Step 5 To delete an identity rule, click **Delete** ( ).

Step 6 To create a rule category, click **Add Category** and choose the position and the rule.

Step 7 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Troubleshoot user control

If you notice unexpected user rule behavior, consider tuning your rule, identity source, or realm configurations. For other related troubleshooting information, see:

- Troubleshoot Cisco ISE/ISE-PIC or Cisco TrustSec issues, on page 1927
- Troubleshoot the TS agent identity source, on page 1938
- Troubleshoot the captive portal identity source, on page 1906
- Troubleshoot realms and user downloads, on page 1877

Rules targeting realms, users, or user groups are not matching traffic

If you configure a TS Agent or ISE/ISE-PIC device to monitor a large number of user groups, or if you have a very large number of users mapped to hosts on your network, the system may drop user records due to your Firewall Management Center user limit. As a result, rules with user conditions may not match traffic as expected.

Rules targeting user groups or users within user groups are not matching traffic as expected

If you configure a rule with a user group condition, your LDAP or Active Directory server must have user groups configured. The system cannot perform user group control if the server organizes the users in basic object hierarchy.

Rules targeting users in secondary groups are not matching traffic as expected

If you configure a rule with a user group condition that includes or excludes users who are members of a secondary group on your Active Directory server, your server may be limiting the number of users it reports.

By default, Active Directory servers limit the number of users they report from secondary groups. You must customize this limit so that all of the users in your secondary groups are reported to the Firewall Management Center and eligible for use in rules with user conditions.

Rules are not matching users when seen for the first time

After the system detects activity from a previously-unseen user, the system retrieves information about them from the server. Until the system successfully retrieves this information, activity seen by this user is *not* handled by matching rules. Instead, the user session is handled by the next rule it matches (or the policy's default action, if applicable).

For example, this might explain when:

- Users who are members of user groups are not matching rules with user group conditions.
- Users who were reported by a TS Agent or ISE device are not matching rules, when the server used for user data retrieval is an Active Directory server.

Note that this might also cause the system to delay the display of user data in event views and analysis tools.

Rules are not matching all ISE/ISE-PIC users

This is expected behavior. You can perform user control on ISE/ISE-PIC users who were authenticated by an Active Directory domain controller. You cannot perform user control on ISE/ISE-PIC users who were authenticated by an LDAP, RADIUS, or RSA domain controller.

Users and groups using too much memory

If processing users and groups is using too much memory, health alerts are displayed. Remember that all user sessions are propagated to all devices managed by the Firewall Management Center. If your Firewall Management Center manages devices with different amounts of memory, the device with the least amount of memory determines the number of user sessions the system can handle without errors.

It's not possible to tune memory allocated to identity processes; even if a device has available memory, it can report out-of-memory issues. If issues persist, you have these options:

- Segregate lower capacity managed devices on subnets and configure ISE/ISE-PIC to not report passive authentication data to those subnets.

  See the chapter on managing network devices in the *Cisco Identity Services Engine Administrator Guide*.
- Unsubscribe from Security Group Tags (SGTs).
- Upgrade your managed device to a model with more memory.

CHAPTER 56

Prefilter Policies

The prefilter policy is the first security policy applied to incoming connections. Prefilter rules evaluate traffic on layer 3/4 criteria only, that is, protocol and source/destination IP address and port. They give you a chance to make early decisions on connections so you can avoid further processing and improve device performance.

- Prefilter policies, on page 1967
- Requirements and prerequisites for prefilter policies, on page 1976
- Guidelines and limitations for the prefilter policy, on page 1976
- Guidelines and limitations for encapsulated traffic handling, on page 1977

- Configure prefilter policies, on page 1979
- Examples of prefilter policy, on page 1988
- History for the prefilter policy, on page 1992

Prefilter policies

A prefilter policy is a security policy that

- serves as the first security policy applied to incoming connections
- evaluates traffic on layer 3/4 criteria only, including protocol and source/destination IP address and port
- enables early decisions on connections to avoid further processing and improve device performance, and
- can fast path connections and make them eligible for flow offload.

Prefilter policy actions

Use prefilter policies to implement these main actions:

- Improve performance—The sooner you exclude traffic that does not require inspection, the better. Specifically, you can perform these actions.
  - Offload trusted flows—If your device supports flow offload, use the prefilter Fastpath action to identify flows you trust to be eligible for offloading to NIC processing. No further processing, including inspection, is needed for these connections. Refer to Best practices for fastpath prefiltering, on page 1978 and Large flow offloads, on page 1971.
  - Block unwanted connections—For example, if you want to block entire subnets, protocols, or TCP/UDP ports, configure this in the prefilter policy.

- Rezone plain text encapsulated tunnels so you can handle them as a unit in the access control policy. Some protocols, such as GRE, create plain-text tunnels that include many connections. By rezoning a tunnel, you assign it a tag, which you can select in access control rules as a source or destination zone. This allows you to apply customized intrusion or other rules to the tunneled traffic and provides granular insight and control.

Note VPN or other encrypted tunnels are not plain-text tunnels and cannot be rezoned.

You must assign each access control policy a prefilter policy. However, the system comes with a pre-defined prefilter policy that might work for you.

Default prefilter policy

A default prefilter policy only analyzes plain-text encapsulated tunnels. It is automatically assigned when you create a new access control policy. It cannot be deleted from the system.

Default prefilter policy characteristics

Every access control policy must have an assigned prefilter policy. For convenience, the system includes a default prefilter policy that is automatically assigned when you create a new access control policy.

You can instead change the default policy to block all plain-text tunnels. See Configuring the default action, on page 1981.

If you want to do any other customization, including adding prefilter or tunnel rules, you must create your own prefilter policy and assign it to the appropriate access control policies, as explained in Assign access control policy to devices, on page 1583.

Prefilter policy rule order

Prefilter policy rule order is a traffic processing mechanism that determines which tunnel rules and prefilter rules handle network traffic first and applies the default action for unmatched tunnels.

Rule processing sequence

In a prefilter policy, tunnel rules, prefilter rules, and a default action handle network traffic:

- Tunnel and prefilter rules—First, rules in a prefilter policy handle traffic in the order you specify. Tunnel rules match specific tunnels only. Prefilter rules have a wider range of constraints.

  Rules are match in top-down order, first match wins. Thus, rule order is critical. For example, you might want to block an entire subnet except for two specific IP addresses on the subnet. In that case:

  - The first rule should specify the two allowable IP addresses as the source network, and the rule action would be Analyze. Connections from these two IP addresses would match this rule, and the next rule would not be processed.
  - The next rule should specify the entire subnet as the source network, with Block for the rule action.

  For more information, see Tunnel vs prefilter rules, on page 1969.

- Default action (tunnels only)—If a tunnel does not match any rules, the default action handles it. The default action can block these tunnels or continue access control on their individual encapsulated connections (Analyze action).

  There is no default action for nonencapsulated traffic. If a nonencapsulated connection does not match any prefilter rules, the system continues with access control. These connections might subsequently be blocked by other policies, or ultimately allowed.

If you need to change rule order, you can:

- Drag and drop the rule to the right location.
- Right click the rule and **Cut**, then find the right location, right click, and select **Paste Above** or **Paste Below**.
- Edit the rule and use the **Insert** control to change its location.

Tunnel vs prefilter rules

Choose to configure a tunnel rule or a prefilter rule based on the type of traffic you want to match and the actions or analysis you intend to perform.

Characteristic	Tunnel Rules	Prefilter Rules
Primary function	Quickly fastpath, block, or rezone plaintext, passthrough tunnels.	Quickly fastpath or block any other connection that benefits from early handling.
Encapsulation and port/protocol criteria	Encapsulation conditions match only plaintext tunnels over selected protocols: GRE, IP-in-IP, IPv6-in-IP, Teredo.	Port conditions can use a wider range of port and protocol constraints than tunnel rules; see Port, protocol, and ICMP code rule conditions (concept), on page 1323.
Network criteria	Tunnel endpoint conditions constrain the endpoints of the tunnels you want to handle.	Network conditions constrain the source and destination hosts in each connection.
Direction	Bidirectional or unidirectional (configurable). Tunnel rules are bidirectional by default, so they can handle all traffic between tunnel endpoints.	Unidirectional only (nonconfigurable). Prefilter rules match source-to-destination traffic only. Return traffic for allowed connections is also permitted.
Rezone sessions for further analysis	Supported, using tunnel zones; see Using tunnel zones to apply access control at the tunnel level, on page 1970.	Not applicable.

