherwise deploying these file policy configurations does not cause a restart, deploying non-file-policy configurations can cause restarts.

- Take either of these actions:
  - Enable or disable **Inspect Archives** when the deployed access control policy includes at least one file policy.
  - Add the first or remove the last file policy rule when **Inspect Archives** is enabled (note that at least one rule is required for **Inspect Archives** to be meaningful).
- Enable or disable **Store files** in a **Detect Files** or **Block Files** rule.
- Add the first or remove the last active file rule that combines the **Malware Cloud Lookup** or **Block Malware** rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**).

Note that access control rules that deploy these file policy configurations to security zones or tunnel zones cause a restart only when your configuration meets these conditions:

- Source or destination security zones in your access control rule must match the security zones associated with interfaces on the target devices.
- Unless the destination zone in you access control rule is *any*, a source tunnel zone in the rule must match a tunnel zone assigned to a tunnel rule in the prefilter policy.

Identity policy

- When SSL decryption is disabled (that is, when the access control policy does not include an SSL policy), add the first or remove the last active authentication rule.

  An active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Network discovery

- Enable or disable non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy.

Device management

- MTU: Change the highest MTU value among all non-management interfaces on a device.
- Automatic Application Bypass (AAB): The currently deployed AAB configuration activates when a malfunction of the Snort process or a device misconfiguration causes a single packet to use an excessive amount of processing time. The result is a partial restart of the Snort process to alleviate extremely high latency or prevent a complete traffic stall. This partial restart causes a few packets to pass without inspection, or drop, depending on how the device handles traffic.

TLS server identity discovery

Enabling or disabling **TLS Server Identity Discovery** will result in a Snort 2 restart.

Note Snort 3 does not restart when **TLS Server Identity Discovery** is enabled or disabled.

Updates

- System update: Deploy configurations the first time after a software update that includes a new version of the Snort binary or data acquisition library (DAQ).
- For managed devices running Snort 3, deploying configurations the first time after installing a vulnerability database (VDB) update may temporarily interrupt application detection, but there will be no traffic interruptions.

Actions that immediately restart the snort process

These actions immediately restart the Snort process without requiring deployment. How the restart affects traffic depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Applications or application detectors

- Activate or deactivate a system or custom application detector.
- Delete an activated custom detector.
- **Save and Reactivate** an activated custom detector.
- Create a user-defined application.

When you perform any of these actions, a message warns you that continuing will restart the Snort process. The message allows you to cancel. The system restarts Snort on all managed devices in the current domain and any child domain.

High availability configuration

Create or break a Firewall Threat Defense high availability pair.

When you create or break a high availability pair, a message warns you that creating or breaking a high availability pair restarts the Snort process on the primary and secondary devices. The message allows you to cancel.

Requirements and prerequisites for deployment management

Before using the configuration deployment feature in the Firewall Management Center, ensure you meet these requirements.

- You must have **Administrator**, **Network Admin**, or **Security Approver** privileges to access the deployment features.
- Before deploying policy changes, you can compare the differences between the current device configuration and the pending policy, ensuring accuracy before you finalize the deployment. To use this feature, you must have the appropriate access rights, valid licenses for the specific policy, and be in the correct domain context.
-

Best practices for deploying configuration changes

Reliable management connection

The management connection between the Firewall Management Center and the device is a secure, TLS-1.3-encrypted communication channel between itself and the device.

To ensure reliable management connection, use a direct management path instead of routing management traffic through an additional encrypted tunnel, such as a Site-to-Site VPN. If the tunnel fails, you could lose management connectivity.

To maintain a reliable management connection, exclude management traffic from the VPN tunnel if it exits a VPN-terminating interface.

Caution Avoid routing a device's management connection through a VPN tunnel that terminates on the device itself. If a configuration update causes the tunnel to drop, you will lose the management connection and cannot recover the device configuration unless you connect directly to the device.

Maximum concurrent deployments

Avoid deploying to more than 25 percent of the maximum devices allowed for a Firewall Management Center in the same deployment task. For example, for the FMCv300, the maximum deployment task size is 75 devices (25 percent of 300). Deploying concurrently to more devices can cause performance issues.

Deployment of shared policies

For best performance, deploy to devices that use the same policies. Create a separate deployment task for each group of devices that share policies.

Time to deploy and memory limitations

Deployment time depends on multiple factors, including:

- The configurations you send to the device. For example, if you dramatically increase the number of Security Intelligence entries you block, deployment can take longer.
- Device model and memory. On devices with less memory, deployment can take longer.

Keep your configurations within the capability of your devices. If you exceed the maximum number of rules or policies supported by a target device, Firewall Management Center displays a warning. The maximum depends on a number of factors—not only memory and the number of processors on the device, but also on policy and rule complexity. For information on optimizing policies and rules, refer to Best practices for access control rules, on page 1625.

Use a maintenance window to lessen the impact of traffic interruptions

We *strongly* recommend you deploy in a maintenance window or at a time when interruptions will have the least impact.

- When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 129 and Configurations that restart the snort process when deployed or activated, on page 131.
- For the Firewall Threat Defense devices, the **Inspect Interruption** column in the **Deploy** dialog warns you when deploying might interrupt traffic flow or inspection. You can proceed with, cancel, or delay deployment. For more information, refer to Inspection interruption warnings during deployment, on page 127.

Configuration deployment

Configuration deployment is the process of deploying configuration and policy updates to your Fireall Threat Defense devices after you make changes. This process allows you to apply changes to multiple components including device configurations, security policies, and network discovery settings.

Deployment components

Deploying updates applies to these components:

- Device and interface configurations
- Device-related policies, such as NAT, VPN, QoS, and platform settings policy
- Access control and related policies: DNS, file, identity, intrusion, network analysis, prefilter, SSL
- Network discovery policy
- Intrusion rule updates
- Configurations and objects associated with any of these elements

You can configure the system for automatic deployment by scheduling a deploy task or by setting the system to deploy when importing intrusion rule updates. Automating policy deployment is especially useful if you allow intrusion rule updates to modify system-provided base policies for intrusion and network analysis. Intrusion rule updates can also modify default values for the advanced preprocessing and performance options in your access control policies.

You can view deployment status in the **Notifications** pane.

Deploy configuration changes

Apply new or updated device configurations to managed devices.

After you change a device configuration, you must deploy the changes for them to take effect. Deploy during a maintenance window or off-peak hours to minimize potential traffic and inspection disruption.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 129 and Configurations that restart the snort process when deployed or activated, on page 131.

Before you begin

- Confirm that all managed devices use the same revision of the Security Zones object. If you have edited security zone objects: Do not deploy configuration changes to any device until you edit the zone setting for interfaces on *all* devices you want to sync. You must deploy to all managed devices at the same time.
- To preview the deployment changes, enable REST API access. To enable the REST API access, follow the steps in *Enabling REST API Access* in the *Cisco Secure Firewall Management Center Administration Guide* .

Note The deployment process fails if the device configuration is being read at the device CLI during deployment. Do not execute commands such as **show running-config** during the deployment.

Procedure

Step 1 In the Firewall Management Center menu bar, click **Deploy**.

Step 2 For a quick deployment, check specific devices and then click **Deploy**, or click **Deploy All** to deploy to all devices. For additional deployment options, click **Advanced Deploy**.

The rest of this procedure applies to the **Advanced Deploy** screen.

Step 3 Click **Expand Arrow** ( ) to view device-specific configuration changes to be deployed.

- The **Modified By** column lists the users who have modified the policies or objects. On expanding the device listing, you can view the users who have modified the policies against each policy listing. For

information about when the **System** user is shown (instead of the logged-in user), refer to System username, on page 126.

Note Usernames are not provided for deleted policies and objects.

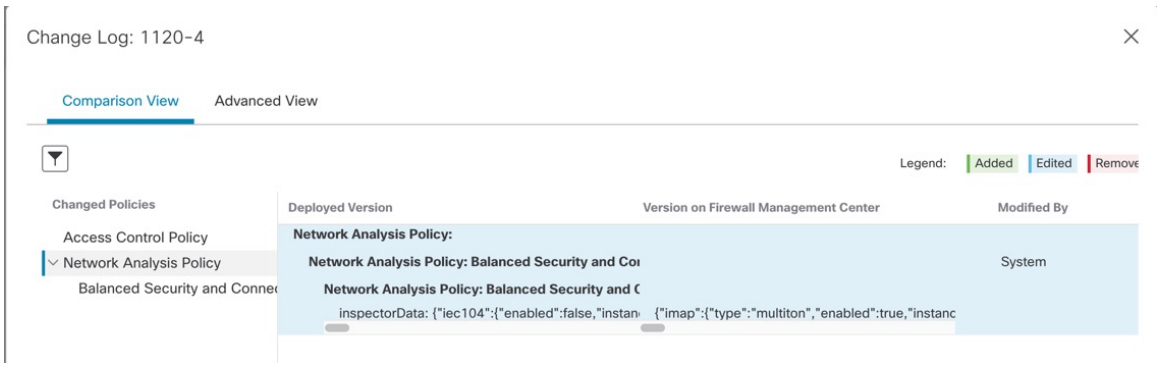
- The **Inspect Interruption** column indicates if traffic inspection interruption may be caused in the device during deployment.

  When the status indicates (Yes) that deploying will interrupt inspection, and perhaps traffic, on the Firewall Threat Defense device, the expanded list indicates the specific configurations causing the interruption with the **Inspect Interruption** ( ).

  If the entry is blank in this column for a device, then it indicates that there will be no traffic inspection interruptions on that device during deployment.

  For information about identifying configurations that interrupt traffic inspection and might interrupt traffic when deployed to the Firewall Threat Defense devices, refer to Inspection interruption warnings during deployment, on page 127.

- The **Last Modified Time** column specifies when you last made the configuration changes.
- The **Preview** column allows you to preview the changes for the next deployment.
- The **Status** column provides the status for each deployment. For more information, see Deployment status, on page 141.



Step 4 In the **Preview** column, click **Preview** ( ) to see the configuration changes that you can deploy.

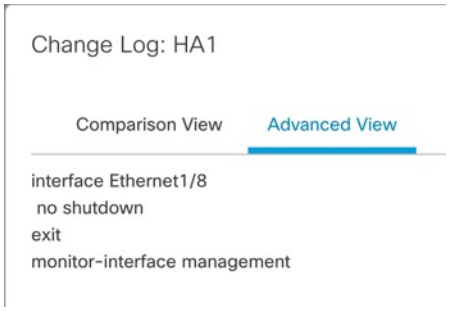
Note If you change the Firewall Management Center name in **System** ( ) > **Configuration** > **Information** , the deployment preview does not specify this change, yet it requires a deployment.

For unsupported features for Preview, see Deployment preview, on page 122.

The **Comparison View** tab lists all the policy and object changes. The left pane lists all the different policy types that have changed on the device, organized in a tree structure.

Figure 33: Comparison View

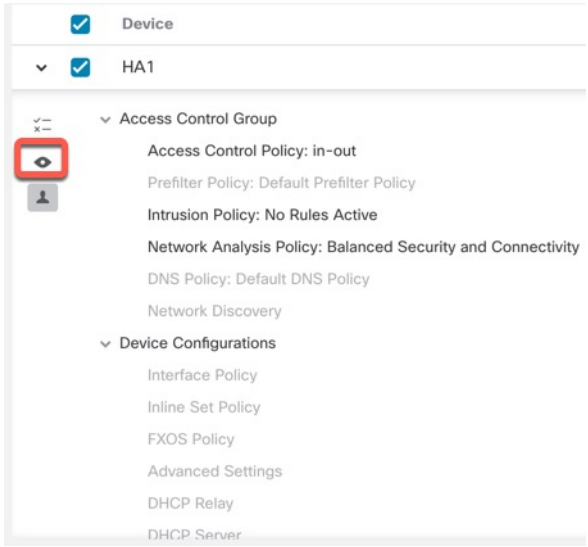
The **Filter**( ) lets you filter the policies at the user level and policy level.



The right pane lists all the additions, changes, or deletions in the policy, or the object selected in the left pane. The two columns on the right pane provide the last deployed configuration settings (in the **Deployed Version** column) versus the changes that are due for deployment (in the **Version on Firewall Management Center** column). The last-deployed configuration settings are derived from a snapshot of the last saved deployment in the Firewall Management Center and not from the device. The background colors of the settings are color-coded as per the legend available on the top-right of the page.

The **Modified By** column lists the users who have modified, or added the configuration settings. At the policy level, the Firewall Management Center displays all the users who have modified the policy, and at the rule level, the Firewall Management Center displays only the last user who has modified the rule.

You can download a copy of the change log by clicking the **Download Report** button.



The **Advanced View** tab shows the CLI commands that will be applied. This view is useful if you are familiar with ASA CLI, which is used on the back end of the Firewall Threat Defense.

Figure 34: Advanced View

Step 5 Use **Show or Hide Policy** ( ) to selectively view or hide the associated unmodified policies.

Figure 35: Show or Hide Policy

Step 6 Check the box next to the device name to deploy all configuration changes, or click **Policy selection** ( ) to select individual policies or configurations to deploy while withholding the remaining changes without deploying them.

You can also view the interdependent changes for a certain policy or configuration using this option. The Firewall Management Center dynamically detects dependencies between policies (for example, between an access control policy and an intrusion policy), and between the shared objects and the policies. Interdependent changes are indicated using color-coded tags to identify a set of interdependent deployment changes. When one of the deployment changes is selected, the interdependent changes are automatically selected.

For more information, refer to Guidelines for selective policy deployment, on page 123.

Note

- When the changes in shared objects are deployed, the impacted policies should also be deployed along with them. When you select a shared object during deployment, the impacted policies are automatically selected.
- Selective deployment is not supported for scheduled deployments and deployments using REST APIs. You can only opt for complete deployment of all the changes in these cases.
- The pre-deployment checks for warnings and errors are performed not only on the selected policies, but on all the policies that are out-of-date. Therefore, the warnings or errors list shows the deselected policies as well.
- Similarly, the **Inspect Interruption** column indication on the Deployment page considers all out-of-date policies and not just the selected policies. For information on the **Inspect Interruption** column, refer to Inspection interruption warnings during deployment, on page 127.

Step 7 After you select the devices or policies to deploy, click **Estimate** to get a rough estimate of the deployment duration .

Figure 36: Estimate

Figure 37: Deploy Time

The time duration is a rough estimate (having around 70% accuracy), and the actual time taken for deployment may vary for a few scenarios. The estimate is dependable for deployments of up to 20 devices.

When an estimate is not available, it indicates that the data is not available, since the first successful deployment on the selected device is pending. This situation could occur after the Firewall Management Center reimage, version upgrade, or after a high availability failover.

Note The estimate is incorrect and unreliable for bulk policy changes (in case of bulk policy migrations), and selective deployments because the estimate is based on the heuristic technique.

Step 8 For more details about the Pre-readiness assessment states, refer to .

Step 9 Click **Deploy**.

Configuration changes are deployed to the selected devices. You receive confirmation messages regarding success, warnings, or errors.

What to do next

If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

You have the following choices:

- Deploy—Continue deploying without resolving warning conditions. Check the **Ignore warnings** checkbox, to ignore warnings and deploy the changes. You cannot proceed if the system identifies errors.
- Close—Exit without deploying. Resolve the error and warning conditions, and attempt to deploy the configuration again.
- (Optional) Monitor deployment status; see *Viewing Deployment Messages* in the *Cisco Secure Firewall Management Center Administration Guide* .
- If the deployment fails, refer to Best practices for deploying configuration changes, on page 133 .
- During deployment, if there are specific configuration changes in the deployment, the deployment failure may lead to traffic being interrupted. For example, in a cluster environment, an erroneous configuration of an IP address that is not in the same subnet as the Site IPs is configured on the interface. Due to this error, deployment fails and the device attempts to clear the configuration while the rollback operation is being processed. These events collectively lead to a deployment failure that interrupts the traffic.

  See the following table to know what configuration changes may cause traffic interruption when deployment fails.

Table 11: Traffic interruption scenarios

Configuration Changes	Exists?	Traffic Impacted?
Threat Defense Service changes in an access control policy	Yes	Yes
VRF	Yes	Yes
Interface	Yes	Yes
QoS	Yes	Yes

Note The configuration changes interrupting traffic during deployment is valid only if both the Firewall Management Center and the Firewall Threat Defense are of version 6.2.3 or later.

Redeploy existing configurations to a device

Force-deploying existing configurations to a managed device ensures that its policy rules are fully regenerated and applied. This procedure is recommended during maintenance windows or when disruption to network traffic is minimal. Force-deploy takes longer than regular deployment because it generates all policy rules for the device.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 129 and Configurations that restart the snort process when deployed or activated, on page 131.

Before you begin

- Review the guidelines described in Best practices for deploying configuration changes, on page 133.
- Plan to perform the redeployment during a maintenance window or low-impact period.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device where you want to force deployment.

Step 3 Click **Device**.

Step 4 Click **Edit** ( ) next to the **General** section heading.

Step 5 Click **Force Deploy** ( ).

Step 6 Click **Deploy**.

The system identifies any errors or warnings with the configurations you are deploying. You can click **Proceed** to continue without resolving warning conditions. However, you cannot proceed if the system identifies an error.

What to do next

- (Optional) Monitor deployment status; see *Viewing Deployment Messages* in the *Cisco Secure Firewall Management Center Administration Guide*.
- If deploy fails, see Best practices for deploying configuration changes, on page 133.

Deployment management

Firewall Management Center provides a set of deployement management options to oversee configuration changes across your Firewall Threat Defense devices. These options enable you to monitor real-time deployment status, track historical records, and ensure configuration integrity through rollback capabilities. Additionally, you can utilize built-in reporting and policy comparison features to audit changes, verify compliance, and troubleshoot issues.

Deployment status

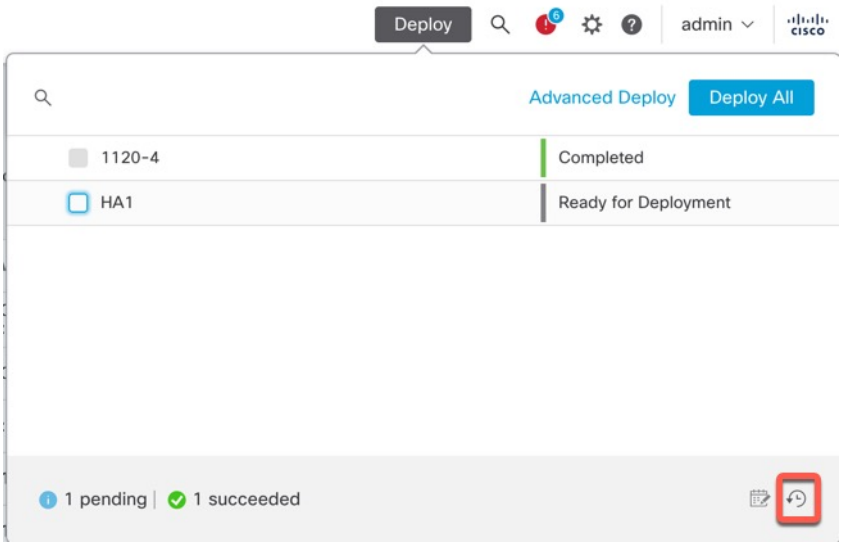
On the **Deployment** page, the **Status** column provides the deployment status for each device. If a deployment is in progress, a live progress indicator is displayed; otherwise, one of these deployment status values appears:

- **Pending**: Indicates that there are changes in the device that need be deployed.
- **Warnings or errors**: Indicates that the pre-deployment checks have identified warnings or errors for the deployment. You may continue deployment if there are warnings, but not if there are errors.

Note The status column provides the warning or error status only for a single user session on the **Deployment** page. If you navigate away or refresh the page, the status changes to **Pending**.

- **Failed**: Indicates that the previous deployment attempt failed. Click the status to view the details.
- **In queue**: Indicates that deployment is initiated, and the system is yet to start the deployment process.
- **Completed**: Indicates that deployment has completed successfully.

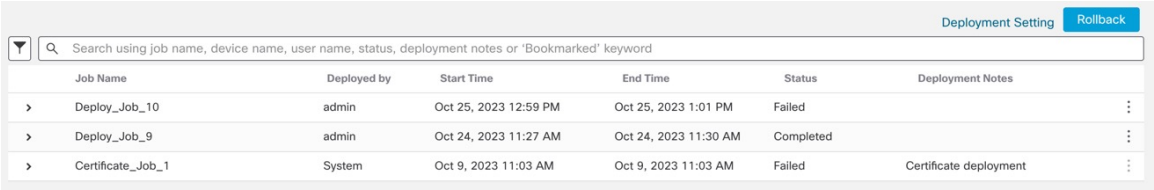
View deployment history



View deployment history to track and analyze past deployment activities, including successful deployments, failed deployments, and rollback operations.

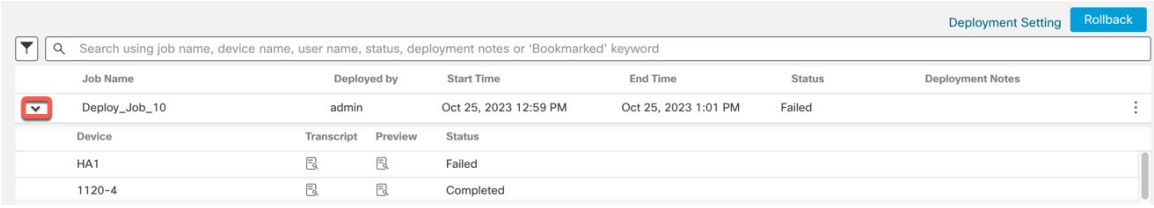
In the deployment history, the last 10 successful deployments, the last 5 failed deployments, and last 5 rollback deployments are captured.

Procedure



Step 1 On the Firewall Management Center menu bar, click **Deploy** and then click **Deployment History** ( ).

Figure 38: Deployment history icon



A list of all the previous deployment and rollback jobs is displayed in reverse chronological order.

Figure 39: Deployment history page

Step 2 Click **Expand Arrow** (›) next to the required deployment job to view the devices included in the job and their deployment statuses.

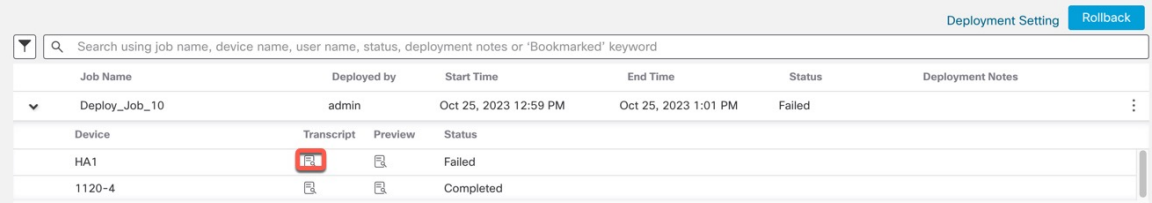
Figure 40: Expand

- View notes in the **Deployment Notes** column.

  Deployment notes are custom notes that a user can add as part of the deployment, and these notes are optional.

Step 3 (Optional) Click **Transcript Details** ( ) to view the commands sent to the device, and the responses received.

Figure 41: Transcript details icon



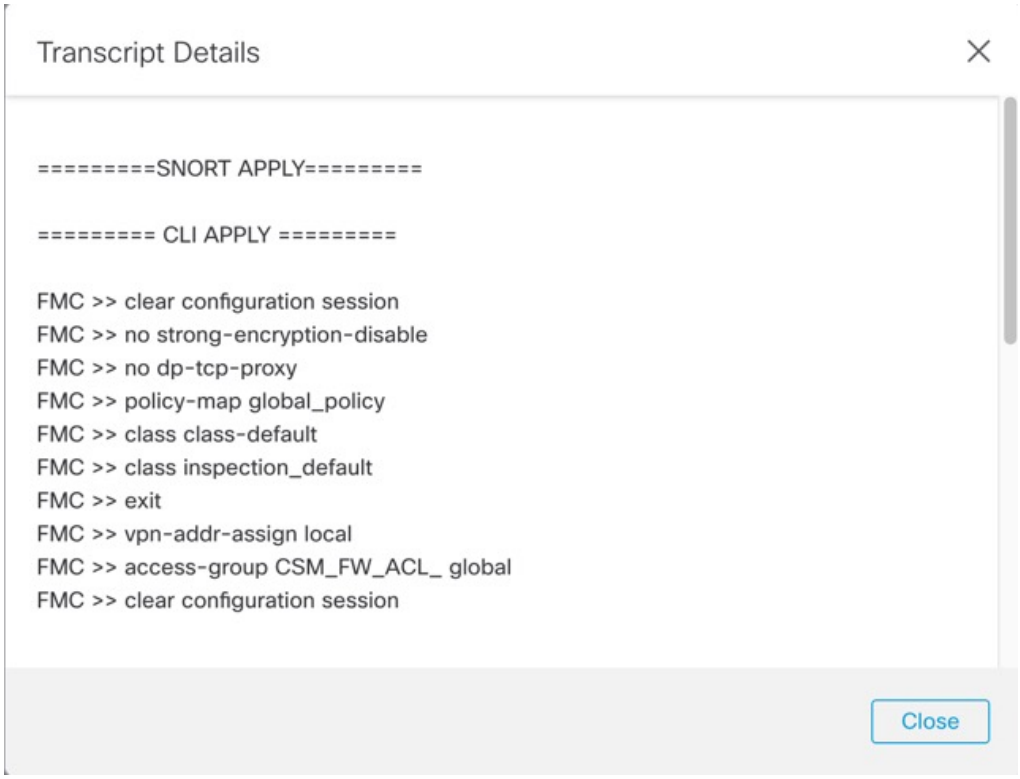


Figure 42: Transcript details

The transcript includes the following sections:

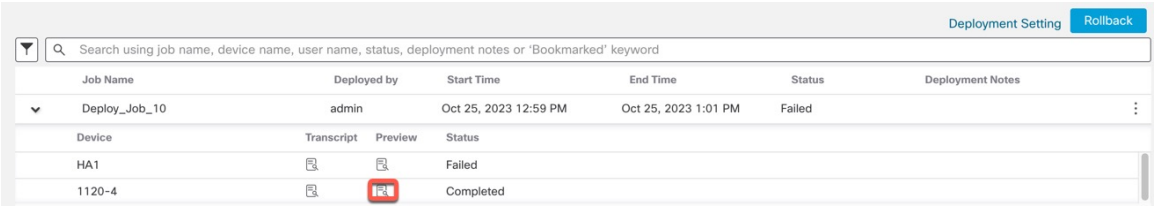
- **Snort Apply**—If there are any failures or responses from Snort-related policies, then the messages are displayed in this section. Normally, the section is empty.
- **CLI Apply**—This section covers features that are configured using commands that are sent to the device.

Note The transcript for the rollback operation does not provide the CLI commands information. To view the rollback commands, see View the deployment rollback transcript, on page 150.

- **Infrastructure Messages**—This section shows the status of different deployment modules.

In the **CLI Apply** section, the deployment transcript includes commands that are sent to the device, and any responses returned from the device. These responses can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands. Examining these errors can be particularly helpful if you are using FlexConfig policies to configure customized features. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

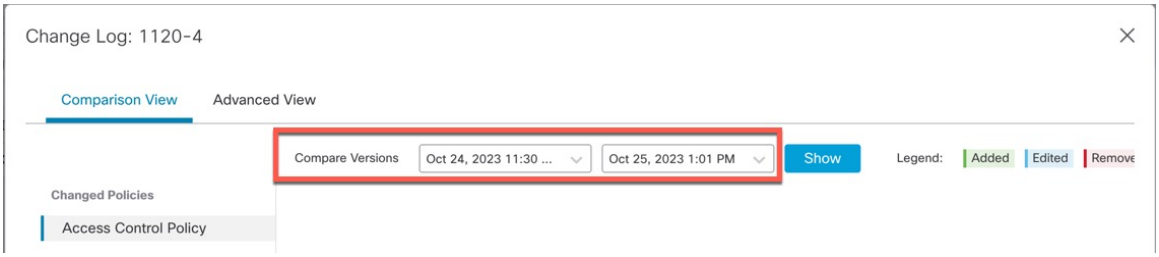
Note There is no distinction that is made in the transcript between commands that are sent for managed features and those generated from FlexConfig policies.



For example, the following sequence shows that Firewall Management Center sent commands to configure GigabitEthernet0/0 with the logical name **outside**. The device responded that it automatically set the security level to 0. Firewall Threat Defense does not use the security level for anything.

```
========= CLI APPLY =========

FMC >> interface GigabitEthernet0/0
FMC >>  nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```



Step 4 (Optional) Click **Preview** ( ) to view the policy and object changes deployed on the device versus the previously deployed version.

Figure 43: Preview icon

a. To compare any two versions and view the change log, choose the required versions in the drop-down boxes and click the **Show** button. The drop-down boxes show the deployment job name and the end time of the deployment.

Figure 44: Compare versions

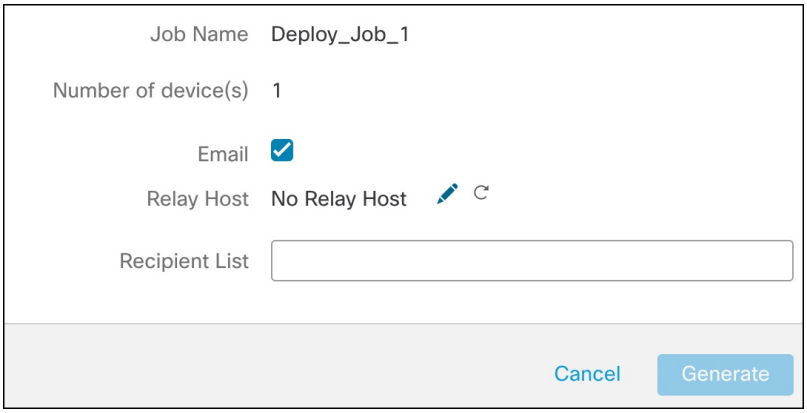
Note The drop-down boxes also show failed deployments.

b. The **Modified By** column lists the users who have modified the policies or objects.

1. At the policy level, Firewall Management Center displays all the user names who have modified the policy.
2. At the rule level, Firewall Management Center displays the last user who has modified the rule.

c. You can also download a copy of the change log by clicking **Download Report**.

Note



- Deployment history preview is not supported for certificate enrollments, HA operations, and failed deployments.
- When a device is registered, preview is not supported for the job history record that is created.

Step 5 (Optional) Against each deployment job, click the **More** (⋮) icon and execute other actions:

- **Bookmark**—To bookmark the deployment job.
- **Edit Deployment Notes**—To edit your custom deployment notes that you added for a deployment job.
- **Generate Report**—To generate a deployment report, which can be used for auditing. This report includes job properties with preview and transcript information, and the report can be downloaded as a PDF file.

a. Click **Generate Report** to generate a deployment report.

Figure 45: Generate report

b. In the **Generate Report** popup window, check the **Email** checkbox.

c. The report can also be sent through email if mail relay host is configured. If the mail relay host in not configured, use the **Edit** (✎) icon to configure or modify the mail relay host. For more information, see *Configuring a Mail Relay Host and Notification Address* in the *Cisco Secure Firewall Management Center Administration Guide*.

d. In the **Recipient List**, you can enter multiple email adddresses, separated by semicolons.

e. Click **Generate** to generate the report, and this report is emailed to the recipients.

f. In the Notifications task tab, you can track the progress. After the report generation is complete, click the link in the notification task tab to download the PDF report.

Set the number of configuration versions to retain

The Firewall Management Center stores device configuration history files as configuration versions. You can specify the number of configuration versions that you want to retain for a device. This setting allows you to estimate the size of the device configuration files on the disk and keep it within the allowed limit. Reducing the number of configuration versions can reduce the backup size and improve the high-availability synchronization speed of the Firewall Management Center.

Before you begin

- This feature is not supported in Version 7.4.0.
- In a high-availability deployment, configuration version settings are only available on the active Firewall Management Center.

Procedure

Step 1 Choose **Deploy** > **Deployment History** ( ).

Step 2 Click **Deployment Setting**.

Step 3 Choose the number of configuration versions that you want to retain for a device from the **Number of Versions to Retain** drop-down list.

Note Reducing the number of versions removes the oldest configuration versions to match the version size you have selected. You will not be able to preview or roll back to the removed versions.

- **Maximum Permitted Disk Size**: The maximum size for storing configuration versions is 20 GB. The Firewall Management Center calculates the size of configuration versions periodically and sends a health alert if the size of the configuration versions exceeds 20 GB. To resolve the health alert, choose a **Number of Versions to Retain** for which the estimated configuration version size is less than 20 GB.
- **Current Configuration Version Size**: The size of the configuration files on the Firewall Management Center for the previous deployment.
- **Estimated Configuration Version Size**: The approximate size of the configuration files on the Firewall Management Center. It is calculated based on the number of configuration versions you chose to retain.

Step 4 Click **Save**.

Deployment rollback

Deployment rollback is the process of reverting a device to a previously saved configuration state. This operation allows you to restore the device to its earlier state if a recent policy deployment results in unintended traffic behavior.

Note Rollback is a disruptive operation. Executing a rollback terminates all existing connections and resets routing tables, which will cause a temporary interruption of traffic.

Identifying the disruptive configuration

When a deployment has caused unintended traffic interruption, identify the specific change responsible for the condition. To compare current and previous deployments:

Before a rollback

1. Choose **Deploy** > **Deployment History**, expand the last deployed job that caused the traffic disruption, and click the **Preview** ( ).

   The preview page lets you compare deployments to identify specific changes from previous configurations.

2. After identifying the change causing the problem, rectify the configuration and redeploy it on the device.

After a rollback

1. After a successful rollback, choose **Deploy** > **Deployment**, and click the **Preview** icon next to the rolled back device.
2. View the changes between the rolled back configuration and the current changes in the Firewall Management Center that are pending deployment.
3. After identifying the change causing the problem, rectify the configuration, and redeploy it on the device.

Rollback reverts most configurations, but some exceptions apply. Refer the table below for details.

Rollback guidelines

Follow these guidelines to ensure successful configuration rollbacks.

- You have to perform a deployment before you can roll back again.
- After you perform a rollback, the rolled back devices are marked as out-of-date on the Firewall Management Center. The changes you made to the configuration are still pending for the next deployment. To see the pending changes, choose **Deploy** > **Deployment**, and click the **Preview** icon next to the rolled back device.
- For devices with very large access lists, if the **Object Group Search** setting is disabled, then the rollback operation may take a longer duration to complete. To verify the **Object Group Search** setting, choose **Devices** > **Device Management**, and then select the device and click **Edit Advanced Settings**.
- For the Firepower 4100/9300, make sure your current Firewall Chassis Manager interface configuration is the same for any rollback versions. Otherwise, the rollback interface configuration may not match your actual interfaces.

- Independent certificate enrollments are also listed as deployment jobs in the Deployment History page. However, you cannot roll back to these versions. A rollback from a deployment version created after certificate enrollments reverts the certificate associations as well. In the next deployment after a rollback, manually associate the certificates before proceeding with the deployment.
- If a deployment for a device with a FlexConfig object configured with a deployment frequency set to **Once** is rolled back, then you will not be able to redeploy the object even though it is displayed as out-of-date on the Preview page. After a rollback, you will have to manually unassign and then reassign the FlexConfig object to the device before the next deployment.

Rollback limitations

Observe these limitations that restrict the use of rollback functionality.

- You can roll back to any one of the last 10 versions before the currently deployed version. Rollback to versions prior to these are not supported. The rollback icon is greyed out for unsupported versions.
- Rollback is not supported if the manager access interface (Manager or data interface) is different between the rollback version and the current version.
- If you upgrade the Firewall Management Center, all rollback versions from the previous software release will no longer be available for devices, even if you did not upgrade the devices.
- If you upgrade the device, you can only roll back to versions on the current software release.
- For High Availability, rollback is not supported in these scenarios:
  - When the version you want to roll back to contains the high-availability bootstrap configuration. In other words, the deployment when you first formed high availability for the standalone devices.
  - When a device that is currently in standalone mode was part of a high availability pair in the previous deployment version.
- For clustering:
  - Rollback is not supported when a device that is currently in standalone mode was part of a cluster in the previous deployment version.
  - (Secure Firewall 3100/4200 and Firewall Threat Defense Virtual in a private cloud) If you change the clustering bootstrap configuration or add or delete nodes, you cannot roll back to a version prior to those changes.

Table 12: Configurations reverted and not reverted during rollback

Configurations that are reverted during a rollback	Configurations that are not reverted during a rollback
• All policy configurations • Interface configurations • SRU configurations • VDB configurations • LSP configurations • VPN configurations • FXOS configurations	• Snort binaries • Geo DB

Perform a rollback

Use rollback to revert a device to a previously deployed configuration when the traffic through the device is affected in an unintended way after a policy deployment.

You can roll back a device to a previously deployed configuration. After a policy deployment, if the traffic through the device is affected in an unintended way, rollback provides an option to revert the device to the earlier state, which existed before the faulty deployment.

Rollback reverts the configuration only on the selected devices.

Procedure

Step 1 Choose **Deploy >Deployment History** ( ).

A list of all the previous deployment jobs is displayed in reverse chronological order.

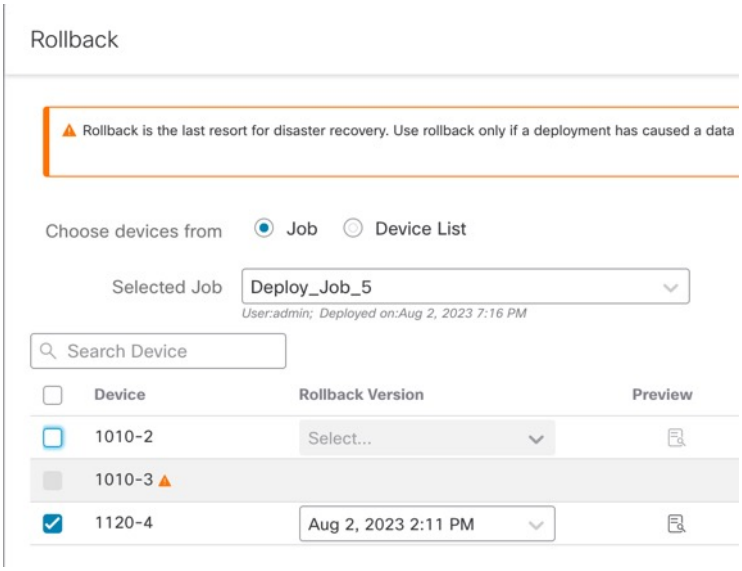
Step 2 Click **Rollback**.

Step 3 Filter the list of devices displayed by either clicking **Job** and choosing a job from the **Selected Job** drop-down list, or by clicking **Device List**.

Step 4 (Optional) Enter the device name in the **Search Device** search box to filter the device list.

Step 5 Check the box next to the devices you want to roll back and choose the version for each device from the **Rollback Version** drop-down list.

Figure 46: Selected job list



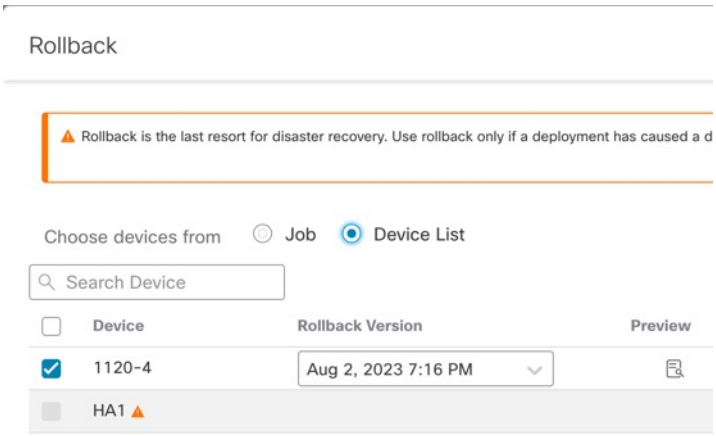


Figure 47: Device list

The job names and associated deployment notes are also listed for a particular rollback version.

Step 6 (Optional) Click the **Preview** ( ) to view the changes deployed in the selected version.

Step 7 Click **Rollback** to restore the selected devices to the chosen configuration version.

What to do next

To verify rollback status, go to **Deploy** > **Deployment** and check the rollback status next to the device name.

View the deployment rollback transcript

View the CLI commands that were executed during a successful rollback operation to understand what changes were made to the device configuration.

Rollback transcript is a written version of the commands that are sent to the device, along with the responses returned from the device. If a rollback operation has failed, the reason for the failure can be viewed by clicking **Deploy**, and then click the **Deployment History** (). However, to know the CLI commands executed for a successful rollback operation, follow the steps given below after a rollback operation has completed.

Note

- The CLI command information is available after a rollback is complete and is available only until the next deployment. The first deployment after a rollback operation erases all the rollback-related information.
- For any rollback deployment, the deployment notes are updated automatically as rollback job. In the **Deployment History** page, the user can filter the rollback jobs easily using the search option.

Procedure

Step 1 On the Secure Firewall Management Center menu bar, choose **System** () > **Health** > **Monitor**.
Step 2 Select the device, which was rolled back, from the left pane.
Step 3 Click **View System & Troubleshooting Details** link.
Step 4 Click **Advanced Troubleshooting**.
Step 5 Click **Threat Defense CLI**.
Step 6 Select **show** from the **Command** drop-down box.
Step 7 Enter `running` in the **Parameter** field.
Step 8 Click **Execute**.

Download policy changes report for multiple devices

Download reports on the policy and object changes made since your last deployment for multiple Firewall Threat Defense devices. Reports help you review pending changes before completing deployment. The reports are provided as a zip file containing:

- A pending changes report for each device, previewing modifications to policy or objects that are to be deployed on the device. For more information, refer to Deploy configuration changes, on page 135 and Deployment Preview.
- A consolidated report categorizing each device by report status.

Procedure

Step 1 Choose **Deploy** > **Advanced Deploy**.
Step 2 Check the check box next to the devices for which you want to generate a pending policy changes report, and then click **Pending Changes Reports**.
Step 3 Click **Pending Changes Reports**. Reports are generated in the background.

Step 4 On the Firewall Management Center menu bar, choose **Notifications** > **Tasks** to view the report generation task.

When the report request task is complete, the download link appears within the task notification.

Step 5 Click the **Download Report(s)** link to download the reports.

Compare policies

Policy comparison allows you to examine the differences between two policies or between a saved policy and the running configuration to review policy changes for compliance with your organization's standards or to optimize system performance.

You can compare these policy types:

- DNS
- File
- Health
- Identity
- Network Analysis
- SSL

The comparison view displays both policies in a side-by-side format. Differences between the two policies are highlighted:

- Blue indicates that the highlighted setting is different in the two policies, and the difference is noted in red text.
- Green indicates that the highlighted setting appears in one policy but not the other.

Before you begin

You can compare policies only if you have access rights and any required licenses for the specific policy, and you are in the correct domain for configuring the policy.

Procedure

Step 1 Access the management page for the policy you want to compare:

- DNS—**Policies** > **Access Control heading** > **DNS**
- File—**Policies** > **Access Control heading** > **Malware & File**
- Health—**System** (⚙) > **Health** > **Policy**
- Identity—**Policies** > **Access Control heading** > **Identity**
- Network Analysis—**Policies** > **Access Control heading** > **Access Control**, and then click **Network Analysis Policy** or **Policies** > **Access Control heading** > **Intrusion**, and then click **Network Analysis Policies**.

Note If your custom user role limits access to the first path listed here, use the second path to access the policy.

- SSL—**Policies** > **Access Control heading** > **Decryption**

Step 2 Click **Compare Policies**.

Step 3 From the **Compare Against** drop-down list, choose the type of comparison you want to make:

- To compare two different policies, choose **Other Policy**.
- To compare two revisions of the same policy, choose **Other Revision**.
- To compare another policy to the currently active policy, choose **Running Configuration**.

Step 4 Depending on the comparison type you choose, you have various choices:

- If you are comparing two different policies, choose the policies you want to compare from the **Policy A** and **Policy B** drop-down lists.
- If you are comparing the running configuration to another policy, choose the second policy from the **Policy B** drop-down list.

Step 5 Click **OK**.

Step 6 Review the comparison results:

- Comparison Viewer—To use the comparison viewer to navigate individually through policy differences, click **Previous** or **Next** above the title bar.
- Comparison Report—To generate a PDF report that lists the differences between the two policies, click **Comparison Report**.

Generate current policy reports

You can generate two types of reports for most policies: a single-policy report detailing the policy's current saved configuration, and a comparison report listing differences between two policies. You can generate a single-policy report for all policy types except health.

Note Intrusion policy reports combine the settings in the base policy with the settings of the policy layers, and make no distinction between which settings originated in the base policy or policy layer.

Before you begin

- Ensure you have the required access rights and licenses for the specific policy.
- Verify you are operating within the correct domain for the policy you wish to report.

Procedure

Step 1 Access the management page for the policy for which you want to generate a report:

- Access Control—**Policies** > **Access Control heading** > **Access Control**
- DNS—**Policies** > **Access Control heading** > **DNS**
- File—**Policies** > **Access Control heading** > **Malware & File**
- Health—**System** (⚙) > **Health** > **Policy**
- Identity—**Policies** > **Access Control heading** > **Identity**
- Intrusion—**Policies** > **Access Control heading** > **Intrusion**
- NAT—**Devices** > **NAT**
- Network Analysis—**Policies** > **Access Control heading** > **Access Control**, and then click **Network Analysis Policy** or **Policies** > **Access Control heading** > **Intrusion**, and then click **Network Analysis Policies**

Note If your custom user role limits access to the first path listed here, use the second path to access the policy.

- SSL—**Policies** > **Access Control heading** > **Decryption**

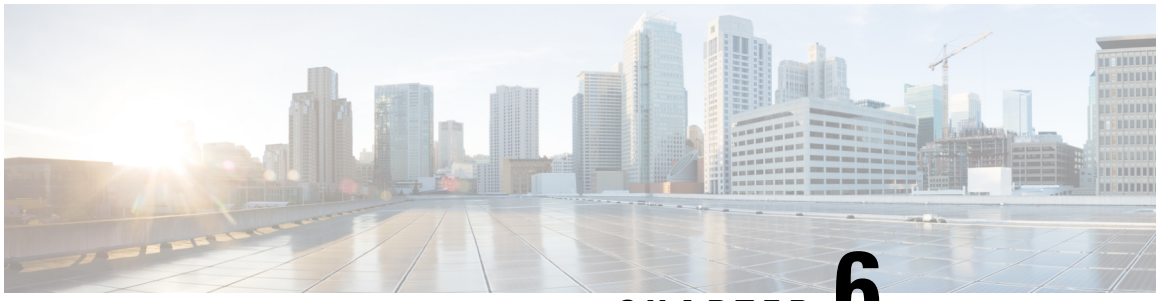
Step 2 Click **Report** (📄) next to the policy for which you want to generate a report.

History for configuration deployment

This reference provides a chronological history of configuration deployment features introduced across different software versions, including deployment rollback capabilities, advanced deployment views, report generation, and deployment preview functionality.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Set the number of deployment history files to retain for device rollback.	7.2.6 7.4.1	Any	You can now set the number of deployment history files to retain for device rollback, up to ten (the default). This can help you save disk space on the Firewall Management Center. New/modified screens: **Deploy** > **Deployment History** > **Deployment Setting** > **Configuration Version Setting**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
View and generate reports on configuration changes since your last deployment.	7.2.6 7.4.1	Any	You can generate, view, and download the reports as a zip file on configuration changes since your last deployment: • A *policy changes* report for each device that previews the additions, changes, or deletions in the policy, or the objects that are to be deployed on the device. • A *consolidated* report that categorizes each device based on the status of policy changes report generation. This is especially useful after you upgrade either the Firewall Management Center or Firewall Threat Defense, so that you can see the changes made by the upgrade before you deploy. New/modified screens: **Deploy** > **Advanced Deploy**.
Generate and email a report when you deploy configuration changes.	7.2	Any	You can now generate a report for any deployment. New/modified screens: **Deploy** > **Deployment History icon** > **More** > **Generate Report**
Deployment preview and user information in preview.	7.0	Any	The Deployment page has the following newly added features: • On the **Deployment** page, the **Modified By** column lists the users who have modified the policies against each policy listing. • Filter support for deployment – The Filter icon provided on the **Deployment** page provides an option to filter the device listings that are pending deployment. The Filter icon provides options to filter the listings based on selected devices and user names. • Deployment History Preview – Click **Preview** to view the policy and object changes deployed on the device versus the previously deployed version. In the deployment history, the last 10 successful deployments, the last five failed deployments, and last five rollback deployments are captured. • Deployment Notes – The **Deployment Notes** are custom and optional notes that a user can add as part of deployment. You can view the **Deployment Notes** column in the **Deployment History** page. • Deployment rollback is available for Snort 3 policies as well.
Roll back deployment on Firewall Threat Defense devices.	6.7	6.7	Rollback is a deployment functionality provided to remove the existing deployment on Firewall Threat Defense devices and to reconfigure the device with the previously deployed configuration. New/modified pages: The **Deploy** > **Deployment History** page provides a new Rollback column with the rollback icons. Similar rollback icons can also be found when the jobs are expanded, to initiate rollback at the device level.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
New deployment web interface.	6.6	Any	The **Deploy** button on the Firewall Management Center menu bar is changed to **Deploy** menu. There are two new sub-menu options under it. These are **Deployment** and **Deployment History**. The Deployment page has undergone an improvement along with newly added features, and the new Deployment History page provides a legend of all the previous deployments. The Deployment page has the following newly added features: • Deployment status - On the Deployment page, the Status column provides the deployment status for each device. • Deployment estimate - The **Estimate** link is available on the Deployment page after you select a device, a policy, or a configuration. The **Estimate** link provides an estimate of the deployment duration once clicked. • Deployment preview - Preview provides a snapshot of all the policy and object changes to be deployed on the device. The policy changes include the new policies, changes in the existing policies, and the deleted policies. The object changes include the added and modified objects which are used in policies. • Selective policy deployment - Firewall Management Center allows you to select a specific policy within the list of all the changes on the device that are due for deployment and deploy only the selected policy.

PART II

High Availability and Scalability

- Multi-Instance Mode, on page 159
- Logical Devices on the Firepower 4100/9300, on page 223
- High Availability for Devices, on page 283
- Clustering: Secure Firewall 3100/4200, on page 323
- Clustering: Private Cloud , on page 385
- Clustering: Public Cloud, on page 437
- Clustering: Firepower 4100/9300, on page 529

CHAPTER 6

Multi-Instance Mode

You can deploy the Secure Firewall 3100 as a single device (*appliance mode*) or as multiple container instances (*multi-instance mode*). This chapter describes how to deploy the device in multi-instance mode.

- Multi-instance mode, on page 159
- Licenses for instances, on page 171
- Requirements and prerequisites for instances, on page 171
- Guidelines and limitations for instances, on page 172
- Instance configuration, on page 175
- Multi-instance mode, on page 219
- Multi-instance mode feature and version history, on page 222

Multi-instance mode

Multi-instance mode is a deployment mode that enables multiple container instances on a single chassis that act as completely independent devices.

Multi-instance modes and appliance modes

A multi-instance mode and an appliance mode are deployment types for network devices that

- determine whether the device operates as a single instance or supports multiple, independent instances,
- offer distinct management and configuration options at both the chassis and instance levels, and
- provide different approaches to resource allocation, interface assignment, and monitoring.

You can run the device in either appliance mode or multi-instance mode.

Appliance mode

Appliance mode is the default. The device runs the native Firewall Threat Defense image and acts as a single device. The only chassis-level configuration available (on the **Chassis Manager** page) is for network module management (breakout ports or enabling/disabling a network module).

Multi-instance mode

If you change to multi-instance mode, the device runs the Secure Firewall eXtensible Operating System (FXOS) on the chassis, while each instance runs separate Firewall Threat Defense images. You can configure the mode using the FXOS CLI.

Because multiple instances run on the same chassis, you need to perform chassis-level management of:

- CPU and memory resources using resource profiles.
- Interface configuration and assignment.
- Deployment and monitoring of instances.

For a multi-instance device, you add the *chassis* to the Firewall Management Center and configure chassis-level settings on the **Chassis Manager** page.

Chassis management interface

A chassis management interface is a network hardware feature that

- provides a dedicated pathway for device management and control,
- supports multi-instance modes by allowing each software instance its own management IP address, and
- separates management, eventing, and application access to streamline security, access, and monitoring.

Chassis management

The chassis uses the dedicated Management interface on the device. Multi-instance mode does not support using a data interface for chassis management or DHCP addressing for the Management interface.

You can only configure the chassis Management interface at the Firewall Threat Defense CLI (at initial setup) or FXOS CLI (after you convert to multi-instance mode). Refer to Enable multi-instance mode, on page 175 for initial setup. Refer to Change chassis management settings at the FXOS CLI, on page 216 to change Management interface settings in multi-instance mode.

Note By default, SSH is not allowed to this interface in multi-instance mode unless you enable the SSH server and an SSH access list. This difference means that you can connect to the application-mode threat defense Management interface using SSH, but after you convert to multi-instance mode, you can no longer connect using SSH by default. For more information, refer to Configure SSH and SSH access list, on page 201.

Instance management

All instances share the chassis management interface, and each instance has its own IP address on the Management network. After you add the instance and specify the IP address, you can make changes to the network settings at the Firewall Threat Defense CLI.

The instance Management IP address allows SSH by default.

Instance interfaces

A chassis interface is a network connection point that

- allows flexible assignment to instances through physical connections or VLAN subinterfaces,
- enables sharing (physical or VLAN) between multiple instances for efficient resource use, and
- restricts certain interface features (like subinterfaces or sharing) in multi-instance clusters, except for control links.

To provide flexible physical interface use for instances, you can create VLAN subinterfaces on the chassis and also share interfaces (VLAN or physical) between multiple instances. Refer to Shared interface scalability, on page 163 and Configure a subinterface, on page 187.

Note This chapter discusses *chassis* VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense instance. For more information, refer to Chassis interfaces vs. instance interfaces, on page 161.

Interface types

An interface type is a network configuration element that

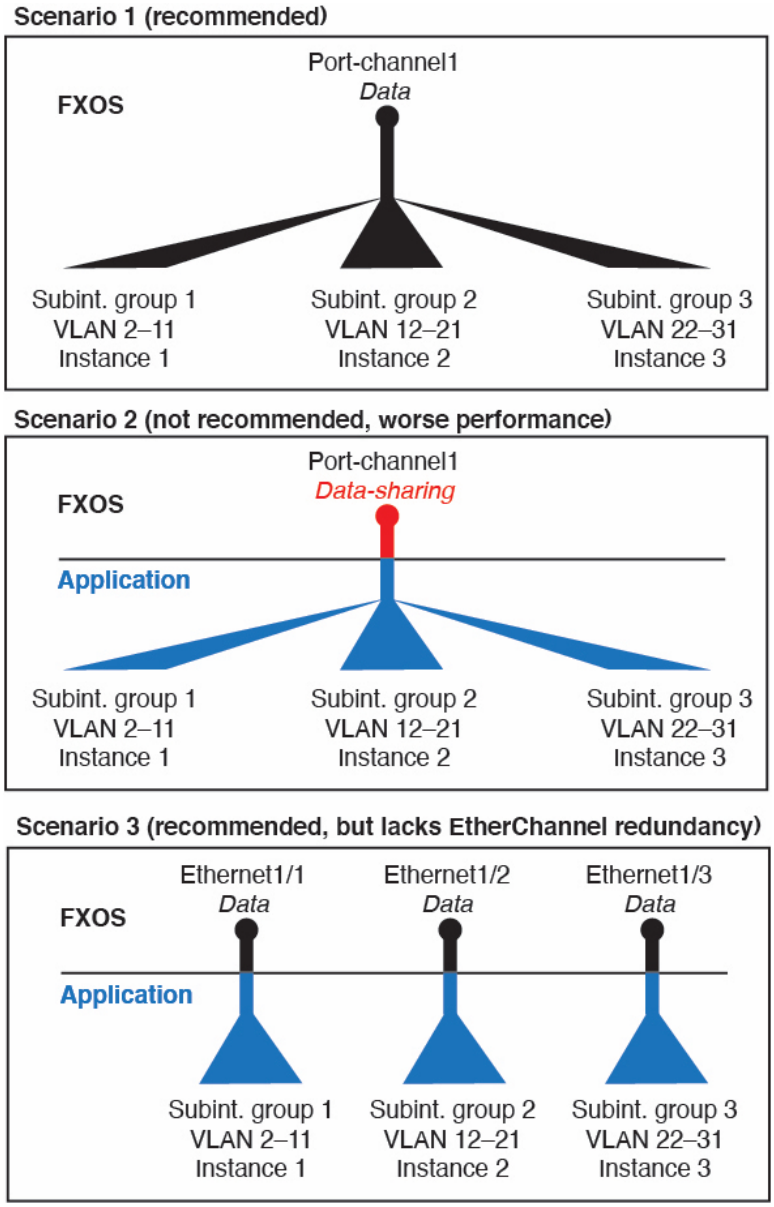
- determines how physical interfaces, VLAN subinterfaces, and EtherChannel interfaces are used in deployment, and
- defines whether interfaces can be shared among instances or dedicated to specific traffic.

Physical interfaces, VLAN subinterfaces, and EtherChannel interfaces can be one of these types:

- Data: Use for regular data or the failover link. Data interfaces cannot be shared between instances, and instances cannot communicate over the backplane to other instances. For traffic on Data interfaces, all traffic must exit the chassis on one interface and return on another interface to reach another instance. You can add VLAN subinterfaces to a data interface to provide separate failover links per High Availability pair.
- Data-sharing: Use for regular data. These data interfaces can be shared by one or more instances. Each instance can communicate over the backplane with all other instances that share this interface. Shared interfaces can affect the number of instances you can deploy. Shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode), inline sets, passive interfaces, or failover links.

Chassis interfaces vs. instance interfaces

Chassis interfaces vs. instance interfaces is an interface management model that



- manages basic Ethernet settings of physical interfaces, VLAN subinterfaces for instances, and EtherChannel interfaces at the chassis level,
- configures higher level settings within the instance, such as IP addresses for EtherChannels, and
- allows independent administrative control of interface states in both chassis and instance locations.

VLAN subinterfaces

You can create VLAN subinterfaces within the instance, just as you would for any device.

You can *also* create VLAN subinterfaces in the chassis. The instance-defined subinterfaces are not subject to the chassis limit. Choosing in which location to create subinterfaces depends on your network deployment and personal preference. For example, to share a subinterface, you must create the subinterface on the chassis. Another scenario that favors chassis subinterfaces comprises allocating separate subinterface groups on a single interface to multiple instances. For example, you want to use Port-channel1 with VLAN 2–11 on instance A, VLAN 12–21 on instance B, and VLAN 22–31 on instance C. If you create these subinterfaces in the instance, then you would have to share the parent interface in the chassis, which may not be desirable. See this illustration that shows the three ways you can accomplish this scenario:

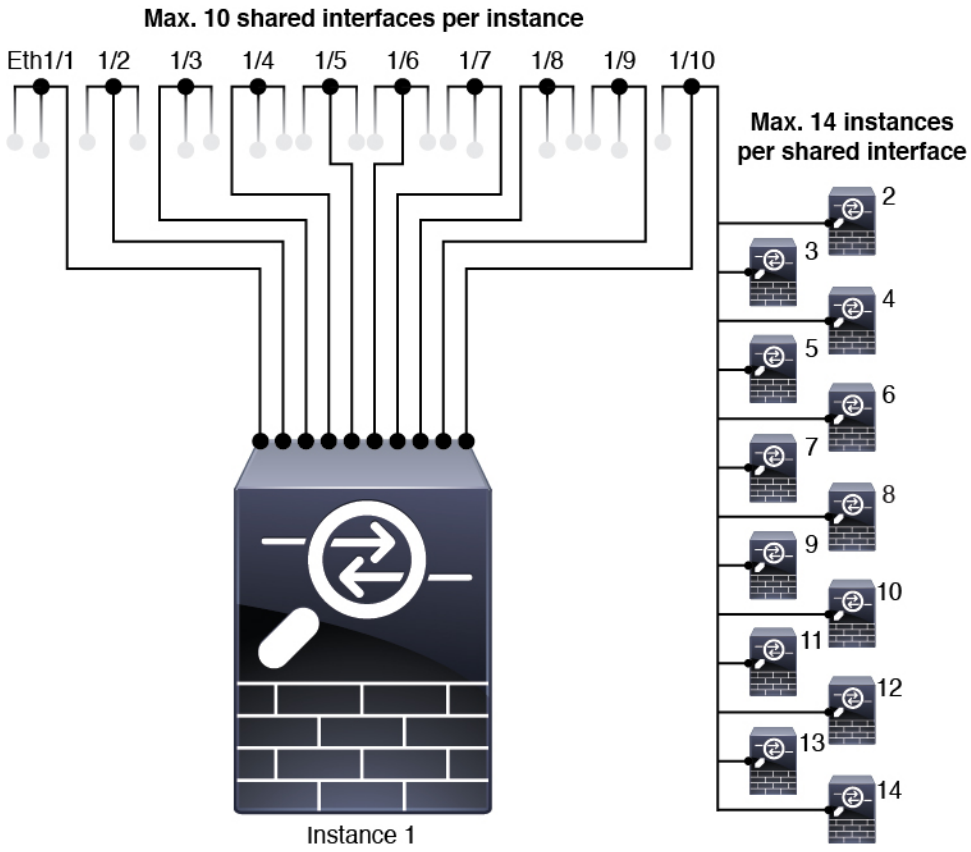
Figure 48: VLANs in the chassis vs. the instance

Independent interface states in the chassis and in the instance

You can administratively enable and disable interfaces in both the chassis and in the instance. For an interface to be operational, the interface must be enabled in both locations. Because the interface state is controlled independently, you may have a mismatch between the chassis and instance.

The default state of an interface within the instance depends on the type of interface. For example, the physical interface or EtherChannel is disabled by default within the instance, but a subinterface is enabled by default.

Shared interface scalability



A shared interface is a network resource that

- allows multiple logical connections to transmit data concurrently,
- adapts bandwidth allocation based on real-time demand, and
- enhances scalability to support growing numbers of devices and traffic flows.

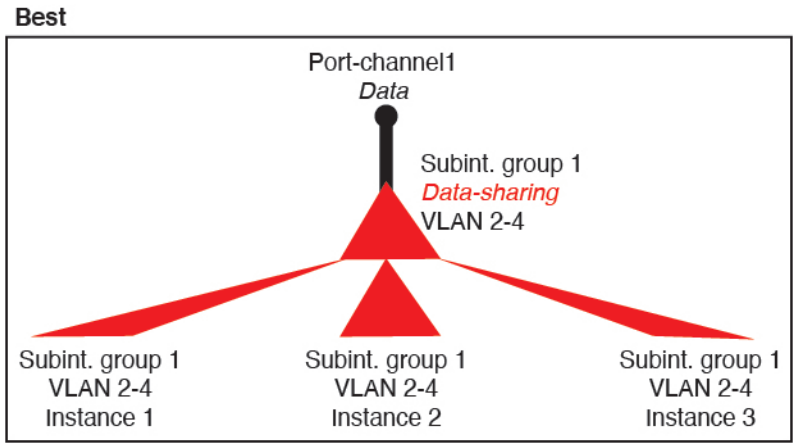
Instances can share data-sharing type interfaces. This capability lets you conserve physical interface usage as well as support flexible networking deployments. When you share an interface, the chassis uses unique MAC addresses to forward traffic to the correct instance. However, shared interfaces can cause the forwarding table to grow large due to the need for a full mesh topology within the chassis (every instance must be able to communicate with every other instance that is sharing the same interface). Therefore, there are limits to how many interfaces you can share.

In addition to the forwarding table, the chassis maintains a VLAN group table for VLAN subinterface forwarding. You can create up to 500 VLAN subinterfaces.

See the following limits for shared interface allocation:

Shared interface best practices

This topic outlines the best practices to follow when configuring shared interfaces to maximize performance and security.



For optimal scalability of the forwarding table, share as few interfaces as possible. Instead, you can create up to 500 VLAN subinterfaces on one or more physical interfaces and then divide the VLANs among the container instances.

When sharing interfaces, follow these practices in the order of most scalable to least scalable:

1. Best: Share subinterfaces under a single parent, and use the same set of subinterfaces with the same group of instances.

   For example, create a large EtherChannel to bundle all of your like-kind interfaces together, and then share subinterfaces of that EtherChannel: Port-Channel1.2, 3, and 4 instead of Port-Channel2, Port-Channel3, and Port-Channel4. When you share subinterfaces from a single parent, the VLAN group table provides better scaling of the forwarding table than when sharing physical/EtherChannel interfaces or subinterfaces across parents.

Figure 49: Best: Shared Subinterface Group on One Parent

If you do not share the same set of subinterfaces with a group of instances, your configuration can cause more resource usage (more VLAN groups). For example, share Port-Channel1.2, 3, and 4 with instances 1, 2, and 3 (one VLAN group) instead of sharing Port-Channel1.2 and 3 with instances 1 and 2, while sharing Port-Channel1.3 and 4 with instance 3 (two VLAN groups).

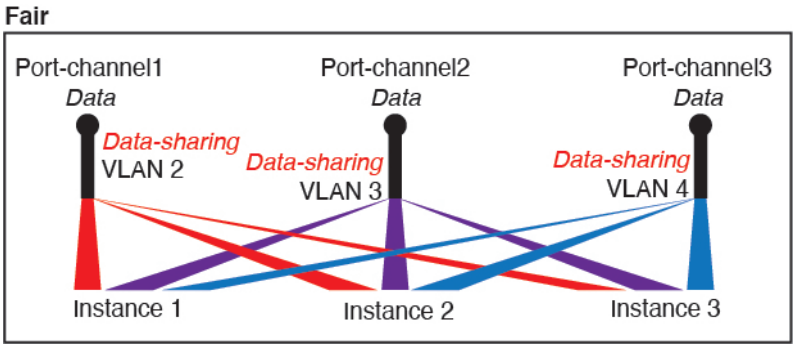


Figure 50: Good: Sharing Multiple Subinterface Groups on One Parent

2. Fair: Share subinterfaces across parents.

   For example, share Port-Channel1.2, Port-Channel2.3, and Port-Channel3.4 instead of Port-Channel2, Port-Channel4, and Port-Channel4. Although this usage is not as efficient as only sharing subinterfaces on the same parent, it still takes advantage of VLAN groups.

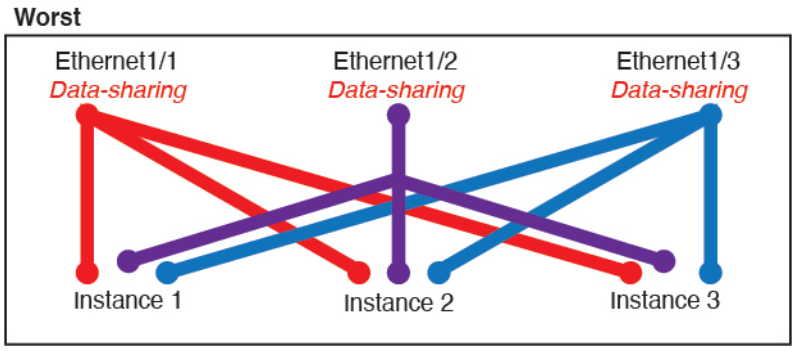

Figure 51: Fair: Shared Subinterfaces on Separate Parents

3. Worst: Share individual parent interfaces (physical or EtherChannel).

   This method uses the most forwarding table entries.

Figure 52: Worst: Shared Parent Interfaces

How the chassis classifies packets

The chassis processes incoming and outgoing packets as they pass through a device, ensuring that each packet is handled according to its type, destination, and security requirements.

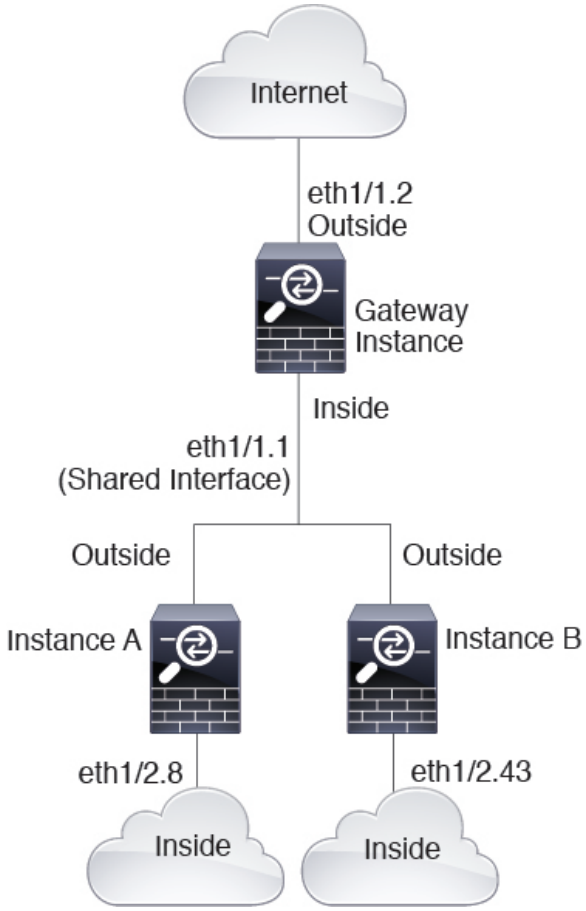
Each packet that enters the chassis must be classified so that the chassis can determine to which instance to send a packet.

- Unique Interfaces: If only one instance is associated with the ingress interface, the chassis classifies the packet into that instance. For bridge group member interfaces (in transparent mode or routed mode), inline sets, or passive interfaces, this method is used to classify packets at all times.
- Unique MAC Addresses: The chassis automatically generates unique MAC addresses for all interfaces, including shared interfaces. If multiple instances share an interface, then the classifier uses unique MAC addresses assigned to the interface in each instance. An upstream router cannot route directly to an instance without unique MAC addresses. You can also set the MAC addresses manually when you configure each interface within the application.

Note If the destination MAC address is a multicast or broadcast MAC address, the packet is duplicated and delivered to each instance.

Classification examples

This reference provides examples to help you understand different classification scenarios and their implementation.



Cascading container instances

Cascading instances connect one instance's outside interface to another's inside interface, simplifying configuration by sharing parameters in the top instance. Avoid using shared interfaces with High Availability to prevent MAC address conflicts; use unique interfaces and an external switch instead.

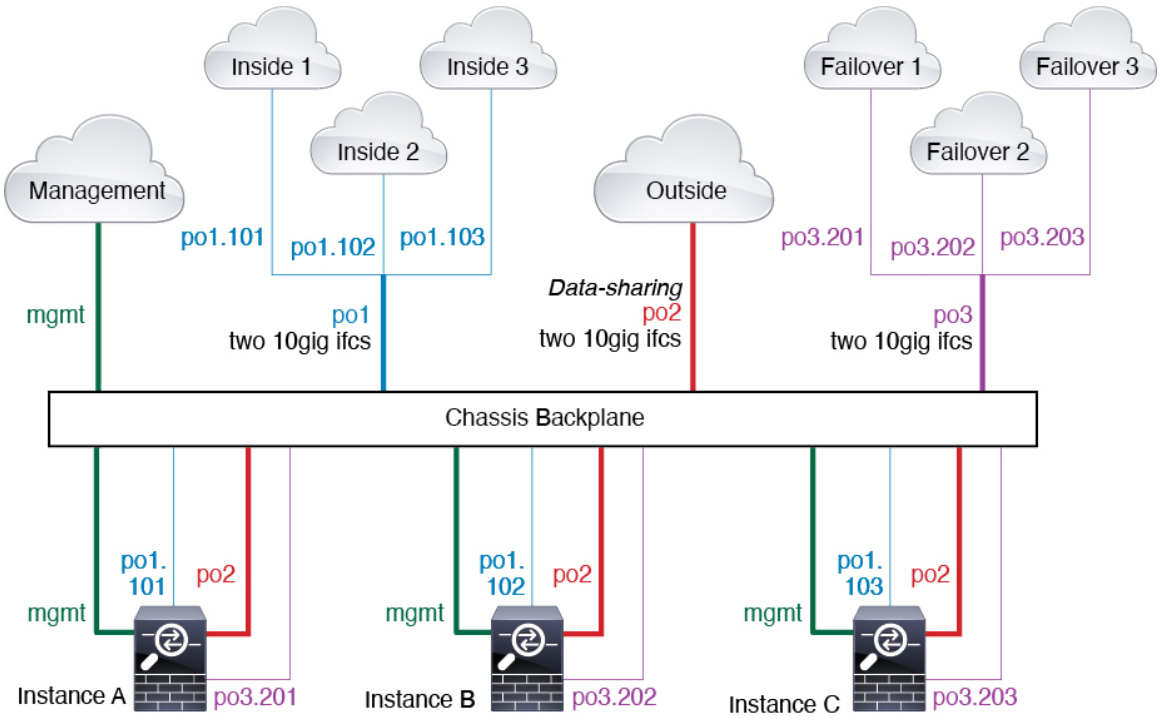
Placing an instance directly in front of another instance is called *cascading instances*; the outside interface of one instance is the same interface as the inside interface of another instance. You might want to cascade instances if you want to simplify the configuration of some instances by configuring shared parameters in the top instance.

The following figure shows a gateway instance with two instances behind the gateway.

Figure 53: Cascading Instances

Note Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.

Typical multi-instance deployments



A typical multi-instance deployment is a firewall configuration that

- supports multiple container instances operating simultaneously,
- configures distinct interfaces for management, inside, outside, and failover connectivity, and
- utilizes dedicated subinterfaces and EtherChannels to enhance performance and reliability.

The following example includes three container instances in routed firewall mode. They include the following interfaces:

- Management: All instances and the chassis use the dedicated Management interface. Within each instance (and the chassis), the interface uses a unique IP address on the same management network.
- Inside: Each instance uses a subinterface on Port-Channel1 (data type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Each subinterface is on a separate network.
- Outside: All instances use the Port-Channel2 interface (data-sharing type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same outside network.
- Failover: Each instance uses a subinterface on Port-Channel3 (data type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Each subinterface is on a separate network.

Figure 54: Typical multi-instance deployment

Automatic MAC addresses for instance interfaces

An automatic MAC address for instance interfaces is a network identifier that is automatically generated and assigned to instance interfaces in multi-instance deployments.

The chassis automatically generates MAC addresses for instance interfaces, and guarantees that a shared interface in each instance uses a unique MAC address.

If you manually assign a MAC address to a shared interface within the instance, then the manually-assigned MAC address is used. If you later remove the manual MAC address, the autogenerated address is used. In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, we suggest that you manually set the MAC address for the interface within the instance.

Because autogenerated addresses start with A2, you should not start manual MAC addresses with A2 due to the risk of overlapping addresses.

The chassis generates the MAC address using the following format:

A2*xx.yyzz.zzzz*

Where *xx.yy* is a user-defined prefix or a system-defined prefix, and *zz.zzzz* is an internal counter generated by the chassis. The system-defined prefix matches the lower 2 bytes of the first MAC address in the burned-in MAC address pool that is programmed into the IDPROM. Use **connect fxos**, then **show module** to view the MAC address pool. For example, if the range of MAC addresses shown for module 1 is b0aa.772f.f0b0 to b0aa.772f.f0bf, then the system prefix will be f0b0.

The user-defined prefix is an integer that is converted into hexadecimal. For an example of how the user-defined prefix is used, if you set a prefix of 77, then the chassis converts 77 into the hexadecimal value 004D (*yyxx*). When used in the MAC address, the prefix is reversed (*xxyy*) to match the chassis native form:

A2**4D.00***zz.zzzz*

For a prefix of 1009 (03F1), the MAC address is:

A2**F1.03***zz.zzzz*

Performance scaling factors for multi-instance modes

A performance scaling factor is a throughput adjustment metric that

- enables calculation of effective throughput in multi-instance appliance modes,
- considers the percentage of CPU cores assigned to each instance, and
- accounts for efficiency reductions compared to single-instance (appliance mode) operation.

The maximum throughput (connections, VPN sessions) for a platform is calculated for an appliance mode device's use of memory and CPU (and this value is shown in **show resource usage**). If you use multiple instances, then you need to calculate the throughput based on the percentage of CPU cores that you assign to the instance. For example, if you use an instance with 50% of the cores, then you should initially calculate 50% of the throughput. Moreover, the throughput available to an instance may be less than that available to an appliance.

For detailed instructions on calculating the throughput for instances, refer to https://www.cisco.com/c/en/us/products/collateral/security/firewalls/white-paper-c11-744750.html.

Instances and high availability

A high availability pair is a deployment option that

- uses two instances on separate chassis to ensure service continuity,
- allows for multiple high availability pairs to be created from available instances, and
- permits standalone instances to exist alongside high availability pairs within the same chassis.

You can use High Availability using an instance on 2 separate chassis; for example, if you have 2 chassis, each with 10 instances, you can create 10 High Availability pairs. You can also have standalone instances on the same chassis as High Availability instances. For more information about the requirements, refer to Requirements and prerequisites for instances, on page 171.

Note Clustering is not supported.

Licenses for instances

This reference provides information about how licenses are assigned and consumed for chassis and feature instances.

All licenses are consumed per chassis and not per instance. Refer to these details.

- Essentials licenses are assigned to the chassis as a whole, one per chassis.
- Feature licenses are assigned to each instance, but you only *consume* one license per feature per chassis.

Requirements and prerequisites for instances

This reference provides the requirements and prerequisites for deploying instances on Secure Firewall models, including supported models, upgrade paths, resource limitations per model, software requirements, high availability requirements, and management center requirements.

Model support

- Secure Firewall 3110
- Secure Firewall 3120
- Secure Firewall 3130
- Secure Firewall 3140

Note The Secure Firewall 3105 is not supported.

Maximum container instances and resources per model

For each container instance, you can specify the number of CPU cores (or more specifically, threads) to assign to the instance. We use the term "core" generically to account for different hardware architecture. RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

Table 13: Maximum container instances and resources per model

Model	Max. Container Instances	Available CPU Cores (Threads)
Secure Firewall 3110	3	22
Secure Firewall 3120	5	30

Model	Max. Container Instances	Available CPU Cores (Threads)
Secure Firewall 3130	7	46
Secure Firewall 3140	10	62

Software requirements

- You can run different versions of Firewall Threat Defense software on each instance as long as they are all compatible with the version of FXOS running on the chassis.
- You cannot deploy an instance with a patch version of the Firewall Threat Defense software because it is not a complete bundle. You need to first deploy the major or maintenance version, and then patch it after deployment.

High availability requirements

- The two instances in a High Availability configuration must:
  - Be on separate chassis.
  - Be on the same model.
  - Have the same interfaces assigned. All interfaces must be preconfigured in the chassis identically before you enable High Availability.
  - Use the same resource profile attributes. The profile names can be different, but the definitions need to match.

Firewall Management Center requirements

For chassis management and all instances on the chassis, you must use the same Firewall Management Center due to the licensing implementation.

Guidelines and limitations for instances

This reference provides guidelines and limitations for managing instances on chassis, including general requirements, interface configurations, VLAN subinterfaces, EtherChannels, data-sharing interfaces, and MAC address considerations.

General guidelines

- A single Firewall Management Center must manage all instances on a chassis, as well as manage the chassis itself.
- For instances, these features are not supported:
  - TLS crypto acceleration
  - Clustering
  - Firewall Management Center UCAPL/CC mode

- Flow offload to hardware
- LLDP

- Primary management of the chassis by Security Cloud Control cloud-delivered Firewall Management Center and separate analytics-only management of the chassis by an on-prem Firewall Management Center is not supported. You can however add Security Cloud Control-managed instances to an analytics-only on-prem Firewall Management Center.

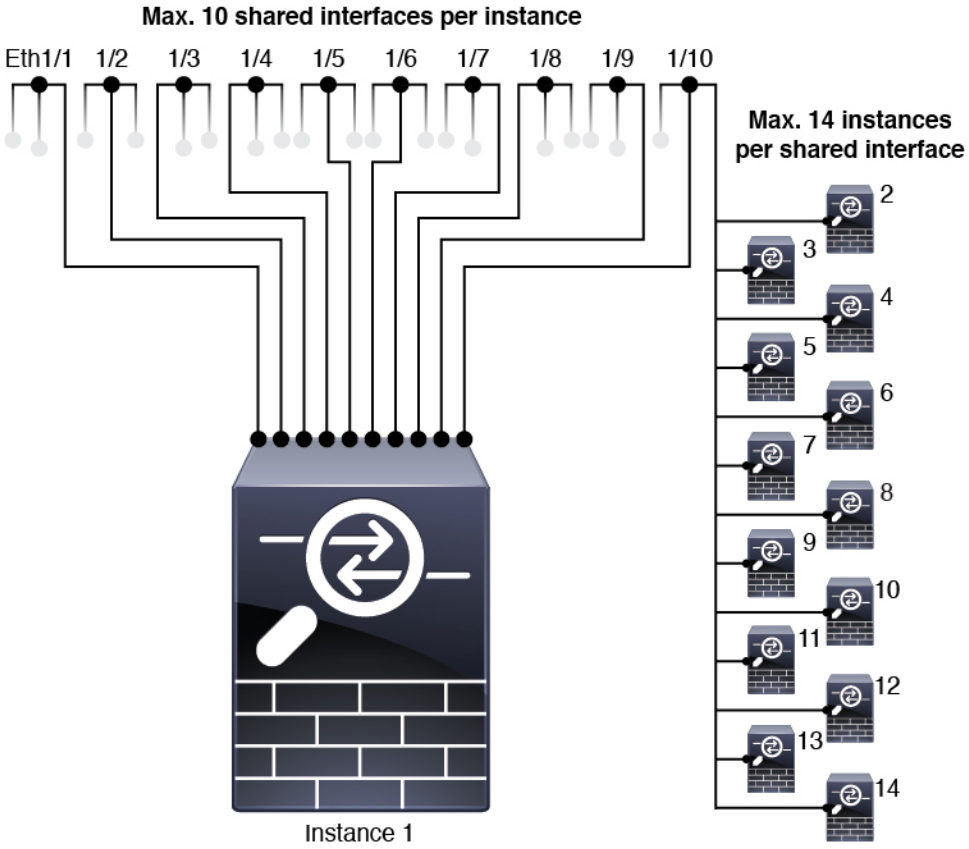
Management interface

- No support for a data interface for chassis management; only the dedicated Management interface can be used
- No DHCP addressing for the Management interface
- The management connection requires TCP port 8305; do not change the value from the default.

VLAN subinterfaces

- This document discusses *chassis* VLAN subinterfaces only. You can separately create subinterfaces within the instance.
- If you assign a parent interface to an instance, it only passes untagged (non-VLAN) traffic. Do not assign the parent interface unless you intend to pass untagged traffic.
- Subinterfaces are supported on Data or Data-sharing type interfaces.
- You can create up to 500 VLAN IDs.
- You cannot use subinterfaces for an inline set or as a passive interface.
- If you use a subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links. You cannot use some subinterfaces as failover links, and some as regular data interfaces.

EtherChannels



- You can configure up to 48 EtherChannels, limited by the number of physical interfaces.
- The EtherChannel can have up to 8 active interfaces.
- All interfaces in the EtherChannel must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, unless you set the speed to **Detect SFP**; in this case, you can use different interface capacities, and the lowest common speed is used.
- The chassis does not support LACPDUs that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **VLAN dot1Q tag native** command, then the chassis will drop the tagged LACPDUs. Be sure to disable native VLAN tagging on the neighboring switch.
- In Cisco IOS software versions earlier than 15.1(1)S2, the chassis did not support connecting an EtherChannel to a switch stack. With default switch settings, if the chassis EtherChannel is connected cross stack, and if the primary switch is powered down, then the EtherChannel connected to the remaining

switch will not come up. To improve compatibility, set the **stack-MAC persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.

Data-sharing interfaces

- Maximum 14 instances per shared interface. For example, you can allocate Ethernet1/1 to Instance1 through Instance14.

  Maximum 10 shared interfaces per instance. For example, you can allocate Ethernet1/1.1 through Ethernet1/1.10 to Instance1.

- You cannot use a data-sharing interface with a transparent firewall mode instance.
- You cannot use a data-sharing interface with inline sets or passive interfaces.
- You cannot use a data-sharing interface for the failover link.

Default MAC addresses

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. For more information, refer to Automatic MAC addresses for instance interfaces, on page 169.

Instance configuration

Prepare the chassis and management environment to enable instance configuration on your device.

Before you configure instances, you need to enable multi-instance mode, add the chassis to the Firewall Management Center, and configure chassis interfaces. You can also customize the chassis settings.

Enable multi-instance mode

You need to connect to the Firewall Threat Defense CLI at the console port to enable multi-instance mode. After you configure the mode, you can add it to the Firewall Management Center.

Note Although you can connect to SSH on the management port, we recommend using the console port to avoid multiple disconnections. This procedure covers the console port.

Procedure

Step 1 Connect to the chassis console port.

The console port connects to the FXOS CLI.

Step 2 Log in with the username **admin** and the password **Admin123**.

The first time you log in to FXOS, you are prompted to change the password.

Note If the password was already changed, and you do not know it, you must reimage the device to reset the password to the default. Refer to the FXOS troubleshooting guide for the reimage procedure.

Example:

```
firepower login: admin
Password: Admin123
Successful login attempts for user 'admin' : 1

[...]

Hello admin. You must change your password.
Enter new password: ********
Confirm new password: ********
Your password was updated successfully.

[...]

firepower#
```

Step 3 Check your current mode, Native or Container. If the mode is Native, you can continue with this procedure to convert to multi-instance (Container) mode.

show system detail

Example:

```
firepower # show system detail

Systems:
    Name: firepower
    Mode: Stand Alone
    System IP Address: 172.16.0.50
    System IPv6 Address: ::
    System Owner:
    System Site:
    Deploy Mode: Native
    Description for System:
firepower #
```

Step 4 Connect to the Firewall Threat Defense CLI.

connect ftd

Example:

```
firepower# connect ftd
>
```

Step 5 The first time you log in to the Firewall Threat Defense, you are prompted to accept the General Terms. You are then presented with the CLI setup script.

The setup script lets you set the Management interface IP address and other settings. However, when you convert to multi-instance mode, the only settings that are retained are the following:

- Admin password (that you set at initial login)
- DNS servers
- Search domains

You will reset the Management IP address and gateway as part of the multi-instance mode command. After you convert to multi-instance mode, you can change Management settings at the FXOS CLI. For more information, refer to Change chassis management settings at the FXOS CLI, on page 216.

Step 6 Enable multi-instance mode, set the chassis management interface settings, and identify the Firewall Management Center. You can use IPv4 and/or IPv6 static addressing; DHCP is not supported. After you enter the command, you will be prompted to erase the configuration and reboot. Enter **ERASE** (all caps). The system reboots and, as part of changing the mode, erases the configuration with the exception of the Management network settings you set in the command and the admin password. The chassis hostname is set to "firepower-*model*."

IPv4:

configure multi-instance network ipv4 *ip_address network_mask gateway_ip_address* **manager** *manager_name* {*hostname* | *ipv4_address* | **DONTRESOLVE**} *registration_key nat_id*

IPv6:

configure multi-instance network ipv6 *ipv6_address prefix_length gateway_ip_address* **manager** *manager_name* {*hostname* | *ipv6_address* | **DONTRESOLVE**} *registration_key nat_id*

See the following **manager** components:

- {*hostname* | *ipv4_address* | **DONTRESOLVE**}: Specifies either the FQDN or IP address of the Firewall Management Center. At least one of the devices, either the Firewall Management Center or the chassis, must have a reachable IP address to establish the two-way, SSL-encrypted communication channel between the two devices. If you don't specify a manager hostname or IP address in this command, then enter **DONTRESOLVE**; in this case, the chassis must have a reachable IP address or hostname, and you must specify the *nat_id*.
- *registration_key*: Enter a one-time registration key of your choice that you will also specify on the Firewall Management Center when you register the chassis. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).
- *nat_id*: Specifies a unique, one-time string of your choice that you will also specify on the Firewall Management Center when you register the chassis when one side does not specify a reachable IP address or hostname. It is required if you do not specify a manager address or hostname, however, we recommend that you always set the NAT ID even when you specify a hostname or IP address. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the Firewall Management Center.

To change the mode back to appliance mode, you must use the FXOS CLI and enter **scope system** and then **set deploymode native**. For more information, refer to Change chassis management settings at the FXOS CLI, on page 216.

Example:

```
> configure multi-instance network ipv4 172.16.0.104 255.255.255.0 172.16.0.1 manager
fmc1 172.16.0.103 impala67 winchester1
WARNING: This command will discard any FTD configuration (except admin's credentials).
Make sure you back up your content. All previous content will be lost. System is going to
be re-initialized.
Type ERASE to confirm:ERASE
Exit...
>
```

Add a multi-instance chassis to the Firewall Management Center

Add the multi-instance chassis to the Firewall Management Center to enable centralized management and configuration of all chassis settings and instances.

The management center and the chassis share a separate management connection using the chassis MGMT interface.

You can use the Firewall Management Center to configure all chassis settings as well as instances. The Secure Firewall Chassis Manager or configuration at the FXOS CLI is not supported.

Before you begin

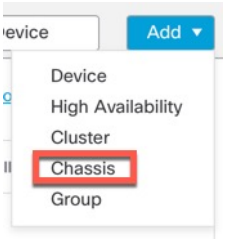
Convert the chassis to multi-instance mode. For more information, refer to Enable multi-instance mode, on page 175.

Procedure

Step 1 In the Firewall Management Center, add the chassis using the chassis management IP address or hostname.

a) Choose **Devices** > **Device Management**, and then from **Add** drop-down list, choose **Chassis**.

Figure 55: Add chassis



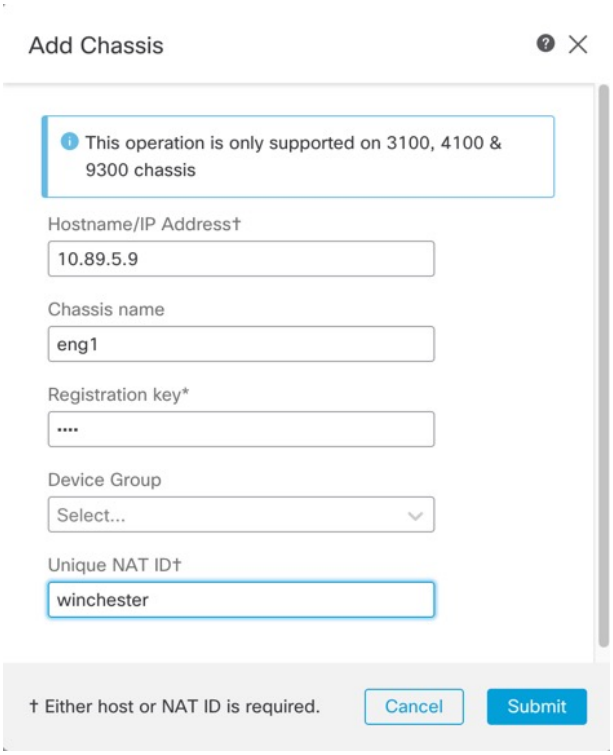


Figure 56: Add chassis

b) In the **Hostname/IP Address** field, enter the IP address or the hostname of the chassis you want to add.

If you don't know the hostname or IP address, you can leave this field blank specify the **Unique NAT ID**.

c) In the **Chassis Name** field, enter a name for the chassis as you want it to display in the Firewall Management Center.

d) In the **Registration Key** field, enter the same registration key that you used when you configured the chassis to be managed by the Firewall Management Center.

The registration key is a one-time-use shared secret. The key can include alphanumeric characters and hyphens (-).

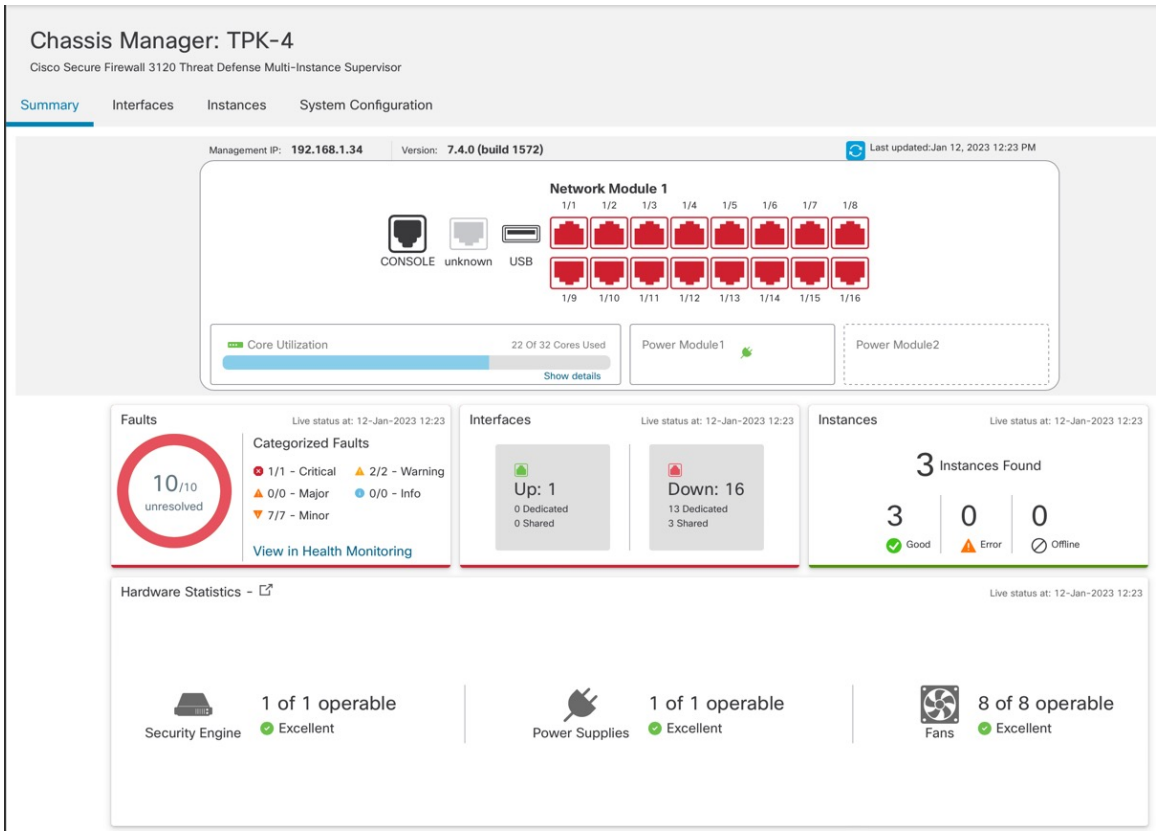
e) In a multidomain deployment, regardless of your current domain, assign the chassis to a leaf **Domain**.

If your current domain is a leaf domain, the chassis is automatically added to the current domain. If your current domain is not a leaf domain, post-registration, you must switch to the leaf domain to configure the chassis. A chassis can only belong to one domain.

f) (Optional) Add the chassis to a **Device Group**.

g) If you used a NAT ID during chassis setup, expand enter the same NAT ID in the **Unique NAT ID** field.

The NAT ID can include alphanumeric characters and hyphens (-).



h) Click **Submit**.

The chassis is added to the **Devices** > **Device Management** page.

Step 2 To view and configure the chassis, click **Manage** in the **Chassis** column, or click **Edit** ( ).

The **Chassis Manager** page opens for the chassis to the **Summary** page.

Figure 57: Chassis summary

Chassis interface configuration

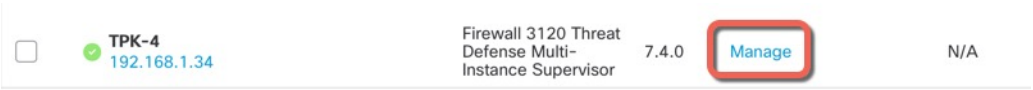
A chassis interface is a physical network interface that

- enables connection to the firewall's internal and external networks,
- supports configuration of basic Ethernet settings, VLAN subinterfaces, and EtherChannel grouping, and
- defaults to a disabled state until explicitly enabled by an administrator.

Additional information

Note To configure breakout ports and perform other network module operations, refer to Network module management for Secure Firewall 3100/4200, on page 625.

Note For information about the **Sync Device** button, refer to Sync Interface Changes with the Firewall Management Center, on page 622.



Configure a physical interface

You can physically enable and disable interfaces, as well as set the interface speed and duplex and other hardware settings. To use an interface, it must be physically enabled for the chassis and logically enabled in the instance. By default, physical interfaces are disabled. For VLAN subinterfaces, the admin state is inherited from the parent interface.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

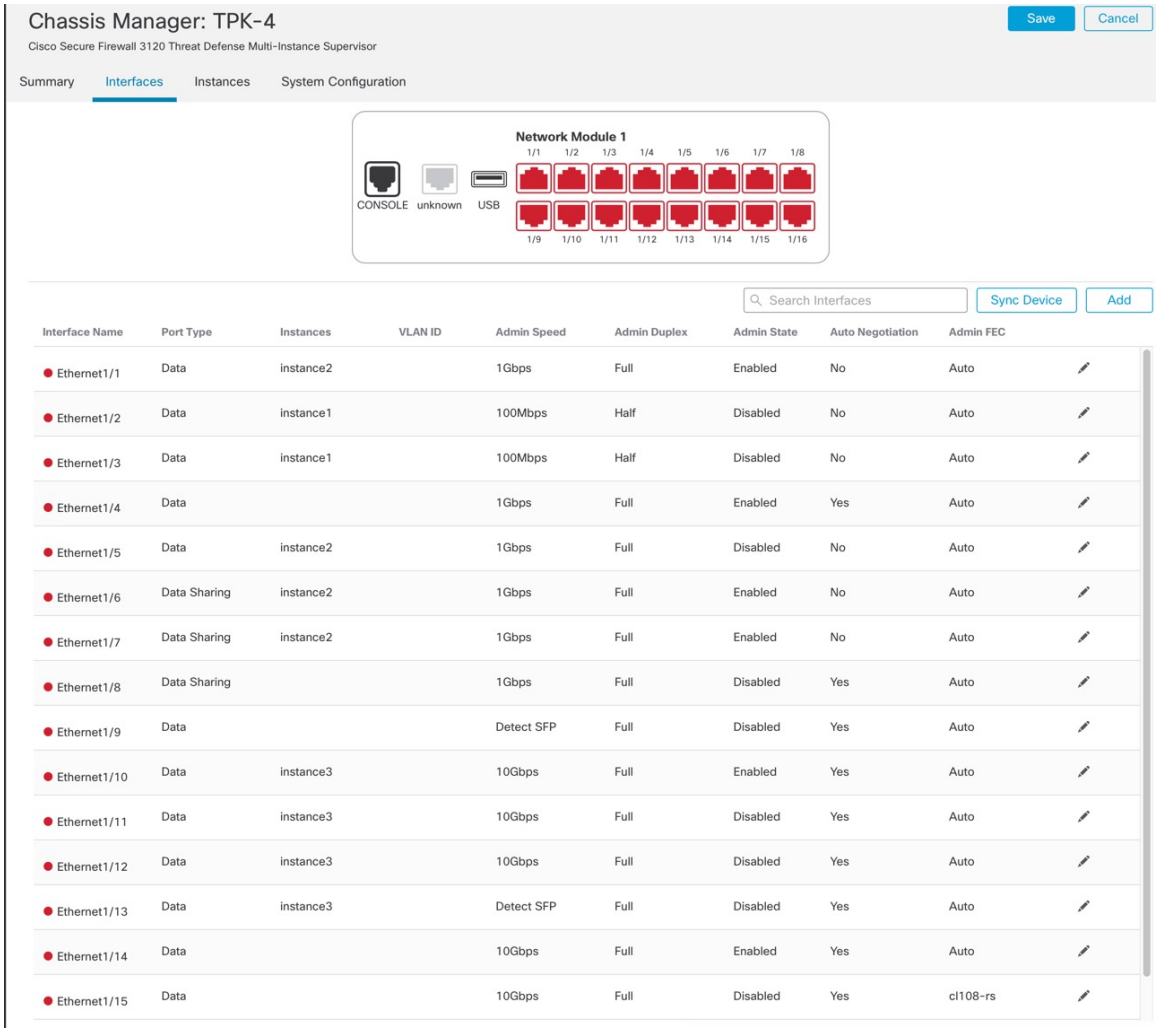


Figure 58: Manage Chassis

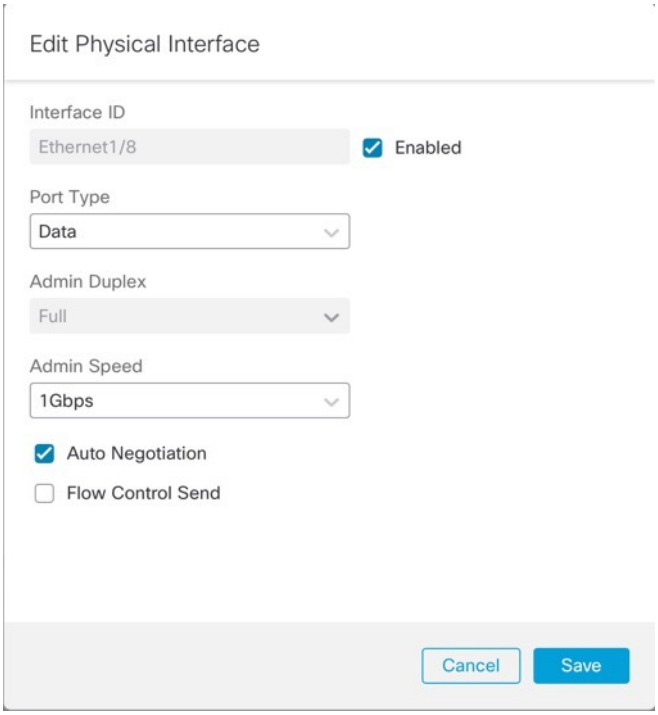
The **Chassis Manager** page opens for the chassis to the **Summary** page.



Step 2 Click **Interfaces**.

Figure 59: Interfaces

Step 3 Click **Edit** (✎) for the interface you want to edit.

Figure 60: Edit Physical Interface

Step 4 Enable the interface by checking the **Enabled** check box.

- For the **Port Type**, choose **Data** or **Data Sharing**.

  Figure 61: Port Type

- Set the **Admin Duplex**.

  Speeds of 1Gbps and higher only support **Full** duplex. SFP interfaces only support **Full** duplex.

- Set the **Admin Speed**.

  For SFPs, Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.

Step 5 (Optional) Check **Flow Control Send** to enable pause (XOFF) frames for flow control.

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If the threat defense port experiences congestion (exhaustion of queuing resources on the internal switch) and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

Note The Firewall Threat Defense supports transmitting pause frames so that the remote peer can rate-control the traffic.

However, receiving of pause frames is not supported.

The internal switch has a global pool of 8000 buffers of 250 bytes each, and the switch allocates buffers dynamically to each port. A pause frame is sent out every interface with flow control enabled when the buffer usage exceeds the global high-water mark (2 MB (8000 buffers)); and a pause frame is sent out of a particular interface when its buffer exceeds the port high-water mark (.3125 MB (1250 buffers)). After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark (1.25 MB globally (5000 buffers); .25 MB per port (1000 buffers)). The link partner can resume traffic after receiving an XON frame.

Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

Step 6 (Optional) Check **Auto Negotiation** to set the interface to negotiate the speed, link status, and flow control. You cannot edit this setting for speeds lower than 1Gbps. For SFP interfaces, you can only disable auto-negotiation when the speed is set to 1Gbps.

Step 7 Click **Save** and then **Save** in the top right of the **Interfaces** page.

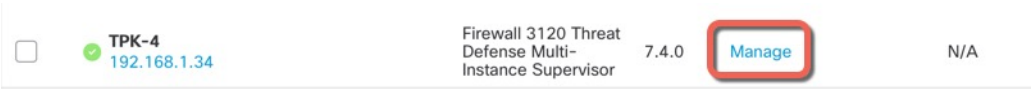
You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Configure an EtherChannel

An EtherChannel (also known as a port channel) can include up to 8 member interfaces of the same media type and capacity, and must be set to the same speed and duplex. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, unless you set the speed to **Detect SFP**; in this case, you can use different interface capacities, and the lowest common speed is used.

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices. LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

When the chassis creates an EtherChannel, the EtherChannel stays in a **Suspended** state for Active LACP mode or a **Down** state for On LACP mode until you assign it to a logical device, even if the physical link is up. The EtherChannel will be brought out of this **Suspended** state when it is added to an instance.



Before you begin

Enable physical interfaces and set hardware parameters. For more information, refer to Configure a physical interface, on page 180.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

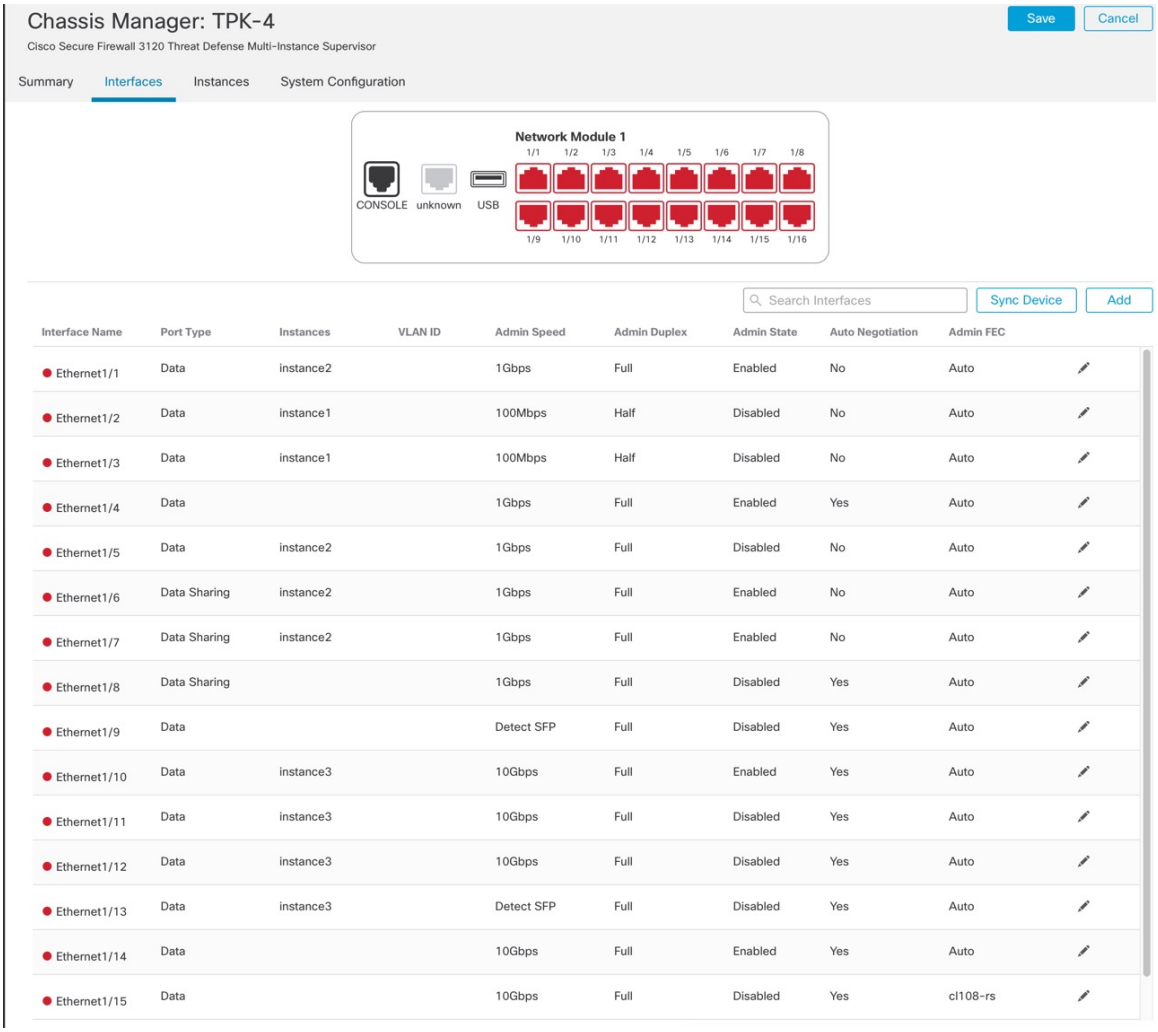


Figure 62: Manage Chassis

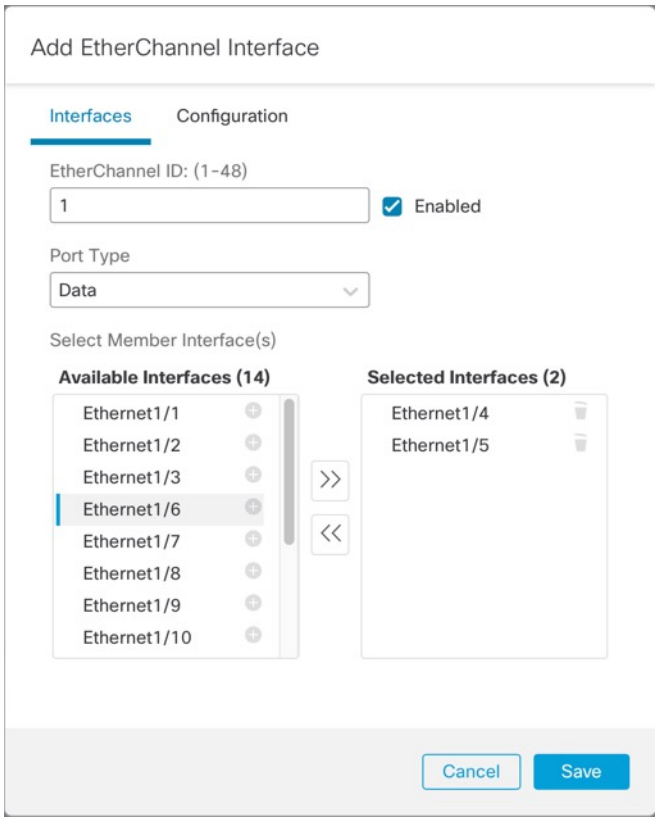
The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **Interfaces**.

Figure 63: Interfaces



Step 3 Click **Add** > **EtherChannel Interface**.

Figure 64: Add EtherChannel

Step 4 Set the following **Interfaces** parameters.

Figure 65: Interfaces settings

a) For the **EtherChannel ID**, specify an ID between 1 and 48.
b) Check **Enabled**.
c) For the **Port Type**, choose **Data** or **Data Shared**.

   For information about the port type, refer to Interface types, on page 161.

d) To add a physical interface to the EtherChannel, select click **Add** (⊕) in the **Available Interfaces** list to move it to the **Selected Interfaces** list.

   To add or remove all interfaces, click the double arrow button.

Note You cannot add an interface that is already assigned to an instance.

Step 5 (Optional) Set the following **Configuration** parameters.

Many of these settings (excluding the LACP settings) set the requirements for interfaces to be included in the EtherChannel; they do not override the settings of member interfaces. So if you check **LLDP Transmit**, for example, you should only add interfaces that have that setting. If you set the **Admin Speed** to 1 Gbps, then only 1Gbps interfaces can be included.

Figure 66: Configuration settings

a) Choose the required **Admin Duplex** for the member interfaces, **Full Duplex** or **Half Duplex**.

If you add a member interface that is configured with the specified duplex, it will not successfully join the port channel.

b) Choose the required **Admin Speed** for the member interfaces from the drop-down list.

If you add a member interface that is not at the specified speed, it will not successfully join the port channel.

c) Choose the **LACP Mode**, **Active** or **On**.

- **Active**—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- **On**—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

Note It may take up to three minutes for an EtherChannel to come up to an operational state if you change its mode from On to Active or from Active to On.

d) Choose the **LACP Rate**, **Default**, **Fast**, or **Normal**.

The default is **Fast**.

e) Choose the required Link Layer Discovery Protocol (LLDP) settings for member interfaces by checking **LLDP Transmit** and/or **LLDP Receive**.

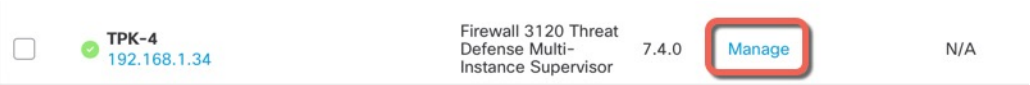
f) Check the required **Flow Control Send** setting for member interfaces.

Step 6 Click **Save** and then **Save** in the top right of the **Interfaces** page.

You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Configure a subinterface

You can add up to 500 subinterfaces to your chassis.



VLAN IDs per interface must be unique, and within an instance, VLAN IDs must be unique across all assigned interfaces. You can reuse VLAN IDs on *separate* interfaces as long as they are assigned to different instances. However, each subinterface still counts towards the limit even though it uses the same ID.

This section discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the instance. For more information, refer to Chassis interfaces vs. instance interfaces, on page 161.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

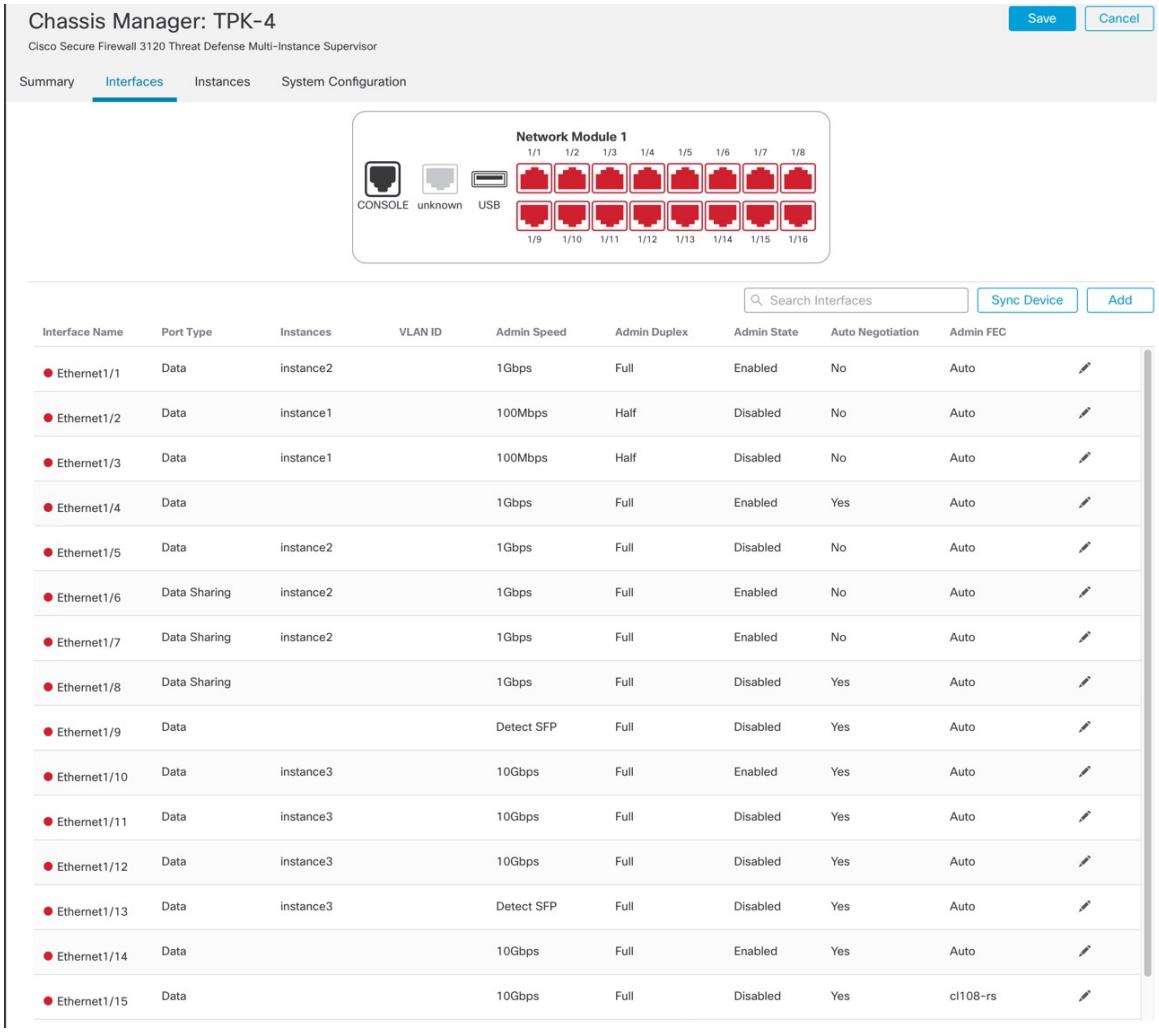


Figure 67: Manage Chassis

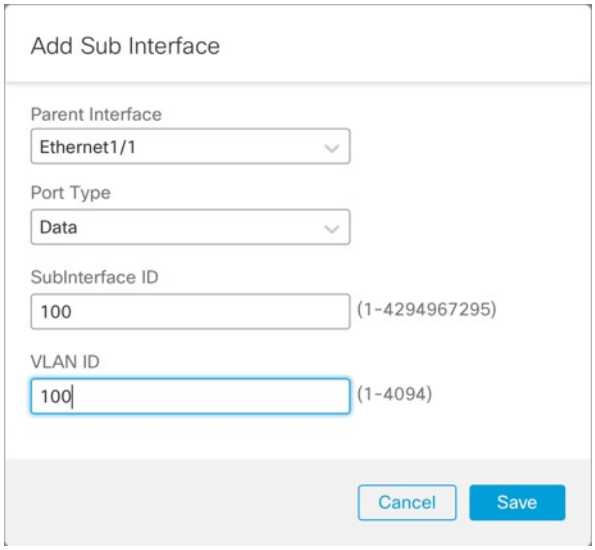
The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **Interfaces**.

Figure 68: Interfaces



Step 3 Click **Add** > **Subinterface**.

Figure 69: Add subinterface

Step 4 Set the following parameters.

Figure 70: Subinterface settings

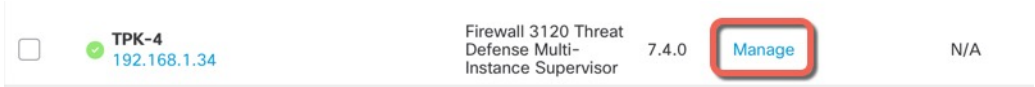
Step 5 Click **Save** and then **Save** in the top right of the **Interfaces** page.

You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Add an instance

Use this task when you need to add one or more instances to a chassis already in multi-instance mode. The number of supported instances depends on your model; refer to Requirements and prerequisites for instances, on page 171.

Before you begin



Enable multi-instance mode, on page 175 and Add a multi-instance chassis to the Firewall Management Center, on page 177.

Follow these steps to add an instance to a chassis in multi-instance mode:

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

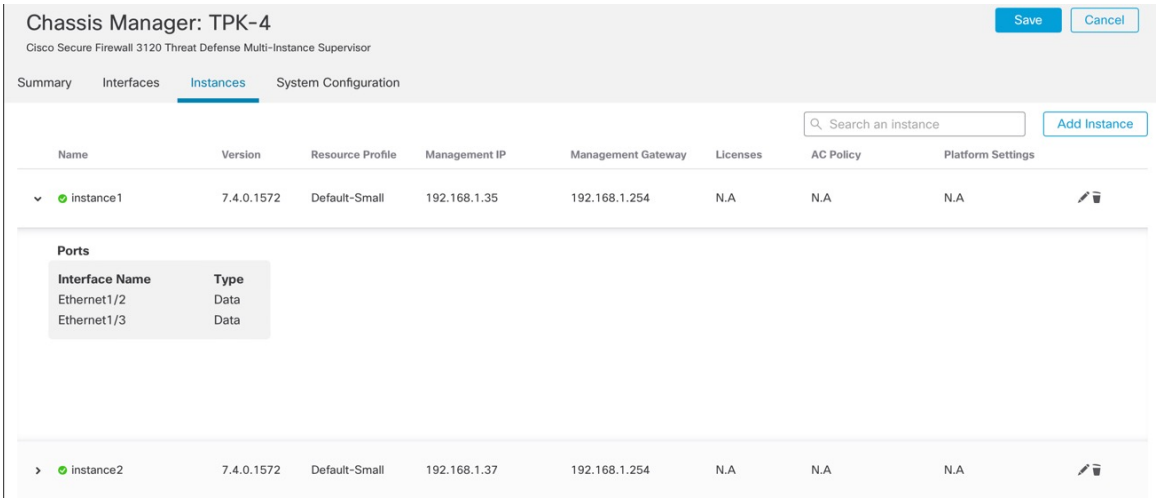


Figure 71: Manage Chassis

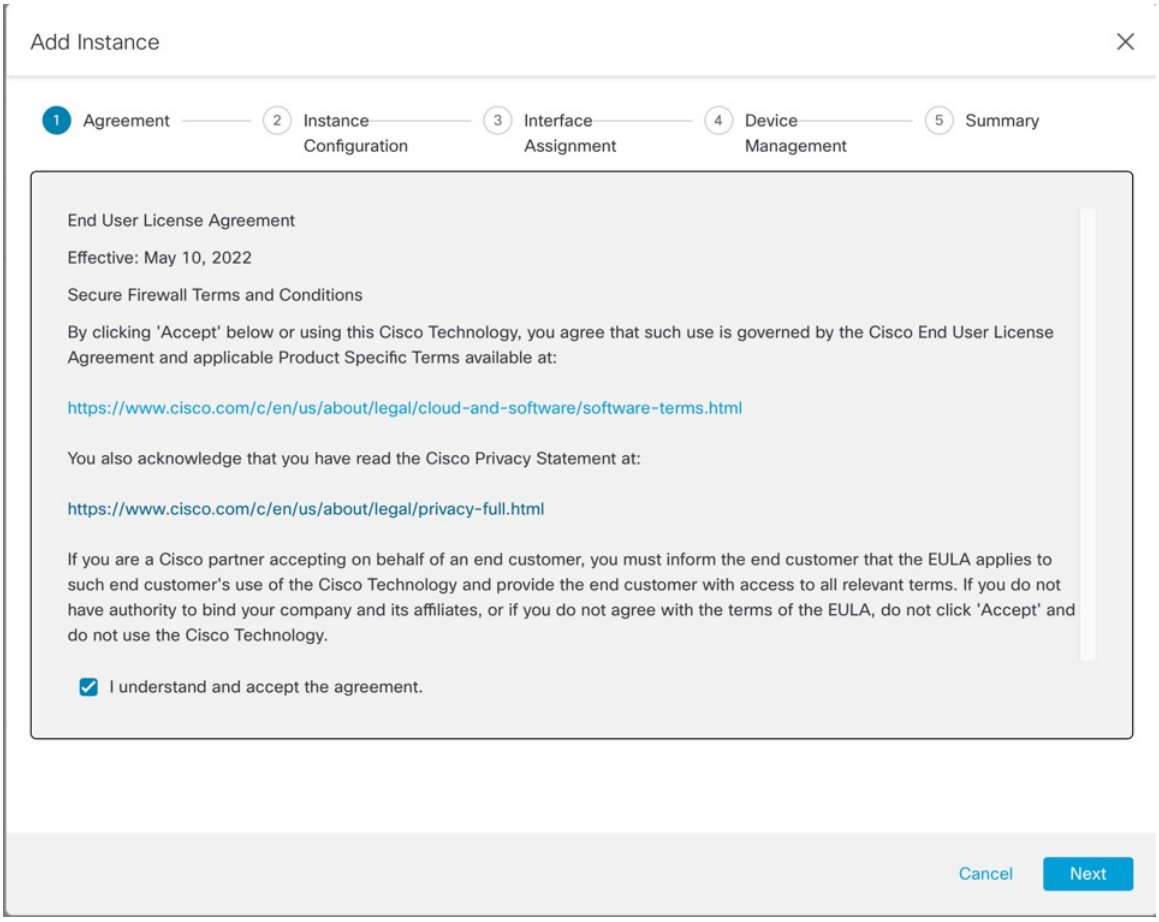
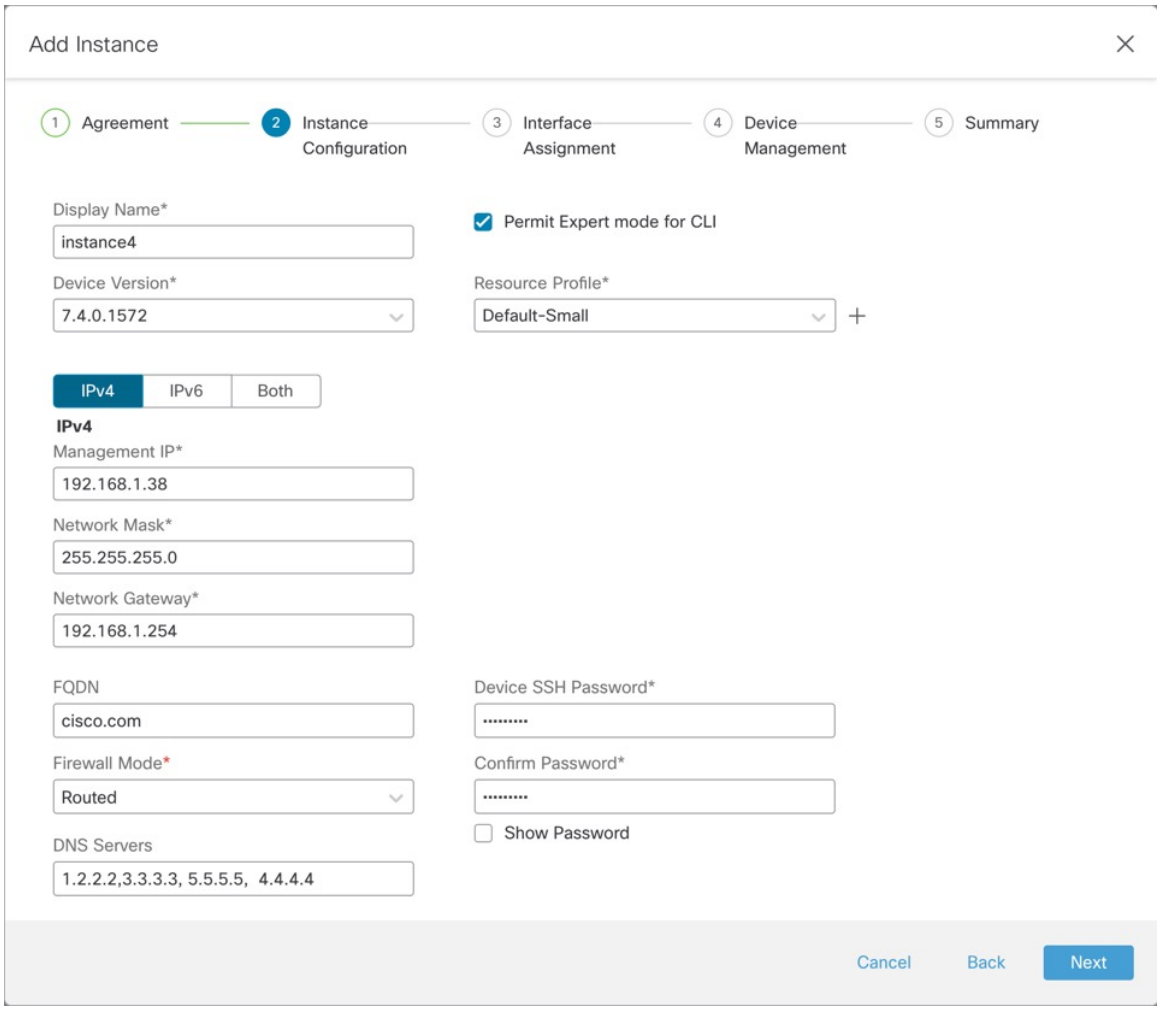
The **Chassis Manager** page opens for the chassis to the **Summary** page.



Step 2 Click **Instances**, and click **Add Instance**.

Figure 72: Instances



Step 3 On **Agreement**, check **I understand and accept the agreement**, then click **Next**.

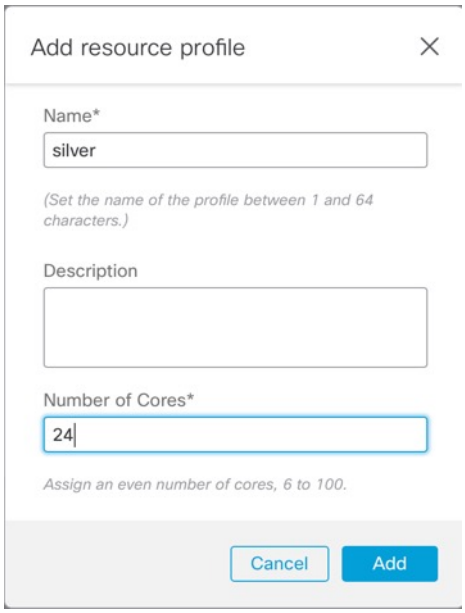
Figure 73: Agreement

Step 4 On **Instance Configuration**, set the instance parameters, then click **Next**.

Figure 74: Instance configuration

- **Display Name**
- **Device Version**: Versions listed are packages currently downloaded to the chassis. Patch versions are not listed and cannot be used because they don't contain the entire bundle. To upgrade to a new package, refer to **Devices** > **Upgrade** > **Chassis Upgrade**. When you upgrade, both the old Firewall Threat Defense version and the new Firewall Threat Defense version will be listed in the menu. To download an older package, you need to use the FXOS CLI. Note: Both FXOS and Firewall Threat Defense images are included in the same package. For more information, refer to troubleshooting guide.

  For example:



```
firepower-3110# scope firmware
firepower-3110# download image
https://10.10.7.89/Cisco_FTD_SSP_FP3K_Upgrade-7.4.1-1.sh.DEV.tar
Please use the command 'show download-task' or 'show download-task detail' to check
download progress.
% Download-task Cisco_FTD_SSP_FP3K_Upgrade-7.4.1-1.sh.DEV.tar : completed successfully.
```

- **IPv4**, **IPv6**, or **Both**: Set a **Management IP** address on the same network as the chassis Management interface. Set the **Network Mask** and gateway (likely the same gateway as the chassis). The chassis Management interface is shared with each instance, and each instance has its own IP address on the network. You can SSH to this IP address by default to reach the Firewall Threat Defense CLI.
- (Optional) **FQDN**
- **Firewall Mode**: **Routed** or **Transparent**. For more information about the firewall mode, refer to Transparent or Routed Firewall Mode, on page 71.
- **DNS Servers**: Enter a comma-separated list of DNS servers for management traffic only.
- (Optional) **Permit Expert Mode for CLI**: Expert Mode provides Firewall Threat Defense shell access for advanced troubleshooting.

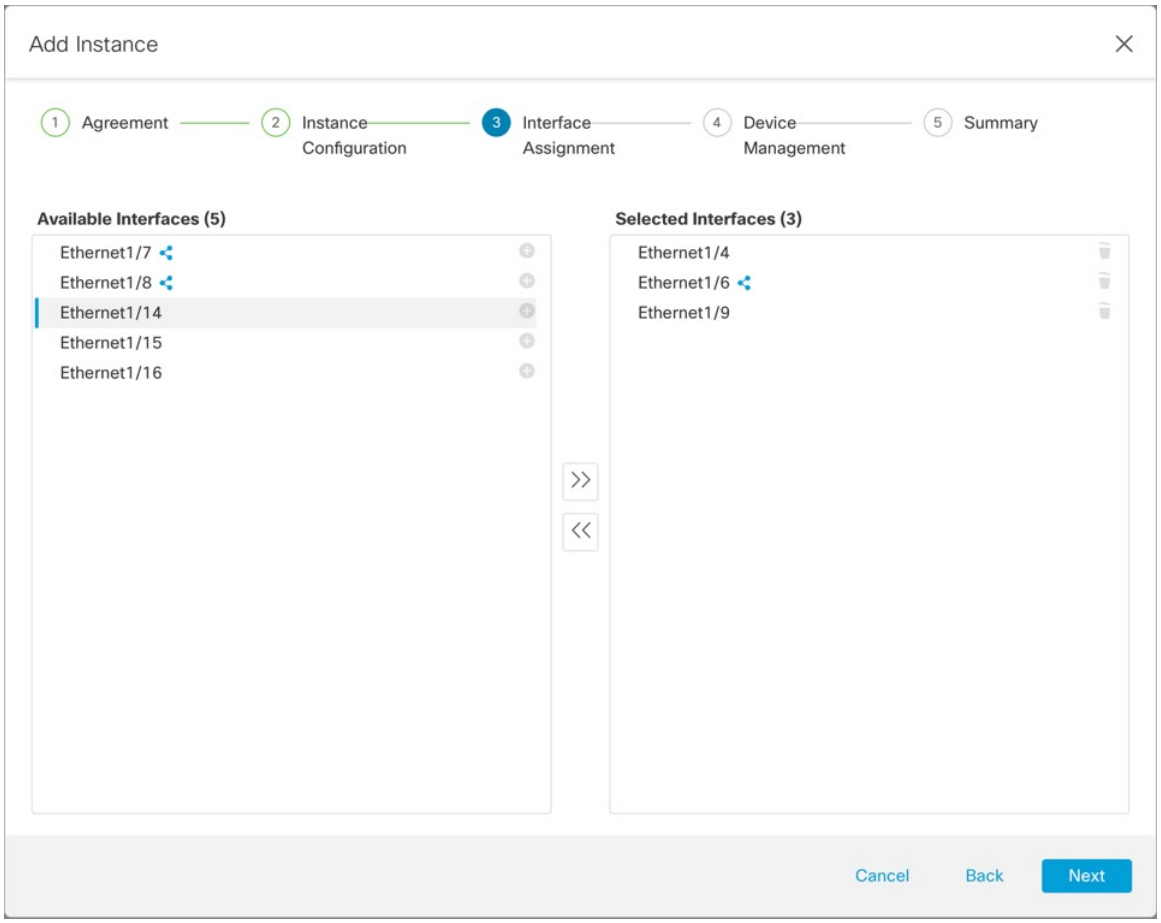
  If you enable this option, then users who access the instance directly from an SSH session can enter Expert Mode. If you disable this option, then only users who access the instance from the FXOS CLI can enter Expert Mode. We recommend disabling this option to increase isolation between instances.

  Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the Firewall Threat Defense CLI.
- **Resource Profile**: The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance. The chassis includes these default resource profiles: Default-Small, Default-Medium, and Default-Large. You can add additional profiles for this chassis by clicking **Add** (+). You cannot later edit the resource profile.

Figure 75: Add resource profile

  - The minimum number of cores is 6.

Note Instances with a smaller number of cores might experience relatively higher CPU utilization than those with larger numbers of cores. Instances with a smaller number of cores are more sensitive to traffic load changes. If you experience traffic drops, try assigning more cores.



- You can assign cores as an even number (6, 8, 10, 12, 14 etc.) up to the maximum.
- The maximum number of cores available depends on the model; refer to Requirements and prerequisites for instances, on page 171.

If you later assign a different resource profile, then the instance will reload, which can take approximately 5 minutes. Note that for an established High Availability pair , if you assign a different-sized resource profile, be sure to make all members the same size as soon as possible.

- **Device SSH Password**: Set the Firewall Threat Defense admin user password for CLI access, either SSH or console. Repeat the password in the **Confirm Password** field.

Step 5 On **Interface Assignment**, assign the chassis interfaces to the instance, then click **Next**.

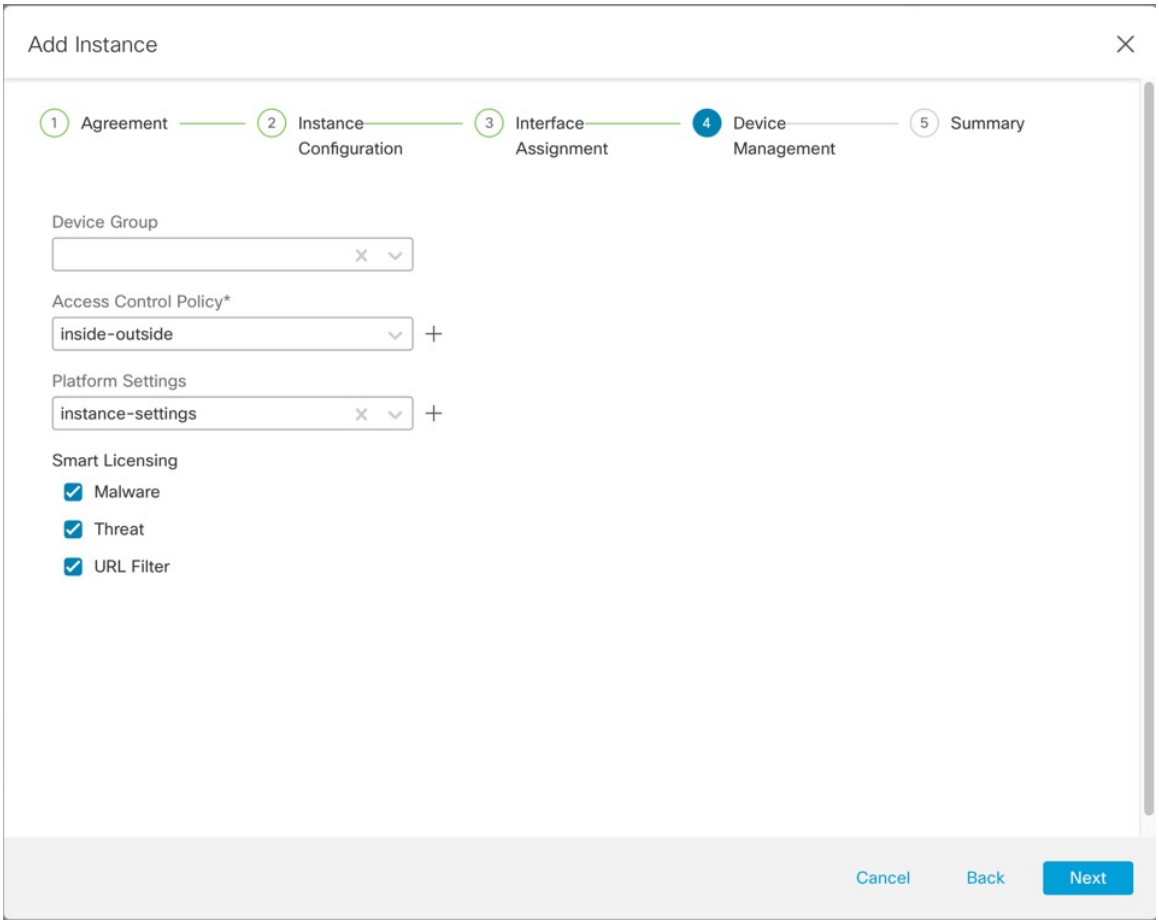


Figure 76: Interface assignment

Shared interfaces show the sharing icon ( ).

Step 6 On **Device Management**, set the device-specific settings, then click **Next**.

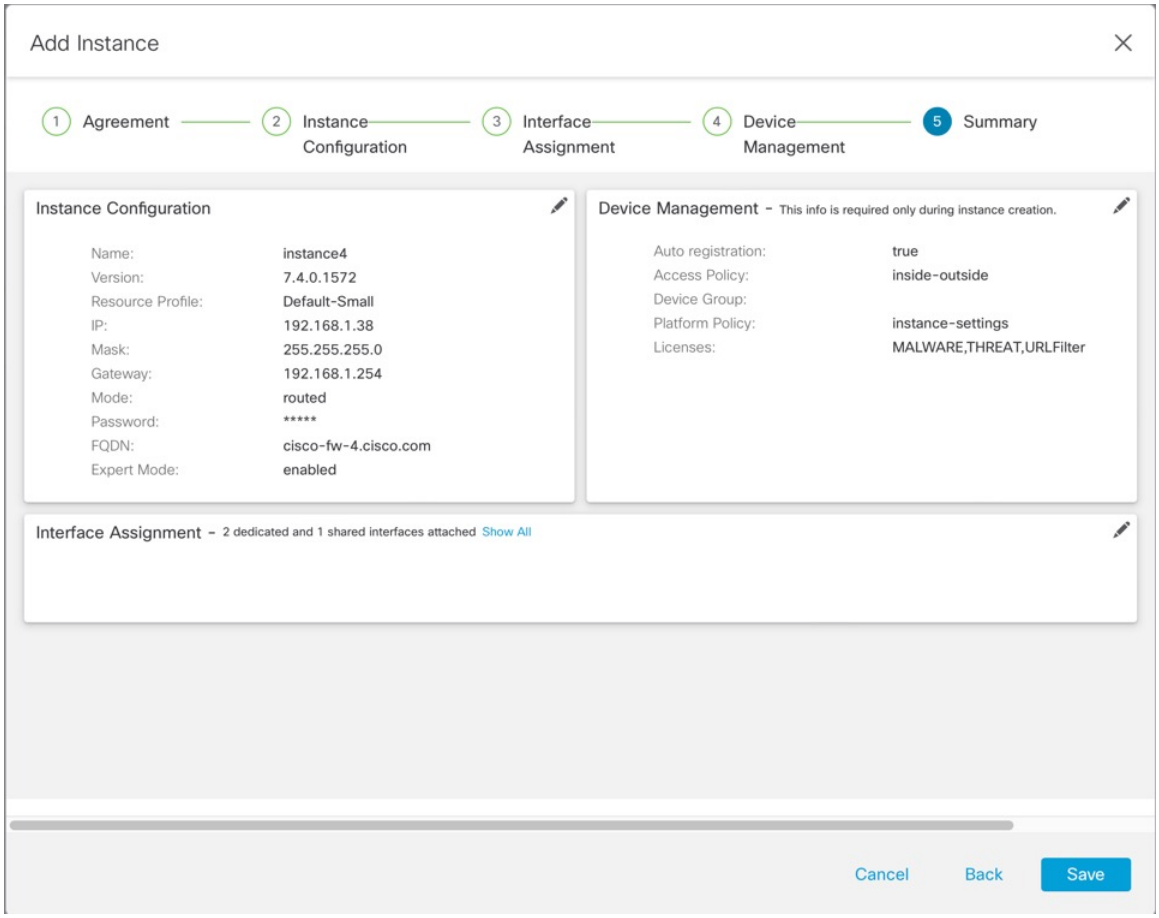

Figure 77: Device management

- **Device Group**
- **Access Control Policy**: Choose an existing access control policy, or create a new policy.
- **Platform Settings**: Choose an existing platform setting policy, or create a new policy.
- **Smart Licensing**

Step 7 On **Summary**, confirm your settings, then click **Save**.

Figure 78: Summary

You can edit any settings on this screen before saving the instance. After you save, the instance is added to the **Instances** screen.

Step 8 On the **Instances** screen, click **Save**.

Deploy the chassis configuration.

After deployment, the instance will be added as a device on the **Device Management** page.

Note Before you delete an instance, you must first unregister it on the **Device Management** page. If you delete the instance without unregistering it, the instance will remain as a stale entry in **Device Management**.

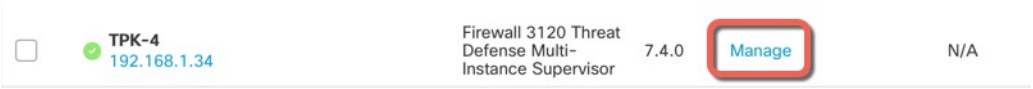
System configuration customization

You can configure chassis-level settings such as SNMP. You can also import or export the chassis FXOS configuration.

Configure SNMP

You can access chassis-level MIBs through the data interface of one of the instances, which you specify in the chassis system configuration. You can only use this instance for chassis SNMP information. You cannot access SNMP through the chassis Management interface.

Before you begin



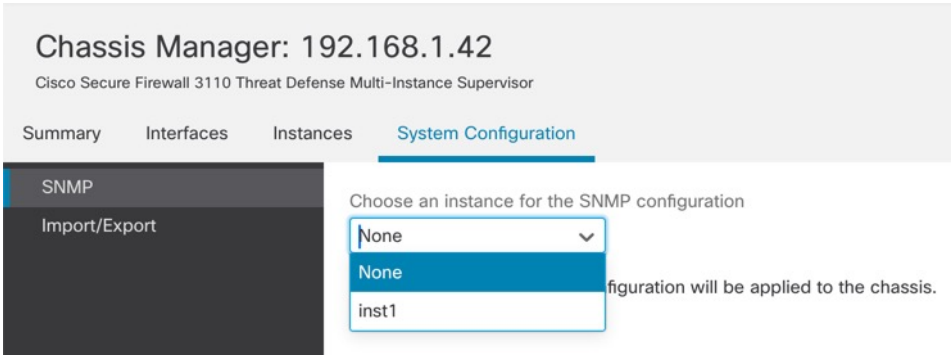
Configure SNMP for one of the instances. For more information, refer to Configure SNMP for a security device, on page 870.

Follow these steps to configure SNMP:

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

Figure 79: Manage Chassis



The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **System Configuration**.

Step 3 Click **SNMP**, and choose the instance from the drop-down list.

Figure 80: SNMP

SNMP on the chassis will be accessible from the selected instance.

Step 4 Click **Save**.

Step 5 Deploy the chassis configuration.

Import or export the chassis configuration

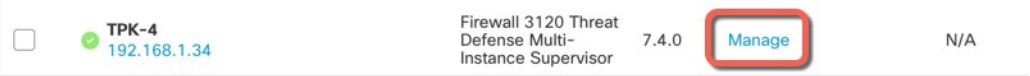
You can use the configuration export feature to export an XML file containing chassis configuration settings to your local computer. You can later import that configuration file to quickly apply the configuration settings to your chassis to return to a known good configuration or to recover from a system failure.

Note You can't import the chassis configuration to a new chassis.

When exporting, only chassis configurations are exported; instance configuration settings are not exported. Instances need to be backed up separately using the device backup/restore feature.

When importing, all existing configurations on the chassis will be replaced by the configuration in the import file.

Before you begin



When you import the configuration to the same chassis, make sure the chassis matches for the following:

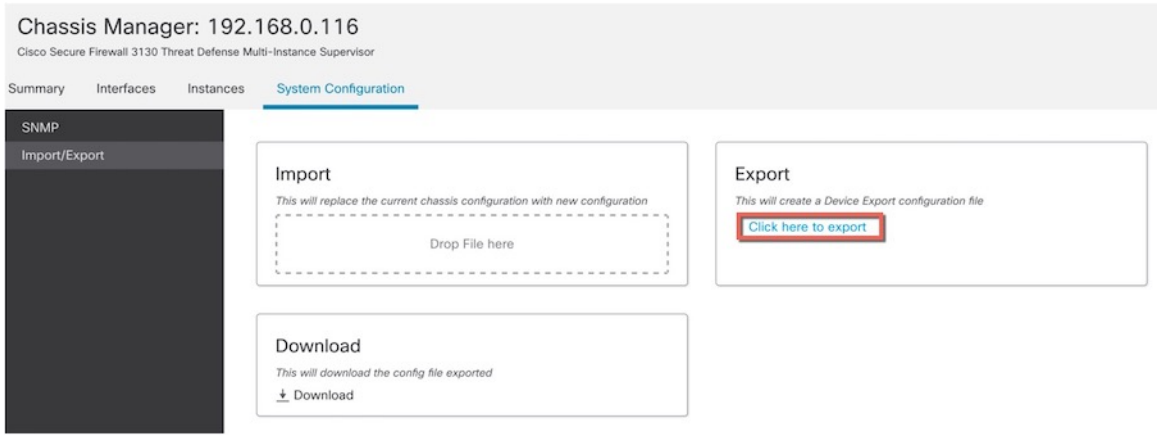
- Same chassis software version
- Same Firewall Threat Defense instance images
- Same network modules

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

Figure 81: Manage Chassis

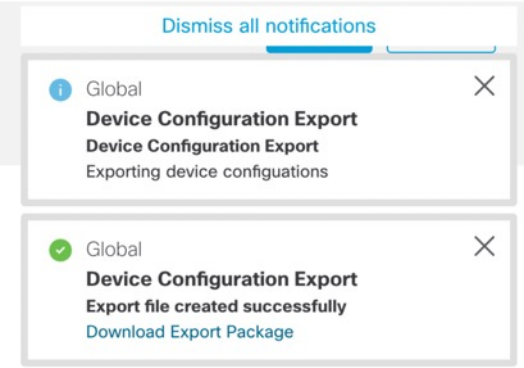
The **Chassis Manager** page opens for the chassis to the **Summary** page.



Step 2 Click **System Configuration**.

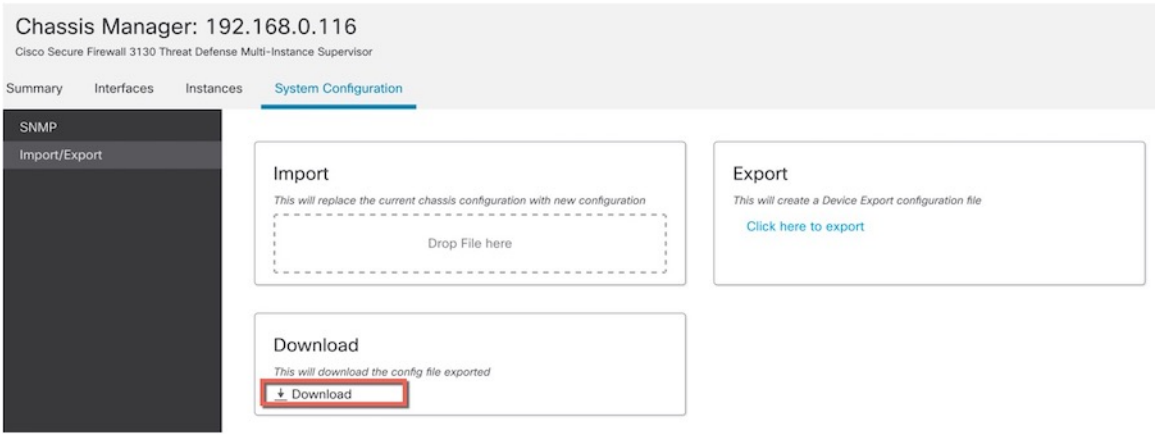
Step 3 Click **Import/Export**.

Step 4 To export the configuration, follow these steps.



a) In the **Export** area, click **Click here to export**.

Figure 82: Create Export File



b) Monitor the notifications for the **Export file created successfully** message.

Figure 83: Export File Created Successfully

c) Download the export file by clicking the notification message (**Download Export Package**) or by clicking **Download**.

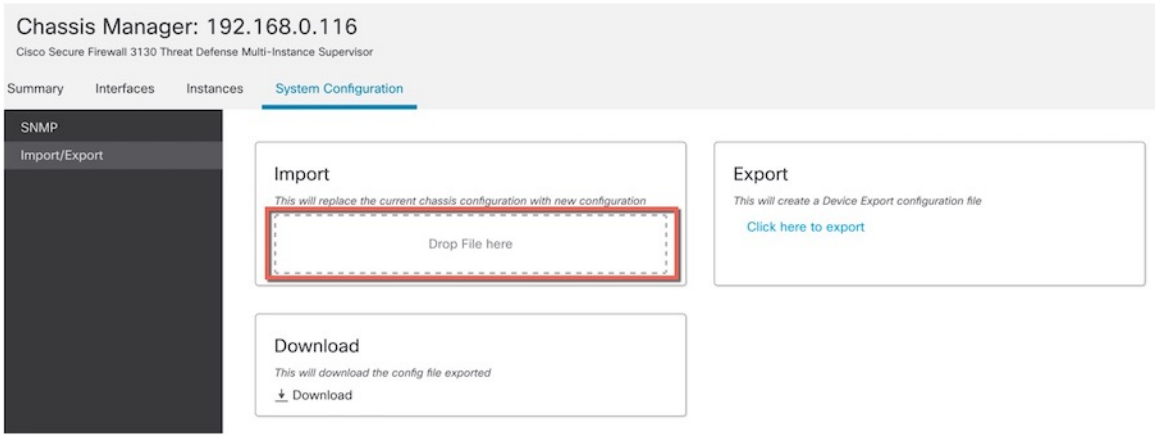


Figure 84: Download

The file is saved with the .sfo extension.

Step 5 To import a configuration, drag the **.sfo** file on the **Import** > **Drop File here** area.

Figure 85: Import

Chassis platform settings

Chassis platform settings are configuration features that configure a range of features for managing the chassis and can be shared among multiple chassis.

Chassis platform settings configure a range of features for managing the chassis. You can share the policy among multiple chassis. If you want different settings per chassis, you must create multiple policies.

Create a chassis platform settings policy

Use the **Platform Settings** page (**Devices** > **Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The **Status** column shows the device targets for the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings**.

Step 2 For an existing policy, you can **Copy** ( ), **Edit** ( ), or **Delete** ( ) the policy.

Caution You should not delete a policy that is the last-deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is good practice to deploy a different policy to those targets.

Step 3 To create a new policy, click **New Policy**.

a) Choose **Chassis Platform Settings** from the drop-down list.
b) Enter a **Name** for the new policy and optionally, a **Description**.
c) Optionally, choose the **Available Chassis** where you want to apply the policy and click **Add** to add the selected chassis.
d) Click **Save**.

The system creates the policy and opens it for editing.

Step 4 To change the target chassis for a policy, click **Edit** ( ) next to the platform settings policy that you want to edit.

a) Click **Policy Assignment**.

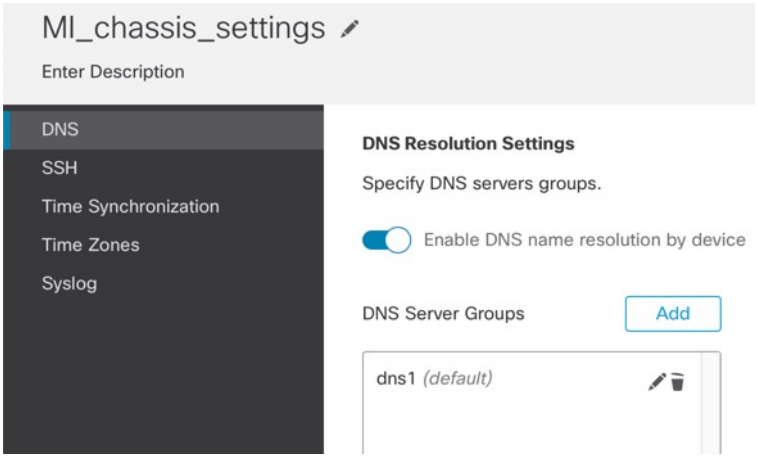
b) To assign a chassis to the policy, select it in the **Available Chassis** list and click **Add**.

c) To remove a chassis assignment, click **Delete** ( ) next to a chassis in the **Selected Chassis** list.

d) Click **OK**.

Configure DNS

You need to specify a DNS server if the chassis requires resolution of hostnames to IP addresses. These chassis DNS settings are separate from the DNS settings per instance, which are configured in the device platform settings.



When you configure multiple DNS servers, the chassis uses servers in a random order. You can configure up to four servers across four DNS server groups. For example, you can configure a single server group with four servers, or you can configure four server groups with one server each.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **DNS**.

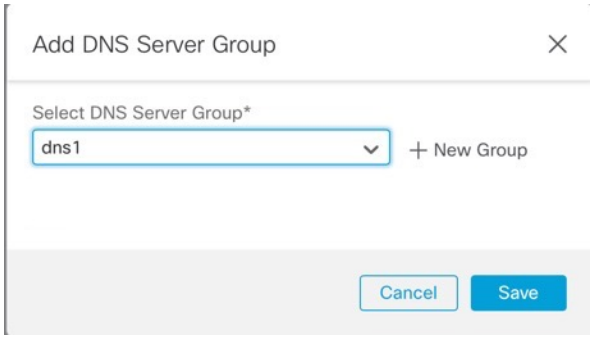


Figure 86: DNS

Step 3 Enable the **Enable DNS name resolution by device** slider.

Step 4 Click **Add** to add a DNS server group.

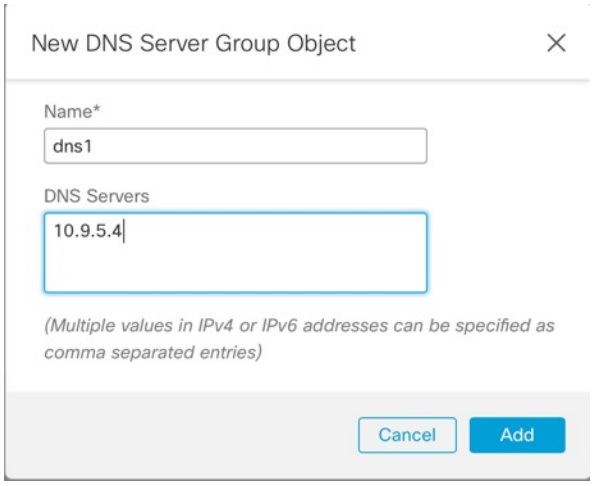

Figure 87: Add DNS server group

Step 5 Either select an existing DNS server group (refer to Create a DNS server group object, on page 2366), or click (+) **New Group**.

If you add a new group, you see this dialog box. Provide a name and up to four DNS server IP addresses as comma-separated values, and click **Add**.

Figure 88: New DNS server group object

Step 6 Click **Save** to add the DNS server to the list.

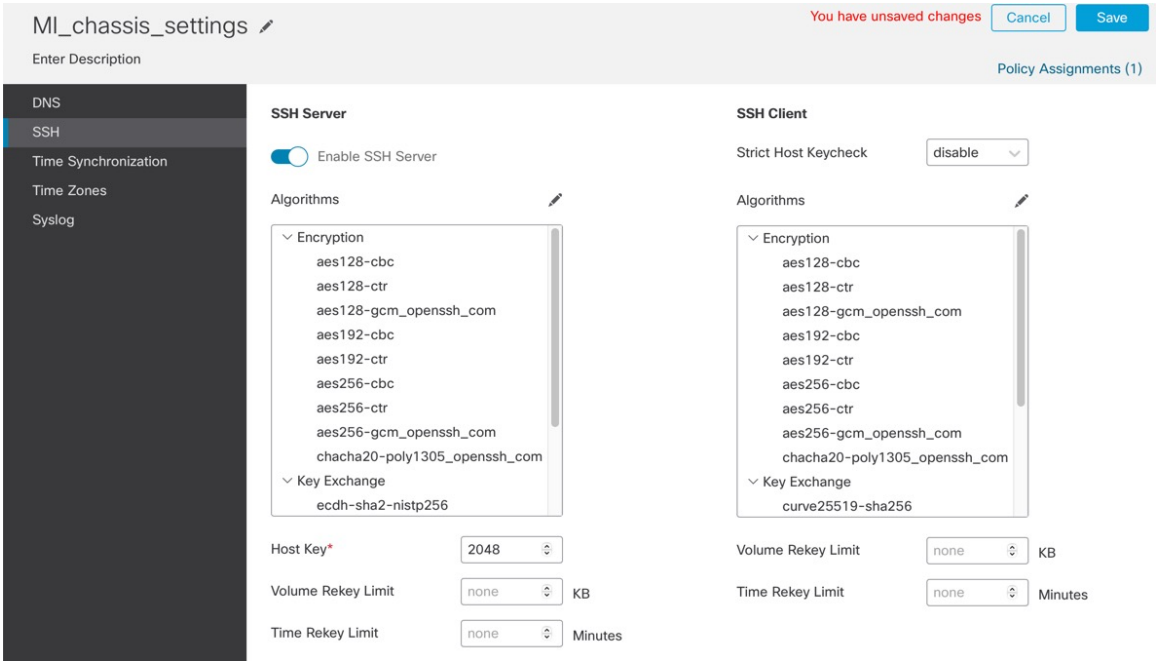
Step 7 Repeat these steps to add additional server groups.

Make sure you only identify a maximum of four DNS servers in all groups combined.

Step 8 Click **Save** to save all policy changes.

Configure SSH and SSH access list

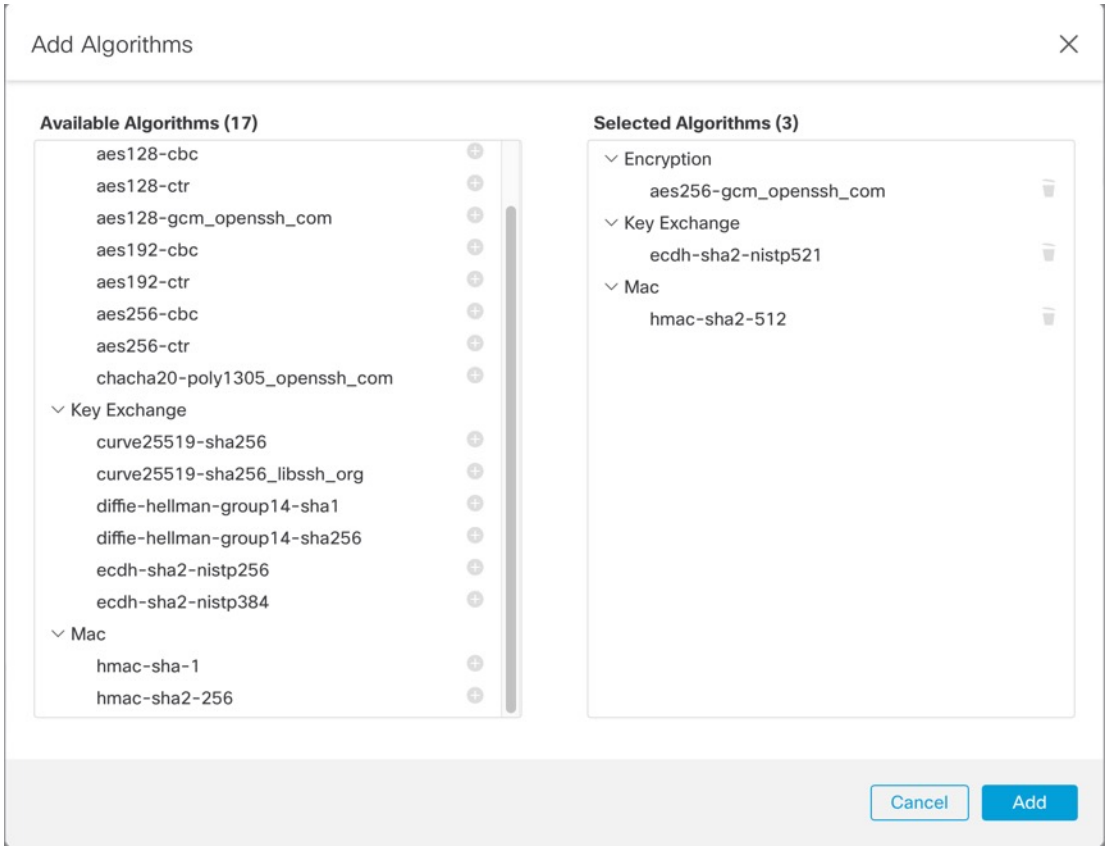
To allow SSH sessions from the admin user to the chassis on the Management interface, enable the SSH server and configure the allowed networks.



Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **SSH**.



Step 3 To enable SSH access to the chassis, enable the **Enable SSH Server** slider.

Figure 89: SSH

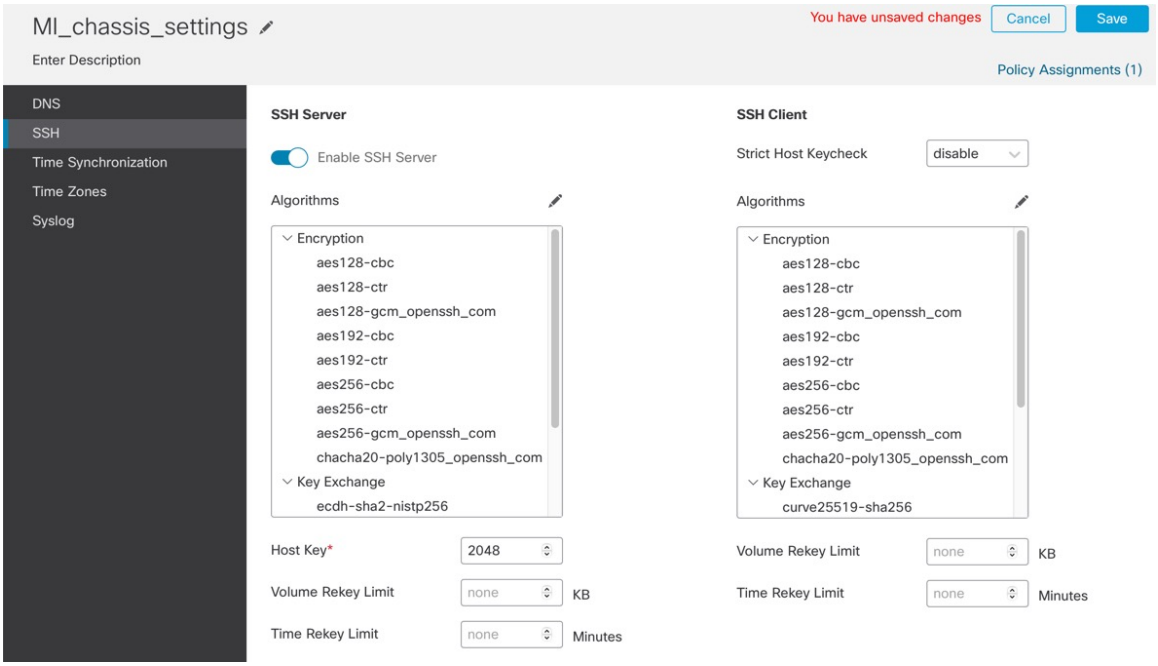
Step 4 To set the allowed **Algorithms**, click **Edit** ( ).

Figure 90: Add Algorithms

a) Select the **Encryption** algorithms.
b) Select the **Key Exchange** algorithms.

   The key exchange provides a shared secret that cannot be determined by either party alone. The key exchange is combined with a signature and the host key to provide host authentication. This key-exchange method provides explicit server authentication.

c) Select the **Mac** integrity algorithms.



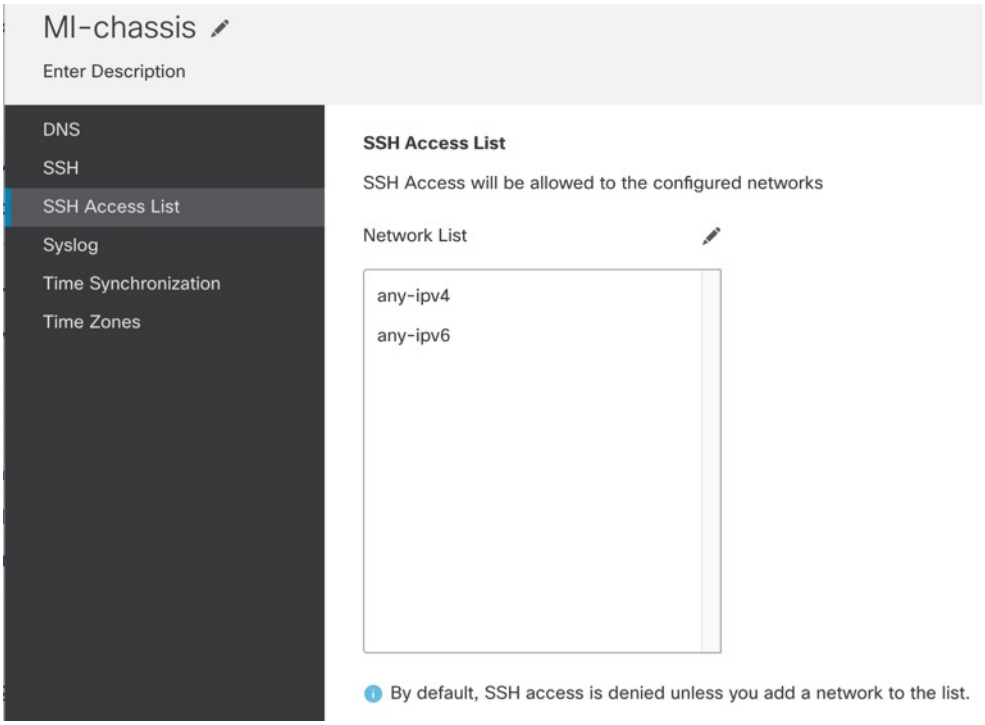
Step 5 For **Host Key**, enter the modulus size for the RSA key pairs.

The modulus value (in bits) is in multiples of 8 from 1024 to 2048. The larger the key modulus size you specify, the longer it takes to generate an RSA key pair. We recommend a value of 2048.

Step 6 For the server **Volume Rekey Limit**, set the amount of traffic in KB allowed over the connection before FXOS disconnects from the session.. For the server **Time Rekey Limit**, set the minutes for how long an SSH session can be idle before FXOS disconnects the session.

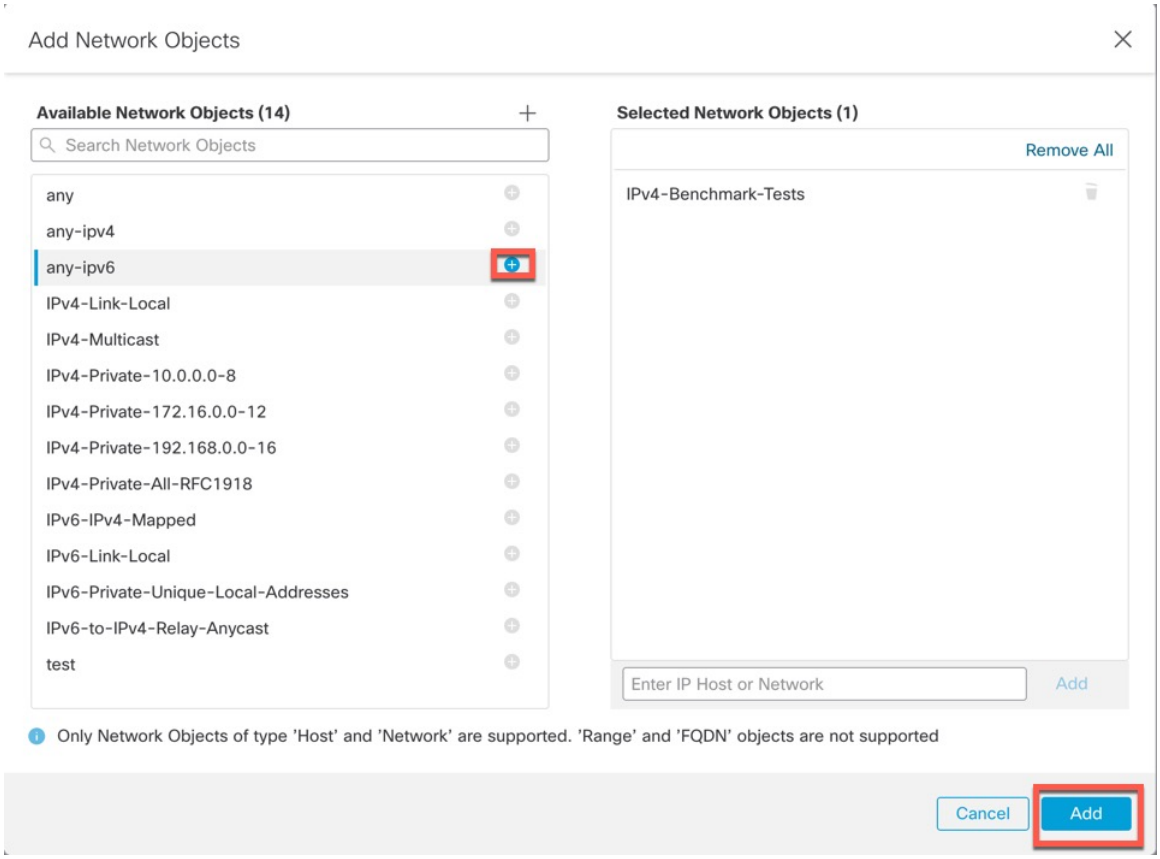
Step 7 For the **SSH Client**, configure the following settings.

Figure 91: SSH



- **Strict Host Keycheck**—Choose **enable**, **disable**, or **prompt** to control SSH host key checking.
  - **enable**—The connection is rejected if the host key is not already in the FXOS known hosts file. You must manually add hosts at the FXOS CLI using the **enter ssh-host** command in the system/services scope.
  - **prompt**—You are prompted to accept or reject the host key if it is not already stored on the chassis.
  - **disable**—(The default) The chassis accepts the host key automatically if it was not stored before.
- **Algorithms**: Click **Edit** (✎). and select the **Encryption**, **Key Exchange**, and **Mac** algorithms.
- **Volume Rekey Limit**: Set the amount of traffic in KB allowed over the connection before FXOS disconnects from the session.
- **Time Rekey Limit**: Set the minutes for how long an SSH session can be idle before FXOS disconnects the session.

Step 8 Choose **SSH Access List**. You need to allow access to IP addresses or networks before you can use SSH.



You can add up to 25 access lists.

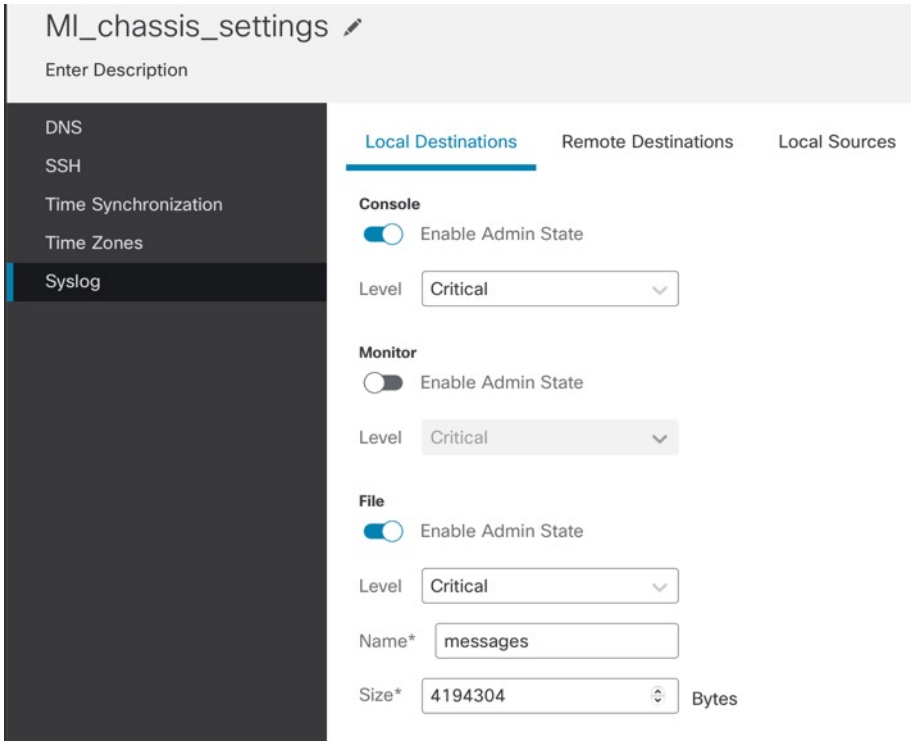
Figure 92: SSH Access List

Step 9 Click **Edit** ( ) to add network objects and click **Save**. You can also manually enter IP addresses. Click **Save** to save all policy changes.

Figure 93: Network Objects

Configure syslog

You can enable syslogs from the chassis. These syslogs come from the chassis' FXOS operating system.



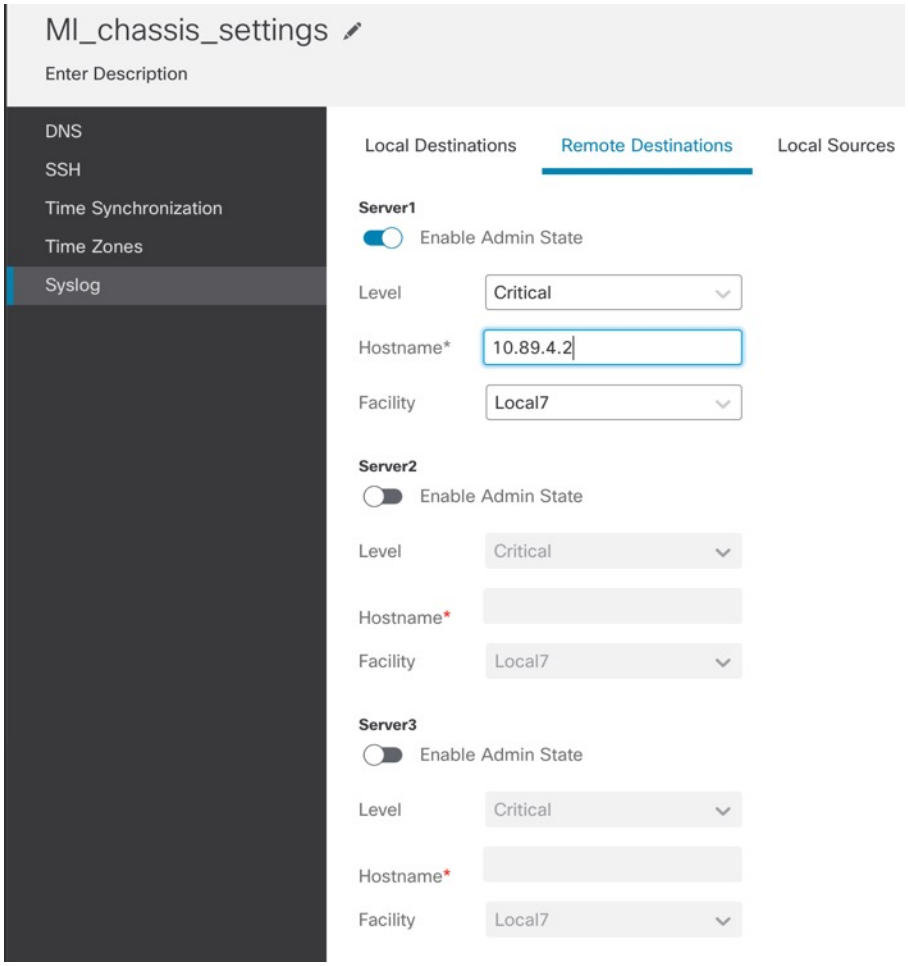
Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **Syslog**.

Step 3 Click the **Local Destinations** tab, and complete the following fields.

Figure 94: Syslog local destinations

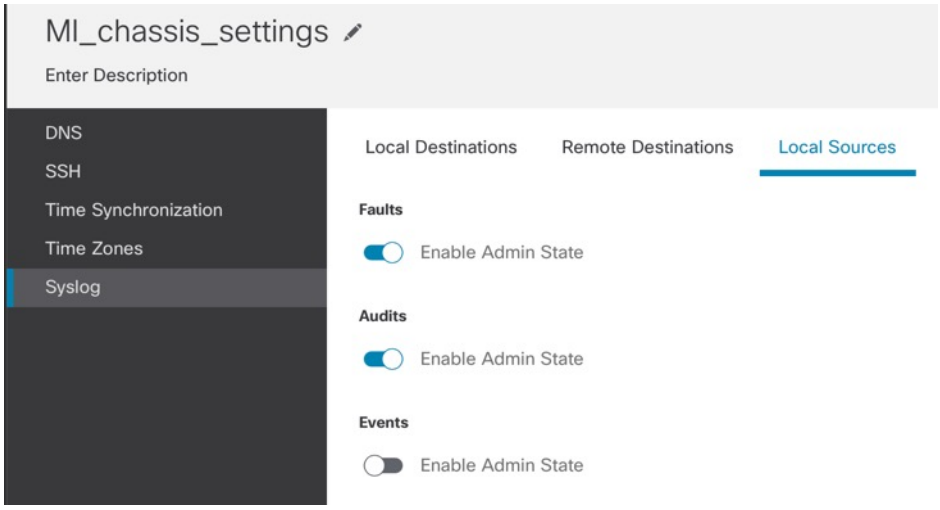


Name	Description
Console Section	
Admin State field	Whether the chassis displays syslog messages on the console. Check the **Enable** check box if you want to have syslog messages displayed on the console as well as added to the log. If the **Enable** check box is unchecked, syslog messages are added to the log but are not displayed on the console.
Level field	If you checked the **Enable** check box for **Console - Admin State**, select the lowest message level that you want displayed on the console. The chassis displays that level and above on the console. This can be one of the following: • **Emergencies** • **Alerts** • **Critical**
Monitor Section	

Name	Description
Admin State field	Whether the chassis displays syslog messages on the monitor. Check the **Enable** check box if you want to have syslog messages displayed on the monitor as well as added to the log. If the **Enable** check box is unchecked, syslog messages are added to the log but are not displayed on the monitor.
Level drop-down list	If you checked the **Enable** check box for **Monitor - Admin State**, select the lowest message level that you want displayed on the monitor. The system displays that level and above on the monitor. This can be one of the following: • **Emergencies** • **Alerts** • **Critical** • **Errors** • **Warnings** • **Notifications** • **Information** • **Debugging**

Step 4 On the **Remote Destinations** tab, complete the following fields for up to three external logs that can store messages generated by the chassis:

Figure 95: Syslog remote destinations



By sending syslog messages to a remote destination, you can archive messages according to the available disk space on the external syslog server, and manipulate logging data after it is saved. For example, you could specify actions to be executed when certain types of syslog messages are logged, extract data from the log and save the records to another file for reporting, or track statistics using a site-specific script.

Name	Description
Admin State field	Check the **Enable** check box if you want to have syslog messages stored in a remote log file.

Name	Description
Level drop-down list	Select the lowest message level that you want the system to store. The system stores that level and above in the remote file. This can be one of the following: • **Emergencies** • **Alerts** • **Critical** • **Errors** • **Warnings** • **Notifications** • **Information** • **Debugging**
Hostname/IP Address field	The hostname or IP address on which the remote log file resides. **Note** You must configure a DNS server if you use a hostname rather than an IP address.
Facility drop-down list	Choose a system log facility for syslog servers to use as a basis to file messages. This can be one of the following: • **Local0** • **Local1** • **Local2** • **Local3** • **Local4** • **Local5** • **Local6** • **Local7**

Step 5 Click the **Local Sources** tab, and complete the following fields.

Figure 96: Syslog local sources

Name	Description
Faults > **Enable Admin State**	Enable system fault logging.
Audits > **Enable Admin State**	Enable audit logging.
Events > **Enable Admin State**	Enable system event logging.

Step 6 Click **Save** to save all policy changes.

Configure time synchronization

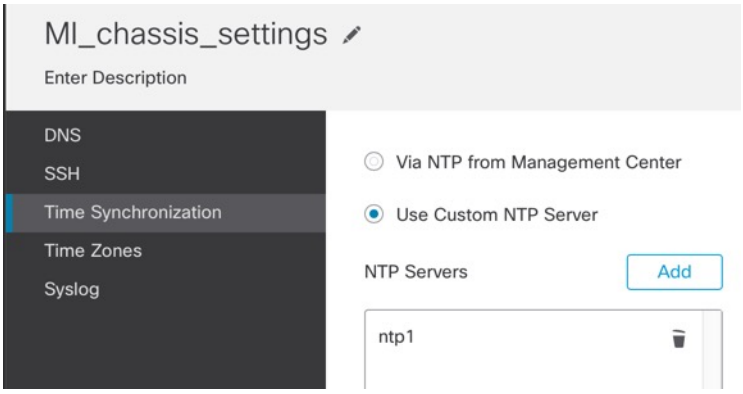
NTP is used to implement a hierarchical system of servers that provide precisely synchronized time among network systems. This kind of accuracy is required for time-sensitive operations, such as validating CRLs, which include a precise time stamp. You can configure up to four NTP servers.

Note

- FXOS uses NTP version 3.
- If the stratum value of an external NTP server is 13 or greater, the application instance cannot sync to the NTP server on the FXOS chassis. Each time a NTP client syncs to a NTP server, the stratum value increases by one.

  If you have set up your own NTP server, you can find its stratum value in the /etc/ntp.conf file on the server. If the NTP server has stratum value of 13 or greater you can either change the stratum value in the ntp.conf file and restart the server, or use a different NTP server (for example: pool.ntp.org).

Before you begin



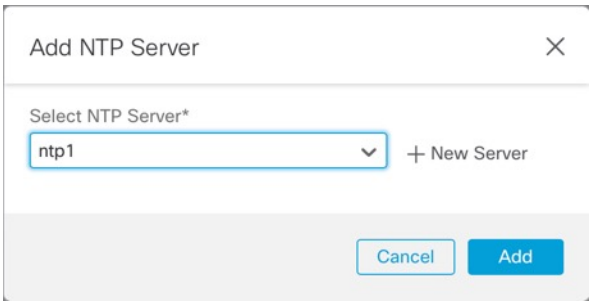
If you use a hostname for the NTP server, you must configure a DNS server. For more information, refer to Configure DNS, on page 200.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **Time Synchronization**.

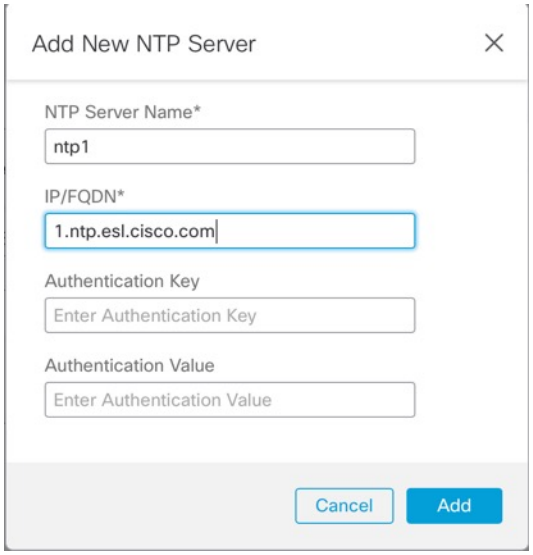
Figure 97: Time synchronization



Step 3 If you want to obtain the time from the Firewall Management Center, click **Via NTP from Management Center**.

This option ensures both the chassis and the Firewall Management Center have the same time.

Step 4 To use an external NTP server, click **Use Custom NTP Server**.



a) Click **Add** to add a server.

Figure 98: Add NTP server

b) Choose any already-defined servers from the drop-down menu and click **Add**, or click **New Server** to add a new server.

Figure 99: Add new NTP server

c) For a new server, enter the following fields, and click **Add**.

- **NTP Server Name**: A name to identify this server.
- **IP/FQDN**: The IP address or hostname of the server.
- **Authentication Key** and **Authentication Value**: Obtain the key ID and value from the NTP server. For example, to generate the SHA1 key on NTP server Version 4.2.8p8 or later with OpenSSL installed, enter the **NTP-keygen -M** command, and then view the key ID and value in the NTP.keys file. The key is used to tell both the client and server which value to use when computing the message digest.

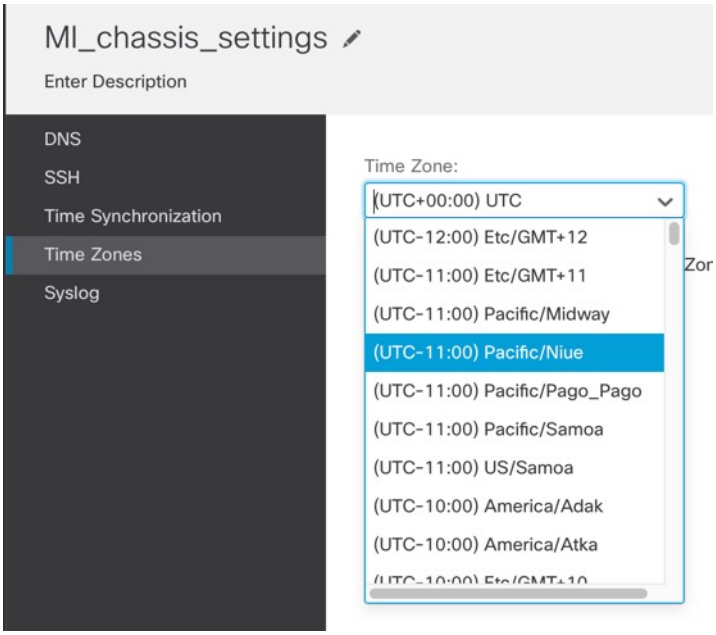
  Only SHA1 is supported for NTP server authentication.

Step 5 Click **Save** to save all policy changes.

Configure time zones

Time zone configuration is essential for maintaining accurate timestamps in system logs and ensuring proper time-based functionality across the device.

Before you begin



Follow these steps to configure the time zone for the chassis:

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **Time Zones**.

Figure 100: Time zones

Step 3 Choose your **Time Zone** from the drop-down menu.

Step 4 Click **Save** to save all policy changes.

Multi-instance mode management

This section describes less common tasks, including changing settings at the FXOS CLI or changing interfaces assigned to the chassis.

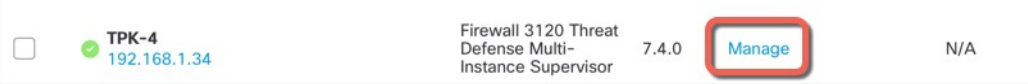
Change interfaces assigned to an instance

You can allocate or unallocate an interface on the instance. Adding a new interface, or deleting an unused interface, has minimal impact on the instance configuration. You can also edit the membership of an allocated EtherChannel without affecting the instance.

Deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the instance configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface.

Policies that refer to security zones are not affected.

Note For high availability, you need to make the same interface changes for the other unit. Otherwise, high availability might not operate correctly.



Before you begin

- Configure your interfaces according to Instance configuration, on page 175.
- If you plan to add an already-allocated interface to an EtherChannel, you need to unallocate the interface from the instance first, then add the interface to the EtherChannel. For a new EtherChannel, you can then allocate the EtherChannel to the instance.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

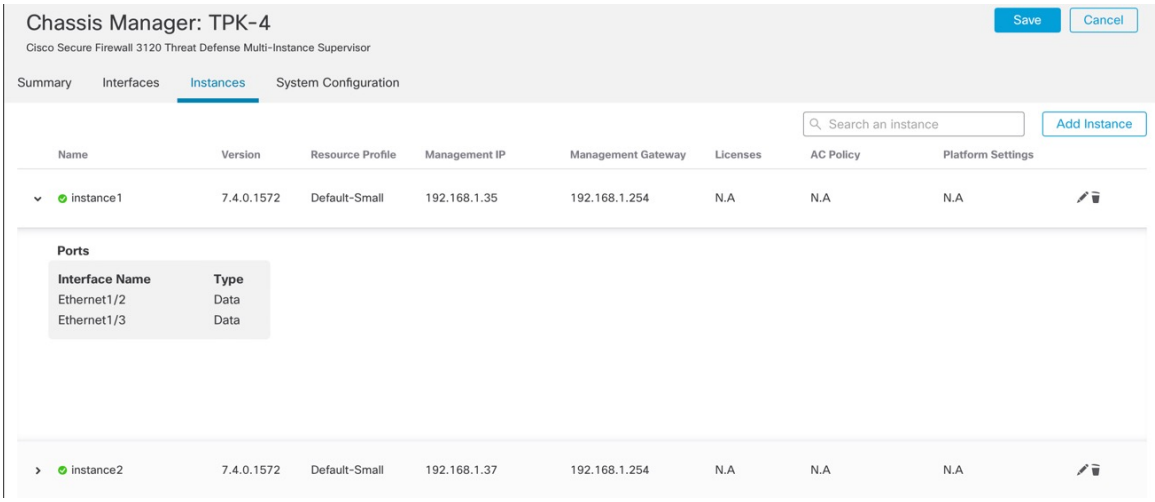


Figure 101: Manage Chassis

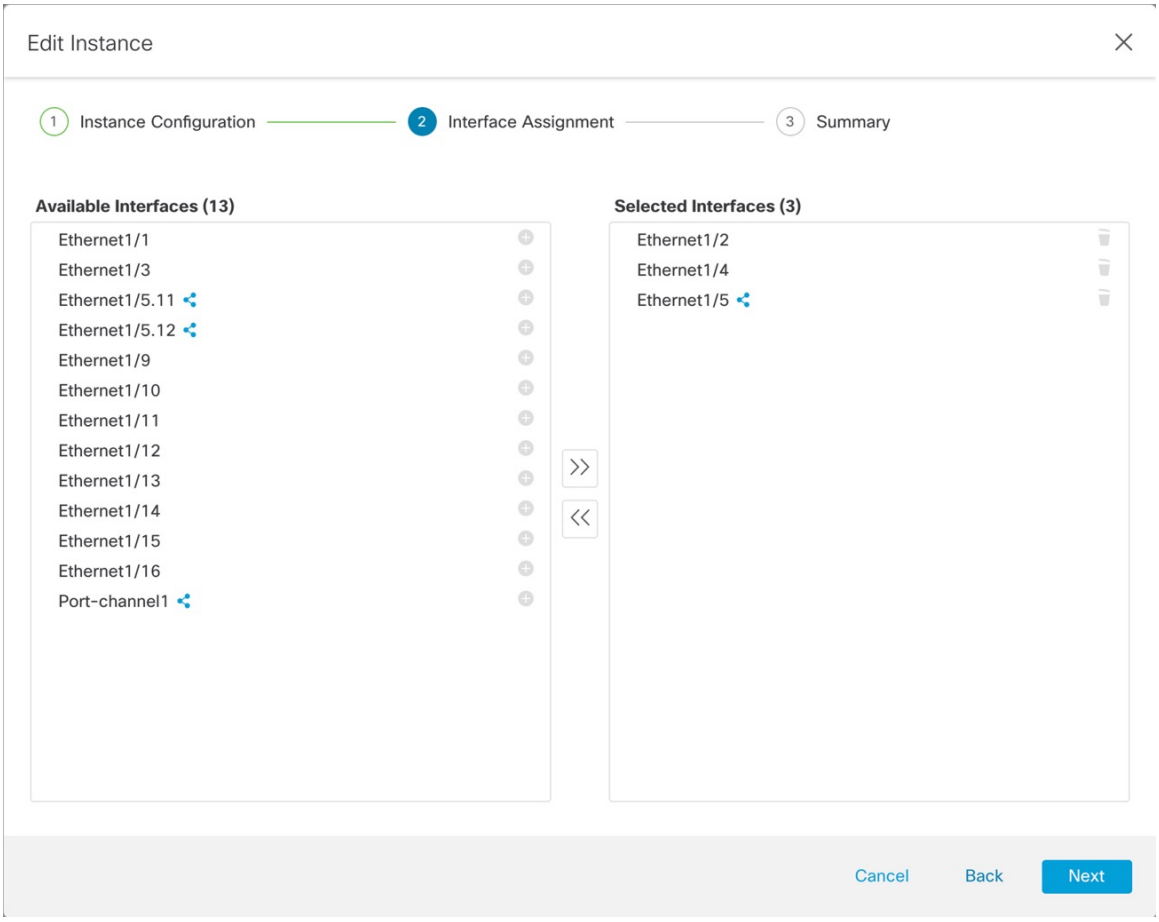
The **Chassis Manager** page opens for the chassis to the **Summary** page.



Step 2 Click **Instances**, and click **Edit** ( ) next to the instance for which you want to change interfaces.

Figure 102: Instances

Step 3 Click **Next** until you get to the **Interface Assignment** screen.

Figure 103: Interface assignment

Shared interfaces show the sharing icon ( ).

Step 4 Make your interface changes, and then click **Next**.

Step 5 Click **Save** on the **Summary** screen.

Step 6 For high availability, you need to make the same interface changes for the other unit. Otherwise, high availability might not operate correctly.

Change chassis management settings at the FXOS CLI

If you want to change the chassis management interface IP address and gateway, change the Firewall Management Center to a new manager, change the admin password, or disable multi-instance mode, you can do so from the FXOS CLI.

Procedure

Step 1 Connect to the chassis console port.

The console port connects to the FXOS CLI.

Note We recommend using the console port. You can also connect using SSH to the management interface, if configured in the chassis platform settings in the Firewall Management Center; however, if you change the management IP address, you will be disconnected.

Step 2 Log in with the username **admin** and the password you set during initial setup.

Step 3 Change the Management IP address. You can use a static IPv4 and/or IPv6 address.

IPv4:

scope fabric-interconnect

set out-of-band static IP *ip_address* **netmask** *network_mask* **gw** *gateway_ip_address*

IPv6:

scope fabric-interconnect

scope ipv6-config

set out-of-band static ipv6 *ipv6_address* **ipv6-prefix** *prefix_length* **ipv6-gw** *gateway_address*

Example:

IPv4:

```
firepower-3110# scope fabric-interconnect
firepower-3110 /fabric-interconnect # set out-of-band static ip 10.5.23.8 netmask
255.255.255.0
gw 10.5.23.1
```

IPv6:

```
firepower-3110# scope fabric-interconnect
firepower-3110 / fabric-interconnect # scope ipv6-config
firepower-3110 / fabric-interconnect /ipv6-config # set out-of-band static ipv6 2001:DB8::34
ipv6-prefix 64 ipv6-gw 2001:DB8::1
```

Step 4 Change the Firewall Management Center.

You should first unregister the chassis from the current Firewall Management Center.

enter device-manager *manager_name* [**hostname** {*hostname* | *ipv4_address* | *ipv6_address*}] [**NAT-ID** *nat_id*]

You are prompted for the registration key.

You can enter this command from any scope.

- **hostname** {*hostname* | *ipv4_address* | *ipv6_address*}: Specifies either the FQDN or IP address of the Firewall Management Center. At least one of the devices, either the Firewall Management Center or the chassis, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices. If you do not specify a **hostname**, then the chassis must have a reachable IP address or hostname and you must specify the **NAT-ID**.

- **NAT-ID** *nat_id*: Specifies a unique, one-time string of your choice that you will also specify on the Firewall Management Center when you register the chassis when one side does not specify a reachable IP address or hostname. It is required if you do not specify a **hostname**, however we recommend that you always set the NAT ID even when you specify a hostname or IP address. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the Firewall Management Center.
- **Registration Key:** *reg_key*: You will be prompted for a one-time registration key of your choice that you will also specify on the Firewall Management Center when you register the chassis. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).

Example:

```
firepower-3110# enter device-manager boulder_fmc hostname 10.89.5.35 nat-id 93002
(Valid registration key characters: [a-z],[A-Z],[0-9],[-]. Length: [2-36])
Registration Key: Impala67
```

Step 5 Change the admin password.

scope security

set password

Enter a password: *password*

Confirm the password: *password*

Example:

```
firepower-3110# scope security
firepower-3110 /security # set password
Enter new password: Sw@nsong67
Confirm new password: Sw@nsong67
firepower-3110 /security #
```

Step 6 Disable multi-instance mode and set the system back to appliance mode.

scope system

set deploymode native

You are prompted to reboot.

Example:

```
firepower-3110# scope system
firepower-3110 /system # set deploymode native
All configuration and bootable images will be lost and system will reboot.
If there was out of band upgrade, it might reboot with the base version and
need to re-image to get the expected running version.
Do you still want to change deploy mode? (yes/no):yes
firepower-3110 /system #
```

To change the mode back to multi-instance mode, enter **set deploymode container**. You can check the current mode using the **show system detail** command.

Multi-instance mode

This section helps you troubleshoot and diagnose your multi-instance mode chassis and instances.

Multi-instance setups

A multi-instance setup is a system configuration approach that

- enables running multiple independent instances on a single hardware platform,
- allows flexible allocation of resources to each instance, and
- supports both container and native (appliance) operating modes.

show system detail

This FXOS command shows the current mode, Native or Container. If the mode is Native (also known as appliance mode), you can convert to multi-instance (Container) mode. Note that the prompt/name in multi-instance mode is generic "firepower-<model>" while the prompt in appliance mode is the hostname you set for the Firewall Threat Defense (by default "firepower")

```
firepower # show system detail

Systems:
    Name: firepower
    Mode: Stand Alone
    System IP Address: 172.16.0.50
    System IPv6 Address: ::
    System Owner:
    System Site:
    Deploy Mode: Native
    Description for System:
firepower #
```

scope system > show

This FXOS command shows the current mode in a table format. Note that the prompt/name in multi-instance mode is generic "firepower-<model>" while the prompt in appliance mode is the hostname you set for the Firewall Threat Defense.