How the system processes plain-text tunnels

Some protocols, such as GRE, create plain-text (not encrypted) tunnels that contain (or encapsulate) multiple inner connections. These connections might flow between discontinuous networks. These tunnels are especially useful for routing custom protocols over IP networks, IPv6 traffic over IPv4 networks, and so on.

Summary

A plain-text tunnel has two sets of IP headers:

- Outer headers: Specify tunnel endpoint addresses for prefilter policy handling
- Inner headers: Contain actual connection endpoint addresses for granular inspection

Workflow

The system processes plain-text tunnels through these stages:

1. The system receives a plain-text tunnel with dual IP header structure.
   - Outer header—An outer encapsulation header specifies the source and destination IP addresses of the tunnel endpoints—the routed interfaces of the network devices on either side of the tunnel.
   - Inner headers—Inner payload headers specify the source and destination IP addresses of the encapsulated connections' actual endpoints. There are separate headers for each connection contained within the tunnel.

   For regular, non-tunneled connections, there is only the "outer" header, as the connection does not contain any subordinate connections.
2. The prefilter policy processes the outer tunnel headers to determine handling approach.

   The prefilter policy uses outer headers to handle traffic. You can block or fast path entire plaintext, passthrough tunnels at this stage.

   If you do not want to allow plain-text tunnels at all, you can set the default action in the prefilter policy to block all plain-text tunnels. This block does not apply to encrypted tunnels such as VPN.
3. The system exposes inner headers for tunnels that pass prefilter analysis.

   Any tunnels that you analyze (that is, not block or fast path) have these inner headers exposed for use by the rest of the security policies and other features such as QoS. These features use the innermost detectable level of headers to ensure the most granular level of inspection and handling possible. This ensures that bad actors cannot hide illegitimate traffic within a plain-text tunnel.

   Alternatively, you can use tunnel zones to re-tag tunneled traffic so that you can write access control rules specifically for select tunnels. This lets you customize intrusion inspection or other layer 7 filtering to connections contained with a tunnel. See Using tunnel zones to apply access control at the tunnel level, on page 1970.

Using tunnel zones to apply access control at the tunnel level

A tunnel zone represents certain types of plaintext, passthrough tunnels that you explicitly tag for special analysis. Although a tunnel zone is not an interface object, you can use it as an interface constraint in some configurations.

Tunnel zone implementation

As explained in How the system processes plain-text tunnels, on page 1969, once a plain-text tunneled connection passes through the prefilter policy, the access control policy applies its rules to each connection contained within the tunnel.

However, you might want to apply the same policy to all the connections within a tunnel. For example, you might have a special intrusion policy you want to use for tunneled connections.

To make it possible to apply access control rules to all connections within a tunnel, you must use the prefilter policy to re-zone the tunnel. Rezoning applies a tunnel zone tag to the plain-text tunnel. You can then use that tunnel zone instead of a security zone when you define the source interface criterion of an access control rule.

Because a tunnel zone does not contain interfaces, the source interface through which the tunnel enters the device is not relevant. You can apply a tunnel zone tag to multiple tunnels that enter the device through different interfaces and access control treats them all in the same way.

Note Connections in rezoned tunnels do not match security zone constraints in an access control rule. After you rezone a tunnel, access control rules match encapsulated connections with their newly assigned tunnel zone, not the original security zone.

See Rezone tunnels for customized inspection, on page 1988 for a walkthrough of a tunnel zone implementation, and a discussion of the implications of rezoning without explicitly handling rezoned traffic.

Large flow offloads

A large flow offload is a hardware-based traffic processing feature that

- handles certain fastpathed traffic in the NIC hardware rather than in the Firewall Threat Defense software
- results in higher throughput and lower latency for data-intensive applications such as large file transfers, and
- includes both static flow offload (based on prefilter policy configuration) and dynamic flow offload (based on trust and other criteria).

Supported models and offload types

For the following models, certain traffic that you configure to be fastpathed by a prefilter policy is handled by the hardware (specifically, in the NIC), not by the Firewall Threat Defense software:

- Firepower 4100/9300
- Secure Firewall 3100 (static only)
- Secure Firewall 4200 (static only)

Offloaded flows continue to receive limited stateful inspection, such as basic TCP flag and option checking. The system can selectively escalate packets to the firewall system for further processing if necessary.

Two types of flow offload are available:

- *Static flow offload*: Offloads flows based on prefilter policy configuration that applies the Fastpath action.
- *Dynamic flow offload*: By default, devices offload flows based on other criteria, including trust.

Applications that can benefit from offloading large flows include:

- High Performance Computing (HPC) Research sites, where the firewall is deployed between storage and high compute stations. When one research site backs up using FTP file transfer or file sync over NFS,

the large amount of data traffic affects all connections. Offloading FTP file transfer and file sync over NFS reduces the impact on other traffic.

- High Frequency Trading (HFT), where the firewall is deployed between workstations and the Exchange, mainly for compliance purposes. Security is usually not a concern, but latency is a major concern.

Flows that can be offloaded include:

- (Static flow offload only.) Connections that are fastpathed by the prefilter policy.
- Standard or 802.1Q tagged Ethernet frames only.
- (Dynamic flow offload only):
  - Inspected flows that the inspection engine decides no longer need inspection. These flows include:
    - Flows handled by access control rules that apply the Trust action and are based on security zone, source and destination network and port matching only.
    - TLS/SSL flows that are not selected for decryption using a decryption policy.
    - Flows that are trusted by the Intelligent Application Bypass (IAB) policy either explicitly or due to exceeding flow bypass thresholds.
    - Flows that match file or intrusion policies that result in trusting the flow.
    - Any allowed flow that no longer needs to be inspected.
  - IPS preprocessor inspected flows:
    - SSH and SMTP.
    - FTP preprocessor secondary connections.
    - Session Initiation Protocol (SIP) preprocessor secondary connections.
  - Intrusion rules that use keywords (also referred to as *options*)

Important For details, exceptions, and limitations to the above, see Restrictions for flow offload implementation, on page 1973.

Static flow offload configuration

To offload eligible traffic to hardware, create a prefilter policy rule that applies the **Fastpath** action. Use prefilter rules for TCP/UDP, and tunnel rules for GRE.

(Not recommended.) To disable flow offload, use FlexConfig:

- Disable static (and thereby dynamic) flow offload: **no flow-offload enable**
- Re-enable flow offload: **flow-offload enable**

For more information, see *Cisco Secure Firewall ASA Series Command Reference*.

Dynamic flow offload configuration

Dynamic flow offload is enabled by default. However, dynamic offload occurs only if static flow offload is enabled, regardless of whether prefiltering is configured.

To disable dynamic flow offload, use the device CLI:

- Disable dynamic offload: **configure flow-offload dynamic whitelist disable**
- Re-enable dynamic offload: **configure flow-offload dynamic whitelist enable**

Restrictions for flow offload implementation

Device limitations

The feature is supported on the following devices:

- Secure Firewall 3100 (static only)
- Secure Firewall 4200 (static only)
- Firepower 4100/9300

Flows that cannot be offloaded

Do not attempt to offload these flow types:

- Any flows that do not use IPv4 addressing, such as IPv6 addressing.
- Flows for any protocol other than TCP, UDP, and GRE.

Note PPTP GRE connections cannot be offloaded.

- Flows on interfaces configured in passive, inline, or inline tap mode. Routed and switched interfaces are the only types supported.
- (3100/4200.) Offload based on inner header for tunnelled flows.
- (3100/4200.) Multi-instance offload.
- Flows that require inspection by Snort or other inspection engines. In some cases, such as FTP, the secondary data channel can be offloaded although the control channel cannot be offloaded.
- IPsec and TLS/DTLS VPN connections that terminate on the device.

Note The Secure Firewall 3100 and Secure Firewall 4200 platforms are exceptions to this restriction. These platforms support flow-offload for IPsec and DTLS VPN connections terminating to the device. For detailed information on this feature and its implementation, please refer to the release notes specific to the Secure Firewall 3100 and Secure Firewall 4200 platforms.

- Flows that require encryption or decryption. For example, connections decrypted due to a decryption policy.
- Multicast flows in routed mode. They are supported in transparent mode if there are only two member interfaces in a bridge group.
- TCP Intercept flows.
- TCP state bypass flows. You cannot configure flow offload and TCP state bypass on the same traffic.
- Flows tagged with security groups.
- Reverse flows that are forwarded from a different cluster node, in the case of asymmetric flows in a cluster.
- Centralized flows in a cluster, if the flow owner is not the control unit.
- Flows that include IP options cannot be dynamically offloaded.