```
firepower-3110# scope system
firepower-3110 /system # show

Systems:
    Name       Mode        Deploy Mode System IP Address System IPv6 Address
    ---------- ----------- ----------- ----------------- -------------------
```

```
    firepower-3110
               Stand Alone Container   10.89.5.42        ::

3110-1# scope system
3110-1 /system # show

Systems:
    Name       Mode        Deploy Mode System IP Address System IPv6 Address
    ---------- ----------- ----------- ----------------- -------------------
    3110-1     Stand Alone Native      10.89.5.41        ::
3110-1 /system #
```

Instance interfaces

An instance interface is a physical or virtual network interface on a device that

- enables connectivity between multiple logical instances within a system,
- facilitates assignment of interfaces to one or more instances, and
- supports configuration of forwarding rules using ECMP and multicast groups.

show portmanager switch forward-rules hardware mac-filter

This command shows the internal switch-forwarding rule for two instances with a dedicated physical interface assigned to each instance. Ethernet 1/2 is assigned to ftd1 and Ethernet 1/1 is assigned to ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

```
secfw-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN    SRC_PORT    PC_ID    SRC_ID    DST_PORT      PKT_CNT       DMAC
1        0          17        0        17          19         29164  0:0:0:0:0:0
2        0          19        0        19          17         67588  0:0:0:0:0:0
3        0           1        0       101        1541             0  a2:5b:83:0:0:15
4        0           1        0       101        1541          8181  ff:ff:ff:ff:ff:ff
5        0           2        0       102        1540             0  a2:5b:83:0:0:18
6        0           2        0       102        1540           431  ff:ff:ff:ff:ff:ff
7        0          17        0         0           0         11133  0:0:0:0:0:0
8        0          17        0         0           0             0  0:0:0:0:0:0
```

This command shows the internal switch-forwarding rule for two instances with shared physical interfaces assigned to two instances. Ethernet 1/1 is shared between ftd1 and ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

MCAST group 4096 is used for replicating broadcast traffic between ftd1 and ftd2.

```
firepower-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN    SRC_PORT    PC_ID    SRC_ID    DST_PORT      PKT_CNT       DMAC
1        0          17        0        17          19          2268  0:0:0:0:0:0
2        0          19        0        19          17          4844  0:0:0:0:0:0
3        0           1        0       101        1541             0  a2:5b:83:0:0:9
4        0           1        0       101        4096           546  ff:ff:ff:ff:ff:ff
5        0           1        0       101        1540             0  a2:5b:83:0:0:c
6        0          17        0         0           0          1263  0:0:0:0:0:0
7        0          17        0         0           0             0  0:0:0:0:0:0
```

This command shows the internal switch-forwarding rule for two instances with shared subinterfaces assigned to both instances. Ethernet 1/1.2452 is shared between ftd1 and ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

MCAST group 4097 is used for replicating broadcast traffic between ftd1 and ftd2.

```
firepower-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN   SRC_PORT   PC_ID   SRC_ID   DST_PORT     PKT_CNT      DMAC
1        0         17       0       17         19       21305  0:0:0:0:0:0
2        0         19       0       19         17       50976  0:0:0:0:0:0
3     2452          1       0      101       1541         430  a2:5b:83:0:0:f
4     2452          1       0      101       4097           0  ff:ff:ff:ff:ff:ff
5     2452          1       0      101       1540           0  a2:5b:83:0:0:12
6        0         17       0        0          0       11038  0:0:0:0:0:0
7        0         17       0        0          0           0  0:0:0:0:0:0
```

show portmanager switch ecmp-groups detail

Use this command to list each Instance Ecmp-Vport-Physical port mapping detail.

Note Physical-Port 18 is the backplane uplink interface between the internal switch and the instance.

```
firepower-3140(local-mgmt)# show portmanager switch ecmp-groups detail
       ECMP-GROUP  VPORT      PHYSICAL-PORT
1      1536        256        18
2      1537        257        18
3      1538        258        18
4      1539        259        18
5      1540        260        18
6      1541        261        18
7      1542        262        18
8      1543        263        18
9      1544        264        18
10     1545        265        18
```

show portmanager switch mcast-groups detail

Use this command to list MCAST group membership details.

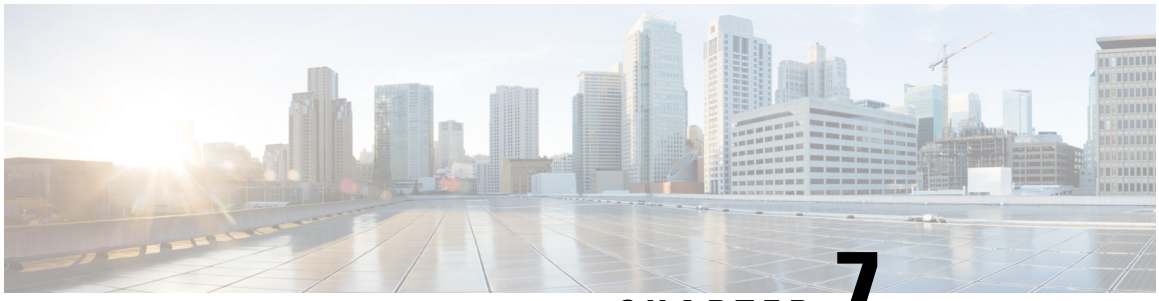
```
firepower-3140(local-mgmt)# show portmanager switch mcast-groups detail
       MCAST-GROUP
1      4096
       Member-ports
       Ethernet 1/1
       ECMP-ID 1541
       ECMP-ID 1540
```

show portmanager counters mcast-group

Use this command to check the MCAST group packet counter.

```
firepower-3140(local-mgmt)# show portmanager counters mcast-group 4096
PKT_CNT: 8106
```

show portmanager counters ecmp



Use this command to check the ECMP group packet counter.

```
firepower-3140(local-mgmt)# show portmanager counters ecmp 1541
PKT_CNT: 430
```

Multi-instance mode feature and version history

This reference documents the history of multi-instance mode capabilities, including instance limit increases, platform support expansions, and management interface improvements for Secure Firewall devices.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Multi-instance mode for the Secure Firewall 3100.	7.4.1	7.4.1	You can deploy the Secure Firewall 3100 as a single device (*appliance mode*) or as multiple container instances (*multi-instance mode*). In multi-instance mode, you can deploy multiple container instances on a single chassis that act as completely independent devices. Note that in multi-instance mode, you upgrade the operating system and the firmware (*chassis upgrade*) separately from the container instances (*Firewall Threat Defense upgrade*). New/modified screens: • **Devices** > **Device Management** > **Add** > **Chassis** • **Devices** > **Device Management** > **Device** > **Chassis Manager** • **Devices** > **Platform Settings** > **New Policy** > **Chassis Platform Settings** • **Devices** > **Chassis Upgrade** New/modified Firewall Threat Defense CLI commands: **configure multi-instance network ipv4**, **configure multi-instance network ipv6** New/modified FXOS CLI commands: **create device-manager**, **set deploymode** Platform restrictions: Not supported on the Secure Firewall 3105.

CHAPTER 7

Logical Devices on the Firepower 4100/9300

The Firepower 4100/9300 is a flexible security platform on which you can install one or more *logical devices*. Before you can add the Firewall Threat Defense to the Firewall Management Center, you must configure chassis interfaces, add a logical device, and assign interfaces to the device on the Firepower 4100/9300 chassis using the Secure Firewall Chassis Manager or the FXOS CLI. This chapter describes basic interface configuration and how to add a standalone or High Availability logical device using the Secure Firewall Chassis Manager. To use the FXOS CLI, see the FXOS CLI configuration guide. For more advanced FXOS procedures and troubleshooting, see the FXOS configuration guide.

- Supported interfaces, on page 223
- Logical devices, on page 238
- Licenses for container instances, on page 247
- Requirements and prerequisites for logical devices, on page 248
- Guidelines and limitations for logical devices, on page 255
- Configure interfaces, on page 259
- Configure logical devices, on page 264
- History for logical devices, on page 276

Supported interfaces

The Firepower 4100/9300 chassis supports physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces. EtherChannel interfaces can include up to 16 member interfaces of the same type.

Chassis management interface

A chassis management interface is a network interface that is used for management of the FXOS chassis by SSH or Firewall Chassis Manager.

The chassis management interface appears at the top of the **Interfaces** tab as **MGMT**. You can only enable or disable this interface on the **Interfaces** tab.

To configure parameters for this interface, you must configure them from the CLI. To view information about this interface in the FXOS CLI, connect to local management and show the management port:

Firepower # **connect local-MGMT**

Firepower(local-MGMT) # **show MGMT-port**

Note The chassis management interface does not support jumbo frames.

Interface types

Physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces are categorized into different types by their specific functions.

for different purposes.

These interface types are available, each defined by its specific function and configuration requirements:

- Data—Use for regular data. Data interfaces cannot be shared between logical devices, and logical devices cannot communicate over the backplane to other logical devices. For traffic on Data interfaces, all traffic must exit the chassis on one interface and return on another interface to reach another logical device.
- Data-sharing—Use for regular data. These data interfaces are supported only with container instances and can be shared by one or more logical devices or container instances (Firewall Threat Defense using Firewall Management Center only). Each container instance can communicate over the backplane with all other instances that share this interface. Shared interfaces can affect the number of container instances you can deploy. Shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode), inline sets, passive interfaces, clusters, or failover links.
- Mgmt—Use to manage application instances. These interfaces can be shared by one or more logical devices to access external hosts; logical devices cannot communicate over this interface with other logical devices that share the interface. You can only assign one management interface per logical device. Depending on your application and manager, you can later enable management from a data interface; but you must assign a management interface to the logical device even if you don't intend to use it after you enable data management. For information about the separate chassis management interface, see Chassis management interface, on page 223.

Note Changing the management interface will cause reboot of the logical device. For example, changing management interface from e1/1 to e1/2 causes the logical device to reboot so that the change can take effect.

- Eventing—Use as a secondary management interface for Firewall Threat Defense-using-Firewall Management Center devices. To use this interface, you must configure its IP address and other parameters at the Firewall Threat Defense CLI. For example, you can separate management traffic from events (such as web events). See the management center configuration guide for more information. Eventing interfaces can be shared by one or more logical devices to access external hosts; logical devices cannot communicate over this interface with other logical devices that share the interface. If you later configure a data interface for management, you cannot use a separate eventing interface.

Note A virtual Ethernet interface is allocated when each application instance is installed. If the application does not use an eventing interface, then the virtual interface will be in an admin down state.

```
Firepower # show interface Vethernet775
Firepower # Vethernet775 is down (Administratively down)
Bound Interface is Ethernet1/10
Port description is server 1/1, VNIC ext-mgmt-nic5
```

- Cluster—Use as the cluster control link for a clustered logical device. By default, the cluster control link is automatically created on Port-channel 48. The Cluster type is only supported on EtherChannel interfaces. For multi-instance clustering, you cannot share a Cluster-type interface across devices. You can add VLAN subinterfaces to the Cluster EtherChannel to provide separate cluster control links per cluster. If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster. The Firewall Device Manager and Security Cloud Control do not support clustering.

Note This chapter discusses FXOS VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense application. For more information, refer to FXOS interfaces and application interfaces, on page 226.

Interface type support for the Firewall Threat Defense and ASA applications in standalone and cluster deployments is shown in the table.

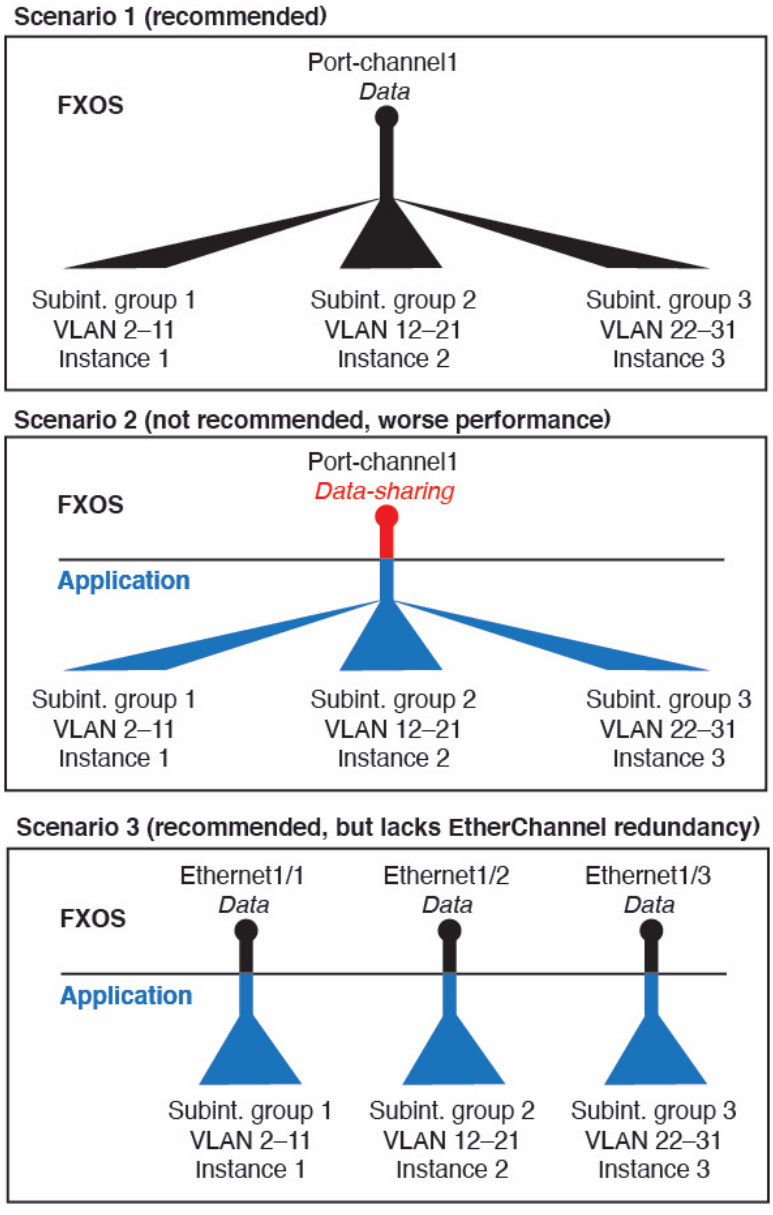
Table 14: Interface type support

Application		Data	Data: Subinterface	Data-Sharing	Data-Sharing: Subinterface	Mgmt	Eventing	Cluster (EtherChannel only)	Cluster: Subinterface
Firewall Threat Defense	Standalone Native Instance	Yes	—	—	—	Yes	Yes	—	—
	Standalone Container Instance	Yes	Yes	Yes	Yes	Yes	Yes	—	—
	Cluster Native Instance	Yes (EtherChannel only for inter-chassis cluster)	—	—	—	Yes	Yes	Yes	—
	Cluster Container Instance	Yes (EtherChannel only for inter-chassis cluster)	—	—	—	Yes	Yes	Yes	Yes
ASA	Standalone Native Instance	Yes	—	—	—	Yes	—	Yes	—
	Cluster Native Instance	Yes (EtherChannel only for inter-chassis cluster)	—	—	—	Yes	—	Yes	—

FXOS interfaces and application interfaces

The Firepower 4100/9300 manages the basic Ethernet settings of physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces. Within the application, you configure higher-level settings. For example, you can only create EtherChannels in FXOS, but you can assign an IP address to the EtherChannel within the application.

These sections describe the interaction between FXOS and the application for interfaces.



VLAN subinterfaces

For all logical devices, you can create VLAN subinterfaces within the application.

For container instances in standalone mode only, you can *also* create VLAN subinterfaces in FXOS. Multi-instance clusters do not support subinterfaces in FXOS except on the Cluster-type interface.

Application-defined subinterfaces are not subject to the FXOS limit. Choosing in which operating system to create subinterfaces depends on your network deployment and personal preference. For example, to share a subinterface, you must create the subinterface in FXOS. Another scenario that favors FXOS subinterfaces comprises allocating separate subinterface groups on a single interface to multiple instances. For example, you want to use Port-channel1 with VLAN 2–11 on instance A, VLAN 12–21 on instance B, and VLAN 22–31 on instance C. If you create these subinterfaces within the application, then you would have to share the parent interface in FXOS, which may not be desirable. See this illustration that shows the three ways you can accomplish this scenario:

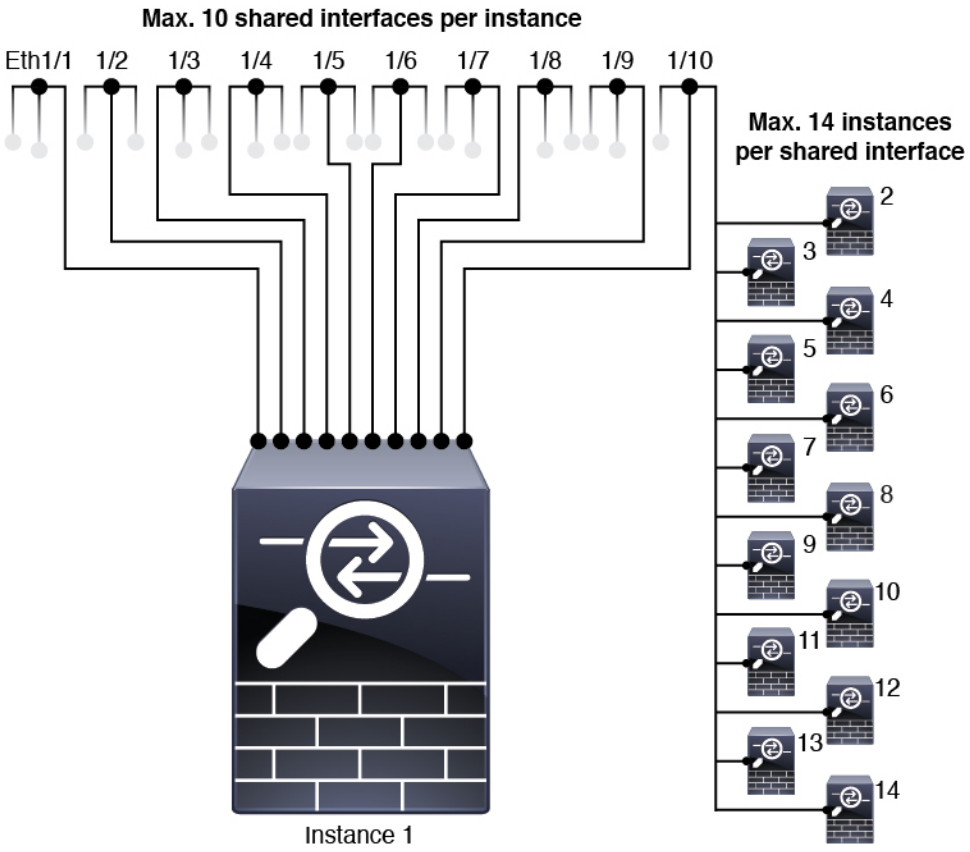
Figure 104: VLANs in FXOS vs. the application for container instances

Independent interface states in the chassis and in the application

You can administratively enable and disable interfaces in both the chassis and the application. For an interface to be operational, the interface must be enabled in both operating systems. Because the interface state is controlled independently, you may have a mismatch between the chassis and application.

The default state of an interface within the application depends on the type of interface. For example, the physical interface or EtherChannel is disabled by default within the application, but a subinterface is enabled by default.

Shared interface scalability



A shared interface is a network resource that

- allows multiple logical connections to transmit data concurrently,
- adapts bandwidth allocation based on real-time demand, and
- enhances scalability to support growing numbers of devices and traffic flows.

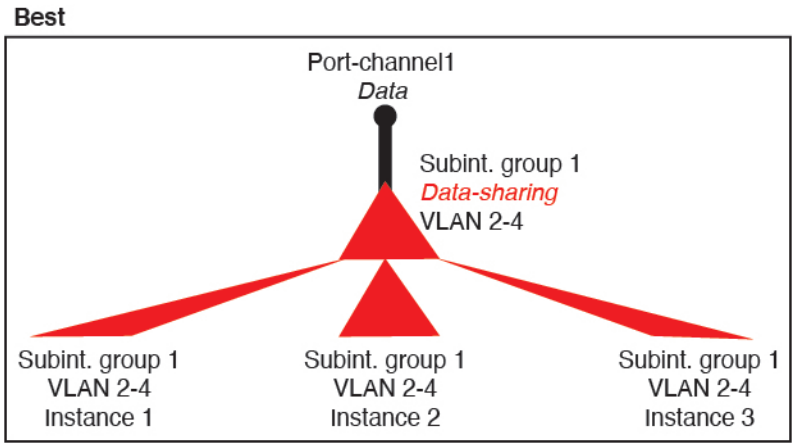
Instances can share data-sharing type interfaces. This capability lets you conserve physical interface usage as well as support flexible networking deployments. When you share an interface, the chassis uses unique MAC addresses to forward traffic to the correct instance. However, shared interfaces can cause the forwarding table to grow large due to the need for a full mesh topology within the chassis (every instance must be able to communicate with every other instance that is sharing the same interface). Therefore, there are limits to how many interfaces you can share.

In addition to the forwarding table, the chassis maintains a VLAN group table for VLAN subinterface forwarding. You can create up to 500 VLAN subinterfaces.

See the following limits for shared interface allocation:

Shared interface best practices

This topic outlines the best practices to follow when configuring shared interfaces to maximize performance and security.



For optimal scalability of the forwarding table, share as few interfaces as possible. Instead, you can create up to 500 VLAN subinterfaces on one or more physical interfaces and then divide the VLANs among the container instances.

When sharing interfaces, follow these practices in the order of most scalable to least scalable:

1. Best: Share subinterfaces under a single parent, and use the same set of subinterfaces with the same group of instances.

   For example, create a large EtherChannel to bundle all of your like-kind interfaces together, and then share subinterfaces of that EtherChannel: Port-Channel1.2, 3, and 4 instead of Port-Channel2, Port-Channel3, and Port-Channel4. When you share subinterfaces from a single parent, the VLAN group table provides better scaling of the forwarding table than when sharing physical/EtherChannel interfaces or subinterfaces across parents.

Figure 105: Best: Shared Subinterface Group on One Parent

If you do not share the same set of subinterfaces with a group of instances, your configuration can cause more resource usage (more VLAN groups). For example, share Port-Channel1.2, 3, and 4 with instances 1, 2, and 3 (one VLAN group) instead of sharing Port-Channel1.2 and 3 with instances 1 and 2, while sharing Port-Channel1.3 and 4 with instance 3 (two VLAN groups).

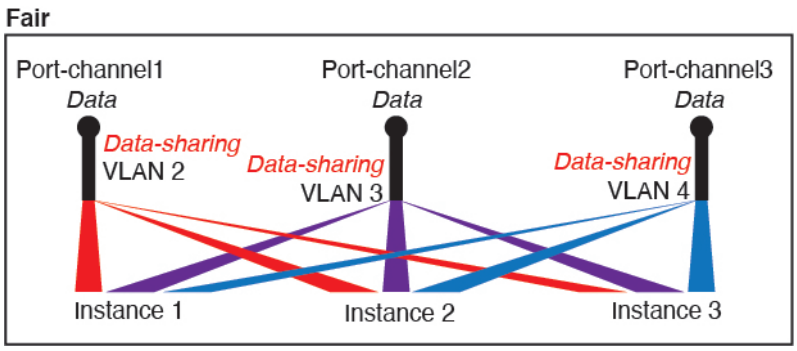


Figure 106: Good: Sharing Multiple Subinterface Groups on One Parent

2. Fair: Share subinterfaces across parents.

   For example, share Port-Channel1.2, Port-Channel2.3, and Port-Channel3.4 instead of Port-Channel2, Port-Channel4, and Port-Channel4. Although this usage is not as efficient as only sharing subinterfaces on the same parent, it still takes advantage of VLAN groups.

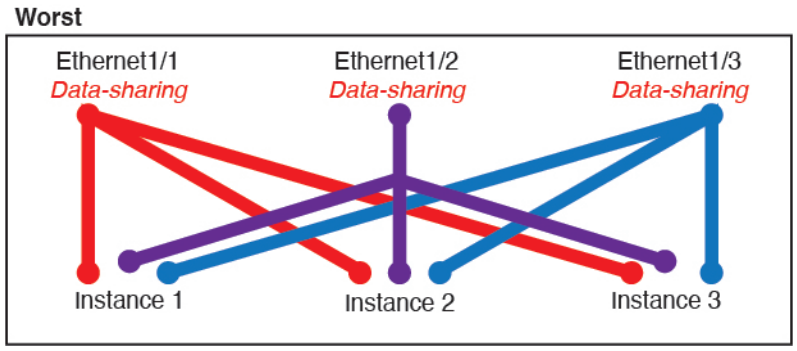

Figure 107: Fair: Shared Subinterfaces on Separate Parents

3. Worst: Share individual parent interfaces (physical or EtherChannel).

   This method uses the most forwarding table entries.

Figure 108: Worst: Shared Parent Interfaces

Shared Interface Usage Examples

See the following tables for examples of interface sharing and scalability. The below scenarios assume use of one physical/EtherChannel interface for management shared across all instances, and another physical or EtherChannel interface with dedicated subinterfaces for use with High Availability.

- Table 15: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with Three SM-44s, on page 232
- Table 16: Subinterfaces on One Parent and Instances on a Firepower 9300 with Three SM-44s, on page 233
- Table 17: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with One SM-44, on page 235
- Table 18: Subinterfaces on One Parent and Instances on a Firepower 9300 with One SM-44, on page 236

Firepower 9300 with Three SM-44s

The following table applies to three SM-44 security modules on a 9300 using only physical interfaces or EtherChannels. Without subinterfaces, the maximum number of interfaces are limited. Moreover, sharing multiple physical interfaces uses more forwarding table resources than sharing multiple subinterfaces.

Each SM-44 module can support up to 14 instances. Instances are split between modules as necessary to stay within limits.

Table 15: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with Three SM-44s

Dedicated Interfaces	Shared Interfaces	Number of Instances	% Forwarding Table Used
32: • 8 • 8 • 8 • 8	**0**	**4:** • Instance 1 • Instance 2 • Instance 3 • Instance 4	16%

View shared interface resources

To view forwarding table and VLAN group usage, see the **Devices & Network** > **Interface Forwarding Utilization** area.

For example:

Inline set link state propagation for the Firewall Threat Defense

Inline set link state propagation is a network feature that automatically synchronizes the link state between two paired interfaces in an inline set.

An inline set acts like a bump on the wire and binds two interfaces together to slot into an existing network. This function allows the system to be installed in any network environment without the configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally, but all traffic received on these interfaces is retransmitted out of an inline set unless explicitly dropped.

When you configure an inline set in the Firewall Threat Defense application and enable link state propagation, the Firewall Threat Defense sends inline set membership to the FXOS chassis. Link state propagation means that the chassis automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up, also. In other words, if the link state of one interface changes, the chassis senses the change and updates the link state of the other interface to match it. Note that the chassis requires up to 4 seconds to propagate link state changes. Link state propagation is especially useful in resilient network environments where routers are configured to reroute traffic automatically around network devices that are in a failure state.

Note Do not enable Hardware Bypass and link state propagation for the same inline set.

Logical devices

A logical device is a virtualization construct that lets you run one application instance (either ASA or Firewall Threat Defense) and also one optional decorator application (Radware DefensePro) to form a service chain.

When you add a logical device, you also define the application instance type and version, assign interfaces, and configure bootstrap settings that are pushed to the application configuration.

Note For the Firepower 9300, you can install different application types (ASA and Firewall Threat Defense) on separate modules in the chassis. You can also run different versions of an application instance type on separate modules.

Standalone and clustered logical devices

You can add these logical device types:

- Standalone—A standalone logical device operates as a standalone unit or as a unit in a High Availability pair.
- Cluster—A clustered logical device lets you group multiple units together, providing all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. Multiple module devices, like the Firepower 9300, support intra-chassis clustering. For the Firepower 9300, all three modules must participate in the cluster, for both native and container instances. The Firewall Device Manager does not support clustering.

Logical device application instances

Application instances run in the following deployment types:

- Native instance—A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance.
- Container instance—A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances. Multi-instance capability is only supported for the Firewall Threat Defense using Firewall Management Center; it is not supported for the ASA or the Firewall Threat Defense using Firewall Device Manager.

Note Multi-instance capability is similar to ASA multiple context mode, although the implementation is different. Multiple context mode partitions a single application instance, while multi-instance capability allows independent container instances. Container instances allow hard resource separation, separate configuration management, separate reloads, separate software updates, and full Firewall Threat Defense feature support. Multiple context mode, due to shared resources, supports more contexts on a given platform. Multiple context mode is not available on the Firewall Threat Defense.

For the Firepower 9300, you can use a native instance on some modules and container instances on the other modules.

Container instance interfaces

To provide flexible physical interface use for container instances, you can create VLAN subinterfaces in FXOS and also share interfaces (VLAN or physical) between multiple instances. Native instances cannot use VLAN subinterfaces or shared interfaces. A multi-instance cluster cannot use VLAN subinterfaces or shared

interfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel. For more information, refer to Shared interface scalability, on page 163 and Add a VLAN subinterface for container instances, on page 263.

Note This document discusses FXOS VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense application. For more information, refer to FXOS interfaces and application interfaces, on page 226.

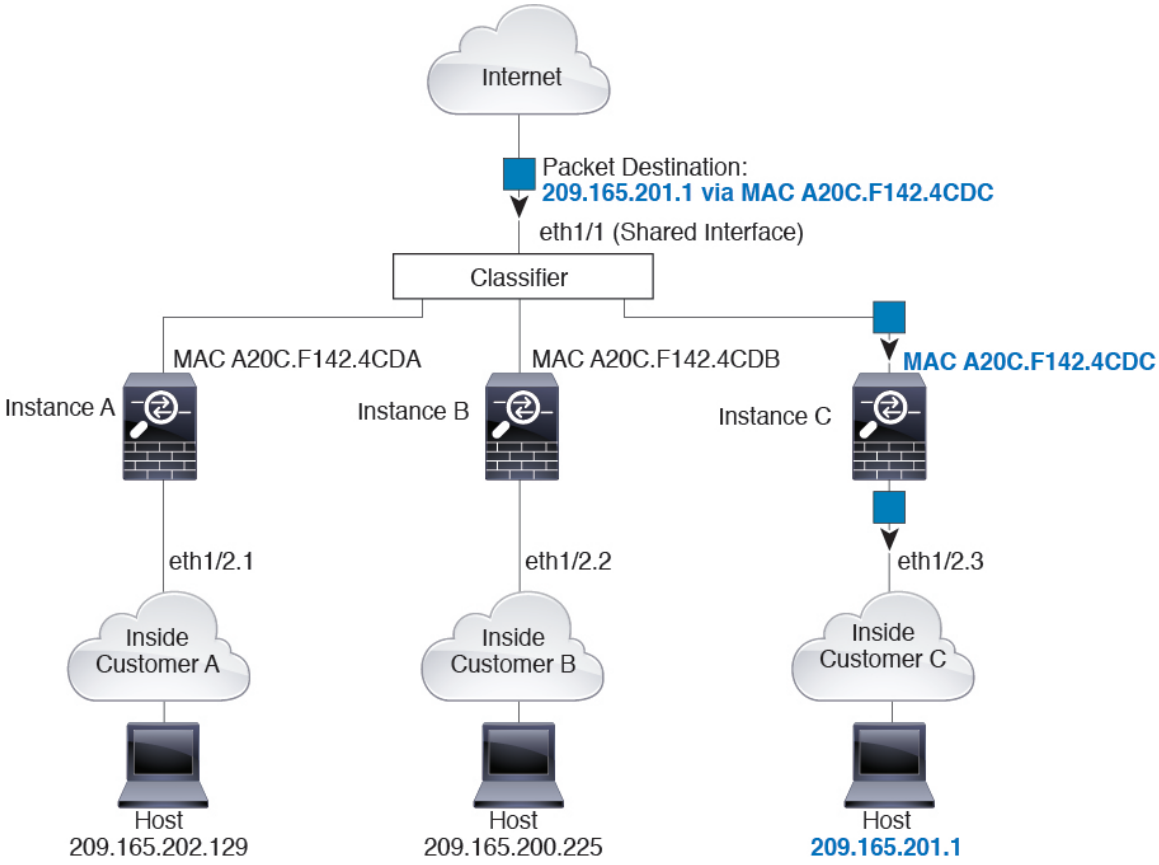
How the chassis classifies packets

The chassis processes incoming and outgoing packets as they pass through a device, ensuring that each packet is handled according to its type, destination, and security requirements.

Each packet that enters the chassis must be classified so that the chassis can determine to which instance to send a packet.

- Unique Interfaces: If only one instance is associated with the ingress interface, the chassis classifies the packet into that instance. For bridge group member interfaces (in transparent mode or routed mode), inline sets, or passive interfaces, this method is used to classify packets at all times.
- Unique MAC Addresses: The chassis automatically generates unique MAC addresses for all interfaces, including shared interfaces. If multiple instances share an interface, then the classifier uses unique MAC addresses assigned to the interface in each instance. An upstream router cannot route directly to an instance without unique MAC addresses. You can also set the MAC addresses manually when you configure each interface within the application.

Note If the destination MAC address is a multicast or broadcast MAC address, the packet is duplicated and delivered to each instance.



Classification examples

These examples demonstrate how packet classification works in various network configurations and firewall deployment scenarios.

Packet classification with a shared interface using MAC addresses

This figure shows multiple instances sharing an outside interface. The classifier assigns the packet to Instance C because Instance C includes the MAC address to which the router sends the packet.

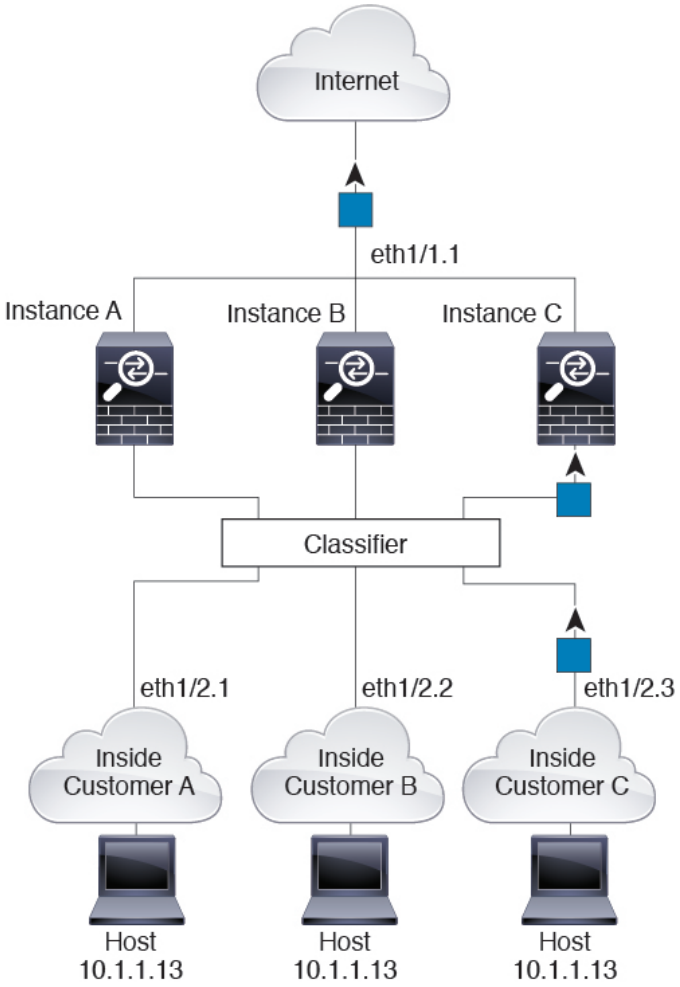


Figure 109: Packet classification with a shared interface using MAC addresses

Incoming traffic from inside networks

Note that all new incoming traffic must be classified, even from inside networks. This figure shows a host on the Instance C inside network accessing the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

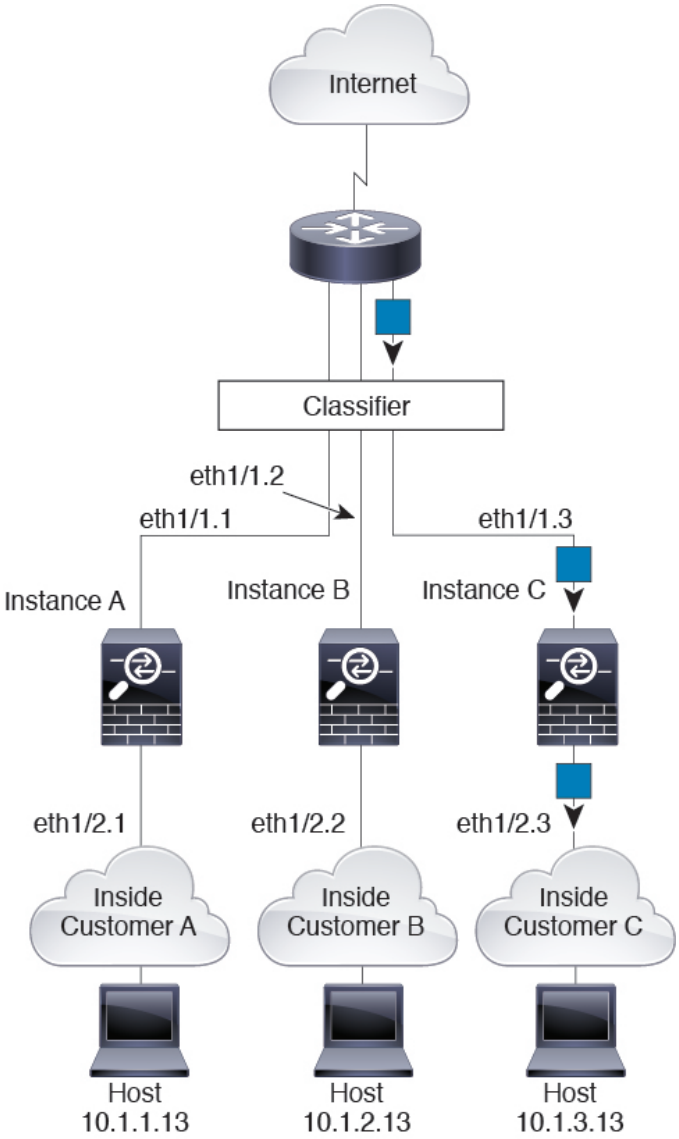

Figure 110: Incoming traffic from inside networks

Transparent firewall instances

For transparent firewalls, you must use unique interfaces. This figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

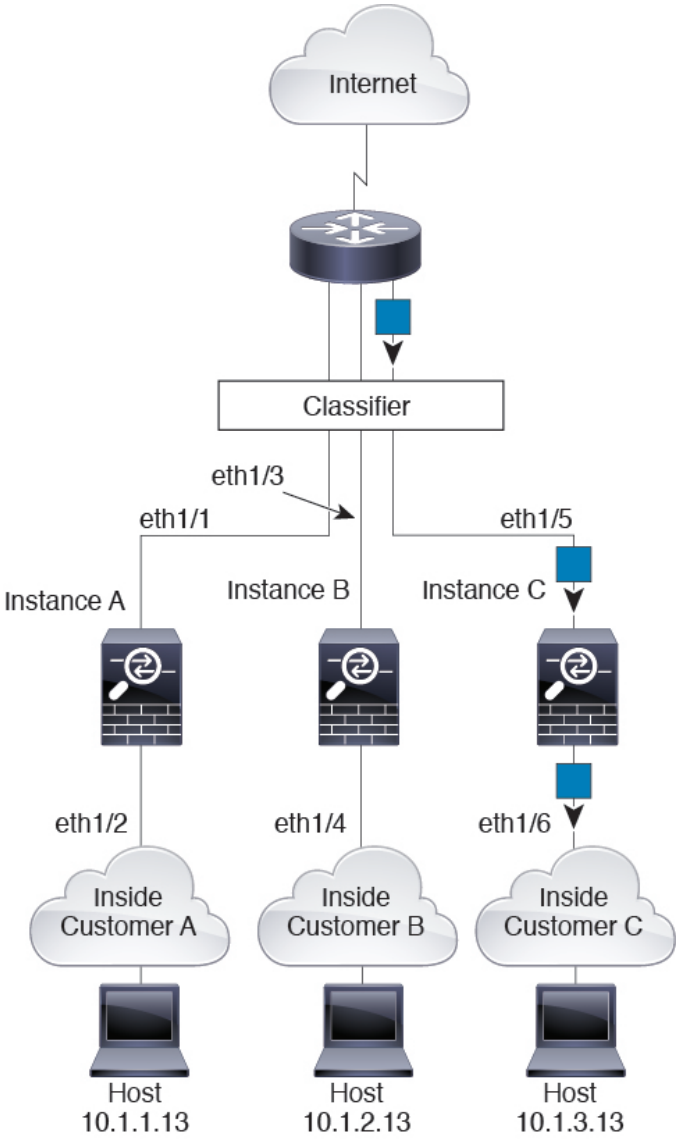

Figure 111: Transparent firewall instances

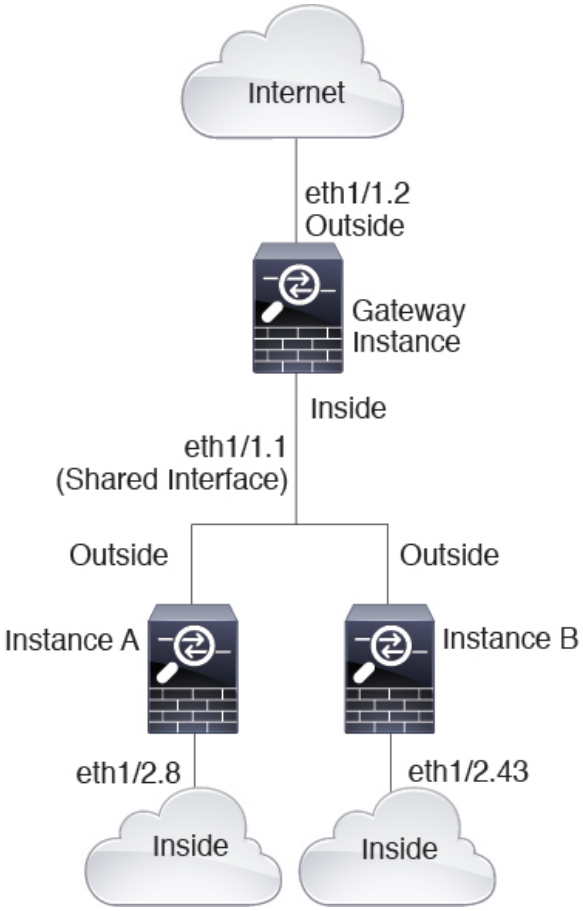
Inline sets

For inline sets, you must use unique interfaces and they must be physical interfaces or EtherChannels. This figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/5, which is assigned to Instance C.

Figure 112: Inline sets



Cascading container instances

Cascading instances connect one instance's outside interface to another's inside interface, simplifying configuration by sharing parameters in the top instance. Avoid using shared interfaces with High Availability to prevent MAC address conflicts; use unique interfaces and an external switch instead.

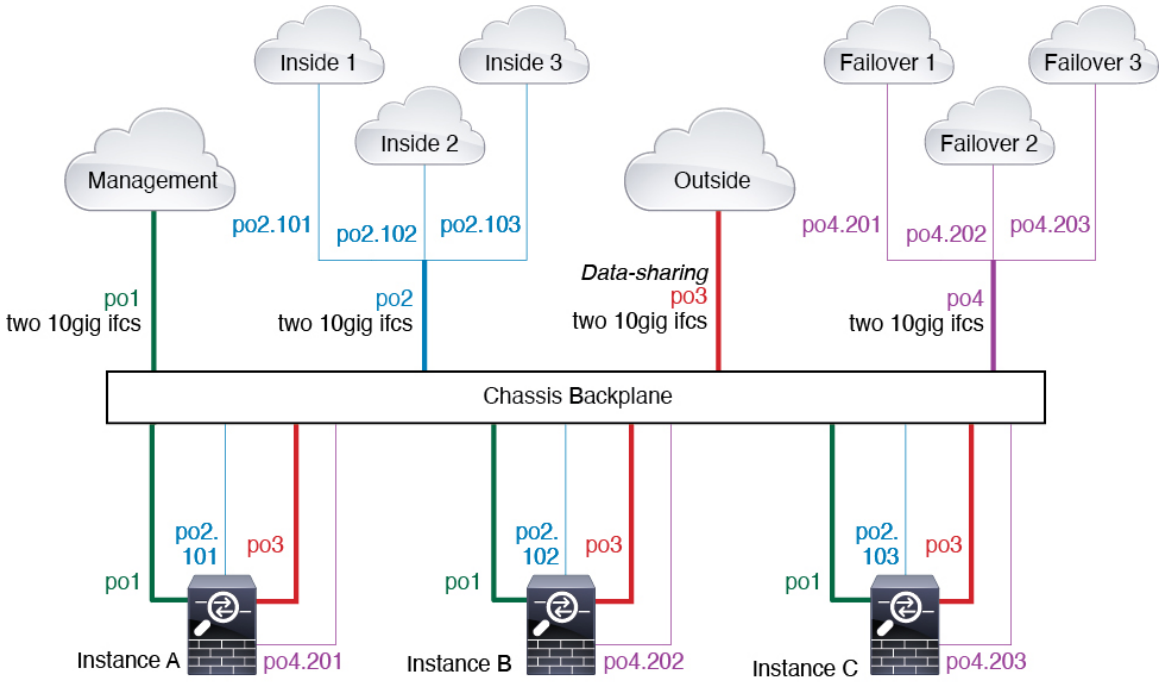
Placing an instance directly in front of another instance is called *cascading instances*; the outside interface of one instance is the same interface as the inside interface of another instance. You might want to cascade instances if you want to simplify the configuration of some instances by configuring shared parameters in the top instance.

The following figure shows a gateway instance with two instances behind the gateway.

Figure 113: Cascading Instances

Note Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.

Typical multi-instance deployment



This example includes three container instances in routed firewall mode and their interface configurations.

The container instance include these interfaces:

- Management—All instances use the Port-Channel1 interface (management type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same management network.
- Inside—Each instance uses a subinterface on Port-Channel2 (data type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Each subinterface is on a separate network.

- Outside—All instances use the Port-Channel3 interface (data-sharing type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same outside network.
- Failover—Each instance uses a subinterface on Port-Channel4 (data type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Each subinterface is on a separate network.

Figure 114: Typical Multi-Instance deployment

Automatic MAC Addresses for Container Instance Interfaces

The chassis automatically generates MAC addresses for instance interfaces, and guarantees that a shared interface in each instance uses a unique MAC address.

If you manually assign a MAC address to a shared interface within the instance, then the manually-assigned MAC address is used. If you later remove the manual MAC address, the autogenerated address is used. In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, we suggest that you manually set the MAC address for the interface within the instance.

Because autogenerated addresses start with A2, you should not start manual MAC addresses with A2 due to the risk of overlapping addresses.

The chassis generates the MAC address using the following format:

A2*xx.yyzz.zzzz*

Where *xx.yy* is a user-defined prefix or a system-defined prefix, and *zz.zzzz* is an internal counter generated by the chassis. The system-defined prefix matches the lower 2 bytes of the first MAC address in the burned-in MAC address pool that is programmed into the IDPROM. Use **connect fxos**, then **show module** to view the MAC address pool. For example, if the range of MAC addresses shown for module 1 is b0aa.772f.f0b0 to b0aa.772f.f0bf, then the system prefix will be f0b0.

The user-defined prefix is an integer that is converted into hexadecimal. For an example of how the user-defined prefix is used, if you set a prefix of 77, then the chassis converts 77 into the hexadecimal value 004D (*yyxx*). When used in the MAC address, the prefix is reversed (*xxyy*) to match the chassis native form:

A2**4D.00***zz.zzzz*

For a prefix of 1009 (03F1), the MAC address is:

A2**F1.03***zz.zzzz*

Container instance resource management

To specify resource usage per container instance, create one or more resource profiles in FXOS. When you deploy the logical device or application instance, you specify the resource profile that you want to use. The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance. To view the available resources per model, refer to Requirements and prerequisites for container instances, on page 250. To add a resource profile, refer to Add a resource profile for container instances , on page 264.

Performance scaling factor for multi-instance capability

The maximum throughput (connections, VPN sessions, and TLS proxy sessions) for a platform is calculated for a native instance's use of memory and CPU (and this value is shown in **show resource usage**). If you use multiple instances, then you need to calculate the throughput based on the percentage of CPU cores that you assign to the instance. For example, if you use a container instance with 50% of the cores, then you should initially calculate 50% of the throughput. Moreover, the throughput available to a container instance may be less than that available to a native instance.

For detailed instructions on calculating the throughput for instances, refer to Firepower NGFW Multi-Instance Performance on 4100 and 9300 Series Appliances.

Container instances and high availability

You can configure high availability using a container instance on 2 separate chassis. For example, if you have 2 chassis, each with 10 instances, you can create 10 high availability pairs. Note that high availability is not configured in FXOS; configure each high availability pair in the application manager.

For detailed requirements, refer to Requirements and prerequisites for high availability configuration, on page 251 and Add a high availability pair, on page 271.

Container instances and clustering

You can create a cluster of container instances using one container instance per security module/engine. For details, see Requirements and prerequisites for clustering, on page 251.

Licenses for container instances

All licenses are consumed per security engine/chassis (for the Firepower 4100) or per security module (for the Firepower 9300), and not per container instance. See the details:

- Essentials licenses are automatically assigned: one per security module/engine.
- Feature licenses are manually assigned to each instance; but you only consume one license per feature per security module/engine. For example, for the Firepower 9300 with 3 security modules, you only need

one URL Filtering license per module for a total of 3 licenses, regardless of the number of instances in use.

For example:

Table 19: Sample license usage for container instances on a Firepower 9300

Firepower 9300	Instance	Licenses
Security Module 1	Instance 1	Essentials, URL Filtering, Malware Defense
	Instance 2	Essentials, URL Filtering
	Instance 3	Essentials, URL Filtering
Security Module 2	Instance 4	Essentials, IPS
	Instance 5	Essentials, URL Filtering, Malware Defense, IPS
Security Module 3	Instance 6	Essentials, Malware Defense, IPS
	Instance 7	Essentials, IPS

Table 20: Total number of licenses

Essentials	URL Filtering	Malware Defense	IPS
3	2	3	2

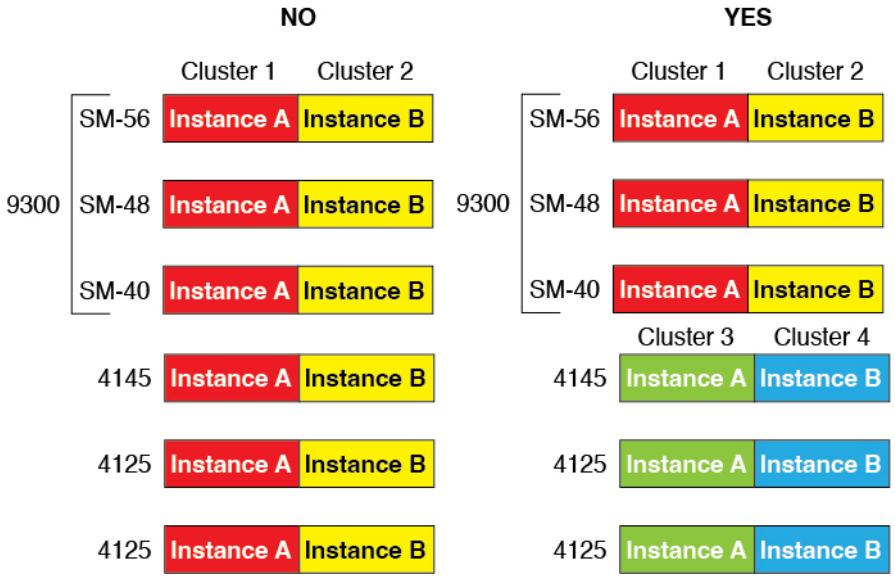
Requirements and prerequisites for logical devices

See the following sections for requirements and prerequisites.

Requirements and prerequisites for hardware and software combinations

Review these baseline requirements and prerequisites for FXOS hardware and software combinations.

The Firepower 4100/9300 supports multiple models, security modules, application types, and high availability and scalability features. See the following requirements for allowed combinations.



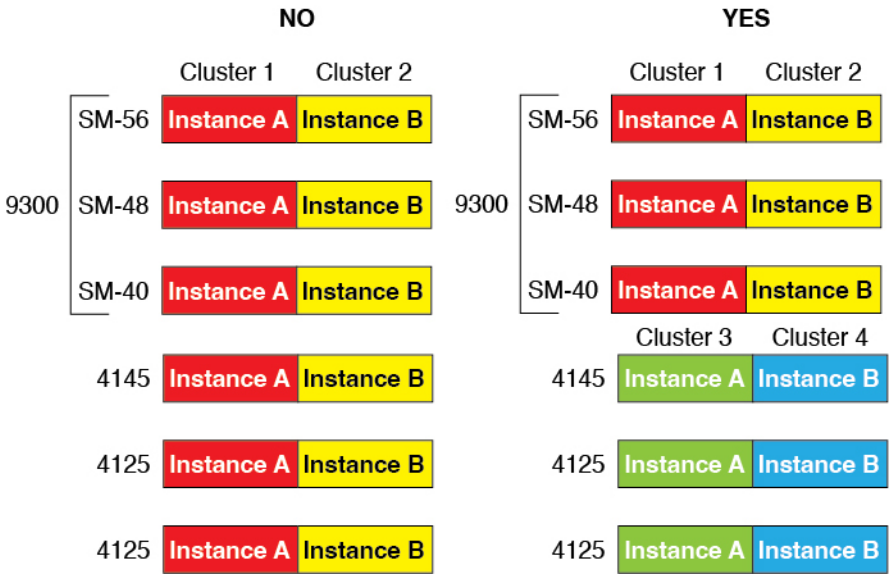
Firepower 9300 Requirements

The Firepower 9300 includes 3 security module slots and multiple types of security modules. See these requirements:

- Security Module Types—You can install modules of different types in the Firepower 9300. For example, you can install the SM-48 as module 1, SM-40 as module 2, and SM-56 as module 3.
- Native instance Clustering—All security modules in the cluster, whether it is intra-chassis or inter-chassis, must be the same type. You can have different quantities of installed security modules in each chassis,

although all modules present in the chassis must belong to the cluster including any empty slots. For example, you can install 2 SM-40s in chassis 1, and 3 SM-40s in chassis 2. You cannot use clustering if you install 1 SM-48 and 2 SM-40s in the same chassis.

- Container instance Clustering—You can create a cluster using instances on different model types. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. You *cannot* mix the Firepower 9300 and the Firepower 4100 in the same cluster, however.



- High Availability—High Availability is only supported between same-type modules on the Firepower 9300. However, the two chassis can include mixed modules. For example, each chassis has an SM-40, SM-48, and SM-56. You can create High Availability pairs between the SM-40 modules, between the SM-48 modules, and between the SM-56 modules.
- ASA and Firewall Threat Defense application types—You can install different application types on separate modules in the chassis. For example, you can install ASA on module 1 and module 2, and Firewall Threat Defense on module 3.
- ASA or Firewall Threat Defense versions—You can run different versions of an application instance type on separate modules, or as separate container instances on the same module. For example, you can install the Firewall Threat Defense 6.3 on module 1, Firewall Threat Defense 6.4 on module 2, and Firewall Threat Defense 6.5 on module 3.

Firepower 4100 requirements

The Firepower 4100 comes in multiple models. See these requirements:

- Native and Container instances—When you install a container instance on a Firepower 4100, that device can only support other container instances. A native instance uses all of the resources for a device, so you can only install a single native instance on the device.
- Native instance Clustering—All chassis in the cluster must be the same model.
- Container instance Clustering—You can create a cluster using instances on different model types. For example, you can create a cluster using an instance on a Firepower 4145 and a 4125. You *cannot* mix the Firepower 9300 and the Firepower 4100 in the same cluster, however.

- High Availability—High Availability is only supported between same-type models.
- ASA and Firewall Threat Defense application types—The Firepower 4100 can only run a single application type.
- The Firewall Threat Defense container instance versions—You can run different versions of Firewall Threat Defense as separate container instances on the same module.

Requirements and prerequisites for container instances

For information about high-availability or clustering requirements with multi-instance, see Requirements and prerequisites for high availability configuration, on page 251 and see Requirements and prerequisites for clustering, on page 251.

Supported application types

The Firewall Threat Defense using Firewall Management Center

Maximum container instances and resources per model

For each container instance, you can specify the number of CPU cores to assign to the instance. RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

Table 21: Maximum container instances and resources per model

Model	Max. Container Instances	Available CPU Cores	Available RAM	Available Disk Space
Firepower 4112	3	22	78 GB	308 GB
Firepower 4115	7	46	162 GB	308 GB
Firepower 4125	10	62	162 GB	644 GB

Model	Max. Container Instances	Available CPU Cores	Available RAM	Available Disk Space
Firepower 4140	7	70	222 GB	311.8 GB
Firepower 4145	14	86	344 GB	608 GB
Firepower 9300 SM-40 security module	13	78	334 GB	1359 GB
Firepower 9300 SM-48 security module	15	94	334 GB	1341 GB
Firepower 9300 SM-56 security module	18	110	334 GB	1314 GB

Firewall Management Center Requirements

For all instances on a Firepower 4100 chassis or Firepower 9300 module, you must use the same Firewall Management Center due to the licensing implementation.

Requirements and prerequisites for high availability configuration

The two units in a high availability configuration must meet these requirements:

- Be on a separate chassis; intra-chassis High Availability for the Firepower 9300 is not supported.
- Be the same model.
- Have the same interfaces assigned to the High Availability logical devices.
- Have the same number and types of interfaces. All interfaces must be preconfigured in FXOS identically before you enable High Availability.

High availability is only supported between same-type modules on the Firepower 9300; but the two chassis can include mixed modules. For example, each chassis has an SM-56, SM-48, and SM-40. You can create High Availability pairs between the SM-56 modules, between the SM-48 modules, and between the SM-40 modules.

For container instances, each unit must use the same resource profile attributes.

For container instances: Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.

For other high availability system requirements, see High availability system requirements, on page 284.

Requirements and prerequisites for clustering

This topic provides the necessary prerequisites and hardware support details for configuring clustering on supported security appliances.

Cluster model support

The Firewall Threat Defense supports clustering on the following models:

- Firepower 9300— You can include up to 16 nodes in the cluster. For example, you can use 1 module in 16 chassis, or 2 modules in 8 chassis, or any combination that provides a maximum of 16 modules. Supports clustering with multiple chassis and clustering isolated to security modules within one chassis.
- Firepower 4100—Supported for up to 16 nodes using clustering with multiple chassis.

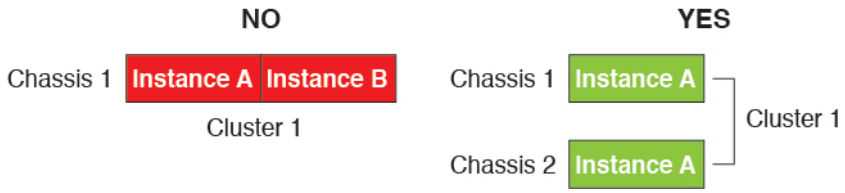
User roles

The following user roles are required to manage clustering configurations:

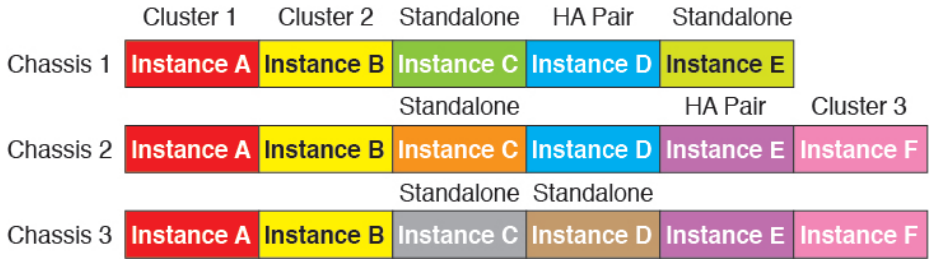
- Admin
- Access Admin
- Network Admin

Clustering hardware and software requirements

All chassis in a cluster:



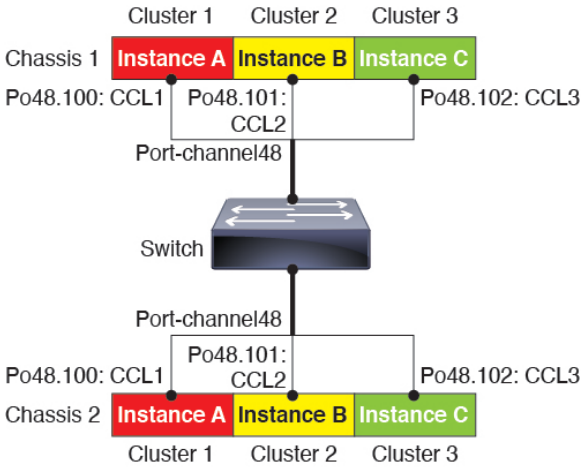
- Native instance clustering—For the Firepower 4100: All chassis must be the same model. For the Firepower 9300: All security modules must be the same type. For example, if you use clustering, all modules in the Firepower 9300 must be SM-40s. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots.
- Container instance clustering—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.



- Must run the identical FXOS and application software except at the time of an image upgrade. Mismatched software versions can lead to poor performance, so be sure to upgrade all nodes in the same maintenance window.
- Must include the same interface configuration for interfaces you assign to the cluster, such as the same Management interface, EtherChannels, active interfaces, speed and duplex, and so on. You can use different network module types on the chassis as long as the capacity matches for the same interface IDs and interfaces can successfully bundle in the same spanned EtherChannel. Note that all data interfaces must be EtherChannels in clusters with multiple chassis. If you change the interfaces in FXOS after you enable clustering (by adding or removing interface modules, or configuring EtherChannels, for example), then perform the same changes on each chassis, starting with the data nodes, and ending with the control node.
- Must use the same NTP server. For Firewall Threat Defense, the Firewall Management Center must also use the same NTP server. Do not set the time manually.

Multi-instance clustering requirements

- No intra-security-module/engine clustering—For a given cluster, you can only use a single container instance per security module/engine. You cannot add 2 container instances to the same cluster if they are running on the same module.



- Mix and match clusters and standalone instances—Not all container instances on a security module/engine need to belong to a cluster. You can use some instances as standalone or High Availability nodes. You can also create multiple clusters using separate instances on the same security module/engine.

- All 3 modules in a Firepower 9300 must belong to the cluster—For the Firepower 9300, a cluster requires a single container instance on all 3 modules. You cannot create a cluster using instances on module 1 and 2, and then use a native instance on module 3, or example.

- Match resource profiles—We recommend that each node in the cluster use the same resource profile attributes; however, mismatched resources are allowed when changing cluster nodes to a different resource profile, or when using different models.
- Dedicated cluster control link—For clusters with multiple chassis, each cluster needs a dedicated cluster control link. For example, each cluster can use a separate subinterface on the same cluster-type EtherChannel, or use separate EtherChannels.

- No shared interfaces—Shared-type interfaces are not supported with clustering. However, the same Management and Eventing interfaces can used by multiple clusters.
- No subinterfaces—A multi-instance cluster cannot use FXOS-defined VLAN subinterfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel.
- Mix chassis models—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

- Maximum 6 nodes—You can use up to six container instances in a cluster.

Switch requirements

- Be sure to complete the switch configuration and successfully connect all the EtherChannels from the chassis to the switch(es) before you configure clustering on the Firepower 4100/9300 chassis.
- For supported switch characteristics, see Cisco FXOS Compatibility.

Guidelines and limitations for logical devices

This section provides guidelines and limitations for configuring and managing logical devices.

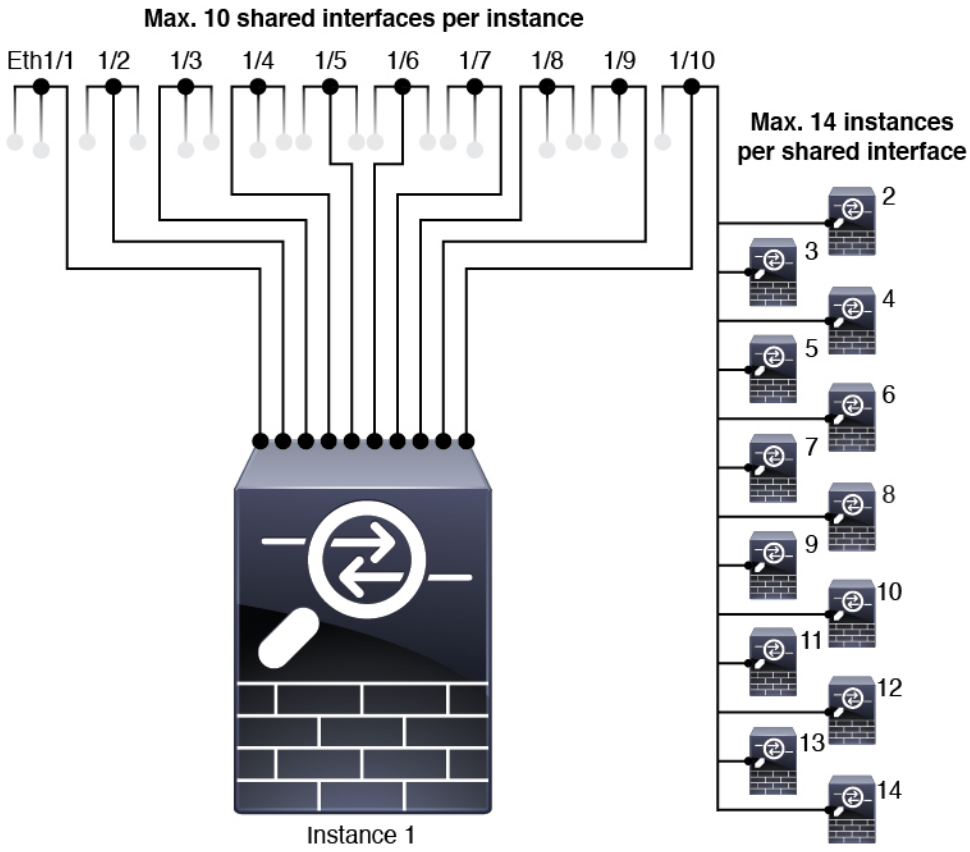
Guidelines and limitations for interface configuration

VLAN subinterfaces

Consider these guidelines when configuring VLAN subinterfaces in your network deployment.

- This document discusses FXOS VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense application. For more information, refer to FXOS interfaces and application interfaces, on page 226.
- Subinterfaces can only be assigned to container instances.

Note If you assign a parent interface to a container instance, it only passes untagged (non-VLAN) traffic. Do not assign the parent interface unless you intend to pass untagged traffic. For Cluster type interfaces, the parent interface cannot be used.



- Subinterfaces are supported on Data or Data-sharing type interfaces, as well as Cluster type interfaces. If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.
- For multi-instance clustering, FXOS subinterfaces are not supported on Data interfaces. However, subinterfaces are supported for the cluster control link, so you can use either a dedicated EtherChannel or a subinterface of an EtherChannel for the cluster control link. Note that *application*-defined subinterfaces are supported for Data interfaces.
- You can create up to 500 VLAN IDs.
- See these limitations within the logical device application; keep these limitations in mind when planning your interface allocation.
  - You cannot use subinterfaces for an inline set or as a passive interface.
  - If you use a subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links. You cannot use some subinterfaces as failover links, and some as regular data interfaces.

Data-sharing interfaces

Consider these limitations when configuring data-sharing interfaces.

- You cannot use a data-sharing interface with a native instance.
- Maximum 14 instances per shared interface. For example, you can allocate Ethernet1/1 to Instance1 through Instance14.

  Maximum 10 shared interfaces per instance. For example, you can allocate Ethernet1/1.1 through Ethernet1/1.10 to Instance1.

- You cannot use a data-sharing interface in a cluster.
- See these limitations within the logical device application; keep these limitations in mind when planning your interface allocation.
  - You cannot use a data-sharing interface with a transparent firewall mode device.
  - You cannot use a data-sharing interface with Firewall Threat Defense inline sets or passive interfaces.
  - You cannot use a data-sharing interface for the failover link.

Inline Sets for Firewall Threat Defense

Consider these guidelines when using inline sets for Firewall Threat Defense.

- Supported for physical interfaces (both regular and breakout ports) and EtherChannels. Subinterfaces are not supported.
- Link state propagation is supported.
- Do not enable Hardware Bypass and link state propagation for the same inline set.

Hardware bypass

Consider these limitations when configuring hardware bypass functionality.

- Supported for the Firewall Threat Defense; you can use them as regular interfaces for the ASA.

- The Firewall Threat Defense only supports Hardware Bypass with inline sets.
- Hardware Bypass-capable interfaces cannot be configured for breakout ports.
- You cannot include Hardware Bypass interfaces in an EtherChannel and use them for Hardware Bypass; you can use them as regular interfaces in an EtherChannel.
- Hardware Bypass is not supported with High Availability.
- Do not enable Hardware Bypass and link state propagation for the same inline set.

Default MAC addresses

For native instances:

Default MAC address assignments depend on the type of interface.

- Physical interfaces—The physical interface uses the burned-in MAC address.
- EtherChannels—For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses a unique MAC address from a pool; interface membership does not affect the MAC address.

For container instances:

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See Automatic MAC Addresses for Container Instance Interfaces, on page 246.

General guidelines for firewall mode, HA, and multi-instance configurations

Firewall mode configuration

You can set the firewall mode to routed or transparent in the bootstrap configuration for the Firewall Threat Defense.

High availability configuration

Configure high availability within the application configuration and use appropriate interfaces for failover and state links.

- Configure high availability within the application configuration.
- You can use any data interfaces as the failover and state links. Data-sharing interfaces are not supported.

Multi-Instance configuration

Enable multiple context mode and multi-instance capabilities according to platform-specific requirements and limitations.

- Multi-instance capability with container instances is only available for the Firewall Threat Defense using Firewall Management Center.

- For Firewall Threat Defense container instances, a single Firewall Management Center must manage all instances on a security module/engine.
- For Firewall Threat Defense container instances, the following features are not supported:
  - Radware DefensePro link decorator
  - Firewall Management Center UCAPL/CC mode
  - Flow offload to hardware

Configure interfaces

By default, physical interfaces are disabled. You can enable interfaces, add EtherChannels, add VLAN subinterfaces, and edit interface properties.

Enable or disable an interface

You can change the **Admin State** of each interface to be enabled or disabled. By default, physical interfaces are disabled. For VLAN subinterfaces, the admin state is inherited from the parent interface.

Procedure

Step 1 Choose **Interfaces** to open the Interfaces page.

The Interfaces page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 To enable the interface, click the disabled **Slider disabled** () so that it changes to the enabled **Slider enabled** ().

Click **Yes** to confirm the change. The corresponding interface in the visual representation changes from gray to green.

Step 3 To disable the interface, click the enabled **Slider enabled** () so that it changes to the disabled **Slider disabled** ().

Click **Yes** to confirm the change. The corresponding interface in the visual representation changes from green to gray.

Configure a physical interface

Configure physical interface settings including enable/disable state, speed, duplex, type, and auto-negotiation to ensure proper network connectivity.

You can physically enable and disable interfaces, as well as set the interface speed and duplex. To use an interface, it must be physically enabled in FXOS and logically enabled in the application.

Note

- For QSFPH40G-CUxM, auto-negotiation is enabled by default and you cannot disable it.
- If you replace an SFP on a port with a different SFP module, the speed, duplex, and auto-negotiation of the interface is not updated automatically. You must manually reconfigure the interface.

Before you begin

An interface that is already a member of an EtherChannel cannot be modified individually. Be sure to configure settings before you add it to the EtherChannel.

Procedure

Step 1 Choose **Interfaces** to open the Interfaces page.

The **All Interfaces** page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 Click **Edit** in the row for the interface you want to edit to open the **Edit Interface** dialog box.

Step 3 Configure the interface settings:

a) To enable the interface, check the **Enable** check box. To disable the interface, uncheck the **Enable** check box.

b) Choose the interface **Type**:

See Interface types, on page 224 for details about interface type usage.

- **Data**
- **Data-sharing**—For container instances only.
- **Mgmt**
- **Firepower-eventing**—For Firewall Threat Defense only.
- **Cluster**—Do not choose the **Cluster** type; by default, the cluster control link is automatically created on Port-channel 48.

c) Choose the speed of the interface from the **Speed** drop-down list.

d) If your interface supports **Auto Negotiation**, click the **Yes** or **No** radio button.

If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the platform interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, for the port to be connected you must disable the default auto-negotiation on the platform and the switch.

e) Choose the duplex of the interface from the **Duplex** drop-down list.

f) Choose a previously-configured **Network Control Policy**. For more information on how to configure a Network Control Policy, see Configure a Network Control Policy.

g) Explicitly configure **Debounce Time (ms)**. Enter a value between 0-15000 milli-seconds.

Note Configuring Debounce Time is not supported on 1G interfaces.

Step 4 Click **OK**.

Add an EtherChannel (port channel)

An EtherChannel (also known as a port channel) can include up to 16 member interfaces of the same media type and capacity, and must be set to the same speed and duplex. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface. The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices.

You can configure each physical Data or Data-sharing interface in an EtherChannel to be:

- Active—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- On—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

Note It may take up to three minutes for an EtherChannel to come up to an operational state if you change its mode from On to Active or from Active to On.

Non-data interfaces only support active mode.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

When the Firepower 4100/9300 creates an EtherChannel, the EtherChannel stays in a **Suspended** state for Active LACP mode or a **Down** state for On LACP mode until you assign it to a logical device, even if the physical link is up. The EtherChannel will be brought out of this **Suspended** state in the following situations:

- The EtherChannel is added as a data or management interface for a standalone logical device
- The EtherChannel is added as a management interface or cluster control link for a logical device that is part of a cluster
- The EtherChannel is added as a data interface for a logical device that is part of a cluster and at least one unit has joined the cluster

Note that the EtherChannel does not come up until you assign it to a logical device. If the EtherChannel is removed from the logical device or the logical device is deleted, the EtherChannel will revert to a **Suspended** or **Down** state.

Procedure

Step 1 Choose **Interfaces** to open the Interfaces page.

The **All Interfaces** page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 Click **Add Port Channel** above the interfaces table to open the **Add Port Channel** dialog box.

Step 3 Enter an ID for the port channel in the **Port Channel ID** field. Valid values are between 1 and 47.

Port-channel 48 is reserved for the cluster control link when you deploy a clustered logical device. If you do not want to use Port-channel 48 for the cluster control link, you can delete it and configure a Cluster type EtherChannel with a different ID.You can add multiple Cluster type EtherChannels and add VLAN subinterfaces for use with multi-instance clustering. For intra-chassis clustering, do not assign any interfaces to the Cluster EtherChannel.

Step 4 To enable the port channel, check the **Enable** check box. To disable the port channel, uncheck the **Enable** check box.

Step 5 Choose the interface **Type**:

See Interface types, on page 224 for details about interface type usage.

- **Data**
- **Data-sharing**—For container instances only.
- **Mgmt**
- **Firepower-eventing**—For Firewall Threat Defense only.
- **Cluster**

Step 6 Set the required **Admin Speed** for the member interfaces from the drop-down list.

If you add a member interface that is not at the specified speed, it will not successfully join the port channel.

Step 7 For Data or Data-sharing interfaces, choose the LACP port-channel **Mode**, **Active** or **On**.

For non-Data or non-Data-sharing interfaces, the mode is always active.

Step 8 Set the required **Admin Duplex** for the member interfaces, **Full Duplex** or **Half Duplex**.

If you add a member interface that is configured with the specified duplex, it will not successfully join the port channel.

Step 9 To add an interface to the port channel, select the interface in the **Available Interface** list and click **Add Interface** to move the interface to the Member ID list.

You can add up to 16 member interfaces of the same media type and capacity. The member interfaces must be set to the same speed and duplex, and must match the speed and duplex that you configured for this port channel. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface.

Tip You can add multiple interfaces at one time. To select multiple individual interfaces, click on the desired interfaces while holding down the **Ctrl** key. To select a range of interfaces, select the first interface in the range, and then, while holding down the **Shift** key, click to select the last interface in the range.

Step 10 To remove an interface from the port channel, click the **Delete** button to the right of the interface in the Member ID list.

Step 11 Click **OK**.

Add a VLAN subinterface for container instances

You can add between 250 and 500 VLAN subinterfaces to the chassis, depending on your network deployment.You can add up to 500 subinterfaces to your chassis.

For multi-instance clustering, you can only add subinterfaces to the Cluster-type interface; subinterfaces on data interfaces are not supported.

VLAN IDs per interface must be unique, and within a container instance, VLAN IDs must be unique across all assigned interfaces. You can reuse VLAN IDs on separate interfaces as long as they are assigned to different container instances. However, each subinterface still counts towards the limit even though it uses the same ID.

This document discusses FXOS VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense application. For more information on when to use FXOS subinterfaces and application subinterfaces, refer to FXOS interfaces and application interfaces, on page 226.

Procedure

Step 1 Choose **Interfaces** to open the **All Interfaces** tab.

The **All Interfaces** tab provides both a visual representation and a tabular list of all currently installed interfaces.

Step 2 Click **Add New** > **Subinterface** to open the **Add Subinterface** dialog box.

Step 3 Do these steps to configure the subinterface:

a) Choose the interface **Type**:

See Interface types, on page 224 for details about interface type usage.

- **Data**
- **Data-sharing**
- **Cluster**—If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.

For Data and Data-sharing interfaces: The type is independent of the parent interface type; you can have a Data-sharing parent and a Data subinterface, for example.

b) Choose the parent **Interface** from the drop-down list.

You cannot add a subinterface to a physical interface that is currently allocated to a logical device. If other subinterfaces of the parent are allocated, you can add a new subinterface as long as the parent interface itself is not allocated.

c) Enter a **Subinterface ID**, between 1 and 4294967295.

This ID will be appended to the parent interface ID as *interface_id.subinterface_id*. For example, if you add a subinterface to Ethernet1/1 with the ID of 100, then the subinterface ID will be: Ethernet1/1.100. This ID is not the same as the VLAN ID, although you can set them to match for convenience.

d) Set the **VLAN ID** between 1 and 4095.

Step 4 Click **OK**.

Expand the parent interface to view all subinterfaces under it.

Configure logical devices

Add a standalone logical device or a high-availability pair on the Firepower 4100/9300.

Add a resource profile for container instances

To specify resource usage per container instance, create one or more resource profiles. When you deploy the logical device/application instance, you specify the resource profile that you want to use. The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

- The minimum number of cores is 6.

Note Instances with a smaller number of cores might experience relatively higher CPU utilization than those with larger numbers of cores. Instances with a smaller number of cores are more sensitive to traffic load changes. If you experience traffic drops, try assigning more cores.

- You can assign cores as an even number (6, 8, 10, 12, 14 etc.) up to the maximum.
- The maximum number of cores available depends on the security module/chassis model; see Requirements and prerequisites for container instances, on page 250.

The chassis includes a default resource profile called "Default-Small," which includes the minimum number of cores. You can change the definition of this profile, and even delete it if it is not in use. Note that this profile is created when the chassis reloads and no other profile exists on the system.

Changing the resource profile after you assign it is disruptive. See the following guidelines:

- You cannot change the resource profile settings if it is currently in use. You must disable any instances that use it, then change the resource profile, and finally reenable the instance.

- If you change the resource profile settings after you add the Firewall Threat Defense instance to the Firewall Management Center, then update the inventory for each unit on the Firewall Management Center.

  Choose **Devices** > **Device Management**, click **Edit** ( ) for the instance, then click **Refresh** ( ) on the **Device** > **Inventory Details** area.

- If you assign a different profile to an instance, it reboots.
- If you assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:
  1. Break high availability.
  2. Assign the new profile to both units.
  3. Re-establish high availability.
- If you assign a different profile to instances in an established cluster, which allows mismatched profiles, then apply the new profile on the data nodes first; after they all come back up, you can apply the new profile to the control node.

Procedure

Step 1 Choose **Platform Settings** > **Resource Profiles**, and click **Add**.

The **Add Resource Profile** dialog box appears.

Step 2 Set the following parameters.

- **Name**: Sets the name of the profile between 1 and 64 characters. Note that you cannot change the name of this profile after you add it.
- **Description**: Sets the description of the profile up to 510 characters.
- **Number of Cores**: Sets the number of cores for the profile, between 6 and the maximum, depending on your chassis, as an even number.

Step 3 Click **OK**.

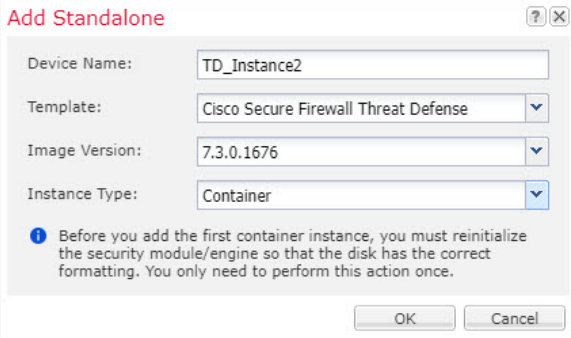
Add a Standalone Firewall Threat Defense

Standalone logical devices work either alone or in a High Availability pair. On the Firepower 9300 with multiple security modules, you can deploy either a cluster or standalone devices. The cluster must use all modules, so you cannot mix and match a 2-module cluster plus a single standalone device, for example.

You can use native instances on some modules, and container instances on the other module(s).

Before you begin

- Download the application image you want to use for the logical device from Cisco.com, and then upload that image to the Firepower 4100/9300.



Note For the Firepower 9300, you can install different application types (ASA and Firewall Threat Defense) on separate modules in the chassis. You can also run different versions of an application instance type on separate modules.

- Configure a management interface to use with the logical device. The management interface is required. Note that this management interface is not the same as the chassis management port that is used only for chassis management (and that appears at the top of the **Interfaces** tab as **MGMT**).
- You can later enable management from a data interface; but you must assign a Management interface to the logical device even if you don't intend to use it after you enable data management. See the **configure network management-data-interface** command in the FTD command reference for more information.
- You must also configure at least one Data type interface. Optionally, you can also create a firepower-eventing interface to carry all event traffic (such as web events). See Interface types, on page 224 for more information.
- For container instances, if you do not want to use the default profile, add a resource profile according to Add a resource profile for container instances , on page 264.
- For container instances, before you can install a container instance for the first time, you must reinitialize the security module/engine so that the disk has the correct formatting. Choose **Security Modules** or **Security Engine**, and click the **Reinitialize icon**. An existing logical device will be deleted and then reinstalled as a new device, losing any local application configuration. If you are replacing a native instance with container instances, you will need to delete the native instance in any case. You cannot automatically migrate a native instance to a container instance.
- Gather the following information:
  - Interface IDs for this device
  - Management interface IP address and network mask
  - Gateway IP address
  - Firewall Management Center IP address and/or NAT ID of your choosing
  - DNS server IP address
  - Firewall Threat Defense hostname and domain name

Procedure

Step 1 Choose **Logical Devices**.

Step 2 Click **Add** > **Standalone**, and set the following parameters:

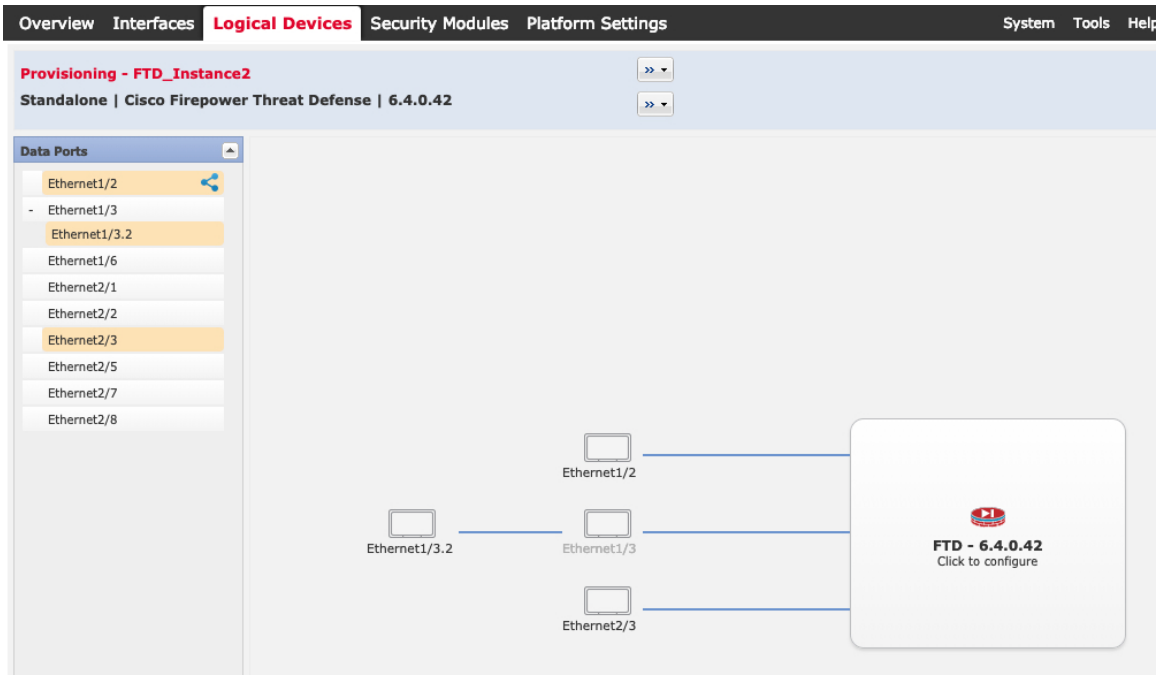
a) Provide a **Device Name**.

This name is used by the chassis supervisor to configure management settings and to assign interfaces; it is not the device name used in the application configuration.

Note You cannot change this name after you add the logical device.

b) For the **Template**, choose **Cisco Firepower Threat Defense**.

c) Choose the **Image Version**.



d) Choose the **Instance Type**: **Container** or **Native**.

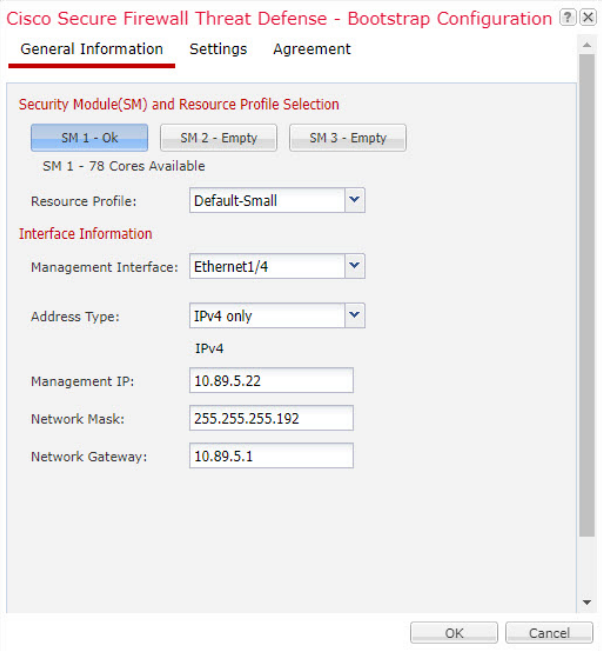
A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance. A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances.

e) Click **OK**.

You see the Provisioning - *device name* window.

Step 3 Expand the **Data Ports** area, and click each interface that you want to assign to the device.

You can only assign data and data-sharing interfaces that you previously enabled on the **Interfaces** page. You will later enable and configure these interfaces in Firewall Management Center, including setting the IP addresses.



You can only assign up to 10 data-sharing interfaces to a container instance. Also, each data-sharing interface can be assigned to at most 14 container instances. A data-sharing interface is indicated by the sharing icon ( ).

Hardware Bypass-capable ports are shown with the following icon: . For certain interface modules, you can enable the Hardware Bypass feature for Inline Set interfaces only (see the Firewall Management Center configuration guide). Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures. If you do not assign both interfaces in a Hardware Bypass pair, you see a warning message to make sure your assignment is intentional. You do not need to use the Hardware Bypass feature, so you can assign single interfaces if you prefer.

Step 4 Click the device icon in the center of the screen.

A dialog box appears where you can configure initial bootstrap settings. These settings are meant for initial deployment only, or for disaster recovery. For normal operation, you can later change most values in the application CLI configuration.

Step 5 On the **General Information** page, complete the following:

a) (For the Firepower 9300) Under **Security Module Selection** click the security module that you want to use for this logical device.

b) For a container instance, specify the **Resource Profile**.

If you later assign a different resource profile, then the instance will reload, which can take approximately 5 minutes.

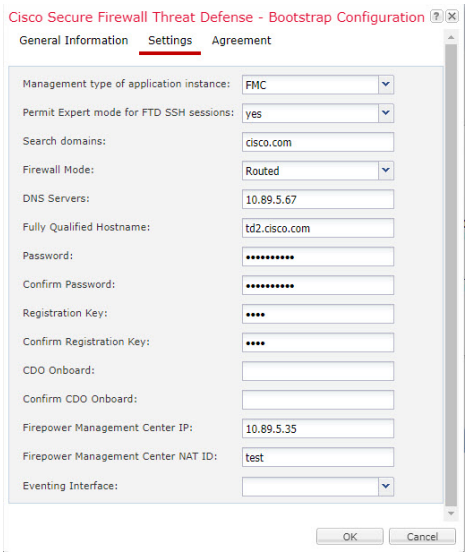
Note If you later assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:

1. Break high availability.
2. Assign the new profile to both units.
3. Re-establish high availability.

c) Choose the **Management Interface**.

This interface is used to manage the logical device. This interface is separate from the chassis management port.

d) Choose the management interface **Address Type**: **IPv4 only**, **IPv6 only**, or **IPv4 and IPv6**.



e) Configure the **Management IP** address.

Set a unique IP address for this interface.

f) Enter a **Network Mask** or **Prefix Length**.

g) Enter a **Network Gateway** address.

Step 6 On the **Settings** tab, complete the following:

a) For a native instance, in the **Management type of application instance** drop-down list, choose **FMC**.

   Native instances also support Firewall Device Manager as a manager. After you deploy the logical device, you cannot change the manager type.

b) Enter the **Firepower Management Center IP** of the managing Firewall Management Center. If you do not know the Firewall Management Center IP address, leave this field blank and enter a passphrase in the **Firepower Management Center NAT ID** field.

c) For a container instance, **Permit Expert mode from FTD SSH sessions**: **Yes** or **No**. Expert Mode provides Firewall Threat Defense shell access for advanced troubleshooting.

   If you choose **Yes** for this option, then users who access the container instance directly from an SSH sesssion can enter Expert Mode. If you choose **No**, then only users who access the container instance from the FXOS CLI can enter Expert Mode. We recommend choosing **No** to increase isolation between instances.

   Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the Firewall Threat Defense CLI.

d) Enter the **Search Domains** as a comma-separated list.

e) Choose the **Firewall Mode**: **Transparent** or **Routed**.

   In routed mode, the Firewall Threat Defense is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices.

   The firewall mode is only set at initial deployment. If you re-apply the bootstrap settings, this setting is not used.

f) Enter the **DNS Servers** as a comma-separated list.

   The Firewall Threat Defense uses DNS if you specify a hostname for the Firewall Management Center, for example.

g) Enter the **Fully Qualified Hostname** for the Firewall Threat Defense.

h) Enter a **Registration Key** to be shared between the Firewall Management Center and the device during registration.

You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the Firewall Management Center when you add the Firewall Threat Defense.

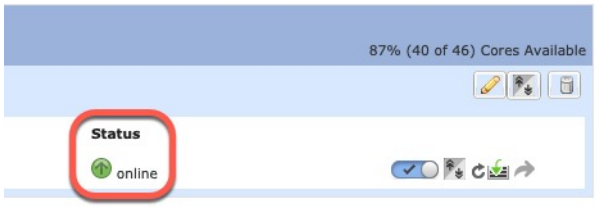
i) Enter a **Password** for the Firewall Threat Defense admin user for CLI access.

j) Choose the **Eventing Interface** on which events should be sent. If not specified, the management interface will be used.

This interface must be defined as a Firepower-eventing interface.

k) For a container instance, set the **Hardware Crypto** as **Enabled** or **Disabled**.

This setting enables TLS crypto acceleration in hardware, and improves performance for certain types of traffic. This feature is enabled by default. You can enable TLS crypto acceleration for up to 16 instances per security module. This feature is always enabled for native instances. To view the percentage of hardware crypto resources allocated to this instance, enter the **show hw-crypto** command.



Step 7 On the **Agreement** tab, read and accept the end user license agreement (EULA).

Step 8 Click **OK** to close the configuration dialog box.

Step 9 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for the status of the new logical device. When the logical device shows its **Status** as **online**, you can start configuring the security policy in the application.

Step 10 See the Firewall Management Center configuration guide to add the Firewall Threat Defense as a managed device and start configuring your security policy.

Add a high availability pair

Firewall Threat Defense High Availability (also known as failover) is configured within the application, not in FXOS. However, to prepare your chassis for high availability, see the following steps.

Before you begin

Refer to Requirements and prerequisites for high availability configuration, on page 251.

Procedure

Step 1 Allocate the same interfaces to each logical device.

Step 2 Allocate 1 or 2 data interfaces for the failover and state link(s).

These interfaces exchange high availability traffic between the 2 chassis. We recommend that you use a 10 GB data interface for a combined failover and state link. If you have available interfaces, you can use separate failover and state links; the state link requires the most bandwidth. You cannot use the management-type interface for the failover or state link. We recommend that you use a switch between the chassis, with no other device on the same network segment as the failover interfaces.

For container instances, data-sharing interfaces are not supported for the failover link. We recommend that you create subinterfaces on a parent interface or EtherChannel, and assign a subinterface for each instance to use as a failover link. Note that you must use all subinterfaces on the same parent as failover links. You cannot use one subinterface as a failover link and then use other subinterfaces (or the parent interface) as regular data interfaces.

Step 3 Enable High Availability on the logical devices. Refer to High Availability for Devices, on page 283.

Step 4 If you need to make interface changes after you enable High Availability, perform the changes on the standby unit first, and then perform the changes on the active unit.

Change an Interface on a Firewall Threat Defense Logical Device

You can allocate or unallocate an interface, or replace a management interface on the Firewall Threat Defense logical device. You can then sync the interface configuration in the Firewall Management Center.

Adding a new interface, or deleting an unused interface has minimal impact on the Firewall Threat Defense configuration. However, deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the Firewall Threat Defense configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Policies that refer to security zones are not affected. You can also edit the membership of an allocated EtherChannel without affecting the logical device or requiring a sync on the Firewall Management Center.

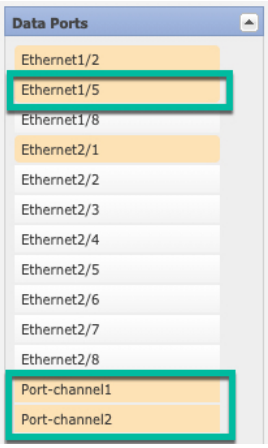
Deleting an interface will delete any configuration associated with that interface.

Before you begin

- Configure your interfaces, and add any EtherChannels according to Configure a physical interface, on page 259 and Add an EtherChannel (port channel), on page 261.
- If you want to add an already-allocated interface to an EtherChannel (for example, all interfaces are allocated by default to a cluster), you need to unallocate the interface from the logical device first, then add the interface to the EtherChannel. For a new EtherChannel, you can then allocate the EtherChannel to the device.
- If you want to replace the management or eventing interface with a management EtherChannel, then you need to create the EtherChannel with at least 1 unallocated data member interface, and then replace the current management interface with the EtherChannel. After the Firewall Threat Defense device reboots (management interface changes cause a reboot), and you sync the configuration in the Firewall

Management Center, you can add the (now unallocated) management interface to the EtherChannel as well.

- For clustering or High Availability, make sure you add or remove the interface on all units before you sync the configuration in the Firewall Management Center. We recommend that you make the interface changes on the data/standby unit(s) first, and then on the control/active unit. Note that new interfaces are added in an administratively down state, so they do not affect interface monitoring.
- In mult-instance mode, for changing a sub-interface with an another sub-interface with the same vlan tag, you must first remove all the configuration (including nameif config) of the interface and then unalloacte the interface from Firewall Chassis Manager. Once unallocated, add the new interface and then use sync interfaces from the Firewall Management Center.



Procedure

Step 1 In the Firewall Chassis Manager, choose **Logical Devices**.

Step 2 Click the **Edit** icon at the top right to edit the logical device.

Step 3 Allocate a new data interface by selecting the interface in the **Data Ports** area.

Do not delete any interfaces yet.

Step 4 Replace the management or eventing interface:

For these types of interfaces, the device reboots after you save your changes.

a) Click the device icon in the center of the page.
b) On the **General** or **Cluster Information** tab, choose the new **Management Interface** from the drop-down list.
c) On the **Settings** tab, choose the new **Eventing Interface** from the drop-down list.
d) Click **OK**.

If you change the IP address of the Management interface, then you must also change the IP address for the device in the Firewall Management Center: go to **Devices** > **Device Management** > **Device/Cluster**. In the **Management** area, set the IP address to match the bootstrap configuration address.

Step 5 Click **Save**.

Step 6 Sync the interfaces in the Firewall Management Center.

a) Log into the Firewall Management Center.
b) Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.
c) Click the **Sync Device** button on the top left of the **Interfaces** page.
d) After the changes are detected, you will see a red banner on the **Interfaces** page indicating that the interface configuration has changed. Click the **Click to know more** link to view the interface changes.
e) If you plan to delete an interface, manually transfer any interface configuration from the old interface to the new interface.

   Because you have not yet deleted any interfaces, you can refer to the existing configuration. You will have additional opportunity to fix the configuration after you delete the old interface and re-run the validation. The validation will show you all locations in which the old interface is still used.

f) Click **Validate Changes** to make sure your policy will still work with the interface changes.

   If there are any errors, you need to change your policy and rerun the validation.

g) Click **Save**.
h) Click **Deploy** > **Deployment**.
i) Select the devices and click **Deploy** to deploy the policy to the assigned devices. The changes are not active until you deploy them.

Step 7 In the Firewall Chassis Manager, unallocate a data interface by de-selecting the interface in the **Data Ports** area.

Step 8 Click **Save**.

Step 9 Sync the interfaces again in the Firewall Management Center.

Connect to the Console of the Application

Use the following procedure to connect to the console of the application.

Procedure

Step 1 Connect to the module CLI using a console connection or a Telnet connection.

connect module *slot_number* {**console** | **telnet**}

To connect to the security engine of a device that does not support multiple security modules, always use **1** as the *slot_number*.

The benefits of using a Telnet connection is that you can have multiple sessions to the module at the same time, and the connection speed is faster.

Example:

```
Firepower# connect module 1 console
Telnet escape character is '~'.
Trying 127.5.1.1...
Connected to 127.5.1.1.
Escape character is '~'.

CISCO Serial Over LAN:
Close Network Connection to Exit

Firepower-module1>
```

Step 2 Connect to the application console.

connect ftd *name*

To view the instance names, enter the command without a name.

Example:

```
Firepower-module1> connect ftd ftd1
Connecting to ftd(ftd-native) console... enter exit to return to bootCLI
[...]
>
```

Step 3 Exit the application console to the FXOS module CLI.

- Firewall Threat Defense—Enter **exit**

Step 4 Return to the supervisor level of the FXOS CLI.

Exit the console:

a) Enter **~**

You exit to the Telnet application.

b) To exit the Telnet application, enter:

telnet>**quit**

Exit the Telnet session:

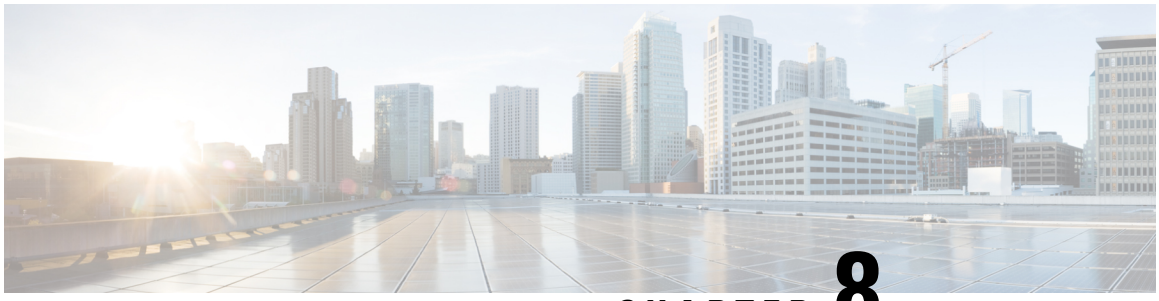
a) Enter **Ctrl-], .**

History for logical devices

This table provides a chronological history of feature updates and improvements for logical devices, enabling you to track feature availability and requirements across different Firewall Management Center versions.

Table 22: Logical devices feature history

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Synchronization between the Firewall Threat Defense operational link state and the physical link state	6.7	Any	The chassis can now synchronize the Firewall Threat Defense operational link state with the physical link state for data interfaces. Currently, interfaces will be in an Up state as long as the FXOS admin state is up and the physical link state is up. The Firewall Threat Defense application interface admin state is not considered. Without synchronization from Firewall Threat Defense, data interfaces can be in an Up state physically before the Firewall Threat Defense application has completely come online, for example, or can stay Up for a period of time after you initiate Firewall Threat Defense shutdown. For inline sets, this state mismatch can result in dropped packets because external routers may start sending traffic to the Firewall Threat Defense before the Firewall Threat Defense can handle it. This feature is disabled by default and can be enabled per logical device in FXOS. **Note** This feature is not supported for clustering, container instances, or Firewall Threat Defense with a Radware vDP decorator. It is also not supported for the ASA. New/Modified Firepower Chassis Manager screens: **Logical Devices** > **Enable Link State** New/Modified FXOS commands: **set link-state-sync enabled**, **show interface expand detail**
Firewall Threat Defense configuration backup and restore using Firewall Management Center for container instances	6.7	Any	You can now use the Firewall Management Center backup/restore tool on Firewall Threat Defense container instances. New/Modified Firewall Management Center screens: **System** > **Tools** > **Backup/Restore** > **Managed Device Backup** New/Modified Firewall Threat Defense CLI commands: **restore** Supported platforms: Firepower 4100/9300 **Note** Requires FXOS 2.9.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Support for VLAN subinterfaces on a Cluster type interface (multi-instance use only)	6.6	Any	For use with multi-instance clusters, you can now create VLAN subinterfaces on cluster-type interfaces. Because each cluster requires a unique cluster control link, VLAN subinterfaces provide a simple method to fulfill this requirement. You can alternatively assign a dedicated EtherChannel per cluster. Multiple cluster interfaces are now allowed. New/Modified Firepower Chassis Manager screens: **Interfaces** > **All Interfaces** > **Add New** drop-down menu **Subinterface** > **Type** field New/Modified FXOS commands: **set port-type cluster** **Note** Requires FXOS 2.8.1.
Firewall Threat Defense on the Firepower 4112	6.6	Any	We introduced the Firepower 4112. **Note** Requires FXOS 2.8.1.
TLS crypto acceleration for multiple container instances	6.5	Any	TLS crypto acceleration is now supported on multiple container instances (up to 16) on a Firepower 4100/9300 chassis. Previously, you could enable TLS crypto acceleration for only one container instance per module/security engine. New instances have this feature enabled by default. However, the upgrade does not enable acceleration on existing instances. Instead, run the **enter hw-crypto** and then the **set admin-state enabled** FXOS commands. New/Modified Firepower Chassis Manager screens: Click **Logical Devices** > **Add Device** > **Settings** and then click the **Hardware Crypto** drop-down list. **Note** Requires FXOS 2.7.1.
Firewall Threat Defense on the Firepower 4115, 4125, and 4145	6.4	Any	We introduced the Firepower 4115, 4125, and 4145. **Note** Requires FXOS 2.6.1.157.
Firepower 9300 SM-40, SM-48, and SM-56 support	6.4	Any	We introduced the following three security modules: SM-40, SM-48, and SM-56. **Note** Requires FXOS 2.6.1.157.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Support for ASA and Firewall Threat Defense on separate modules of the same Firepower 9300	6.4	Any	You can now deploy ASA and Firewall Threat Defense logical devices on the same Firepower 9300. **Note** Requires FXOS 2.6.1.157.
Support for SSL hardware acceleration on one Firewall Threat Defense container instance on a module/security engine	6.4	Any	You can now enable SSL hardware acceleration for one container instance on a module/security engine. SSL hardware acceleration is disabled for other container instances, but enabled for native instances. New/Modified FXOS commands: **config hwCrypto enable** No modified screens. **Note** Requires FXOS 2.6.1.157.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Multi-instance capability for Firewall Threat Defense on the Firepower 4100/9300	6.3	Any	You can now deploy multiple logical devices, each with a Firewall Threat Defense container instance, on a single security engine/module. Formerly, you could only deploy a single native application instance. To provide flexible physical interface use, you can create VLAN subinterfaces in FXOS and also share interfaces between multiple instances. Resource management lets you customize performance capabilities for each instance. You can configure High Availability using a container instance on 2 separate chassis. Clustering is not supported. **Note** Multi-instance capability is similar to ASA multiple context mode, although the implementation is different. Multiple context mode is not available on the Firewall Threat Defense. New/Modified Firewall Management Center screens: • **Devices** > **Device Management** > **Edit** icon **Interfaces** tab New/Modified Firepower Chassis Manager screens: • **Overview** > **Devices** • **Interfaces** > **All Interfaces** > **Add New** drop-down menu **Subinterface** • **Interfaces** > **All Interfaces** > **Type** • **Logical Devices** > **Add Device** • **Platform Settings** > **Mac Pool** • **Platform Settings** > **Resource Profiles** New/Modified FXOS commands: **connect ftd name**, **connect module telnet**, **create bootstrap-key PERMIT_EXPERT_MODE**, **create resource-profile**, **create subinterface**, **scope auto-macpool**, **set cpu-core-count**, **set deploy-type**, **set port-type data-sharing**, **set prefix**, **set resource-profile-name**, **set vlan**, **scope app-instance ftd name**, **show cgroups container**, **show interface**, **show mac-address**, **show subinterface**, **show tech-support module app-instance**, **show version** Supported platforms: Firepower 4100/9300

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Cluster control link customizable IP Address for the Firepower 4100/9300	6.3	Any	By default, the cluster control link uses the 127.2.0.0/16 network. You can now set the network when you deploy the cluster in FXOS. The chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: 127.2. *chassis_id*. *slot_id*. However, some networking deployments do not allow 127.2.0.0/16 traffic to pass. Therefore, you can now set a custom /16 subnet for the cluster control link in FXOS, except for loopback (127.0.0.0/8) and multicast (224.0.0.0/4) addresses. New/modified Firepower Chassis Manager screens: • **Logical Devices** > **Add Device** > **Cluster Information** > **CCL Subnet IP** field New/Modified FXOS commands: **set cluster-control-link network** Supported platforms: Firepower 4100/9300
Support for data EtherChannels in On mode	6.3	Any	You can now set data and data-sharing EtherChannels to either to Active LACP mode or On mode. Other types of EtherChannels only support Active mode. New/Modified Firepower Chassis Manager screens: • **Interfaces** > **All Interfaces** > **Edit Port Channel** > **Mode** New/Modified FXOS commands: **set port-channel-mode** Supported platforms: Firepower 4100/9300
Support for EtherChannels in Firewall Threat Defense inline sets	6.2	Any	You can now use EtherChannels in a Firewall Threat Defense inline set. Supported platforms: Firepower 4100/9300
Inter-chassis clustering for 6 Firewall Threat Defense modules	6.2	Any	You can now enable inter-chassis clustering for the Firewall Threat Defense. You can include up to 6 modules in up to 6 chassis. New/modified Firepower Chassis Manager screens: • **Logical Devices** > **Configuration** Supported platforms: Firepower 4100/9300
Hardware bypass support on the Firepower 4100/9300 for supported network modules	6.1	Any	Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures. New/Modified screens: • **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** Supported platforms: Firepower 4100/9300

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Inline set link state propagation support for the Firewall Threat Defense	6.1	Any	When you configure an inline set in the Firewall Threat Defense application and enable link state propagation, the Firewall Threat Defense sends inline set membership to the FXOS chassis. Link state propagation means that the chassis automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. New/Modified FXOS commands: **show fault |grep link-down**, **show interface detail** Supported platforms: Firepower 4100/9300
Support for intra-chassis clustering on the Firewall Threat Defense on the Firepower 9300	6.0.1	Any	The Firepower 9300 supports intra-chassis clustering with the Firewall Threat Defense application. CHAPTER 8

High Availability for Devices

The following topics describe how to configure Active/Standby failover to accomplish high availability of the Firewall Threat Defense.

- Secure Firewall Threat Defense high availability, on page 283
- Config-sync optimization, on page 302
- Requirements and prerequisites for high availability, on page 303
- Guidelines for High availability, on page 303
- Add a high availability pair, on page 306
- Configure optional high availability parameters, on page 309
- Manage High availability, on page 311
- Monitoring High availability, on page 319
- Troubleshoot configuration sync failure, on page 320
- History for high availability, on page 320

Secure Firewall Threat Defense high availability

Secure Firewall Threat Defense high availability is a failover configuration that

- requires two identical Firewall Threat Defense devices connected through a dedicated failover link and optionally a state link
- supports Active/Standby failover where one unit passes traffic while the standby unit does not actively pass traffic synchronizes configuration and state information, and
- monitors the health of the active unit (hardware, interfaces, software, and environmental status) to determine if failover conditions are met.

Failover process details

When a failover occurs, the active unit fails over to the standby unit, which then becomes active. The health of the active unit (hardware, interfaces, software, and environmental status) is monitored to determine if specific failover conditions are met. If those conditions are met, failover occurs.

Note High availability is not supported on Firewall Threat Defense Virtual running in the public cloud. See the Secure Firewall Threat Defense Virtual getting started guides for more information about configuring the Firewall Threat Defense Virtual device for high availability.

High availability system requirements

High availability system requirements are specifications that define the hardware, software, and license prerequisites for Firewall Threat Defense devices to function in a High availability configuration.

Hardware requirements

Hardware requirements are specifications that ensure two units in a High availability configuration can

- maintain identical hardware configurations including model, interfaces, modules, and RAM
- support proper synchronization and failover functionality, and
- ensure reliable high availability operation.

Hardware requirement specifications

The two units in a High availability configuration must meet these requirements:

- Be the same model. In addition, for container instances, they must use the same resource profile attributes.

  For the Firepower 9300, High Availability is only supported between same-type modules. However, the two chassis can include mixed modules. For example, each chassis has an SM-56, SM-48, and SM-40. You can create High Availability pairs between the SM-56 modules, between the SM-48 modules, and between the SM-40 modules.

  If you change the resource profile after you add the High Availability pair to the Firewall Management Center, update the inventory for each unit on the **Devices** > **Device Management** > **Device** > **System** > **Inventory** dialog box.

  If you assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:

  1. Break high availability.
  2. Assign the new profile to both units.
  3. Re-establish high availability.

- Have the same number and types of interfaces.

  For the Firepower 4100/9300 chassis, all interfaces must be preconfigured in FXOS identically before you enable High availability. If you change the interfaces after you enable High availability, make the interface changes in FXOS on the Standby unit, and then make the same changes on the Active unit.

If you are using units with different flash memory sizes in your High availability configuration, make sure the unit with the smaller flash memory has enough space to accommodate the software image files and the

configuration files. If it does not, configuration synchronization from the unit with the larger flash memory to the unit with the smaller flash memory will fail.

Software requirements

Software requirements are configuration specifications that High availability units must meet to function properly in a failover configuration.

Required software specifications

The two units in a High availability configuration must meet these requirements:

- Be in the same firewall mode (routed or transparent).
- Have the same software version.
- Be in the same domain or group on the Firewall Management Center.
- Have the same NTP configuration. See Synchronize time on FTD devices, on page 908.
- Configuration changes must be fully deployed to the devices.
- Not have DHCP or PPPoE configured in any of their interfaces.
- (Firepower 4100/9300) Have the same flow offload mode, either both enabled or both disabled.

License requirements for Firewall Threat Defense devices in a high availability pair

Both Firewall Threat Defense units in a high availability configuration must have the same licenses.

High availability configurations require two license entitlements: one for each device in the pair.

Before high availability is established, it does not matter which licenses are assigned to the secondary/standby device. During high availability configuration, the Firewall Management Center releases any unnecessary licenses assigned to the standby unit and replaces them with identical licenses assigned to the primary/active unit.

For example, if the active unit has a Essentials license and a IPS license, and the standby unit has only a Essentials license, the Firewall Management Center communicates with the Smart Software Manager to obtain an available IPS license from your account for the standby unit. If your license account does not include enough purchased entitlements, your account becomes Out-of-Compliance until you purchase the correct number of licenses.

Failover and stateful failover links

A failover link and stateful failover link are dedicated connections that

- establish communication between the two units in a failover configuration
- require the same interface to be used between corresponding devices for consistency, and
- transmit critical failover and state information between the paired units.

Configuration recommendations

Cisco recommends to use the same interface between two devices in a failover link or a stateful failover link. For example, in a failover link, if you have used eth0 in device 1, use the same interface (eth0) in device 2 as well.

Failover link

A failover link is a communication mechanism that enables two units in a failover pair to constantly communicate to determine the operating status of each unit.

Failover link data

This below information is communicated over the failover link:

- The unit state (active or standby)
- Hello messages (keep-alives)
- Network link status
- MAC address exchange
- Configuration replication and synchronization

Interface for the failover link

A failover link interface is a dedicated communication channel that

- exists solely for failover communication between high availability units
- uses an unused data interface (physical, or EtherChannel)
- cannot be shared with normal networking interfaces or user data traffic, and
- requires specific interface sizing based on the device model.

Interface restrictions and requirements

You can use an unused data interface (physical, or EtherChannel) as the failover link; however, you cannot specify an interface that is currently configured with a name. You also cannot use a subinterface with the exception of a subinterface defined on the chassis for multi-instance mode. The failover link interface is not configured as a normal networking interface; it exists for failover communication only. This interface can only be used for the failover link (and also for the state link).

The Firewall Threat Defense does not support sharing interfaces between user data and the failover link. You also cannot use separate subinterfaces on the same parent for the failover link and for data (multi-instance chassis subinterfaces only). If you use a chassis subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links.

Note When using an EtherChannel as the failover or state link, you must confirm that the same EtherChannel with the same member interfaces exists on both devices before establishing high availability.

See these guidelines for the failover link:

- Firepower 4100/9300—You cannot use the management-type interface for the failover link.
- See these guidelines for sizing the link.

Table 23: Failover link size

Model	Interface Size for Combined Failover and State Link
Firepower 1010	1 Gbps
Firepower 1100	1 Gbps
Secure Firewall 3100	Secure Firewall 3105—1 Gbps Secure Firewall 3110—1 Gbps Secure Firewall 3120—1 Gbps Secure Firewall 3130—10 Gbps Secure Firewall 3140—10 Gbps
Secure Firewall 4200	10 Gbps
Firepower 9300	10 Gbps

The alternation frequency is equal to the unit hold time.

Note If you have a large configuration and a low unit hold time, alternating between the member interfaces can prevent the secondary unit from joining/re-joining. In this case, disable one of the member interfaces until after the secondary unit joins.

For an EtherChannel used as the failover link, to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a failover link.

Connect the failover link

The failover link enables communication and coordination between units in a failover configuration.

You need to establish a physical connection between the failover units to enable proper failover functionality.

Procedure

Connect the failover link using one of the following methods:

- Using a switch, with no other device on the same network segment (broadcast domain or VLAN) as the failover interfaces of the Firewall Threat Defense device.
- Using an Ethernet cable to connect the units directly, without the need for an external switch.

If you do not use a switch between the units and the interface fails, the link is brought down on both peers. This condition may hamper troubleshooting efforts because you cannot easily determine which unit has the failed interface and caused the link to come down.

The failover link is physically connected and ready for failover configuration.

Stateful failover links

A stateful failover link is a network connection that

- passes connection state information between failover units, and
- must be configured to enable stateful failover functionality.

State link configuration requirements

To use Stateful Failover, you must configure a Stateful Failover link (also known as the state link) to pass connection state information.

Shared failover links

A shared failover link is an interface conservation method that enables multiple network functions to use the same failover connection, though dedicated interfaces for state and failover links should be considered for large configurations and high traffic networks.

Dedicated interface for the stateful failover link

A dedicated interface for the stateful failover link is a data interface configuration that uses a dedicated physical or EtherChannel interface specifically for the state link in failover deployments.

Performance considerations

You can use a dedicated data interface—such as a physical or EtherChannel interface—for the state link. For requirements about a dedicated state link, refer to Interface for the failover link, on page 286. See the section on connecting the state link for additional information Connect the failover link, on page 287.

For optimum performance with long-distance failover, the state link latency should be less than 10 milliseconds but no more than 250 milliseconds. If latency exceeds 10 milliseconds, performance might degrade due to retransmission of failover messages.

Failover and data link interruption avoidance

Failover and data link interruption avoidance is a network design practice that

- ensures failover links and data interfaces travel through different paths to decrease the chance that all interfaces fail at the same time
- prevents failover operation suspension when the failover link is down, and
- maintains network resilience by using proper connection scenarios.

Connection scenarios

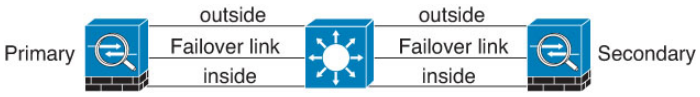
We recommend that failover links and data interfaces travel through different paths to decrease the chance that all interfaces fail at the same time. If the failover link is down, the failover operation is suspended until the health of the failover link is restored.

These connection scenarios help design a resilient failover network.

Scenario 1—Not recommended

If a single switch or a set of switches are used to connect both failover and data interfaces between two Firewall Threat Defense devices, then when a switch or inter-switch-link is down, both Firewall Threat Defense devices become active. Therefore, the two connection methods shown in these figures are **not** recommended.

Figure 115: Connecting with a single switch—not recommended



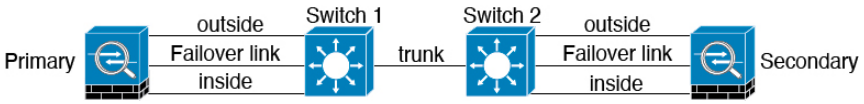


Figure 116: Connecting with a double-switch—not recommended

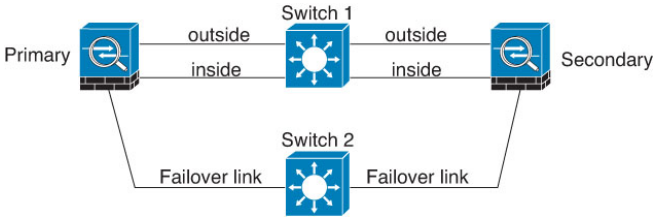
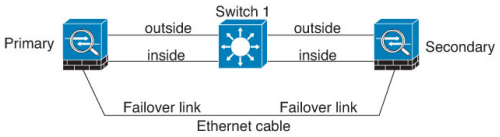
Scenario 2—Recommended

We recommend that failover links not use the same switch as the data interfaces. Instead, use a different switch or use a direct cable to connect the failover link, as shown in these figures.

Figure 117: Connecting with a different switch





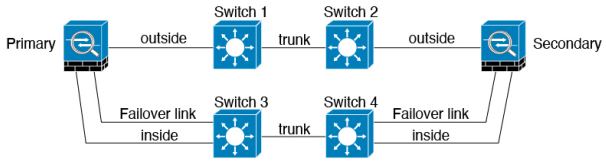


Figure 118: Connecting with a cable

Scenario 3—Recommended

If the Firewall Threat Defense data interfaces are connected to more than one set of switches, then a failover link can be connected to one of the switches, preferably the switch on the secure (inside) side of network, as shown in this figure.

Figure 119: Connecting with a secure switch

MAC addresses and IP addresses in High availability

MAC addresses and IP addresses in High availability are network addressing mechanisms that

- provide unique identification for network interfaces during failover scenarios
- maintain network connectivity when primary devices become unavailable, and
- ensure seamless traffic flow between active and standby configurations.

Address configuration types

When you configure your interfaces, you can specify an active IP address and a standby IP address on the same network. Generally, when a failover occurs, the new active unit takes over the active IP addresses and MAC addresses. Because network devices see no change in the MAC to IP address pairing, no ARP entries change or time out anywhere on the network.

Note Although recommended, the standby address is not required. Without a standby IP address, the active unit cannot perform network tests to check the standby interface health; it can only track the link state. You also cannot connect to the standby unit on that interface for management purposes.

The IP address and MAC address for the state link do not change at failover.

Active/standby configurations use specific address handling methods:

For Active/Standby High availability, see the following for IP address and MAC address usage during a failover event:

1. The active unit always uses the primary unit's IP addresses and MAC addresses.
2. When the active unit fails over, the standby unit assumes the IP addresses and MAC addresses of the failed unit and begins passing traffic.
3. When the failed unit comes back online, it is now in a standby state and takes over the standby IP addresses and MAC addresses.

However, if the secondary unit boots without detecting the primary unit, then the secondary unit becomes the active unit and uses its own MAC addresses, because it does not know the primary unit MAC addresses. When the primary unit becomes available, the secondary (active) unit changes the MAC addresses to those of the primary unit, which can cause an interruption in your network traffic. Similarly, if you swap out the primary unit with new hardware, a new MAC address is used.

If you disable high availability and set the failover configurations to a disabled state, you will need to manually resume high availability, or reboot the device. It is recommended to use the command **configure**

high-availability resume and resume the high availability instead of rebooting the device. If you reload the standby unit with the failover configuration disabled, the standby unit boots up as the active unit and uses the primary unit's IP addresses and MAC addresses. This leads to duplicate IP addresses and causes network traffic disruptions. Use the command **configure high-availability resume** to enable failover and restore the traffic flow.

Note If you enable failover on a standalone device, the data interfaces go down at negotiation state of failover, interrupting traffic.

Virtual MAC addresses guard against this disruption, because the active MAC addresses are known to the secondary unit at startup, and remain the same in the case of new primary unit hardware. We recommend that you configure the virtual MAC address on both the primary and secondary units to ensure that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit. If you do not configure virtual MAC addresses, you might need to clear the ARP tables on connected routers to restore traffic flow. The Firewall Threat Defense does not send gratuitous ARPs for static NAT addresses when the MAC address changes, so connected routers do not learn of the MAC address change for these addresses.

For Active/Active failover, see the following for IP address and MAC address usage during a failover event:

1. The primary unit autogenerates active and standby MAC addresses for all interfaces in failover group 1 and 2 contexts. You can also manually configure the MAC addresses if necessary, for example, if there are MAC address conflicts.
2. Each unit uses the active IP addresses and MAC addresses for its active failover group, and the standby addresses for its standby failover group. For example, the primary unit is active for failover group 1, so it uses the active addresses for contexts in failover group 1. It is standby for the contexts in failover group 2, where it uses the standby addresses.
3. When a unit fails over, the other unit assumes the active IP addresses and MAC addresses of the failed failover group and begins passing traffic.
4. When the failed unit comes back online, and you enabled the preempt option, it resumes the failover group.

Virtual MAC addresses provide specialized functionality:

The Firewall Threat Defense has multiple methods to configure virtual MAC addresses. We recommend using only one method. If you set the MAC address using multiple methods, the MAC address used depends on many variables, and might not be predictable.

For multi-instance capability, the FXOS chassis autogenerates only primary MAC addresses for all interfaces. You can overwrite the generated MAC address with a virtual MAC address with both the primary and secondary MAC addresses, but predefining the secondary MAC address is not essential; setting the secondary MAC address does ensure that to-the-box management traffic is not interrupted in the case of new secondary unit hardware.

MAC address table updates occur during failover events:

During failover, the device that is designated as the new active device generates multicast packets for each MAC address entry in the MAC table and sends them to all the bridge group interfaces. This action prompts the upstream switches in the bridge group to update their routing tables with the new active device's interface to ensure accurate traffic forwarding.

The time taken to generate multicast packets and update the routing tables of the upstream switches depends on the number of entries in the MAC address table and the number of bridge group interfaces. Use the **show failover statistics state-switch-delay** command to display statistics related to the delays encountered during failover events.

Stateful failover

A stateful failover is a high availability mechanism that

- continuously passes per-connection state information from the active unit to the standby unit
- maintains connection information after a failover occurs, and
- allows supported end-user applications to continue communication sessions without reconnecting.

Stateful failover operation

During Stateful Failover, the active unit continually passes per-connection state information to the standby unit. After a failover occurs, the same connection information is available at the new active unit. Supported end-user applications are not required to reconnect to keep the same communication session.

Supported features

Supported features are high availability capabilities that

- enable state information to be passed to the standby Firewall Threat Defense device during Stateful Failover
- maintain connection states and critical information for seamless traffic flow, and
- ensure minimal disruption during failover events.

State information types

For Stateful Failover, these state information types are passed to the standby device:

- NAT translation table.
- TCP and UDP connections and states, including HTTP connection states. Other types of IP protocols, and ICMP, are not parsed by the active unit, because they get established on the new active unit when a new packet arrives.
- Snort connection states, inspection results, and pin hole information, including strict TCP enforcement.
- The ARP table
- The Layer 2 bridge table (for bridge groups)
- The ISAKMP and IPsec SA table
- GTP PDP connection database
- SIP signaling sessions and pin holes.
- Static and dynamic routing tables—Stateful Failover participates in dynamic routing protocols, like OSPF and EIGRP, so routes that are learned through dynamic routing protocols on the active unit are maintained

in a Routing Information Base (RIB) table on the standby unit. Upon a failover event, packets travel normally with minimal disruption to traffic because the active secondary unit initially has rules that mirror the primary unit. Immediately after failover, the re-convergence timer starts on the newly active unit. Then the epoch number for the RIB table increments. During re-convergence, OSPF and EIGRP routes become updated with a new epoch number. Once the timer is expired, stale route entries (determined by the epoch number) are removed from the table. The RIB then contains the newest routing protocol forwarding information on the newly active unit.

Note Routes are synchronized only for link-up or link-down events on an active unit. If the link goes up or down on the standby unit, dynamic routes sent from the active unit may be lost. This is normal, expected behavior.

- DHCP Server—DHCP address leases are not replicated. However, a DHCP server configured on an interface will send a ping to make sure an address is not being used before granting the address to a DHCP client, so there is no impact to the service. State information is not relevant for DHCP relay or DDNS.
- Access control policy decisions—Decisions related to traffic matching (including URL, URL category, geolocation, and so forth), intrusion detection, malware, and file type are preserved during failover. However, for connections being evaluated at the moment of failover, there are the following caveats:
  - AVC—App-ID verdicts are replicated, but not detection states. Proper synchronization occurs as long as the App-ID verdicts are complete and synchronized before failover occurs.
  - Intrusion detection state—Upon failover, once mid-flow pickup occurs, new inspections are completed, but old states are lost.
  - File malware blocking—The file disposition must become available before failover.
  - File type detection and blocking—The file type must be identified before failover. If failover occurs while the original active device is identifying the file, the file type is not synchronized. Even if your file policy blocks that file type, the new active device downloads the file.
- User identity decisions from the identity policy, including the user-to-IP address mappings gathered passively through ISE Session Directory, and active authentication through captive portal. Users who are actively authenticating at the moment of failover might be prompted to authenticate again.
- Network AMP—Cloud lookups are independent from each device, so failover does not affect this feature in general. Specifically:
  - Signature Lookup—If failover occurs in the middle of a file transmission, no file event is generated and no detection occurs.
  - File Storage—If failover occurs when the file is being stored, it is stored on the original active device. If the original active device went down while the file was being stored, the file does not get stored.
  - File Pre-classification (Local Analysis)—If failover occurs in the middle of pre-classification, detection fails.
  - File Dynamic Analysis (Connectivity to the cloud)—If failover occurs, the system might submit the file to the cloud.

  - Archive File Support—If failover occurs in the middle of an analysis, the system loses visibility into the file/archive.
  - Custom Blocking—If failover occurs, no events are generated.
- Security Intelligence decisions. However, DNS-based decisions that are in process at the moment of failover are not completed.
- RA VPN—Remote access VPN end users do not have to reauthenticate or reconnect the VPN session after a failover. However, applications operating over the VPN connection could lose packets during the failover process and not recover from the packet loss.
- From all the connections, only established ones will be replicated on the Standby device.

Unsupported features

Unsupported features are device capabilities that

- are not passed to the standby Firewall Threat Defense in Stateful Failover
- do not maintain state information during failover events, and
- may require re-establishment after a failover occurs.

State information limitations

For Stateful Failover, the following state information is not passed to the standby Firewall Threat Defense:

- Sessions in plaintext tunnels other than GREv0 and IPv4-in-IP. Sessions inside tunnels are not replicated and the new active node will not be able to reuse existing inspection verdicts to match the correct policy rules.
- Decrypted TLS/SSL connections—The decryption states are not synchronized, and if the active unit fails, then decrypted connections will be reset. New connections will need to be established to the new active unit. Connections that are not decrypted (in other words, those that match a TLS/SSL Do Not Decrypt rule action) are not affected and are replicated correctly.
- Multicast routing.

Bridge group requirements for high availability

Bridge group requirements for high availability are special considerations that

- address traffic loss on bridge group member interfaces during failover
- prevent switch ports from entering blocking state for 30 to 50 seconds, and
- provide workarounds to maintain connectivity during topology changes.

High availability workarounds

There are special considerations for high availability when using bridge groups.

When the active unit fails over to the standby unit, the switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss on the

bridge group member interfaces while the port is in a blocking state, you can configure one of the following workarounds:

- Switch port is in Access mode—Enable the STP PortFast feature on the switch:

```
interface interface_id
  spanning-tree portfast
```

  The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, it eventually transitions into STP blocking mode.

- If the switch port is in Trunk mode, or you cannot enable STP PortFast, then you can use one of the following less desirable workarounds that impacts failover functionality or STP stability:
  - Disable interface monitoring on the bridge group and member interfaces.
  - Increase the interface hold time in the failover criteria to a high value that will allow STP to converge before the unit fails over.
  - Decrease the STP timers on the switch to allow STP to converge faster than the interface hold time.

Failover health monitoring

Failover health monitoring is a system capability that monitors each unit for overall health and interface health.

Health monitoring tests

The Firewall Threat Defense device performs tests to determine the state of each unit. This section includes information about how the Firewall Threat Defense device performs tests to determine the state of each unit.

Unit health monitoring

Unit health monitoring is a failover mechanism that

- determines the health of peer units by monitoring the failover link with hello messages
- sends LANTEST messages on each data interface when three consecutive hello messages are missed, and
- initiates appropriate failover actions based on peer unit responsiveness.

Unit health monitoring behavior

The Firewall Threat Defense device determines the health of the other unit by monitoring the failover link with hello messages. If a unit does not receive three consecutive hello messages on the failover link, the sends LANTEST messages on each data interface, including the failover link, to validate whether the peer is responsive. The action that the Firewall Threat Defense device takes depends on the response from the other unit. These are the possible actions:

- If the Firewall Threat Defense device receives a response on the failover link, then it does not fail over.
- If the Firewall Threat Defense device does not receive a response on the failover link, but it does receive a response on a data interface, then the unit does not failover. The failover link is marked as failed. You

should restore the failover link as soon as possible because the unit cannot fail over to the standby while the failover link is down.

- If the Firewall Threat Defense device does not receive a response on any interface, then the standby unit switches to active mode and classifies the other unit as failed.

Note During a high-availability failover event, the Firewall Threat Defense device device may briefly appear as **Offline** in the device's health monitoring dashboard. This happens because health alerts are cleared during the process and are only updated after the process is complete. Wait for the failover operation to finish.

Heartbeat module redundancy

Heartbeat module redundancy is a high availability feature that

- sends heartbeat messages using the data plane transport infrastructure to supplement control plane heartbeat packets
- increments a counter when the peer receives heartbeat packets in the data plane
- prevents false failover or split-brain scenarios when the control plane is congested with traffic.

Heartbeat module redundancy behavior

Each unit in the HA periodically sends a broadcast keepalive heartbeat packet over the failover link. If the control plane is too busy handling traffic, sometimes the heartbeat packets do not reach the peers, or the peers do not process the heartbeat packets due to CPU overloading. When peers cannot communicate the keepalive status within the configurable timeout period, a false failover or split-brain scenario occurs.

The heartbeat module in the data plane helps to avoid the occurrence of false failover or split-brain due to traffic congestion in the control plane.

- The additional heartbeat module works similarly to the control plane module but sends and receives heartbeat messages using the data plane transport infrastructure.
- When the peer receives heartbeat packets in the data plane, a counter gets incremented.
- If the heartbeat transfer in the control plane fails, the node checks the heartbeat counter in the data plane. If the counter is incrementing, then the peer is alive, and the cluster does not perform a failover in this situation.

Note

- The additional heartbeat module is enabled by default whenever HA is enabled. You do not have to set a poll interval for the additional heartbeat module in the data plane. This module uses the same heartbeat interval that you set for the control plane.

Interface monitoring

Interface monitoring is a failover capability that

- tracks the health of up to 1025 interfaces to detect interface failures

- performs interface tests when hello messages are not received within 15 seconds, and
- triggers failover when the number of failed interfaces meets the defined threshold.

Interface monitoring operation

When a unit does not receive hello messages on a monitored interface for 15 seconds, it runs interface tests. If one of the interface tests fails for an interface, but this same interface on the other unit continues to successfully pass traffic, then the interface is considered to be failed, and the device stops running tests.

If the threshold you define for the number of failed interfaces is met (see **Devices** > **Device Management**, and then **High Availability** > **Failover Trigger Criteria**), and the active unit has more failed interfaces than the standby unit, then a failover occurs. If an interface fails on both units, then both interfaces go into the "Unknown" state and do not count towards the failover limit defined by failover interface policy.

An interface becomes operational again if it receives any traffic. A failed device returns to standby mode if the interface failure threshold is no longer met.

If an interface has IPv4 and IPv6 addresses configured on it, the device uses the IPv4 addresses to perform the health monitoring. If an interface has only IPv6 addresses configured on it, then the device uses IPv6 neighbor discovery instead of ARP to perform the health monitoring tests. For the broadcast ping test, the device uses the IPv6 all nodes address (FE02::1).

Interface tests

Interface tests are monitoring mechanisms that:

- evaluate interface operational status during failover scenarios
- run sequentially with approximately 1.5 second duration per test, and
- determine interface failure status on Firewall Threat Defense device units.

Interface test sequence

The Firewall Threat Defense device uses these interface tests in sequence:

1. Link Up/Down test—A test of the interface status. If the Link Up/Down test indicates that the interface is down, then the device considers it failed, and testing stops. If the status is Up, then the device performs the Network Activity test.
2. Network Activity test—A received network activity test. At the start of the test, each unit clears its received packet count for its interfaces. As soon as a unit receives any eligible packets during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then the device starts the ARP test.
3. ARP test—A test for successful ARP replies. Each unit sends a single ARP request for the IP address in the most recent entry in its ARP table. If the unit receives an ARP reply or other network traffic during the test, then the interface is considered operational. If the unit does not receive an ARP reply, then the device sends a single ARP request for the IP address in the *next* entry in the ARP table. If the unit receives an ARP reply or other network traffic during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic, and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then the device starts the Broadcast Ping test.

4. Broadcast Ping test—A test for successful ping replies. Each unit sends a broadcast ping, and then counts all received packets. If the unit receives any packets during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic, and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then testing starts over again with the ARP test. If both units continue to receive no traffic from the ARP and Broadcast Ping tests, then these tests will continue running in perpetuity.

Interface status

Interface status is a monitoring indicator that

- shows the current operational state of monitored interfaces in a failover configuration
- tracks traffic reception and hello packet communication between peer units, and
- determines whether an interface is actively monitored by the failover process.

Interface status types

Monitored interfaces can have these status types:

- **Unknown**: Initial status. This status can also mean the status cannot be determined.
- **Normal**: The interface is receiving traffic.
- **Normal (Waiting)**: The interface is up, but has not yet received a hello packet from the corresponding interface on the peer unit.
- **Normal (Not-Monitored)**: The interface is up, but is not monitored by the failover process.
- **Testing**: Hello messages are not heard on the interface for five poll times.
- **Link Down**: The interface or VLAN is administratively down.
- **Link Down (Waiting)**: The interface or VLAN is administratively down and has not yet received a hello packet from the corresponding interface on the peer unit.
- **Link Down (Not-Monitored)**: The interface or VLAN is administratively down, but is not monitored by the failover process.
- **No Link**: The physical link for the interface is down.
- **No Link (Waiting)**: The physical link for the interface is down and has not yet received a hello packet from the corresponding interface on the peer unit.
- **No Link (Not-Monitored)**: The physical link for the interface is down, but is not monitored by the failover process.
- **Failed**: No traffic is received on the interface, yet traffic is heard on the peer interface.

Failover triggers and detection timing

Failover triggers and detection timing are high availability mechanisms that:

- initiate automatic switchover when specific failure conditions occur on the active unit,

- monitor system health through configurable detection thresholds and timing parameters, and
- ensure service continuity by transferring control to the standby unit when failures exceed defined limits.

Failover triggering events and timing parameters

These events trigger failover in a Firepower high availability pair:

- More than 50% of the Snort instances on the active unit are down.
- Disk space on the active unit is more than 90% full.
- The **no failover active** command is run on the active unit or the **failover active** command is run on the standby unit.
- The active unit has more failed interfaces than the standby unit.
- Interface failure on the active device exceeds the threshold configured.

  By default, failure of a single interface causes failover. You can change the default value by configuring a threshold for the number of interfaces or a percentage of monitored interfaces that must fail for the failover to occur. If the threshold is exceeded on the active device, failover occurs. If the threshold is exceeded on the standby device, the unit moves to **Fail** state.

  To change the default failover criteria, enter this command in global configuration mode:

Table 24: Interface policy command

Command	Purpose
failover interface-policy num [%] `hostname (config)# failover interface-policy 20%`	Changes the default failover criteria. When specifying a specific number of interfaces, the *num* argument can be from 1 to 250. When specifying a percentage of interfaces, the *num* argument can be from 1 to 100.

This table shows the failover triggering events and associated failure detection timing. If failover occurs, you can view the reason for the failover in the Message Center, along with various operations pertaining to the high availability pair. You can configure these thresholds to a value within the specified minimum-maximum range.

Table 25: Firewall Threat Defense failover times

Failover triggering event	Minimum	Default	Maximum
Active unit loses power, hardware goes down, or the software reloads or crashes. When any of these occur, the monitored interfaces or failover link do not receives any hello message.	800 milliseconds	15 seconds	45 seconds
Active unit interface physical link down.	500 milliseconds	5 seconds	15 seconds
Active unit interface up, but connection problem causes interface testing.	5 seconds	25 seconds	75 seconds

Active/standby failover

Active/standby failover is a high availability configuration that

- lets you use a standby Firewall Threat Defense device to take over the functionality of a failed unit,
- enables the standby unit to become the active unit when the active unit fails, and
- allows the failed unit to come back online as the standby unit if the problem is temporary.

The failed unit must be replaced if the problem is not temporary. Set the standby unit to primary before replacing the failed unit to retain the configuration of the secondary unit.

For multiple context mode, the ASA can fail over the entire unit (including all contexts) but cannot fail over individual contexts separately.

Primary/secondary roles and active/standby status

Primary/secondary roles and active/standby status are failover configuration concepts that

- define unit hierarchy, with primary units taking precedence during simultaneous startup
- determine IP address and MAC address usage patterns during failover operations, and
- establish traffic flow responsibilities between paired units in Active/Standby failover configurations.

Primary and secondary unit differences

When setting up Active/Standby failover, you configure one unit to be primary and the other to be secondary. During configuration, the primary unit's policies are synchronized to the secondary unit. At this point, the two units act as a single device for device and policy configuration. However, for events, dashboards, reports and health monitoring, they continue to display as separate devices.

The main differences between the two units in a failover pair are related to which unit is active and which unit is standby, namely which IP addresses to use and which unit actively passes traffic.

However, a few differences exist between the units depending on which unit is primary (as specified in the configuration) and which unit is secondary:

- The primary unit always becomes the active unit if both units start up at the same time (and are of equal operational health).
- The primary unit MAC addresses are always coupled with the active IP addresses. The exception to this rule occurs when the secondary unit becomes active and cannot obtain the primary unit MAC addresses over the failover link. In this case, the secondary unit MAC addresses are used.

Active unit determination at startup

Active unit determination at startup is a high availability process that

- sets a unit to standby if it boots and detects a peer already running as active,
- sets a unit to active if it boots and does not detect a peer, and
- sets the primary unit as active and secondary unit as standby if both units boot simultaneously.

Failover events

A failover event is a system condition that

- triggers an active unit to transfer control to a standby unit in Active/Standby failover configurations
- occurs on a unit basis, and
- follows specific failover policies that determine whether failover occurs and what actions each unit takes.

Failover event policies and actions

This table shows the failover action for each failure event. For each failure event, the table shows the failover policy (failover or no failover), the action taken by the active unit, the action taken by the standby unit, and any special notes about the failover condition and actions.

Table 26: Failover events

Failure Event	Policy	Active Unit Action	Standby Unit Action	Notes
Active unit failed (power or hardware)	Failover	n/a	Become active Mark active as failed	No hello messages are received on any monitored interface or the failover link.
Formerly active unit recovers	No failover	Become standby	No action	None.
Standby unit failed (power or hardware)	No failover	Mark standby as failed	n/a	When the standby unit is marked as failed, then the active unit does not attempt to fail over, even if the interface failure threshold is surpassed.
Failover link failed during operation	No failover	Mark failover link as failed	Mark failover link as failed	You should restore the failover link as soon as possible because the unit cannot fail over to the standby unit while the failover link is down.
Failover link failed at startup	No failover	Become active Mark failover link as failed	Become active Mark failover link as failed	If the failover link is down at startup, both units become active.
State link failed	No failover	No action	No action	State information becomes out of date, and sessions are terminated if a failover occurs.
Interface failure on active unit above threshold	Failover	Mark active as failed	Become active	None.
Interface failure on standby unit above threshold	No failover	No action	Mark standby as failed	When the standby unit is marked as failed, then the active unit does not attempt to fail over even if the interface failure threshold is surpassed.

Config-sync optimization

Config-sync optimization is a configuration synchronization enhancement that

- compares configuration hash values between active and joining devices to determine if full synchronization is necessary
- enables faster device rejoining by skipping full configuration synchronization when hash values match, and
- reduces maintenance window and upgrade time during high availability operations.

Guidelines and limitations of configuration sync optimization

When a device reboots or rejoins after a suspend or resume high availability, the joining device clears its running configuration. The active device then sends its entire configuration to the joining device for a full configuration synchronization. If the active device has a large configuration, this process can take several minutes.

The configuration sync optimization functionality enables comparing the configuration of the joining device and the active device by exchanging configuration hash values. If the hash computed on both active and joining devices match, the joining device skips full configuration synchronization and rejoin the high availability configuration. This functionality ensures faster peering and reduces maintenance window and upgrade time.

Guidelines and limitations:

- The configuration sync optimization functionality is enabled by default.
- Firewall Threat Defense multiple context mode supports configuration sync optimization by sharing the context order during full configuration synchronization, allowing comparison of context order during subsequent node-rejoin.
- If you configure passphrase and failover IPsec key, then configuration sync optimization is not effective as the hash value computed in the active and standby devices differs.
- If you configure the device with dynamic ACL or SNMPv3, configuration sync optimization is not effective.
- Active device synchronizes full configuration with flapping LAN links as default behavior. During failover flaps between active and standby devices, configuration sync optimization is not triggered and devices perform a full configuration synchronization.
- Configuration sync optimization gets triggered when the high availability configuration recovers from an interruption or loss of network communication between the active and standby devices.

Monitoring config-sync optimization:

- Syslog messages are generated displaying whether the hash values computed on the active and joining unit match, does not match, or if the operation timeout expires.
- The syslog message also displays the time elapsed, from the time of sending the hash request to the time of getting and comparing the hash response.

Note The Configuration State in **show failover state** command displays the config sync state status during HA joining. This state does not reflect the later config deployments or changes, and replication on device until a resync has been initiated.

Requirements and prerequisites for high availability

Guidelines for High availability

Model Support

- 1010:
  - You should not use the switch port functionality when using High availability. Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Though Firewall Management Center allows you to configure switch ports / VLAN interfaces in HA, it may lead to misconfiguration due to network loops when connecting to external switches.
  - You can only use a firewall interface as the failover link.
- Firepower 9300—Intra-chassis High Availability is not supported.
- The Firewall Threat Defense Virtual on public cloud networks such as Microsoft Azure and Amazon Web Services are not supported with High availability because Layer 2 connectivity is required.

Additional Guidelines

- When a device that is part of a Threat Defense HA pair with site-to-site VPN configuration is reverted to a previous version, re-establishing the HA pair or deployment may fail. In this scenarion, you must follow these steps:

  1. After the revert, choose **Devices** > **VPN** > **Site to Site**.
  2. Select the VPN topology associated with the HA device.
  3. Re-select the correct VPN interface for the affected device.
  4. Save the VPN topology.
  5. Deploy configuration on the device.
  6. Re-establish the HA pair.

- When the active unit fails over to the standby unit, the connected switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss while the port is in a blocking state, you can enable the STP PortFast feature on the switch:

  interface *interface_id* **spanning-tree portfast**

  This workaround applies to switches connected to both routed mode and bridge group interfaces. The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, the port eventually transitions into STP blocking mode.

- Configuring port security on the switches connected to the Firewall Threat Defense device failover pair can cause communication problems when a failover event occurs. This problem occurs when a secure MAC address configured or learned on one secure port moves to another secure port, a violation is flagged by the switch port security feature.

- For Active/Standby High availability and a VPN IPsec tunnel, you cannot monitor both the active and standby units using SNMP over the VPN tunnel. The standby unit does not have an active VPN tunnel, and will drop traffic destined for the NMS. You can instead use SNMPv3 with encryption so the IPsec tunnel is not required.

- Both the peer devices go into unknown state and high-availability configuration fails if you run clish in any of the peer devices while creating a High Availability pair.

- Immediately after failover, the source address of syslog messages will be the failover interface address for a few seconds.

- For better convergence (during a failover), you must shut down the interfaces on a HA pair that are not associated with any configuration or instance.

- In high availability deployments with a shared failover and state interfaces, if the connectivity over failover interface fails while the standby unit is in sync config state, and eventually when the standby unit switches to active state, it results in a split brain. This is observed even when there is a monitored interface.

  The connectivity over failover interface can fail in the following situations:

  - After the standby unit reboots, the connectivity over failover interface fails while the standby unit is in sync config state.

- After enabling previously disabled failover on the standby unit, the connectivity over failover interface fails while the standby unit is in sync config state.

To avoid split brain, use failover and state interfaces. If the connectivity failures over the failover interfaces persist, isolate the new active (previously standby) unit from the network.

- If you configure failover encryption in evaluation mode, the systems use DES for the encryption. If you then register the devices using an export-compliant account, the devices will use AES after a reboot. Thus, if a system reboots for any reason, including after installing an upgrade, the peers will be unable to communicate and both units will become the active unit. We recommend that you do not configure encryption until after you register the devices. If you do configure this in evaluation mode, we recommend you remove the encryption before registering the devices.
- When using SNMPv3 with failover, if you replace a failover unit, then SNMPv3 users are not replicated to the new unit. You must remove the users, re-add them, and then redeploy your configuration to force the users to replicate to the new unit.
- The device does not share SNMP client engine data with its peer.
- If you have a very large number of access control and NAT rules, the size of the configuration can prevent efficient configuration replication, resulting in the standby unit taking an excessively long time to reach standby ready state. This can also impact your ability to connect to the standby unit during replication through the console or SSH session. To enhance configuration replication performance, enable transactional commit for both access rules and NAT, using the **asp rule-engine transactional-commit access-group** and **asp rule-engine transactional-commit nat** commands.
- A unit in a High availability pair transitioning to the standby role synchronizes its clock with the active unit.

  Example:

```
firepower#show clock
01:00:52 UTC Mar 1 2022

...
01:01:18 UTC Mar 1 2022 <======= Incorrect (previous) clock
Cold Standby               Sync Config               Detected an Active mate

19:38:21 UTC Apr 9 2022 <======= Updated clock
Sync Config                Sync File System          Detected an Active mate
...
firepower/sec/stby#show clock
19:38:40 UTC Apr 9 2022
```

- The units in High availability do not dynamically synchronize the clock. Here are some examples of events when synchronization takes place:
  - A new High availability pair is created.
  - High availability is broken and re-created.
  - Communication over the failover link was disrupted and reestablished.
  - Failover status was manually changed at the CLI using the **no failover/failover** or **configure high-availability suspend/resume** (Firewall Threat Defense) commands.
- Enabling High availability forces all routes to be deleted and are re-added after the High availability progression changes to the Active state. You could experience connection loss during this phase.

- If you replace the primary unit, then when you re-create high-availability, you should set the replacement unit as the *secondary* unit so that the configurations are replicated from the former secondary unit to the replacement unit. If you set the replacement unit as primary, you will accidentally overwrite the configuration that is present on the operational unit.
- Configure identical strong encryption on both Threat Defense devices before forming the High availability. If they are non-identical, the HA peers may enter a split-brain state.
- Deploying Firepower 1100 and 2100 devices in high availability with hundreds of interfaces configured on them can result in increased delay in the failover time (seconds).
- In the High availability configuration, short-lived connections, usually using port 53, are closed quickly and never transferred or synchronized from Active to Standby, so there might be a difference in the number of connections on both High availability devices. This is expected behavior for short-lived connections. You can try to compare the connections that are long-lived (for example, more than 30-60 seconds).
- In the High availability configuration, embryonic connections—connection requests that have not yet completed the three-way handshake process—are closed quickly and not synchronized between the active and standby devices. This design ensures HA system efficiency and security. For this reason, there might be a difference in the number of connections on both High availability devices, which is to be expected.
- If the failover LAN link is not connected back-to-back and instead connected through one or more switches, a failure within the intermediate path can cause the active unit to lose connectivity with the standby unit, resulting in inconsistent active/standby states. Although this does not impact High availability functionality, it is recommended to check and recover the failover-link path between the active and standby units.

  When the failover LAN link is down, it is not recommended to deploy any configuration, as it may not be replicated to the peer unit.
- See the Secure Firewall Threat Defense Virtual getting started guides and review your Firewall Threat Defense Virtual device configurations for high availability.
- In OSPF, after a failover, the OSPF connection with the peer device becomes invalid. Terminate the invalid connection, and then establish a new OSPF connection.
- In transparent mode, if you have problems with the active unit losing the MAC address of the hot-standby router (HSRP), create a static mapping for the MAC address.
- UCAPL or CC compliance mode cannot be changed if the threat defense device is in high availability. Modify the compliance mode before forming the high availability pair.

Add a high availability pair

Establish an Active/Standby high-availability pair to ensure network protection continuity in case of device failure.

When establishing an Active/Standby high-availability pair, you designate one of the devices as primary and the other as secondary. The Firewall Management Center deploys a merged configuration to the paired devices. If there is a conflict, the primary device setting is used. In a multidomain deployment, devices in a high-availability pair must belong to the same domain.

Note The failover link and the stateful failover link are in a private IP space and are only used for communication between peers in a high-availability pair. After high availability is established, selected interface links and encryption settings cannot be modified without breaking the high-availability pair and reconfiguring it.

Caution Creating or breaking a high-availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129. The system warns you that continuing to create a high-availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Before you begin

Confirm that both devices:

- Are the same model.
- Have the same number and type of interfaces.
- Are in the same domain and group.
- Have normal health status and are running the same software.
- Are either in routed or transparent mode.

Note Only routed mode is supported for manager access on a data interface.

- Have the same NTP configuration. See Synchronize time on FTD devices, on page 908.
- Are fully deployed with no uncommitted changes.
- Do not have DHCP or PPPoE configured on any interfaces.
- For manager access on a data interface:
  - Use the same data interface on both devices for manager access.
  - Redundant manager access data interface is not supported.
  - You cannot use DHCP; only a static IP address is supported. Features that rely on DHCP cannot be used, including DDNS and zero-touch provisioning.

Note If you use zero-touch provisioning to register the device, when you use the outside interface for manager access, it uses DHCP by default. Before you can enable high availability, you need to change the IP address to a static address. See Change the device IP address, on page 763. Alternatively, you can use the Management interface instead; DHCP is supported on Management with high availability.

- Have different static IP addresses in the same subnet.
- Use the same manager configuration (**configure manager add** command) to ensure that the connectivity is the same.
- You cannot use the data interface as the failover or state link.

Note The high availability formation is possible between the two Firewall Threat Defense devices when the certificate available on the primary device is not present on the secondary device. When high availability is formed, the certificate will be synched on the secondary device.

Procedure

Step 1 Add both devices to the Firewall Management Center according to Registration with the management center, on page 32.

Step 2 Choose **Devices** > **Device Management**.

Step 3 From the **Add** drop-down menu, choose **High Availability**.

Step 4 Enter a display **Name** for the high-availability pair.

Step 5 Under **Device Type**, choose **Firepower Threat Defense**.

Step 6 Choose the **Primary Peer** device for the high-availability pair.

Step 7 Choose the **Secondary Peer** device for the high-availability pair.

Step 8 Click **Continue**.

Step 9 Under **LAN Failover Link**, choose an **Interface** with enough bandwidth to reserve for failover communications.

Note Only interfaces that do not have a logical name and do not belong to a security zone, will be listed in the **Interface** drop-down in the **Add High Availability Pair** dialog.

Step 10 Type any identifying **Logical Name**.

Step 11 Type a **Primary IP** address for the failover link on the active unit.

This address should be on an unused subnet.

Note 169.254.1.0/24 and fd00:0:0:*::/64 are internally used subnets and cannot be used for the failover or state links.

Step 12 Optionally, choose **Use IPv6 Address**.

Step 13 Type a **Secondary IP** address for the failover link on the standby unit. This IP address must be in the same subnet as the primary IP address.

Step 14 If IPv4 addresses are used, type a **Subnet Mask** that applies to both the primary and secondary IP addresses.

Step 15 Optionally, under **Stateful Failover Link**, choose the same **Interface**, or choose a different interface and enter the high availability configuration information.

Note 169.254.1.0/24 and fd00:0:0:*::/64 are internally used subnets and cannot be used for the failover or state links.

Step 16 (Optional) Choose **Enabled** and choose the **Key Generation** method for IPsec Encryption between the failover links.

Step 17 Click **OK**. This process takes a few minutes as the process synchronizes system data.

After a successful configuration, the high availability pair is established with one device as active and the other as standby. .

Note We recommend to back up the devices. You can use the backup to quickly replace the devices when they fail and to restore the high availability service without being delinked from the Firewall Management Center. For more information, see *Cisco Secure Firewall Management Center Administration Guide*.

Configure optional high availability parameters

You can view the initial High Availability Configuration on the Firewall Management Center. You cannot edit these settings without breaking the high availability pair and then re-establishing it. To edit these settings, you must first break the high availability pair and re-establish it. You can modify the Failover Trigger Criteria to improve failover results. Interface Monitoring helps you determine which interfaces are best suited for failover.

Configure standby IP addresses and interface monitoring

Configure standby IP addresses for high availability interfaces to enable the active unit to perform network tests and check standby interface health beyond just tracking link state.

For each interface, set a standby IP address. Although recommended, the standby address is not required. Without a standby IP address, the active unit cannot perform network tests to check the standby interface health; it can only track the link state.

By default, monitoring is enabled on all named physical interfaces and, for the 1010, all VLAN interfaces,. You might want to exclude interfaces attached to less critical networks from affecting your failover policy. Switch ports are not eligible for interface monitoring.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click the **Edit** ( ).

Step 3 Click the **High Availability** tab.

Step 4 In the **Monitored Interfaces** area, click the **Edit** (✎) next to the interface you want to edit.

Step 5 Check the **Monitor this interface for failures** check box.

Step 6 On the **IPv4** tab, enter the **Standby IP Address**.

This address must be a free address on the same network as the active IP address.

Step 7 If you configured the IPv6 address manually, on the **IPv6** tab, click the **Edit** (✎) next to the active IP address, enter the **Standby IP Address**, and click **OK**.

This address must be a free address on the same network as the active IP address. For autogenerated and **Enforce EUI 64** addresses, the standby address is automatically generated.

Step 8 Click **OK**.

Edit high availability failover criteria

This task allows you to customize failover criteria for high availability device pairs to match your specific network deployment requirements.

You can customize failover criteria based on your network deployment.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click the **Edit** (✎).

Step 3 Choose **High Availability**.

Step 4 Next to **Failover Trigger Criteria**, click the **Edit** (✎).

Step 5 Under **Interface Failure Threshold**, choose the number or percentage of interfaces that must fail before the device fails over.

Step 6 Under **Hello packet Intervals**, choose how often hello packets are sent over the failover link.

Note If you use remote access VPN on the Firepower 2100, use the default hello packet intervals. Otherwise, you might see high CPU usage that can cause a failover to occur.

Step 7 Click **OK**.

Configure virtual MAC addresses

Configure active and standby MAC addresses to minimize loss of traffic during failover and provide redundancy against IP address mapping for failover.

You can configure active and standby MAC addresses for failover using the following methods in the Secure Firewall Management Center:

- From the **Advanced tab** on the **Edit Interface** page during interface configuration; see Configure the MAC address, on page 718.
- From the **Add Interface MAC Address** dialog-box which is accessed from the **High Availability** page; see this procedure.

Note To configure the MAC address in both primary and secondary units (so that the MAC address is transferred to all sub-interfaces to both the high-availability units), the recommended approach is to use the **Interfaces** tab to replicate the MAC addresses on sub-interfaces over both active and standby high-availability units.

If you configure active and standby MAC addresses in both locations, the addresses defined during interface configuration take precedence for failover.

You can minimize loss of traffic during failover by designating active and standby MAC addresses to the physical interface. This feature offers redundancy against IP address mapping for failover.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Click **High Availability**.

Step 4 Click the **Add** ( ) icon next to Interface MAC Addresses.

Step 5 Choose a **Physical Interface**.

Step 6 Enter the **Active Interface MAC Address**.

Step 7 Enter the **Standby Interface MAC Address**.

Step 8 Click **OK**.

Note For detailed information, see Task 2, steps from 10 to 14 in Configure FTD High Availability on Firepower Appliances.

Manage High availability

This section describes how to manage High availability units after you enable High availability, including how to change the High availability setup and how to force failover from one unit to another.

Switch the Active Peer in the Firewall Threat Defense High Availability Pair

This task allows you to manually switch the active and standby units in a high availability pair, effectively forcing failover for reasons such as persistent fault or health events on the current active unit.

After you establish the Firewall Threat Defense high availability pair, you can manually switch the active and standby units, effectively forcing failover for reasons such as persistent fault or health events on the current active unit. Both units should be fully deployed before you complete this procedure.

Before you begin

Refresh node status for a single Firewall Threat Defense high availability pair, on page 312. This ensures that the status on the Firewall Threat Defense high availability device pair is in sync with the status on the Firewall Management Center.

Follow these steps to switch the active peer in the high availability pair:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high availability pair where you want to change the active peer, click the **Switch Active Peer**.

Step 3 Choose an option:

- Click **Yes** to immediately make the standby device the active device in the high availability pair.
- Click **No** to cancel and return to the Device Management page.

Refresh node status for a single Firewall Threat Defense high availability pair

Refresh the high availability node status to obtain accurate information about the active and standby device in a high availability pair when communication issues result in out of sync data.

Whenever active or standby devices in the Firewall Threat Defense high availability pair are rebooted, the Firewall Management Center may not display accurate high availability status for either device. This is because when the device reboots, the high availability status is immediately updated on the device and its corresponding event is sent to the Firewall Management Center. However, the status may not be updated on the Firewall Management Center because the communication between the device and the Firewall Management Center is yet to be established.

Communication failures or weak communication channels between the Firewall Management Center and devices may result in out of sync data. When you switch the active and standby devices in a high availability pair, the change may not be reflected in the Firewall Management Center even after a significant time duration.

In these scenarios, you can refresh the high availability node status to obtain accurate information about the active and standby device in a high availability pair.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high availability pair where you want to refresh the node status, click the **Refresh HA Node Status**.

Step 3 Click **Yes** to refresh the node status.

Suspend and resume high availability

You can suspend a unit in a high-availability pair, which is useful when:

- Both units are in an active-active situation, and fixing the communication on the failover link does not correct the problem.
- You want to troubleshoot an active or standby unit and do not want the units to fail over during that time.

When you suspend high availability, the currently active device remains active and continues handling all user connections. However, failover criteria are no longer monitored, and the system will never fail over to the now pseudo-standby device.

When using a data interface for manager access, the management connection will be broken until after you resume.

The primary difference between suspending high availability and breaking high availability is that on a suspended high-availability device, the high-availability configuration is retained. When you break high availability, the configuration is erased. Thus, you have the option to resume high availability on a suspended system, which enables the existing configuration and makes the two devices function as a failover pair again.

To suspend high availability, use the **configure high-availability suspend** command.

```
> configure high-availability suspend
Please ensure that no deployment operation is in progress before suspending
high-availability.
Please enter 'YES' to continue if there is no deployment operation in
progress and 'NO' if you wish to abort: YES
Successfully suspended high-availability.
```

If you suspend high availability from the active unit, the configuration is suspended on both the active and standby units. The standby unit interface configuration is also erased. If you suspend it from the standby unit, it is suspended on the standby unit only, but the active unit will not attempt to fail over to a suspended unit.

To resume failover, use the **configure high-availability resume** command.

```
> configure high-availability resume
Successfully resumed high-availablity.
```

You can resume a unit only if it is in Suspended state. The unit will negotiate active/standby status with the peer unit.

Note Suspending high availability is a temporary state. If you reload a unit, it resumes the high-availability configuration automatically and negotiates the active/standby state with the peer.

Replace a unit in Firewall Threat Defense high availability pair

This reference explains the process for replacing a failed unit in a Firewall Threat Defense high availability pair, including both backup restore and manual replacement procedures.

To replace a failed unit in the Firewall Threat Defense high availability pair using a backup file, see *Restoring Firewall Management Centers and Managed Devices* in the *Cisco Secure Firewall Management Center Administration Guide*.

If you do not have a backup of the failed device, you must break high availability. Then, register the replacement device to the Secure Firewall Management Center and reestablish high availability. The process varies depending on whether the device is primary or secondary:

- Replace a Primary Firewall Threat Defense HA Unit with no Backup, on page 314
- Replace a Secondary Firewall Threat Defense HA Unit with no Backup, on page 315

Replace a Primary Firewall Threat Defense HA Unit with no Backup

This task replaces a failed primary unit in a Firewall Threat Defense high availability pair to restore redundancy and maintain network protection.

Follow these steps below to replace a failed primary unit in the Firewall Threat Defense high availability pair. Failing to follow these steps can overwrite the existing high availability configuration.

Caution Creating or breaking the Firewall Threat Defense high availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129. The system warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Caution Never move a disk from sensor or Firewall Management Center to another device without reimaging the disk. This is an unsupported configuration and can cause breakage in functionality.

Procedure

Step 1 Choose **Force Break** to separate the high availability pair; see Break a high availability pair, on page 316.

Note The break operation removes all the configuration related to HA from Firewall Threat Defense and Firewall Management Center, and you need to recreate it manually later. To successfully configure the same HA pair, ensure that you save the IPs, MAC addresses, and monitoring configuration of all the interfaces/subinterfaces prior to executing the HA break operation.

Step 2 Unregister the failed primary Firewall Threat Defense device from the Firewall Management Center; see Delete (Unregister) a Device from the Firewall Management Center , on page 54.

Step 3 Register the replacement Firewall Threat Defense to the Firewall Management Center; see Registration with the management center, on page 32.

Step 4 Configure high availability, using the existing secondary/active unit as the primary device and the replacement device as the secondary/standby device during registration; see Add a high availability pair, on page 306.

Replace a Secondary Firewall Threat Defense HA Unit with no Backup

This task allows you to restore high availability functionality by replacing a failed secondary unit in an Firewall Threat Defense high availability pair.

When a secondary unit fails in a high availability configuration, you need to replace it and recreate the HA pair to maintain network redundancy and protection.

Caution Creating or breaking the Firewall Threat Defense high availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129. The system warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Procedure

Step 1 Choose **Force Break** to separate the high availability pair.

See Break a high availability pair, on page 316.

Note The break operation removes all the configuration related to HA from Firewall Threat Defense and Firewall Management Center, and you need to recreate it manually later. To successfully configure the same HA pair, ensure that you save the IPs, MAC addresses, and monitoring configuration of all the interfaces/subinterfaces prior to executing the HA break operation.

Step 2 Unregister the secondary Firewall Threat Defense device from the Firewall Management Center.

See Delete (Unregister) a Device from the Firewall Management Center , on page 54.

Step 3 Register the replacement Firewall Threat Defense to the Firewall Management Center.

See Registration with the management center, on page 32.

Step 4 Configure high availability, using the existing primary/active unit as the primary device and the replacement device as the secondary/standby device during registration.

See Add a high availability pair, on page 306.

Break a high availability pair

Break a high availability pair to remove the high-availability configuration from both units while maintaining traffic flow on the active unit.

When you break a high-availability pair, the high-availability configuration is removed from both units.

When using the Management interface for manager access: The active unit remains up and passing traffic. The standby unit interface configuration is erased.

When using a data interface for manager access: See the following details.

- The active unit remains up and passing traffic.
- The standby unit data interfaces are shut down except for the manager access interface, which remains up using the standby IP address so it can maintain the management connection.
- In a remote branch deployment setup, all standby unit data interfaces that are assigned with a logical name are shut down except for the manager access interface, which remains up to maintain the management connection.
- If the primary unit is in the standby state:
  - The IP addresses for manager access are swapped permanently in the Firewall Management Center configuration: the primary unit uses the standby IP address, and the secondary unit uses the active IP address.
  - If the Firewall Management Center initiated the management connection, and you specified a hostname for the device, then you need to update the DNS server so the swapped IP addresses are associated with the correct hostnames.
  - Breaking high availability causes a deployment to the standby unit. If the management connection is not yet reestablished because of the swapped IP addresses, the deployment may fail. In this case, you will need to manually trigger the deployment later (after the management connection is established). Be sure to complete the standby deployment before deploying changes to the active unit.

Policies that were not deployed to the active unit prior to the break operation continue to remain un-deployed after the break operation is complete. Deploy the policies on the standalone device after the break operation is complete.

Note

- When IPsec is enabled on high availability interfaces on the Firewall Threat Defense device, the device cannot prioritize the encrypted packets into the high-priority receive queue. As a result, during high-volume data traffic scenarios, attempts to break high availability may fail as the device cannot efficiently manage and prioritize the large number of encrypted connections. To view the device's resource usage and the maximum throughput, use the `show resource usage` command.
- If you cannot reach the high-availability pair using the Firewall Management Center, connect to the CLI on each device and enter **configure high-availability disable** to manually break high availability. See also Delete (Unregister) a High Availability Pair and Register to a New Firewall Management Center, on page 318.

Caution Breaking the Firewall Threat Defense high-availability pair immediately restarts the Snort process on the primary and secondary units, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Before you begin

- Refresh node status for a single Firewall Threat Defense high availability pair, on page 312. This ensures that the status on the high-availability pair is in sync with the status on the Firewall Management Center.

Follow these steps to break a high availability pair:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high-availability pair you want to break, click **More** (⋮) and choose **Break**.

Step 3 If the standby peer does not respond, check **Force Break**.

Step 4 Click **Yes**.

The Break operation removes the high-availability configuration from the active and standby units.

A FlexConfig policy deployed on the active unit may show a deployment failure after the break high-availability operation. You must alter and re-deploy the FlexConfig policy on the active unit.

What to do next

If you are using a FlexConfig policy on the active unit, alter and re-deploy the FlexConfig policy to eliminate deployment errors.

Note After you break high availability, the Firewall Threat Defense device that was operating as the active unit will still have the standby unit's IP address listed in its configuration. To resolve this, do an additional deployment on the formerly active Firewall Threat Defense device to remove the standby unit's IP address from its configuration.

Delete (Unregister) a High Availability Pair and Register to a New Firewall Management Center

This task allows you to unregister a High Availability pair from the Firewall Management Center, which keeps the High Availability pair intact. You might want to unregister the pair if you want to register it to a new Firewall Management Center or if the Firewall Management Center can no longer reach the pair.

Unregistering a High Availability pair:

- Severs all communication between the Firewall Management Center and the pair.
- Removes the pair from the **Device Management** page.
- Returns the pair to local time management if the pair's platform settings policy is configured to receive time from the Firewall Management Center using NTP.
- Leaves the configuration intact, so the pair continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the pair again to the same or a different Firewall Management Center causes the configuration to be removed, so the pair will stop processing traffic at that point; the High Availability configuration remains intact so you can add the pair as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

Before you begin

- This procedure requires CLI access to the primary unit.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the High Availability pair you want to unregister, click **More** (⋮) and choose **Delete**.

Step 3 Click **Yes**. The device High Availability pair is unregistered.

Step 4 You can register the pair to a new (or the same) Firewall Management Center by adding the primary unit as a new device.

a) Determine the primary unit by connecting to the CLI on one unit, and entering the **show failover** command.

The first line of the output shows whether this unit is Primary or Secondary.