Additional limitations

Consider these operational restrictions when implementing flow offload:

- Flow offload and Dead Connection Detection (DCD) are not compatible. Do not configure DCD on connections that can be offloaded.
- If more than one flow that matches flow offload conditions are queued to be offloaded at the same time to the same location on the hardware, only the first flow is offloaded. The other flows are processed normally. This is called a *collision*. Use the **show flow-offload flow** command in the CLI to display statistics for this situation.
- Dynamic flow offload disables all TCP normalizer checks.
- Although offloaded flows pass through FXOS interfaces, statistics for these flows do not appear on the logical device interface. Thus, logical device interface counters and packet rates do not reflect offloaded flows.

Conditions for reversing offload

After a flow is offloaded, packets within the flow are returned to the firewall operating system for further processing if they meet these conditions:

- They include TCP options other than Timestamp.
- They are fragmented.
- They are subject to Equal-Cost Multi-Path (ECMP) routing, and ingress packets move from one interface to another.
- A change to the routing table applies to the flow. A packet is returned to the device to determine the new route.

Prefilter vs access control policy

Prefilter and access control policies both allow you to block and trust traffic. In a prefilter policy, the "trust" functionality is called "fastpathing" because it skips more inspection. If you do not configure a custom prefilter

policy, you can only approximate, but not replicate, prefilter functionality using Block and Trust rules placed early in the access control policy.

Characteristic	Prefilter Policy	Access Control Policy
Primary function	Quickly fastpath or block certain types of plaintext or passthrough tunnels, or tailor subsequent inspection to encapsulated traffic. Fastpath or block any other connections that benefit from early handling.	Inspect and control all network traffic, using simple or complex criteria, including contextual information and deep inspection results.
Sequence within access control	First The system matches traffic to prefilter criteria before all other access control configurations. Thus, fast-pathing in a prefilter policy skips many other policies and inspections.	Last Other policies that might inspect a connection, including Security Intelligence and decryption, are applied before access control rules are evaluated.
Rule actions	Fewer You can stop further inspection (Fastpath and Block) or allow further analysis with the rest of access control (Analyze).	More Access control rules have a larger variety of actions, including monitoring, deep inspection, block with reset, and interactive blocking. See Access control rule actions, on page 1614.
Bypass capability	Fastpath rule action Fastpathing traffic in the prefilter stage bypasses all further inspection and handling. This includes: • Security Intelligence • User identity discovery (identity policy) • Decryption • Access control rules • Deep inspection of packet payloads • Discovery • Rate limiting	Trust rule action Traffic trusted by access control rules is only exempt from intrusion inspection and discovery. If another policy that requires inspection is applied to a connection that is eventually trusted, the connection is inspected anyway. Trust means that intrusion and file policies are not applied to the connection.
Rule criteria	Limited Rules in the prefilter policy use simple network criteria: IP address, VLAN tag, port, and protocol. For tunnels, tunnel endpoint conditions specify the IP address of the routed interfaces of the network devices on either side of the tunnel.	Robust Access control rules use network criteria, but also user, application, requested URL, and other contextual information available in packet payloads. Network conditions specify the IP address of source and destination hosts.

Characteristic	Prefilter Policy	Access Control Policy
IP headers used (tunnel handling)	Outermost Using outer headers allows you to handle entire plaintext, passthrough tunnels. For nonencapsulated traffic, prefiltering still uses "outer" headers—which in this case are the only headers.	Innermost possible For a nonencrypted tunnel, access control acts on its individual encapsulated connections, not the tunnel as a whole. See How the system processes plain-text tunnels, on page 1969.
Rezone encapsulated connections for further analysis	Rezones tunneled traffic Tunnel zones allow you to tailor subsequent inspection to prefiltered, encapsulated traffic.	Uses tunnel zones Access control uses the tunnel zones you assign during prefiltering. See Using tunnel zones to apply access control at the tunnel level, on page 1970.
Connection logging	Fastpathed and blocked traffic only. Allowed connections may still be logged by other configurations.	Any connection

Requirements and prerequisites for prefilter policies

This reference provides the requirements and prerequisites necessary for configuring prefilter policies, including supported models, domain requirements, and required user roles.

Model support

- Network Admin

Guidelines and limitations for the prefilter policy

You can log connections fast pathed and blocked by the prefilter policy. Prefilter connection events contain information on whether and how logged connections—including entire tunnels—were prefiltered. However, because fast pathed and blocked connections are not subject to deep inspection, associated connection events contain limited information.

Access control uses a hierarchical implementation that complements multitenancy. Along with other advanced settings, you can lock a prefilter policy association, enforcing that association in all descendant access control policies. For more information, see Access control policy inheritance, on page 1572.

When you deploy a prefilter policy, its rules are not applied on the existing connections. Hence, traffic on an existing connection is not bound by the new policy that is deployed. In addition, the policy hit count is incremented only for the first packet of a connection that matches a policy. Thus, the traffic on an existing connection that could match a policy is omitted from the hit count. To have the rules effectively applied, clear the existing connections, and then deploy the policy.

For a prefilter rule with action as Fastpath and logging options disabled, you might observe that the end-of-flow events are still generated in the system. However, the events are not visible on the management center event pages.

Guidelines and limitations for encapsulated traffic handling

Supported encapsulated traffic types

This topic discusses guidelines for the following types of encapsulated traffic:

- Generic Routing Encapsulation (GRE)
- Point-to-Point Protocol (PPTP). (This protocol is not handled by tunnel rules in the prefilter policy.)
- IPinIP
- IPv6inIP
- Teredo

GRE tunnel limitations

GRE tunnel processing is limited to IPv4 and IPv6 passenger flows. Other protocols, such as PPTP and WCCP, are not supported within the GRE tunnel.

GRE v1 and PPTP bypass restrictions

GRE v1 (sometimes referred to as *stateful GRE*) and PPTP traffic bypass outer flow processing.

- Sessions are over a single tunnel that is not load-balanced.
- There is no HA or clustering replication.
- Primary and secondary flow relationships are not maintained.
- Prefilter policy white and black lists are not supported.

Passenger flow processing is supported for IPv6inIP and Teredo but the following limitations apply:

GRE v0 sequence number field requirement

All endpoints sending traffic on the network must send GREv0 traffic with the sequence number field as optional; otherwise, the sequence number field is removed. RFC 1701 and RFC 2784 both specify the sequence field as optional.

Tunnel interface compatibility

Prefilter and access control policy rules are applied to all tunnel types on routed, transparent, inline-set, inline-tap, and passive interfaces.

Protocol references

For more information about the GRE and PPTP protocols, see the following:

- RFC 1701, RFC 2784, and RFC 2890 (GRE protocol v0)
- RFC 2637 (PPTP and GRE protocol v1)

Best practices for fastpath prefiltering

When you use the fastpath action in a prefilter rule, the matching traffic bypasses inspection and is simply transmitted through the device. Use this action for traffic that you can trust and that would not benefit from any of the security features available. Some examples of traffic that you can set fastpath prefiltering for are given below.

- VPN traffic that is going through the device. That is, the device is not an endpoint in the VPN topology.
- SQL traffic between trusted endpoints on the internal network.
- Scanner traffic. Scanner probes can create a lot of false-positive responses from intrusion policies.
- Voice/video.
- Backups.
- Management traffic (sftunnel) that traverses Firewall Threat Defense devices. Performing deep inspection on management traffic (using access control policies) can cause issues. You can prefilter based on port TCP/8305 between the management center and managed devices.

The Threat Defense Snort engine maintains state for each traffic flow and is designed to inspect each flow exactly once. Duplicate or double inspection is unsupported when repeated traffic maps to the same Snort flow key, because the subsequent instance is associated with the existing per-flow state and may be identified as an anomaly.

This can occur when a flow re-enters the device through a different interface or VLAN, is rerouted by an ACI fabric with different VLAN tags, or traverses VRF cross-VLAN paths. The resulting drop may appear in packet-tracer or capture output as:

```
Drop-reason: (stream) Blocked or blacklisted by the stream preprocessor.
```

If a flow-identifying attribute differs such that the traffic maps to a different Snort flow key, Snort can process the flows independently. However, differences in fields that are not part of the flow key do not create a separate flow.

From an optimal network architecture perspective, each traffic flow, in both directions, should traverse the Snort engine only once. If duplicate inspection cannot be avoided, use a prefilter or fastpath rule to bypass Snort inspection for the affected flows.

Configure prefilter policies

Configure prefilter policies to perform custom prefiltering and to control tunnel traffic analysis on managed devices.

To perform custom prefiltering, configure prefilter policies and assign them to access control policies. It is through the access control policy that prefilter policies get assigned to managed devices.

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Prefilter**.

At the top of the page, there are convenient links to some related features: object management and access control.

You cannot tell from the prefilter page, or when editing a prefilter policy, whether it is used by an access control policy or which policies use it.

Step 2 Do any of the following:

- Create—Click **New Policy** to create a custom prefilter policy. You are prompted for a name and an optional description. The new policy is opened for edit after you click **Save**. A new prefilter policy has no rules and a default action of Analyze all tunnel traffic.
- Edit—Click **Edit** ( ) to open a policy so that you can add rules or otherwise modify it.
- Copy—Click **Copy** ( ). You are prompted for a name. The copy is added to the list when you click **OK**, but it is not opened for edit.
- Delete—Click **Delete** ( ) to remove a policy. You cannot delete a policy that is currently being used by an access control policy.

Step 3 When editing a prefilter policy, you can do the following:

- Set the default action—Set the default action for tunnels at the bottom of the policy. See Configuring the default action, on page 1981.
- Add prefilter rules—Click **Add Prefilter Rule**. The rule is added to the bottom of the policy. See Configure prefilter rules, on page 1981.
- Add tunnel rules—Click **Add Tunnel Rule**. The rule is added to the bottom of the policy. See Configure tunnel rules, on page 1984.
- Insert rules—Right click the rule before where you want to add the new rule, and select either **Insert New Prefilter Rule** or **Insert New Tunnel Rule**, as appropriate.

- Copy/cut and paste rules—To copy a rule, right-click the rule and select **Copy**. You can also cut the rule (remove it) by selecting **Cut**. Then, select where you want to insert the rule, right click, and select either **Paste Above** or **Paste Below**. When copying, a number in parentheses is added to the rule name; you should edit the rule and change the name and other criteria as needed. Cut rules retain the original name.
- Edit a rule—Click **Edit** ( ) to open the rule editor. You can also click on any element for the rule in the table. See Configure prefilter rules, on page 1981 and Configure tunnel rules, on page 1984.
- Delete rules—Click **Delete** ( ) to remove a rule.
- Move a rule—Click a rule and drag and drop it to the right location. Alternatively, cut the rule and then paste it in the right location. You can also change the rule location while editing it.

  Properly creating and ordering rules is a complex task, but one that is essential to building an effective deployment. If you do not plan carefully, rules can preempt other rules or contain invalid configurations. For more information, see Prefilter policy rule order, on page 1968.
- Move a prefilter rule to an associated access control policy—To move a prefilter rule from the prefilter policy to an associated access control policy, right-click the rule and select **Move to another policy**. You cannot move tunnel rules to an access control policy. See Move prefilter rules to an access control policy, on page 1987.
- View hit counts—To view statistics on how many connections matched each rule, click **Analyze Hit Counts**. See View rule hit counts, on page 1586.
- Search for rules—Use the **Search Rules** box to do a plain text search. Type the string and press enter. The search box shows the number of hits and up/down buttons to move through them.

  Matches are highlighted in the table. Matches include partial hits, but only to explicitly set items. For example, entering "any" does not match the default network, but "any-ipv4" will match because it is a network object and not a passive default. Action and rule type do not match the search string.
- View object details—To see the contents of an object used in a rule, right click the object and select **Object Details**.
- Change the policy description—To modify the description of a policy, click in the description text below the policy name at the top of the page. Click away from the description to save changes.

Be sure to click **Save** to save any changes you make.

Step 4 Use the prefilter policy in the appropriate access control policies.

For each access control policy that should use a custom prefilter policy:

- Edit the access control policy and select the prefilter policy in the **Prefilter Policy** link or in the advanced settings. See Associate prefilter, decryption, and identity policies with an access control, on page 1585.
- If you applied tunnel zone tags in any tunnel rules, create access control rules that use those tunnel zones as source interface criteria.

What to do next

Deploy the changes.

If you deploy time-based rules, specify the time zone of the device to which the policy is assigned. See Configure a time zone for a device, on page 911.

Configuring the default action

Use the default action to determine how plain-text encapsulated tunnels that do not match any tunnel rules should be handled.

The default action does not apply to non-tunnel traffic. Any other connections that do not match prefilter rules are passed on for processing by subsequent policies.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Prefilter** and create or edit a prefilter policy.

Step 2 Choose a **Default Action: Tunneled Traffic** option:

a. **Analyze all tunnel traffic**—These tunnels are allowed and their encapsulated connections are evaluated by the access control and other policies

Block all tunnel traffic—Tunnels are dropped and no longer evaluated.

Step 3 If you select **Block all tunnel traffic**, click **Logging** ( ) next to the default action.

See *Logging Connections with a Policy Default Action* in the *Cisco Secure Firewall Management Center Administration Guide* You can configure default action logging for blocked tunnels only.

Configure prefilter rules

Configure prefilter rules to provide early blocking for unwanted traffic and to fast path traffic that does not benefit from access control inspection.

Use prefilter rules in a non-default prefilter policy to provide early blocking for unwanted traffic, and to fast path traffic that does not benefit from access control inspection.

If your device supports flow offload, fast path traffic is eligible for flow offload if it meets all other criteria. See Large flow offloads, on page 1971.

Before you begin

You cannot create rules in the default prefilter policy. If you have not created a custom prefilter policy, do so now.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Prefilter** and create or edit a prefilter policy.

Click **Add Prefilter Rule**.

You can also right-click a rule and select **Insert New Prefilter Rule**.

Select whether the rule should be **Enabled**. A rule must be enabled to affect traffic through the device.

Step 2 Select the **Action** to be taken on matching traffic.

- Fastpath—Exempts matching traffic from all further inspection AND control, including access control, identity requirements, AND rate limiting. These connections are eligible for flow offload if the device supports it.
- Block—Blocks matching traffic without further inspection of any kind.
- Analyze—Allows traffic to continue to be analyzed by the rest of access control. If passed by access control AND any related deep inspection, this traffic may also be rate limited.

Step 3 Select where to **Insert** the rule.

The default is to insert the rule at the end of the policy, but you can select an existing rule and insert the new rule before or after that rule. The action of the first rule that matches a connection is applied to that connection, so order matters.

Step 4 (Optional.) Select the object that defines the **Time Range** for the rule.

You can limit what times of day, or which days, a rule is operational. For example, the rule could apply during business hours only. Select an existing time range object OR create a new one. For more information, see Create a time range object, on page 2435.

Step 5 Configure the traffic matching conditions for the rule.

The rule is applied to connections that match all of the conditions. Within a condition type, separate elements are OR'ed, so that matching any of the selected items counts as a match. For the rule as a whole, all condition types are AND'ed: a connection must match at least one item on each tab to match the rule. You can use these types of conditions:

- **Interface Objects**—Select the security zones OR interface groups that contain the interfaces to which the rule should apply. The default, no objects selected, applies the rule to all interfaces on the device.
- **Networks**—Select the network objects that define the source (**Add to Source**) OR destination (**Add to Destination**) IP addresses, OR both. The default (no objects selected) matches all source AND destination IP addresses.
- **VLAN tags**—Select the objects that define the VLANs to which the rule should apply. For more information, see VLAN tags rule conditions, on page 1983.
- **Ports**—Select the TCP/UDP ports, OR other protocol, for the connections AND add them to the source OR destination criteria. Source criteria is TCP/UDP only, but you can select other protocols for the destination. For more information, see Port rule conditions for prefilter rules, on page 1983.

Step 6 (Fastpath AND Block rules only.) Click **Logging** and configure how matching connections should be logged.

For more information, see *Logging Connections with Tunnel AND Prefilter Rules* in the *Cisco Secure Firewall Management Center Administration Guide*.

Step 7 (Optional.) Click **Comment** and add comments to the rule. Use comments to help you understand the purpose of the rule and its change history.

Step 8 Click **Add**. If you need to move the rule, do so now.

Step 9 Click **Save** to save the policy.

VLAN tags rule conditions

VLAN tags rule conditions are filtering mechanisms to control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic.

VLAN tag filtering behavior

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

Port rule conditions for prefilter rules

Port conditions match traffic based on the source and destination ports.