```
> show failover
Failover unit Primary
Failover LAN Interface: failover GigabitEthernet0/2 (up)
```

```
Reconnect timeout 0:00:00
Unit Poll frequency 1 seconds, holdtime 15 seconds
Failover On

[...]
```

b) At the primary unit's CLI, identify the new Firewall Management Center using the **configure manager add** command. See Modify Firewall Threat Defense management interface settings at the CLI , on page 763.

c) Choose **Devices** > **Device Management**, and then click **Add** > **Device**.

You only need to add the primary unit as a device, and the Firewall Management Center will discover the secondary unit.

Monitoring High availability

Monitoring High availability is a system capability that enables you to view the High availability status.

View failover history

View the failover history of both high availability devices in a single view to understand the chronological order of failover events and their reasons.

You can view the failover history of both high availability devices in a single view. The history displays in chronological order and includes the reason for any failover.

Before you begin

Follow these steps to view failover history:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Choose **Summary**.

Step 4 Under General, click **View** ( ).

View stateful failover statistics

This task allows you to monitor the stateful failover link statistics to assess the performance and health of your high availability configuration.

You can view the stateful failover link statistics of both the primary and secondary devices in the high availability pair.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Choose **High Availability**.

Step 4 Under Stateful Failover Link, click **View** ( ).

Step 5 Choose a device to view statistics.

Troubleshoot configuration sync failure

When forming a failover pair, the joining unit clears its running configuration and replicates the entire configuration from the active unit. Upon completing full configuration sync, the joining unit assumes the standby ready role and establishes the failover pair. After the unit joins the failover pair, any configuration change on the active unit are also replicated on the standby unit to keep both the units synchronized.

If the standby unit fails to replicate any configuration change commands, it reports configuration sync failure and exit the high availability by disabling failover. This section describes steps for identifying and troubleshooting configuration sync failure error reported by the standby unit.

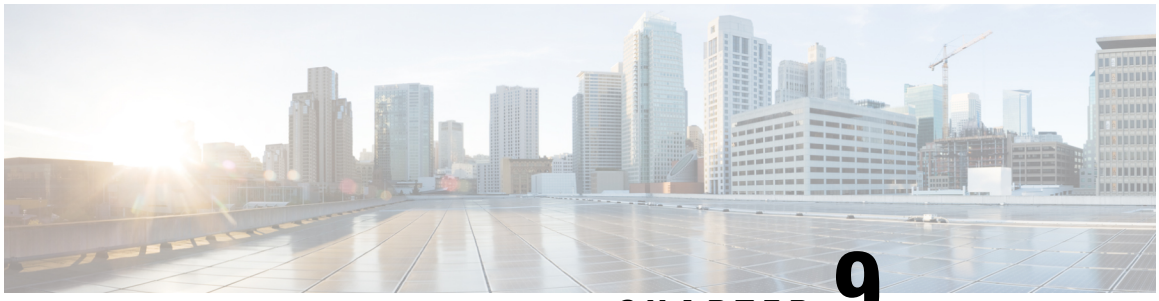
To view the configuration sync errors or stats, you can use these CLI commands through an SSH session or the Threat Defense CLI:

- **show failover config-sync errors all** to display all configuration synchronization errors related to failover.
- **show failover config-sync stats all** to view statistics regarding failover configuration synchronization.

To re-enable high availability:

- Re-enable failover by executing the **failover reset** command on the active unit.
- If re-enabling the failover is not successful, delete or update the configuration change that the standby unit failed to replicate, and then re-enable the failover.

Note If the maximum interface limit is reached, the number of VPN tunnels on the active and standby units may be inconsistent. In this situation run the**write standby**command on the active unit to sync the configuration.



History for high availability

This reference provides a chronological history of high availability features, enhancements, and improvements implemented across various software versions. The information helps you track the evolution of high availability capabilities and understand when specific features were introduced.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
High availability support for the manager access data interface	7.4	7.4	You can now use a data interface for manager access with Firewall Threat Defense high availability.
Unregistering a high-availability pair now allows you to re-register without breaking the pair	7.3	Any	When you DELETE (unregister) a high-availability pair, you no longer have to manually break the pair at the CLI and re-register standalone devices. You can now add the primary unit to a new Firewall Management Center, and the standby unit will be discovered automatically. Re-registering the pair will still erase the configuration, and your policies will need to be re-applied.
Policy rollback support for high availability	7.2	Any	The **configure policy rollback** command is supported for high availability.
Config-Sync Optimization feature for faster HA peering	7.2	Any	The Config-Sync Optimization feature enables comparing the configuration of the joining unit and the active unit by exchanging config-hash values. If the hash computed on both active and joining units match, the joining unit skips full config-sync and rejoin the HA. This feature enables faster HA peering and reduces maintenance window and upgrade time.
Improvements to the upgrade workflow for clustered and high-availability devices	7.1	Any	We made improvements to the upgrade workflow for clustered and high-availability devices: • The upgrade wizard now correctly displays clustered and high-availability units as groups, rather than as individual devices. The system can identify, report, and preemptively require fixes for group-related issues you might have. For example, you cannot upgrade a cluster on the Firepower 4100/9300 if you have made unsynced changes on Firepower Chassis Manager. • We improved the speed and efficiency of copying upgrade packages to clusters and high-availability pairs. Previously, the FMC copied the package to each group member sequentially. Now, group members can GET the package from each other as part of their normal sync process. • You can now specify the upgrade order of data units in a cluster. The control unit always upgrades last.
Clearing routes in a high-availability group or cluster.	7.1	Any	In previous releases, the **clear route** command cleared the routing table on the unit only. Now, when operating in a high-availability group or cluster, the command is available on the active or control unit only, and clears the routing table on all units in the group or cluster.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details

FTD High Availability Hardening	6.2.3	Any	Version 6.2.3 introduces features for FTD devices in high availability:
			• Whenever active or standby FTD devices in a high-availability pair restart, the FMC may not display accurate high-availability status for either managed device. However, the status may not upgrade on the FMC because the communication between the device and the FMC is not established yet. The **Refresh Node Status** option on the **Devices** > **Device Management** page allows you to refresh the high-availability unit status to obtain accurate information about the active and standby device in a high-availability pair.
			• The **Devices** > **Device Management** page of the FMC UI has a new **Switch Active Peer** icon.
			• Version 6.2.3 includes a new REST API object, **Device High Availability Pair Services**, that contains four functions:
			  • **DELETE ftddevicehapairs**
			  • **PUT ftddevicehapairs**
			  • **POST ftddevicehapairs**
			  • **GET ftddevicehapairs**

CHAPTER 9

Clustering: Secure Firewall 3100/4200

Clustering lets you group multiple Firewall Threat Defense nodes together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

Note Some features are not supported when using clustering. See Unsupported features with clustering, on page 370.

- Clustering for the Secure Firewall 3100/4200, on page 323
- Licenses for clustering, on page 325
- Prerequisites for clustering, on page 325
- Guidelines for clustering, on page 326

- Cluster node management, on page 351
- Monitor the cluster, on page 361
- Troubleshoot the cluster, on page 365
- Clustering examples, on page 368
- Reference for Clustering, on page 370
- History for Clustering, on page 382

Clustering for the Secure Firewall 3100/4200

This section describes the clustering architecture and how it works.

How a cluster fits into your network

The cluster consists of multiple firewalls acting as a single unit. To act as a cluster, the firewalls need the following infrastructure:

- Isolated, high-speed backplane network for intra-cluster communication, known as the *cluster control link*.
- Management access to each firewall for configuration and monitoring.

Infrastructure requirements

When you place the cluster in your network, the upstream and downstream routers need to be able to load-balance the data coming to and from the cluster using Spanned EtherChannels. Interfaces on multiple members of the cluster are grouped into a single EtherChannel; the EtherChannel performs load balancing between units.

Control and data node roles

One member of the cluster is the control node. If multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority. All other members are data nodes. When you first create the cluster, you specify which node you want to be the control node, and it will become the control node simply because it is the first node added to the cluster.

All nodes in the cluster share the same configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Cluster interfaces

You can configure data interfaces as Spanned EtherChannels. Refer Cluster interfaces, on page 331 for more information.

Interface type restrictions

- You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).
-

Note Individual interfaces are not supported, with the exception of a management interface.

Cluster control links

A cluster control link is a dedicated hardware interface that each unit must allocate for cluster communication. For more information, refer Cluster control link, on page 331.

Configuration replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management network

You must manage each node using the Management interface; management from a data interface is not supported with clustering.

Licenses for clustering

Lists the licensing requirements for clustering.

Feature license assignment

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the Firewall Management Center, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster by clicking **Edit Licenses** in **System** (⚙) > **Licenses** > **Smart Licenses** or choosing **Devices** > **Device Management**, clicking **Edit** (✎) for the cluster, and then in the **License** area, clicking **Edit** (✎).

APEX, PLUS, and VPN-Only licenses are not supported for clustering. Before you create a cluster, remove unsupported license assignments from the devices that will become cluster nodes.

Note If you add the cluster before the Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Prerequisites for clustering

Review these prerequisites before configuring clustering on Secure Firewall devices.

Model requirements

- Secure Firewall 3100—Maximum 8 nodes
- Secure Firewall 4200—Maximum 8 nodes

User roles

- Admin
- Access Admin
- Network Admin

Hardware and software requirements

- All units in a cluster must be the same model.
- All units must include the same number of interfaces and the same network modules, and must use the same network module slot assignments.
- The Firewall Management Center access must be from the Management interface; data interface management is not supported.
- All units must run the identical software except at the time of an image upgrade. Hitless upgrade is supported. For a cluster that uses centralized VPN, all units must run the same software version. After an upgrade or downgrade, complete the operation on all units and verify that every unit runs the target software version before you resume VPN traffic.
- All units must be in the same firewall mode, routed or transparent.
- All units must use the same compliance mode.
- If core allocation is supported, all units must use the same core allocation profile.
- All units must be in the same domain and the same group, with no deployment pending or in progress.
- The control node must not have any unsupported features configured (refer Unsupported features with clustering, on page 370), and data nodes must not have any VPN configured. The control node can have site-to-site VPN configured.

Note

- Clustering is not supported for Threat Defense instances, such as instances in container mode.
- All units must use the same compliance mode.
- If core allocation is supported, all units must use the same core allocation profile.

Switch requirements

Be sure to complete the switch configuration before you configure clustering. Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. By default, the cluster control link MTU is set to 100 bytes higher than the data interfaces. If the switches have an MTU mismatch, the cluster formation will fail.

Guidelines for clustering

Configuration requirements

Ensure that firewall mode configuration matches on all units in the cluster.

- High Availability is not supported with clustering.
- The cluster control link is only supported using IPv4.

Switch and EtherChannel configuration

Disable the LACP Graceful Convergence feature on all cluster-facing EtherChannel interfaces for Cisco Nexus switches.

Topology change management

When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Threat Defense device or the switch, adding an additional switch to form a VSS or vPC) you should disable the health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.

Operational considerations

Expect temporary, limited packet, or connection drop when adding a unit to an existing cluster or when reloading a unit.

- In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel, when the syslog server port is down and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the ASA cluster. These messages can result in some units of the ASA cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Default clustering settings

Review the default clustering configuration settings before deployment.

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Firewall Mode

The firewall mode must match on all units.

High Availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Switches

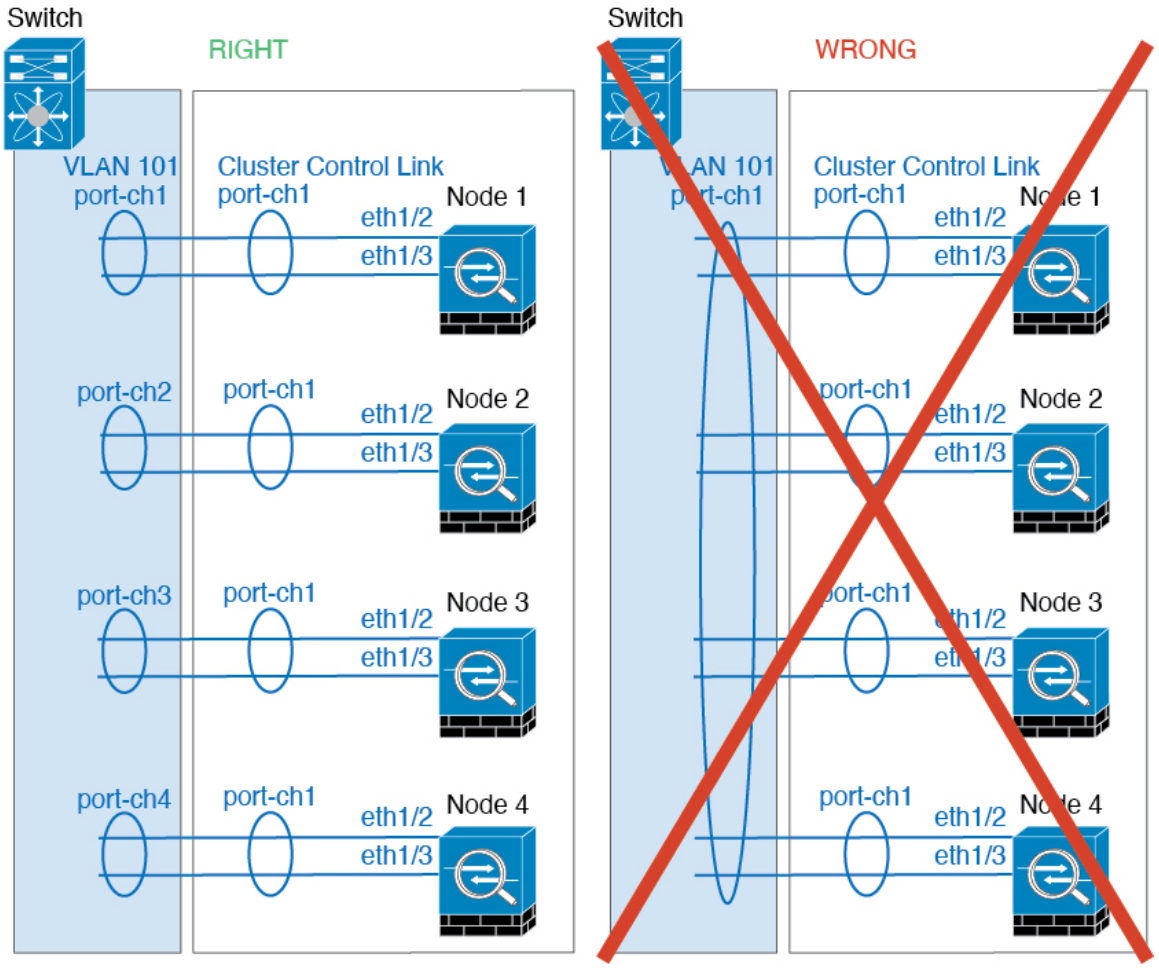
- Make sure connected switches match the MTU for both cluster data interfaces and the cluster control link interface. You should configure the cluster control link interface MTU to be at least 100 bytes higher than the data interface MTU, so make sure to configure the cluster control link connecting switch appropriately. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. In addition, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Cisco IOS XR systems, if you want to set a non-default MTU, set the IOS XR interface MTU to be 14 bytes higher than the cluster device MTU. Otherwise, OSPF adjacency peering attempts may fail unless the **mtu-ignore** option is used. Note that the cluster device MTU should match the IOS XR IPv4 MTU. This adjustment is not required for Cisco Catalyst and Cisco Nexus switches.
- On the switch, we recommend that you use one of these EtherChannel load-balancing algorithms: **source-dest-ip** or **src-dst-mixed-ip-port** (see the Cisco Nexus OS and Cisco IOS-XE **port-channel load-balance** command).

  Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the devices in a cluster.
- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.
- On Supervisor 2T EtherChannels, the default hash distribution algorithm is adaptive. To avoid asymmetric traffic in a VSS design, change the hash algorithm on the port-channel connected to the cluster device to fixed:

  router(config)# **port-channel** *id* **hash-distribution fixed**

  Do not change the algorithm globally; you may want to take advantage of the adaptive algorithm for the VSS peer link.
- On the switch(es) for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the cluster unit to speed up the join process for new units.
- Switches on the cluster control link path should not verify the L4 checksum. Redirected traffic over the cluster control link does not have a correct L4 checksum. Switches that verify the L4 checksum could cause traffic to be dropped.
- Port-channel bundling downtime should not exceed the configured keepalive interval.
- You should disable the LACP Graceful Convergence feature on all cluster-facing EtherChannel interfaces for Cisco Nexus switches.

EtherChannels



- In Catalyst 3750-X Cisco IOS software versions earlier than 15.1(1)S2, the cluster unit did not support connecting an EtherChannel to a switch stack. With default switch settings, if the cluster unit EtherChannel is connected cross stack, and if the control unit switch is powered down, then the EtherChannel connected

to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.

- Spanned vs. Device-Local EtherChannel Configuration—Be sure to configure the switch appropriately for Spanned EtherChannels vs. Device-local EtherChannels.
  - Spanned EtherChannels—For cluster unit Spanned EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.

  - Device-local EtherChannels—For cluster unit Device-local EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels on the switch; do not combine multiple cluster unit EtherChannels into one EtherChannel on the switch.

Additional guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Threat Defense or the switch, adding an additional switch to form a VSS or vPC) you should disable the health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel, when the syslog server port is down and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the ASA cluster. These messages can result in some units of the ASA cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a

new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Defaults for clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Clustering configuration

To add a cluster to the Firewall Management Center, add each node to the Firewall Management Center as a standalone unit, configure interfaces on the unit you want to make the control node, and then form the cluster.

Cluster interfaces

You can configure data interfaces as Spanned EtherChannels.

You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).

Each unit must also dedicate at least one hardware interface as the cluster control link.

Cluster control link

A cluster control link is a dedicated hardware interface that enables communication between cluster units and supports cluster operation coordination.

Each unit must dedicate at least one hardware interface as the cluster control link. We recommend using an EtherChannel for the cluster control link if available.

Cluster control link traffic

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Cluster control link interfaces and network

You can use any physical interface or EtherChannel for the cluster control link. You cannot use a VLAN subinterface as the cluster control link. You also cannot use the Management interface.

Each cluster control link has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

Note For a 2-member cluster, do not directly connect the cluster control link from one node to the other node. If you directly connect the interfaces, then when one unit fails, the cluster control link fails, and thus the remaining healthy unit fails. If you connect the cluster control link through a switch, then the cluster control link remains up for the healthy unit.

If you need to directly connect the units (for testing purposes, for example), configure and enable the cluster control link interface on both nodes before forming the cluster.

Size the cluster control link

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features.

For example:

- NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units.
- When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth.

A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

Note If your cluster has large amounts of asymmetric (rebalanced) traffic, then you should increase the cluster control link size.

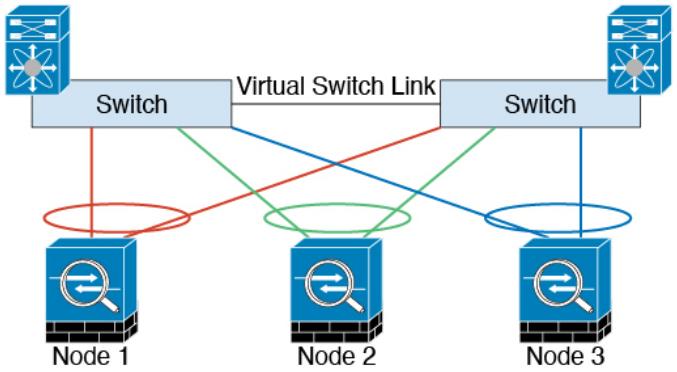
Cluster control link MTU ping testing

Use Cluster control link MTU ping testing to

- verify MTU compatibility between cluster nodes during the join process
- use ping-based fragmentation tests to confirm the network path supports proper packet handling, and
- allow nodes to join even if tests fail while providing diagnostic messages for troubleshooting MTU mismatches.

When a node joins the cluster, the control node send a ping with a payload size of twice the MTU. This process tests the network's ability to handle packet fragmentation because the underlying IP layer will fragment packets that exceed the MTU limit.

A successful ping confirms that the network path supports proper fragmentation and that the cluster control link can reliably process traffic at the configured MTU size.



If the ping fails, view these messages:

- **show cluster history**—`Event: CCL MTU test to unit name failed`
- Console WARNING—`WARNING: Unit name is not reachable in CCL jumbo frame ICMP test, please check cluster interface and switch MTU configuration`

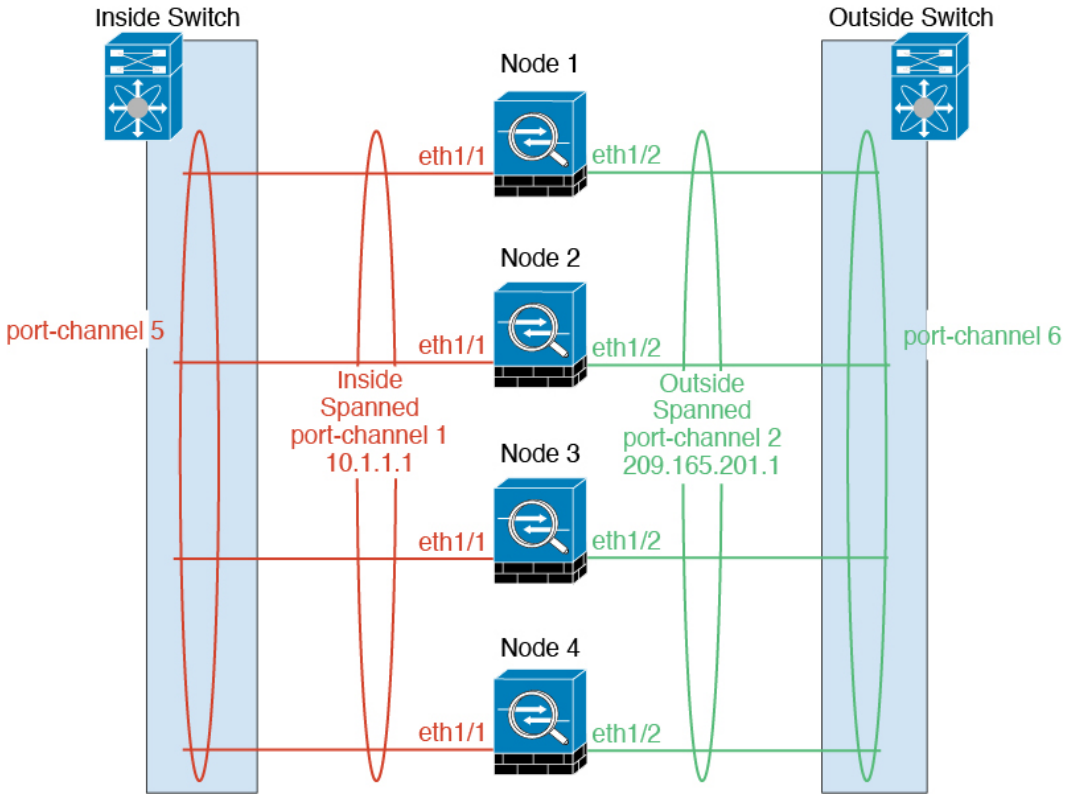
Even if the ping fails, the node is allowed to join the cluster. In this case, you need to resolve the MTU mismatch as soon as possible.

Cluster control link redundancy

The diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS), Virtual Port Channel (vPC), StackWise, or StackWise Virtual environment. All links in the EtherChannel are active. When the switch is part of a redundant system, then you can connect firewall interfaces within the same EtherChannel to separate switches in the redundant system. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a Spanned EtherChannel.

Cluster control link reliability for inter-chassis clustering

To ensure cluster control link functionality, be sure the round-trip time (RTT) between units is less than 20 ms. This maximum latency enhances compatibility with cluster members installed at different geographical sites. To check your latency, perform a ping on the cluster control link between units.



The cluster control link must be reliable, with no out-of-order or dropped packets; for example, for inter-site deployment, you should use a dedicated link.

Spanned EtherChannels

You can group one or more interfaces per chassis into an EtherChannel that spans all chassis in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

For regular firewall interfaces:A Spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the BVI, not to the bridge group member interface.

The EtherChannel inherently provides load balancing as part of basic operation.

Guidelines for maximum throughput

To achieve maximum throughput, follow these guidelines:

- Use a symmetric load-balancing hash algorithm, meaning that packets from both directions will have the same hash and will be sent to the same Firewall Threat Defense in the Spanned EtherChannel. We recommend using the source and destination IP address (the default) or the source and destination port as the hashing algorithm.
- Use the same type of line cards when connecting the Firewall Threat Defenses to the switch so that hashing algorithms applied to all packets are the same.

Load balancing

The EtherChannel link is selected using a proprietary hash algorithm, based on source or destination IP addresses and TCP and UDP port numbers.

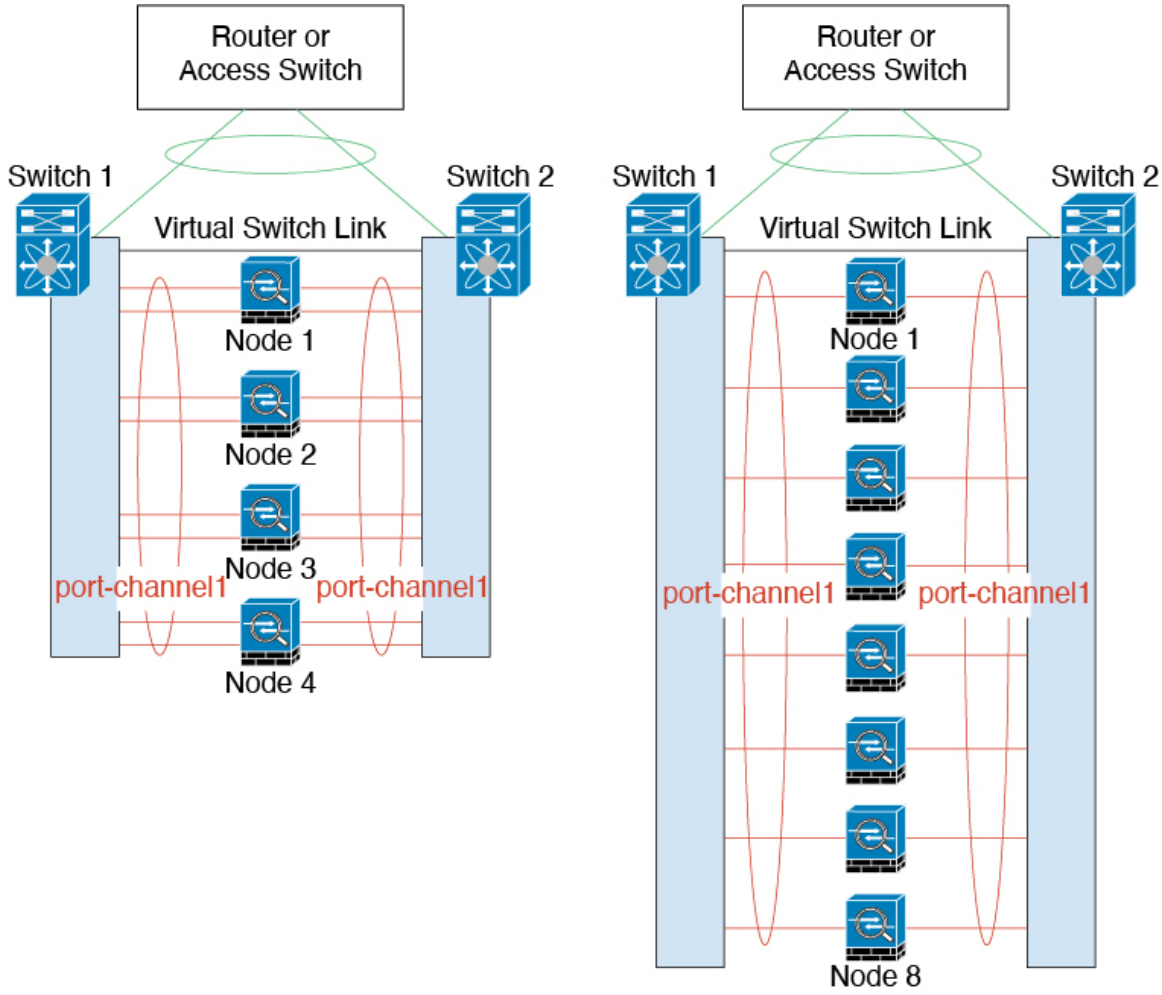
Note On the switch, we recommend that you use one of the following algorithms: **source-dest-IP** or **source-dest-IP-port** (see the Cisco Nexus OS or Cisco IOS **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the nodes in a cluster.

The number of links in the EtherChannel affects load balancing.

Symmetric load balancing is not always possible. If you configure NAT, then forward and return packets will have different IP addresses and/or ports. Return traffic will be sent to a different unit based on the hash, and the cluster will have to redirect most returning traffic to the correct unit.

EtherChannel redundancy

The EtherChannel has built-in redundancy. It monitors the line protocol status of all links. If one link fails, traffic is re-balanced between remaining links. If all links in the EtherChannel fail on a particular unit, but other units are still active, then the unit is removed from the cluster.



Connecting to a redundant switch system

You can include multiple interfaces per Firewall Threat Defense in the Spanned EtherChannel. Multiple interfaces per Firewall Threat Defense are especially useful for connecting to both switches in a VSS, vPC, StackWise, or StackWise Virtual system.

Depending on your switches, you can configure up to 32 active links in the spanned EtherChannel. This feature requires both switches in the vPC to support EtherChannels with 16 active links each (for example the Cisco Nexus 7000 with F2-Series 10 Gigabit Ethernet Module).

For switches that support 8 active links in the EtherChannel, you can configure up to 16 active links in the spanned EtherChannel when connecting to two switches in a redundant system.

This figure shows a 16-active-link spanned EtherChannel in a 4-node cluster and an 8-node cluster.

Cable and add devices to the Firewall Management Center

Before configuring clustering, you need to prepare your devices. In particular, the cluster will not come up unless all nodes can communicate over the cluster control link. Therefore, before you form the cluster, the cluster control link must be ready to go.

Procedure

Step 1 Cable the cluster control link network, management network, and data networks.

Step 2 Configure the upstream and downstream equipment.

a) For the cluster control link network, set the MTU to be at least 100 bytes higher than the data interface MTU.

By default, the data interface MTU is 1500 bytes, so the cluster control link MTU on the cluster node will be set to 1600 bytes. If you use higher MTUs on your data interfaces, increase the cluster control link MTU on connecting switches accordingly.

b) Configure cluster control link interfaces on upstream and downstream equipment, including for an optional EtherChannel.

For more information, refer to Cluster control link interfaces and network, on page 332 for cluster control link requirements.

c) Configure data interfaces on upstream and downstream equipment, including Spanned EtherChannels.

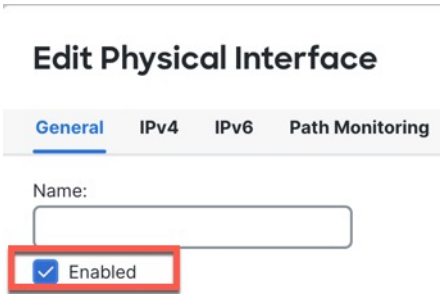
For more information, refer to Cluster interfaces, on page 331 for information about how to cable Spanned EtherChannels.

Step 3 Add each node to the Firewall Management Center as a standalone device in the same domain and group.

For more information, refer to Add a Device Using a Registration Key , on page 32.You can create a cluster with a single device, and then add more nodes later. The initial settings (licensing, access control policy) that you set when you add a device will be inherited by all cluster nodes from the control node. You will choose the control node when forming the cluster.

Step 4 Enable the cluster control link on the device you want to be the control node.

When you add the other nodes, they will inherit the cluster control link configuration.



Note Do *not* configure the name or IP addressing for the cluster control link. The MTU of the cluster control link interface is automatically set to 100 bytes more than the highest data interface MTU when you form the cluster, so you do not need to set it now. However, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation. If the MTU is set in this range when you add the cluster, we recommend returning to the **Interfaces** page and manually increasing it above 8362. When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size matching the cluster control link MTU. If the ping fails, a notification is generated so you can fix the MTU mismatch on connecting switches and try again.

a) On the device you want to be the control node, choose **Devices** > **Device Management**, and click **Edit** ( ).

b) Click **Interfaces**.

c) Enable the interface. If you are going to use an EtherChannel for the cluster control link, enable all members.For more information, refer to Enable the physical interface and configure Ethernet settings, on page 611.

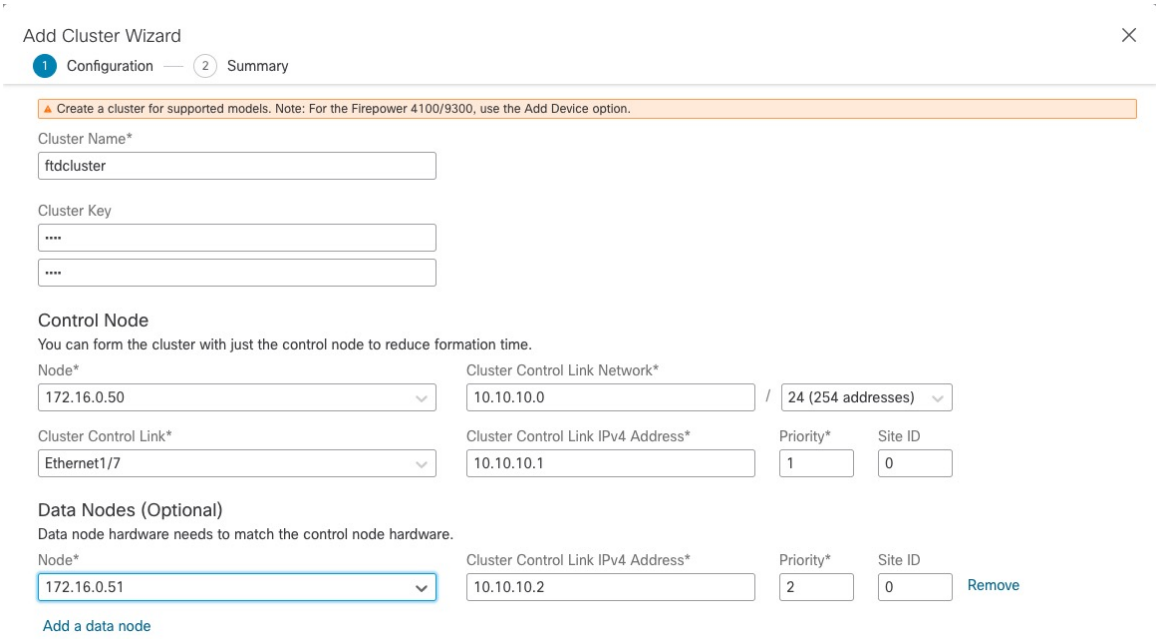
Figure 120: Enable the cluster control link interface

d) (Optional) Add an EtherChannel.For more information, refer to Configure an EtherChannel, on page 619.

We recommend using the On mode for cluster control link member interfaces to reduce unnecessary traffic on the cluster control link (Active mode is the default). The cluster control link does not need the overhead of LACP traffic because it is an isolated, stable network. **Note:** We recommend setting *data* EtherChannels to Active mode.

e) Click **Save** and then **Deploy** to deploy the interface changes to the control node.

Create a Cluster



Form a cluster from one or more devices in the Firewall Management Center.

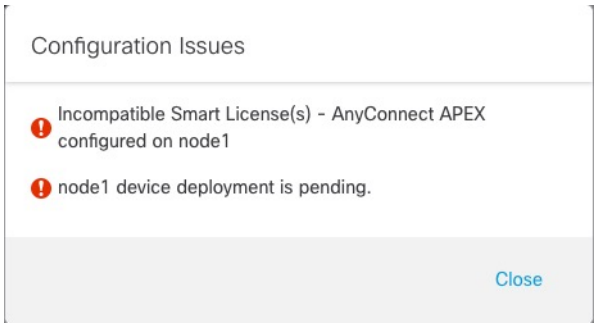
Procedure

Step 1 Choose **Devices** > **Device Management**, and then choose **Add** > **Cluster**.

The **Add Cluster Wizard** appears.

Figure 121: Add Cluster Wizard

Step 2 Specify a **Cluster Name** and an authentication **Cluster Key** for control traffic.



- **Cluster Name**—An ASCII string of 1 to 38 characters. The cluster name can contain only letters, digits, underscores (_), and hyphens (-).
- **Cluster Key**—An ASCII string of 1 to 63 characters. The cluster key cannot be a single digit and must not contain spaces. The **Cluster Key** value is used to generate the encryption key. This encryption does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in clear text.

Step 3 For the **Control Node**, configure these parameters:

- **Node**—Choose the device that you want to be the control node initially. When the Firewall Management Center forms the cluster, it will add this node to the cluster first so it will be the control node.

Note If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation. For example:

Figure 122: Configuration Issues

To resolve the above issues, remove the unsupported VPN license and deploy pending configuration changes to the device.

- **Cluster Control Link Network**—Specify an IPv4 subnet; IPv6 is not supported for this interface. Specify a **24**, **25**, **26**, or **27** subnet.
- **Cluster Control Link**—Choose the physical interface or EtherChannel you want to use for the cluster control link.

Note The MTU of the cluster control link interface is automatically set to 100 bytes more than the highest data interface MTU; by default, the MTU is 1600 bytes. We do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation. If the MTU is set in this range when you add the cluster, we recommend increasing the MTU above 8362. Choose **Devices** > **Device Management** and then click **Interfaces**.

Make sure you configure switches connected to the cluster control link to the correct (higher) MTU; otherwise, cluster formation can fail.

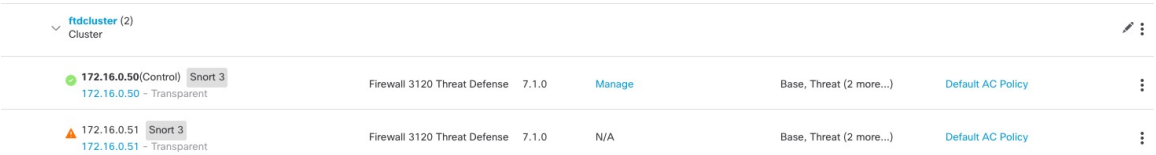
- **Cluster Control Link IPv4 Address**—This field will be auto-populated with the first address on the cluster control link network. You can edit the host address if desired.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority. Even if you set the priority to be lower than other nodes, this node will still be the control node when the cluster is first formed.

- **Site ID**—(FlexConfig feature) Enter the site ID for this node between 1 and 8. A value of 0 disables inter-site clustering. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature.

Step 4 For **Data Nodes (Optional)**, click **Add a data node** to add a node to the cluster.

You can form the cluster with only the control node for faster cluster formation, or you can add all nodes now. Set the following for each data node:

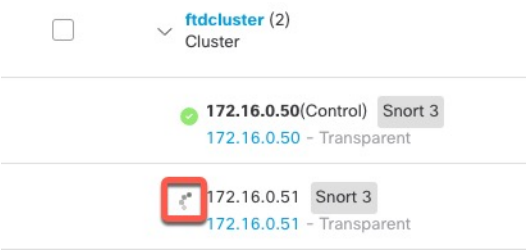
- **Node**—Choose the device that you want to add.



Note If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation.

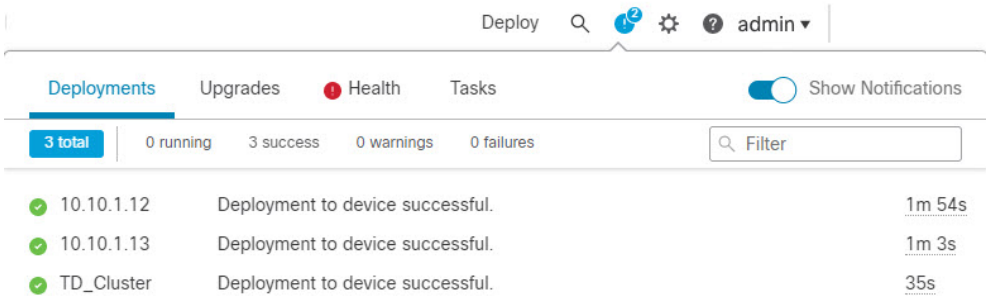
- **Cluster Control Link IPv4 Address**—This field will be auto-populated with the next address on the cluster control link network. You can edit the host address if desired.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority.
- **Site ID**—(FlexConfig feature) Enter the site ID for this node between 1 and 8. A value of 0 disables inter-site clustering. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature.

Step 5 Click **Continue**. Review the **Summary**, and then click **Save**.



The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster nodes.

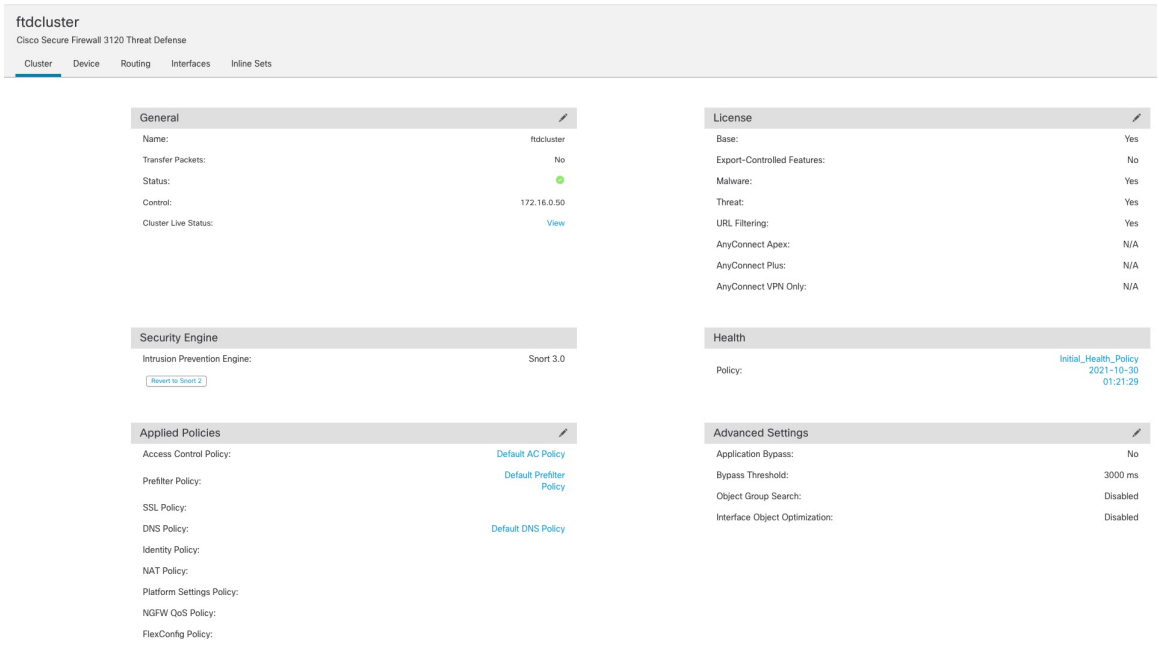
Figure 123: Cluster Management



A node that is currently registering shows the loading icon.

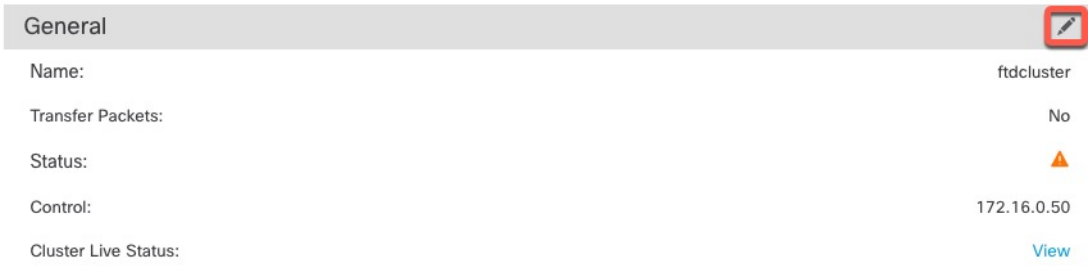
Figure 124: Node Registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**. The Firewall Management Center updates the Cluster Registration task as each node registers.



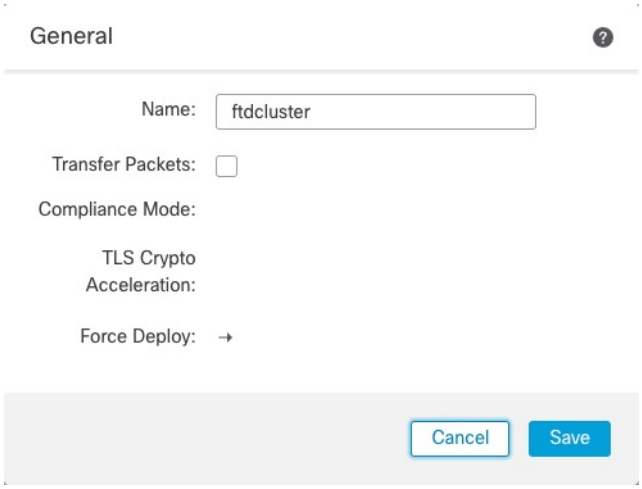
Step 6 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.



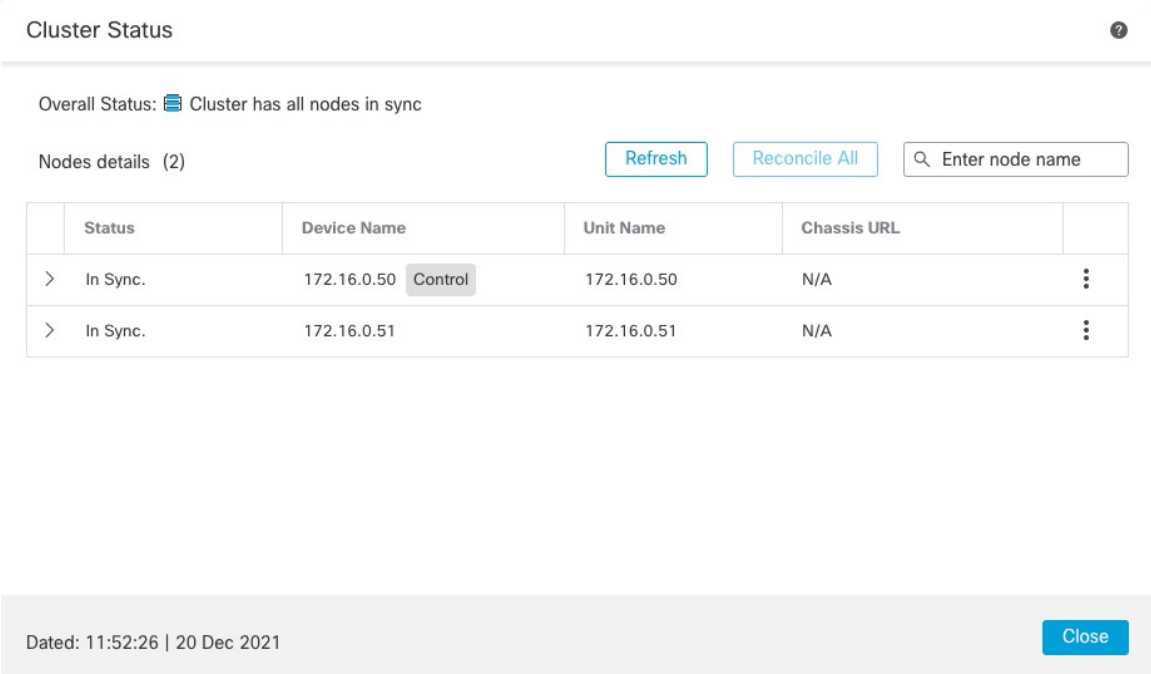
Step 7 On the **Devices** > **Device Management** and then choose **Add**, **Cluster** screen, you see **General** and other settings for the cluster.

Figure 125: Cluster Settings



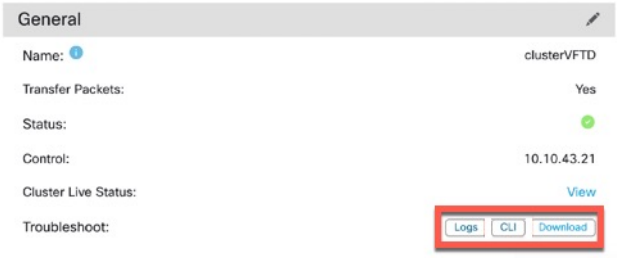
See these cluster-specific items in the **General** area:

- **General** > **Name**—Change the cluster display name by clicking the **Edit** (✎).



Then set the **Name** field.

- **General > Cluster Live Status**—Click the **View** link to open the **Cluster Status** dialog box.



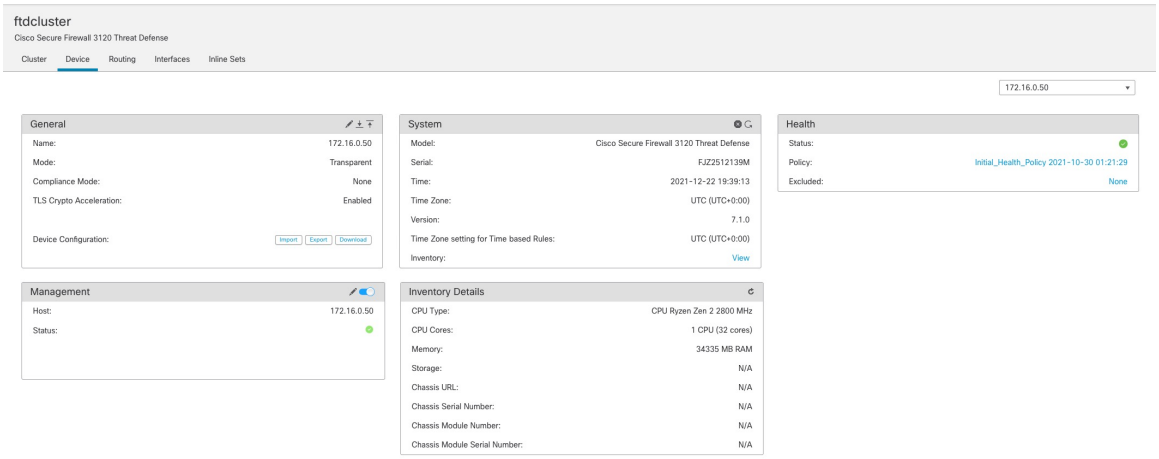
The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile All**. You can also ping the cluster control link from a node. Refer Perform a ping on the cluster control link, on page 367.

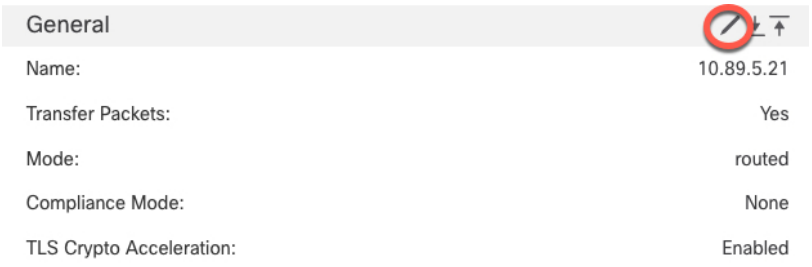
- **General > Troubleshoot**—You can generate and download troubleshooting logs, and you can view cluster CLIs. Refer Troubleshoot the cluster, on page 365 .

Figure 126: Troubleshoot

Step 8 On the **Devices** > **Device Management** and then choose **Add**, **Device**, you can choose each member in the cluster from the top right drop-down menu and configure these settings.

Figure 127: Device Settings





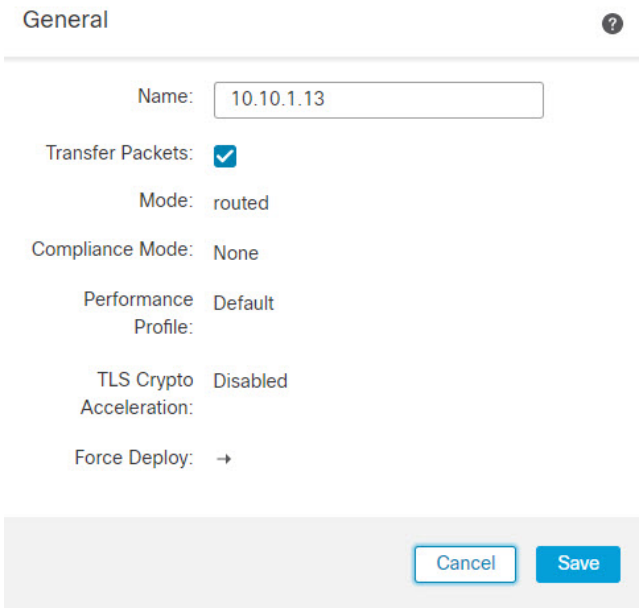


Figure 128: Choose Node

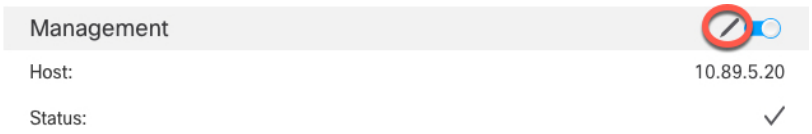

- **General > Name**—Change the cluster member display name by clicking the **Edit** ( ) .

Then set the **Name** field.

- **Management > Host** —If you change the management IP address in the device configuration, you must match the new address in the Firewall Management Center so that it can reach the device on the network. First disable the connection, edit the **Host** address in the **Management** area, then re-enable the connection.

Configure interfaces

Configure interfaces to enable proper cluster communication and operation.

Configure data interfaces as Spanned EtherChannels.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** ( ) next to the cluster.

Step 2 Click **Interfaces**.

Step 3 Configure Spanned EtherChannel data interfaces.

a) Configure one or more EtherChannels. See Configure an EtherChannel, on page 619.

You can include one or more member interfaces in the EtherChannel. Because this EtherChannel is spanned across all of the nodes, you only need one member interface per node; however, for greater throughput and redundancy, multiple members are recommended.

b) (Optional) For regular firewall interfaces, configure VLAN subinterfaces on the EtherChannel. The rest of this procedure applies to the subinterfaces. See Add a subinterface, on page 669.

c) Click **Edit** ( ) for the EtherChannel interface.

d) Configure the name and other parameters. For regular firewall interfaces, see Configure routed mode interfaces, on page 690 or, for transparent mode, Bridge group interfaces, on page 695. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 727.

- If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. By default, the cluster control link MTU is 1600 bytes. If you want to increase the MTU of data interfaces, first increase the cluster control link MTU. Note that we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For routed mode, DHCP, PPPoE, IPv6 autoconfig and manual link-local addresses are not supported. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254). In this case, no IP addresses are reserved for the network or broadcast addresses.

e) Set a unique, manual global MAC address for the EtherChannel. Click **Advanced**, and in the **Active MAC Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

Do not set the **Standby MAC Address**; it is ignored.

You must configure a unique MAC address not currently in use on your network for a Spanned EtherChannel to avoid potential network connectivity problems. With a manually-configured MAC address, the MAC address stays with the current control unit. If you do not configure a MAC address, then if the control unit changes, the new control unit uses a new MAC address for the interface, which can cause a temporary network outage.

f) Click **OK**. Repeat the above steps for other data interfaces.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure cluster health monitor settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

Figure 129: Cluster Health Monitor Settings

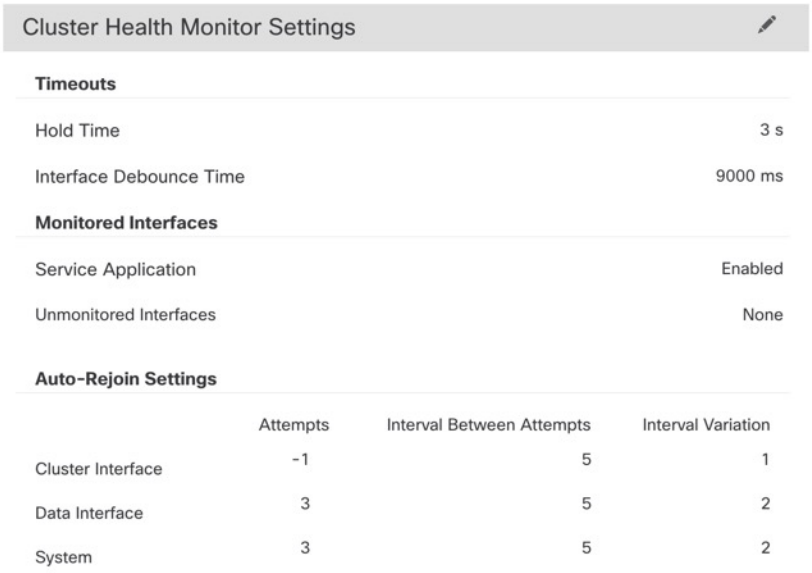

Table 27: Cluster Health Monitor Settings Section Table Fields

Field	Description
Timeouts	
Hold Time	Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.
Interface Debounce Time	Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.
Monitored Interfaces	The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster.
Service Application	Shows whether the Snort and disk-full processes are monitored.
Unmonitored Interfaces	Shows unmonitored interfaces.
Auto-Rejoin Settings	
Cluster Interface	Shows the auto-rejoin settings after a cluster control link failure.

Field	Description
Attempts	Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.
Data Interfaces	Shows the auto-rejoin settings after a data interface failure.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.
System	Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.

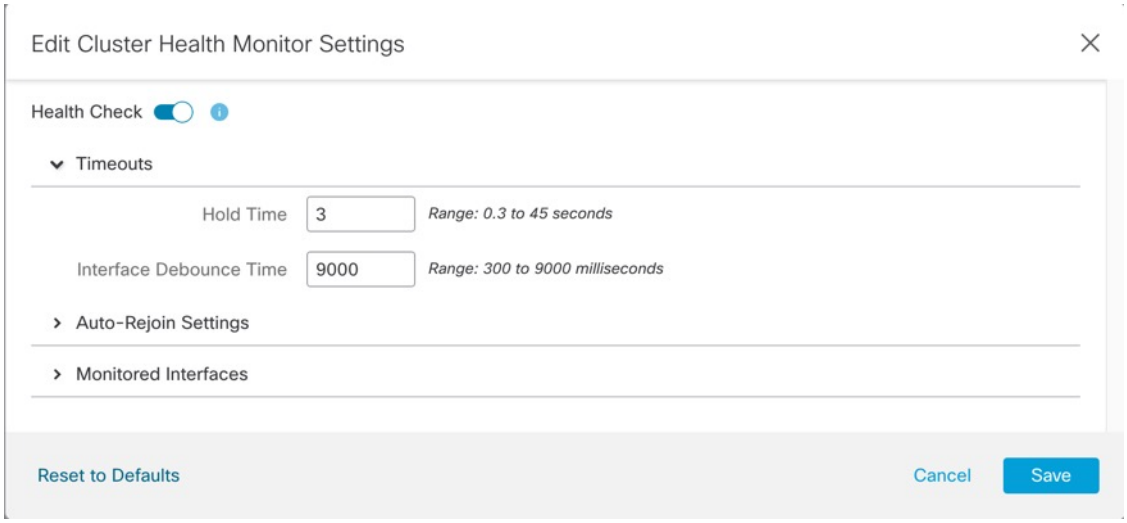
Note If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

Procedure

Step 1 Choose **Devices** > **Device Management**.



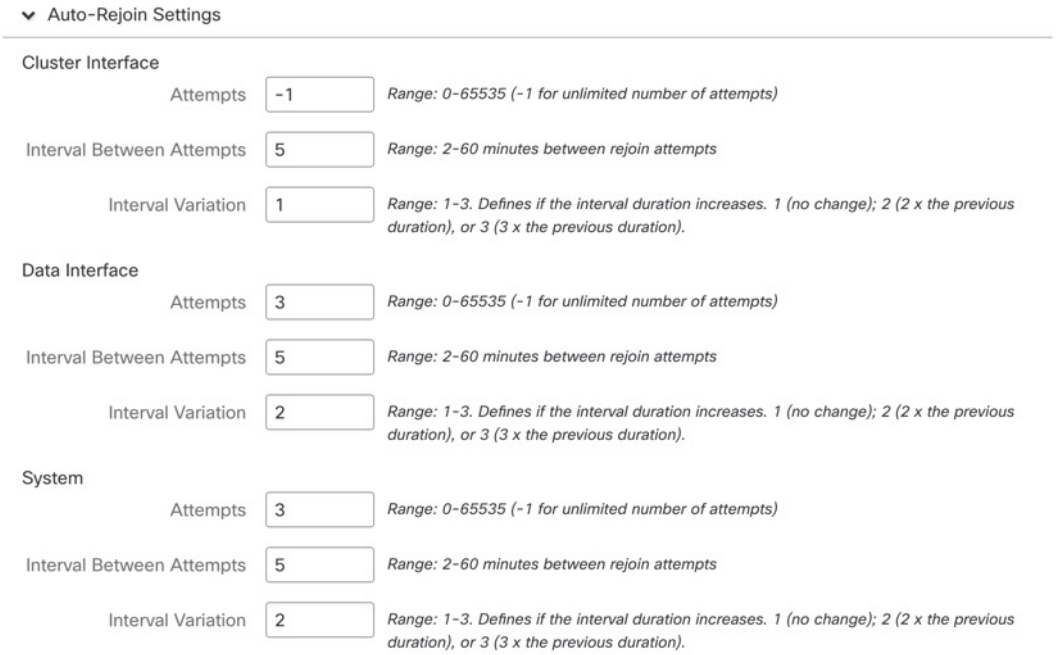
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider .

Figure 130: Disable the System Health Check



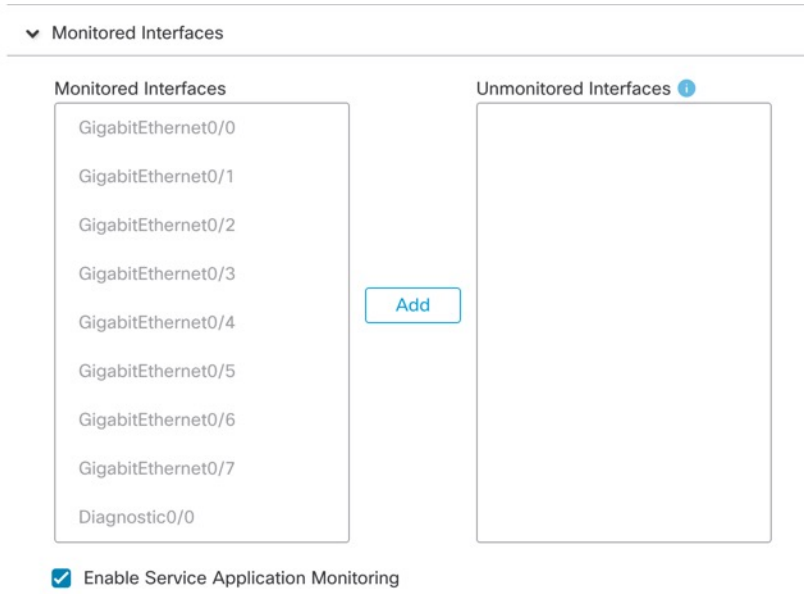
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 131: Configure Auto-Rejoin Settings



Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 132: Configure Monitored Interfaces

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

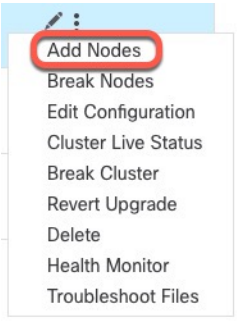
You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save** and deploy the configuration changes.

Cluster node management

After you deploy the cluster, you can change the configuration and manage cluster nodes.



Add a new cluster node

You can add one or more new cluster nodes to an existing cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Add Nodes**.

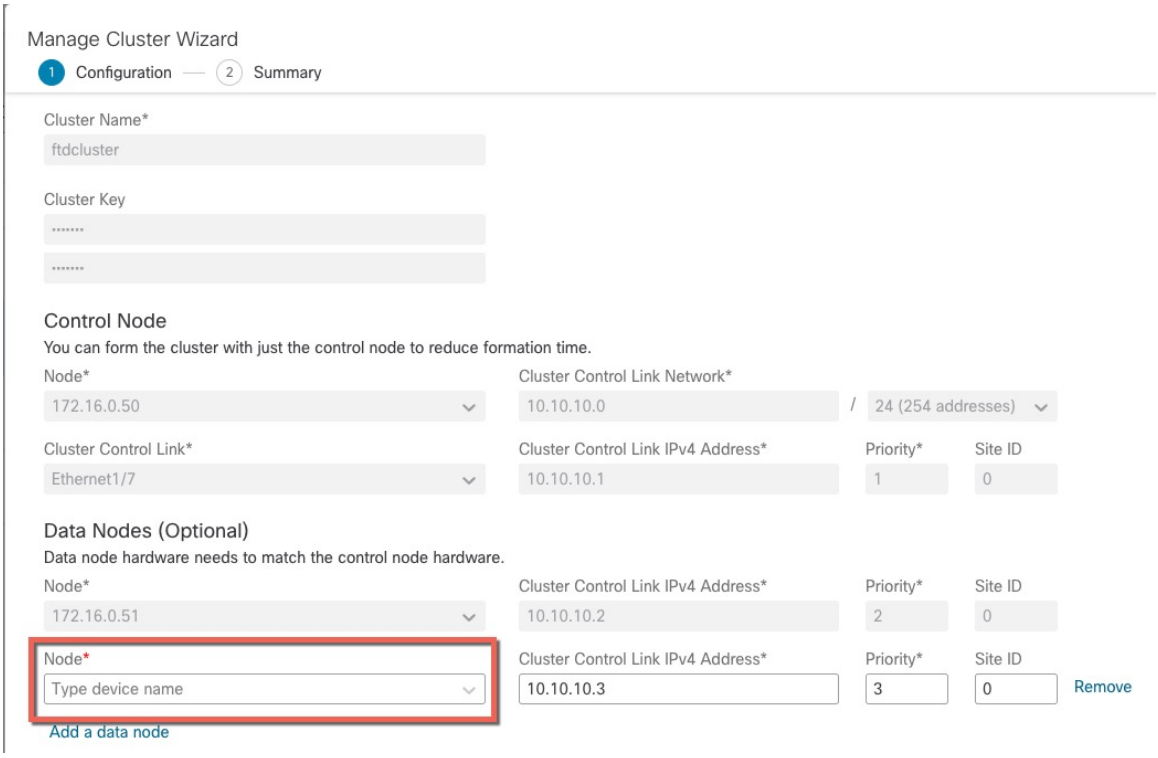


Figure 133: Add nodes

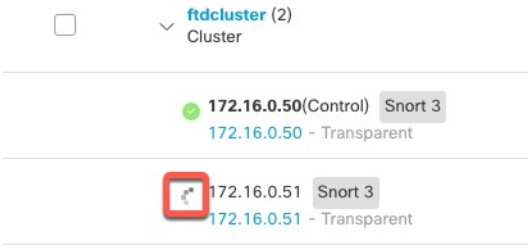
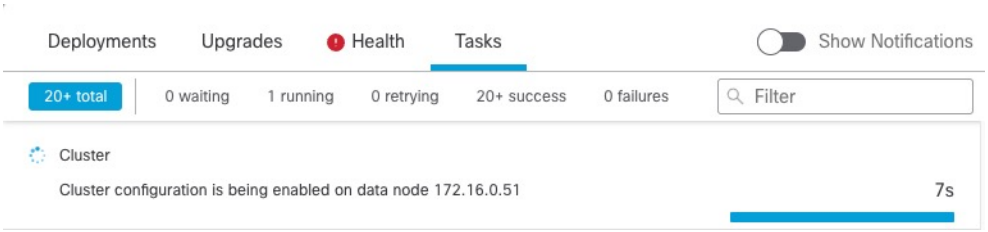
The **Manage Cluster Wizard** appears.

Step 2 From the **Node** menu, choose a device, adjust the IP address, priority, and Site ID if desired.

Figure 134: Manage cluster wizard



Step 3 To add additional nodes, click **Add a data node**.

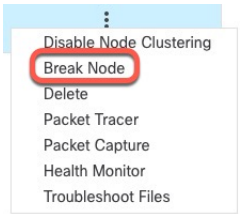


Step 4 Click **Continue**. Review the **Summary**, and then click **Save**

The node that is currently registering shows the loading icon.

Figure 135: Node registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**.



Break a node

You can remove a node from the cluster so that it becomes a standalone device. You cannot break the control node unless you break the entire cluster. The data node has its configuration erased.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the node you want to break, and choose **Break Node**.

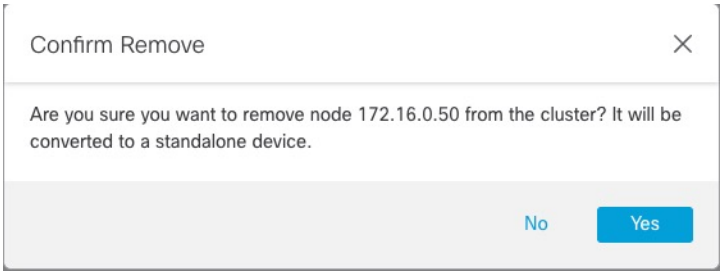


Figure 136: Break a node

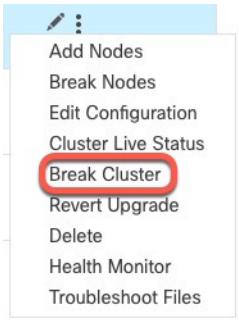
You can optionally break one or more nodes from the cluster More menu by choosing **Break Nodes**.

Step 2 You are prompted to confirm the break; click **Yes**.

Figure 137: Confirm break

You can monitor the cluster node break by clicking the **Notifications** icon and choosing **Tasks**.

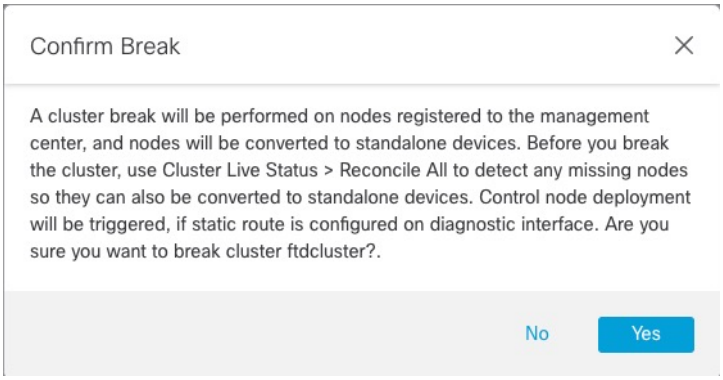
Break the cluster



You can break the cluster and convert all nodes to standalone devices. The control node retains the interface and security policy configuration, while data nodes have their configuration erased.

Procedure

Step 1 Make sure all cluster nodes are being managed by the Firewall Management Center by reconciling nodes. For more information, refer to Reconcile cluster nodes, on page 358.



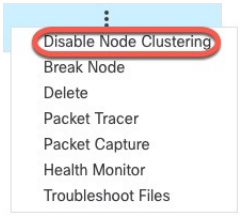
Step 2 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Break Cluster**.

Figure 138: Break cluster

Step 3 You are prompted to break the cluster; click **Yes**.

Figure 139: Confirm break

You can monitor the cluster break by clicking the **Notifications** icon and choosing **Tasks**.



Disable clustering

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the Firewall Management Center device list. When a node becomes inactive, all data interfaces are shut down.

Procedure

Step 1 For the unit you want to disable, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Disable Node Clustering**.

Figure 140: Disable clustering

If you disable clustering on the control node, one of the data nodes will become the new control node. Note that for centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node. You cannot disable clustering on the control node if it is the only node in the cluster.

Step 2 Confirm that you want to disable clustering on the node.

The node will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, refer Rejoin the cluster, on page 356.

Rejoin the cluster

If a node was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster. Refer Rejoin the cluster, on page 378 for more information about why a node can be removed from a cluster.

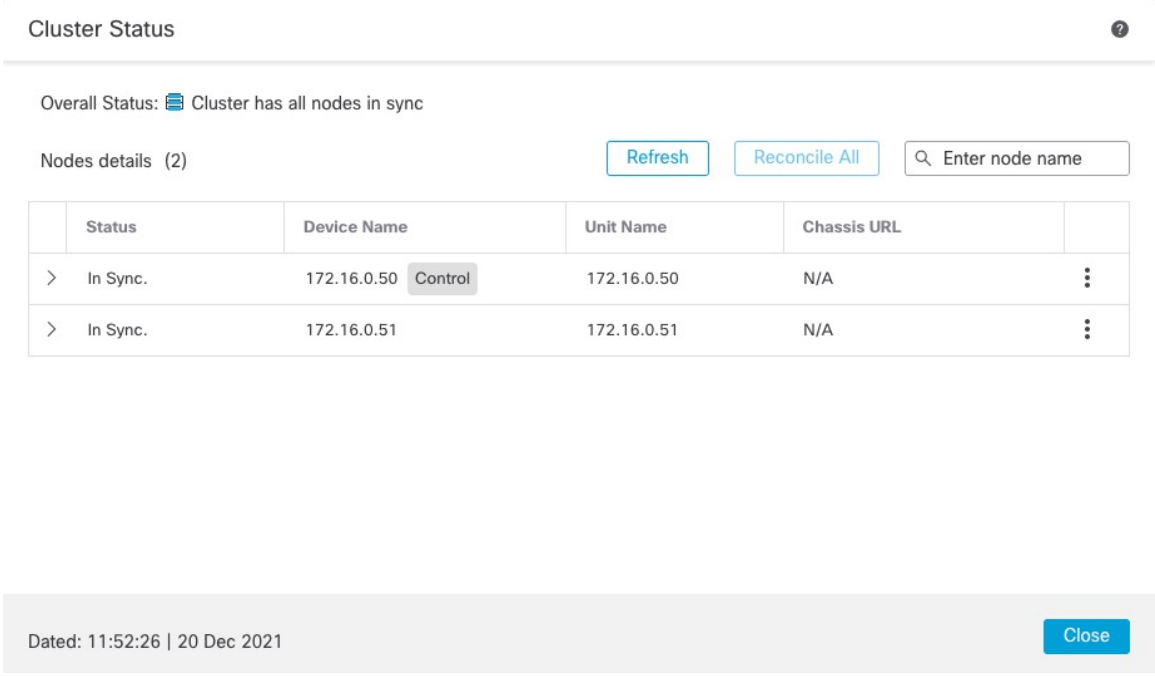
Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Enable Node Clustering**.

Step 2 Confirm that you want to enable clustering on the unit.

Change the control node

Use this procedure when you need to specify the exact unit you want to become the control node. For centralized features, forcing a control node change will drop all connections, requiring you to re-establish the connections on the new control node.



Caution The best method to change the control node is to disable clustering on the control node, wait for a new control election, and then re-enable clustering. If you must specify the *exact* unit you want to become the control node, use the procedure in this section. Note that for centralized features, if you force a control node change using either method, then all connections are dropped, and you have to re-establish the connections on the new control node.

Follow these steps to change the control node:

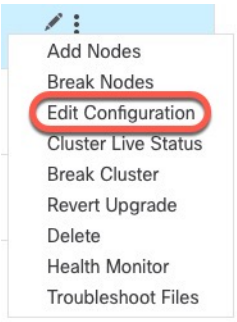
Procedure

Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management More** (⋮) **Cluster Live Status**.

Figure 141: Cluster status

Step 2 For the unit you want to become the control unit, choose **More** (⋮) **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Check the check box, and click **OK**.



Edit the cluster configuration

You can edit the cluster configuration. If you change the cluster key, cluster control link interface, or cluster control link network, the cluster will be broken and reformed automatically. Until the cluster is reformed, you may experience traffic disruption. If you change the cluster control link IP address for a node, node priority, or site ID, only the affected nodes are broken and readded to the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Edit Configuration**.

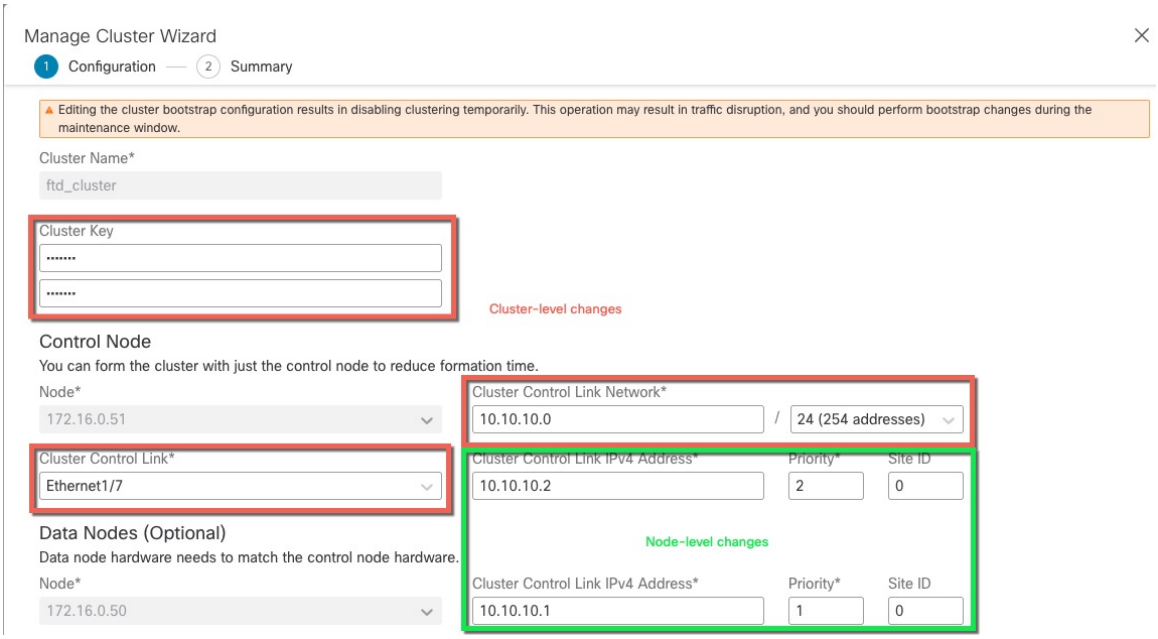


Figure 142: Edit configuration

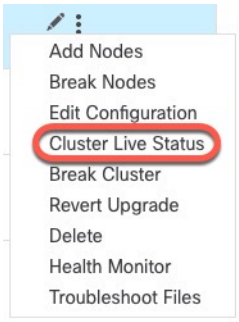
The **Manage Cluster Wizard** appears.

Step 2 Update the cluster configuration.

Figure 143: Manage cluster wizard

If the cluster control link is an EtherChannel, you can edit the interface membership and LACP configuration by clicking **Edit** (✎) next to the interface drop-down menu.

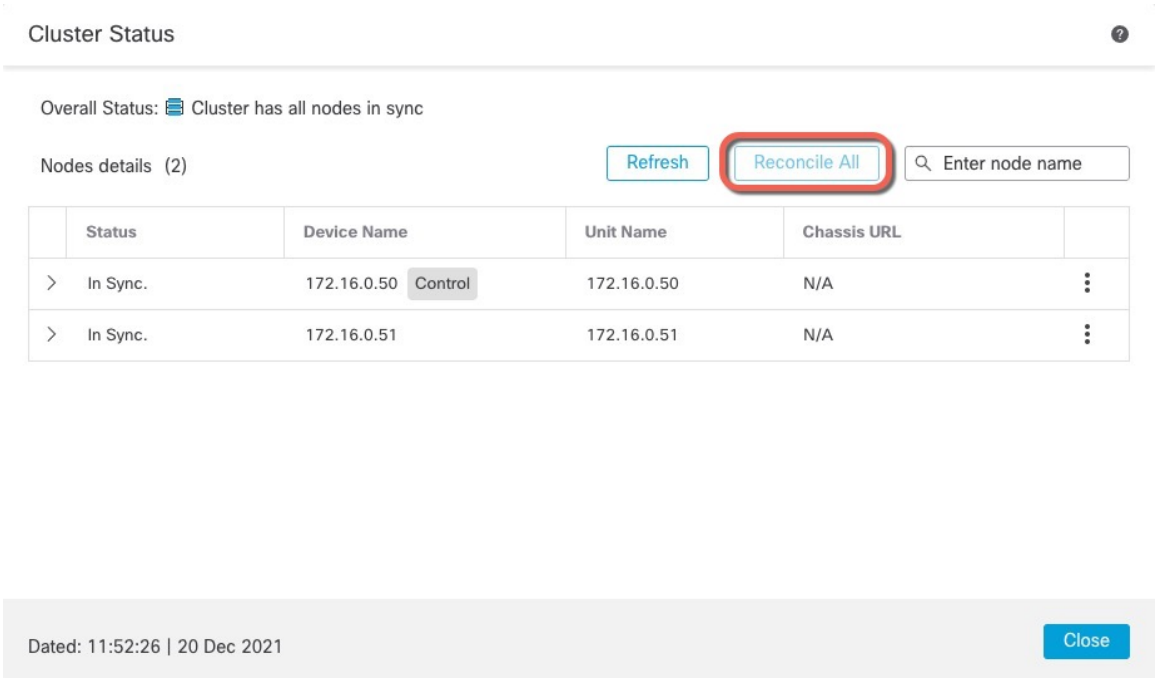
Step 3 Click **Continue**. Review the **Summary**, and then click **Save**



Reconcile cluster nodes

If a cluster node fails to register, you can reconcile the cluster membership from the device to the Firewall Management Center. For example, a data node might fail to register if the Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure



Step 1 Choose **Devices** > **Device Management More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Figure 144: Cluster live status

Step 2 Click **Reconcile All**.

Figure 145: Reconcile all

For more information about the cluster status, refer to Monitor the cluster, on page 361.

Delete (Unregister) the Cluster or Nodes and Register to a New Firewall Management Center

You can unregister the cluster from the Firewall Management Center, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new Firewall Management Center.

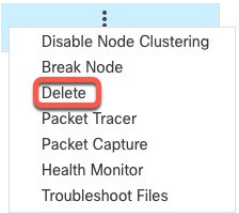
You can also unregister a node from the Firewall Management Center without breaking the node from the cluster. Although the node is not visible in the Firewall Management Center, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the Firewall Management Center, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

Unregistering a cluster:

- Severs all communication between the Firewall Management Center and the cluster.
- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the Firewall Management Center using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different Firewall Management Center causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so you can add the cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.



Before you begin

This procedure requires CLI access to one of the nodes.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster or node, and choose **Delete**.

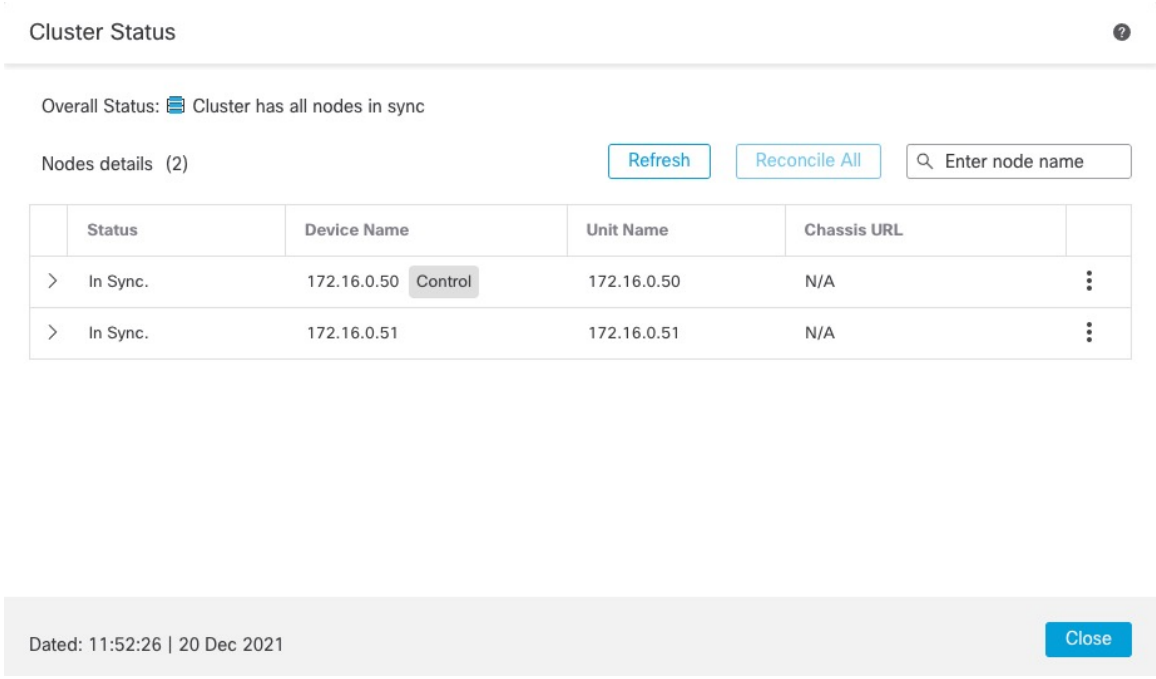
Figure 146: Delete cluster or node

Step 2 You are prompted to delete the cluster or node; click **Yes**.

Step 3 You can register the cluster to a new (or the same) Firewall Management Center by adding one of the cluster members as a new device.

You only need to add one of the cluster nodes as a device, and the rest of the cluster nodes will be discovered.

a) Connect to one cluster node's CLI, and identify the new Firewall Management Center using the **configure manager add** command. See Modify Firewall Threat Defense management interface settings at the CLI , on page 763.
b) Choose **Devices** > **Device Management**, and then click **Add** > **Device**.



Step 4 To re-add an unregistered node, refer to Reconcile cluster nodes, on page 358.

Monitor the cluster

You can monitor the cluster in the Firewall Management Center and at the Firewall Threat Defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management More** (⋮) icon or from the **Devices** > **Device Management** > **Cluster** page **General** area **Cluster Live Status** link.

Figure 147: Cluster status

The Control node has a graphic indicator identifying its role.

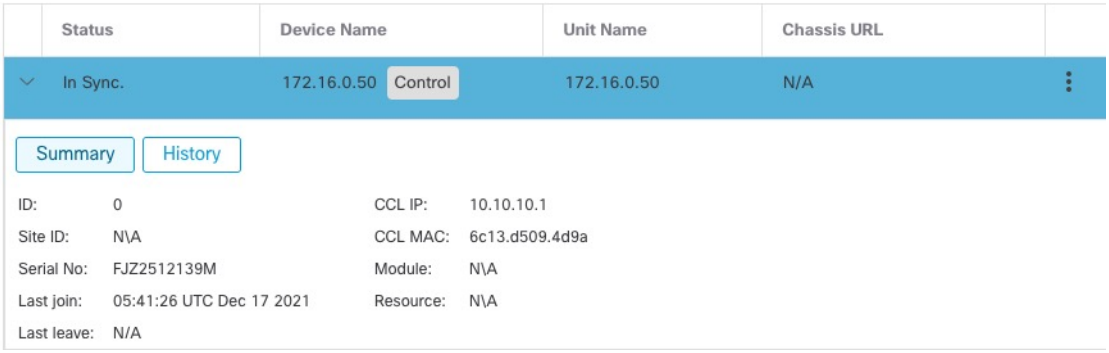
Cluster member **Status** includes these states:

- **In Sync**—The node is registered with the Firewall Management Center.
- **Pending Registration**—The node is part of the cluster, but has not yet registered with the Firewall Management Center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- **Clustering is disabled**—The node is registered with the Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.

- **Joining cluster**—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Firewall Management Center.

For each node, you can view the **Summary** or the **History**.

Figure 148: Node summary



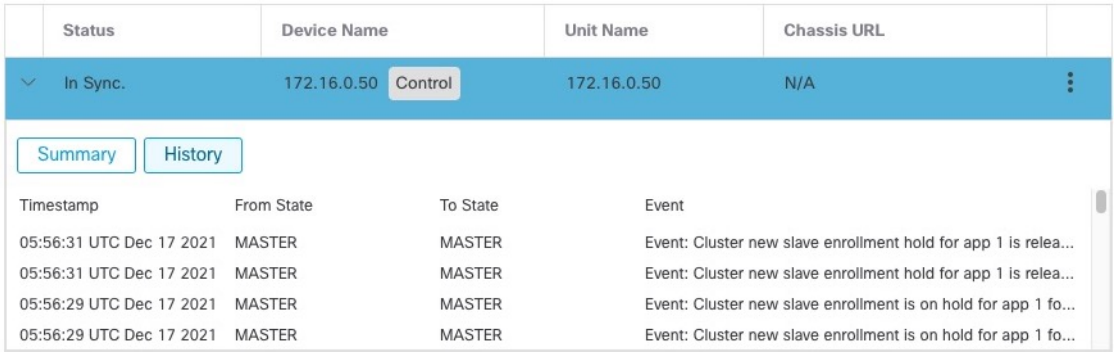


Figure 149: Node history

- **System** (⚙) > **Tasks** page.

  The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management***cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Cluster health monitor dashboard

The cluster health monitor dashboard provides visibility into cluster status, metrics, and statistics.

View cluster health

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

- You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.
- Ensure you have created a cluster from one or more devices in the Firewall Management Center.

Procedure

	Command or Action	Purpose
Step 1	Choose **System** (⚙) > **Health** > **Monitor**.	Use the Monitoring navigation pane to access node-specific health monitors.
Step 2	In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.	
Step 3	To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:	• Overview— Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information. • Load Distribution— Traffic and packet distribution across the cluster nodes. • Member Performance— Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation. • CCL— Interface status and aggregate traffic statistics. You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.
Step 4	You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks.	Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

	Command or Action	Purpose
	Select **Custom** from the drop-down to configure a custom start and end date.	
Step 5	Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.	The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.
Step 6	(For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.	Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.
Step 7	(For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:	• Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information. • CPU — CPU utilization, including the CPU usage by process and by physical cores. • Memory — Device memory utilization, including data plane and Snort memory usage. • Interfaces — Interface status and aggregate traffic statistics. • Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts. • Snort — Statistics that are related to the Snort process. • ASP drops — Statistics related to the dropped packets against various reasons. You can navigate through the various metrics dashboards by clicking on the labels. For more information, refer to Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

	Command or Action	Purpose
Step 8	Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.	For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 28: Cluster metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number
Packets	Packet distribution count in the cluster for every second.	number

Troubleshoot the cluster

Use these methods to troubleshoot the devices and clusters:

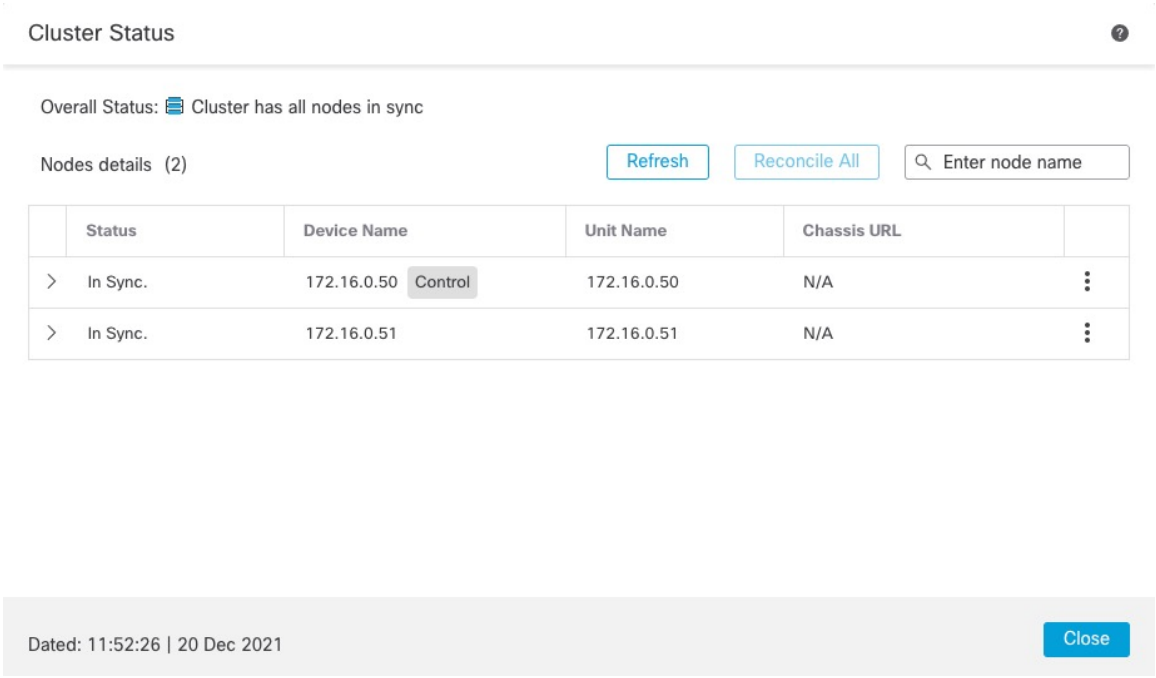
- Use **Logs** to generates troubleshooting files for all nodes in the cluster. Use this option when you need one cluster-level collection instead of generating troubleshooting files from each node separately.
- Use **CLI** to run a predefined set of cluster diagnostic commands and displays the output. Use this option to check cluster configuration, member state, cluster health, control-plane transport statistics, packet drops, interface status, CPU usage, memory buffers, ARP entries, and reachability. The **CLI** option displays command output; it does not open an interactive CLI session.

Commands
show running-config cluster: Review the cluster group configuration, local unit, cluster interface, priority, health-check, auto-rejoin, and cLACP settings.
show cluster info: Confirm that clustering is enabled and identify the control node, member state, software version, serial number, CCL IP address, CCL MAC address, and last join or leave state.
show cluster info health: Check unit, interface, service, and overall cluster health.
show cluster info transport cp: Review control-plane transport counters, including reliable and unreliable message counters, errors, retransmits, drops, and buffer conditions.
show version: Capture platform, software, build, UUID, LSP, VDB, uptime, resource, and license context.
show asp drop: Identify accelerated security path packet or flow drop reasons and counters.
show counters: Review protocol, feature, and cluster CCL counters.
show arp: Verify ARP entries for interfaces that participate in cluster communication.
show int ip brief: Check interface IP addresses and administrative and line protocol status.
show blocks: Check buffer availability and failed allocations.
show cpu detailed: Check data path, control point, and total CPU usage.
show interface *ccl_interface*: Review interface state, MTU, MAC address, IP address, traffic counters, errors, and drops for the cluster-related interface.
ping *ccl_ip* **size** *ccl_mtu* **repeat 2**: Test reachability to a cluster peer by using the packet size selected by the tool.

- Use the **CCL Ping** when you need to test cluster control link connectivity between joined cluster nodes.
- Troubleshooting files—If a node fails to join the cluster, a troubleshooting file is automatically generated. You can also generate and download troubleshooting files from the **Devices** > **Device Management** and then choose **Add**, **ClusterGeneral** area. For more information, refer to Generate troubleshooting files, on page 745.

  You can also generate files from the **Device Management** page. Click **More** (⋮) and choose **Troubleshoot Files**.
- CLI output—Choose **Devices** > **Device Management** and then choose **Add**, **ClusterGeneral** area, you can view a set of pre-defined CLI outputs that can help you troubleshoot the cluster. These commands are automatically run for the cluster:

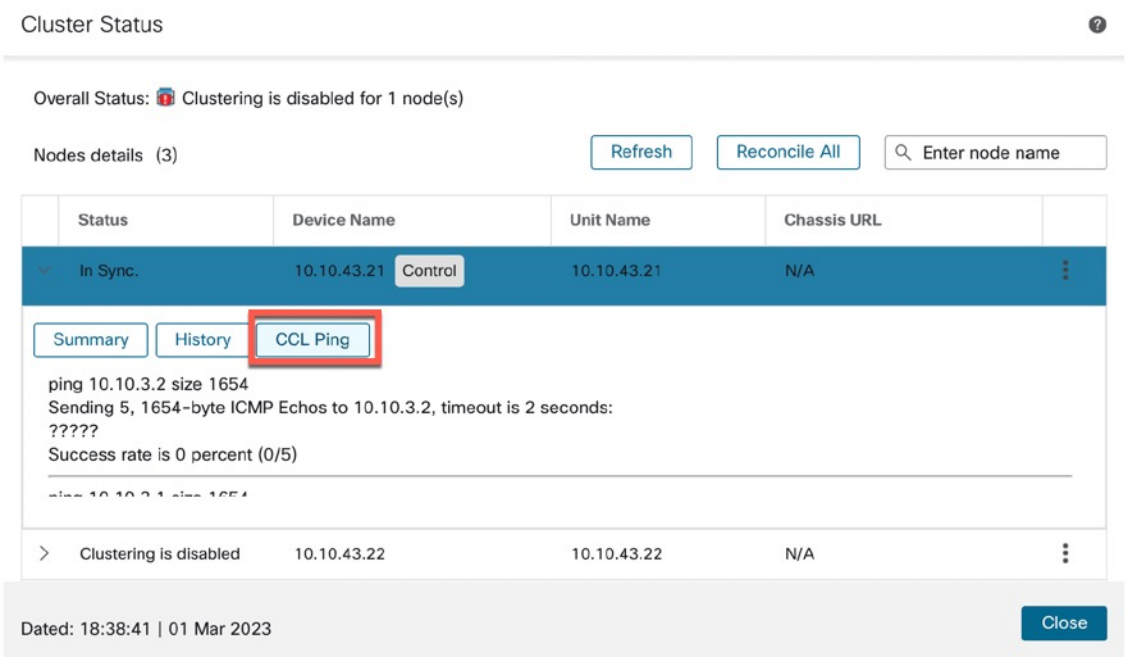
  You can also enter any **show** command in the **Command** field.



Perform a ping on the cluster control link

You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs.

Procedure



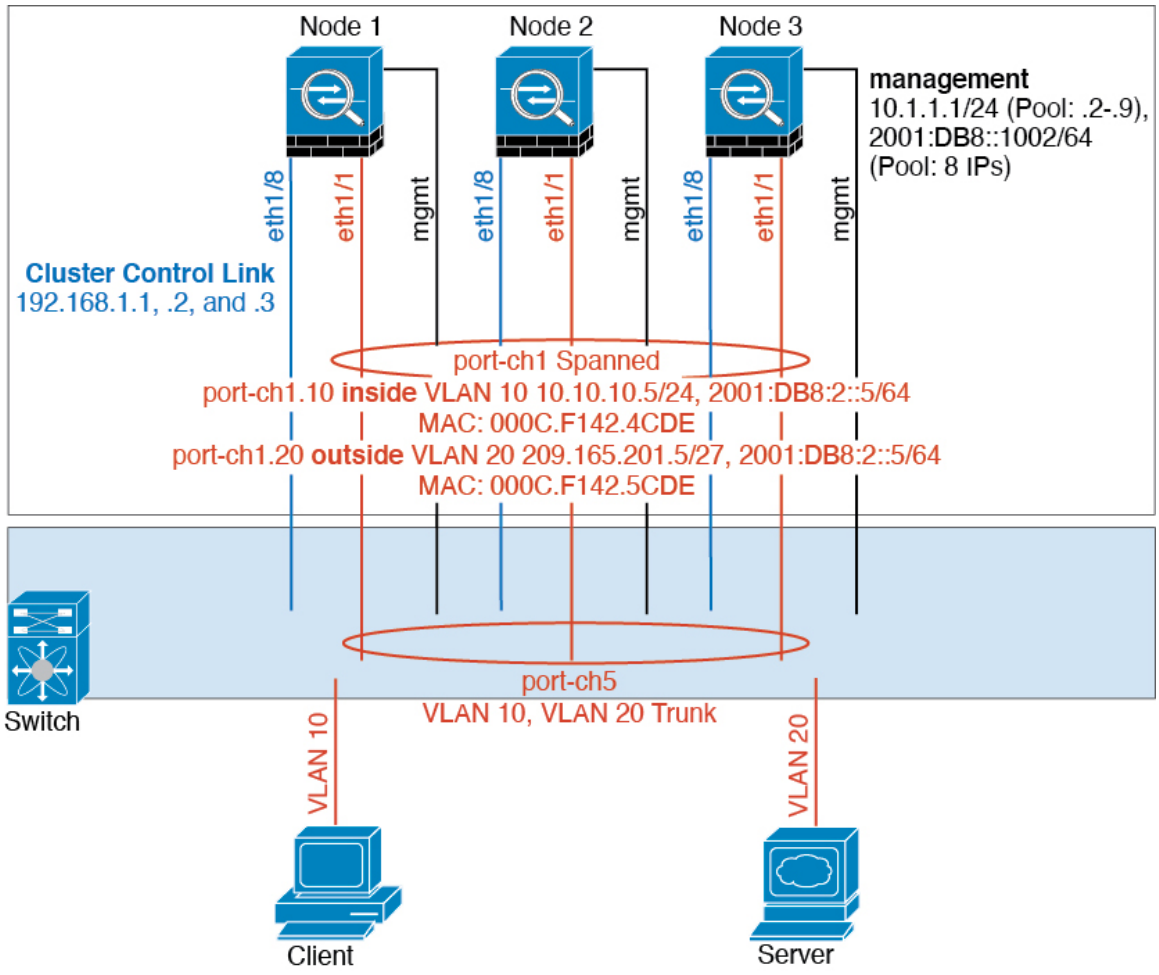
Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) icon next to the cluster, and choose **Cluster Live Status**.

Figure 150: Cluster status

Step 2 Expand one of the nodes, and click **CCL Ping**.

Figure 151: CCL ping

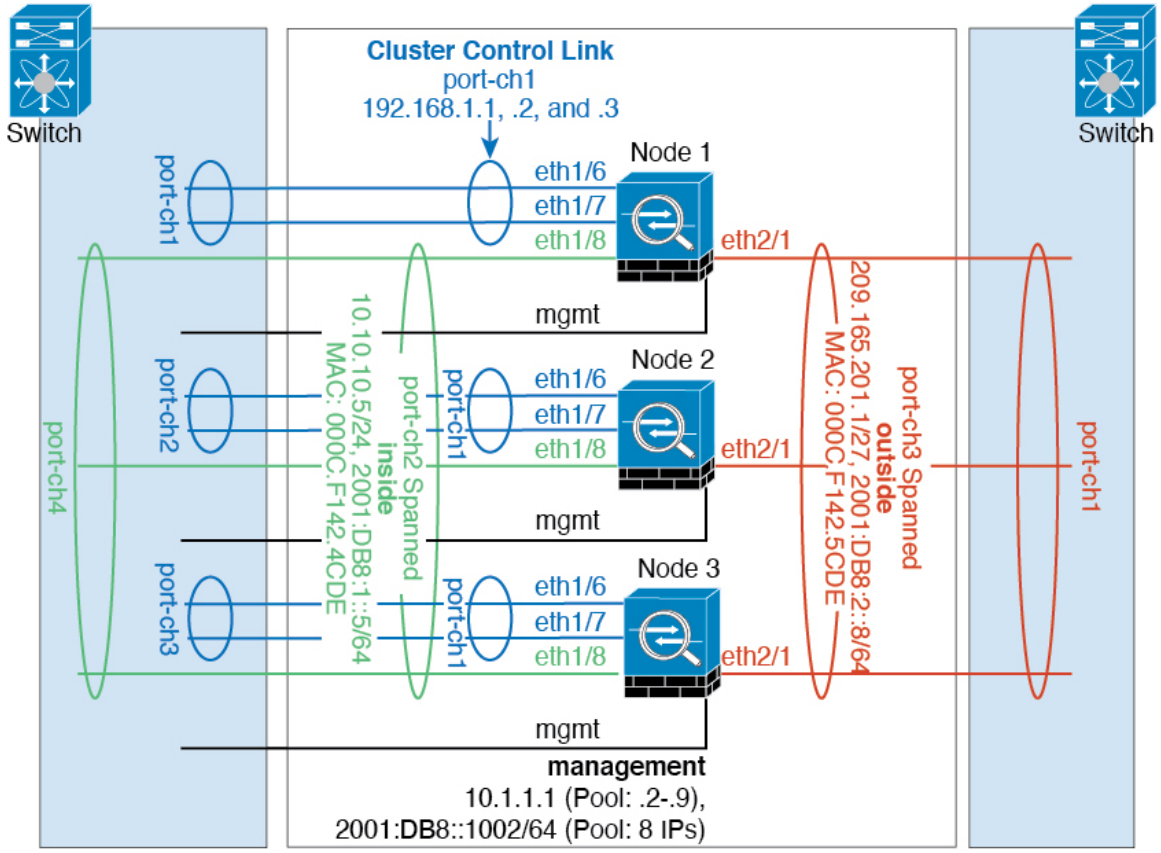
The node sends a ping on the cluster control link to every other node using a packet size that matches the maximum MTU.



Clustering examples

These examples include examples for typical deployments.

Firewall on a stick



Data traffic from different security domains are associated with different VLANs. For example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each Threat Defense has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. The Threat Defense is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the Threat Defense becomes unavailable, the switch will rebalance traffic between the remaining units.

Traffic segregation

You may prefer physical separation of traffic between the inside and outside network.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

Reference for Clustering

This section includes more information about how clustering operates.

Firewall Threat Defense features and clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported features with clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, refer to the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. For more information, refer to FlexConfig policies, on page 921.

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Firewall Management Center UCAPL/CC mode
- DHCP client, server, and proxy. DHCP relay is supported.

Centralized features for clustering

These features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, refer to the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. For more information, refer to FlexConfig policies, on page 921.

- These application inspections are supported:
  - DCERPC and ESMTP
  - NetBIOS and PPTP
  - RSH
  - SQLNET and SUNRPC
  - TFTP

- XDMCP

- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

Connection settings and clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

NAT and clustering

NAT can impact the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different devices in the cluster because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the device that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link.

Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

Guidelines for NAT and clustering

General guidelines for NAT and clustering

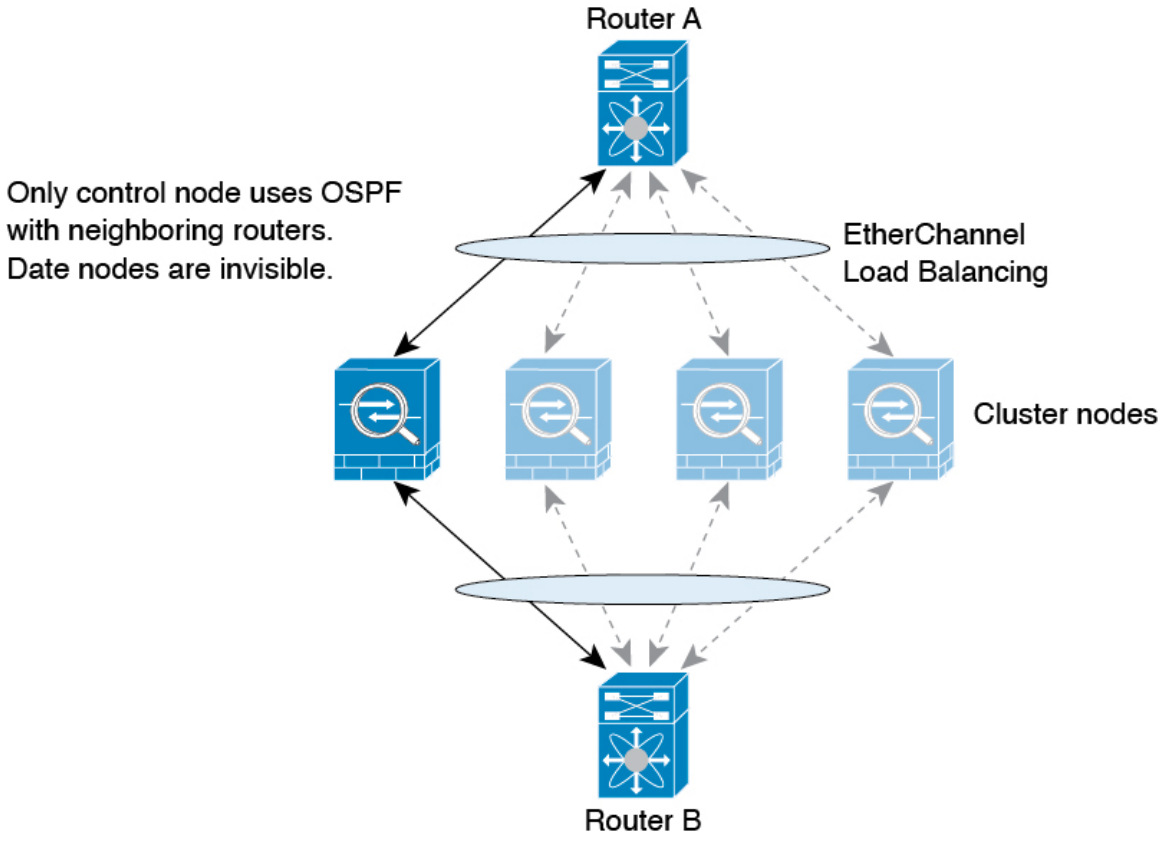
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able

to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.

- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

PAT with port block allocation guidelines

- Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
- Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
- On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
- When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.



Limitations for NAT and Clustering

- No static PAT for these inspections:
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.

Dynamic routing

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.

Figure 152: Dynamic routing in spanned EtherChannel mode

After the data node learn the routes from the control node, each node makes forwarding decisions independently.

The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

SIP inspection and clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and clustering

You should always use the local address, and not the main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and clustering

Syslog and clustering is a network management configuration that enables logging functionality within clustered network environments.

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

Cisco TrustSec and clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and clustering

Site-to-site VPN is a centralized feature; only the control node supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned EtherChannel address, connections are automatically forwarded to the control node.

VPN-related keys and certificates are replicated to all nodes.

Performance scaling factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

Throughput calculation

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control node election

Summary

The key components involved in the control node election process are:

- Cluster nodes: Communicate over the cluster control link and participate in the election process
- Election requests: Broadcast every 3 seconds by nodes when clustering is enabled
- Priority values: Set between 1 and 100 where 1 is the highest priority
- Control node: The elected node that coordinates cluster operations

Workflow

These stages describe how cluster nodes elect a control node:

1. When clustering is enabled for a node (or when it first starts up with clustering already enabled), the node broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request. The priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node. The existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, the node with highest priority retains the role while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High availability within clusters

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node health monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

Split brain scenario

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

Interface monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

- **Spanned EtherChannel**—Uses cluster Link Aggregation Control Protocol (cLACP). Each node monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel. The status is reported to the control node.

When you enable health monitoring, all physical interfaces (including the main EtherChannel) are monitored by default; you can optionally disable monitoring per interface. Only named interfaces can be monitored. For example, the named EtherChannel must fail to be considered failed, which means all member ports of an EtherChannel must fail to trigger cluster removal.

A node is removed from the cluster if its monitored interfaces fail. The amount of time before the Firewall Threat Defense removes a member from the cluster depends on whether the node is an established member or is joining the cluster. If the interface is down on an established member, then the Firewall Threat Defense removes the member after 9 seconds. The Firewall Threat Defense does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface status changes during this time will not cause the Firewall Threat Defense to be removed from the cluster. For non-EtherChannels, the node is removed after 500 ms, regardless of the member state.

Status after failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The device automatically tries to rejoin the cluster, depending on the failure event.

Note When the device becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoin the cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data path connection state replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 29: Features replicated across the cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—

Traffic	State Support	Notes
SNMP Engine ID	No	—

How the cluster manages connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection roles

These roles are defined for each connection:

- **Owner**—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- **Backup owner**—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.
- **Director**—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

  ICMP/ICMPv6 hash details:

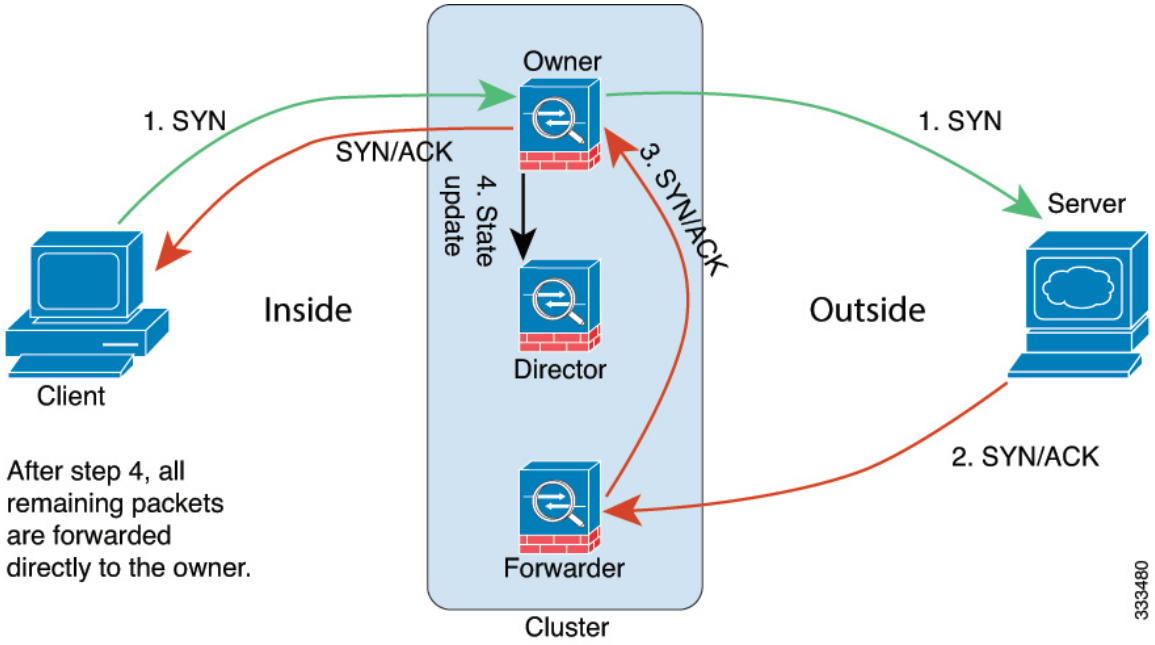
  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.
- **Forwarder**—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner.

A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- **Fragment Owner**—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

New connection ownership



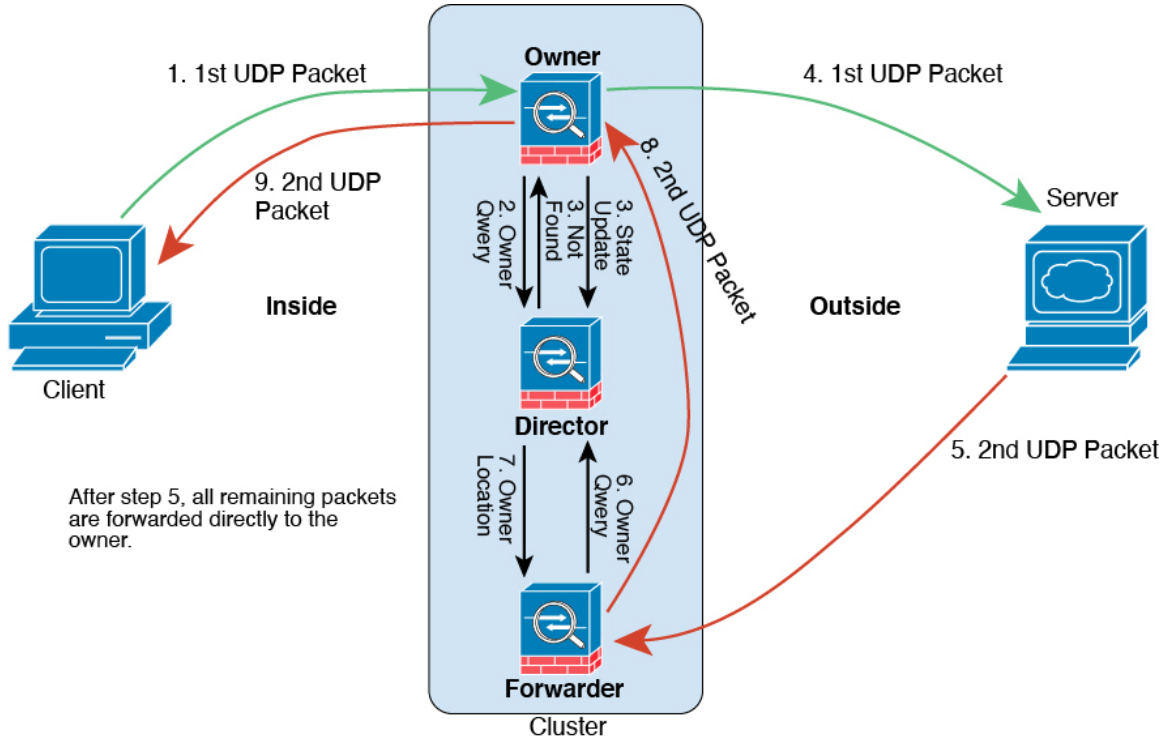
Traffic redirection is not supported in this release. When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. All the subsequent packets for the same connection should arrive the same node. If any connection packets arrive at a different node, they will be dropped. If a reverse flow arrives at a different node, it will be dropped as well. For centralized features, if the connections do not arrive on the control node, they will be dropped.

Sample data flow for TCP

Summary

This example shows the establishment of a new connection.

Workflow



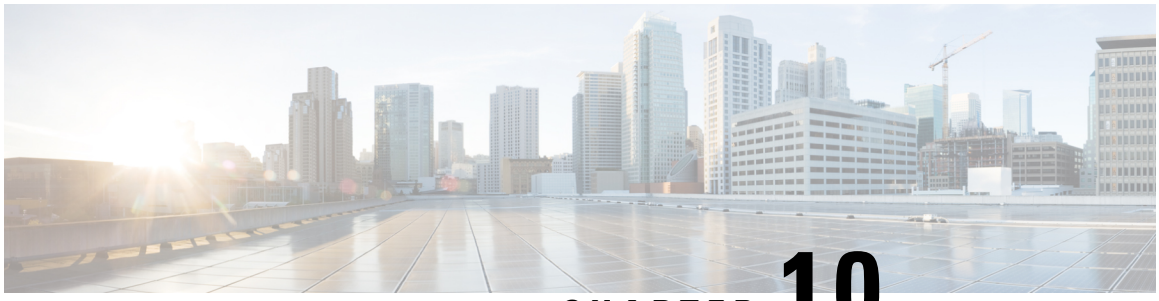
1. The SYN packet originates from the client and is delivered to one device (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different device (based on the load balancing method). This device is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample data flows for ICMP and UDP

Summary

This example shows the establishment of a new connection.

Workflow



1. The first UDP packet originates from the client and is delivered to one device (based on the load balancing method).
2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for Clustering

Lists the clustering features introduced in each release.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Cluster control link ping tool.	7.2.6 7.4.1	Any	You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs. New/modified screens: **Devices** > **Device Management** > **More** > **Cluster Live Status.**
Troubleshooting file generation and download available from Device and Cluster pages.	7.4.1	7.4.1	You can generate and download troubleshooting files for each device on the Device page and also for all cluster nodes on the Cluster page. For a cluster, you can download all files as a single compressed file. You can also include cluster logs for the cluster for cluster nodes. You can alternatively trigger file generation from the **Devices** > **Device Management** > **More** > **Troubleshoot Files** menu. New/modified screens: • **Devices** > **Device Management** > **Device** > **General** • **Devices** > **Device Management** > **Cluster** > **General**
Automatic generation of a troubleshooting file on a node when it fails to join the cluster.	7.4.1	7.4.1	If a node fails to join the cluster, a troubleshooting file is automatically generated for the node. You can download the file from **Tasks** or from the **Cluster** page.
View CLI output for a device or device cluster.	7.4.1	Any	You can view a set of pre-defined CLI outputs that can help you troubleshoot the device or cluster. You can also enter any **show** command and see the output. New/modified screens: **Devices** > **Device Management** > **Cluster** > **General**
Clustering for the Secure Firewall 4200	7.4.0	7.4.0	The Secure Firewall 4200 supports Spanned EtherChannel clustering for up to 8 nodes.
Cluster health monitor settings	7.3.0	Any	You can now edit cluster health monitor settings. New/modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Cluster health monitor dashboard	7.3.0	Any	You can now view cluster health on the cluster health monitor dashboard. New/modified screens: **System** > **Health** > **Monitor**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Automatic configuration of the cluster control link MTU	7.2.0	7.2.0	The MTU of the cluster control link interface is now automatically set to 100 bytes more than the highest data interface MTU; by default, the MTU is 1600 bytes.
Clustering for the Secure Firewall 3100	7.1.0	7.1.0	The Secure Firewall 3100 supports Spanned EtherChannel clustering for up to 8 nodes. New/modified screens: • **Devices** > **Device Management** > **Add Cluster** • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** Supported platforms: Secure Firewall 3100

CHAPTER 10

Clustering: Private Cloud

Clustering lets you group multiple Firewall Threat Defense Virtuals together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. You can deploy Firewall Threat Defense Virtual clusters in a private cloud using VMware and KVM. Only routed firewall mode is supported.

Note Some features are not supported when using clustering. See Unsupported features and clustering, on page 422.

About clustering: private cloud

This section describes the clustering architecture and how it works.

How the cluster fits into your network

The cluster consists of multiple firewalls acting as a single device. To act as a cluster, the firewalls need the following infrastructure:

- Isolated network for intra-cluster communication, known as the cluster control link, using VXLAN interfaces. VXLANs, which act as Layer 2 virtual networks over Layer 3 physical networks, let the Firewall Threat Defense Virtual send broadcast/multicast messages over the cluster control link.
- Management access to each firewall for configuration and monitoring. The Firewall Threat Defense Virtual deployment includes a Management 0/0 interface that you will use to manage the cluster nodes.

When you place the cluster in your network, the upstream and downstream routers need to be able to load-balance the data coming to and from the cluster using Layer 3 Individual interfaces and one of the following methods:

- Policy-Based Routing—The upstream and downstream routers perform load balancing between nodes using route maps and ACLs.
- Equal-Cost Multi-Path Routing—The upstream and downstream routers perform load balancing between nodes using equal cost static or dynamic routes.

Layer 2 Spanned EtherChannels are not supported.

Control and data node roles

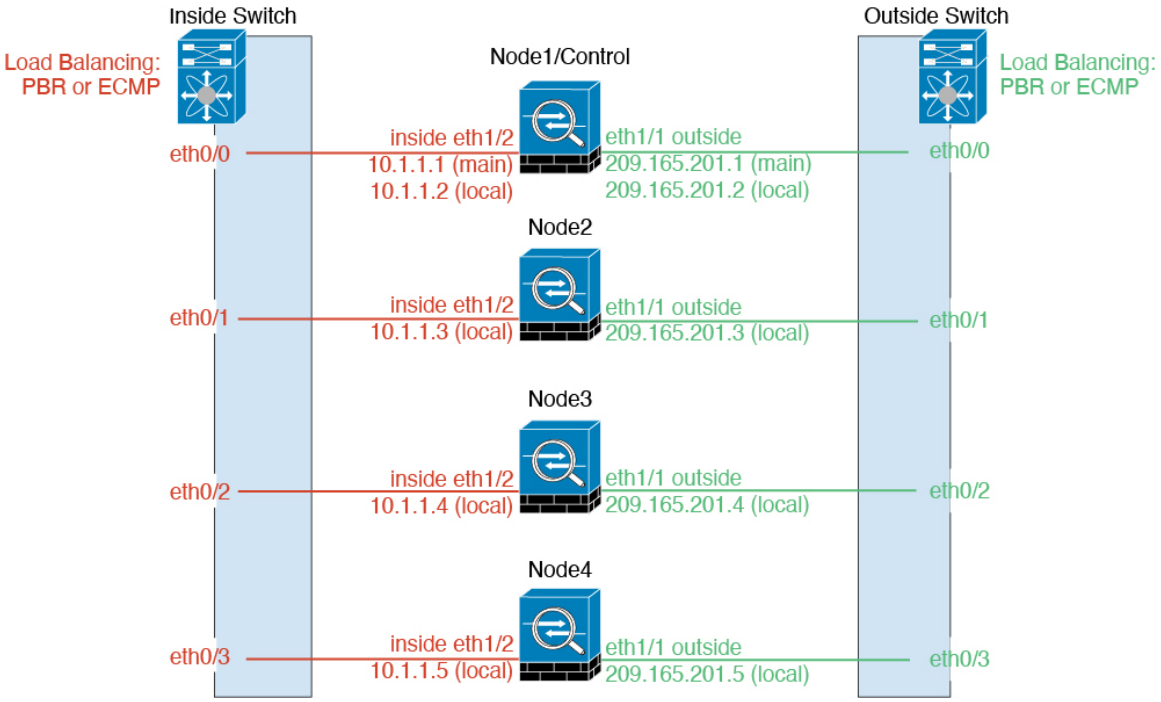
When you add a cluster in the Firewall Management Center , you choose one firewall to be the control node, and all additional firewalls to be data nodes. When you first create the cluster, the control node you specify will become the control node simply because it is the first node added to the cluster. Later, if multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority.

When you create the cluster and deploy the cluster configuration, the Firewall Management Center deploys a special bootstrap configuration to each node that includes fundamental settings such as the cluster control link configuration. The bootstrap configuration lets each node join the cluster. Most bootstrap settings are defined in the cluster wizard; however, you define the cluster control link interface hardware configuration (for example, creating an EtherChannel or setting the Ethernet speed) on the control node before you create the cluster. The cluster control link settings are copied to the bootstrap configuration for each node.

All nodes in the cluster share the same policy configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster. After you create the cluster, all configuration changes are made at the cluster level and are shared by all nodes.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Individual interfaces



You can configure cluster interfaces as individual interfaces.

Individual interfaces are normal routed interfaces, each with their own *local IP address* used for routing. The *main cluster IP address* for each interface is a fixed address that always belongs to the control node. When the control node changes, the main cluster IP address moves to the new control node, so management of the cluster continues seamlessly.

IPS-only interfaces (inline sets and passive interfaces) are not supported as Individual interfaces.

Because interface configuration must be done only on the control node, configure a pool of IP addresses for a given interface on the cluster nodes, including one for the control node.

Load balancing must be configured separately on the upstream switch.

Layer 2 Spanned EtherChannels are not supported.

Policy-based routing

When using individual interfaces, each Firewall Threat Defense interface maintains its own IP address and MAC address. One method of load balancing is Policy-Based Routing (PBR).

We recommend this method if you are already using PBR, and want to take advantage of your existing infrastructure.

PBR makes routing decisions based on a route map and ACL. You must manually divide traffic between all Firewall Threat Defenses in a cluster. Because PBR is static, it may not achieve the optimum load balancing result at all times. To achieve the best performance, we recommend that you configure the PBR policy so that forward and return packets of a connection are directed to the same Firewall Threat Defense.

For example, if you have a Cisco router, redundancy can be achieved by using Cisco IOS PBR with Object Tracking. Cisco IOS Object Tracking monitors each Firewall Threat Defense using ICMP ping. PBR can then enable or disable route maps based on reachability of a particular Firewall Threat Defense.

Equal-cost multi-path routing

When using Individual interfaces, each Firewall Threat Defense interface maintains its own IP address and MAC address. One method of load balancing is Equal-Cost Multi-Path (ECMP) routing.

We recommend this method if you are already using ECMP, and want to take advantage of your existing infrastructure.

ECMP routing considerations

ECMP routing can forward packets over multiple best paths that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses and/or source and destination ports can be used to send a packet to one of the next hops.

If you use static routes for ECMP routing, then the Firewall Threat Defense failure can cause problems; the route continues to be used, and traffic to the failed Firewall Threat Defense will be lost.

If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each Firewall Threat Defense to participate in dynamic routing.

Cluster Control Link

Each node must dedicate one interface as a VXLAN (VTEP) interface for the cluster control link. For more information about VXLAN, see Configure VXLAN interfaces, on page 680 .

VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

VTEP Source Interface

The VTEP source interface is a regular Firewall Threat Defense Virtual interface with which you plan to associate the VNI interface. You can configure one VTEP source interface to act as the cluster control link. The source interface is reserved for cluster control link use only. Each VTEP source interface has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

VNI Interface

A VNI interface is similar to a VLAN interface. It is a virtual interface that keeps network traffic separated on a given physical interface by using tagging. You can only configure one VNI interface. Each VNI interface has an IP address on the same subnet.

Peer VTEPs

Unlike regular VXLAN for data interfaces, which allows a single VTEP peer, Firewall Threat Defense Virtual clustering allows you to configure multiple peers.

Cluster control link traffic overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Configuration replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management network

You must manage each node using the Management interface. Management from a data interface is not supported with clustering.

Licenses for clustering: Private cloud

Performance tier license requirements

Each Firewall Threat Defense Virtual cluster node requires the same performance tier license. We recommend using the same number of CPUs and memory for all members, or else performance will be limited on all nodes to match the least capable member. The throughput level will be replicated from the control node to each data node so they match.

Feature license assignment

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the Firewall Management Center, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster by clicking **Edit Licenses** in **System** (⚙) > **Licenses** > **Smart Licenses** or choosing **Devices** > **Device Management**, clicking **Edit** (✎) for the cluster, and then in the **License** area, clicking **Edit** (✎).

Note If you add the cluster before the Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Note APEX, PLUS, and VPN-Only licenses are not supported for clustering. Before you create a cluster, remove unsupported license assignments from the devices that will become cluster nodes.

Prerequisites for clustering: Private cloud

This reference provides the complete set of requirements that must be met before configuring clustering for threat defense virtual devices in private cloud deployments.

Model requirements

- FTDv5, FTDv10, FTDv20, FTDv30, FTDv50, FTDv100
- VMware or KVM
- A maximum of 16 nodes in a cluster in a 4x4 configuration is supported. You can set up a maximum of four hosts with a maximum of four threat defense virtual instances in each host.

User roles

- Admin
- Access Admin
- Network Admin

Hardware and software requirements

All units in a cluster:

- Must have jumbo frame reservation enabled for the cluster control link. Do this in the Day 0 configuration when you deploy the Firewall Threat Defense Virtual by setting `"DeploymentType": "Cluster"`. Otherwise, you must restart each node to enable jumbo frames after the cluster has formed and is healthy.
- (KVM only) Must use CPU hard partitioning (CPU pinning) for all VMs on the KVM host.
- Must be the same performance tier. We recommend using the same number of CPUs and memory for all nodes, or performance will be limited on all nodes to match the least capable node.
- Must use the management interface for Firewall Management Center communications. Data interface management is not supported.
- Must run the same version, except during upgrade. Hitless upgrade is supported.
- Must be in the same domain and group.
- Must not have any deployment pending or in progress.
- Must not have any unsupported features configured on the control node: Unsupported features and clustering, on page 422.
- Must not have VPN configured on the data nodes. The control node can have site-to-site VPN configured.

Firewall Management Center Requirements

Make sure the Firewall Management Center NTP server is set to a reliable server that is reachable by all cluster nodes to ensure proper clock sync. By default, the device uses the same NTP server as the Firewall Management Center. If the time is not set to be the same on all cluster nodes, they can be removed automatically from the cluster.

Switch requirements

Be sure to complete the switch configuration before you configure clustering. Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. By default, the cluster control link MTU is set to 154 bytes higher than the data interfaces. If the switches have an MTU mismatch, the cluster formation will fail.

Guidelines for clustering: Private cloud

High availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Additional clustering guidelines

Consider these additional guidelines when configuring clustering:

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firewall Threat Defense Virtual, adding an additional switch to form a VSS or vPC, configuring IP addresses or interface flap on the cluster) you should disable the health check feature and also disable interface monitoring for the interfaces that are affected by the topology changes. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.
- We do not support VXLAN for data interfaces; only the cluster control link supports VXLAN.

Default cluster configurations

Consider these default configurations when setting up clustering:

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.

- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Upgrade guidelines

Configure clustering: private cloud

To configure clustering after you deploy your Firewall Threat Defense Virtuals, perform the following tasks.

Add nodes to the Management Center

This task allows you to prepare cluster nodes for clustering configuration by adding them to the management center as individual devices.

Before configuring clustering, deploy each cluster node, then add the devices as standalone units on the Firewall Management Center.

Procedure

Step 1 Deploy each cluster node by following the procedures given in the Secure Firewall Threat Defense Virtual getting started guides.

All units in a cluster:

- Must have jumbo frame reservation enabled for the cluster control link. Do this in the Day 0 configuration when you deploy the Firewall Threat Defense Virtual by setting `"DeploymentType": "Cluster"`. Otherwise, you must restart each node to enable jumbo frames after the cluster has formed and is healthy.
- (KVM only) Must use CPU hard partitioning (CPU pinning) for all VMs on the KVM host.

Step 2 Add each node to the Firewall Management Center as a standalone device in the same domain and group.

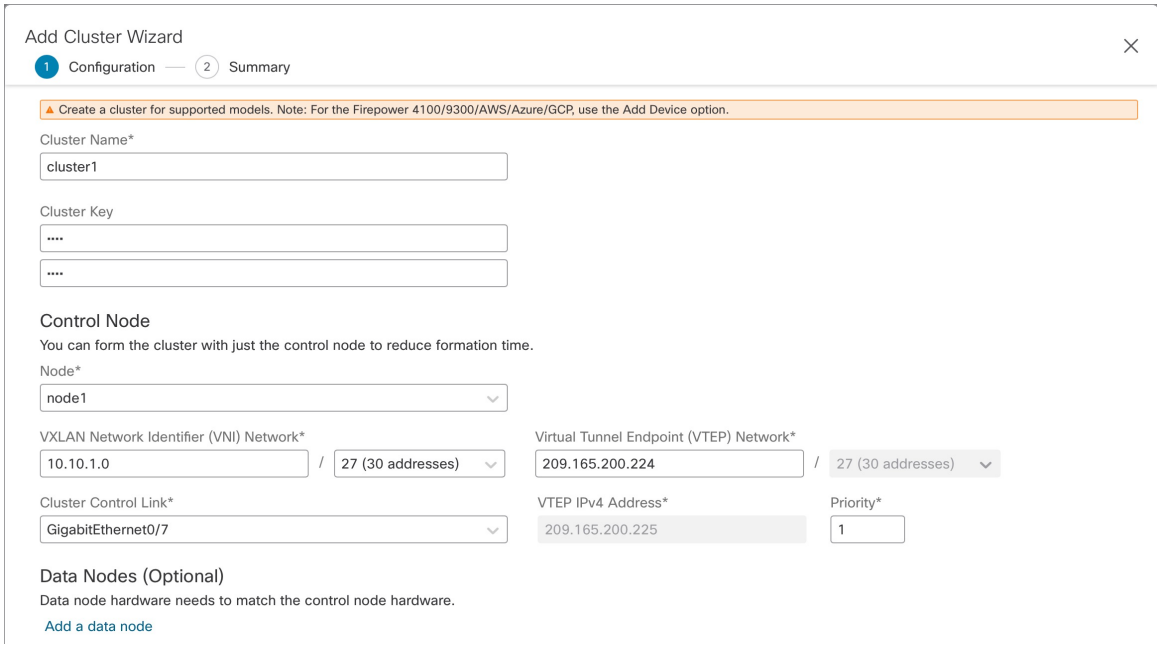
See Add a Device Using a Registration Key , on page 32. You can create a cluster with a single device, and then add more nodes later. The initial settings (licensing, access control policy) that you set when you add a device will be inherited by all cluster nodes from the control node. You will choose the control node when forming the cluster.

Create a cluster

Creating a cluster allows multiple devices to work together as a single logical unit, providing high availability and increased throughput capacity.

Form a cluster from one or more devices in the Firewall Management Center.

Before you begin



Some features are not compatible with clustering. Wait to configure until clustering is enabled. Some features will block cluster creation if they are already configured. For example, do not configure any IP addresses on interfaces, or unsupported interface types such as BVIs.

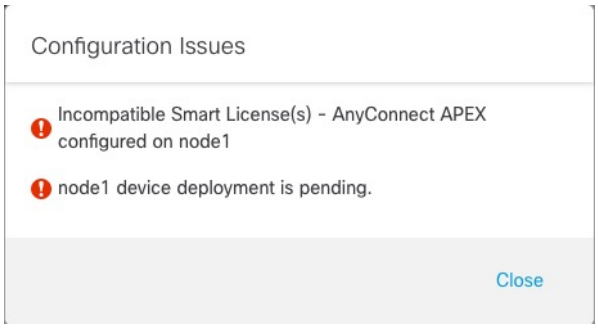
Procedure

Step 1 Choose **Devices** > **Device Management**, and then choose **Add** > **Cluster**.

The **Add Cluster Wizard** appears.

Figure 153: Add Cluster Wizard

Step 2 Specify a **Cluster Name** and an authentication **Cluster Key** for control traffic.



- **Cluster Name**—An ASCII string of 1 to 38 characters. The cluster name can contain only letters, digits, underscores (_), and hyphens (-).
- **Cluster Key**—An ASCII string of 1 to 63 characters. The cluster key cannot be a single digit and must not contain spaces. The **Cluster Key** value is used to generate the encryption key. This encryption does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in clear text.

Step 3 For the **Control Node**, set the following:

- **Node**—Choose the device that you want to be the control node initially. When the Firewall Management Center forms the cluster, it will add this node to the cluster first so it will be the control node.

Note If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation. For example:

Figure 154: Configuration Issues

To resolve the above issues, remove the unsupported VPN license and deploy pending configuration changes to the device.

- **VXLAN Network Identifier (VNI) Network**—Specify an IPv4 subnet for the VNI network; IPv6 is not supported for this network. Specify a **24**, **25**, **26**, or **27** subnet. An IP address will be auto-assigned to each node on this network. The VNI network is the encrypted virtual network that runs on top of the physical VTEP network.
- **Cluster Control Link**—Choose the physical interface you want to use for the cluster control link.
- **Virtual Tunnel Endpoint (VTEP) Network**—Specify an IPv4 subnet for the physical interface network; IPv6 is not supported for this network. The VTEP network is a different network than the VNI network, and it is used for the physical cluster control link.
- **VTEP IPv4 Address**—This field will be auto-populated with the first address on the VTEP network.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority. Even if you set the priority to be lower than other nodes, this node will still be the control node when the cluster is first formed.

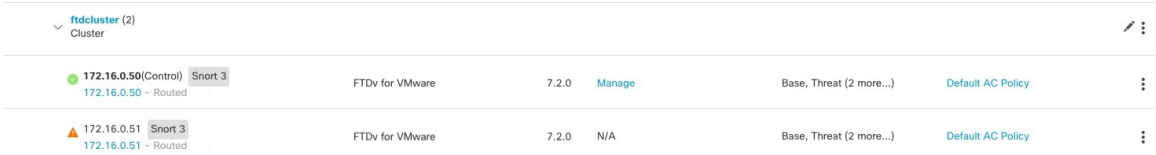
Step 4 For **Data Nodes (Optional)**, click **Add a data node** to add a node to the cluster.

You can form the cluster with only the control node for faster cluster formation, or you can add all nodes now. Set the following for each data node:

- **Node**—Choose the device that you want to add.

Note If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation.

- **VTEP IPv4 Address**—This field will be auto-populated with the next address on the VTEP network.



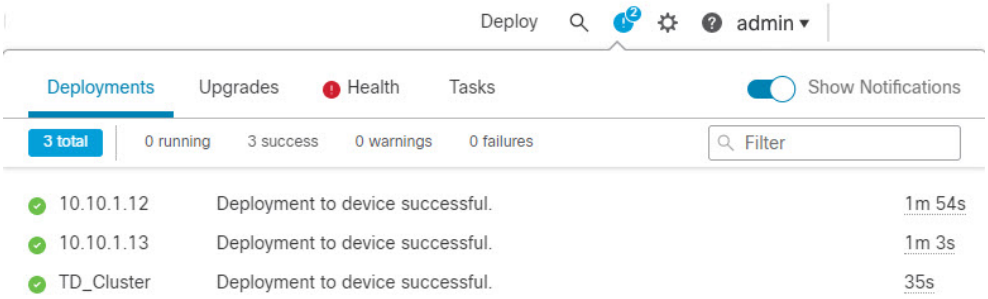
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority.

Step 5 Click **Continue**. Review the **Summary**, and then click **Save**.

The cluster bootstrap configuration is saved to the cluster nodes. The bootstrap configuration includes the VXLAN interface used for the cluster control link.

The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster nodes.

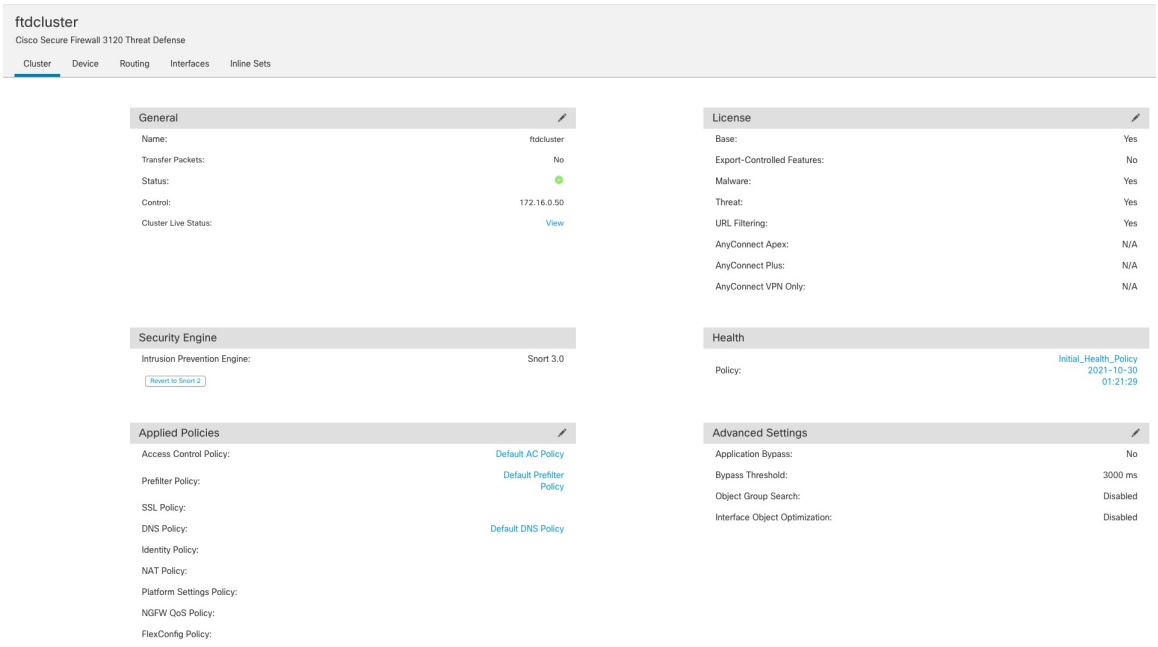
Figure 155: Cluster Management



A node that is currently registering shows the loading icon.

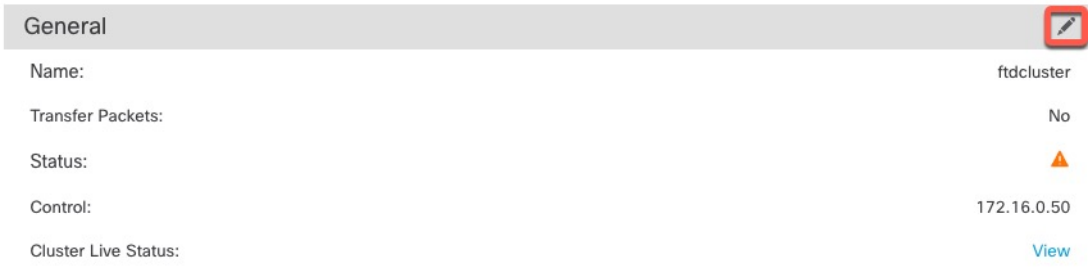
Figure 156: Node Registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**. The Firewall Management Center updates the Cluster Registration task as each node registers.



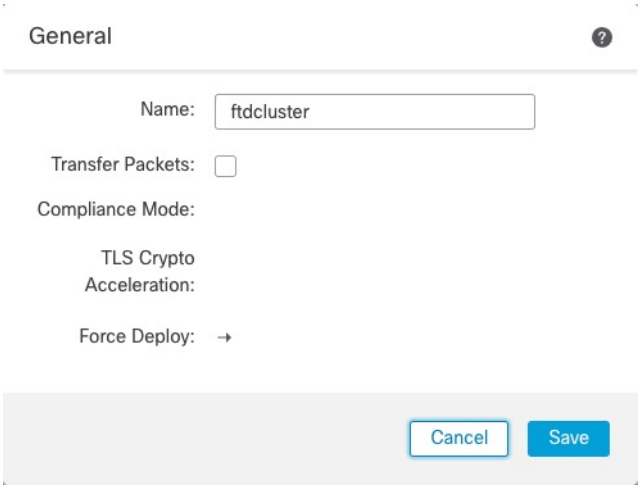
Step 6 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.



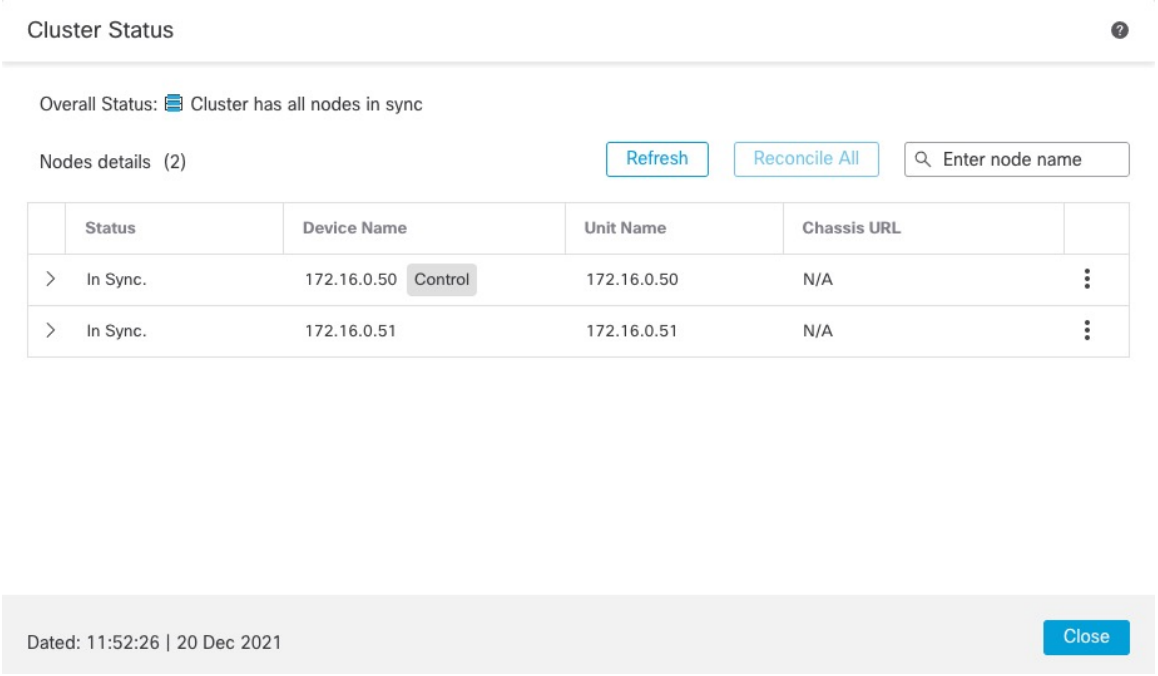
Step 7 On the **Devices** > **Device Management**, **Cluster** screen, you see **General** and other settings for the cluster.

Figure 157: Cluster Settings



See the following cluster-specific items in the **General** area:

- **General > Name**—Change the cluster display name by clicking the **Edit** (✎).



Then set the **Name** field.

- **General > View**—Click the **View** link to open the **Cluster Status** dialog box.

The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile All**.You can also ping the cluster control link from a node. See Perform a ping on the cluster control link, on page 367.

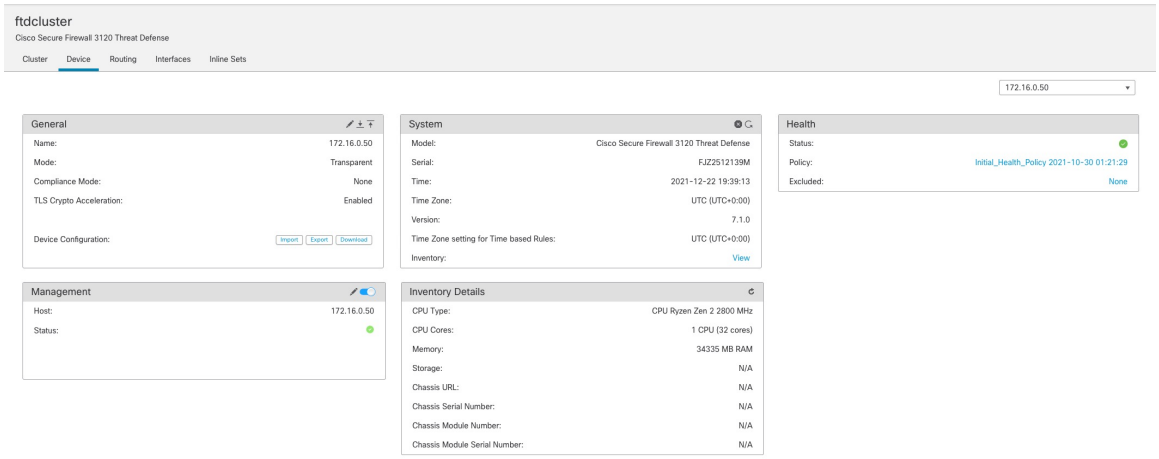
- **General > Troubleshoot**— Use **Logs** to generate troubleshooting files for all nodes in the cluster, **CLI** to view output from predefined cluster diagnostic commands, and **Download** to download the generated cluster troubleshooting archive

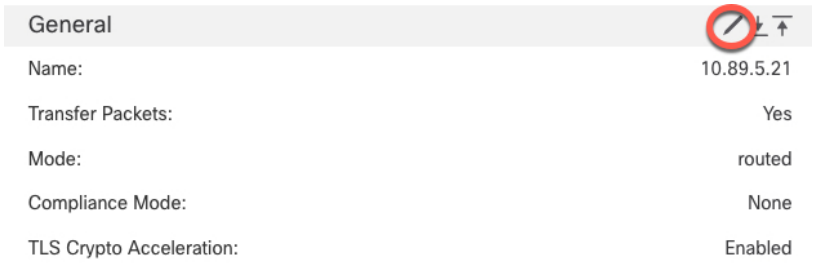
  For more information, refer to Troubleshoot the cluster, on page 365.

Figure 158: Troubleshoot

Step 8 On the **Devices** > **Device Management** and then click **Add** > **Device**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.

Figure 159: Device Settings





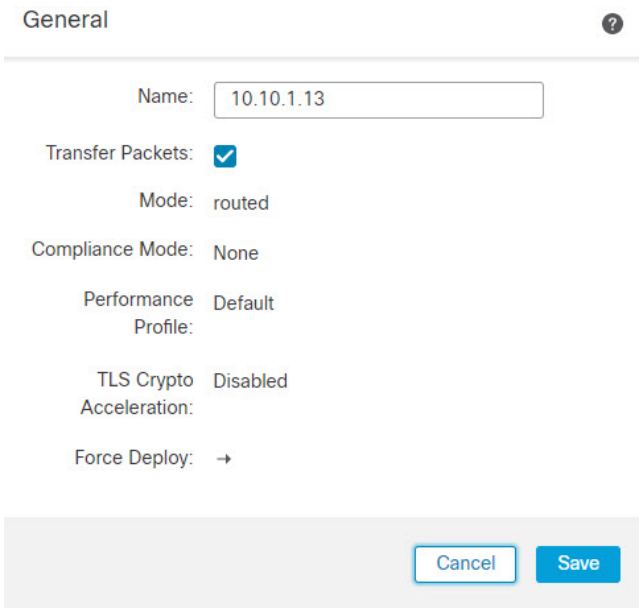


Figure 160: Choose Node

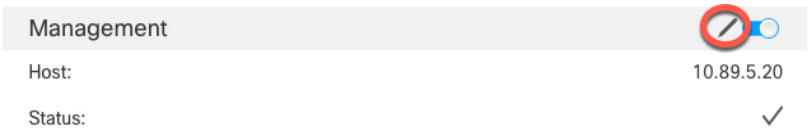


- **General > Name**—Change the cluster member display name by clicking the **Edit** ( ).

Then set the **Name** field.

- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the Firewall Management Center so that it can reach the device on the network. First disable the connection, edit the **Host** address in the **Management** area, then re-enable the connection.

Step 9 If you deployed your cluster nodes without enabling jumbo-frame reservation, then restart all cluster nodes to enable jumbo frames, which are required for the cluster control link. See Shut down or restart the device, on page 55.

If you previously enabled jumbo-frame reservation, you can skip this step.

Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead (100 bytes) and VXLAN overhead (54 bytes). When you create the cluster, the MTU is set to 154 bytes higher than the highest data interface MTU (1654 by default). If you later increase the data interface MTU, be sure to also increase the cluster control link MTU. For example, because the maximum MTU is 9198 bytes, then the highest data interface MTU can be 9044, while the cluster control link can be set to 9198. See Configure the MTU, on page 717.

Make sure you configure switches connected to the cluster control link to the correct (higher) MTU; otherwise, cluster formation might fail.

Configure interfaces

Configure interfaces to be compatible with clustering by setting up individual interfaces that are normal routed interfaces, each with their own IP address taken from a pool of IP addresses.

Individual interfaces are normal routed interfaces, each with their own IP address taken from a pool of IP addresses. The Main cluster IP address is a fixed address for the cluster that always belongs to the current control node. All data interfaces must be Individual interfaces.

Note You cannot use subinterfaces.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Address Pools** to add an IPv4 address pool, an IPv6 address pool, or both. See Configure address pools, on page 2356.

Include at least as many addresses as there are units in the cluster. The Virtual IP address is not a part of this pool, but needs to be on the same network. You cannot determine the exact Local address assigned to each unit in advance.

Step 2 Choose **Devices** > **Device Management**, and click **Edit** ( ) next to the cluster.

Step 3 Click **Interfaces**, and then click **Edit** ( ) for a data interface.

Step 4 On the **IPv4**, enter the **IP Address** and mask. This IP address is a fixed address for the cluster, and always belongs to the current control unit.

Step 5 From the **IPv4 Address Pool** drop-down list, choose the address pool you created.

Note If you want to manually assign a MAC address to this interface, you need to create a **MAC-address pool** using FlexConfig.

Step 6 On **IPv6** > **Basic**, from the **IPv6 Address Pool** drop-down list, choose the address pool you created.

Step 7 Configure other interface settings as normal.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Cluster Health Monitor Settings

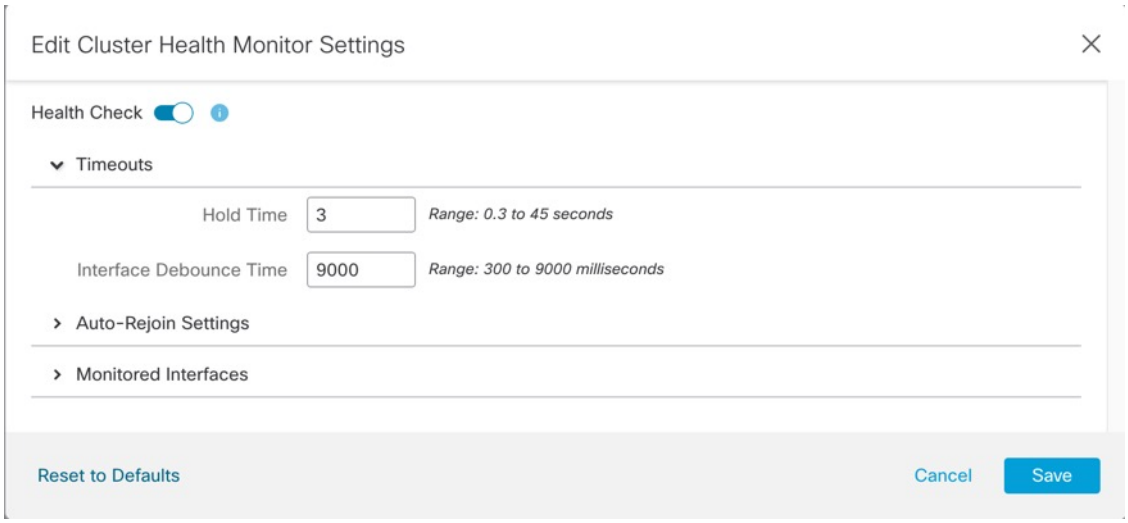
This task allows you to modify cluster health monitor settings to control how cluster nodes monitor system health and automatically rejoin the cluster after failures.

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings for monitoring cluster node health. You can monitor any port-channel ID, any single physical interface ID, and the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link. It is always monitored.

When a topology change occurs (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature. Also, disable interface monitoring for any interfaces that are disabled. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Procedure

Step 1 Choose **Devices** > **Device Management**.



Step 2 Next to the cluster you want to modify, click **Edit** ( ).

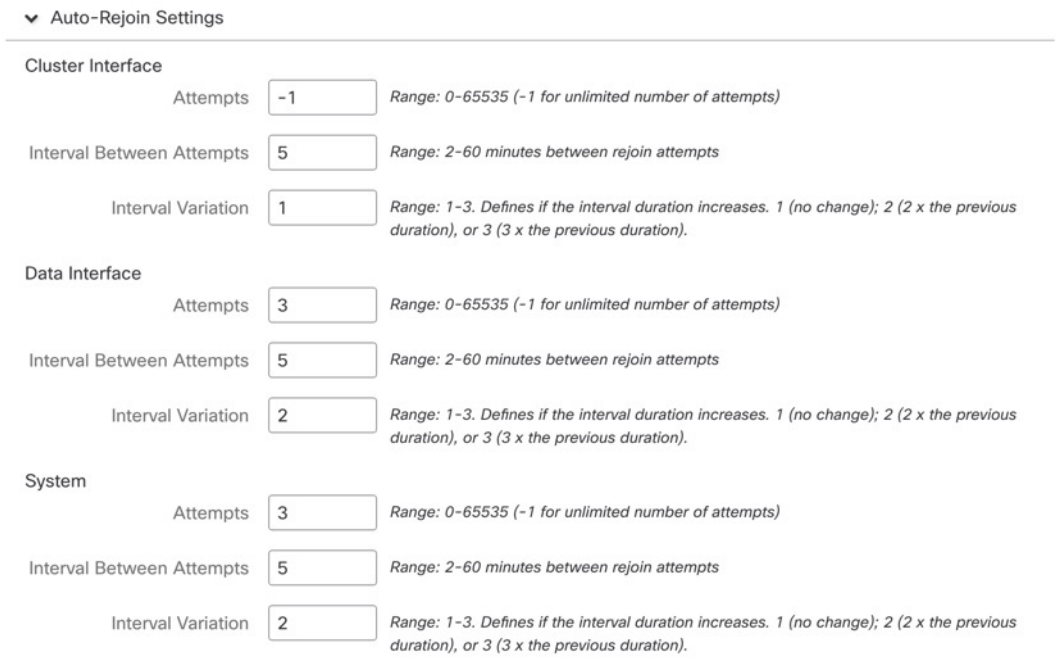
Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider.

Figure 161: Disable the system health check

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.



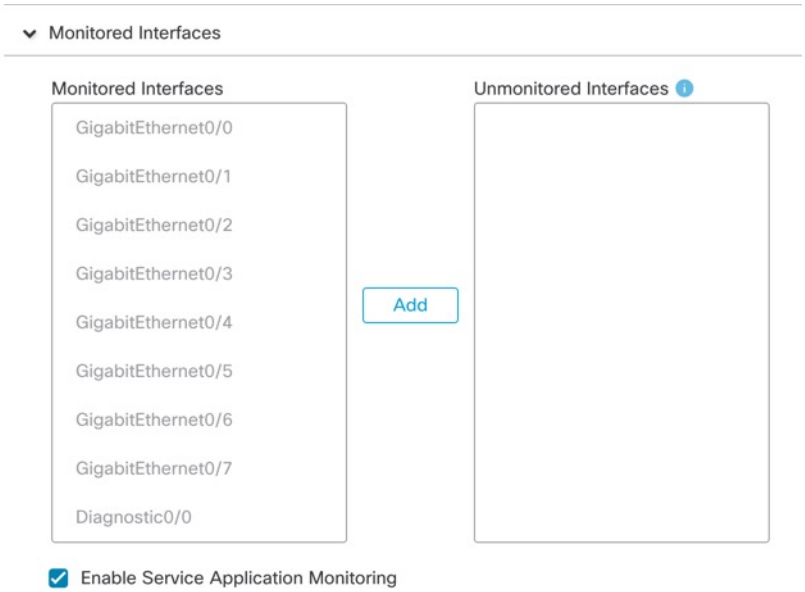
Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between 0.3 and 45 seconds. The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the specified number of milliseconds before marking the interface as failed and removing the node from the cluster. If an EtherChannel transitions from a down state to an up state, such as after the switch reloads

or enables an EtherChannel, a longer debounce time can prevent the interface from appearing failed on a cluster node if another cluster node bundles the ports more quickly.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 162: Configure Auto-Rejoin settings



Set values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 163: Configure monitored interfaces

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The time required to remove a member from the cluster depends on the type of interface and whether the node is established or is joining the cluster. By default, health check is enabled for all interfaces and the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

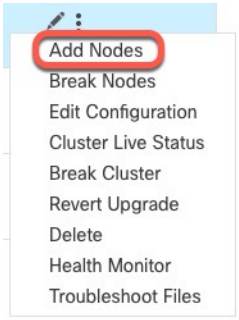
Step 9 Click **Save**.

Deploy configuration changes; see Deploy configuration changes, on page 135.

Manage cluster nodes

Describes how to manage cluster nodes to maintain high availability and optimal performance across your Cisco Secure Firewall cluster deployment.

Add a new cluster node



Adding new cluster nodes expands cluster capacity and provides additional redundancy for your security infrastructure.

You can add one or more new cluster nodes to an existing cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) for the cluster, and choose **Add Nodes**.

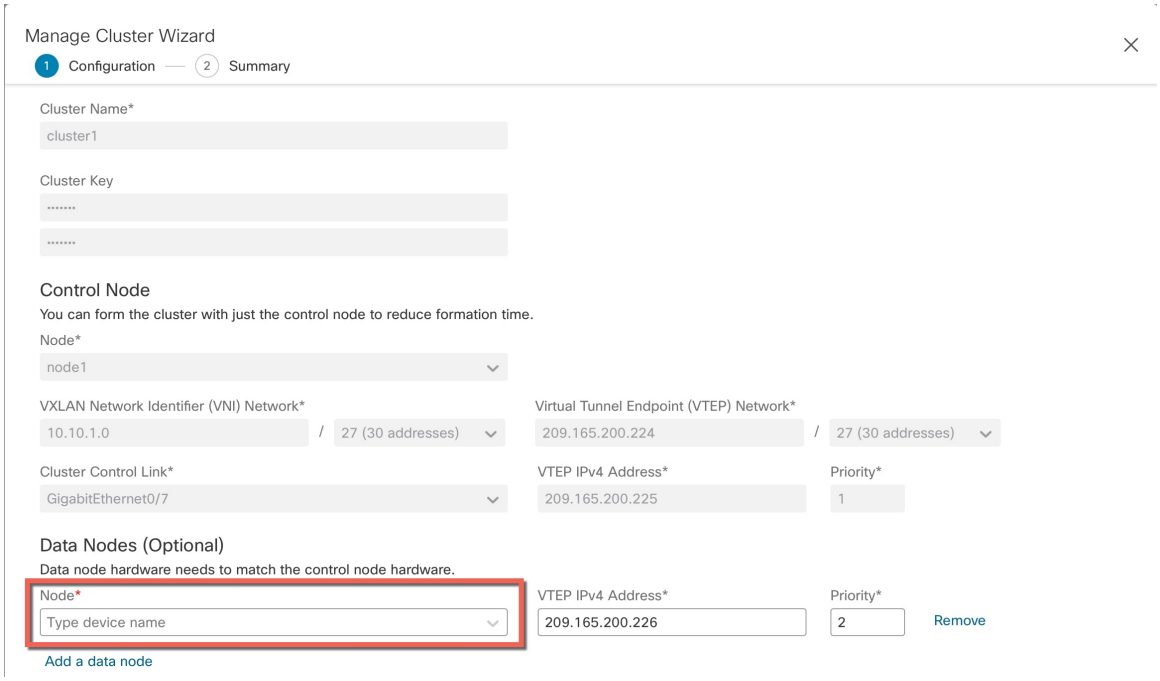


Figure 164: Add nodes

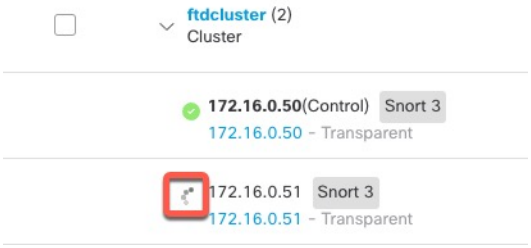
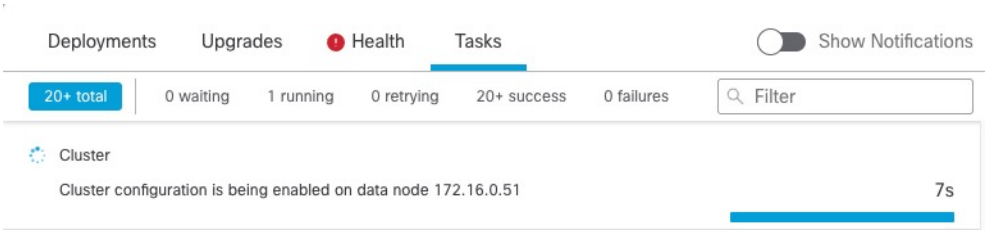
The **Manage Cluster Wizard** appears.

Step 2 From the **Node** menu, choose a device, and adjust the IP address and priority if desired.

Figure 165: Manage cluster wizard



Step 3 To add additional nodes, click **Add a data node**.



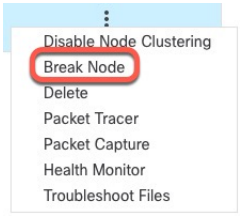
Step 4 Click **Continue**. Review the **Summary**, and then click **Save**

The node that is currently registering shows the loading icon.

Figure 166: Node registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**.

Break a node



Breaking a node removes it from the cluster configuration, converting it to a standalone device.

You can remove a node from the cluster so that it becomes a standalone device. You cannot break the control node unless you break the entire cluster. The data node has its configuration erased.

Procedure

Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) for the node you want to break, and choose **Break Node**.

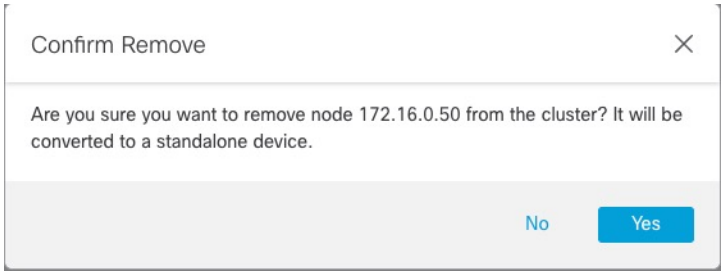


Figure 167: Break a node

You can optionally break one or more nodes from the cluster More menu by choosing **Break Nodes**.

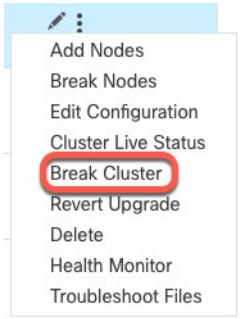
Step 2 You are prompted to confirm the break. Click **Yes**.

Figure 168: Confirm break

You can monitor the cluster node break by clicking the **Notifications** icon and choosing **Tasks**.

Break the cluster

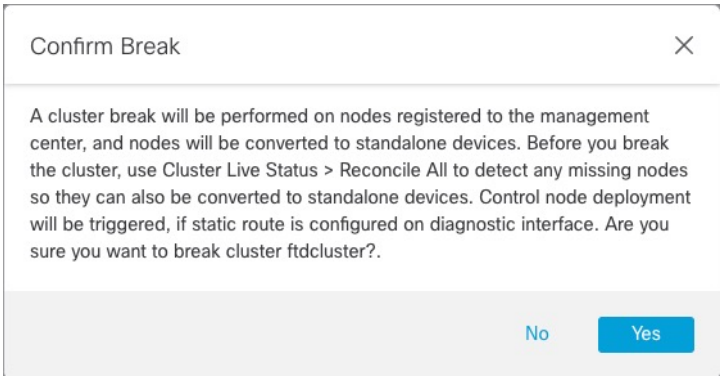
Break the cluster to convert all nodes to standalone devices when clustering is no longer needed.



You can break the cluster and convert all nodes to standalone devices. The control node retains the interface and security policy configuration, while data nodes have their configuration erased.

Procedure

Step 1 Make sure all cluster nodes are being managed by the Firewall Management Center by reconciling nodes. Refer to Reconcile cluster nodes, on page 411.



Step 2 Choose **Devices** > **Device Management**, click the **More** (⋮) for the cluster, and choose **Break Cluster**.

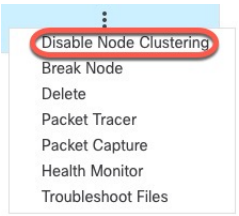
Figure 169: Break cluster

Step 3 You are prompted to break the cluster. Click **Yes**.

Figure 170: Confirm break

You can monitor the cluster break by clicking the **Notifications** icon and choosing **Tasks**.

Disable clustering



Temporarily deactivate a node in a cluster while keeping it visible in the device list.

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the Firewall Management Center device list. When a node becomes inactive, all data interfaces are shut down.

Procedure

Step 1 For the unit you want to disable, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Disable Node Clustering**.

Figure 171: Disable clustering

If you disable clustering on the control node, one of the data nodes will become the new control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to reestablish the connections on the new control node. You cannot disable clustering on the control node if it is the only node in the cluster.

Step 2 Confirm that you want to disable clustering on the node.

The node will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, refer to Rejoin the cluster, on page 409.

Rejoin the cluster

Rejoin a node to the cluster after it was removed because of failure or when clustering was manually disabled.

If a node was removed from the cluster, for example, due to a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster. Refer to Rejoining the cluster, on page 429 for more information about why a node can be removed from a cluster.

Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Enable Node Clustering**.

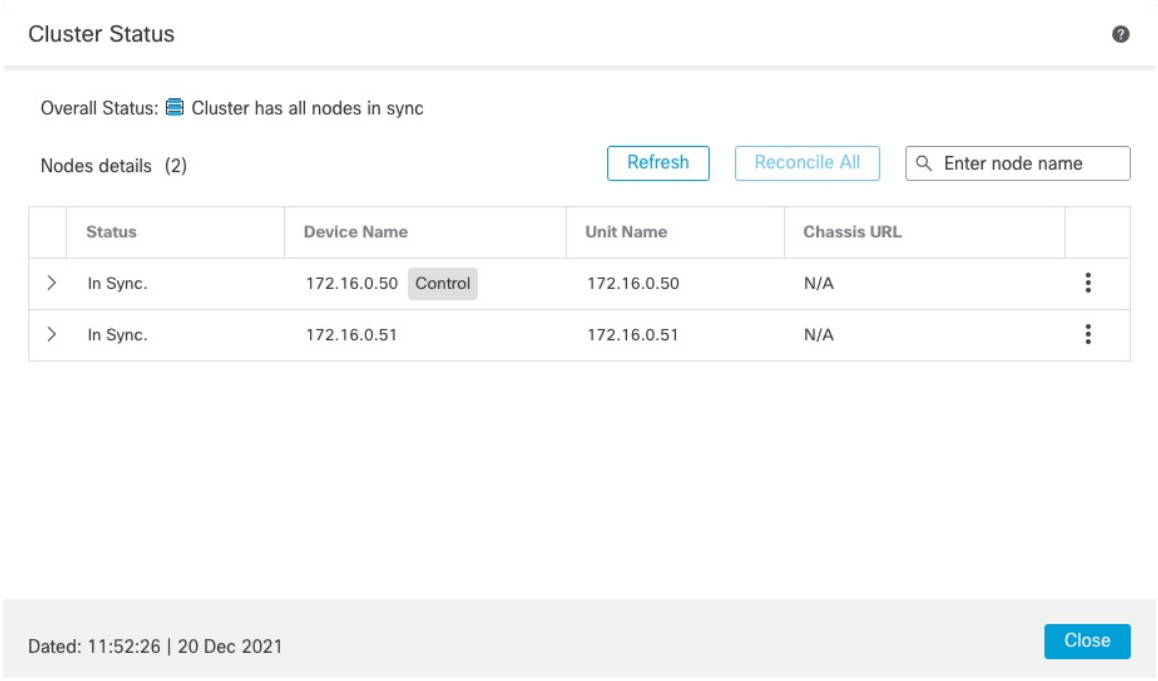
Step 2 Confirm that you want to enable clustering on the node.

Change the control node

This task changes the control node in a cluster when you need to specify the exact unit you want to become the control node.

The best method to change the control node is to disable clustering on the control node, wait for a new control election, and then re-enable clustering. Use this procedure when you must specify the exact unit you want to become the control node.

Caution If you must specify the *exact* unit you want to become the control node, use the procedure in this section. Note that for centralized features, if you force a control node change using either method, then all connections are dropped, and you have to re-establish the connections on the new control node.



Before you begin

Follow these steps to change the control node:

Procedure

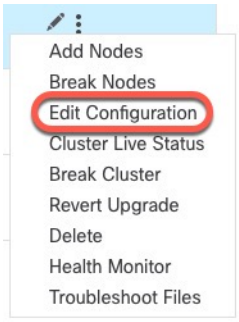
Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management**, **More** (⋮) > **Cluster Live Status**.

Figure 172: Cluster status

Step 2 For the unit you want to become the control unit, choose **More** > **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Select the checkbox and click **OK**.

Edit the cluster configuration



Edit the cluster configuration to modify cluster settings and parameters as needed for your network environment.

You can edit the cluster configuration. If you change any values other than the VTEP IP address for a node or node priority, the cluster will be broken and reformed automatically. Until the cluster is reformed, you may experience traffic disruption. If you change the VTEP IP address for a node or node priority, only the affected nodes are broken and readded to the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click the **More** for the cluster, and choose **Edit Configuration**.

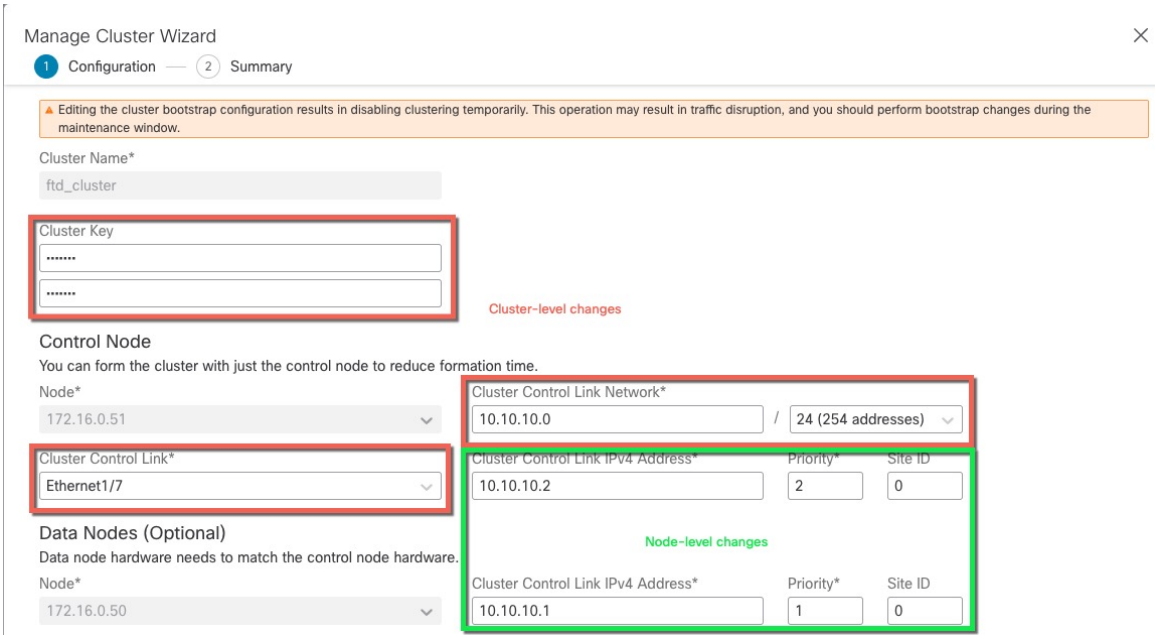


Figure 173: Edit configuration

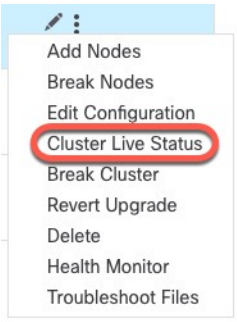
The **Manage Cluster Wizard** appears.

Step 2 Update the cluster configuration.

Figure 174: Manage cluster wizard

Step 3 Click **Continue**. Review the **Summary**, and then click **Save**.

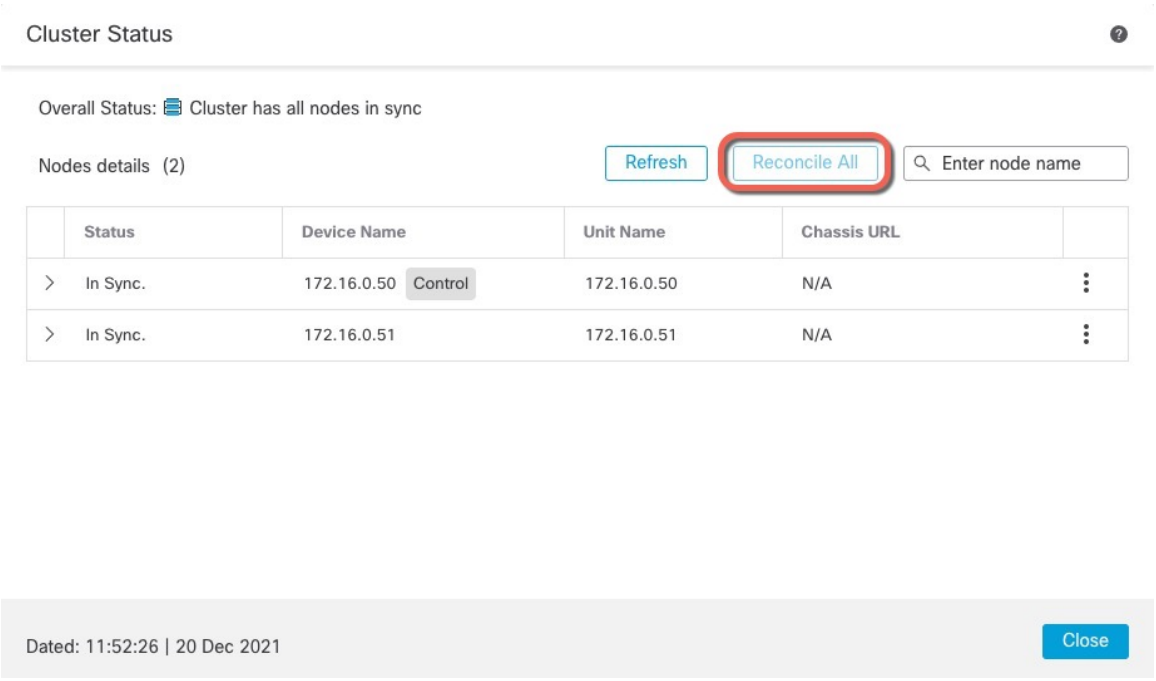
Reconcile cluster nodes



Use this procedure to reconcile cluster membership when a cluster node fails to register with the Firewall Management Center.

If a cluster node fails to register, you can reconcile the cluster membership from the device to the Firewall Management Center. For example, a data node might fail to register if the Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure



Step 1 Choose **Devices** > **Device Management**, **More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Figure 175: Cluster live status

Step 2 Click **Reconcile All**.

Figure 176: Reconcile all

Delete (Unregister) the cluster or nodes and register to a New Firewall Management Center

This task allows you to unregister cluster nodes from the current management center and register them to a different Management Center system.

Use this procedure when you need to move cluster nodes between Management Centers or when reconfiguring your management infrastructure.

You can unregister the cluster from the Firewall Management Center, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new Firewall Management Center.

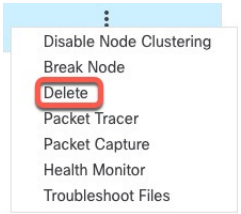
You can also unregister a node from the Firewall Management Center without breaking the node from the cluster. Although the node is not visible in the Firewall Management Center, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the Firewall Management Center, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

Unregistering a cluster:

- Severs all communication between the Firewall Management Center and the cluster.
- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the Firewall Management Center using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different Firewall Management Center causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so you can add the cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.



Before you begin

This procedure requires CLI access to one of the nodes.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster or node, and choose **Delete**.

Figure 177: Delete cluster or node

Step 2 You are prompted to delete the cluster or node; click **Yes**.

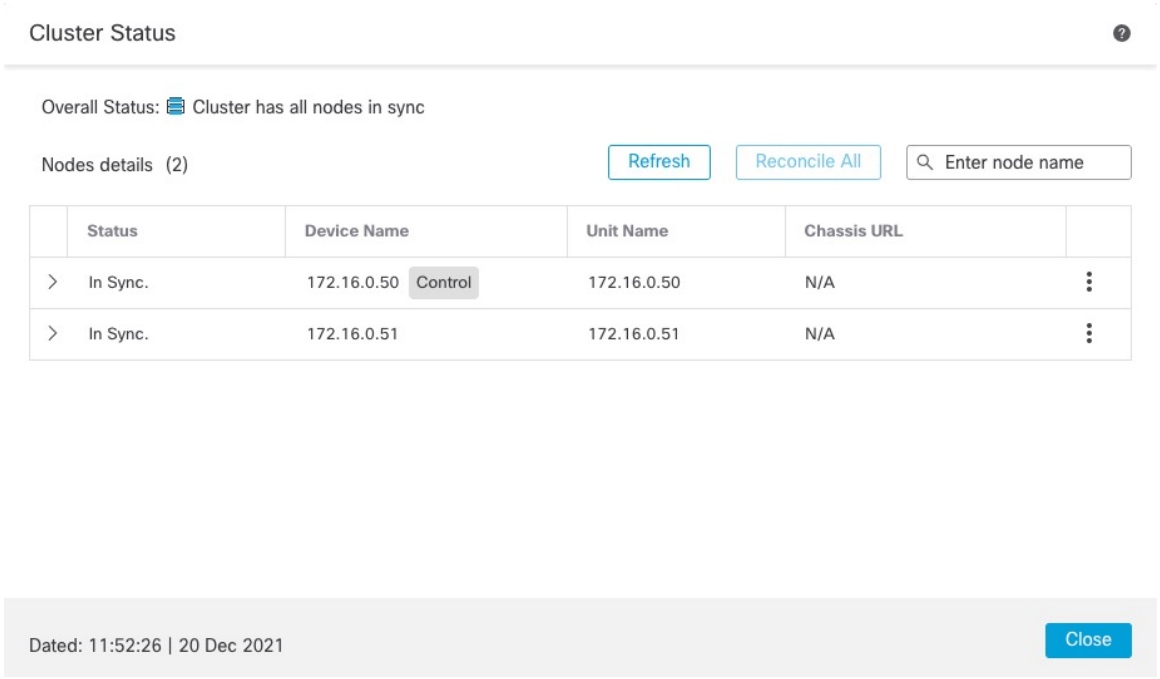
Step 3 You can register the cluster to a new or the same Firewall Management Center by adding one of the cluster nodes as a new device.

a) Connect to the CLI of one cluster node, and identify the new Firewall Management Center using the **configure manager add** command. See Modify Threat Defense Management Interfaces at the CLI.

b) Choose **Devices** > **Device Management**, and then click **Add Device**.

Add one of the cluster nodes as a device. The system will discover the remaining cluster nodes.

Step 4 To re-add a deleted node, refer to Reconcile cluster nodes, on page 411.



Monitor cluster status

You can monitor the cluster in the Firewall Management Center and at the Firewall Threat Defense CLI.

Monitor cluster status through these methods:

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management**, click **Add**, choose the **Cluster** page **General** area **Cluster Live Status** link.

Figure 178: Cluster status

The Control node has a graphic indicator identifying its role.

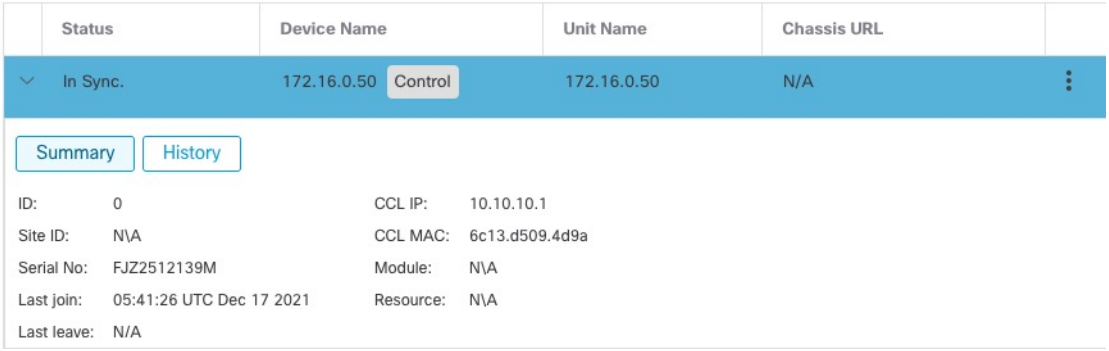
Cluster member **Status** includes these states:

- In Sync—The node is registered with the Firewall Management Center.

- Pending Registration—The node is part of the cluster, but has not yet registered with the Firewall Management Center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The node is registered with the Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Firewall Management Center.

For each node, you can view the **Summary** or the **History**.

Figure 179: Node summary



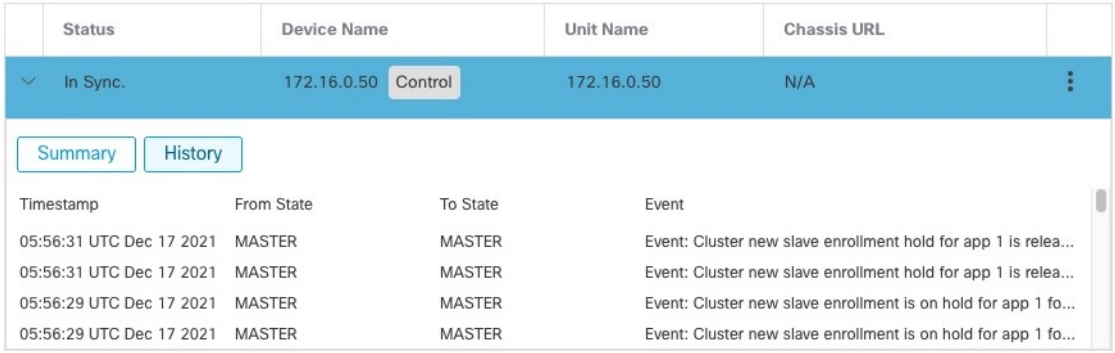


Figure 180: Node history

- **System** (⚙) > **Tasks** page.

  The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management** and then click **Add** > **Device** *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Cluster health monitor

When a Firewall Threat Defense is the control node of a cluster, the Firewall Management Center collects various metrics periodically from the device metric data collector.

The cluster health monitor is comprised of these components:

- Overview dashboard: Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard: Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.

- Member Performance dashboard: Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard: Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links: Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range: An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.

- Custom Dashboard: Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

View the cluster health monitor

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

Ensure you have created a cluster from one or more devices in the Firewall Management Center.

Follow these steps to view the cluster health monitor:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 Click on the cluster name to view the cluster health statistics.

The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution: Traffic and packet distribution across the cluster nodes.
- Member Performance: Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL: Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 Configure the time range from the drop-down in the upper-right corner.

The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 View device monitor health and performance metrics in several predefined dashboards.

The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU: CPU utilization, including the CPU usage by process and by physical cores.
- Memory: Device memory utilization, including data plane and Snort memory usage.
- Interfaces: Interface status and aggregate traffic statistics.
- Connections: Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort: Statistics that are related to the Snort process.
- ASP drops: Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. Refer to Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 30: Cluster Metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes

Metric	Description	Format
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number
Packets	Packet distribution count in the cluster for every second.	number

Troubleshoot the cluster

Use these methods to troubleshoot the devices and clusters:

- Use **Logs** to generates troubleshooting files for all nodes in the cluster. Use this option when you need one cluster-level collection instead of generating troubleshooting files from each node separately.
- Use **CLI** to run a predefined set of cluster diagnostic commands and displays the output. Use this option to check cluster configuration, member state, cluster health, control-plane transport statistics, packet drops, interface status, CPU usage, memory buffers, ARP entries, and reachability. The **CLI** option displays command output; it does not open an interactive CLI session.

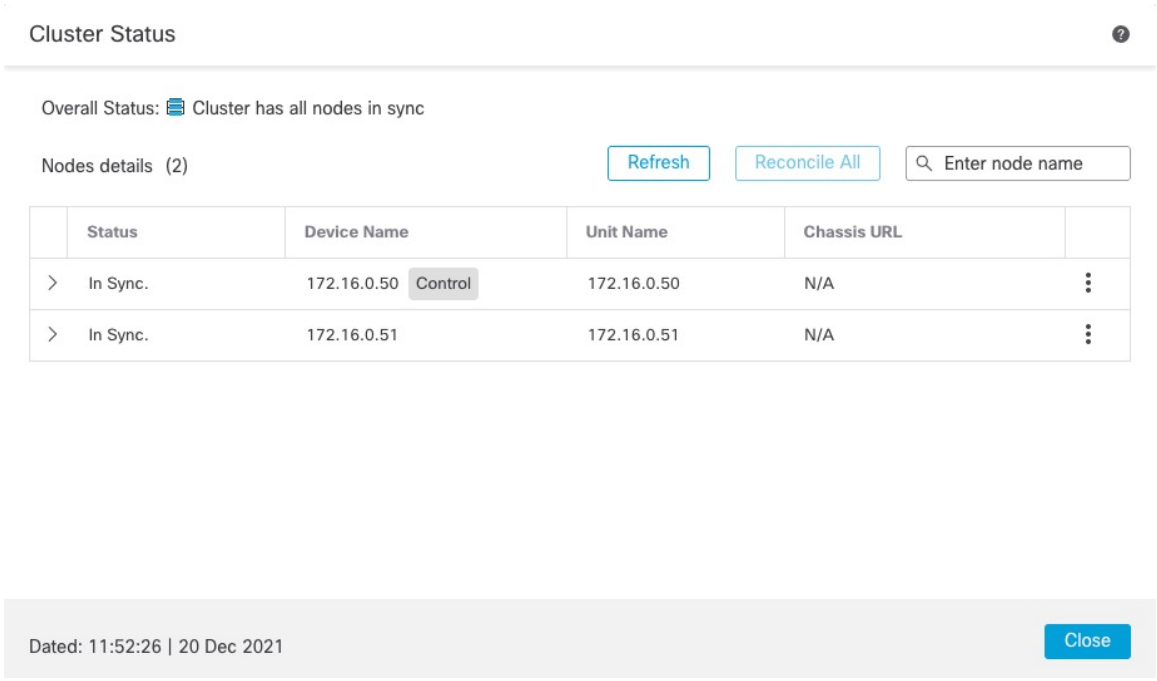
Commands
show running-config cluster: Review the cluster group configuration, local unit, cluster interface, priority, health-check, auto-rejoin, and cLACP settings.
show cluster info: Confirm that clustering is enabled and identify the control node, member state, software version, serial number, CCL IP address, CCL MAC address, and last join or leave state.
show cluster info health: Check unit, interface, service, and overall cluster health.
show cluster info transport cp: Review control-plane transport counters, including reliable and unreliable message counters, errors, retransmits, drops, and buffer conditions.
show version: Capture platform, software, build, UUID, LSP, VDB, uptime, resource, and license context.
show asp drop: Identify accelerated security path packet or flow drop reasons and counters.
show counters: Review protocol, feature, and cluster CCL counters.
show arp: Verify ARP entries for interfaces that participate in cluster communication.
show int ip brief: Check interface IP addresses and administrative and line protocol status.
show blocks: Check buffer availability and failed allocations.
show cpu detailed: Check data path, control point, and total CPU usage.

Commands
show interface *ccl_interface*: Review interface state, MTU, MAC address, IP address, traffic counters, errors, and drops for the cluster-related interface.
ping *ccl_ip* **size** *ccl_mtu* **repeat 2**: Test reachability to a cluster peer by using the packet size selected by the tool.

- Use the **CCL Ping** when you need to test cluster control link connectivity between joined cluster nodes.
- Troubleshooting files—If a node fails to join the cluster, a troubleshooting file is automatically generated. You can also generate and download troubleshooting files from the **Devices** > **Device Management** and then choose **Add**, **ClusterGeneral** area. For more information, refer to Generate troubleshooting files, on page 745.

  You can also generate files from the **Device Management** page. Click **More** (⋮) and choose **Troubleshoot Files**.
- CLI output—Choose **Devices** > **Device Management** and then choose **Add**, **ClusterGeneral** area, you can view a set of pre-defined CLI outputs that can help you troubleshoot the cluster. These commands are automatically run for the cluster:

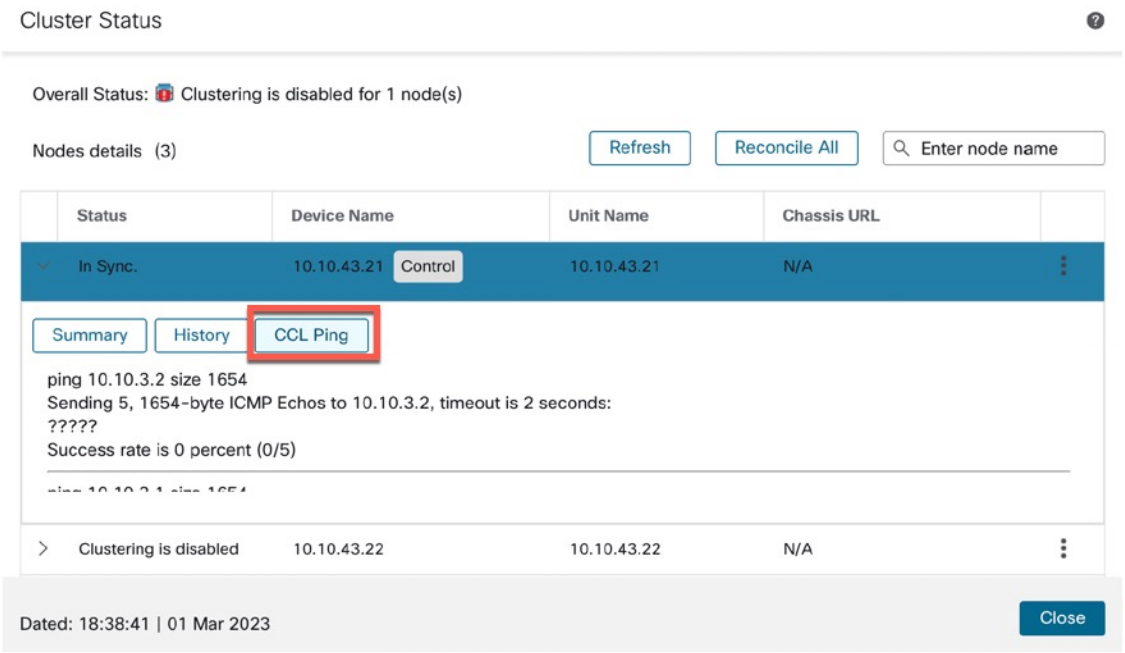
  You can also enter any **show** command in the **Command** field.



Perform a ping on the cluster control link

You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs.

Procedure



Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) icon next to the cluster, and choose **Cluster Live Status**.

Figure 181: Cluster status

Step 2 Expand one of the nodes, and click **CCL Ping**.

Figure 182: CCL ping

The node sends a ping on the cluster control link to every other node using a packet size that matches the maximum MTU.

Reference for clustering

This section includes more information about how clustering operates.

Threat Defense features and clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported features and clustering

Centralized features for clustering

These features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, refer to the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. For more information, refer to FlexConfig policies, on page 921.

- These application inspections are supported:
  - DCERPC and ESMTP
  - NetBIOS and PPTP
  - RSH
  - SQLNET and SUNRPC
  - TFTP
  - XDMCP

- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

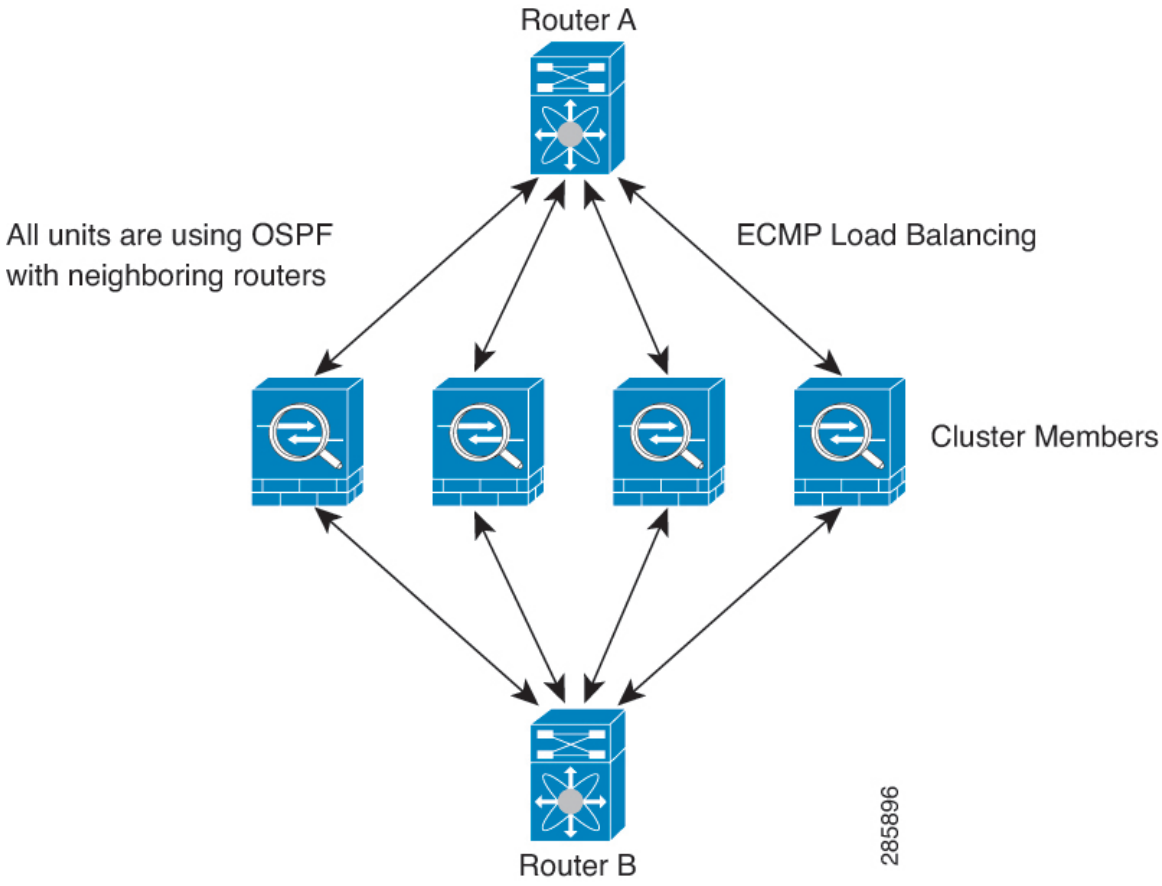
Connection settings and clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic routing and clustering

Dynamic routing and clustering are network configuration approaches that

- enable each node to run the routing protocol as a standalone router in Individual interface mode,
- allow routes to be learned by each node independently, and
- require separate router IDs for each node when communicating with external routers.



Routing behavior and load balancing

In Individual interface mode, ECMP is used to load balance traffic between multiple equal-cost paths. External routers can discover multiple paths to destinations through different cluster nodes.

Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when communicating with external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

Figure 183: Dynamic routing in individual interface mode

FTP and clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

NAT and clustering

Provides information about NAT behavior and limitations in clustering deployments.

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different Firewall Threat Defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the Firewall Threat Defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- No Proxy ARP—For individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with an ASA that may no longer be in the cluster. The upstream router requires a static route or policy-based routing (PBR) with Object Tracking for the mapped addresses, which must point to the main cluster IP address.
- No interface PAT on an individual interface—Interface PAT is not supported for Individual interfaces.
- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP

- RSH
- SQLNET
- TFTP
- XDMCP
- SIP

- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP inspection and clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

Cisco trustsec and clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and clustering

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

For connections to an individual interface when using Policy-Based Routing (PBR) or Equal-Cost Multi-Path (ECMP), you must always connect to the Main cluster IP address, not a Local address.

VPN-related keys and certificates are replicated to all nodes.

Note Remote access VPN is not supported with clustering.

Performance scaling factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

Throughput calculation

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control node election

The key components involved in the control node election process are:

- Cluster nodes: Communicate over the cluster control link and participate in the election process
- Election requests: Broadcast every three seconds by nodes when clustering is enabled
- Priority values: Set between 1 and 100 where 1 is the highest priority
- Control node: The elected node that coordinates cluster operations

These stages describe how cluster nodes elect a control node:

1. When clustering is enabled for a node (or when it first starts up with clustering already enabled), the node broadcasts an election request every three seconds.
2. Any other nodes with a higher priority respond to the election request. The priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node. The existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split-brain" scenario where multiple control nodes exist temporarily, the node with the highest priority retains the role, while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High availability within the cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node health monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

Split brain scenario

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

Interface monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

All physical interfaces are monitored; only named interfaces can be monitored. You can optionally disable monitoring per interface.

A node is removed from the cluster if its monitored interfaces fail. The node is removed after 500 milliseconds.

Status after failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Firewall Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the Firewall Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data path connection state replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 31: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—

Traffic	State Support	Notes
SNMP Engine ID	**No**	—

How the cluster manages connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.
- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

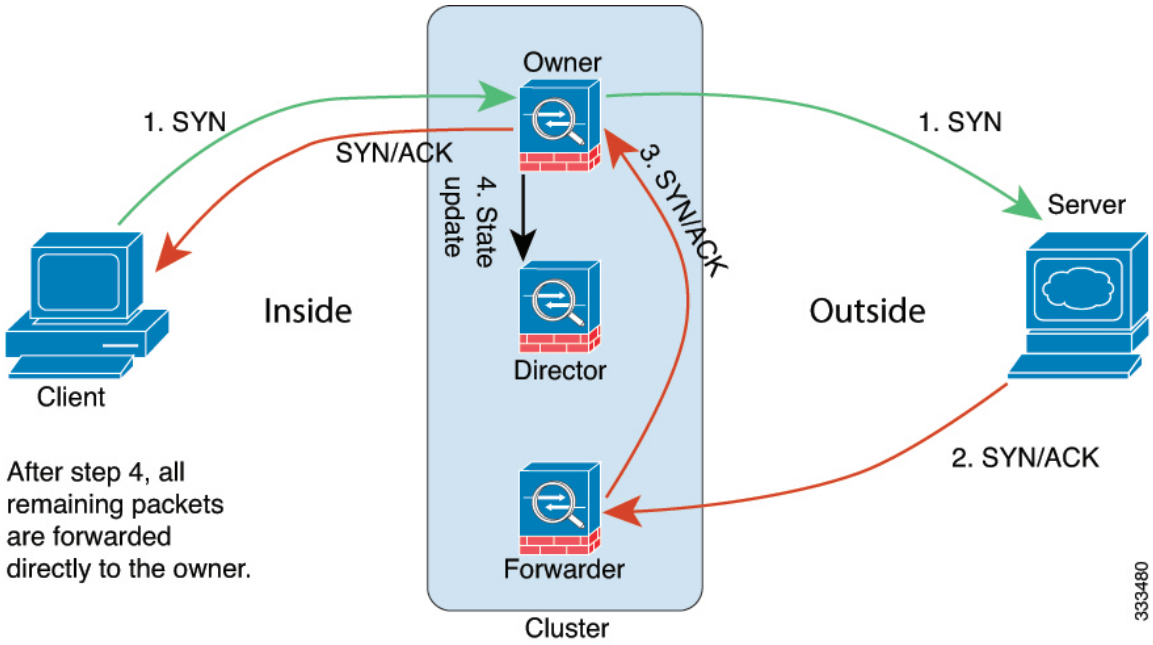
  ICMP/ICMPv6 hash details:

  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.
- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner.

A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.



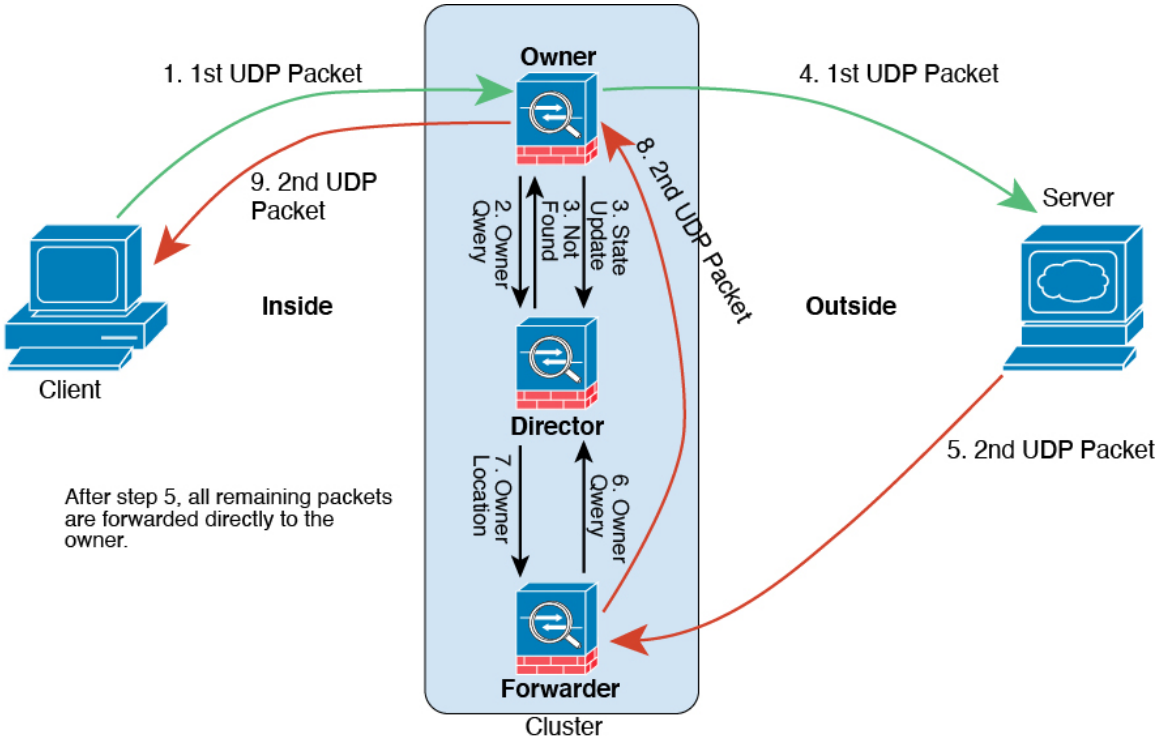
Port Address Translation Connections

New connection ownership

Traffic redirection is not supported in this release. When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. All the subsequent packets for the same connection should arrive the same node. If any connection packets arrive at a different node, they will be dropped. If a reverse flow arrives at a different node, it will be dropped as well. For centralized features, if the connections do not arrive on the control node, they will be dropped.

Sample data flow for TCP

The following example shows the establishment of a new connection.



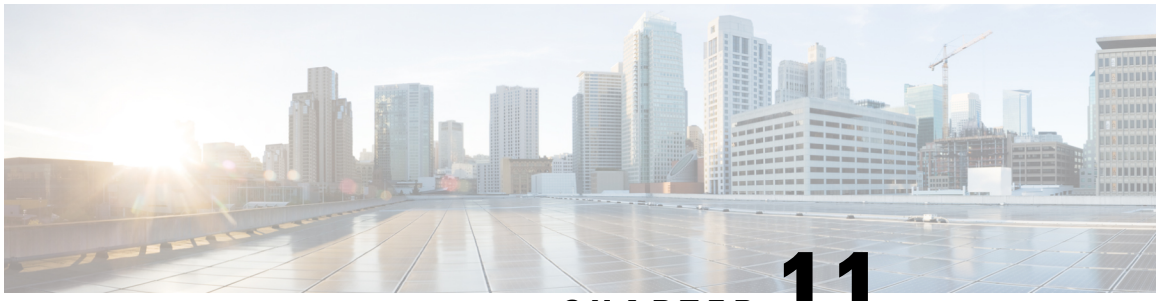
1. The SYN packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different Firewall Threat Defense (based on the load balancing method). This Firewall Threat Defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample data flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. *Figure 184: ICMP and UDP Data Flow*

The first UDP packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method).



2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for clustering: private cloud

This reference provides the feature history for clustering functionality in private cloud environments, including version information, platform compatibility, and detailed descriptions of enhancements and new capabilities.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Clustering for the Firewall Threat Defense Virtual on VMware and KVM	7.4.1	7.4.1	The Firewall Threat Defense Virtual now supports individual interface clustering for up to 16 nodes on VMware and KVM.
Cluster control link ping tool.	7.2.6/7.4.1	Any	You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs. New/modified screens: **Devices** > **Device Management** > **More** > **Cluster Live Status.**
Troubleshooting file generation and download available from Device and Cluster pages.	7.4.1	7.4.1	You can generate and download troubleshooting files for each device on the Device page and also for all cluster nodes on the Cluster page. For a cluster, you can download all files as a single compressed file. You can also include cluster logs for the cluster for cluster nodes. You can alternatively trigger file generation from the **Devices** > **Device Management** > **More** > **Troubleshoot Files** menu. New/modified screens: • **Devices** > **Device Management** > **Device** > **General** • **Devices** > **Device Management** > **Cluster** > **General**
Automatic generation of a troubleshooting file on a node when it fails to join the cluster.	7.4.1	7.4.1	If a node fails to join the cluster, a troubleshooting file is automatically generated for the node. You can download the file from **Tasks** or from the **Cluster** page.
View CLI output for a device or device cluster.	7.4.1	Any	You can view a set of pre-defined CLI outputs that can help you troubleshoot the device or cluster. You can also enter any **show** command and see the output. New/modified screens: **Devices** > **Device Management** > **Cluster** > **General**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Cluster health monitor settings	7.3.0	Any	You can now edit cluster health monitor settings. New/Modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Cluster health monitor dashboard	7.3.0	Any	You can now view cluster health on the cluster health monitor dashboard. New/Modified screens: **System** > **Health** > **Monitor**
Clustering for the Firewall Threat Defense Virtual on VMware and KVM	7.2.0	7.2.0	The Firewall Threat Defense Virtual supports Individual interface clustering for up to 4 nodes on VMware and KVM. New/Modified screens: • **Devices** > **Device Management** > **Add Cluster** • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** Supported platforms: Firewall Threat Defense Virtual on VMware and KVM

CHAPTER 11

Clustering: Public Cloud

Clustering lets you group multiple Firewall Threat Defense Virtuals together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. You can deploy Firewall Threat Defense Virtual clusters in a public cloud using the following public cloud platforms:

- Amazon Web Services (AWS)
- Microsoft Azure
- Google Cloud Platform (GCP)

Currently, only routed firewall mode is supported.

Note Some features are not supported when using clustering. See Unsupported Features and Clustering.

About Threat Defense Virtual clustering in the public cloud

This section describes the clustering architecture and how it works.

How the cluster fits into your network

The cluster consists of multiple firewalls acting as a single device. To act as a cluster, the firewalls need the following infrastructure:

- Isolated network for intra-cluster communication, known as the cluster control link, using VXLAN interfaces. VXLANs, which act as Layer 2 virtual networks over Layer 3 physical networks, let the Firewall Threat Defense Virtual send broadcast or multicast messages over the cluster control link.
- Load Balancer(s)—For external load balancing, you have the following options depending on your public cloud:
  - AWS Gateway Load Balancer

    The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Firewall Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint) using a Geneve interface single-arm proxy.
  - Azure Gateway Load Balancer

    In an Azure service chain, Firewall Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Firewall Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.
  - Native GCP load balancers, internal and external
  - Equal-Cost Multi-Path Routing (ECMP) using inside and outside routers such as Cisco Cloud Services Router

    ECMP routing can forward packets over multiple “best paths” that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses or source and destination ports, or both, can be used to send a packet to one of the next hops. If you use static routes for ECMP routing, then the Firewall Threat Defense failure can cause problems; the route continues to be used, and traffic to the failed Firewall Threat Defense will be lost. If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each Firewall Threat Defense to participate in dynamic routing.

Note Layer 2 Spanned EtherChannels are not supported for load balancing.

Individual interfaces

You can configure cluster interfaces as individual interfaces.

Individual interfaces are normal routed interfaces, each with their own local IP address. The IP address for the interface will be configured automatically via DHCP. Static IP configuration is not supported.

Control and data node roles

When you add a cluster in the Firewall Management Center , you choose one firewall to be the control node, and all additional firewalls to be data nodes. When you first create the cluster, the control node you specify will become the control node simply because it is the first node added to the cluster. Later, if multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority.

When you create the cluster and deploy the cluster configuration, the Firewall Management Center deploys a special bootstrap configuration to each node that includes fundamental settings such as the cluster control link configuration. The bootstrap configuration lets each node join the cluster. Most bootstrap settings are defined in the cluster wizard; however, you define the cluster control link interface hardware configuration (for example, creating an EtherChannel or setting the Ethernet speed) on the control node before you create the cluster. The cluster control link settings are copied to the bootstrap configuration for each node.

All nodes in the cluster share the same policy configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster. After you create the cluster, all configuration changes are made at the cluster level and are shared by all nodes.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Cluster Control Link

Each node must dedicate one interface as a VXLAN (VTEP) interface for the cluster control link. For more information about VXLAN, see Configure VXLAN interfaces, on page 680 .

VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

VTEP Source Interface

The VTEP source interface is a regular Firewall Threat Defense Virtual interface with which you plan to associate the VNI interface. You can configure one VTEP source interface to act as the cluster control link. The source interface is reserved for cluster control link use only. Each VTEP source interface has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

VNI Interface

A VNI interface is similar to a VLAN interface. It is a virtual interface that keeps network traffic separated on a given physical interface by using tagging. You can only configure one VNI interface. Each VNI interface has an IP address on the same subnet.

Peer VTEPs

Unlike regular VXLAN for data interfaces, which allows a single VTEP peer, Firewall Threat Defense Virtual clustering allows you to configure multiple peers.

Cluster control link traffic overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Configuration replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management network

You must manage each node using the management interface. Management from a data interface is not supported with clustering.

Licenses for Threat Defense Virtual clustering

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

Note APEX, PLUS, and VPN-Only licenses are not supported for clustering. Before you create a cluster, remove unsupported license assignments from the devices that will become cluster nodes.

Performance tier license requirements

Each Firewall Threat Defense Virtual cluster node requires the same performance tier license. We recommend using the same number of CPUs and memory for all members, or else performance will be limited on all nodes to match the least capable member. The throughput level will be replicated from the control node to each data node so they match.

When you add the control node to the Firewall Management Center, you can specify the feature licenses you want to use for the cluster. You can modify licenses for the cluster in the **Devices** > **Device Management**, **Cluster** > **License** area.

Note If you add the cluster before the Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and prerequisites for Threat Defense Virtual clustering

This reference provides the requirements and prerequisites for Threat Defense Virtual clustering, including model specifications, user roles, hardware and software requirements, and MTU configuration.

Model requirements

- FTDv5, FTDv10, FTDv20, FTDv30, FTDv50, FTDv100

Note FTDv5 and FTDv10 do not support Amazon Web Services (AWS) Gateway Load Balancer (GWLB) and Azure GWLB.

- Supported public cloud services:
  - Amazon Web Services (AWS)
  - Microsoft Azure
  - Google Cloud Platform (GCP)
- Maximum of 16 nodes

See also the general requirements for the Firewall Threat Defense Virtual in the Secure Firewall Threat Defense Virtual getting started guides.

User roles

- Admin
- Access Admin
- Network Admin

Hardware and software requirements

All units in a cluster:

- Must be in the same performance tier. We recommend using the same number of CPUs and memory for all nodes, or else performance will be limited on all nodes to match the least capable node.

- Must run the identical software except at the time of an image upgrade. Hitless upgrade is supported.
- The Firewall Management Center access must be from the Management interface. Data interface management is not supported.
- Multiple Availability Zone deployment is supported from Firewall Threat Defense Virtual version 7.6.0 and later. The earlier versions supports only single Availability Zone deployment.
- Cluster requires a minimum of *four* interfaces: Management, Diagnostics, Data (Geneve), and CCL (Cluster Control Link).
- Cluster control link interfaces of all units must be in the same subnet.

MTU

Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. If there is an MTU mismatch, the cluster formation will fail.

The cluster control link MTU should be 154 bytes higher than the data interfaces. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead (100 bytes) plus VXLAN overhead (54 bytes).

For AWS with GWLB, the data interface uses Geneve encapsulation. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. You should set the source interface MTU to be the network MTU + 326 bytes. So for the standard 1500 MTU network path, the source interface MTU should be 1826, and the cluster control link MTU should be +154, 1980.

For Azure with GWLB, the data interface uses VXLAN encapsulation. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. You should set the cluster control link MTU to be the source interface MTU + 80 bytes.

The table shows the default values for the cluster control link MTU and the data interface MTU.

Note

- We do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Threat Defense Virtual clusters on Azure, modifying the cluster control link (CCL) MTU via FlexConfig in Management Center is not recommended, as it may cause cluster stability issues.

Table 32: Default MTU

Public Cloud	Cluster Control Link MTU	Data Interface MTU
AWS with GWLB	1980	1826
AWS	1654	1500
Azure with GWLB	1454	1374
Azure	1454	1300
GCP	1554	1400

Guidelines for Threat Defense Virtual clustering

High availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Multi-zone clustering

Multi-zone clustering is supported for up to three zones.

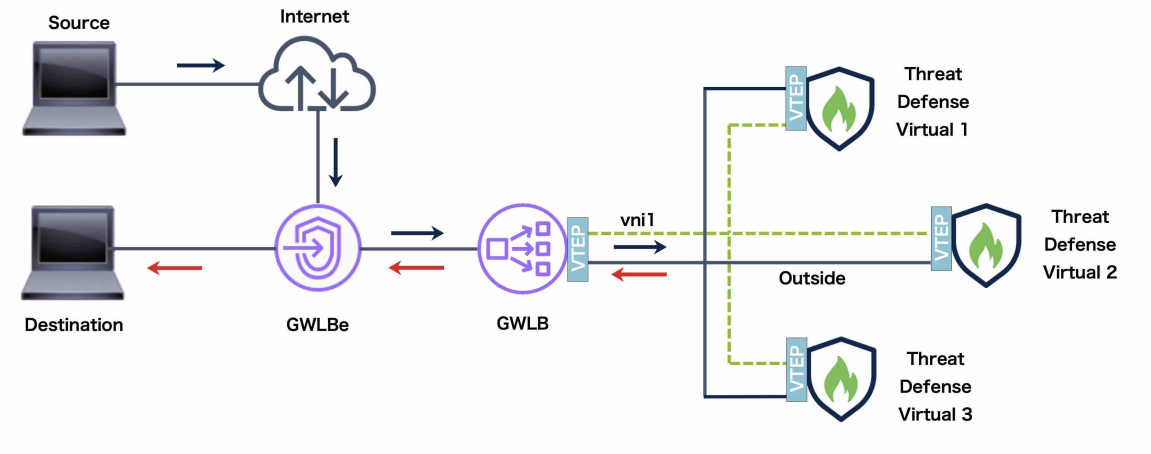
Additional guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firewall Threat Defense or the switch, adding an additional switch to form a VSS or vPC or VNet) you should disable the health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a node to an existing cluster, or when reloading a node, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- Do not power off a node without first disabling clustering on the node.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new node. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.
- Dynamic scaling is supported from Secure Firewall version 7.3.
- If you are using Secure Firewall versions 7.2 or 7.3, Stateful Target Failover is not supported when you deploy the cluster on AWS.
- Perform a global deployment after the completion of each maintenance window.
- Ensure that you do not remove more than one device at a time from the auto scale group (AWS) / instance group (GCP) / scale set (Azure). We also recommend that you run the **cluster disable** command on the device before removing the device from the auto scale group (AWS) / instance group (GCP) / scale set (Azure).
- If you want to disable data nodes and the control node in a cluster, we recommend that you disable the data nodes before disabling the control node. If a control node is disabled while there are other data nodes in the cluster, one of the data nodes has to be promoted to be the control node. Note that the role change could disturb the cluster.
- In the customized day 0 configuration scripts given in this guide, you can change the IP addresses as per your requirement, provide custom interface names, and change the sequence of the CCL-Link interface.

- If you experience CCL instability issues, such as intermittent ping failures, after deploying a Threat Defense Virtual cluster on a cloud platform, we recommend that you address the reasons that are causing CCL instability. Also, you can increase the hold time as a temporary workaround to mitigate CCL instability issues to a certain extent. For more information on how to change the hold time, see Edit Cluster Health Monitor Settings.
- When you are configuring your security firewall rule or security group for the Management Center virtual, you must include both Private and Public IP addresses of the Firewall Threat Defense Virtual in the Source IP address range. Also, ensure to specify the Private and Public IP addresses of the Firewall Management Center Virtual in the security firewall rule or security group of the Firewall Threat Defense Virtual. This is important to ensure proper registration of nodes during clustering deployment.

Defaults for clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.



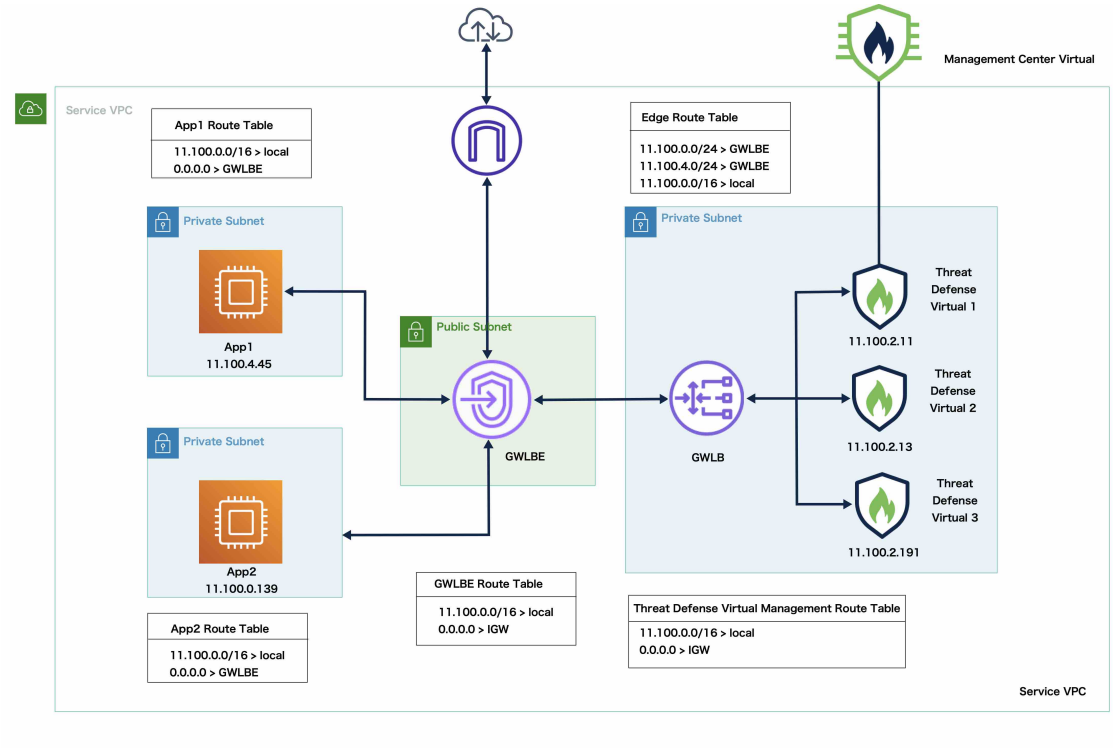
Deploy the cluster in AWS

You can deploy a cluster in AWS manually or by using CloudFormation templates to deploy a stack. You can use the cluster with AWS Gateway Load Balancer, or with a non-native load balancer such as the Cisco Cloud Services Router.

AWS gateway load balancer and Geneve single-arm proxy

This use case is the only currently supported use case for Geneve interfaces. The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint). The following figure shows traffic forwarded to the Gateway Load Balancer from the Gateway Load Balancer endpoint. The Gateway Load Balancer balances traffic among multiple Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer (U-turn traffic). The Gateway Load Balancer then sends the traffic back to the Gateway Load Balancer endpoint and to the destination.

Figure 185: Geneve Single-Arm Proxy



Note Transport Layer Security (TLS) Server Identity Discovery is not supported with Geneve single-arm setup on AWS.

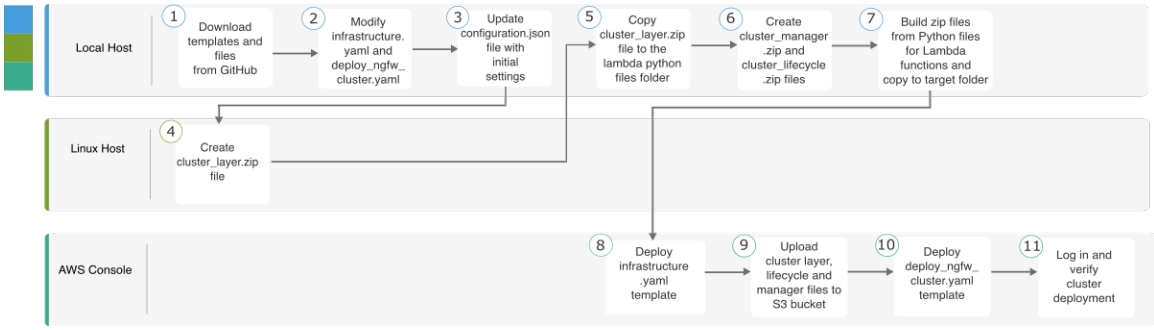
Sample topology

The sample topology provided below

- depicts both inbound and outbound traffic flow through security appliances,
- includes three Threat Defense Virtual instances in a cluster connected to a GWLB, and
- uses a Management Center Virtual instance to manage the cluster.

Traffic flow

Inbound traffic from the internet goes to the GWLB endpoint which then transmits the traffic to the GWLB. Traffic is then forwarded to the Threat Defense Virtual cluster. After the traffic has been inspected by a Threat Defense Virtual instance in the cluster, it is forwarded to the application VM, App1 /App2.



Outbound traffic from App1/App2 is transmitted to the GWLB endpoint which then sends it out to the internet.

End-to-end process for deploying Threat Defense Virtual cluster on AWS

Provides a workflow to help users successfully deploy and verify a Threat Defense Virtual cluster on AWS using either template-based or manual deployment processes.

Template-based Deployment

The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster on AWS.

	Workspace	Steps
1	Local Host	Clone the repository from GitHub
2	Local Host	Modify *infrastructure.yaml* and *deploy_ngfw_cluster.yaml* templates.
3	Local Host	Update the *Configuration.json* file with FMC object names.
4	Linux Host	Create *cluster_layer.zip* file.
5	Local Host	Copy *cluster_layer.zip* file to the Lambda python files folder.
6	Local Host	Create *cluster_manager.zip*, *custom_metrics_publisher.zip*, and *cluster_lifecycle.zip* files.
7	Local Host	Build zip files from Python files for Lambda functions and copy to target folder.
8	AWS Console	Deploy *infrastructure.yaml* template.
9	AWS Console	Upload *cluster_layer.zip*, *cluster_lifecycle.zip*, *custom_metrics_publisher.zip*, and *cluster_manager.zip* to the S3 bucket.
10	AWS Console	Deploy *deploy_ngfw_cluster.yaml* template.
11	AWS Console	Log in and verify cluster deployment.

Manual Deployment

The following flowchart illustrates the workflow for manual deployment of the Threat Defense Virtual cluster on AWS.

	Workspace	Steps
1	Local Host	Create day 0 configuration script.
2	AWS Console	Deploy Threat Defense Virtual instance.
3	AWS Console	Attach interfaces to instance.
4	AWS Console	Verify if nodes have joined cluster.
5	AWS Console	Create target group and GWLB; attach target group to the GWLB.
6	AWS Console	Register instances with the target group using data interface IP.
7	Management Center	Register control node.

Templates

The templates are available in GitHub. The parameter values are self-explanatory with the parameter names, default values, allowed values, and description, given in the template.

- infrastructure.yaml – Template for infrastructure deployment.
- deploy_ngfw_cluster.yaml – Template for cluster deployment.

Note Ensure that you check the list of supported AWS instance types before deploying cluster nodes. This list is found in the *deploy_ngfw_cluster.yaml* template, under allowed values for the parameter InstanceType.

Deploy the Stack in AWS Using a CloudFormation template

Deploy the stack in AWS using the customized CloudFormation template.

Before you begin

- You need an Amazon Linux virtual machine with Python 3.
- To allow the cluster to auto-register with the Firewall Management Center , you need to create two users with administrative privileges on the Firewall Management Center that can use the REST API. See the *Cisco Secure Firewall Management Center Administration Guide* .
- Add an access policy in the Firewall Management Center that matches the name of the policy that you specified in `Configuration.json` .

Procedure

Step 1 Prepare the template.

a) Clone the GitHub repository to your local folder. See https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/aws .

b) Modify **infrastructure.yaml** and **deploy_ngfw_cluster.yaml** with the required parameters.

c) Modify **cluster/aws/lambda-python-files/Configuration.json** with initial settings.

For example:

```
{
  "licenseCaps": ["BASE", "MALWARE", "THREAT"],
  "performanceTier": "FTDv50",
  "fmcIpforDeviceReg": "DONTRESOLVE",
  "RegistrationId": "cisco",
  "NatId": "cisco",
  "fmcAccessPolicyName": "AWS-ACL"
}
```

- Keep the fmcIpforDeviceReg setting as DONTRESOLVE.
- The fmcAccessPolicyName needs to match an access policy on the Firewall Management Center .

Note FTDv5 and FTDv10 tiers are not supported.

d) Create a file named **cluster_layer.zip** to provide essential Python libraries to Lambda functions.

We recommend using Amazon Linux with Python 3.9 installed to create the cluster_layer.zip file.

Note If you need an Amazon Linux environment, you can create an EC2 instance using Amazon Linux 2023 AMI or use AWS Cloudshell, which runs the latest version of Amazon Linux.

For creating the cluster-layer.zip file, you need to first create requirements.txt file that consists of the python library package details and then run the shell script.

1. Create the requirements.txt file by specifying the python package details.

   The following is the sample package details that you provide in the requirements.txt file:

```
$ cat requirements.txt
pycryptodome
paramiko
requests
scp
jsonschema
cffi
zipp
importlib-metadata
```

2. Run the following shell script to create cluster_layer.zip file.