Port condition types

Depending on the rule type, "port" can represent any of these types:

- TCP and UDP—You can control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP(6)/22. TCP and UDP are the only source ports supported. You can also specify them as destination ports.
- ICMP—You can control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3. When you select ICMP as a destination port, you are prompted to specify the type and code.
- Protocol—You can control traffic using other protocols that do not use ports. Not all protocols are supported. You must select the protocol as a destination port.

Source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching Non-TCP Traffic with Port Conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. However, when matching GRE, IP in IP, IPv6 in IP, or Teredo Port 3544, configure tunnel rules instead of port conditions in prefilter rules.

Configure tunnel rules

Configure tunnel rules to control how encapsulated tunnel traffic is processed by the firewall system.

- Provide early blocking for unwanted encapsulated tunnel traffic.
- Fast path tunnels that do not benefit from access control inspection.
- Place encapsulated tunnels into a tunnel zone, called rezoning, so that you can write access control rules to apply inspection to the connections within the tunnel as a whole.

The prefilter policy's default action applies to encapsulated tunnels. Thus, create rules for tunnel traffic only to apply different actions to specific tunnels.

For example, if the default action is to analyze tunnels, this means that all tunnels are passed on to the access control policies AND other policies that inspect, allow, AND potentially block connections, AND these policies will evaluate the inner connections. If that default action is what you want for all tunnels, then you do not need to create any tunnel rules.

If instead:

- The default action is to block encapsulated tunnels, use rules to exempt specific tunnels from blocking AND either pass them to other access control policies (analyze action) OR bypass any additional processing (fastpath).
- There are tunnels where you want to apply access control rules to all encapsulated connections, create rules to rezone the tunnels to the appropriate tunnel zone tag AND also write rules in the access control policy for those tunnel zone tags.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Prefilter**. Create or edit a prefilter policy.

Step 2 Click **Add Tunnel Rule**.

You can also right-click a rule AND select **Insert New Tunnel Rule**.

a) Enter a **Name** for the rule.
b) Select whether the rule should be **Enabled**.

A rule must be enabled to affect traffic through the device.

c) Select where to **Insert** the rule.

The default is to insert the rule at the end of the policy, but you can select an existing rule AND insert the new rule before OR after that rule. The action of the first rule that matches a connection is applied to that connection, so order matters.

d) (Optional.) Select the object that defines the **Time Range** for the rule.

You can limit what times of day, OR which days, a rule is operational. For example, the rule could apply during business hours only. Select an existing time range object OR create a new one. For more information, see Create a time range object, on page 2435.

Step 3 Select the **Action** to be taken on matching traffic.

- Fastpath—Exempts matching traffic from all further inspection AND control, including access control, identity requirements, AND rate limiting. Fastpathing a tunnel fastpaths all encapsulated connections. These connections are eligible for flow offload if the device supports it.
- Block—Blocks matching traffic without further inspection of any kind. Blocking a tunnel blocks all encapsulated connections.
- Analyze—Allows traffic to continue to be analyzed by the rest of access control using inner headers.. If passed by access control AND any related deep inspection, this traffic may also be rate limited.

a) (Analyze rules only; when rezoning only.) Select a tunnel zone tag in **Assign Tunnel Zone** if your intention is to rezone the tunnel.

Leave this option blank if you want access control to apply to the encapsulated connections within the tunnel without special processing. For more information about rezoning AND tunnel group tags, see:

- Using tunnel zones to apply access control at the tunnel level, on page 1970
- Creating tunnel zones, on page 1986
- Rezone tunnels for customized inspection, on page 1988

Caution Exercise caution when assigning tunnel zones. Connections in rezoned tunnels may not match security zone constraints in later evaluation. See Rezone tunnels for customized inspection, on page 1988 for a brief walkthrough of a tunnel zone implementation, AND a discussion of the implications of rezoning without explicitly handling rezoned traffic.

Step 4 Select one of these options to set the direction for the rule:

- **Match tunnels only from source** (unidirectional)—Match source-to-destination traffic only. Matching traffic must originate from one of the specified source interfaces OR tunnel endpoints, AND leave through one of the destination interfaces OR tunnel endpoints. Return traffic for allowed connections is also permitted. (Note that prefilter rules are always unidirectional.)

- **Match tunnels from source AND destination** (bidirectional)—Match both source-to-destination traffic AND destination-to-source traffic. The effect is identical to writing two unidirectional rules, one the mirror of the other. This is the default.

Step 5 Click the **Encapsulation & Ports** tab and select the protocols for this rule.

You must select at least one of these options in a tunnel rule to specify the encapsulation protocol used. The list includes the IP protocol number for the option.

- **GRE** (47)
- **IP-in-IP** (4)
- **IPv6-in-IP** (41)
- **Teredo** (UDP (17)/3455)

Step 6 Configure the traffic matching conditions for the rule.

The rule is applied to connections that match all of the conditions. Within a condition type, separate elements are OR'ed, so that matching any of the selected items counts as a match. For the rule as a whole, all condition types are AND'ed: a connection must match at least one item on each tab to match the rule. You can use these types of conditions:

- **Interface Objects**—Select the security zones OR interface groups that contain the interfaces to which the rule should apply. The default, no objects selected, applies the rule to all interfaces on the device.
- **Tunnel Endpoints**—The network objects that define the source (**Add to Source**) AND destination (**Add to Destination**) IP addresses of the tunnel. The default (no objects selected) matches all source AND destination IP addresses.
- **VLAN tags**—Select the objects that define the VLANs to which the rule should apply. For more information, see VLAN tags rule conditions, on page 1983.

Step 7 (Fastpath AND Block rules only.) Click **Logging** AND configure how matching connections should be logged.

For more information, see *Logging Connections with Tunnel AND Prefilter Rules* in the *Cisco Secure Firewall Management Center Administration Guide*.

Step 8 (Optional.) Click **Comment** AND add comments to the rule.

Use comments to help you understand the purpose of the rule AND its change history.

Step 9 Click **Add**.

If you need to move the rule, do so now.

Click **Save** to save the policy.

Creating tunnel zones

Create a tunnel zone tag to represent certain types of plaintext, passthrough tunnels that you explicitly tag for special analysis.

A *tunnel zone* represents certain types of plaintext, passthrough tunnels that you explicitly tag for special analysis. A tunnel zone is not an interface object, even though you can use it as an interface constraint in access control rules, as explained in Using tunnel zones to apply access control at the tunnel level, on page 1970.

You can create zones in the object manager or when editing a tunnel rule.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Tunnel Zone** from the list of object types.

Step 3 Click **Add Tunnel Zone**.

You can also edit an existing tunnel or delete a tunnel zone that is not being used in a tunnel rule.

Step 4 Enter a **Name** and, optionally, a **Description**.

Step 5 Click **Save**.

What to do next

- Assign the tunnel zone to plaintext, passthrough tunnels as part of a tunnel rule. See Configure tunnel rules, on page 1984.
- Use the tunnel zone as source interface criteria in an access control rule.

Move prefilter rules to an access control policy

Moving prefilter rules to an access control policy allows you to reposition rules for better policy organization and effectiveness when the rules would function more appropriately within the access control policy structure.

You can move prefilter rules from a prefilter policy to the associated access control policy.

Before you begin

Note the following conditions before you proceed:

- Only prefilter rules can be moved to an access control policy. Tunnel rules cannot be moved.
- The prefilter rules can be moved only to an access control policy that uses the prefilter policy. Because you can use the same prefilter policy in multiple access control policies, you need to select the policies to which the rule should be moved.
- The prefilter rules that use interface groups to define interface criteria cannot be moved. You can move only those rules that use security zones, or that include no interface criteria.
- The **Action** parameter in the prefilter rule is changed to a suitable action in the access control rule when moved.
  - **Analyze** becomes allow.
  - **Block** becomes block.

- **Fastpath** becomes trust.

- The logging configuration in the rule is retained.
- The comments in the prefilter rule configuration are lost after moving the rule. However, a new comment is added in the moved rule mentioning the source prefilter policy.
- While moving rules from the source policy, if another user modifies those rules, you are warned. You can continue with the process after refreshing the page.

Procedure

Step 1 In the prefilter policy editor, select the rules that you want to move with a left-click on your mouse.

Tip To select multiple rules, use Shift+click.

Step 2 Right-click the selected rules and choose **Move to another policy**.

Step 3 Select the destination access control policies and click **Add** to add them to the list of selected policies.

Step 4 From the **Place Rules** drop-down list, choose where you want to position the moved rules:

- To position as the last set of rules in the **Default** section, choose **At the bottom (within the Default section)**.
- To position as the first set of rules in the **Mandatory** section, choose **At the top (within the Mandatory section)**.

Step 5 Click **Move**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Examples of prefilter policy

These topics provide examples of using the prefilter policy.

Rezone tunnels for customized inspection

Rezone GRE tunnels to enable customized inspection policies for encapsulated traffic while maintaining different inspection policies for other traffic in the same security zone.

This example procedure summarizes how you might rezone GRE tunnels for further analysis, using tunnel zones. You can adapt the concepts described here to other scenarios requiring tailored traffic inspection of connections encapsulated in plaintext or passthrough tunnels.

Consider a situation where your organization's internal traffic flows through the Trusted security zone. The Trusted security zone represents a set of interfaces across multiple managed devices deployed in various locations. Your organization's security policy requires that you allow internal traffic after deep inspection for exploits and malware.

Internal traffic sometimes includes plaintext, passthrough, GRE tunnels between particular endpoints. Because the traffic profile of this encapsulated traffic is different from your "normal" interoffice activity—perhaps it is known and benign—you can limit inspection of certain encapsulated connections while still complying with your security policy.

In this example, after you deploy configuration changes:

- Plaintext, passthrough, GRE-encapsulated tunnels detected in the Trusted zone have their individual encapsulated connections evaluated by one set of intrusion and file policies.
- All other traffic in the Trusted zone is evaluated with a different set of intrusion and file policies.

You accomplish this task by *rezoning* GRE tunnels. Rezoning ensures that access control associates GRE-encapsulated connections with a custom *tunnel* zone, rather than their original Trusted *security* zone. Rezoning is required due to the way access control handles encapsulated traffic; see How the system processes plain-text tunnels, on page 1969 and Using tunnel zones to apply access control at the tunnel level, on page 1970.

Procedure

Step 1 Configure custom intrusion and file policies that tailor deep inspection to encapsulated traffic, and another set of intrusion and file policies tailored to nonencapsulated traffic.

Step 2 Configure custom prefiltering to rezone GRE tunnels flowing through the Trusted security zone.

Create a custom prefilter policy and associate it with access control. In that custom prefilter policy, create a tunnel rule (in this example, **`GRE_tunnel_rezone`**) and a corresponding tunnel zone (**`GRE_tunnel`**). For more information, see Configure tunnel rules, on page 1984.

Table 110: GRE_tunnel_rezone tunnel rule

Rule Component	Description
Interface object condition	Match internal-only tunnels by using the Trusted security zone as both a Source Interface Object and Destination Interface Object constraint.
Tunnel endpoint condition	Specify the source and destination endpoints for the GRE tunnels used in your organization. Tunnel rules are bidirectional by default. If you do not change the **Match tunnels from...** option, it does not matter which endpoints you specify as source and which as destination.
Encapsulation condition	Match GRE traffic.
Assign Tunnel Zone	Create the **`GRE_tunnel`** tunnel zone, and assign it to tunnels that match the rule.
Action	Analyze (with the rest of access control).

Step 3 Configure access control to handle connections in rezoned tunnels.

In the access control policy deployed to your managed devices, ensure that the prefilter policy is used. Then, configure a rule (in this example, **`GRE_inspection`**) that handles the traffic you rezoned. For more information, see Create and edit access control rules, on page 1631.

Table 111: GRE_inspection access control rule

Rule Component	Description
Security zone condition	Match rezoned tunnels by using the GRE_tunnel tunnel zone as a Source Zone constraint.
Action	Allow, with deep inspection enabled. Choose the file and intrusion policies tailored to inspect encapsulated internal traffic.

Caution If you skip this step, the rezoned connections may match **any** access control rule not constrained by security zone. If the rezoned connections do not match any access control rules, they are handled by the access control policy default action. Make sure this is your intent.

Step 4 Configure access control to handle nonencapsulated connections flowing through the Trusted security zone.

In the same access control policy, configure a rule (in this example, **`internal_default_inspection`**) that handles non-rezoned traffic in the Trusted security zone.

Table 112: Internal_default_inspection access control rule

Rule Component	Description
Security zone condition	Match non-rezoned internal-only traffic by using the Trusted security zone as both a Source Zone and Destination Zone constraint.
Action	Allow, with deep inspection enabled. Choose the file and intrusion policies tailored to inspect nonencapsulated internal traffic.

Step 5 Evaluate the position of the new access control rules relative to preexisting rules. Change rule order if necessary.

If you place the two new access control rules next to each other, it does not matter which you place first. Because you rezoned GRE tunnels, the two rules cannot preempt each other.

Step 6 Save all changes.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Offload large flows

This task helps improve performance quickly for large connections that you know you can trust by proactively identifying connections as being offload eligible through matching them to a prefilter fastpath rule.

You can use the prefilter policy to configure static flow offload. If your hardware model supports it, flow offload moves eligible fast path connections to NIC processing, avoiding performance intensive inspection.

Some hardware models will dynamically identify off-loadable connections automatically, but you can proactively identify connections as being offload eligible by matching them to a prefilter fastpath rule. This static configuration helps you improve performance quickly for large connections that you know you can trust.

In the following example, it is assumed that two servers are behind sufficient protection so that you can trust the connections between them. Perhaps one server is using the other for backups. Thus, you can write a fastpath rule for any traffic going from the main server, 10.100.1.20/24, to the backup server, 10.100.2.2/24. The example assumes the servers are accessible through regular, physical routed interfaces.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Prefilter** and create or edit a custom prefilter policy.

Step 2 Click **Add Prefilter Rule**.

You can also right-click a rule and select **Insert New Prefilter Rule**.

Step 3 Enter a **Name** for the rule. For example, Offload_Server_A.

Step 4 In **Action**, select **Fastpath**.

Step 5 In **Insert**, select the rule above or below which the rule should be inserted.

You can also move the rule after you create it.

Step 6 Click the **Networks** tab and specify the source and destination servers.

- In the edit box below **Source Networks**, type 10.100.1.20 and click **Add**.
- In the edit box below **Destination Networks**, type 10.100.2.2 and click **Add**.

Step 7 (Optional.) Configure the other traffic matching characteristics for the flow.

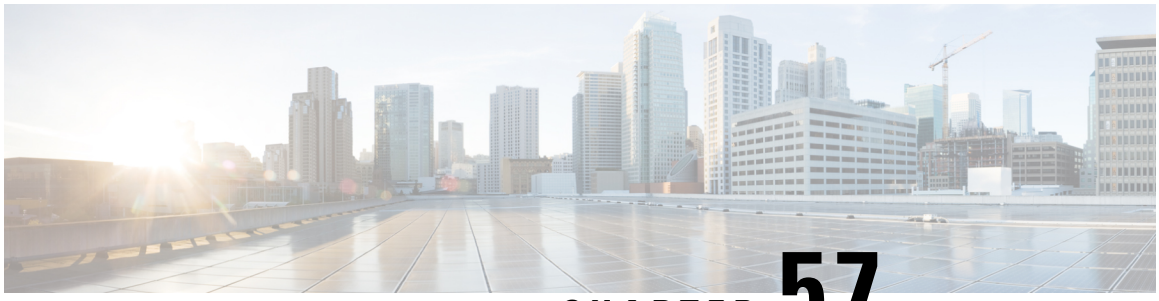
Click these tabs to fill in the criteria. Only the Networks tab needs to be configured for this example, so configure these settings only if they make sense for your situation.

- **Interface objects**—The security zones or interface objects that define the source or destination interfaces, or both. This specification is not needed for this example.
- **VLANs**—Because this example uses routed physical interfaces instead of switch interfaces, this setting is not relevant. Even in those circumstances, you do not need to limit the rule based on VLAN.
- **Ports**—If you want to limit the offload to specific TCP/UDP ports, you can specify them. This limits the scope of the rule to these ports only.

Step 8 (Optional.) Click **Logging** and decide whether you want to see syslog events for matching traffic.

Step 9 Click **Add** to add the rule.

Take the time to move the rule to the right location in the policy if it is not already there.



Click **Save** to save the policy.

The next time you deploy the configuration, the rule will be applied to the target devices.