```
$ pip3 install --platform manylinux2014_x86_64
--target=./python/lib/python3.9/site-packages
--implementation cp --python-version 3.9 --only-binary=:all:
--upgrade -r requirements.txt
$ zip -r cluster_layer.zip ./python
```

Note If you encounter a dependency conflict error during installation, such as urllib3 or cryptography, it is recommended that you include the conflicting packages along with their recommended versions in the requirements.txt file. After that, you can run the installation again to resolve the conflict.

e) Copy the resulting **cluster_layer.zip** file to the lambda python files folder - `cluster/aws/lambda-python-files` .

f) Create the **cluster_layer.zip** , **custom_metrics_publisher.zip** , **cluster_manger.zip** and **lifecycle_ftdv.zip** files.

A make.py file can be found in the cloned repository (`cluster/aws/make.py`). This will zip the python files into a Zip file and copy to a target folder.

python3 make.py build

Note If you are using a private IP address for the Management Center Virtual registration, then make sure that you set USE_PUBLIC_IP_FOR_FMC_CONN to False in the `cisco-ftdv/cluster/aws/lambda-python-files/constant.py` file.

Step 2 Deploy **infrastructure.yaml** and note the output values for cluster deployment. Before deploying the infrastructure stack, it is important to identify the AWS region and the availability zones that will be used. Each AWS region has a different set of availability zones and VPC infrastructure. Therefore, it is essential to select the correct region and availability zones for your deployment.

a) On the AWS Console, go to **CloudFormation** and click **Create stack** ; select **With new resources(standard)** .

b) Select **Upload a template file** , click **Choose file** , and select **infrastructure.yaml** from the target folder.

c) Click **Next** and provide the required information.

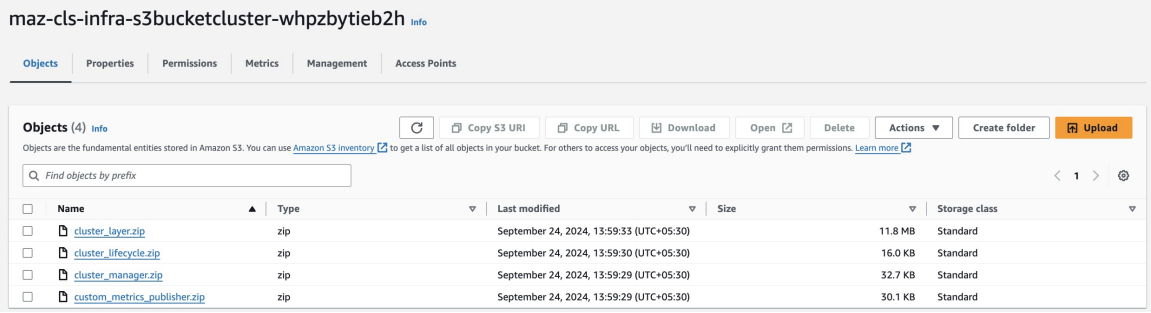
e

Parameter	Allowed Values/Type	Description
ClusterName	String	Enter unique Cluster name.
ClusterNumber	Number	Enter unique Cluster number.
VpcCidr	String	Enter the CIDR block for a new VPC
NoOfAZs	Number	Select 2 or 3 Availability Zones (AZs) for releases 7.6.0 and above; for lower releases, Select 1AZ.

Parameter	Allowed Values/Type	Description
		Management, Inside, Outside and CCL subnets will be distributed across the chosen AZs accordingly.
ListOfAZs	List	Select Availability Zones (Count should match with Number of Availability Zones)
MgmtSubnetNames	CommaDelimitedList	Management subnets name (With Internet GW as Route)
MgmtSubnetCidrs	CommaDelimitedList	Management subnets Cidr list
InsideSubnetNames	CommaDelimitedList	Inside subnets name (With Private Route)
InsideSubnetCidrs	CommaDelimitedList	Inside subnets Cidr list
CCLSubnetNames	CommaDelimitedList	Enter CCL subnet name
CCLSubnetCidrs	CommaDelimitedList	Enter CCL subnet CIDR
LambdaAZs	List	Select 2 Availability Zones for Lambda
LambdaSubnetNames	CommaDelimitedList	Enter Lambda Subnets name (With NAT GW as Route), for Lambda Functions
LambdaSubnetCidrs	CommaDelimitedList	Enter Lambda Subnet CIDRs

d) Enter a unique **Cluster Name** and **Cluster Number** for the cluster.
e) Select the availability zone from the **Availability Zone** list. This field lists only availability zones based on the AWS region that you select for deploying the infrastructure stack using the ClusterFormation template.
f) Click **Next** , then **Create stack** .
g) After the deployment is complete, go to **Outputs** and note the S3 **BucketName** .

Figure 186: Output of infrastructure.yaml



Outputs (13)

Search outputs

Key	Value	Description	Export name
BucketName	maz-cls-infra-s3bucketcluster-whpzbytieb2h	Name of the Amazon S3 bucket	-
BucketUrl	http://maz-cls-infra-s3bucketcluster-whpzbytieb2h.s3-website-us-east-1.amazonaws.com	URL of S3 Bucket Static Website	-
CCLSubnetIds	subnet-0bc04e2cc9e53e5c0,subnet-0d7d046a0fca25615,subnet-03ef42bf527551569	List of CCL subnet IDs (comma seperated)	-
EIPforNATgw	3.218.44.132	EIP reserved for NAT GW	-
FmcInstanceSGID	sg-076880aa64df2db5c	Security Group ID for FMC if user would like to launch in this VPC itself	-
InInterfaceSGId	sg-06ed933d6624fe51b	Security Group ID for Inside Interfaces	-
InsideSubnetIds	subnet-03d12cab8ee0eafff,subnet-0be9158b0970aebab,subnet-0b53c96fceb7c1f4d	List of Inside subnet IDs (comma seperated)	-
InstanceSGId	sg-0680b74be473186aa	Security Group ID for Instances Management Interface	-
LambdaSecurityGroupId	sg-057da2a9954e0d204	Security Group ID for Lambda Functions	-
LambdaSubnetIds	subnet-03439803d989e6bdf,subnet-087488a9d6ffc95cd	List of lambda subnet IDs (comma seperated)	-
ListOfAZs	us-east-1a,us-east-1b,us-east-1c	Availability zones for NGFWv instances	-
MgmtSubnetIds	subnet-06f0bbbd3f207a504,subnet-0c339dc43688cddc9,subnet-0a67629632a655de7	List of Mangement subnet IDs (comma seperated)	-
VpcName	vpc-09c2b0ad995e2fb24	Name of the VPC created	-

Step 3 Upload **cluster_layer.zip** , **cluster_manager.zip** , **custom_metrics_publisher.zip** , and **cluster_lifecycle.zip** to the S3 bucket created by **infrastructure.yaml** .

Figure 187: S3 Bucket

Note Make sure that the Elastic IP address of the Lambda NAT Gateway is added to the security group associated with the Management Center Virtual.

Step 4 Deploy **deploy_ngfw_cluster.yaml** .

a) Go to **CloudFormation** and click on **Create stack** ; select **With new resources(standard)** .

b) Select **Upload a template file** , click **Choose file** , and select **deploy_ngfw_cluster.yaml** from the target folder.

c) Click **Next** and provide the required information.

d) Provide the following cluster and infrastructure configuration information.

Parameter	Allowed Values/Type	Description
Cluster Configuration		
ClusterGrpNamePrefix	String	This is the cluster name Prefix. The cluster number will be added as a suffix.
ClusterNumber	String	This is the cluster number. This will be suffixed to the cluster name (msa-ftdv-infra). For example, if this value is 1 , the group name will be msa-ftdv-infra-1. It should be at least 1 digit, but not more than 3 digits. Default: 1.
ClusterSize	Numbers	This is the total number of Firewall Threat Defense Virtual nodes in a cluster. Minimum: 1 Maximum:16
Infrastructure Details		
NoOfAZs	String	This is the total number of availability zones into which Firewall Threat Defense Virtual is deployed. (The number of availability zones varies from a Minimum 1 to Maximum 3 depending on a region).

Parameter	Allowed Values/Type	Description
		The subnet will be created in these availability zones. The availability zones available in this list is based on the region selected for deploying the cluster. **Note** Management, Inside, and Cluster Control Link (CCL) subnets are created across three availability zones based on this parameters.
AZ	String	The availability zone list is based on the region you plan to deploy. In Availability Zone list, select the valid availability zone (1 availability zone or 2 availability zones or 3 availability zones). Count should match with the value of Number of Availability Zones parameter.
NotifyEmailID	String	Email address to which cluster events email will be sent. You must accept a subscription email request to receive this email notification. For example, admin@company.com.
VpcId	String	The VPC ID for the cluster group. Type: AWS::EC2::VPC::Id
S3BktName	String	The S3 Bucket that contains the uploaded Lambda zip files. You must specify correct bucket name.
MgmtSubnetIds	List	Enter only one subnet per availability zone. If you select multiple subnets from a same availability zone, then selecting an incorrect subnet may cause issues while deploying the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::Subnet::Id>
InsideSubnetIds	List	Enter at least one subnet per availability zone. If multiple subnets from the same Availability Zone are selected, then selecting an incorrect subnet may cause issues while deploying the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::Subnet::Id>
LambdaSubnets	List	Enter at least two subnets for the Lambda functions. The two subnets you enter must have a NAT gateway to enable the Lambda functions to communicate with AWS services, which are public DNS.

Parameter	Allowed Values/Type	Description
		Type: List<AWS::EC2::Subnet::Id>
CCLSubnetIds	String	Enter at least one subnet per availability zone. If multiple subnets from the same Availability Zone are selected, then selecting an incorrect subnet may cause issues while deploying the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::Subnet::Id>
CCLSubnetRanges	String	Enter IP addresses range of CCL subnets for different availability zones. Exclude first 4 reserved IP addresses. IP address pool for Cluster Control Link (CCL). IP address is allocated to the CCL interfaces of the Firewall Threat Defense Virtual instance from CCL IP address pool.
MgmtInterfaceSG	List	Select security group ID for the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::SecurityGroup::Id>
InsideInterfaceSG	List	Select security group ID for the inside interface of Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::SecurityGroup::Id>
LambdaSG	List	Select a security group for the Lambda functions. Ensure outbound connections are set to ANYWHERE . Type: List<AWS::EC2::SecurityGroup::Id>
CCLInterfaceSG	List	Select a security group ID for CCL interface of the Firewall Threat Defense Virtual instances.
GWLB Configuration		
DeployGWLBE	String	Click Yes to deploy the GWLB endpoint. By default, the value is set to No .
VpcIdLBE	String	Enter VPC to deploy Gateway Load Balancer Endpoint. **Note** Do not enter any value in this field if you are not deploying the GWLB endpoint.
GWLBESubnetId	String	Enter only one subnet ID. **Note**

Parameter	Allowed Values/Type	Description
		Do not enter any value in this field if you are not deploying the GWLB endpoint. Ensure that the subnet belongs to the correct VPC, and the availability zones that you have specified.
TargetFailover	String	Enable Target Failover support when a target fails or deregisters. (By default, the value of this parameter is set to rebalance). • no_rebalance : Directs existing flows to failed targets and new flows to healthy targets, ensuring backward compatibility. • rebalance : Redistributes existing flows while ensuring that new flows go to healthy targets. rebalance is supported from Firewall Threat Defense Virtual Version 7.4.1 and later.
TgHealthPort	String	Enter Health Check Port for GWLB. **Note** By default, this port must not be used for traffic. Ensure the value you provide is a valid TCP port. Default: 8080
Cisco NGFWv Instance Configuration		
InstanceType	String	Cisco Firewall Threat Defense Virtual EC2 instance type. Ensure that the AWS Region supports Instance Type you select. By default, **c5.xlarge** is selected.
LicenseType	String	Choose Cisco Firewall Threat Defense Virtual EC2 instance license type. Ensure that the AMI ID that you enter in **AMI-ID** parameter is of the same licensing type. By default, **BYOL** is selected.
AssignPublicIP	String	Set the value as **true** to assign a public IP address for Firewall Threat Defense Virtual from the AWS IP address pool.
AmiID	String	Choose the correct AMI ID as per the region, version, and license type (BYOL or PAYG). Firewall Threat Defense Virtual 7.2 and later support clustering, and Firewall Threat Defense Virtual Version

Parameter	Allowed Values/Type	Description
		7.6 and later support the autoscaling and multiple availability zone enhancements. Type: AWS::EC2::Image::Id
ngfwPassword	String	Firewall Threat Defense Virtual instance password. All Firewall Threat Defense Virtual instances come up with a default password, which is in the Userdata field of the Launch Template (Cluster Group). The password is activated after Firewall Threat Defense Virtual is accessible. Minimum length must be 8 characters. The password can either be a plain text password or a KMS encrypted password.
KmsArn	String	Enter ARN of an existing KMS (AWS KMS key to encrypt at rest). If you specify a value in this field, then the Firewall Threat Defense Virtual instance's admin password must be an encrypted password. Example of generating an encrypted password: " aws kms encrypt --key-id <KMS ARN> --plaintext <password> " The password encryption must be done using only the specified ARN.
FMC Automation Configuration		
fmcDeviceGrpName	String	Enter a unique name for the cluster group in management center.
fmcPublishMetrics	String	Select **`true`** to create a Lambda Function to poll management center and publish specific device group metrics to AWS CloudWatch. Allowed values: • true • false By default, the value is set to true .
fmcMetricsUsername	String	Enter a unique internal user name for polling memory metrics from management center. The user must have privileges of Network Admin and Maintenance User or more .

Parameter	Allowed Values/Type	Description
fmcMetricsPassword	String	Enter the password. If you have mentioned KMS Master Key ARN parameter, ensure to provide an encrypted password. Ensure to enter the correct password because entering incorrect password may result in failure of metrics collection.
fmcServer	String	The IP address can be an external IP address or the IP address reachable in Firewall Threat Defense Virtual management subnet in the VPC. Minimum length: 7 Maximum length:15
fmcOperationsUsername	String	Provide a unique internal user name for Firewall Management Center Virtual for CloudWatch. The user must have Administrator privileges.
fmcOperationsPassword	String	Enter the password. If you have mentioned KMS Master Key ARN parameter, ensure to provide an encrypted password.
Scaling Configuration		
CpuThresholds	CommaDelimitedList	(Optional) Specifying non-zero lower and upper thresholds will create scale policies. If (0,0) is selected, no CPU scaling alarm or policies will be created. Evaluation points and data points are at default or recommended values. By default, autoscaling is enabled in this template. Autoscale can be disabled after deployment.
MemoryThresholds	CommaDelimitedList	Specifying non-zero lower and upper threshold will create scale policies. If (0,0) is selected, no memory scaling alarm or policies will be created. Evaluation points and data points are at default or recommended values.

e) Click **Next** , then **Create stack** .

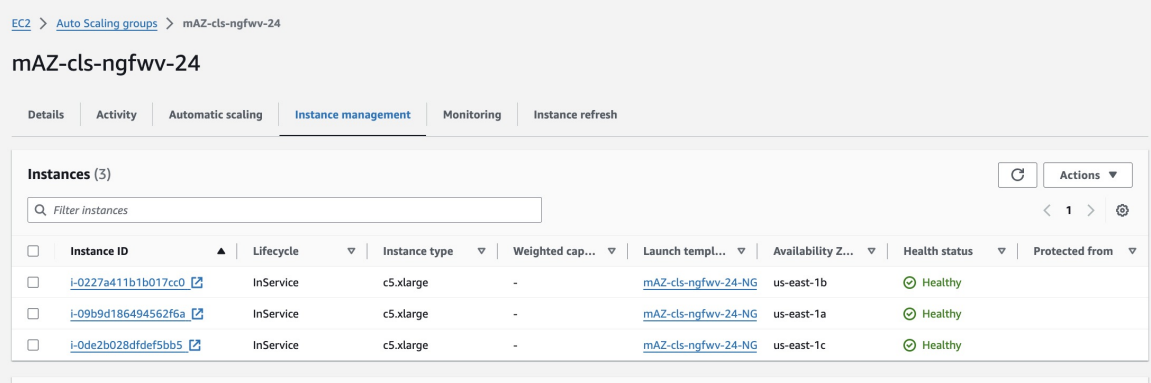
The Lambda functions manage the rest of the process, and the Firewall Threat Defense Virtual s will automatically register with the Firewall Management Center .

Figure 188: Deployed Resources

The status changes from CREATE_IN_PROGRESS to CREATE COMPLETE, indicating successful deployment.

Step 5 Verify the cluster deployment by logging into any one of the nodes and using the **show cluster info** command.

Figure 189: Cluster Nodes



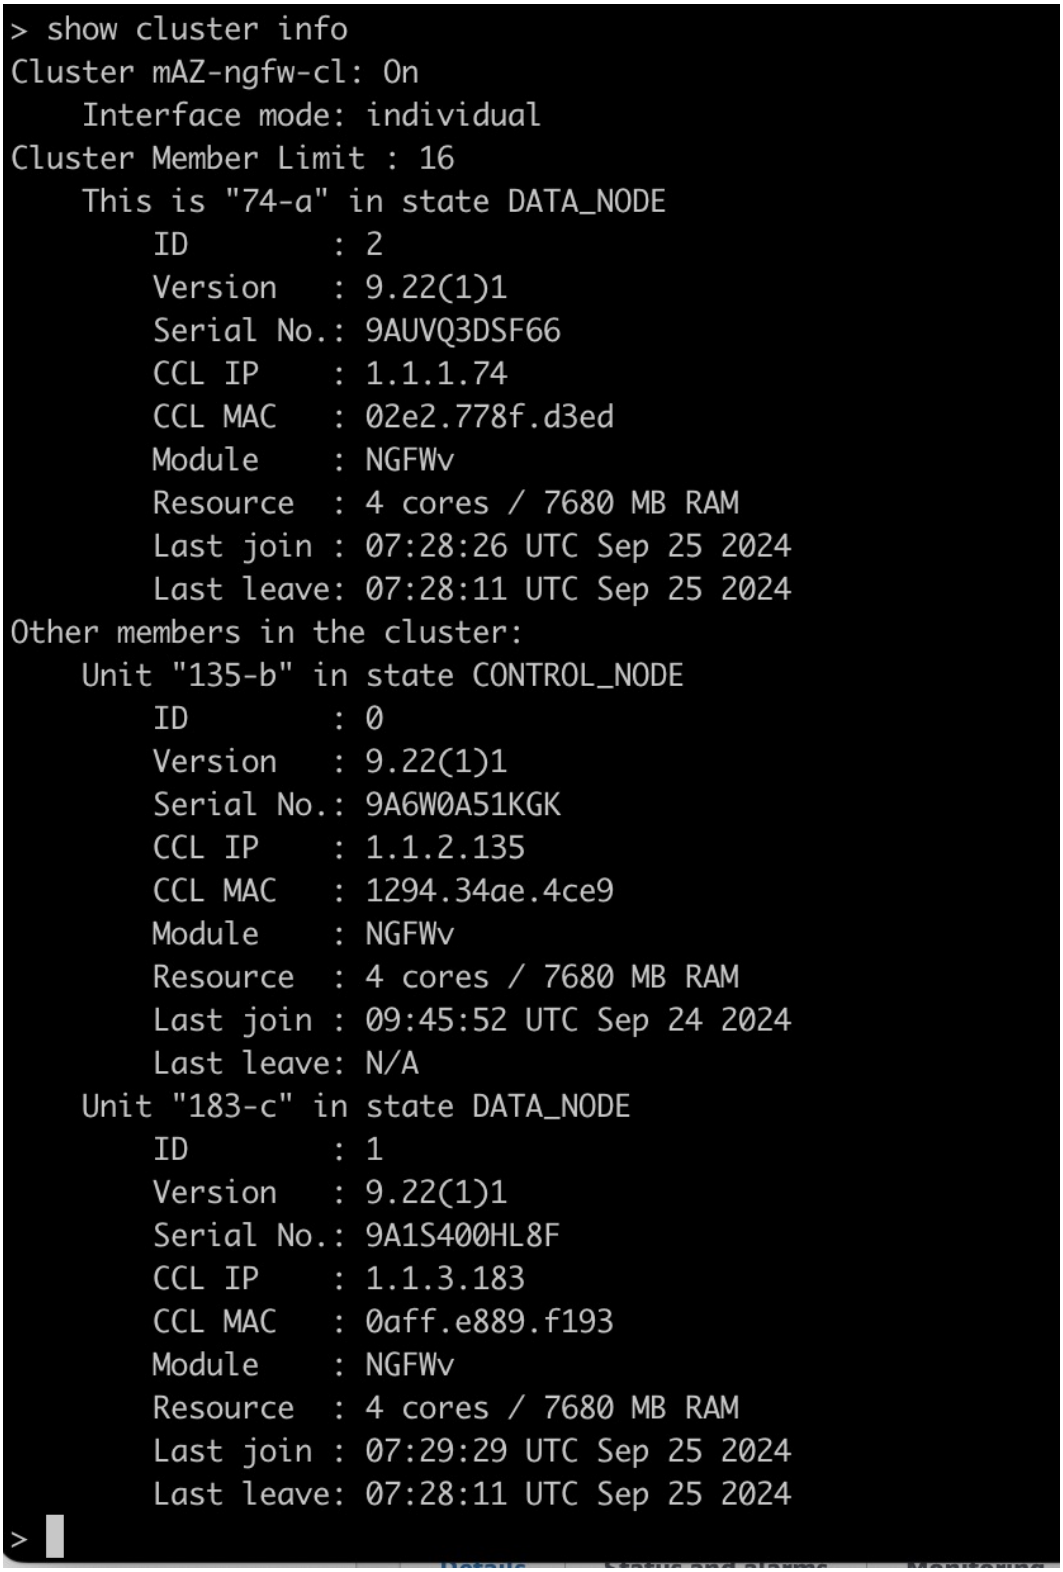


Figure 190: show cluster info

Manual cluster deployment in AWS

To deploy the cluster manually, prepare the day 0 configuration, deploy each node, and then add the control node to the Firewall Management Center.

On version 7.6.4-69 and from 10.0.0, each cluster node requires a unique AWS instance tag "cluster-node-id" with a value ranging from 1 to 16 for internal cluster configuration. Please ensure that the tag is added before the device boots up.

For example: key "cluster-node-id" -> value "1"

Additionally, make sure that "Allow tags in instance metadata" is set to "Enabled."

Create the Day0 configuration for AWS

You can use either a fixed configuration or a customized configuration. We recommend using the fixed configuration.

Create the Day0 configuration with a fixed configuration for AWS

The fixed configuration will auto-generate the cluster bootstrap configuration.

Single availability zone - Day0 configuration with a fixed configuration for AWS

```
{
    "AdminPassword": "password",
    "Hostname": "hostname",
    "FirewallMode": "Routed",
    "ManageLocally": "No",
    "Cluster": {
        "CclSubnetRange": "ip_address_start ip_address_end",
        "ClusterGroupName": "cluster_name",
        [For Gateway Load Balancer] "Geneve": "{Yes | No}",
        [For Gateway Load Balancer] "HealthProbePort": "port"
    }
}
```

For example:

```
{
 "AdminPassword": "Sup3rnatural",
 "Hostname": "ciscoftdv",
 "FirewallMode": "Routed",
 "ManageLocally": "No",
 "Cluster": {
              "CclSubnetRange": "10.5.90.4 10.5.90.30",
  "ClusterGroupName": "ftdv-cluster",
  "Geneve": "Yes",
  "HealthProbePort": "7777"
 }
}
```

Configure the cluster infrastructure subnet range

Use a cluster infrastructure subnet range to allocate IP addresses within a /27 CIDR block. This range provides the usable IP addresses for your cluster infrastructure.

Before you begin

- Review the table to determine valid start and end IP addresses for the /27 CIDR blocks you plan to use.
- The first four IP addresses in each subnet (including the network address) are reserved by AWS. Configure the **CclSubnetRange** to begin with the fifth IP address in the subnet.

The table shows the valid start and end IP addresses for each /27 CIDR allocation.

Table 33: CclSubnetRange mapping

CIDR	Start IP Address	End IP Address
x.y.z.0/27	x.y.z.4	x.y.z.30
x.y.z.32/27	x.y.z.36	x.y.z.62
x.y.z.64/27	x.y.z.68	x.y.z.94
x.y.z.96/27	x.y.z.100	x.y.z.126
x.y.z.128/27	x.y.z.132	x.y.z.158
x.y.z.160/27	x.y.z.164	x.y.z.190
x.y.z.192/27	x.y.z.196	x.y.z.222
x.y.z.224/27	x.y.z.228	x.y.z.254

Complete these steps to configure the cluster infrastructure subnet range.

Procedure

Step 1 Identify the /27 CIDR block assigned to your cluster infrastructure subnet.

Step 2 Find the matching CIDR in the mapping table.

Step 3 Replace "x.y.z" with the first three octets of your subnet. For example, 172.20.10 or 10.100.5.

Step 4 Configure the range by entering the start and end IP addresses from the mapping table for your subnet.

- Example 1:
  - CIDR: 172.20.10.64/27
  - Subnet range: 172.20.10.68 to 172.20.10.94
- Example 2:
  - CIDR: 10.100.5.128/27

- Subnet range: 10.100.5.132 to 10.100.5.158

Deploy cluster nodes

Deploy cluster nodes to form a functional cluster that can handle traffic distribution and provide high availability for network security services.

Deploy the cluster nodes so they form a cluster.

Procedure

Step 1 Deploy the Threat Defense Virtual instance by using the cluster day 0 configuration with the required number of interfaces - four interfaces if you are using Gateway Load Balancer (GWLB), or five interfaces if you are using non-native load balancer. To do this, in the **Configure Instance Details** > **Advanced Details** section, paste the cluster day 0 configuration.

Note Ensure that you attach interfaces to the instances in the order given below.

- AWS Gateway Load Balancer - four interfaces - management, diagnostic, inside, and cluster control link.
- Non-native load balancers - five interfaces - management, diagnostic, inside, outside, and cluster control link.

For more information on deploying Threat Defense Virtual on AWS, refer to Deploy the Threat Defense Virtual on AWS.

Step 2 Repeat Step 1 to deploy the required number of additional nodes.

Step 3 Use the **show cluster info** command on the Threat Defense Virtual console to verify if all nodes have successfully joined the cluster.

Step 4 Configure the AWS Gateway Load Balancer.

a) Create a target group and GWLB.

b) Attach the target group to the GWLB.

Note Ensure that you configure the GWLB to use the correct security group, listener configuration, and health check settings.

c) Register the data interface (inside interface) with the Target Group using IP addresses.

For more information, refer to Create a Gateway Load Balancer.

Step 5 Add the control node to the Management Center. Refer to Add the cluster to the Management Center (manual deployment), on page 493.

Target failover for Secure Firewall Threat Defense Virtual clustering with GWLB in AWS

Threat Defense Virtual clustering in AWS utilizes the Gateway Load Balancer (GWLB) to balance and forward network packets for inspection to a designated Threat Defense Virtual node. The GWLB is designed to continue sending network packets to the target node in the event of a failover or deregistration of that node.

The Target Failover feature in AWS enables GWLB to redirect network packets to a healthy target node in the event of node deregistration during planned maintenance or a target node failure. It takes advantage of the cluster's stateful failover.

Configuration methods

In AWS, you can configure Target Failover through the AWS Elastic Load Balancing (ELB) API or AWS console.

Note If a target node fails while the GWLB routes traffic using certain protocols such as SSH, SCP, CURL, and so on, then there may be a delay in redirecting traffic to a healthy target. This delay is due to rebalancing and rerouting of traffic flow.

- AWS API — In the AWS ELB API *modify-target-group-attributes*, you can define the flow handling behavior by modifying the parameters.
  - target_failover.on_unhealthy - It defines how the GWLB handles the network flow when the target becomes unhealthy.
  - target_failover.on_deregistration - It defines how the GWLB handles the network flow when the target is deregistered.

  This command shows the sample API parameter configuration of defining these two parameters.

```
aws elbv2 modify-target-group-attributes \
--target-group-arn arn:aws:elasticloadbalancing:…/my-targets/73e2d6bc24d8a067 \
--attributes \
Key=target_failover.on_unhealthy, Value=rebalance[no_rebalance] \
Key=target_failover.on_deregistration, Value=rebalance[no_rebalance]
```

  For more information, refer to TargetGroupAttribute in the AWS documentation.
- AWS Console — In the EC2 console, you can enable the Target Failover option on the Target Group page by configuring these options.
  - Edit Target Groups Attributes
  - Enable Target Failover
  - Verify Rebalance Flows

  For more information about how to enable Target Failover, refer to Enable target failover for Secure Firewall Threat Defense Virtual clustering in AWS, on page 465.

Enable target failover for Secure Firewall Threat Defense Virtual clustering in AWS

This task enables target failover configuration in AWS to ensure network flow continuity when Firewall Threat Defense Virtual cluster targets fail or become deregistered.

The data interface of Firewall Threat Defense Virtual is registered to a target group of GWLB in AWS. In the Firewall Threat Defense Virtual clustering, each instance is associated with a Target Group. The GWLB load balances and sends the traffic to this healthy instance identified or registered as a target node in the target group.

Before you begin

You must have deployed the cluster in AWS either by manual method or using CloudFormation templates.

If you are deploying a cluster using a CloudFormation template, you can also enable the **Target Failover** parameter by assigning the **rebalance** attribute that is available under **GWLB Configuration** section of the cluster deployment file, `deploy_ftdv_clustering.yaml`. In the template, by default, the value is set to **rebalance** for this parameter. However, the default value for this parameter is set to **no_rebalance** on the AWS console.

Where,

- **no_rebalance** - GWLB continues to send the network flow to the failed or deregistered target.
- **rebalance** - GWLB sends the network flow to another healthy target when the existing target is failed or deregistered.

For information on deploying stack in AWS, refer to:

- Deploy the Cluster in AWS Manually
- Deploy the Stack in AWS Using a CloudFormation Template

Procedure

Step 1 On the AWS Console, go to **Services > EC2**

Step 2 Click **Target Groups** to view the target groups page.

Step 3 Select the target group to which the Firewall Threat Defense Virtual data interface IPs are registered. The target group details page is displayed, where you can enable the Target failover attributes.

Step 4 Go to the **Attributes** menu.

Step 5 Click **Edit** to edit the attributes.

Step 6 Toggle the **Rebalance flows** slider button to the right to enable target failover to configure GWLB to rebalance and forward the existing network packets to a healthy target node in the event of target failover or deregistration.

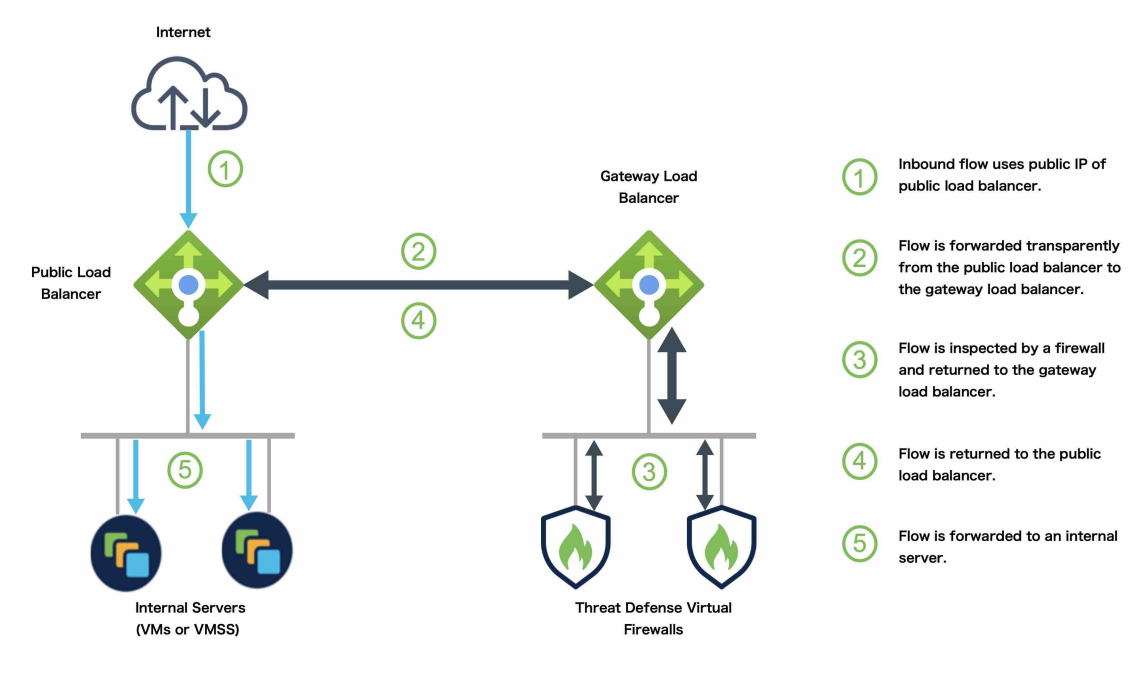
Deploy the cluster in Azure

You can use the cluster with the Azure Gateway Load Balancer (GWLB), or with a non-native load balancer. To deploy a cluster in Azure, use Azure Resource Manager (ARM) templates to deploy a Virtual Machine Scale Set.

Sample topology for GWLB-based cluster deployment

Sample topologies for deploying Gateway Load Balancer (GWLB) clusters are given below.

Figure 191: Inbound traffic use case and topology with GWLB



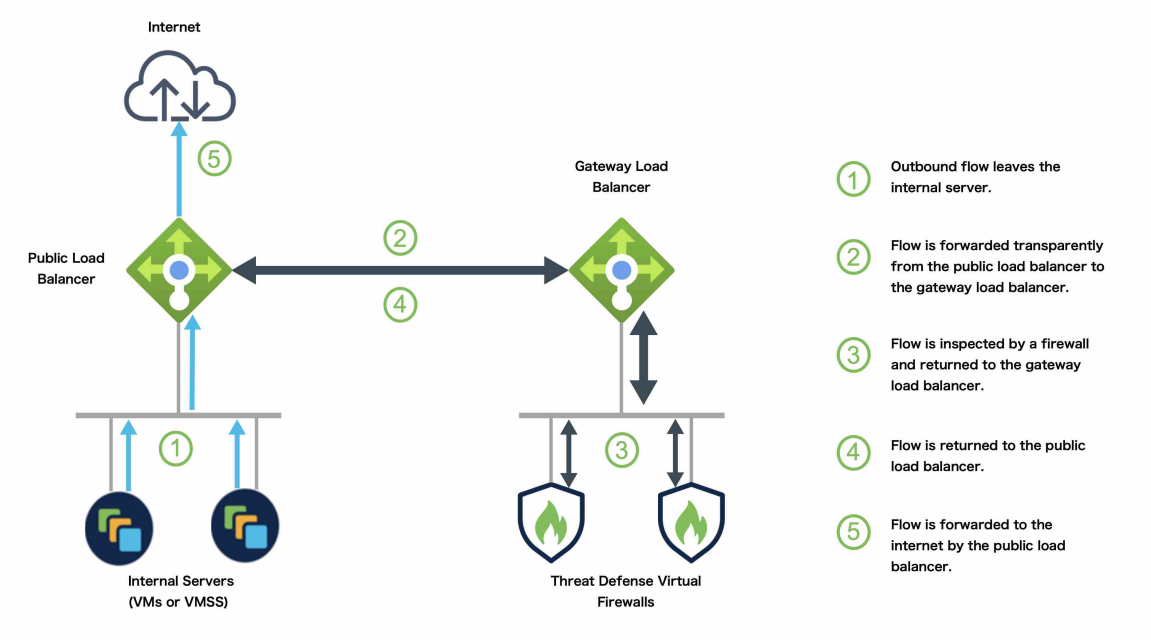


Figure 192: Outbound traffic use case and topology with GWLB

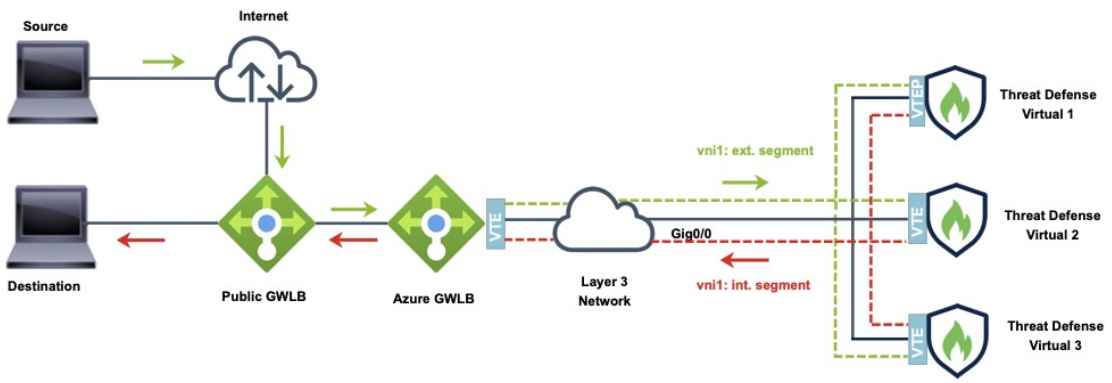
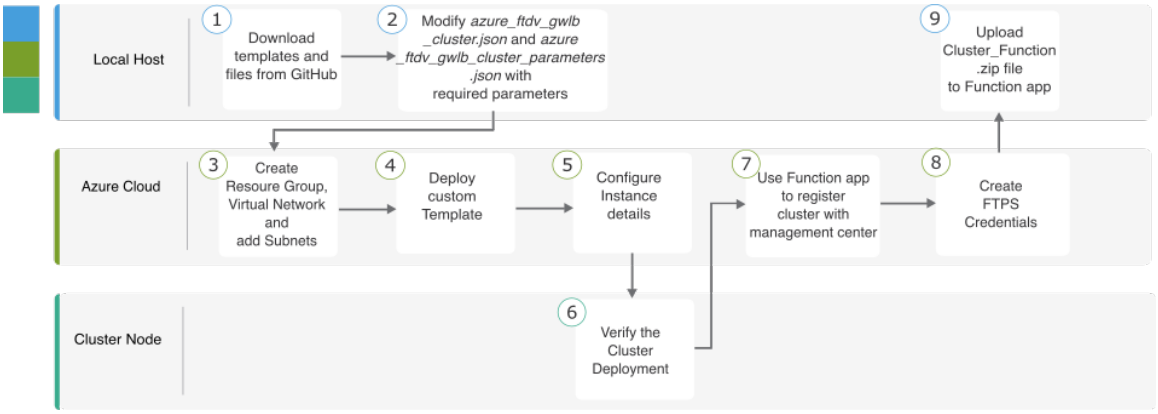


Azure gateway load balancer and paired proxy

In an Azure service chain, Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.

The figure shows traffic forwarded to the Azure Gateway Load Balancer from the Public Gateway Load Balancer on the external VXLAN segment. The Gateway Load Balancer balances traffic among multiple Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer on the internal VXLAN segment. The Azure Gateway Load Balancer then sends the traffic back to the Public Gateway Load Balancer and to the destination.

Figure 193: Azure gateway load balancer with paired proxy



Traffic flow between GWLBe to GWLB (Geneve Single-Arm Proxy) in Azure

End-to-end process for deploying Threat Defense Virtual cluster in Azure with GWLB

Provides a workflow to help users successfully deploy and verify a Threat Defense Virtual cluster on Azure with GWLB using either template-based or manual deployment processes.

Template-based Deployment

The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster in Azure with GWLB.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.
2	Local Host	Modify *azure_ftdv_gwlb_cluster.json* and *azure_ftdv_gwlb_cluster_parameters.json* with the required parameters.

	Workspace	Steps
3	Azure Cloud	Create the resource group, virtual network, and subnets.
4	Azure Cloud	Deploy custom template.
5	Azure Cloud	Configure instance details.
6	Cluster Node	Verify cluster deployment.
7	Azure Cloud	Use the Function app to register the cluster with the Management Center.
8	Azure Cloud	Create FTPS credentials.
9	Local Host	Upload *Cluster_Function.zip* file to the Function app.

Manual Deployment

The following flowchart illustrates the workflow of manual deployment of Threat Defense Virtual cluster in Azure with GWLB.

	Workspace	Steps
1	Local Host	Create a VMSS from the Marketplace image.
2	Local Host	Attach interfaces.
3	Local Host	Add day 0 configuration in the customData field.
4	Local Host	Update scaling instance count.
5	Local Host	Configure GWLB.

	Workspace	Steps
6	Management Center	Add control node.

Templates

The templates are available in GitHub. The parameter values are self-explanatory with the parameter names and values given in the template.

- azure_ftdv_gwlb_cluster_parameters.json – Template to enter parameters for the Firewall Threat Defense Virtual cluster.
- azure_ftdv_gwlb_cluster.json – Template to deploy Firewall Threat Defense Virtual cluster.

Prerequisites for Azure GWLB cluster deployment

Complete these prerequisite tasks before deploying the Azure GWLB cluster.

- To allow the cluster to auto-register to the management center, create a user with Network Admin & Maintenance User privileges on the management center. Users with these privileges can use REST API. Refer to the Cisco Secure Firewall Management Center Administration Guide.
- Add an access policy in the management center that matches the name of the policy that you will specify during template deployment.
- Ensure that the Management Center Virtual is licensed appropriately.
- Perform these steps after the cluster is added to the Management Center Virtual:
  1. Configure platform settings with the health check port number in the Management Center. For more information on configuring this, see Platform Settings.
  2. Create a static route for data traffic. For more information on creating a static route, see Add a Static Route.

     Sample static route configuration:

```
Network: any-ipv4
Interface: vxlan_tunnel
Leaked from Virtual Router: Global
Gateway: vxlan_tunnel_gw
Tunneled: false
Metric: 2
```

Note *vxlan_tunnel_gw* is the data subnet's gateway IP address.

Deploy cluster on Azure with GWLB using an Azure resource manager template

This task creates a clustered deployment of Firewall Threat Defense Virtual instances on Azure using Gateway Load Balancer (GWLB) through Azure Resource Manager templates.

Deploy the Virtual Machine Scale Set for Azure GWLB using the customized Azure Resource Manager (ARM) template. The templates mentioned in the steps below are available on GitHub.

Procedure

Step 1 Prepare the template.

a) Clone the GitHub repository to your local folder. See https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/azure.

b) Modify azure_ftdv_gwlb_cluster.json and azure_ftdv_gwlb_cluster_parameters.json with the required parameters.

Step 2 Log in to the Azure Portal: https://portal.azure.com.

Step 3 Create a Resource Group.

a) In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b) Choose the required **Region**.

Step 4 Create a virtual network with three subnets: Management, Data, and Cluster Control Link (CCL).

a) Create the virtual network.

1. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
2. Choose the required **Region**. Click **Next: IP addresses**.

In the **IP Addresses** tab, click **Add subnet** and add the following subnets – Management, Data, and Cluster Control Link.

b) Add the subnets.

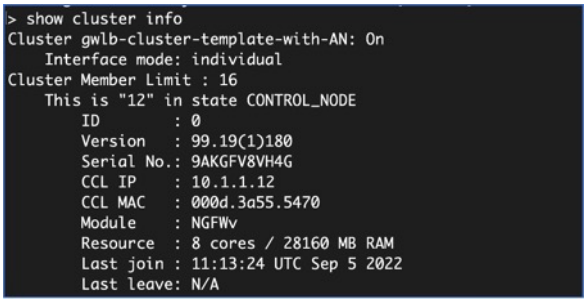
Step 5 Deploy the custom template.

a) Click **Create** > **Template deployment (deploy using custom templates)**.

b) Click **Build your own template in the editor**.

c) Click **Load File**, and upload **azure_ftdv_gwlb_cluster.json**.

d) Click **Save**.



Step 6 Configure the Instance details.

a) Enter the required values and then click **Review + create**.

b) Click **Create** after the validation is passed.

c) After the instance is running, verify the cluster deployment by logging into any one of the nodes and entering the **show cluster info** command.

Figure 194: Show cluster info

Step 7 In the Azure Portal, click the Function app to register the cluster with the Firewall Management Center.

Note If you do not want to use the Function app, you can alternatively register the control node to the Firewall Management Center directly by using **Add** > **Device** (not **Add** > **Cluster**). The rest of the cluster nodes will register automatically.

Step 8 Create FTPS Credentials by clicking **Deployment Center** > **FTPS credentials** > **User scope** > **Configure Username and Password**, and then click **Save**.

Step 9 Upload the Cluster_Function.zip file to the Function app by executing the following **curl** command in the local terminal.

curl -X POST -u *username* **--data-binary @"Cluster_Function.zip" https://** *Function_App_Name***.scm.azurewebsites.net/api/zipdeploy**

Note The **curl** command might take few minutes (~2 to 3 minutes) to complete command execution.

The function will be uploaded to the Function app. The function will start, and you can see the logs in the storage account's outqueue. The device registration with the Management Center will be initiated.

Figure 195: Functions

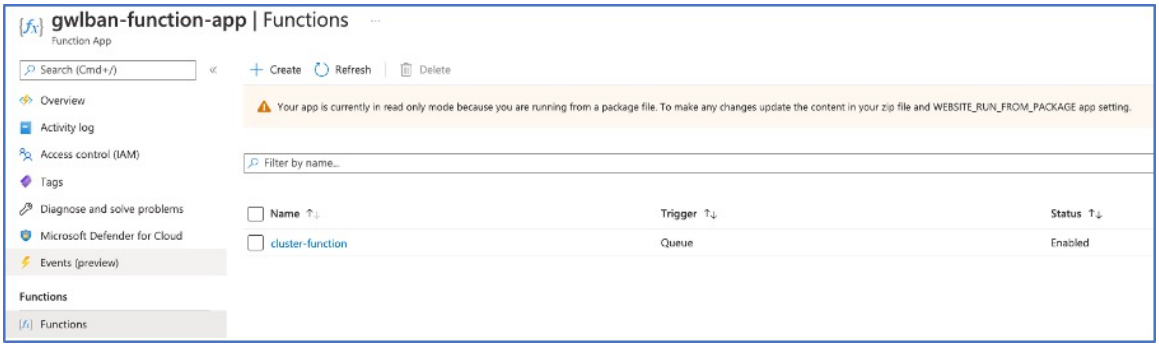


Figure 196: Queues

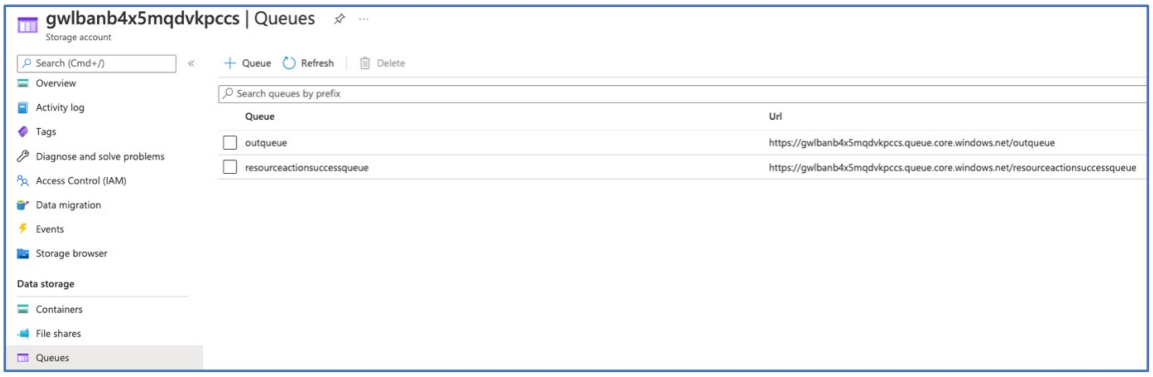

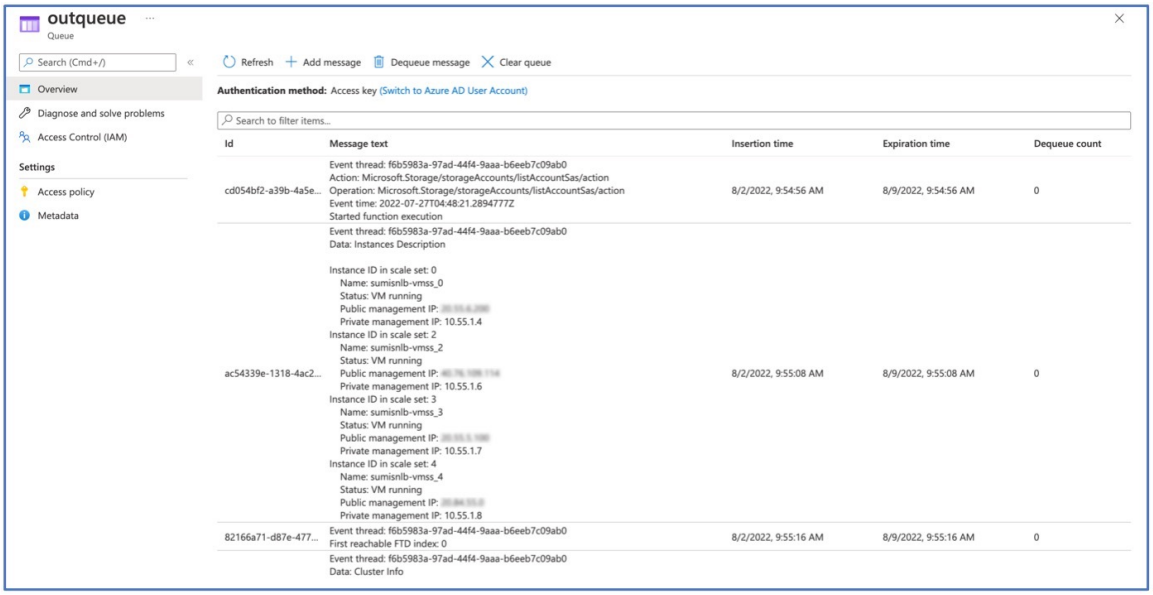

Figure 197: Outqueue

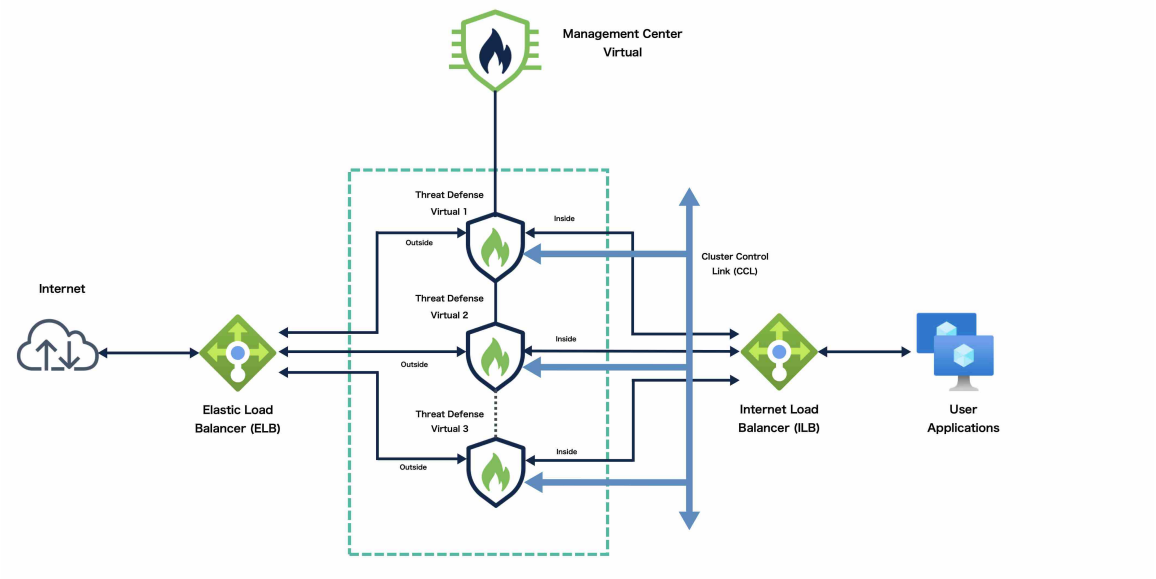
Sample topology for NLB-based cluster deployment



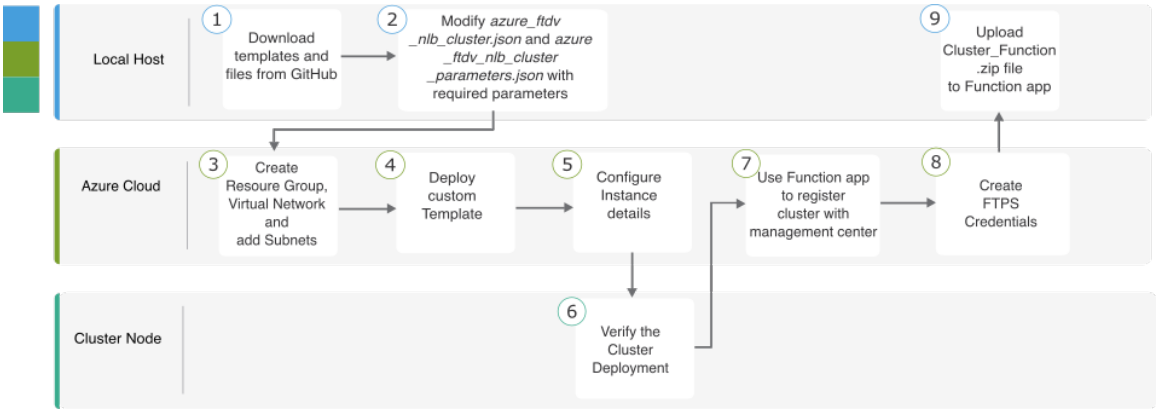
The sample topology provided here

- places the Threat Defense Virtual cluster between internal and external load balancers,
- uses a Management Center Virtual instance to manage the cluster, and
- depicts both inbound and outbound traffic flow patterns.

Traffic flow patterns

This topology shows how traffic moves through the network components:

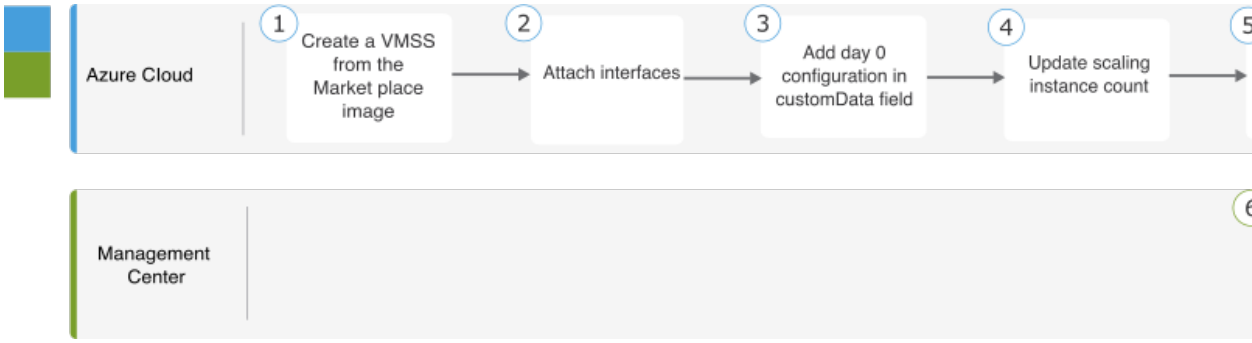
- **Inbound traffic**: Traffic from the internet goes to the external load balancer, which transmits the traffic to the Threat Defense Virtual cluster. After the traffic has been inspected by a Threat Defense Virtual instance in the cluster, it is forwarded to the application virtual machine (VM).
- **Outbound traffic**: Traffic from the application VM is transmitted to the internal load balancer. Traffic is then forwarded to the Threat Defense Virtual cluster and then sent out to the internet.



End-to-end process for deploying Threat Defense Virtual cluster in Azure with NLB

Provides a workflow to help users successfully deploy and verify a Threat Defense Virtual cluster on Azure with NLB using either template-based or manual deployment processes.

Template-based Deployment



The following flowchart illustrates the workflow of template-based deployment of Threat Defense Virtual cluster in Azure with NLB.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.
2	Local Host	Modify *azure_ftdv_nlb_cluster.json* and *azure_ftdv_nlb_cluster_parameters.json* with the required parameters.
3	Azure Cloud	Create the resource group, virtual network, and subnets.
4	Azure Cloud	Deploy custom template.
5	Azure Cloud	Configure instance details.
6	Cluster Node	Verify cluster deployment.
7	Azure Cloud	Use the Function app to register the cluster with the Management Center.
8	Azure Cloud	Create FTPS credentials.
9	Local Host	Upload *Cluster_Function.zip* file to the Function app.

Manual Deployment

The following flowchart illustrates the workflow of manual deployment of Threat Defense Virtual cluster in Azure with NLB.

	Workspace	Steps
1	Local Host	Create a VMSS from the Marketplace image.
2	Local Host	Attach interfaces.
3	Local Host	Add day 0 configuration in the customData field.

	Workspace	Steps
4	Local Host	Update scaling instance count.
5	Local Host	Configure NLB.
6	Management Center	Add control node.

Templates

The templates are available in GitHub. The parameter values are self-explanatory with the parameter names and values given in the template.

These templates provide the necessary components for cluster deployment:

- azure_ftdv_nlb_cluster_parameters.json – Template to enter parameters for the Firewall Threat Defense Virtual cluster.
- azure_ftdv_nlb_cluster.json – Template to deploy Firewall Threat Defense Virtual cluster.

Prerequisites for Azure NLB cluster deployment

Before deploying an Azure Network Load Balancer cluster, ensure that you complete these prerequisite tasks.

- To allow the cluster to auto-register with the Management Center, create a user with Network Admin & Maintenance User privileges on the Management Center. Users with these privileges can use REST API. Refer to the Cisco Secure Firewall Management Center Administration Guide.
- Add an access policy in the Management Center that matches the name of the policy that you will specify during template deployment.
- Ensure that the Management Center Virtual is licensed appropriately.
- After the cluster is added to the Management Center Virtual, complete these configuration steps:
  1. Configure platform settings with the health check port number in the Management Center. For more information on configuring this, refer to Platform Settings.
  2. Create static routes for traffic from outside and inside interfaces. For more information on creating a static route, refer to Add a Static Route.

Important Configure static routes for both interface gateway paths when Azure Load Balancer health probes are enabled on both inside and outside interfaces of FTDv cluster nodes. Do not rely on a single default route. Azure health probes may arrive on either interface, so FTDv must respond using the correct interface path. Missing routing configuration can cause probe drops and load balancer health check failures. If SSH on port 22 is used as the health probe and SSH is enabled on both interfaces through Platform Settings, verify return path routing for both interfaces. Similarly, if HTTP is used as the health probe and HTTP or HTTPS is enabled on both interfaces through Platform Settings, verify return path routing for both interfaces.

Note Ensure that you do not configure your virtual network using the Microsoft-owned IP address range that includes 168.63.129.16. This configuration causes a conflict with the health probe's IP address. For more information, refer to Microsoft Azure design guidance.

Sample static route configuration for the outside interface:

```
Network: any-ipv4
Interface: outside
Leaked from Virtual Router: Global
Gateway: ftdv-cluster-outside
Tunneled: false
Metric: 10
```

Note *ftdv-cluster-outside* is the outside subnet's gateway IP address.

Sample static route configuration for the inside interface:

```
Network: any-ipv4
Interface: inside
Leaked from Virtual Router: Global
Gateway: ftdv-cluster-inside-gw
Tunneled: false
Metric: 11
```

Note *ftdv-cluster-inside-gw* is the inside subnet's gateway IP address.

3. Configure NAT rule for data traffic. For more information on configuring NAT rules, refer to Network Address Translation.

Deploy cluster on Azure with NLB using an Azure resource manager template

This task enables you to deploy a cluster for Azure NLB using the customized Azure Resource Manager (ARM) template for scalable network security.

Deploy the cluster for Azure NLB using the customized Azure Resource Manager (ARM) template. Note that the templates mentioned in the steps below are available on GitHub.

Procedure

Step 1 Prepare the template.

a) Clone the GitHub repository to your local folder. See https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/azure.

b) Modify azure_ftdv_nlb_cluster.json and azure_ftdv_nlb_cluster_parameters.json with the required parameters.

Step 2 Log in to the Azure Portal: https://portal.azure.com.

Step 3 Create a Resource Group.

a) In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b) Choose the required **Region**.

Step 4 Create a virtual network with 5 subnets: Management, Diagnostic, Inside, Outside, and Cluster Control Link.

a) Create the virtual network.

1. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
2. Choose the required **Region**. Click **Next: IP addresses**.

b) Add the subnets.

In the **IP Addresses** tab, click **Add subnet** and add the following subnets – Management, Diagnostic, Inside, Outside, and Cluster Control Link.

Step 5 Deploy the custom template.

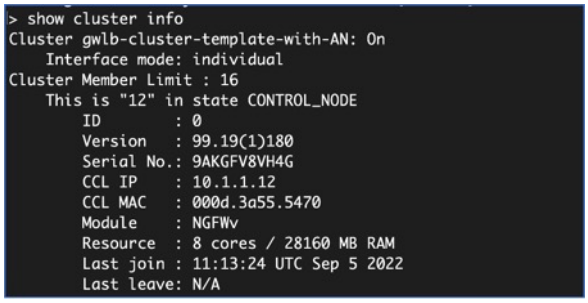
a) Click **Create** > **Template deployment (deploy using custom templates)**.

b) Click **Build your own template in the editor**.

c) Click **Load File**, and upload **azure_ftdv_nlb_cluster.json**.

d) Click **Save**.

Step 6 Configure the instance details.



a) Enter the required values and then click **Review + create**.

Note For the cluster control link starting and ending addresses, specify only as many addresses as you need (up to 16). A larger range can affect performance.

b) Click **Create** after the validation is passed.

c) After the instance is running, verify the cluster deployment by logging into any one of the nodes and using the **show cluster info** command.

Figure 198: Show cluster info

Step 7 In the Azure Portal, click the Function app to register the cluster to the Firewall Management Center.

Note If you do not want to use the Function app, you can alternatively register the control node with the Management Center directly by using **Add** > **Device** (not **Add** > **Cluster**). The rest of the cluster nodes will register automatically.

Step 8 Create FTPS Credentials by clicking **Deployment Center** > **FTPS credentials** > **User scope** > **Configure Username and Password**, and then click **Save**.

Step 9 Upload the Cluster_Function.zip file to the Function app by executing the **curl** command in the local terminal.

curl -X POST -u *username* **--data-binary @"Cluster_Function.zip" https://** *Function_App_Name***.scm.azurewebsites.net/api/zipdeploy**

Note The **curl** command might take a few minutes (~2 to 3 minutes) to complete command execution.

The function will be uploaded to the Function app. The function will start, and you can see the logs in the storage account's outqueue. The device registration with the Management Center will be initiated.

Manual cluster deployment in Azure

To deploy the cluster manually, prepare the day0 configuration, deploy each node, and then add the control node to the Firewall Management Center .

Create the Day0 configuration for Azure

You can use either a fixed configuration or a customized configuration.

Create the Day0 configuration with a fixed configuration for Azure

The fixed configuration will auto-generate the cluster bootstrap configuration.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end",
```

```
"ClusterGroupName": "cluster_name",
"HealthProbePort": "port_number",
"GatewayLoadBalancerIP": "ip_address",
"EncapsulationType": "vxlan",
"InternalPort": "internal_port_number",
"ExternalPort": "external_port_number",
"InternalSegId": "internal_segment_id",
"ExternalSegId": "external_segment_id"
}
```

Example

A sample day 0 configuration is given below.

```
"Cluster": {
"CclSubnetRange": "10.45.3.4 10.45.3.30",     //mandatory user input
"ClusterGroupName": "ngfwv-cluster",          //mandatory user input
"HealthProbePort": "7777",                    //mandatory user input
"GatewayLoadBalancerIP": "10.45.2.4",         //mandatory user input
"EncapsulationType": "vxlan",
"InternalPort": "2000",
"ExternalPort": "2001",
"InternalSegId": "800",
"ExternalSegId": "801"
}
```

Note If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration

For the Azure health check settings, be sure to specify the **HealthProbePort** you set here.

For the **CclSubnetRange** variable, specify a range of IP addresses starting from x.x.x.4. Ensure that you have at least 16 available IP addresses for clustering. Some examples of start and end IP addresses are given below.

Note All cluster infrastructure subnets must use /27 CIDR

Table 34: Examples of start and end IP addresses

CIDR	Start IP Address	End IP Address
10.1.1.0/27	10.1.1.4	10.1.1.30
10.1.1.32/27	10.1.1.36	10.1.1.62
10.1.1.64/27	10.1.1.68	10.1.1.94
10.1.1.96/27	10.1.1.100	10.1.1.126
10.1.1.128/27	10.1.1.132	10.1.1.158
10.1.1.160/27	10.1.1.164	10.1.1.190
10.1.1.192/27	10.1.1.196	10.1.1.222

CIDR	Start IP Address	End IP Address
10.1.1.224/27	10.1.1.228	10.1.1.254

Create the Day0 configuration with a customized configuration for azure

You can enter the entire cluster bootstrap configuration using commands.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end",
"ClusterGroupName": "cluster_name",
"HealthProbePort": "port_number",
"GatewayLoadBalancerIP": "ip_address",
"EncapsulationType": "vxlan",
"InternalPort": "internal_port_number",
"ExternalPort": "external_port_number",
"InternalSegId": "internal_segment_id",
"ExternalSegId": "external_segment_id"
}
```

Deploy cluster nodes manually - GWLB-based deployment

This task allows you to deploy cluster nodes so they form a cluster in Azure using Gateway Load Balancer-based deployment.

Deploy the cluster nodes so they form a cluster.

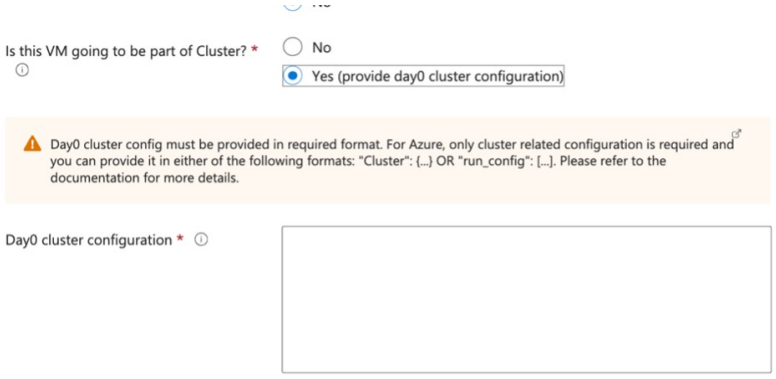
Procedure

Step 1 Log in to the Azure Portal: https://portal.azure.com

Step 2 Create a Resource Group.

a. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b. Choose the required **Region**.



Step 3 Create a Virtual Network with the necessary subnets: Management, Data and Cluster Control Link (CCL).

Note Configure the CCL with the smallest subnet mask as required. Wider subnets can impact performance.

Refer to the Azure document for creating the Virtual Network and subnet: https://learn.microsoft.com/en-us/azure/virtual-network/quickstart-create-virtual-network?tabs=portal

Step 4 Go to the Marketplace and search for **Cisco Secure Firewall Threat Defense Virtual – BYOL and PAYG** and click **Create**.

Step 5 Fill the required details and choose **Yes** for **Is this VM going to be part of Cluster?**

Paste the following cluster-related configuration in the text box.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end", //mandatory user input
"ClusterGroupName": "cluster_name", //mandatory user input
"HealthProbePort": "port_number", //mandatory user input
"GatewayLoadBalancerIP": "ip_address",  //mandatory user input
"EncapsulationType": "vxlan",
"InternalPort": "internal_port_number",
"ExternalPort": "external_port_number",
"InternalSegId": "internal_segment_id",
"ExternalSegId": "external_segment_id"
}
```

a) Click **Next** and select the **Virtual Network & Subnets**.

b) Click **Review + create**. Wait for the Threat Defense Virtual deployment to complete.

Step 6 Connect to the Threat Defense Virtual device and use the **show cluster info** command to confirm the cluster formation is successful.

```
> show cluster info
Cluster ngfwv-cluster: On
    Interface mode: individual
Cluster Member Limit : 16
    This is "4" in state CONTROL_NODE
        ID        : 0
        Version   : 9.23(1)
        Serial No.: 9AC1VMGJKAQ
        CCL IP    : 169.254.200.4
        CCL MAC   : 6045.bda8.e07b
        Module    : NGFWv
        Resource  : 4 cores / 14336 MB RAM
        Last join : 05:22:55 UTC Jul 14 2025
        Last leave: N/A
Other members in the cluster:
    There is no other unit in the cluster
>
```

Step 7 Configure the Azure Gateway Load Balancer. Refer to Auto Scale with Azure Gateway Load Balancer Use Case for more information.

Step 8 Add the control node to the Firewall Management Center. Refer to Add the cluster to the Management Center (manual deployment), on page 493.

Deploy cluster nodes manually - NLB-based deployment

Deploy cluster nodes manually to establish a functional cluster configuration in Azure using NLB-based deployment.

Deploy the cluster nodes so they form a cluster.

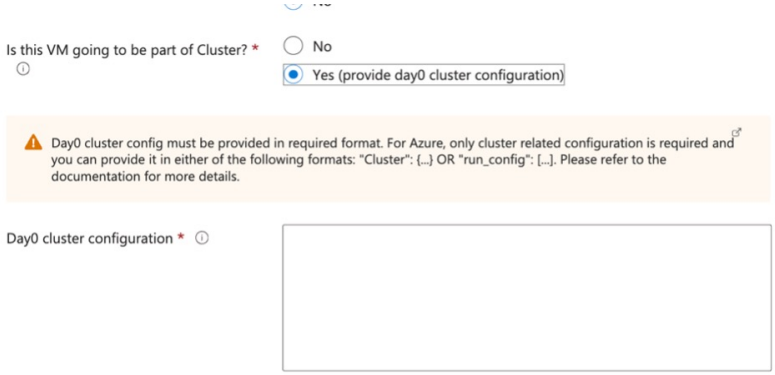
Procedure

Step 1 Log in to the Azure Portal: https://portal.azure.com

Step 2 Create a Resource Group.

a. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b. Choose the required **Region**.



Step 3 Create a Virtual Network with the necessary subnets: Management, Inside, Outside and Cluster Control Link (CCL).

Note Configure the CCL with the smallest subnet mask as required. Wider subnets can impact performance.

Refer to the Azure document for creating the Virtual Network and subnet: https://learn.microsoft.com/en-us/azure/virtual-network/quickstart-create-virtual-network?tabs=portal

Step 4 Go to the Marketplace and search for **Cisco Secure Firewall Threat Defense Virtual – BYOL and PAYG** and click **Create**.

Step 5 Fill the required details and choose **Yes** for **Is this VM going to be part of Cluster?**

Paste the following cluster-related configuration in the text box.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end", //mandatory user input
"ClusterGroupName": "cluster_name" //mandatory user input
}
```

Step 6 Click **Next** and select the **Virtual Network & Subnets**.

Step 7 Click **Review + create**. Wait until the Threat Defense Virtual deployment is completed.

Step 8 Connect to the Threat Defense Virtual device and use the **show cluster info** command to confirm the cluster formation is successful.

```
> show cluster info
Cluster ngfwv-cluster: On
    Interface mode: individual
Cluster Member Limit : 16
    This is "4" in state CONTROL_NODE
        ID        : 0
        Version   : 9.23(1)
        Serial No.: 9AC1VMGJKAQ
        CCL IP    : 169.254.200.4
        CCL MAC   : 6045.bda8.e07b
        Module    : NGFWv
        Resource  : 4 cores / 14336 MB RAM
        Last join : 05:22:55 UTC Jul 14 2025
        Last leave: N/A
Other members in the cluster:
    There is no other unit in the cluster
>
```

Step 9 Add the control node to the Management Center. Refer to Add the cluster to the Management Center (manual deployment), on page 493.

Troubleshoot cluster deployment in Azure

This reference provides troubleshooting guidance for resolving common issues that may occur during cluster deployment in Azure, including traffic flow problems, cluster formation failures, and role assignment errors.

- Issue: No traffic flow

  Troubleshooting:

  - Check if the health probe status of the Threat Defense Virtual instances deployed with a GWLB is healthy.
  - If the Threat Defense Virtual instance's health probe status is unhealthy-
    - Check if the static route is configured in the Management Center Virtual.
    - Check if the default gateway is the data subnet's gateway IP address.
    - Check if the Threat Defense Virtual instance is receiving health probe traffic.
    - Check if the access list configured in the Management Center Virtual allows health probe traffic.

- Issue: Cluster is not formed

  Troubleshooting:

  - Check the IP address of the NVE-only cluster interface. Ensure that you can ping the NVE-only cluster interface of other nodes.
  - Check the IP address of the NVE-only cluster interfaces are part of the object group.
  - Ensure that the NVE interface is configured with the object group .

- Ensure that the cluster interface in the cluster group has the right VNI interface. This VNI interface has the NVE with the corresponding object group.
- Ensure that the nodes are pingable from each other. Since each node has its own cluster interface IP, these should be pingable from each other.
- Check if the CCL subnet's start and end address mentioned during template deployment is correct. The start address should begin with the first available IP address in the subnet. For example, if the subnet is 192.168.1.0/27. The start address should be 192.168.1.4 (the three IP addresses at the start are reserved by Azure).
- Check if the Management Center Virtual has a valid license.

- Issue: Role-related error while deploying resources again in the same resource group.

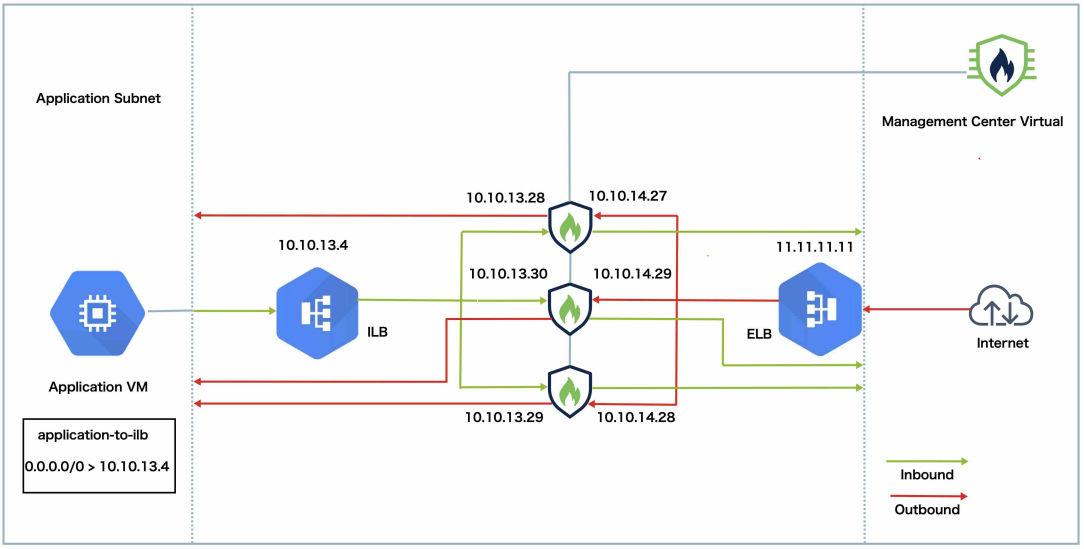
  Troubleshooting: Remove the roles given below by using these commands on the terminal.

  Error message:

```
"error": {
"code": "RoleAssignmentUpdateNotPermitted",
"message": "Tenant ID, application ID, principal ID, and scope are not allowed to be
updated."}
```

  - **az role assignment delete --resource-group** <*Resource Group Name*> **--role "Storage Queue Data Contributor"**
  - **az role assignment delete --resource-group** <*Resource Group Name*> **--role "Contributor"**

Deploy the cluster in GCP



To deploy a cluster in GCP, you can either manually deploy or use an instance template to deploy an instance group. You can use the cluster with native GCP load balancers or non-native load balancers such as the Cisco Cloud Services Router.

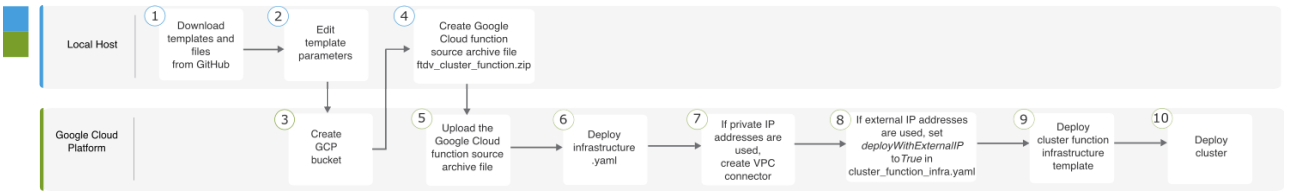
Note Outbound traffic requires interface NAT and is limited to 64,000 connections.

Sample topology for GCP clustering autoscale solution

Understand the architecture and traffic flow of a typical GCP clustering autoscale deployment.

Figure 199: Sample Topology

The topology shows both inbound and outbound traffic flow.

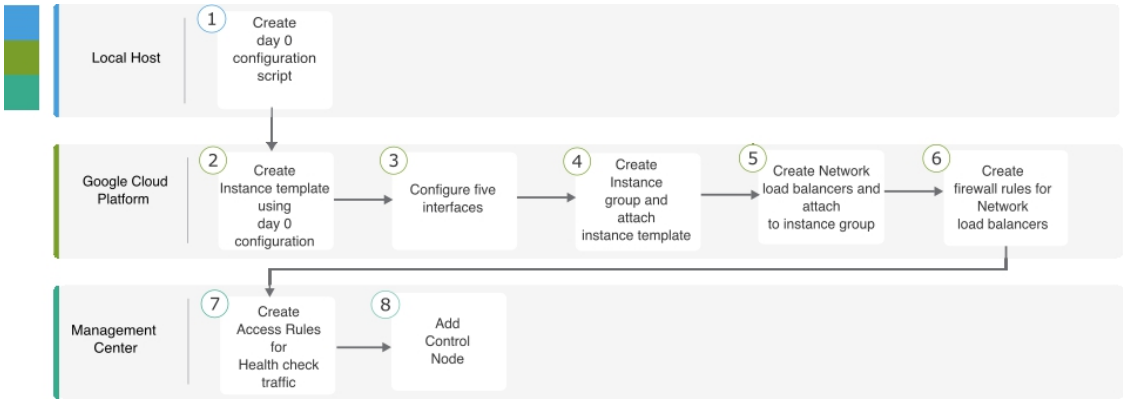


1. The Threat Defense Virtual cluster is placed between the internal and external load balancers. A Management Center Virtual instance is used to manage the cluster.
2. Inbound traffic from the internet goes to the external load balancer, which then transmits the traffic to the Threat Defense Virtual cluster.
3. The Threat Defense Virtual instance in the cluster inspects the traffic, and after inspection, forwards the traffic to the application VM.
4. Outbound traffic from the application VM goes to the internal load balancer. The load balancer forwards this traffic to the Threat Defense Virtual cluster, which sends it to the internet.

End-to-end process for deploying Threat Defense Virtual cluster in GCP

Provides a workflow to help users successfully deploy and verify a Threat Defense Virtual cluster on GCP using either template-based or manual deployment processes.

Template-based Deployment



The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster on GCP.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.
2	Local Host	Edit template parameters.
3	Google Cloud Platform	Create GCP bucket.
4	Local Host	Create Google Cloud function source archive file *ftdv_cluster_function.zip*.
5	Google Cloud Platform	Upload the Google function source archive file.
6	Google Cloud Platform	Deploy infrastructure.yaml.
7	Google Cloud Platform	If private IP addresses are used, create VPC connector.
8	Google Cloud Platform	If external IP addresses are used, set *deployWithExternalIP* to *True* in *cluster_function_infra.yaml*.
9	Google Cloud Platform	Deploy cluster function infrastructure template.
10	Google Cloud Platform	Deploy cluster.

Manual Deployment

The following flowchart illustrates the workflow for manual deployment of the Threat Defense Virtual cluster on GCP.

	Workspace	Steps
1	Local Host	Create day 0 configuration script.

	Workspace	Steps
2	Google Cloud Platform	Create instance template using day 0 configuration.
3	Google Cloud Platform	Configure the interfaces.
4	Google Cloud Platform	Create instance group and attach instance template.
5	Google Cloud Platform	Create NLB and attach to instance group.
6	Google Cloud Platform	Create firewall rules for NLB.
7	Management Center	Create access rules for health check traffic.
8	Management Center	Add control node.

Templates

The templates are available in GitHub. The parameter values are self-explanatory with the parameter names and values given in the template.

- Cluster deployment template for East-West traffic - deploy_ngfw_cluster_yaml
- Cluster deployment template for North-South traffic - deploy_ngfw_cluster.yaml

Deploy the instance group in GCP using an instance template

Deploy a scalable instance group in Google Cloud Platform using pre-configured instance templates to establish a Secure Firewall cluster with automated management capabilities.

Deploy the instance group in GCP using an instance template.

Before you begin

- Download the templates from GitHub to your local folder.
- Use Google Cloud Shell for deployment. Alternatively, you can use Google SDK on any macOS/Linux/Windows machine.
- To allow the cluster to auto-register with the Management Center, you need to create a user with administrative privileges on the Management Center that can use the REST API. See the *Cisco Secure Firewall Management Center Administration Guide*.
- Add an access policy in the Management Center that matches the name of the policy that you specified in *cluster_function_infra.yaml*.

Procedure

Step 1 Edit the **infrastructure.yaml**, **cluster_function_infra.yaml** and **deploy_ngfw_cluster.yaml** templates with the required *resourceNamePrefix* parameter (for example, ngfwvcls) and other required user inputs.

From Secure Firewall version 7.4.1, you can deploy the cluster without the diagnostic interface. To deploy the cluster with only the Outside, Inside, Management, and CCL interfaces, set the *withDiagnostic* variable to **False** in both the **infrastructure.yaml** and the **deploy_ngfw_cluster.yaml** files.

Note that there is a **deploy_ngfw_cluster.yaml** file in both the **east-west** and **north-south** folders in GitHub. Download the appropriate template as per your traffic flow requirement.

Step 2 Create a bucket using Google Cloud Shell to upload the Google cloud function source archive file *ftdv_cluster_function.zip*.

gsutil mb --pap enforced gs://*resourceNamePrefix***-ftdv-cluster-bucket/**

Ensure that the *resourceNamePrefix* variable here matches the *resourceNamePrefix* variable that you specified in **cluster_function_infra.yaml**.

Step 3 Create an archive file for the cluster infrastructure.

Example:

```
zip -j ftdv_cluster_function.zip ./cluster-function/*
```

Step 4 Upload the Google source archive that you created earlier.

gsutil cp ftdv_cluster_function.zip gs://*resourceNamePrefix***-ftdv-cluster-bucket/**

Step 5 Deploy infrastructure for the cluster.

gcloud deployment-manager deployments create *cluster_name* **--config infrastructure.yaml**

Step 6 If you are using private IP addresses, perform the steps given below:

a) Launch and set up the Management Center Virtual with a Threat Defense Virtual management VPC.

b) Create a VPC connector to connect the Google Cloud functions with the Threat Defense Virtual management VPC.

gcloud compute networks VPC-access connectors create *VPC-connector-name* **--region us-central1 --subnet** *resourceNamePrefix***-ftdv-mgmt-subnet28**

Step 7 If the Management Center is remote from the Threat Defense Virtual, and the Threat Defense Virtual needs an external IP address, ensure that you set **deployWithExternalIP** to **True** in **cluster_function_infra.yaml**.

Step 8 Deploy the cluster function infrastructure.

gcloud deployment-manager deployments create *cluster_name* **--config cluster_function_infra.yaml**

Step 9 Deploy the cluster.

a. For North-South topology deployment:

gcloud deployment-manager deployments create *cluster_name* **--config north-south/deploy_ngfw_cluster.yaml**

b. For East-West topology deployment:

gcloud deployment-manager deployments create *cluster_name* **--config east-west/deploy_ngfw_cluster.yaml**

Manual cluster deployment in GCP

To deploy the cluster manually, prepare the day0 configuration, deploy each node, and then add the control node to the Firewall Management Center .

Create the Day0 configuration with a fixed configuration for GCP

The fixed configuration will auto-generate the cluster bootstrap configuration.

```
{
    "AdminPassword": "password",
    "Hostname": "hostname",
    "FirewallMode": "Routed",
    "ManageLocally": "No",
                "Diagnostic": "OFF",       //Optional user input from version 7.4.1 - use
to deploy cluster without Diagnostic interface
    "Cluster": {
        "CclSubnetRange": "ip_address_start ip_address_end",
        "ClusterGroupName": "cluster_name"
    }
}
```

For example:

```
{
    "AdminPassword": "DeanW1nche$ter",
    "Hostname": "ciscoftdv",
    "FirewallMode": "Routed",
    "ManageLocally": "No",
    "Cluster": {
        "CclSubnetRange": "10.10.55.2 10.10.55.253",     //mandatory user input
        "ClusterGroupName": "ftdv-cluster"               //mandatory user input
    }
}
```

Note If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration.

For the **CclSubnetRange** variable, note that you cannot use the first two IP addresses and the last two IP addresses in the subnet. See Reserved IP addresses in IPv4 subnets for more information. Ensure that you have at least 16 available IP addresses for clustering. Some examples of start and end IP addresses are given below.

Note All cluster infrastructure subnets must use /27 CIDR.

Table 35: Examples of start and end IP addresses

CIDR	Start IP Address	End IP Address
10.1.1.0/27	10.1.1.2	10.1.1.29
10.1.1.32/27	10.1.1.34	10.1.1.61
10.1.1.64/27	10.1.1.66	10.1.1.93
10.1.1.96/27	10.1.1.98	10.1.1.125
10.1.1.128/27	10.1.1.130	10.1.1.157
10.1.1.160/27	10.1.1.162	10.1.1.189
10.1.1.192/27	10.1.1.194	10.1.1.221
10.1.1.224/27	10.1.1.226	10.1.1.253

Deploy cluster nodes manually

Deploy cluster nodes to form a functional cluster on Google Cloud Platform (GCP) with proper network load balancing and management integration.

Deploy the cluster nodes so they form a cluster. For clustering on GCP, you cannot use the 4 vCPU machine type. The 4 vCPU machine type only supports four interfaces, and five are needed. Use a machine type that supports five interfaces, such as c2-standard-8.

Procedure

Step 1 Create an instance template using the day 0 configuration (in the **Metadata** > **Startup Script** section) with 5 interfaces: outside, inside, management, diagnostic, and cluster control link.

See Secure Firewall Threat Defense Virtual getting started guides.

Step 2 Create an instance group, and attach the instance template.

Step 3 Create GCP network load balancers (internal and external), and attach the instance group.

Step 4 For GCP network load balancers, allow health checks in your security policy on the Management Center. Refer to Allow health checks for GCP network load balancers, on page 491.

Step 5 Add the control node to the Management Center. Refer to Add the cluster to the Management Center (manual deployment), on page 493.

Allow health checks for GCP network load balancers

Google Cloud provides health checks to determine if backends respond to traffic. This configuration allows health check traffic through firewall rules and access rules, redirects health check traffic to the Google metadata server using dynamic manual NAT rules, and sets up routing for GCP health checks across all interfaces used for health probes.

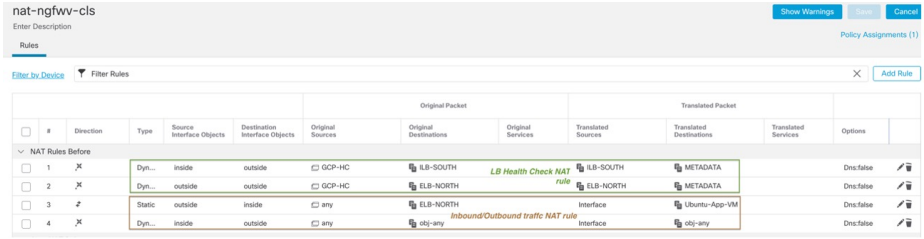
Configuration requirements

Refer to https://cloud.google.com/load-balancing/docs/health-checks to create firewall rules for network load balancers. Then in the Firewall Management Center, create access rules to allow the health check traffic. See https://cloud.google.com/load-balancing/docs/health-check-concepts for the required network ranges. See Access Control Rules, on page 1609.

You also need to configure dynamic manual NAT rules to redirect the health check traffic to the Google metadata server at 169.254.169.254. See Configure dynamic manual NAT, on page 1214.

You can set up a route for GCP health checks across all interfaces that are used to configure their health probes. You can achieve this by creating a route with a higher metric on interfaces where a route for GCP health checks is not already available.

North-South NAT rules sample configuration



```
nat (inside,outside) source dynamic GCP-HC ILB-SOUTH destination static ILB-SOUTH METADATA
nat (outside,outside) source dynamic GCP-HC ELB-NORTH destination static ELB-NORTH METADATA

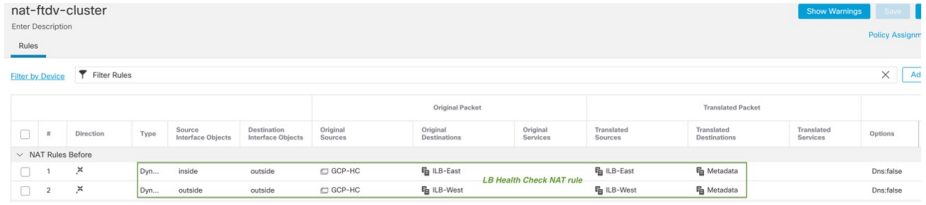
nat (outside,inside) source static any interface destination static ELB-NORTH Ubuntu-App-VM
nat (inside,outside) source dynamic any interface destination static obj-any obj-any

object network Metadata
 host 169.254.169.254

object network ILB-SOUTH
host <ILB_IP>
object network ELB-NORTH
host <ELB_IP>

object-group network GCP-HC
 network-object 35.191.0.0 255.255.0.0
 network-object 130.211.0.0 255.255.252.0
 network-object 209.85.204.0 255.255.252.0
 network-object 209.85.152.0 255.255.252.0
```

East-West NAT rules sample configuration



```
nat (inside,outside) source dynamic GCP-HC ILB-East destination static ILB-East Metadata
nat (outside,outside) source dynamic GCP-HC ILB-West destination static ILB-West Metadata

object network Metadata
 host 169.254.169.254

object network ILB-East
host <ILB_East_IP>
object network ILB-West
host <ILB_West_IP>

object-group network GCP-HC
```

```
network-object 35.191.0.0 255.255.0.0
network-object 130.211.0.0 255.255.252.0
network-object 209.85.204.0 255.255.252.0
network-object 209.85.152.0 255.255.252.0
```

North-South and East-West traffic routing configuration sample