History for the prefilter policy

This reference tracks the evolution of prefilter policy features across software releases, helping administrators understand when specific capabilities were introduced or modified.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Moving prefilter rules to an access control policy	6.7	Any	You can move prefilter rules from a prefilter policy to the associated access control policy. New/modified pages: In the prefilter policy page, the right-click menu for the selected rules provides a new **Move to another policy** option. Supported platforms: Firewall Management Center
Time-based rules	6.6	Any	Ability to apply prefilter and tunnel rules depending on the date and time, as determined by the time zone of the device.
View Object Details from prefilter rule page	6.6	Any	Feature introduced: Option to view details for an object or object group when viewing prefilter rules. New options: Right-clicking a value in any of these columns in the prefilter rule list offers an option to view object details: Source Networks, Destination Networks, Source Port, Destination Port, and VLAN Tag.

CHAPTER 57

DNS Policies for Security Intelligence

The following topics explain DNS policies, DNS rules, and how to deploy DNS policies to managed devices.

- DNS policies, on page 1993
- Cisco umbrella DNS policies, on page 1994
- DNS policy components, on page 1995
- License requirements for DNS policies, on page 1996
- Requirements and prerequisites for DNS policies, on page 1996
- Managing DNS and Umbrella DNS Policies, on page 1996
- DNS rules, on page 1998
- DNS rules, on page 2005
- Requirement: deploy DNS policy configuration changes, on page 2008
- Cisco umbrella DNS policies, on page 2008

DNS policies

A DNS policy is a security configuration that

- blocks traffic based on the domain name requested by a client, using a Security Intelligence Block list
- uses Cisco-provided domain name intelligence to filter traffic
- supports custom lists and feeds of domain names tailored to your deployment, and
- requires association with an access control policy for deployment to managed devices.

DNS policy behavior

Traffic on a DNS policy Block list is immediately blocked and therefore is not subject to any further inspection—not for intrusions, exploits, malware, and so on, but also not for network discovery. You can use a Security Intelligence Do Not Block list to override a Block list and force access control rule evaluation, and, recommended in passive deployments, you can use a "monitor-only" setting for Security Intelligence filtering. This allows the system to analyze connections that would have been blocked by a Block list, but also logs the match to the Block list and generates an end-of-connection Security Intelligence event.

Note DNS-based Security Intelligence may not work as intended for a domain name unless the DNS server deletes a domain cache entry due to expiration, or a client's DNS cache or the local DNS server's cache is cleared or expires.

You configure DNS-based Security Intelligence using a DNS policy and associated DNS rules. To deploy it to your devices, you must associate your DNS policy with an access control policy, then deploy your configuration to managed devices.

Cisco umbrella DNS policies

A Cisco Umbrella DNS policy is a security mechanism that

- redirects DNS queries to Cisco Umbrella for domain validation and policy enforcement,
- allows or blocks requests based on domain names and applies DNS-based security policies, and
- provides two lines of protection through local DNS inspection and cloud-based Cisco Umbrella policies.

DNS query redirection process

Cisco Umbrella DNS Connection in the management center helps to redirect DNS queries to Cisco Umbrella. This allows Cisco Umbrella to validate requests, allow or block them based on the domain names, and apply DNS-based security policy on the request. If you use Cisco Umbrella, you must configure the Cisco Umbrella Connection (**Integration** > **Other Integrations** > **Cloud Services** and choose the **Cisco Umbrella Connection**) to redirect DNS queries to Cisco Umbrella.

The Umbrella Connector is part of the system's DNS inspection. If your existing DNS inspection policy map decides to block or drop a request based on your DNS inspection settings, the request is not forwarded to Cisco Umbrella. Thus, you have two lines of protection:

- Your local DNS inspection policy
- Your Cisco Umbrella cloud-based policy

When redirecting DNS lookup requests to Cisco Umbrella, the Umbrella Connector adds an EDNS (Extension mechanisms for DNS) record. An EDNS record includes the device identifier information, organization ID, and client IP address. Your cloud-based policy can use those criteria to control access in addition to the reputation of the FQDN. You can also elect to encrypt the DNS request using DNSCrypt to ensure the privacy of usernames and internal IP addresses.

To redirect DNS requests from the management center to Cisco Umbrella:

1. Configure the Cisco Umbrella connection settings.
2. Create and configure an Umbrella DNS policy.
3. Associate the Umbrella DNS policy with an access control policy.
4. Deploy the changes.

For detailed information about how to set up the Umbrella DNS Connector in the management center, see Configuring the Umbrella DNS Connector for Cisco Secure Firewall Management Center.

DNS policy components

DNS policy components are configuration elements that

- enable blocking of connections based on domain name using a Block list
- exempt connections from blocking using a Do Not Block list, and
- provide granular network traffic handling through configurable rules and settings.

DNS policy configuration options

These configurations can be changed after creating a DNS policy:

- **Name and Description**: Each DNS policy must have a unique name. A description is optional.
- **Rules**: Rules provide a granular method of handling network traffic based on the domain name. Rules in a DNS policy are numbered, starting at 1. The system matches traffic to DNS rules in top-down order by ascending rule number.

When you create a DNS policy, the system populates it with a default Global Do-Not-Block List for DNS rule and a default Global Block List for DNS rule. Both rules are fixed to the first position in their respective categories. You cannot modify these rules, but you can disable them.

Note If multitenancy is enabled for your Firewall Management Center, the system is organized into a hierarchy of domains, including ancestor and descendant domains. These domains are distinct and separate from the domain names used in DNS management.

A descendant list contains the domains on the Block or Do Not Block lists of system subdomain users. From an ancestor domain, you cannot view the contents of descendant lists. If you do not want subdomain users to add domains to a Block or Do Not Block list:

- disable the descendant list rules, and
- enforce Security Intelligence using the access control policy inheritance settings

The system evaluates rules in this order:

1. Global Do-Not-Block List for DNS rule (if enabled)
2. Descendant DNS Do-Not-Block Lists rule (if enabled)
3. Rules with a Do Not Block action
4. Global Block List for DNS rule (if enabled)
5. Descendant DNS Block Lists rule (if enabled)
6. Rules with an action other than Do Not Block

Usually, the system handles DN-based network traffic according to the *first* DNS rule where *all* the rule's conditions match the traffic. If no DNS rules match the traffic, the system continues evaluating the traffic based on the associated access control policy's rules. DNS rule conditions can be simple or complex.

License requirements for DNS policies

This reference provides the license requirements necessary for implementing DNS policies across different Firepower system configurations.

Threat Defense License

IPS

Classic License

Protection

Requirements and prerequisites for DNS policies

This reference provides the requirements and prerequisites needed to configure and implement DNS policies, including model support, domain compatibility, and required user roles.

Model support

Any

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin

Important You must apply the Network Discovery policy on the device for a successful DNS validation on the traffic.

Managing DNS and Umbrella DNS Policies

Use the DNS Policy page to create, edit, delete, copy, and compare custom DNS and Umbrella DNS policies for comprehensive network security management.

Use the DNS Policy page (**Policies** > **Access Control heading** > **DNS**) to manage custom DNS and Umbrella DNS policies.

In addition to custom policies that you create, the system provides the Default DNS Policy and Default Umbrella DNS Policy. The default DNS policy uses the default Block list and Do Not Block list. You can edit and use this system-provided custom policies.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **DNS**.

Step 2 Manage your DNS policy:

- Compare—To compare DNS policies, click **Compare Policies** and proceed as described in Compare policies, on page 152.
- Copy—To copy a DNS policy, click **Copy** ( ) and proceed as described in Edit DNS policies, on page 1998.
- Create—To create a new Umbrella DNS policy, click **New Policy** > **Umbrella DNS Policy** and proceed as described in Create an umbrella DNS policy, on page 2012.
- Delete—To delete a DNS or Umbrella DNS policy, click **Delete** ( ), then confirm you want to delete the policy.
- Edit—To modify an existing DNS policy, click **Edit** ( )) and proceed as described in Edit DNS policies, on page 1998. To modify an existing Umbrella DNS policy, click **Edit** ( )) and proceed as described in Edit Umbrella DNS policies and rules, on page 2012.

You have successfully managed your DNS policies. The policies are now available for deployment to your network devices for DNS-based security filtering.

Create basic DNS policies

Creating a basic DNS policy establishes a foundation for DNS traffic filtering and management that you can customize to meet your organization's security requirements.

When you create a new DNS policy, it contains default settings. You must then edit it to customize the behavior.

Follow these steps to create a basic DNS policy:

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **DNS**.

Step 2 Click **Add DNS Policy** > **DNS Policy**.

Step 3 Give the policy a unique **Name** and, optionally, a **Description**.

Step 4 Click **Save**.

The DNS policy is created with default settings and appears in the DNS policies list.

What to do next

Configure the policy. See Edit DNS policies, on page 1998.