```
route outside 0.0.0.0 0.0.0.0 <Outside_Gateway> 1
route inside 35.191.0.0 255.255.0.0 <Inside_Gateway> 1
route inside 130.211.0.0 255.255.252.0 <Inside_Gateway> 1
route inside 209.85.152.0 255.255.252.0 <Inside_Gateway> 1
route inside 209.85.204.0 255.255.252.0 <Inside_Gateway> 1
```

If a default route is not available, then policy-based routing can be used to route the traffic for health checks.

Note Set the NAT > Translated destination port to 80.

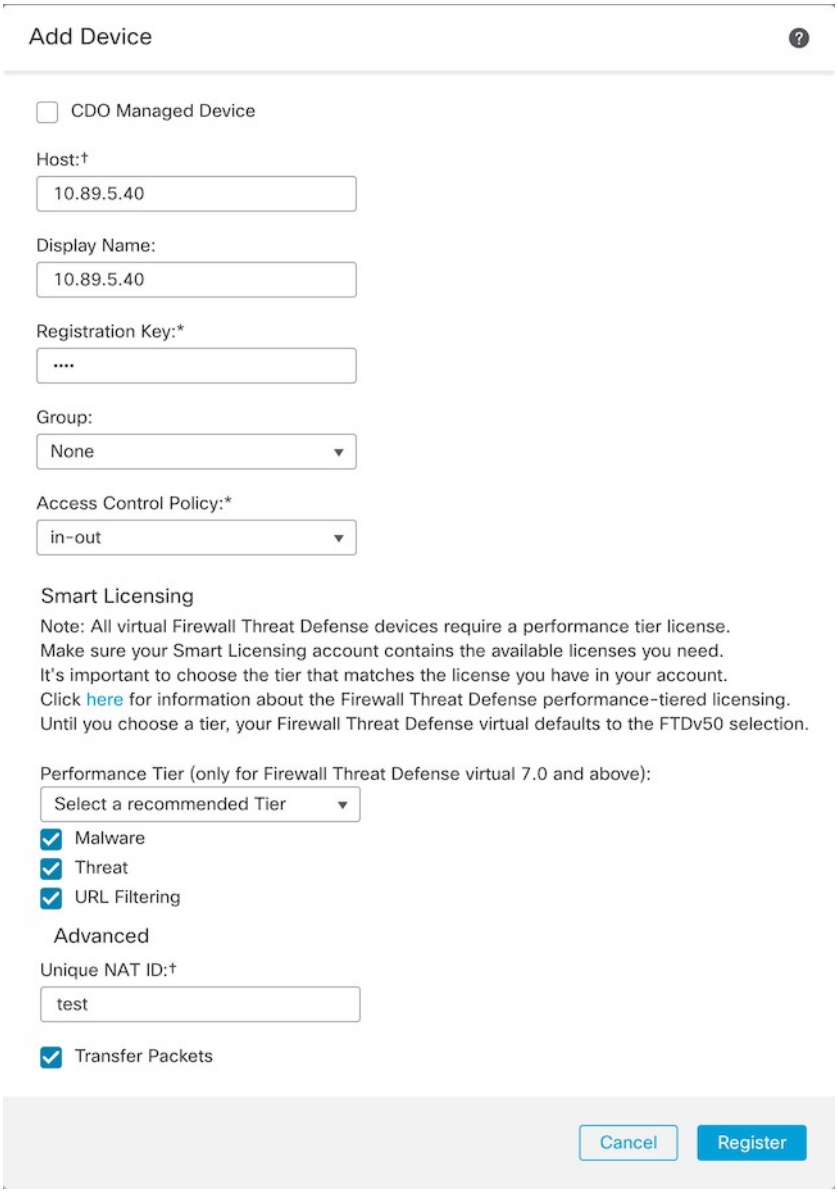
Add the cluster to the Management Center (manual deployment)

This task registers a manually deployed cluster with the Firewall Management Center to enable centralized management and configuration of the cluster units.

Use this procedure to add the cluster to the Firewall Management Center if you manually deployed the cluster. If you used a template, the cluster will auto-register on the Firewall Management Center.

Add one of the cluster units as a new device to the Firewall Management Center; the Firewall Management Center automatically detects all other cluster members.

Before you begin



- All cluster units must be in a successfully formed cluster before adding the cluster to the Firewall Management Center. You should also check which unit is the control unit. Use the Firewall Threat Defense **show cluster info** command.

Follow these steps to add the cluster to the Management Center for manual deployment:

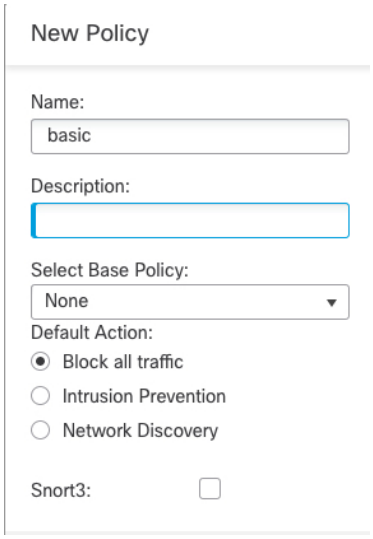
Procedure

Step 1 In the Firewall Management Center, choose **Devices** > **Device Management**, and then choose **Add** > **Add Device** to add the control unit using the unit's management IP address.

Figure 200: Add device

a) In the **Host** field, enter the IP address or hostname of the control unit.

We recommend adding the control unit for the best performance, but you can add any unit of the cluster.



If you used a NAT ID during device setup, you may not need to enter this field. For more information, see NAT environments, on page 8.

b) In the **Display Name** field, enter a name for the control unit as you want it to display in the Firewall Management Center.

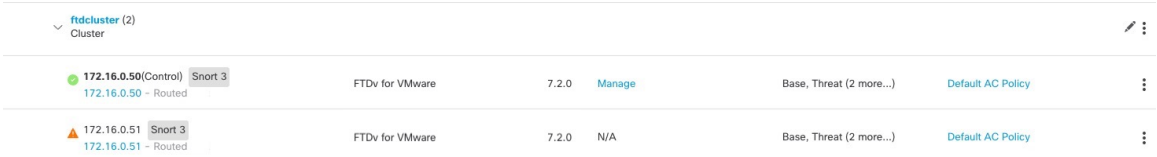
This display name is not for the cluster; it is only for the control unit you are adding. You can later change the name of other cluster members and the cluster display name.

c) In the **Registration Key** field, enter the same registration key that you used during device setup. The registration key is a one-time-use shared secret.
d) (Optional) Add the device to a device **Group**.
e) Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If you create a new policy, you create a basic policy only. You can later customize the policy as needed.

f) Choose licenses to apply to the device.
g) If you used a NAT ID during device setup, expand the **Advanced** section and enter the same NAT ID in the **Unique NAT ID** field.
h) Select the **Transfer Packets** check box to allow the device to transfer event metadata and packet data associated with intrusion events to the Firewall Management Center.

This option is enabled by default. The transferred packet data is used for intrusion-event analysis. It does not necessarily contain the complete original packet as transmitted on the wire or the complete traffic session. For intrusion events generated by Snort inspection, the device can transfer only the Protocol Data Unit (PDU) or packet content associated with the intrusion-rule match.



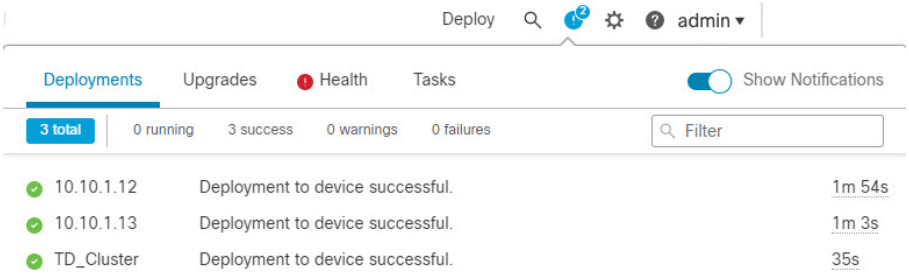
If you disable this option, the device sends only event information to the Firewall Management Center; packet data is not sent.

i) Click **Register**.

The Firewall Management Center identifies and registers the control unit, and then registers all data units. If the control unit does not successfully register, then the cluster is not added. A registration failure can occur if the cluster was not up, or because of other connectivity issues. In this case, we recommend that you try re-adding the cluster unit.

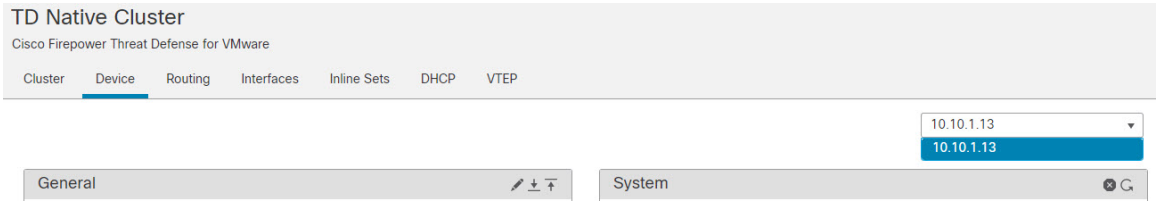
The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster units.

Figure 201: Cluster management



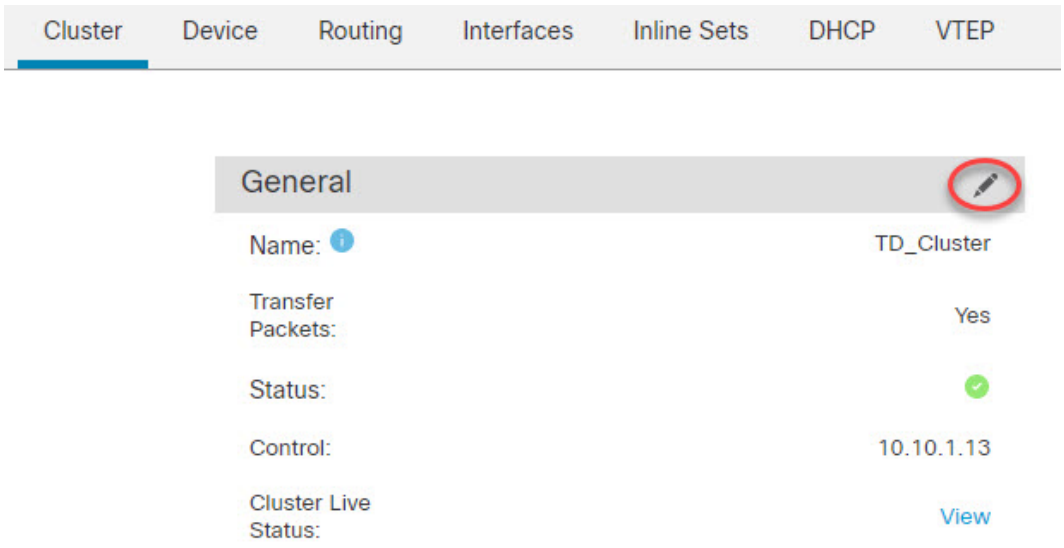
A unit that is currently registering shows the loading icon.

Figure 202: Node registration



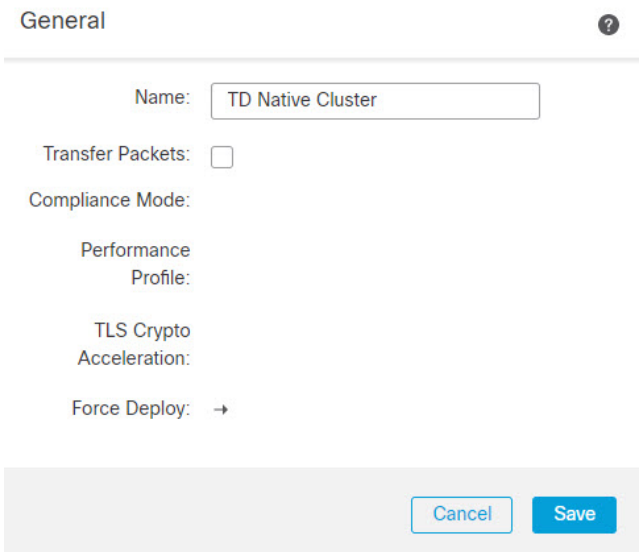
You can monitor cluster unit registration by clicking the **Notifications** icon and choosing **Tasks**. The Firewall Management Center updates the Cluster Registration task as each unit registers. If any units fail to register, see Reconcile Cluster Nodes, on page 504.

Step 2 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

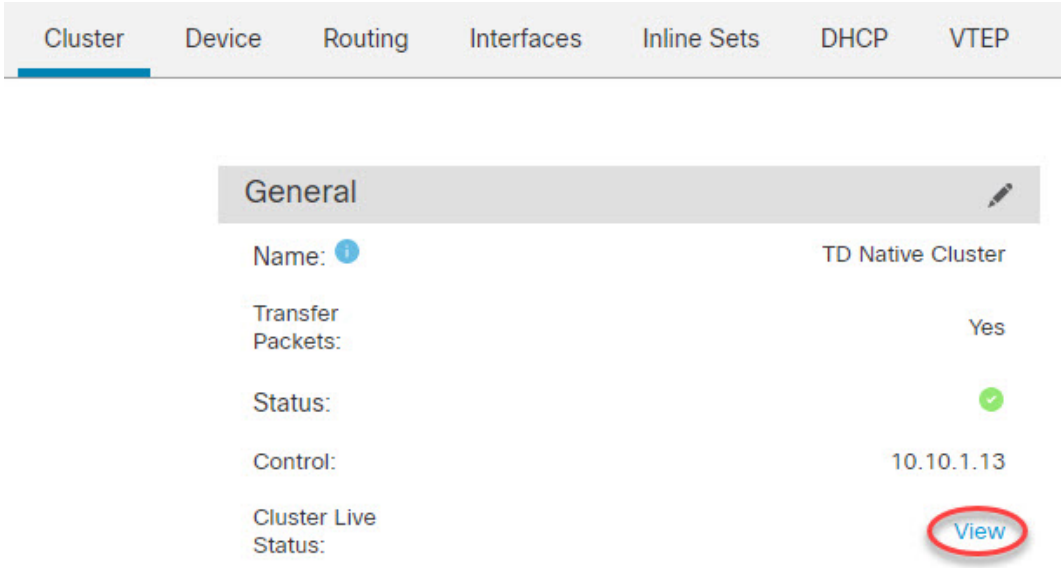


Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.

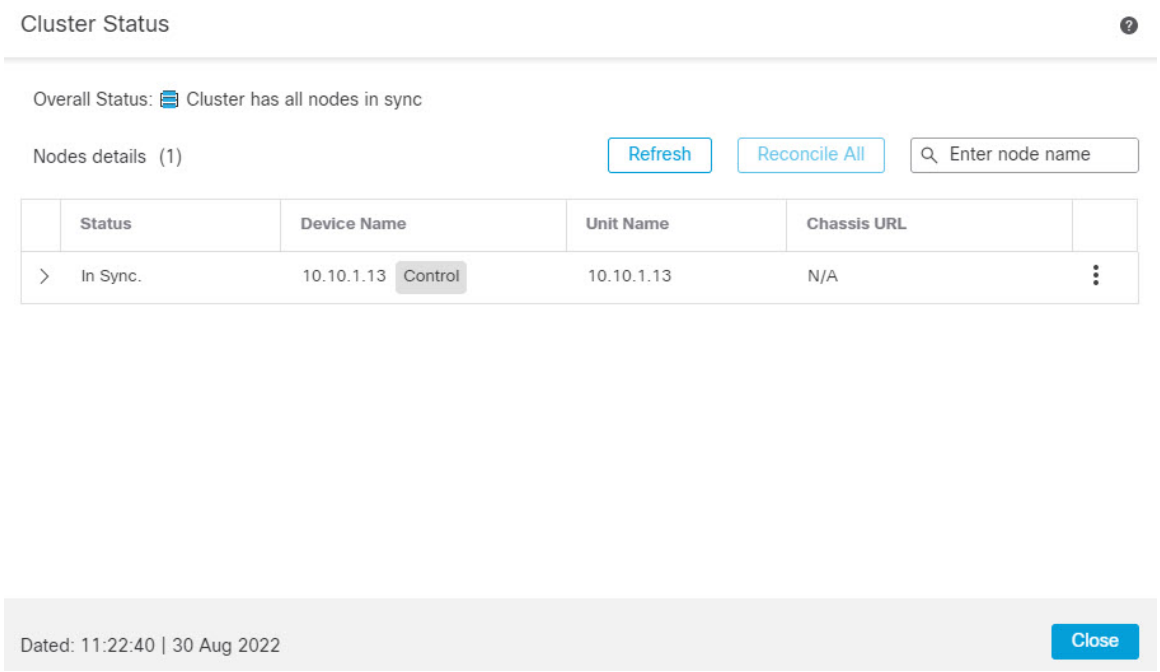
Step 3 On the **Devices** > **Device Management** and then choose **Add**, **Cluster** screen, you see **General**, **License**, **System**, and **Health** settings.



See these cluster-specific items:

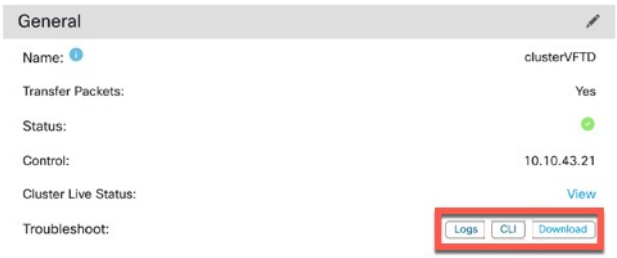


- **General** > **Name**—Change the cluster display name by clicking the **Edit** (✎).



Then set the **Name** field.

- **General > Cluster Live Status**—Click the **View** link to open the **Cluster Status** dialog box.



The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile**.You can also ping the cluster control link from a node. See Perform a ping on the cluster control link, on page 367.

- **General > Troubleshoot**—You can generate and download troubleshooting logs, and you can view cluster CLIs. See Troubleshoot the cluster, on page 365.

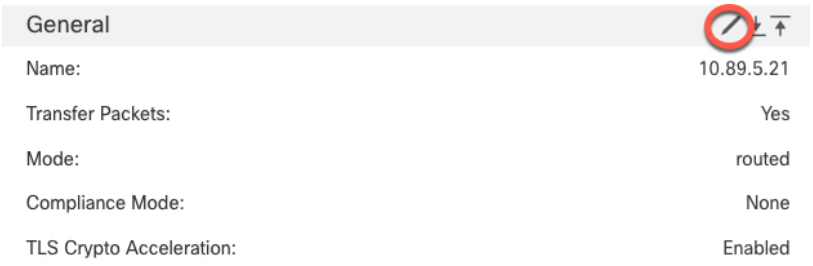


Figure 203: Troubleshoot

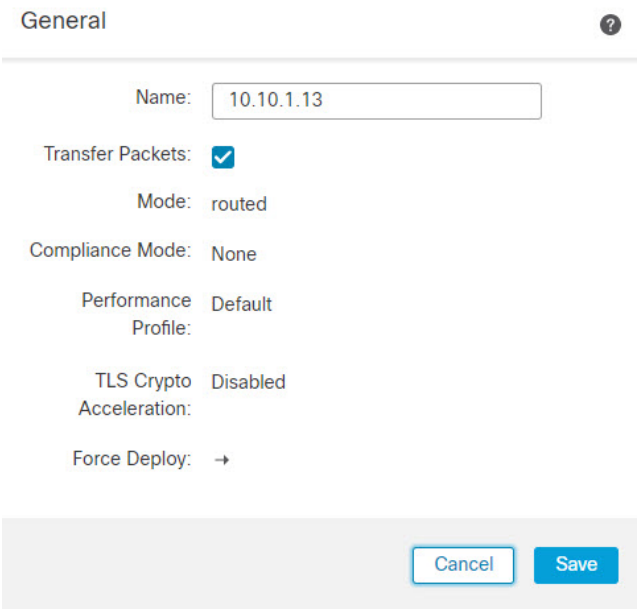
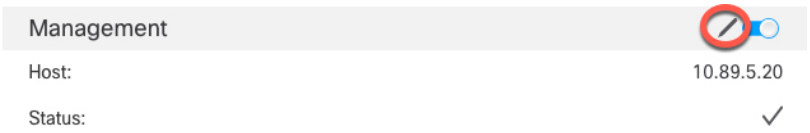


- **License**—Click **Edit** (✎) to set license entitlements.

Step 4 On the **Devices** > **Device Management** and then click **Add** > **Device**, you can choose each member in the cluster from the top right drop-down menu and configure these settings.



- **General > Name**—Change the cluster member display name by clicking the **Edit** (✎).

Then set the **Name** field.

- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the Firewall Management Center so that it can reach the device on the network; edit the **Host** address in the **Management** area.

Edit cluster health monitor settings

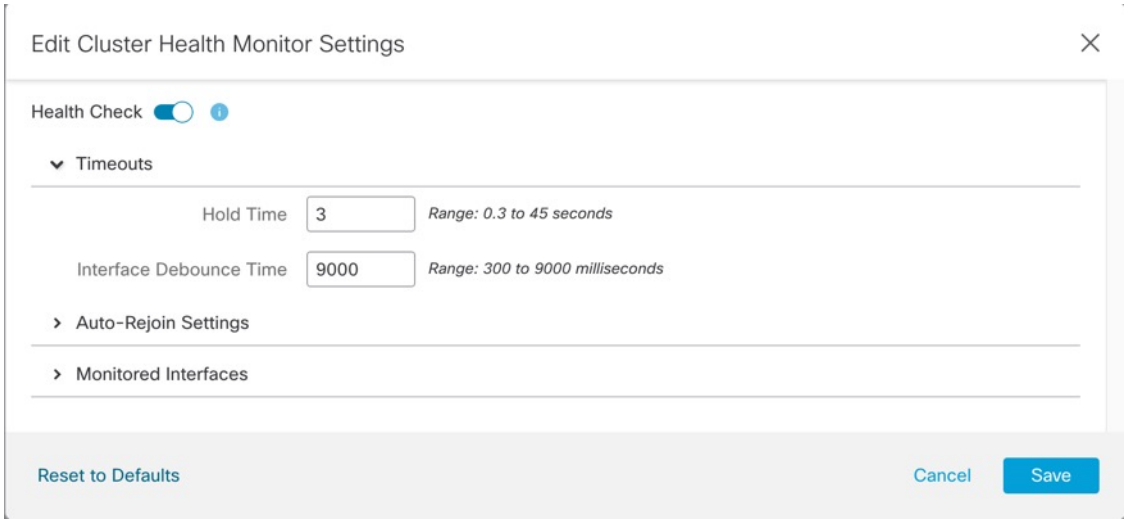
This task allows you to modify cluster health monitor settings to control how cluster nodes monitor system health and automatically rejoin the cluster after failures.

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings for monitoring cluster node health. You can monitor any port-channel ID, any single physical interface ID, and the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link. It is always monitored.

When a topology change occurs (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature. Also, disable interface monitoring for any interfaces that are disabled. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Procedure

Step 1 Choose **Devices** > **Device Management**.



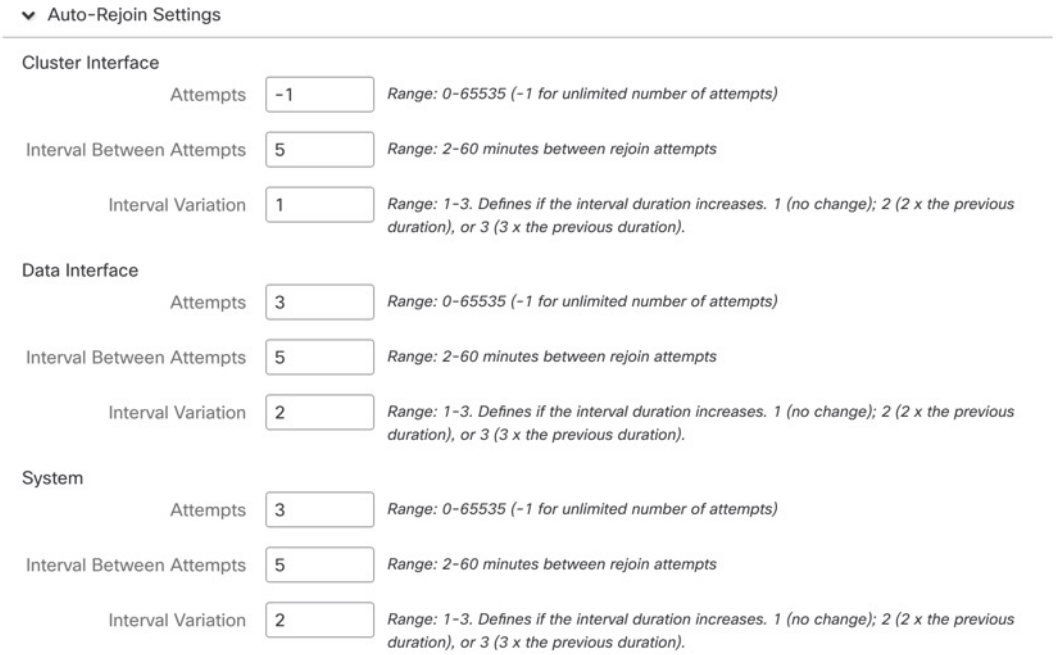
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider.

Figure 204: Disable the system health check



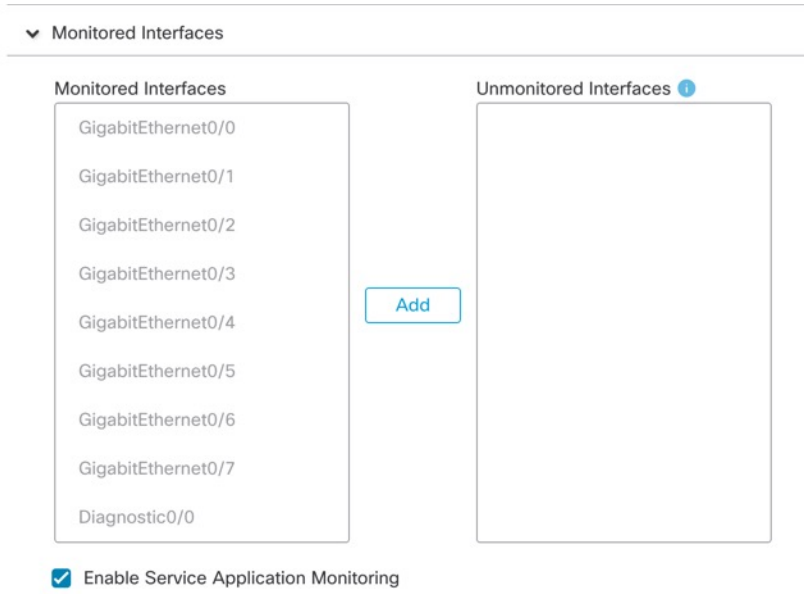
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between 0.3 and 45 seconds. The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the specified number of milliseconds before marking the interface as failed and removing the node from the cluster. If an EtherChannel transitions from a down state to an up state, such as after the switch reloads or enables an EtherChannel, a longer debounce time can prevent the interface from appearing failed on a cluster node if another cluster node bundles the ports more quickly.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 205: Configure Auto-Rejoin settings



Set values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 206: Configure monitored interfaces

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The time required to remove a member from the cluster depends on the type of interface and whether the node is established or is joining the cluster. By default, health check is enabled for all interfaces and the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Deploy configuration changes; see Deploy configuration changes, on page 135.

Manage cluster nodes

Explains how to add, remove, and configure cluster nodes in your deployment.

Disable clustering

Disable clustering to temporarily deactivate a node in preparation for deleting the node or for maintenance purposes.

You may want to deactivate a node to delete it or for temporary maintenance. This procedure temporarily deactivates a node, but the node will still appear in the Firewall Management Center device list. When a node becomes inactive, all data interfaces are shut down.

Note Do not power off the node without first disabling clustering.

Procedure

Step 1 For the unit you want to disable, choose **Devices** > **Device Management**, click the **More** (⋮), and choose **Disable Node Clustering**.

Step 2 Confirm that you want to disable clustering on the node.

The node will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, refer to Rejoin the Cluster.

Rejoin the cluster

Rejoin a node to the cluster after it was removed because of failure or when clustering was manually disabled.

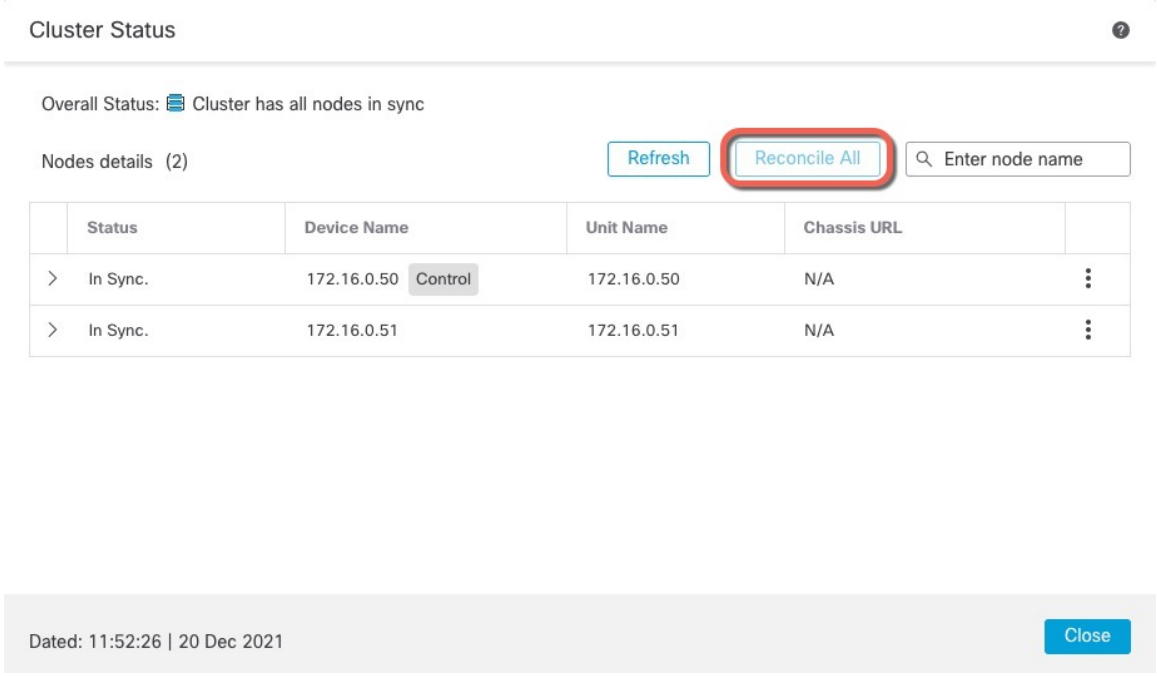
If a node was removed from the cluster, for example, due to a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster. Refer to Rejoining the cluster, on page 429 for more information about why a node can be removed from a cluster.

Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Enable Node Clustering**.

Step 2 Confirm that you want to enable clustering on the node.

Reconcile Cluster Nodes



If a cluster node fails to register, you can reconcile the cluster membership from the device to the Firewall Management Center. For example, a data node might fail to register if the Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure

Step 1 Choose **Devices** > **Device Management More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Step 2 Click **Reconcile All**.

Figure 207: Reconcile All

Delete (Unregister) the cluster or nodes and register with a new Firewall Management Center

This task allows you to move cluster nodes from one management center to another by safely removing them from their current management center and re-registering them with a new one.

You can unregister the cluster from the Firewall Management Center, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new Firewall Management Center.

You can also unregister a node from the Firewall Management Center without breaking the node from the cluster. Although the node is not visible in the Firewall Management Center, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the Firewall Management Center, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

Unregistering a cluster:

- Severs all communication between the Firewall Management Center and the cluster.

- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the Firewall Management Center using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different Firewall Management Center causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so you can add the cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

Before you begin

This procedure requires CLI access to one of the nodes.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster or node, and choose **Delete**.

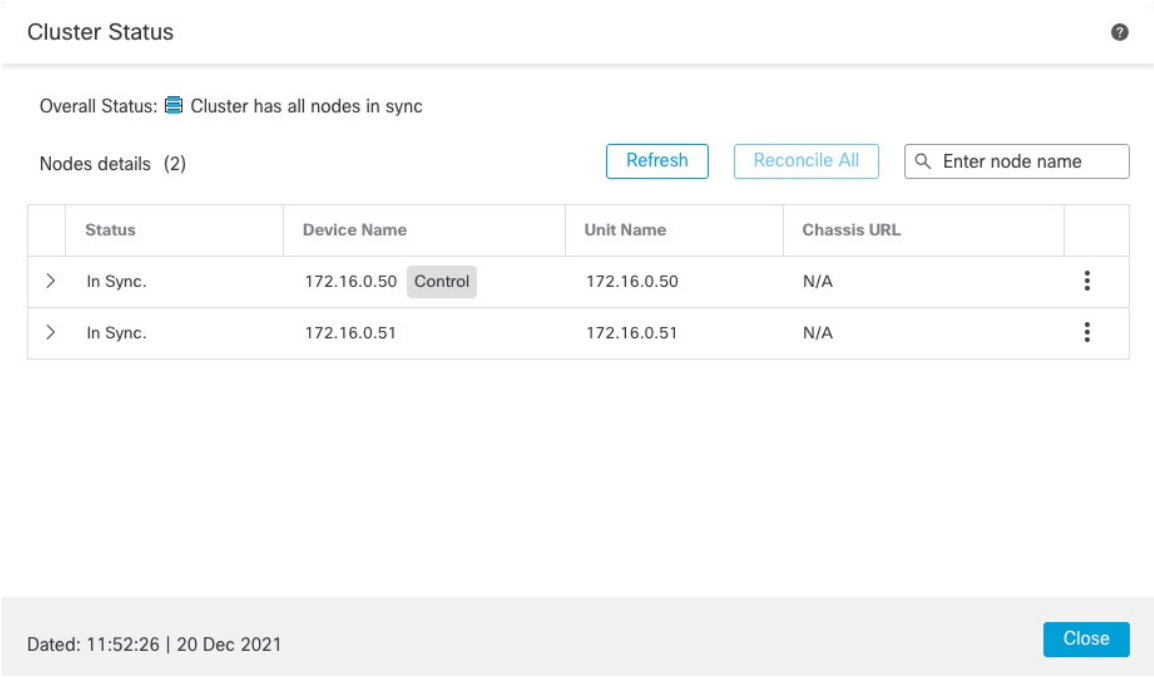
Step 2 You are prompted to delete the cluster or node; click **Yes**.

Step 3 You can register the cluster with a new (or the same) Firewall Management Center by adding one of the cluster members as a new device.

Add one of the cluster nodes as a device. The system will discover the remaining nodes.

a) Connect to the CLI of a cluster node, and identify the new Firewall Management Center using the **configure manager add** command.
b) Choose **Devices** > **Device Management**, and then click **Add Device**.

Step 4 To re-add a deleted node, refer to Reconcile Cluster Nodes, on page 504.



Monitor cluster status

You can monitor the cluster in the Firewall Management Center and at the Firewall Threat Defense CLI.

Monitor cluster status through these methods:

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management**, click **Add**, choose the **Cluster** page **General** area **Cluster Live Status** link.

Figure 208: Cluster status

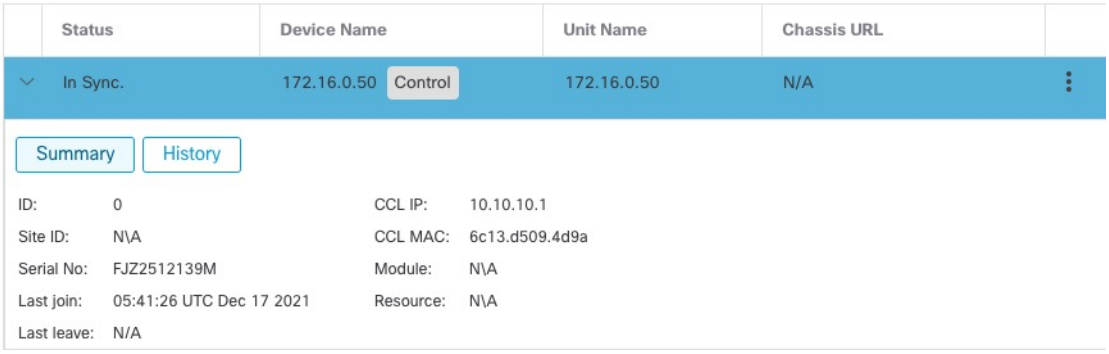
The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes these states:

- In Sync—The node is registered with the Firewall Management Center.
- Pending Registration—The node is part of the cluster, but has not yet registered with the Firewall Management Center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The node is registered with the Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Firewall Management Center.

For each node, you can view the **Summary** or the **History**.

Figure 209: Node summary



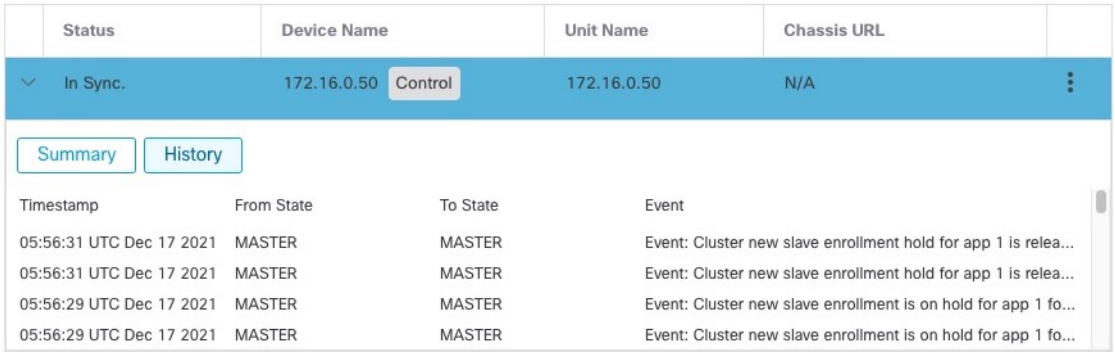


Figure 210: Node history

- **System** (⚙) > **Tasks** page.

  The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management** and then click **Add** > **Device** *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Cluster health monitor

When a Firewall Threat Defense is the control node of a cluster, the Firewall Management Center collects various metrics periodically from the device metric data collector.

The cluster health monitor is comprised of these components:

- Overview dashboard: Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard: Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.

- Member Performance dashboard: Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard: Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links: Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range: An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard: Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

View the cluster health monitor

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

Ensure you have created a cluster from one or more devices in the Firewall Management Center.

Follow these steps to view the cluster health monitor:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 Click on the cluster name to view the cluster health statistics.

The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution: Traffic and packet distribution across the cluster nodes.
- Member Performance: Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL: Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 Configure the time range from the drop-down in the upper-right corner.

The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 View device monitor health and performance metrics in several predefined dashboards.

The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU: CPU utilization, including the CPU usage by process and by physical cores.

- Memory: Device memory utilization, including data plane and Snort memory usage.
- Interfaces: Interface status and aggregate traffic statistics.
- Connections: Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort: Statistics that are related to the Snort process.
- ASP drops: Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. Refer to Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 36: Cluster Metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number
Packets	Packet distribution count in the cluster for every second.	number

Troubleshoot the cluster

Use these methods to troubleshoot the devices and clusters:

- Use **Logs** to generates troubleshooting files for all nodes in the cluster. Use this option when you need one cluster-level collection instead of generating troubleshooting files from each node separately.
- Use **CLI** to run a predefined set of cluster diagnostic commands and displays the output. Use this option to check cluster configuration, member state, cluster health, control-plane transport statistics, packet drops, interface status, CPU usage, memory buffers, ARP entries, and reachability. The **CLI** option displays command output; it does not open an interactive CLI session.

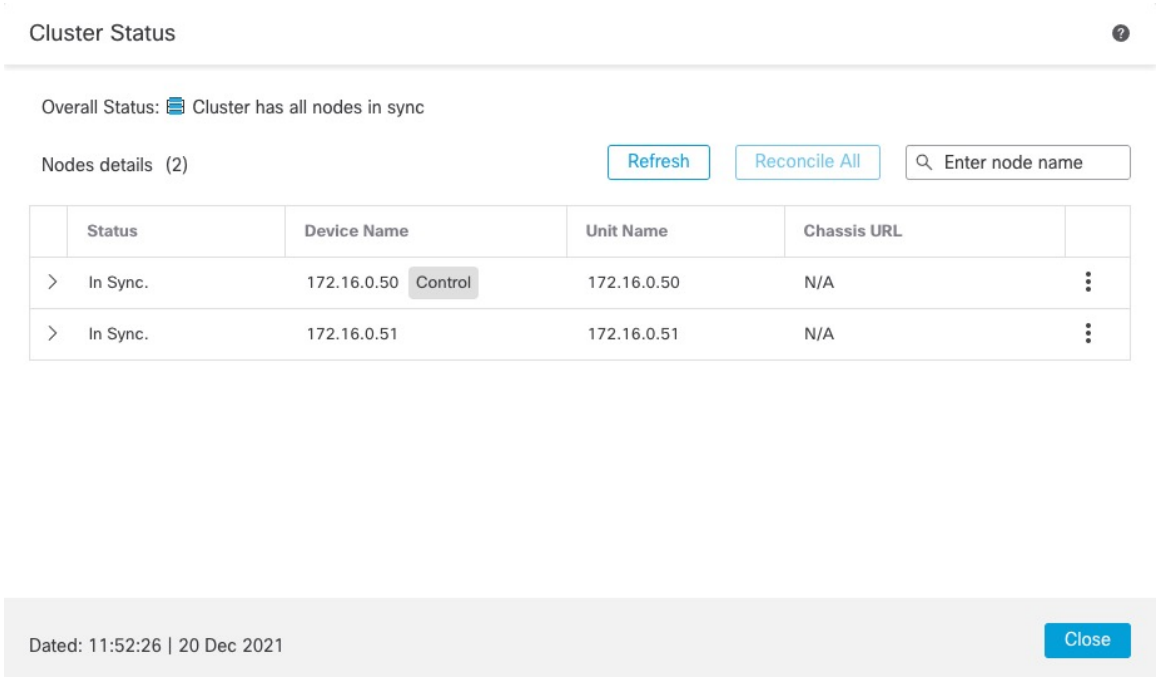
Commands
show running-config cluster: Review the cluster group configuration, local unit, cluster interface, priority, health-check, auto-rejoin, and cLACP settings.
show cluster info: Confirm that clustering is enabled and identify the control node, member state, software version, serial number, CCL IP address, CCL MAC address, and last join or leave state.
show cluster info health: Check unit, interface, service, and overall cluster health.
show cluster info transport cp: Review control-plane transport counters, including reliable and unreliable message counters, errors, retransmits, drops, and buffer conditions.
show version: Capture platform, software, build, UUID, LSP, VDB, uptime, resource, and license context.
show asp drop: Identify accelerated security path packet or flow drop reasons and counters.
show counters: Review protocol, feature, and cluster CCL counters.
show arp: Verify ARP entries for interfaces that participate in cluster communication.
show int ip brief: Check interface IP addresses and administrative and line protocol status.
show blocks: Check buffer availability and failed allocations.
show cpu detailed: Check data path, control point, and total CPU usage.
show interface *ccl_interface*: Review interface state, MTU, MAC address, IP address, traffic counters, errors, and drops for the cluster-related interface.
ping *ccl_ip* **size** *ccl_mtu* **repeat 2**: Test reachability to a cluster peer by using the packet size selected by the tool.

- Use the **CCL Ping** when you need to test cluster control link connectivity between joined cluster nodes.
- Troubleshooting files—If a node fails to join the cluster, a troubleshooting file is automatically generated. You can also generate and download troubleshooting files from the **Devices** > **Device Management** and then choose **Add**, **ClusterGeneral** area. For more information, refer to Generate troubleshooting files, on page 745.

You can also generate files from the **Device Management** page. Click **More** (⋮) and choose **Troubleshoot Files**.

- CLI output—Choose **Devices** > **Device Management** and then choose **Add**, **ClusterGeneral** area, you can view a set of pre-defined CLI outputs that can help you troubleshoot the cluster. These commands are automatically run for the cluster:

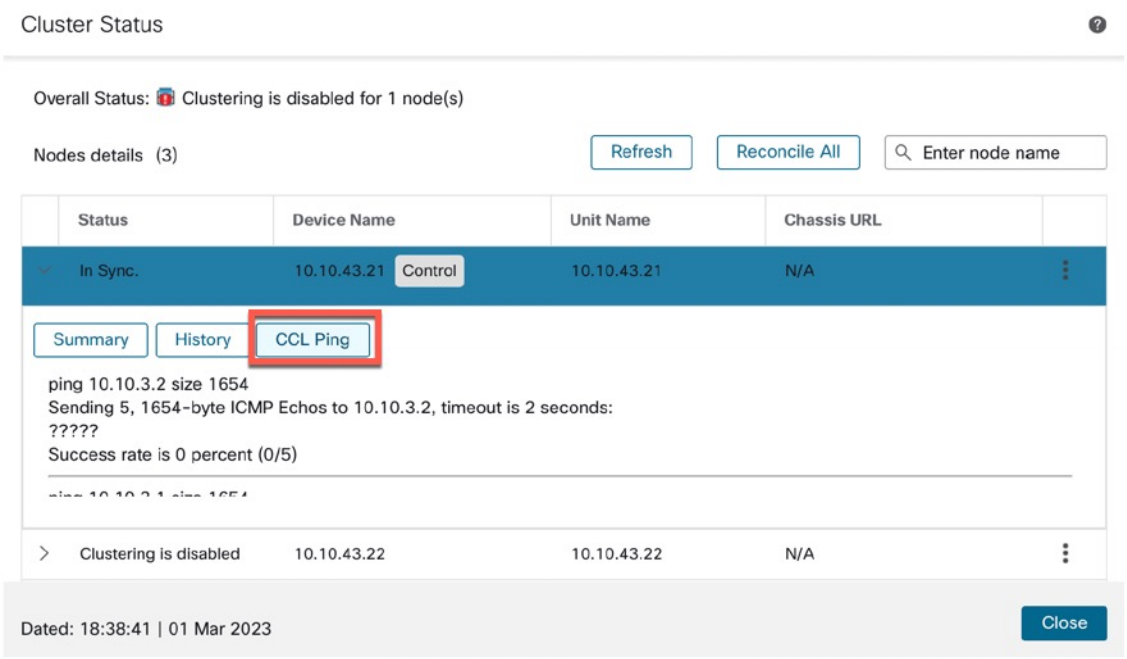
  You can also enter any **show** command in the **Command** field.



Perform a ping on the cluster control link

You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs.

Procedure



Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) icon next to the cluster, and choose **Cluster Live Status**.

Figure 211: Cluster status

Step 2 Expand one of the nodes, and click **CCL Ping**.

Figure 212: CCL ping

The node sends a ping on the cluster control link to every other node using a packet size that matches the maximum MTU.

Upgrade the cluster

This task upgrades a Firewall Threat Defense Virtual cluster to a new software version by updating the cloud instance template and performing a managed upgrade.

The cluster upgrade process involves updating both the cloud infrastructure template and the software package through the management center. The upgrade is performed one node at a time to maintain cluster availability.

Before you begin

- Before you upgrade a cluster in the public cloud, copy the target version image to your cloud image repository and update the image ID in the cluster deployment template (we actually recommend replacing the existing template with a modified copy). This ensures that after the upgrade, new instances — for example, instances launched during cluster scaling — will use the correct version. If the marketplace does not have the image you need, such as when the cluster has been patched, create a custom image from a snapshot of a standalone Firewall Threat Defense Virtual instance running the correct version, with no instance-specific (day 0) configurations.

Follow these steps to upgrade a Firewall Threat Defense Virtual cluster:

Procedure

Step 1 Upload the target image version to the cloud image storage.

Step 2 Update the cloud instance template of the cluster with the updated target image version.

a) Create a copy of the instance template with the target image version.

b) Attach the newly created template to cluster instance group.

Step 3 Upload the target image version upgrade package to the Firewall Management Center.

Step 4 Perform a readiness check on the cluster that you want to upgrade.

Step 5 After a successful readiness check, initiate the installation of the upgrade package.

Step 6 The Firewall Management Center upgrades the cluster nodes one at a time.

Step 7 The Firewall Management Center displays a notification after successful upgrade of the cluster.

There is no change to the serial number and UUID of the instance after the upgrade.

Reference for clustering

This section includes more information about how clustering operates.

Threat Defense features and clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported features and clustering

Centralized features for clustering

These features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. For more information, refer to FlexConfig policies, on page 921.

- These application inspections are supported:
  - DCERPC and ESMTP
  - NetBIOS and PPTP
  - RSH
  - SQLNET and SUNRPC
  - TFTP
  - XDMCP
- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

Cisco Trustsec and clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

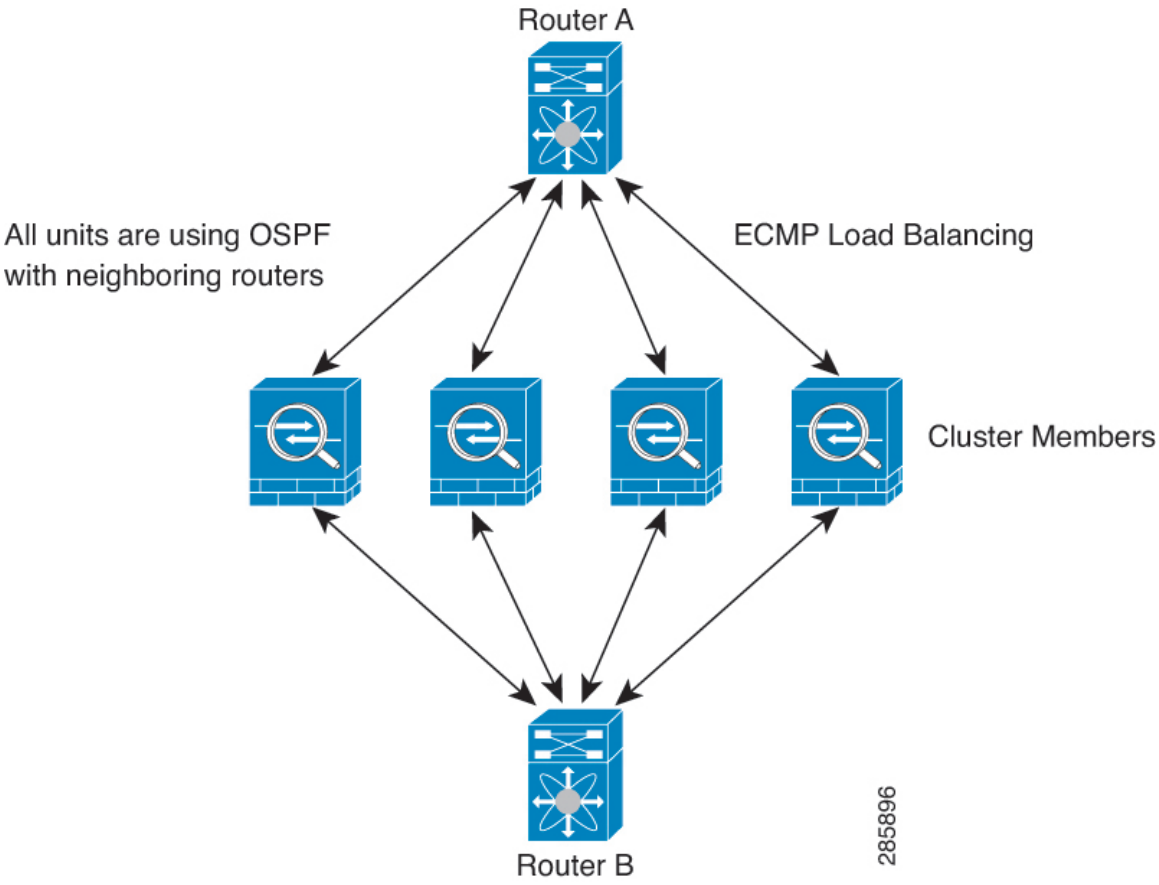
Connection settings and clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic routing and clustering

Dynamic routing and clustering are network configuration approaches that

- enable each node to run the routing protocol as a standalone router in Individual interface mode,
- allow routes to be learned by each node independently, and
- require separate router IDs for each node when communicating with external routers.



Routing behavior and load balancing

In Individual interface mode, ECMP is used to load balance traffic between multiple equal-cost paths. External routers can discover multiple paths to destinations through different cluster nodes.

Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when communicating with external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

Figure 213: Dynamic routing in individual interface mode

FTP and clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

NAT and clustering

Provides information about NAT behavior and limitations in clustering deployments.

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different Firewall Threat Defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the Firewall Threat Defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- No Proxy ARP—For individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with an ASA that may no longer be in the cluster. The upstream router requires a static route or policy-based routing (PBR) with Object Tracking for the mapped addresses, which must point to the main cluster IP address.
- No interface PAT on an individual interface—Interface PAT is not supported for Individual interfaces.
- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.

- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP inspection and clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

VPN and Clustering

Site-to-site VPN is a centralized feature; only the control node supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

For connections to an Individual interface when using PBR or ECMP, you must always connect to the Main cluster IP address, not a Local address.

VPN-related keys and certificates are replicated to all nodes.

Performance scaling factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

Throughput calculation

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control node election

Summary

The key components involved in the control node election process are:

- Cluster nodes: Communicate over the cluster control link and participate in the election process
- Election requests: Broadcast every 3 seconds by nodes when clustering is enabled
- Priority values: Set between 1 and 100 where 1 is the highest priority
- Control node: The elected node that coordinates cluster operations

Workflow

These stages describe how cluster nodes elect a control node:

1. When clustering is enabled for a node (or when it first starts up with clustering already enabled), the node broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request. The priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node. The existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, the node with highest priority retains the role while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High availability within the cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node health monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

Split brain scenario

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

Interface monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

All physical interfaces are monitored; only named interfaces can be monitored. You can optionally disable monitoring per interface.

A node is removed from the cluster if its monitored interfaces fail. The node is removed after 500 milliseconds.

Status after failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Firewall Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the Firewall Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data path connection state replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 37: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—
SNMP Engine ID	**No**	—

How the cluster manages connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.
- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

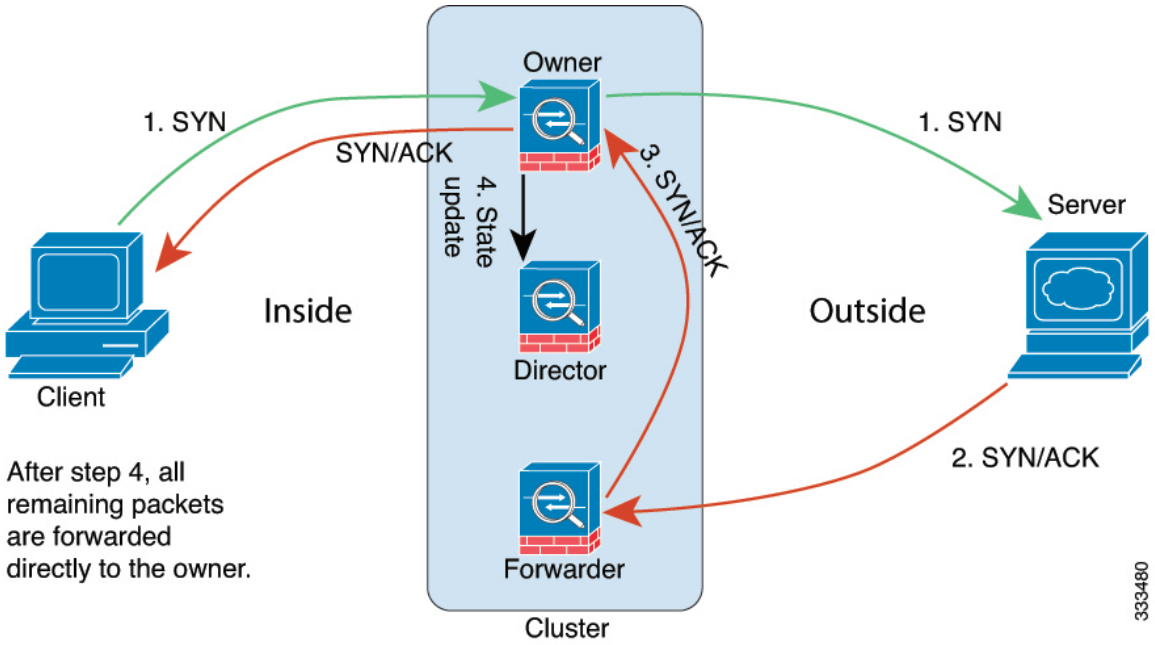
  ICMP/ICMPv6 hash details:

- For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
- For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
- For other packets, both source and destination ports are 0.

- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.



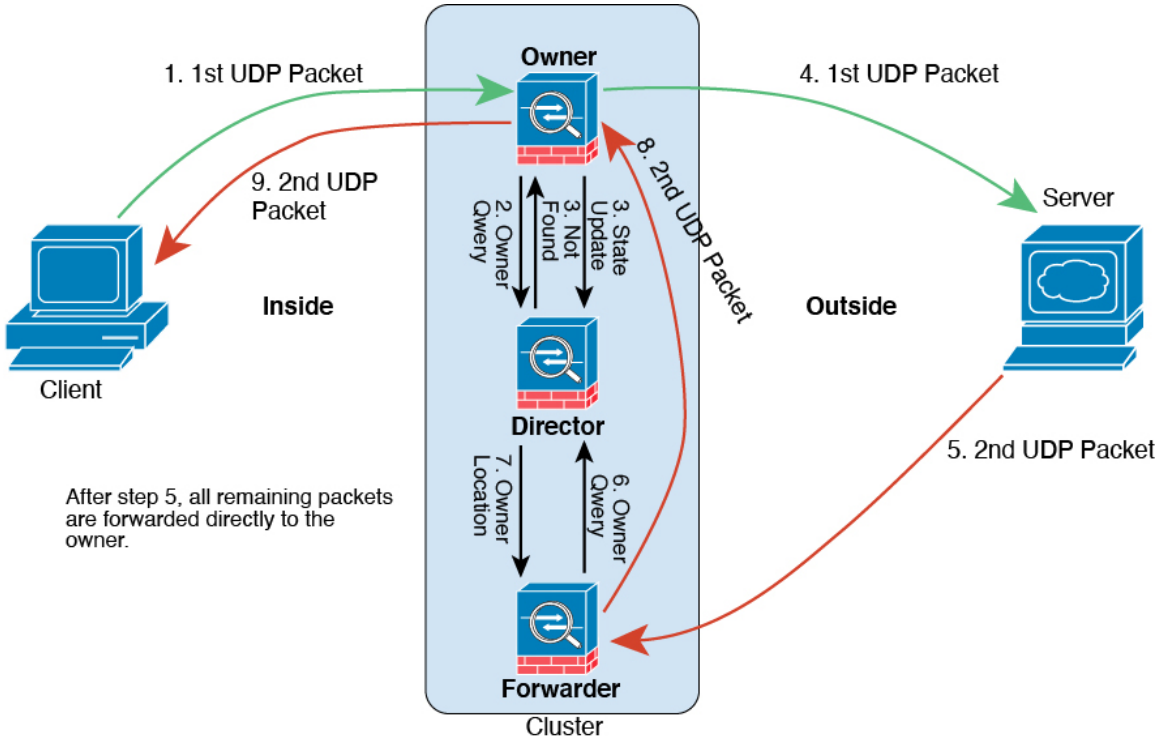
Port Address Translation Connections

New connection ownership

Traffic redirection is not supported in this release. When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. All the subsequent packets for the same connection should arrive the same node. If any connection packets arrive at a different node, they will be dropped. If a reverse flow arrives at a different node, it will be dropped as well. For centralized features, if the connections do not arrive on the control node, they will be dropped.

Sample data flow for TCP

The following example shows the establishment of a new connection.



1. The SYN packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different Firewall Threat Defense (based on the load balancing method). This Firewall Threat Defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

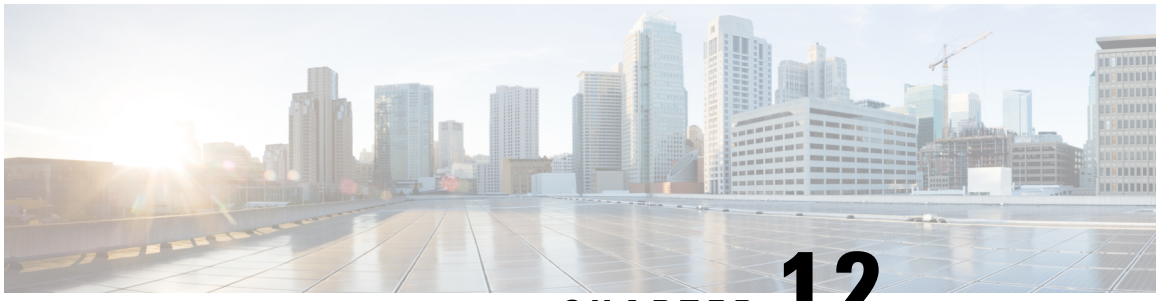
Sample data flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. *Figure 214: ICMP and UDP Data Flow*

The first UDP packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.



History for Threat Defense Virtual clustering in the public cloud

This reference provides the historical timeline and version information for Threat Defense Virtual clustering features introduced across different software releases and deployment platforms in public cloud environments.

Table 38: Feature history

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Cluster control link ping tool.	7.2.6/7.4.1	Any	You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs. New/modified screens: **Devices** > **Device Management** > **More** > **Cluster Live Status.**
Troubleshooting file generation and download available from Device and Cluster pages.	7.4.1	7.4.1	You can generate and download troubleshooting files for each device on the Device page and also for all cluster nodes on the Cluster page. For a cluster, you can download all files as a single compressed file. You can also include cluster logs for the cluster for cluster nodes. You can alternatively trigger file generation from the **Devices** > **Device Management** > **More** > **Troubleshoot Files** menu. New/modified screens: • **Devices** > **Device Management** > **Device** > **General** • **Devices** > **Device Management** > **Cluster** > **General**
View CLI output for a device or device cluster.	7.4.1	Any	You can view a set of pre-defined CLI outputs that can help you troubleshoot the device or cluster. You can also enter any **show** command and see the output. New/modified screens: **Devices** > **Device Management** > **Cluster** > **General**
Cluster health monitor settings.	7.3.0	Any	You can now edit cluster health monitor settings. New/Modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Cluster health monitor dashboard.	7.3.0	Any	You can now view cluster health on the cluster health monitor dashboard. New/Modified screens: **System** > **Health** > **Monitor**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details

CHAPTER 12

Clustering: Firepower 4100/9300

Clustering lets you group multiple Firewall Threat Defense nodes together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

Note Some features are not supported when using clustering. See Unsupported features with clustering, on page 585.

About clustering on the Firepower 4100/9300 chassis

When you deploy a cluster on the Firepower 4100/9300 chassis, it does the following:

- For native instance clustering: Creates a *cluster-control link* (by default, port-channel 48) for node-to-node communication.

  For multi-instance clustering: You should pre-configure subinterfaces on one or more cluster-type EtherChannels; each instance needs its own cluster control link.

  For a cluster isolated to security modules within one Firepower 9300 chassis, this link utilizes the Firepower 9300 backplane for cluster communications.

  For clustering with multiple chassis, you need to manually assign physical interface(s) to this EtherChannel for communications between chassis.

- Creates the cluster bootstrap configuration within the application.

  When you deploy the cluster, the chassis supervisor pushes a minimal bootstrap configuration to each unit that includes the cluster name, cluster control link interface, and other cluster settings.

- Assigns data interfaces to the cluster as *Spanned* interfaces.

  For a cluster isolated to security modules within one Firepower 9300 chassis, spanned interfaces are not limited to EtherChannels, like it is for clustering with multiple chassis. The Firepower 9300 supervisor uses EtherChannel technology internally to load-balance traffic to multiple modules on a shared interface, so any data interface type works for Spanned mode. For clustering with multiple chassis, you must use Spanned EtherChannels for all data interfaces.

Note Individual interfaces are not supported, with the exception of a management interface.

- Assigns a management interface to all units in the cluster.

Bootstrap configuration

A bootstrap configuration is a minimal cluster configuration that includes cluster name, cluster control link interface, and other cluster settings.

When you deploy the cluster, the Firepower 4100/9300 chassis supervisor pushes a minimal bootstrap configuration to each unit that includes the cluster name, cluster control link interface, and other cluster settings.

Cluster members

Cluster members are security devices that work together to accomplish the sharing of the security policy and traffic flows.

Cluster member roles and management

One member of the cluster is the **control** unit. The control unit is determined automatically. All other members are **data** units.

You must perform all configuration on the control unit only; the configuration is then replicated to the data units.

Some features do not scale in a cluster, and the control unit handles all traffic for those features. .

Cluster control link

Cluster control link traffic includes both control and data traffic.

For native instance clustering: The cluster control link is automatically created using the Port-channel 48 interface.

For multi-instance clustering: You should pre-configure subinterfaces on one or more cluster-type EtherChannels; each instance needs its own cluster control link.

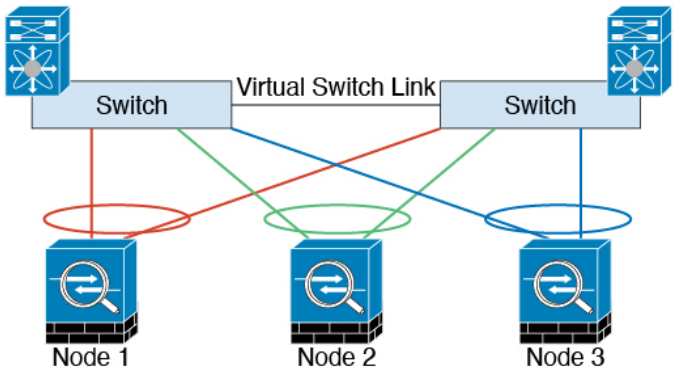
For a cluster isolated to security modules within one Firepower 9300 chassis, this interface has no member interfaces. This Cluster type EtherChannel utilizes the Firepower 9300 backplane for cluster communications. For clustering with multiple chassis, you must add one or more interfaces to the EtherChannel.

For a cluster with two chassis, do not directly connect the cluster control link from one chassis to the other chassis. If you directly connect the interfaces, then when one unit fails, the cluster control link fails, and thus the remaining healthy unit fails. If you connect the cluster control link through a switch, then the cluster control link remains up for the healthy unit.

Size the cluster control link

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features.

For example:



- NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units.
- When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth.

A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

Note If your cluster has large amounts of asymmetric (rebalanced) traffic, then you should increase the cluster control link size.

Cluster control link redundancy

The diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS), Virtual Port Channel (vPC), StackWise, or StackWise Virtual environment. All links in the EtherChannel are active. When the switch is part of a redundant system, then you can connect firewall interfaces within the same EtherChannel to separate switches in the redundant system. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a Spanned EtherChannel.

Cluster control link reliability for inter-chassis clustering

To ensure cluster control link functionality, be sure the round-trip time (RTT) between units is less than 20 ms. This maximum latency enhances compatibility with cluster members installed at different geographical sites. To check your latency, perform a ping on the cluster control link between units.

The cluster control link must be reliable, with no out-of-order or dropped packets; for example, for inter-site deployment, you should use a dedicated link.

Cluster control link network

The Firepower 4100/9300 chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: 127.2.*chassis_id*.*slot_id*. For multi-instance clusters, which typically use different VLAN subinterfaces of the same EtherChannel, the same IP address can be used for different clusters because of VLAN separation. The cluster control link network cannot include any routers between units; only Layer 2 switching is allowed.

Management network

We recommend connecting all units to a single management network. This network is separate from the cluster control link.

Management interface

You must assign a Management type interface to the cluster. This interface is a special individual interface as opposed to a Spanned interface. The management interface lets you connect directly to each unit. This Management logical interface is separate from the other interfaces on the device. It is used to set up and register the device to the Secure Firewall Management Center. It uses its own local authentication, IP address, and static routing.

Management interface configuration

Each cluster member uses a separate IP address on the management network that you set as part of the bootstrap configuration.

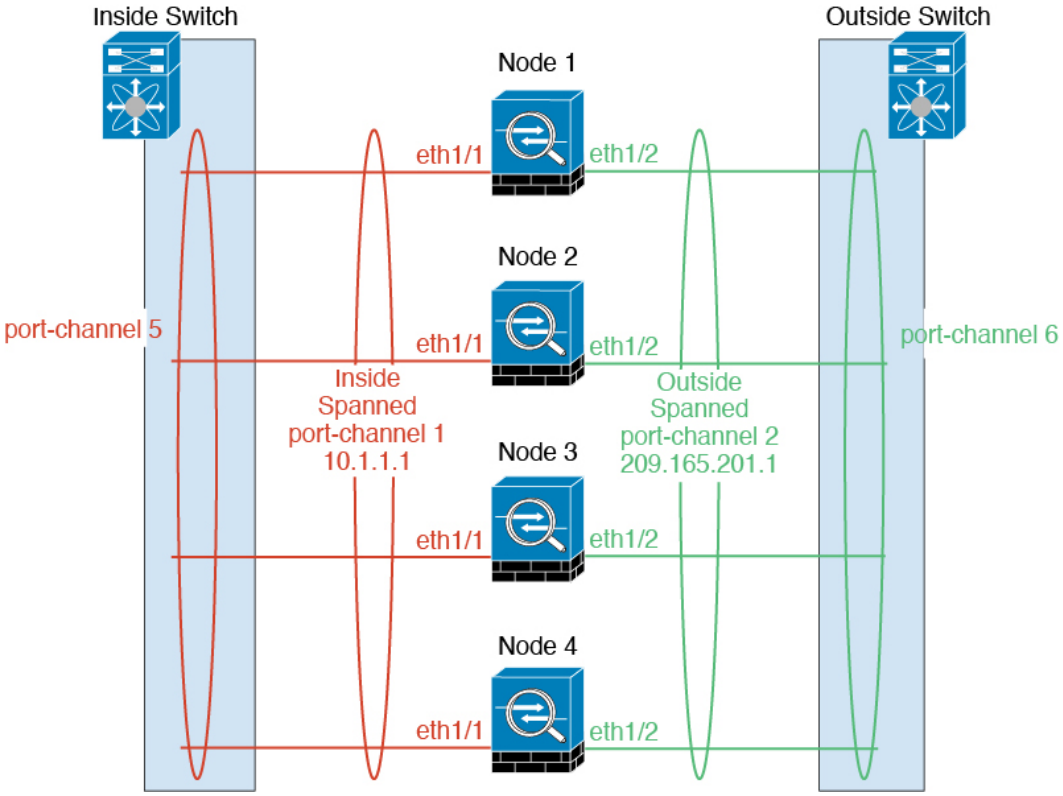
Cluster interfaces

For a cluster isolated to security modules within one Firepower 9300 chassis, you can assign either physical interfaces or EtherChannels (also known as port channels) to the cluster. The assigned interfaces are Spanned interfaces that load-balance traffic across all cluster members.

For clustering with multiple chassis, you can only assign data EtherChannels to the cluster. These Spanned EtherChannels include the same member interfaces on each chassis. On the upstream switch, all these interfaces are part of a single EtherChannel, so the switch does not recognize that it is connected to multiple devices.

You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).

Individual interfaces are not supported except for a management interface.



Spanned EtherChannels

You can group one or more interfaces per chassis into an EtherChannel that spans all chassis in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

For regular firewall interfaces:A Spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the BVI, not to the bridge group member interface.

The EtherChannel inherently provides load balancing as part of basic operation.

For multi-instance clusters, each cluster requires dedicated data EtherChannels; you cannot use shared interfaces or VLAN subinterfaces.

Connecting to a redundant switch system

We recommend connecting EtherChannels to a redundant switch system such as a VSS, vPC, StackWise, or StackWise Virtual system to provide redundancy for your interfaces.

Configuration replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Licenses for clustering

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

Note APEX, PLUS, and VPN-Only licenses are not supported for clustering. Before you create a cluster, remove unsupported license assignments from the devices that will become cluster nodes.

When you add a cluster node to the Firewall Management Center, you can specify the feature licenses you want to use for the cluster. You can modify licenses for the cluster in the **Devices** > **Device Management** and the choose the **Add**, **Cluster** and then **License** area.

Note If you add the cluster before the Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and prerequisites for clustering

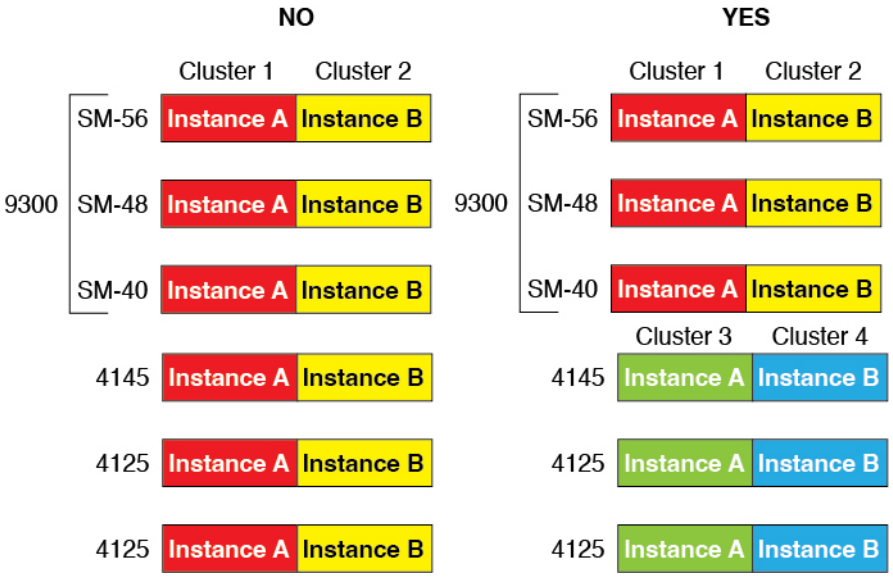
This topic provides the necessary prerequisites and hardware support details for configuring clustering on supported security appliances.

Cluster model support

The Firewall Threat Defense supports clustering on the following models:

- Firepower 9300— You can include up to 16 nodes in the cluster. For example, you can use 1 module in 16 chassis, or 2 modules in 8 chassis, or any combination that provides a maximum of 16 modules. Supports clustering with multiple chassis and clustering isolated to security modules within one chassis.
- Firepower 4100—Supported for up to 16 nodes using clustering with multiple chassis.

User roles



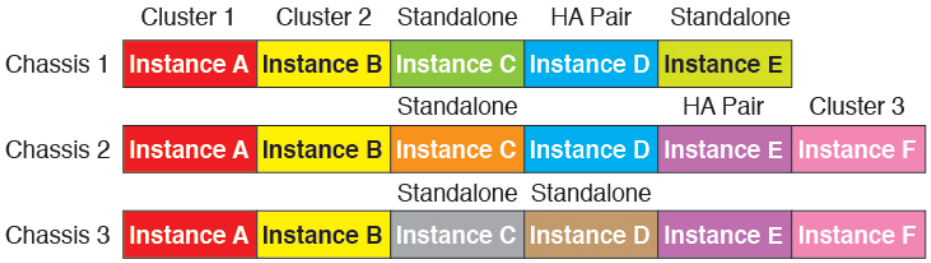
The following user roles are required to manage clustering configurations:

- Admin
- Access Admin
- Network Admin

Clustering hardware and software requirements

All chassis in a cluster:

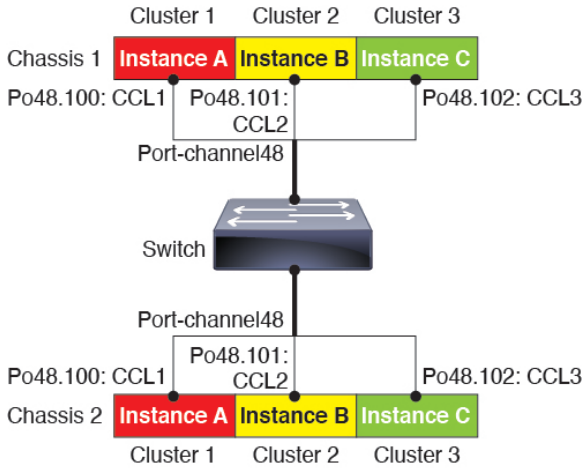
- Native instance clustering—For the Firepower 4100: All chassis must be the same model. For the Firepower 9300: All security modules must be the same type. For example, if you use clustering, all modules in the Firepower 9300 must be SM-40s. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots.
- Container instance clustering—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.



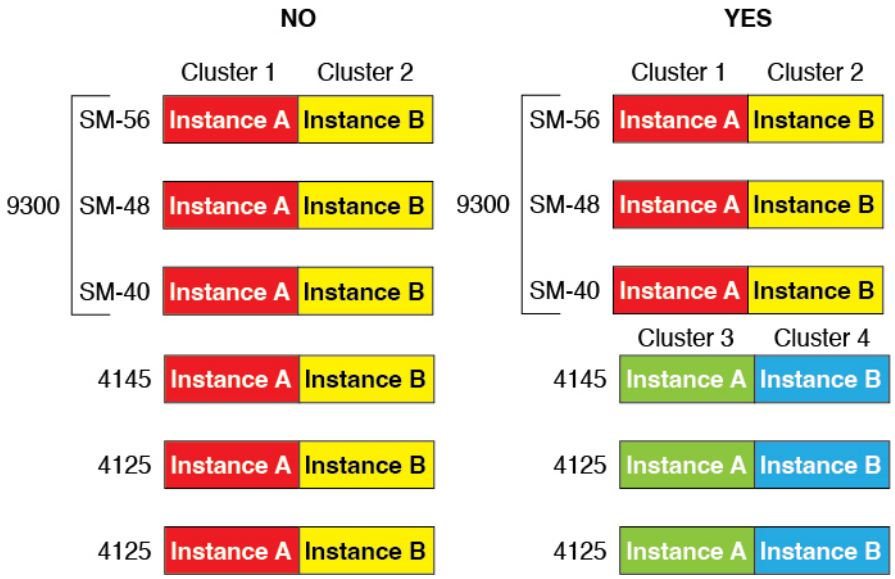
- Must run the identical FXOS and application software except at the time of an image upgrade. Mismatched software versions can lead to poor performance, so be sure to upgrade all nodes in the same maintenance window.
- Must include the same interface configuration for interfaces you assign to the cluster, such as the same Management interface, EtherChannels, active interfaces, speed and duplex, and so on. You can use different network module types on the chassis as long as the capacity matches for the same interface IDs and interfaces can successfully bundle in the same spanned EtherChannel. Note that all data interfaces must be EtherChannels in clusters with multiple chassis. If you change the interfaces in FXOS after you enable clustering (by adding or removing interface modules, or configuring EtherChannels, for example), then perform the same changes on each chassis, starting with the data nodes, and ending with the control node.
- Must use the same NTP server. For Firewall Threat Defense, the Firewall Management Center must also use the same NTP server. Do not set the time manually.

Multi-instance clustering requirements

- No intra-security-module/engine clustering—For a given cluster, you can only use a single container instance per security module/engine. You cannot add 2 container instances to the same cluster if they are running on the same module.



- Mix and match clusters and standalone instances—Not all container instances on a security module/engine need to belong to a cluster. You can use some instances as standalone or High Availability nodes. You can also create multiple clusters using separate instances on the same security module/engine.



- All 3 modules in a Firepower 9300 must belong to the cluster—For the Firepower 9300, a cluster requires a single container instance on all 3 modules. You cannot create a cluster using instances on module 1 and 2, and then use a native instance on module 3, or example.

- Match resource profiles—We recommend that each node in the cluster use the same resource profile attributes; however, mismatched resources are allowed when changing cluster nodes to a different resource profile, or when using different models.
- Dedicated cluster control link—For clusters with multiple chassis, each cluster needs a dedicated cluster control link. For example, each cluster can use a separate subinterface on the same cluster-type EtherChannel, or use separate EtherChannels.

- No shared interfaces—Shared-type interfaces are not supported with clustering. However, the same Management and Eventing interfaces can used by multiple clusters.
- No subinterfaces—A multi-instance cluster cannot use FXOS-defined VLAN subinterfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel.
- Mix chassis models—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

- Maximum 6 nodes—You can use up to six container instances in a cluster.

Switch requirements

- Be sure to complete the switch configuration and successfully connect all the EtherChannels from the chassis to the switch(es) before you configure clustering on the Firepower 4100/9300 chassis.

- For supported switch characteristics, see Cisco FXOS Compatibility.

Clustering guidelines and limitations

Clustering is a deployment method that groups multiple security devices into a single logical unit to provide high availability and increased throughput.

Switches for Clustering

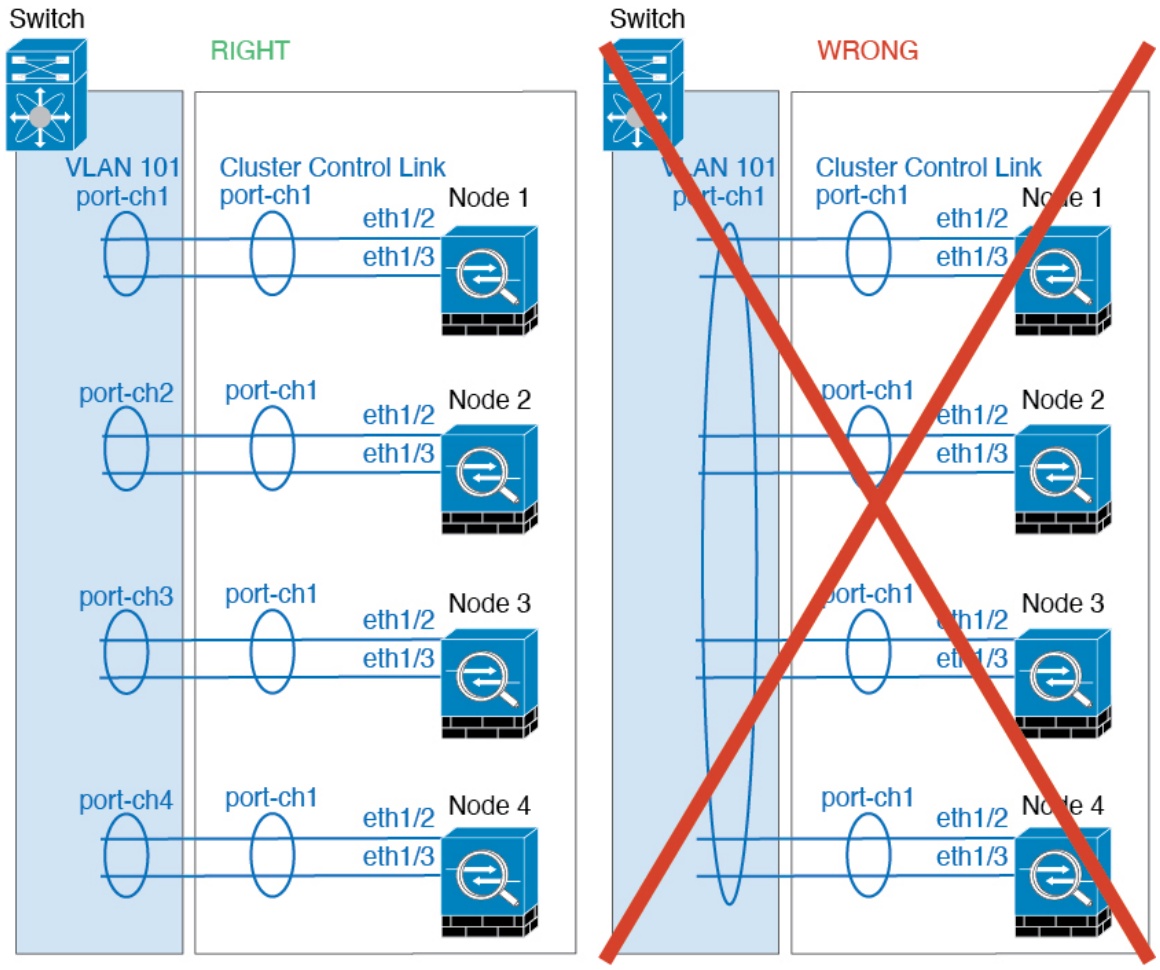
- Make sure connected switches match the MTU for both cluster data interfaces and the cluster control link interface. You should configure the cluster control link interface MTU to be at least 100 bytes higher than the data interface MTU, so make sure to configure the cluster control link connecting switch appropriately. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. In addition, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Cisco IOS XR systems, if you want to set a non-default MTU, set the IOS XR interface MTU to be 14 bytes higher than the cluster device MTU. Otherwise, OSPF adjacency peering attempts may fail unless the **mtu-ignore** option is used. Note that the cluster device MTU should match the IOS XR *IPv4* MTU. This adjustment is not required for Cisco Catalyst and Cisco Nexus switches.
- On the switch(es) for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the cluster unit to speed up the join process for new units.
- On the switch, we recommend that you use one of the following EtherChannel load-balancing algorithms: **source-dest-ip** or **src-dst-mixed-ip-port** (see the Cisco Nexus OS and Cisco IOS-XE **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the devices in a cluster.
- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.
- Switches on the cluster control link path should not verify the L4 checksum. Redirected traffic over the cluster control link does not have a correct L4 checksum. Switches that verify the L4 checksum could cause traffic to be dropped.
- Port-channel bundling downtime should not exceed the configured keepalive interval.
- On Supervisor 2T EtherChannels, the default hash distribution algorithm is adaptive. To avoid asymmetric traffic in a VSS design, change the hash algorithm on the port-channel connected to the cluster device to fixed:

  router(config)# **port-channel** *id* **hash-distribution fixed**

  Do not change the algorithm globally; you may want to take advantage of the adaptive algorithm for the VSS peer link.

- Firepower 4100/9300 clusters support LACP graceful convergence. So you can leave LACP graceful convergence enabled on connected Cisco Nexus switches.
- When you see slow bundling of a Spanned EtherChannel on the switch, you can enable LACP rate fast for an individual interface on the switch. FXOS EtherChannels have the LACP rate set to fast by default.

Note that some switches, such as the Nexus series, do not support LACP rate fast when performing in-service software upgrades (ISSUs), so we do not recommend using ISSUs with clustering.



EtherChannels for Clustering

- In Catalyst 3750-X Cisco IOS software versions earlier than 15.1(1)S2, the cluster unit did not support connecting an EtherChannel to a switch stack. With default switch settings, if the cluster unit EtherChannel is connected cross stack, and if the control unit switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- Spanned vs. Device-Local EtherChannel Configuration—Be sure to configure the switch appropriately for Spanned EtherChannels vs. Device-local EtherChannels.
  - Spanned EtherChannels—For cluster unit *Spanned* EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.

  - Device-local EtherChannels—For cluster unit *Device-local* EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels

on the switch; do not combine multiple cluster unit EtherChannels into one EtherChannel on the switch.

Additional Guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firepower 4100/9300 chassis or the switch, adding an additional switch to form a VSS, vPC, StackWise, or StackWise Virtual) you should disable the health check feature, and also disable interface monitoring for the disabled interfaces . When the topology change is complete, and the configuration change is synced to all units, you can re-enable the health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang connections; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel interface, when the syslog server port is down, and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the cluster. These messages can result in some units of the cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.

- We recommend connecting EtherChannels to a VSS, vPC, StackWise, or StackWise Virtual for redundancy.
- Within a chassis, you cannot cluster some security modules and run other security modules in standalone mode; you must include all security modules in the cluster.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Defaults

- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is set to unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is set to 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Configure clustering

You can easily deploy the cluster from the Firepower 4100/9300 supervisor. All initial configuration is automatically generated for each unit. You can then add the units to the Firewall Management Center and group them into a cluster.

FXOS: Add a Firewall Threat Defense cluster

A cluster is a deployment configuration that allows you to group security modules to increase capacity and redundancy.

Cluster Deployment Modes

In native mode: You can add a cluster to a single Firepower 9300 chassis that is isolated to security modules within the chassis, or you can use multiple chassis.

In multi-instance mode: You can add one or more clusters to a single Firepower 9300 chassis that are isolated to security modules within the chassis (you must include an instance on each module), or add one or more clusters on multiple chassis.

For clusters on multiple chassis, you must configure each chassis separately. Add the cluster on one chassis; you can then copy the bootstrap configuration from the first chassis to the next chassis for ease of deployment

Create a Firewall Threat Defense cluster

You can easily deploy the cluster from the Firepower 4100/9300 chassis supervisor. All initial configuration is automatically generated for each unit.

For clustering on multiple chassis, you must configure each chassis separately. Deploy the cluster on one chassis; you can then copy the bootstrap configuration from the first chassis to the next chassis for ease of deployment.

In a Firepower 9300 chassis, you must enable clustering for all 3 module slots, or for container instances, a container instance in each slot, even if you do not have a module installed. If you do not configure all 3 modules, the cluster will not come up.

Before you begin

- Download the application image you want to use for the logical device from Cisco.com, and then upload that image to the Firepower 4100/9300 chassis.
- For container instances, if you do not want to use the default profile, add a resource profile according to Add a resource profile for container instances , on page 264.
- For container instances, before you can install a container instance for the first time, you must reinitialize the security module/engine so that the disk has the correct formatting. Choose **Security Modules** or **Security Engine**, and click the Reinitialize icon (). An existing logical device will be deleted and then reinstalled as a new device, losing any local application configuration. If you are replacing a native instance with container instances, you will need to delete the native instance in any case. You cannot automatically migrate a native instance to a container instance.
- Gather the following information:
  - Management interface ID, IP addresses, and network mask
  - Gateway IP address
  - Firewall Management Center IP address and/or NAT ID of your choosing
  - DNS server IP address
  - Firewall Threat Defense hostname and domain name

Procedure

Step 1 Configure interfaces.

a) Add at least one Data type interface or EtherChannel (also known as a port-channel) before you deploy the cluster. See Add an EtherChannel (port channel), on page 261 or Configure a physical interface, on page 259.

For clustering on multiple chassis, all data interfaces must be Spanned EtherChannels with at least one member interface. Add the same EtherChannels on each chassis. Combine the member interfaces from all cluster units into a single EtherChannel on the switch. See Clustering guidelines and limitations, on page 538 for more information about EtherChannels.

For multi-instance clustering, you cannot use FXOS-defined VLAN subinterfaces or data-sharing interfaces in the cluster. Only application-defined subinterfaces are supported. See FXOS interfaces and application interfaces, on page 226 for more information.

b) Add a Management type interface or EtherChannel. See Add an EtherChannel (port channel), on page 261 or Configure a physical interface, on page 259.

The management interface is required. Note that this management interface is not the same as the chassis management interface that is used only for chassis management (in FXOS, you might see the chassis management interface displayed as MGMT, management0, or other similar names).

For clustering on multiple chassis, add the same Management interface on each chassis.

For multi-instance clustering, you can share the same management interface across multiple clusters on the same chassis, or with standalone instances.

c) For clustering on multiple chassis, add a member interface to the cluster control link EtherChannel (by default, port-channel 48). See Add an EtherChannel (port channel), on page 261.

Do not add a member interface for a cluster isolated to security modules within one Firepower 9300 chassis. If you add a member, the chassis assumes this cluster will be using multiple chassis, and will only allow you to use Spanned EtherChannels, for example.

On the **Interfaces** tab, the port-channel 48 cluster type interface shows the **Operation State** as **failed** if it does not include any member interfaces. For a cluster isolated to security modules within one Firepower 9300 chassis, this EtherChannel does not require any member interfaces, and you can ignore this Operational State.

Add the same member interfaces on each chassis. The cluster control link is a device-local EtherChannel on each chassis. Use separate EtherChannels on the switch per device. See Clustering guidelines and limitations, on page 538 for more information about EtherChannels.

For multi-instance clustering, you can create additional Cluster type EtherChannels. Unlike the Management interface, the cluster control link is not sharable across multiple devices, so you will need a Cluster interface for each cluster. However, we recommend using VLAN subinterfaces instead of multiple EtherChannels; see the next step to add a VLAN subinterface to the Cluster interface.

d) For multi-instance clustering, add VLAN subinterfaces to the cluster EtherChannel so you have a subinterface for each cluster. See Add a VLAN subinterface for container instances, on page 263.

If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.

e) (Optional) Add an eventing interface. See Add an EtherChannel (port channel), on page 261 or Configure a physical interface, on page 259.

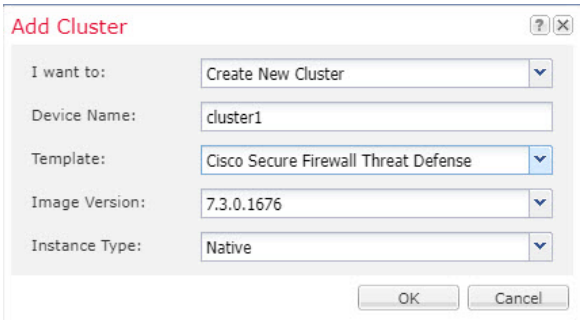
This interface is a secondary management interface for the Firewall Threat Defense devices. To use this interface, you must configure its IP address and other parameters at the Firewall Threat Defense CLI. For example, you can separate management traffic from events (such as web events). See the **configure network** commands in the Firewall Threat Defense command reference.

For clustering on multiple chassis, add the same eventing interface on each chassis.

Step 2 Choose **Logical Devices**.

Step 3 Click **Add** > **Cluster**, and set the following parameters:

Figure 215: Native Cluster



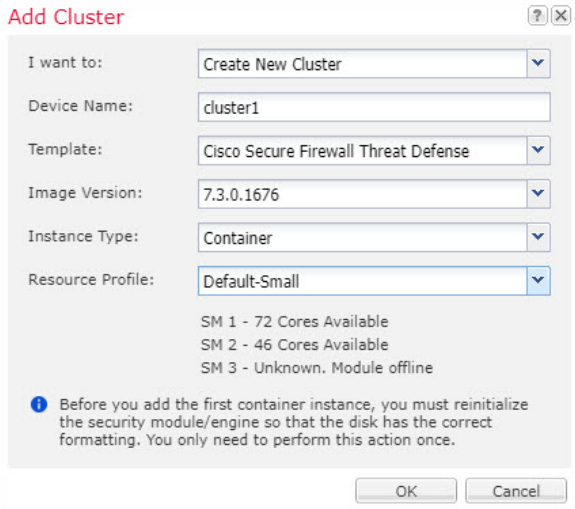


Figure 216: Multi-Instance Cluster

a) Choose **I want to:** > **Create New Cluster**
b) Provide a **Device Name**.

   This name is used internally by the chassis supervisor to configure management settings and to assign interfaces; it is not the device name used in the application configuration.

c) For the **Template**, choose **Cisco Firepower Threat Defense**.
d) Choose the **Image Version**.
e) For the **Instance Type**, choose either **Native** or **Container**.

   A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance. A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances.

f) (Container Instance only) For the **Resource Type**, choose one of the resource profiles from the drop-down list.

   For the Firepower 9300, this profile will be applied to each instance on each security module. You can set different profiles per security module later in this procedure; for example, if you are using different security module types, and you want to use more CPUs on a lower-end model. We recommend choosing the correct profile before you create the cluster. If you need to create a new profile, cancel out of the cluster creation, and add one using Add a resource profile for container instances , on page 264.

Note If you assign a different profile to instances in an established cluster, which allows mismatched profiles, then apply the new profile on the data nodes first; after they reboot and come back up, you can apply the new profile to the control node.

g) Click **OK**.

You see the Provisioning - *device name* window.

Step 4 Choose the interfaces you want to assign to this cluster.

For native mode clustering: All valid interfaces are assigned by default. If you defined multiple Cluster type interfaces, deselect all but one.

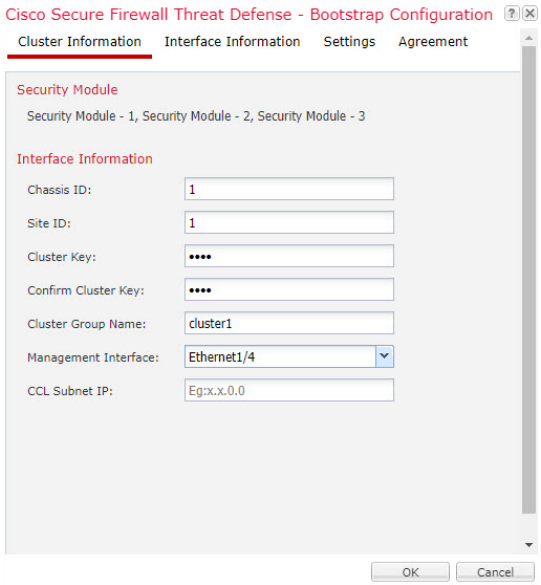
For multi-instance clustering: Choose each data interface you want to assign to the cluster, and also choose the Cluster type port-channel or port-channel subinterface.

Step 5 Click the device icon in the center of the screen.

A dialog box appears where you can configure initial bootstrap settings. These settings are meant for initial deployment only, or for disaster recovery. For normal operation, you can later change most values in the application CLI configuration.

Step 6 On the **Cluster Information** page, complete the following.

Figure 217: Native Cluster



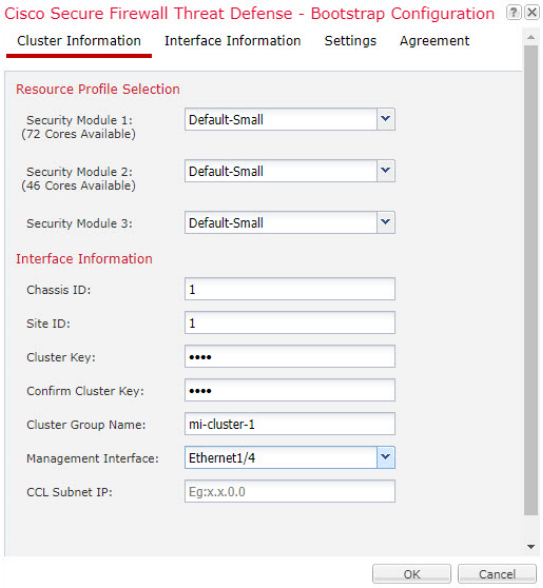


Figure 218: Multi-Instance Cluster

a) (Container Instance for the Firepower 9300 only) In the **Security Module (SM) and Resource Profile Selection** area, you can set a different resource profile per module; for example, if you are using different security module types, and you want to use more CPUs on a lower-end model.

b) For clustering on multiple chassis, in the **Chassis ID** field, enter a chassis ID. Each chassis in the cluster must use a unique ID.

   This field only appears if you added a member interface to cluster control link Port-Channel 48.

c) For inter-site clustering, in the **Site ID** field, enter the site ID for this chassis between 1 and 8. FlexConfig feature. Additional inter-site cluster customizations to enhance redundancy and stability, such as director

localization, site redundancy, and cluster flow mobility, are only configurable using the Firewall Management Center FlexConfig feature.

d) In the **Cluster Key** field, configure an authentication key for control traffic on the cluster control link.

The shared secret is an ASCII string from 1 to 63 characters. The shared secret is used to generate the key. This option does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear.

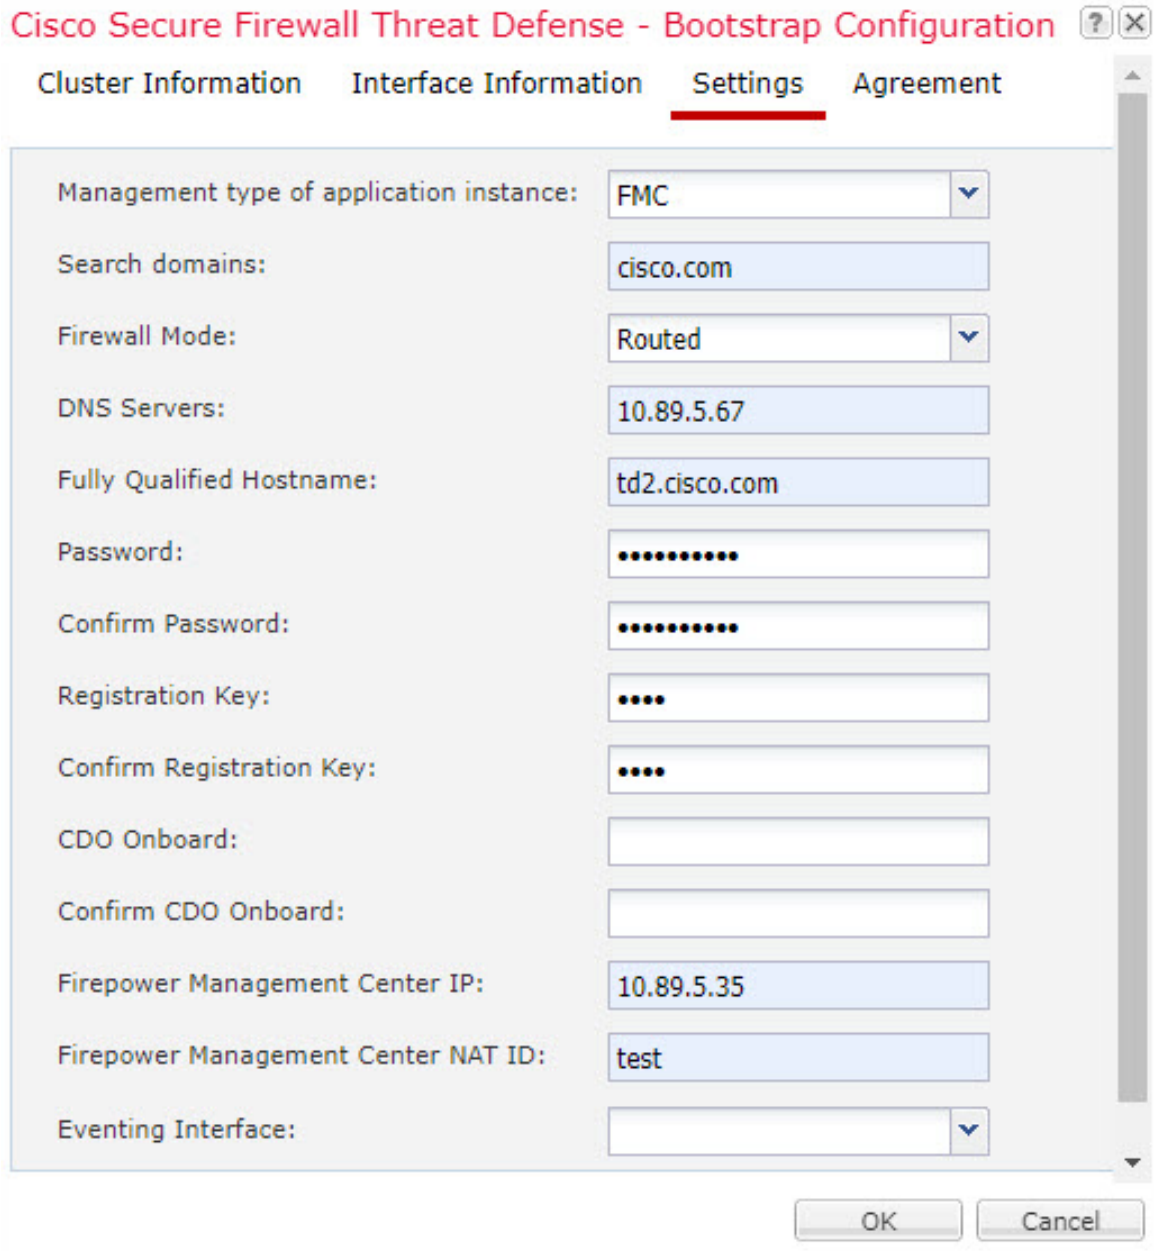
e) Set the **Cluster Group Name**, which is the cluster group name in the logical device configuration.

The name must be an ASCII string from 1 to 38 characters.

Important From 2.4.1, spaces in cluster group name will be considered as special characters and may result in error while deploying the logical devices. To avoid this issue, you must rename the cluster group name without a space.

f) Choose the **Management Interface**.

This interface is used to manage the logical device. This interface is separate from the chassis management port.



If you assign a Hardware Bypass-capable interface as the Management interface, you see a warning message to make sure your assignment is intentional.

g) (Optional) Set the **CCL Subnet IP** as ***a.b*.0.0**.

By default, the cluster control link uses the 127.2.0.0/16 network. However, some networking deployments do not allow 127.2.0.0/16 traffic to pass. In this case, specify any /16 network address on a unique network for the cluster, except for loopback (127.0.0.0/8), multicast (224.0.0.0/4), and internal (169.254.0.0/16) addresses. If you set the value to 0.0.0.0, then the default network is used.

The chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: *a.b.chassis_id.slot_id*.

Step 7 On the **Settings** page, complete the following.

a) In the **Registration Key** field, enter the key to be shared between the Firewall Management Center and the cluster members during registration.

   You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the Firewall Management Center when you add the Firewall Threat Defense.

b) Enter a **Password** for the Firewall Threat Defense admin user for CLI access.

c) In the **Firepower Management Center IP** field, enter the IP address of the managing Firewall Management Center. If you do not know the Firewall Management Center IP address, leave this field blank and enter a passphrase in the **Firepower Management Center NAT ID** field.

d) (Optional) For a container instance, **Permit Expert mode from FTD SSH sessions**: **Yes** or **No**. Expert Mode provides Firewall Threat Defense shell access for advanced troubleshooting.

If you choose **Yes** for this option, then users who access the container instance directly from an SSH sesssion can enter Expert Mode. If you choose **No**, then only users who access the container instance from the FXOS CLI can enter Expert Mode. We recommend choosing **No** to increase isolation between instances.

Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the Firewall Threat Defense CLI.

e) (Optional) In the **Search Domains** field, enter a comma-separated list of search domains for the management network.

f) (Optional) From the **Firewall Mode** drop-down list, choose **Transparent** or **Routed**.

In routed mode, the Firewall Threat Defense is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a "bump in the wire," or a "stealth firewall," and is not seen as a router hop to connected devices.

The firewall mode is only set at initial deployment. If you re-apply the bootstrap settings, this setting is not used.

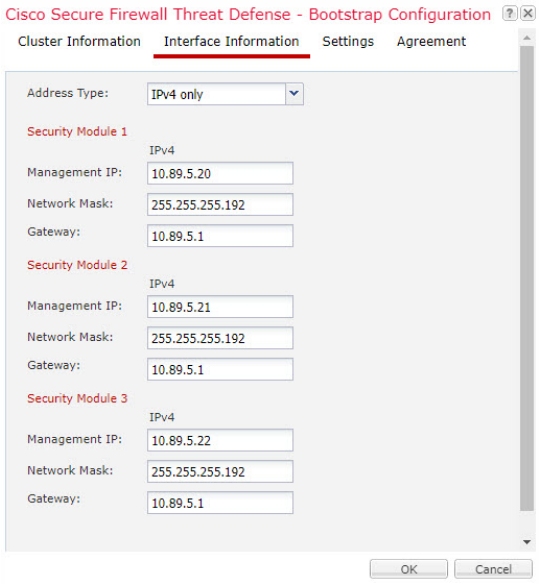
g) (Optional) In the **DNS Servers** field, enter a comma-separated list of DNS servers.

The Firewall Threat Defense uses DNS if you specify a hostname for the Firewall Management Center, for example.

h) (Optional) In the **Firepower Management Center NAT ID** field, enter a passphrase that you will also enter on the Firewall Management Center when you add the cluster as a new device.

Normally, you need both IP addresses (along with a registration key) for both routing purposes and for authentication: the Firewall Management Center specifies the device IP address, and the device specifies the Firewall Management Center IP address. However, if you only know one of the IP addresses, which is the minimum requirement for routing purposes, then you must also specify a unique NAT ID on both sides of the connection to establish trust for the initial communication and to look up the correct registration key. You can specify any text string as the NAT ID, from 1 to 37 characters. The Firewall Management Center and device use the registration key and NAT ID (instead of IP addresses) to authenticate and authorize for initial registration.

i) (Optional) In the **Fully Qualified Hostname** field, enter a fully qualified name for the Firewall Threat Defense device.



Valid characters are the letters from a to z, the digits from 0 to 9, the dot (.), and the hyphen (-); maximum number of characters is 253.

j) (Optional) From the **Eventing Interface** drop-down list, choose the interface on which events should be sent. If not specified, the management interface will be used.

To specify a separate interface to use for events, you must configure an interface as a *firepower-eventing* interface. If you assign a Hardware Bypass-capable interface as the Eventing interface, you see a warning message to make sure your assignment is intentional.

Step 8 On the **Interface Information** page, configure a management IP address for each security module in the cluster. Select the type of address from the **Address Type** drop-down list and then complete the following for each security module.

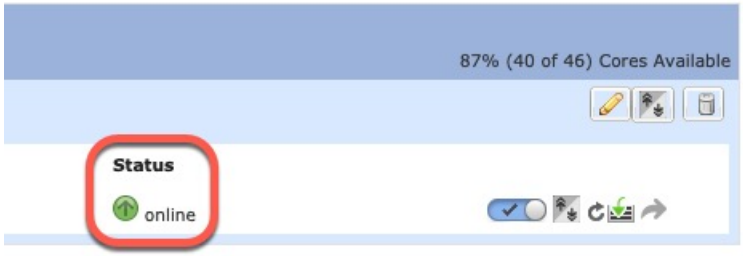
Note You must set the IP address for all 3 module slots in a chassis, even if you do not have a module installed. If you do not configure all 3 modules, the cluster will not come up.

a) In the **Management IP** field, configure an IP address.

Specify a unique IP address on the same network for each module.

b) Enter a **Network Mask** or **Prefix Length**.

c) Enter a **Network Gateway** address.



Step 9 On the **Agreement** tab, read and accept the end user license agreement (EULA).

Step 10 Click **OK** to close the configuration dialog box.

Step 11 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for the status of the new logical device. When the logical device shows its **Status** as **online**, you can add the remaining cluster chassis, or for a cluster isolated to security modules within one Firepower 9300 chassis, start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.

Step 12 For clustering on multiple chassis, add the next chassis to the cluster:

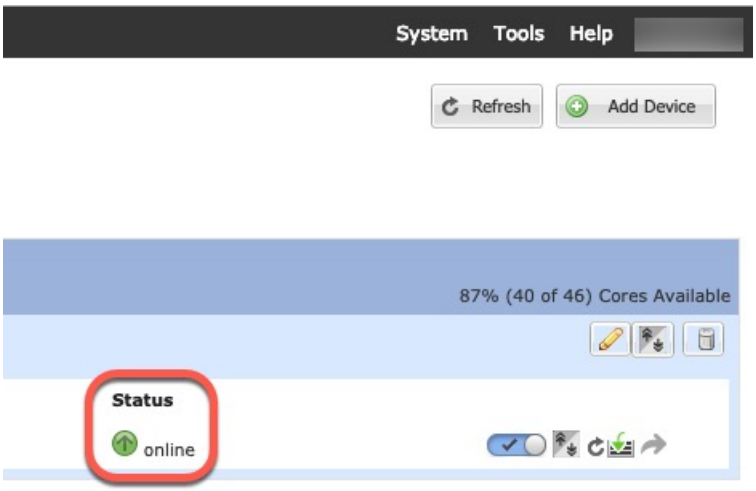
a) On the first chassis of the Firewall Chassis Manager, click the **Show Configuration icon** at the top right; copy the displayed cluster configuration.

b) Connect to the Firewall Chassis Manager on the next chassis, and add a logical device according to this procedure.

c) Choose **I want to:** > **Join an Existing Cluster**.

d) Click **OK**.

e) In the **Copy Cluster Details** box, paste in the cluster configuration from the first chassis, and click **OK**.



f) Click the device icon in the center of the screen. The cluster information is mostly pre-filled, but you must change the following settings:

- **Chassis ID**—Enter a unique chassis ID.
- **Site ID**—For inter-site clustering, enter the site ID for this chassis between 1 and 8. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the Firewall Management Center FlexConfig feature.
- **Cluster Key**—(Not prefilled) Enter the same cluster key.
- **Management IP**—Change the management address for each module to be a unique IP address on the same network as the other cluster members.

Click **OK**.

g) Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for each cluster member for the status of the new logical device. When the logical device for each cluster member shows its **Status** as **online**, you can start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.

Step 13 Add each unit separately to the Firewall Management Center using the management IP addresses, and then group them into a cluster at the web interface.

All cluster units must be in a successfully-formed cluster on FXOS prior to adding them to Firewall Management Center.

Step 14 Add the control unit to the Firewall Management Center using the management IP address.

All cluster units must be in a successfully-formed cluster on FXOS prior to adding them to Firewall Management Center.

The Firewall Management Center then automatically detects the data units.

Add more cluster nodes

Add or replace the Firewall Threat Defense cluster node in an existing cluster. When you add a new cluster node in FXOS, the Firewall Management Center adds the node automatically.

Note The FXOS steps in this procedure only apply to adding a new chassis ; if you are adding a new module to a Firepower 9300 where clustering is already enabled, the module will be added automatically.

Before you begin

- In the case of a replacement, you must delete the old cluster node from the Firewall Management Center . When you replace it with a new node, it is considered to be a new device on the Firewall Management Center .
- The interface configuration must be the same on the new chassis. You can export and import FXOS chassis configuration to make this process easier.

Procedure

Step 1 If you previously upgraded the Firewall Threat Defense image using the Firewall Management Center , perform the following steps *on each chassis in the cluster* .

When you upgraded from the Firewall Management Center , the startup version in the FXOS configuration was not updated, and the standalone package was not installed on the chassis. Both of these items need to be set manually so the new node can join the cluster using the correct image version.

Note If you only applied a patch release, you can skip this step. Cisco does not provide standalone packages for patches.

a) Install the running Firewall Threat Defense image on the chassis using the **System** > **Updates** page.

b) Click **Logical Devices** and click the Set Version icon ( ) . For a Firepower 9300 with multiple modules, set the version for each module.

The **Startup Version** shows the original package you deployed with. The **Current Version** shows the version you upgraded to.

c) In the **New Version** drop-down menu, choose the version that you uploaded. This version should match the **Current Version** displayed, and will set the startup version to match the new version.

d) On the new chassis, make sure the new image package is installed.

Step 2 In an existing cluster chassis Firewall Chassis Manager , click **Logical Devices** .

Step 3 Click the **Show Configuration icon** at the top right; copy the displayed cluster configuration.

Step 4 Connect to the Firewall Chassis Manager on the new chassis, and click **Add** > **Cluster** .

Step 5 For the **Device Name** , provide a name for the logical device, and click **OK** ..

Step 6 In the **Copy Cluster Details** box, paste in the cluster configuration from the first chassis, and click **OK** .

Step 7 Click the device icon in the center of the screen. The cluster information is partly pre-filled, but you must fill in the following settings:

Figure 219: Cluster Information

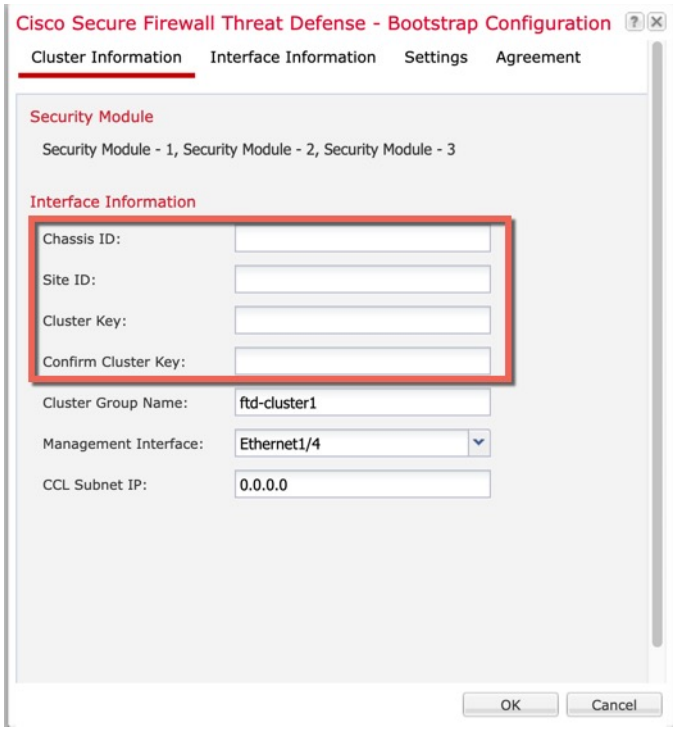


Figure 220: Interface Information

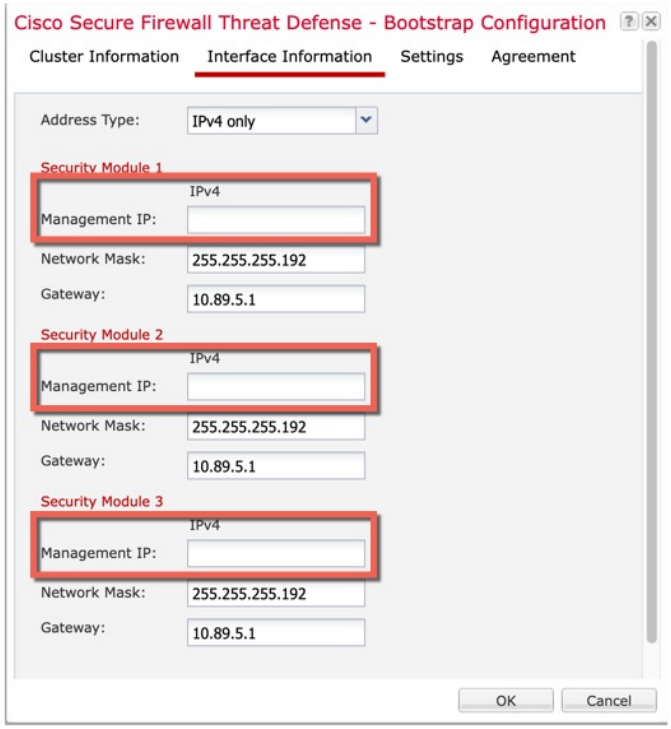

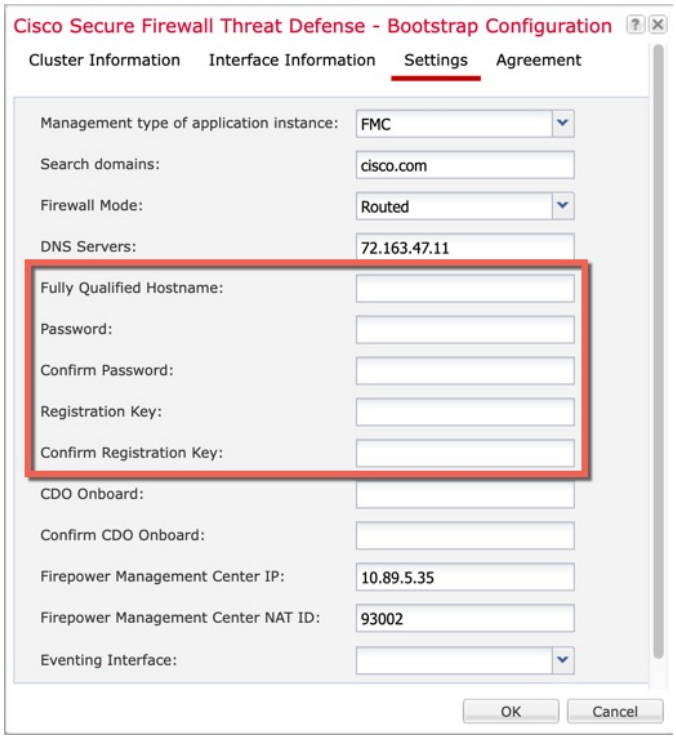

Figure 221: Settings

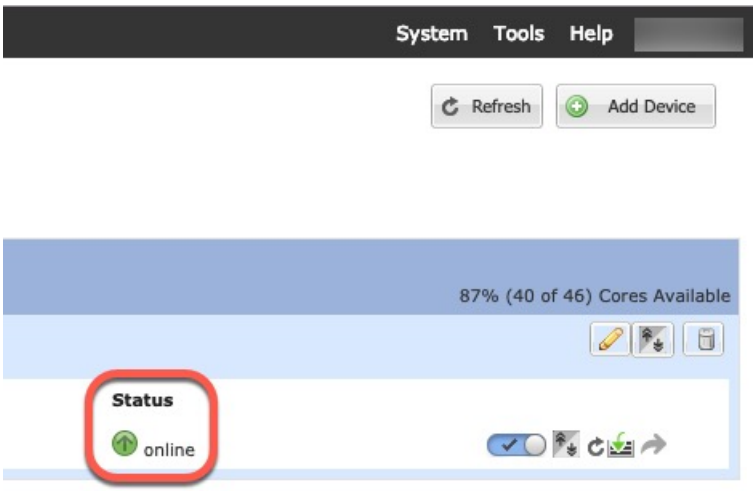


- **Chassis ID** —Enter a unique chassis ID.
- **Site ID** —For inter-site clustering, enter the site ID for this chassis between 1 and 8. This feature is only configurable using the Firewall Management Center FlexConfig feature.
- **Cluster Key** —Enter the same cluster key.
- **Management IP** —Change the management address for each module to be a unique IP address on the same network as the other cluster members.
- **Fully Qualified Hostname** —Enter the same hostname.
- **Password** —Enter the same password.
- **Registration Key** —Enter the same registration key.

Click **OK** .

Step 8 Click **Save** .

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for each cluster member for the status of the new logical device. When the logical device for each cluster member shows its **Status** as **online** , you can start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.

What to do next

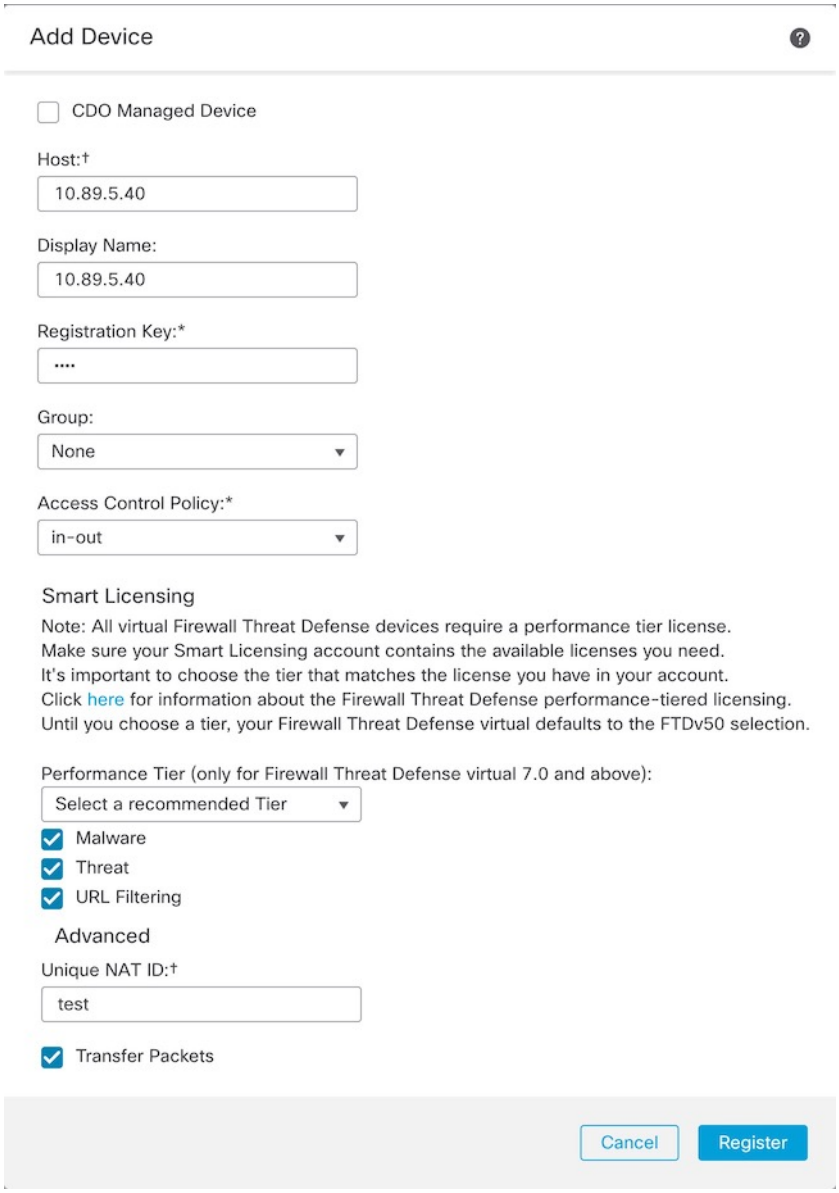
1. To add another chassis to the cluster, repeat the procedure in Create a Firewall Threat Defense cluster , on page 541 except you must configure the following settings to be unique; otherwise, use the same configuration for both chassis.
   - Chassis ID
   - Management IP addresses

   Also be sure to set the startup version to the currently running version on the cluster nodes.
2. In the Firewall Management Center , choose **Devices** > **Device Management** , and select the **Add** > **Device** to add the new logical device.
3. Choose **Add** > **Cluster** .
4. Choose the current control unit from the drop-down list.

   When you choose a control unit that is already in a cluster, then the existing cluster name is auto-filled, and all eligible data units are added to the box, including the new unit you just added to the Firewall Management Center .
5. Click **Add** , and then **Deploy** . The cluster is updated to include the new member.

Firewall Management Center: Add a cluster

Add one of the cluster units as a new device to the Secure Firewall Management Center; the Firewall Management Center auto-detects all other cluster members.



Before you begin

- All cluster units must be in a successfully-formed cluster on FXOS prior to adding the cluster to the Firewall Management Center. You should also check which unit is the control unit. Refer to the Firewall Chassis Manager **Logical Devices** screen or use the Firewall Threat Defense **show cluster info** command.

Procedure

Step 1 In the Firewall Management Center, choose **Devices** > **Device Management**, and then choose **Add** > **Add Device** to add the control unit using the unit's management IP address you assigned when you deployed the cluster.

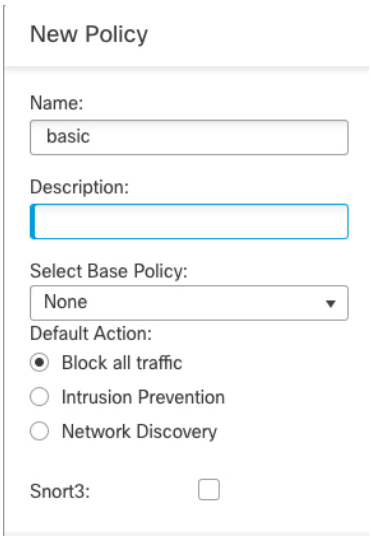
Figure 222: Add Device

a) In the **Host** field, enter the IP address or hostname of the control unit.

We recommend adding the control unit for the best performance, but you can add any unit of the cluster.

If you used a NAT ID during device setup, you may not need to enter this field. For more information, see NAT environments, on page 8.

b) In the **Display Name** field, enter a name for the control unit as you want it to display in the Firewall Management Center.



This display name is not for the cluster; it is only for the control unit you are adding. You can later change the name of other cluster members and the cluster display name.

c) In the **Registration Key** field, enter the same registration key that you used when you deployed the cluster in FXOS. The registration key is a one-time-use shared secret.

d) (Optional) Add the device to a device **Group**.

e) Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If you create a new policy, you create a basic policy only. You can later customize the policy as needed.

f) Choose licenses to apply to the device.

g) If you used a NAT ID during device setup, expand the **Advanced** section and enter the same NAT ID in the **Unique NAT ID** field.

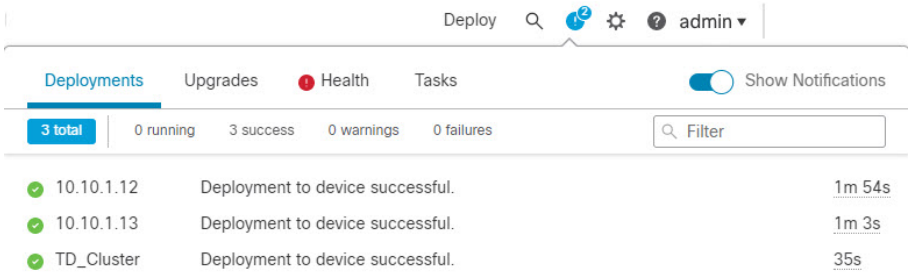
h) Select the **Transfer Packets** check box to allow the device to transfer event metadata and packet data associated with intrusion events to the Firewall Management Center.

This option is enabled by default. The transferred packet data is used for intrusion-event analysis. It does not necessarily contain the complete original packet as transmitted on the wire or the complete traffic session. For intrusion events generated by Snort inspection, the device can transfer only the Protocol Data Unit (PDU) or packet content associated with the intrusion-rule match.

If you disable this option, the device sends only event information to the Firewall Management Center; packet data is not sent.

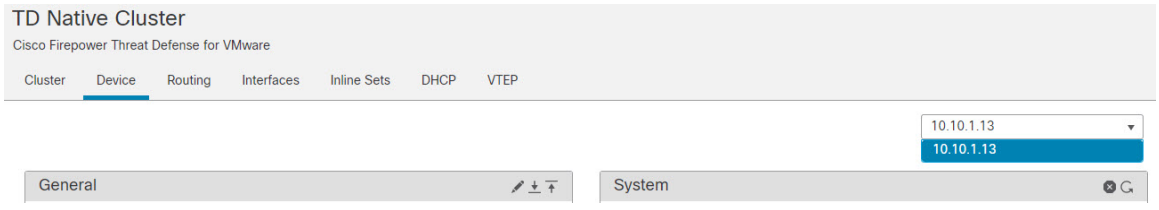
i) Click **Register**.

The Firewall Management Center identifies and registers the control unit, and then registers all data units. If the control unit does not successfully register, then the cluster is not added. A registration failure can occur if the cluster was not up on the chassis, or because of other connectivity issues. In this case, we recommend that you try re-adding the cluster unit.



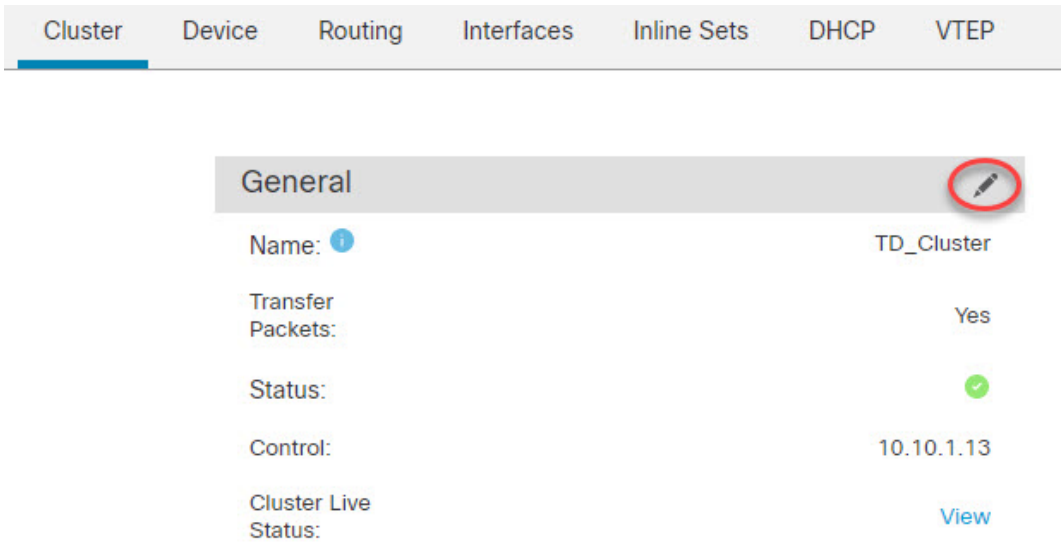
The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster units.

A unit that is currently registering shows the loading icon.



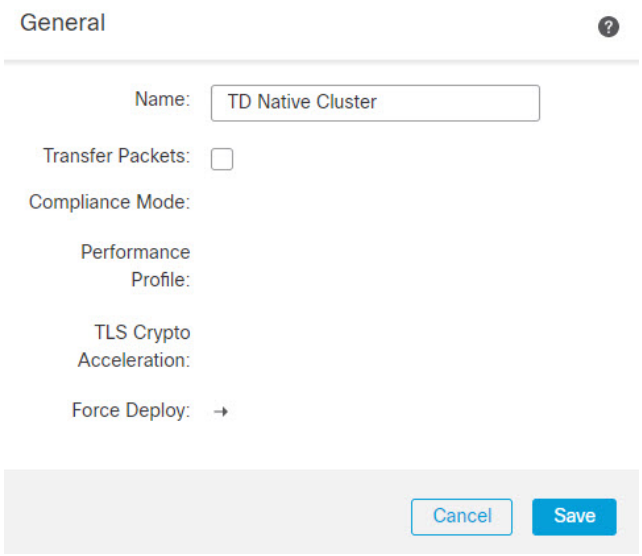
You can monitor cluster unit registration by clicking the **Notifications** icon and choosing **Tasks**. The Firewall Management Center updates the Cluster Registration task as each unit registers. If any units fail to register, see Reconcile cluster members, on page 574.

Step 2 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

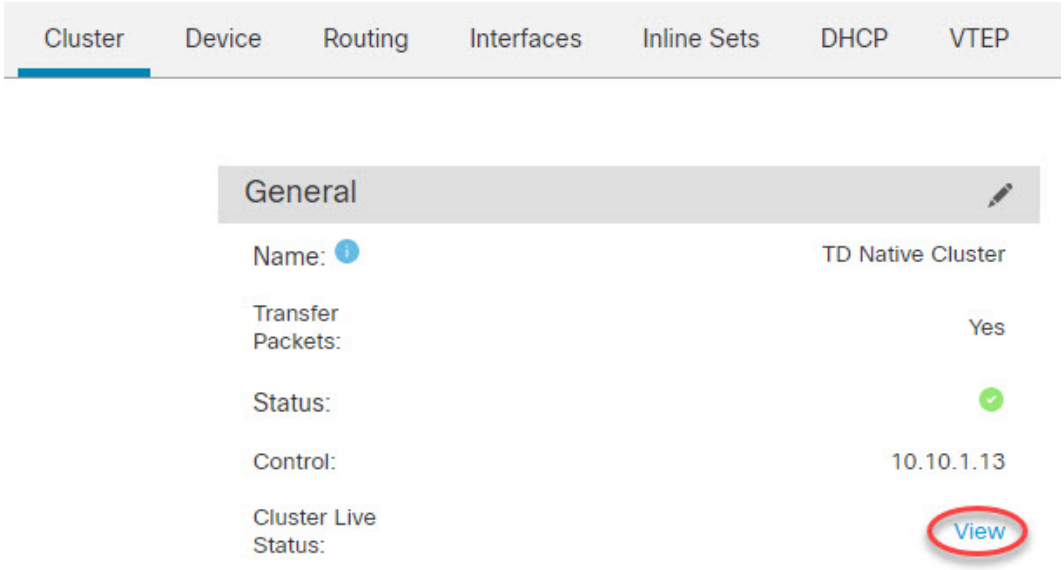


Most configuration can be applied to the cluster as a whole, and not member units in the cluster. For example, you can change the display name per unit, but you can only configure interfaces for the whole cluster.

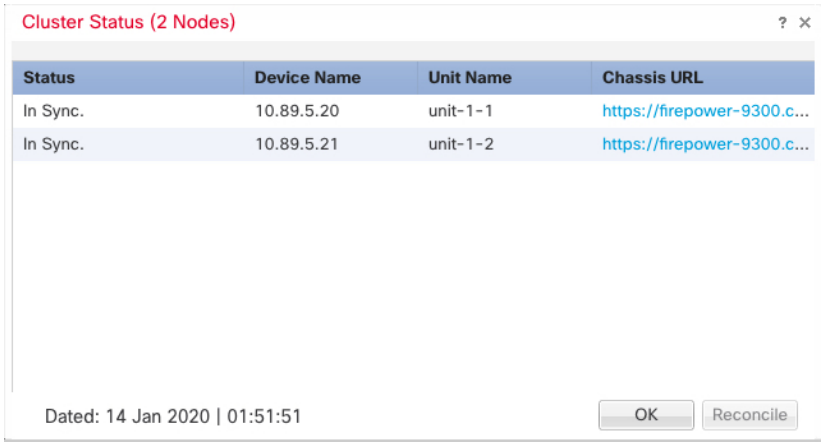
Step 3 On the **Devices** > **Device Management**and choose the **Add**, **Cluster** screen, you see **General**, **License**, **System**, and **Health** settings.



See the following cluster-specific items:

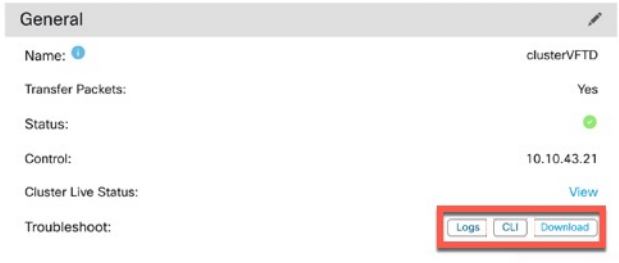


- **General** > **Name**—Change the cluster display name by clicking the **Edit** (✎).



Then set the **Name** field.

- **General > View cluster status**—Click the **View cluster status** link to open the **Cluster Status** dialog box.



The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile**.

- **General** > **Troubleshoot**—You can generate and download troubleshooting logs, and you can view cluster CLIs. See Troubleshoot the cluster, on page 365.

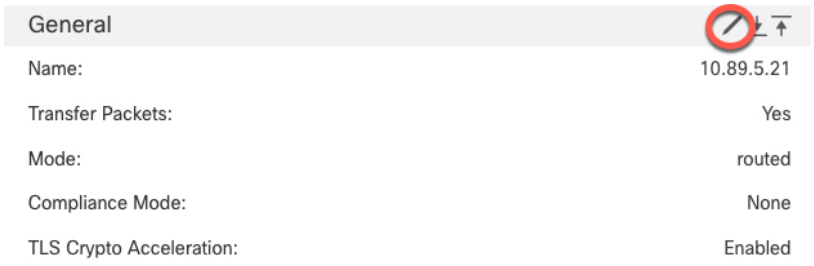


Figure 223: Troubleshoot

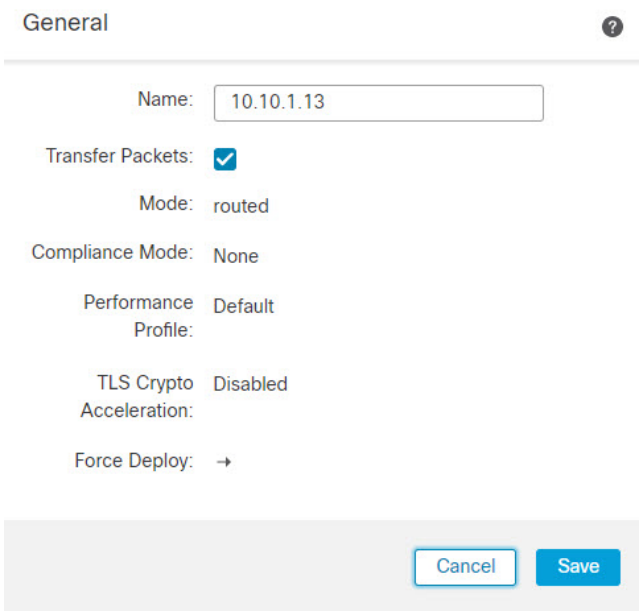
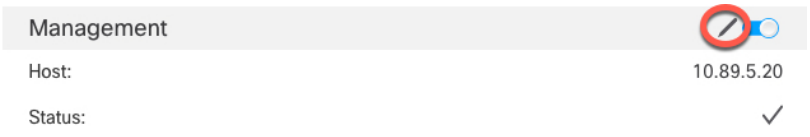


- **License**—Click **Edit** (✎) to set license entitlements.

Step 4 On the **Devices** > **Device Management** and then choose **Add Device**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.



- **General > Name**—Change the cluster member display name by clicking the **Edit** ( ).

Then set the **Name** field.

- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the Firewall Management Center so that it can reach the device on the network; edit the **Host** address in the **Management** area.

Firewall Management Center: Configure cluster, data interfaces

This procedure configures basic parameters for each data interface that you assigned to the cluster when you deployed it in FXOS. For clustering on multiple chassis, data interfaces are always Spanned EtherChannel

interfaces. For the cluster control link interface for a cluster isolated to security modules within one Firepower 9300 chassis, you must increase the MTU from the default.

Note When using Spanned EtherChannels for clustering on multiple chassis, the port-channel interface will not come up until clustering is fully enabled. This requirement prevents traffic from being forwarded to a unit that is not an active unit in the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** (✎) next to the cluster.

Step 2 Click **Interfaces**.

Step 3 Configure the cluster control link.

For clustering on multiple chassis, set the cluster control link MTU to be at least 100 bytes higher than the highest MTU of the data interfaces. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. We suggest setting the MTU to the maximum of 9184; the minimum value is 1400 bytes. For example, because the maximum MTU is 9184, then the highest data interface MTU can be 9084, while the cluster control link can be set to 9184.

For native clusters: The cluster control link interface is Port-Channel48 by default. If you don't know which interface is the cluster control link, check the FXOS configuration for chassis for the Cluster-type interface assigned to the cluster.

a) Click **Edit** (✎) for the cluster control link interface.
b) On the **General** page, in the **MTU** field, enter a value between 1400 and 9184but not between 2561 and 8362. Due to block pool handling, this MTU size is not optimal for system operation. We suggest using the maximum, 9184.
c) Click **OK**.

Step 4 Configure data interfaces.

a) (Optional) For regular firewall interfaces, configure VLAN subinterfaces on the data interface. The rest of this procedure applies to the subinterfaces. See Add a subinterface, on page 669.
b) Click **Edit** (✎) for the data interface.
c) Configure the name and other parameters. For regular firewall interfaces, see Configure routed mode interfaces, on page 690 or, for transparent mode, Bridge group interfaces, on page 695. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 727..

Note If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. See, Step 3, on page 563 to increase the cluster control link MTU, after which you can continue configuring the data interfaces.

d) For clustering on multiple chassis, set a unique. manual global MAC address for the EtherChannel. Click **Advanced**, and in the **Active Mac Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

Do not set the **Standby Mac Address**; it is ignored.

You must configure a unique MAC address not currently in use on your network for a Spanned EtherChannel to avoid potential network connectivity problems. With a manually-configured MAC address, the MAC address stays with the current control unit. If you do not configure a MAC address, then if the control unit changes, the new control unit uses a new MAC address for the interface, which can cause a temporary network outage.

e) Click **OK**. Repeat the above steps for other data interfaces.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Firewall Management Center: Configure Cluster Health Monitor Settings

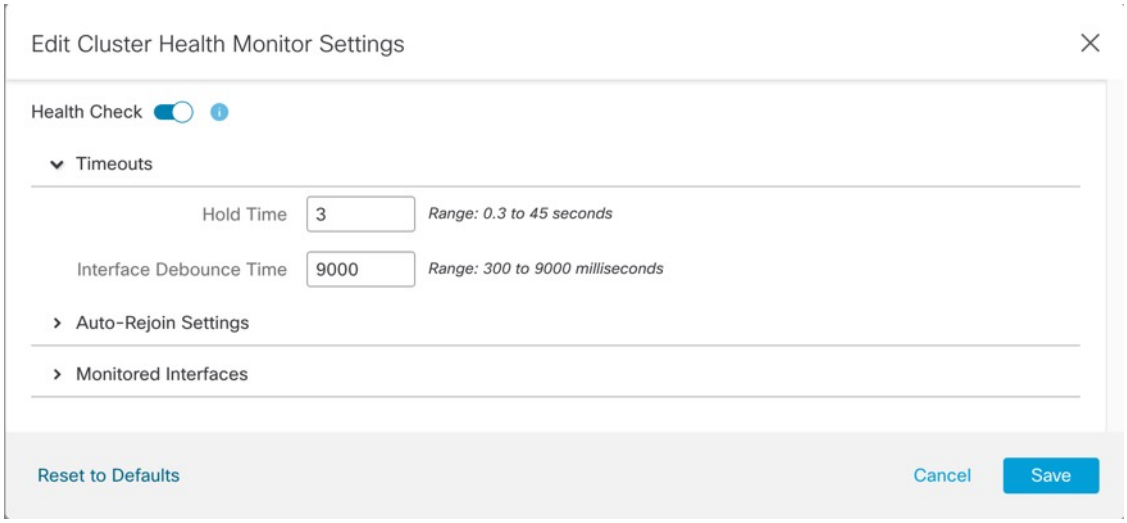
This task allows you to modify cluster health monitor settings to control how cluster nodes monitor system health and automatically rejoin the cluster after failures.

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings for monitoring cluster node health. You can monitor any port-channel ID, any single physical interface ID, and the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link. It is always monitored.

When a topology change occurs (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature. Also, disable interface monitoring for any interfaces that are disabled. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Procedure

Step 1 Choose **Devices** > **Device Management**.



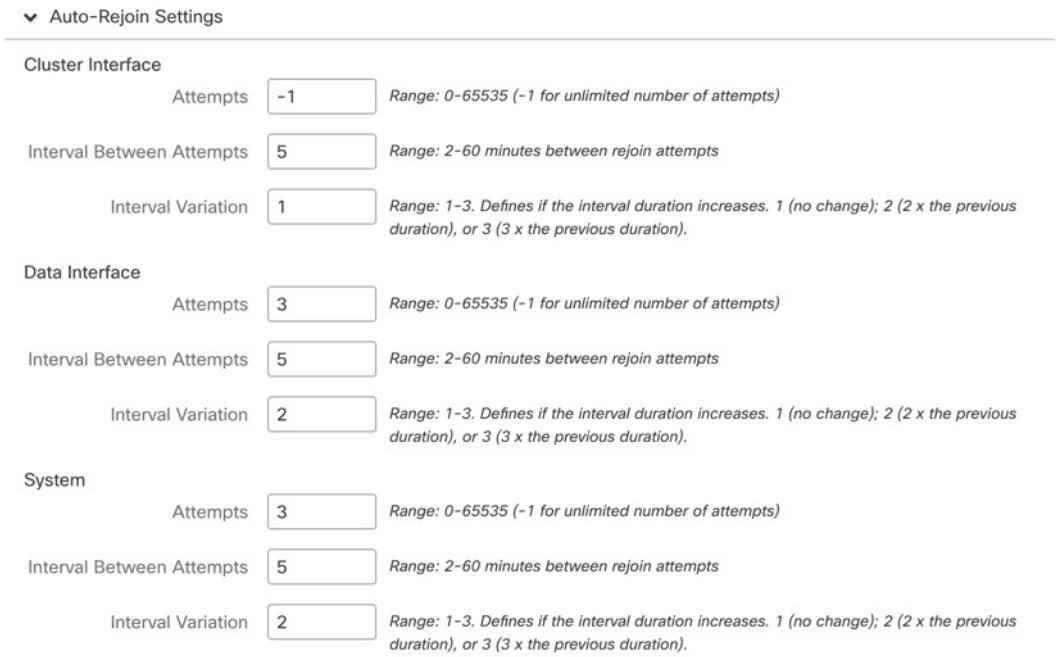
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider.

Figure 224: Disable the system health check



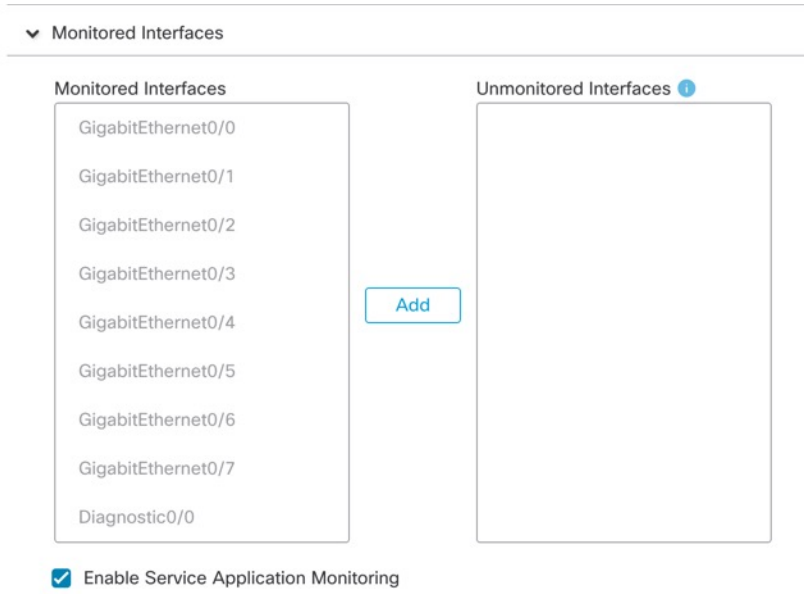
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between 0.3 and 45 seconds. The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the specified number of milliseconds before marking the interface as failed and removing the node from the cluster. If an EtherChannel transitions from a down state to an up state, such as after the switch reloads or enables an EtherChannel, a longer debounce time can prevent the interface from appearing failed on a cluster node if another cluster node bundles the ports more quickly.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 225: Configure Auto-Rejoin settings



Set values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 226: Configure monitored interfaces

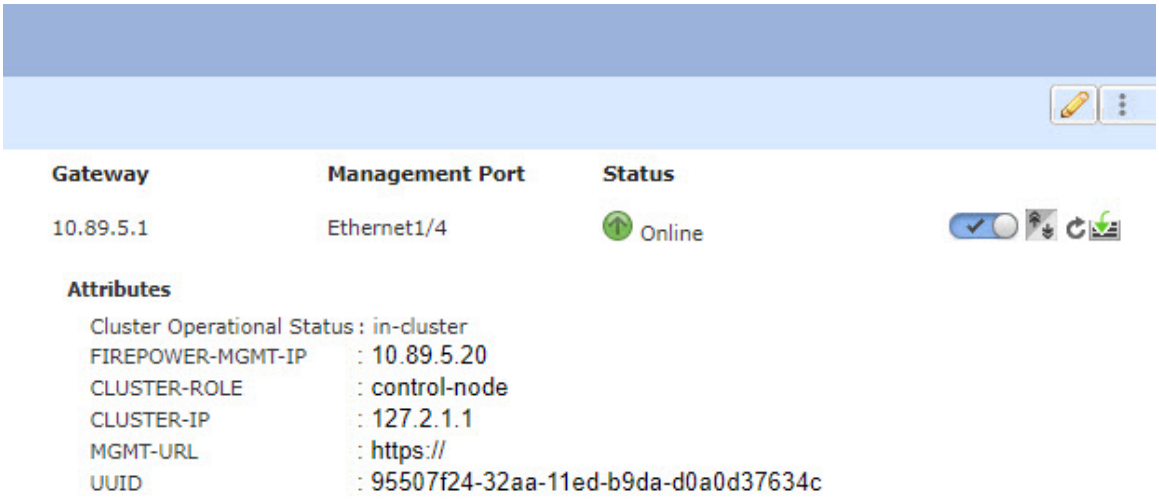
The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The time required to remove a member from the cluster depends on the type of interface and whether the node is established or is joining the cluster. By default, health check is enabled for all interfaces and the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Deploy configuration changes; see Deploy configuration changes, on page 135.



FXOS: Remove a cluster node

The following sections describe how to remove nodes temporarily or permanently from the cluster.

Temporary removal

A cluster node will be automatically removed from the cluster due to a hardware or network failure, for example. This removal is temporary until the conditions are rectified, and it can rejoin the cluster. You can also manually disable clustering.

To check whether a device is currently in the cluster, check the cluster status on the Firewall Chassis Manager **Logical Devices** page:

For Firewall Threat Defense using the Firewall Management Center, you should leave the device in the Firewall Management Center device list so that it can resume full functionality after you reenable clustering.

- Disable clustering in the application—You can disable clustering using the application CLI. Enter the **cluster remove unit** *name* command to remove any node other than the one you are logged into. The bootstrap configuration remains intact, as well as the last configuration synced from the control node, so you can later re-add the node without losing your configuration. If you enter this command on a data node to remove the control node, a new control node is elected.

  When a device becomes inactive, all data interfaces are shut down; only the Management interface can send and receive traffic. To resume traffic flow, re-enable clustering. The Management interface remains up using the IP address the node received from the bootstrap configuration. However if you reload, and the node is still inactive in the cluster , the Management interface is disabled.

  To reenable clustering, on the Firewall Threat Defense enter **cluster enable**.

- Disable the application instance—In the Firewall Chassis Manager on the **Logical Devices** page, click the **Slider enabled** ( ). You can later reenable it using the **Slider disabled** ( ).

- Shut down the security module/engine—In the Firewall Chassis Manager on the **Security Module/Engine** page, click the **Power Off icon**.

- Shut down the chassis—In the Firewall Chassis Manager on the **Overview** page, click the **Shut Down icon**.

Permanent removal

You can permanently remove a cluster node using the following methods.

For Firewall Threat Defense using the Firewall Management Center, be sure to remove the node from the Firewall Management Center device list after you disable clustering on the chassis.

- Delete the logical device—In the Firewall Chassis Manager on the **Logical Devices** page, click the **Delete** ( ). You can then deploy a standalone logical device, a new cluster, or even add a new logical device to the same cluster.
- Remove the chassis or security module from service—If you remove a device from service, you can add replacement hardware as a new node of the cluster.

Firewall Management Center: Manage cluster members

After you deploy the cluster, you can change the configuration and manage cluster members.

Add a new cluster member

When you add a new cluster member in FXOS, the Secure Firewall Management Center adds the member automatically.

Before you begin

- Make sure the interface configuration is the same on the replacement unit as for the other chassis.

Follow these steps to add a new cluster member:

Procedure

Step 1 Add the new unit to the cluster in FXOS. Refer to the FXOS configuration guide.

Wait for the new unit to be added to the cluster. Refer to the Firewall Chassis Manager **Logical Devices** screen or use the Firewall Threat Defense **show cluster info** command to view cluster status.

Step 2 The new cluster member is added automatically. To monitor the registration of the replacement unit, view the following:

- **Cluster Status** dialog box (which is available from the **Devices** > **Device Management**, **More** ( ) icon or from the **Devices** > **Device Management** and choose the **Add**, **Cluster** tab **General** area **Cluster Live Status** link)—A unit that is joining the cluster on the chassis shows "Joining cluster..." After it joins the cluster, the Firewall Management Center attempts to register it, and the status changes to "Available for Registration". After it completes registration, the status changes to "In Sync." If the registration fails, the unit will stay at "Available for Registration". In this case, force a re-registration by clicking **Reconcile**.
- System status **Tasks** —The Firewall Management Center shows all registration events and failures.
- **Devices** > **Device Management** and then choose **Add Device**—When you expand the cluster on the devices listing page, you can see when a unit is registering when it has the loading icon to the left.

Replace a cluster member

You can replace a cluster member in an existing cluster. The Firewall Management Center auto-detects the replacement unit. However, you must manually delete the old cluster member in the Firewall Management Center. This procedure also applies to a unit that was reinitialized; in this case, although the hardware remains the same, it appears to be a new member.

Before you begin

- Make sure the interface configuration is the same on the replacement unit as for other chassis.

Follow these steps to replace a cluster member:

Procedure

Step 1 For a new chassis, if possible, backup and restore the configuration from the old chassis in FXOS.

If you are replacing a module in a Firepower 9300, you do not need to perform these steps.

If you do not have a backup FXOS configuration from the old chassis, first perform the steps in Add a new cluster member, on page 569.

For information about all of the below steps, refer to the FXOS configuration guide.

a) Use the configuration export feature to export an XML file containing logical device and platform configuration settings for your Firepower 4100/9300 chassis.
b) Import the configuration file to the replacement chassis.
c) Accept the license agreement.
d) If necessary, upgrade the logical device application instance version to match the rest of the cluster.

Step 2 In the Firewall Management Center for the old unit, choose **Devices** > **Device Management**, **More** (⋮) > **Delete** .

Step 3 Confirm that you want to delete the unit.

The unit is removed from the cluster and from the Firewall Management Center devices list.

Step 4 The new or reinitialized cluster member is added automatically. To monitor the registration of the replacement unit, view the following:

- **Cluster Status** dialog box (**Devices** > **Device Management**, **More** (⋮) icon or **Devices** > **Device Management** and then choose **Add**, **Cluster** page, **General** area, **Cluster Live Status** link)—A unit that is joining the cluster on the chassis shows "Joining cluster..." After it joins the cluster, the Firewall Management Center attempts to register it, and the status changes to "Available for Registration". After it completes registration, the status changes to "In Sync." If the registration fails, the unit will stay at "Available for Registration". In this case, force a re-registration by clicking **Reconcile All**.

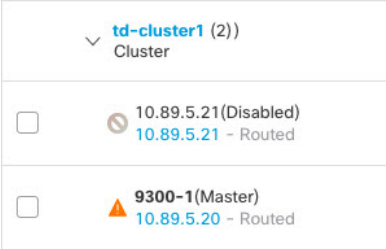
- Click **System** (⚙), and then click **Tasks**—The Firewall Management Center shows all registration events and failures.
- **Devices** > **Device Management**, and then click **Add** > **Device**—When you expand the cluster on the devices listing page, you can see when a unit is registering when it has the loading icon to the left.

Deactivate a member

You may want to deactivate a member in preparation for deleting the unit, or temporarily for maintenance. This procedure is meant to temporarily deactivate a member; the unit will still appear in the Firewall Management Center device list.

Note When a unit becomes inactive, all data interfaces are shut down; only the Management interface can send and receive traffic. To resume traffic flow, reenable clustering. The Management interface remains up using the IP address the unit received from the bootstrap configuration. However if you reload, and the unit is still inactive in the cluster, the management interface is disabled. You must use the console for any further configuration.

Procedure



Step 1 For the unit you want to deactivate, choose **Devices** > **Device Management**, **More** (⋮), and then **Disable Clustering**.

You can also deactivate a unit from the **Cluster Status** dialog box (**Devices** > **Device Management**, **More** (⋮), and **Cluster Live Status**).

Step 2 Confirm that you want to disable clustering on the unit.

The unit will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To re-enable clustering, refer to Rejoin the cluster, on page 572.

Rejoin the cluster

If a unit was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster. See Rejoining the cluster, on page 592 for more information about why a unit can be removed from a cluster.

Procedure

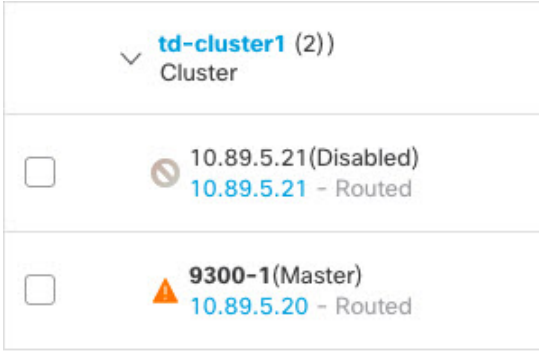
Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, **More** (⋮) > **Enable Clustering**.

You can also reactivate a unit from the **Cluster Status** dialog box (**Devices** > **Device Management**, **More** (⋮) > **Cluster Live Status**).

Step 2 Confirm that you want to enable clustering on the unit.

Delete (Unregister) a data node

If you need to permanently remove a cluster node (for example, if you remove a module on the Firepower 9300, or remove a chassis), then you should unregister it from the Firewall Management Center.



Do not unregister the node if it is still a healthy part of the cluster, or if you only want to disable the node temporarily. To remove it permanently from the cluster in FXOS, see FXOS: Remove a cluster node, on page 567. If you unregister it from the Firewall Management Center, and it is still part of the cluster, it will continue to pass traffic, and could even become the control node—a control node that the Firewall Management Center can no longer manage.

Before you begin

To manually deactivate the node, see Deactivate a member, on page 571. Before you unregister a node, the node must be inactive, either manually or because of a health failure.

Procedure

Step 1 Make sure the node is ready to be unregistered from the Firewall Management Center. On **Devices** > **Device Management**, make sure the node shows **(Disabled)**.

You can also view each node's status on the **Cluster Status** dialog box available from **More** (⋮). If the status is stale, click **Reconcile All** on the **Cluster Status** dialog box to force an update.

Step 2 In the Firewall Management Center for the data node you want to delete, choose **Devices** > **Device Management** and then click **Add** > **DeviceMore** (⋮) > **Delete**.

Step 3 Confirm that you want to delete the node.

The node is removed from the cluster and from the Firewall Management Center devices list.

Change the control unit

The best method to change the control unit is to disable clustering on the control unit, wait for a new control election, and then re-enable clustering.

Caution If you must specify the *exact* unit you want to become the control unit, use the procedure in this section. Note that for centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

Procedure

Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management**, **More** (⋮) > **Cluster Live Status**.

You can also access the **Cluster Status** dialog box from **Devices** > **Device Management** and choose the **Add**, **Cluster** page, **General** area, and **Cluster Live Status** link.

Step 2 For the unit you want to become the control unit, choose **More** (⋮) > **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Check the check box, and click **OK**.

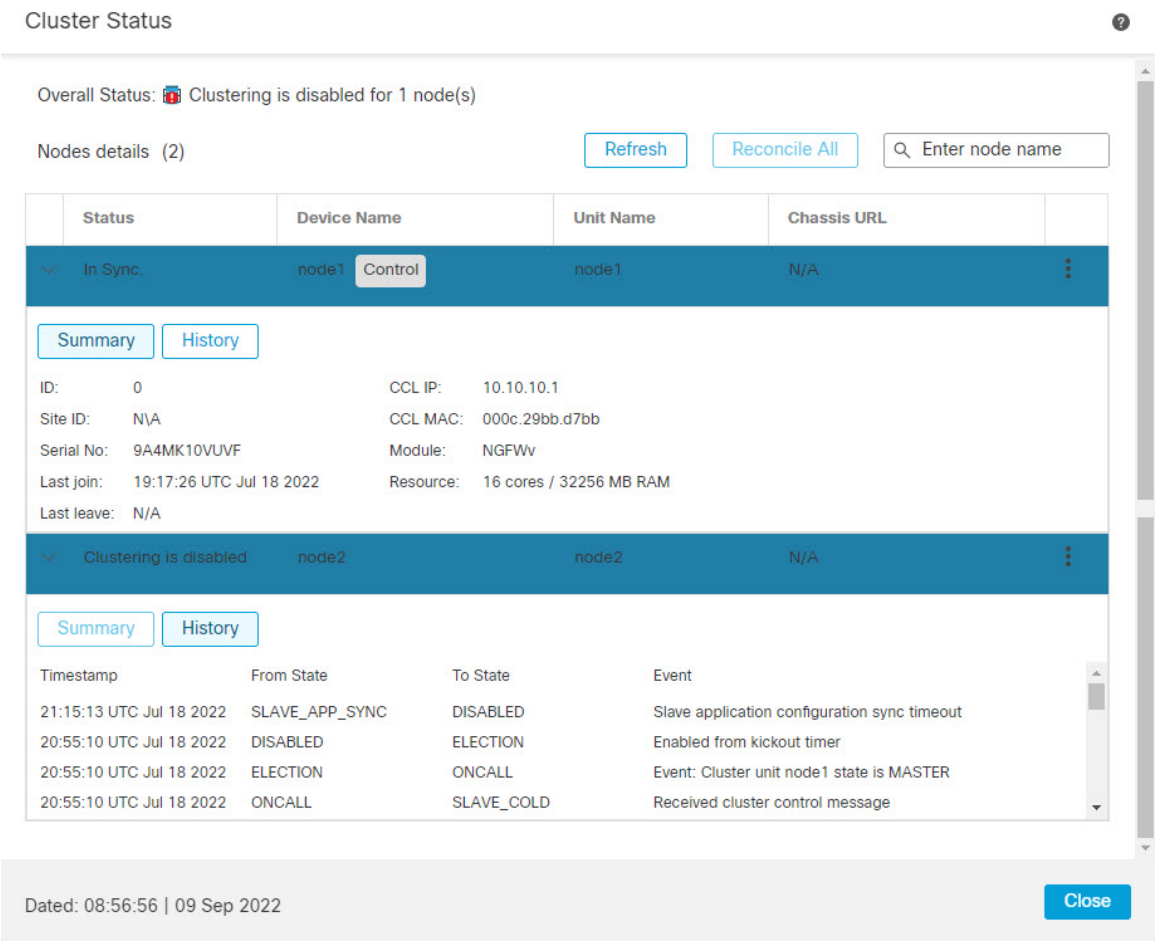
Reconcile cluster members

If a cluster member fails to register, you can reconcile the cluster membership from the chassis to the Secure Firewall Management Center. For example, a data unit might fail to register if the Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure

Step 1 Choose **Devices** > **Device Management**, **More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

You can also open the **Cluster Status** dialog box from the **Devices** > **Device Management** page **General** area, **Cluster Live Status** link.



Step 2 Click **Reconcile All**.

For more information about the cluster status, refer to Firewall Management Center: Monitor the cluster, on page 574.

Firewall Management Center: Monitor the cluster

You can monitor the cluster in Secure Firewall Management Center and at the Firewall Threat Defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management** and then chose **Add**, **Cluster** page, **General** area, and **Cluster Live Status** link.

The Control unit has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The unit is registered with the Firewall Management Center.
- Pending Registration—The unit is part of the cluster, but has not yet registered with the Firewall Management Center. If a unit fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The unit is registered with the Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the unit from the cluster.
- Joining cluster...—The unit is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Firewall Management Center.

For each unit, you can view the **Summary** or the **History**.

For each unit from the **More** (⋮) menu , you can perform the following status changes:

- **Disable Clustering**
- **Enable Clustering**

- **Change Role to Control**

- Click **System** (⚙), and then click **Tasks**.

  The **Tasks** page shows updates of the Cluster Registration task as each unit registers.

- **Devices** > **Device Management** and then choose **Add Device** *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member units, including the control unit shown with its role next to the IP address. For units that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

The Control unit has a graphic indicator identifying its role.

Cluster member **Status** includes these states:

- In Sync.—The unit is registered with the Firewall Management Center.
- Pending Registration—The unit is part of the cluster, but has not yet registered with the Firewall Management Center. If a unit fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The unit is registered with the Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the unit from the cluster.
- Joining cluster...—The unit is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Firewall Management Center.

For each unit, you can view the **Summary** or the **History**.

For each unit from the **More** (⋮) menu, you can perform these status changes:

- **Disable Clustering**
- **Enable Clustering**
- **Change Role to Control**

Tasks page

Click **System** (⚙), and then click **Tasks**.

The **Tasks** page shows updates of the Cluster Registration task as each unit registers.

Device management page

Devices > **Device Management** and then choose **Add Device** *cluster_name*.

When you expand the cluster on the devices listing page, you can see all member units, including the control unit shown with its role next to the IP address. For units that are still registering, you can see the loading icon.

CLI commands for cluster monitoring

show cluster {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

To view aggregated data for the entire cluster or other information, use the **show cluster** command.

show cluster info [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

To view cluster information, use the **show cluster info** command.

Cluster Health Monitor Dashboard

When a Firewall Threat Defense is the control node of a cluster, the Firewall Management Center collects various metrics periodically from the device metric data collector.

The cluster health monitor is comprised of these components:

- Overview dashboard: Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard: Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.

- Member Performance dashboard: Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard: Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links: Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range: An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard: Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

Viewing cluster health

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

Ensure you have created a cluster from one or more devices in the Firewall Management Center.

Follow these steps to view the cluster health monitor:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 Click on the cluster name to view the cluster health statistics.

The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution: Traffic and packet distribution across the cluster nodes.
- Member Performance: Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL: Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 Configure the time range from the drop-down in the upper-right corner.

The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 View device monitor health and performance metrics in several predefined dashboards.

The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU: CPU utilization, including the CPU usage by process and by physical cores.

- Memory: Device memory utilization, including data plane and Snort memory usage.
- Interfaces: Interface status and aggregate traffic statistics.
- Connections: Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort: Statistics that are related to the Snort process.
- ASP drops: Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. Refer to Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 39: Cluster Metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number
Packets	Packet distribution count in the cluster for every second.	number

Troubleshoot the cluster

Use these methods to troubleshoot the devices and clusters:

- Use **Logs** to generates troubleshooting files for all nodes in the cluster. Use this option when you need one cluster-level collection instead of generating troubleshooting files from each node separately.
- Use **CLI** to run a predefined set of cluster diagnostic commands and displays the output. Use this option to check cluster configuration, member state, cluster health, control-plane transport statistics, packet drops, interface status, CPU usage, memory buffers, ARP entries, and reachability. The **CLI** option displays command output; it does not open an interactive CLI session.

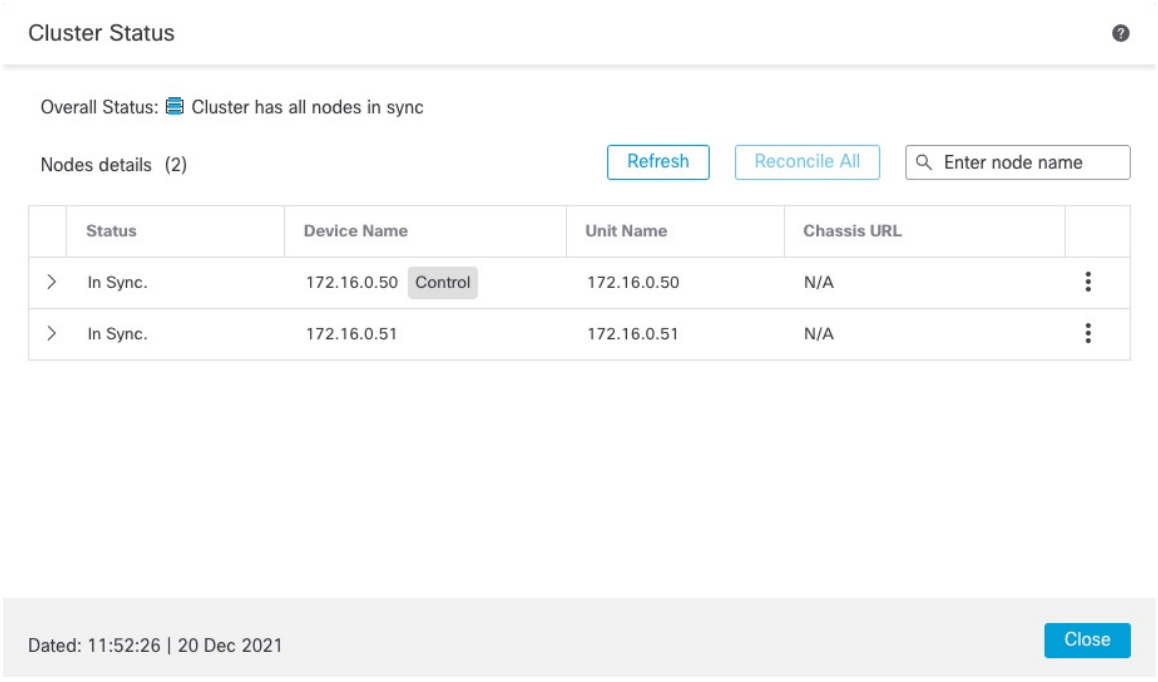
Commands
show running-config cluster: Review the cluster group configuration, local unit, cluster interface, priority, health-check, auto-rejoin, and cLACP settings.
show cluster info: Confirm that clustering is enabled and identify the control node, member state, software version, serial number, CCL IP address, CCL MAC address, and last join or leave state.
show cluster info health: Check unit, interface, service, and overall cluster health.
show cluster info transport cp: Review control-plane transport counters, including reliable and unreliable message counters, errors, retransmits, drops, and buffer conditions.
show version: Capture platform, software, build, UUID, LSP, VDB, uptime, resource, and license context.
show asp drop: Identify accelerated security path packet or flow drop reasons and counters.
show counters: Review protocol, feature, and cluster CCL counters.
show arp: Verify ARP entries for interfaces that participate in cluster communication.
show int ip brief: Check interface IP addresses and administrative and line protocol status.
show blocks: Check buffer availability and failed allocations.
show cpu detailed: Check data path, control point, and total CPU usage.
show interface *ccl_interface*: Review interface state, MTU, MAC address, IP address, traffic counters, errors, and drops for the cluster-related interface.
ping *ccl_ip* **size** *ccl_mtu* **repeat 2**: Test reachability to a cluster peer by using the packet size selected by the tool.

- Use the **CCL Ping** when you need to test cluster control link connectivity between joined cluster nodes.
- Troubleshooting files—If a node fails to join the cluster, a troubleshooting file is automatically generated. You can also generate and download troubleshooting files from the **Devices** > **Device Management** and then choose **Add**, **ClusterGeneral** area. For more information, refer to Generate troubleshooting files, on page 745.

You can also generate files from the **Device Management** page. Click **More** (⋮) and choose **Troubleshoot Files**.

- CLI output—Choose **Devices** > **Device Management** and then choose **Add**, **ClusterGeneral** area, you can view a set of pre-defined CLI outputs that can help you troubleshoot the cluster. These commands are automatically run for the cluster:

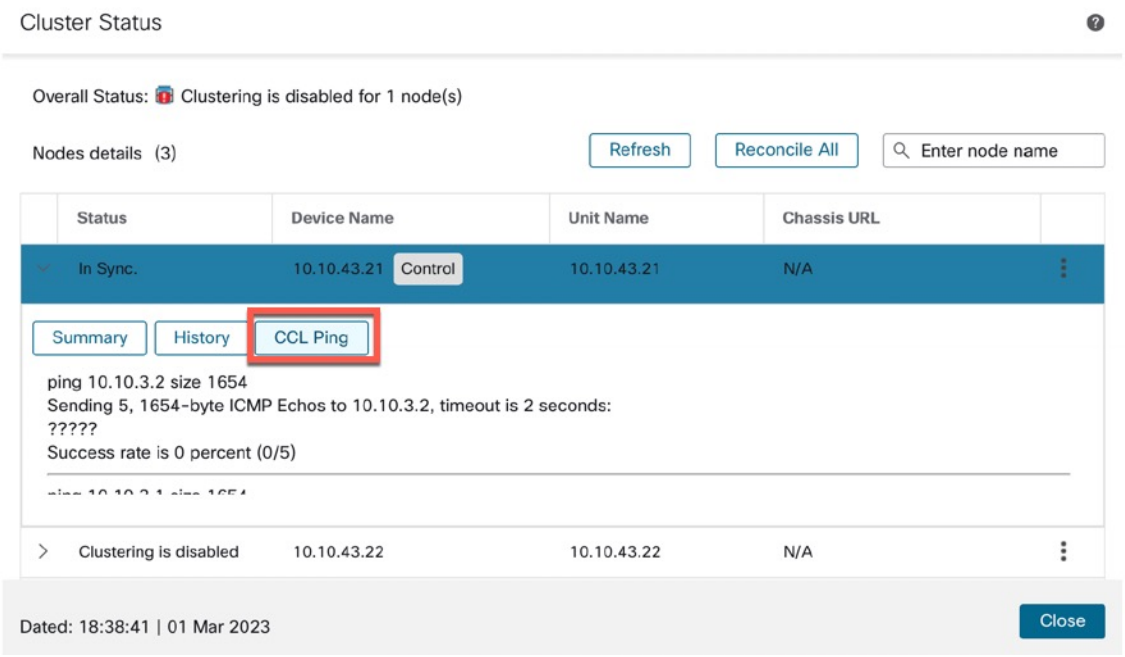
  You can also enter any **show** command in the **Command** field.



Perform a ping on the cluster control link

You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs.

Procedure



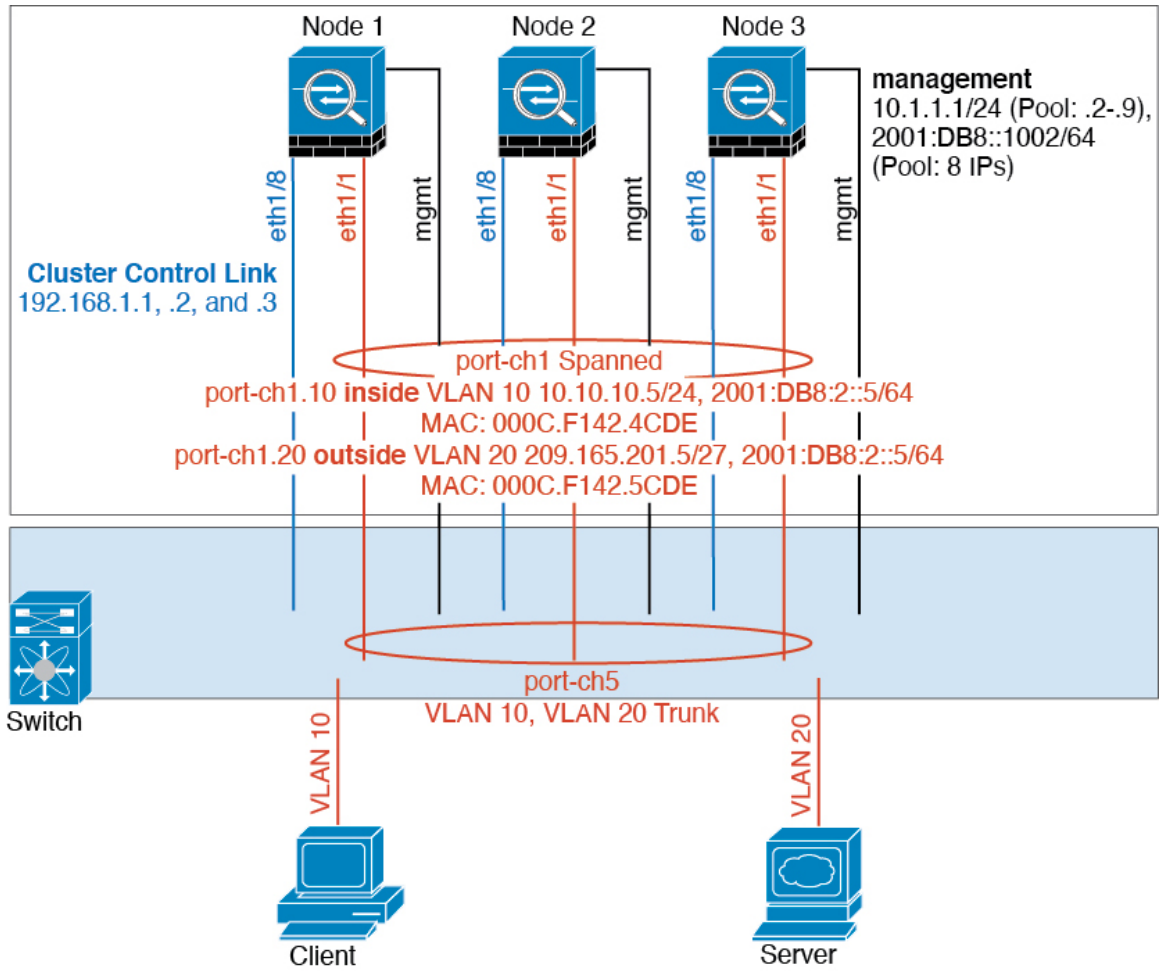
Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) icon next to the cluster, and choose **Cluster Live Status**.

Figure 227: Cluster status

Step 2 Expand one of the nodes, and click **CCL Ping**.

Figure 228: CCL ping

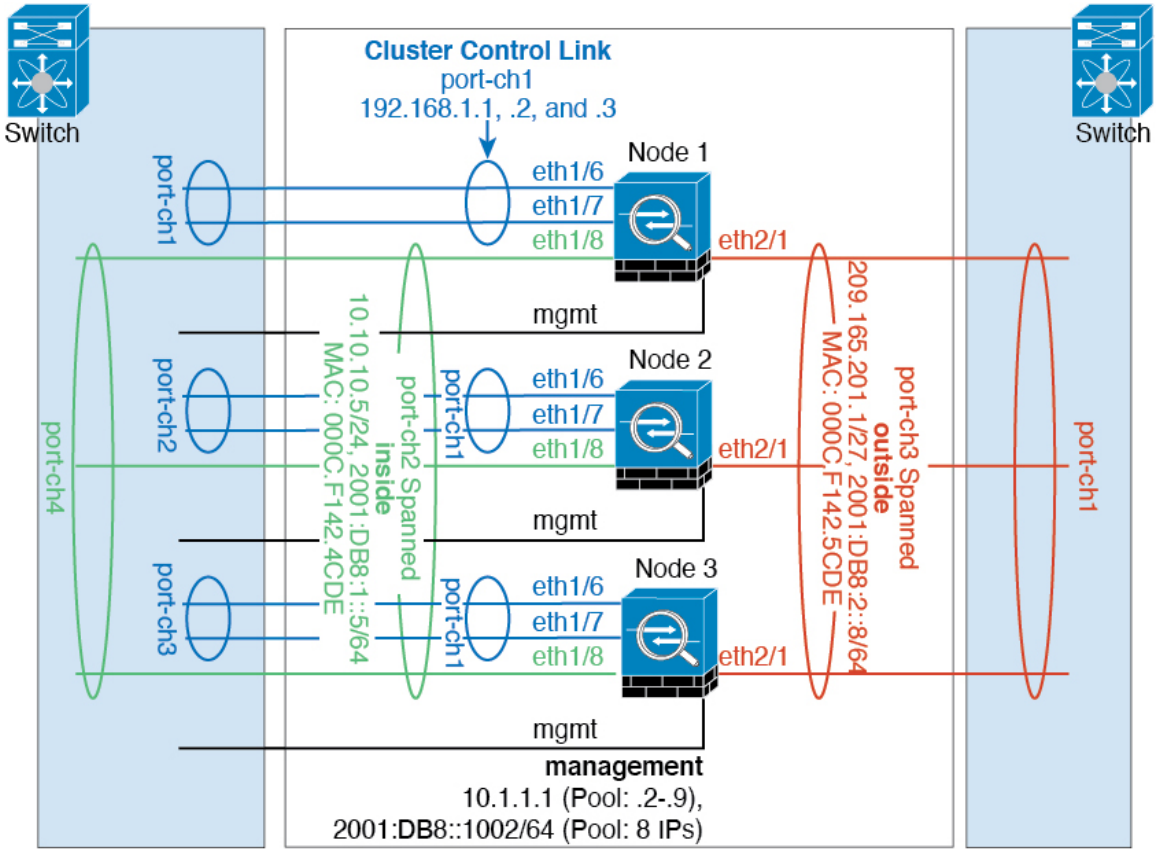
The node sends a ping on the cluster control link to every other node using a packet size that matches the maximum MTU.



Examples for Clustering

These examples include typical deployments.

Firewall on a stick



Data traffic from different security domains are associated with different VLANs. For example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each Threat Defense has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. The Threat Defense is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the Threat Defense becomes unavailable, the switch will rebalance traffic between the remaining units.

Traffic segregation

Provides the necessary bootstrap and interface configurations to implement traffic segregation using spanned EtherChannels in a cluster environment.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

Reference for clustering

This section includes more information about how clustering operates.

Firewall Threat Defense features and clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported features with clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. See FlexConfig policies, on page 921.

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Firewall Management Center UCAPL/CC mode
- DHCP client, server, and proxy. DHCP relay is supported.

Centralized features for clustering

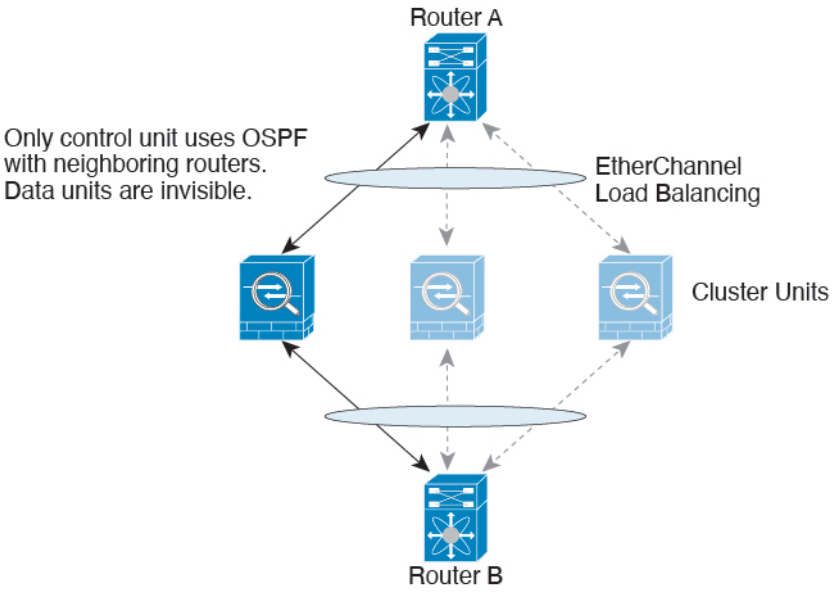
The following features are only supported on the control unit, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member units to the control unit over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control units before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control unit.

For centralized features, if the control unit fails, all connections are dropped, and you have to re-establish the connections on the new control unit.

- Site-to-site VPN
- The following application inspections:
  - DCERPC
  - NetBIOS
  - RSH
  - SUNRPC
  - TFTP
  - XDMCP
- Dynamic routing
- Static route monitoring



Connection settings

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic routing and clustering

The routing process only runs on the control unit, and routes are learned through the control unit and replicated to secondaries. If a routing packet arrives at a data unit, it is redirected to the control unit.

Figure 229: Dynamic Routing

After the data units learn the routes from the control unit, each unit makes forwarding decisions independently.

The OSPF LSA database is not synchronized from the control unit to data units. If there is a control unit switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

FTP and clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

Multicast routing and clustering

The control unit handles all multicast routing packets and data packets until fast-path forwarding is established. After the connection is established, each data unit can forward multicast data packets.

NAT and clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different Firewall Threat Defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When

a packet arrives at the Firewall Threat Defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP

- RSH
- SQLNET
- TFTP
- XDMCP
- SIP

- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP inspection and clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

TLS/SSL connections and clustering

The decryption states of TLS/SSL connections are not synchronized, and if the connection owner fails, then the decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Cisco TrustSec and clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and clustering

Site-to-site VPN is a centralized feature; only the control unit supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control unit and does not take advantage of the cluster high availability capabilities. If the control unit fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control unit is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned interface address, connections are automatically forwarded to the control unit.

VPN-related keys and certificates are replicated to all units.

Performance scaling factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, for TCP throughput, the Firepower 9300 with 3 SM-40 modules can handle approximately 135 Gbps of real world firewall traffic when running alone. For 2 chassis, the maximum combined throughput will be approximately 80% of 270 Gbps (2 chassis x 135 Gbps): 216 Gbps.

Control unit election

The control unit election is a automated process where cluster members determine which unit manages centralized features.

Election process and rules

Members of the cluster communicate over the cluster control link to elect a control unit as follows:

1. When you deploy the cluster, each unit broadcasts an election request every 3 seconds.
2. Any other units with a higher priority respond to the election request; the priority is set when you deploy the cluster and is not configurable.
3. If after 45 seconds, a unit does not receive a response from another unit with a higher priority, then it becomes the control unit.
4. If a unit later joins the cluster with a higher priority, it does not automatically become the control unit; the existing control unit always remains as the control unit unless it stops responding, at which point a new control unit is elected.
5. In a *split brain* scenario when there are temporarily multiple control units, then the unit with highest priority retains the role while the other units return to data unit roles.

Note You can manually force a unit to become the control unit. For centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

High availability within the cluster

Clustering provides high availability by monitoring chassis, unit, and interface health and by replicating connection states between units.

Chassis-application monitoring

Chassis-application health monitoring is always enabled. The Firepower 4100/9300 chassis supervisor checks the Firewall Threat Defense application periodically (every second). If the Firewall Threat Defense device is up and cannot communicate with the Firepower 4100/9300 chassis supervisor for 3 seconds, the Firewall Threat Defense device generates a syslog message and leaves the cluster.

If the Firepower 4100/9300 chassis supervisor cannot communicate with the application after 45 seconds, it reloads the Firewall Threat Defense device. If the Firewall Threat Defense device cannot communicate with the supervisor, it removes itself from the cluster.

Unit health monitoring

Each unit periodically sends a broadcast keepaliveheartbeat packet over the cluster control link. If the control node does not receive any keepaliveheartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining node.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role. See Control unit election, on page 590 for more information.

Interface monitoring

Each node monitors the link status of all hardware interfaces in use, and reports status changes to the control node. For clustering on multiple chassis, Spanned EtherChannels use the cluster Link Aggregation Control Protocol (cLACP). Each chassis monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel, and informs the Firewall Threat Defense application if the interface is down. When you enable health monitoring, all physical interfaces are monitored by default (including the main EtherChannel for EtherChannel interfaces). Only named interfaces that are in an Up state can be monitored. For example, all member ports of an EtherChannel must fail before a *named* EtherChannel is removed from the cluster. You can optionally disable monitoring per interface.

If a monitored interface fails on a particular node, but it is active on other nodes, then the node is removed from the cluster. The amount of time before the Firewall Threat Defense device removes a node from the cluster depends on whether the node is an established member or is joining the cluster. The Firewall Threat Defense device does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface status changes during this time will not cause the Firewall Threat Defense device to be removed from the cluster. For an established member, the node is removed after 500 ms.

For clustering on multiple chassis, if you add or delete an EtherChannel from the cluster, interface health-monitoring is suspended for 95 seconds to ensure that you have time to make the changes on each chassis.

Decorator application monitoring

When you install a decorator application on an interface, such as the Radware DefensePro application, then both the Firewall Threat Defense device and the decorator application must be operational to remain in the cluster. The unit does not join the cluster until both applications are operational. Once in the cluster, the unit monitors the decorator application health every 3 seconds. If the decorator application is down, the unit is removed from the cluster.

Status after failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Firewall Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the Firewall Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

Rejoining scenarios and automatic retry behavior

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

- Failed Chassis-Application Communication—When the Firewall Threat Defense application detects that the chassis-application health has recovered, it tries to rejoin the cluster automatically.

Data path connection state replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 40: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—
SNMP Engine ID	**No**	—

How the cluster manages connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.

- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

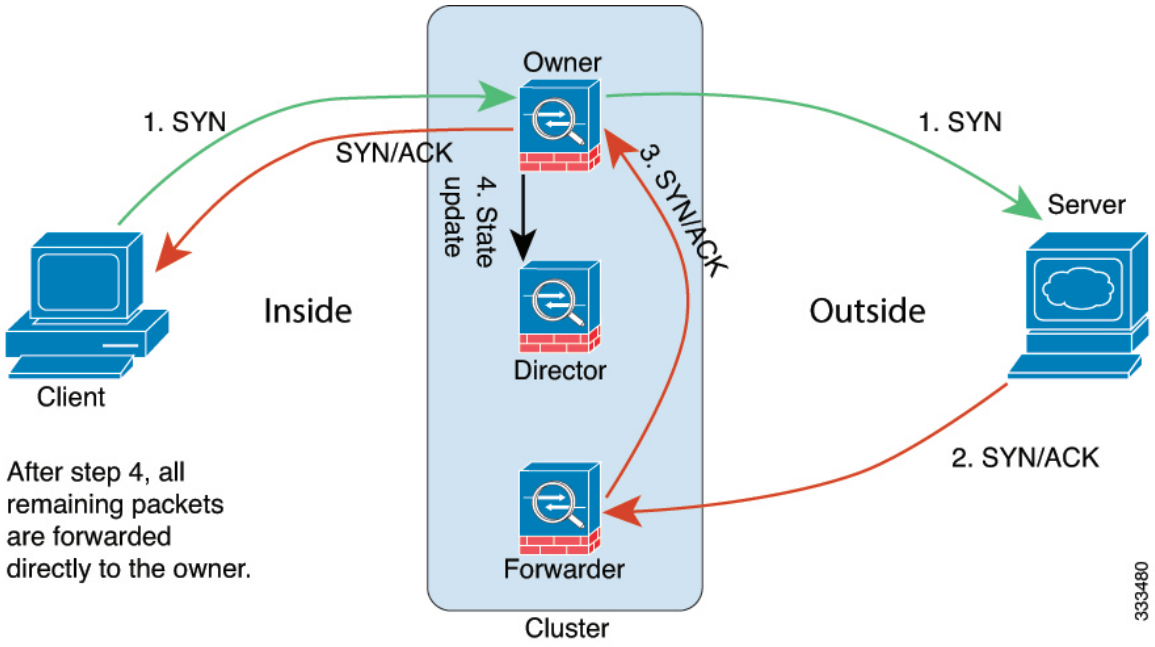
  ICMP/ICMPv6 hash details:

  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.

- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.



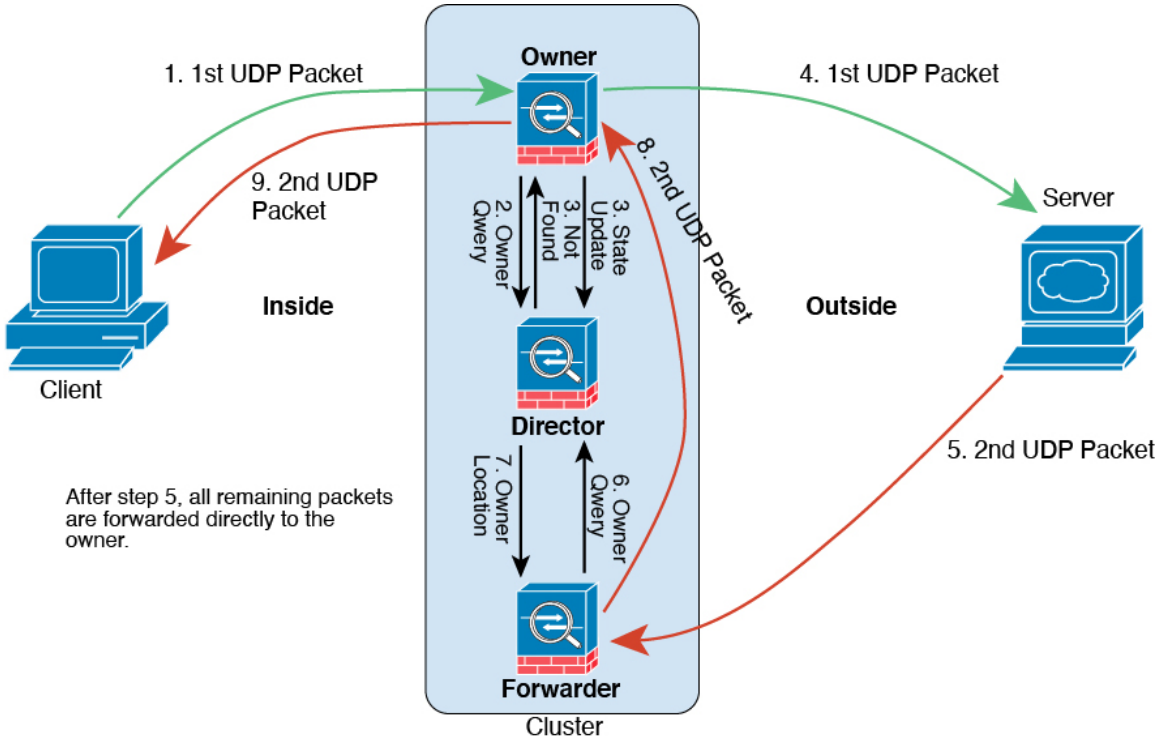
Port Address Translation Connections

New connection ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Sample data flow for TCP

The following example shows the establishment of a new connection.



1. The SYN packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different Firewall Threat Defense (based on the load balancing method). This Firewall Threat Defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample data flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. ***Figure 230: ICMP and UDP Data Flow***

The first UDP packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for clustering

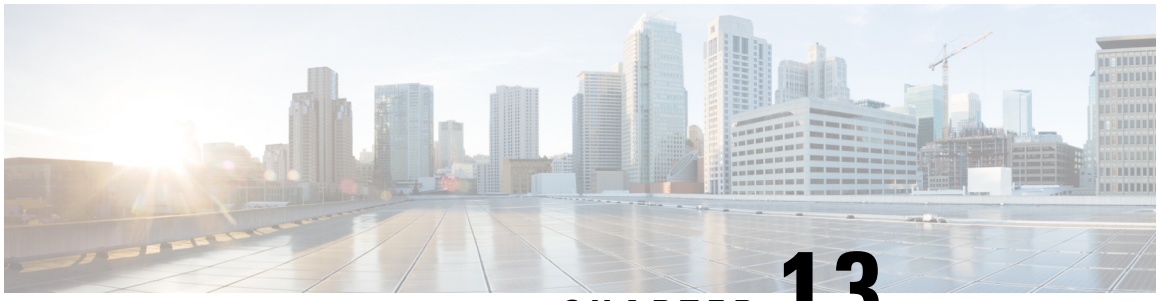
Table 41:

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Cluster control link ping tool.	7.2.6/7.4.1	Any	You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs. New/modified screens: **Devices** > **Device Management** > **More** > **Cluster Live Status.**
Troubleshooting file generation and download available from Device and Cluster pages.	7.4.1	7.4.1	You can generate and download troubleshooting files for each device on the Device page and also for all cluster nodes on the Cluster page. For a cluster, you can download all files as a single compressed file. You can also include cluster logs for the cluster for cluster nodes. You can alternatively trigger file generation from the **Devices** > **Device Management** > **More** > **Troubleshoot Files** menu. New/modified screens: • **Devices** > **Device Management** > **Device** > **General** • **Devices** > **Device Management** > **Cluster** > **General**
View CLI output for a device or device cluster.	7.4.1	Any	You can view a set of pre-defined CLI outputs that can help you troubleshoot the device or cluster. You can also enter any **show** command and see the output. New/modified screens: **Devices** > **Device Management** > **Cluster** > **General**
Cluster health monitor settings.	7.3.0	Any	You can now edit cluster health monitor settings. New/Modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Cluster health monitor dashboard.	7.3.0	Any	You can now view cluster health on the cluster health monitor dashboard. New/Modified screens: **System** > **Health** > **Monitor**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Support for 16-node clusters.	7.2.0	7.2.0	You can now configure 16 node clusters for the Firepower 4100/9300. Previously, the maximum was 6 units. New/Modified screens: none. Supported platforms: Firepower 4100/9300
Cluster deployment for firewall changes completes faster.	7.1.0	7.1.0	Cluster deployment for firewall changes now completes faster. New/Modified screens: none.
Improved PAT port block allocation for clustering.	7.0.0	7.0.0	The improved PAT port block allocation ensures that the control unit keeps ports in reserve for joining nodes, and proactively reclaims unused ports. To best optimize the allocation, you can set the maximum nodes you plan to have in the cluster using the **cluster-member-limit** command using FlexConfig. The control unit can then allocate port blocks to the planned number of nodes, and it will not have to reserve ports for extra nodes you don't plan to use. The default is 16 nodes. You can also monitor syslog 747046 to ensure that there are enough ports available for a new node. New/Modified commands: **cluster-member-limit** (FlexConfig), **show nat pool cluster** [**summary**], **show nat pool ip detail**
Cluster deployment for Snort changes completes faster, and fails faster when there is an event.	6.7.0	6.7.0	Cluster deployment for Snort changes now completes faster. Also, when a cluster has an event that causes a Firewall Management Center deployment to fail, the failure now occurs more quickly. New/Modified screens: none.
Improved cluster management.	6.7.0	6.7.0	Firewall Management Center has improved cluster management functionality that formerly you could only accomplish using the CLI, including: • Enable and disable cluster units • Show cluster status from the Device Management page, including History and Summary per unit • Change the role to the control unit New/Modified screens: • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** > **General** area **> Cluster Live Status** link **Cluster Status** Supported platforms: Firepower 4100/9300

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Multi-instance clustering.	6.6.0	6.6.0	You can now create a cluster using container instances. On the Firepower 9300, you must include one container instance on each module in the cluster. You cannot add more than one container instance to the cluster per security engine/module. We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. New/Modified FXOS commands: **set port-type cluster** New/modified Firepower Chassis Manager screens: • **Logical Devices** > **Add Cluster** • **Interfaces** > **All Interfaces** > **Add New** drop-down menu**Subinterface Type field** Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Configuration sync to data units in parallel.	6.6.0	6.6.0	The control unit now syncs configuration changes with data units in parallel by default. Formerly, synching occurred sequentially. New/Modified screens: none.
Messages for cluster join failure or eviction added to **show cluster history**.	6.6.0	6.6.0	New messages were added to the **show cluster history** command for when a cluster unit either fails to join the cluster or leaves the cluster. New/Modified commands: **show cluster history** New/Modified screens: none.
Initiator and responder information for Dead Connection Detection (DCD), and DCD support in a cluster.	6.5.0	6.5.0	If you enable Dead Connection Detection (DCD), you can use the **show conn detail** command to get information about the initiator and responder. Dead Connection Detection allows you to maintain an inactive connection, and the **show conn** output tells you how often the endpoints have been probed. In addition, DCD is now supported in a cluster. New/Modified commands: **show conn** (output only). Supported platforms: Firewall Threat Defense on the Firepower 4100/9300

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Adding clusters is easier.	6.3.0	6.3.0	You can now add any unit of a cluster to the Firewall Management Center, and the other cluster units are detected automatically. Formerly, you had to add each cluster unit as a separate device, and then group them into a cluster. Adding a cluster unit is also now automatic. Note that you must delete a unit manually. New/Modified screens: **Devices** > **Device Management** > **Add** drop-down menu **Device** > **Add Device** dialog box **Devices** > **Device Management** > **Cluster** tab**General** area**Cluster Registration Status** **Current Cluster Summary** link **Cluster Status** dialog box Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Support for site-to-site VPN with clustering as a centralized feature.	6.2.3.3	6.2.3.3	You can now configure site-to-site VPN with clustering. Site-to-site VPN is a centralized feature; only the control unit supports VPN connections. Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Automatically rejoin the cluster after an internal failure.	6.2.3	6.2.3	Formerly, many internal error conditions caused a cluster unit to be removed from the cluster, and you were required to manually rejoin the cluster after resolving the issue. Now, a unit will attempt to rejoin the cluster automatically at the following intervals: 5 minutes, 10 minutes, and then 20 minutes. Internal failures include: application sync timeout; inconsistent application statuses; and so on. New/Modified command: **show cluster info auto-join** No modified screens. Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Clustering on multiple chassis for 6 modules; Firepower 4100 support.	6.2.0	6.2.0	With FXOS 2.1.1, you can now enable clustering on multiple chassis of the Firepower 9300 and 4100. For the Firepower 9300, you can include up to 6 modules. For example, you can use 1 module in 6 chassis, or 2 modules in 3 chassis, or any combination that provides a maximum of 6 modules. For the Firepower 4100, you can include up to 6 chassis. **Note** Inter-site clustering is also supported. However, customizations to enhance redundancy and stability, such as site-specific MAC and IP addresses, director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature. No modified screens. Supported platforms: Firewall Threat Defense on the Firepower 4100/9300



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Clustering on multiple modules with one Firepower 9300 chassis.	6.0.1	6.0.1	You can cluster up to 3 security modules within the Firepower 9300 chassis. All modules in the chassis must belong to the cluster. New/Modified screens: **Devices** > **Device Management** > **Add** > **Add Cluster** **Devices** > **Device Management** > **Cluster** Supported platforms: Firewall Threat Defense on the Firepower 9300

PART III

Interfaces and Device Settings

CHAPTER 13

Interface Overview

The Firewall Threat Defense device includes data interfaces that you can configure in different modes, as well as a management interface.

- Management interface, on page 605
- Interface Mode and Types, on page 607
- Security zones and interface groups, on page 607
- Auto-MDI/MDIX feature, on page 609
- Redundant interfaces (deprecated), on page 609
- Default settings for interfaces, on page 609
- Create security zone and interface group objects, on page 610
- Enable the physical interface and configure Ethernet settings, on page 611
- Configure EtherChannel interfaces, on page 614
- Sync Interface Changes with the Firewall Management Center, on page 622
- Network module management for Secure Firewall 3100/4200, on page 625
- Merge the management and diagnostic interfaces, on page 640
- History for interfaces, on page 645

Management interface

A management interface is a shared physical interface that enables communication between the diagnostic logical interface and the management logical interface on security appliances.

Interface configuration details

In Version 7.3 and earlier, the physical management interface is shared between the Diagnostic logical interface and the Management logical interface. In Version 7.4 and later, the diagnostic interface is merged with management for a simplified user experience.

Management interface

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the Firewall Management Center. It uses its own IP address and static routing.

Management interface configuration and monitoring

You can configure its settings at the CLI using the **configure network** command. You can also view its status on the **Devices** > **Device Management** page. If you change the IP address at the CLI after you add it to the Firewall Management Center, you can match the IP address in the Secure Firewall Management Center in the **Devices** > **Device Management** area.

You can alternatively manage the Firewall Threat Defense using a data interface instead of the management interface.

Diagnostic interface

Diagnostic interface shares a physical port with the Management interface but requires different IP addresses on the same network. A diagnostic interface allows only management traffic.

Legacy diagnostic interface support

For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available.

If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically.

If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. To manually merge the Management and Diagnostic interfaces, see Merge the management and diagnostic interfaces, on page 640. Configurations that prevent an automatic merge include these:

- A data interface named "management"—This name is reserved for use with the merged Management interface.
- IP Address on Diagnostic
- DNS enabled on Diagnostic
- Syslog, SNMP, RADIUS or AD (for remote access VPN) source interface is Diagnostic
- RADIUS or AD (for remote access VPN) with no source interface specified, and there is at least one interface configured as management-only (including Diagnostic)—The default route lookup for these services has changed from the management-only routing table to the data routing table, with no fallback to management. Therefore, you cannot use a management-only interface other than Management.
- Static routes on Diagnostic
- Dynamic routing on Diagnostic
- HTTP server on Diagnostic
- ICMP on Diagnostic
- DDNS for Diagnostic
- FlexConfig using Diagnostic

For more information about how the legacy Diagnostic interface operates, see the 7.3 version of this guide.

Interface Mode and Types

You can deploy Firewall Threat Defense interfaces in two modes: Regular firewall mode and IPS-only mode. You can include both firewall and IPS-only interfaces on the same device.

Regular Firewall Mode

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See Transparent or Routed Firewall Mode, on page 71 for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the Firewall Threat Defense device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

IPS-Only Mode

You can configure your device in either a passive or inline IPS deployment. In a passive deployment, you deploy the system out-of-band from the flow of network traffic. In an inline deployment, you configure the system transparently on a network segment by binding two interfaces together.

Security zones and interface groups

You can assign each interface to a security zone, an interface group, or both. You then apply your security policy based on zones or groups. For example, you can assign the "inside" interface on one or more devices to the "inside" zone, and the "outside" interfaces to the "outside" zone. You can then configure your access control policy to enable traffic to go from the inside zone to the outside zone for every device using the same zones.

Security zones and interface groups functionality

To view the interfaces that belong to each object, choose **Objects** > **Object Management** and click **Interface**. This page lists the security zones and interface groups configured on your managed devices. You can expand each interface object to view the type of interfaces in each interface object.

Note Policies that apply to **any** zone (a global policy) apply to interfaces in zones as well as any interfaces that are not assigned to a zone.

Note The Management interface does not belong to a zone or interface group.

Security zones and interface groups have different membership and usage characteristics:

- Security zones—An interface can belong to only one security zone.
- Interface groups—An interface can belong to multiple interface groups (and to one security zone).

  You can use interface groups in NAT policies, prefilter policies, and QoS policies, as well as features that let you specify the interface name directly, such as Syslog servers or DNS servers.

Some policies only support security zones, while other policies support zones and groups. Unless you need the functionality an interface group provides, you should default to using security zones because security zones are supported for all features.

You cannot change an existing security zone to an interface group or vice-versa. Instead, you must create a new interface object.

Note Although tunnel zones are not interface objects, you can use them in place of security zones in certain configurations; see Using tunnel zones to apply access control at the tunnel level, on page 1970.

Interface objects are categorized by these types:

- Passive—For IPS-only passive or ERSPAN interfaces.
- Inline—For IPS-only inline set interfaces.
- Switched—For regular firewall bridge group interfaces.
- Routed—For regular firewall routed interfaces.
- ASA—(Security zones only) For legacy ASA FirePOWER device interfaces.
- Management—(Interface groups only) For management-only interfaces.
- Loopback—(Interface groups only) For loopback interfaces.

All interfaces in an interface object must be of the same type. After you create an interface object, you cannot change the type of interfaces it contains.

The interface (or zone name) itself does not provide any default behavior in regarding the security policy. We recommend using names that are self-describing to avoid mistakes in future configuration. A good name signifies a logical segment or traffic specification, for example:

- Names of internal interfaces—InsideV110, InsideV160, InsideV195
- Names of DMZ interfaces—DMZV11, DMZV12, DMZV-TEST
- Names of external interfaces—Outside-ASN78, Outside-ASN91

Auto-MDI/MDIX feature

Auto-MDI/MDIX is a feature that eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. The feature is enabled by default with auto-negotiation on RJ-45 interfaces and requires either speed or duplex to be set to auto-negotiate. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. For Gigabit Ethernet, when the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

Redundant interfaces (deprecated)

Redundant interfaces were supported for the ASA 5500-X platforms only. We don't recommend configuring them for other platforms.

Default settings for interfaces

This section lists default settings for interfaces.

Default state of interfaces

The default state of an interface depends on the type.

- Physical interfaces—Disabled. The exception is the Management interface that is enabled for initial setup. Physical interfaces includes switch ports.
- VLAN subinterfaces—Enabled. However, for traffic to pass through the subinterface, the physical interface must also be enabled.
- EtherChannel port-channel interfaces (ISA 3000)—Enabled. However, for traffic to pass through the EtherChannel, the channel group physical interfaces must also be enabled.
- EtherChannel port-channel interfaces (Firepower and Secure Firewall models)—Disabled.

Note For the Firepower 4100/9300, you can administratively enable and disable interfaces in both the chassis and in the Firewall Management Center. For an interface to be operational, the interface must be enabled in both operating systems. Because the interface state is controlled independently, you may have a mismatch between the chassis and Firewall Management Center.

Default speed and duplex

By default, the speed and duplex for copper (RJ-45) interfaces are set to auto-negotiate.

By default, the speed and duplex for fiber (SFP) interfaces are set to the maximum speed, with auto-negotiation enabled. If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example,

N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

For the Secure Firewall 3100/4200 the speed is set to detect the installed SFP speed.

Create security zone and interface group objects

Create empty interface objects that can be populated with interfaces later, or create security zones while configuring interfaces to provide logical grouping and management of device interfaces.

Add security zones and interface groups to which you can assign device interfaces.

Tip You can create empty interface objects and add interfaces to them later. To add an interface, the interface must have a name. You can also create security zones (but not interface groups) while configuring interfaces.

Before you begin

Understand the usage requirements and restrictions for each type of interface object. See Security zones and interface groups, on page 607.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Interface**.

Step 2 Click **Add** > **Security Zone** or **Add** > **Interface Group**.

Step 3 Enter a **Name**.

Do not use the same name as a network or port object. These object names are deployed to the device, and duplicate names result in a failed deployment.

Step 4 Choose an **Interface Type**.

Step 5 (Optional) From the **Device** > **Interfaces** drop-down list, choose a device that contains interfaces you want to add.

You do not need to assign interfaces on this screen; you can instead assign interfaces to the zone or group when you configure the interface.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Enable the physical interface and configure Ethernet settings

Before you begin

If you changed the physical interfaces on the device after you added it to the Firewall Management Center , you need to refresh the interface listing by clicking **Sync Interfaces from device** on the top left of **Interfaces** . For the 3100 /4200 , which supports hot swapping, see Network module management for Secure Firewall 3100/4200, on page 625 before you change interfaces on a device.

This section describes how to:

- Enable the physical interface. By default, physical interfaces are disabled (with the exception of the Management interface).
- Set a specific speed and duplex. By default, speed and duplex are set to Auto.

This procedure only covers a small subset of interface settings. Refrain from setting other parameters at this point. For example, you cannot name an interface that you want to use as part of an EtherChannel interface. The exact interface options vary depending on your model and interface type.

Note For the Firepower 4100/9300 , you configure basic interface settings in FXOS. See Configure a physical interface, on page 259 for more information.

Note For switch ports, see Configure switch ports, on page 650 .

You can also click the **Virtual Tunnels** tab to view details of dynamic and static VTIs of route-based VPNs on the device. For more information, see View virtual tunnel interface details, on page 1388 .

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Enable the interface by checking the **Enabled** check box.

a) (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 4 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed** .

- **Duplex** —Choose **Full** or **Half** . SFP interfaces only support **Full** duplex.
- **Speed** —Choose a speed (varies depending on the model). For SFPs, choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always full, autonegotiation is enabled, and FEC is set to auto. For dual-speed transceivers, the lower speed is used. This option is

useful if you later change the network module to a different model, and want the speed to update automatically. Some switches and transceivers don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

Note You cannot modify the speed of a high availability or a cluster control link interface.

- **Auto-negotiation** —Set the interface to negotiate the link status and flow control.

  Except for the 1100 and 2100 , autonegotiation is set separately from the speed. Some switches don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

- **Forward Error Correction Mode** —For 25Gbps and higher interfaces, enable Forward Error Correction (FEC).

  For an EtherChannel member interface, configure FEC before adding it to the EtherChannel. If you remove the interface from EtherChannel and then reboot, reconfigure the FEC for the interface.

  Some switches don't support auto mode for FEC, especially for larger interfaces. Be sure to manually configure the setting, depending on the switch support. We don't recommend disabling FEC because the EtherChannel may not function correctly.

  The setting chosen when you use **auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 42: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 108 RS-FEC	Clause 108 RS-FEC
25G-LR	Clause 108 RS-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 108 RS-FEC	Clause 74 FC-FEC
25G-AOC *x* M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate
25/50/100G	Clause 91 RS-FEC	Clause 91 RS-FEC

Note From Version 7.4.2, Firewall Threat Defense supports the SFP 10G_25G_CSR_S module. To avoid link-down issues after a reboot, Forward Error Correction (FEC) must be enabled on these interfaces.

Step 5 (Optional) Enable Link Layer Discovery Protocol (LLDP) by clicking **Hardware Configuration** > **Network Connectivity** .

- **Enable LLDP Receive** —Enables the firewall to receive LLDP packets from its peers.
- **Enable LLDP Transmit** —Enables the firewall to send LLDP packets to its peers.

Step 6 (Optional) Enable pause (XOFF) frames for flow control by clicking **Hardware Configuration** > **Network Connectivity** , and checking **Flow Control Send** .

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If the threat defense port experiences congestion (exhaustion of queuing resources on the internal switch) and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

Note The Firewall Threat Defense supports transmitting pause frames so that the remote peer can rate-control the traffic.

However, receiving of pause frames is not supported.

The internal switch has a global pool of 8000 buffers of 250 bytes each, and the switch allocates buffers dynamically to each port. A pause frame is sent out every interface with flowcontrol enabled when the buffer usage exceeds the global high-water mark (2 MB (8000 buffers)); and a pause frame is sent out of a particular interface when its buffer exceeds the port high-water mark (.3125 MB (1250 buffers)). After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark (1.25 MB globally (5000 buffers); .25 MB per port (1000 buffers)). The link partner can resume traffic after receiving an XON frame.

Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

Step 7 In the **Mode** drop-down list, choose one of the following:

- **None** —Choose this setting for regular firewall interfaces and inline sets. The mode will automatically be changed to Routed, Switched, or Inline based on further configuration.
- **Passive** —Choose this setting for passive IPS-only interfaces.
- **Erspan** —Choose this setting for ERSPAN passive IPS-only interfaces.

Step 8 In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to distribute the traffic across multiple egress interfaces.

Step 9 Click **OK** .

Click **Save**.

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Continue configuring interfaces.

- Regular Firewall Interfaces, on page 649
- Inline Sets and Passive Interfaces, on page 727

Configure EtherChannel interfaces

This section tells how to configure EtherChannel interfaces.

Note For the Firepower 4100/9300, you configure EtherChannels in FXOS. Refer to Add an EtherChannel (port channel), on page 261 for more information.

About EtherChannels

This section describes EtherChannels.

EtherChannels

An 802.3ad EtherChannel is a logical interface, called a port-channel interface) that consists of a bundle of individual Ethernet links, known as a channel group. This approach increases the bandwidth for a single network. A port channel interface is used in the same way as a physical interface when you configure interface-related features.

You can configure up to 48 EtherChannels, depending on how many interfaces your model supports.

Channel group interfaces

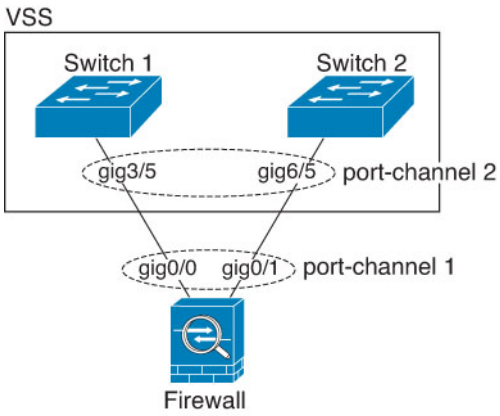
Channel group interfaces enable EtherChannel aggregation with specific capacity and configuration requirements. Understanding these interface specifications ensures proper EtherChannel deployment and performance.

Each channel group can have up to 8 active interfaces, except for the ISA 3000, which support 16 active interfaces. On switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group. Only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.

All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.

The EtherChannel aggregates traffic across all the available active interfaces in the channel. A proprietary hash algorithm selects the interface, using criteria such as source or destination MAC addresses, IP addresses, TCP and UDP port numbers, and VLAN numbers.

EtherChannel connection to other devices



An EtherChannel connection to other devices requires the connected device to support 802.3ad EtherChannels for compatibility.

EtherChannel connection requirements and configurations

The device to which you connect the Firewall Threat Defense EtherChannel must also support 802.3ad EtherChannels. For example, you can connect to the Catalyst 6500 switch or the Cisco Nexus 7000.

When the switch is part of a Virtual Switching System (VSS) or Virtual Port Channel (vPC), you can connect Firewall Threat Defense interfaces within the same EtherChannel to separate switches in the VSS/vPC. The switch interfaces are members of the same EtherChannel port-channel interface because the separate switches act like a single switch.

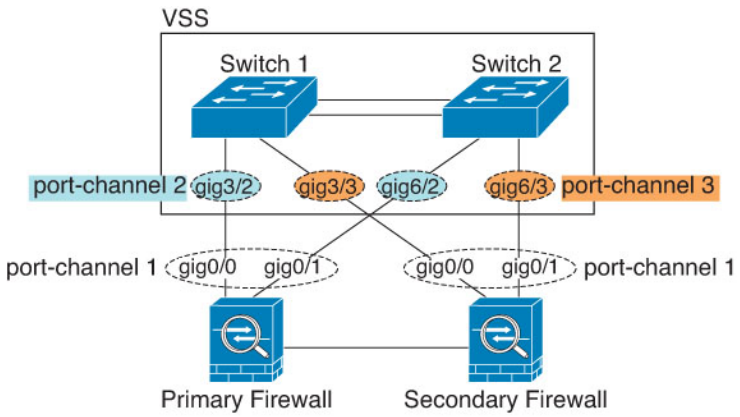


Figure 231: Connecting to a VSS/vPC

Note If the Firewall Threat Defense device is in transparent firewall mode, and you place the Firewall Threat Defense device between two sets of VSS/vPC switches, then be sure to disable Unidirectional Link Detection (UDLD) on any switch ports connected to the Firewall Threat Defense device with an EtherChannel. If you enable UDLD, then a switch port may receive UDLD packets sourced from both switches in the other VSS/vPC pair. The receiving switch will place the receiving interface in a down state with the reason "UDLD Neighbor mismatch".

If you use the Firewall Threat Defense device in an Active/Standby failover deployment, you need to create separate EtherChannels on the switches in the VSS/vPC, one for each Firewall Threat Defense device. On each Firewall Threat Defense device, a single EtherChannel connects to both switches. Even if you could group all switch interfaces into a single EtherChannel connecting to both Firewall Threat Defense devices,the EtherChannel would not be established because of the separate Firewall Threat Defense system IDs. Also, using a single EtherChannel would not be desirable because you do not want traffic sent to the standby Firewall Threat Defense device.

Figure 232: Active/Standby failover and VSS/vPC

Link aggregation control protocol

The Link Aggregation Control Protocol (LACP) is a network protocol that aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices.

LACP interface configuration modes

You can configure each physical interface in an EtherChannel to be:

- Active—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- Passive—Receives LACP updates. A passive EtherChannel can only establish connectivity with an active EtherChannel. Not supported on hardware models.
- On—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

Load balancing

Load balancing is a distribution mechanism that distributes packets to interfaces in the EtherChannel and ensures transparent failover when active interfaces go down by rebalancing traffic between remaining links.

Load balancing operation details

The Firewall Threat Defense device distributes packets to the interfaces in the EtherChannel by hashing the source and destination IP address of the packet (this criteria is configurable). The resulting hash is divided by the number of active links in a modulo operation where the resulting remainder determines which interface owns the flow. All packets with a *hash_value* **mod** *active_links* result of 0 go to the first interface in the EtherChannel, packets with a result of 1 go to the second interface, packets with a result of 2 go to the third interface, and so on. For example, if you have 15 active links, then the modulo operation provides values from 0 to 14. For 6 active links, the values are 0 to 5, and so on.

If an active interface goes down and is not replaced by a standby interface, then traffic is rebalanced between the remaining links. The failure is masked from both Spanning Tree at Layer 2 and the routing table at Layer 3, so the switchover is transparent to other network devices.

EtherChannel MAC address

An EtherChannel MAC address is a network identifier that is shared by all interfaces in the EtherChannel group. This makes the EtherChannel transparent to network applications and users by presenting one logical connection.

All interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links.

Platform-specific MAC address behavior

MAC address assignment for EtherChannel interface varies by hardware platform.

Firepower and Secure Firewall Hardware

The port-channel interface uses the MAC address of the internal interface Internal-Data 0/1. You can manually configure a MAC address for the port-channel interface if needed. All EtherChannel interfaces on a chassis use the same MAC address, so be aware that if you use SNMP polling, for example, multiple interfaces will have the same MAC address.

Note Member interfaces only use the Internal-Data 0/1 MAC address after a reboot. Prior to rebooting, the member interface uses its own MAC address. If you add a new member interface after a reboot, you will have to perform another reboot to update its MAC address.

Guidelines for EtherChannels and redundant interfaces

Provides essential configuration rules and limitations for implementing EtherChannels and redundant interfaces to maintain network stability and high availability.

Bridge Group

In routed mode, Firewall Management Center -defined EtherChannels are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.

High availability

- When you use an EtherChannel interface as a High availability link, it must be pre-configured on both units in the High availability pair; you cannot configure it on the primary unit and expect it to replicate to the secondary unit because the High availability link itself is required for replication .
- If you use an EtherChannel interface for the state link, no special configuration is required; the configuration can replicate from the primary unit as normal. For the Firepower 4100/9300 chassis , all interfaces, including EtherChannels, need to be pre-configured on both units.
- You can monitor EtherChannel interfaces for High availability . When an active member interface fails over to a standby interface, this activity does not cause the EtherChannel interface to appear to be failed when being monitored for device-level High availability . Only when all physical interfaces fail does the

EtherChannel interface appear to be failed (for an EtherChannel interface, the number of member interfaces allowed to fail is configurable) .

- If you use an EtherChannel interface for a High availability or state link, then to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a High availability link. To alter the configuration, you need to temporarily disable High availability , which prevents High availability from occurring for the duration.

Model Support

- You cannot add EtherChannels in the Firewall Management Center for the Firepower 4100/9300 or the Firewall Threat Defense Virtual . The Firepower 4100/9300 supports EtherChannels, but you must perform all hardware configuration of EtherChannels in FXOS on the chassis.
- You cannot use Firepower 1010 or Secure Firewall 1210/1220 switch ports or VLAN interfaces in EtherChannels.

Clustering

- To configure a spanned EtherChannel or an individual cluster interface, see the clustering chapter.

General Redundant Interface Guidelines

- You can configure up to 8 redundant interface pairs.
- All the Firewall Threat Defense configuration refers to the logical redundant interface instead of the member physical interfaces.
- You cannot use a redundant interface as part of an EtherChannel, nor can you use an EtherChannel as part of a redundant interface. You cannot use the same physical interfaces in a redundant interface and an EtherChannel interface. You can, however, configure both types on the Firewall Threat Defense device if they do not use the same physical interfaces.
- If you shut down the active interface, then the standby interface becomes active.
- Redundant interfaces do not support the Management *slot* / *port* interfaces as members. You can, however, set a redundant interface comprised of non- Management interfaces as management-only.

General EtherChannel Guidelines

- You can configure up to 48 EtherChannels, depending on how many interfaces are available on your model.
- Each channel group can have up to 8 active interfaces, except for ASA models and the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- When you add the first member interface, it sets the required hardware properties of all member interfaces.
    - The media type of member interfaces can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix RJ-45 and SFP interfaces.

  - All interfaces must be set to the same speed and duplex.
  - The first interface sets the speed *capacity* , which cannot be changed later.

- The device to which you connect the Firewall Threat Defense EtherChannel must also support 802.3ad EtherChannels.
- The Firewall Threat Defense device does not support LACPDUs that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **vlan dot1Q tag native** command, then the Firewall Threat Defense device will drop the tagged LACPDUs.
- The LACP rate depends on the model. When you set the rate (normal or fast), the device requests that rate from the connecting switch.
- In Cisco IOS software versions earlier than 15.1(1)S2, Firewall Threat Defense does not support connecting an EtherChannel to a switch stack. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time.
- Match the speed, duplex, and auto-negotiation settings on every EtherChannel member interface and its corresponding peer port. For a 10/100-Mbps member link, use auto-negotiation at both ends, or use the same fixed speed and duplex settings at both ends. If one end is fixed at full duplex while the other end uses auto-negotiation, the auto-negotiating side defaults to half duplex, resulting in a duplex mismatch.
- All the Firewall Threat Defense configuration refers to the logical EtherChannel interface instead of the member physical interfaces.

Configure an EtherChannel

Create an EtherChannel port-channel interface to aggregate multiple physical interfaces into a single logical interface for increased bandwidth and redundancy.

This section describes how to create an EtherChannel port-channel interface, assign interfaces to the EtherChannel, and customize the EtherChannel.

Note For the Firepower 4100/9300, you configure EtherChannels in FXOS. See Add an EtherChannel (port channel), on page 261 for more information.

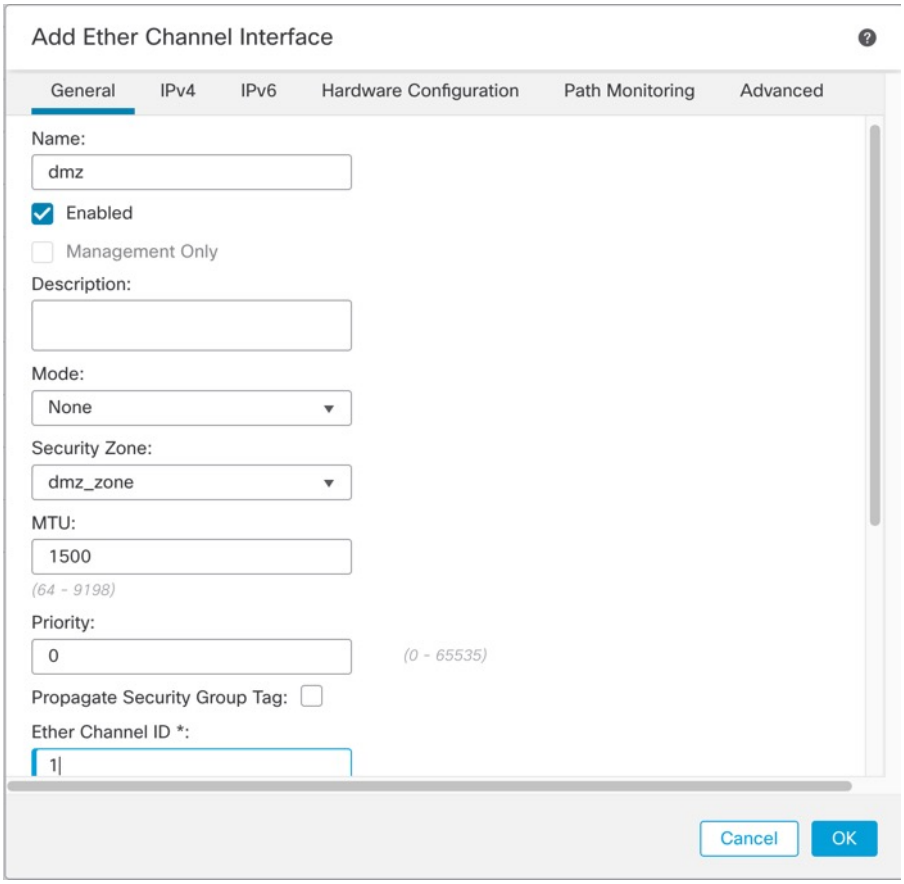
Before you begin

- When you add the first member interface, it sets the required hardware properties of all member interfaces. See Guidelines for EtherChannels and redundant interfaces, on page 617 for more details about member interface requirements.
- You cannot add a physical interface to the channel group if you configured a name for it. You must first remove the name.

Note If you are using a physical interface already in your configuration, removing the name will clear any configuration that refers to the interface.

Follow these steps to configure an EtherChannel:

Procedure



Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Enable the member interfaces according to Enable the physical interface and configure Ethernet settings, on page 611.

Step 3 Click **Add Interfaces** > **Ether Channel Interface**.

Step 4 On the **General** tab, set the **Ether Channel ID** to a number between 1 and 48 (1 and 8 for the Firepower 1010).

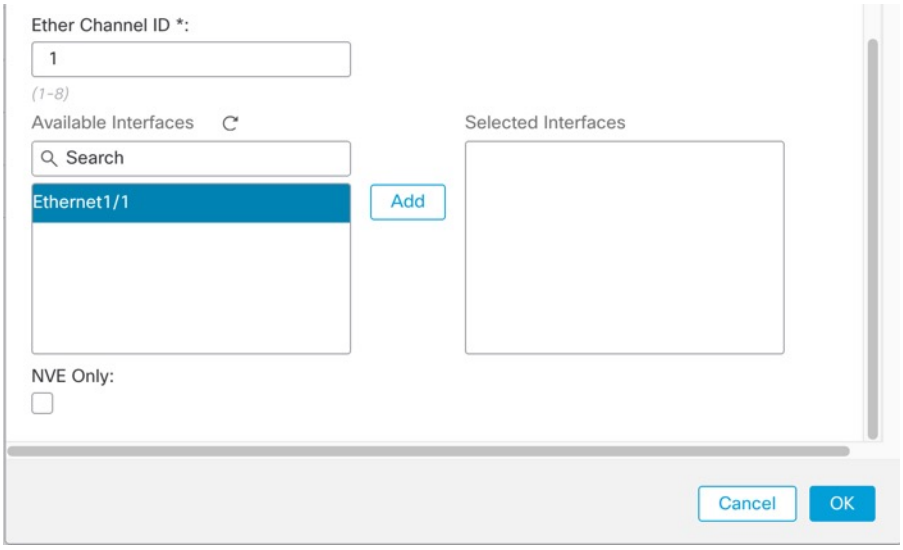


Figure 233: Add EtherChannel interface

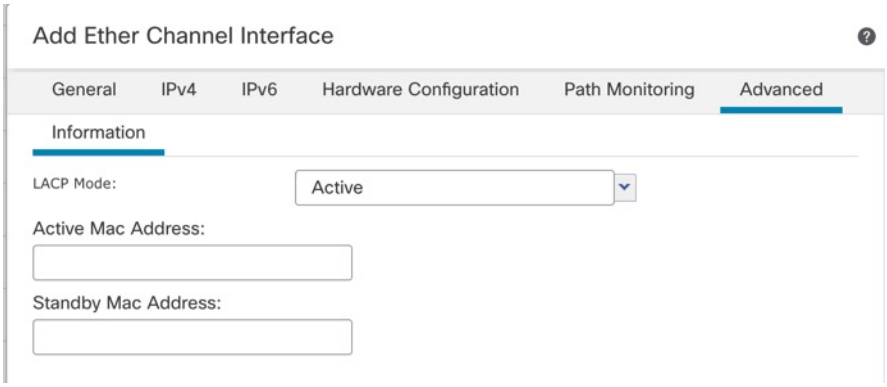
Step 5 In the **Available Interfaces** area, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members.



Make sure all interfaces are the same type and speed capability.

Figure 234: Available interfaces

Step 6 (Optional) Click the **Advanced** tab to customize the EtherChannel. Set the following parameters on the **Information** sub-tab:

Figure 235: Advanced

- (ISA 3000 only) **Load Balancing**—Select the criteria used to load balance the packets across the group channel interfaces. By default, the Firewall Threat Defense device balances the packet load on interfaces according to the source and destination IP address of the packet. If you want to change the properties on which the packet is categorized, choose a different set of criteria. For example, if your traffic is biased heavily towards the same source and destination IP addresses, then the traffic assignment to interfaces in the EtherChannel will be unbalanced. Changing to a different algorithm can result in more evenly distributed traffic. For more information about load balancing, see Load balancing, on page 616.
- **LACP Mode**—Choose Active, Passive, or On. We recommend using Active mode (the default). Passive mode is only available for the ISA 3000 only.
- (Secure Firewall 3100/4200 only) **LACP Rate**—Choose Default, Normal, or Fast. The defualt is Normal (also known as slow). Sets the LACP data unit receive rate for a physical interface in the channel group. We recommend that you set the same rate on both sides.

- (ISA 3000 only) **Active Physical Interface: Range**—From the left drop-down list, choose the minimum number of active interfaces required for the EtherChannel to be active, between 1 and 16. The default is 1. From the right drop-down list, choose the maximum number of active interfaces allowed in the EtherChannel, between 1 and 16. The default is 16. If your switch does not support 16 active interfaces, be sure to set this command to 8 or fewer.
- **Active MAC Address**—Set a manual MAC address if desired. The mac_address is in H.H.H format, where H is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE is entered as 000C.F142.4CDE.

Step 7 Click the **Hardware Configuration** tab and set the Duplex and Speed for all member interfaces.

Step 8 Click **OK**.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

For regular firewall interfaces:

- Add a VLAN subinterface. See Add a subinterface, on page 669.
- Configure the routed or transparent mode interface parameters: Configure routed mode interfaces, on page 690 or Bridge group interfaces, on page 695. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 727.

Sync Interface Changes with the Firewall Management Center

Synchronize interface changes to ensure the Firewall Management Center and device configurations remain aligned when physical interfaces are added or removed.

Interface changes on the device can cause the Firewall Management Center and the device to get out of sync. The Firewall Management Center can detect interface changes by one of these methods:

- Event sent from the device
- Synchronize when you deploy from the Firewall Management Center

  If the Firewall Management Center detects interface changes when it attempts to deploy, the deployment will fail. You must first accept the interface changes.
- Manual synchronization

There are two types of interface changes performed outside of Firewall Management Center that need to be synchronized:

- Addition or deletion of physical interfaces—Adding a new interface, or deleting an unused interface has minimal impact on the Firewall Threat Defense configuration. However, deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the Firewall Threat Defense configuration, including access rules, NAT, SSL, identity rules,

VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected. You can also edit the membership of an allocated EtherChannel without affecting the logical device or requiring a sync on the Firewall Management Center.

When the Firewall Management Center detects changes, the **Interface** page shows status (removed, changed, or added) to the left of each interface.

- Firewall Management Center access interface changes—If you configure a data interface for managing management center using the **configure network management-data-interface** command, you must manually make matching configuration changes in management center and then acknowledge the changes. These interface changes cannot be made automatically.

This procedure describes how to manually sync interface changes if required and how to acknowledge the detected changes. If interface changes are temporary, you should not save the changes in the Firewall Management Center; you should wait until the device is stable, and then re-sync.

Before you begin

- User roles:
  - Admin
  - Access Admin
  - Network Admin

Follow these steps to sync interface changes with the Firewall Management Center:

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

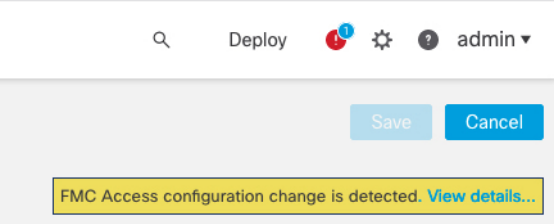
Step 2 If required, click **Sync Device** on the top left of **Interfaces**.

Step 3 After the changes are detected, see these steps.

Addition or Deletion of Physical Interfaces

a) You will see a red banner on **Interfaces** indicating that the interface configuration has changed. Click the **Click to know more** link to view the interface changes.

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

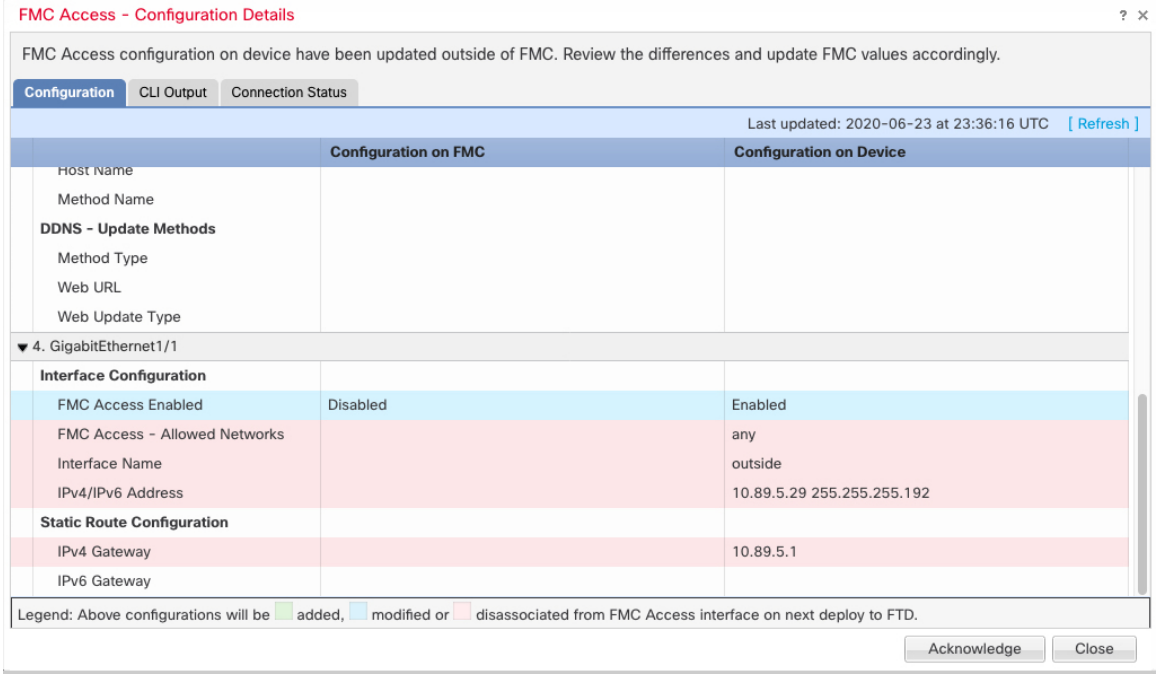


If there are any errors, you need to change your policy and rerun the validation.

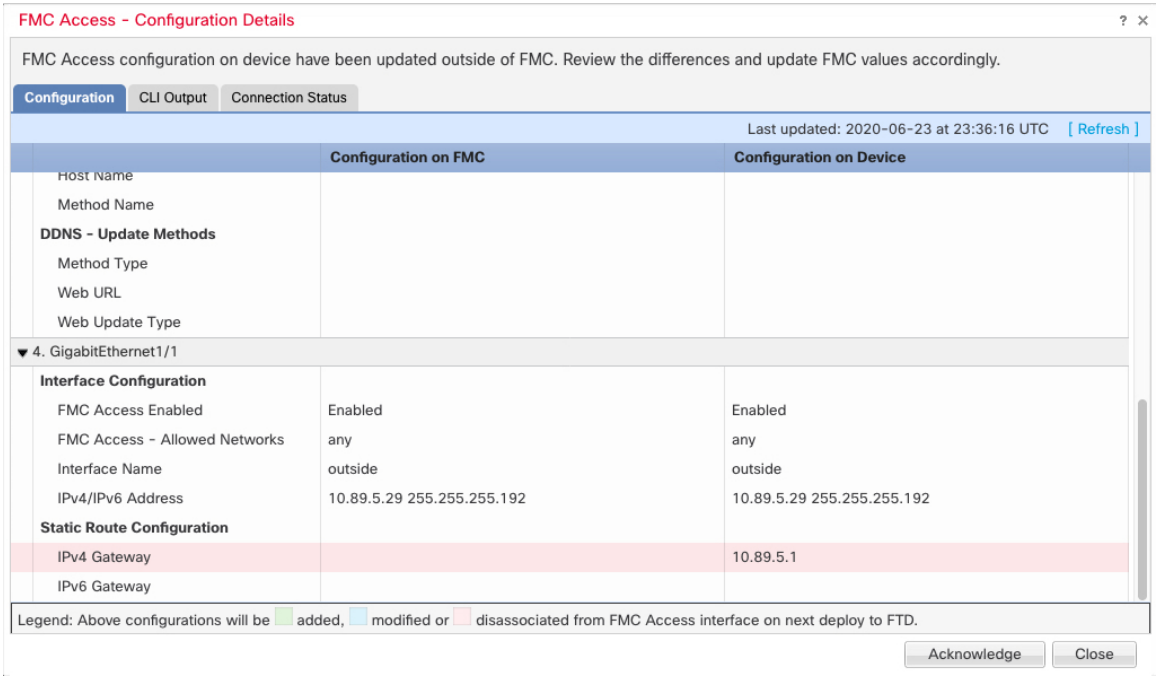
c) Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices.

FMC Access Interface Changes



a) You will see a yellow banner in the top right of the **Device** page indicating that the Firewall Management Center access configuration has changed. Click the **View details** link to view the interface changes.



The **FMC Access - Configuration Details** dialog box opens.

b) Take note of all highlighted configurations, especially the pink highlighted ones. You need to match any values on the Firewall Threat Defense by manually configuring them on the Firewall Management Center.

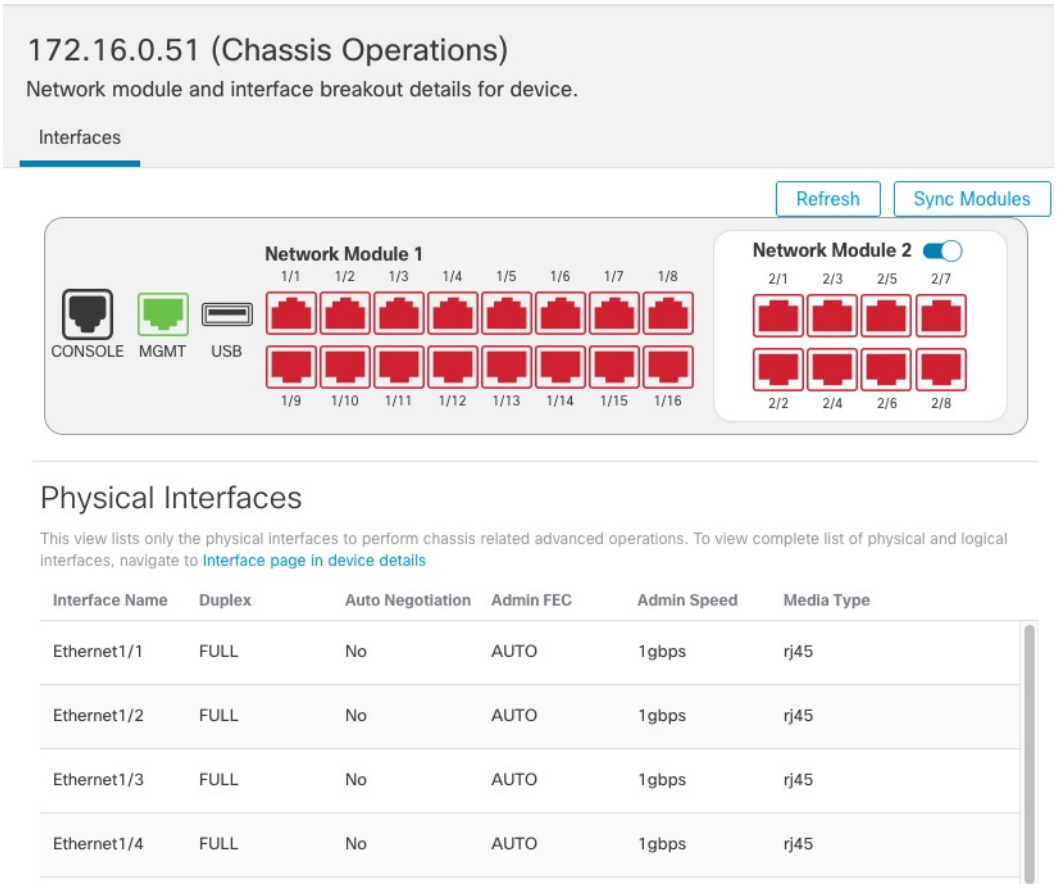
For example, the pink highlights show configuration that exists on the Firewall Threat Defense but not yet on the Firewall Management Center.

This example shows this page after configuring the interface in Firewall Management Center; the interface settings match, and the pink highlight was removed.

c) Click **Acknowledge**.

We recommend that you do not click **Acknowledge** until you have finished the Firewall Management Center configuration, and are ready to deploy. Clicking **Acknowledge** removes the block on deployment. The next time you deploy, the Firewall Management Center configuration will overwrite any remaining conflicting settings on the Firewall Threat Defense. It is your responsibility to manually fix the configuration in the Firewall Management Center before you re-deploy.

d) You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices.



Network module management for Secure Firewall 3100/4200

If you install a network module before powering on the device, the network module becomes enabled and ready for use automatically.

Network module management operations

To view physical interface details for the device, and to manage the network module, open the **Chassis Operations** page. From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit. The **Chassis Operations** page opens for the device.

Figure 236: Chassis operations

Click **Refresh** to refresh interface status. Click **Sync Modules** if you made a hardware change on the device that you need to detect.

If you need to make changes to your network module installation after initial bootup, then see the following procedures.

Configure breakout ports

This task configures breakout ports to create smaller ports from 40GB or higher interfaces, allowing you to split a single high-capacity interface into multiple physical Ethernet ports that can be used like any other physical Ethernet port, including being added to EtherChannels.

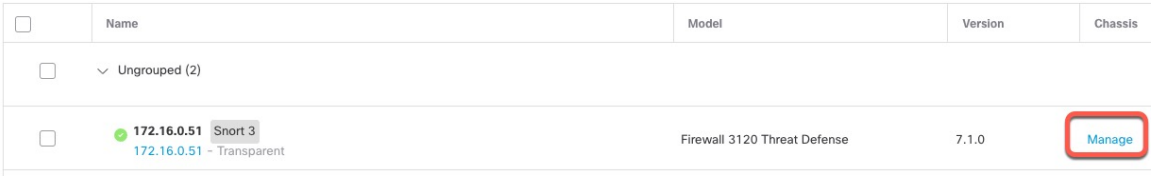
You can configure smaller breakout ports for each 40GB or higher interface. This procedure tells you how to break out and rejoin the ports. The breakout ports can be used just like any other physical Ethernet port, including being added to EtherChannels. For example, you can break out four 10GB ports from a 40GB interface. The exact size and number of ports depends on your model.

Changes are immediate; you do not need to deploy to the device. After you break or rejoin, you cannot roll back to the previous interface state.

Before you begin

- You must use a supported breakout cable. See the hardware installation guide for more information.

- The interface cannot be in use for the following before breaking or rejoining:
  - Failover link
  - Cluster control link
  - Have a subinterface
  - EtherChannel member
  - BVI member
  - Manager access interface
- Breaking or rejoining an interface that is used directly in your security policy can impact the configuration; however, the action is not blocked.



Follow these steps to configure breakout ports:

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column.

For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 237: Manage chassis

The **Chassis Operations** page opens for the device (in multi-instance mode, this page is called **Chassis Manager**). This page shows physical interface details for the device.

Step 2 Break out ports from a 40GB or higher interface.

a) Click **Break** ( ) to the right of the interface.

Click **Yes** on the confirmation dialog box. If the interface is in use, you will see an error message. You must resolve any use cases before you can retry the breakout.

For example, to break out the Ethernet2/1 40GB interface, the resulting child interfaces will be identified as Ethernet2/1/1, Ethernet2/1/2, Ethernet2/1/3, and Ethernet2/1/4.

On the interfaces graphic, a port that is broken out has this appearance:

Figure 238: Breakout ports

b) Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

Figure 239: Go to interface page

c) At the top of the **Interfaces** page, click **Click to know more**.

The **Interface Changes** dialog box opens.

Figure 240: View interface changes

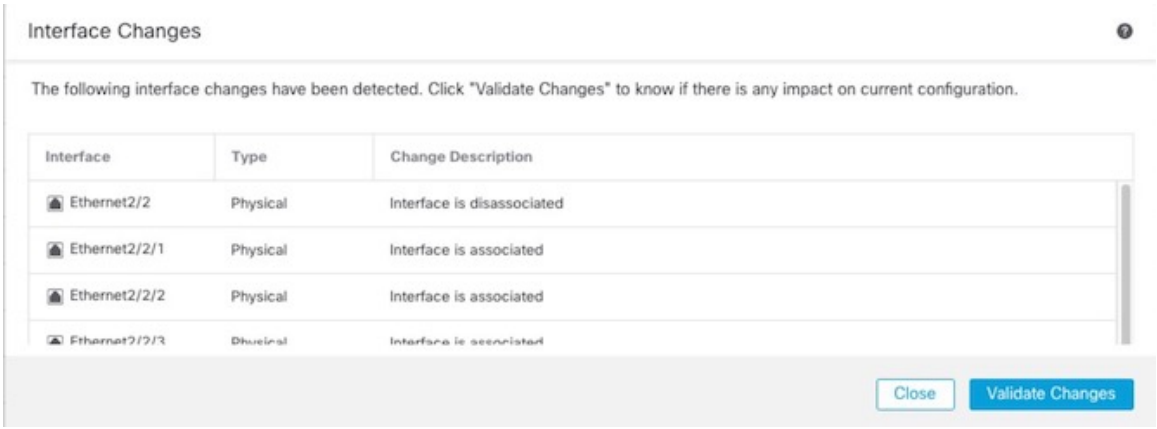


Figure 241: Interface changes

d) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, change your policy and rerun the validation.

Replacing the parent interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

e) Click **Close** to return to the **Interfaces** page.

f) Click **Save** to save the interface changes to the firewall.

g) If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

You do not need to deploy just to save the breakout port changes.

Step 3 Rejoin breakout ports.

You must rejoin all child ports for the interface.

a) Click **Join** ( ) to the right of the interface.

Click **Yes** on the confirmation dialog box. If any child ports are in use, you will see an error message. You must resolve any use cases before you can retry the rejoin.

b) Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

Figure 242: Go to interface page

c) At the top of the **Interfaces** page, click **Click to know more**.

The **Interface Changes** dialog box opens.

Figure 243: View interface changes

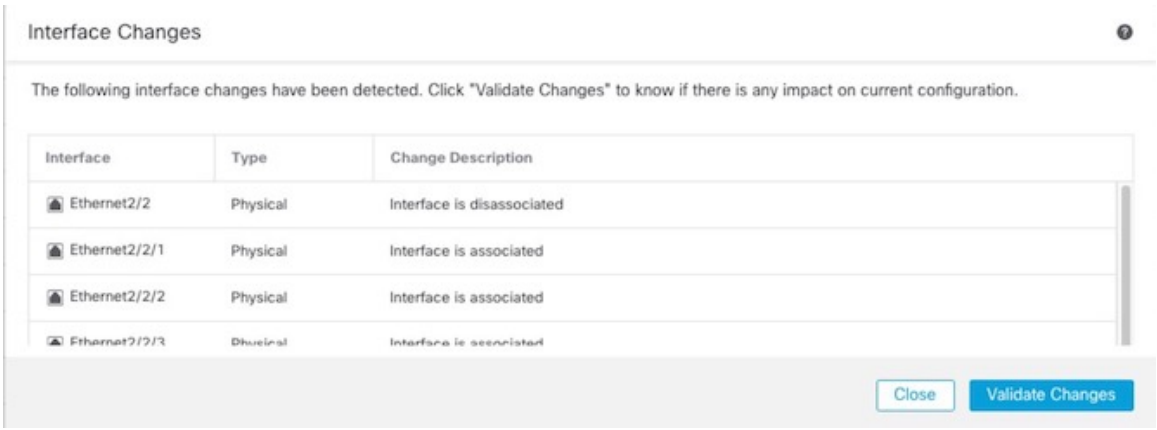

Figure 244: Interface changes

d) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Replacing the child interfaces that are used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

e) Click **Close** to return to the **Interfaces** page.

f) Click **Save** to save the interface changes to the firewall.

g) If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

You do not need to deploy just to save the breakout port changes.

Add a network module

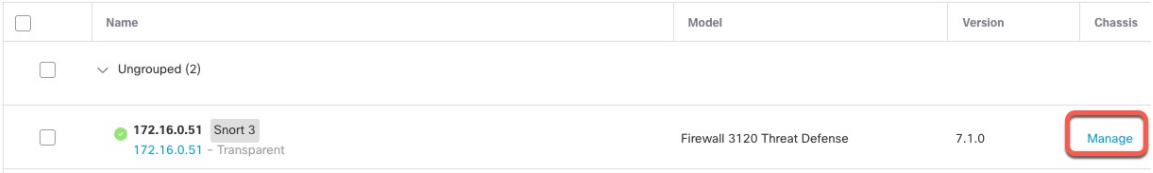
This task enables you to add network module functionality to a firewall that is already operational, expanding its interface capabilities.

Adding a new module requires a reboot of the firewall system.

Procedure

Step 1 Install the network module according to the hardware installation guide.

For clustering or High Availability, install the network module on all nodes.



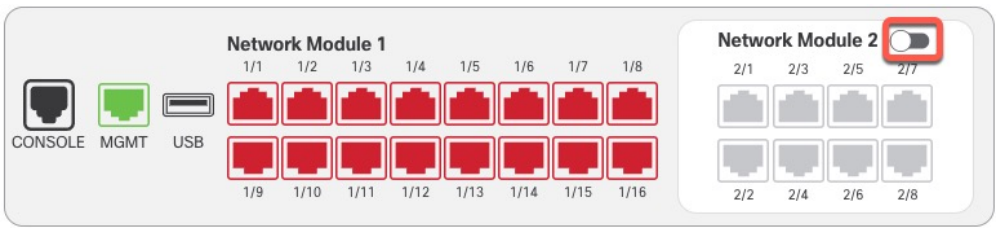
Step 2 Reboot the firewall; see Shut down or restart the device, on page 55.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 312), and reboot the former control node/active unit.

Step 3 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column.

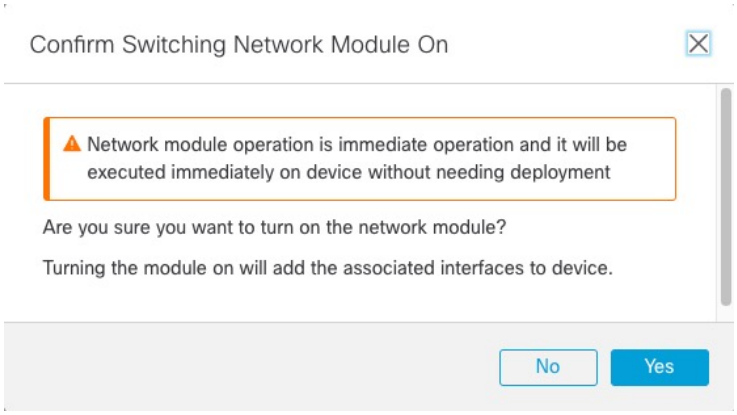
For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 245: Manage chassis



The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 4 Click **Sync Modules** to update the page with the new network module details.



Step 5 On the interfaces graphic, click the slider ( ) to enable the network module.

Figure 246: Enable the network module

Step 6 You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 247: Confirm enable

Step 7 You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

Figure 248: Go to interface page

Step 8 (Optional) At the top of the **Interfaces** page, you see a message that the interface configuration has changed. You can click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 249: View interface changes

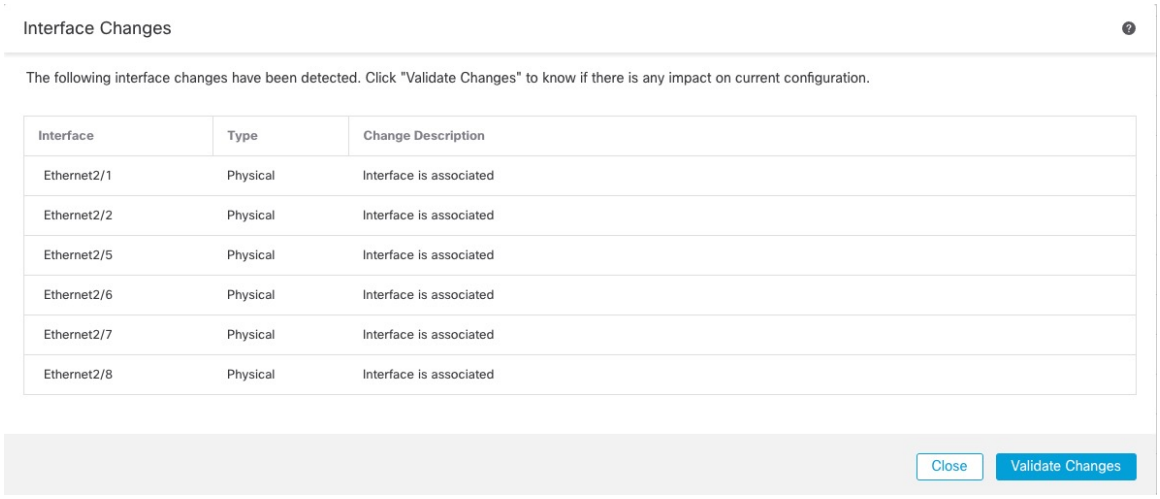


Figure 250: Interface changes

Click **Close** to return to the **Interfaces** page. (Because you are adding a new module, there shouldn't be any configuration impact, so you do not need to click **Validate Changes**.)

Step 9 Click **Save** to save the interface changes to the firewall.

Hot swap the network module

You can hot swap a network module for a new module of the same type without having to reboot.

You must shut down the current module to remove it safely. This procedure describes how to shut down the old module, install a new module, and enable it.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit. You cannot disable a network module if the cluster control link/failover link is on the module.

Procedure

Step 1 For clustering or High Availability, perform the following steps.

- **Clustering**—Ensure the unit you want to perform the hot swap on is a data node; then break the node so it is no longer in the cluster.

  You will add the node back to the cluster after you perform the hot swap. Alternatively, you can perform all operations on the control node, and the network module changes will sync to all data nodes. However, you will lose use of those interfaces on all nodes during the hot swap.

- **High Availability**—To avoid failing over when you disable the network module:
  - If the failover link is on the network module, you must break High Availability. See Break a high availability pair, on page 316. Disabling the network module with an active failover link is not allowed.
  - Disable interface monitoring for interfaces on the network module. See Configure standby IP addresses and interface monitoring, on page 309.

Step 2 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column.

For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

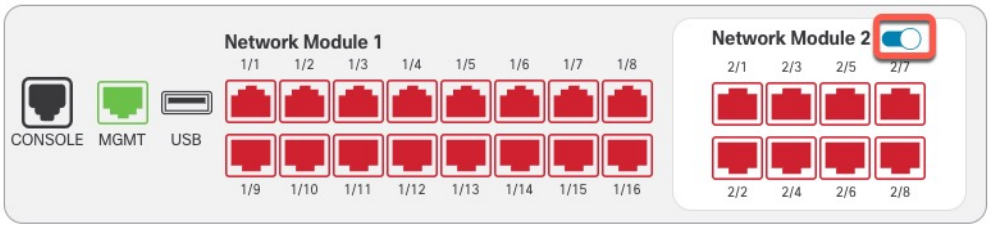

Figure 251: Manage chassis

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 3 On the interfaces graphic, click the slider ( ) to disable the network module.

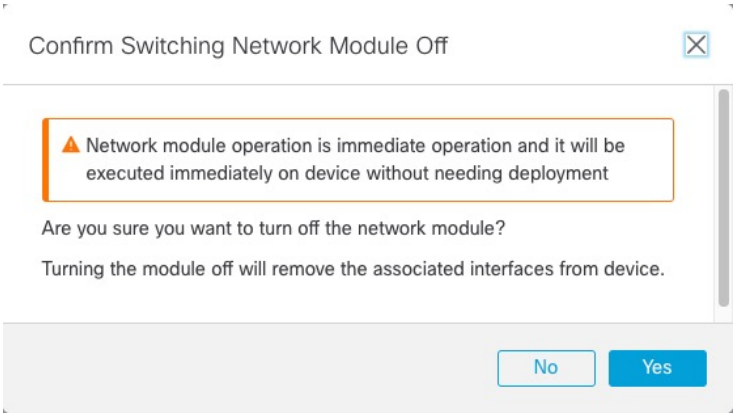

Figure 252: Disable the network module

Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

Step 4 You are prompted to confirm that you want to turn the network module off. Click **Yes**.

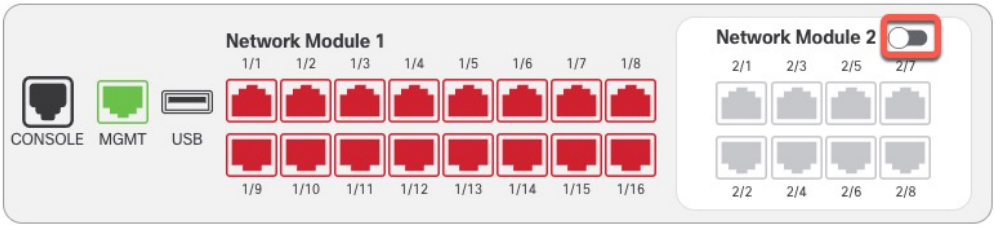

Figure 253: Confirm disable

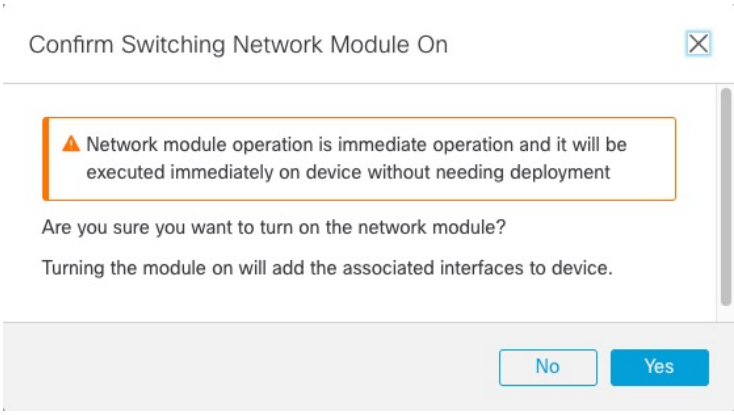
Step 5 On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.



Step 6 In the Firewall Management Center, enable the new module by clicking the slider ( ).

Figure 254: Enable the network module

Step 7 You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 255: Confirm enable

Step 8 For clustering or High Availability, perform the following steps.

- **Clustering**—Add the node back to the cluster.
- **High Availability**—
  - If you broke High Availability, then reform High Availability. See Add a high availability pair, on page 306.
  - Reenable interface monitoring for interfaces on the network module. See Configure standby IP addresses and interface monitoring, on page 309.

Replace the network module with a different type

Replace an existing network module with a different type to accommodate new interface requirements or hardware upgrades.

If you replace a network module with a different type, then a reboot is required. If the new module has fewer interfaces than the old module, you will have to manually remove any configuration related to interfaces that will no longer be present.

For clustering or High Availability, you can only perform chassis operations on the control node or active unit.

Before you begin

For High Availability, you cannot disable a network module if the failover link is on the module. You will have to break the high availability pair (see Break a high availability pair, on page 316), which means you will have downtime when you reboot the active unit. After the units finish rebooting, you can reform High Availability.

Follow these steps to replace the network module with a different type:

Procedure

Step 1 For clustering or High Availability, perform the following steps.

- **Clustering**—To avoid downtime, you can break each node one at a time so it is no longer in the cluster when you perform the network module replacement.

  Add the node back to the cluster after the replacement.

- **High Availability**—To avoid failing over when you replace the network module, disable interface monitoring for interfaces on the network module. See Configure standby IP addresses and interface monitoring, on page 309.

Step 2 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column.

For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 256: Manage chassis

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 3 On the interfaces graphic, click the slider ( ) to disable the network module.

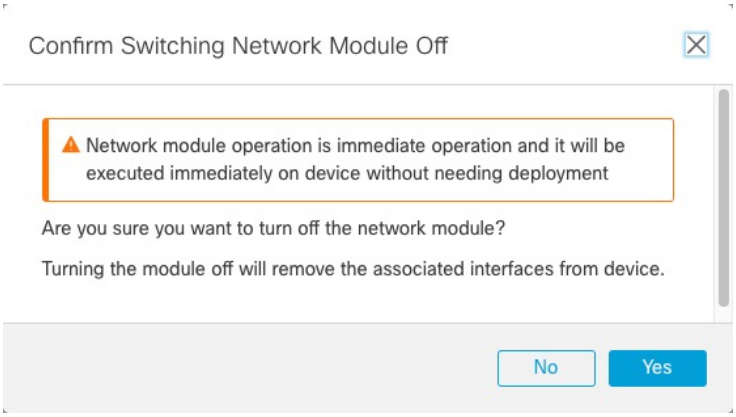


Figure 257: Disable the network module

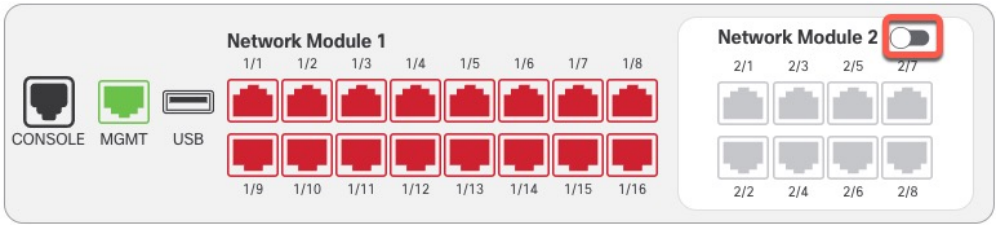
Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

a) You are prompted to confirm that you want to turn the network module off. Click **Yes**.

Figure 258: Confirm disable

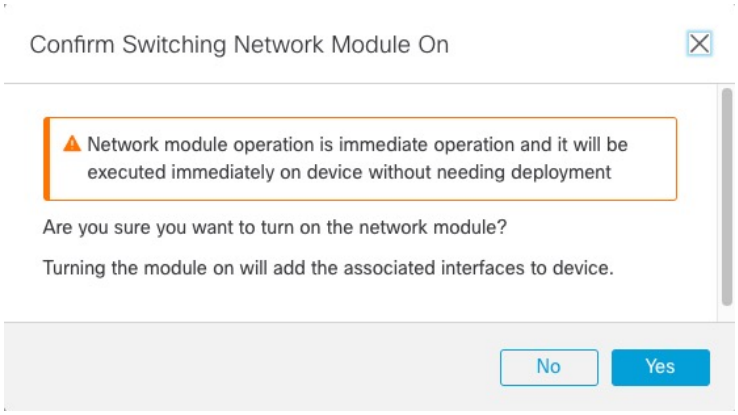
Step 4 On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.



Reboot the firewall. Refer to Shut down or restart the device, on page 55 for guidance.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 312), and reboot the former control node/active unit.

Step 5 In the Firewall Management Center, click **Sync Modules** to update the page with the new network module details.



Step 6 Enable the new module by clicking the slider ( ).

Figure 259: Enable the network module

a) Click **Yes** when prompted to confirm that you want to turn the network module on.

Figure 260: Confirm enable

Step 7 Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

Figure 261: Go to interface page

Step 8 If the network module has *fewer* interfaces:

a) At the top of the **Interfaces** page, click **Click to know more**.

The **Interface Changes** dialog box opens.

Figure 262: View interface changes

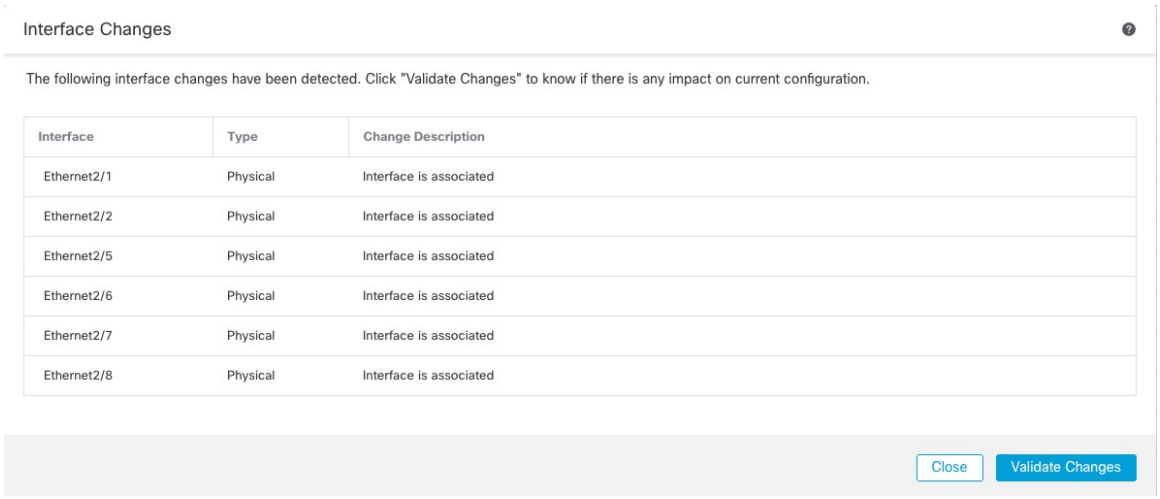


Figure 263: Interface changes

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

Step 9 To change the interface speed, see Enable the physical interface and configure Ethernet settings, on page 611.

The default speed is set to Detect SFP, which detects the correct speed from the SFP installed. You only need to fix the speed if you manually set the speed to a particular value and you now need a new speed.

Click **Save** to save the interface changes to the firewall.

What to do next

- If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.
- For clustering, add the node back to the cluster.
- For high availability, reenable interface monitoring for interfaces on the network module. See Configure standby IP addresses and interface monitoring, on page 309.

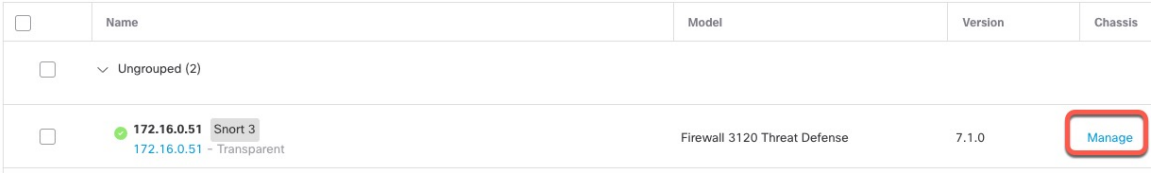
Remove the network module

Remove a network module permanently from the chassis when it is no longer needed or requires replacement.

If you want to permanently remove the network module, follow these steps. Removing a network module requires a reboot.

For clustering or High Availability, you can only perform chassis operations on the control node or active unit.

Before you begin



For clustering or High Availability, make sure the cluster or failover link is not on the network module.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column.

For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

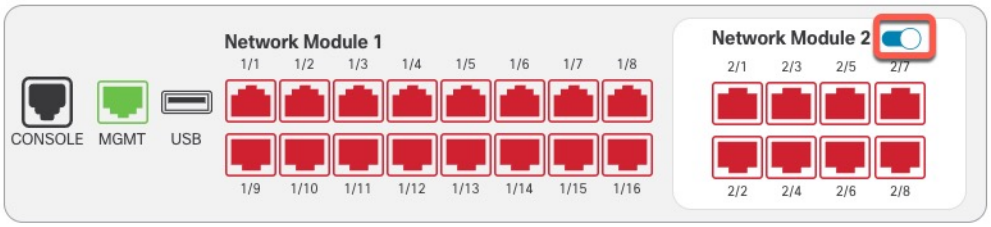


Figure 264: Manage chassis

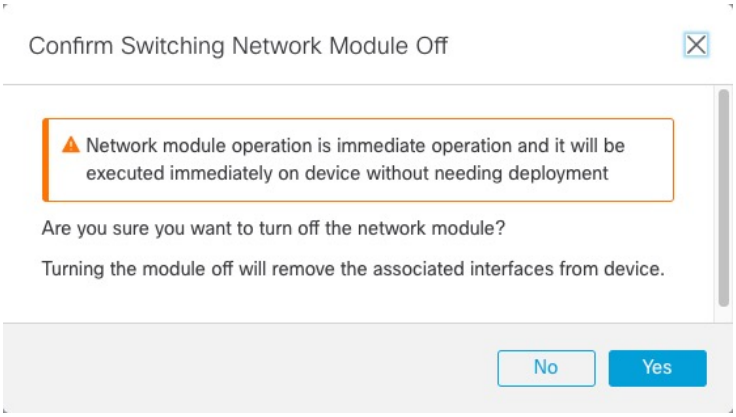
The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.



Step 2 On the interfaces graphic, click the slider ( ) to disable the network module.

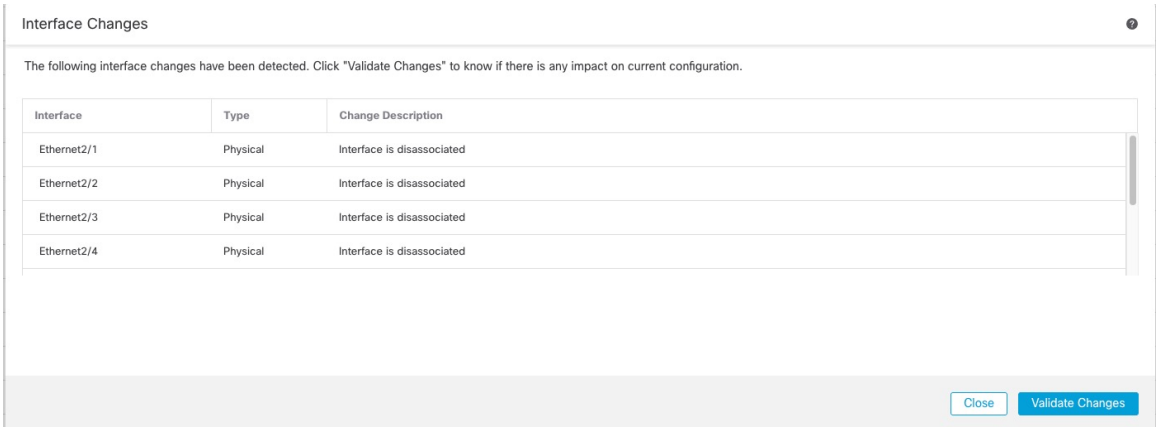
Figure 265: Disable the network module

Step 3 You are prompted to confirm that you want to turn the network module off. Click **Yes**.

Figure 266: Confirm disable

Step 4 You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

Figure 267: Go to interface page



Step 5 At the top of the **Interfaces** page, you see a message that the interface configuration has changed.

Figure 268: View interface changes

a) Click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 269: Interface changes

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

Step 6 Click **Save** to save the interface changes to the firewall.

Step 7 If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

Step 8 Reboot the firewall; see Shut down or restart the device, on page 55.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 312), and reboot the former control node/active unit.

Merge the management and diagnostic interfaces

This task merges the Management and Diagnostic interfaces on devices that have existing Diagnostic interface configurations that prevent automatic merging.

Starting with version 7.4, Firewall Threat Defense supports a merged Management and Diagnostic interface. "If your configuration uses the Diagnostic interface, the interfaces are not merged automatically. You must perform this procedure to complete the merge. This procedure requires you to acknowledge configuration changes and, in some cases, manually fix the configuration.

The Backup/Restore and Firewall Management Center configuration rollback functions save and restore the merged state, whether it is non-merged or merged. For example, if you merge the interfaces and then restore an old non-merged configuration, the restored configuration will be in a non-merged state.

This table shows the available configuration on the legacy Diagnostic interface, and how the merge is completed.

Before you begin

- To view the current mode of the device, enter the **show management-interface convergence** command at the Firewall Threat Defense CLI. The following output shows that the Management interfaces are merged:

```
> show management-interface convergence
management-interface convergence
>
```

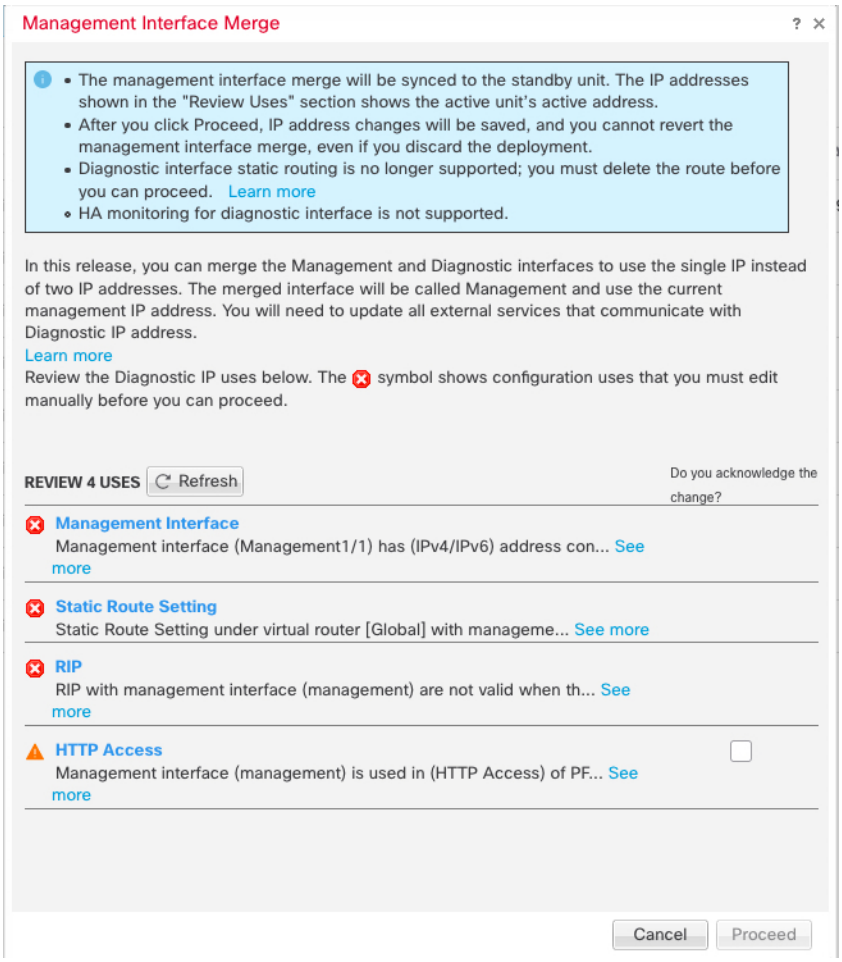
  The following output shows that the Management interfaces are not merged:

```
> show management-interface convergence
no management-interface convergence
>
```

- For High Availability pairs and clusters, perform this task on the active/control unit. The merged configuration will be replicated automatically to the standby/data units.

Follow these steps to merge the Management and Diagnostic interfaces:

Procedure



Step 1 Choose **Devices** > **Device Management**, and click **Edit** ( ) for your Firewall Threat Defense. The **Interfaces** page is selected by default. .

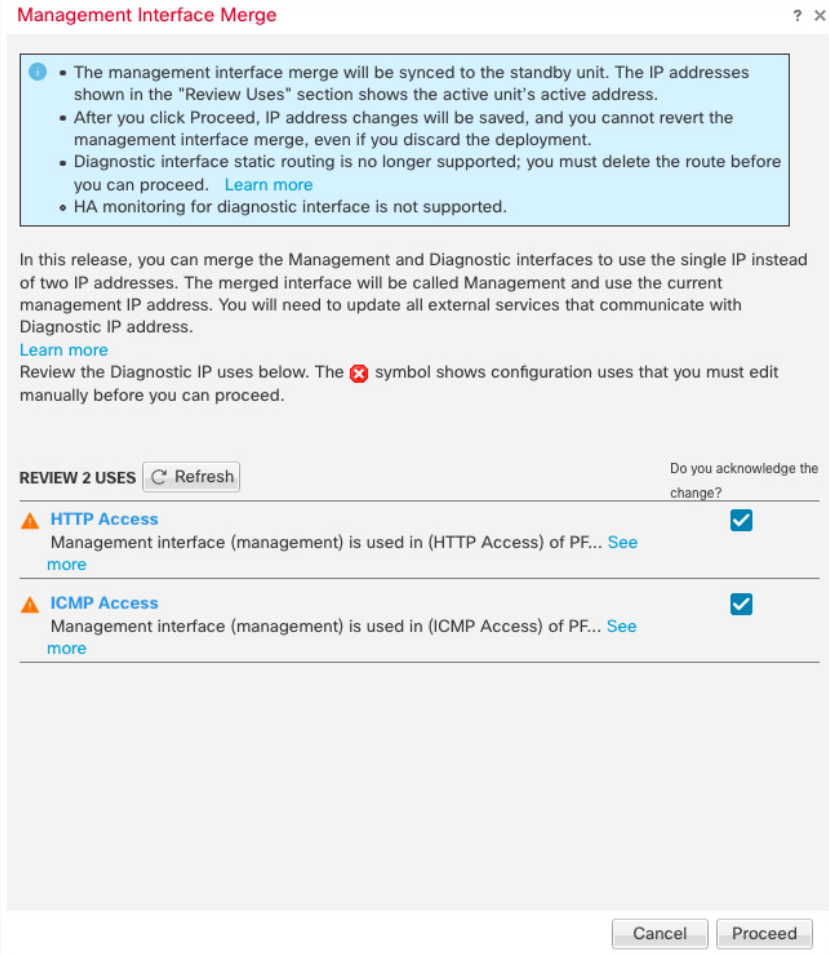
Step 2 Edit the Diagnostic interface, and remove the IP address.

You cannot complete the merge until after you have removed the Diagnostic IP address.

Step 3 Click **Management Interface Merge** in the **Management Interface action needed** area.

The **Management Interface Merge** dialog box shows all the occurrences of the Diagnostic interface in the configuration. For any occurrences that require you to manually remove or change the configuration, they will appear with a warning icon. Platform Settings that will no longer work on your device are marked with a caution icon and require your acknowledgement.

Step 4 If you need to manually remove or change any listed configurations, do the following.



a) Click **Cancel** to close the **Management Interface Merge** dialog box.

b) Navigate to the feature area. You can then delete the item, or choose a data interface instead.

c) Reopen the **Management Interface Merge** dialog box.

There should no longer be any warnings.

Step 5 For each configuration caution, click the box in **Do you acknowledge the change?** column, and then click **Proceed**.

After the configuration is merged, you see a success banner:

Step 6 Deploy the new merged configuration.

Caution After you deploy the merged configuration, you can unmerge the interfaces from Firewall Management Center; however the Diagnostic interface will have to be reconfigured manually. See Unmerge the management interface, on page 644. Also, if you restore a configuration that is unmerged, or roll back to an unmerged configuration, then the device will revert to that unmerged configuration.

After the merge, the Management interface is shown on the **Interfaces** page, although it is read-only.

Step 7 After the merge, if you had any external services that communicated with the Diagnostic interface, you need to change their configuration to use the Management interface IP address.

For example:

- SNMP client

- RADIUS server—RADIUS servers often verify the IP address for incoming traffic, so you need to change that IP address to the Management address. Moreover, for a High Availability pair, you need to allow both the primary and secondary Management IP addresses; the Diagnostic interface used to support a single "floating" IP address that stayed with the active unit, but Management does not support that functionality.

Unmerge the management interface

This task separates the merged Management and Diagnostic interface into two distinct interfaces. This is useful when migrating network configurations or when separate interface management is required for specific network architectures.

The Firewall Threat Defense 7.4 and later supports a merged Management and Diagnostic interface. If you need to unmerge your interfaces, perform this procedure. We recommend using unmerged mode temporarily while you migrate your network to a merged mode deployment. Separate Management and Diagnostic interfaces may not be supported in all future releases.

Unmerging the interfaces does not restore your original Diagnostic configuration (if you upgraded and then merged your interfaces). You will need to reconfigure the Diagnostic interface manually. Also, the Management interface will now be named "management"; you cannot rename it "diagnostic."

Alternatively, if you used the Backup function to save an old unmerged configuration, you can restore that configuration or you can use the or Firewall Management Center configuration rollback feature, and the device will be in an unmerged state with the Diagnostic configuration intact.

Before you begin

- To view the current mode of the device, enter the **show management-interface convergence** command at the Firewall Threat Defense CLI. The following output shows that the Management interfaces are merged:

```
> show management-interface convergence
management-interface convergence
>
```

  The following output shows that the Management interfaces are not merged:

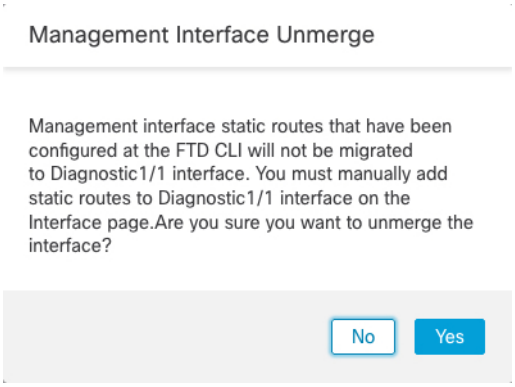
```
> show management-interface convergence
no management-interface convergence
>
```

- For High Availability pairs and clusters, perform this task on the active/control unit. The merged configuration will be replicated automatically to the standby/data units.

Follow these steps to unmerge the Management Interface:

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** ( ) for your Firewall Threat Defense. The **Interfaces** page is selected by default.



Step 2 For the Management interface, click **Unmerge Management Interface** ( ).

Figure 270: Management interface selection

Step 3 Click **Yes** to confirm that you want to unmerge the interface.

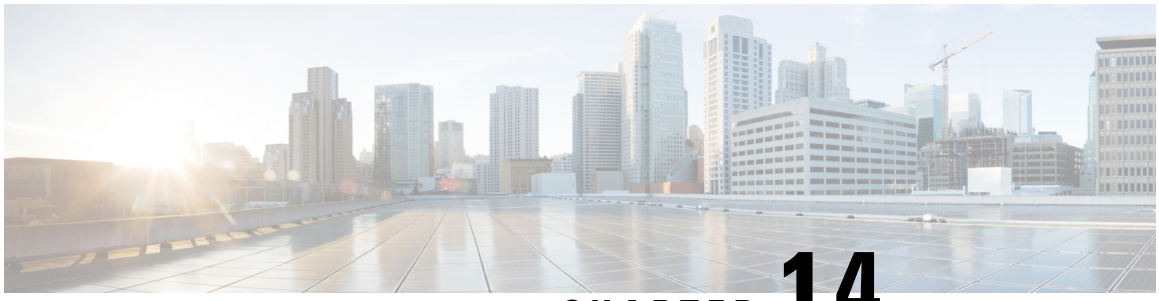
Figure 271: Unmerge confirmation

Step 4 Deploy the new unmerged configuration.

Note If you restore a configuration that is merged, or roll back to a merged configuration, then the device will revert to that merged configuration.

After the merge, the Management interface is no longer shown on the **Interfaces** page.

History for interfaces



This reference provides the complete version history for interface-related features, enhancements, and changes across different versions of the Secure Firewall system.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Loopback and Management type interface group objects	7.4.0	7.4.0	You can now create interface group objects that include only management-only interfaces or only loopback interfaces. You can then use these groups for management features such as DNS servers, HTTP access, or SSH. Loopback groups are supported for any feature that supports loopback interfaces. Note that DNS does not support management interfaces. New/Modified screens: **Objects** > **Object Management** > **Interface** > **Add** > **Interface Group**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Merged Management and Diagnostic interfaces	7.4.0	7.4.0	For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available. If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically. If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Note that support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. Merged mode also changes the behavior of AAA traffic to use the data routing table by default. The management-only routing table can now only be used if you specify the management-only interface (including Management) in the configuration. New/Modified screens: **Devices** > **Device Management** > **Interfaces** New/Modified commands: **show management-interface convergence**
Default Forward Error Correction (FEC) on Secure Firewall 3100 fixed ports changed to Clause 108 RS-FEC from Clause 74 FC-FEC for 25 GB+ SR, CSR, and LR transceivers	7.2.4	7.2.4	When you set the FEC to Auto on the Secure Firewall 3100 fixed ports, the default type is now set to Clause 108 RS-FEC instead of Clause 74 FC-FEC for 25 GB+ SR, CSR, and LR transceivers.
LLDP support for the Firepower 2100, Secure Firewall 3100	7.2.0	7.2.0	You can enable Link Layer Discovery Protocol (LLDP) for Firepower 2100 and Secure Firewall 3100 interfaces. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Network Connectivity** New/Modified commands: **show LLDP status**, **show LLDP neighbors**, **show LLDP statistics**
Pause Frames for Flow Control for the Secure Firewall 3100	7.2.0	7.2.0	If you have a traffic burst, dropped packets can occur if the burst exceeds the buffering capacity of the FIFO buffer on the NIC and the receive ring buffers. Enabling pause frames for flow control can alleviate this issue. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Network Connectivity**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Support for hot swapping the network module for the Secure Firewall 3100	7.1.0	7.1.0	You can add or remove the network module on the Secure Firewall 3100 while the firewall is powered up. To replace a module with another module of the same type, you do not need to reboot. After initial bootup, adding a module, permanently removing a module, or replacing a module with a new type requires a reboot. New/Modified screens: **Devices** > **Device Management** > **Chassis Operations**
Support for Forward Error Correction for the Secure Firewall 3100	7.1.0	7.1.0	Secure Firewall 3100 25 Gbps interfaces support Forward Error Correction (FEC). FEC is enabled by default and set to Auto. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **Hardware Configuration**
Support for setting the speed based on the SFP for the Secure Firewall 3100	7.1.0	7.1.0	The Secure Firewall 3100 supports speed detection for interfaces based on the SFP installed. Detect SFP is enabled by default. This option is useful if you later change the network module to a different model, and want the speed to update automatically. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **Hardware Configuration**
LLDP support for the Firepower 1100.	7.1.0	7.1.0	You can enable Link Layer Discovery Protocol (LLDP) for Firepower 1100 interfaces. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **LLDP** New/Modified commands: **show LLDP status**, **show LLDP neighbors**, **show LLDP statistics**
Interface auto-negotiation is now set independently from speed and duplex, interface sync improved.	7.1.0	7.1.0	Interface auto-negotiation is now set independently from speed and duplex. Also, when you sync the interfaces in Firewall Management Center, hardware changes are detected more effectively. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Speed** Supported platforms: Firepower 1000, 2100, Secure Firewall 3100

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Firepower 1100/2100 series fiber interfaces now support disabling auto-negotiation.	6.7.0	6.7.0	You can now configure a Firepower 1100/2100 series fiber interface to disable flow control and link status negotiation. Previously, when you set the fiber interface speed (1000 or 10000 Mbps) on these devices, flow control and link status negotiation was automatically enabled. You could not disable it. Now, you can deselect **Auto-negotiation** and set the speed to 1000 to disable flow control and link status negotiation. You cannot disable negotiation at 10000 Mbps. New/modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Speed**

CHAPTER 14

Regular Firewall Interfaces

This chapter includes regular firewall Firewall Threat Defense interface configuration including EtherChannels, VLAN subinterfaces, IP addressing, and more.

Note For initial interface configuration on the Firepower 4100/9300, see Configure interfaces, on page 259.

- Requirements and prerequisites for regular firewall interfaces, on page 649
- Configure switch ports, on page 650
- Loopback interfaces, on page 661
- Guidelines for Loopback Interfaces, on page 662
- Configure a loopback interface, on page 662
- Rate-Limit traffic to the loopback interface, on page 663
- VLAN subinterfaces and 802.1Q trunking, on page 667
- Configure VXLAN Interfaces, on page 671
- Configure routed and transparent mode interfaces, on page 686
- Advanced interface settings, on page 711
- History for Regular Firewall Interfaces, on page 723

Requirements and prerequisites for regular firewall interfaces

This reference provides the requirements and prerequisites for configuring regular firewall interfaces, including supported models and required user roles.

Model support

Firewall Threat Defense

User roles

- Admin
- Access Admin
- Network Admin

Configure switch ports

For supported platforms, you can configure each interface to run as a regular firewall interface or as a Layer 2 hardware switch port. This section includes tasks for starting your switch port configuration, including enabling or disabling the switch mode and creating VLAN interfaces and assigning them to switch ports. This section also describes how to customize Power over Ethernet (PoE) on supported interfaces.

About switch ports

This section describes the switch ports for models with Layer 2 switches.

Switch ports and interfaces

Switch ports and firewall operate at different OSI layers to handle traffic forwarding.

Port and interface types

For each physical interface, you can set its operation as a firewall interface or as a switch port. This information describes physical interface and port types as well as logical VLAN interfaces to which you assign switch ports:

- Physical firewall interface—In routed mode, these interfaces forward traffic between networks at Layer 3, using the configured security policy to apply firewall and VPN services. In transparent mode, these interfaces are bridge group members that forward traffic between the interfaces on the same network at Layer 2, using the configured security policy to apply firewall services. In routed mode, you can also use Integrated Routing and Bridging with some interfaces as bridge group members and others as Layer 3 interfaces. By default, the Ethernet 1/1 interface is configured as a firewall interface. You can also configure these interfaces to be IPS-only (passive interfaces).
- Physical switch port—Switch ports forward traffic at Layer 2, using the switching function in hardware. Switch ports on the same VLAN can communicate with each other using hardware switching, and traffic is not subject to the Firewall Threat Defense security policy. Access ports accept only untagged traffic, and you can assign them to a single VLAN. Trunk ports accept untagged and tagged traffic, and can belong to more than one VLAN. By default, Ethernet 1/2 and subsequent ports are configured as access switch ports on VLAN 1. You cannot configure the Management interface as a switch port.
- Logical VLAN interface—These interfaces operate the same as physical firewall interfaces, with the exception that you cannot create subinterfaces, IPS-only interfaces (inline sets and passive interfaces), or EtherChannel interfaces. When a switch port needs to communicate with another network, then the Firewall Threat Defense device applies the security policy to the VLAN interface and routes to another logical VLAN interface or firewall interface. You can even use Integrated Routing and Bridging with VLAN interfaces as bridge group members. Traffic between switch ports on the same VLAN are not subject to the Firewall Threat Defense security policy, but traffic between VLANs in a bridge group are subject to the security policy, so you may choose to layer bridge groups and switch ports to enforce the security policy between certain segments.

Power Over Ethernet

PoE is available on Ethernet 1/7 and Ethernet 1/8 using IEEE 802.3af (PoE) and 802.3at (PoE+) up to 30 watts per port.

Note PoE is not supported on the 1010E.

PoE+ uses Link Layer Discovery Protocol (LLDP) to negotiate the power level. Power is only supplied when needed.

If you shut down the interface, then you disable power to the device.

Auto-MDI/MDIX feature

Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase.

Auto-MDI/MDIX configuration details

For all switch ports, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. The interface enables Auto-MDI/MDIX when either the speed or duplex is set to auto-negotiate. If you set both the speed and duplex to fixed values, auto-negotiation is disabled, and Auto-MDI/MDIX is also disabled. When the speed and duplex are set to 1000 and full, the interface always auto-negotiates. Auto-MDI/MDIX enabled in this state, and disabling it is not possible.

Prerequisites for switch ports

This reference provides model support and other prerequisites for switch ports.

Model support

- Firepower 1010

Guidelines for switch ports

Context mode restrictions

Multiple context mode is not supported on several firewall models, with specific exceptions for the Secure Firewall 1210/1220.

- The Firepower 1010 does not support multiple context mode.
- The Secure Firewall 1210/1220 does not support multiple context mode.

High availability and clustering limitations

Do not use switch port functionality when using High availability because switch ports operate in hardware and continue to pass traffic on both active and standby units.

- No cluster support.
- Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching

capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Theoretically, you can put a single switch port on a VLAN and successfully use High availability, but a simpler setup is to use physical firewall interfaces instead.

- You can only use a firewall interface as the failover link.

Logical VLAN interfaces (SVIs) configuration requirements

Ensure unique VLAN IDs between logical VLAN interfaces and VLAN subinterfaces on firewall interfaces to prevent conflicts.

- If you also use VLAN subinterfaces on a firewall interface, you cannot use the same VLAN ID as for a logical VLAN interface.
- MAC Addresses:
  - Routed firewall mode—All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See Configure the MAC address, on page 718.
  - Transparent firewall mode—Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See Configure the MAC address, on page 718.

Bridge groups restrictions

You cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.

VLAN interface and switch port unsupported features

VLAN interfaces and switch ports do not support these features.

- Dynamic routing
- Multicast routing
- Equal-Cost Multi-Path routing (ECMP)
- Inline sets or Passive interfaces
- EtherChannels—Switch ports cannot be part of an EtherChannel. PoE is also not supported on a port in an EtherChannel.
- Failover and state link
- Security group tagging (SGT)

Other guidelines and limitations

Configure a maximum of 60 named interfaces and ensure the Management interface is not configured as a switch port.

Default settings

Know the default interface assignments for each firewall model to properly plan your configuration.

- Ethernet 1/1 is a firewall interface.

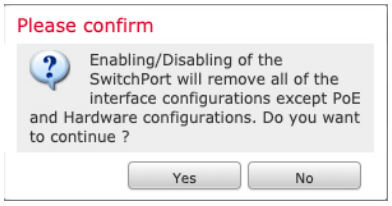
- Ethernet 1/2 through Ethernet 1/8 are switch ports assigned to VLAN 1.
- Default Speed and Duplex—By default, the speed and duplex are set to auto-negotiate.

Configure switch ports and power over ethernet

To configure switch ports and PoE, complete the following tasks.

Enable or disable switch port mode

Set each interface independently to be either a firewall interface or a switch port based on your network requirements.



You can set each interface independently to be either a firewall interface or a switch port. By default, Ethernet 1/1 is a firewall interface, and the remaining Ethernet interfaces are configured as switch ports.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

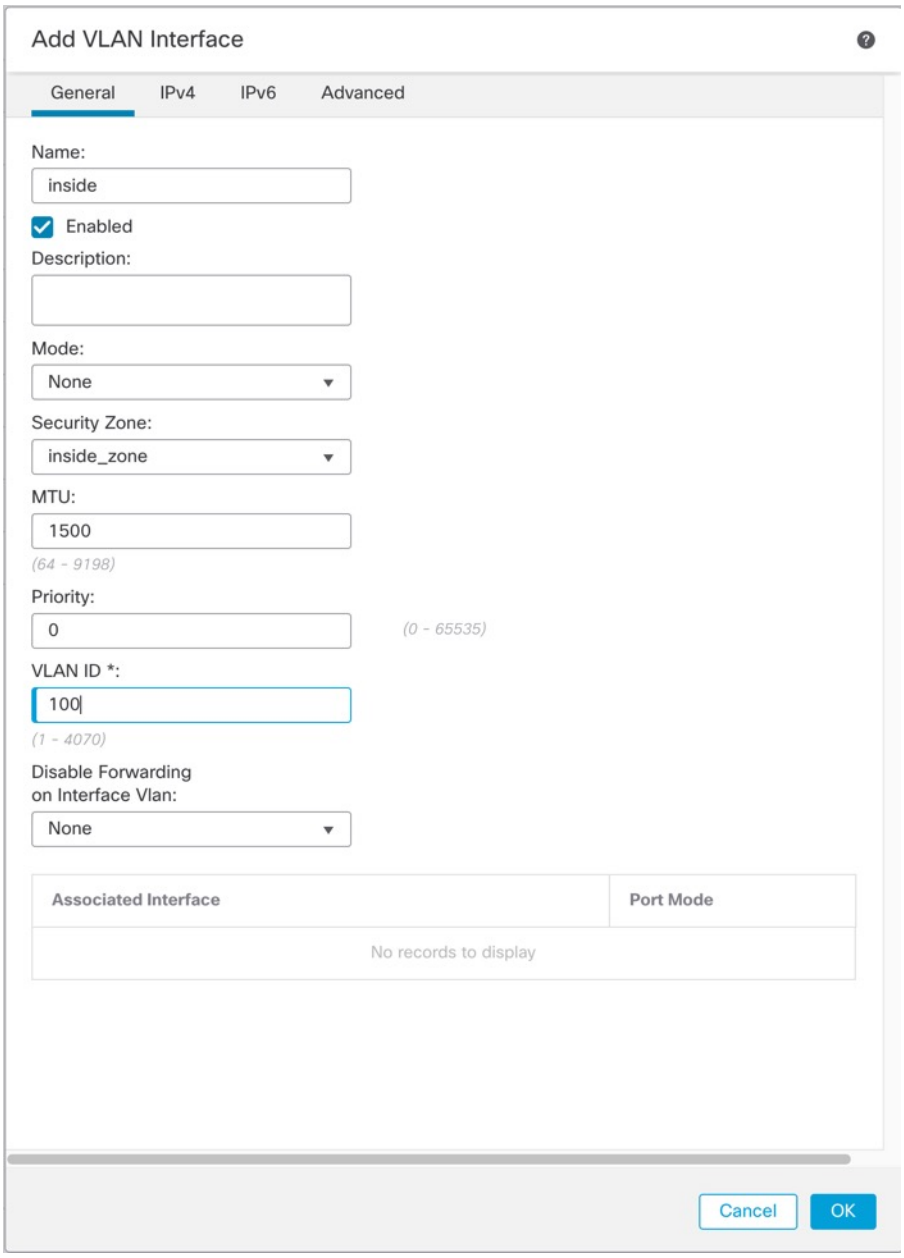
Step 2 Set the switch port mode by clicking the slider in the **SwitchPort** column so it shows as **Slider enabled** ( ) or **Slider disabled** ( ).

By default, switch ports are set to access mode in VLAN 1. You must manually add a logical VLAN 1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the Firewall Threat Defense security policy (see Configure a VLAN interface, on page 653). You cannot set the Management interface to switch port mode. When you change the switch port mode, all unsupported configuration is removed:

In addition, the interface is disabled if it was already enabled. Be sure to reenable the interface.

Configure a VLAN interface

Configure VLAN interfaces to enable traffic routing and participation in the Firewall Threat Defense security policy.



By default, switch ports are assigned to VLAN1; however, you must manually add the logical VLAN1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the Firewall Threat Defense security policy.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Add Interfaces** > **VLAN Interface**.

Step 3 On **General**, set the following VLAN-specific parameters:

If you are editing an existing VLAN interface, the **Associated Interface** table shows switch ports on this VLAN.

a) Set the **VLAN ID** between 1 and 4070, excluding IDs in the range 3968 to 4047, which are reserved for internal use.

You cannot change the VLAN ID after you save the interface; the VLAN ID is both the VLAN tag used, and the interface ID in your configuration.

b) (Optional) Choose a VLAN ID for **Disable Forwarding on Interface VLAN** to disable forwarding to another VLAN.

For example, you have one VLAN assigned to the outside for internet access, one VLAN assigned to an inside business network, and a third VLAN assigned to your home network. The home network does not need to access the business network, so you can disable forwarding on the home VLAN. The business network can access the home network, but the home network cannot access the business network.

Step 4 To complete the interface configuration, see one of these procedures:

- Configure routed mode interfaces, on page 690
- Configure general bridge group member interface parameters, on page 695

Step 5 Click **OK**.

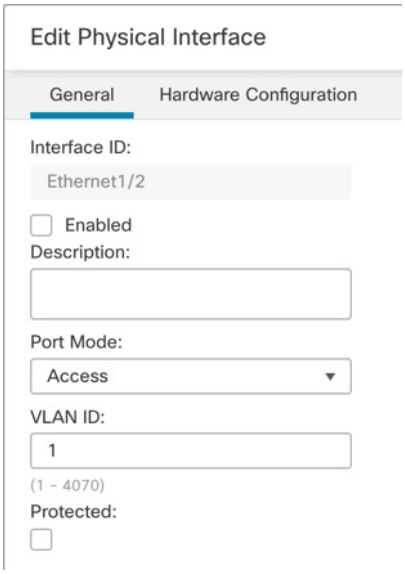
Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure switch ports as access ports

Configure switch ports as access ports to assign them to a single VLAN for network segmentation and traffic management.

To assign a switch port to a single VLAN, configure it as an access port. Access ports accept only untagged traffic. By default, Ethernet 1/2 through Ethernet 1/8 switch ports are enabled and assigned to VLAN 1.



Note The device does not support Spanning Tree Protocol for loop detection in the network. Therefore you must ensure that any connection with the Firewall Threat Defense does not end up in a network loop.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Figure 272: Edit physical interface

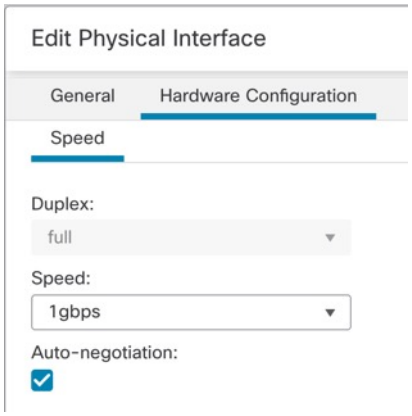
Step 3 Enable the interface by checking the **Enabled** check box.

Step 4 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 Set the **Port Mode** to **Access**.

Step 6 In the **VLAN ID** field, set the VLAN for this switch port, between 1 and 4070.



The default VLAN ID is 1.

Step 7 (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Step 8 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

Figure 273: Hardware configuration

Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

Note If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

Step 9 Click **OK**.

Click **Save**.

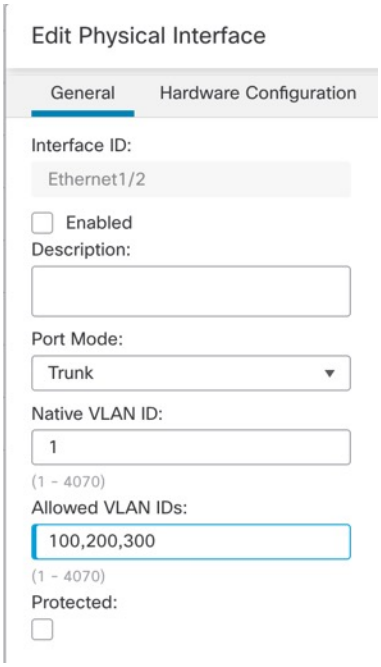
What to do next

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure switch ports as trunk ports

This task creates a trunk port that can carry multiple VLANs using 802.1Q tagging.

This procedure describes how to create a trunk port that can carry multiple VLANs using 802.1Q tagging. Trunk ports accept untagged and tagged traffic. Traffic on allowed VLANs pass through the trunk port unchanged.



When the trunk receives untagged traffic, it tags it to the native VLAN ID so that the Firewall Threat Defense device can forward the traffic to the correct switch ports or can route it to another firewall interface. When the Firewall Threat Defense device sends native VLAN ID traffic out of the trunk port, it removes the VLAN tag. Be sure to set the same native VLAN on the trunk port on the other switch so that the untagged traffic will be tagged to the same VLAN.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Figure 274: Set trunk port mode

Step 3 Enable the interface by checking the **Enabled** check box.

Step 4 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 Set the **Port Mode** to **Trunk**.

Step 6 Set the VLAN IDs:

a) In the **Native VLAN ID** field, set the native VLAN for this switch port, between 1 and 4070.

The default native VLAN ID is 1.

Each port can only have one native VLAN, but every port can have either the same or a different native VLAN.

b) In the **Allowed VLAN IDs** field, enter the VLANs for this trunk port between 1 and 4070.

You can identify up to 20 IDs in one of these ways:

- A single number (n)
- A range (n-x)

- Numbers and ranges separated by commas, for example:

  5,7-10,13,45-100

  You can enter spaces instead of commas.

If you include the native VLAN in this field, it is ignored; the trunk port always removes the VLAN tagging when sending native VLAN traffic out of the port. Moreover, it will not receive traffic that still has native VLAN tagging.

Step 7 (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Step 8 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

Step 9 Click **OK**.

Click **Save**.

What to do next

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Power over Ethernet

Configure Power over Ethernet (PoE) settings to control power delivery to connected devices and optimize power allocation.

Power over Ethernet (PoE) ports provide power for devices such as IP phones or wireless access points. PoE is enabled by default. This procedure describes how to disable and enable PoE and how to set optional parameters.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for Ethernet1/7 or 1/8 .

Step 3 Click **PoE**.

Figure 275: PoE

Step 4 Check the **Enable PoE** check box.

PoE is enabled by default.

Step 5 Choose autonegotiation or manual power.

- **Auto Negotiate Consumption Wattage**—Delivers power automatically to the powered device using a wattage appropriate to the class of the powered device. The firewall uses LLDP to further negotiate the correct wattage. When you connect a device of a certain class, it will be provisioned up to the maximum for that class in case it ever needs to use more power. For example, if you add a class 4 device that requests 12.95W, it will be allocated 30W even if it doesn't currently use all that power. Some devices can renegotiate power needs. If you know your device needs less power than is allocated, you can instead set the **Consumption Wattage** manually to free up the power for other devices.
- **Consumption Wattage**—Uncheck the **Auto Negotiate Consumption Wattage** check box to set the manual wattage to manually specify the wattage in milliwatts, from 4000 to 30000. Use this option if

you want to set the watts manually and disable LLDP negotiation. For manual allocation, the class will show in **show power inline** output as *n/a* because the class is not used to decide the power consumption.

View the current PoE status using the **show power inline** command.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Loopback interfaces

A loopback interface is a software-only interface that emulates a physical interface. This interface is reachable on IPv4 and IPv6 through multiple physical interfaces. The loopback interface helps to overcome path failures. It is accessible from any physical interface. If one interface goes down, you can access the loopback interface from another.

Loopback interfaces can be used for:

- AAA
- BGP
- DNS
- HTTP
- ICMP
- IPsec flow offload—Secure Firewall /3100/4200 only
- NetFlow
- SNMP
- SSH
- Static and dynamic VTI tunnels
- Syslog

The Firewall Threat Defense can distribute the loopback address using dynamic routing protocols, or you can configure a static route on the peer device to reach the loopback IP address through one of the Firewall Threat Defense's physical interfaces. You cannot configure a static route on the Firewall Threat Defense that specifies the loopback interface.

Related Topics

Guidelines for Loopback Interfaces, on page 662
Configure a loopback interface, on page 662

Guidelines for Loopback Interfaces

This topic outlines the specific constraints and supported configurations for loopback interfaces in various network environments.

Firewall Mode

- Supported in routed mode only.

High availability and Clustering

- No clustering support.

Additional Guidelines and Limitations

- TCP sequence randomization is always disabled for traffic from the physical interface to the loopback interface.

Configure a loopback interface

Configure a loopback interface to provide a virtual interface that remains active regardless of physical interface status, commonly used for routing protocols and management purposes.

Loopback interfaces are virtual interfaces that provide stable IP addresses for device management and routing protocols. They remain active as long as the device is operational, making them ideal for network management tasks.

Before you begin

Follow these steps to add a loopback interface for a device:

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 From the **Add Interfaces** drop-down list, choose **Loopback Interface**.

Step 3 In the **General** tab, configure the following parameters:

a) **Name**—Enter a name for the loopback interface.
b) **Enabled**—Check the check box to enable the loopback interface.
c) **Loopback ID**—Enter the loopback ID between 1 to 1024.
d) **Description**—Enter a description for the loopback interface.

Step 4 Configure the routed mode interface parameters. See Configure routed mode interfaces, on page 690.

Rate-Limit traffic to the loopback interface

You should rate-limit traffic going to the loopback interface IP address to prevent excessive load on the system. You can add a connection limit rule to the global service policy.

Rate-limiting protects the system from Denial of Service (DoS) attacks and ensures stable performance by controlling the number of connections to critical interface addresses.

Before you begin

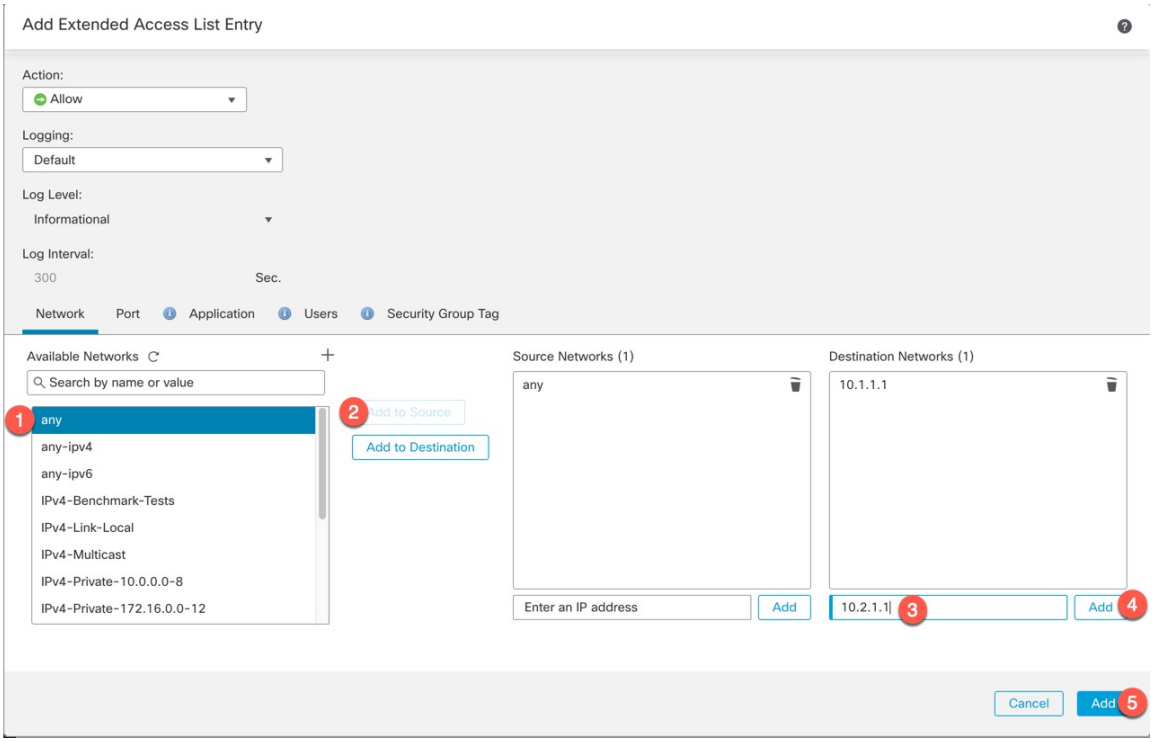
Follow these steps to rate-limit traffic to the loopback interface:

Procedure

Step 1 Create an extended access list identifying traffic to the loopback interface IP address(es).

a. Choose **Objects** > **Object Management** > **Access List** > **Extended**.

b. Click **Add Extended Access List** to create a new ACL.

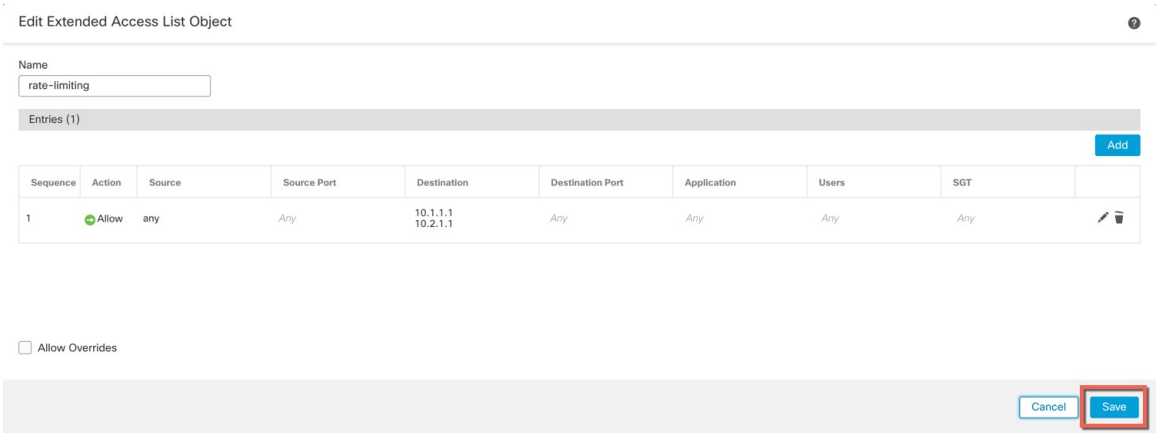


c. In the **New Extended Access List Object** dialog box, enter a name for the ACL (no spaces allowed), and click **Add** to create a new entry.

Figure 276: Name ACL and add entry

d. Configure the source (any) and destination addresses (loopback IP addresses) on the **Network** tab.

Figure 277: Source and destination networks



Note Keep the default **Action** as **Allow** (match) and other settings as-is.

- Source—Select **any** from the **Available Networks** list, and click **Add to Source**. You can also narrow this access list by specifying the source IP addresses instead of **any**.
- Destination—Type an address in the edit box below the **Destination Networks** list and click **Add**. Repeat for each loopback interface.

e. Click **Add** to add the entry to the ACL.

f. Click **Save** to save the ACL.

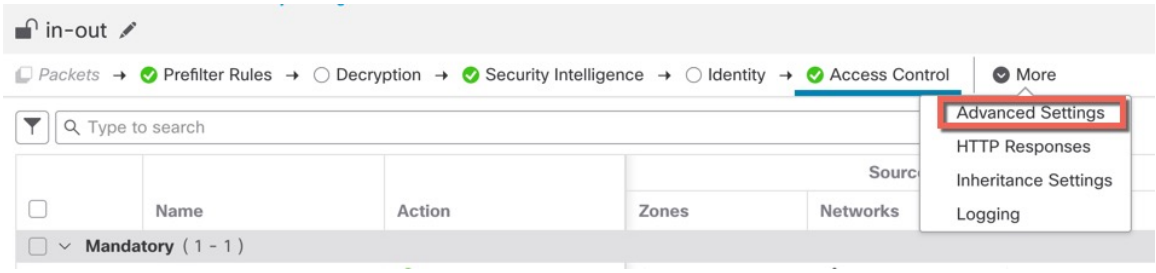


Figure 278: Save ACL

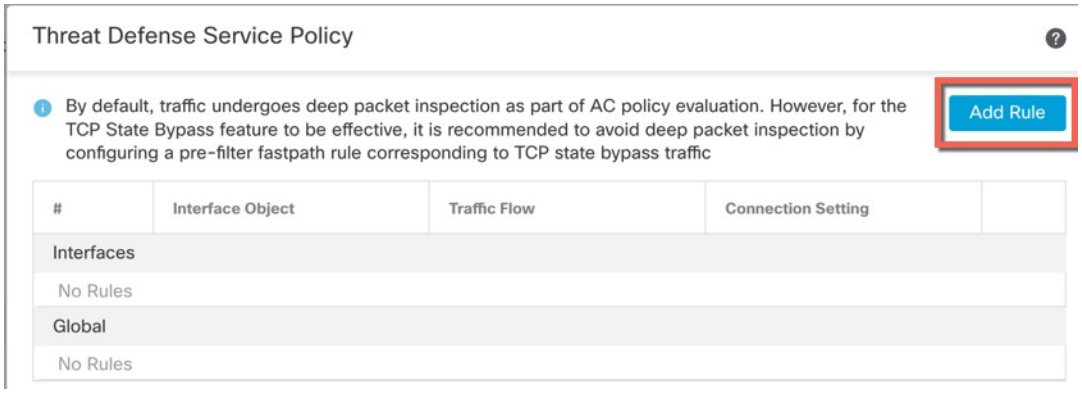
Step 2 Choose **Policies** > **Access Control heading** > **Access Control**, and click **Edit** (✎) for the access control policy assigned to your device.

Step 3 Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Figure 279: Advanced settings



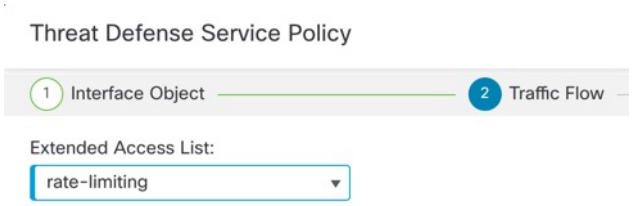
Step 4 Click **Edit** (✎) in the **Threat Defense Service Policy** group.

Figure 280: Threat defense service policy

Step 5 Click **Add Rule** to create a new rule.

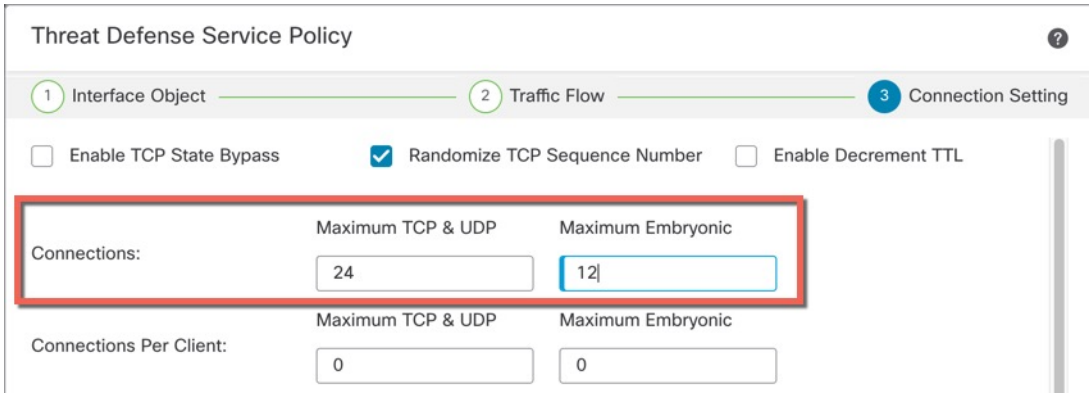
Figure 281: Add rule

The service policy rule wizard opens to step you through the process of configuring the rule.



Step 6 In the **Interface Object** step, click **Global** to create a global rule, which applies to all interfaces, then click **Next**.

Figure 282: Global policy



Step 7 In the **Traffic Flow** step, select the extended access list object you created in Step 1, on page 663, and then click **Next**.

Figure 283: Choose extended access list

Step 8 In the **Connection Setting** step, set the **Connections** limits.

Figure 284: Set connection limits

Set the **Maximum TCP & UDP** connections to the expected number of connections for the loopback interface, and the **Maximum Embryonic** connections to a lower number. For example, you can set it to 5/2, or 10/5, or 1024/512, depending on the expected loopback interface sessions you need.

Setting the embryonic connection limit enables TCP Intercept, which protects the system from a DoS attack perpetrated by flooding an interface with TCP SYN packets.

Step 9 Click **Finish** to save your changes.

Click **OK**.

Click **Save** on the **Advanced Settings** window.

What to do next

Deploy the changes to the affected devices.

VLAN subinterfaces and 802.1Q trunking

VLAN subinterfaces let you divide a physical, redundant, or EtherChannel interface into multiple logical interfaces that are tagged with different VLAN IDs. An interface with one or more VLAN subinterfaces is automatically configured as an 802.1Q trunk. Because VLANs let you keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or devices.

Guidelines for VLAN subinterfaces

Model support

- 1010—VLAN subinterfaces are not supported on switch ports or VLAN interfaces.

High availability and clustering

Do not use a subinterface for the failover or state link or for the cluster control link. The exception is for multi-instance mode: you can use a *chassis*-defined subinterface for these links.

Additional guidelines

- Preventing untagged packets on the physical interface—If you use subinterfaces, disable the physical interface from passing traffic. The physical interface transmits untagged packets. This behavior also applies to the active physical interface in a redundant interface pair and also to EtherChannel links. For the subinterface to pass traffic, the physical, redundant, or EtherChannel interface must be enabled. If you want to let the physical, redundant, or EtherChannel interface pass untagged packets, you can configure the name as usual.
- Configure subinterfaces only on non-Management interfaces. Avoid using the dedicated Management interface configured at the CLI or a data interface used for manager access.
- All subinterfaces on the same parent interface must be either members of bridge groups or routed interfaces; you cannot mix and match.
- The Firewall Threat Defense does not support the Dynamic Trunking Protocol (DTP), so configure the connected switch port to trunk unconditionally.
- Assign unique MAC addresses to the subinterfaces that are defined on the Firewall Threat Defense. Subinterfaces use the same burned-in MAC address of the parent interface by default. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense.

Note If you manually assign a MAC address, be sure to assign MAC addresses to all subinterfaces on the same physical interface to avoid unexpected behavior and outages.

Maximum number of VLAN subinterfaces by device model

Your device model limits the maximum number of VLAN subinterfaces that you can configure. Note that you can configure subinterfaces on data interfaces only, you cannot configure them on the management interface.

This table explains the limits for each device model.

Model	Maximum VLAN Subinterfaces
Firepower 1010	60
Firepower 1120	512
Firepower 1140, 1150	1024
Firepower 2100	1024
Secure Firewall 3100	1024
Secure Firewall 4200	1024

Model	Maximum VLAN Subinterfaces
Firepower 4100	1024
Firepower 9300	1024
Firewall Threat Defense Virtual	50
ISA 3000	100

Add a subinterface

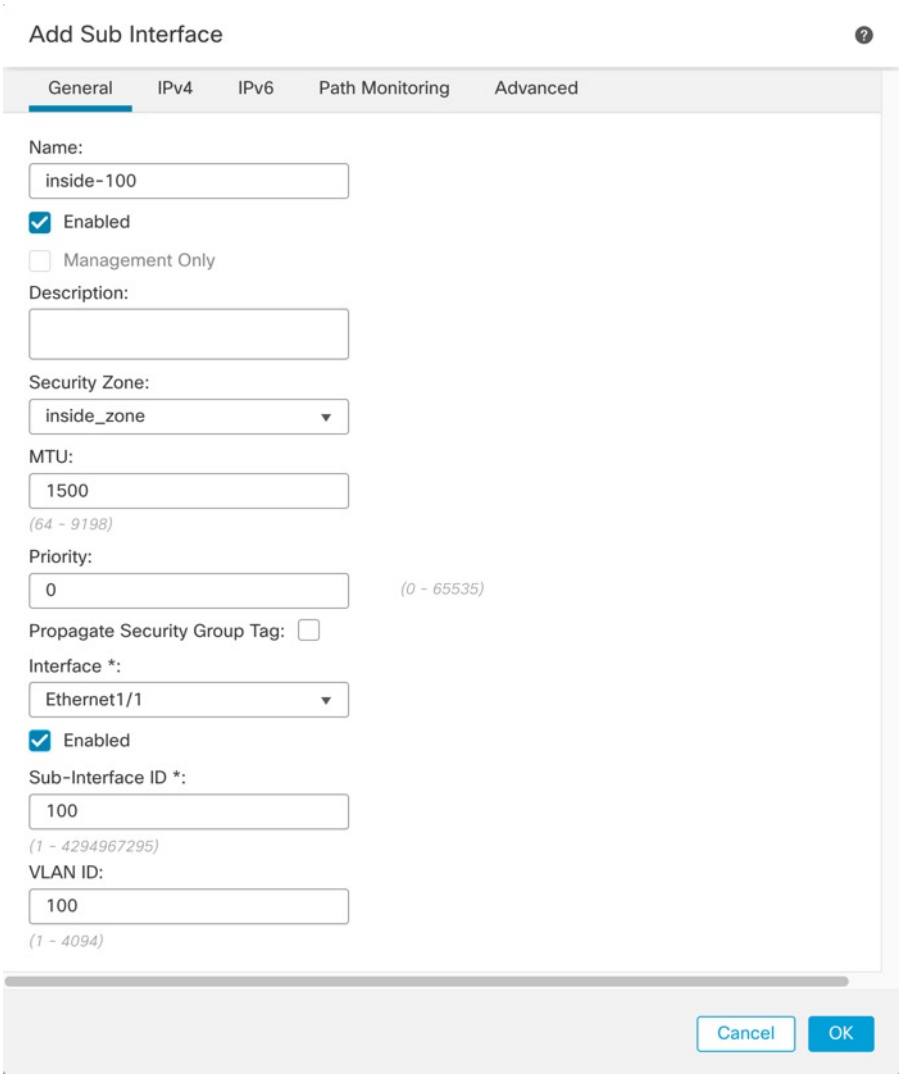
This task enables you to add subinterfaces to physical, redundant, or port-channel interfaces for network segmentation using VLAN tagging.

Add one or more subinterfaces to a physical, redundant, or port-channel interface.

For the Firepower 4100/9300, you can configure subinterfaces in FXOS for use with container instances; see Add a VLAN subinterface for container instances, on page 263. These subinterfaces appear in the Firewall Management Center interface list. You can also add subinterfaces in Firewall Management Center, but only on parent interfaces that do not already have subinterfaces defined in FXOS.

Note The parent physical interface passes untagged packets. You may not want to pass untagged packets, so be sure not to include the parent interface in your security policy.

Procedure



Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Enable the parent interface according to Enable the physical interface and configure Ethernet settings, on page 611.

Step 3 Click **Add Interfaces** > **Sub Interface**.

Step 4 On **General**, set these parameters:

Figure 285: Add subinterface

a) **Interface**—Choose the physical, redundant, or port-channel interface to which you want to add the subinterface.

b) **Sub-Interface ID**—Enter the subinterface ID as an integer between 1 and 4294967295. The number of subinterfaces allowed depends on your platform. You cannot change the ID after you set it.

c) **VLAN ID**—Enter the VLAN ID between 1 and 4094 that will be used to tag the packets on this subinterface.

   This VLAN ID must be unique.

Step 5 Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 7 Configure the routed or transparent mode interface parameters. See Configure routed mode interfaces, on page 690 or Bridge group interfaces, on page 695.

Configure VXLAN Interfaces

This chapter tells how to configure Virtual eXtensible LAN (VXLAN) interfaces. VXLAN interfaces act as Layer 2 virtual networks over Layer 3 physical networks to stretch Layer 2 networks.

VXLAN interfaces

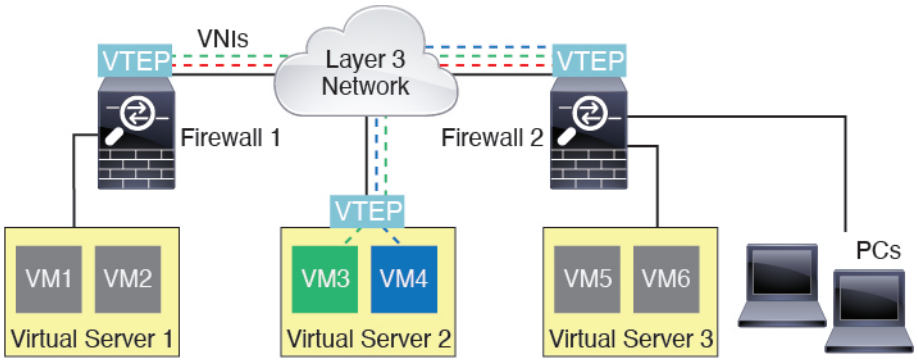
Virtual Extensible Local Area Network (VXLAN) is a network encapsulation protocol that provides flexible placement of multitenant segments throughout the data center. VXLAN offers higher scalability, supporting up to 16 million Layer 2 segments. VXLAN delivers Ethernet Layer 2 network services similar to VLAN and provides greater extensibility and flexibility.

Additional information

For detailed information about VXLAN, see RFC 7348.

encapsulation

The Firewall Threat Defense supports two types of VXLAN encapsulation:



- VXLAN (all models)—VXLAN uses MAC Address-in-User Datagram Protocol (MAC-in-UDP) encapsulation. The original Layer 2 frame has a VXLAN header added and is then placed in a UDP-IP packet.
- Geneve (Firewall Threat Defense Virtual only)—Geneve has a flexible inner header that is not limited to the MAC address. Geneve encapsulation is required for transparent routing of packets between an Amazon Web Services (AWS) Gateway Load Balancer and appliances, and for sending extra information.

VXLAN tunnel endpoints

A VXLAN tunnel endpoint (VTEP) devices performs VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces to which you apply your security policy, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

VTEP network communication

This figure shows two Firewall Threat Defenses and Virtual Server 2 acting as VTEPs across a Layer 3 network, extending the VNI 1, 2, and 3 networks between sites. The Firewall Threat Defenses act as bridges or gateways between VXLAN and non-VXLAN networks.

The underlying IP network between VTEPs is independent of the VXLAN overlay. Encapsulated packets are routed based on the outer IP address header, which has the initiating VTEP as the source IP address and the terminating VTEP as the destination IP address. For VXLAN encapsulation: The destination IP address can be a multicast group when the remote VTEP is not known. With Geneve, the Firewall Threat Defense only supports static peers. The destination port for VXLAN is UDP port 4789 by default (user configurable). The destination port for Geneve is 6081.

VTEP source interface

A VTEP source interface is a regular interface (physical, EtherChannel, or even VLAN) that you plan to associate with all VNI interfaces. You can configure one VTEP source interface per Firewall Threat Defense Virtual.

VTEP source interface characteristics

The VTEP source interface can be devoted wholly to VXLAN traffic, although it is not restricted to that use. You can use the interface to handle regular traffic and apply a security policy to it. However, for VXLAN traffic, you must apply all security policies to the VNI interfaces. The VTEP interface serves as a physical port only.

In transparent firewall mode, the VTEP source interface is not part of a BVI. You must configure an IP address for it, similar to how the management interface is configured.

Because you can only configure one VTEP source interface, you cannot configure both VXLAN and Geneve interfaces on the same device. There is an exception for Firewall Threat Defense Virtual clustering on AWS or Azure, where you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a Geneve (AWS) or VXLAN (Azure) interface can be used for the Gateway Load Balancer.

VNI interfaces

A VNI interface is a virtual interface that keeps network traffic separated on a given physical interface by using tagging. VNI interfaces are similar to VLAN interfaces. You can apply your security policy directly to each interface.

VNI interface configuration details

You can add only one VTEP interface. All VNI interfaces are associated with the same VTEP interface. There is an exception for Firewall Threat Defense Virtual clustering on AWS or Azure. For AWS clustering, you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a Geneve interface can be used for the AWS Gateway Load Balancer. For Azure clustering, you can have two VTEP

source interfaces: a VXLAN interface is used for the cluster control link, and a second VXLAN interface can be used for the Azure Gateway Load Balancer.

How VXLAN and Geneve packets are processed

Summary

The key components involved in VXLAN and Geneve packet processing are:

- VTEP source interface: Performs encapsulation and decapsulation of VXLAN and Geneve traffic
- Inner MAC frame: The original packet payload that gets encapsulated
- Outer frame: The encapsulated packet with VXLAN or Geneve headers
- Remote VTEP: The destination endpoint for encapsulated traffic

Workflow

These stages describe how VXLAN and Geneve packet processing work:

1. Traffic entering and exiting the VTEP source interface is subject to VXLAN processing, specifically encapsulation or decapsulation.

   Encapsulation processing includes these tasks:

   - The VTEP source interface encapsulates the inner MAC frame with the VXLAN header.
   - The UDP checksum field is set to zero.
   - The Outer frame source IP is set to the VTEP interface IP.
   - The Outer frame destination IP is decided by a remote VTEP IP lookup.

   Decapsulation: the Firewall Threat Defense only decapsulates a VXLAN packet if:

   - It is a UDP packet with the destination port set to 4789 (this value is user configurable).
   - The ingress interface is the VTEP source interface.
   - The ingress interface IP address is the same as the destination IP address.
   - The VXLAN packet format is compliant with the standard.

2. Traffic entering and exiting the VTEP source interface is subject to Geneve processing, specifically encapsulation or decapsulation.

   Encapsulation processing includes these tasks:

   - The VTEP source interface encapsulates the inner MAC frame with the Geneve header.
   - The UDP checksum field is set to zero.
   - The Outer frame source IP is set to the VTEP interface IP.
   - The Outer frame destination IP is set the peer IP address that you configured.

   Decapsulation; the Firewall Threat Defense only decapsulates a Geneve packet if:

- It is a UDP packet with the destination port set to 6081 (this value is user configurable).
- The ingress interface is the VTEP source interface.
- The ingress interface IP address is the same as the destination IP address.
- The Geneve packet format is compliant with the standard.

Peer VTEPs

A peer VTEP is a VXLAN Tunnel Endpoint that enables the Firewall Threat Defense to send packets to devices behind remote VTEPs.

When the Firewall Threat Defense sends a packet to a device behind a peer VTEP, the Firewall Threat Defense needs two important pieces of information:

- The destination MAC address of the remote device
- The destination IP address of the peer VTEP

The Firewall Threat Defense maintains a mapping of destination MAC addresses to remote VTEP IP addresses for the VNI interfaces.

VXLAN peer configuration methods

There are two ways in which the Firewall Threat Defense can find this information:

- A single peer VTEP IP address can be statically configured on the Firewall Threat Defense.

  For IPv4: The Firewall Threat Defense then sends a VXLAN-encapsulated ARP broadcast to the VTEP to learn the end node MAC address.

  For IPv6: The Firewall Threat Defense then sends an IPv6 Neighbor Solicitation message to the IPv6 solicited-node multicast address. The peer VTEP responds with an IPv6 Neighbor Advertisement message with its link-local address.

- A group of peer VTEP IP addresses can be statically configured on the Firewall Threat Defense.

  For IPv4: The Firewall Threat Defense then sends a VXLAN-encapsulated ARP broadcast to the VTEP to learn the end node MAC addresses.

  For IPv6: The Firewall Threat Defense then sends an IPv6 Neighbor Solicitation message to the IPv6 solicited-node multicast address. The peer VTEP responds with an IPv6 Neighbor Advertisement message with its link-local address.

- A multicast group can be configured on each VNI interface (or on the VTEP as a whole).

  For IPv4: The Firewall Threat Defense sends a VXLAN-encapsulated ARP broadcast packet within an IP multicast packet through the VTEP source interface. The response to this ARP request enables the Firewall Threat Defense to learn both the remote VTEP IP address along with the destination MAC address of the remote end node.

  For IPv6: The Firewall Threat Defense sends a Multicast Listener Discovery (MLD) Report message through the VTEP source interface to indicate that the Firewall Threat Defense is listening on the VTEP interface for the multicast address traffic.

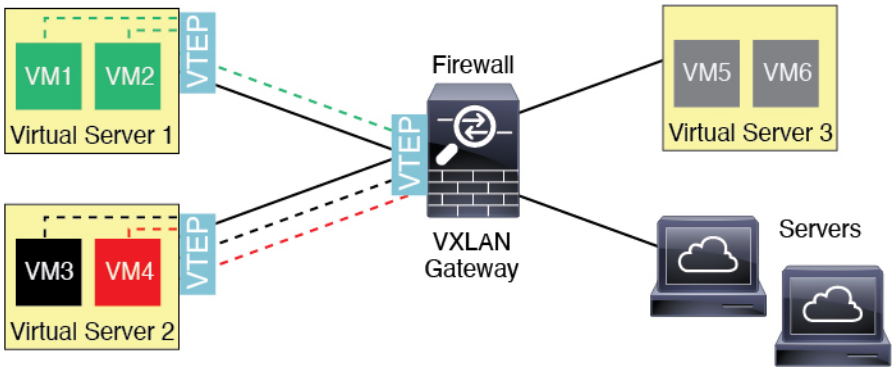
  This option is not supported with Geneve.

Geneve peer configuration

The Firewall Threat Defense Virtual only supports statically defined peers. You can define the Firewall Threat Defense Virtual peer IP address on the AWS Gateway Load Balancer. Because the Firewall Threat Defense Virtual never initiates traffic to the Gateway Load Balancer, you do not also have to specify the Gateway Load Balancer IP address on the Firewall Threat Defense Virtual. It learns the peer IP address when it receives Geneve traffic. Multicast groups are not supported with Geneve.

VXLAN use cases

This section describes the use cases for implementing VXLAN on the Firewall Threat Defense.

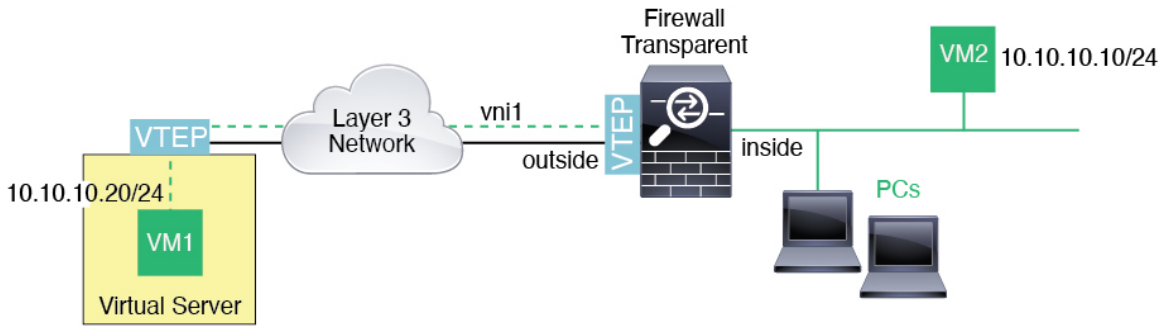


VXLAN bridge or gateway overview

A VTEP acts as a bridge or gateway between end nodes, such as VMs, servers, and PCs, and the VXLAN overlay network.

VXLAN Packet Processing

For incoming frames received with VXLAN encapsulation over the VTEP source interface, the Firewall Threat Defense strips out the VXLAN header and forwards it to a physical interface connected to a non-VXLAN network based on the destination MAC address of the inner Ethernet frame.

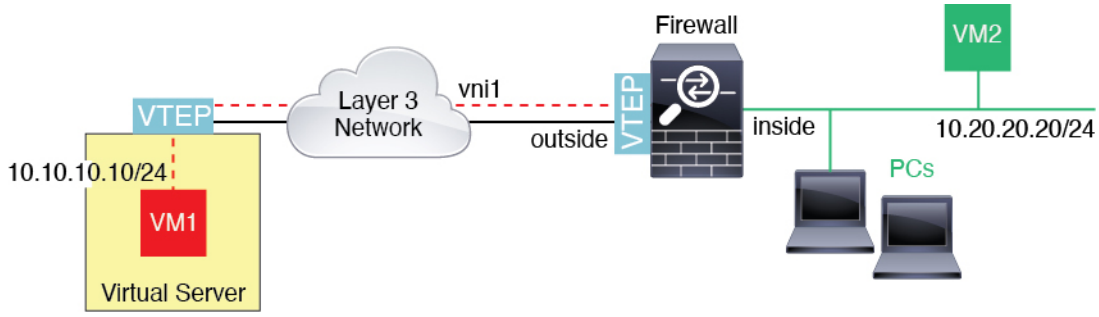


The Firewall Threat Defense always processes VXLAN packets rather than forwarding them untouched between two other VTEPs.

VXLAN bridge

A VXLAN bridge is a network configuration where the Firewall Threat Defense connects a remote VXLAN segment to a local segment.

When you use a bridge group (transparent firewall mode, or optionally routed mode), the Firewall Threat Defense can serve as a VXLAN bridge between a (remote) VXLAN segment and a local segment where both are in the same network. In this case, one member of the bridge group is a regular interface while the other member is a VNI interface.



VXLAN gateway (routed mode)

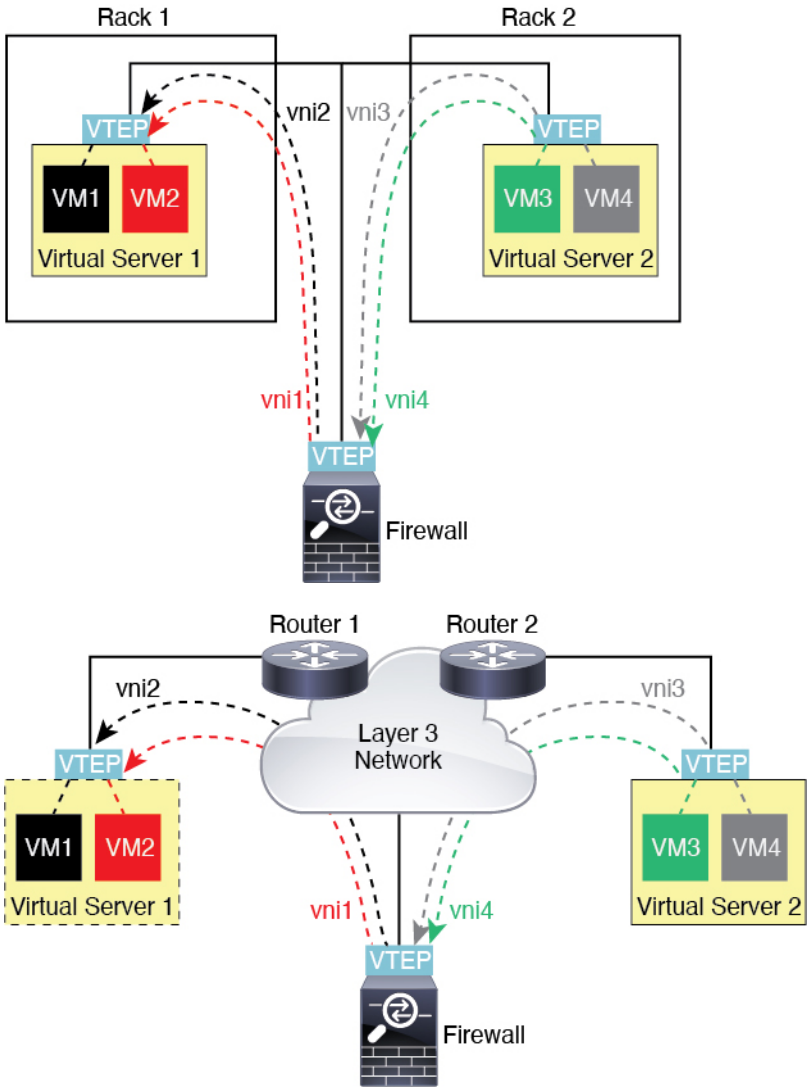
The Firewall Threat Defense functions as a router between VXLAN and non-VXLAN domains, connecting devices on different networks.

VXLAN Gateway Visual Representation

This figure illustrates the VXLAN gateway connectivity.

Router Between VXLAN Domains

A VXLAN-stretched Layer 2 domain enables a VM to utilize a Firewall Threat Defense as its default gateway regardless of physical proximity.



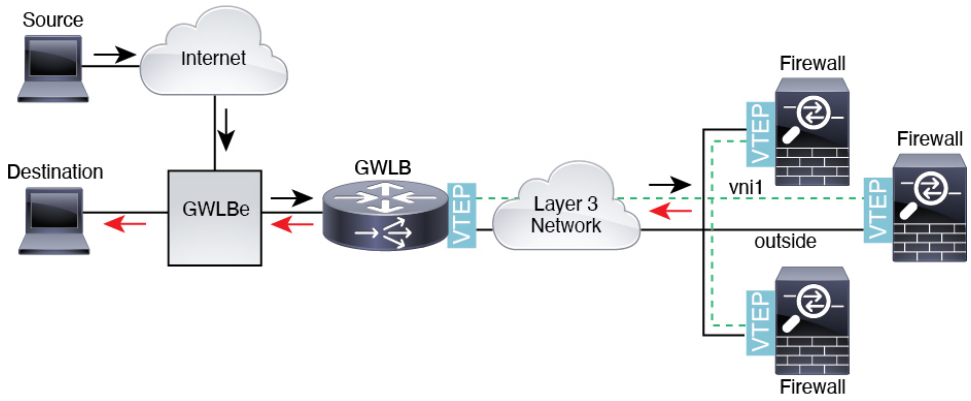
Routing Process and Packet Flow

The following steps outline the packet flow between VMs across VXLAN domains:

1. For packets from VM3 to VM1, the destination MAC address is the Firewall Threat Defense MAC address, because the Firewall Threat Defense is the default gateway.
2. The VTEP source interface on Virtual Server 2 receives packets from VM3, then encapsulates the packets with VNI 3's VXLAN tag and sends them to the Firewall Threat Defense .
3. When the Firewall Threat Defense receives the packets, it decapsulates the packets to get the inner frames.
4. The Firewall Threat Defense uses the inner frames for route lookup, then finds that the destination is on VNI 2. If it does not already have a mapping for VM1, the Firewall Threat Defense sends an encapsulated ARP broadcast on the multicast group IP on VNI 2.
5. The Firewall Threat Defense encapsulates the packets again with the VXLAN tag for VNI 2 and sends the packets to Virtual Server 1. Before encapsulation, the Firewall Threat Defense changes the inner frame destination MAC address to be the MAC of VM1.

6. When Virtual Server 1 receives the VXLAN packets, it decapsulates the packets and delivers the inner frames to VM1.

Note The Firewall Threat Defense must use dynamic VTEP peer discovery because it has multiple VTEP peers in this scenario.



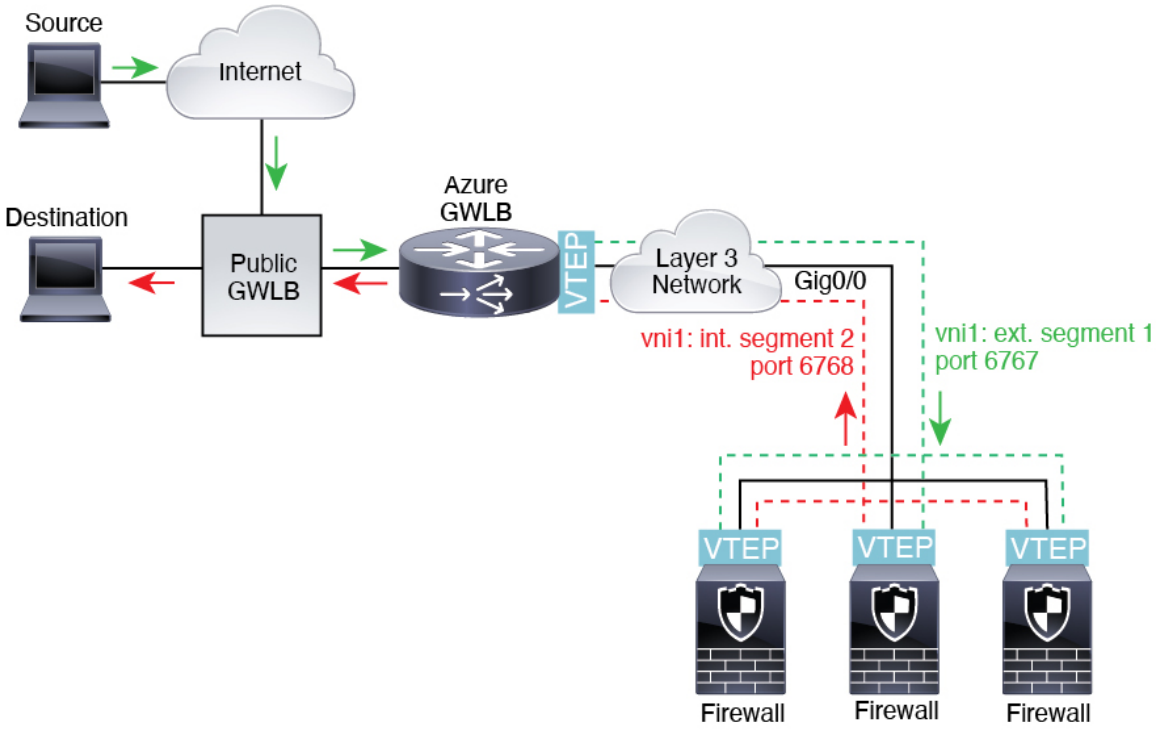
Geneve Single-Arm Proxy

In a Geneve single-arm proxy deployment, network traffic is routed through a centralized proxy device for inspection and policy enforcement.

Note This use case is the only currently supported use case for Geneve interfaces.

The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Firewall Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint). The following figure shows traffic forwarded to the Gateway Load Balancer from the Gateway Load Balancer endpoint. The Gateway Load Balancer balances traffic among multiple Firewall Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer (U-turn traffic). The Gateway Load Balancer then sends the traffic back to the Gateway Load Balancer endpoint and to the destination.

Figure 286: Geneve Single-Arm Proxy



Azure Gateway Load Balancer and Paired Proxy

In an Azure service chain, Firewall Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Firewall Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.

The following figure shows traffic forwarded to the Azure Gateway Load Balancer from the Public Gateway Load Balancer on the external VXLAN segment. The Gateway Load Balancer balances traffic among multiple Firewall Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer on the internal VXLAN segment. The Azure Gateway Load Balancer then sends the traffic back to the Public Gateway Load Balancer and to the destination.

Figure 287: Azure Gateway Load Balancer with Paired Proxy

Requirements and prerequisites for VXLAN interfaces

This reference provides the model requirements and prerequisites for configuring VXLAN interfaces on supported platforms.

Model requirements

- VXLAN encapsulation is supported on all models.
- Geneve encapsulation is supported for these models:
  - Firewall Threat Defense Virtual in Amazon Web Services (AWS)
- VXLAN in *paired proxy mode* is supported for these models:
  - Firewall Threat Defense Virtual in Azure
- Firepower 1010 switch ports and VLAN interfaces are not supported as VTEP interfaces.

Guidelines for VXLAN interfaces

Firewall mode restrictions

Geneve interfaces are only supported in routed firewall mode.

- Paired proxy VXLAN interfaces are only supported in routed firewall mode.

IPv6 support restrictions

The VNI interface supports both IPv4 and IPv6 traffic.

- For VXLAN encapsulation, the VTEP source interface supports both IPv4 and IPv6. The Firewall Threat Defense Virtual cluster control link VTEP source interface only supports IPv4.

  For Geneve, the VTEP source interface only supports IPv4.

Clustering restrictions

Clustering does not support VXLAN in Individual Interface mode except for the cluster control link (Firewall Threat Defense Virtual only) Only Spanned EtherChannel mode supports VXLAN.

An exception is made for AWS, which can use an additional Geneve interface for use with the GWLB and for Azure, which can use an additional paired proxy VXLAN interface for use with the GWLB.

Routing restrictions

Only static routing or Policy Based Routing is supported on the VNI interface; dynamic routing protocols are not supported.

VPN restrictions

You cannot configure the VTEP source interface for VPN or use it as a VTI.

MTU requirements

If the source interface MTU is less than the required minimum, the Firewall Threat Defense automatically raises the MTU to meet encapsulation requirements.

- VXLAN encapsulation—If the source interface MTU is less than 1554 bytes for IPv4 or 1574 bytes for IPv6, then the Firewall Threat Defense automatically raises the MTU to 1554 bytes or 1574 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 54 bytes for IPv4 or +64 bytes for IPv6. For the Firewall Threat Defense Virtual, this MTU requires a restart to enable jumbo frame reservation.
- Geneve encapsulation—If the source interface MTU is less than 1806 bytes, then the Firewall Threat Defense automatically raises the MTU to 1806 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 306 bytes. This MTU requires a restart to enable jumbo frame reservation.

Configure VXLAN or Geneve interfaces

You can configure either VXLAN or Geneve interfaces.

Configure VXLAN interfaces

Configure VXLAN interfaces to enable virtualized network overlay functionality and network segmentation.

VXLAN provides Layer 2 overlay network capabilities over existing Layer 3 infrastructure. You can configure either VXLAN or Geneve interfaces, but not both simultaneously.

Note You can configure either VXLAN or Geneve (Firewall Threat Defense Virtual only). For Geneve interfaces, see Configure geneve interfaces, on page 683.

Note For Azure GWLB, the VXLAN interface is configured when you deploy the VM using the ARM template. You can use this section to change your configuration.

Follow these steps to configure VXLAN interfaces.

Procedure

Step 1 Configure the VTEP source interface, on page 681.

Step 2 Configure the VNI interface, on page 682.

Step 3 (Azure GWLB) Allow gateway load balancer health checks, on page 685.

Configure the VTEP source interface

This task enables you to set up VXLAN network virtualization by configuring a Network Virtualization Endpoint (NVE) on your firewall device.

You can configure one VTEP source interface per Firewall Threat Defense device. The VTEP is defined as a Network Virtualization Endpoint (NVE). VXLAN is the default encapsulation type. An exception is made for clustering on the Firewall Threat Defense Virtual in Azure, where you can use one VTEP source interface for the cluster control link and a second one for the data interface connected to the Azure GWLB.

Procedure

Step 1 If you want to specify a group of peer VTEPs, add a network object with the peer IP addresses. See Create a network object, on page 2388.

Step 2 Choose **Devices** > **Device Management**.

Step 3 Click **Edit** ( ) next to the device on which you want to configure VXLAN.

Step 4 (Optional) Specify that the source interface is NVE-only.

This setting is optional for routed mode where this setting restricts traffic to VXLAN and common management traffic only on this interface. This setting is automatically enabled for transparent firewall mode.

a) Click **Interfaces**.

b) Click **Edit** ( ) for the VTEP source interface.

c) On the **General** page, check the check box of **NVE Only**.

Step 5 Click **VTEP** if it is not already displaying.

Step 6 Check **Enable NVE**.

Step 7 Click **Add VTEP**.

a) For the **Encapsulation Type**, choose **VXLAN**.

For AWS, you can choose between **VXLAN** and **Geneve**. Other platforms have **VXLAN** chosen automatically.

b) Enter the value for the **Encapsulation port** within the specified range.

The default value is 4789.

c) Select the **VTEP Source Interface**.

Select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1554 bytes for IPv4 or 1574 bytes for IPv6, then the Firewall Management Center automatically raises the MTU to 1554 bytes or 1574 bytes.

d) Select the **Neighbor Address**. The available options are:

- **None**—No neighbor address is specified.
- **Peer VTEP**—Specify a peer VTP address.
- **Peer Group**—Specify a network object with the peer IP addresses.
- **Default Multicast**—Specify a default multicast group for all associated VNI interfaces. If you do not configure the multicast group per VNI interface, then this group is used. If you configure a group at the VNI interface level, then that group overrides this setting.

Step 8 Click **OK**.

Step 9 Click **Save**.

What to do next

Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Configure the VNI interface

Add a VNI interface, associate it with the VTEP source interface, and configure basic interface parameters.

For the Firewall Threat Defense Virtual in Azure, you can configure either a regular VXLAN interface, or you can configure a paired proxy mode VXLAN interface for use with the Azure GWLB. Paired proxy mode is the only supported mode with clustering.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure VXLAN.

Step 3 Click **Interfaces**.

Step 4 Click **Add Interfaces**, and then choose **VNI Interface**.

a) Enter the interface **Name** and **Description**.

b) From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

c) Enter a value for the **Priority** field within the specified range. By default, 0 is selected.
d) Enter a value for the **Priority** field within the specified range. By default, 0 is selected.
e) Enter a value for the **VNI ID** between 1 and 10000.

This ID is only an internal interface identifier.

Step 5 (Paired Proxy VXLAN for Azure gateway load balancer) Enable proxy paired mode and set the required parameters.

a) Check **Proxy Paired**.
b) Set the **Internal Port** between 1024 and 65535.
c) Set the **Internal Segment ID** between 1 and 16777215.
d) Set the **External Port** between 1024 and 65535.
e) Set the **External Segment ID** between 1 and 16777215.

Step 6 (Regular VXLAN) Enter a value for the **VNI Segment ID** between 1 and 16777215.

The segment ID is used for VXLAN tagging.

Step 7 Enter the **Multicast Group IP Address**.

If you do not set the multicast group for the VNI interface, the default group from the VTEP source interface configuration is used, if available. If you manually set a VTEP peer IP for the VTEP source interface, you cannot specify a multicast group for the VNI interface.

Step 8 Check **NVE Mapped to VTEP Interface**.

This option associates this interface with the VTEP source interface.

Step 9 Click **OK**.

Click **Save** to save the interface configuration.

What to do next

Configure the routed or transparent interface parameters. See Configure routed and transparent mode interfaces, on page 686.

Configure geneve interfaces

To configure Geneve interfaces for Firewall Threat Defense Virtual, perform the following steps.

Note You can configure either VXLAN or Geneve. For information about VXLAN interfaces, see Configure VXLAN interfaces, on page 680.

1. Configure the VTEP source interface, on page 684.
2. Configure the VNI, on page 684.
3. Allow gateway load balancer health checks, on page 685.

Configure the VTEP source interface

Configure the VTEP source interface to enable network virtualization functionality on the device.

You can configure one VTEP source interface per Firewall Threat Defense Virtual device. The VTEP is defined as a Network Virtualization Endpoint (NVE).

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure Geneve.

Step 3 Click **VTEP**.

Step 4 Check **Enable NVE**.

Step 5 Click **Add VTEP**.

a) For the **Encapsulation Type**, choose **Geneve**.

b) Enter the value for the **Encapsulation port** within the specified range.

We do not recommend changing the Geneve port; AWS requires a port of 6081.

c) Select the **VTEP Source Interface**.

You can select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1806 bytes, then the Firewall Management Center automatically raises the MTU to 1806 bytes.

d) Click **OK**.

Step 6 Click **Save**.

Step 7 Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Configure the VNI

This task enables you to add a VNI interface and configure its basic parameters for Geneve functionality on your device.

Add a VNI, associate it with (VTEP) source interface, and configure basic interface parameters.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure Geneve.

Step 3 Click **Interfaces**.

Step 4 Click **Add Interfaces**, and then choose **VNI Interface**.

a) In the **Name** and **Description** fields, provide relevant information.

b) In the **VNI ID** field, enter a value between 1 and 10000.

Note This ID is only an internal interface identifier.

Step 5 Check the **Enable Proxy** check box.

Note When the AWS proxy is enabled on the VNI interface of your device, configuring NAT is not allowed.

This option enables single-arm proxy, and allows traffic to exit the same interface it entered (U-turn traffic). If you edit the interface later , you cannot disable single-arm proxy. To disable single-arm proxy, delete the existing interface and create a new VNI interface.

This option is only available for a Geneve VTEP.

Step 6 Select **NVE Mapped to VTEP Interface**.

This option associates this interface with the VTEP source interface.

Step 7 Click **OK**.

Step 8 Click **Save**.

What to do next

Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Allow gateway load balancer health checks

The AWS or Azure gateway load balancer (GWLB) requires appliances to answer a health check properly. The GWLB will only send traffic to appliances that are considered healthy.

Configure one of these methods to enable proper health check responses.

Procedure

Step 1 Configure SSH. See Configure Secure Shell

Allow SSH from the GWLB IP address. The GWLB will attempt to establish a connection to the Firewall Threat Defense Virtual, and the Firewall Threat Defense Virtual's prompt to log in is taken as proof of health. An SSH login attempt will time out after 1 minute. You will need to configure a longer health check interval on the GWLB to accommodate this timeout.

Step 2 Configure HTTP(S) Redirection Using Static Interface NAT with Port Translation.

You can configure the Firewall Threat Defense Virtual to redirect health checks to a metadata HTTP(S) server. For HTTP(S) health checks, the HTTP(S) server must reply to the GWLB with a status code in the range 200 to 399. Because the Firewall Threat Defense Virtual has limits on the number of simultaneous management connections, you may choose to offload the health check to an external server.

Static interface NAT with port translation lets you redirect a connection to a port (such as port 80) to a different IP address. For example, translate an HTTP packet from the GWLB with a destination of the Firewall Threat Defense Virtual outside interface so that it appears to be from the Firewall Threat Defense Virtual outside interface with a destination of the HTTP server. The Firewall Threat Defense Virtual then forwards the packet to the mapped destination address. The HTTP server responds to the Firewall Threat Defense Virtual outside interface, and then the Firewall Threat Defense Virtual forwards the response back to the GWLB. You need an access rule that allows traffic from the GWLB to the HTTP server.

a) Permit HTTP(S) traffic on the outside interface from the GWLB network in an access rule. See Access Control Rules, on page 1609.
b) For HTTP(S), translate the source GWLB IP address to the Firewall Threat Defense Virtual outside interface IP address; then translate the destination of the outside interface IP address to the HTTP(S) server IP address. See Configure static manual NAT, on page 1232.

Configure routed and transparent mode interfaces

This section includes tasks to complete the regular interface configuration for all models in routed or transparent firewall mode.

Routed and transparent mode interfaces

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

Interface types by firewall mode

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See Transparent or Routed Firewall Mode, on page 71 for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the Firewall Threat Defense device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

Dual IP stack (IPv4 and IPv6)

A dual IP stack is a network configuration that enables both IPv6 and IPv4 addresses on the same interface on Firewall Threat Defense device. Make sure you configure a default route for both IPv4 and IPv6.

31-bit subnet masks

A 31-bit subnet mask includes only two addresses for point-to-point connections.

31-bit subnet mask implementation

For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. Normally, the first and last address in a 2-address subnet is reserved for the network and broadcast, so a 2-address subnet is not usable. However, if you have a point-to-point connection and do not need network or broadcast addresses, a 31-bit subnet is a useful way to preserve addresses in IPv4.

31-bit subnet mask use cases

The failover link between two Firewall Threat Defenses only requires two addresses. Any packet that is transmitted by one end of the link is always received by the other, and broadcasting is unnecessary. You can also have a directly-connected management station running SNMP or Syslog.

Note: 31-bit subnet and clustering compatibility

You can use a 31-bit subnet mask for cluster interfaces, excluding the management interface and the cluster control link.

31-bit subnet and failover

A Firewall Threat Defense using a 31-bit subnet for its interface IP address can't configure a standby IP address due to insufficient addresses.

Interface monitoring limitations

When using a 31-bit subnet for the Firewall Threat Defense interface IP address, you cannot configure a standby IP address for the interface because there are not enough addresses. Normally, an interface for failover should have a standby IP address so the active unit can perform interface tests to ensure standby interface health. Without a standby IP address, the Firewall Threat Defense cannot perform any network tests; only the link state can be tracked.

For the failover and optional separate state link, which are point-to-point connections, you can also use a 31-bit subnet.

31-bit subnet and management

If you have a directly-connected management station, you can use a point-to-point connection for SSH or HTTP on the Firewall Threat Defense, or for SNMP or Syslog on the management station.

Recommendation: 31-bit subnet unsupported features

The 31-bit subnet does not support certain network features that require multiple host addresses.

- BVI interfaces for bridge groups—The bridge group requires at least 3 host addresses: the BVI, and two hosts connected to two bridge group member interfaces. you must use a /29 subnet or smaller.
- Multicast Routing

Guidelines and limitations for routed and transparent mode interfaces

Context mode

- PPPoE is not supported in multiple context mode.

- For multiple context mode in transparent mode, each context must use different interfaces; you cannot share an interface across contexts.
- For multiple context mode in transparent mode, each context typically uses a different subnet. You can use overlapping subnets, but your network topology requires router and NAT configuration to make it possible from a routing standpoint.

High availability, Clustering, and Multi-Instance

Do not configure failover links with the procedures in this chapter. See the High availability chapter for more information.

- For cluster interfaces, see the clustering chapter for requirements.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- When you use High availability, you must set the IP address and standby address for data interfaces manually; DHCP and PPPoE are not supported. Set the standby IP addresses on the **Devices** > **Device Management** > **High Availability** tab in the **Monitored Interfaces** area. See the High availability chapter for more information.

IPv6

IPv6 is supported on all interfaces.

- You can only configure IPv6 addresses manually in transparent mode.
- The Firewall Threat Defense device does not support IPv6 anycast addresses.
- DHCPv6 and prefix delegation options are not supported with transparent mode, clustering, or High availability.

Model guidelines

For the Firewall Threat Defense Virtual on VMware with bridged ixgbevf interfaces, bridge groups are not supported.

- For the Firepower 2100 series, bridge groups are not supported in routed mode.

VLAN IDs for the ASASM

- If you add an interface for a VLAN that is not yet assigned to the ASA by the switch, the interface will be in the down state. When you assign the VLAN to the ASA, the interface changes to an up state. See the **show interface** command for more information about interface states.

Transparent mode and bridge group guidelines

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The Firewall Threat Defense device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.

- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the Firewall Threat Defense device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).
- Management interfaces are not supported as bridge group members.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the Firewall Threat Defense Virtual on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
- For the Firepower 2100 series, bridge groups are not supported in routed mode.
- For the / 1010/ , you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.
- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.
- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the Firewall Threat Defense as the default gateway.
- In transparent mode, the *default* route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.
- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, Firewall Threat Defense-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the Firewall Threat Defense when using bridge group members. If there are two neighbors on either side of the Firewall Threat Defense running BFD, then the Firewall Threat Defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

Additional guidelines and requirements

The Firewall Threat Defense supports only one 802.1Q header in a packet and does not support multiple headers (known as Q-in-Q support) for firewall interfaces.**Note:** For inline sets and passive interfaces, the FTD supports Q-in-Q up to two 802.1Q headers in a packet, with the exception of the Firepower 4100/9300, which only supports one 802.1Q header.

- Interface problems, such as frequent up/down status changes, can prevent the floating connection timer from applying correctly to the connections going through the interface. If you have problems with an

interface's status, consider clearing all connections after the status becomes stable to clear invalid connections.

Configure routed mode interfaces

Before you begin

- Firepower 4100/9300
  1. Configure a physical interface, on page 259
  2. (Optional) Configure any special interfaces.
     - Add an EtherChannel (port channel), on page 261
     - Add a VLAN subinterface for container instances, on page 263 in FXOS
     - Configure a loopback interface, on page 662
     - Add a subinterface, on page 669 in Firewall Management Center
     - Configure VXLAN interfaces, on page 680

- (Optional) **All other models:**
  - Configure an EtherChannel, on page 619
  - Configure a loopback interface, on page 662
  - Add a subinterface, on page 669
  - Configure VXLAN interfaces, on page 680
  - Firewall Threat Defense Virtual on AWS: Configure geneve interfaces, on page 683
  - Firepower 1010 : Configure a VLAN interface, on page 653

This procedure describes how to set the name, security zone, and IPv4 address.

Note Not all fields are supported for all interface types.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 In the **Name** field, enter a name up to 48 characters in length.

You cannot start the name with the phrase "cluster". It is reserved for internal use.

Step 4 Enable the interface by checking the **Enabled** check box.

a) (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.

b) (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

c) In the **Mode** drop-down list, choose **None** .

Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types.

d) From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New** .

The routed interface is a Routed-type interface, and can only belong to Routed-type zones.

e) See Configure the MTU, on page 717 for information about the **MTU** .

f) In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to route the traffic across multiple egress interfaces. For more information, see Configure policy-based routing policy, on page 1166.

Step 5 Click the **IPv4** tab. To set the IP address, use one of the following options from the **IP Type** drop-down list.

High Availability, clustering , and loopback interfaces only support static IP address configuration; DHCP and PPPoE are not supported.

- **Use Static IP** —Enter the IP address and subnet mask. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254 or /31). In this case, no IP addresses are reserved for the network or broadcast addresses. You cannot set the standby IP address in this case. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices** > **Device Management** page, click **High Availability** in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- **Use DHCP** —Configure the following optional parameters:
  - **Obtain default route using DHCP** —Obtains the default route from the DHCP server.
  - **DHCP route metric** —Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.
- **Use PPPoE** —If the interface is connected to a DSL, cable modem, or other connection to your ISP, and your ISP uses PPPoE to provide your IP address, configure the following parameters:
  - **VPDN Group Name** —Specify a group name of your choice to represent this connection.
  - **PPPoE User Name** —Specify the username provided by your ISP.
  - **PPPoE Password/Confirm Password** —Specify and confirm the password provided by your ISP.
  - **PPP Authentication** —Choose **PAP** , **CHAP** , or **MSCHAP** .

    PAP passes a cleartext username and password during authentication and is not secure. With CHAP, the client returns the encrypted [challenge plus password], with a cleartext username in response to the server challenge. CHAP is more secure than PAP, but it does not encrypt data. MSCHAP is similar to CHAP but is more secure because the server stores and compares only encrypted passwords rather than cleartext passwords as in CHAP. MSCHAP also generates a key for data encryption by MPPE.

- **PPPoE route metric** —Assign an administrative distance to the learned route. Valid values are from 1 to 255. By default, the administrative distance for the learned routes is 1.
- **Enable Route Settings** —To manually configure the PPPoE IP address, check this box and then enter the **IP Address** .

  If you select the **Enable Route Settings** check box and leave the **IP Address** blank, the **ip address pppoe setroute** command is applied as shown in this example:

```
interface GigabitEthernet0/2
nameif inside2_pppoe
cts manual
  propagate sgt preserve-untag
  policy static sgt disabled trusted
security-level 0
pppoe client vpdn group test
pppoe client route distance 10
ip address pppoe setroute
```

- **Store Username and Password in Flash** —Stores the username and password in flash memory.

  The Firewall Threat Defense device stores the username and password in a special location of NVRAM.

Step 6 (Optional) Configure these fields, if you require them.

a) (Optional) See Configure IPv6 addressing, on page 699 to configure IPv6 addressing on the **IPv6** tab.

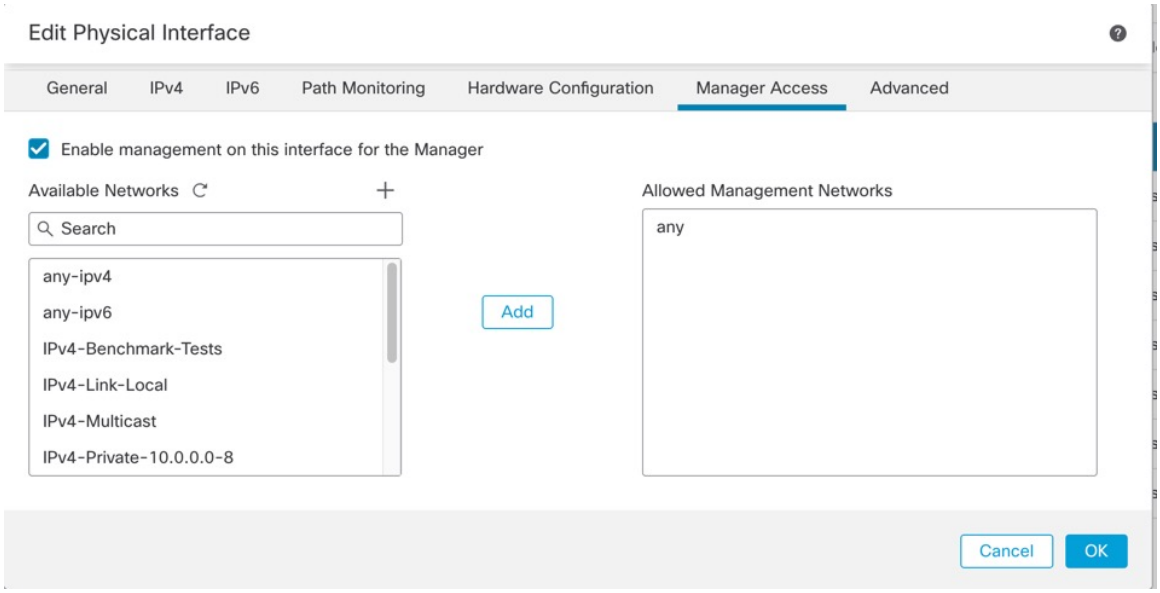
b) (Optional) See Configure the MAC address, on page 718 to manually configure the MAC address on the **Advanced** tab.

c) Enable Firewall Management Center manager access on a data interface on the **Manager Access** page.

You can enable manager access from a data interface when you first setup the Firewall Threat Defense . If you want to enable or disable manager access after you added the Firewall Threat Defense to the Firewall Management Center , see:

- Enable manager access: Change the manager access interface from management to data, on page 779

Note You cannot enable manager access unless you first initiate the manager interface migration from Management to a data interface. After you initiate the migration, you can enable manager access on the **Manager Access** page and save the configuration successfully.



- Disable manager access: Change the manager access interface from data to management, on page 783

If you want to change the manager access interface from one data interface to another data interface, you must disable manager access on the original data interface, but do not disable the interface itself yet; the original data interface must be used to perform the deployment. If you want to use the same IP address on the new manager access interface, you can delete or change the IP configuration on the original interface; this change should not affect the deployment. If you use a different IP address for the new interface, then also change the device IP address shown in the Firewall Management Center ; see Update the Hostname or IP Address in the Firewall Management Center, on page 772 . Be sure to also update related configuration to use the new interface such as static routes, DDNS, and DNS settings.

Manager access from a data interface has the following limitations:

- You can only enable manager access on a physical, data interface. You cannot use a subinterface or EtherChannel, nor can you create a subinterface on the manager access interface. You can also use the Firewall Management Center to enable manager access on a single secondary interface for redundancy.
- This interface cannot be management-only.
- Routed firewall mode only, using a routed interface.
- PPPoE is not supported. If your ISP requires PPPoE, you will have to put a router with PPPoE support between the Firewall Threat Defense and the WAN modem.
- The interface must be in the global VRF only.
- SSH is not enabled by default for data interfaces, so you will have to enable SSH later using the Firewall Management Center. Because the Management interface gateway will be changed to be the data interfaces, you also cannot SSH to the Management interface from a remote network unless you add a static route for the Management interface using the **configure network static-routes** command. For Firewall Threat Defense Virtual on Amazon Web Services, a console port is not available, so you should maintain your SSH access to the Management interface: add a static route for Management before you continue with your configuration. Alternatively, be sure to finish all CLI configuration (including the **configure manager add** command) before you configure the data interface for manager access and you are disconnected.
- You cannot use separate management and event-only interfaces.
- Clustering is not supported. You must use the Management interface in this case.

Figure 288: Manager Access

- Check **Enable management on this interface for the manager** to use this data interface for management instead of the dedicated Management interface.

- (Optional) In the **Allowed Management Networks** box, add the networks from which you want to allow manager access. By default, any networks are allowed.

Step 7 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed**.

- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
- **Speed**—Choose a speed (varies depending on the model).For SFPs, choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always full, autonegotiation is enabled, and FEC is set to auto. For dual-speed transceivers, the lower speed is used. This option is useful if you later change the network module to a different model, and want the speed to update automatically. Some switches and transceivers don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

Note You cannot modify the speed of a high availability or a cluster control link interface.

- **Auto-negotiation**—Set the interface to negotiate the link status and flow control.

  Except for the 1100 and 2100, autonegotiation is set separately from the speed. Some switches don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

- **Forward Error Correction Mode**—For 25Gbps and higher interfaces, enable Forward Error Correction (FEC).

  For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. If you remove the interface from the EtherChannel, after rebooting, you may need to reconfigure the FEC for the interface.

  Some switches don't support auto mode for FEC, especially for larger interfaces. Be sure to manually configure the setting, depending on the switch support. We don't recommend disabling FEC; if you do so, the EtherChannel may not come up properly.

  The setting chosen when you use **auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 43: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 108 RS-FEC	Clause 108 RS-FEC
25G-LR	Clause 108 RS-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 108 RS-FEC	Clause 74 FC-FEC
25G-AOC*x*M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate
25/50/100G	Clause 91 RS-FEC	Clause 91 RS-FEC

Note From Version 7.4.2, Firewall Threat Defense supports the SFP 10G_25G_CSR_S module. To avoid link-down issues after a reboot, Forward Error Correction (FEC) must be enabled on these interfaces.

Step 8 Click **OK** .

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Bridge group interfaces

A bridge group is a group of interfaces that the Secure Firewall Threat Defense device bridges instead of routes.

Bridge group support

Bridge groups are supported in both transparent and routed firewall mode.

For more information about bridge groups, see Bridge groups, on page 73.

To configure bridge groups and associated interfaces, perform these steps.

Configure general bridge group member interface parameters

This task configures the name and security zone for each bridge group member interface to enable bridge group functionality.

The same bridge group can include different types of interfaces: physical interfaces, VLAN subinterfaces, Firepower 1010 VLAN interfaces, EtherChannels, and redundant interfaces. The Management interface is not supported. In routed mode, EtherChannels are not supported. For the Firepower 4100/9300, data-sharing type interfaces are not supported.

Before you begin

- Firepower 4100/9300
  1. Configure a physical interface, on page 259
  2. (Optional) Configure any special interfaces.
     - Add an EtherChannel (port channel), on page 261
     - Add a VLAN subinterface for container instances, on page 263 in FXOS

- Add a subinterface, on page 669 in Firewall Management Center

- (Optional) **All other models:**
  - Configure an EtherChannel, on page 619
  - Add a subinterface, on page 669
  - Firepower 1010: Configure a VLAN interface, on page 653

Follow these steps to configure general bridge group member interface parameters:

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Configure these fields:

a) In the **Name** field, enter a name up to 48 characters in length.

You cannot start the name with the phrase "cluster". It is reserved for internal use.

b) Enable the interface by checking the **Enabled** check box.

c) (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.

d) (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

e) In the **Mode** drop-down list, choose **None**.

Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types. After you assign this interface to a bridge group, the mode will show as **Switched**.

f) From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

The bridge group member interface is a Switched-type interface, and can only belong to Switched-type zones. Do not configure any IP address settings for this interface. You will set the IP address for the Bridge Virtual Interface (BVI) only. Note that the BVI does not belong to a zone, and you cannot apply access control policies to the BVI.

Step 4 Refer to Configure the MTU, on page 717 for information about **MTU**.

Step 5 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed** .

- **Duplex** —Choose **Full** or **Half** . SFP interfaces only support **Full** duplex.
- **Speed** —Choose a speed (varies depending on the model). For SFPs, choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always full, autonegotiation is enabled, and FEC is set to auto. For dual-speed transceivers, the lower speed is used. This option is useful if you later change the network module to a different model, and want the speed to update automatically. Some switches and transceivers don't support autonegotiation, especially for higher speed

interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

Note You cannot modify the speed of a high availability or a cluster control link interface.

- **Auto-negotiation** —Set the interface to negotiate the link status and flow control.

  Except for the 1100 and 2100 , autonegotiation is set separately from the speed. Some switches don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

- **Forward Error Correction Mode** —For 25Gbps and higher interfaces, enable Forward Error Correction (FEC).

  For an EtherChannel member interface, configure FEC before adding it to the EtherChannel. If you remove the interface from EtherChannel and then reboot, reconfigure the FEC for the interface.

  Some switches don't support auto mode for FEC, especially for larger interfaces. Be sure to manually configure the setting, depending on the switch support. We don't recommend disabling FEC because the EtherChannel may not function correctly.

  The setting chosen when you use **auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 44: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 108 RS-FEC	Clause 108 RS-FEC
25G-LR	Clause 108 RS-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 108 RS-FEC	Clause 74 FC-FEC
25G-AOC *x* M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate
25/50/100G	Clause 91 RS-FEC	Clause 91 RS-FEC

Note From Version 7.4.2, Firewall Threat Defense supports the SFP 10G_25G_CSR_S module. To avoid link-down issues after a reboot, Forward Error Correction (FEC) must be enabled on these interfaces.

Step 6 (Optional) Refer to Configure IPv6 addressing, on page 699 to configure IPv6 addressing on the **IPv6** tab.

Step 7 (Optional) Refer to Configure the MAC address, on page 718 to manually configure the MAC address on the **Advanced** tab.

Step 8 Click **OK**.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure the bridge virtual interface (BVI)

Configure a Bridge Virtual Interface (BVI) to provide IP addressing for each bridge group, which enables traffic routing and management functionality for the bridge group members.

Each bridge group requires a BVI for which you configure an IP address. The Firewall Threat Defense uses this IP address as the source address for packets originating from the bridge group. The BVI IP address must be on the same subnet as the connected network. For IPv4 traffic, the BVI IP address is required to pass any traffic. For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations.

For routed mode, if you provide a name for the BVI, then the BVI participates in routing. Without a name, the bridge group remains isolated as in transparent firewall mode.

Before you begin

You cannot add the BVI to a security zone; therefore, you cannot apply Access Control policies to the BVI. You must apply your policy to the bridge group member interfaces based on their zones.

Follow these steps to configure the Bridge Virtual Interface (BVI):

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Choose **Add Interfaces** > **Bridge Group Interface**.

a) (Routed Mode) In the **Name** field, enter a name up to 48 characters in length.

You must name the BVI if you want to route traffic outside the bridge group members, for example, to the outside interface or to members of other bridge groups. The name is not case-sensitive.

Step 3 In the **Bridge Group ID** field, enter the bridge group ID between 1 and 250.

Step 4 In the **Description** field, enter a description for this bridge group.

Step 5 On the **Interfaces** tab, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members of the bridge group.

Step 6 Click the **IPv4** tab.

a) (Routed Mode) To set the IP address, use one of the following options from the **IP Type** drop-down list.

High Availability and clustering interfaces only support static IP address configuration; DHCP is not supported.

- **Use Static IP**—Enter the IP address and subnet mask. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices** > **Device Management**, click the **High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- **Use DHCP**—Configure the following optional parameters:
  - **Obtain default route using DHCP**—Obtains the default route from the DHCP server.
  - **DHCP route metric**—Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.

b) (Transparent Mode) In the **IP Address** field, enter the IPv4 address and subnet mask.

Do not assign a host address (/32 or 255.255.255.255) to the BVI. Also, do not use other subnets that contain fewer than 3 host addresses (one each for the upstream router, downstream router, and transparent firewall) such as a /30 subnet (255.255.255.252). The Firewall Threat Defense device drops all ARP packets to or from the first and last addresses in a subnet. For example, if you use a /30 subnet and assign a reserved address from that subnet to the upstream router, then the Firewall Threat Defense device drops the ARP request from the downstream router to the upstream router.

For High Availability, set the standby IP address on the **Devices** > **Device Management** page, click the **High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

Step 7 (Optional) Refer to Configure IPv6 addressing, on page 699 to configure IPv6 addressing.

Step 8 (Optional) Refer to Add a static ARP entry, on page 718 and Add a static MAC address and disable MAC learning for a bridge group, on page 720 (for transparent mode only) to configure the **ARP** and **MAC** settings.

Step 9 Click **OK**.

Click **Save**.

What to do next

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure IPv6 addressing

This section describes how to configure IPv6 addressing in routed and transparent mode.

About IPv6

This section includes information about IPv6.

IPv6 addressing

IPv6 addressing provides 128 bits of network addressing, which provides more than enough globally unique IP addresses. It supports both public global addresses and private link-local addresses, and

IPv6 address types

You can configure two types of unicast addresses for IPv6:

- Global—The global address is a public address that you can use on the public network. For a bridge group, this address needs to be configured for the BVI, and not per member interface. You can also configure a global IPv6 address for the management interface in transparent mode.
- Link-local—The link-local address is a private address that you can only use on the directly-connected network. Routers do not forward packets using link-local addresses; they are only for communication on a particular physical network segment. They can be used for address configuration or for the Neighbor Discovery functions such as address resolution. In a bridge group, only member interfaces have link-local addresses; the BVI does not have a link-local address.

At a minimum, you need to configure a link-local address for IPv6 to operate. If you configure a global address, a link-local address is automatically configured on the interface, so you do not also need to specifically configure a link-local address. For bridge group member interfaces, when you configure the global address on the BVI, the Firewall Threat Defense device automatically generates link-local addresses for member interfaces. If you do not configure a global address, then you need to configure the link-local address, either automatically or manually.

Modified EUI-64 interface IDs

RFC 3513: Internet Protocol Version 6 (IPv6) Addressing Architecture requires that the interface identifier portion of all unicast IPv6 addresses, except those that start with binary value 000, be 64 bits long and be constructed in Modified EUI-64 format. The Firewall Threat Defense device can enforce this requirement for hosts attached to the local link.

Address verification process

When this feature is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the IPv6 packets do not use the Modified EUI-64 format for the interface identifier, the packets are dropped and this system log message is generated:

```
325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link.

IPv6 prefix delegation client configuration

The Firewall Threat Defense can act as a DHPCv6 Prefix Delegation client so that the client interface, for example the outside interface connected to a cable modem, can receive one or more IPv6 prefixes that the Firewall Threat Defense can then subnet and assign to its inside interfaces.

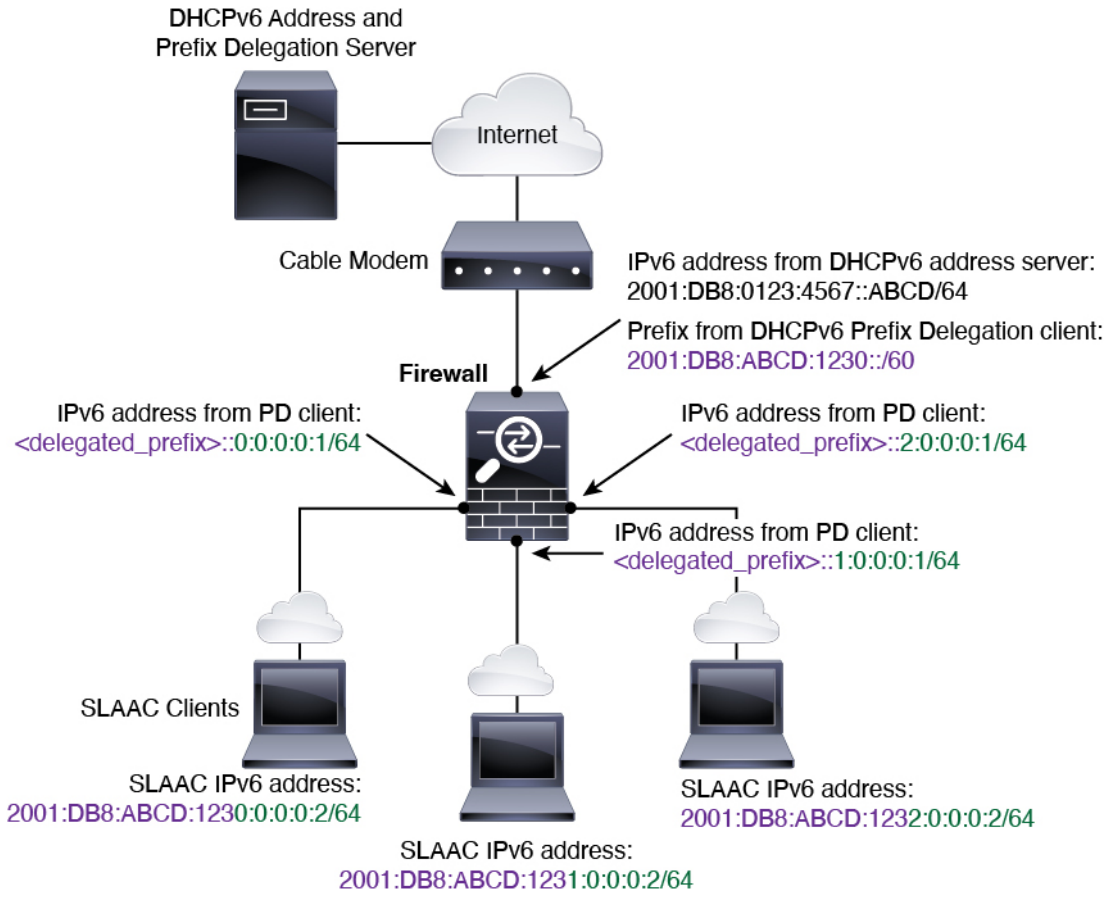
IPv6 prefix delegation

IPv6 prefix delegation enables the Firewall Threat Defense to function as a Dynamic Host Control Protocol for IPv6 (DHCPv6) prefix delegation client and receive one or more IPv6 prefixes. This feature allows the Firewall Threat Defense to subnet and assign these prefixes to its inside interfaces. It enable the hosts connected to inside interfaces to use Stateless Address Auto Configuration (SLAAC) to obtain global IPv6 addresses.

Client and server behavior

The client interface, such as the outside interface connected to a cable modem, receives IPv6 prefixes that the Firewall Threat Defense can then subnet and assign to its inside interfaces. The inside Firewall Threat Defense interfaces do not in turn act as Prefix Delegation servers; the Firewall Threat Defense can only provide global IP addresses to SLAAC clients.

If a router is connected to the Firewall Threat Defense, it can act as a SLAAC client to obtain its IP address. However, if you want to use a subnet of the delegated prefix for the networks behind the router, you must manually configure those addresses on the router's inside interfaces.



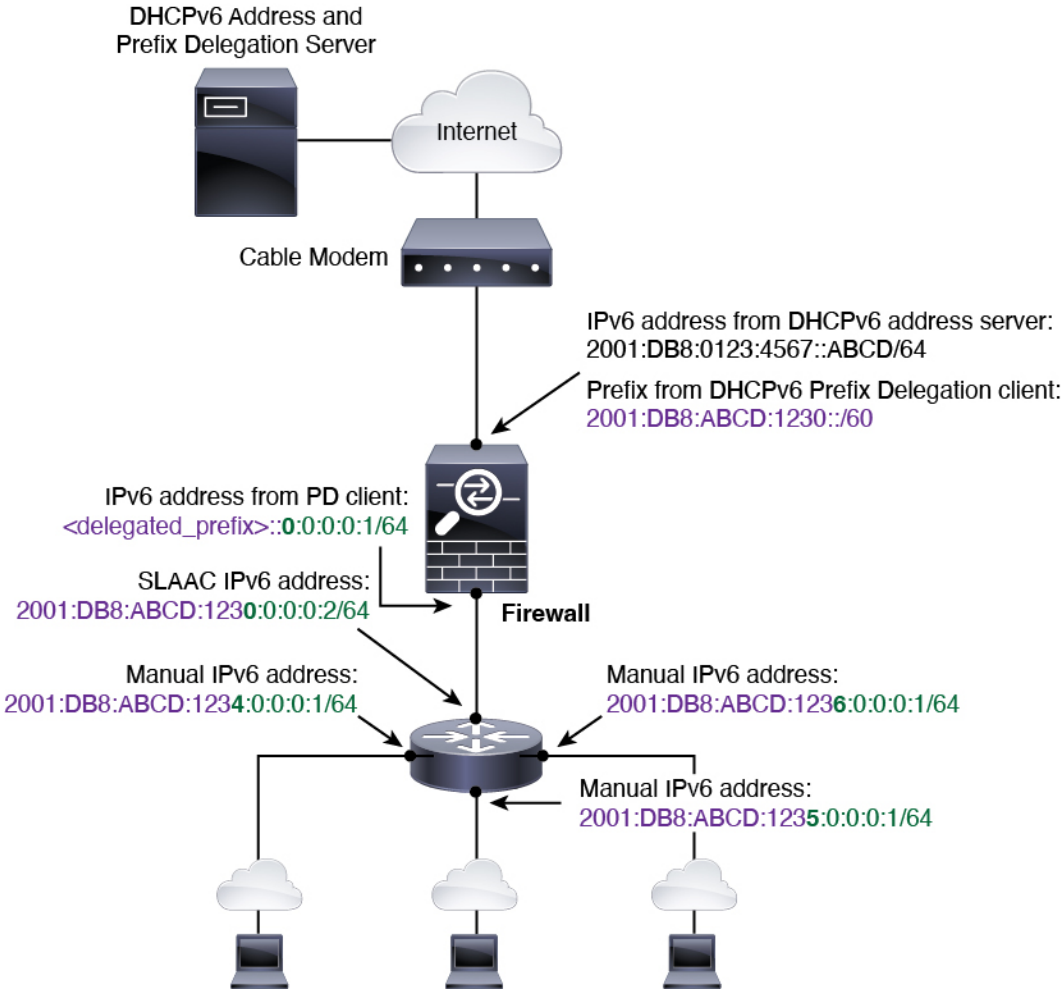
The Firewall Threat Defense includes a light DHCPv6 server. This server provides information, such as the DNS server and domain name, to SLAAC clients when they send Information Request (IR) packets to the Firewall Threat Defense. The Firewall Threat Defense only accepts IR packets, and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages. In other words, the addresses are based on the prefix that the Firewall Threat Defense received using Prefix Delegation.

IPv6 prefix delegation /64 subnet example

Here is an IPv6 prefix delegation /64 subnet example that demonstrates how a device subnets delegated prefixes into /64 networks and assigns global IPv6 addresses to interfaces.

IPv6 prefix delegation /64 subnet configuration

This example shows the Firewall Threat Defense receiving an IP address on the outside interface using the DHCPv6 address client. It also gets a delegated prefix using the DHCPv6 Prefix Delegation client. The Firewall Threat Defense subnets the delegated prefix into /64 networks and assigns global IPv6 addresses to its inside interfaces dynamically using the delegated prefix plus a manually configured subnet (::0, ::1, or ::2) and IPv6 address (0:0:0:1) per interface. SLAAC clients connected to those inside interfaces obtain IPv6 addresses on each /64 subnet.



IPv6 prefix delegation /62 subnet examples

IPv6 prefix delegation /62 subnet enables subnetting of prefixes into 4 /62 subnets for downstream router delegation. It allows manual configuration of /64 subnets on router interfaces when dynamic prefix assignment is not available.

IPv6 /62 subnet delegation configuration

This example shows the Firewall Threat Defense subnetting the prefix into 4 /62 subnets: 2001:DB8:ABCD:123**0**::/62, 2001:DB8:ABCD:123**4**::/62, 2001:DB8:ABCD:123**8**::/62, and 2001:DB8:ABCD:123**C**::/62. The Firewall Threat Defense uses one of 4 available /64 subnets on 2001:DB8:ABCD:1230::/62 for its inside network (::0). You can then manually use additional /62 subnets for downstream routers. The router shown uses 3 of 4 available /64 subnets on 2001:DB8:ABCD:1234::/62 for its inside interfaces (::4, ::5, and ::6). In this case, the inside router interfaces cannot dynamically obtain the delegated prefix, so you need to view the delegated prefix on the Firewall Threat Defense, and then use that prefix for your router configuration. Usually, ISPs delegate the same prefix to a given client when the lease expires, but if the Firewall Threat Defense receives a new prefix, you will have to modify the router configuration to use the new prefix. The DHCP unique identifier (DUID) is persistent across reboots.

Enable the IPv6 prefix delegation client

Enable the DHCPv6 Prefix Delegation client to obtain one or more IPv6 prefixes that can be subnetted and assigned to inside networks.

Enable the DHCPv6 Prefix Delegation client on one or more interfaces. The Firewall Threat Defense obtains one or more IPv6 prefixes that it can subnet and assign to inside networks. Typically, the interface on which you enable the prefix delegation client obtains its IP address using the DHCPv6 address client; only other Firewall Threat Defense interfaces use addresses derived from the delegated prefix.

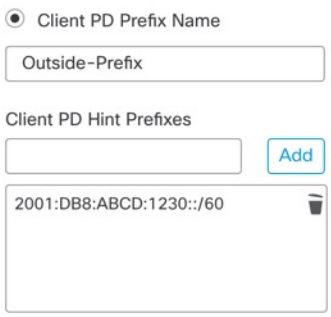
This feature is supported only in routed mode.

This feature is not supported in clustering or High Availability.

Before you begin

When you use Prefix Delegation, you must set the Firewall Threat Defense IPv6 neighbor discovery router advertisement interval to be much lower than the preferred lifetime of the prefix assigned by the DHCPv6 Server to prevent IPv6 traffic interruption. For example, if the DHCPv6 server sets the preferred Prefix Delegation lifetime to 300 seconds, you should set the Firewall Threat Defense RA interval to be 150 seconds. To set the preferred lifetime, use the **show ipv6 general-prefix** command. To set the Firewall Threat Defense RA interval, see Configure IPv6 neighbor discovery, on page 709. The default is 200 seconds.

Procedure



Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **IPv6** page, and then click **DHCP**.

Step 4 Click **Client PD Prefix Name** and enter a name for this prefix.

Figure 289: Enable the prefix delegation client

The name can be up to 200 characters.

Step 5 (Optional) Enter the prefix and prefix length in the **Client PD Hint Prefixes** field to provide one or more hints to the DHCP server about the delegated prefix you want to receive, then click **Add**.

Typically you want to request a particular prefix length, such as ::/60, or if you have received a particular prefix before and want to ensure you get it again when the lease expires, you can enter the whole prefix as the hint. If you enter multiple hints (different prefixes or lengths), then it is up to the DHCP server which hint to honor, or whether to honor the hint at all.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure a global IPv6 address

Before you begin

For IPv6 neighbor discovery for bridge groups, you must explicitly allow Neighbor Solicitation (ICMPv6 type 135) and Neighbor Advertisement (ICMPv6 type 136) packets through the Firewall Threat Defense bridge group member interfaces using a bidirectional access rule.

To configure a global IPv6 address for any routed mode interface and for the transparent or routed mode BVI, perform the following steps.

Note Configuring the global address automatically configures the link-local address, so you do not need to configure it separately. For bridge groups, configuring the global address on the BVI automatically configures link-local addresses on all member interfaces.

For subinterfaces defined on the Firewall Threat Defense , we recommend that you also set the MAC address manually, because they use the same burned-in MAC address of the parent interface. IPv6 link-local addresses are generated based on the MAC address, so assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense . See Configure the MAC address, on page 718 .

Firewall Threat Defense Feature History:

- 7.3—DHCPv6 Address client
- 7.3—DHCPv6 Prefix Delegation client
- 7.3—DHCPv6 stateless server

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click the **IPv6** page.

For routed mode, the **Basic** page is selected by default. For transparent mode, the **Address** page is selected by default.

Step 4 On the **Basic** page, check **Enable IPv6** .

Use this option if you want to only configure the link-local addresses. Otherwise, configuring an IPv6 address enables IPv6 processing automatically.

Step 5 Configure the global IPv6 address using one of the following methods.

For failover and clustering, and for loopback interfaces, you must set the IP address manually. For clustering, manually configuring the link-local address is also not supported.

- (Routed interface) Stateless autoconfiguration—Check the **Autoconfiguration** check box.

  Enabling stateless autoconfiguration on the interface configures IPv6 addresses based upon prefixes received in Router Advertisement messages. A link-local address, based on the Modified EUI-64 interface ID, is automatically generated for the interface when stateless autoconfiguration is enabled.

  Although RFC 4862 specifies that hosts configured for stateless autoconfiguration do not send Router Advertisement messages, the Firewall Threat Defense device does send Router Advertisement messages in this case. Click the **Settings** tab and click the **IPv6** tab and then uncheck the **Enable RA** check box to suppress messages.

- Manual configuration—To manually configure a global IPv6 address:

a. Click the **Address** page, and click (+) **Add Address** .

   The **Add Address** dialog box appears.

b. In the **Address** field, enter either a full global IPv6 address, including the interface ID, or enter the IPv6 prefix, along with the IPv6 prefix length. (Routed Mode) If you only enter the prefix, then be sure to check the **Enforce EUI 64** check box to generate the interface ID using the Modified EUI-64 format. For example, 2001:0DB8::BA98:0:3210/48 (full address) or 2001:0DB8::/48 (prefix, with EUI 64 checked).

   For High Availability (if you did not set **Enforce EUI 64**), set the standby IP address on the **Devices** > **Device Management** page, click **High Availability** in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

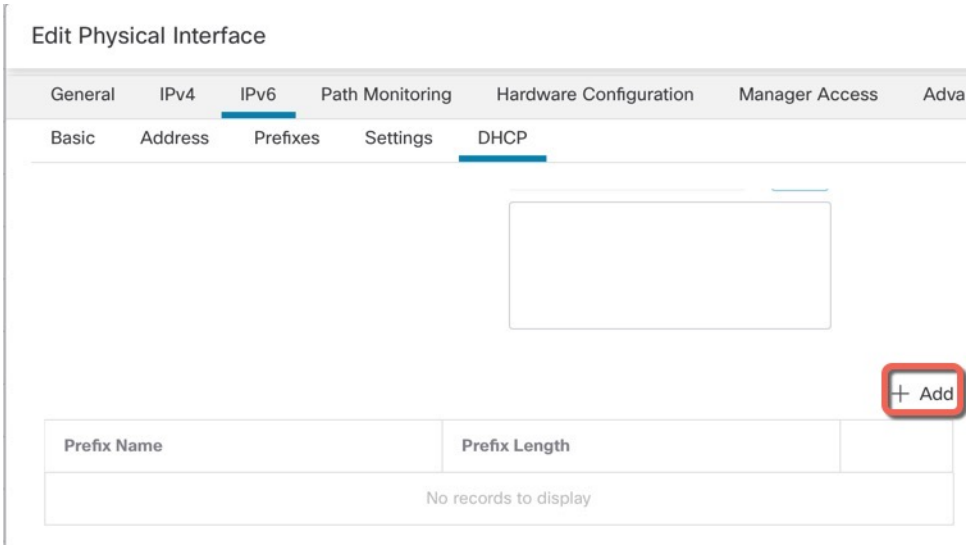
- (Routed interface) Obtain an address using DHCPv6—To use DHCPv6:

Figure 290: Enable the DHCPv6 Client

a. Click the **DHCP** page.

b. Check the check box of **Enable DHCP Client** .

c. (Optional) Check the check box of **Enable default route using DHCP** to obtain a default route from Router Advertisements.



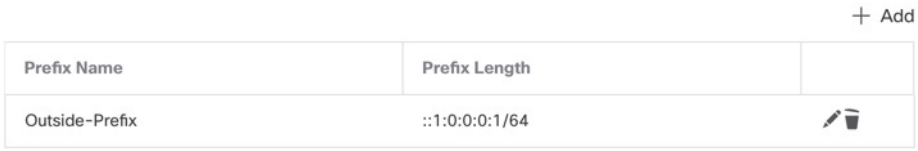
- (Routed interface) Use a delegated prefix—To assign an IPv6 address using the delegated prefix:

  This feature requires the Firewall Threat Defense to have the DHCPv6 Prefix Delegation client enabled *on a different interface* . See Enable the IPv6 prefix delegation client, on page 703 .

a. Click the **DHCP** page.

b. Click (+) .

Figure 291: Use a Delegated Prefix



c. Enter the IPv6 address and **Prefix Length** .

Typically, the delegated prefix will be /60 or smaller so you can subnet to multiple /64 networks. /64 is the supported subnet length if you want to support SLAAC for connected clients. You should specify an address that completes the /60 subnet, for example ::1:0:0:0:1. Enter :: before the address in case the prefix is smaller than /60. For example, if the delegated prefix is 2001:DB8:1234:5670::/60, then the global IP address assigned to this interface is 2001:DB8:1234:5671::1/64. The prefix that is advertised in router advertisements is 2001:DB8:1234:5671::/64. In this example, if the prefix is smaller than /60, the remaining bits of the prefix will be 0's as indicated by the leading ::. For example, if the prefix is 2001:DB8:1234::/48, then the IPv6 address will be 2001:DB8:1234::1:0:0:0:1/64.

d. Click **OK** .

Figure 292: Prefix Delegation Table

e. Optionally enable the DHCPv6 stateless server on this interface (see Enable the DHCPv6 stateless server, on page 836). If you do so, we recommend that you also check the **Enable DHCP for non-address config** option.

Step 6 For Routed interfaces, you can optionally set these values on the **Basic** page:

- To enforce the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link, check the **Enforce EUI-64** check box.
- To manually set the link-local address, enter an address in the **Link-Local address** field.

A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:feee:6a82. If you do not want to configure a global address, and only need to configure a link-local address, you have the option of manually defining the link-local address. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.

Clustering does not support manual link-local addresses.

Step 7 For Routed interfaces, you can optionally set the following values on the **DHCP** page:

- Check the **Enable DHCP for address config** check box to set the Managed Address Config flag in the IPv6 router advertisement packet.

  This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain addresses, in addition to the derived stateless autoconfiguration address.

- Check the **Enable DHCP for non-address config** check box to set the Other Address Config flag in the IPv6 router advertisement packet.

  This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address. Use this option when using the DHCPv6 stateless server with DHCPv6 prefix delegation.

Step 8 For Routed interfaces, see Configure IPv6 neighbor discovery, on page 709 to configure settings on the **Prefixes** and **Settings** pages. For BVI interfaces, see the following parameters on the **Settings** page:

- **DAD attempts** —The maximum number of DAD attempts , between 1 and 600. Set the value to 0 to disable duplicate address detection (DAD) processing. This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses . 1 attempt is the default.
- **NS Interval** —The interval between IPv6 neighbor solicitation retransmissions on an interface , between 1000 and 3600000 ms . The default value is 1000 ms.
- **Reachable Time** —The amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred , between 0 and 3600000 ms . The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value. The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

Step 9 Click **OK** .

Click **Save**.

What to do next

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure IPv6 neighbor discovery

Before you begin

Supported in Routed mode only. For IPv6 neighbor settings supported in transparent mode, see Configure a global IPv6 address, on page 704 .

The IPv6 neighbor discovery process uses ICMPv6 messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), verify the readability of a neighbor, and keep track of neighboring routers.

Nodes (hosts) use neighbor discovery to determine the link-layer addresses for neighbors known to reside on attached links and to quickly purge cached values that become invalid. Hosts also use neighbor discovery to find neighboring routers that are willing to forward packets on their behalf. In addition, nodes use the protocol to actively keep track of which neighbors are reachable and which are not, and to detect changed link-layer addresses. When a router or the path to a router fails, a host actively searches for functioning alternates.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click **IPv6** , and then **Prefixes**.

To configure the IPv6 router advertisements with IPv6 prefixes, perform these steps:

a) Click ( ) **Add Prefix** .
b) In the **Address** field, enter the IPv6 address with the prefix length or check the **Default** check box to use the default prefix.
c) (Optional) Uncheck the **Advertisement** check box to indicate that the IPv6 prefix is not advertised. For the **Default** prefix, this setting only applies to on-link prefixes. Off-link prefixes will still be advertised unless you uncheck **Advertisement** for a specific off-link prefix.
d) Check the **Off Link** check box to indicate that the specified prefix is assigned to the link. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be locally reachable on the link. This prefix should not be used for on-link determination.
e) To use the specified prefix for autoconfiguration, check the **Autoconfiguration** check box.
f) For the **Prefix Lifetime** , click **Duration** or **Expiration Date** .

- **Duration** —Enter a **Preferred Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being valid. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default is 2592000 (30 days). Enter a **Valid Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being preferred. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default setting is 604800 (seven days). Alternatively, check the **Infinite** check box to set an unlimited duration.
- **Expiration Date** —Choose a **Valid** and **Preferred** date and time.

g) Click **OK** .

Step 4 Click **Settings**.

a) (Optional) Set the maximum number of **DAD attempts** , between 1 and 600. 1 attempt is the default. Set the value to 0 to disable duplicate address detection (DAD) processing.

This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses.

During the stateless autoconfiguration process, Duplicate Address Detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces.

When a duplicate address is identified, the state of the address is set to DUPLICATE, the address is not used, and the following error message is generated:

```
325002: Duplicate address ipv6_address/MAC_address on interface
```

If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface. If the duplicate address is a global address, the address is not used.

b) (Optional) Configure the interval between IPv6 neighbor solicitation retransmissions in the **NS Interval** field, between 1000 and 3600000 ms.

The default value is 1000 ms.

Neighbor solicitation messages (ICMPv6 Type 135) are sent on the local link by nodes attempting to discover the link-layer addresses of other nodes on the local link. After receiving a neighbor solicitation message, the destination node replies by sending a neighbor advertisement message (ICPMv6 Type 136) on the local link.

After the source node receives the neighbor advertisement, the source node and destination node can communicate. Neighbor solicitation messages are also used to verify the reachability of a neighbor after the link-layer address of a neighbor is identified. When a node wants to verifying the reachability of a neighbor, the destination address in a neighbor solicitation message is the unicast address of the neighbor.

Neighbor advertisement messages are also sent when there is a change in the link-layer address of a node on a local link.

Step 5 (Optional) Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred in the **Reachable Time** field, between 0 and 3600000 ms.

The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value.

The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

Step 6 (Optional) To suppress the router advertisement transmissions, uncheck the **Enable RA** check box. If you enable router advertisement transmissions, you can set the RA lifetime and interval.

Router advertisement messages (ICMPv6 Type 134) are automatically sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message.

You may want to disable these messages on any interface for which you do not want the Firewall Threat Defense to supply the IPv6 prefix (for example, the outside interface).

- **RA Lifetime** —Configure the router lifetime value in IPv6 router advertisements, between 0 and 9000 seconds.

The default is 1800 seconds.

- **RA Interval** —Configure the interval between IPv6 router advertisement transmissions, between 3 and 1800 seconds.

  The default is 200 seconds.

  To prevent synchronization with other IPv6 nodes, the firewall randomly adjusts the value that you set (jitter).

Step 7 Click **OK**.

Click **Save**.

What to do next

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Advanced interface settings

This section describes how to configure MAC addresses for regular firewall mode interfaces, how to set the maximum transmission unit (MTU), and how to set other advanced parameters.

About advanced interface configuration

This section describes advanced interface settings.

MAC addresses

Media Access Control (MAC) address is a unique physical address of a network device.

You can manually assign MAC addresses to override the default. For container instances, the FXOS chassis automatically generates unique MAC addresses for all interfaces.

Note You might want to assign unique MAC addresses to subinterfaces defined on the Firewall Threat Defense, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense device.

Note For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

Default MAC addresses

This reference provides information about default MAC addresses used in network devices and their configurations.

Default MAC address assignments depend on the type of interface.

- Physical interfaces—The physical interface uses the burned-in MAC address.
- VLAN interfaces (Firepower 1010)—Routed firewall mode: All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See Configure the MAC address, on page 718.

  Transparent firewall mode: Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See Configure the MAC address, on page 718.
- EtherChannels—For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses a unique MAC address from a pool; interface membership does not affect the MAC address.
- EtherChannels (ASA Models)—The port-channel interface uses the lowest-numbered channel group interface MAC address as the port-channel MAC address. Alternatively you can configure a MAC address for the port-channel interface. We recommend configuring a unique MAC address in case the group channel interface membership changes. If you remove the interface that was providing the port-channel MAC address, then the port-channel MAC address changes to the next lowest numbered interface, thus causing traffic disruption.
- Subinterfaces (Firewall Threat Defense-defined)—All subinterfaces of a physical interface use the same burned-in MAC address. You might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense.

For container instances:

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See Automatic MAC Addresses for Container Instance Interfaces, on page 246.

MTU

Maximum Transmission Unit (MTU) specifies the maximum frame *payload* size that the Firewall Threat Defense can transmit on a given Ethernet interface. The MTU value *excludes* Ethernet headers, VLAN tags, or other overhead. For example, if you set the MTU to 1500, the expected frame size is 1518 bytes including the headers, or 1522 when VLAN tagging is used. Do not set the MTU value higher to accommodate these headers.

VXLAN and geneve encapsulation requirements

For Geneve, the entire Ethernet datagram is being encapsulated, so the new IP packet is larger and requires a larger MTU. Set the Firewall Threat Defense VTEP source interface MTU to the network MTU plus 306 bytes.

Path MTU discovery

Path MTU Discovery enables all devices in a network path between two hosts to coordinate the MTU so they can standardize on the lowest MTU in the path.

Path MTU discovery support

The Firewall Threat Defense supports Path MTU Discovery (as defined in RFC 1191).

Default MTU

The default MTU on the Firewall Threat Defense device is 1500 bytes. This value does not include the 18-22 bytes for the Ethernet header, VLAN tagging, or other overhead.

MTU and fragmentation

IPv4 packets that are larger than the specified MTU are fragmented into multiple frames.

Packet handling details

For IPv4, if an outgoing IP packet is larger than the specified MTU, it is fragmented into 2 or more frames. Fragments are reassembled at the destination (and sometimes at intermediate hops), and fragmentation can cause performance degradation. For IPv6, packets are typically not allowed to be fragmented at all. Therefore, your IP packets should fit within the MTU size to avoid fragmentation.

For TCP packets, the endpoints typically use their MTU to determine the TCP maximum segment size (MTU - 40, for example). If additional TCP headers are added along the way, for example for site-to-site VPN tunnels, then the TCP MSS might need to be adjusted down by the tunneling entity. See TCP MSS, on page 714.

For UDP or ICMP, the application should take the MTU into account to avoid fragmentation.

Note The Firewall Threat Defense can receive frames larger than the configured MTU as long as there is room in memory.

Full reassembly for inspected fragmented packets

The FTD performs virtual reassembly by default. However, when features such as DNS or voice media inspection are active, the firewall performs full reassembly before forwarding. This ensures packets are processed correctly by inspection engines.

For example, SIP packets subject to inspection require full reassembly. If SIP inspection is disabled, the system maintains virtual reassembly. To avoid issues, we recommend reducing SIP message size or using TCP or TLS for large messages rather than sending large SIP INVITE packets over UDP.

The firewall merges fragments in memory. If the egress interface MTU is smaller than the reassembled packet, the device will refragment the data to fit. To verify behavior, use packet captures on the egress interface and adjust MTU settings as needed.

MTU and jumbo frames configuration

A larger MTU lets you send larger packets. Larger packets might be more efficient for your network.

- Matching MTUs on the traffic path—We recommend that you set the MTU on all Firewall Threat Defense interfaces and other device interfaces along the traffic path to be the same. Matching MTUs prevents intermediate devices from fragmenting the packets.
- Accommodating jumbo frames—You can set the MTU 9000 bytes or higher when you enable jumbo frames. The maximum depends on the model.

TCP MSS

The TCP maximum segment size (MSS) is the size of the TCP payload *before* any TCP and IP headers are added. TCP MSS values are exchanged between client and server during the three-way handshake when establishing connections. UDP packets are not affected.

TCP MSS configuration and behavior

You can set the TCP MSS on the Firewall Threat Defense device for through traffic using the Sysopt_Basic object in FlexConfig. By default, the maximum TCP MSS is set to 1380 bytes. This setting is useful if the Firewall Threat Defense device must increase the packet size for IPsec VPN encapsulation. However, for non-IPsec endpoints, you should disable the maximum TCP MSS on the Firewall Threat Defense device.

If you set a maximum TCP MSS and either endpoint of a connection requests a TCP MSS larger than this value, the Firewall Threat Defense device overwrites the TCP MSS in the request packet with the Firewall Threat Defense device maximum. If the host or server does not request a TCP MSS, the Firewall Threat Defense device assumes the RFC 793-default value of 536 bytes for IPv4 or 1220 bytes for IPv6, but does not modify the packet.

You can also configure the minimum TCP MSS. If a host or server requests a very small TCP MSS, the Firewall Threat Defense device can increase the value. By default, the minimum TCP MSS is not enabled.

For to-the-box traffic, including for SSL VPN connections, this setting does not apply. The Firewall Threat Defense device derives the TCP MSS from MTU: MTU minus 40 for IPv4 or MTU minus 60 for IPv6.

TCP MSS adjustment scenario

For example, you leave the default MTU as 1500 bytes. A host requests an MSS of 1500 minus the TCP and IP header length, which sets the MSS to 1460. If the Firewall Threat Defense device maximum TCP MSS is 1380 (the default), then the Firewall Threat Defense device changes the MSS value in the TCP request packet to 1380. The server then sends packets with 1380-byte payloads. The Firewall Threat Defense device can add up to 120 bytes of headers to the packet, and the resulting packet fits within the MTU size of 1500 bytes.

Default TCP MSS

A default TCP MSS is a network configuration setting that sets the maximum TCP MSS on the Firewall Threat Defense device to 1380 bytes by default, accommodates IPv4 IPsec VPN connections where the headers can equal up to 120 bytes, and fits within the default MTU of 1500 bytes.

Suggested maximum TCP MSS setting

The default TCP MSS assumes the Firewall Threat Defense device acts as an IPv4 IPsec VPN endpoint and has an MTU of 1500. When the Firewall Threat Defense device acts as an IPv4 IPsec VPN endpoint, it needs to accommodate up to 120 bytes for TCP and IP headers.

If you change the MTU value, use IPv6, or do not use the Firewall Threat Defense device as an IPsec VPN endpoint, then you should change the TCP MSS setting using the Sysopt_Basic object in FlexConfig.

Note If you explicitly set an MSS, a component such as TLS/SSL decryption or server discovery might require a particular MSS.In that case, the component sets the MSS based on the interface MTU and ignores your MSS setting.

- Normal traffic—Disable the TCP MSS limit and accept the value established between connection endpoints. Because connection endpoints typically derive the TCP MSS from the MTU, non-IPsec packets usually fit this TCP MSS.
- IPv4 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 120. For example, if you use jumbo frames and set the MTU to 9000, then you need to set the TCP MSS to 8880 to take advantage of the new MTU.
- IPv6 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 140.

ARP inspection for bridge group traffic

This reference describes ARP inspection functionality for bridge group traffic in transparent firewall configurations.

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the Firewall Threat Defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the Firewall Threat Defense device drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the Firewall Threat Defense device to either forward the packet out all interfaces (flood), or to drop the packet.

Note The dedicated Management interface never floods packets even if this parameter is set to flood.

MAC address tables

A MAC address table associates each MAC address with its source interface for accurate packet routing.

MAC address table behavior

When you use bridge groups, the Firewall Threat Defense learns and builds a MAC address table in a way similar to a normal bridge or switch. When a device sends a packet through the bridge group, the Firewall Threat Defense adds the MAC address to its table. The table associates the MAC address with the source interface so that the Firewall Threat Defense knows to send any packets addressed to the device out the correct interface. Because traffic between bridge group members is subject to the Firewall Threat Defense security policy, if the destination MAC address of a packet is not in the table, the Firewall Threat Defense does not flood the original packet on all interfaces as a normal bridge does. Instead, it generates the packets for directly-connected devices or for remote devices.

- Packets for directly-connected devices—The Firewall Threat Defense generates an ARP request for the destination IP address so that it can learn which interface receives the ARP response.
- Packets for remote devices—The Firewall Threat Defense generates a ping to the destination IP address so that it can learn which interface receives the ping reply.

The original packet is dropped.

Default settings

This reference provides default configuration settings for ARP inspection, MAC address table entries, and interface behavior for MAC address learning.

- If you enable ARP inspection, the default setting is to flood non-matching packets.
- The default timeout value for dynamic MAC address table entries is five minutes.
- By default, each interface automatically learns the MAC addresses of entering traffic, and the Firewall Threat Defense device adds corresponding entries to the MAC address table.

Note Secure Firewall Threat Defense device generates a reset packet to reset a connection that is denied by a stateful inspection engine. Here, the destination MAC address of the packet is not determined based on the ARP table lookup but instead it is taken directly from the packets (connections) that are being denied.

Guidelines for ARP inspection and the MAC address table

Consider these configuration support limitations for ARP inspection and MAC address table management:

- ARP inspection is only supported for bridge groups.
- MAC address table configuration is only supported for bridge groups.

Configure the MTU

Customize the MTU on the interface, for example, to allow jumbo frames.

For the ISA 3000 and the Firewall Threat Defense Virtual: Changing the MTU above 1500 bytes automatically enables jumbo-frame reservation. You must restart the system before you can use jumbo frames. For the Firewall Threat Defense Virtual that supports clustering, you can enable jumbo-frame reservation in the Day0 configuration, so in that case, you do not need to restart. After you restart, you cannot disable jumbo-frame reservation. An exception is for the Firewall Threat Defense Virtual, where you can disable jumbo-frame reservation in the Day0 configuration, if supported. If you use an interface in an inline set, the MTU setting is not used. However, the jumbo-frame reservation setting *is* relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo-frame reservation, you must set the MTU of *any* interface above 1500 bytes.

Jumbo frames are enabled by default on other platforms.

Caution Changing the highest MTU value on the device for a data interface restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Inspection is interrupted on all data interfaces, not just the interface you modified. Whether this interruption drops traffic or passes it without further inspection depends on the model of the managed device and the interface type. This caution does not apply to management-only interfaces. See Snort restart traffic behavior, on page 129 for more information.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 On the **General** tab, set the **MTU**. The minimum and maximum depends on your platform.

The default is 1500 bytes.

Step 4 Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 6 For the ISA 3000 and the Firewall Threat Defense Virtual, if you set the MTU above 1500 bytes, restart the system to enable jumbo-frame reservation. See Shut down or restart the device, on page 55.

Configure the MAC address

This task allows you to manually assign MAC addresses to interfaces, including active and standby MAC addresses for high availability configurations.

You might need to manually assign a MAC address. You can also set the Active and Standby MAC addresses on the **Devices** > **Device Management** window by choosing **High Availability** from the **Add** drop-down list. If you set the MAC address for an interface on both screens, the addresses on the **Interfaces** > **Advanced** tab take precedence.

Note For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Advanced** tab.

The **Information** tab is selected.

Step 4 Set the active and standby MAC addresses.

a) In the **Active MAC Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

b) In the **Standby MAC Address** field, enter a MAC address for use with High Availability.

If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

Step 5 Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Add a static ARP entry

Add static ARP entries to control ARP packet flow and support ARP inspection for bridge group members or routed interfaces.

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection (see Configure ARP inspection, on page 850). ARP inspection compares ARP packets with *static* ARP entries in the ARP table.

For routed interfaces, you can enter static ARP entries, but dynamic entries are usually sufficient. For routed interfaces, the ARP table is used to deliver packets to directly-connected hosts. Although senders identify a packet destination by an IP address, the actual delivery of the packet on Ethernet relies on the Ethernet MAC address. When a router or host wants to deliver a packet on a directly connected network, it sends an ARP request asking for the MAC address associated with the IP address, and then delivers the packet to the MAC address according to the ARP response. The host or router keeps an ARP table so it does not have to send ARP requests for every packet it needs to deliver. The ARP table is dynamically updated whenever ARP responses are sent on the network, and if an entry is not used for a period of time, it times out. If an entry is incorrect (for example, the MAC address changes for a given IP address), the entry must time out before it can be updated with the new information.

For transparent mode, the Firewall Threat Defense only uses dynamic ARP entries in the ARP table for traffic to and from the Firewall Threat Defense device, such as management traffic.

Before you begin

This screen is only available for named interfaces.

Follow these steps to add a static ARP entry:

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **ARP** tab (called **ARP and MAC** for transparent mode).

Step 4 Click ( )**Add ARP Config**.
The **Add ARP Config** dialog box appears.

Step 5 In the **IP Address** field, enter the IP address of the host.

Step 6 In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b.

Step 7 To perform proxy ARP for this address, check the **Enable Alias** check box.

If the Firewall Threat Defense device receives an ARP request for the specified IP address, then it responds with the specified MAC address.

Step 8 Click **OK**, and then click **OK** again to exit the Advanced settings.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Add a static MAC address and disable MAC learning for a bridge group

Add static MAC addresses to the MAC address table and optionally disable MAC address learning to guard against MAC spoofing and control traffic flow through the Firewall Threat Defense device.

Normally, MAC addresses are added to the MAC address table dynamically as traffic from a particular MAC address enters an interface. You can disable MAC address learning. If you do not statically add MAC addresses to the table, no traffic can pass through the Firewall Threat Defense device. You can also add static MAC addresses to the MAC address table. One benefit to adding static entries is to guard against MAC spoofing. If a client uses the same MAC address as a static entry and sends traffic to an interface that does not match the static entry, the Firewall Threat Defense device drops the traffic and generates a system message. When you add a static ARP entry (see Add a static ARP entry, on page 718), a static MAC address entry is automatically added to the MAC address table.

Before you begin

This screen is only available for named BVIs in transparent mode.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **ARP and MAC** tab.

Step 4 (Optional) Disable MAC learning by unchecking the **Enable MAC Learning** check box.

Step 5 To add a static MAC address, click **Add MAC Config**.
The **Add MAC Config** dialog box appears.

Step 6 In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b. Click **OK**.

Step 7 Click **OK** to exit the Advanced settings.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Set security configuration parameters

This task configures security parameters on named interfaces to prevent IP spoofing attacks and control packet fragmentation behavior. You can enable anti-spoofing protection, configure full fragment reassembly, and customize fragment handling settings.

This section describes how to prevent IP spoofing, allow full fragment reassembly, and override the default fragment setting at the device level in **Platform Settings**.

Anti-spoofing

This section lets you enable Unicast Reverse Path Forwarding on an interface. Unicast RPF guards against IP spoofing (a packet uses an incorrect source IP address to obscure its true source) by ensuring that all packets have a source IP address that matches the correct source interface according to the routing table.

Normally, the Firewall Threat Defense device only looks at the destination address when determining where to forward the packet. Unicast RPF instructs the device to also look at the source address. This is why it is called Reverse Path Forwarding. For any traffic that you want to allow through the Firewall Threat Defense device, the device routing table must include a route back to the source address. See RFC 2267 for more information.

For outside traffic, for example, the Firewall Threat Defense device can use the default route to satisfy the Unicast RPF protection. If traffic enters from an outside interface, and the source address is not known to the routing table, the device uses the default route to correctly identify the outside interface as the source interface.

If traffic enters the outside interface from an address that is known to the routing table, but is associated with the inside interface, then the Firewall Threat Defense device drops the packet. Similarly, if traffic enters the inside interface from an unknown source address, the device drops the packet because the matching route (the default route) indicates the outside interface.

Unicast RPF is implemented as follows:

- ICMP packets have no session, so each packet is checked.
- UDP and TCP have sessions, so the initial packet requires a reverse route lookup. Subsequent packets arriving during the session are checked using an existing state maintained as part of the session. Non-initial packets are checked to ensure they arrived on the same interface used by the initial packet.

Fragment per packet

By default, the Firewall Threat Defense device allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments through the Firewall Threat Defense device. Fragmented packets are often used as DoS attacks.

Fragment reassembly

The Firewall Threat Defense device performs the following fragment reassembly processes:

- IP fragments are collected until a fragment set is formed or until a timeout interval has elapsed.
- If a fragment set is formed, integrity checks are performed on the set. These checks include no overlapping, no tail overflow, and no chain overflow.
- IP fragments that terminate at the Firewall Threat Defense device are always fully reassembled.
- If **Full Fragment Reassembly** is disabled (the default), the fragment set is forwarded to the transport layer for further processing.
- If **Full Fragment Reassembly** is enabled, the fragment set is first coalesced into a single IP packet. The single IP packet is then forwarded to the transport layer for further processing.

Full reassembly for inspected fragmented packets

The Firewall Threat Defense performs virtual reassembly by default. However, when features such as DNS or voice media inspection are active, the firewall performs full reassembly before forwarding. This ensures packets are processed correctly by inspection engines.

For example, SIP packets subject to inspection require full reassembly. If SIP inspection is disabled, the system maintains virtual reassembly. To avoid issues, we recommend reducing SIP message size or using TCP or TLS for large messages rather than sending large SIP INVITE packets over UDP.

The firewall merges fragments in memory. If the egress interface MTU is smaller than the reassembled packet, the device will refragment the data to fit. To verify behavior, use packet captures on the egress interface and adjust MTU settings as needed.

Before you begin

This screen is only available for named interfaces.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **Security Configuration** tab.

Step 4 To enable Unicast Reverse Path Forwarding, check the **Enable Anti Spoofing** check box.

Step 5 To enable full fragment reassembly, check the **Allow Full Fragment Reassembly** check box.

Step 6 To change the number of fragments allowed per packet, check the **Override Default Fragment Setting** check box, and set the following values:

- **Size**—Set the maximum number of packets that can be in the IP reassembly database waiting for reassembly. The default is 200. Set this value to 1 to disable fragments.
- **Chain**—Set the maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets.
- **Timeout**—Set the maximum number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded. The default is 5 seconds.

Step 7 Click **OK**.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

History for Regular Firewall Interfaces

Provides a comprehensive history of interface-related features, including hardware support, protocol enhancements, and configuration changes for Secure Firewall devices.

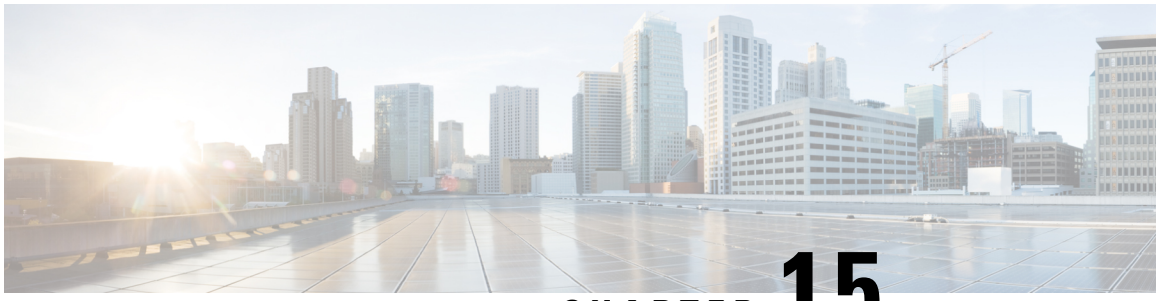


Table 45: History for Regular Firewall Interfaces

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Recursive DNS Server (RDNSS) and DNS Search List (DNSSL) options to advertise a list of DNS servers and domains to IPv6 clients	10.0.0 20251121	10.0.0	You can now configure Recursive DNS Server (RDNSS) and DNS Search List (DNSSL) options to provide DNS servers and domains to SLAAC clients using router advertisements. New/modified screens: **Devices** > **Device Management** > **Interfaces** > **Add/Edit Interfaces** > **IPv6** > **Settings** New/modified commands: **show ipv6 nd detail** , **show ipv6 nd ra dns-search-list** , **show ipv6 nd ra dns server** , **show ipv6 nd summary**
Secure Firewall 200 hardware switch support	10.0.0 20251121	10.0.0	The Secure Firewall 200 supports setting each Ethernet interface to be a switch port or a firewall interface.
Secure Firewall 1210CP IEEE 802.3bt support (PoE++ and Hi-PoE)	7.7.0	7.7.0	See the following improvements related to support for IEEE 802.3bt: • PoE++ and Hi-PoE—Up to 90W per port. • Single- and dual-signature powered devices (PDs). • Power budgeting is done on a first-come, first-served basis. • Power budget fields were added to **show power inline** . New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **PoE** New/Modified commands: **show power inline**
For models with built-in-switches, subinterfaces can't use VLAN 1	7.6	7.6	For models with built-in switches, you cannot create a subinterface using VLAN 1. VLAN 1 is reserved for the logical VLAN interface for switch ports. If you upgrade a 1010 to 7.6 or later, and you have assigned VLAN 1 to a subinterface, you must change the VLAN ID for your subinterface to a new VLAN. You will not be able to deploy the configuration using VLAN 1.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Secure Firewall supports Dual-Arm Deployment Mode on AWS with GWLB	7.6	7.6	The Secure Firewall supports the dual-arm deployment mode on AWS with GWLB. This mode enables the firewall to directly forward internet-bound traffic to the internet through the internet gateway after traffic inspection, while also performing network address translation (NAT).
Secure Firewall 1210/1220 hardware switch support	7.6	7.6	The Secure Firewall 1210/1220 supports setting each Ethernet interface to be a switch port or a firewall interface
Secure Firewall 1210CP PoE+ support on Ethernet ports 1/5-1/8	7.6	7.6	The Secure Firewall 1210CP supports Power over Ethernet+ (PoE+) on Ethernet ports 1/5-1/8.
VXLAN VTEP IPv6 support	7.4	Any	You can now specify an IPv6 address for the VXLAN VTEP interface. IPv6 is not supported for the threat defense virtual cluster control link or for Geneve encapsulation. New/Modified screens: • **Devices** > **Device Management** > **Edit** > **VTEP** > **Add VTEP** **Devices** > **Device Management** > **Edit** > **Interfaces** > **Add Interfaces** > **VNI Interface** Requires Firewall Threat Defense version 7.4. You can specify an IPv6 address for the VXLAN VTEP interface for Secure Firewall 4200 Series devices only.
Loopback interface support for BGP and management traffic	7.4	Any	You can use a loopback interface for: AAA, BGP, DNS, HTTP, ICMP, IPsec Flow Offload, NetFlow, SNMP, SSH, and Syslog. Requires Firewall Threat Defense version 7.4.
Loopback interface support for VTI	7.3	Any	You can now add a loopback interface. The loopback interface helps to overcome path failures. If an interface goes down, you can access all interfaces through the IP address assigned to the loopback interface. For VTI, in addition to setting a loopback interface as the source interface, support has also been added to inherit the IP address from a loopback interface instead of a statically configured IP address. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Add Interfaces** > **Add Loopback Interface**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
IPv6 DHCP	7.3	Any	The Firewall Threat Defense now supports the following features for IPv6 addressing: DHCPv6 Address client, DHCPv6 Prefix Delegation client, BGP router advertisement for delegated prefixes, and DHCPv6 stateless server. New/Modified screens: • **Devices** > **Device Management** > **Interfaces** > **Add/Edit Interfaces** > **IPv6** > **DHCP** • **Objects** > **Object Management** > **DHCP IPv6 Pool** New/Modified commands: **show bgp ipv6 unicast** , **show ipv6 dhcp** , **show ipv6 general-prefix**
Paired proxy VXLAN for the Firewall Threat Defense Virtual for the Azure Gateway Load Balancer	7.3	Any	You can configure a paired proxy mode VXLAN interface for the Firewall Threat Defense Virtual in Azure for use with the Azure Gateway Load Balancer (GWLB). New/Modified screens: **Devices** > **Device Management** > **Device** > **Interfaces** > **Add Interfaces** > **VNI Interface** Supported platforms: Firewall Threat Defense Virtual in Azure
VXLAN support	7.2	Any	VXLAN encapsulation support was added. New/Modified screens: **Devices** > **Device Management** > **Device** > **VTEP** , **Devices** > **Device Management** > **Device** > **Interfaces** > **Add Interfaces** > **VNI Interface** , and **Devices** > **Device Management** > **Device** > **Interfaces** edit physical interface **> General** Supported platforms: All.
Geneve support for the Firewall Threat Defense Virtual	7.1	Any	Geneve encapsulation support was added for the Firewall Threat Defense Virtual to support single-arm proxy for the Amazon Web Services (AWS) Gateway Load Balancer. This feature requires Snort 3.
31-bit Subnet Mask	7.0	Any	For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. This feature is not supported for BVIs for bridge groups or with multicast routing. New/Modified screens: **Devices** > **Device Management** > **Interfaces**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Synchronization between the Firewall Threat Defense operational link state and the physical link state for the Firepower 4100/9300	6.7	Any	The Firepower 4100/9300 chassis can now synchronize the Firewall Threat Defense operational link state with the physical link state for data interfaces. **Note** This feature is not supported for clustering, container instances, or Firewall Threat Defense with a Radware vDP decorator. It is also not supported for ASA. New/Modified Firepower Chassis Manager screens: **Logical Devices** > **Enable Link State** New/Modified FXOS commands: **set link-state-sync enabled** , **show interface expand detail**
Firepower 1010 hardware switch support	6.5	Any	The Firepower 1010 supports setting each Ethernet interface to be a switch port or a firewall interface.
Firepower 1010 PoE+ support on Ethernet 1/7 and Ethernet 1/8	6.5	Any	The Firepower 1010 supports Power over Ethernet+ (PoE+) on Ethernet 1/7 and Ethernet 1/8 when they are configured as switch ports.
VLAN subinterfaces for use with container instances	6.3.0	Any	To provide flexible physical interface use, you can create VLAN subinterfaces in FXOS and also share interfaces between multiple instances.
Data-sharing interfaces for container instances	6.3.0	Any	To provide flexible physical interface use, you can share interfaces between multiple instances.
Integrated Routing and Bridging	6.2.0	Any	Integrated Routing and Bridging provides the ability to route between a bridge group and a routed interface. The bridge group participates in routing by using a Bridge Virtual Interface (BVI) to act as a gateway for the bridge group.

CHAPTER 15

Inline Sets and Passive Interfaces

You can configure IPS-only passive interfaces, passive ERSPAN interfaces, and inline sets.

- IPS interfaces, on page 727
- Requirements and prerequisites for inline sets, on page 731
- Guidelines for configuring inline sets and passive interfaces, on page 733
- Configure a passive interface, on page 735
- Configure Inline Sets, on page 736
- History for inline sets and passive interfaces, on page 740

IPS interfaces

Intrusion Prevention System (IPS) interfaces include passive interfaces, passive Enhanced Remote Switch Port Analyzer (ERSPAN) interfaces, and inline sets. Interfaces in IPS-only mode bypass many firewall checks and support only IPS security policy (Snort). Implement IPS-only interfaces if you have a separate firewall protecting these interfaces and want to avoid firewall function overhead.

Note The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes.

Inline sets

An inline set acts like a bump on the wire and binds one or more interface pairs together to slot into an existing network. This function allows the Firewall Threat Defense to be installed in any network environment without requiring configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally and retransmit all traffic out of the other interface in the inline pair unless traffic is explicitly dropped. When you have multiple inline pairs in an inline set, traffic can only pass between the interfaces in the pair; it can't pass between interfaces in different pairs.

Tap mode functionality

With tap mode, the Firewall Threat Defense is deployed inline, but the network traffic flow is undisturbed. Instead, the Firewall Threat Defense makes a copy of each packet so that it can analyze the packets. Note that

rules of these types do generate intrusion events when they are triggered, and the table view of intrusion events indicates that the triggering packets would have dropped in an inline deployment.

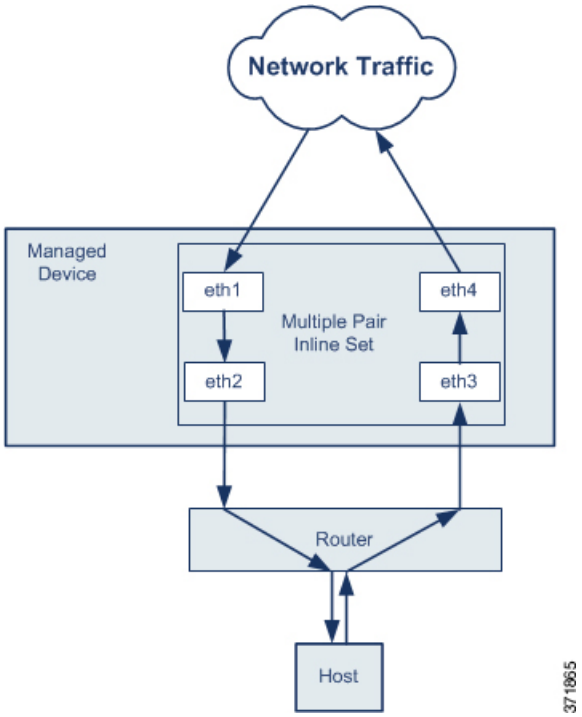
There are benefits to using tap mode with Firewall Threat Defense that are deployed inline:

- You can set up the cabling between the Firewall Threat Defense and the network as if the Firewall Threat Defense were inline and analyze the kinds of intrusion events the Firewall Threat Defense generates.
- Based on the results, you can modify your intrusion policy and add the drop rules that best protect your network without impacting its efficiency.
- When you are ready to deploy the Firewall Threat Defense inline, you can disable tap mode and begin dropping suspicious traffic without having to reconfigure the cabling between the Firewall Threat Defense and the network.

Note Tap mode *significantly* impacts Firewall Threat Defense performance, depending on the traffic.

Note Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode or the firewall-type interfaces.

Multiple inline pairs and asynchronous routing



Asynchronous routing is a network configuration that routes traffic between a host on your network and external hosts through different inline pairs, depending on whether the traffic is inbound or outbound. It requires multiple inline pairs in an inline set to correctly analyze network traffic.

If you deploy asynchronous routing, but you include only one inline pair in an inline set, the device might not correctly analyze your network traffic because it might see only half of the traffic.

Multiple inline pairs configuration

Adding multiple inline pairs to the same inline set lets the system identify the inbound and outbound traffic as part of the same traffic flow. For passive interfaces only, you can also achieve this by including the interface pairs in the same security zone.

Figure 293: Asynchronous routing

Note If you assign multiple inline pairs to a single inline set, but you experience issues with duplicate traffic, you might need to reassign your inline pairs to separate inline sets or modify your security zones.

If fragments of a packet are received on different interface pairs, they are not reassembled and get dropped. Make sure all the fragments of the packet are received and sent on the same interface pair.

Passive interfaces

Passive interfaces monitor traffic flowing across a network using a switch SPAN or mirror port. The SPAN or mirror port allows for traffic to be copied from other ports on the switch. This function allows the system to view network traffic without participating in the flow of data.

Passive interface functionality

The SPAN or mirror port allows for traffic to be copied from other ports on the switch. When you configure the Firewall Threat Defense in a passive deployment, the Firewall Threat Defense cannot take certain actions such as blocking or shaping traffic.

Encapsulated remote switched port analyzer (ERSPAN) interfaces allow you to monitor traffic from source ports distributed over multiple switches and use GRE to encapsulate the traffic. ERSPAN interfaces are only allowed when the Firewall Threat Defense is in routed firewall mode.

Note Using SR-IOV interfaces as passive interfaces on NGFWv is not supported on some Intel network adapters (such as Intel X710 or 82599) using SR-IOV drivers due to a promiscuous mode restriction. In such cases, use a network adapter that supports this functionality. See Intel Ethernet Products for more information on Intel network adapters.

Hardware Bypass for inline sets

Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. It maintains network connectivity when software or hardware failures occur and is available for certain interface modules on supported models.

Supported interface modules

For information about which interface modules support this feature, see Requirements and prerequisites for inline sets, on page 731.

Hardware Bypass triggers

Hardware Bypass can be triggered in these scenarios.

- Firewall Threat Defense crash
- Firewall Threat Defense reboot
- Security Module reboot
- Chassis crash
- Chassis reboot
- Manual trigger
- Chassis power loss
- Security Module power loss

Note Hardware bypass is intended for unplanned/unexpected failure scenarios, and is not automatically triggered during planned software upgrades. Hardware bypass activates only at the end of a planned upgrade process, when the Firewall Threat Defense application reboots.

Hardware bypass switchover

When you switch from normal operation to hardware bypass, or back to normal operation, you may experience several seconds of interrupted traffic. During this time, connections may drop.

Connection interruption factors

Several factors can affect the length of the traffic interruption during hardware bypass switchover.

- Copper port auto-negotiation
- Behavior of the optical link partner such as how it handles link faults and de-bounce timing
- Spanning tree protocol convergence
- Dynamic routing protocol convergence

You may also experience dropped connections due to application identification errors when analyzing connections midstream after the returning to normal operations.

Snort Fail Open vs. Hardware Bypass

Snort Fail Open and Hardware Bypass allow traffic to flow during system failures.

Functionality differences

You can configure the Snort Fail Open option for inline sets other than those in tap mode. This option either drops traffic or allows traffic to pass without inspection when the Snort process is busy or down. Snort Fail Open is supported on all inline sets except those in tap mode, not just on interfaces that support Hardware Bypass.

The Hardware Bypass functionality allows traffic to flow during a hardware failure, including a complete power outage, and certain limited software failures. A software failure that triggers Snort Fail Open does not trigger a Hardware Bypass.

Hardware Bypass status

When the system has power, the Bypass LED indicates the Hardware Bypass status. See the Firepower chassis hardware installation guide for LED descriptions.

Requirements and prerequisites for inline sets

This reference provides the requirements and prerequisites that must be met before configuring inline sets, including user role permissions and hardware bypass support information.

User roles

- Admin
- Access Admin
- Network Admin

Hardware Bypass Support

The Firewall Threat Defense supports Hardware Bypass for interface pairs on specific network modules on the following models:

- Firepower 2130 and 2140
- Secure Firewall 3100
- Firepower 4100

- Secure Firewall 4200
- Firepower 9300

Note The ISA 3000 has a separate implementation for Hardware Bypass, which you can enable using FlexConfig only (see FlexConfig policies, on page 921). Do not use this chapter to configure ISA 3000 Hardware Bypass.

Note You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.

The supported Hardware Bypass network modules for these models include:

- Firepower 2130 and 2140:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR2K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR2K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR2K-NM-6X10LR-F)
- Secure Firewall 3100:
  - 6-port 1G SFP Fail-to-Wire Network Module, SX (multimode) (FPR3K-XNM-6X1SXF)
  - 6-port 10G SFP Fail-to-Wire Network Module, SR (multimode) (FPR3K-XNM-6X10SRF)
  - 6-port 10G SFP Fail-to-Wire Network Module, LR (single mode) (FPR3K-XNM-6X10LRF)
  - 6-port 25G SFP Fail-to-Wire Network Module, SR (multimode) (FPR3K-XNM-X25SRF)
  - 6-port 25G Fail-to-Wire Network Module, LR (single mode) (FPR3K-XNM-6X25LRF)
  - 8-port 1G Copper Fail-to-Wire Network Module, RJ45 (copper) (FPR3K-XNM-8X1GF)
- Secure Firewall 4200:
  - 6-port 1G SFP Fail-to-Wire Network Module, SX (multimode) (FPR4K-XNM-6X1SXF)
  - 6-port 10G SFP Fail-to-Wire Network Module, SR (multimode) (FPR4K-XNM-6X10SRF)
  - 6-port 10G SFP Fail-to-Wire Network Module, LR (single mode) (FPR4K-XNM-6X10LRF)
  - 6-port 25G SFP Fail-to-Wire Network Module, SR (multimode) (FPR4K-XNM-X25SRF)
  - 6-port 25G Fail-to-Wire Network Module, LR (single mode) (FPR4K-XNM-6X25LRF)
  - 8-port 1G Copper Fail-to-Wire Network Module, RJ45 (copper) (FPR4K-XNM-8X1GF)
- Firepower 4100:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR4K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR4K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR4K-NM-6X10LR-F)

- Firepower 2-port 40G SR FTW Network Module single-wide (FPR4K-NM-2X40G-F)
- Firepower 8-port 1G Copper FTW Network Module single-wide (FPR-NM-8X1G-F)

- Firepower 9300:
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR9K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR9K-NM-6X10LR-F)
  - Firepower 2-port 40G SR FTW Network Module single-wide (FPR9K-NM-2X40G-F)

Hardware Bypass can only use the following port pairs:

- 1 & 2
- 3 & 4
- 5 & 6
- 7 & 8

Guidelines for configuring inline sets and passive interfaces

Firewall mode restrictions

Use ERSPAN interfaces only when the device is in routed firewall mode.

Clustering restrictions

Consider clustering limitations when configuring inline sets and passive interfaces.

- Link State Propagation for an inline set is not supported with clustering.

Multi-Instance mode restrictions

Use unshared physical interfaces or EtherChannels when configuring multi-instance mode.

- Multi-instance shared interfaces are not supported. You must use an unshared interface.
- Multi-instance chassis-defined subinterfaces are not supported. You must use a physical interface or EtherChannel.

General configuration guidelines

Consider these interface and traffic inspection requirements when configuring inline sets and passive interfaces.

- Inline sets and passive interfaces support only physical interfaces and EtherChannels. You cannot use VLANs or other virtual interfaces, including multi-instance chassis-defined subinterfaces.
- Because IPS interfaces do not support regular firewall protections, traffic must pass through the same Firewall Threat Defense to ensure all traffic is inspected according to the IPS security policy (Snort).
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the Firewall Threat Defense when using inline sets. If there are two neighbors on either side of the Firewall Threat Defense

running BFD, then the Firewall Threat Defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

- For inline sets and passive interfaces, the Firewall Threat Defense supports up to two 802.1Q headers in a packet (also known as Q-in-Q support), with the exception of the Firepower 4100/9300, which only supports one 802.1Q header. **Note:** Firewall-type interfaces do not support Q-in-Q, and only support one 802.1Q header.
- Firewall Threat Defense does not support frames with Ethertype 0x8988. If a source in the Application Centric Infrastructure (ACI) fabric has Precision Time Protocol (PTP) enabled, ACI inserts Ethertype 0x8988 into data-plane frames before mirroring. Firewall Threat Defense drops frames with Ethertype 0x8988 and does not inspect them.

Hardware Bypass Guidelines

Consider Hardware Bypass limitations and clustering requirements when configuring inline sets.

- Hardware Bypass ports are supported only for inline sets.
- Hardware Bypass ports cannot be part of an EtherChannel.
- Hardware Bypass is not supported in high availability mode.
- Hardware Bypass ports are supported with intra-chassis clustering on the Firepower 9300. Ports are placed in Hardware Bypass mode when the last unit in the chassis fails. Inter-chassis clustering is not supported, because inter-chassis clustering only supports Spanned EtherChannels; Hardware Bypass ports cannot be part of an EtherChannel.
- If all modules in an intra-chassis cluster on the Firepower 9300 fail, then Hardware Bypass is triggered on the final unit, and traffic continues to pass. When units come back up, Hardware Bypass returns to standby mode. If rules matching application traffic are used, connections might be dropped and require reestablishment. Connections are dropped because state information is not retained on the cluster unit, and the unit cannot identify the traffic as belonging to an allowed application. To prevent a traffic drop, use a port-based rule instead of an application-based rule, if appropriate for your deployment.
- You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.

Unsupported firewall features on IPS interfaces

These firewall features are not supported on IPS interfaces.

- DHCP server
- DHCP relay
- DHCP client
- TCP Intercept
- Routing
- NAT
- VPN
- Application inspection

- QoS
- NetFlow
- VXLAN

Configure a passive interface

Configure a passive or ERSPAN interface to enable network monitoring and traffic analysis capabilities on your security device.

This section describes how to:

- Enable the interface. By default, interfaces are disabled.
- Set the interface mode to Passive or ERSPAN. For ERSPAN interfaces, you will set the ERSPAN parameters and the IP address.
- Change the MTU. By default, the MTU is set to 1500 bytes. For more information about the MTU, see MTU, on page 712.
- Set a specific speed and duplex (if available). By default, speed and duplex are set to Auto.

Note For the Secure Firewall Threat Defense on the FXOS chassis, you configure basic interface settings on the Firepower 4100/9300. See Configure a physical interface, on page 259 for more information.

Before you begin

- If you are using EtherChannels, add them according to Configure an EtherChannel, on page 619.

Follow these steps to configure a passive interface:

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 In the **Mode** drop-down list, choose **Passive** or **ERSPAN**.

Step 4 Enable the interface by checking the **Enabled** check box.

Set these values:

a. In the **Name** field, enter a name up to 48 characters in length.

b. From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

c. Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 (Optional) On **General**, set the **MTU** between 64 and 9198 bytes; for the Secure Firewall Threat Defense Virtual and Secure Firewall Threat Defense on the FXOS chassis, the maximum is 9000 bytes.

The default is 1500 bytes.

Step 6 For ERSPAN interfaces, set the following parameters:

- **Flow ID**—Configure the ID used by the source and destination sessions to identify the ERSPAN traffic, between 1 and 1023. This ID must also be entered in the ERSPAN destination session configuration.
- **Source IP**—Configure the IP address used as the source of the ERSPAN traffic.
- **IPv4**—Set the IPv4 address and mask

Step 7 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The exact speed and duplex options depend on your hardware.

- **Duplex**—Choose **Full**, **Half**, or **Auto**. Auto is the default.
- **Speed**—Choose **10**, **100**, **1000**, or **Auto**. Auto is the default.

Step 8 Click **OK**.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Inline Sets

Enable traffic inspection by configuring multiple inline sets using physical interfaces or EtherChannels, including optional Hardware Bypass.

Inline sets allow you to designate pairs of interfaces or EtherChannels for traffic inspection, with optional Hardware Bypass. You can configure multiple inline pairs per set.

Note For the Firepower 4100/9300 , you configure basic interface settings in FXOS on the chassis. See Configure a physical interface, on page 259 for more information.

Before you begin

- If you are using EtherChannels, add them according to Configure an EtherChannel, on page 619 .
- We recommend that you set STP PortFast for STP-enabled switches that connect to the Firewall Threat Defense inline pair interfaces. This setting is especially useful for Hardware Bypass configurations and can reduce bypass times.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 For each interface in the inline pair, name the interface and enable it. Also configure necessary hardware settings, ensuring they match between interfaces in the inline pair. You can configure multiple pairs of interfaces.

a) Click **Edit** ( ) for the interface you want to edit.
b) In the **Name** field, enter a name up to 48 characters in length.
c) Enable the interface by checking the **Enabled** check box.
d) (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

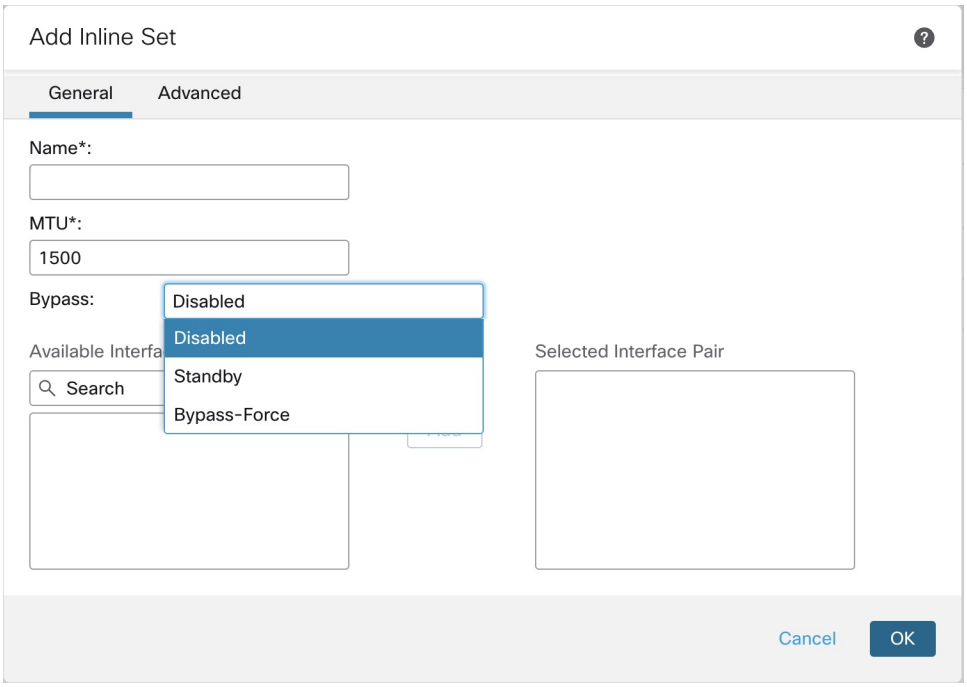
e) Leave the **Mode** as **None** .

After you add this interface to an inline set, this field will show Inline for the mode.

f) Do not set the security zone yet; you must set it after you create the inline set later in this procedure.
g) (Optional) Set the duplex and speed by clicking **Hardware Configuration** .

The exact speed and duplex options depend on your hardware.

- **Duplex** —Choose **Full** , **Half** , or **Auto** . Auto is the default.
- **Speed** —Choose **10** , **100** , **1000** , or **Auto** . Auto is the default.



h) Click **OK** .

Do not set any other settings for this interface.

Step 3 Click **Inline Sets**.

Step 4 Click **Add Inline Set**.

Figure 294: Add Inline Set

The **Add Inline Set** dialog box appears with **General** selected.

Step 5 In the **Name** field, enter a name for the set.

Step 6 (Optional) Change the **MTU** to enable jumbo frames.

For inline sets, the MTU setting is not used. However, the jumbo frame setting is relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo frames, you must set the MTU of *any* interface on the device above 1500 bytes.

Step 7 Configure Hardware Bypass.

a) For the **Bypass** mode, choose one of the following options:

- **Disabled** —Set Hardware Bypass to disabled for interfaces where Hardware Bypass is supported, or use interfaces where Hardware Bypass is not supported.
- **Standby** —Set Hardware Bypass to the standby state on supported interfaces. Only pairs of Hardware Bypass interfaces are shown. In the standby state, the interfaces remain in normal operation until there is a trigger event.
- **Bypass-Force** —Manually forces the interface pair to go into a bypass state. **Inline Sets** shows **Yes** for any interface pairs that are in Bypass-Force mode.

b) In the **Available Interfaces Pairs** area, click a pair and then click **Add** to move it to the **Selected Interface Pair** area.

All possible pairings between named and enabled interfaces with the mode set to None show in this area.

Step 8 (Optional) Click **Advanced** to set the following optional parameters:

- **Tap Mode** —Set to inline tap mode.

Note that you cannot enable this option and strict TCP enforcement on the same inline set.

Note Perform Tap mode changes during a maintenance window. Changing the mode while the device is passing traffic can cause traffic disruption.

Note Tap mode significantly impacts the Firewall Threat Defense performance, depending on the traffic.

- **Propagate Link State** —Configure link state propagation.

  Link state propagation automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up, also. In other words, if the link state of one interface changes, the device senses the change and updates the link state of the other interface to match it. Note that devices require up to 4 seconds to propagate link state changes. Link state propagation is especially useful in resilient network environments where routers are configured to reroute traffic automatically around network devices that are in a failure state.

Note Do not enable **Propagate Link State** when using clustering.

- **Snort Fail Open** —Enable or disable either or both of the **Busy** and **Down** options if you want new and existing traffic to pass without inspection (enabled) or drop (disabled) when the Snort process is busy or down.

  By default, traffic passes without inspection when the Snort process is down, and drops when it is busy.

  When the Snort process is:

  - Busy—It cannot process traffic fast enough because traffic buffers are full, indicating that there is more traffic than the device can handle, or because of other software resource issues.
  - Down—It is restarting because you deployed a configuration that requires it to restart. See Configurations that restart the snort process when deployed or activated, on page 131 .

  When the Snort process is down and comes back up, it inspects *new* connections. To prevent false positives and false negatives, it does not inspect existing connections on inline, routed, or transparent interfaces because initial session information might have been lost while it was down.

Note When Snort fails open, features that rely on the Snort process do not function. These include application control and deep inspection. The system performs only basic access control using simple, easily determined transport and network layer characteristics.

Note The **Strict TCP Enforcement** option is not supported.

Step 9 Set the security zone for each interface.

a) Click **Interfaces** .

b) Click **Edit** ( ) for the member interface.

c) From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New** .

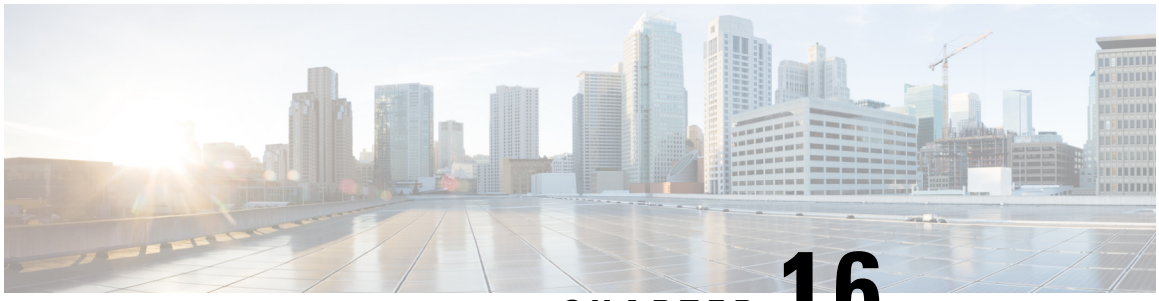
You can only set the zone after you add the interface to the inline set; adding it to an inline set configures the mode to Inline and lets you choose inline-type security zones.

d) Click **OK** .

Click **Save**.

What to do next

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.



History for inline sets and passive interfaces

This reference provides the chronological history of features related to inline sets and passive interfaces, including hardware bypass support, synchronization capabilities, and EtherChannel support across various Cisco security platforms.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Hardware bypass support on the Secure Firewall 4200 for supported network modules	7.4.0	7.4.0	The Secure Firewall 4200 supports hardware bypass functionality when using the hardware bypass network modules. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** Supported platforms: Secure Firewall 4200
Hardware bypass support on the Secure Firewall 3100 for supported network modules	7.2	Any	The Secure Firewall 3100 now supports hardware bypass functionality when using the hardware bypass network modules. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** Supported platforms: Secure Firewall 3100

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Synchronization between the Firewall Threat Defense operational link state and the physical link state for the Firepower 4100/9300	6.7	Any	The Firepower 4100/9300 chassis can now synchronize the Firewall Threat Defense operational link state with the physical link state for data interfaces. Currently, interfaces will be in an Up state as long as the FXOS admin state is up and the physical link state is up. The Firewall Threat Defense application interface admin state is not considered. Without synchronization from Firewall Threat Defense, data interfaces can be in an Up state physically before the Firewall Threat Defense application has completely come online, for example, or can stay Up for a period of time after you initiate a shutdown. For inline sets, this state mismatch can result in dropped packets because external routers may start sending traffic to the Firewall Threat Defense before the Firewall Threat Defense can handle it. This feature is disabled by default, and can be enabled per logical device in FXOS. **Note** This feature is not supported for clustering, container instances, or Firewall Threat Defense with a Radware vDP decorator. It is also not supported for ASA. New/Modified Firepower Chassis Manager screens: **Logical Devices** > **Enable Link State** New/Modified FXOS commands: **set link-state-sync enabled**, **show interface expand detail** Supported platforms: Firepower 4100/9300
Hardware bypass support on the Firepower 2130 and 2140 for supported network modules	6.3.0	Any	The Firepower 2130 and 2140 now support hardware bypass functionality when using the hardware bypass network modules. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** Supported platforms: Firepower 2130 and 2140
Support for EtherChannels in Firewall Threat Defense inline sets or passive interface	6.2.0	Any	You can now use EtherChannels in a Firewall Threat Defense inline set or passive interface.
Hardware bypass support on the Firepower 4100/9300 for supported network modules	6.1.0	Any	Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** Supported platforms: Firepower 4100/9300

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Inline set link state propagation support for the Firewall Threat Defense	6.1.0	Any	When you configure an inline set in the Firewall Threat Defense application and enable link state propagation, the Firewall Threat Defense sends inline set membership to the FXOS chassis. Link state propagation means that the chassis automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. New/Modified FXOS commands: **show fault |grep link-down**, **show interface detail**

CHAPTER 16

Device Settings

After you add a device, you can edit device-related settings on the **Device** page.

1. Choose **Devices** > **Device Management**.
2. Next to the device you want to modify, click **Edit** ( ).
3. Click **Device**.

- Edit general settings, on page 743
- Edit license settings, on page 755
- View system information, on page 756
- View the inspection engine, on page 757
- Edit health settings, on page 757
- Edit management settings, on page 757
- View inventory details, on page 793
- Edit applied policies, on page 794
- Edit advanced settings, on page 796
- Edit deployment settings, on page 800
- Edit cluster health monitor settings, on page 802
- Hot swap an SSD, on page 805
- Configure SNMP for FXOS, on page 808
- Configure alarms for the ISA 3000, on page 811
- History for Device Settings, on page 823

Edit general settings

Edit general device settings to customize the device name, packet transfer options, and force deployment settings for managed devices.

The **General** section of the **Device** page displays the settings described in this table.

Figure 295: General

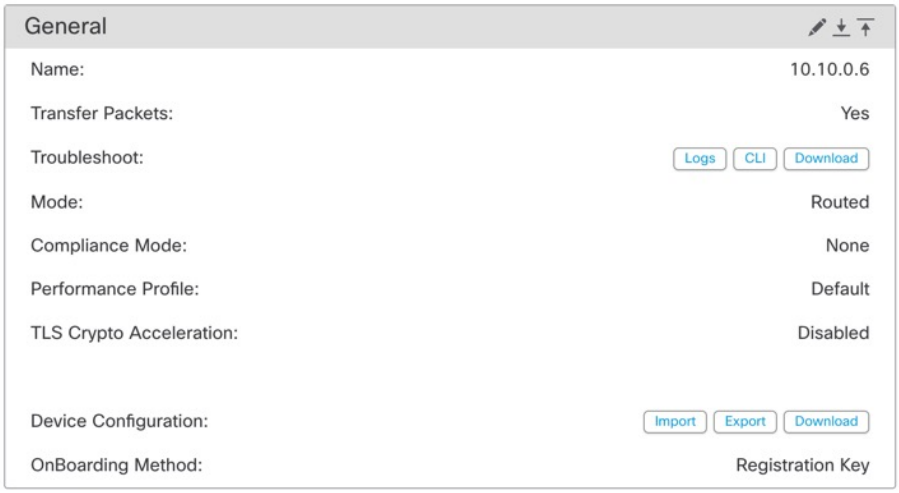


Table 46: General section table fields

Field	Description
Name	The display name of the device on the Firewall Management Center.
Transfer Packets	This displays whether or not the managed device sends packet data with the events to the Firewall Management Center.
Troubleshoot	Lets you generate and download troubleshooting files and also see CLI command output. See Generate troubleshooting files, on page 745 and View CLI output, on page 747.
Mode	The displays the mode of the management interface for the device: **routed** or **transparent**.
Compliance Mode	This displays the security certifications compliance for a device. Valid values are CC, UCAPL and None.
Performance Profile	This displays the core allocation performance profile for the device, as configured in the platform settings policy.
TLS Crypto Acceleration:	Shows whether TLS crypto acceleration is enabled or disabled.
Device Configuration	Lets you copy, export, or import a configuration. See Copy a configuration to another device, on page 749 and Export and import the device configuration, on page 751.
OnBoarding Method	Shows whether the device was registered using a registration key or using the serial number (zero-touch provisioning).

You can edit some of these settings from this section.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to modify, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **General** section, click **Edit** ( ).

a) Enter a **Name** for the managed device.
b) Check **Transfer Packets** to allow packet data to be stored with events on the Firewall Management Center.
c) Click **Force Deploy** to force deployment of current policies and device configuration to the device.

Note Force-deploy consumes more time than the regular deployment since it involves the complete generation of the policy rules to be deployed on the Firewall Threat Defense.

Step 5 For **Troubleshoot** actions, see Generate troubleshooting files, on page 745 and View CLI output, on page 747.

Step 6 For **Device Configuration** actions, see Copy a configuration to another device, on page 749 and Export and import the device configuration, on page 751.

Step 7 Click **Deploy**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Generate troubleshooting files

Generate troubleshooting files to collect diagnostic information for individual devices or all cluster nodes that can be used for technical support and issue resolution.

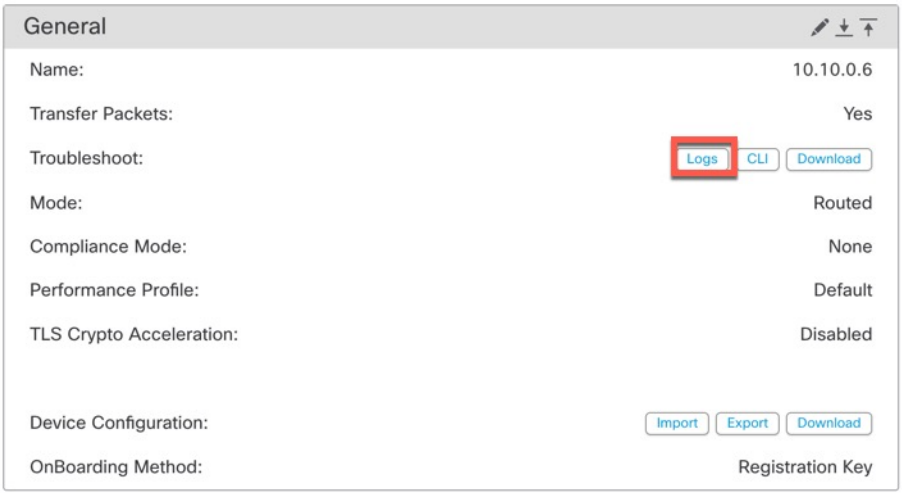
You can generate and download troubleshooting files for each device and also for all cluster nodes. For a cluster, you can download all files as a single compressed file. You can also include logs for the cluster nodes.

Alternatively, trigger file generation from the **Devices** > **Device Management**. From the **More** ( ) drop-down list, choose **Troubleshoot Files**.

Procedure

Step 1 Choose **Devices** > **Device Management**.

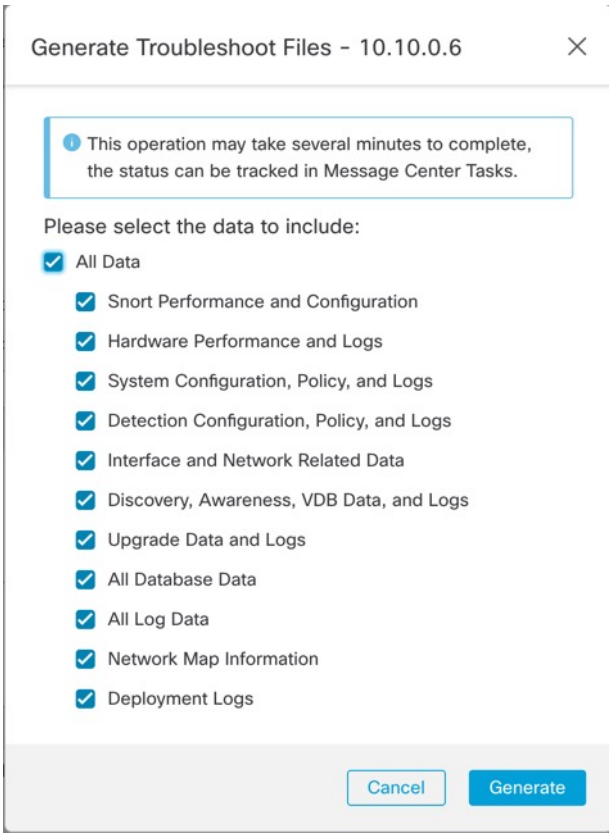
Step 2 Next to the device or cluster you want to view, click **Edit** ( ).



In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 3 Click **Device** or **Cluster**.

Step 4 Generate logs for the device or for all cluster nodes.



a) In the **General** area, **Troubleshoot** section, click **Logs**.

Figure 296: Logs

b) You are prompted to choose the logs you want to include. For a cluster, under **Device**, choose **All Devices** or an individual node. A cluster also has the **Cluster Logs** available.

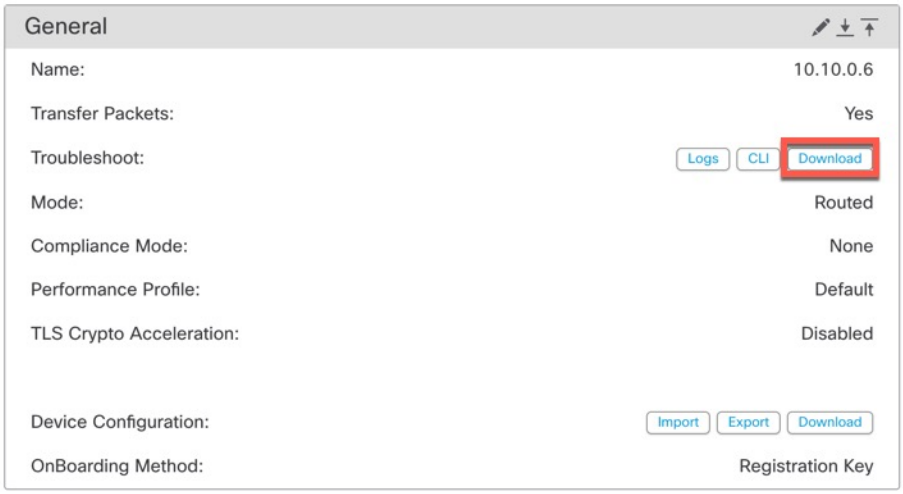


Figure 297: Generate troubleshoot files

c) Click **Generate**.

Step 5 To download the generated logs, in the **General** area, **Troubleshoot** section, click **Download**.

Figure 298: Download

The logs are downloaded to your computer.

View CLI output

This task allows you to troubleshoot devices and clusters by viewing pre-defined CLI command outputs and executing custom show commands for diagnostic purposes.

You can view a set of pre-defined CLI outputs that can help you troubleshoot the device or cluster. You can also enter any **show** command and see the output.

For a device, the following commands are executed:

- **show version**
- **show asp drop**
- **show counters**
- **show int ip brief**
- **show blocks**
- **show cpu detailed**

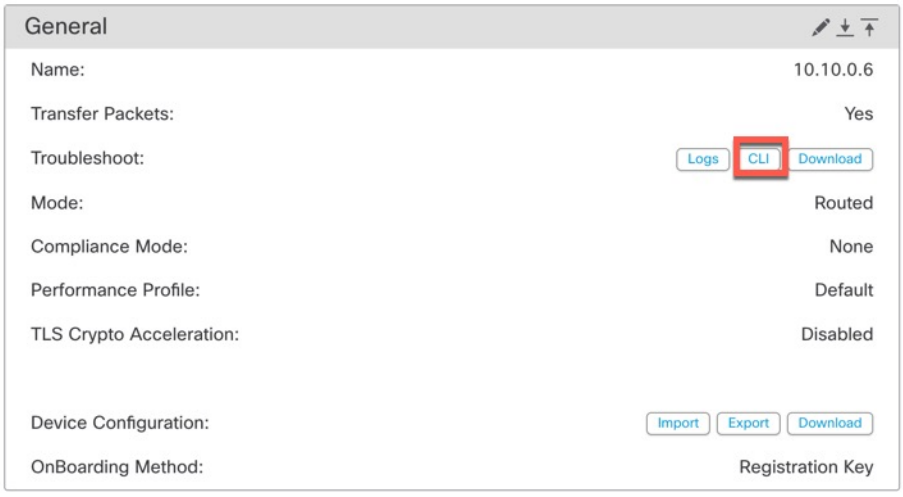
For a cluster or cluster node:

- **show running-config cluster**
- **show cluster info**
- **show cluster info health**
- **show cluster info transport cp**

- **show version**
- **show asp drop**
- **show counters**
- **show arp**
- **show int ip brief**
- **show blocks**
- **show cpu detailed**
- **show interface** *ccl_interface*
- **ping** *ccl_ip* **size** *ccl_mtu* **repeat 2**

Procedure

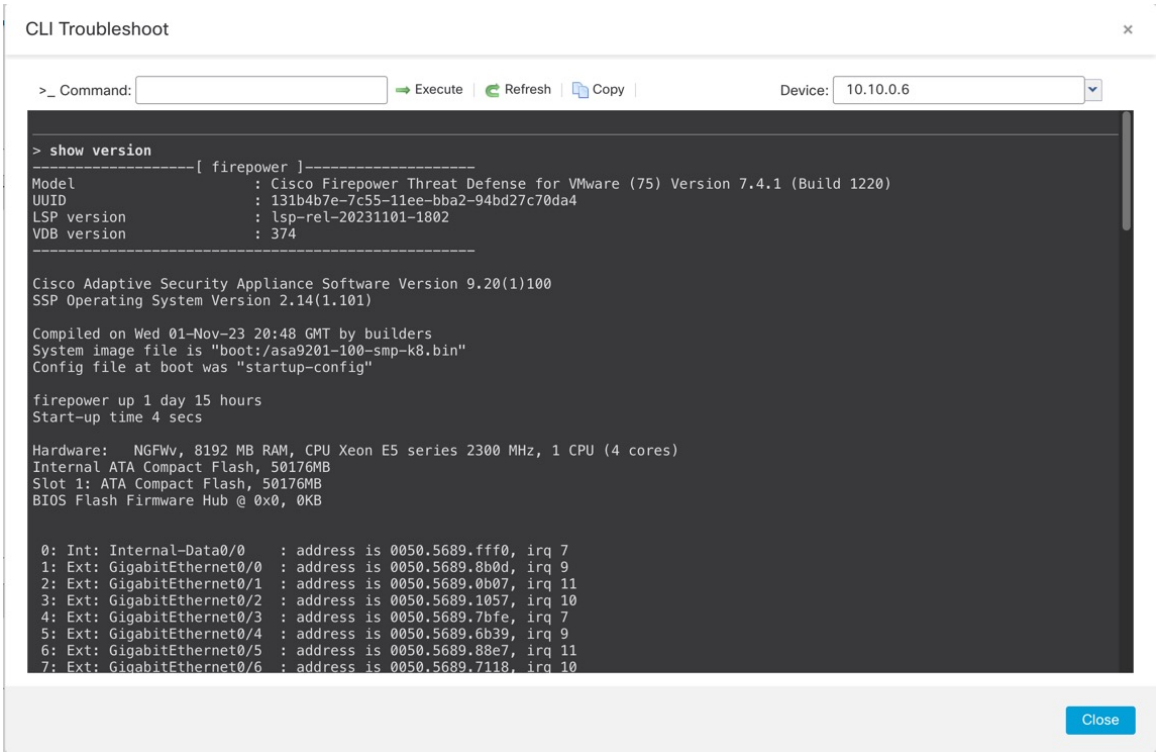
Step 1 Choose **Devices** > **Device Management**.



Step 2 Next to the device or cluster you want to view, click **Edit** ( ).

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 3 Click **Device** or **Cluster**.



Step 4 In the **General** area, **Troubleshoot** section, click **CLI**.

Figure 299: CLI

The **CLI Troubleshoot** dialog box appears with the pre-defined CLIs executed.

Figure 300: CLI troubleshoot

Step 5 On the **CLI Troubleshoot** dialog box, you can perform these tasks.

- Enter a **show** command in the **Command** field, and click **Execute**. The new command output will be added to the window.
- Click **Refresh** to re-run the predefined CLIs.
- Click **Copy** to copy the output to your clipboard.
- For a cluster, choose a different node from the **Device** drop-down list.

Step 6 Click **Close**.

Copy a configuration to another device

Copy configurations and policies from a pre-configured device to a new device, instead of manually reconfiguring the new device.

When a new device is deployed in the network, you can copy configurations and policies from a pre-configured device, instead of manually reconfiguring the new device.

Before you begin

Confirm that:

- The source and destination devices are the same model and are running the same version of the software.

- The source is either a standalone device or a high availability pair.
- The destination device is a standalone device.
- The source and destination devices have the same number of physical interfaces.
- The source and destination devices are in the same firewall mode: routed or transparent.
- The source and destination devices are in the same security-certifications-compliance mode.
- The source and destination devices are in the same domain.
- No configuration deployment is in progress on the source or the destination devices.
- For a restored Management Center, ensure that you retain the source device in a disabled state, register the destination device, execute Copy Configuration procedure, and then finally remove the source device.

Follow these steps to copy a configuration to another device:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to modify, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **General** section, do one of the following:

- Click **Get Device Configuration** ( ) to copy device configuration from another device to the new device. On the **Get Device Configuration** page, select the source device in the **Select Device** drop-down list.
- Click **Push Device Configuration** ( ) to copy device configuration from the current device to the new device. On the **Push Device Configuration** page, select the destination to which configuration is to be copied in the **Target Device** drop-down list.

Step 5 (Optional) Check **Include shared policies configuration** check box to copy policies.

Shared policies such as AC policy, NAT, Platform Settings and FlexConfig policies can be shared across multiple devices.

Step 6 Click **OK**.

You can monitor the status of the copy device configuration task on **Tasks** in the Message Center.

When the copy device configuration task is initiated, it erases the configuration on the target device and copies the configuration of the source device to the destination device.

Warning When you have completed the copy device configuration task, you cannot revert the target device to its original configuration.

Export and import the device configuration

Export device-specific configuration to create a backup that can be imported for the same device in various scenarios including moving the device to a different Firewall Management Center, restoring old configurations, or reregistering a device.

You can export all device-specific configurations available on the Device pages, including:

- Interfaces
- Inline Sets
- Routing
- DHCP
- VTEP
- Associated objects

You can then import the saved configuration for the same device in these use cases:

- Moving the device to a different Firewall Management Center—First delete the device from the original Firewall Management Center, then add the device to the new Firewall Management Center. Then you can import the saved configuration.
- Moving the device between domains—When you move a device between domains, some device-specific configuration is not retained because supporting objects (such as interface groups for security zones) do not exist in the new domain. By importing the configuration after the domain move, any necessary objects are created for that domain, and the device configuration is restored.
- Restore an old configuration—If you deployed changes that negatively impacted the operation of the device, you can import a backup copy of a known working configuration to restore a previous operational state.
- Reregistering a device—If you delete a device from the Firewall Management Center, but then want to add it back, you can import the saved configuration.

Before you begin

Review these guidelines:

- You can only import the configuration to the same device (the UUID must match). You cannot import a configuration to a different device, even if it is the same model.
- Do not change the version running on the device between exporting and importing; the version must match.
- If you make inventory changes after your export (such as adding or deleting network modules or configuring or joining breakout ports), the device inventory will not match the Firewall Management Center. In this case, the device inventory will be maintained, and you will be prompted to sync the interfaces (see Sync Interface Changes with the Firewall Management Center, on page 622) and discard incompatible configuration in the Firewall Management Center when you try to deploy. You will have to repeat the inventory changes and related configuration in the Firewall Management Center.
- If you export a standalone configuration, you cannot import it to a high availability pair or vice versa.

- When moving the device to a different Firewall Management Center, the target Firewall Management Center version must be the same as the source version.
- If an object doesn't exist, it will be created. If an object exists, but the value is different, refer to this table:

Table 47: Object import action

Scenario	Import Action
Object exists with the same name and value.	Reuse existing objects.
Object exists with the same name but different value.	Network and Port objects: Create object overrides for this device. See Object overrides, on page 2342. Interface objects: Create new objects. For example, if both the type (security zone or interface group) and the interface type (routed or switched, for example) do not match, then a new object is created. All other objects: Reuse existing objects even though the values are different.
Object doesn't exist.	Create new objects.

Follow these steps to export and import the device configuration:

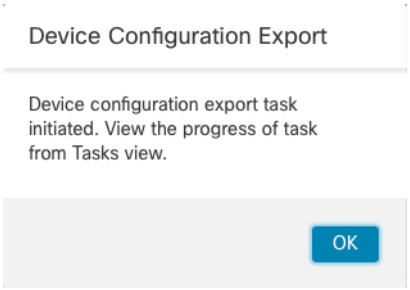
Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to edit, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 Export the configuration.



a) In the **General** area, click **Export**.

Figure 301: Export device configuration

You are prompted to acknowledge the export; click **OK**.

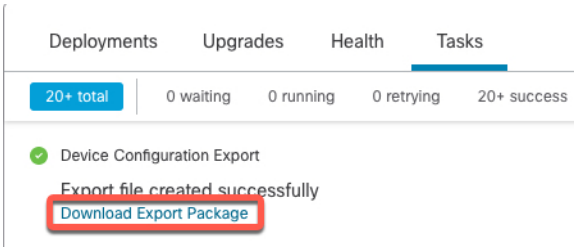


Figure 302: Acknowledge export

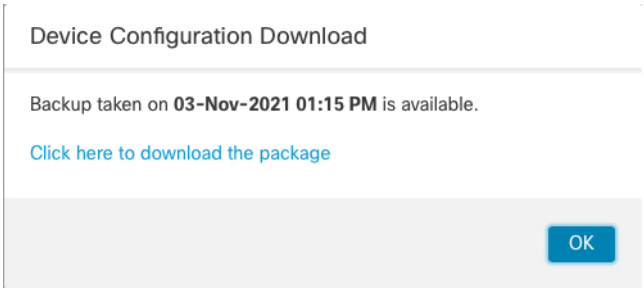
You can view the export progress in the **Tasks** page.



b) Click **Notifications**, and then click the **Tasks** tab. Verify if the export has completed, and then click **Download Export Package**. Alternatively, you can click the **Download** button in the **General** area.

Figure 303: Export task

You are prompted to download the package; click **Click here to download the package** to save the file locally, and then click **OK** to exit the dialog box.

Figure 304: Download package

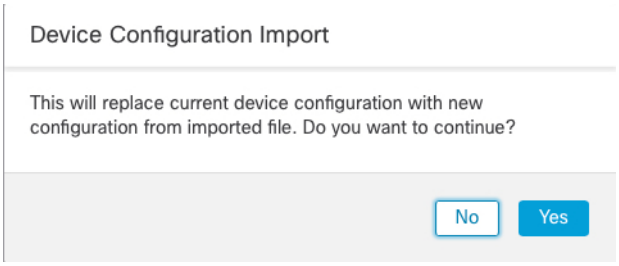
Step 5 Import the configuration.

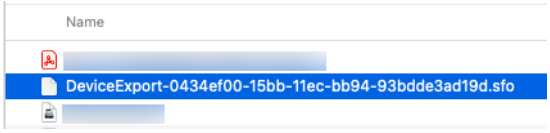
a) In the **General** area, click **Import**.

Figure 305: Import device configuration

You are prompted to acknowledge that the current configuration will be replaced. Click **Yes** and then navigate to the configuration package (with the suffix .sfo; note that this file is different from the Backup/Restore files).

Figure 306: Import package





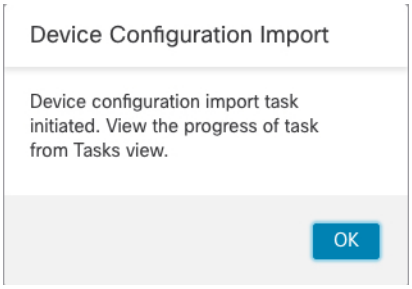


Figure 307: Navigate to package

You are prompted to acknowledge the import; click **OK**.

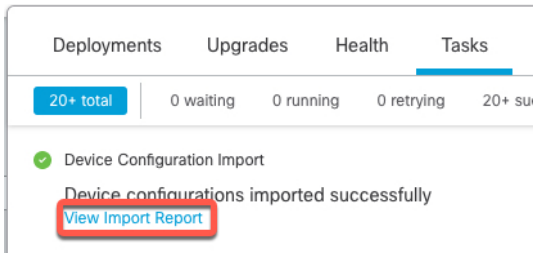

Figure 308: Acknowledge import

You can view the import progress in the **Tasks** page.

b) To view the import reports, click **Notifications**, and then click the **Tasks** tab. Click **View Import Report**.

Figure 309: View import report

The **Device Configuration Import Reports** page provides links to available reports.

Cisco Firepower Management Center

Device Configuration Import Reports

Device	Shared Policies	Device Configurations
0434ef00-15bb-11ec-bb94-93bdde3ad19d	Report does not exist	Device configurations import report

c) Deploy configuration changes; see Deploy configuration changes, on page 135.

Edit license settings

Enable or disable specific licenses on your managed device to control which features are available for use.

The **License** section of the **Device** page displays the licenses enabled for the device.

You can enable licenses on your device if you have available licenses on your Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to enable or disable licenses, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **License** section, click **Edit** ( ).

Step 5 Check or clear the check box next to the license you want to enable or disable for the managed device.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

View system information

The **System** section of the **Device** page displays a read-only table containing system information. You can also shut down or restart the device from this pane, using the icons at the top-right corner.

Figure 310: System

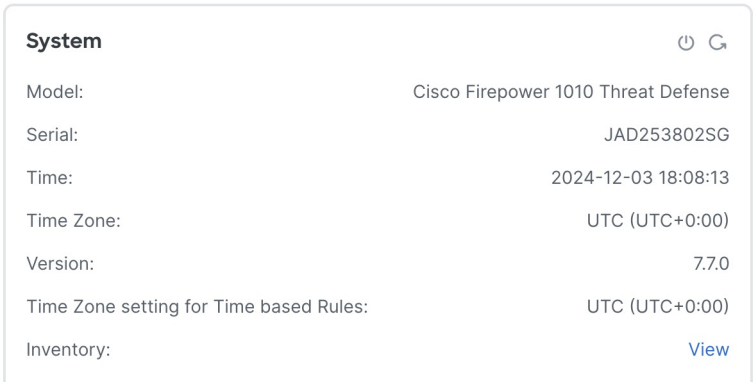

Table 48: System section table fields

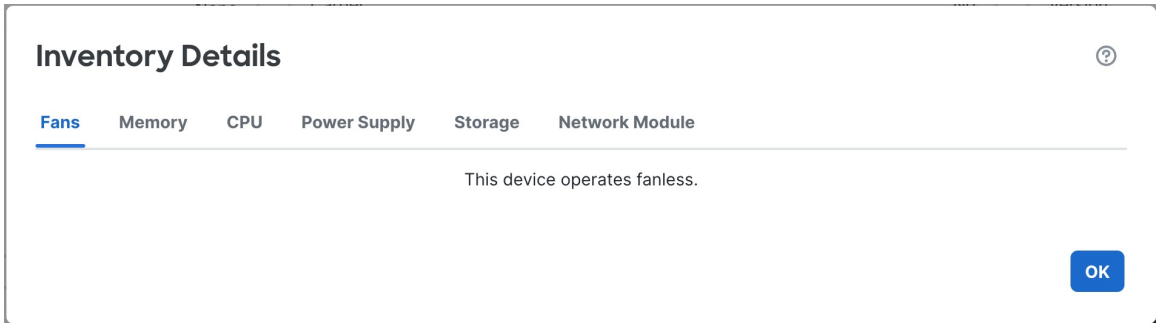


Field	Description
Shut Down Device ( )	Shuts down the device. See Shut down or restart the device, on page 55.
Restart Device ( )	Restarts the device. See Shut down or restart the device, on page 55.
Model	Model name and number.
Serial	PCB (circuit board) serial number. The firewall includes two serial numbers: the chassis serial number and the PCB serial number. The chassis serial number is shown in the Inventory section.
Time	Current system time of the device.
Time Zone	Time zone.
Version	Version of the software currently installed on the managed device.
Time Zone setting for Time based rules	Current system time of the device in the time zone specified in device platform settings.
Inventory	Inventory details. See View Device Inventory.

View device inventory

Click **View** next to **Inventory** in the **System** section to view a table of device inventory information including Fans, Memory, CPU, Power Supply, Storage, and Network Modules.

The **Inventory Details** table displays information about all the Cisco products installed in the Firewall Threat Defense devices assigned with a product identifier (PID). The PID is the product name using which the product can be ordered.

Figure 311: Inventory details

View the inspection engine

The Inspection Engine section of the **Device** page shows whether your device uses Snort 2 or Snort 3. To switch the inspection engine, see *Custom Snort 3 Intrusion Policies for Access Control*.

Note Snort3 is default for Secure Firewall 1200. It does not support Snort2.

Edit health settings

The **Health** section of the **Device** page displays the information described in this table.

Table 49: Health section table fields

Field	Description
Status	An icon that represents the current health status of the device. Clicking the icon displays the Health Monitor for the appliance.
Policy	A link to a read-only version of the health policy currently deployed at the device.
Excluded	A link to the **Health Exclude** page, where you can enable and disable health exclusion modules.

Edit management settings

These settings control how the Firewall Management Center establishes the management connection with the device.

Configure a redundant manager access data interface

This task configures a redundant manager access data interface to ensure continuous management connectivity. The secondary interface provides automatic failover capabilities when the primary management interface becomes unavailable, maintaining device management functionality.

When you use a data interface for manager access, you can configure a secondary data interface to take over management functions if the primary interface goes down. You can configure only one secondary interface. The device uses SLA monitoring to track the viability of the static routes and an ECMP zone that contains both interfaces so management traffic can use both interfaces.

High availability is not supported.

Before you begin

- The secondary interface needs to be in a separate security zone from the primary interface.
- All of requirements apply to the primary interface also apply to the secondary interface. See Using the Firewall Threat Defense data interface for management, on page 5.

Follow these steps to configure a redundant manager access data interface:

Procedure

Step 1 On the **Devices** > **Device Management** page, click **Edit** ( ) for the device.

Step 2 Enable manager access for the secondary interface.

This setting is in addition to standard interface settings such as enabling the interface, setting the name, setting the security zone, and setting a static IPv4 address.

a) Choose **Interfaces** > **Edit Physical Interface** > **Manager Access**.
b) Check **Enable management on this interface for the Manager**.
c) Click **OK**.

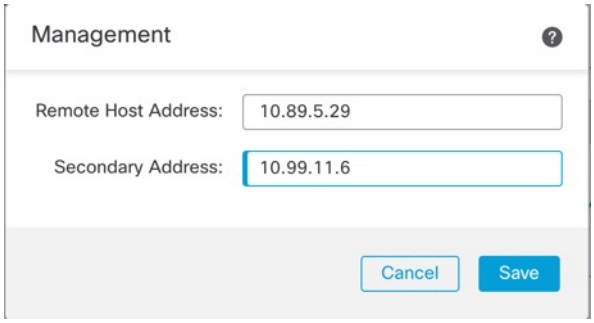
Both interfaces show **(Manager Access)** in the interface listing.

Figure 312: Interface listing

Interface	Logical Name	Type	Security Zones
Diagnostic1/1	diagnostic	Physical	
Ethernet1/1 (Manager Access)	outside	Physical	outside
Ethernet1/2		Physical	
Ethernet1/3		Physical	
Ethernet1/4		Physical	
Ethernet1/5		Physical	
Ethernet1/6		Physical	
Ethernet1/7		Physical	
Ethernet1/8 (Manager Access)	redundant	Physical	mgmt

Step 3 Add the secondary address to the **Management** settings.

a) Click **Device**, and view the **Management** area.

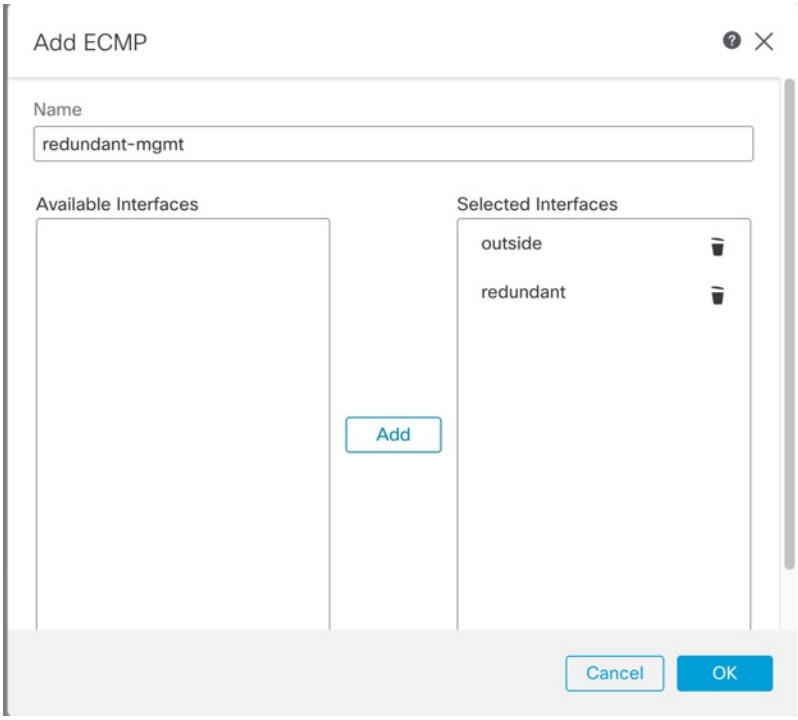


b) Click **Edit** ( ).

Figure 313: Edit management address

c) In the **Management** dialog box, modify the name or IP address in the **Secondary Address** field

Figure 314: Management IP address

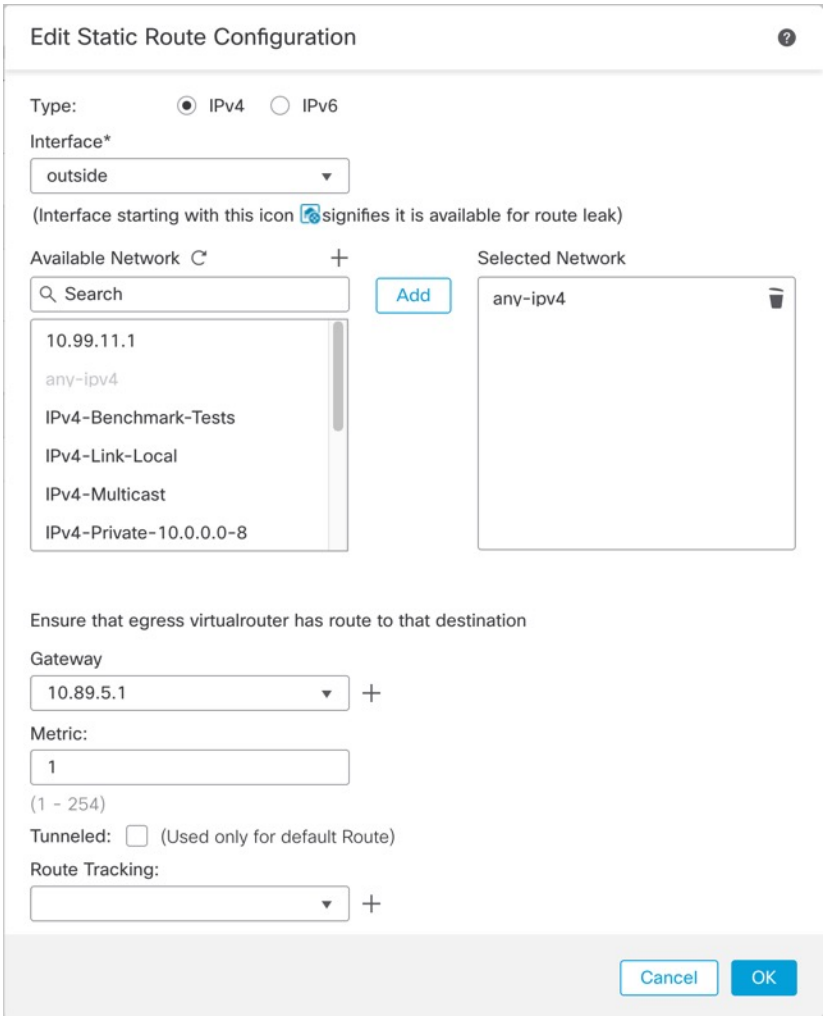


d) Click **Save**.

Step 4 Create an ECMP zone with both interfaces.

a) Click **Routing**.
b) From the virtual router drop-down, choose the virtual router in which the primary and secondary interfaces reside.
c) Click **ECMP**, and then click **Add**.
d) Enter a **Name** for the ECMP zone.
e) Select the primary and secondary interfaces under the **Available Interfaces** box, and then click **Add**.

Figure 315: Add an ECMP zone



f) Click **OK**, and then **Save**.

Step 5 Add equal-cost default static routes for both interfaces and enable SLA tracking on both.

The routes should be identical except for the gateway and should both have metric 1. The primary interface should already have a default route that you can edit.

Figure 316: Add/Edit static route

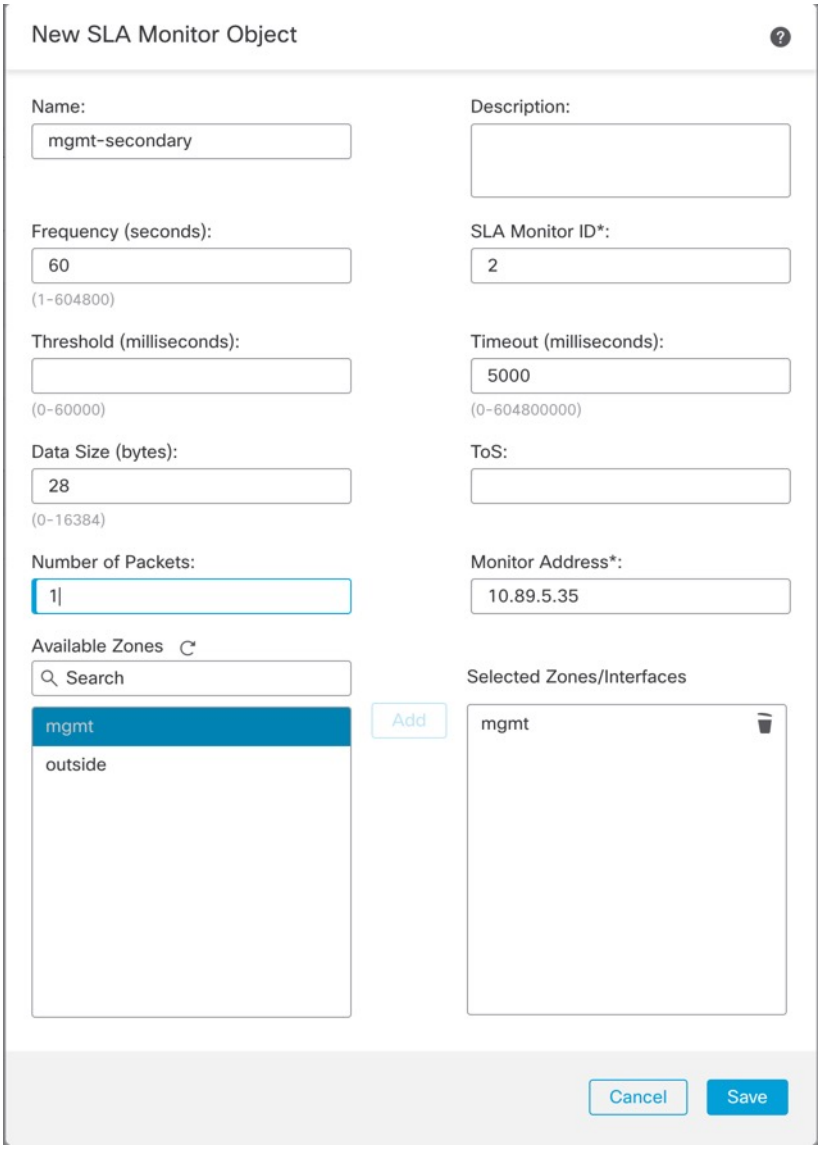
a) Click **Static Route**.

b) Either click **Add Route** to add a new route, or click **Edit** ( ) for an existing route.

c) From the **Interface** drop-down, choose the interface.

d) For the destination network, select **any-ipv4** from the **Available Networks** box and click **Add**.

e) Enter the default **Gateway**.



f) For **Route Tracking**, click **Add** ( ) to add a new SLA monitor object.

g) Enter the required parameters including the following:

- The **Monitor Address** as the Firewall Management Center IP address.
- The zone for the primary or secondary management interface in **Available Zones**; for example, choose the outside zone for the primary interface object, and the mgmt zone for the secondary interface object.

See Configure an SLA monitor, on page 2433 for more information.

Figure 317: Add SLA monitor

h) Click **Save**, then choose the SLA object you just created in the **Route Tracking** drop-down list.
i) Click **OK**, and then **Save**.

Repeat for the default route for the other management interface.

Step 6 Deploy configuration changes; see Deploy configuration changes, on page 135.

To deploy this feature, the Firewall Management Center enables the secondary interface for management traffic, including auto-generated policy-based routing configuration for management traffic to get to the right data interface. The Firewall Management Center also deploys a second instance of the **configure network management-data-interface** command. Note that if you edit the secondary interface at the CLI, you cannot

configure the gateway or otherwise alter the default route, because the static route for this interface can only be edited in the Firewall Management Center.

Change manager access interface settings

Changing manager interface settings on the device or on the Firewall Management Center can disrupt the management connection. Review these scenarios that change interface settings and reestablish the management connection.

Change the device IP address

Change the device IP address, and then update the address in the Firewall Management Center.

Set the device IP address

Use one of these methods to set the manager access interface IP address.

Modify Firewall Threat Defense management interface settings at the CLI

Many management interface settings are set during device initial setup; this task allows you to update them, add event-only interfaces (if supported), or configure static routes, DNS domains, and other advanced settings. Use the CLI when you need direct device access or troubleshooting. If you wish to configure network settings for a data interface used for management, use the device management center interface instead.

Note This topic applies to the dedicated management interface. You can alternatively configure a data interface for management. If you want to change network settings for that interface, you should do so within Firewall Management Center and not at the CLI. If you need to troubleshoot a disrupted management connection, and need to make changes directly on the Firewall Threat Defense , see Modify the Firewall Threat Defense data interface used for management at the CLI, on page 768 .

For information about the Firewall Threat Defense CLI, see the *Cisco Secure Firewall Threat Defense Command Reference* .

Before you begin

- You can create user accounts that can log into the CLI using the **configure user add** command ; see Add an internal user at the CLI, on page 87 . You can also configure AAA users according to Configure external authentication, on page 855 .
- Be cautious when making changes to the management interface using SSH. If you cannot re-connect because of a configuration error, access the device console port.
- In high-availability configurations, when you modify the management IP address of a registered device from the device CLI or from the Firewall Management Center , the standby Firewall Management Center does not reflect the changes even after a high-availability synchronization. To ensure that the standby Firewall Management Center is also updated, switch roles between the two Firewall Management Center s, making the secondary Firewall Management Center as the active unit. Modify the management IP address of the registered device on the **Device Management** page of the standby Firewall Management Center .

Procedure

Step 1 Connect to the device CLI, either from the console port or using SSH.

See Log into the Command-Line Interface on the device, on page 13 .

Step 2 Log in with the Admin username and password.

Step 3 (Firepower 4100/9300 /Secure Firewall 4200 only) Enable the second management interface as an event-only interface.

configure network management-interface enable management1

configure network management-interface disable-management-channel management1

You always need a management interface for management traffic. If your device has a second management interface, you can enable it for event-only traffic.

(Optional) Disable events for the main management interface using the **configure network management-interface disable-events-channel** command. In either case, the device will try to send events on the event-only interface, and if that interface is down, it will send events on the management interface even if you disable the event channel.

You cannot disable both event and management channels on an interface.

To use a separate event interface, you must enable an event-only interface on the Firewall Management Center that is dedicated exclusively to event traffic. See the *Cisco Secure Firewall Management Center Administration Guide* .

Example:

```
> configure network management-interface enable management1
Configuration updated successfully
> configure network management-interface disable-management-channel management1
Configuration updated successfully
>
```

Step 4 Configure the IP address of the management interface and/or event interface:

If you do not specify the *management_interface* argument, then you change the network settings for the default management interface. When configuring an event interface, be sure to specify the *management_interface* argument. The event interface can be on a separate network from the management interface, or on the same network. If you are connected to the interface you are configuring, you will be disconnected. You can re-connect to the new IP address.

a) Configure the IPv4 address:

- Manual configuration:

  configure network ipv4 manual *ip_address netmask gateway_ip* [*management_interface*]

  Note that the *gateway_ip* in this command is used to create the default route for the device. If you configure an event-only interface, then you must enter the *gateway_ip* as part of the command; however, this entry just configures the default route to the value you specify and does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you set the *gateway_ip* for use with the management interface, and then create a static route separately for the event-only interface using the **configure network static-routes** command.

Example:

```
> configure network ipv4 manual 10.10.10.45 255.255.255.0 10.10.10.1 management1
Setting IPv4 network configuration.
Network settings changed.
>
```

- DHCP (supported on the default management interface only):

  configure network ipv4 dhcp

b) Configure the IPv6 address:

- Stateless autoconfiguration:

  configure network ipv6 router [*management_interface*]

  Example:

```
> configure network ipv6 router management0
Setting IPv6 network configuration.
Network settings changed.
>
```

- Manual configuration:

  configure network ipv6 manual *ip6_address ip6_prefix_length* [*ip6_gateway_ip*] [*management_interface*]

  Note that the *ipv6_gateway_ip* in this command is used to create the default route for the device. If you configure an event-only interface, then you must enter the *ipv6_gateway_ip* as part of the command; however, this entry just configures the default route to the value you specify and does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you set the *ipv6_gateway_ip* for use with the management interface, and then create a static route separately for the event-only interface using the **configure network static-routes** command.

  Example:

```
> configure network ipv6 manual 2001:0DB8:BA98::3210 64 management1
Setting IPv6 network configuration.
Network settings changed.
>
```

- DHCPv6 (supported on the default management interface only):

  configure network ipv6 dhcp

c) For IPv6, enable or disable ICMPv6 Echo Replies and Destination Unreachable messages. These messages are enabled by default.

configure network ipv6 destination-unreachable { **enable** | **disable** }

configure network ipv6 echo-reply { **enable** | **disable** }

You might want to disable these packets to guard against potential denial of service attacks. Disabling Echo Reply packets means you cannot use IPv6 ping to the device management interfaces for testing purposes.

Example:

```
> configure network ipv6 destination-unreachable disable
> configure network ipv6 echo-reply disable
```

Step 5 Enable a DHCP server on the default management interface to provide IP addresses to connected hosts:

configure network ipv4 dhcp-server-enable *start_ip_address end_ip_address*

Example:

```
> configure network ipv4 dhcp-server-enable 10.10.10.200 10.10.10.254
DHCP Server Enabled
>
```

You can only configure a DHCP server when you set the management interface IP address manually. This command is not supported on the Firewall Management Center Virtual . To display the status of the DHCP server, enter **show network-dhcp-server** :

```
> show network-dhcp-server
DHCP Server Enabled
10.10.10.200-10.10.10.254
```

Step 6 Add a static route for the event-only interface if the Firewall Management Center is on a remote network. Otherwise, all traffic will match the default route through the management interface.

configure network static-routes { **ipv4** | **ipv6** } **add** *management_interface destination_ip netmask_or_prefix gateway_ip*

For the default route, do not use this command; you can only change the default route gateway IP address when you use the **configure network ipv4** or **ipv6** commands (see Step 4, on page 764).

Example:

```
> configure network static-routes ipv4 add management1 192.168.6.0 255.255.255.0 10.10.10.1
Configuration updated successfully
> configure network static-routes ipv6 add management1 2001:0DB8:AA89::5110 64
2001:0DB8:BA98::3211
Configuration updated successfully
>
```

To display static routes, enter **show network-static-routes** (the default route is not shown):

```
> show network-static-routes
---------------[ IPv4 Static Routes ]---------------
Interface                : management1
Destination              : 192.168.6.0
Gateway                  : 10.10.10.1
Netmask                  : 255.255.255.0
[…]
```

Step 7 Do these settings:

a) Set the hostname:

configure network hostname *name*

Example:

```
> configure network hostname farscape1.cisco.com
```

Syslog messages do not reflect a new hostname until after a reboot.

b) Set the search domains:

configure network dns searchdomains *domain_list*

Example:

```
> configure network dns searchdomains example.com,cisco.com
```

Set the search domain(s) for the device, separated by commas. These domains are added to hostnames when you do not specify a fully-qualified domain name in a command, for example, **ping system** . The domains are used only on the management interface, or for commands that go through the management interface.

c) Set up to 3 DNS servers, separated by commas:

configure network dns servers *dns_ip_list*

Example:

```
> configure network dns servers 10.10.6.5,10.20.89.2,10.80.54.3
```

d) Set the remote management port for communication with the Firewall Management Center :

configure network management-interface tcpport *number*

Example:

```
> configure network management-interface tcpport 8555
```

The Firewall Management Center and managed devices communicate using a two-way, TLS-1.3-encrypted communication channel, which by default is on port 8305. Do not change the management port when using multi-instance mode; only port 8305 is supported.

Note We recommend that you keep the default settings for the remote management port, but if the management port conflicts with other communications on your network, you can choose a different port. If you change the management port, you must change it for *all* devices in your deployment that need to communicate with each other.

e) (Firewall Threat Defense only) Set the management or eventing interface MTU. The MTU is 1500 bytes by default.

configure network mtu [*bytes*] [*interface_id*]

- *bytes* —Sets the MTU in bytes. For the management interface, the value can be between 64 and 1500 if you enable IPv4, and 1280 to 1500 if you enable IPv6. For the eventing interface, the value can be between 64 and 9000 if you enable IPv4, and 1280 to 9000 if you enable IPv6. If you enable both IPv4 and IPv6, then the minimum is 1280. If you do not enter the *bytes* , you are prompted for a value.
- *interface_id* —Specifies the interface ID on which to set the MTU. Use the **show network** command to see available interface IDs, for example management0, management1, br1, and eth0, depending on the platform. If you do not specify an interface, then the management interface is used.

Example:

```
> configure network mtu 8192 management1
MTU set successfully to 1500 from 8192 for management1
Refreshing Network Config...
NetworkSettings::refreshNetworkConfig MTU value at start 8192
Interface management1 speed is set to '10000baseT/Full'
NetworkSettings::refreshNetworkConfig MTU value at end 8192
>
```

f) Configure an HTTP proxy. The device is configured to directly connect to the internet on ports TCP/443 (HTTPS) and TCP/80 (HTTP). You can use a proxy server, to which you can authenticate via HTTP Digest. After issuing the command, you are prompted for the HTTP proxy address and port, whether

proxy authentication is required, and if it is required, the proxy username, proxy password, and confirmation of the proxy password.

Note For proxy password on Firewall Threat Defense , you can use A-Z, a-z, and 0-9 characters only.

configure network http-proxy

Example:

```
> configure network http-proxy
Manual proxy configuration
Enter HTTP Proxy address: 10.100.10.10
Enter HTTP Proxy Port: 80
Use Proxy Authentication? (y/n) [n]: Y
Enter Proxy Username: proxyuser
Enter Proxy Password: proxypassword
Confirm Proxy Password: proxypassword
```

Step 8 If you change the device management IP address, then see the following tasks for Firewall Management Center connectivity. Perform these tasks depending on how you identified the Firewall Management Center during initial device setup using the **configure manager add** command (see Register with a new management center, on page 46) :

- **IP address — No action.** If you identified the Firewall Management Center using a reachable IP address, then the management connection will be reestablished automatically after several minutes. We recommend that you also change the device IP address shown in Firewall Management Center to keep the information in sync; see Update the Hostname or IP Address in the Firewall Management Center, on page 772. This action can help reestablish the connection faster. If you specified an unreachable Firewall Management Center IP address, then you must manually reestablish the connection using Update the Hostname or IP Address in the Firewall Management Center, on page 772
- **NAT ID only — Manually reestablish the connection.** If you identified the Firewall Management Center using only the NAT ID, then the connection does not automatically reestablish. In this case, change the device management IP address in Firewall Management Center according to Update the Hostname or IP Address in the Firewall Management Center, on page 772 .

Modify the Firewall Threat Defense data interface used for management at the CLI

This task allows you to specify a new data interface to replace the old interface when the management connection has been disrupted and you need to restore connectivity between the Firewall Threat Defense and the Firewall Management Center.

If the management connection is active, make changes to an existing data interface using the Firewall Management Center (see Modify the Firewall Threat Defense data interface used for management in the GUI, on page 771). For initial setup of the data management interface, see the **configure network management-data-interface** command in Complete the Firewall Threat Defense Initial Configuration Using the CLI , on page 21.

For high-availability pairs, perform all CLI steps on both units. Within the Firewall Management Center, perform steps only on the active unit. Once the configuration changes are deployed, the standby unit synchronizes configuration and other state information from the active unit.

Note This topic applies to the data interface that you configured for Management, not the dedicated Management interface. If you want to change network settings for the Management interface, see Modify Firewall Threat Defense management interface settings at the CLI , on page 763.

For information about the Firewall Threat Defense CLI, see the *Cisco Secure Firewall Threat Defense Command Reference*.

Before you begin

If you are changing the data management interface to a new interface, move the current interface cable to the new interface.

Procedure

Step 1 Connect to the device CLI.

Use the console port when executing these commands. If you are performing initial setup, then you may be disconnected from the Management interface. If you are editing the configuration due to a disrupted management connection and have SSH access to the dedicated management interface, you can use the SSH connection.

See Log into the Command-Line Interface on the device, on page 13.

a) Log in with the **admin** username and password.

Step 2 Disable the interface so you can reconfigure its settings.

configure network management-data-interface disable

Note If you only want to set a new IPv4 address on the same interface and not make any other changes, you can skip this step. Other changes require you to disable the interface first.

Example:

```
> configure network management-data-interface disable

 Configuration updated successfully..!!

Configuration disable was successful, please update the default route to point to a gateway
 on management interface using the command 'configure network'
```

Step 3 Configure the new data interface for manager access.

configure network management-data-interface

You are then prompted to configure basic network settings for the data interface.

If you change the data management interface to a new interface on the same network, use the same settings as for the previous interface except the interface ID. In addition, for the **Do you wish to clear all the device configuration before applying ? (y/n) [n]:** option, choose **y**. This choice will clear the old data management

interface configuration, so that you can successfully reuse the IP address and interface name on the new interface.

```
> configure network management-data-interface
Data interface to use for management: ethernet1/4
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]: y

Configuration done with option to allow manager access from any network, if you wish to
change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

a) Limit data interface access to the Firewall Management Center on a specific network.

configure network management-data-interface client *ip_address netmask*

By default, all networks are allowed.

Step 4 Update the Hostname or IP Address in the Firewall Management Center, on page 772.

The connection may be reestablished automatically, but disabling and reenabling the connection in the Firewall Management Center will help the connection reestablish faster. Or you may need to update the device IP address in the Firewall Management Center according to the linked procedure.

Step 5 Check that the management connection was reestablished.

sftunnel-status-brief

See the sample output for a connection that is up, with peer channel and heartbeat information:

```
> sftunnel-status-brief
PEER:10.10.17.202
Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
via '10.10.17.222'
Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202' via
 '10.10.17.222'
Registration: Completed.
IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

Step 6 In the Firewall Management Center, choose **Devices** > **Device Management**, and click **Edit** (). In the **Device** area, against the **Management** field, click **Refresh** next to **Manager Access - Configuration Details**.

The Firewall Management Center detects the interface and default route configuration changes and blocks deployment to the device. When you change the data interface settings locally on the device, you must reconcile those changes in the Firewall Management Center manually. You can view the discrepancies between the Firewall Management Center and the device on the **Configuration** tab.

Step 7 Choose **Interfaces**, and make the changes.

a) Remove the IP address and name from the old data management interface and disable manager access for this interface.

b) Configure the new data management interface with the new settings (the ones you used at the CLI) and enable manager access for it.

Step 8 Under the **Routing** tab, click **Static Route**, and change the default route from the old data management interface to the new one.

Step 9 Return to the **Manager Access - Configuration Details** dialog box, and click **Acknowledge** to remove the deployment block.

The next time you deploy, the Firewall Management Center configuration will overwrite any remaining conflicting settings on the Firewall Threat Defense. It is your responsibility to manually fix the configuration in the Firewall Management Center before you re-deploy.

You will see expected messages of "Config was cleared" and "Manager access changed and acknowledged."

Modify the Firewall Threat Defense data interface used for management in the GUI

Configure the data interface IP address settings to change the management connection or update the interface used for manager access.

If the management connection is up but you want to change the IP address of the data interface used for manager access, follow these steps. For example, if you register a device using zero-touch provisioning, then you need to change the IP address to a static address before you can enable high availability.

You can alternatively change interface settings at the CLI, but we recommend using that method only if the management connection is down. Any changes you make at the CLI should be replicated in the GUI.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** (✎) next to the device.

Step 2 Choose **Interfaces**.

Step 3 If you want to change the interface used for manager access:

a) Remove the IP address and name from the old data management interface and disable manager access for this interface.

b) Configure the new data management interface with the new settings and enable manager access for it.

c) If you use a static IP address, you are reminded to make sure you have a default route. Click **Yes**.

d) Click **OK** to exit the interface.

e) Click **Save** on the **Interfaces** page.

Step 4 If you only want to change the IP address:

a) Change the IP address.

b) For a static IP address, you are reminded to make sure you have a default route. Click **Yes**.

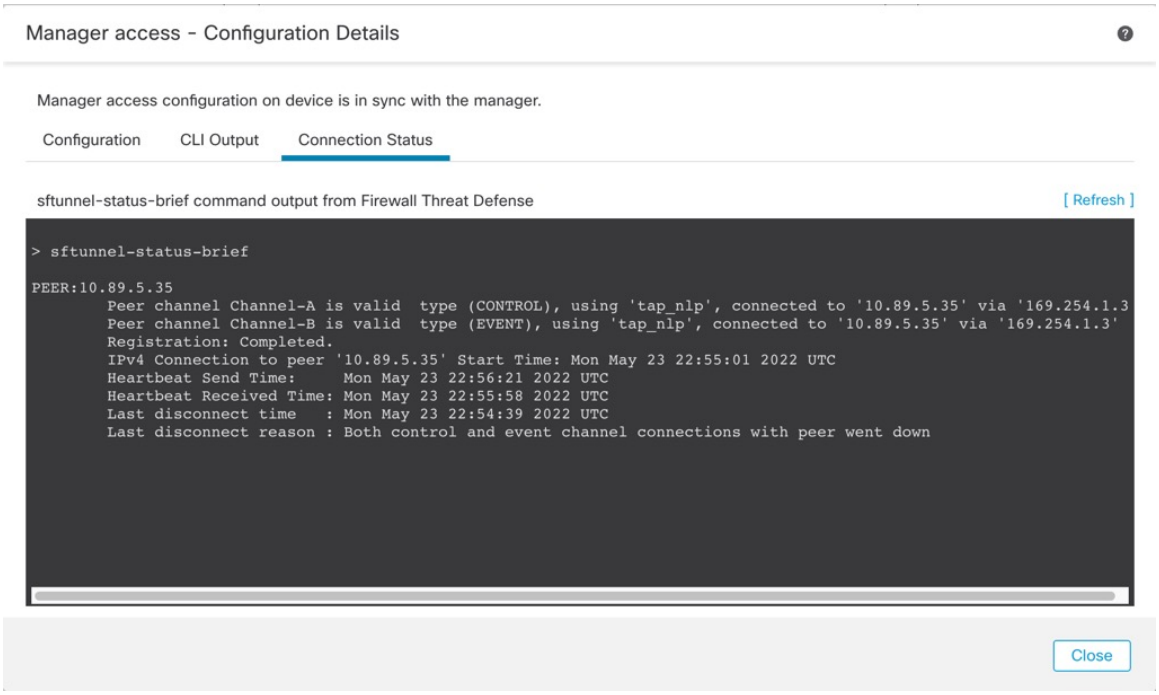
c) Click **OK** to exit the interface.

d) Click **Save** on the **Interfaces** page.

Step 5 Click the **Routing** tab, click **Static Route**, and then add or change the default or static route for the manager access interface.

Step 6 Deploy configuration changes; see Deploy configuration changes, on page 135.

The Firewall Management Center will deploy the configuration changes over the current connection. After the deployment, the data interface will have a new IP address, so the management connection will need to be reestablished.



Step 7 Update the Hostname or IP Address in the Firewall Management Center, on page 772.

Step 8 Ensure the management connection is reestablished.

In the **Device** area, against the **Management** field, click **Manager Access Details: Configuration** and then click **Connection Status**.

The following status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

Figure 318: Connection status

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 792.

Update the Hostname or IP Address in the Firewall Management Center

This task allows you to manually update the hostname or IP address on the managing Firewall Management Center when device network settings have been modified outside of the management interface.

If you edit the hostname or IP address of a device after you added it to the Firewall Management Center (using the device's CLI, for example), you need to use this procedure to manually update the hostname or IP address on the managing Firewall Management Center.

To change the device management IP address on the device, see Modify Firewall Threat Defense management interface settings at the CLI , on page 763.

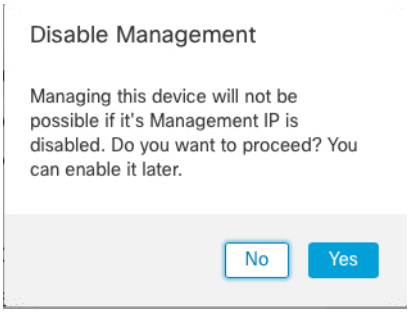
If you used only the NAT ID when registering the device, then the IP shows as **NO-IP** on this page, and you do not need to update the IP address/hostname.

If you used zero-touch provisioning to register the device on the outside interface, the hostname is automatically generated along with a matching DDNS configuration. You cannot edit the hostname in this case.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to modify management options, click **Edit** ( ).



Step 3 Click **Device** and view the **Management** area.

Step 4 Disable management temporarily by clicking the slider so it is disabled **Slider disabled** ( ).

Figure 319: Disable management

You are prompted to proceed with disabling management; click **Yes**.

Disabling management blocks the connection between the Firewall Management Center and the device, but does **not** delete the device from the Firewall Management Center.

Step 5 Edit the **Remote Host Address** IP address and optional **Secondary Address** (when using a redundant data interface) or hostname by clicking **Edit** ( ).

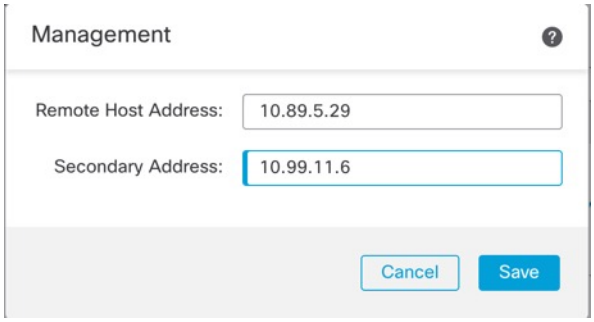


Figure 320: Edit management address

Step 6 In the **Management** dialog box, modify the name or IP address in the **Remote Host Address** field and the optional **Secondary Address** field. Click **Save**.

For information about using a secondary manager access data interface, see Configure a redundant manager access data interface, on page 758.

Figure 321: Management IP address

Step 7 Reenable management by clicking the slider so it is enabled **Slider enabled** ( ).

Figure 322: Enable management connection

Change the Firewall Management Center IP Address

This task ensures the Firewall Management Center IP address or hostname matches between the management center and device CLI, maintaining consistent configurations and network resiliency.

If you change the Firewall Management Center IP address or hostname, you should also change the value at the device CLI so the configurations match. Although in most cases, the management connection will be reestablished without changing the Firewall Management Center IP address or hostname on the device, in at

least one case, you must perform this task for the connection to be reestablished: when you added the device to the Firewall Management Center and you specified the NAT ID only. Even in other cases, we recommend keeping the Firewall Management Center IP address or hostname up to date for extra network resiliency.

Procedure

Step 1 Change the Firewall Management Center IP address.

Caution Be careful when making changes to the Firewall Management Center interface to which you are connected; if you cannot re-connect because of a configuration error, you need to access the Firewall Management Center console port to re-configure the network settings in the Linux shell. You must contact Cisco TAC to guide you in this operation.

a) Choose **System** (⚙) > **Configuration** > **Management Interfaces**.
b) In the **Interfaces** area, click **Edit** next to the interface that you want to configure.
c) Change the IP address, and click **Save**.

Step 2 At the Firewall Threat Defense CLI, view the Firewall Management Center identifier.

show managers

Example:

```
> show managers
Type                      : Manager
Host                      : 10.10.1.4
Display name              : 10.10.1.4
Identifier                : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration              : Completed
Management type           : Configuration
```

Step 3 At the Firewall Threat Defense CLI, edit the Firewall Management Center IP address or hostname.

configure manager edit *identifier* {**hostname** {*ip_address* | *hostname*} | **displayname** *display_name*}

If the Firewall Management Center was originally identified by **DONTRESOLVE** and a NAT ID, you can change the value to a hostname or IP address using this command. You cannot change an IP address or hostname to **DONTRESOLVE**.

The management connection will go down, and then reestablish. You can monitor the state of the connection using the **sftunnel-status** command.

Example:

```
> configure manager edit f7ffad78-bf16-11ec-a737-baa2f76ef602 hostname 10.10.5.1
```

Change both Firewall Management Center and Threat Defense IP addresses

You might want to change both Firewall Management Center and Firewall Threat Defense IP addresses if you need to move them to a new network.

Procedure

Step 1 Disable the management connection.

For a high-availability pair or cluster, perform these steps on all units.

a) Choose **Devices** > **Device Management**.

b) Next to the device, click **Edit** ( ).

c) Click **Device**, and view the **Management** area.

d) Disable management temporarily by clicking the slider so it is disabled ( ).

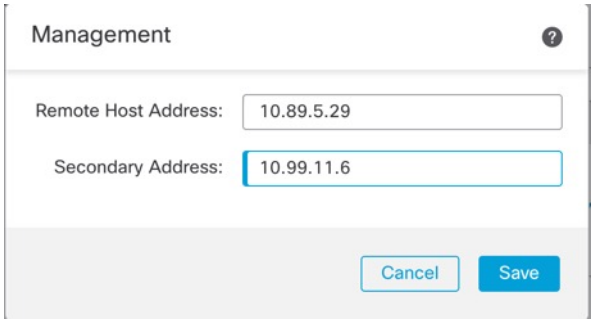
Figure 323: Disable Management

You are prompted to proceed with disabling management; click **Yes**.

Step 2 Change the device IP address in the Firewall Management Center to the new device IP address.

You will change the IP address on the device later.

For a high-availability pair or cluster, perform these steps on all units.



a) Edit the **Remote Host Address** IP address and optional **Secondary Address** (when using a redundant data interface) or hostname by clicking **Edit** ( ).

Figure 324: Edit Management Address

b) In the **Management** dialog box, modify the name or IP address in the **Remote Host Address** field and the optional **Secondary Address** field, and click **Save**.

Figure 325: Management IP Address

Step 3 Change the Firewall Management Center IP address.

Caution Be careful when making changes to the Firewall Management Center interface to which you are connected. If you cannot re-connect because of a configuration error, you need to access the Firewall Management Center console port to re-configure the network settings in the Linux shell. You must contact Cisco TAC to guide you in this operation.

a) Choose **System** (⚙) > **Configuration** > **Management Interfaces**.
b) In the **Interfaces** area, click **Edit** next to the interface that you want to configure.
c) Change the IP address, and click **Save**.

Step 4 Change the manager IP address on the device.

For a high-availability pair or cluster, perform these steps on all units.

a) At the Firewall Threat Defense CLI, view the Firewall Management Center identifier.

show managers

Example:

```
> show managers
Type                      : Manager
Host                      : 10.10.1.4
Display name              : 10.10.1.4
Identifier                : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration              : Completed
Management type           : Configuration
```

b) Edit the Firewall Management Center IP address or hostname.

configure manager edit *identifier* { **hostname** { *ip_address* | *hostname* } | **displayname** *display_name* }

If the Firewall Management Center was originally identified by **DONTRESOLVE** and a NAT ID, you can change the value to a hostname or IP address using this command. You cannot change an IP address or hostname to **DONTRESOLVE**.

Example:

```
                                > configure manager edit
f7ffad78-bf16-11ec-a737-baa2f76ef602
                                hostname
```

```
10.10.5.1
```

Step 5 Change the IP address of the manager access interface at the console port.

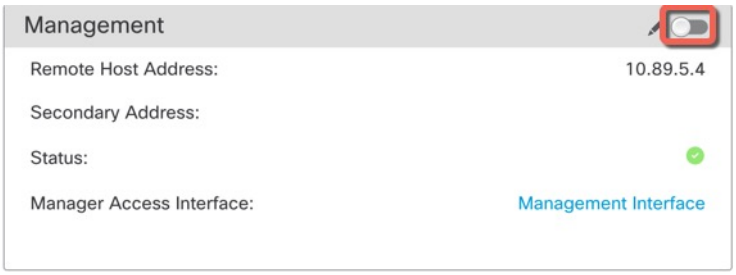
For a high-availability pair or cluster, perform these steps on all units.

If you use the dedicated Management interface:

configure network ipv4

configure network ipv6

If you use the dedicated Management interface:



configure network management-data-interface disable

configure network management-data-interface

Step 6 Re-enable management by clicking the slider ( ).

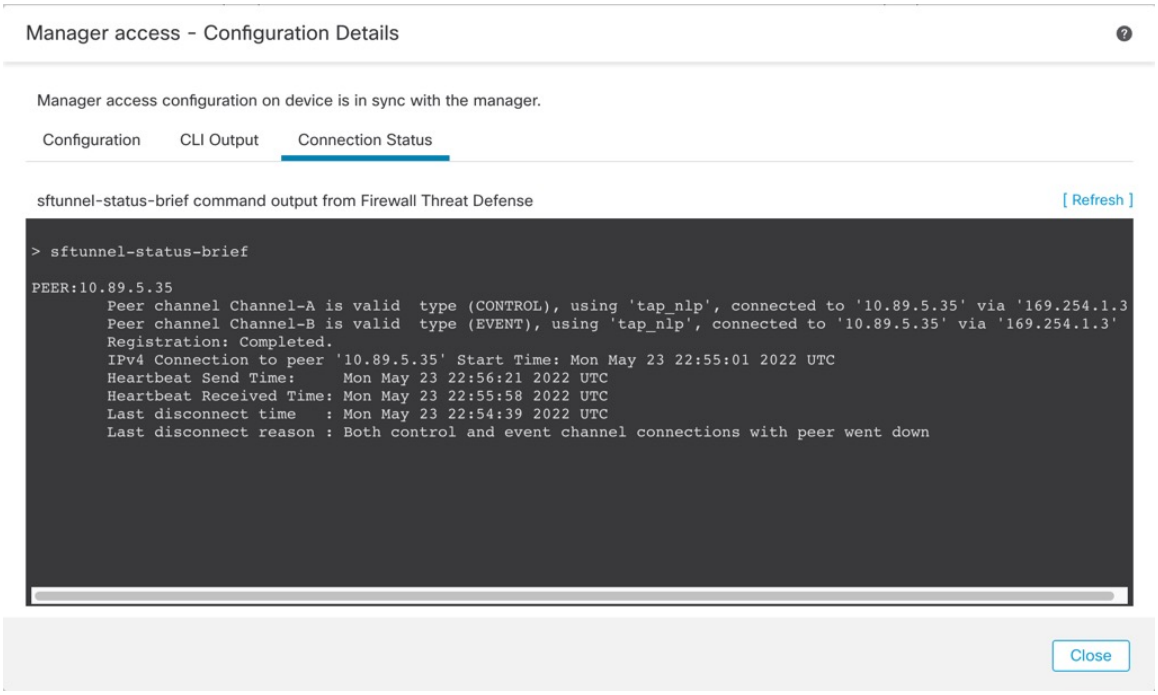
For a high-availability pair or cluster, perform these steps on all units.

Figure 326: Enable Management Connection

Step 7 (If you use a data interface for manager access) Refresh the data interface settings in the Firewall Management Center.

For a high-availability pair, perform this step on both units.

a) Choose **Devices** > **Device Management**, and click **Manager Access - Configuration Details** , and then click **Refresh**.
b) Choose **Devices** > **Device Management**, and click the **Interfaces** tab and set the IP address to match the new address.
c) Return to the **Manager Access - Configuration Details** dialog box, and click **Acknowledge** to remove the deployment block.



Step 8 Ensure the management connection is reestablished.

In the Firewall Management Center, check the management connection status. Navigate to the **Devices** > **Device Management**, and click **Management** section under the **Device** tab. Then, click **Manager Access - Configuration Details** to view the **Connection Status** page.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

This status indicates a successful connection for a data interface and displays the internal "tap_nlp" interface.

Figure 327: Connection Status

Step 9 (For a high-availability Firewall Management Center pair) Repeat configuration changes on the secondary Firewall Management Center.

a) Change the secondary Firewall Management Center IP address.
b) Specify the new peer addresses on both units.
c) Make the secondary unit the active unit.
d) Disable the device management connection.
e) Change the device IP address in the Firewall Management Center.
f) Re-enable the management connection.

Change the manager access interface

After you register the device, you can change the manager access interface between the Management interface and a data interface.

Change the manager access interface from management to data

You can manage the Firewall Threat Defense from either the dedicated management interface or from a data interface. If you want to change the manager access interface after you added the device to the Firewall Management Center , follow these steps to migrate from the Management interface to a data interface. To migrate the other direction, refer to Change the manager access interface from data to management, on page 783 .

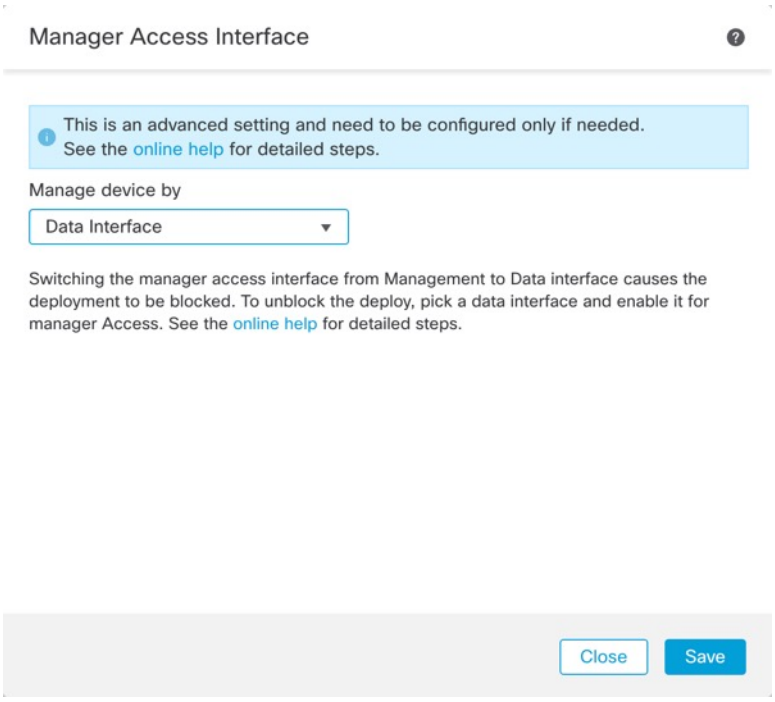
When you initiate the manager access migration from management to data, the Firewall Management Center applies a block on deployment to the Firewall Threat Defense. To remove the block, enable manager access on the data interface.

Before you begin

For high-availability pairs:

- Ensure that you configure a standby IP address for data-managed interfaces before changing the manager access interface from management to data. For more information about configuring standby IP address, refer to Configure standby IP addresses and interface monitoring, on page 309.
- For high-availability pairs, unless stated otherwise, perform all steps only on the active unit. After deploying the configuration changes, the standby unit synchronizes configuration and other state information from the active unit.
-

For high-availability pairs, unless stated otherwise, perform all steps only on the active unit. After deploying the configuration changes, the standby unit synchronizes configuration and other state information from the active unit.



Procedure

Step 1 Initiate the interface migration.

a) On the **Devices** > **Device Management** page, click **Edit** ( ) for the device. Click **Device** , and in the **Management** area, click the **Manager Access Interface** link.

The **Manager Access Interface** field shows the current Management interface. When you click the link, choose the new interface type, **Data Interface** , in the **Manage device by** drop-down list.

Figure 328: Manager Access Interface

b) Click **OK** and then **Close** .

You must now complete the remaining steps in this procedure to enable manager access on the data interface. The **Management** area now shows **Manager Access Interface: Data Interface** , and **Manager Access Details: Configuration** .

Figure 329: Manager Access

If you click **Configuration** , the **Manager Access - Configuration Details** dialog box opens. The **Manager Access Mode** shows a Deploy pending state.

Step 2 Enable manager access on the data interface (s) . Click **Interfaces** , click **Edit** ( ) for the interface, and then click **Manager Access** .

Check **Enable management access** and click **OK** . By default, all networks are allowed, but you can limit access as long as the Firewall Management Center address is allowed.

If the manager access interface uses a static IP address, you are reminded to configure routing for it.

Click **Save** on the **Interfaces** page. See Configure routed mode interfaces, on page 690 for more information about interface settings. You can enable manager access on one routed data interface , plus an optional secondary interface . Make sure these interfaces are fully configured with a name and IP address and that they are enabled.

If you use a secondary interface for redundancy, see Configure a redundant manager access data interface, on page 758 for additional required configuration.

Step 3 (Optional) If you use DHCP for the interface, enable the web type DDNS method on the DDNS page. Navigate to **Devices** > **Device Management** , and then click **DDNS** under the **DHCP** tab.

See Configure Dynamic DNS, on page 838 . DDNS ensures the Firewall Management Center can reach the Firewall Threat Defense at its Fully-Qualified Domain Name (FQDN) if the FTD's IP address changes.

Step 4 Make sure the Firewall Threat Defense can route to the Firewall Management Center through the data interface. Add a static route if necessary on the Static Route page. Navigate to **Devices** > **Device Management** and then click **Static Route** under the **Routing** tab.

See Add a static route, on page 977 .

Step 5 (Optional) Configure DNS in a Platform Settings policy: choose **Devices** > **Platform Settings** , and click **DNS** . Apply the policy to this device.

See Configure DNS server settings, on page 852 . DNS is required if you use DDNS. You may also use DNS for FQDNs in your security policies.

Step 6 (Optional) Enable SSH for the data interface in a Platform Settings policy, and apply it to this device at **Devices** > **Device Management** page. Click **Edit** ( ) for the device and then click **SSH Access** .

See Configure Secure Shell (SSH) access, on page 867 . SSH is not enabled by default on the data interfaces, so if you want to manage the Firewall Threat Defense using SSH, you need to explicitly allow it.

Step 7 Deploy configuration changes; see Deploy configuration changes, on page 135.

You will see a validation error to confirm that you are changing the manager access interface. Check **Ignore warnings** and deploy again.

The Firewall Management Center will deploy the configuration changes over the current Management interface. After the deployment, the data interface is now ready for use, but the original management connection to Management is still active.

Step 8 After deployment, perform these actions.

a) At the Firewall Threat Defense CLI (preferably from the console port), set the Management interface to use a static IP address and set the gateway to use the data interfaces. For high availability, perform this step on both units.

```
configure network
{
ipv4
 |
ipv6
}
manual
ip_address netmask
data-interfaces
```

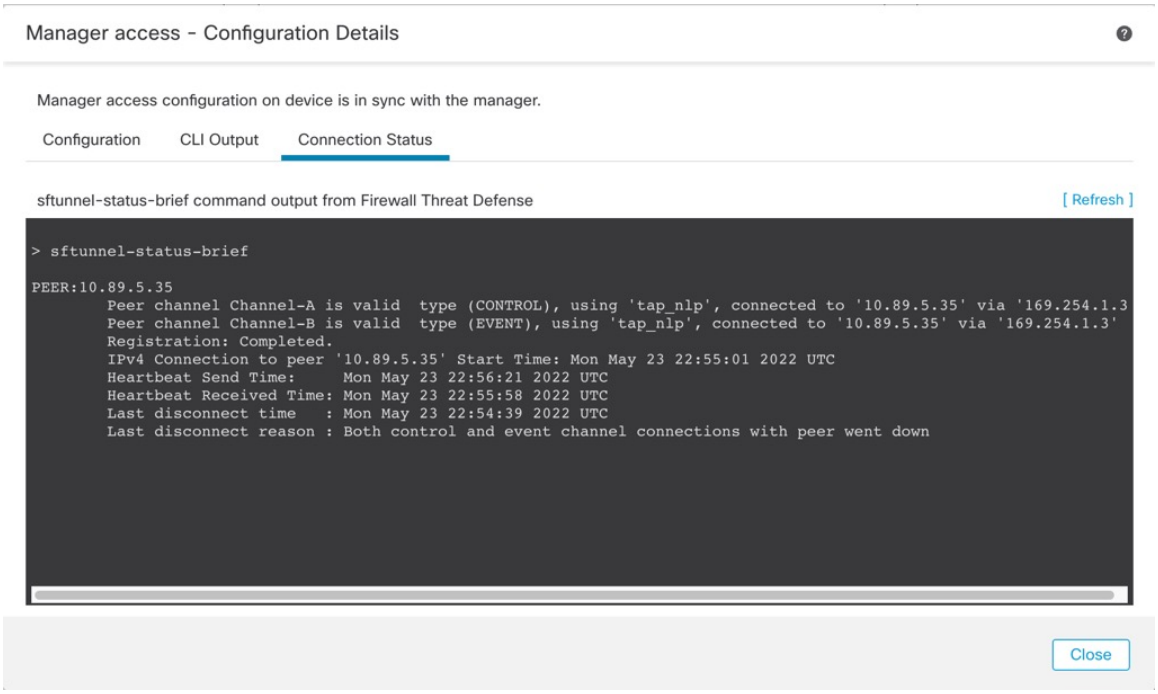
- *ip_address netmask* —Although you do not plan to use the Management interface, you must set a static IP address, for example, a private address so that you can set the gateway to **data-interfaces** (see the next bullet). You cannot use DHCP because the default route, which must be **data-interfaces** , might be overwritten with one received from the DHCP server.
- **data-interfaces** —This setting forwards management traffic over the backplane so it can be routed through the manager access data interface.

We recommend that you use the console port instead of an SSH connection because when you change the Management interface network settings, your SSH session will be disconnected.

b) If necessary, re-cable the Firewall Threat Defense so it can reach the Firewall Management Center on the data interface. For high availability, perform this step on both units.

c) In the Firewall Management Center , disable the management connection, update the **Remote Host Address** IP address and optional **Secondary Address** for the Firewall Threat Defense in the **Devices** > **Device Management** page in the **Management** area under the **Device** tab, and reenable the connection.

Refer to Update the Hostname or IP Address in the Firewall Management Center, on page 772 . If you used the Firewall Threat Defense hostname or just the NAT ID when you added the Firewall Threat Defense to the Firewall Management Center , you don't have to update the value. To restart the connection, you must disable and re-enable the management connection.



Step 9 Ensure the management connection is reestablished.

In the **Devices** > **Device Management** page, click **Manager Access Details: Configuration** and then click **Connection Status** .

Alternatively, you can check at the Firewall Threat Defense CLI. Enter the **sftunnel-status-brief** command to view the management connection status.

This status indicates a successful connection for a data interface, showing the internal "tap_nlp" interface.

Figure 330: Connection Status

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 792 .

Change the manager access interface from data to management

This task enables you to migrate manager access from a data interface to the dedicated management interface, allowing you to manage the Firewall Threat Defense through the Management interface instead of a data interface.

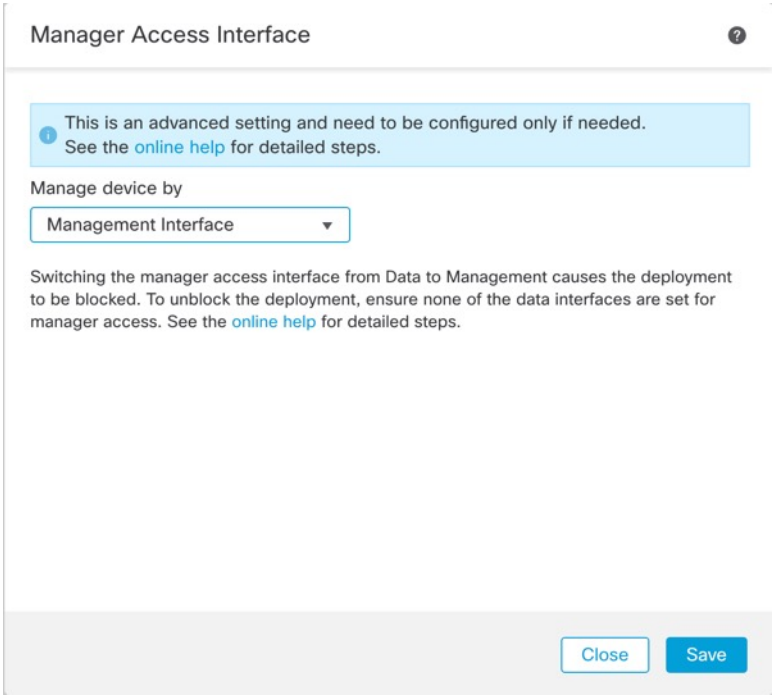
You can manage the Firewall Threat Defense from either the dedicated management interface or from a data interface. If you want to change the manager access interface after you added the device to the Firewall Management Center, follow these steps to migrate from a data interface to the management interface. To migrate the other direction, see Change the manager access interface from management to data, on page 779.

Initiating the manager access migration from data to management causes the Firewall Management Center to apply a block on deployment to the Firewall Threat Defense. You must disable manager access on the data interface to remove the block.

Before you begin

For high-availability pairs, unless stated otherwise, perform all steps only on the active unit. Once the configuration changes are deployed, the standby unit synchronizes configuration and other state information from the active unit.

Follow these steps to disable manager access on a data interface, and also configure other required settings.



Procedure

Step 1 Initiate the interface migration.

a) On the **Devices** > **Device Management** page, click **Edit** (✎) for the device. Click **Device**, and in the **Management** area, click the link for **Manager Access Interface**.

The **Manager Access Interface** field shows the current management interface as data. When you click the link, choose the new interface type, **Management Interface**, in the **Manage device by** drop-down list.

Figure 331: Manager access interface

b) Click **Save**.

Click **OK** and then **Close**.

You must now complete the remaining steps in this procedure to enable manager access on the Management interface. The **Management** area now shows the **Manager Access Interface: Management Interface**.

Figure 332: Manager access

Step 2 Disable manager access on the data interface(s). Click **Interfaces**, click **Edit** (✎) for the interface, and then click **Manager Access**.

Uncheck **Enable management access** and click **OK**. Click **Save** on the **Interfaces** page. This step removes the block on deployment.

Step 3 If you have not already done so, configure DNS settings for the data interface in a Platform Setting policy, and apply it to this device at **Devices** > **Device Management** page. Click **Edit** (✎) for the device and then click **DNS**.

See Configure DNS server settings, on page 852. The Firewall Management Center deployment that disables manager access on the data interface will remove any local DNS configuration. If that DNS server is used in any security policy, such as an FQDN in an Access Rule, then you must re-apply the DNS configuration using the Firewall Management Center.

Step 4 Deploy configuration changes; see Deploy configuration changes, on page 135.

The Firewall Management Center will deploy the configuration changes over the current data interface.

Step 5 If necessary, re-cable the Firewall Threat Defense so it can reach the Firewall Management Center on the Management interface. For High Availability, perform this step on both units.

Step 6 At the Firewall Threat Defense CLI, configure the Management interface IP address and gateway using a static IP address or DHCP. For high availability, perform this step on both units.

When you originally configured the data interface for manager access, the Management gateway was set to data-interfaces, which forwarded management traffic over the backplane so it could be routed through the manager access data interface. You now need to set an IP address for the gateway on the management network.

Static IP address:

configure network {**ipv4** | **ipv6**} **manual** *ip_address netmask gateway_ip*

DHCP:

configure network{**ipv4** | **ipv6**} **DHCP**

Step 7 In the Firewall Management Center, disable the management connection, update the **Remote Host Address** IP address and optional **Secondary Address** for the Firewall Threat Defense in the **Devices** > **Device Management**, **Management** section under **Device** tab, and reenable the connection.

See Update the Hostname or IP Address in the Firewall Management Center, on page 772. If you used the Firewall Threat Defense hostname or just the NAT ID when you added the Firewall Threat Defense to the Firewall Management Center, you do not need to update the value; however, you need to disable and reenable the management connection to restart the connection.

Step 8 Ensure the management connection is reestablished.

In the Firewall Management Center, check the management connection status on the **Devices** > **Device Management**, **Management** section under **Device** tab, **Status** field or view notifications in the Firewall Management Center.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 792.

View manager access details for data interface management

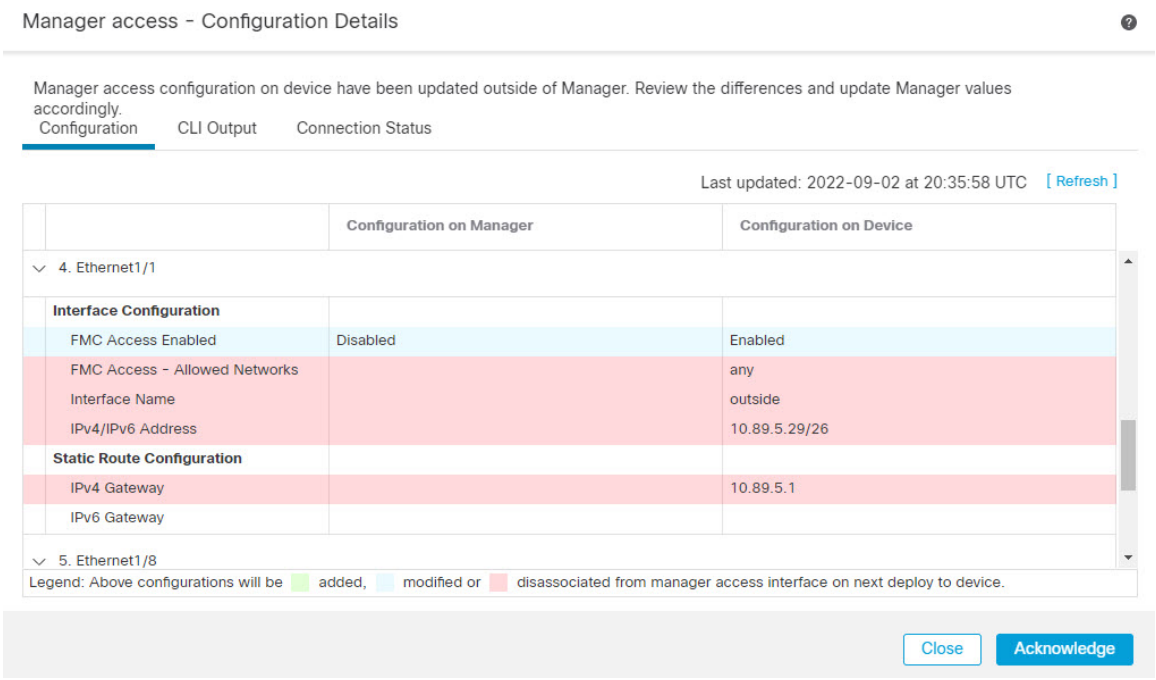
If you use a data interface for Firewall Management Center management instead of the dedicated management interface, you must be careful about changing the interface and network settings for the device in the Firewall Management Center to prevent disruption of the connection. When you change data interface settings locally on the device, you must reconcile them manually in the Firewall Management Center.

Use the **Devices** > **Device Management** > **Device** > **Management** > **Manager Access - Configuration Details** dialog box to resolve any discrepancies between the Firewall Management Center and the Firewall Threat Defense local configuration.

Typically, you configure the manager access data interface as part of initial Firewall Threat Defense setup before you add the Firewall Threat Defense to the Firewall Management Center. When you add the Firewall Threat Defense to the Firewall Management Center, the Firewall Management Center discovers and maintains the interface configuration, which includes interface name and IP address, static route to the gateway, DNS servers, and DDNS server. The DNS server configuration is maintained locally if discovered during registration, but it is not added to the Platform Settings policy in Firewall Management Center.

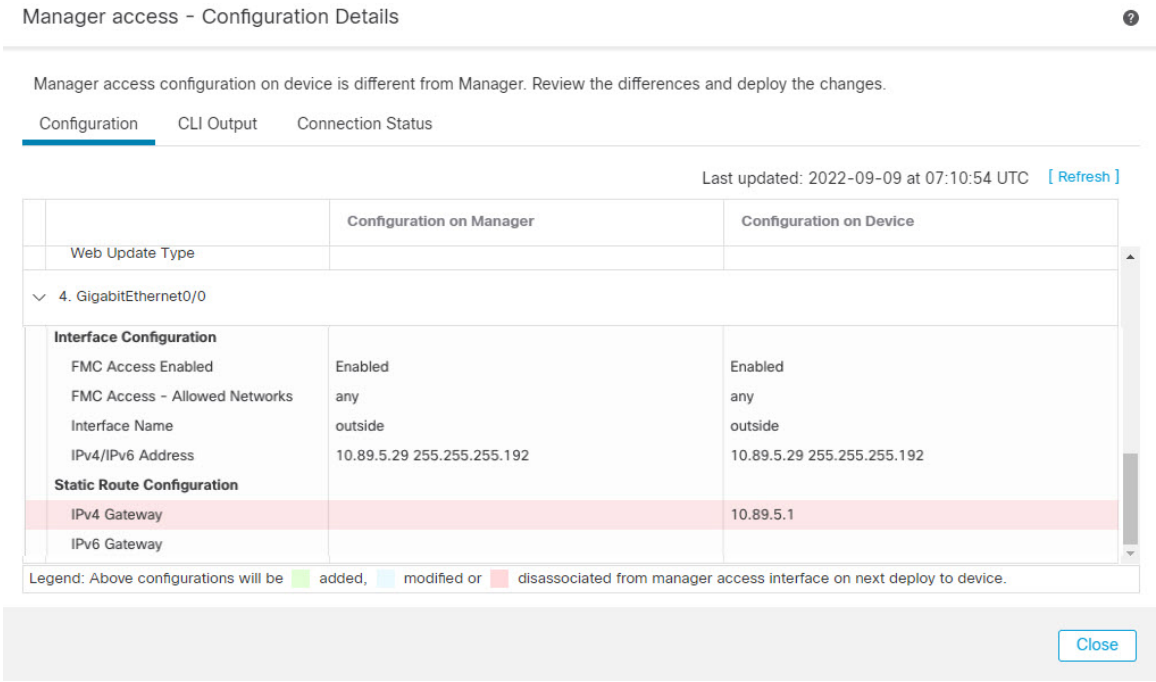
After you add the Firewall Threat Defense to the Firewall Management Center, if you change the data interface settings on the Firewall Threat Defense locally using the **configure network management-data-interface** command, the Firewall Management Center detects the configuration changes and blocks deployment to the Firewall Threat Defense. The Firewall Management Center detects the configuration changes using one of these methods:

- Deploy to the Firewall Threat Defense. Before the Firewall Management Center deploys, it will detect the configuration differences and stop the deployment.
- The **Sync** button in the **Interfaces** page.
- The **Refresh** button on the **Manager Access - Configuration Details** dialog box.



To remove the block, you must go to the **Manager Access - Configuration Details** dialog box and click **Acknowledge**. The next time you deploy, the Firewall Management Center configuration will overwrite any remaining conflicting settings on the Firewall Threat Defense. It is your responsibility to manually fix the configuration in the Firewall Management Center before you re-deploy.

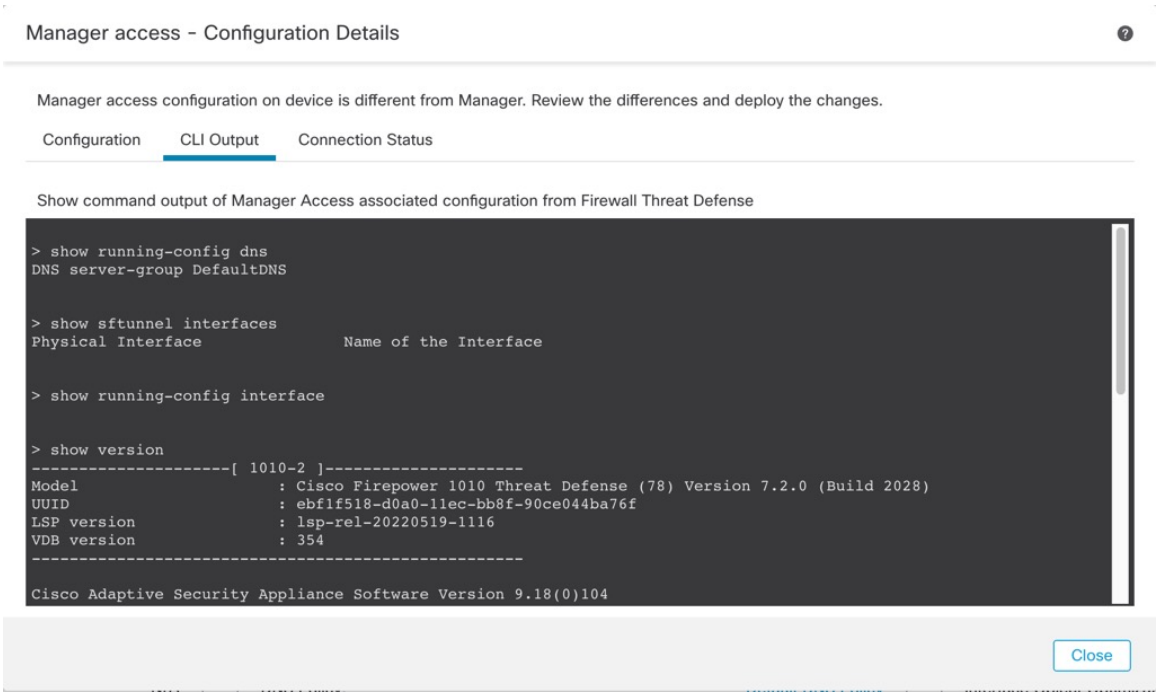
Configuration



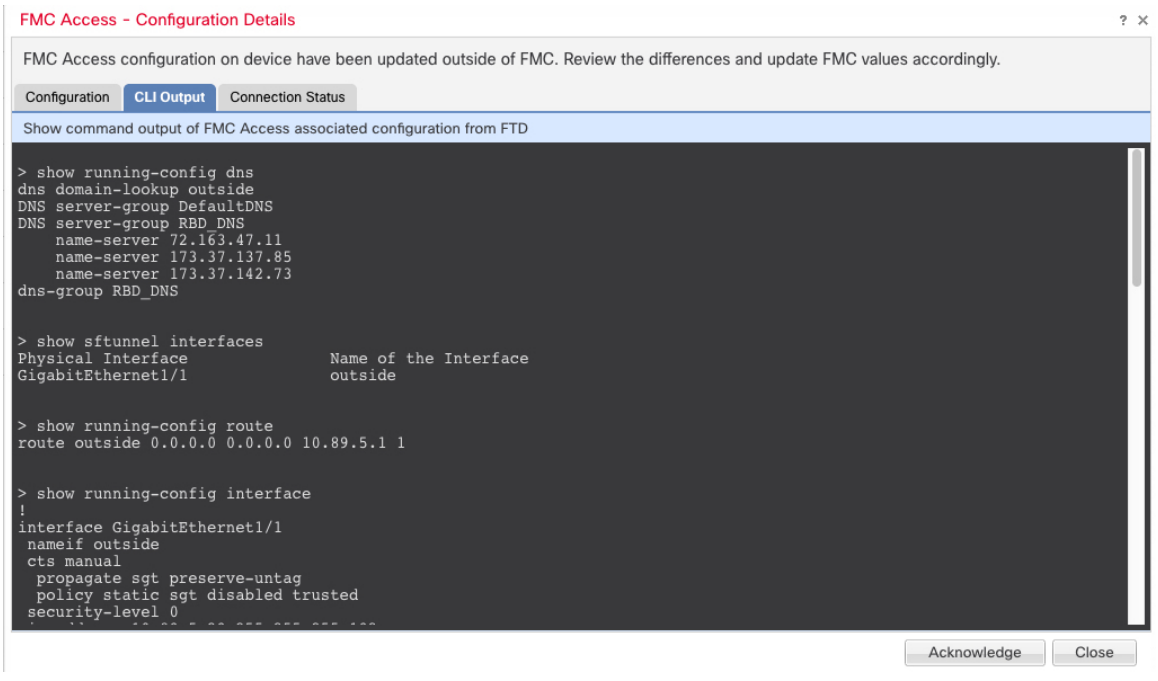
View the configuration comparison of the manager access data interface on the Firewall Management Center and the Firewall Threat Defense.

This example shows the configuration details of the Firewall Threat Defense where the **configure network management-data-interface** command was entered on the Firewall Threat Defense. Pink highlights indicate

that, if you **Acknowledge** the differences but do not match the configuration in the Firewall Management Center, then the Firewall Threat Defense configuration will be removed. Blue highlights mark configurations that will be modified on the Firewall Threat Defense. Green highlights mark configurations that will be added to the Firewall Threat Defense.



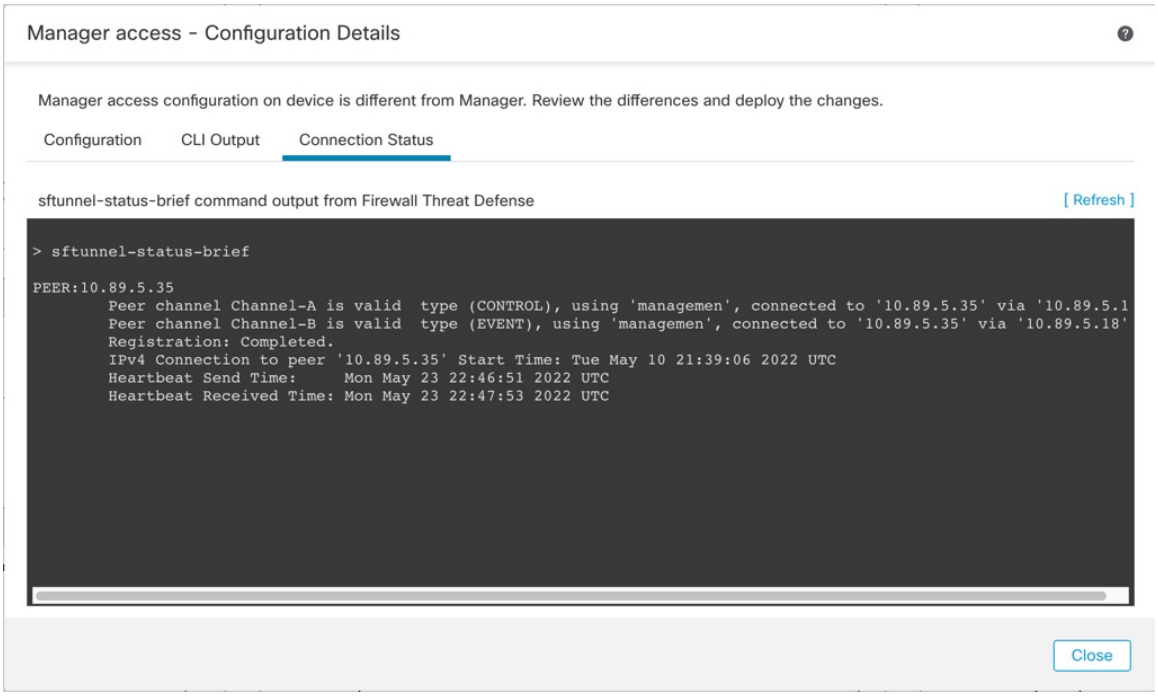
This example shows the page after configuring the interface in the Firewall Management Center. The interface settings match, and the pink highlight was removed.



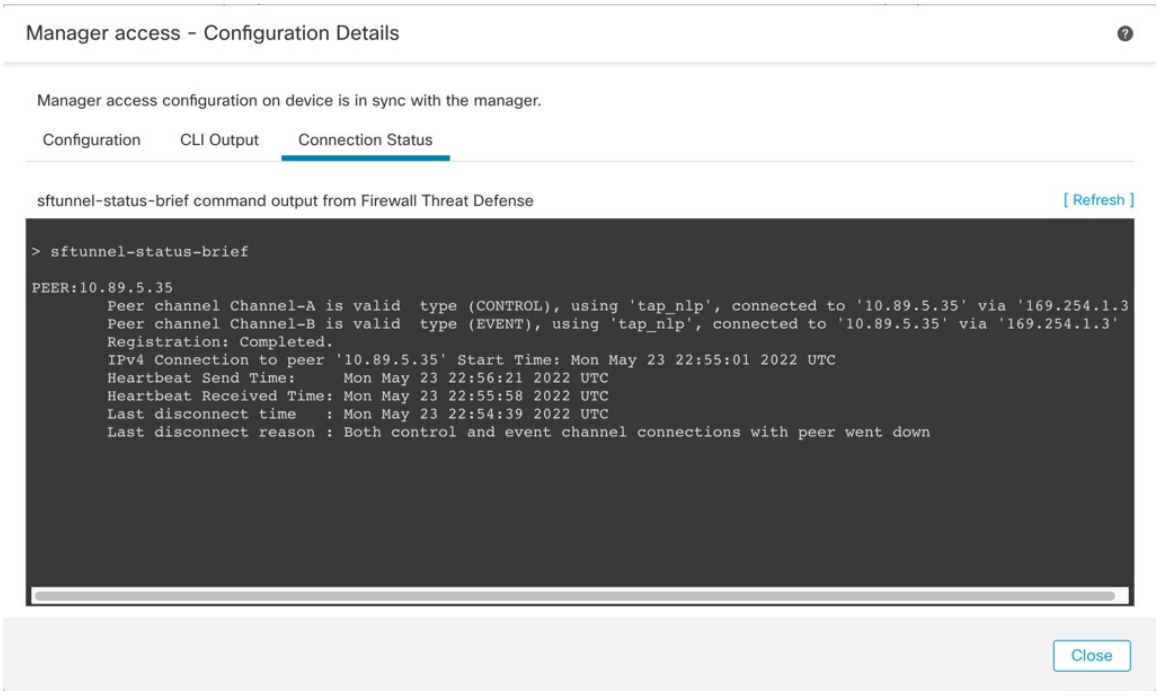
CLI output

View the CLI configuration of the manager access data interface, which is useful if you are familiar with the underlying CLI.

Figure 333: CLI output



Connection status



View the management connection status. In this example, the management connection still uses the Management "management0" interface.

Figure 334: Connection status

This status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

Figure 335: Connection status

This sample output shows a connection that is down. No peer channel "connected to" information or heartbeat information appears:

```
> sftunnel-status-brief
PEER:10.10.17.202
Registration: Completed.
Connection to peer '10.10.17.202' Attempted at Mon Jun 15 09:21:57 2020 UTC
Last disconnect time : Mon Jun 15 09:19:09 2020 UTC
Last disconnect reason : Both control and event channel connections with peer went down
```

This sample output shows a connection that is up, with peer channel and heartbeat information displayed:

```
> sftunnel-status-brief
PEER:10.10.17.202
Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
via '10.10.17.222'
Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202' via
 '10.10.17.222'
Registration: Completed.
IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

Troubleshoot the management connection

This reference provides information to help diagnose and resolve management connection issues.

Manually Roll Back the configuration if the Firewall Management Center loses Connectivity

Use this task to restore management connectivity when a configuration change deployed from the Firewall Management Center affects network connectivity and you need to roll back to the last-deployed configuration.

If you use a data interface on the Firewall Threat Defense for manager access and deploy a configuration change from the Firewall Management Center that affects network connectivity, you can roll back the configuration on the Firewall Threat Defense to the last-deployed configuration to restore management connectivity. Afterward, update the configuration settings in Firewall Management Center to maintain network connectivity, and re-deploy. You can use the rollback feature even if you do not lose connectivity; it is not limited to this troubleshooting situation.

Alternatively, you can enable auto rollback of the configuration if you lose connectivity after a deployment; see Edit deployment settings, on page 800.

See these guidelines:

- Only the previous deployment is available locally on the Firewall Threat Defense; you cannot roll back to any earlier deployments.
- Rollback is supported for high availability but not supported for clustering deployments.
- The rollback only affects configurations that you can set in the Firewall Management Center. For example, the rollback does not affect any local configuration related to the dedicated Management interface, which you can only configure at the Firewall Threat Defense CLI. If you change data interface settings after the last Firewall Management Center deployment using the **configure network management-data-interface** command and then you use the rollback command, those settings are not be preserved. They roll back to the last-deployed Firewall Management Center settings.
- UCAPL/CC mode cannot be rolled back.
- Out-of-band SCEP certificate data that was updated during the previous deployment cannot be rolled back.
- During the rollback, connections will drop because the current configuration will be cleared.

Procedure

Step 1 At the Firewall Threat Defense CLI, roll back to the previous configuration.

configure policy rollback

After the rollback, the Firewall Threat Defense notifies the Firewall Management Center about the successful completion. The deployment screen In the Firewall Management Center displays a banner indicating that the configuration was rolled back.

Note If the rollback fails and the Firewall Management Center management is restored, refer to https://www.cisco.com/c/en/us/support/docs/security/firepower-ngfw-virtual/215258-troubleshooting-firepower-threat-defense.html for common deployment problems. In some cases, the rollback may fail after the Firewall Management Center management access is restored. Resolve any Firewall Management Center configuration issues and redeploy from the Firewall Management Center.

Example:

For the Firewall Threat Defense that uses a data interface for manager access:

```
> configure policy rollback

The last deployment to this FTD was on June 1, 2020 and its status was Successful.
Do you want to continue [Y/N]?

Y

Rolling back complete configuration on the FTD. This will take time.
.....................
Policy rollback was successful on the FTD.
Configuration has been reverted back to transaction id:
Following is the rollback summary:
...................
.....................
>
```

Step 2 Check that the management connection was reestablished.

In Firewall Management Center, check the management connection status on the Connection Status page. Navigate to **Devices** > **Device Management** and then navigate to **Management** area under the **Devices** tab. Then in the **Manager Access - Configuration Details** screen, click **Connection Status**.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 792.

Troubleshoot Management Connectivity on a Data Interface

This topic helps you troubleshoot the loss of management connectivity when using a data interface for manager access instead of the dedicated Management interface.

If you use a data interface for manager access instead of the dedicated Management interface, exercise caution when changing the interface and network settings for the Firewall Threat Defense in the Firewall Management Center to avoid disrupting the connection. If you change the management interface type after adding the Firewall Threat Defense to the Firewall Management Center (switching between data and Management interfaces), misconfiguration of interfaces and network settings can result in loss of management connectivity.

Use the following methods to troubleshoot management connectivity:

- View management connection status: Check the status in the **Devices** > **Device Management** page or use **sftunnel-status-brief** at the CLI.
- View network information: Use **show network** to verify Management and manager access data interface settings.
- Check registration: Use **show managers** to confirm registration completion.
- Ping the manager: Use **ping** or **ping system** to test connectivity.
- Capture packets: Use **capture** on the `nlp_int_tap` interface to trace management traffic.
- Check interface status: Use **show interface detail** for the `nlp_int_tap` interface.

- Check routing and NAT: Use **show route** and **show nat** to verify routing and internal NAT rules.
- Check DDNS: Use **debug ddns** and related commands to verify DDNS updates.

```
> sftunnel-status-brief
PEER:10.10.17.202
Registration: Completed.
Connection to peer '10.10.17.202' Attempted at Mon Jun 15 09:21:57 2020 UTC
Last disconnect time : Mon Jun 15 09:19:09 2020 UTC
Last disconnect reason : Both control and event channel connections with peer went
down
```

```
> show network
===============[ System Information ]===============
Hostname                  : FTD-4
Domains                   : cisco.com
DNS Servers               : 72.163.47.11
DNS from router           : enabled
Management port           : 8305
IPv4 Default route
Gateway                 : data-interfaces
...
```

Note At the Firewall Threat Defense CLI, check that the Firewall Management Center registration was completed. Note that this command will not show the *current* status of the management connection.

Refer to https://cisco.com/go/fmc-reg-error for Firewall Management Center log file information.

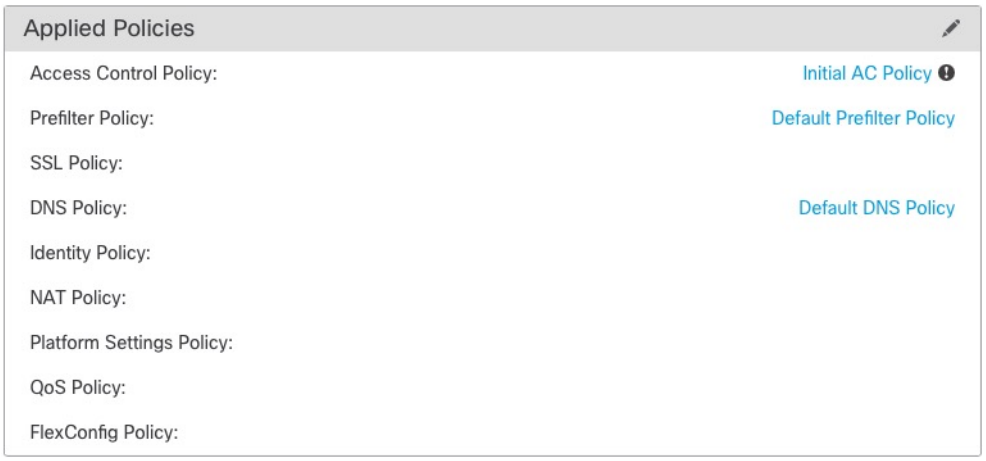
View inventory details

The **Inventory Details** section of the **Device** page shows chassis details such as the CPU and memory.

Figure 336: Inventory details

This section shows the chassis serial number. The firewall includes two serial numbers: the chassis serial number and the PCB (circuit board) serial number. The PCB serial number is shown in the System section. The Firewall Threat Defense Virtual does not have a chassis serial number.

Note For physical Firewall Threat Defense devices, the Memory field in **Inventory Details** shows only the data plane memory, not the total system memory.



To update information, click **Refresh** ( ).

Edit applied policies

This task allows you to assign or modify policies for an individual firewall device, including access control policies and other security policies that govern device behavior.

The **Applied Policies** section of the **Device** page displays the following policies applied to your firewall:

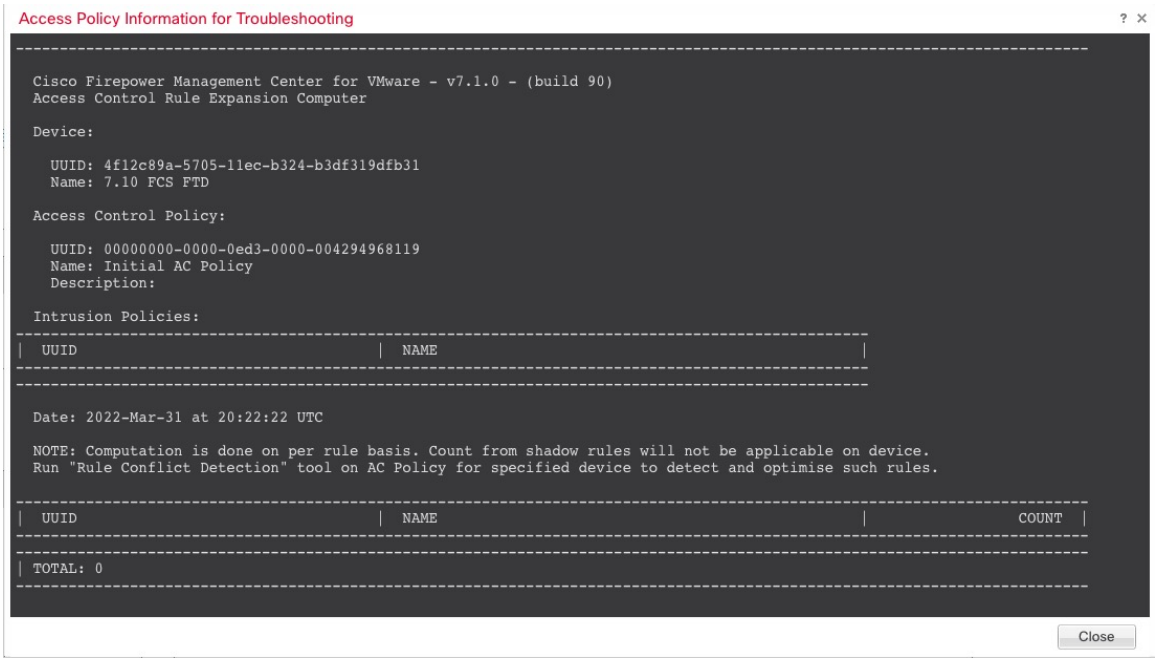


Figure 337: Applied policies

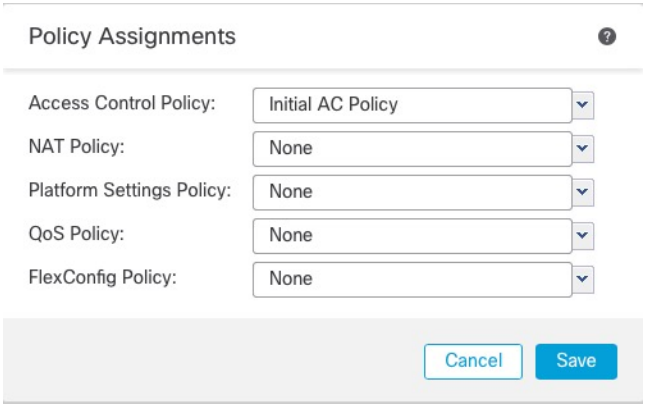
For policies with links, you can click the link to view the policy.

For the Access Control Policy, view the **Access Policy Information for Troubleshooting** dialog box by clicking the **Exclamation** ( ) icon. This dialog box shows how access rules are expanded into access control entries (ACEs).

Figure 338: Access policy information for troubleshooting

Procedure



Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to assign policies, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **Applied Policies** section, click **Edit** ( ).

Figure 339: Policy assignments

Step 5 For each policy type, choose a policy from the drop-down menu. Only existing policies are listed.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Edit advanced settings

The **Advanced Settings** section of the **Device** page displays a table of advanced configuration settings, as described below. You can edit any of these settings.

Table 50: Advanced settings table fields

Field	Description
Application Bypass	The state of Automatic Application Bypass on the device.
Bypass Threshold	The Automatic Application Bypass threshold, in milliseconds.
Object Group Search	The state of object group search on the device. While operating, the FTD device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in Firepower Management Center. It impacts only how the device interprets and processes them while matching connections to access control rules. **Note** By default, the **Object Group Search** is enabled when you add threat defense for the first time in the management center.
Interface Object Optimization	The state of interface object optimization on the device. During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source/destination interface pair. If you enable interface object optimization, the system will instead deploy a single rule per access control/prefilter rule, which can simplify the device configuration and improve deployment performance. If you select this option, also select the **Object Group Search** option to reduce memory usage on the device.

These topics explain how to edit the advanced device settings.

Note For information about the Transfer Packets setting, see Edit general settings, on page 743.

Configure automatic application bypass

Automatic Application Bypass (AAB) enables packet processing to continue when Snort detection becomes unavailable or exceeds processing time limits. This feature ensures network traffic flow continuity while providing diagnostic information for troubleshooting detection engine failures.

Automatic Application Bypass (AAB) allows packets to bypass detection if Snort is down or, for a Classic device, if a packet takes too long to process. AAB causes Snort to restart within ten minutes of the failure, and generates troubleshooting data that can be analyzed to investigate the cause of the Snort failure.

Caution AAB activation partially restarts the Snort process, which temporarily interrupts the inspection of a few packets.Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Note the following behavior:

Firewall Threat Defense Behavior: If Snort is down, then AAB is triggered after the specified timer duration. If Snort is up, then AAB is never triggered, even if packet processing exceeds the configured timer.

Classic Device Behavior: AAB limits the time allowed to process packets through an interface. You balance packet processing delays with your network's tolerance for packet latency.

The feature functions with any deployment; however, it is most valuable in inline deployments.

Typically, you use Rule Latency Thresholding in the intrusion policy to fast-path packets after the latency threshold value is exceeded. Rule Latency Thresholding does not shut down the engine or generate troubleshooting data.

If detection is bypassed, the device generates a health monitoring alert.

By default the AAB is disabled; to enable AAB follow these steps:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to edit advanced device settings, click **Edit** ( ).

Step 3 Click **Device**, then click **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Automatic Application Bypass**.

Step 5 Enter a **Bypass Threshold** from 250 ms to 60,000 ms. The default setting is 3000 milliseconds (ms).

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure object group search

This task enables object group search on a Firewall Threat Defense device to reduce memory requirements for access control policies that include network or interface objects.

While operating, the Firewall Threat Defense device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in Firewall Management Center. It impacts only how the device interprets and processes them while matching connections to access control rules.

Enabling object group search reduces memory requirements for access control policies that include network or interface objects. However, it is important to note that object group search might also decrease rule lookup performance and thus increase CPU utilization. You should balance the CPU impact against the reduced memory requirements for your specific access control policy. In most cases, enabling object group search provides a net operational improvement.

By default, the object group search is enabled for the threat defense devices that are added for the first time in the Firewall Management Center. In the case of upgraded devices, if the device is configured with disabled object group search, then you need to manually enable it. You can enable it on one device at a time; you cannot enable it globally. We recommend that you enable it on a device to which you deploy access rules that use network or interface objects.

Note

- If you enable object group search and then configure and operate the device for a while, be aware that subsequently disabling the feature might lead to undesirable results.
- When you disable object group search, your existing access control rules will be expanded in the device's running configuration. If the expansion requires more memory than is available on the device, your device can be left in an inconsistent state and you might see a performance impact.
- If your device is operating normally, do not disable the object group search after you have enabled it.

Before you begin

- Model support—Firewall Threat Defense
- We recommend that you also enable transactional commit on each device. From the device CLI, enter the **asp rule-engine transactional-commit access-group** command.
- Changing this setting can be disruptive to system operation while the device recompiles the ACLs. We recommend that you change this setting during a maintenance window.
- You can use FlexConfig to configure the **object-group-search threshold** command to enable a threshold to help prevent performance degradation. When operating with a threshold, for each connection, both the source and destination IP addresses are matched against network objects. If the number of objects matched by the source address times the number matched by the destination address exceeds 10,000, the connection is dropped. Configure your rules to prevent an excessive number of matches.

Follow these steps to configure object group search:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the Firewall Threat Defense device where you want to configure the rule, click the **Edit** ( ).

Step 3 Click the **Device** tab, then click the **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Object Group Search**.

Step 5 To have object group search work on interface objects in addition to network objects, check **Interface Object Optimization**.

If you do not select **Interface Object Optimization**, the system deploys separate rules for each source/interface pair, rather that use the security zones and interface groups used in the rules. This means the interface groups are not available for object group search processing.

Step 6 Click **Save**.

Configure interface object optimization

Interface object optimization enables the system to deploy a single rule per access control/prefilter rule instead of generating separate rules for each source/destination interface pair, simplifying device configuration and improving deployment performance.

During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source and destination interface pair. Enabling interface object optimization deploys a single rule per access control or prefilter rule. This approach simplifies device configuration and can improve deployment performance. If you select this option, also select the **Object Group Search** option to reduce evice memory usage.

Interface object optimization is disabled by default. You can enable it on one device at a time; you cannot enable it globally.

Note If you disable interface object optimization, the system deploys existing access control rules without using interface objects. This process might take longer. If object group search is enabled, its benefits do not apply to interface objects, and the device's running configuration might show expanded access control rules. If this expansion requires more memory than is available, the device can become inconsistent, which may affect performance

Before you begin

Model support—Firewall Threat Defense

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the Firewall Threat Defense device where you want to configure the rule, click the **Edit** ( ).

Step 3 Under the **Device** tab, click **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Interface Object Optimization**.

Step 5 Click **Save**.

Edit deployment settings

Configure the deployment settings to enable auto rollback of the deployment if the management connection fails as a result of the deployment. For example, if you use data for management center access and then you misconfigure the data interface.

The **Deployment Settings** section of the **Device** page displays information for managing automatic rollback configuration. As an alternative, you can manually roll back the configuration using the **configure policy rollback** command (see Manually Roll Back the configuration if the Firewall Management Center loses Connectivity, on page 791).

Figure 340: Deployment settings

Table 51: Deployment settings

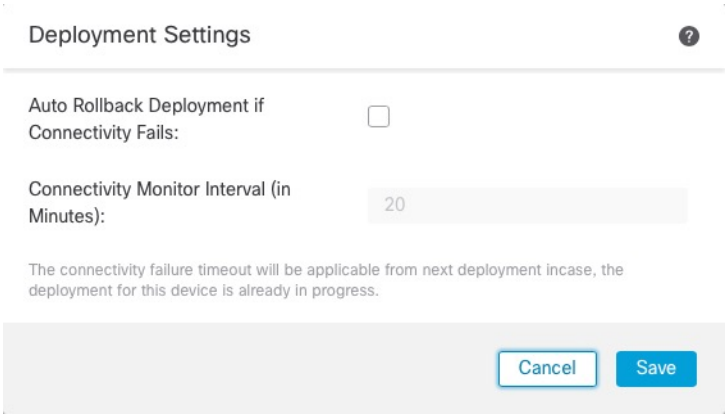
Field	Description
Auto Rollback Deployment if Connectivity Fails	Enabled or Disabled. You can enable auto rollback if the management connection fails as a result of the deployment; specifically if you use data for management center access, and then you misconfigure the data interface.
Connectivity Monitor Interval (in Minutes)	Shows the amount of time to wait before rolling back the configuration.

Consider the following guidelines:

- Only the previous deployment is available locally on the Firewall Threat Defense; you cannot roll back to any earlier deployments.
- Rollback is supported for high availability but not supported for clustering deployments.
- The rollback only affects configurations that you can set in the Firewall Management Center. For example, the rollback does not affect any local configuration related to the dedicated Management interface, which you can only configure at the Firewall Threat Defense CLI. If you change data interface settings after the last Firewall Management Center deployment using the **configure network management-data-interface** command and then you use the rollback command, those settings are not be preserved. They roll back to the last-deployed Firewall Management Center settings.

- UCAPL/CC mode cannot be rolled back.
- Out-of-band SCEP certificate data that was updated during the previous deployment cannot be rolled back.
- During the rollback, connections will drop because the current configuration will be cleared.

Procedure



Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to assign policies, click **Edit** ( ).

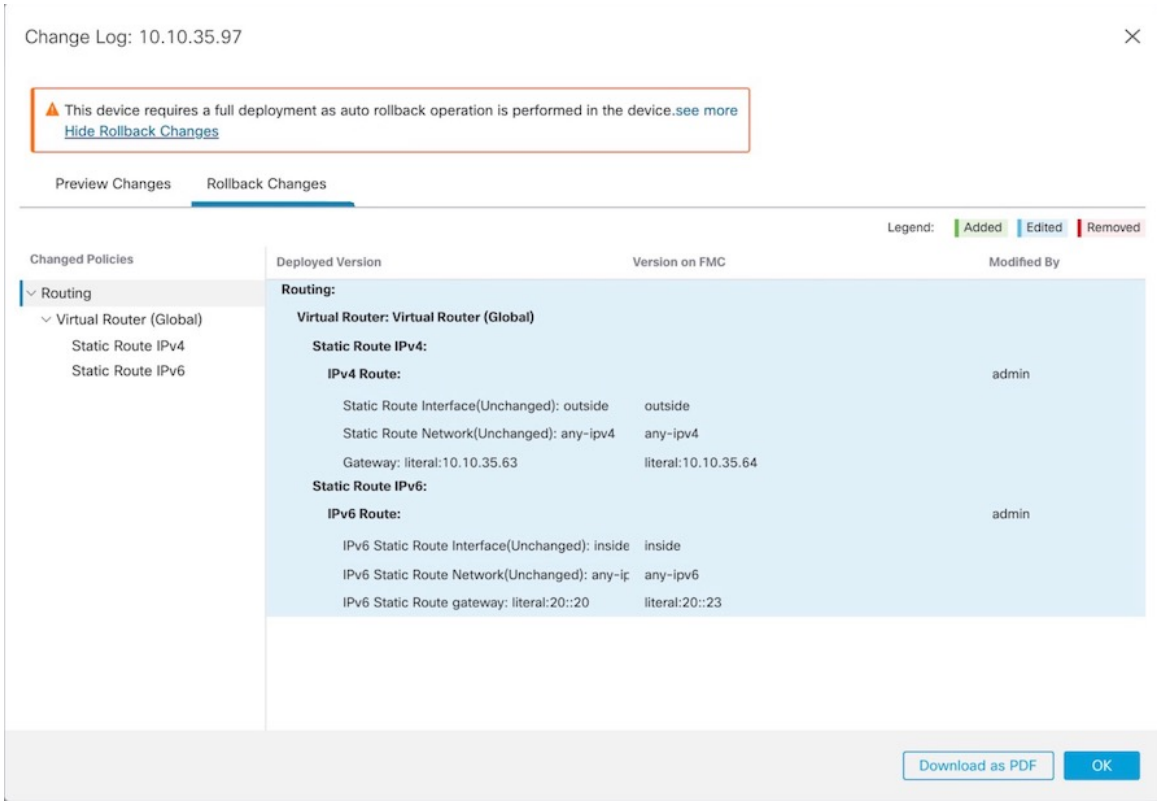
Step 3 Click **Device**.

Step 4 In the **Deployment Settings** section, click **Edit** ( ).

Figure 341: Deployment settings

Step 5 Check **Auto Rollback Deployment if Connectivity Fails** to enable auto rollback.

Step 6 Set the **Connectivity Monitor Interval (in minutes)** to configure the wait time before rolling back the configuration. The default is 20 minutes.



Step 7 If a rollback occurs, consider these next steps.

- If the auto rollback was successful, you see a success message instructing you to do a full deployment.
- Go to **Deploy** > **Advanced Deploy** page and click the **Preview** ( ) icon to view the parts of the configuration that were rolled back (see Deploy configuration changes, on page 135).

  To view the changes, click **Show Rollback Changes**.

  To hide the changes, click **Hide Rollback Changes**.

Figure 342: Rollback changes

- In the Deployment History Preview, you can view the rollback changes. See View deployment history, on page 141.

Step 8 Verify that the management connection was reestablished.

a. In Firewall Management Center, check the management connection status on the connection status page.

b. Navigate to **Devices** > **Device Management** and then in **Management** area under the **Devices** tab, click **Connection Status** to view the **Connection Status** page.

c. At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 792.

Edit cluster health monitor settings

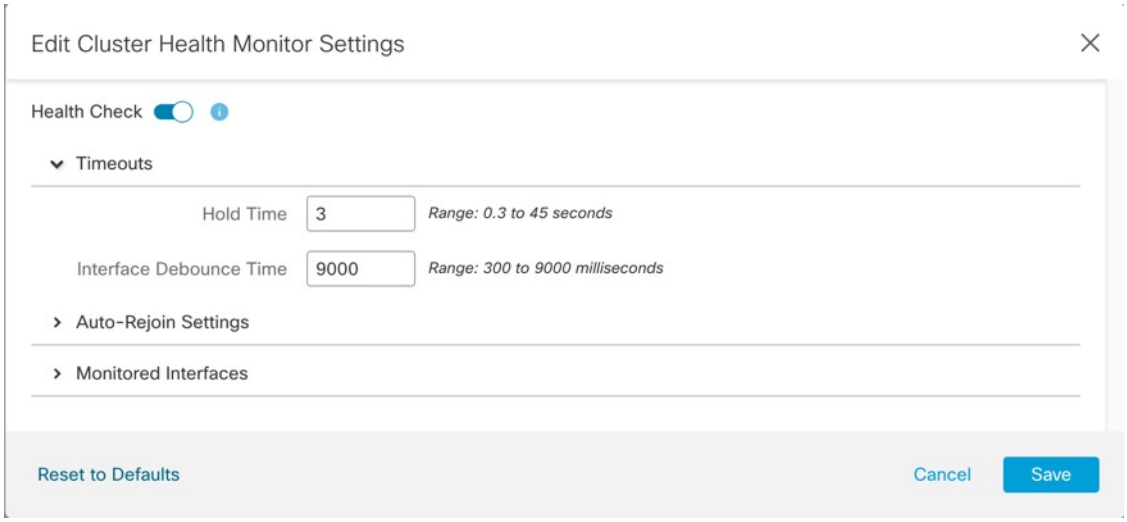
This task allows you to modify cluster health monitor settings to control how cluster nodes monitor system health and automatically rejoin the cluster after failures.

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings for monitoring cluster node health. You can monitor any port-channel ID, any single physical interface ID, and the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link. It is always monitored.

When a topology change occurs (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature. Also, disable interface monitoring for any interfaces that are disabled. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Procedure

Step 1 Choose **Devices** > **Device Management**.



Step 2 Next to the cluster you want to modify, click **Edit** ( ).

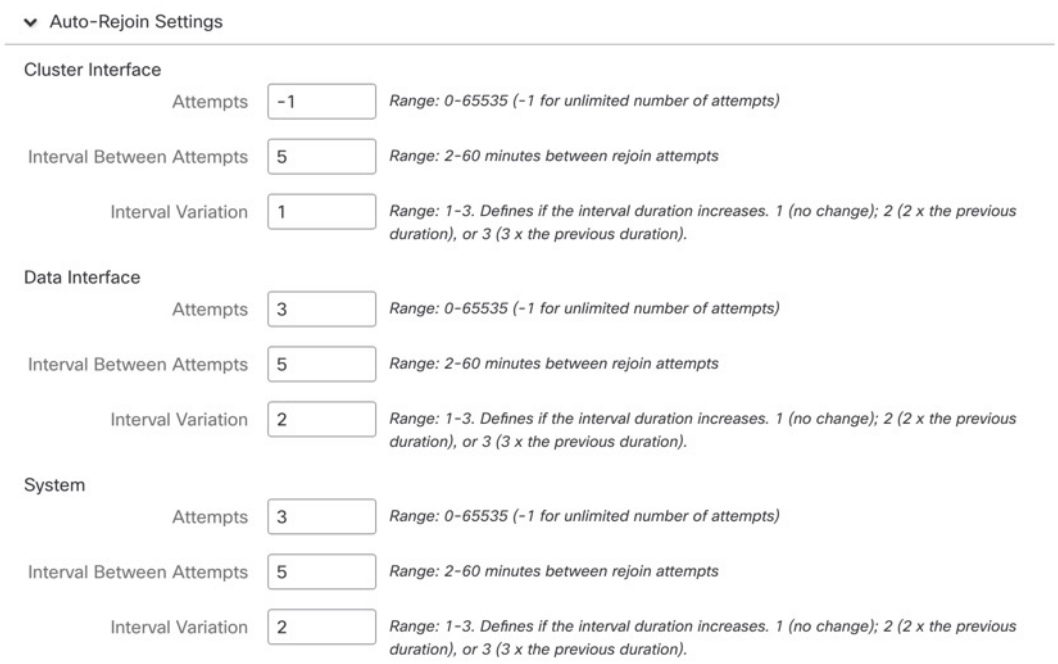
Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider.

Figure 343: Disable the system health check

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.



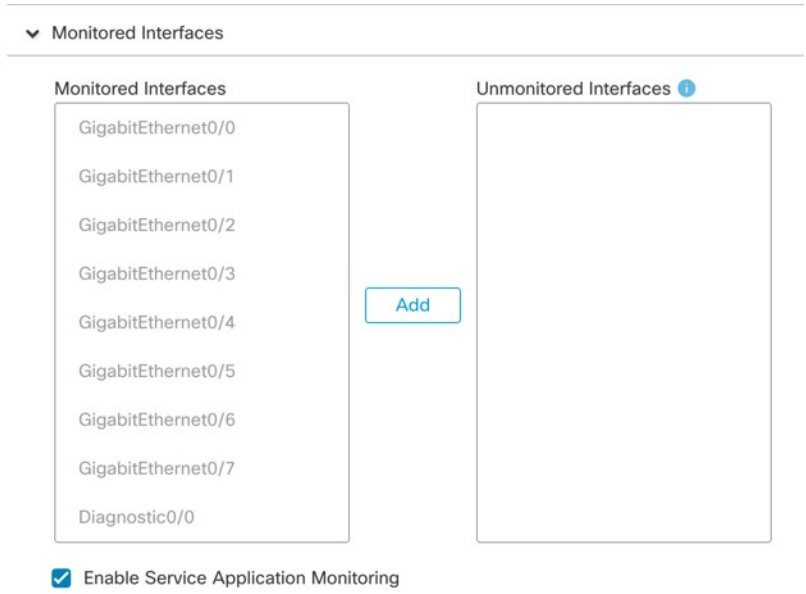
Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between 0.3 and 45 seconds. The default is 3 seconds.

- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the specified number of milliseconds before marking the interface as failed and removing the node from the cluster. If an EtherChannel transitions from a down state to an up state, such as after the switch reloads or enables an EtherChannel, a longer debounce time can prevent the interface from appearing failed on a cluster node if another cluster node bundles the ports more quickly.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 344: Configure Auto-Rejoin settings



Set values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 345: Configure monitored interfaces

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The time required to remove a member from the cluster depends on the type of interface and whether the node is established or is joining the cluster. By default, health check is enabled for all interfaces and the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Deploy configuration changes; see Deploy configuration changes, on page 135.

Hot swap an SSD

Hot swapping SSDs allows you to maintain system operation while replacing faulty drives, removing drives, or adding drives to form a RAID configuration.

If you have two SSDs, they form a RAID when you boot up. You can perform the following tasks at the Firewall Threat Defense CLI while the firewall is powered up:

- Hot swap one of the SSDs—If an SSD is faulty, you can replace it. Note that if you only have one SSD, you cannot remove it while the firewall is powered on.
- Remove one of the SSDs—If you have two SSDs, you can remove one.

- Add a second SSD—If you have one SSD, you can add a second SSD and form a RAID.

  When you use only one SSD in Secure Firewall devices, the **Drive State** will show as **degraded**.

Caution Do not remove an SSD without first removing it from the RAID using this procedure. You can cause data loss.

Procedure

Step 1 Remove one of the SSDs.

a) Remove the SSD from the RAID.

configure RAID remove-secure local-disk {**1** | **2**}

The **remove-secure** keyword removes the SSD from the RAID, disables the self-encrypting disk feature, and performs a secure erase of the SSD. If you only want to remove the SSD from the RAID and want to keep the data intact, you can use the **remove** keyword.

Example:

```
> configure raid remove-secure local-disk 2
```

b) Monitor the RAID status until the SSD no longer shows in the inventory.

show RAID

After the SSD is removed from the RAID, the **Operability** and **Drive State** will show as **degraded**. The second drive will no longer be listed as a member disk.

Example:

```
> show raid
Virtual Drive
ID:                     1
Size (MB):              858306
Operability:            operable
Presence:               equipped
Lifecycle:              available
Drive State:            optimal
Type:                   raid
Level:                  raid1
Max Disks:              2
Meta Version:           1.0
Array State:            active
Sync Action:            idle
Sync Completed:         unknown
Degraded:               0
Sync Speed:             none

RAID member Disk:
Device Name:            nvme0n1
Disk State:             in-sync
Disk Slot:              1
Read Errors:            0
```

```
Recovery Start:             none
Bad Blocks:
Unacknowledged Bad Blocks:

Device Name:                nvme1n1
Disk State:                 in-sync
Disk Slot:                  2
Read Errors:                0
Recovery Start:             none
Bad Blocks:
Unacknowledged Bad Blocks:

> show raid
Virtual Drive
ID:                         1
Size (MB):                  858306
Operability:                degraded
Presence:                   equipped
Lifecycle:                  available
Drive State:                degraded
Type:                       raid
Level:                      raid1
Max Disks:                  2
Meta Version:               1.0
Array State:                active
Sync Action:                idle
Sync Completed:             unknown
Degraded:                   1
Sync Speed:                 none

RAID member Disk:
Device Name:                nvme0n1
Disk State:                 in-sync
Disk Slot:                  1
Read Errors:                0
Recovery Start:             none
Bad Blocks:
Unacknowledged Bad Blocks:
```

c) Physically remove the SSD from the chassis.

Step 2 Add an SSD.

a) Physically add the SSD to the empty slot.

b) Add the SSD to the RAID.

configure RAID add local-disk {**1** | **2**}

It can take several hours to complete syncing the new SSD to the RAID, during which the firewall is completely operational. You can even reboot, and the sync will continue after it powers up. Use the **show RAID** command to show the status.

If you install an SSD that was previously used on another system, and is still locked, enter the following command:

configure RAID add local-disk {**1** | **2**} *psid*

The *psid* is printed on the label attached to the back of the SSD. Alternatively, you can reboot the system, and the SSD will be reformatted and added to the RAID.

Configure SNMP for FXOS

You can configure the Simple Network Management Protocol (SNMP) for the underlying FXOS operating system that controls low-level chassis functions. For SNMP for the Firewall Threat Defense, see Configure SNMP for a security device, on page 870.

SNMP is an application-layer protocol that provides a message format for communication between SNMP managers and agents. SNMP provides a standardized framework and a common language used for the monitoring and management of devices in a network.

The SNMP framework consists of three parts:

- An SNMP manager—The system used to control and monitor the activities of network devices using SNMP.
- An SNMP agent—The software component within the chassis that maintains the data for the chassis and reports the data, as needed, to the SNMP manager. The chassis includes the agent and a collection of MIBs. To enable the SNMP agent and create the relationship between the manager and agent, enable and configure SNMP in the Firewall Management Center.
- A managed information base (MIB)—The collection of managed objects on the SNMP agent.

The chassis supports SNMPv1, SNMPv2c and SNMPv3. Both SNMPv1 and SNMPv2c use a community-based form of security. SNMPv3 uses username and password for security.

Enable SNMP for FXOS

Enable SNMP and configure settings.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **SNMP**.

Step 3 Complete the following fields:

Name	Description
Admin State check box	Whether SNMP is enabled or disabled. Enable this service only if your system includes integration with an SNMP server.
Port field	The port on which the Firepower chassis communicates with the SNMP host. You cannot change the default port.

Name	Description
Community field	The default SNMPv1 or v2 community name or SNMP v3 username and password that the Firepower chassis includes on any trap messages it sends to the SNMP host. Enter a valid community string for SNMPv1 and SNMPv2: • Alphanumeric string between 1 and 32 characters and special characters ! (exclamation), - (hyphen), ~ (tilde), && (double ampersand), [ ] (square brackets), ^ (carat), ' (single quote), " (double quotes), and < > (angle brackets). • Do not use @ (at sign), \ (backslash), ? (question mark) or an empty space. • The string can also be in ASCII characters ranging 0x21 to 0x7E inclusive, excluding HTML interjection vectors, namely single quote ('), double quotes ("), and angle brackets (< >). Enter a valid username and password for SNMPv3: • Username can be alphanumeric string and can include @ (at sign), \ (backslash), . (period), _ (underscore), and - (hyphen). • The password restrictions are same as the community string restrictions. Note that if the **Community** field is already set, the text to the right of the empty field reads **Set: Yes**. If the **Community** field is not yet populated with a value, the text to the right of the empty field reads **Set: No**.
System Admin Name field	The contact person responsible for the SNMP implementation. Enter a string of up to 255 characters, such as an email address or a name and telephone number.
Location field	The location of the host on which the SNMP agent (server) runs. Enter an alphanumeric string up to 510 characters.

Step 4 Click **Save**.

What to do next

Create SNMP traps and users.

Create an SNMP Trap for FXOS

Create traps for SNMP.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **SNMP**.

Step 3 In the **SNMP Traps Configuration** area, click **Add**.

Step 4 In the **SNMP Trap Configuration** dialog box, complete the following fields:

Name	Description
Host Name field	The hostname or IP address of the SNMP host to which the Firepower chassis should send the trap.
Community field	The SNMP v1 or v2 community name or the SNMP v3 username the Firepower chassis includes when it sends the trap to the SNMP host. This must be the same as the community or username that is configured for the SNMP service. Enter an alphanumeric string between 1 and 32 characters. Do not use @ (at sign), \ (backslash), " (double quote), ? (question mark) or an empty space.
Port field	The port on which the Firepower chassis communicates with the SNMP host for the trap. Enter an integer between 1 and 65535.
Version field	The SNMP version and model used for the trap. This can be one of the following: • **V1** • **V2** • **V3**
Type field	If you select **V2** or **V3** for the version, the type of trap to send. This can be one of the following: • **Traps** • **Informs**
Privilege field	If you select **V3** for the version, the privilege associated with the trap. This can be one of the following: • **Auth**—Authentication but no encryption • **Noauth**—No authentication or encryption • **Priv**—Authentication and encryption

Step 5 Click **OK** to close the **SNMP Trap Configuration** dialog box.

Step 6 Click **Save**.

Create an SNMP user for FXOS

Create SNMP users.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **SNMP**.

Step 3 In the **SNMP Users Configuration** area, click **Add**.

Step 4 In the **SNMP User Configuration** dialog box, complete the following fields:

Name	Description
Username field	The username assigned to the SNMP user. Enter up to 32 letters or numbers. The name must begin with a letter and you can also specify _ (underscore), . (period), @ (at sign), and - (hyphen).
Auth Algorithm Type field	The authorization type: **SHA**.
Use AES-128 checkbox	If checked, this user uses AES-128 encryption. **Note** SNMPv3 does not support DES. If you leave the AES-128 box unchecked, no privacy encryption will be done and any configured privacy password will have no effect.
Authentication Password field	The password for the user.
Confirm field	The password again for confirmation purposes.
Encryption Password field	The privacy password for the user.
Confirm field	The privacy password again for confirmation purposes.

Step 5 Click **OK** to close the **SNMP User Configuration** dialog box.

Step 6 Click **Save**.

Configure alarms for the ISA 3000

You can configure the alarm system on a Cisco ISA 3000 device to alert you when undesirable conditions occur.

About alarms

You can configure the ISA 3000 to issue alarms for a variety of conditions. If any conditions do not match the configured settings, the system triggers an alarm, which is reported by way of LEDs, syslog messages, SNMP traps, and through external devices connected to the alarm output interface. By default, triggered alarms issue syslog messages only.

You can configure the alarm system to monitor the following:

- Power supply.
- Primary and secondary temperature sensors.
- Alarm input interfaces.

The ISA 3000 has internal sensors plus two alarm input interfaces and one alarm output interface. You can connect external sensors, such as door sensors, to the alarm inputs. You can connect external alarm devices, such as buzzers or lights, to the alarm output interface.

The alarm output interface is a relay mechanism. Depending on the alarm conditions, the relay is either energized or de-energized. When it is energized, any device connected to the interface is activated. A de-energized relay results in the inactive state of any connected devices. The relay remains in an energized state as long as alarms are triggered.

For information about connecting external sensors and the alarm relay, Refer to Alarms for the Cisco ISA 3000 chapter in Cisco ASA Series General Operations CLI Configuration Guide. see Cisco ISA 3000 Industrial Security Appliance Hardware Installation Guide.

Alarm input interfaces

You can connect the alarm input interfaces (or contacts) to external sensors, such as one that detects if a door is open.

Each alarm input interface has a corresponding LED. These LEDs convey the alarm status of each alarm input. You can configure the trigger and severity for each alarm input. In addition to the LED, you can configure the contact to trigger the output relay (to activate an external alarm), to send syslog messages, and to send SNMP traps.

The following table explains the statuses of the LEDs in response to alarm conditions for the alarm inputs. It also explains the behavior for the output relay, syslog messages, and SNMP traps, if you enable these responses to the alarm input.

Alarm Status	LED	Output Relay	Syslog	SNMP Trap
Alarm not configured	Off	—	—	—
No alarms triggered	Solid green	—	—	—
Alarm activated	Minor alarm—solid red Major alarm—flashing red	Relay energized	Syslog generated	SNMP trap sent
Alarm end	Solid green	Relay de-energized	Syslog generated	—

Alarm output interface

You can connect an external alarm, such as a buzzer or light, to the alarm output interface.

The alarm output interface functions as a relay and also has a corresponding LED, which conveys the alarm status of an external sensor connected to the input interface, and internal sensors such as the dual power supply and temperature sensors. You configure which alarms should activate the output relay, if any.

The following table explains the statuses of the LEDs and output relay in response to alarm conditions. It also explains the behavior for syslog messages, and SNMP traps, if you enable these responses to the alarm.

Alarm Status	LED	Output Relay	Syslog	SNMP Trap
Alarm not configured	Off	—	—	—
No alarms triggered	Solid green	—	—	—
Alarm activated	Solid red	Relay energized	Syslog generated	SNMP trap sent
Alarm end	Solid green	Relay de-energized	Syslog generated	—

Syslog alarms

By default, the system sends syslog messages when any alarm is triggered. You can disable syslog messaging if you do not want the messages.

For syslog alarms to work, you must also enable diagnostic logging. Choose **Devices** > **Platform Settings**, add or edit a Threat Defense platform settings policy that is assigned to the device, and configure destinations and settings on the **Syslog** page. For example, you can configure a syslog server, console logging, or internal buffer logging.

Without enabling a destination for diagnostic logging, the alarm system has nowhere to send syslog messages.

SNMP Alarms

You can optionally configure the alarms to send SNMP traps to your SNMP server. For SNMP trap alarms to work, you must also configure SNMP settings.

Choose **Devices** > **Platform Settings**, add or edit a Threat Defense platform settings policy that is assigned to the device, and enable SNMP and configure settings on the **SNMP** page.

Defaults for alarms

The following table specifies the defaults for alarm input interfaces (contacts), redundant power supply, and temperature.

	Alarm	Trigger	Severity	SNMP Trap	Output Relay	Syslog Message
Alarm Contact 1	Enabled	Closed State	Minor	Disabled	Disabled	Enabled
Alarm Contact 2	Enabled	Closed State	Minor	Disabled	Disabled	Enabled

	Alarm	Trigger	Severity	SNMP Trap	Output Relay	Syslog Message
Redundant Power Supply (when enabled)	Enabled	—	—	Disabled	Disabled	Enabled
Temperature	Enabled for the primary temperature alarm (default values of 92°C and -40°C for the high and low thresholds respectively) Disabled for the secondary alarm.	—	—	Enabled for primary temperature alarm	Enabled for primary temperature alarm	Enabled for primary temperature alarm

Prerequisites for alarms

Model support

Firewall Threat Defense on the ISA 3000.

Configure alarms for the ISA 3000

You use FlexConfig to configure alarms for the ISA 3000. The following topics explain how to configure the different types of alarms.

Configure alarm input contacts

If you connect the alarm input contacts (interfaces) to external sensors, you can configure the contacts to issue alarms based on the input from the sensor. In fact, the contacts are enabled by default to send syslog messages if the contact is closed, that is, if the electrical current stops flowing through the contact. You need to configure the contact only if the defaults do not meet your requirements.

The alarm contacts are numbered 1 and 2, so you need to understand how you have wired the physical pins to configure the correct settings. You configure the contacts separately.

Procedure

Step 1 Create the FlexConfig object to configure the alarm input contacts.

a) Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Configure_Alarm_Contacts.

- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to configure the alarm contacts. The following steps explain the commands.

c) Configure a description for the alarm contact.

alarm contact {**1** | **2**} **description** *string*

For example, to set the description of contact 1 to "Door Open," enter the following:

```
alarm contact 1 description Door Open
```

d) Configure the severity for the alarm contact.

alarm contact {**1** | **2** | **any**} **severity** {**major** | **minor** | **none**}

Instead of configuring one contact, you can specify **any** to change the severity for all contacts. The severity controls the behavior of the LED associated with the contact.

- **major**—The LED blinks red.
- **minor**—The LED is solid red. This is the default.
- **none**—The LED is off.

For example, to set the severity of contact 1 to Major, enter the following:

```
alarm contact 1 severity major
```

e) Configure the trigger for the alarm contact.

alarm contact {**1** | **2** | **any**} **trigger** {**open** | **closed**}

Instead of configuring one contact, you can specify **any** to change the trigger for all contacts. The trigger determines the electrical condition that signals an alert.

- **open**—The normal condition for the contact is closed, that is, the electrical current is running through the contact. An alert is triggered if the contact becomes open, that is, the electrical current stops flowing.
- **closed**—The normal condition for the contact is open, that is, the electrical current does not run through the contact. An alert is triggered if the contact becomes closed, that is, the electrical current starts running through the contact. This is the default.

For example, you connect a door sensor to alarm input contact 1, and its normal state has no electrical current flowing through the alarm contact (it is open). If the door is opened, the contact is closed and electrical current flows through the alarm contact. You would set the alarm trigger to closed so that the alarm goes off when the electrical current starts flowing.

```
alarm contact 1 trigger closed
```

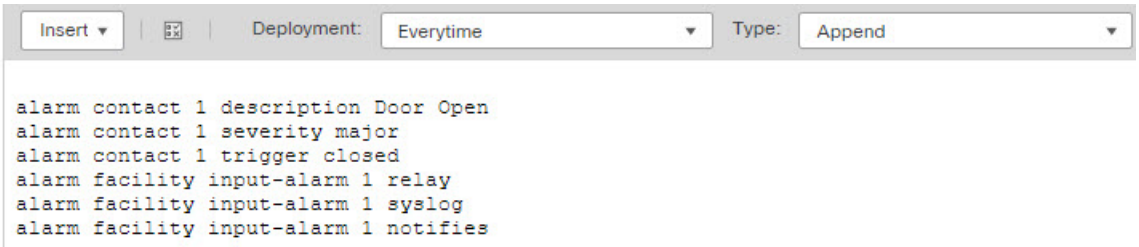
f) Configure the actions to take when the alarm contact is triggered.

alarm facility input-alarm {**1** | **2**} {**relay** | **syslog** | **notifies**}

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message. This option is enabled by default.
- **notifies**—Send an SNMP trap.

For example, to enable all actions for the alarm input contact 1, enter the following:



```
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

g) Verify that the object body contains the commands you want.

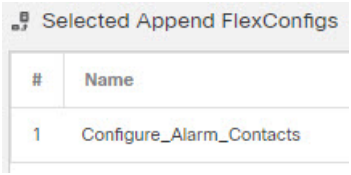
For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
alarm contact 1 description Door Open
alarm contact 1 severity major
alarm contact 1 trigger closed
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

The object body should look similar to the following:

h) Click **Save**.

Step 2 Create the FlexConfig policy and assign it to the devices.



a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the alarm contact FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the alarm contact commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
alarm contact 1 description Door Open
alarm contact 1 severity major
alarm contact 1 trigger closed
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 954.

Configure power supply alarms

The ISA 3000 has two power supplies. By default, the system operates in single-power mode. However, you can configure the system to operate in dual mode, where the second power supply automatically provides power if the primary power supply fails. When you enable dual-mode, the power supply alarm is automatically enabled to send syslog alerts, but you can disable the alert altogether, or also enable SNMP traps or the alarm hardware relay.

The following procedure explains how to enable dual mode, and how to configure the power supply alarms.

Procedure

Step 1 Create the FlexConfig object to configure the power supply alarm.

a) Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Power_Supply_Alarms.

- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to configure the power supply alarms. The following steps explain the commands.

c) Enable dual power supply mode.

power-supply dual

For example:

```
power-supply dual
```

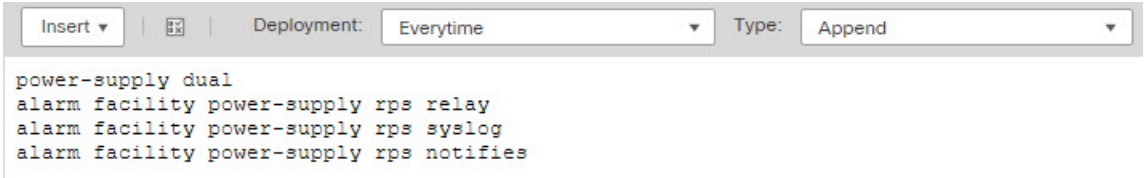
d) Configure the actions to take when the power supply alarm is triggered.

alarm facility power-supply rps {**relay** | **syslog** | **notifies** | **disable**}

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message. This option is enabled by default.
- **notifies**—Send an SNMP trap.
- **disable**—Disable the power supply alarm. Any other actions configured for the power supply alarm are inoperable.

For example, to enable all actions for the power supply alarm, enter the following:



```
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

e) Verify that the object body contains the commands you want.

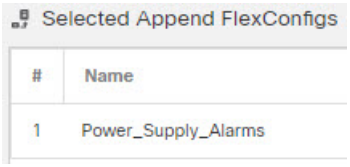
For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

The object body should look similar to the following:

f) Click **Save**.

Step 2 Create the FlexConfig policy and assign it to the devices.



a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the power supply alarm FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the power supply alarm commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 954.

Configure temperature alarms

You can configure alarms based on the temperature of the CPU card in the device.

You can set a primary and secondary temperature range. If the temperature drops below the low threshold, or exceeds the high threshold, the alarm is triggered.

The primary temperature alarm is enabled by default for all alarm actions: output relay, syslog, and SNMP. The default settings for the primary temperature range is -40°C to 92°C.

The secondary temperature alarm is disabled by default. You can set the secondary temperature within the range -35°C to 85°C.

Because the secondary temperature range is more restrictive than the primary range, if you set either the secondary low or high temperature, that setting disables the corresponding primary setting, even if you configure non-default values for the primary setting. You cannot enable two separate high and two separate low temperature alarms.

Thus, in practice, you should configure the primary only, or the secondary only, setting for high and low.

Procedure

Step 1 Create the FlexConfig object to configure the temperature alarms.

a) Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Configure_Temperature_Alarms.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to configure the temperature alarms. The following steps explain the commands.

c) Configure the acceptable temperature range.

alarm facility temperature {**primary** | **secondary**} {**low** | **high**} *temperature*

The temperature is in Celsius. The allowed range for the primary alarm is -40 to 92, which is also the default range. The allowed range for the secondary alarm is -35 to 85. The low value must be lower than the high value.

For example, to set a more restrictive temperature range of -20 to 80, which falls within the allowed range for the secondary alarm, configure the secondary alarm as follows:

```
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
```

d) Configure the actions to take when the temperature alarm is triggered.

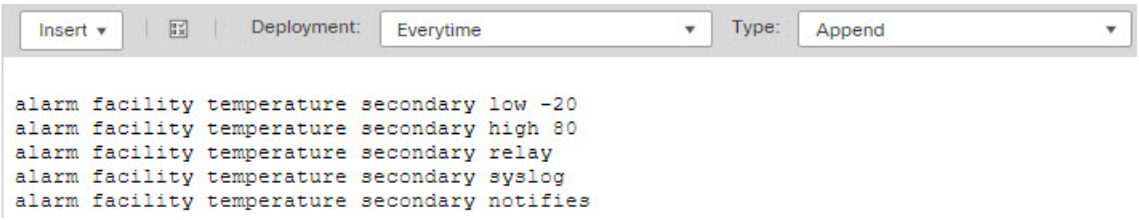
alarm facility temperature {**primary** | **secondary**} {**relay** | **syslog** | **notifies**}

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message.

- **notifies**—Send an SNMP trap.

For example, to enable all actions for the secondary temperature alarm, enter the following:



```
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

e) Verify that the object body contains the commands you want.

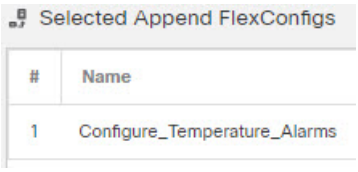
For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

The object body should look similar to the following:

f) Click **Save**.

Step 2 Create the FlexConfig policy and assign it to the devices.



a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the temperature alarms FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the

preview. Note that you will also see commands generated from other changes you have made to managed features. For the temperature alarms commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 954.

Turn off the external alarm

If you are using an external alarm that is attached to the alarm output, and the alarm is triggered, you can turn off the external alarm from the device CLI using the **clear facility-alarm output** command. This command de-energizes the output pin and also turns off the output LED.

Monitoring alarms

The following topics explain how to monitor and manage alarms.

Monitoring alarm status

You can use the following commands in the CLI to monitor alarms.

- **show alarm settings**

  Shows the current configuration for each possible alarm.

- **show environment alarm-contact**

  Shows information about the physical status of the input alarm contacts.

- **show facility-alarm relay**

  Shows information about the alarms that have triggered the output relay.

- **show facility-alarm status** [**info** | **major** | **minor**]

  Shows information on all alarms that have been triggered. You can limit the view by filtering on **major** or **minor** status. The **info** keyword provides the same output as using no keyword.

Monitoring syslog messages for alarms

Depending on the type of alarms you configure, you might see the following syslog messages.

Dual Power Supply Alarms

- %FTD-1-735005: Power Supply Unit Redundancy OK
- %FTD-1-735006: Power Supply Unit Redundancy Lost

Temperature Alarms

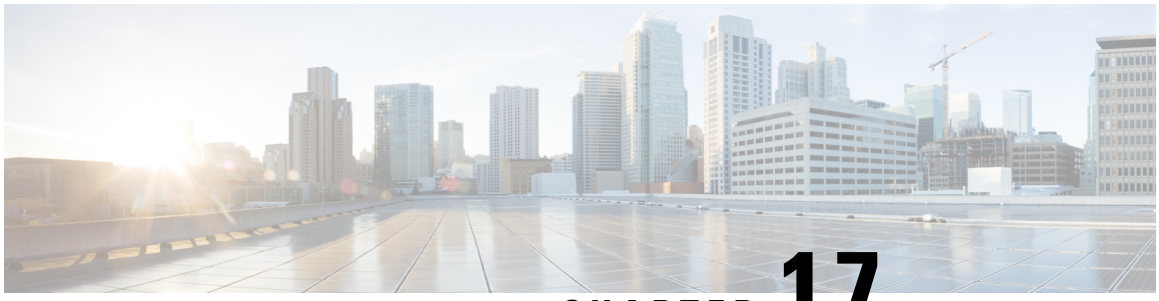
In these alarms, *Celsius* is replaced by the temperature detected on the device, in Celsius.

- %FTD-6-806001: Primary alarm CPU temperature is High *Celsius*
- %FTD-6-806002: Primary alarm for CPU high temperature is cleared
- %FTD-6-806003: Primary alarm CPU temperature is Low *Celsius*
- %FTD-6-806004: Primary alarm for CPU Low temperature is cleared
- %FTD-6-806005: Secondary alarm CPU temperature is High *Celsius*
- %FTD-6-806006: Secondary alarm for CPU high temperature is cleared
- %FTD-6-806007: Secondary alarm CPU temperature is Low *Celsius*
- %FTD-6-806008: Secondary alarm for CPU Low temperature is cleared

Alarm Input Contact Alarms

In these alarms, *description* is the description for the contact that you configured.

- %FTD-6-806009: Alarm asserted for ALARM_IN_1 *alarm_1_description*
- %FTD-6-806010: Alarm cleared for ALARM_IN_1 *alarm_1_description*
- %FTD-6-806011: Alarm asserted for ALARM_IN_2 *alarm_2_description*
- %FTD-6-806012: Alarm cleared for ALARM_IN_2 *alarm_2_description*



History for Device Settings

Provides a comprehensive reference of feature introductions, command modifications, and interface updates related to device settings and management.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
View CLI output for a device or device cluster.	7.4.1	Any	You can view a set of pre-defined CLI outputs that can help you troubleshoot the device or cluster. You can also enter any **show** command and see the output. New/modified screens: **Devices** > **Device Management** > **Cluster** > **General**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Troubleshooting file generation and download available from Device and Cluster pages.	7.4.1	7.4.1	You can generate and download troubleshooting files for each device on the Device page and also for all cluster nodes on the Cluster page. For a cluster, you can download all files as a single compressed file. You can also include cluster logs for the cluster for cluster nodes. You can alternatively trigger file generation from the **Devices** > **Device Management** > **More** > **Troubleshoot Files** menu. New/modified screens: • **Devices** > **Device Management** > **Device** > **General** • **Devices** > **Device Management** > **Cluster** > **General**
Cluster health monitor settings.	7.3.0	Any	You can now edit cluster health monitor settings. New/modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Redundant manager access data interface.	7.3.0	7.3.0	When you use a data interface for manager access, you can configure a secondary data interface to take over management functions if the primary interface goes down. The device uses SLA monitoring to track the viability of the static routes and an ECMP zone that contains both interfaces so management traffic can use both interfaces. New/modified screens: • **Devices** > **Device Management** > **Device** > **Management** • **Devices** > **Device Management** > **Device** > **Interfaces** > **Manager Access**
Policy rollback support for high availability devices.	7.2.0	7.2.0	The **configure policy rollback** command is supported for high availability devices.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Auto rollback of a deployment that causes a loss of management connectivity.	7.2.0	7.2.0	You can now enable auto rollback of the configuration if a deployment causes the management connection between the management center and the threat defense to go down. Previously, you could only manually rollback a configuration using the **configure policy rollback** command. New/modified screens: • **Devices** > **Device Management** > **Device** > **Deployment Settings** • **Deploy** > **Advanced Deploy** > **Preview** • **Deploy** > **Deployment History** > **Preview**
Object group search is enabled by default for access control rules.	7.2.0	7.2.0	The **Object Group Search** setting is enabled by default for managed devices starting with Version 7.2.0. This option is in the **Advanced Settings** section when editing device settings on the Device Management page.
Import and export device configurations.	7.1.0	7.1.0	You can export the device-specific configuration, and you can then import the saved configuration for the same device in the following use cases: • Moving the device to a different FMC. • Restore an old configuration. • Reregistering a device. New/modified screens: **Devices** > **Device Management** > **Device** > **General**
Update the FMC IP address on FTD.	6.7.0	6.7.0	If you change the FMC IP address, you can now use the FTD CLI to update the device. New/modified commands: **configure manager edit**
Alarms for the Cisco ISA 3000 series.	6.7	Any	Configuring alarms for the Cisco ISA 3000 series was validated using FlexConfig. You should be able to configure the alarms in older releases that support FlexConfig, except for the dual power supply alarms. Supported platforms: Secure Firewall Threat Defense

CHAPTER 17

DHCP and DDNS

The following topics explain DHCP and DDNS services and how to configure them on Threat Defense devices.

- About DHCP and DDNS services, on page 827
- Requirements and prerequisites for DHCP and DDNS, on page 829
- Guidelines for DHCP and DDNS services, on page 829
- Configure the DHCPv4 server, on page 831
- DHCPv6 stateless server configuration, on page 833
- Configure the DHCP relay agent, on page 837
- Configure Dynamic DNS, on page 838
- History for DHCP and DDNS, on page 844

About DHCP and DDNS services

This topic describes the DHCP server, DHCP relay agent, and DDNS update.

DHCPv4 servers

A DHCPv4 server provides network configuration parameters, such as IP addresses, to DHCP clients.

- delivers configuration parameters directly to DHCP clients attached to Firewall Threat Defense device interfaces, and
- uses UDP port communication for client-server messaging.

DHCPv4 server communication details

The DHCP communication uses specific network protocols and port assignments:

- IPv4 DHCP client: Uses broadcast rather than multicast address to reach the server and listens for messages on UDP port 68
- DHCP server: Listens for messages on UDP port 67

DHCP options

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. The configuration parameters are carried in tagged items that are stored in the Options field of the DHCP message and the data are also called options. Vendor information is also stored in Options, and all of the vendor information extensions can be used as DHCP options.

Common DHCP options

Cisco IP Phones download their configuration from a TFTP server. When a Cisco IP Phone starts, if it does not have both the IP address and TFTP server IP address preconfigured, it sends a request with option 150 or 66 to the DHCP server to obtain this information.

- DHCP option 150 provides the IP addresses of a list of TFTP servers.
- DHCP option 66 gives the IP address or the hostname of a single TFTP server.
- DHCP option 3 sets the default route.

A single request might include both options 150 and 66. In this case, the DHCP server provides values for both options in the response if they are already configured on the Firewall Threat Defense.

You can use advanced DHCP options to provide DNS, WINS, and domain name parameters to DHCP clients. DHCP option 15 is used for the DNS domain suffix. You can also use the DHCP automatic configuration setting to obtain these values or define them manually. When you use more than one method to define this information, it is passed to DHCP clients in the following sequence:

1. Manually configured settings.
2. Advanced DHCP options settings.
3. DHCP automatic configuration settings.

Domain name configuration precedence

You can manually define the domain name that you want the DHCP clients to receive and then enable DHCP automatic configuration. Although DHCP automatic configuration discovers the domain together with the DNS and WINS servers, the manually defined domain name is passed to DHCP clients with the discovered DNS and WINS server names, because the domain name discovered by the DHCP automatic configuration process is superseded by the manually defined domain name.

DHCPv6 stateless server

A DHCPv6 stateless server is a DHCP IPv6 configuration that

- provides information such as DNS server or domain name when clients send Information Request (IR) packets,
- accepts IR packets but does not assign addresses to clients, and
- works in conjunction with StateLess Address Auto Configuration (SLAAC) and Prefix Delegation features.

DHCPv6 stateless server operation

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature (Enable the IPv6 prefix delegation client, on page 703), you can configure the Firewall Threat Defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the Firewall Threat Defense by defining a DHCP IPv6 Pool and assigning it to the DHCPv6 server. The Firewall Threat Defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the Firewall Threat Defense received using Prefix Delegation.

DHCP relay agents

A DHCP relay agent forwards DHCP requests received on an interface to one or more DHCP servers.

DHCP relay agent operation

DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the Firewall Threat Defense device because it does not forward broadcast traffic. The DHCP relay agent lets you configure the interface of the Firewall Threat Defense device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another device.

Requirements and prerequisites for DHCP and DDNS

This reference provides the model support and user role requirements necessary for configuring DHCP and DDNS functionality.

Model support

Firewall Threat Defense

User roles

- Admin
- Access Admin
- Network Admin

Guidelines for DHCP and DDNS services

Context mode restrictions

DHCPv6 stateless server is not supported in multiple context mode.

Firewall mode restrictions

Consider these firewall mode limitations when configuring DHCP and DDNS services:

- DHCP Relay is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCP Server is supported in transparent firewall mode on a bridge group member interface. In routed mode, the DHCP server is supported on the BVI interface, not the bridge group member interface. The BVI must have a name for the DHCP server to operate.
- DDNS is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCPv6 stateless server is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.

Clustering limitations

DHCPv6 stateless server is not supported with clustering.

IPv6 support

DHCPv4 server guidelines

Follow these guidelines when configuring DHCPv4 server:

- The maximum available DHCP pool is 256 addresses.
- You can configure a DHCP server on any interface with a name and IP address, such as a physical interface, a subinterface, or a BVI in routed mode.
- Do not select an interface that uses DHCP or PPPoE to obtain it's address as a DHCP server interface.
- You can configure only one DHCP server on each interface. Each interface can have its own pool of addresses to use. However the other DHCP settings, such as DNS servers, domain name, options, ping timeout, and WINS servers, are configured globally and used by the DHCP server on all interfaces.
- You cannot configure an interface as a DHCP client if that interface also has DHCP server enabled; you must use a static IP address.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- The Firewall Threat Defense does not support DHCP clients behind DHCP relay servers; the client must be directly connected to the Firewall Threat Defense.
- The DHCP server does not support BOOTP requests.

DHCPv6 server guidelines

Consider these guidelines when configuring DHCPv6 server:

- The DHCPv6 Stateless server cannot be configured on an interface where the DHCPv6 address, Prefix Delegation client, or DHCPv6 relay is configured.

DHCP relay guidelines

Follow these guidelines when configuring DHCP relay:

- You can configure a maximum of 10 DHCPv4 relay servers per virtual router, global (VRF) and interface-specific servers combined, with a maximum of 4 servers per interface.
- You can configure a maximum of 10 DHCPv6 relay servers per virtual router. Interface-specific servers for IPv6 are not supported.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- Do not select an interface that uses DHCP or PPPoE to obtain it's address as a DHCP relay interface.
- DHCP relay services are not available in transparent firewall mode or in routed mode on the BVI or bridge group member interface. You can, however, allow DHCP traffic through using an access rule. To allow DHCP requests and replies through the Firewall Threat Defense, you need to configure two access rules, one that allows DCHP requests from the inside interface to the outside (UDP destination port 67), and one that allows the replies from the server in the other direction (UDP destination port 68).
- For IPv4, clients must be directly-connected to the Firewall Threat Defense and cannot send requests through another relay agent or a router. For IPv6, the Firewall Threat Defense supports packets from another relay server.
- The DHCP clients must be on different interfaces from the DHCP servers to which the Firewall Threat Defense relays requests.
- You cannot enable DHCP Relay on an interface in a traffic zone.

DDNS service configuration

The firewall's DDNS supports only DynDNS service. Hence, ensure that the DDNS is configured with update URL in the following syntax:

https://*username***:***password***@***provider-domain***/***path***?hostname=<h>&myip=<a>**.

Configure the DHCPv4 server

Configure a DHCPv4 server to automatically assign IP addresses, DNS servers, domain names, and other network configuration parameters to DHCP clients on your network.

The DHCPv4 server provides dynamic IP address allocation and network configuration to clients. You can configure global server settings, interface-specific pools, and advanced DHCP options to customize the service for your network requirements.

Before you begin

Follow these steps to configure the DHCPv4 server:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **DHCP** > **DHCP Server**.

Step 3 Configure these DHCP server options:

- **Ping Timeout**—The amount of time in milliseconds that Firewall Threat Defense device waits to time out a DHCP ping attempt. Valid values range from 10 to 10000 milliseconds. The default value is 50 milliseconds.

  To avoid address conflicts, the Firewall Threat Defense device sends two ICMP ping packets to an address before assigning that address to a DHCP client.

- **Lease Length**—The amount of time in seconds that the client may use its allocated IP address before the lease expires. Valid values range from 300 to 1048575 seconds. The default value is 3600 seconds (1 hour).

- (Routed mode) **Auto-configuration**—Enables DHCP auto configuration on the Firewall Threat Defense device. Auto-configuration enables the DHCP server to provide the DHCP clients with the DNS server, domain name, and WINS server information obtained from a DHCP client running on the specified interface. Otherwise, you can disable auto configuration and add the values yourself in Step 4.

- (Routed mode) **Interface**—Specifies the interface to be used for auto configuration. For a device with virtual routing capability, this interface can only be a global virtual router interface.

Step 4 To override auto-configured settings, do the following:

- Enter the domain name of the interface. For example, your device may be in the Your_Company domain.
- From the drop-down list, choose the DNS servers (primary and secondary) configured for the interface. To add a new DNS server, see Create a network object, on page 2388.
- From the drop-down list, choose the WINS servers (primary and secondary) configured for the interface. To add a new WINS server, see Create a network object, on page 2388.

Step 5 Select **Server**, click **Add**, and configure the following options:

- **Interface**—Choose the interface from the drop-down list. In transparent mode, specify a named bridge group member interface. In routed mode, specify a named routed interface or a named BVI; do not specify the bridge group member interface. Note that each bridge group member interface for the BVI must also be named for the DHCP server to operate.
- **Address Pool**—The range of IP addresses from lowest to highest that is used by the DHCP server. The range of IP addresses must be on the same subnet as the selected interface and cannot include the IP address of the interface itself.
- **Enable DHCP Server**—Enables the DHCP server on the selected interface.

Step 6 Click **OK** to save the DHCP server configuration.

Step 7 (Optional) Select **Advanced**, click **Add**, and specify the type of information you want the option to return to the DHCP client:

- **Option Code**—The Firewall Threat Defense device supports the DHCP options listed in RFC 2132, RFC 2562, and RFC 5510 to send information. All DHCP options (1 through 255) are supported except for 1, 12, 50–54, 58–59, 61, 67, and 82. See DHCPv4 servers, on page 827for more information on DHCP option codes.

Note The Firewall Threat Defense device does not verify that the option type and value that you provide match the expected type and value for the option code, as defined in RFC 2132. For more information about option codes and their associated types and expected values, see RFC 2132.

- **Type**—DHCP option type. Available options include **IP**, **ASCII**, and **HEX**. If you chose IP, you must add IP addresses in the IP Address fields. If you chose ASCII, you must add the ASCII value in the ASCII field. If you chose HEX, you must add the HEX value in the HEX field.
- **IP Address 1** and **IP Address 2**—The IP address(es) to be returned with this option code. To add a new IP address, see Create a network object, on page 2388.
- **ASCII**—The ASCII value that is returned to the DHCP client. The string cannot include spaces.
- **HEX**—The HEX value that is returned to the DHCP client. The string must have an even number of digits and no spaces. You do not need to use a 0x prefix.

Step 8 Click **OK** to save the option code configuration.

Step 9 Click **Save** on the DHCP page to save your changes.

a) To view DHCP bindings, use **show dhcpd binding**.

Example:

```
> show dhcpd binding
IP Address Client-id         Lease Expiration  Type
10.0.1.100 0100.a0c9.868e.43 84985 seconds     automatic
```

DHCPv6 stateless server configuration

The DHCPv6 stateless server configuration enables the Firewall Threat Defense to provide network information such as the DNS server or domain name to clients using StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature. When clients send Information Request (IR) packets to Firewall Threat Defense, they receive this information.

Create a DHCP IPv6 pool

Create a DHCP IPv6 pool to define the parameters sent in IR messages from the DHCPv6 server to clients.

Create a DHCP IPv6 pool for use with the DHCPv6 server. The DHCPv6 server provides information such as the DNS server or domain name when they clients send Information Request (IR) packets to the Firewall Threat Defense. The DHCP IPv6 pool defines the parameters to sent in IR messages.

This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

Procedure

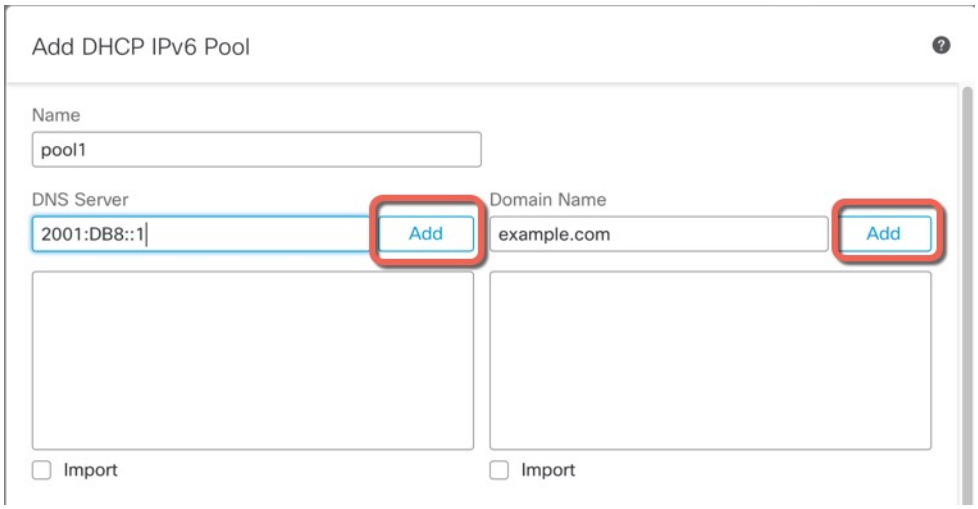
Step 1 Choose **Objects** > **Object Management** > **DHCP IPv6 Pool**.

Step 2 Click **Add** ( ).

Step 3 Configure the **DNS Server** and **Domain Name**.

You can either manually define the values and click **Add**, or you can check **Import** to use one or more parameters that the Firewall Threat Defense obtained from the DHCPv6 server on the Prefix Delegation client interface. You can mix and match manually-configured parameters with imported parameters; however, you cannot configure the same parameter manually and also use **Import**.

Figure 346: Manually define values



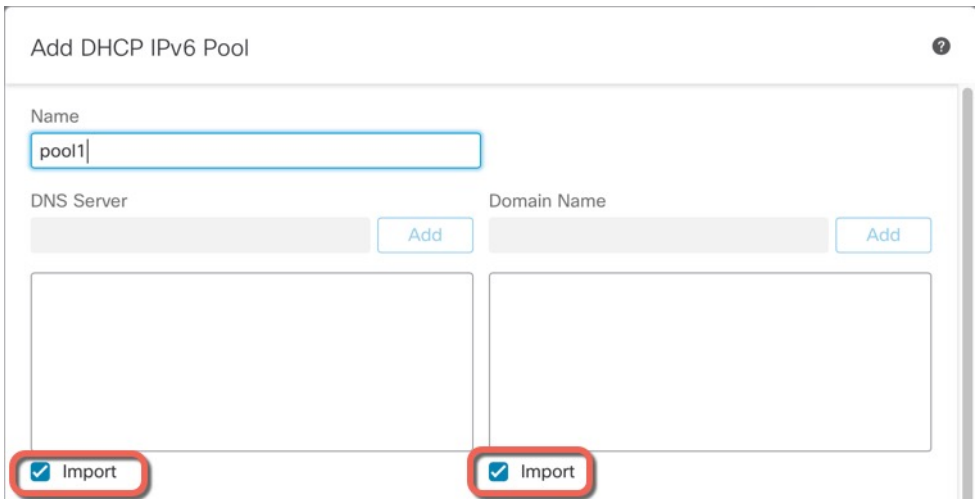


Figure 347: Import values

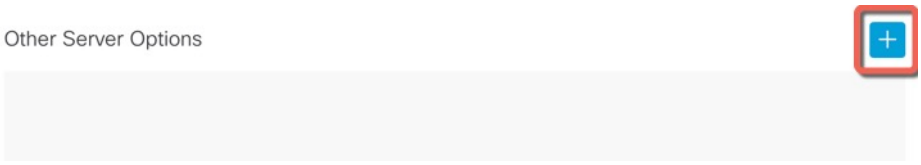
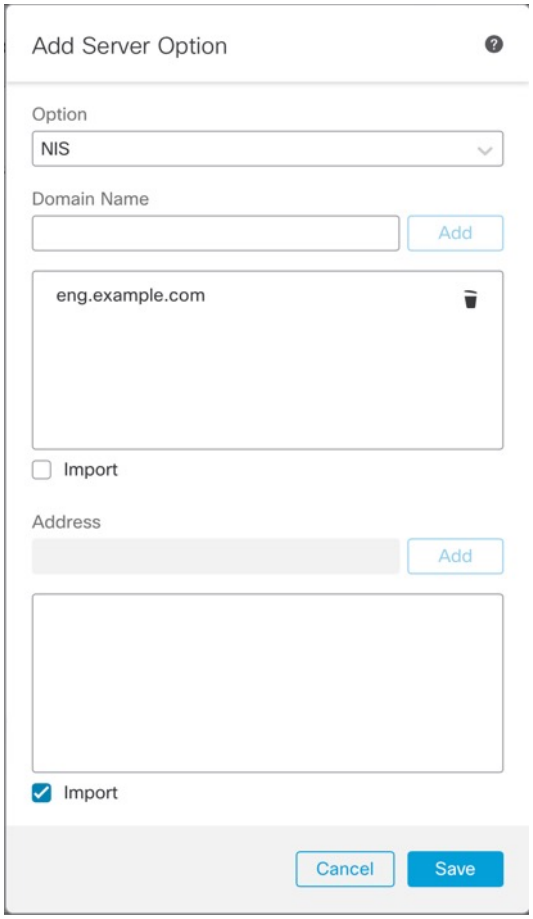


Step 4 Define **Other Server Options**.

You can define the domain name and IP address for these servers:

- NIS
- NISP
- SIP
- SNTP



a) Click **Add** ( ).

Figure 348: Other server options

b) Choose the server type under **Option**, and either manually define the **Domain Name** and **Address**, or check **Import**.

Figure 349: Define server domain name and address

Import uses one or more parameters that the Firewall Threat Defense obtained from the DHCPv6 server on the Prefix Delegation client interface. You can mix and match manually-configured parameters with imported parameters; however, you cannot configure the same parameter manually and also use **Import**.

c) Click **Save**.

d) Repeat for each server type.

Step 5 Click **Save**.

Step 6 Use this pool with the DHCPv6 server. See Enable the DHCPv6 stateless server, on page 836.

Enable the DHCPv6 stateless server

This task enables the DHCPv6 stateless server to provide configuration information to IPv6 autoconfiguration clients without assigning addresses. The server responds to Information Request (IR) packets with DNS server addresses, domain names, and other configuration parameters.

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature (Enable the IPv6 prefix delegation client, on page 703), you can configure the Firewall Threat Defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the Firewall Threat Defense. The Firewall Threat Defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the Firewall Threat Defense received using Prefix Delegation.

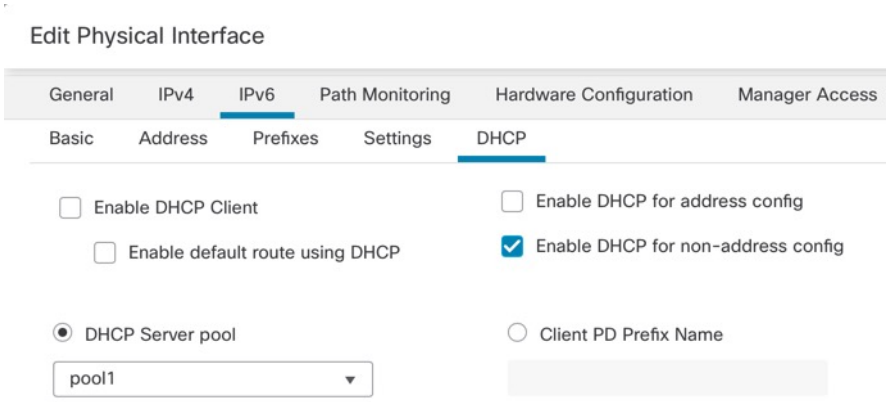
This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

Before you begin

Add a DHCP IPv6 Pool object. See Create a DHCP IPv6 pool, on page 833. This object defines the server parameters included in the IR messages.

Follow these steps to enable the DHCPv6 stateless server:

Procedure



Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **IPv6** page, and then click **DHCP**.

Step 4 Click **DHCP Server Pool**, and choose the object you created earlier.

Figure 350: Enable the DHCPv6 server

Step 5 Check **Enable DHCP for non-address config** to inform SLAAC clients about the DHCPv6 server.

This flag informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure the DHCP relay agent

Configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers when DHCP clients and servers are on different network segments.

You can configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers. DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the Firewall Threat Defense device because it does not forward broadcast traffic.

You can remedy this situation by configuring the interface of the Firewall Threat Defense device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another interface.

Note DHCP Relay is not supported in transparent firewall mode.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **DHCP** > **DHCP Relay**.

Step 3 In the **IPv4 Relay Timeout** and **IPv6 Relay Timeout** fields, enter the amount of time in seconds that the Firewall Threat Defense device waits to time out the DHCP relay agent. Valid values range from 1 to 3600 seconds. The default value is 60 seconds.

The timeout is for address negotiation through the local DHCP Relay agent.

Step 4 (Optional) Check **Trust All Information** to set all client interfaces as trusted.

You can configure interfaces as trusted interfaces to preserve DHCP Option 82. DHCP Option 82 is used by downstream switches and routers for DHCP snooping and IP Source Guard. Normally, if the Firewall Threat Defense DHCP relay agent receives a DHCP packet with Option 82 already set, but the giaddr field (which specifies the DHCP relay agent address that is set by the relay agent before it forwards the packet to the server) is set to 0, then the Firewall Threat Defense will drop that packet by default. You can preserve Option 82 and forward the packet by identifying an interface as a trusted interface.

Step 5 On **DHCP Relay Agent**, click **Add**, and configure these options:

- **Interface**—The interface connected to the DHCP clients.
- **Enable IPv4 Relay**—Enables IPv4 DHCP Relay for this interface.
- **Set Route**—(For IPv4) Changes the default gateway address in the DHCP message from the server to that of the Firewall Threat Defense device interface that is closest to the DHCP client, which relayed the original DHCP request. This action allows the client to set its default route to point to the Firewall Threat Defense device even if the DHCP server specifies a different router. If there is no default router option in the packet, the Firewall Threat Defense device adds one containing the interface address.
- **Enable IPv6 Relay**—Enables IPv6 DHCP Relay for this interface.

Step 6 Click **OK** to save the DHCP relay agent changes.

Step 7 On **DHCP Servers**, click **Add**, and configure these options:

Add the IPv4 and IPv6 server addresses as separate entries, even if they belong to the same server.

- **Server**—The IP address of the DHCP server. Chose an IP address from the drop-down list. To add a new one, see Create a network object, on page 2388
- **Interface**—The interface to which the specified DHCP server is attached. The DHCP Relay agent and the DHCP server cannot be configured on the same interface.

Step 8 Click **OK** to save the DHCP server changes.

Step 9 Click **Save** on the DHCP page to save your changes.

Configure Dynamic DNS

When an interface uses DHCP IP addressing, the assigned IP address can change when the DHCP lease is renewed. When the interface needs to be reachable using a fully qualified domain name (FQDN), the IP address change can cause the DNS server resource records (RRs) to become stale. Dynamic DNS (DDNS) provides a mechanism to update DNS RRs whenever the IP address or hostname changes. You can also use DDNS for static or PPPoE IP addressing.

DDNS updates these RRs on the DNS server: the A RR includes the name-to-IP address mapping, while the PTR RR maps addresses to names.

The Firewall Threat Defense supports these DDNS update methods:

- Standard DDNS—The standard DDNS update method is defined by RFC 2136.

  With this method, the Firewall Threat Defense and the DHCP server use DNS requests to update the DNS RRs. The Firewall Threat Defense or DHCP server sends a DNS request to its local DNS server for information about the hostname and, based on the response, determines the main DNS server that owns the RRs. The Firewall Threat Defense or DHCP server then sends an update request directly to the main DNS server. See these typical scenarios.

  - The Firewall Threat Defense updates the A RR, and the DHCP server updates the PTR RR.

    Typically, the Firewall Threat Defense "owns" the A RR, while the DHCP server "owns" the PTR RR, so both entities need to request updates separately. When the IP address or hostname changes, the Firewall Threat Defense sends a DHCP request (including the FQDN option) to the DHCP server to inform it that it needs to request a PTR RR update.

  - The DHCP server updates both the A and PTR RR.

    Use this scenario if the Firewall Threat Defense does not have the authority to update the A RR. When the IP address or hostname changes, the Firewall Threat Defense sends a DHCP request (including the FQDN option) to the DHCP server to inform it that it needs to request an A and PTR RR update.

  You can configure different ownership depending on your security needs and the requirements of the main DNS server. For example, for a static address, the Firewall Threat Defense should own the updates for both records.

- Web—The Web update method uses the DynDNS Remote API specification (https://help.dyn.com/remote-access-api/).

  With this method when the IP address or hostname changes, the Firewall Threat Defense sends an HTTP request directly to a DNS provider with which you have an account.

Note For devices that were registered using zero-touch provisioning from the outside interface, DDNS is enabled automatically using the "fmcOnly" method, which is similar to the Web method. This method is only available for zero-touch provisioning devices. You can edit some options for this method using this screen, or delete the method and configure a different one. For more information about zero-touch provisioning, see Add a Device Using the Serial Number (Zero-Touch Provisioning) , on page 36.

The **DDNS** page also supports setting DHCP server settings relating to DDNS.

Note DDNS is not supported on the BVI or bridge group member interfaces.

Before you begin

- Configure a DNS server group on **Objects** > **Object Management** > **DNS Server Group**, and then enable the group for the interface on **Devices** > **Platform Settings**, create or edit a Threat Defense policy and click **DNS**. See Configure DNS server settings, on page 852.
- Configure the device hostname. You can configure the hostname when you perform the Firewall Threat Defense initial setup, or by using the **configure network hostname** command. If you do not specify the hostname per interface, then the device hostname is used.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **DHCP** > **DDNS**.

Step 3 Standard DDNS method: Configure a DDNS update method to enable DNS requests from the Firewall Threat Defense.

You do not need to configure a DDNS update method if the DHCP server will perform all requests.

a) On **DDNS Update Methods**, click **Add**.
b) Set the **Method Name**.
c) Click **DDNS**.
d) (Optional) Configure the **Update Interval** between DNS requests. By default when all values are set to 0, update requests are sent whenever the IP address or hostname changes. To send requests regularly, set the **Days** (0-364), **Hours**, **Minutes**, and **Seconds**.
e) Set the **Update Records** you want the Firewall Threat Defense to update.

This setting only affects the records you want to update directly from the Firewall Threat Defense; to determine the records you want the DHCP server to update, configure the DHCP client settings per interface or globally. See, Step 5, on page 841.

- **Not Defined**—Disables DNS updates from the Firewall Threat Defense.
- **Both A and PTR Records**—Sets the Firewall Threat Defense to update both A and PTR RRs. Use this option for static or PPPoE IP addressing.
- **A Records**—Sets the Firewall Threat Defense to update the A RR only. Use this option if you want the DHCP server to update the PTR RR.

f) Click **OK**.
g) Assign this method to the interface in Step 5, on page 841.

Step 4 Web method: Configure a DDNS update method to enable HTTP update requests from the Firewall Threat Defense.

a) On **DDNS Update Methods**, click **Add**.
b) Set the **Method Name**.
c) Click **Web**.
d) Set the **Web Update Type** to update IPv4, IPv6, or both types of addresses.
e) Set the **Web URL**. Specify the update URL. Check with your DNS provider for the URL required.

Use this syntax:

https://*username***:***password***@***provider-domain/path***?hostname=<h>&myip=<a>**

Example:

https://jcrichton:pa$$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>

f) (Optional) Configure the **Update Interval** between DNS requests. By default when all values are set to 0, update requests are sent whenever the IP address or hostname changes. To send requests regularly, set the **Days** (0-364), **Hours**, **Minutes**, and **Seconds**.

g) Click **OK**.

h) Assign this method to the interface in Step 5, on page 841.

i) The web type method for DDNS also requires you to identify the DDNS server root CA to validate the DDNS server certificate for the HTTPS connection. See, Step 9, on page 842.

Step 5 Configure interface settings for DDNS, including setting the update method, DHCP client settings, and the hostname for this interface.

a) On **DDNS Interface Settings**, click **Add**.

b) Choose the **Interface** from the drop-down list.

c) Choose the **Method Name** that you created on the **DDNS Update Methods** page.

(Standard DDNS method) You do not need to assign a method if you want the DHCP server to perform all updates.

d) Set the **Host Name** for this interface.

If you do not set the hostname, the device hostname is used. If you do not specify an FQDN, then the default domain from the DNS server group is appended (for static or PPPoE IP addressing) or the domain name from the DHCP server is appended (for DHCP IP addressing).

e) Standard DDNS method: Configure the **DHCP Client requests DHCP server to update requests** to determine which records you want the DHCP server to update.

The Firewall Threat Defense sends DHCP client requests to the DHCP server. Note that the DHCP server must also be configured to support DDNS. The server can be configured to honor the client requests, or it can override the client (in which case, it will reply to the client so the client does not also try to perform updates that the server is performing).

For static or PPPoE IP addressing, these settings are ignored.

Note You can also set these values globally for all interfaces on the **DDNS** page. The per-interface settings take precedence over the global settings.

- **Not Selected**—Disables DDNS requests to the DHCP server. Even if the client does not request DDNS updates, the DHCP server can be configured to send updates anyway.
- **No Update**—Requests the DHCP server not to perform updates. This setting works in conjunction with a DDNS update method with **Both A and PTR Records** enabled.
- **Only PTR**—Requests that the DHCP server perform the PTR RR update. This setting works in conjunction with a DDNS update method with **A Records** enabled. Use this setting to enable DHCP option 81.
- **Both A and PTR Records**—Requests that the DHCP server perform both A and PTR RR updates. This setting does not require a DDNS update method to be associated with the interface.

f) Click **OK**.

Note The **Dynamic DNS Update** settings relate to DHCP server settings when you enable a DHCP server on the Firewall Threat Defense. See, Step 6, on page 842 for more information.

Step 6 If you enable the DHCP server on an Firewall Threat Defense, you can configure DHCP server settings for DDNS.

To enable the DHCP server, see Configure the DHCPv4 server, on page 831). You can configure the server behavior when DHCP clients use the standard DDNS update method. If the server performs any updates, then if the client lease expires (and is not renewed), the server will request that the DNS server remove the RRs for which it was responsible.

a) You can configure server settings globally or per interface. For global settings, refer to the main **DDNS** page. For per-interface settings, refer to the **DDNS Interface Settings** page. Interface settings take precedence over global settings.

b) Configure which DNS RRs you want the DHCP server to update under **Dynamic DNS Update**.

- **Not Selected**—DDNS updates are disabled, even if the client requests them.
- **Only PTR**—Enables DDNS updates. If you enable the **Override DHCP Client Requests** setting, then the server will only update the PTR RR. Otherwise, the server will update RRs that the client requests. If the client does not send an update request with the FQDN option, the server will request an update for both A and PTR RRs using the hostname discovered in DHCP option 12.
- **Both A and PTR Records**—Enables DDNS updates. If you enable the **Override DHCP Client Requests** setting, then the server will update both the A and PTR RRs. Otherwise, the server will update RRs that the client requests. If the client does not send an update request with the FQDN option, the server will request an update for both A and PTR RRs using the hostname discovered in DHCP option 12.

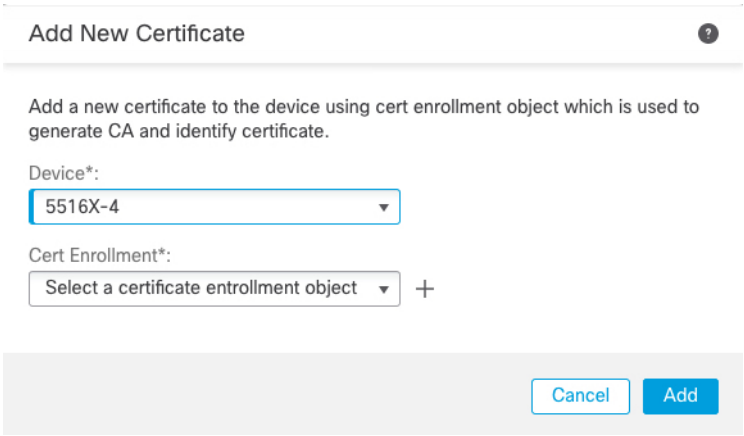
c) To override the update actions requested by the DHCP client, check **Override DHCP Client Requests**.

The server will reply to the client that the request was overridden, so the client does not also try to perform updates that the server is performing.

Step 7 (Optional) Configure general DHCP client settings. These settings are not related to DDNS, but are related to how the DHCP client behaves.

a) On the **DDNS** page, check **Enable DHCP Client Broadcast** to request that the DHCP server broadcast the DHCP reply (DHCP option 1).

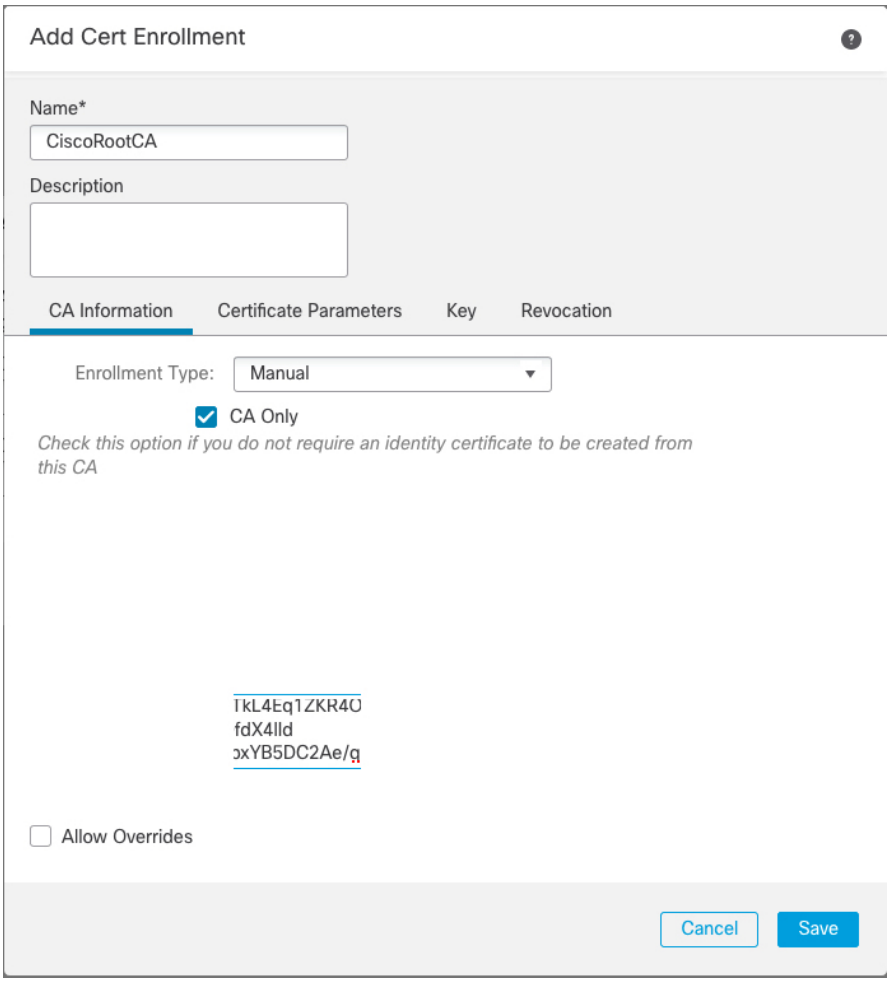
b) To force a MAC address to be stored inside a DHCP request packet for option 61 instead of the default internally generated string, on **DDNS** > **DHCP Client ID Interface**, choose the interface from the **Available Interfaces** list, and then click **Add** to move it to the **Selected Interfaces** list.



Some ISPs expect option 61 to be the interface MAC address. If the MAC address is not included in the DHCP request packet, then an IP address will not be assigned. This setting does not directly relate to DDNS, but is a general DHCP client setting.

Step 8 Click **Save** on the Device page to save your changes.

Step 9 The Web method for DDNS also requires you to identify the DDNS server root CA to validate the DDNS server certificate for the HTTPS connection.

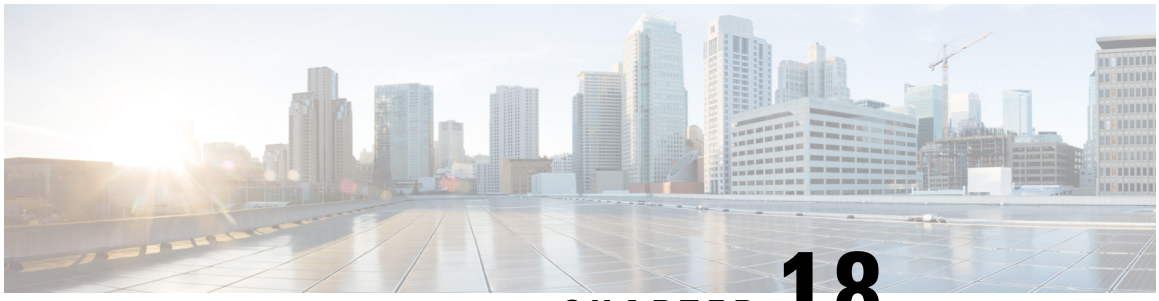


This example shows how to add a DDNS server's CA as a trustpoint.

a) Obtain the DDNS server CA certificate. This procedure shows a manual import using PEM format, but you can also use PKCS12.
b) In Firewall Management Center, choose **Devices** > **Certificates**, and click **Add**.
c) Select a **Device**, and click **Add** (+).

The **Add Cert Enrollment** dialog box appears.

d) Enter these fields, and click **Save**:



- Enter a **Name**.
- Choose **Enrollment Type** > **Manual**.
- Click **CA Only**.
- Paste in the CA text from step 9.a, on page 843.

e) Click **Save**.

History for DHCP and DDNS

This reference provides the release history for DHCP and DDNS features, including version requirements and implementation details for Secure Firewall Management Center and Threat Defense devices.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Configure DHCP relay trusted interfaces from the Firewall Management Center web interface.	7.2.6/7.4.1	Any	**Upgrade impact. Redo any related FlexConfigs after upgrade.** You can now use the Firewall Management Center web interface to configure interfaces as trusted interfaces to preserve DHCP Option 82. If you do this, these settings override any existing FlexConfigs, although you should remove them. DHCP Option 82 is used by downstream switches and routers for DHCP snooping and IP Source Guard. Normally, if the Firewall Threat Defense DHCP relay agent receives a DHCP packet with Option 82 already set, but the giaddr field (which specifies the DHCP relay agent address that is set by the relay agent before it forwards the packet to the server) is set to 0, then Firewall Threat Defense will drop that packet by default. You can preserve Option 82 and forward the packet by identifying an interface as a trusted interface. New/modified screens: **Devices** > **Device Management** > **Add/Edit Device** > **DHCP** > **DHCP Relay**
DHCPv6 Stateless Server	7.3.0	7.3.0	The Firewall Threat Defense now supports a light DHCPv6 stateless server when using the DHCPv6 Prefix Delegation client. The Firewall Threat Defense provides other information such as the domain name to SLAAC clients when they send Information Request (IR) packets to the Firewall Threat Defense. The Firewall Threat Defense only accepts IR packets and does not assign addresses to the clients. New/modified screens: • **Devices** > **Device Management** > **Interfaces** > **Add/Edit Interfaces** > **IPv6** > **DHCP** • **Objects** > **Object Management** > **DHCP IPv6 Pool** New/modified commands: **show ipv6 DHCP**

CHAPTER 18

Platform Settings

Platform settings for Firewall Threat Defense devices configure a range of unrelated features whose values you might want to share among several devices. Even if you want different settings per device, you must create a shared policy and apply it to the desired device.

Note In 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices (7.3 and earlier, and some upgraded 7.4 devices).

- Platform settings policies, on page 848
- List requirements and prerequisites for platform settings policies, on page 848
- Manage platform settings policies, on page 849
- Chassis platform settings, on page 850
- Configure ARP inspection, on page 850
- Configure a banner, on page 852
- Configure DNS server settings, on page 852
- Configure external authentication, on page 855
- Configure fragment settings, on page 861
- Configure HTTP access, on page 862
- Configure ICMP access, on page 864
- Configure NetFlow, on page 865
- Configure Secure Shell (SSH) access, on page 867
- Configure an SMTP server, on page 869
- Configure SNMP for a security device, on page 870
- Configure SSL settings, on page 884
- Syslog, on page 888
- Configure timeouts, on page 906
- Synchronize time on FTD devices, on page 908
- Configure a time zone for a device, on page 911
- Configure UCAPL/CC compliance, on page 911
- Configure a performance profile, on page 912
- History for platform settings, on page 913

Platform settings policies

A platform settings policy is a shared set of features or parameters that

- define aspects of managed devices that are likely to be similar to other managed devices in a deployment, such as time settings and external authentication,
- enable configuration of multiple managed devices at once, providing consistency and streamlining management efforts, and
- apply changes to all managed devices where the policy is used, requiring creation and application of shared policies even for device-specific settings.

Platform settings policy reference information

Use platform settings policies to enforce security requirements, such as displaying a login banner message, and to manage device configurations efficiently.

- You can set a “No Unauthorized Use” message for appliance logins using platform settings policies.
- You can apply multiple platform settings policies to a single Firewall Management Center to accommodate different mail relay hosts or access lists.

Platform settings policy example

Your organization’s security policies may require that appliances display a “No Unauthorized Use” message when a user logs in. With platform settings, you can set the login banner once in a platform settings policy.

Multiple platform settings policy example

If your organization has different mail relay hosts that you use for different circumstances or if you want to test different access lists, you can create several platform settings policies and switch between them, rather than editing a single policy.

List requirements and prerequisites for platform settings policies

You must meet specific requirements and prerequisites before you configure Platform Settings Policies, including supported domains and user roles.

Supported domains

Any

User roles

Admin

Access Admin

Network Admin

Manage platform settings policies

Manage platform settings policies to control device configurations and assignments within your environment. This task allows you to create, edit, or delete policies for supported device types.

Use the **Platform Settings** page (**Devices** > **Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The **Status** column shows the device targets for the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings**.

Step 2 For an existing policy, you can **Copy** ( ), **Edit** ( ), or **Delete** ( ) the policy.

Caution You should not delete a policy that is the last-deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is a good practice to deploy a different policy to those targets.

Step 3 To create a new policy, click **New Policy**.

a) Choose a device type from the drop-down list:

- **Firepower Settings** to create a shared policy for managed Classic devices.
- **Threat Defense Settings** to create a shared policy for managed Firewall Threat Defense devices.
- **Chassis Platform Settings** to create a shared policy for managed Firewall Threat Defense chassis in multi-instance mode.

b) Enter a **Name** for the new policy and optionally, a **Description**.

c) Optionally, choose the **Available Devices** or **Available Chassis** where you want to apply the policy and click **Add** (or drag and drop) to add the selected devices. You can enter a search string in the **Search** field to narrow the list of devices.

d) Click **Save**.

- When you have selected a device and if the device is already applied with a policy, the **Confirm PFS Overwrite** dialog appears. To override the applied policy, click **OK**. The selected device is applied with the new policy.
- The system creates the policy and opens it for editing.

Step 4 To change the target devices for a policy, click **Edit** ( ) next to the platform settings policy that you want to edit.

a) Click **Policy Assignment**.

b) To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** or **Available Chassis** list and click **Add**. You can also drag and drop.

c) To remove a device assignment, click **Delete** ( ) next to a device, high-availability pair, or device group in the **Selected Devices** or **Selected Chassis** list.
d) Click **OK**.

After completing these steps, platform settings policies are created, edited, or deleted as needed, and device assignments are updated accordingly.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Chassis platform settings

Chassis platform settings reference information

Chassis platform settings apply to multiple-instance mode chassis. For more information, see Chassis platform settings, on page 199.

Configure ARP inspection

Configure ARP inspection to ensure that only valid ARP packets are accepted on your network, reducing the risk of ARP spoofing and related attacks.

- Apply ARP inspection policies to specific interfaces and security zones.
- Add static ARP entries for enhanced control and security.

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the Firewall Threat Defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the Firewall Threat Defense device drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the Firewall Threat Defense device to either forward the packet out all interfaces (flood), or to drop the packet.

Note The dedicated Management interface never floods packets even if this parameter is set to flood.

Use this task when you need to protect your network from ARP spoofing by validating ARP packets and controlling ARP traffic on selected interfaces and zones.

Use ARP inspection in environments where network security is a priority and static ARP entries are needed.

Before you begin

Make sure you have device access and permission to edit platform settings and ARP inspection policies.

- Have the list of interfaces and security zones where ARP inspection will be applied.
- Prepare the static ARP entries that you intend to add.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **ARP Inspection**.

Step 3 Add entries to the ARP inspection table.

a) Click **Add** to create a new entry, or click **Edit** if the entry already exists.

b) Select the desired options.

- **Inspect Enabled**—To perform ARP inspection on the selected interfaces and zones.
- **Flood Enabled**—Floods ARP requests that do not match static ARP entries to all interfaces except the originating or dedicated management interface. By default, this behavior is enabled.

  If you choose not to flood ARP requests, only requests that match static ARP entries are allowed.
- **Security Zones**—Add the zones that contain the interfaces on which to perform the selected actions. The zones must be switched zones. For interfaces not in a zone, type the interface name into the field in the Selected Security Zone list and click **Add**. The device applies these rules only if it includes the selected interfaces or zones.

c) Click **OK**.

Step 4 Add static ARP entries according to Add a static ARP entry, on page 718.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

ARP inspection is enabled on the selected interfaces and security zones. Only valid ARP packets are accepted, and static ARP entries are enforced. The policy is active after deployment.

Configure a banner

Configure a banner to display messages to users when they connect to the device command line interface (CLI). This helps inform users and discourage unauthorized access.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Banner**.

Step 3 Configure the banner.

These are some tips and requirements for banners.

- Use only ASCII characters. You can add line returns (press Enter), but do not use tabs.
- You can dynamically add the hostname or domain name of the device by including the variables **$(hostname)** or **$(domain)**.
- Although banners do not have an absolute length restriction, Telnet or SSH sessions close if the system does not have enough memory to process banner messages.
- Create a banner that discourages unauthorized access by avoiding the words "welcome" or "please," which may seem inviting. The sample banner provided discourages intruders.

```
You have logged in to a secure device.
If you are not authorized to access this device,
log out immediately or risk criminal charges.
```

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

The system displays the banner to users when they connect to the device CLI. The changes occur after you deploy the policy.

Configure DNS server settings

Configure DNS server settings to enable hostname resolution for data traffic on managed devices. This task allows you to set up DNS server groups, trusted DNS services, and interface-specific DNS lookups. These configurations support features such as access control rules, NAT, and application detection.

- Set up DNS server groups for resolving FQDNs used in data traffic.
- Configure trusted DNS servers for DNS snooping and application-based PBR.
- Enable DNS lookups on specific interfaces to control routing behavior.

The Domain Name System (DNS) servers are used to resolve hostnames to IP addresses. Data DNS settings apply to services that use FQDNs, such as access control rules and remote access VPN. Special management traffic uses separate DNS settings configured via CLI commands. This procedure applies only to data DNS servers. For management DNS settings, see the CLI **configure network dns servers** and **configure network dns searchdomains** commands.

Managed devices use routing lookups to determine the correct interface for DNS server communications. The system selects the routing table based on the interfaces enabled for DNS. Multiple DNS server groups can be configured to resolve different DNS domains, allowing internal and external DNS resolution as needed.

Trusted DNS servers

You can configure trusted DNS services for DNS snooping. DNS snooping is used to map the application domains to IPs in order to detect the application on the first packet. You can also include the already configured servers in DNS group, DHCP pool, DHCP relay and DHCP client as trusted DNS servers.

For application-based PBR, configure trusted DNS servers. Ensure DNS traffic passes through Firewall Threat Defense in clear text format (because encrypted DNS is not supported) for domain resolution and application detection.

Before you begin

- Ensure you have created one or more DNS server groups. For more information, see Create a DNS server group object, on page 2366.
- Ensure you have created interface objects to connect to the DNS servers.
- Ensure that the managed device has appropriate static or dynamic routes to access the DNS servers.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit a Threat Defense policy.

Step 2 Click **DNS**, and then click the **DNS Settings** tab.

Step 3 Check **Enable DNS name resolution by device**.

Step 4 Configure the DNS server groups.

a) Do any of these actions in the DNS server group list:

- To add a group, click **Add**. You cannot add another group once there are 30 filter domains configured within the existing list of server groups.
- To edit a group, click **Edit** ( ) next to the group.
- To remove a group, click **Delete** ( ) next to the group. When you remove a group, you do not delete the DNS server group object. You remove it only from this list.

b) When adding or editing a group, configure the following settings, then click **OK**:

- **Select DNS Group**—Select an existing DNS server group object, or click **+** to create a new one.
- **Make as default**—Select this option to make this group the default group. Any DNS resolution request that does not match the filters for other groups will be resolved using the servers in this group.

- **Filter Domains**—For non-default groups only, enter a list of domain names separated by commas, such as example.com,example.net. Do not include spaces.

  The group is used only for DNS resolutions for these domains. You can enter up to 30 separate domains across all groups in this DNS platform settings policy. Each domain name can contain up to 127 characters.

  Note that these filter domains are not related to the default domain name for the group. The filter list can be different from the default domain.

Step 5 (Optional) Enter the **Expiry Entry Timer** and **Poll Timer** values in minutes.

These options apply to FQDNs specified in network objects only and do not apply to FQDNs used in other features.

- **Expire Entry Timer** specifies the minimum time-to-live (TTL) value for the DNS entry, in minutes. If the expiration timer is longer than the entry's TTL, the TTL is increased to the expire entry time value. If the TTL is longer than the expiration timer, the expire entry time value is ignored. Upon expiration, the entry is removed from the DNS lookup table. When you remove an entry, the device recompiles the table. Frequent removals can increase the processing load on the device. Some DNS entries can have very short TTL (as short as three seconds); use this setting to virtually extend the TTL. The default is 1 minute. The range is 1 to 65535 minutes.

  For systems running 7.0 or earlier, the expiration time is actually added to the TTL; it does not specify a minimum value.

- **Poll Timer** specifies the time limit after which the device queries the DNS server to resolve the FQDN defined in a network object. An FQDN is resolved periodically when either the poll timer has expired or the TTL of the resolved IP entry has expired, whichever occurs first.

Step 6 Enable DNS lookups on all interfaces or on specific interfaces. These choices also affect which routing tables are used.

Enabling DNS lookups on an interface is not the same as specifying the source interface for lookups. The Firewall Threat Defense always uses a route lookup to determine the source interface. Management-only interfaces other than the dedicated Management interface cannot be used.

- No interfaces selected—This setting enables DNS lookups on all interfaces. The Firewall Threat Defense checks the data routing table only.
- Specific interfaces selected but not the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on the specified interfaces. The Firewall Threat Defense checks the data routing table only.
- Specific interfaces selected plus the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on the specified interfaces and the Management interface. The Firewall Threat Defense checks the data routing table, and if no route is found, falls back to the management-only routing table.
- Only the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on Management. The Firewall Threat Defense checks only the management-only routing table.

Step 7 Configure Trusted DNS servers.

a) Click the **Trusted DNS Servers** tab.

b) By default, the existing DNS servers that are configured in DHCP pool, DHCP relay, DHCP client, or DNS server group are included as trusted DNS servers. If you want to exclude any of them, uncheck the appropriate check boxes.
c) To add trusted DNS servers, under **Specify DNS Servers**, click **Edit**.
d) In the **Select DNS Servers** dialog box, either choose a host object as the trusted DNS server or directly specify the IP address of the trusted DNS server:

1. To choose existing host objects, under **Available Host Objects**, select the required host object and click **Add** to include it to **Selected DNS Servers**. For information on adding the host objects, see Create a network object, on page 2388.
2. To directly provide the IP address (IPv4 or IPv6) of the trusted DNS server, enter the address in the given text field, and click **Add** to include it to **Selected DNS Servers**.
3. Click **Save**. The added DNS servers are displayed in the **Trusted DNS Servers** page.

Note You can configure a maximum of 12 DNS servers per policy.

To search for a DNS server that was added, using either the host name or the IP address, use the search field under **Specify DNS Servers**.

Step 8 Click **Save**.

What to do next

To use FQDN objects for access control rules, create an FQDN network object which can then be assigned to an access control rule. For instructions, see Create a network object, on page 2388.

Configure external authentication

Configure external authentication to allow management users to be authenticated using an LDAP or RADIUS server, as specified in an external authentication object. Centralized user management also enhances security for device access.

Note You must have administrator privileges to perform this task.

When you enable external authentication for management users, the Firewall Threat Defense verifies the user credentials with an LDAP or RADIUS server as specified in an external authentication object.

Sharing External Authentication Objects

External authentication objects can be used by the Firewall Management Center and Firewall Threat Defense devices. You can share the same object between the Firewall Management Center and devices. Alternatively, create separate objects. Note that the Firewall Threat Defense supports defining users on the RADIUS server, while the Firewall Management Center requires you to predefine the user list in the external authentication object. You can choose to use the predefined list method for the Firewall Threat Defense, but if you want to

define users on the RADIUS server, you must create separate objects for the Firewall Threat Defense and the Firewall Management Center.

Note The timeout range is different for the Firewall Threat Defense and the Firewall Management Center, so if you share an object, be sure not to exceed the Firewall Threat Defense's smaller timeout range (1 to 30 seconds for LDAP, and 1 to 300 seconds for RADIUS). If you set the timeout to a higher value, the Firewall Threat Defense external authentication configuration will not work.

Assigning External Authentication Objects to Devices

For the Firewall Management Center, enable the external authentication objects directly on **System** (⚙) > **Users** > **External Authentication**; this setting only affects Firewall Management Center usage, and it does not need to be enabled for managed device usage. For Firewall Threat Defense devices, you must enable the external authentication object in the platform settings that you deploy to the devices, and you can only activate one external authentication object per policy. An LDAP object with CAC authentication enabled cannot also be used for CLI access. Be sure that both the Firewall Threat Defense and the Firewall Management Center can reach the LDAP server, even if you are not sharing the object. The Firewall Management Center is essential to retrieving the user list and downloading it to the device.

Firewall Device Supported Fields

Only a subset of fields in the external authentication object are used for Firewall Threat Defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for the Firewall Management Center, those fields will be used. This procedure only covers the supported fields for the Firewall Threat Defense. For other fields, see *Configure External Authentication for the Firewall Management Center* in the *Cisco Secure Firewall Management Center Administration Guide*.

Usernames

Usernames must be Linux-valid usernames and be lowercase only, using alphanumeric characters plus period (.) or hyphen (-). Special characters such as at sign (@) and slash (/) are not supported. You cannot add these default internal users for external authentication—**root, daemon, bin, sys, sync, games, man, lp, mail, news, uucp, proxy, www-data, backup, list, irc, gnats, ntp, lldpd, bind, dhcp, qemu, rpcuser, rpc, sshd, radiusd, messagebus, admin, mysql, www, sfrna, snorty, sfsnort, sfremediation, nobody, samdme, extuser, p2puser, rloginUser**. You can only add external users (as part of the External Authentication object) in the Firewall Management Center; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the Firewall Management Center.

If you previously configured the same username for an internal user using the **configure user add** command, the Firewall Threat Defense first checks the password against the internal user, and if that fails, it checks the AAA server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported. For users defined on the RADIUS server, be sure to set the privilege level to be the same as any internal users; otherwise you cannot log in using the external user password.

Privilege Level

LDAP users always receive Config privileges. You can define RADIUS users as either config or basic users.

Before you begin

- SSH access is enabled by default on the management interface. To enable SSH access on data interfaces, see Configure Secure Shell (SSH) access, on page 867.
- Inform RADIUS users of the following behavior to set their expectations appropriately:

- The first time an external user logs in, Firewall Threat Defense creates the required structures but cannot simultaneously create the user session. The user simply needs to authenticate again to start the session. The user will see a message similar to this: "New external username identified. Please log in again to start a session."
- If the user's Service-Type attribute is not defined or incorrectly configured in the RADIUS server and you use the RADIUS-defined users for authentication, the user will see a message similar to this: "Your username is not defined with a service type that is valid for this system. You are not authorized to access the system?".

  In some cases, the SSH clients close the CLI window on an unsuccessful SSH connection, even before displaying the failure message. Hence, ensure that the user's Service-Type attribute is correctly defined in the RADIUS server.
- Similarly, if the user's Service-Type authorization was changed since the last login, the user will need to re-authenticate. The user will see a message similar to this: "Your authorization privilege has changed. Please log in again to start a session."

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **External Authentication**, and then click the **Manage External Authentication Server** link.

You can also open the External Authentication screen by clicking **System** > **Users** > **External Authentication**.

Step 3 Click **Add External Authentication Object**.

Step 4 Configure an LDAP Authentication Object.

Step 5 Configure a RADIUS Authentication Object.

Step 6 Return to **System** (⚙) > **Users** > **External Authentication**.

Step 7 Click **Refresh** (↻) to view any newly-added objects.

For LDAP when you specify SSL or TLS encryption, you must upload a certificate for the connection; otherwise, the server will not be listed on this window.

Step 8 Click **Slider enabled** (⬭) next to the External Authentication object you want to use. You can only enable one object.

Step 9 Click **Save**; deploy configuration changes (see Deploy configuration changes, on page 135).

After completing this task, external authentication is enabled for management users. The system verifies user credentials with the configured LDAP or RADIUS server and grants access based on the authentication object and user privileges.

Configure an LDAP External Authentication Object

Configure external authentication to allow management users to be authenticated using an LDAP server.

Note You must have administrator privileges to perform this task.

Procedure

Step 1 In the **External Authentication Object** page, select **LDAP** from the **Authentication Method** drop-down list and enter appropriate values in these fields:

a) Enter a **Name**.

b) (Optional) Enter **Description**.

Step 2 Choose a **Server Type** from the drop-down list.

Step 3 For the **Primary Server** enter these values:

a) Enter a **Host Name/IP Address**.

Note If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

b) Change the **Port** from the default.

Step 4 Enter the **Backup Server** parameters.

Step 5 Enter **LDAP-Specific Parameters**.

- **Base DN**—Enter the base distinguished name for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com`. Alternatively click **Fetch DNs**, and choose the appropriate base distinguished name from the drop-down list.
- (Optional) **Base Filter**—For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)`.
- **User Name**—Enter a distinguished name for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at our example company has a `uid` value of `NetworkAdmin`, you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com`.
- **Password** and **Confirm Password**—Enter and confirm the password for the user.
- (Optional) **Show Advanced Options**—Configure the following advanced options.
  - **Encryption**—Click **None**, **TLS**, or **SSL**.

Note If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS**, the port resets to the default value of 389. If you choose SSL encryption, the port resets to 636.

- **SSL Certificate Upload Path**—For SSL or TLS encryption, you must choose a certificate by clicking **Choose File**.
- (Not Used) **User Name Template**—Not used by the Firewall Threat Defense.
- **Timeout**—Enter the number of seconds before rolling over to the backup connection between 1 and 30. The default is 30.

Note The timeout range is different for the Firewall Threat Defense and the Firewall Management Center, so if you share an object, be sure not to exceed the Firewall Threat Defense's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the Firewall Threat Defense external authentication configuration will not work.

Step 6 (Optional) Set the **CLI Access Attribute** if you want to use a shell access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` shell access attribute to retrieve shell access users by typing `sAMAccountName` in the **CLI Access Attribute** field.

Step 7 Set the **CLI Access Filter**.

Choose one of these methods:

- To use the same filter you specified when configuring authentication settings, choose **Same as Base Filter**.
- To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell`, you can set a base filter of `(manager=shell)`.

The names on the LDAP server must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Step 8 Click **Save**.

Step 9 For LDAP, if you later add or delete users on the LDAP server, you must refresh the user list and redeploy the Platform Settings.

a) Choose **System** ( ) > **Users** > **External Authentication**.

b) Click **Refresh** ( ) next to the LDAP server.

If the user list changed, you will see a message advising you to deploy configuration changes for your device. The Firepower Theat Defense Platform Settings will also show that it is "Out-of-Date on *x* targeted devices."

c) Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure a RADIUS Authentication Object

Configure external authentication to allow management users to be authenticated using a RADIUS server

Note You must have administrator privileges to perform this task.

Procedure

Step 1 In the **External Authentication Object** page, select **RADIUS** from the **Authentication Method** drop-down list and enter appropriate values in these fields:

a) Check the **Enabled Message Authenticator** check box to require the Message-Authenticator attribute in all RADIUS responses, ensuring that every response from the RADIUS server is securely verified by the Firewall Threat Defense.

This feature is enabled by default for new RADIUS servers. We recommend you enable it for existing servers after the upgrade. Disabling message authenticators may expose your firewalls to potential attacks. Ensure that your RADIUS server has the Message-Authenticator configuration.

b) Define users on the RADIUS server using the Service-Type attribute.

This is the list of supported values for the Service-Type attribute:

- Administrator (6)—Provides Config access authorization to the CLI. These users can use all commands in the CLI.
- NAS Prompt (7) or any level other than 6—Provides Basic access authorization to the CLI. These users can use read-only commands, such as **show** commands, for monitoring and troubleshooting purposes.

The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Alternatively, you can predefine users in the external authentication object (see Step Configure external authentication, on page 855). To use the same RADIUS server for the Firewall Threat Defense and Firewall Management Center while using the Service-Type attribute method for the Firewall Threat Defense, create two external authentication objects that identify the same RADIUS server: one object includes the

predefined **CLI Access Filter** users (for use with the Firewall Management Center), and the other object leaves the **CLI Access Filter** empty (for use with Firewall Threat Defenses).

c) Enter a **Name** and optional **Description**.

Step 2 For the **Primary Server**, enter a **Host Name/IP Address**.

Note If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

Step 3 (Optional) Change the **Port** from the default.

Step 4 Enter a **RADIUS Secret Key**.

Step 5 (Optional) Enter the **Backup Server** parameters.

Step 6 Enter **RADIUS-Specific Parameters**.

- **Timeout (Seconds)**—Enter the number of seconds before rolling over to the backup connection. The default is 30.
- **Retries**—Enter the number of times the primary server connection should be tried before rolling over to the backup connection. The default is 3.

Step 7 (Optional) Enter a comma-separated list of usernames in the **Administrator CLI Access User List** field. For example, enter `jchrichton, aerynsun, rygel`.

You may want to use the **CLI Access Filter** method for Firewall Threat Defense so you can use the same external authentication object with Firewall Threat Defense and other platform types. Note that if you want to use RADIUS-defined users, you must leave the **CLI Access Filter** empty.

Make sure that these usernames match usernames on the RADIUS server. The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Note If you want to only define users on the RADIUS server, you must leave this section empty.

Step 8 Click **Save**.

Configure fragment settings

Configure fragment settings to manage the handling of fragmented IP packets on your Firewall Threat Defense device. These settings help prevent Denial of Service (DoS) attacks and ensure applications that require packet fragmentation operate properly.

- Set limits for the number of fragments per packet and for fragments awaiting reassembly.
- Set the timeout for fragment reassembly.
- Allow fragments only if your network applications require them.

By default, the Firewall Threat Defense device allows up to 24 fragments per IP packet. It also allows up to 200 fragments awaiting reassembly. Applications such as NFS over UDP may require fragmented packets, but attackers often use fragmented packets in Denial of Service (DoS) attacks.

These settings establish the defaults for devices assigned this policy. You can override these settings for specific interfaces on a device by selecting **Override Default Fragment Setting** in the interface configuration. When you edit an interface, you can find the option on **Advanced** > **Security Configuration**. Select **Devices** > **Device Management**, edit a Firewall Threat Defense device, and select **Interfaces** to edit interface properties.

- Allow fragments only if required by your network applications.
- Override the default settings for specific interfaces when your configuration requires it.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Fragment Settings**.

Step 3 Configure the available options. To use the default settings, click **Reset to Defaults**.

- **Size (Block)**—The maximum number of packet fragments from all connections collectively that can be waiting for reassembly. The default value is 200 fragments. (One fragment equals one packet segment.)
- **Chain (Fragment)**—The maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets. Set this option to one to disallow fragments.
- **Timeout (Sec)**—The maximum number of seconds to wait for an entire fragmented packet to arrive. The default is five seconds. If all fragments are not received within this time, all fragments are discarded.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Deploy the policy to activate the new fragment settings on assigned devices. Monitor device performance and change fragment settings as needed.

Configure HTTP access

You can enable the HTTPS server to provide a health check mechanism for a cloud load balancer, for example, for the Firewall Threat Defense Virtual on AWS using an Application Load Balancer.

Use HTTPS with the Firewall Threat Defense only as described for health checks and management. You cannot configure the Firewall Threat Defense through a web interface in this management mode.

Configure HTTP access only on data interfaces, including interfaces you set as management-only. Use only data interfaces for HTTP access, not the dedicated Management interface. The Management interface is separate from the other interfaces on the device. Use the Management interface only to set up and register your device to the Firewall Management Center. It has a separate IP address and static routing.

Configure HTTPS access as described in this section. An access rule for the host IP address is not required.

Use HTTPS only on a reachable interface. If your HTTPS host is on the outside interface, initiate the management connection directly to it.

Before you begin

- Configure HTTPS and AnyConnect VPN module of Cisco Secure Client on separate TCP ports if both features are required on the same interface. For example, assign a different port to HTTPS, such as port 4443.
- Create network objects to define the hosts or networks that are allowed for HTTPS connections. You can add these objects as part of this procedure. If you plan to use object groups for IP addresses, ensure the groups exist in the rules. Select **Objects** > **Object Management** to configure objects.

Note Use the **any-ipv4** or **any-ipv6** network object group instead of the system-provided **any** object.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **HTTP Access**.

Step 3 Check the **Enable HTTP Server** check box to enable the HTTP server.

Step 4 (Optional) Change the HTTP port. The default is 443.

Step 5 Identify the interfaces and IP addresses that allow HTTP connections.

Allow HTTP connections only from specific interfaces and client IP addresses by configuring this table. You may use network addresses instead of individual IP addresses.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make HTTP connections. Choose an object from the drop-down menu, or click + to add a new network object.
- **Available Zones/Interfaces**—Add the zones that contain the interfaces to which you will allow HTTP connections. For interfaces not in a zone, type the interface name into the field under the selected **Selected Zones/Interfaces** list. Then click **Add**. The device applies these rules only if it includes the selected interfaces or zones.

c) Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After you complete this task, the device enables HTTP access on the specified interfaces and IP addresses. Use secure connections for health checks or management.

Configure ICMP access

By default, you can send ICMP packets to any interface using either IPv4 or IPv6, with these exceptions:

- The Firewall Threat Defense does not respond to ICMP echo requests directed to a broadcast address.
- The Firewall Threat Defense only responds to ICMP traffic sent to the interface that traffic comes in on; you cannot send ICMP traffic through an interface to a far interface.

To protect the device from attacks, you can use ICMP rules to limit ICMP access to interfaces to particular hosts, networks, or ICMP types. ICMP rules function like access rules, where the rules are ordered, and the first rule that matches a packet defines the action.

If you configure any ICMP rule for an interface, an implicit deny ICMP rule is added to the end of the ICMP rule list, changing the default behavior. Thus, if you want to simply deny a few message types, you must include a permit any rule at the end of the ICMP rule list to allow the remaining message types.

We recommend that you always grant permission for the ICMP unreachable message type (type 3). Denying ICMP unreachable messages disables ICMP path MTU discovery, which can halt IPsec and PPTP traffic. Additionally ICMP packets in IPv6 are used in the IPv6 neighbor discovery process.

Before you begin

Make sure the required objects exist before you configure rules. Select **Objects** > **Object Management** to configure objects. Create network objects or groups to specify the hosts or networks, and port objects to specify the ICMP message types you want to control.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **ICMP Access**.

Step 3 Configure ICMP rules.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **Action**—Whether to permit (allow) or deny (drop) matching traffic.
- **ICMP Service**—The port object that identifies the ICMP message type.
- **Network**—The network object or groupthat identifies the hosts or networks whose access you are controlling.
- **Available Zones/Interfaces**—Add the zones that contain the interfaces that you are protecting. If an interface is not in a zone, type the interface name into the field beneath the **Selected**

Zones/Interfaces list, and click **Add**. A device applies these rules only if it includes the selected interfaces or zones.

c) Click **OK**.

Step 4 (Optional.) Set rate limits on ICMPv4 Unreachable messages.

- **Rate Limit**—Sets the rate limit of unreachable messages, between 1 and 100 messages per second. The default is 1 message per second.
- **Burst Size**—Sets the burst rate, between 1 and 10. The system sends this number of replies, but subsequent replies are not sent until the rate limit is reached.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

ICMP access rules take effect after you deploy the policy to the assigned devices. Your configuration permits or denies ICMP traffic for the hosts or networks you specified.

Configure NetFlow

Configure NetFlow to enable the collection and export of IP network traffic information from your device interfaces. This allows you to analyze traffic patterns, bandwidth usage, and identify sources and causes of network congestion.

The NetFlow feature enables you to collect IP network traffic information as it enters or exits an interface. The collected traffic information is sent as records to a NetFlow Collector server or NetFlow Analyzer. You can analyze the data from NetFlow and determine information such as source and destination of traffic, class of service, traffic pattern, bandwidth usage, type of traffic, traffic volume, and the causes of congestion.

With the native NetFlow configuration support, the traffic information collection that was enabled through syslogs flow exports has to be disabled.

NetFlow provides the option to configure the flow exporter and collectors along with flow event types that must be monitored.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **NetFlow**.

Step 3 Enable the **Enable Flow Export** toggle to enable NetFlow data export.

Step 4 Configure the general NetFlow parameters that control the frequency of events pushed to the collector.

a) **Active Refresh Interval**—For active connections, specify the time interval (in minutes) between flow-update events.

b) **Delay Flow Create**—Specify the delay (in seconds) before sending a flow-create event. If you do not enter any value, there is no delay and the flow-create event is exported as soon as the flow is created.

c) **Template Timeout Rate**—Specify the time interval (in minutes) at which the template records are sent to the collectors.

Step 5 Click **Add Collector** to configure the collector. See Add a collector in NetFlow, on page 866.

Step 6 Click **Add Traffic Class** to configure the traffic class. See Add a traffic class to NetFlow, on page 867.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, NetFlow will be enabled and configured on your device. Traffic data will be exported to the configured collector, allowing you to analyze network traffic patterns and usage.

Add a collector in NetFlow

Use this task when you need to export NetFlow data from Cisco Threat Defense devices to a collector for traffic analysis and monitoring.

This configuration is applicable to Cisco Threat Defense policies with NetFlow enabled.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Choose **NetFlow**.

Step 3 Enable the **Enable Flow Export** toggle to enable NetFlow data export.

Step 4 Click **Add Collector** to configure the collector. You can configure a maximum of five collectors.

Step 5 From the **Host** dropdown list, choose the collector host IP address (IPv4 only) of the NetFlow event collector or server to which the NetFlow packets must be sent. Alternatively, you can click the (+) icon to create a new network host.

Step 6 In the **Port** field, enter the UDP port on the collector to which the NetFlow packets must be sent.

Step 7 From **Available Interfaces or Interface Groups**, choose the interface or interface group through which the collector must be reached. You can choose multiple interfaces or interface groups. The Interface Group object can contain only one interface for a given device. A collector can be reached only through one interface. The object can include a virtual-router-aware interface. Loopback interface is not supported in NetFlow.

You can click the (+) icon to create a new interface group.

Step 8 Click **Add** to add the interfaces you chose. Alternatively, you can also enter the interface name and click **Add** to add the interface.

Step 9 Click **OK**.

Add a traffic class to NetFlow

Use this task when you need to monitor, filter, and export specific types of network traffic using NetFlow on a Threat Defense device. Adding a traffic class helps you focus on relevant traffic for security or operational analysis.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **NetFlow**.

Step 3 Click the **Enable Flow Export** toggle to export NetFlow data.

Step 4 Click **Add Traffic Class** to configure the traffic class.

Step 5 In the **Name** field, enter the name of the traffic class that must match the NetFlow events.

Step 6 In the **Type** field, choose the traffic class to filter the type of traffic you want to capture:

- **Default**—The traffic class that is matched if none of the traffic classes matches the traffic.
- **Access List**—The specific traffic class that must match the traffic captured for the NetFlow events.

Step 7 If you select **Access List** as the **Type**, then select the access list object from the **Access List Object** drop-down list.

Note You can also click the (+) icon to create a new extended access list object. See Configure an extended ACL object, on page 2351.

Step 8 In **Event Types**, check the checkboxes for the different NetFlow events that you want to capture and send to the collectors.

Step 9 Click **OK**.

Configure Secure Shell (SSH) access

If you enabled Firewall Management Center access on a data interface, such as outside, you should enable SSH on that interface using this procedure. This section describes how to enable SSH connections to one or more *data* interfaces on the Firewall Threat Defense.

Note SSH is enabled by default on the Management interface; however, this screen does not affect Management SSH access.

To use SSH, you do not also need an access rule allowing the host IP address. You only need to configure SSH access according to this section.

Data vs. Management SSH

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the Firewall Management Center. SSH for data interfaces shares the internal and external user lists with SSH for the Management interface. Other settings are configured separately. For data interfaces, enable SSH and access lists using this screen. SSH traffic for data interfaces uses the regular routing configuration. Routing for the Management interface configured during setup or at the CLI is not used.

For the Management interface, to configure an SSH access list, see the **configure SSH-access-list** command in the *Cisco Secure Firewall Threat Defense Command Reference*. To configure a static route, see the **configure network static-routes** command. By default, you configure the default route through the Management interface at initial setup.

Interface Access

You can SSH only to a reachable interface(including an interface in a user-defined virtual router); for example, if your SSH host is located on the outside interface, you can only initiate a management connection directly to the outside interface. When you enable SSH in a user-defined virtual router, and you want VPN users to access SSH, be sure to terminate the VPN on the same virtual router. If the VPN is terminated on another virtual router, then you must configure route leaks between the virtual routers.

Ciphers and Key Exchange

SSH supports the following ciphers and key exchange:

- Encryption—aes128-cbc, aes192-cbc, aes256-cbc, aes128-ctr, aes192-ctr, aes256-ctr
- Integrity—hmac-sha2-256
- Key exchange—dh-group14-sha256

SSH Stack

The Firewall Threat Defense uses the CiscoSSH stack, which is based on OpenSSH. CiscoSSH supports FIPS compliance and regular updates, including updates from Cisco and the open source community.

Maximum Attempts

After you make three consecutive failed attempts to log into the CLI using SSH, the device terminates the SSH connection.

Before you begin

- You can configure SSH internal users at the CLI using the **configure user add** command; see Add an internal user at the CLI, on page 87. By default, there is an **admin** user for which you configured the password during initial setup. You can also configure external users on LDAP or RADIUS by configuring **External Authentication** in platform settings. See Configure external authentication, on page 855.
- You need network objects that define the hosts or networks permitted to make SSH connections to the device. You can add objects during the procedure. If you want to use object groups to identify a group of IP addresses, make sure the required groups already exist in the rules. Select **Objects** > **Object Management** to configure objects.

Note You cannot use the system-provided **any** network object. Instead, use **any-ipv4** or **any-ipv6**.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **SSH Access**.

Step 3 Identify the interfaces and IP addresses that allow SSH connections.

Use this table to limit which interfaces will accept SSH connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make SSH connections. Choose an object from the drop-down menu, or click + to add a new network object.
- **Available Zones/Interfaces**—Add the zones that contain the interfaces to which you will allow SSH connections. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zones/Interfaces** list and click **Add**. You can also add loopback interfaces and virtual-router-aware interfaces. These rules will be applied to a device only if the device includes the selected interfaces or zones.

c) Click **OK**.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure an SMTP server

Configure an SMTP server to enable email alerts in Syslog. Ensure the source email address configured for Syslog is a valid account on the SMTP servers.

Before you begin

Ensure that the network objects for the primary and secondary SMTP server addresses exist. Define the objects using **Objects** > **Object Management**. You can also create these objects when you edit the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **SMTP Server**.

Step 3 Select the network objects that identify the **Primary Server IP Address** and optionally, the **Secondary Server IP Address**.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, email alerts can be sent through Syslog using the specified SMTP servers.

Configure SNMP for a security device

Configure SNMP monitoring to allow network management stations to monitor the health and status of Cisco security devices. This task enables centralized visibility and management of devices using SNMP.

- Enable SNMP so that SNMP management stations can monitor devices.
- SNMP versions 1, 2c, and 3, including traps and read access, are supported. SNMP write access is not supported.

Simple Network Management Protocol (SNMP) defines a standard way for network management stations running on PCs or workstations to monitor the health and status of many types of devices, including switches, routers, and security appliances. You can use the SNMP page to configure a firewall device for monitoring by SNMP management stations.

SNMPv3 supports read-only users and encryption with DES(deprecated), 3DES, AES256, AES192, and AES128.

The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption and that were created using a version earlier than 6.5, you can continue to use those users for Firewall Threat Defense devices running versions 6.6 or earlier. However, you cannot edit those users and retain DES encryption or create new users with DES encryption. If your Firewall Management Center manages any Firewall Threat Defense devices running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those Firewall Threat Defense devices will fail.

Note

- You can configure SNMP only on Routed and Diagnostic interfaces.
- To create an alert to an external SNMP server, access **Policies** > **Actions** > **Alerts**.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **SNMP**.

Step 3 Enable SNMP, and configure basic options.

- **Enable SNMP Servers**—Whether to provide SNMP information to the configured SNMP hosts. You can deselect this option to disable SNMP monitoring while retaining the configuration information.
- **Read Community String**, **Confirm**—Enter the password used by a SNMP management station when sending requests to the Firewall Threat Defense device. The SNMP community string (also known as password) is a shared secret among the SNMP management stations and the network nodes. The security

device uses this password to determine if the incoming SNMP request is valid. The password is a case-sensitive alphanumeric string of up to 32 characters; spaces and special characters are not permitted.

- **System Administrator Name**—Enter the name of the device administrator or other contact person. This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
- **Location**—Enter the location of this security device (for example, Building 42, Sector 54). This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
- **Port**—Enter the UDP port on which incoming requests will be accepted. The default is 161.

Step 4 (SNMPv3 only.) Add SNMPv3 users, on page 877.

Step 5 Add SNMP hosts, on page 880.

Step 6 Configure SNMP traps, on page 882.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

SNMP protocol

SNMP protocol is an application-layer protocol that

- facilitates the exchange of management information between network devices, and
- is part of the TCP/IP protocol suite.

SNMP protocol support and access

Firewall Threat Defense provides support for network monitoring using SNMP Versions 1, 2c, and 3, and supports the use of all three versions simultaneously. The SNMP agent runs on the Firewall Threat Defense interface. You can monitor network devices using management systems (NMSs) such as OpenView network management system. Firewall Threat Defense supports SNMP read-only access with a GET request. SNMP does not support write access or the SNMP SET request, so you cannot make changes with SNMP.

You can configure the Firewall Threat Defense to send traps, which are messages sent to the management station when certain events occur. These messages are called event notifications. You can also use the NMS to browse Management Information Bases (MIBs) on the security devices. MIBs are collections of definitions, and the Firewall Threat Defense maintains a database of values for each definition. To browse a MIB, issue a series of GET-NEXT or GET-BULK requests from the NMS to the MIB tree to get values.

The SNMP agent sends a notification to your management station when a specified event occurs, such as a network link going up or down. The notification includes an SNMP OID, which identifies the source device. The agent also replies when your management station requests information.

List SNMP terminology

This reference lists and defines the terms that are commonly used when working with SNMP.

Table 52: SNMP terminology

Term	Description
Agent	The SNMP server running on the Secure Firewall Threat Defense. The SNMP agent has these features: • responds to requests for information and actions from the network management station. • ontrols access to its Management Information Base, the collection of objects that the SNMP manager can view or change. • does not allow SET operations.
Browsing	Monitoring the health of a device from the network management station by polling required information from the SNMP agent on the device. This activity may include issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the network management station to determine values.
Management Information Bases (MIBs)	Standardized data structures for collecting information about packets, connections, buffers, failovers, and other items. MIBs are defined by the product, protocols, and hardware standards used by most network devices. SNMP network management stations can browse MIBs and request specific data or events be sent as they occur.
Network management stations (NMSs)	The PCs or workstations SET up to monitor SNMP events and manage devices.
Object identifier (OID)	The system that identifies a device to its NMS and indicates to users the source of information monitored and displayed.
Trap	Predefined events that generate a message from the SNMP agent to the NMS. Events include alarm conditions such as link-up, link-down, cold-start, warm-start, authentication events, or syslog messages. **coldStart**—The coldStart trap occurs when the SNMP agent starts after the SNMP configuration. This trap also occurs when the agent starts after a system reboot. **Note** For cluster and HA nodes, after a reload, if the interface reboot time exceeds 5 minutes (preset threshold), the trap is dropped. When the cluster and HA nodes have rebooted successfully, all other traps are sent as expected. The **SNMP-server enable traps SNMP coldstart** command is used to enable and disable transmission of these traps.

Describe MIBs and traps

MIBs are either standard or enterprise-specific. Standard MIBs are created by the IETF and described in various RFCs. Traps report significant events, such as errors or failures, on a network device. SNMP traps can be defined in standard or enterprise-specific MIBs. The IETF also creates standard traps, documented in various RFCs. SNMP traps are compiled into ASA software.

If needed, you can also download RFCs, standard MIBs, and standard traps from these locations:

http://www.IETF.org/

Browse the SNMP Object Navigator to look up Cisco MIBs, traps, and OIDs from this location:

https://snmp.cloudapps.cisco.com/Support/SNMP/do/BrowseOID.do?local=en

In addition, download Cisco OIDs by FTP from this location:

ftp://FTP.cisco.com/pub/mibs/oid/oid.tar.gz

List of supported tables and objects in MIBs

This reference lists the supported tables and objects for the specified MIBs, including details for each MIB such as counters, OIDs, and descriptions.

Remote Access VPN polling

Table 53: CISCO-REMOTE-ACCESS-MONITOR-MIB

Counter	OID	Description
Active Sessions	crasNumSessions (1.3.6.1.4.1.9.9.392.1.3.1)	The number of currently active sessions.
Users	crasNumUsers (1.3.6.1.4.1.9.9.392.1.3.3)	The number of users who have active sessions.
Peak Sessions	crasNumPeakSessions (1.3.6.1.4.1.9.9.392.1.3.41)	The number of peak RA sessions since system up.

Site-to-site VPN tunnel polling

Table 54: CISCO-REMOTE-ACCESS-MONITOR-MIB

Counter	OID	Description
LAN to LAN Sessions	crasL2LNumSessions (1.3.6.1.4.1.9.9.392.1.3.29)	The number of currently active LAN to LAN sessions.
Peak LAN to LAN Sessions	crasL2LPeakConcurrentSessions (1.3.6.1.4.1.9.9.392.1.3.31)	The number of peak concurrent LAN to LAN sessions since the system is up.

Connection polling

Table 55: CISCO-FIREWALL-MIB

Counter	OID	Description
Active Connections	cfwConnectionActive (1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.6)	The number of connections currently in use by the entire firewall.

Counter	OID	Description
Peak Connections	cfwConnectionPeak (1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.7)	The highest number of connections in use at any one time since system startup.
Connections Per Second	cfwConnectionPerSecond (1.3.6.1.4.1.9.9.147.1.2.2.3)	The current connections per second rate on the firewall.
Peak Connections Per Second	cfwConnectionPerSecondPeak (1.3.6.1.4.1.9.9.147.1.2.2.4)	The highest number of connections per second on the firewall since system startup.

NAT translation polling

Table 56: CISCO-NAT-EXT-MIB

Counter	OID	Description
Active Translations	cneAddrTranslationNumActive (1.3.6.1.4.1.9.9.532.1.1.1.1)	The total number of address translation entries that are currently available in the NAT device. This indicates the aggregate of the translation entries created from both the static and dynamic address translation mechanisms.
Peak Active Translations	cneAddrTranslationNumPeak (1.3.6.1.4.1.9.9.532.1.1.1.2)	The maximum number of address translation entries that are active at any one time since system startup. This value indicates the high watermark of address translation entries active at any one time since system startup. This object includes the translation entries created from both the static and dynamic address translation mechanisms.

Routing table entries polling

Table 57: IP-FORWARD-MIB

Counter	OID	Description
Active Translations	inetCidrRouteNumber (1.3.6.1.2.1.4.24.6)	The total number of current inetCidrRouteTable entries that are valid.

Interface duplex status polling

Table 58: CISCO-IF-EXTENSION-MIB

Counter	OID	Description
Duplex Status	cieIfDuplexCfgStatus (1.3.6.1.4.1.9.9.276.1.1.2.1.20)	This object specifies the configured duplex status for the given interface.
Detected Duplex Status	cieIfDuplexDetectStatus (1.3.6.1.4.1.9.9.276.1.1.2.1.21)	This object specifies the detected duplex status for the given interface.

Snort 3 intrusion EVENT rate polling

Table 59: CISCO-UNIFIED-FIREWALL-MIB

Counter	OID	Description
Snort 3 Intrusion event Rate	cufwAaicIntrusionEvtRate (1.3.6.1.4.1.9.9.491.1.5.3.2.1)	The rate at which intrusion events were recorded by Snort on this firewall, averaged over the last 300 seconds.

BGP peer-flap trap notification

Table 60: BGP4-MIB

Counter	OID	Description
BGP Peer-flap	bgpBackwardTransition (1.3.6.1.4.1.9.9.491.1.5.3.2.1)	The BGPBackwardTransition event is generated when the BGP FSM moves from a higher numbered state to a lower numbered state.

CPU utilization polling

Table 61: CISCO-PROCESS-MIB

Counter	OID	Description
CPU Total Utilization	cpmCPUTotal1minRev (1.3.6.1.4.1.9.9.109.1.1.1.1.7.1)	Total system CPU utilization for the last one minute.
Individual CPU Core Utilization	Associated parameters and values of cpmCPUTotal1minRev 1.3.6.1.4.1.9.9.109.1.1.1.1.7.2 to 1.3.6.1.4.1.9.9.109.1.1.1.1.7.(n+1)	Individual CPU core utilization values for the last one minute, where 'n' represents the number of cores. Examples: • 3.6.1.4.1.9.9.109.1.1.1.1.7.(n+2) - Aggregate system CPU utilization % (This value is the same as the system CPU usage from .3.6.1.4.1.9.9.109.1.1.1.1.7.1 in single context mode). • 3.6.1.4.1.9.9.109.1.1.1.1.7.(n+3) - Snort average CPU utilization % (total aggregate value of all snort instances) • 3.6.1.4.1.9.9.109.1.1.1.1.7.(n+4) - System PROCESS average % (average of "Sysproc" cores)

Note The SNMP OIDs 1.3.6.1.2.1.25.3.3 and 1.3.6.1.2.1.25.3.4 pertaining to CPU monitoring (hrProcessorTable and hrNetworkTable) were removed on ASA FirePOWER. You can view and MONITOR the CPU health details of the device only through its device manager.

In ENTITY-MIB, two new vendor OIDs were added for the dual EPM 2X100G and 4X200G cards of Secure Firewall 4200 for slot 2 and slot 3—cevFPRNM4X200Gng and cevFPRNM2X100Gng.

Add SNMPv3 users

Add SNMPv3 users to provide secure, authenticated, and encrypted SNMP management access to your device. This task ensures that only authorized users can access SNMPv3 features using specified authentication and encryption algorithms.

You create users for SNMPv3 only. These steps are not applicable for SNMPv1 or SNMPv2c.

Note SNMPv3 only supports read-only users.

SNMP users have a specified username, an authentication password, an encryption password, and authentication and encryption algorithms to use.

Note If you add a new cluster unit or replace a High Availability unit when using SNMPv3 with clustering or High Availability, SNMPv3 users are not replicated to the new unit. Remove the users, add them again, and redeploy your configuration to replicate users to the new unit.

For a successful SNMPv3 user authentication, the authentication key size should be equal to or larger than the encryption key size. For example, a user authentication using SHA-1 with AES256 fails, whereas authentication using SHA256 with AES256 succeeds.

The authentication algorithm options are MD5 (deprecated, pre-6.5 only), SHA, SHA224, SHA256, and SHA384.

Note The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTD devices running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those threat defenses will fail.

The encryption algorithm options are DES (deprecated, pre-6.5 only), 3DES, AES256, AES192, and AES128.

Note The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for threat defenses running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those threat defenses will fail.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Choose **SNMP** > **Users** tab.

Step 3 Click **Add** and completed the following:

a) Select the security level for the user from the **Security Level** drop-down list.

- **Auth**—Authentication but No Privacy, which means that messages are authenticated.
- **No Auth**—No Authentication and No Privacy, which means that no security is applied to messages.
- **Priv**—Authentication and Privacy, which means that messages are authenticated and encrypted.

b) Enter the name of the SNMP user in the **Username** field. Usernames must be 32 characters or fewer.

c) From the **Encryption Password Type** drop-down list, choose one of these options:

- **Clear text**—The Firewall Threat Defense device encrypts the password when you deploy the policy. In High Availability or cluster deployments, choose this option so that each unit localizes the SNMPv3 key with its own SNMP engineID.
- **Encrypted**—The Firewall Threat Defense device directly deploys the precomputed localized key in hexadecimal format.

Note Do not choose **Encrypted** for SNMPv3 users in High Availability or cluster deployments. An encrypted SNMPv3 password is a localized key that is generated from a specific SNMP engineID. Each High Availability or cluster unit has a unique SNMP engineID. If you deploy a localized key generated for one unit to its peer, SNMPv3 polling to the peer fails with an authentication error.

Choose **Clear text** so that each unit localizes the key during deployment.

d) In the **Auth Algorithm Type** drop-down list, select the type of authentication you want to use: SHA, SHA224, SHA256, or SHA384.

Note The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTD devices running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your Firewall Management Center manages any Firewall Threat Defenses running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those Firewall Threat Defenses will fail.

e) In the **Authentication Password** field, enter the password to use for authentication. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values.

Note The length of the password will depend on the authentication algorithm selected. For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

f) In the **Encryption Type** drop-down list, select the type of encryption you want to use: AES128, AES192, AES256, 3DES.

Note To use AES or 3DES encryption, you must have the appropriate license installed on the device.

Note The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for Firewall Threat Defenses running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your Firewall Management Center manages any Firewall Threat Defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those Firewall Threat Defenses will fail.

g) Enter the password to use for encryption in the **Encryption Password** field. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values. For encrypted passwords, the length of the password depends on the encryption type selected. The password sizes are as follows. Each xx is one octal.:

- AES 128 requires 16 octals
- AES 192 requires 24 octals
- AES 256 requires 32 octals
- 3DES requires 32 octals
- DES can be any size

Note For all passwords, the length must be 256 characters or fewer.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

Step 4 Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing these steps, SNMPv3 users are added with the specified authentication and encryption settings. The device is now configured for secure SNMPv3 management access.

Add SNMP hosts

Define SNMP hosts and their communication parameters to enable SNMP management stations to access and monitor the device. This task allows you to specify which hosts are permitted and how they communicate with the device.

Use Host to add or edit entries in the SNMP Hosts table on the SNMP page. These entries represent SNMP management stations allowed to access the Firewall Threat Defense device.

You can add up to 8192 hosts. Only 128 of this number can be for traps.

Note In 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices (7.3 and earlier, and some upgraded 7.4 FTDs).

Before you begin

Ensure that the network objects that define the SNMP management stations exist. Select **Device** > **Object Management** to configure network objects.

Note The supported network objects include IPv6 hosts, IPv4 hosts, IPv4 range and IPv4 subnet addresses.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Choose **SNMP** > **Hosts** tab.

Step 3 Click **Add** and completed the following:

a) In the **IP Address** field, either enter a valid IPv6 or IPv4 host or select the network object that defines the SNMP management station's host address.

The IP address can be an IPv6 host, IPv4 host, IPv4 range or IPv4 subnet.

b) Select the appropriate SNMP version from the **SNMP version** drop-down list.

c) (SNMPv3 only.) Select the username of the SNMP user that you configured from the **User Name** drop-down list.

Note You can associate up to 23 SNMP users per SNMP host.

d) (SNMPv1, 2c only.) In the **Read Community String** field, enter the community string that you have already configured, for read access to the device. Re-enter the string to confirm it.

Note This string is required, only if the string used with this SNMP station is different from the one already defined in the **Enable SNMP Server** section.

e) Select the type of communication between the device and the SNMP management station. You can select both types. Choose from:

- **Poll**—The management station periodically requests information from the device.
- **Trap**—The device sends trap events to the management station as they occur.

Note When the SNMP host IP address is either an IPv4 range or an IPv4 subnet, you can configure either **Poll** or **Trap**, not both.

f) In the **Port** field, enter a UDP port number for the SNMP host. The default value is 162. The valid range is 1 to 65535.

g) Select the interface type for communication between the device and the SNMP management station under the **Reachable By** options. You can select either the Management interface of the device or an available security zone/named interface. Choose from:

- **Device Management Interface**—Communication between the device and the SNMP management station occurs over the Management interface.
  - When you choose this interface for SNMPv3 polling, all configured SNMPv3 users are allowed to poll and are not restricted to the user chosen in 3.c, on page 880. Here, SNMPv1 and SNMPv2c are not allowed from an SNMPv3 host.
  - When you choose this interface for SNMPv1 and SNMPv2c polling, the polling is not restricted at all to the version selected in 3.b, on page 880.
- **Security Zones or Named Interface**—Communication between the device and the SNMP management station occurs over a security zone or interface.
  - Search for zones in the **Available Zones** field.
  - Add the zones that contain the interfaces through which the device communicates with the management station to the **Selected Zone/Interface** field. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zone/Interface** list and click **Add**. You can also choose a loopback interface and virtual-router-aware interfaces. The host will be configured on a device only if the device includes the selected interfaces or zones.

Note VTI tunnel interfaces are not supported for SNMP.

Step 4 Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure SNMP traps

Use SNMP traps to configure event notifications for Firewall Threat Defense. Traps are unsolicited notifications sent from the device to the management station for certain events, such as linkup, linkdown, and syslog event generation. Each SNMP trap includes an object ID (OID) for your device.

Some traps are not applicable to certain hardware models. These traps will be ignored if you apply the policy to one of these models. For example, not all models have field-replaceable units, so the **Field Replaceable Unit Insert/Delete** trap will not be configured on those models.

SNMP traps are defined in standard MIBs or in enterprise-specific MIBs. Standard traps are created by the IETF and documented in various RFCs. The Firewall Threat Defense software includes SNMP traps.

If needed, you can download RFCs, standard MIBs, and standard traps from http://www.IETF.org/.

Browse the complete list of CISCO MIBs, traps, and OIDs using the SNMP Object Navigator on the Cisco website: SNMP Object Navigator.

In addition, download CISCO OIDs by FTP: ftp://ftp.cisco.com/pub/mibs/oid/oid.tar.gz.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **SNMP** > **SNMP Traps** to configure SNMP traps (event notifications) for the Firewall Threat Defense device.

Step 3 Select the appropriate Enable Traps options. You can select either or both options.

a) Check **Enable All SNMP Traps** to select all traps in the subsequent four sections.

b) Check **Enable All Syslog Traps** to enable transmission of trap-related syslog messages.

Note SNMP traps are of higher priority than other notification messages because they are expected to be near real-time. When you enable all SNMP or syslog traps, it is possible for the SNMP process to consume excess resources in the agent and in the network, causing the system to hang. If you notice system delays, unfinished requests, or timeouts, you can selectively enable SNMP and syslog traps. You can also limit the rate at which syslog messages are generated by severity level or message ID. For example, all syslog message IDs that begin with the digits 212 are associated with the SNMP class; see Configure syslog rate limits, on page 902.

Step 4 The event-notification traps in the **Standard** section are enabled by default for an existing policy:

- **Authentication** – Unauthorized SNMP access. This authentication failure occurs for packets with an incorrect community string.
- **Link Up** – One of the device's communication links has become available (it has "come up"), as indicated in the notification.

- **Link Down** – One of the device's communication links has failed, as indicated in the notification.
- **Cold Start** – The device is reinitializing itself such that its configuration or the protocol entity implementation may be altered.
- **Warm Start** – The device is reinitializing itself such that its configuration and the protocol entity implementation is unaltered.

Step 5 Select the desired event-notification traps in the **Entity MIB** section:

- **Field Replaceable Unit Insert** – A Field Replaceable Unit (FRU) has been inserted, as indicated. (FRUs include assemblies such as power supplies, fans, processor modules, interface modules, etc.)
- **Field Replaceable Unit Delete** – A Field Replaceable Unit (FRU) has been removed, as indicated in the notification
- **Configuration Change** – There has been a hardware change, as indicated in the notification

Step 6 Select the desired event-notification traps in the **Resource** section:

- **Connection Limit Reached** – This trap indicates that a connection attempt was rejected because the configured connections limit has been reached.

Step 7 Select the desired event-notification traps in the **Other** section:

- **NAT Packet Discard** – This notification is generated when IP packets are discarded by the NAT function. Available Network Address Translation addresses or ports have fallen below configured threshold.
- **CPU Rising Threshold** – This notification is generated when rising CPU utilization exceeds a predefined threshold for a configured period of time. Check this option to enable CPU rising threshold notifications:
  - **Percentage** – The default value is 70% for the high threshold notification; the range is 10 to 94%. The critical threshold is 95%.
  - **Period** – The default monitoring period is 1 minute; the range is 1 to 60 minutes.
- **Memory Rising Threshold** – This notification is generated when rising memory utilization exceeds a predefined threshold, thus reducing available memory. Check this option to enable memory rising threshold notifications:
  - **Percentage** – The default value is 70% for the high threshold notification; the range is 50 to 95%.
- **Failover** – This notification is generated when there is a change in the failover state as reported by the CISCO-UNIFIED-FIREWALL-MIB.
- **Cluster** – This notification is generated when there is a change in the cluster health as reported by the CISCO-UNIFIED-FIREWALL-MIB.
- **Peer Flap** – This notification is generated when there is BGP route flapping, a situation in which BGP systems send an excessive number of update messages to advertise network reachability information.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, SNMP traps are configured on the Firewall Threat Defense device, and event notifications will be sent to the management station for the selected events. This enables proactive monitoring and timely response to device events.

Configure SSL settings

This task enables you to configure SSL settings for remote access VPN sessions, allowing you to specify protocol versions, security levels, and available algorithms to ensure secure communication.

You must have administrator privileges and be in a leaf domain to perform this task.

Make sure that you are running a fully licensed version of the Secure Firewall Management Center. The SSL Settings are disabled if you are running Secure Firewall Management Center in evaluation mode. SSL Settings are also disabled if the licensed Secure Firewall Management Center version does not meet the export-compliance criteria. If you are using Remote Access VPN with SSL, your Smart Account must have the strong-crypto features enabled. For more information, see *License Types and Restrictions* in the *Cisco Secure Firewall Management Center Administration Guide*.

Before you begin

Ensure you have administrator privileges and are in a leaf domain. Verify that you are running a fully licensed version of the management center with strong-crypto features enabled if using Remote Access VPN with SSL.

Procedure

Step 1 Select **Devices** > **Platform Settings** and create or edit a Firewall Threat Defense policy.

Step 2 Select **SSL**.

Step 3 Add entries to the **Add SSL Configuration** table.

a) Click **Add** to create a new entry, or click **Edit** if the entry already exists.

b) Select the required security configurations from the drop-down list.

- **Protocol Version**—Specifies the TLS protocols to be used while establishing remote access VPN sessions.
- **Security Level**—Indicates the kind of security positioning you would like to set up for the SSL.

Step 4 Select the **Available Algorithms** based on the protocol version that you select and click **Add** to include them for the selected protocol. For more information, see Configure SSL settings, on page 885.

The algorithms are listed based on the protocol version that you select. Each security protocol identifies a unique algorithm for setting up the security level.

Step 5 Click **OK** to save the changes.

What to do next

Select **Deploy** > **Deployment** and click **Deploy** to deploy the policy to the assigned devices.

Configure SSL settings

The Firewall Threat Defense device uses the Secure Sockets Layer (SSL) protocol and Transport Layer Security (TLS) to support secure message transmission for Remote Access VPN connection from remote clients. The SSL Settings window lets you configure SSL versions and encryption algorithms that will be negotiated and used for message transmission during remote VPN access over SSL.

Note Though you configure Firewall Management Center and Firewall Threat Defense to operate in a security certifications (UCAPL, CC, or FIPS) compliance mode, the Firewall Management Center allows configuration of unsupported ciphers. For example, in a FIPS enabled mode, management center allows configuring DH Group 5 which is not FIPS-compliant. However, VPN tunnel does not negotiate due to the non-compliant cipher usage.

Configure the SSL Settings at this location:

Devices > **Platform Settings**, and then click **SSL**.

Fields

Minimum SSL Version as Server—Specify the minimum SSL/TLS protocol version that the Firewall Threat Defense device uses when acting as a server. For example, when it functions as a Remote Access VPN Gateway.

TLS Version—Select one of these TLS versions from the drop-down list:

TLS V1	Accepts SSLv2 client hellos and negotiates TLSv1 (or greater).
TLSV1.1	Accepts SSLv2 client hellos and negotiates TLSv1.1 (or greater).
TLSV1.2	Accepts SSLv2 client hellos and negotiates TLSv1.2 (or greater).
TLSV1.3	Accepts SSLv2 client hellos and negotiates TLSv1.3 (or greater).

Note TLS 1.3 in remote access VPN requires Cisco Secure Client, Version 5.0 and above.

DTLS Version—Select the DTLS versions from the drop-down list, based on the selected TLS version. By default, DTLSv1 is configured on Firewall Threat Defense devices, you can choose the DTLS version as per your requirement.

Note Ensure that the TLS protocol version is higher than or equal to the DTLS protocol version selected. TLS protocol versions support these DTLS versions:

TLS V1	DTLSv1
TLSV1.1	DTLSv1

TLSV1.2	DTLSv1, DTLSv1.2
TLSV1.3	DTLSv1, DTLSv1.2

Diffie-Hellman Group—Choose a group from the drop-down list. Available options are Group1 - 768-bit modulus, Group2 - 1024-bit modulus, Group5 - 1536-bit modulus, Group14 - 2048-bit modulus, 224-bit prime order, and Group24 - 2048-bit modulus, 256-bit prime order. The default is Group1.

Elliptical Curve Diffie-Hellman Group—Choose a group from the drop-down list. Available options are Group19 - 256-bit EC, Group20 - 384-bit EC, and Group21 - 521-bit EC. The default value is Group19.

TLSv1.2 adds support for these ciphers:

- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-GCM-SHA384
- AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-GCM-SHA256
- RSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256

Note
ECDSA and DHE ciphers are the highest priority.

TLSv1.3 adds support for these ciphers:

- TLS_AES_128_GCM_SHA256
- TLS_CHACHA20_POLY1305_SHA256
- TLS_AES_256_GCM_SHA384

The SSL configuration table can be used to specify the protocol version, security level, and Cipher algorithms that you want to support on the Secure Firewall Threat Defense devices.

Protocol Version—Lists the protocol version that the Secure Firewall Threat Defense device supports and uses for SSL connections. Available protocol versions are:

- Default
- TLSV1
- TLSV1.1
- TLSV1.2
- TLSV1.3
- DTLSv1
- DTLSv1.2

Security Level—Lists the cipher security levels that Firewall Threat Defense device supports and uses for SSL connections.

If you have Firewall Threat Defense devices with evaluation license, the security level is Low by default. With Firewall Threat Defense smart license, the default security level is High. You can choose one of these options to configure the required security level:

- **All** includes all ciphers, including NULL-SHA.
- **Low** includes all ciphers, except NULL-SHA.
- **Medium** includes all ciphers, except NULL-SHA, DES-CBC-SHA, RC4-SHA, and RC4-MD5 (this is the default).
- **FIPS** includes all FIPS-compliant ciphers, except NULL-SHA, DES-CBC-SHA, RC4-MD5, RC4-SHA, and DES-CBC3-SHA, TLS_CHACHA20_POLY1305_SHA256.
- **High** includes only AES-256 with SHA-2 ciphers and applies to TLS version 1.2 and the *default* version.
- **Custom** includes one or more ciphers that you specify in the Cipher algorithms/custom string box. This option provides you with full control of the cipher suite using OpenSSL cipher definition strings.

Cipher Algorithms/Custom String—Lists the cipher algorithms that the Firewall Threat Defense device supports and uses for SSL connections. For more information about ciphers using OpenSSL, see https://www.openssl.org/docs/apps/ciphers.html

Ciphers supported by TLSv1.2 only

- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-GCM-SHA384
- AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384

- DHE-RSA-AES256-SHA256
- AES256-SHA256
- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-GCM-SHA256
- AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256
- DHE-RSA-AES128-SHA256
- AES128-SHA256

Note ECDSA and DHE ciphers are the highest priority.

Ciphers not supported by TLSv1.1 or TLSv1.2

- RC4-SHA
- RC4-MD5
- DES-CBC-SHA
- NULL-SHA

Syslog

Logging information

Logging information can help you identify and isolate network or device configuration problems.

- System logging (syslog) can be enabled for Firewall Threat Defense devices.
- Some security events can be sent to a syslog server.

Syslog messages

A syslog message is a log event that

- collects messages from devices to a server running a syslog daemon
- enables aggregation of logs and alerts for centralized management, and
- provides protected long-term storage for logs, supporting troubleshooting and incident handling.

System log configuration details

Devices can send their log messages to a UNIX-style syslog service. A syslog service accepts messages and either stores them in files or prints them, based on a simple configuration file.

Table 62: System logs for Secure Firewall Threat Defense

Logs related to	Details	Configure in
Device and system health, network configuration	This syslog configuration generates messages for features running on the data plane, that is, features that are defined in the CLI configuration that you can view with the **show running-config** command. This includes features such as routing, VPN, data interfaces, DHCP server, NAT, and so forth. Data plane syslog messages are numbered, and they are the same as those generated by devices running ASA software. However, Secure Firewall Threat Defense does not necessarily generate every message type that is available for ASA Software. For information on these messages, see *Cisco Secure Firewall Threat Defense syslog messages* at https://www.cisco.com/c/en/us/td/docs/security/firepower/Syslogs/b_fptd_syslog_guide.html. This configuration is explained in these topics.	**Platform settings**
Security events	This syslog configuration generates alerts for file and malware, connection, Security Intelligence, and intrusion events. For details, see *About sending syslog messages for security events* and subtopics in the *Cisco Secure Firewall Management Center Administration Guide*.	**Platform settings** and the **Logging** in an access control policy
(All devices) Policies, rules, and events	This syslog configuration generates alerts for access control rules, intrusion rules, and other advanced services as described in *Configurations supporting alert responses* in the *Cisco Secure Firewall Management Center Administration Guide*. These messages are not numbered. For information on configuring this type of syslog, see *Creating a syslog alert response* in the *Cisco Secure Firewall Management Center Administration Guide*.	**alert responses** and the **Logging** in an access control policy

You can set up multiple syslog servers and control the messages and events sent to each server. You can also configure varied destinations, such as console, email, or internal buffer.

Syslog message severity levels

The syslog message severity levels define the importance of system messages.

Table 63: Syslog message severity levels

Level Number	Severity Level	Description
0	**emergencies**	You cannot use the system.
1	**alert**	You need to take immediate action.
2	**critical**	The system has critical conditions to be addressed.
3	**error**	Error conditions.
4	**warning**	The system has warnings you should review.
5	**notification**	The system reports significant events you should monitor.
6	**informational**	Informational messages only.
7	**debugging**	The system generates only debugging messages Log at this level only temporarily, when debugging issues. This log level can generate many messages, which might affect system performance.

Note Firewall Threat Defense does not generate syslog messages with a severity level of zero (emergencies).

Syslog message filters

Syslog message filter criteria

You can direct syslog messages to an output destination according to these criteria:

- Syslog message ID number

  (This does not apply to syslog messages for security events such as connection and intrusion events.)

- Syslog message severity level
- Syslog message class (equivalent to a functional area)

  (This rule does not apply to syslog messages for security events, including connection and intrusion events.)

You can create a message list with specific criteria, which you can then specify as the output destination is set. Alternatively, you can configure the Firewall Threat Defense device to send a particular message class to each type of output destination independently of the message list.

(Message lists do not apply to syslog messages for security events such as connection and intrusion events.)

Syslog message classes and associated message ID numbers

Note This topic does not apply to messages for security events (connection, intrusion, etc.)

You can use syslog message classes in two ways:

- Specify an output location for an entire category of syslog messages.
- Create a message list that specifies the message class.

Use the syslog message class to categorize syslog messages by type, such as features or functions of the device. For example, use the RIP class for RIP routing.

Syslog messages in the same class have the same three initial digits in their message ID numbers. For example, the syslog messages for the VPN client feature use ID numbers 611101 to 611323.

Most ISAKMP syslog messages include prepended objects that identify the tunnel. When available, these objects appear before the descriptive text of a syslog message. If the object is unknown when the syslog message is generated, the heading and value combination is omitted.

The objects are prefixed in this manner:

Group = *groupname*, Username = *user*, IP = *IP_address*

The term 'group' here refers to the tunnel-group configuration. The username is from the local database or AAA server. The IP address is the public IP address of the remote access client or Layer 2 peer.

See the message classes and the range of message ID numbers in each class in this table.

Table 64: Syslog message classes and associated message ID numbers

Class	Definition	Syslog Message ID Numbers
access-list*	Access Lists	106
application-firewall*	Application Firewall	415
auth	User Authentication	109, 113
botnet-traffic-filtering*	Botnet Traffic Filtering	338
bridge	Transparent Firewall	110, 220
ca	PKI Certification Authority	717
card-management*	Card Management	323
citrix	Citrix Client	723
clustering*	Clustering	747
config	Command Interface	111, 112, 208, 308
csd	Secure Desktop	724

Class	Definition	Syslog Message ID Numbers
cts	Cisco TrustSec	776
dap	Dynamic Access Policies	734
EAP, eapoudp	EAP or EAPoUDP for Network Admission Control	333, 334
EIGRP	EIGRP Routing	336
email	E-mail Proxy	719
environment-monitoring*	Environment Monitoring	735
ha	Failover	101, 102, 103, 104, 105, 210, 311, 709
identity-based-firewall*	Identity-based Firewall	746
ids	Intrusion Detection System	400, 733
ikev2-toolkit*	IKEv2 Toolkit	750, 751, 752
IP	IP Stack	209, 215, 313, 317, 408
ipaa	IP Address Assignment	735
ips	Intrusion Protection System	400, 401, 420
ipv6*	IPv6	325
licensing*	Licensing	444
MDM-proxy	MDM Proxy	802
NAC	Network Admission Control	731, 732
nacpolicy	NAC Policy	731
nacsettings	NAC Settings to apply NAC Policy	732
NAT-and-PAT*	NAT and PAT	305
network-access-point*	Network Access Point	713
NP	Network Processor	319
NP-SSL*	NP SSL	725
OSPF	OSPF Routing	318, 409, 503, 613
password-encryption*	Password Encryption	742
phone-proxy*	Phone Proxy	337
RIP	RIP Routing	107, 312

Class	Definition	Syslog Message ID Numbers
rm	Resource Manager	321
scansafe*	ScanSafe	775
session	User Session	106, 108, 201, 202, 204, 302, 303, 304, 305, 314, 405, 406, 407, 500, 502, 607, 608, 609, 616, 620, 703, 710
smart-call-home*	Smart Call Home	120
SNMP	SNMP proxy	212
SSL	SSL Stack	725
svc	SSL VPN Client	722
sys	System	199, 211, 214, 216, 306, 307, 315, 414, 604, 605, 606, 610, 612, 614, 615,701, 711, 741
tag-switching	Service Tag Switching	779
threat-detection*	Threat Detection	733
transactional-rule-engine-tre*	Transactional Rule Engine	780
uc-IMS*	UC-IMS	339
vm	VLAN Mapping	730
vpdn	PPTP and L2TP Sessions	213, 403, 603
VPN	IKE and IPsec	316, 320, 402, 404, 501, 602, 702, 713, 714, 715
vpnc	VPN Client	611
vpnfo	VPN Failover	720
vpnlb	VPN Load Balancing	718
VXLAN*	VXLAN	778
webfo	WebVPN Failover	721
webvpn	WebVPN and Secure Client	716

*The management center web interface provisions these classes to facilitate creation of event lists. The device console does not display these classes.

Guidelines for logging

Restrictions for IPv6 logging

- IPv6 is supported. Syslog message can be sent using TCP or UDP.
- Ensure that the interface configured for sending syslogs is enabled, IPv6 capable, and the syslog server is reachable through the designated interface.
- You cannot use IPv6 for secure logging.

Syslog server configuration guidelines

- The syslog server must run a server program called syslogd. Windows includes a syslog server as part of its operating system.
- The syslog server operates based on the syslog-ng process of the firewall system. Do not use external configuration files, such as the *scwx.conf* file from SecureWorks. Because these files are not compatible with the device, using them causes parsing errors and the syslog-ng process fails.
- You can configure up to 16 syslog servers.
- Assign only one list or class to each syslog server and location.
- Do not configure Firewall Management Center as a primary syslog server. The Firewall Management Center can log some syslogs. However, it does not have adequate storage provision to accommodate large amounts of information from connection events for every sensor, especially when multiple sensors are used and all send syslogs.
- The syslog server should be reachable through the Firewall Threat Defense device. Configure the device to deny ICMP unreachable messages on the interface through which the syslog server is reachable, and to send syslogs to the same server. Enable logging for all severity levels. To prevent the syslog server from crashing, suppress the generation of syslogs 313001, 313004, and 313005.
- To view logs generated by the Firewall Threat Defense device, you must specify a logging output destination. If you enable logging without specifying a logging output destination, the Firewall Threat Defense device generates messages but does not save them to a location from which you can view them. You must specify each different logging output destination separately.
- The Firewall Threat Defense syslog supports one-way TLS for secure logging. It does not support client certificate authentication, trustpoint configuration for syslog, or mutual TLS (X.509 certificate authentication).

Interfaces for syslog configuration

- Determining the egress interface for the syslog:
  - If the specified management-only interface has management-access enabled, the management center will perform route table lookups and determine the egress interface (could be data or management) based on best routing logic.
  - If you configure a management-only interface as logging host, that does not have management-access enabled, the management center will use the interface regardless of routing table entries.

Thus, for the management center to always uses a dedicated management path for syslog traffic, configure the management interface without management-access, and then specify the interface in the logging host:

```
interface <management-interface>
management-only ----->Do not include management-access
logging host <management-interface> <syslog-server-ip>
```

- When the syslog rate exceeds 50,000 messages per second, ensure that a data interface is used as egress interface rather than a management interface.
- Configure the data interface as the syslog source interface for production monitoring and auditing. Use the management interface only for temporary testing. This approach ensures optimal syslog reliability and prevents rate-limiting on the management interface.

TCP and UDP connections for syslog

- If you use TCP as the transport protocol, the system opens 4 connections to the syslog server to ensure that messages are not lost. If you collect messages from many devices and the combined connection overhead is too much for the server, use UDP instead.
- The number of UDP connections for syslog is directly related to the number of CPUs on the hardware platform and the number of syslog servers you configure. At any point in time, there can be as many UDP syslog connections as there are CPUs times the number of configured syslog servers. The global UDP connection idle timeout applies to these sessions, and the default duration is two minutes. You can adjust this setting to close sessions more quickly, but the timeout applies to all UDP connections, not just syslog. This is the intended behavior.
- When the Firewall Threat Defense device sends syslogs via TCP, the connection takes about one minute to initiate after the syslogd service restarts.
- When the TCP logging host goes down, it takes approximately six minutes to change its connection status from *Connected* to *Not connected*. Logging relies on TCP to detect the channel state; until then, logging sends the logs through the channel. During this time, when you execute the **show log**, the output would display the TCP logging host as connected. Once the TCP channel is closed, the TCP logging host state is updated to *Not connected*.

Configure syslog logging for Firewall Threat Defense devices

This task enables you to configure syslog logging for Firewall Threat Defense devices, allowing you to monitor and manage system events efficiently.

Syslog logging helps track security events and system activity on your devices. If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages.

See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 896 for more information about platform settings that apply to security event syslog messages.

Before you begin

See requirements in Guidelines for logging, on page 894.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **Syslog** from the table of contents.

Step 3 Click **Logging Setup** to enable logging, specify FTP server settings, and specify Flash usage. For more information, see Configure logging and basic settings, on page 897.

Step 4 Click **Logging Destinations** to enable logging to specific destinations and to specify filtering on message severity level, event class, or on a custom event list. For more information, see Enable logging destinations, on page 898.

You must enable a logging destination to see messages at that destination.

Step 5 Click **E-mail Setup** to specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages. For more information, see Configure syslog messages to be sent to an e-mail address, on page 900.

Step 6 Click **Events List** to define a custom event list that includes an event class, a severity level, and an event ID. For more information, see Create a custom event list, on page 900.

Step 7 Click **Rate Limit** to specify the volume of messages being sent to all configured destinations and define the message severity level to which you want to assign rate limits. For more information, see Configure syslog rate limits, on page 902.

Step 8 Click **Syslog Settings** to specify the logging facility, enable the inclusion of a time stamp, and enable other settings to set up a server as a syslog destination. For more information, see Configure syslog settings, on page 903.

Step 9 Click **Syslog Servers** to specify the IP address, protocol used, format, and security zone for the syslog server that is designated as a logging destination. For more information, see Configure a syslog server, on page 904.

After you complete these steps, your Firewall Threat Defense device sends system events to the specified destinations for monitoring and analysis.

Firewall Threat Defense platform settings that apply to security event syslog messages

Security events include connection, Security Intelligence, intrusion, and file and malware events. Some syslog settings configured on the **Syslog** page and its tabs apply to syslog messages for security events. However, most settings only apply to messages for events related to system health and networking. This reference lists the settings that apply to syslog messages for security events.

Settings that apply to syslog messages for security events:

- **Logging Setup** tab:
  - **Send syslogs in EMBLEM format**
- **Syslog Settings** tab:
  - **Enable Timestamp on Syslog Messages**
  - **Timestamp Format**
  - **Enable Syslog Device ID**

- **Syslog Servers** tab:
  - All options on the **Add Syslog Server** form and the list of configured servers.

Configure logging and basic settings

Enable logging and configure syslog settings so the system generates and manages logs for data plane events. This setup ensures log data is archived and available for analysis or reporting.

Perform this task when you need to generate syslog messages for data plane events and manage log storage on your device. You can manipulate saved logging data. You can also specify actions for certain syslog messages, extract data for reporting, or track statistics using scripts.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 896.

Before you begin

- Determine where logs should be stored, such as an FTP server or flash memory.
- Understand the desired logging level (critical, alerts, emergencies, errors, etc)
- Identify if logging should be enabled on standby or failover units.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Logging Setup** in your device's configuration interface.

Step 3 Enable logging and configure basic logging settings.

- **Enable Logging**—Turns on the data plane system logging.
- **Enable Logging on the Failover Standby Unit**—Turns on logging for the standby device, if available.
- **Send syslogs in EMBLEM format**—Enables EMBLEM format logging for every logging destination. If you enable EMBLEM, you must use the UDP protocol to publish syslog messages. EMBLEM is not compatible with TCP.

  The EMBLEM syslog format is a Cisco-specific convention that is built upon the RFC 3164 and RFC 5424 standards. When EMBLEM is enabled, the syslog message prints a colon (:) after the <PRI> field, which differs from the RFC 5424 format.

Note Syslog messages in RFC5424 format, typically displays the priority value (PRI). However, in Firewall Management Center, if you want to display the PRI value in the syslog messages of the managed Firewall Threat Defense device, ensure to enable the EMBLEM format. Also, the device ID does not appear in EMBLEM-formatted syslog messages.

- **Send debug messages as syslogs**—Redirects debug trace output to the syslog. The syslog message number is 711001 and the default logging level is set to debug. To view these messages, ensure logging is enabled at the console and configured for the debug syslog message number and level.
- **Memory Size of Internal Buffer**—Specify the size of the internal buffer to which syslog messages are saved if the logging buffer is enabled. When the buffer fills up, it is overwritten. The default is 4096 bytes. The range is 4096 to 52428800 bytes.

Step 4 (Optional) Configure the syslog message logging to the Firewall Management Center.

a) Enable VPN logging by checking the **Enable Logging to Secure Firewall Management Center** check box.

b) Choose the syslog severity level for the logging messages in the **Logging Level** drop-down list.

- The logging level for the VPN messages is set to **errors** by default.

  VPN troubleshooting syslogs can add excessive load on the Firewall Management Center. Hence, enable this option with caution. Also, when you configure a device with site-to-site or remote access VPN, it automatically enables sending VPN syslogs to the management center by default. We recommend that you limit the logging level to **error** and above to restrict the excessive flow of syslogs to the Firewall Management Center, especially in case of RAVPN, where multiple devices are involved.

For information on the levels, see Syslog message severity levels, on page 889.

Step 5 (Optional) Save log buffer contents to an FTP server before the buffer is overwritten.

- Enable **FTP Server Buffer Wrap** and enter the necessary destination information in the following fields.
- **IP Address**—Select the host network object that contains the IP address of the FTP server.
- **User Name**—Enter the username to use when connecting to the FTP server.
- **Path**—Enter the path, relative to the FTP root, where the buffer contents should be saved.
- **Password/ Confirm**—Enter and confirm the password used to authenticate the username to the FTP server.

Step 6 (Optional) Save log buffer contents to flash memory before overwriting.

- Check the **Flash** checkbox
- Specify **Maximum flash to be used by logging (KB)** (range: 4-8044176 KB).
- Specify **Minimum free space to be preserved (KB)** (range: 0-8044176 kilobytes.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Logging is enabled and syslog messages are generated and stored based on your configuration. Log data is archived as specified and is accessible for further analysis or reporting.

Enable logging destinations

Enable logging destinations to ensure that syslog messages are received at the specified destination. This task allows you to control which messages are sent by applying message filters to each destination.

To see messages at a logging destination, enable the destination and specify a message filter.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 896.

Before you begin

Before you begin, ensure you have access to the system and the necessary permissions to configure logging destinations.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Logging Destinations**.

Step 3 Click **Add** to enable a destination and apply a logging filter, or edit an existing destination.

Step 4 In the **Logging Destinations** dialog box, select a destination and configure the filter for that destination:

a) Choose the destination to enable in the **Logging Destination** drop-down list. You can create one filter for each destination. Examples include Console, E-Mail, Internal buffer, SNMP trap, SSH Sessions, and Syslog servers.

Note Console and SSH session logging works in the diagnostic CLI only. Enter **system support diagnostic-CLI**.

b) In **Event Class**, choose the filter that will apply to all classes not listed in the table.

You can configure these filters:

- **Filter on severity** —Select the severity level. Messages at this level or higher are sent to the destination
- **Use Event List** —Select the event list that defines the filter. You create these lists on the **Event Lists** page.
- **Disable Logging** —Prevents messages from being sent to this destination.

c) To create filters for each event class, click **Add** for a new filter or edit an existing filter. Select the event class and severity level to limit messages in that class. Click **OK** to save the filter.

For an explanation of the event classes, see Syslog message classes and associated message ID numbers, on page 891.

d) Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, the selected logging destinations will receive syslog messages according to the filters you have configured.

Configure syslog messages to be sent to an e-mail address

Enable syslog messages to be delivered as e-mails to designated recipients so administrators receive important system notifications directly through e-mail.

You can set up a list of recipients for syslog messages to be sent as e-mails.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 896.

Before you begin

- Configure an SMTP server on the platform settings page
- Configure logging and basic settings, on page 897
- Setup Email as the Logging Destination

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Email Setup**.

Step 3 Specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages.

Step 4 Click **Add** to enter a new e-mail address recipient of the specified syslog messages.

Step 5 Set the desired severity level for syslog messages for each recipient.

The severity filter ensures only messages of the specified level and higher are sent via e-mail. For information on the levels, see Syslog message severity levels, on page 889.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Syslog messages are sent as e-mails to the specified recipients according to the configured severity level.

Create a custom event list

Create a custom event list to control which syslog messages are sent to a logging destination. This allows you to filter messages based on event class, severity, and message identifier for more granular control.

An event list is a custom filter you can apply to a logging destination, allowing greater control over which messages are sent. Normally, you filter messages for a destination based solely on severity. Using an event list, you can fine-tune filters using event class, severity, and message ID.

Creating a custom event list is a two-step process. You create a custom list in the **Event Lists**, and then use the event list to define the logging filter for the various types of destination, in the **Logging Destinations**.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 896.

Before you begin

Ensure you have access to the system where syslog event lists can be configured.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Events List**.

Step 3 Click **Add** to create a new list or click an existing list to edit.

a) Enter a unique name for the event list in the **Name** field; avoid spaces.

b) Set criteria to filter messages by severity or event class, select the **Severity/Event Class** tab and add or edit entries.

For information on the available classes see Syslog message classes and associated message ID numbers, on page 891.

For information on the levels, see Syslog message severity levels, on page 889.

Certain event classes do not apply to devices in transparent mode. If you configure these options, the system does not use or deploy them.

c) To identify messages specifically by message ID, select the **Message ID** and add or edit the IDs.

You can enter a range of IDs using a hyphen, for example, 100000-200000. Each message ID you enter must contain six digits. For information on how the initial three digits map to features, see Syslog message classes and associated message ID numbers, on page 891.

For specific message numbers, see Cisco ASA Series Syslog Messages.

d) Click **OK** to save the event list.

Step 4 Click **Logging Destinations** and add or edit the destination that should use the custom event list filter.

See Enable logging destinations, on page 898.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

The system creates the custom event list and applies it to the logging destination you select.

Configure syslog rate limits

Limit the rate at which syslog messages are generated, reducing log flooding and ensuring that important messages are not lost.

Syslog message generation can overwhelm logging systems if not managed properly. Configure rate limits for severity levels or specific message IDs to ensure efficient log management. When limits set for severity level and message ID conflict, the message ID limit takes precedence.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 896.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Rate Limit**.

Step 3 To limit message generation by severity level, click **Logging Level** > **Add**, then configure these options:

- **Logging Level**—Specify the severity level for the rate limit. For information on the levels, see Syslog message severity levels, on page 889.
- **Number of messages**—The maximum number of messages of the specified type allowed in the specified time period.
- **Interval**—The number of seconds before the rate limit counter resets.

Step 4 Click **OK**.

Step 5 To limit message generation by syslog message ID, click **Syslog Level** > **Add**, then configure these options:

- **Syslog ID**—Specify the syslog message ID to be rate limited. For specific message numbers, see Cisco ASA Series Syslog Messages.
- **Number of messages**—Enter the maximum number of messages allowed in the specified interval.
- **Interval**—Set the interval (in seconds) for the rate limit counter to reset.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Syslog message generation is limited based on configured severity levels or message IDs, preventing excessive log messages and supporting efficient log management.

Configure syslog settings

Configure syslog settings to manage how syslog messages are generated and sent to external syslog servers. You can specify the facility code, timestamp, device ID, and control message severity and suppression.

General syslog settings let you choose what information is included in syslog messages sent to syslog servers. This information includes the facility code, timestamp, device ID, severity levels, and message suppression. If you configure devices to send syslog messages about security events (such as connection and intrusion events), some settings do not apply to messages that relate to security events. See *Threat Defense Platform Settings That Apply to Security Event Syslog Messages* in the *Cisco Secure Firewall Management Center Administration Guide*.

Before you begin

Make sure you have access to the device and the permissions needed to change syslog settings.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Syslog Settings**.

Step 3 Choose a system log facility from the **Facility** list as required by your syslog server.

Most UNIX systems use the default LOCAL4(20). Change the facility if your network devices use the same codes. In most cases, you do not need to set the facility value for security event logs.

Step 4 Select the **Enable timestamp on each syslog message** check box to include the date and time a message was generated in the syslog message.

Step 5 Select the desired **Timestamp Format**:

- **Legacy (MMM dd yyyy HH:mm:ss)**: Default format without a timezone (always UTC).
- **RFC 5424 (yyyy-MM-ddTHH:mm:ssZ)**: Uses ISO 8601 with "Z" indicating UTC.

Step 6 To add a device identifier at the start of messages, check the **Enable Syslog Device ID** check box and select the identifier type:

- **Interface**—Use the IP address of a specific interface.

Note VTI tunnel interfaces are not supported for Syslog.

- **User Defined ID**—Enter a custom text string (up to 16 characters).
- **Host Name**—Use the device's hostname.

Step 7 Use the Syslog Message table to adjust severity or suppress messages:

Change a message's severity level or disable its generation if necessary. By default, syslog entries for NetFlow are enabled and appear in the table.

a) To suppress redundant messages due to NetFlow, select **Netflow Equivalent Syslogs**.

This adds the messages to the table as suppressed messages.

Note If any of these syslog equivalents are already in the table, your existing rules are not overwritten.

b) To add a rule, click **Add**.
c) Select the message number (Syslog ID) to change, from the **Syslog ID** drop-down list.
d) Choose the new severity level from the **Logging Level** drop-down list or select **Suppressed** to disable the generation of the message. Usually, you do not change both the severity level and disable the message. However, you can modify both fields if you want.
e) Click **OK** to add the rule to the table.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure a syslog server

This task enables you to configure a syslog server for your device, allowing you to collect and monitor system-generated messages for security and operational visibility.

To configure a syslog server to handle messages generated from your system, perform this task.

If you want this syslog server to receive security events such as connection and intrusion events, see also Firewall Threat Defense platform settings that apply to security event syslog messages , on page 896.

Note In version 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, you must use separate Platform Settings policies for merged and unmerged devices. This requirement also applies to version 7.3 and earlier, and to some Firewall Threat Defense devices upgraded to version 7.4.

Before you begin

- See requirements in Guidelines for logging, on page 894.
- Make sure your devices can reach your syslog collector on the network.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Syslog Server**.

Step 3 Check the **Allow user traffic to pass when TCP syslog server is down (Recommended)** check box, to allow traffic if any syslog server that is using the TCP protocol is down.

Note

- This option is enabled by default. Unless required, we recommend that you allow connections through the threat defense device when the external TCP syslog server is unreachable by the device.
- When the **Allow user traffic to pass when TCP syslog server is down** option is disabled in Firewall Management Center version 6.2.x or earlier, it remains in the Disabled state even after upgrading to version 6.3 or later. You must manually enable this option.
- If this option is disabled and more than one TCP syslog server is configured on the device, user traffic is allowed if at least one server is reachable by thethreat defense device. This option only blocks traffic when none of the configured TCP syslog servers are reachable. The device generates a syslog message that describes the root cause of denied traffic.

  ```
  %FTD-3-414003: TCP Syslog Server intf : IP_Address /port not responding. New connections
  are denied based on logging permit-hostdown policy
  ```

Step 4 In the **Message queue size (messages)** field, enter the queue size for storing syslog messages on the security appliance when the syslog server is busy. The minimum is 1 message. The default is 512. Specify 0 to allow an unlimited number of messages to be queued (subject to available block memory).

If the number of messages exceeds the configured queue size, the excess messages are dropped, resulting in missing syslog entries. To determine the ideal queue size, you need to identify the available block memory. Use the **show blocks** command to know the current memory utilization. For more information on the command and its attributes, see *Cisco Secure Firewall ASA Series Command Reference Guide*. Contact Cisco TAC for assistance.

Step 5 Click **Add** to add a new syslog server.

a) In the **IP Address** drop-down list, select a network host object containing the IP address of the syslog server.

b) Choose the protocol, either TCP or UDP, and enter the port number used for communication between the Firewall Threat Defense device and the syslog server.

UDP is faster and uses fewer resources than TCP on the device.

The default port for UDP is 514. You must manually configure port 1470 for TCP. Valid non-default port values for either protocol are 1025 through 65535.

c) Check the **Log messages in Cisco EMBLEM format (UDP only)** check box to specify whether to log messages in Cisco EMBLEM format (available only if UDP is selected as the protocol).

The EMBLEM syslog format is a Cisco-specific convention that is built upon the RFC 3164 and RFC 5424 standards. Hence, when EMBLEM is enabled, the syslog message prints colon (:) after <PRI> field.

Note Syslog messages in RFC5424 format typically displays the priority value, referred to as PRI. However, in Firewall Management Center, only when you enable logging in Cisco EMBLEM format, the PRI value in the syslog messages of the managed Firewall Threat Defense is displayed. Also, the device ID does not appear in EMBLEM-formatted syslog messages.

d) Check the **Enable Secure Syslog** check box to encrypt the connection between the device and server using SSL or TLS over TCP.

Note You must select TCP as the protocol and its port value ranging between 1025 and 65535 to use this option. Upload the certificate required to communicate with the syslog server on the **Devices** > **Certificates** page. Then, upload the certificate from the Firewall Threat Defense device to the syslog server to complete the secure relationship and allow it to decrypt the traffic. The **Enable Secure Syslog** option is not supported on the device Management interface.

e) Select **Device Management Interface** or **Security Zones or Named Interfaces** to communicate with the syslog server.

- **Device Management Interface**: Send syslogs out of the Management interface. We recommend that you use this option when configuring syslog on Snort events.

Note The **Device Management Interface** option does not support the **Enable Secure Syslog** option.

- **Security Zones or Named Interfaces**: Select the interfaces from the list of **Available Zones** and click **Add**. You can also add virtual-router-aware interfaces.

Important The Firewall Threat Defense data plane (Lina) syslog messages cannot be sent out through the diagnostic interface. Configure other interfaces or the Management interface (Br1/Management0) to send out the data plane syslog messages.

f) Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure timeouts

Configure timeout values for console sessions and protocol connections in a Threat Defense policy to manage session durations and optimize device resource usage.

You can set the global idle timeout durations for the connection and translation slots of various protocols. If the slot has not been used for the idle time specified, the resource is returned to the free pool.

You can also set a timeout for console sessions on the device.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Timeouts**.

Step 3 Configure the timeouts you want to change.

For any setting, select **Custom** to specify your own value or **Default** to use the system default value. In most cases, the maximum timeout is 1193 hours.

You can disable some timeouts by selecting **Disable**.

- **Console Timeout**—The idle time until a connection to the console is closed, range is 0 or 5 to 1440 minutes. The default is 0, which means the session does not time out. If you change the value, existing console sessions will continue to use the previous timeout value. The updated timeout will apply only to new connections.
- **Translation Slot (xlate)**—The idle time until a NAT translation slot is freed. This duration must be at least 1 minute. The default is 3 hours.
- **Connection (Conn)**—The idle time until a connection slot is freed. This duration must be at least 5 minutes. The default is 1 hour.
- **Half-Closed**—The idle time until a TCP half-closed connection closes. A connection is considered half-closed if both the FIN and FIN-ACK have been seen. If only the FIN has been seen, the regular connection timeout applies. The minimum is 30 seconds. The default is 10 minutes.
- **UDP**—The idle time until a UDP connection closes. This duration must be at least 1 minute. The default is 2 minutes.
- **ICMP**—The idle time after which general ICMP states are closed. The default (and minimum) is 2 seconds.
- **RPC/Sun RPC**—The idle time until a SunRPC slot is freed. This duration must be at least 1 minute. The default is 10 minutes.

  In a Sun RPC-based connection, if the parent connection is deleted or times out, a new child connection might not be treated as part of the parent–child relationship. As a result, the new connection could be evaluated according to the system's policy or rules. After the parent connection times out, existing child connections remain valid only until their own timeout value is reached.
- **H.225**—The idle time until an H.225 signaling connection closes. The default is 1 hour. To close a connection immediately after all calls are cleared, a timeout of 1 second (0:0:1) is recommended.
- **H.323**—The idle time after which H.245 (TCP) and H.323 (UDP) media connections close. The default (and minimum) is 5 minutes. Because the same connection flag is set on both H.245 and H.323 media connections, the H.245 (TCP) connection shares the idle timeout with the H.323 (RTP and RTCP) media connection.
- **SIP**—The idle time until a SIP signaling port connection closes. This duration must be at least 5 minutes. The default is 30 minutes.

- **SIP Media**—The idle time until a SIP media port connection closes. This duration must be at least 1 minute. The default is 2 minutes. The SIP media timer is used for SIP RTP/RTCP with SIP UDP media packets, instead of the UDP inactivity timeout.
- **SIP Disconnect**—The idle time after which SIP session is deleted if the 200 OK is not received for a CANCEL or a BYE message, between 0:0:1 and 0:10:0. The default is 2 minutes (0:2:0).
- **SIP Invite**—The idle time after which pinholes for PROVISIONAL responses and media xlates will be closed, between 0:1:0 and 00:30:0. The default is 3 minutes (0:3:0).
- **SIP Provisional Media**—The timeout value for SIP provisional media connections, between 1 and 30 minutes. The default is 2 minutes.
- **Floating Connection**—When multiple routes exist to a network with different metrics, the system uses the one with the best metric at the time of connection creation. If a better route becomes available, then this timeout lets connections be closed so a connection can be reestablished to use the better route. The default is 0 (the connection never times out). To make it possible to use better routes, set the timeout to a value between 0:0:30 and 1193:0:0. This timer does not apply to connections through virtual tunnel interfaces (VTI). If a connection through a VTI gets stuck, you must manually clear it.
- **Xlate PAT**—The idle time until a PAT translation slot is freed, between 0:0:30 and 0:5:0. The default is 30 seconds. You may want to increase the timeout if upstream routers reject new connections using a freed PAT port because the previous connection might still be open on the upstream device.
- **TCP Proxy Reassembly**—The idle timeout after which buffered packets waiting for reassembly are dropped, between 0:0:10 and 1193:0:0. The default is 1 minute (0:1:0).
- **ARP Timeout**—The number of seconds between ARP table rebuilds, from 60 to 4294967. The default is 14,400 seconds (4 hours).

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

The configured timeout values are applied to the Threat Defense policy. Sessions and protocol connections will now use the specified timeout durations after you deploy the policy.

Synchronize time on FTD devices

Use a Network Time Protocol (NTP) server to synchronize the clock settings on your devices. We recommend you configure all Firewall Threat Defenses managed by a Firewall Management Center to use the same NTP server as the Firewall Management Center. Depending on the platform and configuration, the Firewall Threat Defense synchronizes either directly with the configured NTP server or through Firewall Management Center. If the Firewall Threat Defense's configured NTP servers are not reachable for any reason, it synchronizes its time with the Firewall Management Center.

The device supports NTPv4.

Note If you are deploying Firewall Threat Defense on the Firepower 4100/9300 chassis, you must configure NTP on the Firepower 4100/9300 chassis so that Smart Licensing will work properly and to ensure proper timestamps on device registrations. You should use the same NTP server for the Firepower 4100/9300 chassis and the Firewall Management Center.

Before you begin

- If your organization has one or more NTP servers that your Firewall Threat Defense can reach, use the same NTP server or servers for your devices that you have configured for Time Synchronization on the **System** (⚙) > **Configuration** page on your Firewall Management Center.
- If you selected **Use the authenticated NTP server only** when configuring NTP server or servers for the Firewall Management Center, for your devices use only the NTP server or servers that are configured to authenticate with the Firewall Management Center. (The managed devices will use the same NTP servers as the Firewall Management Center, but their NTP connections will not use authentication.)
- If your device cannot reach an NTP server or your organization does not have one, use the **Via NTP FROM Management Center** option as discussed in this procedure.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Time Synchronization**.

Step 3 Configure one of these clock options:

- **Via NTP FROM Management Center**: (Default). The managed device gets time FROM the NTP servers you configured for the Firewall Management Center (except for authenticated NTP servers) and synchronizes time with those servers directly. However, if any of these are true, the managed device synchronizes time FROM the Firewall Management Center:
  - The Firewall Management Center's NTP servers are not reachable by the device.
  - The Firewall Management Center has no unauthenticated servers.

Note NTP synchronization behavior and NTP status output can differ between Firewall Threat Defense Virtual devices and Secure Firewall 3100 appliances when the devices are configured to synchronize time through Firewall Management Center.

- Firewall Threat Defense Virtual devices synchronize directly with the NTP servers configured on Firewall Management Center. If the configured NTP servers become unreachable, the device uses Firewall Management Center as the fallback NTP source.
- Secure Firewall 3100 appliances synchronize with Firewall Management Center instead of directly synchronizing with the external NTP servers configured on Firewall Management Center. In NTP status output, Firewall Management Center can appear as 127.0.0.2.
- On Secure Firewall 3100 appliances, the **ntpq -pn** command can display 127.0.0.2 as the active NTP source, indicating synchronization with Firewall Management Center rather than with external NTP servers.

Example:

```
# ntpq -pn
remote           refid      st t when poll reach   delay   offset   jitter
==============================================================================
127.0.0.2       .FMC.      16 u   10   64   377    0.123    0.045    0.010
```

When you configure Secure Firewall 3100 appliances to synchronize directly with NTP servers instead of synchronizing through Firewall Management Center, and the configured NTP servers become unreachable, the appliance falls back to its local system clock. In this case, the appliance does not use Firewall Management Center as the fallback NTP source.

Consider these platform-specific differences when interpreting show **ntp** and **ntpq -pn** output during NTP validation and troubleshooting.

- **Via NTP FROM**: If your Firewall Management Center is using NTP servers on the network, select this option and enter the fully-qualified DNS name (such as NTP.example.com), or IPv4 or IPv6 address, of the same NTP servers you specified in **System** (⚙) > **Configuration** > **Time Synchronization**. If the NTP servers are not reachable, the Firewall Management Center acts as an NTP server.

When multiple NTP servers are configured, the device uses the NTP server that is deemed appropriate based on the criteria defined in RFC. Thus, the status "Being used" for a specific NTP server indicates that the server is currently used by the device.

Step 4 Click **Save**.

After completing these steps, the Firewall Threat Defense Virtual device synchronizes its clock with the configured NTP server, Management Center, or the local system clock, depending on platform behavior and configuration.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure a time zone for a device

By default, your device uses the UTC time zone. To set a different time zone for the device, use this procedure.

The time zone you specify is used only in policies that use time-based policy application.

Procedure

Step 1 Select **Devices** > **Platform Settings** and create or edit a Firewall Threat Defense policy.

You can also create time zone objects from the **Objects** > **Object Management** > **Time Zone** page.

Step 2 Create a new time zone object by clicking +.

Step 3 Select the time zone.

Step 4 Click **Save**.

What to do next

- Create time range objects, select applicable time ranges in access control and prefilter rules, and assign the parent policies to devices associated with the correct time zone.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure UCAPL/CC compliance

Configure Unified Capabilities Approved Products List (UCAPL) or Common Criteria (CC) compliance to ensure your Secure Firewall Threat Defense device meets security certifications and export-controlled feature requirements.

Use this task when you need to enable security certifications compliance for your device. This is required for export-controlled features and may be necessary for regulatory or organizational compliance.

For more information about this setting and how to enable it for the Firewall Management Center, see the *Cisco Secure Firewall Management Center Administration Guide*.

Caution After you enable this setting, disabling it is not possible. To return the appliance to standard mode, reimage the appliance.

Before you begin

- Secure Firewall Threat Defense devices cannot use an evaluation license; your Smart Software Manager account must be enabled for export-controlled features.
- Secure Firewall Threat Defense devices must be deployed in routed mode.
- You must have administrative privileges to perform this task.

- Security certifications compliance mode cannot be changed if the Firewall Threat Defense device is in high availability. Change the security certifications compliance mode before you create the high availability pair.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **UCAPL/CC Compliance**.

Step 3 To *permanently* enable security certifications compliance on the appliance, you have two choices:

- To enable security certifications compliance in Common Criteria mode, choose **CC** from the drop-down list.
- To enable security certifications compliance in Unified Capabilities Approved Products List (UCAPL) mode, choose **UCAPL** from the drop-down list.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing these steps, your device operates in the selected compliance mode (UCAPL or CC), and the policy is enforced once deployed.

Configure a performance profile

Configure the performance profile to control how CPU cores are allocated between the data plane and Snort processes on supported devices. This configuration optimizes device performance for VPN, improves intrusion prevention, or balances the workload.

The performance profile determines how the CPU cores on the device are assigned to two of the main system processes: the data plane (Lina) and Snort. The data plane handles VPN connections, routing, and basic layer 3/4 processing. Snort provides advanced inspection for intrusion and malware prevention, URL filtering, application filtering, and other deep packet inspection features.

If you use both basic and advanced features, keep the performance profile unchanged. The system is designed to provide a balanced assignment of cores to these processes. This assignment differs based on the hardware model.

However, if you use the device primarily for VPN, or for intrusion and other advanced inspection, you can skew the performance profile so that more cores are assigned to the more heavily used features. This change can improve system performance.

Before you begin

- These settings apply to systems running release 7.3+ only.
- Performance profile is supported on these device types:
  - Firepower 4100/9300

- Secure Firewall 3100/4200 (7.4+)
- Secure Firewall Threat Defense Virtual

- Changing the performance profile is not supported on units in a cluster or high-availability group, or those configured for multi-instance.
- The minimum number for core allocation is 2. Cores are assigned in even numbers based on the selected performance profile.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Performance Profile**.

Step 3 Select a profile:

- **Default**—This is the recommended setting and is the best option if you configure both VPN and intrusion inspection.
- **VPN Heavy with prefilter fastpath**—If you primarily use the device as a VPN endpoint or headend, and you configure rules in the prefilter policy to fastpath VPN traffic, you can choose this option to assign the majority of CPU cores to the data plane. The allocation is 90% data plane, 10% Snort.
- **VPN Heavy with inspection**—If you primarily use the device as a VPN endpoint or headend, but do not use the prefilter policy to fastpath VPN traffic, you can choose this option to assign the majority of CPU cores to the data plane. This option assumes that you leave intrusion inspection, URL filtering, and other advanced functions that use Snort, to a different device in the network. The allocation is 60% data plane, 40% Snort.
- **IPS Heavy**—If you do not configure VPN, but you do use the device for intrusion prevention, you can choose this option to assign the majority of CPU core to the Snort process. The allocation is 30% data plane, 70% Snort.

Step 4 Click **Save**.

Step 5 Deploy the policy to apply your configuration.

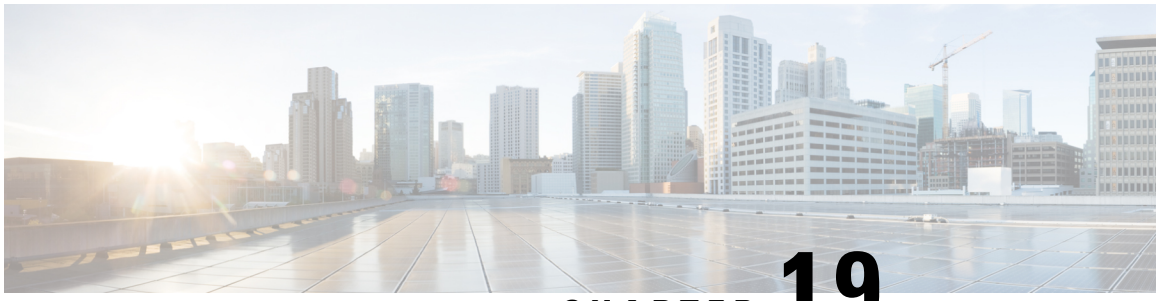
Step 6 After deployment completes, reboot each affected device to apply the new core assignments.

After completing these steps, the device will use the selected performance profile and allocate CPU cores according to your configuration. The new core assignments take effect after you reboot the device.

History for platform settings

This reference provides a historical overview of feature additions, changes, and removals for platform settings in Secure Firewall releases. Use this information to track platform settings support and modifications across software versions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Device management services supported on user-defined VRF interfaces.	7.4.1	7.4.1	Device management services configured in the Firewall Threat Defense platform settings (NetFlow, SSH access, SNMP hosts, syslog servers) are now supported on user-defined Virtual Routing and Forwarding (VRF) interfaces. Platform restrictions: Not supported with container instances or clustered devices.
Chassis platform settings for the Secure Firewall 3100.	7.4.1	7.4.1	New platform settings for multi-instance chassis on the Secure Firewall 3100. New/modified screens: • **Devices** > **Platform Settings** > **Add** > **Chassis Platform Settings** • **Devices** > **Platform Settings** > **Edit** > **Chassis Platform Settings** > **DNS** • **Devices** > **Platform Settings** > **Edit** > **Chassis Platform Settings** > **SSH** • **Devices** > **Platform Settings** > **Edit** > **Chassis Platform Settings** > **Time Synchronization** • **Devices** > **Platform Settings** > **Edit** > **Chassis Platform Settings** > **Time Zones** • **Devices** > **Platform Settings** > **Edit** > **Chassis Platform Settings** > **Syslog** Supported platforms: Secure Firewall 3100
Performance profile support for the Secure Firewall 3100/4200.	7.4.0	7.4.0	The performance profile settings available in the platform settings policy now apply to Secure Firewall 3100/4200 devices.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Loopback interface support for DNS, HTTP, ICMP, NetFlow, SNMP and SSH.	7.4.0	7.4.0	You can create a loopback interface and use it for: • DNS • HTTP • ICMP • NetFlow • SNMP • SSH New/modified screens: • **Devices** > **Platform Settings** > **DNS** > **DNS Settings** **Devices** > **Platform Settings** > **HTTP Access** > **Add** **Devices** > **Platform Settings** > **ICMP Access** > **Add** • **Devices** > **Platform Settings** > **Network flow** > **Add Collector** • **Devices** > **Platform Settings** > **SNMP** > **Hosts** > **Add** • **Devices** > **Platform Settings** > **SSH Access** > **Add**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Merged Management and Diagnostic interfaces.	7.4.0	7.4.0	For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available. If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically. If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Note that support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. Merged mode also changes the behavior of AAA traffic to use the data routing table by default. The management-only routing table can now only be used if you specify the management-only interface (including Management) in the configuration. For platform settings, this means: • You can no longer enable HTTP, ICMP, or SMTP for Diagnostic. • For SNMP, you can allow hosts on Management instead of Diagnostic. • For Syslog servers, you can reach them on Management instead of Diagnostic. • If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices. • DNS lookups no longer fall back to the management-only routing table if you do not specify interfaces. New/modified screens: • **Devices** > **Device Management** > **Interfaces** New/modified commands: **show management-interface convergence**
Performance profile for CPU core allocation.	7.3.0	7.3.0	You can adjust the percentage of system cores assigned to the data plane and Snort to adjust system performance. The adjustment is based on your relative use of VPN and intrusion policies. If you use both, leave the core allocation to the default values. If you use the system primarily for VPN (without applying intrusion policies), or as an IPS (with no VPN configuration), you can skew the core allocation to the data plane (for VPN) or Snort (for intrusion inspection). We added the **Performance Profile** page to the platform settings policy.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
TLS 1.3 in Remote Access VPN.	7.3.0	7.3.0	You can now use TLS 1.3 to encrypt remote access VPN connections. Use threat defense platform settings to specify that the device must use TLS 1.3 protocol when acting as a remote access VPN server. TLS 1.3 adds support for the following ciphers: • TLS_AES_128_GCM_SHA256 • TLS_CHACHA20_POLY1305_SHA256 • TLS_AES_256_GCM_SHA384 This feature requires Cisco Secure Client, Version 5.0 and above. New/modified screens: **Devices** > **Platform Settings** > **New Policy** > **Add/Edit Threat Defense Settings** > **SSL** > **TLS version**
Multiple DNS server groups for resolving DNS requests.	7.2.0	7.2.0	You can configure multiple DNS groups for the resolution of DNS requests from client systems. You can use these DNS server groups to resolve requests for different DNS domains. For example, you could have a catch-all default group that uses public DNS servers, for use with connections to the Internet. You could then configure a separate group to use internal DNS servers for internal traffic, for example, any connection to a machine in the example.com domain. Thus, connections to an FQDN using your organization's domain name would be resolved using your internal DNS servers, whereas connections to public servers use external DNS servers. We changed the **Platform Settings** > **DNS** page.
Network object support for HTTP, ICMP, and SSH platform settings.	7.1.0	7.1.0	You can now use network object groups that contain network objects for hosts or networks when configuring the IP addresses in the Threat Defense Platform Settings policy.
Support to specify trusted DNS servers.	7.1.0	7.1.0	The option to specify DNS servers that you can trust for address resolution while using direct internet access was introduced. We added a tab for configuring the trusted DNS servers when configuring direct internet access: **Devices** > **Platform Settings** > **DNS** > **Trusted DNS Servers**.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Platform settings using the MD5 authentication algorithm or DES encryption for SNMPv3 users can not be deployed to Firewall Threat Defense devices running Versions 7.0+.	7.0.0	7.0.0	The MD5 authentication algorithm and DES encryption for SNMPv3 users on Firewall Threat Defense were deprecated in Version 6.5. If your deployment includes SNMPv3 users using the MD5 authentication algorithm or DES encryption that were created using Version 6.4 or earlier, you can continue to use those users for Firewall Threat Defense devices running Version 6.7 or earlier. However, you cannot edit those users and retain the MD5 or DES settings, and you cannot create new users with the MD5 or DES settings. If your Firewall Management Center manages any Firewall Threat Defenses running Versions 7.0+, deploying a platform settings policy with SNMP v3 users using the MD5 authentication algorithm or DES encryption to those Firewall Threat Defenses will fail. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Hosts**
Specify SHA224 or SHA384 for SNMPv3 users' authorization algorithm.	7.0.0	7.0.0	You can now select SHA224 or SHA384 for SNMPv3 users' authorization algorithm. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Users**
Specify time zone for device.	6.6.0	6.6.0	Specify a local time zone for a managed device, for use in time-based policy application. New/modified screens: **Devices** > **Platform Settings** > **Time Zone**
Specify the Management interface for SNMP communication.	6.6.0	6.6.0	You can now select the Management interface for communication between the device and the SNMP management station. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Hosts**
Specify SHA256 for SNMPv3 users' authorization algorithm.	6.6.0	6.6.0	You can now select SHA256 for SNMPv3 users' authorization algorithm. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Users**
DES encryption and the MD5 authentication algorithm for SNMPv3 users on Firewall Threat Defense have been deprecated.	6.5.0	Any	We recommend that you not use the MD5 authentication algorithm or DES encryption for SNMPv3 users on Firewall Threat Defense devices, as these options have been deprecated. If your deployment includes SNMPv3 users using the MD5 authentication algorithm or DES encryption that were created using a Version 6.4 or earlier, you can continue to use those users. However, you cannot edit those users and retain the MD5 or DES settings, and you cannot create new users with the MD5 or DES settings. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Users**
Allow user traffic to pass when TCP syslog server is down.	6.3.0	6.3.0	We recommend that you allow connections through the threat defense device when the external TCP syslog server is unreachable by the device. The **Allow user traffic to pass when TCP syslog server is down (Recommended to be enabled)** option in the Platform Settings is Enabled by default.
Limit number of SSH login failures.	6.3.0	6.3.0	When a user accesses any device via SSH and fails three successive login attempts, the device terminates the SSH session.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
External authentication added for SSH.	6.2.3	6.2.3	You can now configure external authentication for SSH access to the Firewall Threat Defense using LDAP or RADIUS. New/modified screens: **Devices** > **Platform Settings** > **External Authentication**
Support for UC/APPL compliance mode.	6.2.1	6.2.1	You can enable security certifications compliance in CC mode or UCAPL mode. Enabling security certifications compliance does not guarantee strict compliance with all requirements of the security mode selected. For more information on hardening procedures, refer to the guidelines for this product provided by the certifying entity. New/modified screens: **Devices** > **Platform Settings** > **UC/APPL Compliance**
SSL settings for remote access VPN.	6.2.1	6.2.1	The Firewall Threat Defense device uses the Secure Sockets Layer (SSL) protocol and Transport Layer Security (TLS) to support secure message transmission for Remote Access VPN connection from remote clients. You can configure SSL versions and encryption algorithms that will be negotiated and used for message transmission during remote VPN access over SSL. New/modified screens: **Devices** > **Platform Settings** > **SSL**
External authentication for SSH and HTML removed.	6.1.0	6.1.0	Due to changes to support converged management access, only local users are supported for SSH and HTML to data interfaces. Also, you can no longer SSH to the logical Diagnostic interface; instead you can SSH to the logical Management interface (which shares the same physical port). Previously, only external authentication was supported for SSH and HTML access to Diagnostic and data interfaces, while only local users were supported to the Management interface. New/modified screens: **Devices** > **Platform Settings** > **External Authentication**
Firepower Threat Defense support.	6.0.1	6.0.1	This feature was introduced. New/modified screens: **Devices** > **Platform Settings**

CHAPTER 19

FlexConfig policies

These topics describe how to configure and deploy FlexConfig policies.

- FlexConfig policy overview, on page 921
- Requirements and prerequisites for FlexConfig policies, on page 942
- Guidelines and limitations for FlexConfig, on page 943
- Customize device configuration with FlexConfig policies, on page 943
- Examples for FlexConfig, on page 958
- Migrate FlexConfig policies, on page 964
- History for FlexConfig, on page 966

FlexConfig policy overview

A FlexConfig policy is a container of an ordered list of FlexConfig objects that

- includes a series of Apache Velocity scripting language commands, ASA software configuration commands, and variables that you define
- contains FlexConfig objects that are essentially programs that generate a sequence of ASA commands that will then be deployed to the assigned devices, and
- configures the related feature on the Firewall Threat Defense device.

FlexConfig policy usage and limitations

Firewall Threat Defense uses ASA configuration commands to implement some features, but not all features. There is no unique set of Firewall Threat Defense configuration commands. Instead, the point of FlexConfig is to allow you to configure features that are not yet directly supported through Firewall Management Center policies and settings.

Caution We recommend using FlexConfig policies only if you are an advanced user with a strong ASA background and at your own risk. You may configure any commands that are not prohibited. Enabling features through FlexConfig policies may cause unintended results with other configured features.

Contact the Cisco Technical Assistance Center for support concerning FlexConfig policies that you have configured. The Cisco Technical Assistance Center does not design or write custom configurations on any customer's behalf. Cisco expresses no guarantees for correct operation or interoperability with other features. FlexConfig features may become deprecated at any time. For fully guaranteed feature support, you must wait for the Firewall Management Center support. When in doubt, do not use FlexConfig policies.

Recommended usage for FlexConfig policies

Use FlexConfig policies in two main scenarios to ensure proper firewall configuration and functionality.

- You are converting from ASA to Firewall Threat Defense, and there are compatible features you are using (and need to continue using) that Firewall Management Center does not directly support. In this case, use the **show running-config** command on the ASA to see the configuration for the feature and create your FlexConfig objects to implement it. Experiment with the object's deployment settings (once/every time and append/prepend) to get the right setting. Verify by comparing **show running-config** output on the two devices.
- You are using Firewall Threat Defense but there is a setting or feature that you need to configure, e.g. the Cisco Technical Assistance Center tells you that a particular setting should resolve a specific problem you are encountering. For complicated features, use a lab device to test the FlexConfig and verify that you are getting the expected behavior.

The system includes a set of predefined FlexConfig objects that represent tested configurations. If the feature you need is not represented by these objects, first determine if you can configure an equivalent feature in standard policies. For example, the access control policy includes intrusion detection and prevention, HTTP and other types of protocol inspection, URL filtering, application filtering, and access control. The ASA implements these functions using separate features. Many features are not configured using CLI commands, so not every policy appears in the output of the **show running-config** command.

Note At all times, keep in mind that there is not a one-to-one overlap between ASA and Firewall Threat Defense. Do not attempt to completely recreate an ASA configuration on a Firewall Threat Defense device. You must carefully test any feature that you configure using FlexConfig.

CLI commands in FlexConfig objects

A managed device uses ASA configuration commands to configure some features. Although not all ASA features are compatible with the device, some features can work on the managed device but you cannot configure them through Firewall Management Center policies. You can use FlexConfig objects to specify the CLI required to configure these features.

ASA documentation resources

When using FlexConfig to manually configure a feature, you are responsible for knowing and implementing the commands according to the proper syntax. FlexConfig policies do not validate CLI command syntax. For more information about proper syntax and configuring CLI commands, use the ASA documentation as a reference:

- ASA CLI configuration guides explain how to configure a feature. Find the guides at https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-installation-and-configuration-guides-list.html
- ASA command references provide additional information sorted by command name. Find the references at https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-command-reference-list.html

Determine the ASA software version and current CLI configuration

Determine the ASA software version and examine the current CLI-based configuration to identify which ASA CLI configuration guides to use for instructions on configuring a feature.

Because the system uses ASA software commands to configure some features, you need to determine the current ASA version used in software running on the Firewall Threat Defense device. This version number indicates which ASA CLI configuration guides to use for instructions on configuring a feature. You also should examine the current CLI-based configuration and compare it to the ASA configuration you want to implement.

Keep in mind that any ASA configuration will be very different from a Firewall Threat Defense configuration. Many Firewall Threat Defense policies are configured outside of the CLI, so you cannot see the configuration by looking at the commands. Do not try to create a one-to-one correspondence between an ASA and Firewall Threat Defense configuration.

To view this information, make an SSH connection to the device's management interface and issue the following commands:

- **show version system** and look for the Cisco Adaptive Security Appliance Software Version number. (If you issue the command through the Secure Firewall Management Center CLI tool, omit the **system** keyword.)
- **show running-config** to view the current CLI configuration.
- **show running-config all** to include all the default commands in the current CLI configuration.

You can also issue these commands from within Firewall Management Center using this procedure.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Step 2 Click the name of the device targeted by the FlexConfig policy.

You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.

Step 3 Click **View System and Troubleshoot Details**.

Step 4 Click **Advanced Troubleshooting**.

Step 5 Click **Threat Defense CLI**.

Step 6 Choose the **Device**, then choose **show** as the command, and type **version** or one of the other commands as the parameter.

Step 7 Click **Execute**.

For version, search the output for the Cisco Adaptive Security Appliance Software Version number.

You can select the output and press Ctrl+C, then paste it into a text file for later analysis.

Prohibited CLI commands

The purpose of FlexConfig is to configure features that are available on ASA devices that you cannot configure on Firewall Threat Defense devices using Firewall Management Center.

Thus, you are prevented from configuring ASA features that have equivalents in Firewall Management Center. The following table lists some of these prohibited command areas.

In addition, some **clear** commands are prohibited because they overlap with managed policies, and can delete part of the configuration for a managed policy.

The FlexConfig object editor prevents you from including prohibited commands in the object.

Prohibited CLI Command	Description
AAA	Configuration blocked.
AAA-Server	Configuration blocked.
Access-list	Advanced ACL, Extended ACL, and Standard ACL are blocked. Ethertype ACL is allowed. You can use standard and extended ACL objects defined in the object manager inside the template as variables.
ARP Inspection	Configuration blocked.
As-path Object	Configuration blocked.
Banner	Configuration blocked.
BGP	Configuration blocked.
Clock	Configuration blocked.
Community-list Object	Configuration blocked.
Copy	Configuration blocked.
Delete	Configuration blocked.
DHCP	Configuration blocked.
Enable Password	Configuration blocked.
Erase	Configuration blocked.

Prohibited CLI Command	Description
Fragment Setting	Blocked, except for **fragment reassembly**.
Fsck	Configuration blocked.
HTTP	Configuration blocked.
ICMP	Configuration blocked.
Interface	Only **nameif**, **mode**, **shutdown**, **ip address** and **mac-address** commands are blocked.
Multicast Routing	Configuration blocked.
NAT	Configuration blocked.
Network Object/Object-group	Network object creation in the FlexConfig object is blocked, but you can use network objects and groups defined in the object manager inside the template as variables.
NTP	Configuration blocked.
OSPF/OSPFv3	Configuration blocked.
pager	Configuration blocked.
Password Encryption	Configuration blocked.
Policy-list Object	Configuration blocked.
Prefix-list Object	Configuration blocked.
Reload	You cannot schedule reloads. The system does not use the **reload** command to restart the system, it uses the **reboot** command.
RIP	Configuration blocked.
Route-Map Object	Route-map object creation in the FlexConfig object is blocked, but you can use route map objects defined in the object manager inside the template as variables.
Service Object/Object-group	Service object creation in the FlexConfig object is blocked, but you can use port objects defined in the object manager inside the template as variables.
SNMP	Configuration blocked.
SSH	Configuration blocked.
Static Route	Configuration blocked.
Syslog	Configuration blocked.
Time Synchronization	Configuration blocked.

Prohibited CLI Command	Description
Timeout	Configuration blocked.
VPN	Configuration blocked.

Template scripts

You can use scripting language to control processing within a FlexConfig object. Scripting language instructions are a subset of commands supported in the Apache Velocity 1.3.1 template engine. The Apache Velocity engine is a Java-based scripting language that supports looping, if/else statements, and variables.

To learn how to use the scripting language, see the *Velocity Developer Guide* at http://velocity.apache.org/engine/devel/developer-guide.html.

FlexConfig variables

You can use variables in a FlexConfig object in cases where part of a command or processing instruction depends on runtime information rather than static information. During deployment, the variables are replaced with strings obtained from other device configurations, depending on the type of variable.

FlexConfig variable types

Variables are replaced with strings based on the type of variable.

- Policy object variables are replaced with strings obtained from objects defined in Firewall Management Center.
- System variables are replaced with information obtained from the device itself or from policies configured for it.
- Processing variables are loaded with the contents of policy object or system variables as during script execution. For example, in a loop, you iteratively load one value from a policy object or system variable into a processing variable, then use the processing variable to form a command string or perform another action. These processing variables do not show up in the Variables list within a FlexConfig object. Also, you do not add them using the **Insert** menu in the FlexConfig object editor.
- Secret key variables are replaced with the single string defined for the variable within the FlexConfig object.

Variables start with the $ character, except for secret keys, which start with the @ character. For example, $ifname is a policy object variable in this command, whereas @keyname is a secret key.

```
interface $ifname
key @keyname
```

Note The first time you insert a policy object or system variable, you must do so through the **Insert** menu in the FlexConfig object editor. This action adds the variable to the **Variables** list at the bottom of the FlexConfig object editor. You must type in the variable string on subsequent uses, even when using system variables. If you are adding a processing variable, which does not have an object or system variable assignment, do not use the **Insert** menu. If you are adding a secret key, always use the **Insert** menu. Secret key variables do not show up in the Variables list.

Whether a variable is resolved as a single string, a list of strings, or a table of values depends on the type of policy object or system variable you assign to the variable. (Secret keys always resolve to a single string.) You must understand what will be returned in order to process the variables correctly.

Variable processing

At runtime, a variable can resolve to any of these: a single string; a list of strings of the same type; a list of strings of different types; or a table of named values. Variables that resolve to multiple values can have a determinate or indeterminate length. To process the values correctly, you must understand what will be returned.

The main possibilities include these scenarios.

Single value variables

If a variable always resolves to a single string, use the variable directly without modification in the FlexConfig script.

For example, the predefined text variable tcpMssBytes always resolves to a single value (which must be numeric). The **Sysopt_basic** FlexConfig then uses an if/then/else structure to set the maximum segment size based on the value of another single-value text variable, *tcpMssMinimum*.

Implementation methods

The implementation of single value variables depends on the variable type:

- **Standard text variables**: Use the variable directly in the FlexConfig script. For example, the predefined text variable tcpMssBytes always resolves to a single numeric value.
- **Secret key variables**: Always use the **Insert** menu to add the variable, even for second and subsequent uses. These variables do not show up in the Variables list within the FlexConfig object.
- **Policy object variables for network objects**: Equate to a single IP address specification (host address, network address, or address range). You must know what type of address to expect because ASA commands require specific address types.

Note Policy object variables for network objects also equate to a single IP address specification, either a host address, network address, or address range. However, in this case, you must know what type of address to expect, because the ASA commands require specific address types. For example, if a command requires a host address, using a network object variable that points to an object that contains a network address will result in an error during deployment.

TCP MSS configuration using single value variables

The **Sysopt_basic** FlexConfig uses an if/then/else structure to set the maximum segment size based on the value of another single-value text variable, tcpMssMinimum:

```
#if($tcpMssMinimum == "true")
  sysopt connection tcpmss minimum $tcpMssBytes
#else
  sysopt connection tcpmss $tcpMssBytes
#end
```

In this example, you would use the **Insert** menu in the FlexConfig object editor to add the first use of $tcpMssBytes, but you would type in the variable directly on the #else line.

Multiple value variables with same type values

Several policy object and system variables resolve to multiple values of the same type. For example, an object variable that points to a network object group resolves to a list of the IP addresses within the group. Similarly, the system variable $SYS_FW_INTERFACE_NAME_LIST resolves to a list of interface names.

You can also create text objects for multiple values of the same type. For example, the predefined text object enableInspectProtocolList can contain more than one protocol name.

Processing characteristics

Multiple value variables that resolve to a list of items of the same type are frequently of indeterminate length. For example, you cannot know beforehand how many interfaces on a device are named, as users can configure or unconfigure interfaces at any time.

You would typically use a loop to process multiple value variables of the same type. For example, the predefined FlexConfig **Default_Inspection_Protocol_Enable** uses a #foreach loop to go through the enableInspectProtocolList object and process each value.

```
policy-map global_policy
    class inspection_default
    #foreach ( $protocol in $enableInspectProtocolList)
    inspect $protocol
    #end
```

In this example, the script assigns each value in turn to the $protocol variable, which is then used in an ASA **inspect** command to enable the inspection engine for that protocol. In this case, you simply type in $protocol as a variable NAME. You do not use the **Insert** menu to add it, because you are not assigning an object or system value to the variable. However, you must use the **Insert** menu to add $enableInspectProtocolList.

The system loops through the code between #foreach and #end until there are no values remaining in $enableInspectProtocolList.

Multiple value variables with different types

You can create multiple value text objects and have each value serve a different purpose. For example, the predefined **netflow_Destination** text object should include three values in this order: interface name, destination IP address, and UDP port number.

Objects defined in this way should have a determinate number of values to make them easier to process.

Processing multiple value variables

Use the get method to process these objects. Type **.get(*n*)** at the end of the object name, replacing *n* with an index into the object. Start counting at 0, even though the text object lists its values starting at 1.

NetFlow destination configuration example

The predefined **netflow_Destination** text object should have 3 values, in order, interface name, destination IP address, and UDP port number.

The Netflow_Add_Destination object uses this line to add the 3 values from netflow_Destination to the ASA **flow-export** command:

```
flow-export destination $netflow_Destination.get(0) $netflow_Destination.get(1)
$netflow_Destination.get(2)
```

In this example, you would use the **Insert** menu in the FlexConfig object editor to add the first use of $netflow_Destination, and then add **.get(0)**. But you would type in the variable directly for the **$netflow_Destination.get(1)** and **$netflow_Destination.get(2)** specifications.

Multiple value variables that resolve to a table of values

Some system variables return a table of values. These variables include the string MAP in their names. For example, $SYS_FTD_ROUTED_INTF_MAP_LIST is one such variable. The routed interface map returns data in a table of values. Line breaks have been added for clarity.

Variable structure and processing

These variables return data that includes a table of named values for each item. For example, the ROUTED interface MAP returns data that looks like this (line returns added for clarity):

```
[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=,
intf_logical_name=outside},

{intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=,
intf_logical_name=inside},

{intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=},

{intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=management}]
```

In the above example, information is returned for 4 interfaces. Each interface includes a table of named values. For example, intf_hardwarare_id is the name of the interface hardware name property, and returns strings such as GigabitEthernet0/0.

This type of variable is typically of indeterminate length, so you need to use looping to process the values. You also need to add the property name to the variable name to indicate which value to retrieve.

IS-IS interface configuration

For example, IS-IS configuration requires that you add the ASA **ISIS** command to an interface that has a logical name in interface configuration mode. However, you enter that mode using the interface's hardware name. Thus, you need to identify which interfaces have logical names, then configure just those interfaces using their hardware names. The ISIS_Interface_Configuration predefined FlexConfig does this using an if/then structure nested in a loop. In this code, you can see that the #foreach scripting command loads each interface MAP into the $INTF variable, then the #if statement keys off the intf_logical_name value in the MAP ($INTF.intf_logical_name), and if the value is in the LIST defined in the isisIntfList predefined text variable, enters the interface command using the intf_hardwarare_id value ($INTF.intf_hardwarare_id). You would need to edit the isisIntfList variable to add the names of the interfaces on which to configure IS-IS.

```
#foreach ($intf in $SYS_FTD_ROUTED_INTF_MAP_LIST)
 #if ($isIsIntfList.contains($intf.intf_logical_name))
  interface $intf.intf_hardwarare_id
   isis
   #if ($isIsAddressFamily.contains("ipv6"))
   ipv6 router isis
   #end
 #end
#end
```

Evaluate device variable results

To evaluate what a variable will return by creating a simple FlexConfig object that processes variables and shows their resolved values in a configuration preview.

This method allows you to test and analyze variable resolution without deploying potentially invalid configuration commands to devices.

Procedure

Step 1 Create a simple FlexConfig object that processes an annotated list of variables.

Example:

```
Following is a network object group variable for the
IPv4-Private-All-RFC1918 object:

$IPv4_Private_addresses

Following is the system variable SYS_FW_MANAGEMENT_IP:

$SYS_FW_MANAGEMENT_IP

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

$SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST

Following is the system variable SYS_FTD_ROUTED_INTF_MAP_LIST:

$SYS_FTD_ROUTED_INTF_MAP_LIST
```

```
Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

$SYS_FW_INTERFACE_NAME_LIST
```

Step 2 Assign the FlexConfig object to a FlexConfig policy.

Step 3 Assign the policy to a device.

Step 4 Save the policy.

Step 5 Preview the configuration for that device.

The preview shows the resolved values.

Step 6 Select the preview text, copy it, then paste the output into a text file for analysis.

Example:

```
###Flex-config Prepended CLI ###

###CLI generated from managed features ###

###Flex-config Appended CLI ###
Following is an network object group variable for the
IPv4-Private-All-RFC1918 object:

[10.0.0.0, 172.16.0.0, 192.168.0.0]

Following is the system variable SYS_FW_MANAGEMENT_IP:

192.168.0.171

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

[dns, ftp, h323 h225, h323 ras, rsh, rtsp, sqlnet, skinny, sunrpc,
xdmcp, sip, netbios, tftp, icmp, icmp error, ip-options]

Following is the system variable SYS_FTD_ROUTED_INTF_MAP_LIST:

[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=,
intf_logical_name=outside},

{intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=,
intf_logical_name=inside},

{intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=},

{intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=management}]

Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

[outside, inside, management]
```

Note Do not deploy this FlexConfig to the device, however, because it will not contain any valid configuration commands. You would get deployment errors. After obtaining the preview, delete the FlexConfig object from the FlexConfig policy and save the policy.

You can analyze the resolved variable values in the text file to understand what each variable returns for the device.

FlexConfig policy object variables

A policy object variable is associated with a specific policy object configured in the Object Manager. When you insert a policy object variable in a FlexConfig object, you give the variable a name and select the object associated with it.

Policy object variable types

Although you can give the variable the exact same name as the associated object, the variable itself is not the same thing as the associated object. You must use the **Insert** > **Insert Policy Object** > ***Object Type*** menu in the FlexConfig object editor to add the variable for the first time to the script in the FlexConfig to establish the association with the object. Simply typing in the name of the object preceded by a $ sign does not create a policy object variable.

You can create variables to point to these types of objects. Ensure that you create the right type of object for each variable. To create objects, go to the **Objects** > **Object Management** page.

- **Text Objects**—For text strings, which can include IP addresses, numbers, and other free-form text such as interface or zone names. Select **FlexConfig** > **Text Object** from the table of contents, then click **Add Text Object**. You can configure these objects to contain a single value or multiple values. These objects are highly flexible and built specifically for use within FlexConfig objects. For detailed information, see Configure FlexConfig text objects, on page 950.
- **Network**—For IP addresses. You can use network objects or groups. Select **Network** from the table of contents, then select **Add Network** > **Add Object** or **Add Group**. If you use a group object, the variable returns a list of each IP address specification within the group. Addresses can be host, network, or address ranges, depending on the object contents. See Networks, on page 2386.
- **Security Zones**—For interfaces within a security zone or interface group. Select **Interface** from the table of contents, then select **Add** > **Security Zone** or **Interface Group**. A security zone variable returns a list of the interfaces within that zone or group for the device being configured. See Interfaces, on page 2383.
- **Standard ACL Object**—For standard access control lists. A standard ACL variable returns the name of the standard ACL object. Select **Access List** > **Standard** from the table of contents, then click **Add Standard Access List Object**. See Access lists, on page 2351.
- **Extended ACL Object**—For extended access control lists. An extended ACL variable returns the name of the extended ACL object. Select **Access List** > **Extended** from the table of contents, then click **Add Extended Access List Object**. See Access lists, on page 2351.

- **Route Map**—For route map objects. A route map variable returns the name of the route map object. Select **Route Map** from the table of contents, then click **Add Route Map**. See Configure a route map, on page 2415.

FlexConfig system variables

System variables are replaced with information obtained from the device itself or from policies configured for it. To add a variable for the first time in the FlexConfig script and establish its association with the system variable, use the **Insert** > **Insert System Variable** > ***Variable NAME*** menu in the FlexConfig object editor. Typing the system variable name with a preceding $ sign does not create a system variable in the context of the FlexConfig object.

Before using a variable, check the typical value it returns. Refer to Evaluate device variable results, on page 930.

Table 65: System variables

NAME	Description
SYS_FW_OS_MODE	The operating system MODE of the device. Possible values are ROUTED or TRANSPARENT.
SYS_FW_OS_MULTIPLICITY	Whether the device is running in SINGLE or multiple context MODE. Possible values are SINGLE, MULTI, or NOT_APPLICABLE.
SYS_FW_MANAGEMENT_IP	The MANAGEMENT IP address of the device
SYS_FW_HOST_NAME	The device hostname
SYS_FTD_INTF_POLICY_MAP	A MAP with INTERFACE NAME as key and POLICY-MAP as value. This variable returns nothing if there are no INTERFACE-based service policies defined on the device.
SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST	The LIST of protocols for which inspection is ENABLED.
SYS_FTD_ROUTED_INTF_MAP_LIST	A LIST of ROUTED INTERFACE maps on the device. Each MAP includes a set of named values related to ROUTED INTERFACE configuration.
SYS_FTD_SWITCHED_INTF_MAP_LIST	A LIST of SWITCHED INTERFACE maps on the device. Each MAP includes a set of named values related to SWITCHED INTERFACE configuration.
SYS_FTD_INLINE_INTF_MAP_LIST	A LIST of INLINE INTERFACE maps on the device. Each MAP includes a set of named values related to INLINE set INTERFACE configuration.
SYS_FTD_PASSIVE_INTF_MAP_LIST	A LIST of PASSIVE INTERFACE maps on the device. Each MAP includes a set of named values related to PASSIVE INTERFACE configuration.
SYS_FTD_INTF_BVI_MAP_LIST	A LIST of Bridge Virtual INTERFACE maps on the device. Each MAP includes a set of named values related to BVI configuration.

NAME	Description
SYS_FW_INTERFACE_HARDWARE_ID_LIST	A LIST of the HARDWARE names for interfaces on the device, such as GigabitEthernet0/0.
SYS_FW_INTERFACE_NAME_LIST	A LIST of logical names for interfaces on the device, such as inside.
SYS_FW_INLINE_INTERFACE_NAME_LIST	A LIST of logical names for interfaces configured as PASSIVE or ERSPAN PASSIVE.
SYS_FW_NON_INLINE_INTERFACE_NAME_LIST	A LIST of logical names for interfaces that are NOT part of INLINE sets, such as all ROUTED interfaces.

Predefined FlexConfig objects

The predefined FlexConfig objects provide tested configurations for select features. Use these objects if you need to configure these features, which otherwise cannot be configured using the management center. Note that some objects might become obsolete as features are added to the GUI.

This table lists the available objects. Make note of the associated text objects. You must edit these text objects to customize the behavior of the predefined FlexConfig object. The text objects make it possible for you to customize the configuration using the IP addresses and other attributes required by your network and device.

If you need to modify a predefined FlexConfig object, copy the object, make changes to the copy, and save it with a new name. You cannot directly edit a predefined FlexConfig object.

Although you might be able to configure other ASA-based features using FlexConfig, the configuration of those features has not been tested. If an ASA feature overlaps with something that you can configure in Firewall Management Center policies, do not attempt to configure it through FlexConfig.

For example, Snort inspection includes the HTTP protocol, so do not enable ASA-style HTTP inspection. You cannot add **http** to the enableInspectProtocolList object; this restriction prevents you from misconfiguring your device. Instead, configure the access control policy to perform application or URL filtering, as needed, to implement your HTTP inspection requirements.

Table 66: Predefined FlexConfig objects

FlexConfig Object Name	Description	Associated Text Objects
Default_Inspection_Protocol_Disable	Disables protocols in the global_policy default policy map.	disableInspectProtocolList
Default_Inspection_Protocol_Enable	Enables protocols in the global_policy default policy map.	enableInspectProtocolList
Inspect_IPv6_Configure	Configures IPv6 inspection in the global_policy policy map, logging and dropping traffic based on IPv6 header contents.	IPv6RoutingHeaderDropLogList, IPv6RoutingHeaderLogList, IPv6RoutingHeaderDropList.
Inspect_IPv6_UnConfigure	Clears and disables IPv6 inspection.	—

FlexConfig Object Name	Description	Associated Text Objects
ISIS_Configure	Configures global parameters for IS-IS routing.	isIsNet, isIsAddressFamily, isISType
ISIS_Interface_Configuration	Interface level IS-IS configuration.	isIsAddressFamily, IsIsIntfList Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST
ISIS_Unconfigure	Clears the IS-IS router configuration on the device.	—
ISIS_Unconfigure_All	Clears the IS-IS router configuration from the device, including the router assignment from the device interface.	—
NGFW_TCP_NORMALIZATION	Modifies the default TCP normalization configuration.	—
Policy_Based_Routing	To use this example configuration, copy it, modify the interface name, and use the r-map-object text object to identify a route map object in the object manager.	—
Policy_Based_Routing_Clear	Clears Policy Based Routing configurations from the device.	—
Sysopt_AAA_radius	Ignores the authentication key in RADIUS accounting responses.	—
Sysopt_AAA_radius_negate	Negates the Sysopt_AAA_radius configuration.	—
Sysopt_basic	Configures sysopt wait time , maximum segment size for TCP packets, and detailed traffic statistics.	tcpMssMinimum, tcpMssBytes
Sysopt_basic_negate	Clears sysopt_basic detailed traffic statistics, wait time, and TCP maximum segment size.	—
Sysopt_clear_all	Clears all sysopt configurations from the device.	—
Sysopt_noproxyarp	Configures noproxy-arp CLIs.	Uses system variable SYS_FW_NON_INLINE_INTF_NAME_LIST
Sysopt_noproxyarp_negate	Clears Sysopt_noproxyarp configurations.	Uses system variable SYS_FW_NON_INLINE_INTF_NAME_LIST
Sysopt_Preserve_Vpn_Flow	Configures syopt preserve VPN flow.	—
Sysopt_Preserve_Vpn_Flow_negate	Clears the Sysopt_Preserve_Vpn_Flow configuration.	—

FlexConfig Object Name	Description	Associated Text Objects
Sysopt_Reclassify_Vpn	Configures sysopt reclassify vpn.	—
Sysopt_Reclassify_Vpn_Negate	Negates sysopt reclassify vpn.	—
Threat_Detection_Clear	Clear the threat detection TCP Intercept configuration.	—
Threat_Detection_Configure	Configure threat detection statistics for attacks intercepted by TCP Intercept.	threat_detection_statistics
Wccp_Configure	This template provides an example for configuring WCCP.	isServiceIdentifier, serviceIdentifier, wccpPassword
Wccp_Configure_Clear	Clears WCCP configurations.	—

Deprecated FlexConfig objects

This table lists objects that configure features you can now configure natively in the GUI. Discontinue using these objects at the earliest convenience.

Table 67: Deprecated predefined FlexConfig objects

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.3	DHCPv6_Prefix_Delegation_Configure	Configure one outside (Prefix Delegation client) and one inside interface (recipient of delegated prefix) for IPv6 prefix delegation. To use this template, copy it and modify the variables. Associated text objects: pdoutside, pdinside Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST	Interface IPv6 Settings.
7.3	DHCPv6_Prefix_Delegation_UnConfigure	Removes the DHCPv6 prefix delegation configuration.	Interface IPv6 Settings.
6.3	Default_DNS_Configure	Configure the Default DNS group, which defines the DNS servers that can be used when resolving fully-qualified domain names on the data interfaces. Associated text objects: defaultDNSNameServerList, defaultDNSParameters	Platform settings.

Deprecated Version	FlexConfig Object	Description	Now Configure In
6.3	DNS_Configure	Configure DNS servers in a non-default DNS server group. Copy the object to change the name of the group.	**DNS Server Group** in the object manager.
6.3	DNS_UnConfigure	Removes the DNS server configuration performed by Default_DNS_Configure and DNS_Configure. Copy the object to change the DNS server group names if you altered DNS_Configure.	**DNS Server Group** in the object manager.
7.2	Eigrp_Configure	Configures EIGRP routing next-hop, auto-summary, router-id, eigrp-stub. Associated text objects: eigrpAS, eigrpNetworks, eigrpDisableAutoSummary, eigrpRouterId, eigrpStubReceiveOnly, eigrpStubRedistributed, eigrpStubConnected, eigrpStubStatic, eigrpStubSummary	For all EIGRP objects, see EIGRP, on page 1095. The system does allow you to deploy post-upgrade, but also warns you to redo your EIGRP configurations. To help you with this process, we provide a command-line migration tool.
7.2	Eigrp_Interface_Configure	Configures EIGRP interface authentication mode, authentication key, hello interval, hold time, split horizon. Associated text objects: eigrpIntfList, eigrpAS, eigrpAuthKey, eigrpAuthKeyId, eigrpHelloInterval, eigrpHoldTime, eigrpDisableSplitHorizon Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST	
7.2	Eigrp_Unconfigure	Clears EIGRP configuration for an autonomous system from the device.	
7.2	Eigrp_Unconfigure_all	Clears all EIGRP configurations.	
7.4	Netflow_Add_Destination	Creates and configures a Netflow export destination. Associated text objects: Netflow_Destinations, netflow_Event_Types	Platform settings.
7.4	Netflow_Clear_Parameters	Restores Netflow export global default settings.	Platform settings.

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.4	Netflow_Delete_Destination	Deletes a Netflow export destination. Associated text objects: Netflow_Destinations, netflow_Event_Types	Platform settings.
7.4	Netflow_Set_Parameters	Sets global parameters for Netflow export. Associated text objects: netflow_Parameters	Platform settings.
6.3	TCP_Embryonic_Conn_Limit	Configures embryonic connection limits to protect against SYN Flood Denial of Service (DoS) attacks. Associated text objects: tcp_conn_misc, tcp_conn_limit	Service policy.
6.3	TCP_Embryonic_Conn_Timeout	Configures embryonic connection timeouts to protect against SYN Flood Denial of Service (DoS) attacks. Associated text objects: tcp_conn_misc, tcp_conn_timeout	Service policy.
7.2	VxLAN_Clear_Nve	Removes the NVE 1 configured when VxLAN_Configure_Port_And_Nve is used from the device.	For all VxLAN objects, see Configure VXLAN Interfaces, on page 671. If you configured VXLAN interfaces with FlexConfig in a previous version, they continue to work. In fact, FlexConfig takes precedence in this case—if you redo your VXLAN configurations in the web interface, remove the FlexConfig settings.
7.2	VxLAN_Clear_Nve_Only	Clears the NVE configured on the interface when deployed.	
7.2	VxLAN_Configure_Port_And_Nve	Configures VLAN port and NVE 1. Associated text objects: vxlan_Port_And_Nve	

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.2	VxLAN_Make_Nve_Only	Sets an interface for NVE only. Associated text objects: vxlan_Nve_Only Also uses system variables SYS_FTD_ROUTED_MAP_LIST and SYS_FTD_SWITCHED_INTF_MAP_LIST	
7.2	VxLAN_Make_Vni	Creates a VNI interface. After deploying this you have to unregister and re-register the device to properly discover the VNI interface. Associated text objects: vxlan_Vni	

Predefined text objects

There are several predefined text objects. These objects are associated with variables used in the predefined FlexConfig objects. In most cases, you must edit these objects to add values if you use the associated FlexConfig object, or you will see errors during deployment. Although some of these objects contain default values, others are empty.

For information on editing text objects, refer to Configure FlexConfig text objects, on page 950.

Name	Description	Associated FlexConfig Object
defaultDNSNameServerList (Deprecated.)	The DNS server IP address to configure in the Default DNS group. Starting with version 6.3, configure DNS for the data interfaces in the Threat Defense Platform Settings policy.	Default_DNS_Configure
defaultDNSParameters (Deprecated.)	The parameters to control DNS behavior for the default DNS server group. The object contains separate entries, in order, for retries, timeout, expire-entry-timer, poll-timer, domain-name. Starting with version 6.3, configure DNS for the data interfaces in the Threat Defense Platform Settings policy.	Default_DNS_Configure
disableInspectProtocolList	Disables protocols in the default policy map (global_policy).	Disable_Default_Inspection_Protocol
dnsNameServerList	The DNS server IP address to configure in a user-defined DNS group.	DNS_Configure

Name	Description	Associated FlexConfig Object
dnsParameters	The parameters to control DNS behavior for a non-default DNS server group. The object contains separate entries, in order, for retries, timeout, domain-name, name-server-interface.	DNS_Configure
enableInspectProtocolList	Enables protocols in the default policy map (global_policy). You are prevented from adding protocols whose inspection conflicts with Snort inspection.	Enable_Default_Inspection_Protocol
IPv6RoutingHeaderDropList	The list of IPv6 routing header types that you want to disallow. IPv6 inspection drops packets that contain these headers without logging the drop.	Inspect_IPv6_Configure
IPv6RoutingHeaderDropLogList	The list of IPv6 routing header types that you want to disallow and log. IPv6 inspection drops packets that contain these headers and sends a syslog message about the drop.	Inspect_IPv6_Configure
IPv6RoutingHeaderLogList	The list of IPv6 routing header types that you want to allow but log. IPv6 inspection allows packets that contain these headers, but sends a syslog message about the existence of the header.	Inspect_IPv6_Configure
isIsAddressFamily	The IPv4 or IPv6 address family.	ISIS_Configure ISIS_Interface_Configuration
IsIsIntfList	List of logical interface names.	ISIS_Interface_Configuration
isIsISType	IS Type (level-1, level-2-only or level-1-2).	ISIS_Configure
isIsNet	Network entity.	ISIS_Configure
isServiceIdentifier	When false, uses the standard **web-cache** service identifier.	Wccp_Configure
netflow_Destination	Defines a single NetFlow export destination's interface, destination, and UDP port number.	Netflow_Add_Destination
netflow_Event_Types	Defines the types of events to be exported for a destination as any subset of: **all**, **flow-create**, **flow-defined**, **flow-teardown**, **flow-update**.	Netflow_Add_Destination

Name	Description	Associated FlexConfig Object
netflow_Parameters	Provides the NetFlow export global settings: active refresh interval (number of minutes between flow update events), delay (flow create delay in seconds; default 0 = command will not appear), and template time-out rate in minutes.	Netflow_Set_Parameters
PrefixDelegationInside	Configures the inside interface for DHCPv6 prefix delegation. The object includes multiple entries, in order, interface name, IPv6 suffix with prefix length, and prefix pool name.	None, but could be used with a copy of DHCPv6_Prefix_Delegation_Configure.
PrefixDelegationOutside	Configure the outside DHCPv6 prefix delegation client. The object includes multiple entries, in order, interface name and IPv6 prefix length	None, but could be used with a copy of DHCPv6_Prefix_Delegation_Configure.
serviceIdentifier	Dynamic WCCP service identifier number.	Wccp_Configure
tcp_conn_limit (Deprecated.)	Parameters used for configuring the TCP embryonic connection limits. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Limit
tcp_conn_misc (Deprecated.)	Parameters used for configuring the TCP embryonic connection settings. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Limit, TCP_Embryonic_Conn_Timeout
tcp_conn_timeout (Deprecated.)	Parameters used for configuring the TCP embryonic connection timeouts. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Timeout
tcpMssBytes	Maximum segment size in bytes.	Sysopt_basic
tcpMssMinimum	Checks whether to set maximum segment size (MSS), which is set only if this flag is true.	Sysopt_basic

Name	Description	Associated FlexConfig Object
threat_detection_statistics	Parameters used for threat detection statistics for TCP Intercept.	Threat_Detection_Configure
vxlan_Nve_Only	Parameters for configuring NVE-only on interface: • logical name of interface • IPv4 address (optional for routed interface) • IPv4 netmask (optional for routed interface)	VxLAN_Make_Nve_Only
vxlan_Port_And_Nve	Parameters used for configuring ports and NVE for VXLAN: • vxlan port • source interface (logical name) • type (peer or mcast) • Peer IP Address or default-mcast-group	VxLAN_Configure_Port_And_Nve
vxlan_Vni	Parameters used for creating VNI: • Interface number (1-10000) • segment-id (1-16777215) • nameif (Logical Name of the interface) • type (routed or transparent) • IP address (used in case of routed mode device) or bridge-group number (used in case of transparent mode device) • netmask (If device is in routed mode) or unused	VxLAN_Make_Vni
wccpPassword	WCCP password.	Wccp_Configure

Requirements and prerequisites for FlexConfig policies

This topic outlines the model support, domain requirements, and user role prerequisites required to configure and deploy FlexConfig policies.

Model support

Firewall Threat Defense

Supported domains

Any

User roles

Admin

Guidelines and limitations for FlexConfig

Be cautious with FlexConfig deployments, as configuration mistakes trigger rollbacks that can disrupt your network.

- If you make a mistake in the FlexConfig policy, the system will roll back all changes included in the deployment attempt that includes the failed FlexConfig. Because rollback due to a failed deployment includes clearing the configuration, this can be disruptive to your network.
- Consider timing deployments that include FlexConfig changes to non-business hours. Also, consider isolation the deployment so it includes just FlexConfig changes, and no other policy updates.

When you use the VxLAN_Make_VNI object, you must deploy the same FlexConfig to all units in a cluster or high availability pair before you form the cluster or high availability pair. The Management Center requires the VXLAN interfaces to match on all devices before forming the cluster or high availability pair.

The **webvpn keepout** command must be configured only within the global webvpn configuration mode. The webvpn group-policy attributes or username attributes configuration modes do not support the **keepout** command. Do not include the **keepout** command in a group-policy FlexConfig object.

If you configure any service that applies to connections, such as SIP inspection, go to the device CLI and enter the **clear conn** command to clear connections. When the connections are rebuilt, the new configuration is applied to the sessions.

QoS rules and service policy rules (in the access control policy) are translated to commands on the firewall. This includes creating policy maps. There can be only one policy map per interface. The system automatically combines QoS and service policy configurations in a single policy map per interface.

However, you can also create policy maps manually using FlexConfig. For lower-end firewalls, such as the Secure Firewall 3100, you can create up to 64 policy maps in the configuration. For more powerful firewalls, such as the Firepower 4100, you can create up to 128. Be careful not to exceed this limit, or deployment will fail. You can view the device configuration from the CLI or use the deployment transcript to see how rules are translated to commands.

Customize device configuration with FlexConfig policies

Use FlexConfig policies to customize the configuration of a Firewall Threat Defense device when standard configuration methods are insufficient.

Before using FlexConfig, try to configure all the policies and settings you need using the other features in Firewall Management Center. FlexConfig is a method of last resort to configure ASA-based features that are

compatible with Firewall Threat Defense but which are not otherwise configurable in Firewall Management Center.

Before you begin

Follow these steps to customize device configuration with FlexConfig policies:

Procedure

Step 1 Determine the CLI command sequence that you want to configure.

If you have a functioning configuration on an ASA device, use **show running-config** to get the sequence of commands that you need. Make adjustments to items such as interface names and IP addresses as needed.

If this is for a new feature, it is best to try to implement it on an ASA device in a lab setting to verify that you have the correct command sequence.

For more information, see the following topics:

- Recommended usage for FlexConfig policies, on page 922
- CLI commands in FlexConfig objects, on page 922

Step 2 Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

Examine the predefined FlexConfig objects to determine if any will be able to generate the commands you need. Click **View** (🔍) to see the object contents. If an existing object is close to what you want, start by making a copy of the object, and then edit the copy. See Predefined FlexConfig objects, on page 934.

Examining the objects will also give you an idea of the structure, command syntax, and expected sequencing for a FlexConfig object.

Note If you find any objects that you will use, either directly or as copies, examine the Variables list at the bottom of the object. Make note of the variable names, except those in all capitals that start with SYS, which are system variables. These variables are text objects that you will probably need to edit and define overrides for, especially if the default value column shows the object has no value.

Step 3 If you need to create your own FlexConfig objects, determine what variables you will need and create the associated objects.

The CLI you need to deploy might contain IP addresses, interface names, port numbers, and other parameters that you might want to adjust over time. These are best isolated into variables, which point to objects that contain the necessary values. You might also need variables for strings that are part of the configuration and could change over time.

Also, determine if you need different values for each device to which you will assign the policy. For example, you might want to configure the feature on three devices, but you might need to specify a different interface name or IP address on a given command for each of these devices. If you need to customize the object for each device, ensure that you enable overrides when creating the object and then define the override values per device.

See the list of topics for an explanation of the various types of variables and how to configure the related objects when necessary.

- FlexConfig variables, on page 926
- FlexConfig policy object variables, on page 932
- FlexConfig system variables, on page 933
- Configure FlexConfig text objects, on page 950

Step 4 If you are using the predefined FlexConfig objects, edit the text objects used as variables.

See Configure FlexConfig text objects, on page 950.

Step 5 (If necessary) Configure FlexConfig objects, on page 945.

You need to create objects only if the predefined objects cannot do the job.

Step 6 Configure the FlexConfig policy, on page 951.

a) Set target devices for a FlexConfig policy, on page 952.

You can also assign the policy to devices when you create the policy. The policy must have at least one assigned device before you can preview it.

b) Preview the FlexConfig policy, on page 953.

You must save changes before you can preview the policy.

Verify that the generated commands are the ones intended, and that all variables are resolving correctly.

Step 7 Choose **Deploy** > **Deployment** in the menu bar.

a) Select the devices assigned to the policy, and click **Deploy**.

Wait for deployment to complete.

Step 8 Verify the deployed configuration, on page 954.

Step 9 (If necessary) Remove features configured using FlexConfig, on page 956.

Unlike other types of policy, simply unassigning a FlexConfig from a device might not remove the related configuration. If you want to remove a FlexConfig-generated configuration, follow the cited procedure.

If you are removing a feature because it is now directly supported by the product, check Convert from FlexConfig to managed feature, on page 958.

Configure FlexConfig objects

Before you begin

Keep the following in mind:

- FlexConfig objects translate into commands that are then deployed to the device. These commands are already issued in global configuration mode. Therefore, do not include the **enable** and **configure terminal** commands as part of the FlexConfig object.

- Determine what types of variables you will need, and create any policy objects that you will require. You cannot create objects for variables while editing a FlexConfig object.
- Ensure that your commands do not conflict in any way with the VPN or access control configuration on the devices.
- If there is more than one set of commands for an interface, only the last set of commands is deployed. Therefore, we recommend you not use beginning and ending commands to configure interfaces. For an example of configuring interfaces, refer to the ISIS_Interface_Configuration predefined FlexConfig object.

There are several predefined FlexConfig objects that you can use directly, or you can make copies if you need to edit them. You can also create your own objects from scratch. A FlexConfig object's content can range from a single simple command string to elaborate CLI command structures that use variables and scripting commands to deploy commands whose content can differ from device to device or deployment to deployment.

You can also create FlexConfig policy objects when defining FlexConfig policies.

Procedure

Step 1 Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object** .

Step 2 Do one of the following:

- Click **Add FlexConfig Object** to create a new object.
- Click **Edit** ( ) to edit an existing object.
- Click **View** ( ) to see the contents of a predefined object.
- If you want to edit a predefined object, click **Clone** ( ) to create a new object with the same contents.

Step 3 Enter a **Name** and optionally, a description for the object.

Step 4 In the object body area, enter the commands and instructions to produce the required configuration.

The object content is a sequence of scripting commands and configuration commands that generate a valid ASA software command sequence. The Firewall Threat Defense device uses ASA software commands to configure some features. For more information on scripting and configuration commands, refer to:

- Template scripts, on page 926
- CLI commands in FlexConfig objects, on page 922

You can use variables to supply information that can be known only at runtime, or which can differ from device to device. You simply type in processing variables, but you must use the **Insert** menu to add variables that are associated with policy objects or system variables, or which are secret keys. For a complete discussion of variables, refer to FlexConfig variables, on page 926 .

- To insert system variables, choose **Insert** > **Insert System Variable** > ***Variable Name*** . For a detailed explanation of these variables, see FlexConfig system variables, on page 933 .
- To insert policy object variables, choose **Insert** > **Insert Policy Object** > ***Object Type*** , selecting the appropriate type of object. Then, give the variable a name (which can be the same name as the associated policy object), select the object to associate with the variable, and click **Save** . For a detailed explanation

of these types, see FlexConfig policy object variables, on page 932 . For more detail on the procedure, see Add a policy object variable to a FlexConfig object, on page 948 .

- To insert secret key variables, choose **Insert** > **Secret Key** and define the variable name and value. For more detail on the procedure, see Configure secret keys, on page 949 .

Note You must use the **Insert** menu to create a new policy object or system variable. However, for subsequent uses of that variable, you must type it in, $ included. This is also true for system variables: the first time you use it, add it from the **Insert** menu. Then, type it out for subsequent uses. If you use the **Insert** menu more than once for a system variable, the system variable is added to the Variables list multiple times, and the FlexConfig will not validate, meaning you cannot save your changes. For processing variables (those not associated with a policy object or system variable), simply type in the variable. If you are adding a secret key, always use the **Insert** menu. Secret key variables do not show up in the Variables list.

Step 5 Choose the deployment frequency and type.

- **Deployment** —Whether to deploy the commands in the object **Once** or **Everytime** . The only way to choose the right option is to test the results of deployment.

  Start by selecting **Everytime** . Then, after you attach the object to a FlexConfig policy, deploy the configuration. After a successful deployment, come back to the FlexConfig policy and preview the configuration for one of the assigned devices as described in Preview the FlexConfig policy, on page 953 . If the section labeled `###CLI generated from managed features ###` contains commands that clear or negate the commands in the object, and the `###Flex-config Appended CLI ###` section contains the commands to reconfigure the feature, you know that **Everytime** is the right option.

  Even if you do not see negate commands, make some minor change to the device configuration, then run another deployment. If the deployment completes successfully, you can check the deployment transcript (see Verify the deployed configuration, on page 954). If you see that the commands were issued again (even when they were already configured) without error, then you can keep **Everytime** .

  Change to **Once** only if the system does not first negate the commands in the object before issuing them again, or if the deployment results in errors that are specific to the command. In some cases, the system does not allow you to issue a command that is already configured, but this is the exception.

  Some additional tips:

  - If the FlexConfig object points to system-managed objects such as network or ACL objects, choose **Everytime** . Otherwise, updates to the objects might not get deployed.
  - Use **Once** if the only thing you do in the object is to clear a configuration. Then, remove the object from the FlexConfig policy after the next deployment.

- **Type** —Select one of the following:
  - **Append** —(The default.) Commands in the object are put at the end of the configurations generated from the Firewall Management Center policies. You must use Append if you use policy object variables, which point to objects generated from managed objects. If commands generated for other policies overlap with those specified in the object, you should select this option so your commands are not overwritten. This is the safest option.

- **Prepend** —Commands in the object are put at the beginning of the configurations generated from the Firewall Management Center policies. You would typically use prepend for commands that clear or negate a configuration.

Step 6 (Optional.) Click **Validate** ( ) above the object body to check the integrity of the script.

The object is always validated when you click **Save**. You cannot save an invalid object.

Step 7 Click **Save** .

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Add a policy object variable to a FlexConfig object

Insert variables into a FlexConfig policy object that are associated with other types of policy object, allowing the variables to resolve to the names or content of the associated object when the FlexConfig is deployed to a device.

You can insert variables into a FlexConfig policy object that are associated with other types of policy object. When the FlexConfig is deployed to a device, these variables resolve to the names or content of the associated object.

Use the following procedure for the first use of a policy object variable in a FlexConfig object. If you need to refer to the object again, type in the variable (including the $ sign). To understand how to use these variables, see Variable processing, on page 927.

Before you begin

For information on editing a FlexConfig Object, see Configure FlexConfig objects, on page 945.

Procedure

Step 1 While editing a FlexConfig Policy Object, choose **Insert** > **Insert Policy Object** > ***Object Type***, selecting the appropriate type of object.

Step 2 Enter a name for the variable, and optionally, a description.

The name must be unique within the context of the FlexConfig object. It cannot include spaces. You are allowed to use the exact same name as the object associated with the variable.

Step 3 Select the object to associate with the variable and click **Add** to move it to the **Selected Object** list.

You can associate a variable with a single object only.

Note For text objects, you can select any of the predefined objects as needed. However, many of these objects have no default values. You must update the objects to add the required values either directly or as overrides for the device to which you will deploy the FlexConfig object. Trying to deploy a FlexConfig without updating these objects typically results in deployment errors.

Step 4 Click **Save**.

The variable appears in the Variables list at the bottom of the FlexConfig object editor.

Configure secret keys

Secret keys allow you to mask sensitive information such as passwords in FlexConfig objects, preventing the dissemination of sensitive information while providing special treatment for these variables.

A secret key is any single-string variable whose content you want to mask, such as passwords. The system provides special treatment for these variables to help you prevent the dissemination of sensitive information.

Secret key variables do not show up in the Variables list in the FlexConfig object.

Unlike other types of variables, you can use the **Insert** command every time you need to insert a given secret key variable. With respect to processing, these variables behave like single-value text object variables; see Single value variables, on page 927.

Note Any data defined in a secret key variable is masked from users except when previewing a FlexConfig policy. In addition, if you export a FlexConfig policy, the content of any secret key variable is erased. When you import the policy, you will need to manually edit each secret key variable to enter the data.

Before you begin

For information on editing a FlexConfig Object, see Configure FlexConfig objects, on page 945.

Procedure

Step 1 While editing a FlexConfig Policy Object, choose **Insert** > **Secret Key**.

Step 2 In the **Insert Secret Key** dialog box, do any of the following:

- To create a new key, click **Add Secret Key**, then fill in the following information and click **Add**.
  - **Secret Key Name**—The name of the variable. This name appears in the FlexConfig object prefixed with @.
  - **Password**, **Confirm Password**—The secret string, which is masked with asterisks as you type.
- To insert a secret key variable in the FlexConfig object, select the check box for the variable.

- To edit the value of a secret key variable, click **Edit** ( ) for the variable. Make your changes and click **Add**.
- To delete a secret key variable, click **Delete** ( ) for the variable.

Step 3 Click **Save**.

Configure FlexConfig text objects

Use text objects in FlexConfig objects as the target of policy object variables. During deployment, variables that point to text objects are replaced by the content of the text object.

Use text objects in FlexConfig objects as the target of policy object variables. You can use variables to supply information that can be known only at runtime, or which can differ from device to device. During deployment, variables that point to text objects are replaced by the content of the text object.

Text objects contain free-form strings, which can be keywords, interface names, numbers, IP addresses, and so forth. The content depends on how you will use the information within a FlexConfig script.

Before creating or editing a text object, determine exactly what content you will need. This includes how you intend to process the object, which will help you decide between creating a single string or multiple string object. Read the following topics:

- FlexConfig variables, on page 926
- Variable processing, on page 927

Procedure

Step 1 Choose **Objects** > **Object Management** > **FlexConfig** > **Text Object**.

Step 2 Do one of the following:

- Click **Add Text Object** to create a new object.
- Click **Edit** ( ) to edit an existing object. You are allowed to edit the predefined text objects, which is required if you intended to use the predefined FlexConfig objects.

Step 3 Enter a **Name** and optionally, a description for the object.

Step 4 (New objects only.) Choose a **Variable Type** from the drop-down list:

- **Single**—If the object should contain a single text string.
- **Multiple**—If the object should contain a list of text strings.

You cannot change the variable type after you save the object.

Step 5 If the variable type is **Multiple**, use the up and down arrows to specify a **Count**.

Rows are added or removed from the object as you change the number.

Step 6 Add content to the object.

You can either click in the text box next to a variable number and type in a value, or you can set up device overrides for each device that will be assigned a FlexConfig object that uses the text object. You can also do both, in which case the values configured in the base object act as default values in cases where an override does not exist for a given device.

When editing predefined objects, it is a good practice to use device overrides, so that the system defaults remain in place for other users who might need to use the object in different FlexConfig policies. The approach you take depends on the requirements of your organization.

Tip Some predefined objects require multiple values where each value serves a specific purpose. Read the description text carefully to determine the expected values in the object. In some cases, the instructions specify that you must use overrides instead of changing the base values. In the case of enableInspectProtocolList, you are prevented from entering protocols whose inspection is incompatible with Snort inspection.

If you decide to use device overrides, do the following.

a) Check the check box of **Allow Overrides**.
b) Expand the Overrides area (if necessary) and click **Add**.

   If an override already exists for the device, click edit for the override to change it.

c) On **Targets** in the Add Object Override dialog box, select the device for which you are defining values and click **Add** to move it to the Selected Devices list.
d) Click **Override**, adjust the **Count** as needed, then click in the variable fields and type in the values for the device.
e) Click **Add**.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Configure the FlexConfig policy

Configure a FlexConfig policy to manage device configurations using shared policies that can be assigned to multiple devices.

A FlexConfig policy contains two ordered lists of FlexConfig objects, one prepended list and one appended list. For an explanation of prepend/append, see Configure FlexConfig objects, on page 945.

FlexConfig policies are shared policies that you can assign to multiple devices.

Procedure

Step 1 Choose **Devices** > **FlexConfig**.

Step 2 Do one of the following:

- Click **New Policy** to create a new FlexConfig Policy. You are prompted to enter a name. Optionally, select devices in the Available Devices list and click **Add to Policy** to assign devices. Click **Save**.
- Click **Edit** ( ) to edit an existing Policy. You can change the name or description by clicking them in edit mode.
- Click **Copy** ( ) to create a new policy with the same contents. You are prompted for a name. Device assignments are not retained for the copy.
- Click delete to remove a policy you no longer need.

Step 3 Select the FlexConfig objects required for the policy from the **Available FlexConfig** list and click > to add them to the policy.

Objects are automatically added to the prepended or appended list based on the deployment type specified in the FlexConfig object.

To remove a selected object, click **Delete** ( ) next to an object.

Step 4 For each selected object, click **View** ( ) next to the object to identify the variables used in the object.

Except for system variables, which start with SYS, you need to ensure that the objects associated with the variables are not empty. A blank or brackets with nothing between them, [ ], indicate an empty object. You will need to edit these objects before deploying the policy.

Note If you use object overrides, those values will not show up in this view. Thus, an empty default value does not necessarily mean that you have not updated the object with the required values. Previewing the configuration will show whether the variables resolve correctly for a given device. See Preview the FlexConfig policy, on page 953.

Step 5 Click **Save**.

What to do next

- Set target devices for the policy; see Set target devices for a FlexConfig policy, on page 952.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Set target devices for a FlexConfig policy

This task allows you to assign or change device assignments for a FlexConfig policy after creation.

When you create a FlexConfig policy, you can select the devices that use the policy. You can subsequently change device assignments for the policy as described below.

Note Normally, when you unassign a policy from a device, the system automatically removes the associated configuration upon the next deployment. However, because FlexConfig objects are scripts for deploying customized commands, simply unassigning a FlexConfig policy from a device does not remove the commands that were configuring by the FlexConfig objects. If your intention is to remove FlexConfig-generated commands from a device's configuration, refer to Remove features configured using FlexConfig, on page 956.

Procedure

Step 1 Choose **Devices** > **FlexConfig** and edit a FlexConfig policy.

Step 2 Click **Policy Assignments**.

Step 3 On **Targeted Devices**, build your target list:

- Add—Choose one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**. You can assign the policy to devices, high availability pairs, and clustered devices.
- Delete—Click **Delete** ( ) next to a single device, or select multiple devices, right-click, then choose **Delete Selection**.

Step 4 Click **OK** to save your selection.

Step 5 Click **Save** to save the FlexConfig policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Preview the FlexConfig policy

The FlexConfig policy preview allows you to validate and troubleshoot your configuration before deployment. It translates FlexConfig objects into CLI commands and resolves variables based on device-specific configurations.

Preview a FlexConfig policy to see how the FlexConfig objects get translated into CLI commands. The preview shows the commands that will be generated for a selected device from the scripts and variables used in the FlexConfig objects. The variables are resolved based on the configuration for the device, so you get a clear idea of what will be deployed.

Use the preview to look for potential problems in the FlexConfig objects. Correct the objects until the preview shows the expected results.

You must preview the configuration separately for each device, because the variables can resolve differently based on the device configuration.

Procedure

Step 1 Choose **Devices** > **FlexConfig** and edit a FlexConfig policy.

Step 2 If there are any pending changes, click **Save**.

The preview shows results only for those FlexConfig objects that were in the most recently saved version of the policy. You must save the policy to see a preview of newly-added objects.

Step 3 Click **Preview Config**.

Step 4 Choose a device from the **Select Device** drop-down list.

The system retrieves information from the device and configured policies, and determines what CLI commands will be generated on the next deployment to the device. You can select the output and use Ctrl+C to copy it to the clipboard, where you can paste it into a text file for further analysis.

The preview includes the following sections:

- Flex-config Prepended CLI—These are the commands generated by FlexConfigs that are prepended to the configuration.
- CLI generated from managed features—These are commands generated for policies configured in the Firewall Management Center. Commands are generated for new or changed policies since the last successful deployment to the device. These commands do not represent all commands needed to implement the assigned policies. No commands in this section are generated from FlexConfig objects.
- Flex-config Appended CLI—These are the commands generated by FlexConfigs that are appended to the configuration.

Step 5 Click **Close** to close the preview dialog.

Verify the deployed configuration

This task helps you confirm that your FlexConfig policy deployment completed successfully and that the device configuration matches your expectations.

After you deploy a FlexConfig policy to a device, verify that the deployment was successful and that the resulting configuration is what you expected. Also, verify that the device is performing as expected.

Procedure

Step 1 To verify that deployment was successful:

Check the deployment status and review any error messages or warnings.

- Click **Notifications** in the menu bar, which is unnamed between **Deploy** and **System**.

  The icon looks like one of the following, and it might include a number if there are errors:

  - **Indicates No Warnings** — Indicates no warnings or errors are present on the system.

- Indicates **One or More Warnings** — Indicates one or more warnings and no errors are present on the system.
- **Indicates One or More Errors** — Indicates one or more errors and any number of warnings are present on the system.

- On **Deployments**, verify that the deployment was successful.
- To see more detailed information, especially for failed deployments, click **Show History**.
- Select the deployment job in the list of jobs in the left column.

  Jobs are listed in reverse chronological order, with the most recent job at the top of the list.

- Click download in the **Transcript** column for the device in the right column.

  The deployment transcript includes commands sent to the device, and any responses returned from the device. These response can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands that you sent through FlexConfig. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

Note There is no distinction made in the transcript between commands sent for managed features and those generated from FlexConfig policies.

For example, the following sequence shows that Firewall Management Center sent commands to configure GigabitEthernet0/0 with the logical name outside. The device responded that it automatically set the security level to 0. Firewall Threat Defense does not use the security level for anything. Messages relevant to FlexConfig are in the CLI Apply section of the transcript.

```
========= CLI APPLY =========

FMC >> interface GigabitEthernet0/0
FMC >>  nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

Step 2 Verify that the deployed configuration includes the expected commands.

You can do this by making an SSH connection to the device's management IP address. Use the **show running-config** command to view the configuration.

Alternatively, use the CLI tool within Secure Firewall Management Center.

- Choose **System** (⚙) > **Health** > **Monitor** and click the name of the device.

  You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.

- Click **Advanced Troubleshooting**.
- Click **Threat Defense CLI**.
- Select **show** as the command, and type **running-config** as the parameter.
- Click **Execute**.

  The running configuration appears in the text box. You can select the configuration and press Ctrl+C, then paste it into a text file for later analysis.

Step 3 Verify that the device is performing as expected.

Use the **show** commands related to the feature to see detailed information and statistics. For example, if you enabled additional protocol inspections, the **show service-policy** command provides this information. The exact commands to use are feature-dependent and should be mentioned in the ASA configuration guide and command reference you used to learn how to configure the feature.

If commands that show statistics indicate that numbers are not changing (for example, hit counts, connection counts, and so forth), the configuration might be valid but not meaningful. If you know that traffic is going through the device that should show up in statistics, look for what is missing in your configuration. For example, NAT or access rules might be dropping or changing traffic before a feature can act on it.

You can use the **show** commands from an SSH session or through the Firewall Management Center CLI tool.

However, if the **show** command that you need to use is not available directly within the Firewall Threat Defense CLI, you will need make an SSH connection to the device to use the commands. From the CLI, enter the following command sequence to enter Privileged EXEC mode within the diagnostic CLI. From there, you should be able to enter these otherwise unsupported **show** commands.

```
> system support diagnostic-cli
Attaching to Diagnostic CLI ... Press 'Ctrl+a then d' to detach.
Type help or '?' for a list of available commands.
firepower> enable
Password: <press enter, do not enter a password>
firepower#
```

Remove features configured using FlexConfig

This task allows you to manually remove configuration commands that were deployed using FlexConfig when unassigning the FlexConfig policy from a device might not remove all of the configuration.

If you decide you need to remove a set of configuration commands you configured using FlexConfig, you might need to manually remove that configuration. Unassigning the FlexConfig policy from a device might not remove all of the configuration.

To manually remove the configuration, you create new FlexConfig objects to clear or negate the configuration commands.

Before you begin

To determine if you need to manually remove some or all of the configuration generated by an object:

1. Examine the configuration preview, as described in Preview the FlexConfig policy, on page 953. If the **###CLI generated from managed features ###** section contains the clear or negate commands to remove all of the commands in the FlexConfig object, then you can simply remove the object from the FlexConfig policy, save, and redeploy.
2. Remove the object from the FlexConfig policy, save the change, then preview the configuration again. If the **###CLI generated from managed features ###** section still does not include the required clear or negate commands, you must follow this procedure to manually remove the configuration.

Follow these steps to remove features configured using FlexConfig:

Procedure

Step 1 Choose **Objects** > **Object Management** and create the FlexConfig Objects to clear or negate the configuration commands.

If a feature has a **clear** command that can remove all configuration settings, then use that command. For example, the predefined ISIS_Unconfigure_All object contains a single command that removes all ISIS-related configuration commands:

```
clear configure router isis
```

If there is not a **clear** command for the feature, you need to use the **no** form of each command you want to remove. For example, the predefined Sysopt_basic_negate object removes the commands configured through the predefined Sysopt_basic object.

```
no sysopt traffic detailed-statistics

no sysopt connection timewait
```

You would typically configure a FlexConfig object that removes configurations as a prepended, deploy once object.

Step 2 Choose **Devices** > **FlexConfig** and create a new FlexConfig policy or edit the existing policy.

If you want to preserve the FlexConfig policy that deploys the configuration commands, create a new policy specifically for negating the commands, and assign the devices to the policy. Then, add the new FlexConfig objects to the policy.

If you want to completely remove the FlexConfig configuration objects from all devices, you can simply delete those commands from the existing FlexConfig policy and replace them with the objects that negate the configuration.

Step 3 Click **Save** to save the FlexConfig policy.

Step 4 Click **Preview Config** and verify that the clear and negation commands are generating correctly.

Step 5 Choose **Deploy** > **Deployment** in the menu bar, select the device, and click **Deploy**.

Wait for deployment to complete.

Step 6 Verify that the commands were removed.

View the running configuration on the device to confirm that the commands are removed. For more detailed information, see Verify the deployed configuration, on page 954.

Step 7 While editing the FlexConfig policy, click **Policy Assignments** and remove the device. Optionally, remove the FlexConfig Objects from the policy.

Assuming that the FlexConfig policy simply removes the unwanted configuration commands, there is no need to keep the policy assigned to the device after the removal is complete.

However, if the FlexConfig policy retains options that you still want configured on the device, remove the negation objects from the policy. They are no longer needed.

Convert from FlexConfig to managed feature

This procedure converts deprecated FlexConfig commands to newly supported managed features after a software upgrade.

Each software release adds managed features to the product. These are features you configure directly through policies controlled outside of FlexConfig. This can deprecate FlexConfig commands that you are currently using. Your configurations are not automatically converted. After the upgrade, you cannot assign or create FlexConfig objects using the newly deprecated commands. After upgrading software, examine your FlexConfig policies and objects.

If a feature configured through FlexConfig becomes available as a managed feature, convert the configuration to the managed feature instead of using FlexConfig. In most cases, your existing FlexConfig configurations continue to work after the upgrade, and you can still deploy. However, using deprecated commands may cause deployment issues in certain situations. Configuring a feature in both the GUI and FlexConfig is not supported.

Note Use the migration tool instead of this procedure if the tool supports the feature configuration you are migrating.

Procedure

Step 1 Remove the FlexConfig, as explained in Remove features configured using FlexConfig, on page 956.

Step 2 Configure the settings in the newly supported managed feature.

The release notes have a list of new features for the release.

Examples for FlexConfig

This topic provides a collection of practical examples for implementing FlexConfig policies.

Configure precision time protocol (ISA 3000)

The Precision Time Protocol (PTP) is a time-synchronization protocol developed to synchronize the clocks of various devices in a packet-based network. These device clocks are generally of varying precision and stability. The protocol is designed specifically for industrial, networked measurement and control systems, and is optimal for use in distributed systems because it requires minimal bandwidth and little processing overhead.

A PTP system is a distributed, networked system consisting of a combination of PTP and non-PTP devices. PTP devices include ordinary clocks, boundary clocks and transparent clocks. Non-PTP devices include network switches, routers and other infrastructure devices.

You can configure the Firewall Threat Defense device to be a transparent clock. The Firewall Threat Defense device does not synchronize its clock with the PTP clocks. The Firewall Threat Defense device will use the PTP default profile, as defined on the PTP clocks.

When you configure the PTP devices, you define a domain number for the devices that are meant to function together. Thus, you can configure multiple PTP domains, and then configure each non-PTP device to use the PTP clocks for one specific domain.

Before you begin

Determine the domain number configured on the PTP clocks that the device should use. This example assumes the PTP domain number is 10. Also, determine the interfaces through which the system can reach the PTP clocks in the domain.

These are the guidelines for configuring PTP.

- This feature is only available on the Cisco ISA 3000 appliance.
- Cisco PTP supports multicast PTP messages only.
- PTP is available only for IPv4 networks, not for IPv6 networks.
- PTP configuration is supported on physical Ethernet data interfaces, whether stand-alone or bridge group members. It is not supported on the management interface, subinterfaces, EtherChannels, Bridge Virtual Interfaces (BVI), or any other virtual interfaces.
- PTP flows on VLAN subinterfaces are supported, assuming the appropriate PTP configuration is present on the parent interface.
- You must ensure that PTP packets are allowed to flow through the device. PTP traffic is identified by UDP destination ports 319 and 320, and destination IP address 224.0.1.129, so any access control rule that allows this traffic should work.
- In Routed firewall mode, you must enable multicast routing for PTP multicast groups. In addition, if an interface on which you enable PTP is **not** in a bridge group, you must configure the interface to join the IGMP multicast group 224.0.1.129. If the physical interface is a bridge group member, you do not configure it to join the IGMP multicast group.

Follow these steps to configure Precision Time Protocol on an ISA 3000 device:

Procedure

Step 1 (Routed mode only) Enable Multicast routing, and configure the IGMP group for the interfaces.

In Routed mode, you must enable Multicast routing. In addition, for stand-alone physical interfaces, that is, those that are not bridge group members, you must also configure the interface to join the 224.0.1.129 IGMP group. You cannot configure bridge group members to join an IGMP group, but PTP configuration on bridge group members will work without the IGMP join.

Perform this procedure for each device on which you will configure PTP.

Note Write down the hardware names of each PTP-clock-facing interface on each device, for example, GigabitEthernet1/1.

a) Choose **Devices** > **Device Management**, and edit the device.
b) Click **Routing**.

c) Choose **Multicast Routing** > **IGMP**.
d) Check the **Enable Multicast Routing** check box.
e) Click **Join Group**.
f) Click **Add**, and in the **Add IGMP Join Group Parameters** dialog box, configure the following options and click **OK**.

- **Interface**—Select the PTP-clock-facing stand-alone interface.
- **Join Group**—Click **+** to add a new network object. Create a Host object with the address 224.0.1.129. When configuring additional interfaces, simply select this object. (See Create a network object, on page 2388.)

Repeat this step for each PTP-clock-facing stand-alone interface on the device.

g) Click **Save** on the Routing page.

Step 2 Create the FlexConfig object to enable PTP globally and on the interface.

This procedure assumes that the PTP-clock-facing interface is the same on every device you are configuring. If you have used different interfaces on different devices, you need to create separate objects for each distinct combination. For example, if you use GigabitEthernet1/1 on devices A and B, GigabitEthernet1/2 on devices C and D, and both GigabitEthernet1/1 and 1/2 on devices E and F, you need 3 separate FlexConfig objects, and subsequently, 3 separate FlexConfig policies (explained in the next step).

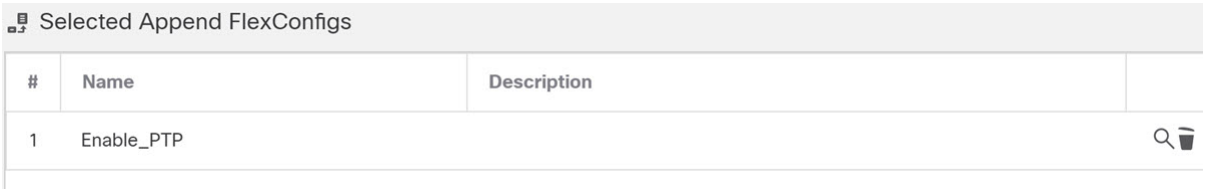
a) Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.
b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Enable_PTP.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features. This ensures that any other changes you make to interface configuration are configured before these commands.
- **Object body**—In the object body, type the commands needed to configure PTP globally and on each PTP-clock-facing interface. For example, the commands needed for the global configuration for PTP domain 10 and the interface configuration on GigabitEthernet1/1 are:

```
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
 ptp enable
```

The object body should look similar to the following:

Step 3 Create the FlexConfig policy and assign it to the devices.



If you created multiple FlexConfig objects for different combinations of PTP-clock-facing interfaces, you need to create separate FlexConfig policies for each object, and assign those policies to the correct devices based on the interfaces you need to configure. Repeat this procedure for each group of devices.

a) Choose **Devices** > **FlexConfig**.
b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

   When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the PTP FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

   The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.
e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.
f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

   The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the PTP FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the PTP commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
 ptp enable
```

Step 4 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 954.

Step 5 Verify the PTP configuration on each device.

From an SSH or Console session into each device, verify the PTP settings:

```
> show ptp clock
 PTP CLOCK INFO
  PTP Device Type: End to End Transparent Clock
  Operation mode: One Step
  Clock Identity: 34:62:88:FF:FE:1:73:81

Configure automatic hardware bypass for power failure (ISA 3000)

Configure automatic hardware bypass to ensure network traffic continues to flow between interface pairs during power outages on ISA 3000 devices.

You can enable hardware bypass so that traffic continues to flow between an interface pair during a power outage. Supported interface pairs are copper interfaces GigabitEthernet 1/1 and 1/2; and GigabitEthernet 1/3 and 1/4. If you have a fiber Ethernet model, only the copper Ethernet pair (GigabitEthernet 1/1 and 1/2) supports hardware bypass.

When hardware bypass is active, traffic passes between these interface pairs at layer 1. The Firewall Threat Defense CLI will see the interfaces as being down. No firewall functions are in place, so make sure you understand the risks of allowing traffic to pass through the device.

In CLI Console or an SSH session, use the **show hardware-bypass** command to monitor the operational status.

Before you begin

For hardware bypass to work:

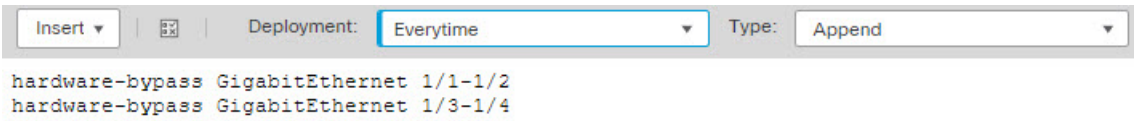
- You must place the interface pairs in the same bridge group.
- You must attach the interfaces to access ports on the switch. Do not attach them to trunk ports.

We recommend that you disable TCP sequence number randomization globally using the Threat Defense Service Policy attached to the access control policy assigned to the device. By default, the ISA 3000 rewrites the initial sequence number (ISN) of TCP connections passing through it to a random number. When hardware bypass is activated, the ISA 3000 is no longer in the data path and does not translate the sequence numbers. The receiving client receives an unexpected sequence number and drops the connection, so the TCP session needs to be re-established. Even with TCP sequence number randomization disabled, some TCP connections will have to be re-established because of the link that is temporarily down during the switchover.

Follow these steps to configure automatic hardware bypass for power failure:

Procedure

Step 1 Create the FlexConfig object to enable automatic bypass.



a. Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

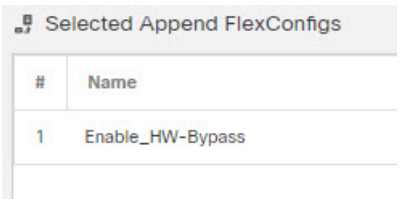
b. Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Enable_HW-Bypass.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to enable automatic hardware bypass. For example, the commands needed for both possible interface pairs:

```
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

The object body should look similar to the following:

Step 2 Create the FlexConfig policy and assign it to the devices.



a. Choose **Devices** > **FlexConfig**.

b. Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c. Select the hardware bypass FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d. Click **Save**.

e. If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f. Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the hardware bypass FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the hardware bypass commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 954.

What to do next

If you want to manually invoke hardware bypass or manually turn it off, you need to create two FlexConfig objects:

- One that manually starts bypass, which would contain one or both of the following commands, depending on whether you want to invoke bypass for both pairs:

```
hardware-bypass manual GigabitEthernet 1/1-1/2
hardware-bypass manual GigabitEthernet 1/3-1/4
```

- One that manually turns off bypass, which would contain one or both of the following commands:

```
no hardware-bypass manual GigabitEthernet 1/1-1/2
no hardware-bypass manual GigabitEthernet 1/3-1/4
```

You would then need to add one or the other object to the FlexConfig policy, and deploy changes, to either turn bypass on or off. You would also need to immediately remove the object from the FlexConfig policy after deployment. If you manually invoke bypass, you would then need to repeat the process to turn it off again. Thus, using this manual method requires frequent and careful editing of the FlexConfig policy and additional deployments.

Migrate FlexConfig policies

This task migrates ECMP, VXLAN, and EIGRP policies from FlexConfig objects to the management center UI to enable direct policy management.

Attention This section on migrating FlexConfig policies is applicable only for migrating ECMP, VXLAN, and EIGRP policies.

The ECMP, VXLAN, and EIGRP policies were configured using the FlexConfig objects and policies in earlier versions of the Firewall Management Center. You can now directly configure these policies in the management center UI. When you are upgrading the management center from earlier versions, the FlexConfig configuration is retained. However, to manage the policies from the UI, you must redo the configuration in the corresponding **Device (Edit)** > **Routing** page and remove the configuration from FlexConfig. To automate creation of the policies in the UI, Firewall Management Center provides an option to migrate the policies from FlexConfig to the UI. However, it does not remove the migrated policies from the FlexConfig. For post-migration procedure, refer to Step 7, on page 966.

Before you begin

- Ensure that the deployed FlexConfig policy is up-to-date and not out-of-date. The migration option will be available only if the policy is up-to-date on at least 1 device. Migration does not take place for those devices that have out-of-date policies.
- If the policy is configured in both FlexConfig and the management center:
  - Migration will not be initiated if the policy is already configured at **Device (Edit)** > **Routing**.
  - During deployment, the management center displays an error message. Example EIGRP migration error message—*EIGRP is configured through FlexConfig object and also under Device Listing ->Routing EIGRP for the device. Maintain the EIGRP configuration in either Routing EIGRP or FlexConfig.*
- If the network objects used in the policy exist in the management center, during migration, they are reused. During migration, when a network object that is matching the IP configuration is not available, a new network object is created as *bb* appended with a timestamp and integer, like ***bb_<timestamp>_<integer>***. For more than one such network object, the integer variable in the name would be incremented by one.

Follow these steps to migrate FlexConfig policies:

Procedure

Step 1 Choose **Devices** > **FlexConfig**, click **Edit** (✎) against the FlexConfig policy that you want to migrate.

Step 2 Click **Migrate Config**.

Note Once migration starts, both **Migrate Config** and FlexConfig **Edit** options are not available.

The **Migrate Config** option is not available, when:

- There are no applicable FlexConfig CLIs to be migrated.
- The FlexConfig policy is not associated with any FlexConfig objects.
- There are no devices that are associated with the FlexConfig policy.

Step 3 In the **Migrate Flex Configuration** dialog box, select the device to which you wish to migrate the configuration, and then click **Ok**.

The migration progress is displayed as task notification. When the migration is complete, click the *View Details* link and download the migration report (PDF format).

Step 4 To view the policy changes, choose **System** (⚙) > **Monitoring** > **Audit** and click on the *Flex Config Migration* message.

Step 5 To view the FlexConfig migration report, choose **System** (⚙) > **Monitoring** > **Audit** and click on the *Flex Config Migration* message. To view the complete migration report, click the **Report** icon.

Step 6 Verify the migrated configuration settings in the corresponding **Device (Edit)** > **Routing**. page.

Step 7 To remove the specific policy config from FlexConfig for the device, in the management center, do the following:

a) Identify the migrated FlexConfig policy for the device.
b) Use the copy option and create duplicate of the FlexConfig policy.
c) Remove the corresponding CLI objects from the duplicated FlexConfig policy.
d) Associate the device to the duplicated FlexConfig policy.

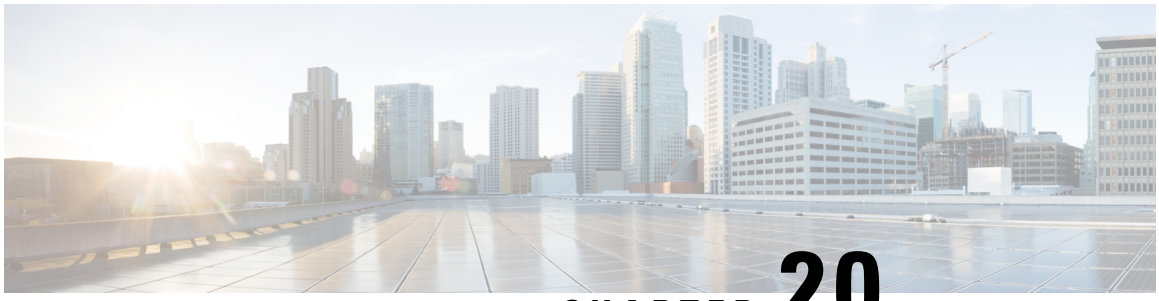
Step 8 Save and deploy the configuration.

History for FlexConfig

This reference provides a summary of feature changes by release for the FlexConfig policy.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Quick recovery after data plane failure for the Firepower 1000/2100 and Firepower 4100/9300.	7.4.1	7.4.1	If the data plane process crashes, the system now reloads only the data plane process instead of rebooting the device. Along with the data plane process reload, Snort and a few other processes also get reloaded. However, if the data plane process crashes during bootup, the device follows the normal reload/reboot sequence, which helps avoid a reload process loop from occurring. This feature is enabled by default for both new and upgraded devices. New/modified CLI commands: **data-plane quick-reload**, **no data-plane quick-reload**, **show data-plane quick-reload status** Supported platforms: Firepower 1000/2100, Firepower 4100/9300 Platform restrictions: Not supported in multi-instance mode. See: *Cisco Secure Firewall Threat Defense Command Reference* and Cisco Secure Firewall ASA Series Command Reference.
Migration tool support.	7.3.0	Any	Support to migrate Flex configured ECMP, VXLAN, and EIGRP policies to management center was introduced. New/modified screens: **Devices** > **FlexConfig** > **Migrate FlexConfig**
Removal of BFD configuration in FlexConfig.	7.3.0	Any	Support to configure BFD policies directly in the management center user interface was introduced. Hence, FlexConfig support to configure BFD policies was removed.
Removal of priority-queue.	7.2.5	7.2.5	Support to configure priority-queue in threat defense was removed.
Removal of EIGRP configuration in FlexConfig.	7.2.0	Any	Support to configure EIGRP directly in the management center user interface was introduced. Hence, FlexConfig support to configure EIGRP policies was removed.
Removal of PBR configuration.	7.1.0	7.1.0	Support to configure the PBR directly in the FMC user interface was introduced. Hence, FlexConfig support to configure PBR for FTD 7.1 and higher was removed. New/modified commands: **policy-route route-map***routemap-object-name*.
Removal of ECMP zone creation support in FlexConfig.	7.1.0	Any	Support to configure the ECMP zones directly in the FMC user interface was introduced. Hence, FlexConfig support to configure ECMP zones was removed.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Precision Time Protocol (PTP) configuration for ISA 3000 devices.	6.5.0	Any	You can use FlexConfig to configure the Precision Time Protocol (PTP) on ISA 3000 devices. PTP is a time-synchronization protocol developed to synchronize the clocks of various devices in a packet-based network. The protocol is designed specifically for industrial, networked measurement and control systems. We now allow you to include the **PTP** (interface mode) command, and the global commands **PTP mode e2etransparent** and **PTP domain**, in FlexConfig objects. New/modified commands: **show PTP**.
Deprecated FlexConfig objects.	6.3.0	Any	Several features that in previous releases you configured using FlexConfig are now directly supported in FMC. You need to remove these FlexConfig objects if you are using them, and convert your configuration to use the new objects. These are the deprecated FlexConfig objects and text objects. • **Default_DNS_Configure**, including the defaultDNSNameServerList and defaultDNSParameters text objects. Now, please configure DNS for the data interfaces using the Platform Settings policy. • **TCP_Embryonic_Conn_Limit**, and the tcp_conn_misc and tcp_conn_limit text objects. Configure these features in the FTD Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device. • **TCP_Embryonic_Conn_Timeout**, and the tcp_conn_misc and tcp_conn_timeout text objects. Configure these features in the FTD Service Policy.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
FlexConfig updates.	6.2.1	Any	As per the Government Certification requirements, all sensitive information like password, shared keys in system-provided or user-defined FlexConfig object should be masked using secret key variables. After you update the FMC to Version 6.2.1+, all sensitive information in FlexConfig Objects are converted to secret key variable format. In addition, these new FlexConfig templates are added: • **Default_DNS_Configure** template allows you to the default DNS group, which is used to resolve hostnames for commands or features that resolve names through the data interfaces. • **TCP Embryonic connection limit and timeout configuration** template allows you to configure embryonic connection limits/timeout CLIs to protect from SYN Flood DoSAttack. • **Turn on threat detection configure and clear** templates allow you to configure threat detection statistics for attacks intercepted by TCP Intercept. • **IPV6 router header inspection** template allows you to configure of IPV6 inspection header for selectively allow/block certain headers with different types (e.g. allowing RH Type 2,mobile). • **DHCPv6 prefix delegation** template allows you to configure one outside (PD client) and one inside interface (recipient of delegated prefix) for IPv6 prefix delegation.
FlexConfig.	6.2.0	Any	The FlexConfig feature allows you use the FMC to deploy ASA CLI template-based functionality to FTD devices. This feature allows you to enable some of the most valuable ASA functions that are not currently available on FTD devices. This functionality is structured as templates and objects that work together in a policy. The default templates are officially supported by Cisco TAC. New/modified screens: • **Devices** > **FlexConfig** • **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Objects** • **Objects** > **Object Management** > **FlexConfig** > **Text Object**

CHAPTER 20

Static and Default Routes

This chapter describes how to configure static and default routes on the Firewall Threat Defense.

- Static and default routes overview, on page 973
- Requirements and prerequisites for static routes, on page 976
- Guidelines for static and default routes, on page 976
- Add a static route, on page 977
- Reference for routing, on page 978

Static and default routes overview

To route traffic to a non-connected host or network, define a route to the host or network, using static or dynamic routing. Generally, you must configure at least one static route: a default route for all traffic that is not routed by other means to a default network gateway, which is typically the next-hop router.

Default routes

The simplest option is to configure a default static route to send all traffic to an upstream router, relying on the router to route the traffic for you. A default route identifies the gateway IP address to which the Firewall Threat Defense sends all IP packets for which it does not have a learned or static route. A default static route is simply a static route with 0.0.0.0/0 (IPv4) or ::/0 (IPv6) as the destination IP address.

Default route configuration requirements

You should always define a default route.

The Firewall Threat Defense has separate routing tables for data interfaces and for management-only interfaces (including the special Linux Management interface). You can only add a default route for the data routing table. The Firewall Threat Defense automatically adds a default route in the management-only routing table that sends traffic to the Linux Management interface, where a separate route lookup occurs in the Linux routing table. You can add static routes to the Linux routing table that can be used by Management using the Firewall Threat Defense CLI **configure network static-routes** command.

Note The *default* Linux route is set with the **configure network ipv4** or **configure network ipv6** command.

Static routes

You might want to use static routes in the following cases:

Use cases for static routes

- Your networks use an unsupported router discovery protocol.
- Your network is small and you can easily manage static routes.
- You do not want the traffic or CPU overhead associated with routing protocols.
- In some cases, a default route is not enough. The default gateway might not be able to reach the destination network, so you must also configure more specific static routes. For example, if the default gateway is outside, then the default route cannot direct traffic to any inside networks that are not directly connected to the Firewall Threat Defense.
- You are using a feature that does not support dynamic routing protocols.
- Virtual routers use static routes to create route leaks. Route leaks enable flow of traffic from an interface of a virtual router to another interface in another virtual router. For more information, see Virtual router interconnection, on page 994.

Route to null0 interface to drop unwanted traffic

Access rules let you filter packets based on the information contained in their headers. A static route to the null0 interface is a complementary solution to access rules. You can use a null0 route to forward unwanted or undesirable traffic so the traffic is dropped.

Performance and routing benefits

Using static null0 routes provides a favorable performance profile. You can also use static null0 routes to prevent routing loops. BGP can leverage the static null0 route for Remotely Triggered Black Hole routing.

Note Though routing traffic to a null0 interface to blackhole it helps to drop unwanted traffic, this method increases the `no-route` ASP drops.

Route priorities

- Routes that identify a specific destination take precedence over the default route.
- When multiple routes exist to the same destination (either static or dynamic), then the administrative distance for the route determines priority. Static routes are set to 1, so they typically are the highest priority routes.
- When you have multiple static routes to the same destination with the same administrative distance, see Equal-cost multi-path routing, on page 987.
- For traffic emerging from a tunnel with the Tunneled option, this route overrides any other configured or learned default routes.

Transparent firewall mode and bridge group routes

For traffic that originates on the Firewall Threat Defense device and is destined through a bridge group member interface for a non-directly connected network, you need to configure either a default route or static routes so the Firewall Threat Defense device knows out of which bridge group member interface to send traffic. Traffic that originates on the Firewall Threat Defense device might include communications to a syslog server or SNMP server. If you have servers that cannot all be reached through a single default route, then you must configure static routes. For transparent mode, you cannot specify the BVI as the gateway interface; only member interfaces can be used. For bridge groups in routed mode, you must specify the BVI in a static route; you cannot specify a member interface. Refer to MAC address and route lookups, on page 77 for more information.

Static route tracking

The static route tracking feature provides a method for tracking the availability of a static route and installing a backup route if the primary route should fail. For example, you can define a default route to an ISP gateway and configure a backup default route to a secondary ISP in case the primary ISP becomes unavailable.

Static route tracking implementation

One of the problems with static routes is that there is no inherent mechanism for determining if the route is up or down. They remain in the routing table even if the next hop gateway becomes unavailable. Static routes are only removed from the routing table if the associated interface on the Firewall Threat Defense device goes down.

The Firewall Threat Defense device implements static route tracking by associating a static route with a monitoring target host on the destination network that the Firewall Threat Defense device monitors using ICMP echo requests. If an echo reply is not received within a specified time period, the host is considered down, and the associated route is removed from the routing table. An untracked backup route with a higher metric is used in place of the removed route.

When selecting a monitoring target, you need to make sure that it can respond to ICMP echo requests. You can choose any network object as the target, but consider using one of these options:

- The address of the ISP gateway (for dual ISP support)
- The address of the next hop gateway (if you are concerned about gateway availability)
- A server on the target network, such as a syslog server, with which the Firewall Threat Defense device needs to communicate
- A persistent network object on the destination network

Note A PC that may be shut down at night is not a good choice.

You can configure static route tracking for statically defined routes or default routes obtained through DHCP or PPPoE. You can only enable PPPoE clients on multiple interfaces with route tracking configured.

Requirements and prerequisites for static routes

Requirement	Description
Model support	Firewall Threat Defense
Supported domains	Any
User roles	Admin Network Admin

Guidelines for static and default routes

Firewall mode and bridge groups

Configure static routes according to your firewall mode and interface requirements.

- In transparent mode, static routes must use the bridge group member interface as the gateway; you cannot specify the BVI.
- In routed mode, you must specify the BVI as the gateway; you cannot specify the member interface.
- Static route tracking is not supported for bridge group member interfaces or on the BVI.

Supported network address

Ensure your network addresses meet static route requirements.

- Static route tracking is not supported for IPv6.
- The Firewall Threat Defense does not support Class E routing, so a Class E network is not routable in static routes.

Clustering

Consider these limitations for clustering and multiple context mode configurations.

- In clustering, static route tracking is only supported on the control node.

Network object group

You cannot use a range of network objects or a network object group having a range of IP addresses in a static route.

ASP and RIB Route Entries

All routes and its distance installed on the device are captured in the ASP routing table. This is common for all static and dynamic routing protocols. Only the best distance route is captured in the RIB table.

Add a static route

A static route defines where to send traffic for specific destination networks. You should at a minimum define a default route. A default route is simply a static route with 0.0.0.0/0 as the destination IP address.

To configure routes for redundant manager access data interfaces, see Configure a redundant manager access data interface, on page 758.

Procedure

Step 1 To configure routes for redundant manager access data interfaces, see Configure a redundant manager access data interface, on page 758.

Step 2 Click **Routing**.

Step 3 (May be required) From the virtual routers drop-down list, select the virtual router for which you are configuring a static route.

Step 4 Select **Static Route**.

Step 5 Click **Add Routes**.

Step 6 Click **IPv4** or **IPv6** depending on the type of static route that you are adding.

Step 7 Choose the **Interface** to which this static route applies.

For transparent mode, choose a bridge group member interface name. For routed mode with bridge groups, you can choose either the bridge group member interface for the BVI name. To "black hole" unwanted traffic, choose the **Null0** interface.

For a device using virtual routing, you can select an interface that belongs to another virtual router. You can create such a static route if you want to leak traffic from this virtual router into the other virtual router. For more information, see Virtual router interconnection, on page 994.

Step 8 In the **Available Network** list, choose the destination network.

To define a default route, create an object with the address 0.0.0.0/0 and select it here.

Note Although you can create and choose a Network Object Group containing a range of IP addresses, the Firewall Management Center does not support using ranges in static routes.

Step 9 In the **Gateway** or **IPv6 Gateway** field, enter or choose the gateway router that is the next hop for this route. You can provide an IP address or a Networks/Hosts object.

When you are using static-route configuration for virtual routers to leak routes, do not specify the next hop gateway.

Step 10 In the **Metric** field, enter the number of hops to the destination network. Valid values range from 1 to 255; the default value is 1.

The metric is a measurement of the "expense" of a route, based on the number of hops (hop count) to the network on which a specific host resides. Hop count is the number of networks that a network packet must traverse, including the destination network, before it reaches its final destination. The metric is used to compare

routes among different routing protocols. The default administrative distance for static routes is 1, giving it precedence over routes discovered by dynamic routing protocols but not directly connected routes. The default administrative distance for routes discovered by OSPF is 110. If a static route has the same administrative distance as a dynamic route, the static route takes precedence. Connected routes always take precedence over static or dynamically discovered routes.

Step 11 (Optional) For a default route, click the **Tunneled** checkbox to define a separate default route for VPN traffic.

You can define a separate default route for VPN traffic if you want your VPN traffic to use a different default route than your non VPN traffic. For example, traffic incoming from VPN connections can be easily directed towards internal networks, while traffic from internal networks can be directed towards the outside. When you create a default route with the tunneled option, all traffic from a tunnel terminating on the device that cannot be routed using learned or static routes, is sent to this route. You can configure only one default tunneled gateway per device. ECMP for tunneled traffic is not supported.

Step 12 (IPv4 static route only) To monitor route availability, enter or choose the name of an SLA (service level agreement) Monitor object that defines the monitoring policy, in the **Route Tracking** field.

See Configure an SLA monitor, on page 2433.

Step 13 Click **Ok**.

Reference for routing

This section describes underlying concepts of how routing behaves within the Firewall Threat Defense.

Path determination

Routing protocols use metrics to evaluate what path will be the best for a packet to travel. A metric is a standard of measurement, such as path bandwidth, that is used by routing algorithms to determine the optimal path to a destination. To aid the process of path determination, routing algorithms initialize and maintain routing tables, which include route information. Route information varies depending on the routing algorithm used.

Path determination process

Routing algorithms fill routing tables with a variety of information. Destination or next hop associations tell a router that a particular destination can be reached optimally by sending the packet to a particular router representing the next hop on the way to the final destination. When a router receives an incoming packet, it checks the destination address and attempts to associate this address with a next hop.

Routing tables also can include other information, such as data about the desirability of a path. Routers compare metrics to determine optimal routes, and these metrics differ depending on the design of the routing algorithm used.

Routers communicate with one another and maintain their routing tables through the transmission of a variety of messages. The routing update message is one such message that generally consists of all or a portion of a routing table. By analyzing routing updates from all other routers, a router can build a detailed picture of network topology. A link-state advertisement, another example of a message sent between routers, informs other routers of the state of the sender links. Link information also can be used to build a complete picture of network topology to enable routers to determine optimal routes to network destinations.

Supported route types

There are several route types that a router can use. The Firewall Threat Defense device uses the following route types:

- Static Versus Dynamic
- Single-Path Versus Multipath
- Flat Versus Hierarchical
- Link-State Versus Distance Vector

Static versus dynamic routing algorithms

Static routing algorithms are actually table mappings established by the network administrator. These mappings do not change unless the network administrator alters them. Algorithms that use static routes are simple to design and work well in environments where network traffic is relatively predictable and where network design is relatively simple.

Dynamic routing algorithms

Because static routing systems cannot react to network changes, they generally are considered unsuitable for large, constantly changing networks. Most of the dominant routing algorithms are dynamic routing algorithms, which adjust to changing network circumstances by analyzing incoming routing update messages. If the message indicates that a network change has occurred, the routing software recalculates routes and sends out new routing update messages. These messages permeate the network, stimulating routers to rerun their algorithms and change their routing tables accordingly.

Dynamic routing algorithms can be supplemented with static routes where appropriate. A router of last resort (a default route for a router to which all unrouteable packets are sent), for example, can be designated to act as a repository for all unrouteable packets, ensuring that all messages are at least handled in some way.

Single-path versus multipath

Some sophisticated routing protocols support multiple paths to the same destination. Unlike single-path algorithms, these multipath algorithms permit traffic multiplexing over multiple lines. The advantages of multipath algorithms are substantially better throughput and reliability, which is generally called load sharing.

Flat versus hierarchical routing

Some routing algorithms operate in a flat space, while others use routing hierarchies.

In a flat routing system, the routers are peers of all others. In a hierarchical routing system, some routers form what amounts to a routing backbone. Packets from non-backbone routers travel to the backbone routers, where they are sent through the backbone until they reach the general area of the destination. At this point, they travel from the last backbone router through one or more non-backbone routers to the final destination.

Routing systems often designate logical groups of nodes, called domains, autonomous systems, or areas.

In hierarchical systems, some routers in a domain can communicate with routers in other domains, while others can communicate only with routers within their domain. In very large networks, additional hierarchical levels may exist, with routers at the highest hierarchical level forming the routing backbone.

The primary advantage of hierarchical routing is that it mimics the organization of most companies and therefore supports their traffic patterns well. Most network communication occurs within small company groups (domains). Because intradomain routers need to know only about other routers within their domain, their routing algorithms can be simplified, and, depending on the routing algorithm being used, routing update traffic can be reduced accordingly.

Link-state versus distance vector

Link-state algorithms (also known as shortest path first algorithms) flood routing information to all nodes in the internetwork. Each router, however, sends only the portion of the routing table that describes the state of its own links. In link-state algorithms, each router builds a picture of the entire network in its routing tables.

Distance vector algorithms (also known as Bellman-Ford algorithms) call for each router to send all or some portion of its routing table, but only to its neighbors. In essence, link-state algorithms send small updates everywhere, while distance vector algorithms send larger updates only to neighboring routers. Distance vector algorithms know only about their neighbors. Typically, link-state algorithms are used in conjunction with OSPF routing protocols.

Supported internet protocols for routing

The Firewall Threat Defense device supports several internet protocols for routing. Each protocol is briefly described in this section.

The device supports these internet routing protocols:

- **Enhanced Interior Gateway Routing Protocol (EIGRP)**

  EIGRP is a Cisco proprietary protocol that provides compatibility and seamless interoperation with IGRP routers. An automatic-redistribution mechanism allows IGRP routes to be imported into Enhanced IGRP, and vice versa, so it is possible to add Enhanced IGRP gradually into an existing IGRP network.

- **Open Shortest Path First (OSPF)**

  OSPF is a routing protocol developed for Internet Protocol (IP) networks by the interior gateway protocol (IGP) working group of the Internet Engineering Task Force (IETF). OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area includes an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

- **Routing Information Protocol (RIP)**

  RIP is a distance-vector protocol that uses hop count as its metric. RIP is widely used for routing traffic in the global Internet and is an interior gateway protocol (IGP), which means that it performs routing within a single autonomous system.

- **Border Gateway Protocol (BGP)**

  BGP is an interautonomous system routing protocol. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP). Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

Routing tables

The Firewall Threat Defense uses separate routing tables for data traffic (through-the-device) and for management traffic (from-the-device). This section describes how the routing tables work. For information about the management routing table, see also Routing table for management traffic, on page 986.

How the routing table is populated

The Firewall Threat Defense routing table can be populated by statically defined routes, directly connected routes, and routes discovered by the dynamic routing protocols. Because the Firewall Threat Defense device can run multiple routing protocols in addition to having static and connected routes in the routing table, it is possible that the same route is discovered or entered in more than one manner.

Route selection criteria

When two routes to the same destination are put into the routing table, the one that remains in the routing table is determined as follows:

- If the two routes have different network prefix lengths (network masks), then both routes are considered unique and are entered into the routing table. The packet forwarding logic then determines which of the two to use.

  For example, if the RIP and OSPF processes discovered the following routes:

  - RIP: 192.168.32.0/24
  - OSPF: 192.168.32.0/19

  Even though OSPF routes have the better administrative distance, both routes are installed in the routing table because each of these routes has a different prefix length (subnet mask). They are considered different destinations and the packet forwarding logic determines which route to use.

- If the Firewall Threat Defense device learns about multiple paths to the same destination from a single routing protocol, such as RIP, the route with the better metric (as determined by the routing protocol) is entered into the routing table.

  Metrics are values associated with specific routes, ranking them from most preferred to least preferred. The parameters used to determine the metrics differ for different routing protocols. The path with the lowest metric is selected as the optimal path and installed in the routing table. If there are multiple paths to the same destination with equal metrics, load balancing is done on these equal cost paths.

- If the Firewall Threat Defense device learns about a destination from more than one routing protocol, the administrative distances of the routes are compared, and the routes with lower administrative distance are entered into the routing table.

Administrative Distances for Routes

You can change the administrative distances for routes discovered by or redistributed into a routing protocol. If two routes from two different routing protocols have the same administrative distance, then the route with the lower *default* administrative distance is entered into the routing table. In the case of EIGRP and OSPF routes, if the EIGRP route and the OSPF route have the same administrative distance, then the EIGRP route is chosen by default.

Administrative distance is a route parameter that the Firewall Threat Defense uses to select the best path when there are two or more different routes to the same destination from two different routing protocols. Because

the routing protocols have metrics based on algorithms that are different from the other protocols, it is not always possible to determine the best path for two routes to the same destination that were generated by different routing protocols.

Each routing protocol is prioritized using an administrative distance value. The following table shows the default administrative distance values for the routing protocols supported by the Firewall Threat Defense.

Table 68: Default Administrative Distance for Supported Routing Protocols

Route Source	Default Administrative Distance
Connected interface	0
VPN route	1
Static route	1
EIGRP Summary Route	5
External BGP	20
Internal EIGRP	90
OSPF	110
IS-IS	115
RIP	120
EIGRP external route	170
Internal and local BGP	200
Unknown	255

The smaller the administrative distance value, the more preference is given to the protocol. For example, if the Firewall Threat Defense receives a route to a certain network from both an OSPF routing process (default administrative distance - 110) and a RIP routing process (default administrative distance - 120), the Firewall Threat Defense chooses the OSPF route because OSPF has a higher preference. In this case, the router adds the OSPF version of the route to the routing table.

A VPN advertised route (V-Route/RRI)) is equivalent to a static route with the default administrative distance 1. But it has a higher preference as with the network mask 255.255.255.255.

In this example, if the source of the OSPF-derived route was lost (for example, due to a power shutdown), the Firewall Threat Defense would then use the RIP-derived route until the OSPF-derived route reappears.

The administrative distance is a local setting. For example, if you change the administrative distance of routes obtained through OSPF, that change would only affect the routing table for the Firewall Threat Defense on which the command was entered. The administrative distance is not advertised in routing updates.

Administrative distance does not affect the routing process. The routing processes only advertise the routes that have been discovered by the routing process or redistributed into the routing process. For example, the RIP routing process advertises RIP routes, even if routes discovered by the OSPF routing process are used in the routing table.

Backup Dynamic and Floating Static Routes

A backup route is registered when the initial attempt to install the route in the routing table fails because another route was installed instead. If the route that was installed in the routing table fails, the routing table maintenance process calls each routing protocol process that has registered a backup route and requests them to reinstall the route in the routing table. If there are multiple protocols with registered backup routes for the failed route, the preferred route is chosen based on administrative distance.

Because of this process, you can create floating static routes that are installed in the routing table when the route discovered by a dynamic routing protocol fails. A floating static route is simply a static route configured with a greater administrative distance than the dynamic routing protocols running on the Firewall Threat Defense. When the corresponding route discovered by a dynamic routing process fails, the static route is installed in the routing table.

How forwarding decisions are made

A forwarding decision is a network routing process that