Edit DNS policies

Edit DNS policies to update policy configurations, modify rule settings, and maintain network security requirements.

Only one person should edit a DNS policy at a time, using a single browser window. If multiple users attempt to save the same policy, only the first set of saved changes are retained.

To protect the privacy of your session, after thirty minutes of inactivity on the policy editor, a warning appears. After sixty minutes, the system discards your changes.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **DNS**.

Step 2 Click **Edit** ( ) next to the DNS policy you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Edit your DNS policy:

- Name and Description—To change the name or description, click the field and type the new information.
- Rules—To add, categorize, enable, disable, or otherwise manage DNS rules, click **Rules** and proceed as described in Create and edit DNS rules, on page 1999.

Step 4 Click **Save**.

The DNS policy is updated with your changes and ready for deployment.

What to do next

- Optionally, further configure the new policy as described in *Logging Connections with Security Intelligence* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

DNS rules

A DNS rule is a Security Intelligence component that

- handles traffic based on the domain name requested by a host,
- operates after any traffic decryption and before access control evaluation, and
- matches traffic in the order specified, with the system handling network traffic according to the *first* DNS rule where *all* the rule's conditions match the traffic.

DNS rule components

In addition to its unique name, each DNS rule has these basic components:

- **State**: By default, rules are enabled. If you disable a rule, the system does not use it to evaluate network traffic, and stops generating warnings and errors for that rule.
- **Position**: Rules in a DNS policy are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.
- **Conditions**: Conditions specify the specific traffic the rule handles. A DNS rule must contain a DNS feed or list condition, and can also match traffic by security zone, network, or VLAN.
- **Action**: A rule's action determines how the system handles matching traffic.

A rule's action determines how the system handles matching traffic:

- Traffic with a **Do Not Block** action is allowed, subject to further access control inspection.
- Monitored traffic is subject to further evaluation by remaining rules on the DNS Block list. If the traffic does not match a DNS Block list rule, it is inspected with access control rules. The system logs a Security Intelligence event for the traffic.
- Traffic on a Block list is dropped without further inspection. You can also return a Domain Not Found response, or redirect the DNS query to a sinkhole server.

Related Topics

Security intelligence, on page 1595

Create and edit DNS rules

Create and edit DNS rules to define how the system handles DNS queries by specifying actions and conditions for domain name resolution.

In a DNS policy, you can add up to a total of 32767 DNS lists to the Block list and Do Not Block list rules; that is, the number of lists in the DNS policy cannot exceed 32767.

Follow these steps to create and edit DNS rules:

Procedure

Step 1 In the DNS policy editor, you have the following options:

- To add a new rule, click **Add DNS Rule**.
- To edit an existing rule, click **Edit** ( ).

Step 2 Enter a **Name**.

Step 3 Configure the rule components, or accept the defaults:

- Action—Choose a rule **Action**; see DNS rule actions, on page 2001.
- Conditions—Configure the rule's conditions; see DNS rule conditions, on page 2002.
- Enabled—Specify whether the rule is **Enabled**.

Step 4 Click **Save**.

The DNS rule is created or updated with the specified configuration and is ready for deployment.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

DNS rule management

DNS rule management is a policy administration feature that enables you to add, edit, move, enable, disable, delete, and otherwise manage DNS rules within your policy.

DNS rule management interface

The **Rules** tab of the DNS policy editor provides the interface for DNS rule management operations.

For each rule, the policy editor displays this information:

- Rule name
- Summary of rule conditions
- Rule action

Additional icons represent **Warning** ( ), **Error** ( ), and other important **Information** ( ). Disabled rules are dimmed and marked `(disabled)` beneath the rule name.

Enable and disable DNS rules

Enable or disable DNS rules to control whether the system uses them to evaluate network traffic and generate warnings and errors.

When you create a DNS rule, it is enabled by default. If you disable a rule, the system does not use it to evaluate network traffic and stops generating warnings and errors for that rule. When viewing the list of rules in a DNS policy, disabled rules are dimmed, although you can still modify them. Note that you can also enable or disable a DNS rule using the DNS rule editor.

Follow these steps to enable or disable DNS rules:

Procedure

Step 1 In the DNS policy editor, right-click the rule and choose a rule state.

Step 2 Click **Save**.

The DNS rule state is updated. Disabled rules appear dimmed in the policy rule list but can still be modified.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

DNS rule order evaluation

DNS rule order evaluation is a traffic processing mechanism that

- matches traffic to DNS rules in top-down order by ascending rule number,
- handles network traffic according to the *first* DNS rule where *all* the rule's conditions match the traffic, and
- applies different continuation behavior based on rule type.

Rule evaluation behavior

Rules in a DNS policy are numbered, starting at 1. The system behavior differs based on rule type:

- For Monitor rules, the system logs the traffic, then continues evaluating traffic against lower-priority DNS Block list rules.
- For non-Monitor rules, the system does **not** continue to evaluate traffic against additional, lower-priority DNS rules after that traffic matches a rule.

Rule order precedence follows this hierarchy:

- The Global Do-Not-Block List for DNS is always first, and takes precedence over all other rules.
- The Do-Not-Block List section precedes the Block List section; Do-Not-Block List rules always take precedence over other rules.
- The Global Block List for DNS is always first in the Block List section, and takes precedence over all other Monitor and Block list rules.
- The Block List section contains Monitor and Block list rules.
- When you first create a DNS rule, the system positions it last in the Do-Not-Block List section if you assign a **Do Not Block** action, or last in the Block List section if you assign any other action.

You can drag and drop rules to reorder them.

DNS rule actions

A DNS rule action is a configuration setting that

- determines handling for matching traffic, governing whether the system will block, not block, or monitor traffic based on rule conditions,
- controls logging behavior, determining when and how details about matching traffic are recorded, and
- impacts action prioritization when configured with TID.

DNS rule action types

If configured, TID also impacts action prioritization. For more information, see Threat Intelligence Director - Firewall Management Center action prioritization , on page 2145.

DNS rules support these action types:

- **Do Not Block**: Allows traffic to pass to the next phase of inspection, which is access control rules. The system does not log *Do Not Block list* matches. Logging of these connections depends on their eventual disposition.
- **Monitor**: Forces connection logging; matching traffic is neither immediately allowed nor blocked. Traffic is matched against additional rules to determine whether to permit or deny it. The first non-Monitor DNS rule matched determines whether the system blocks the traffic. If there are no additional matching rules, the traffic is subject to access control evaluation. For connections monitored by a DNS policy, the system logs end-of-connection Security Intelligence and connection events to the Firewall Management Center database.
- **Drop**: Drops the traffic without further inspection.
- **Domain Not Found**: Returns a non-existent internet domain response to the DNS query, which prevents the client from resolving the DNS request.
- **Sinkhole**: Returns a sinkhole object's IPv4 or IPv6 address in response to the DNS query (A and AAAA records only). The sinkhole server can log, or log and block, follow-on connections to the IP address. If you configure a **Sinkhole** action, you must also configure a sinkhole object.

Logging behavior varies based on the action type:

- For a connection blocked based on the **Drop** or **Domain Not Found** actions, the system logs beginning-of-connection Security Intelligence and connection events. Because blocked traffic is immediately denied without further inspection, there is no unique end of connection to log.
- For a connection blocked based on the **Sinkhole** action, logging depends on the sinkhole object configuration. If you configure your sinkhole object to only log sinkhole connections, the system logs end-of-connection connection events for the follow-on connection. If you configure your sinkhole object to log and block sinkhole connections, the system logs beginning-of-connection connection events for the follow-on connection, then blocks that connection.

DNS rule conditions

A DNS rule condition is a traffic identification criterion that

- identifies the type of traffic that rule handles,
- can be simple or complex, and
- must include a DNS feed or list condition within a DNS rule.

DNS rule condition requirements

You can also optionally control traffic by security zone, network, or VLAN.

When adding conditions to a DNS rule:

- If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion.
- You can configure multiple conditions per rule. Traffic must match **all** the conditions in the rule for the rule to apply to traffic. For example, a rule with a DNS feed or list condition and network condition but no VLAN tag condition evaluates traffic based on the domain name and source or destination, regardless of any VLAN tagging in the session.
- For each condition in a rule, you can add up to 50 criteria. Traffic that matches **any** of a condition's criteria satisfies the condition. For example, you can use a single rule to block traffic based on up to 50 DNS lists and feeds.

Security zone rule conditions

A security zone rule condition is a network traffic control mechanism that

- segments your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices,
- controls or decrypts traffic by its source and destination security zones, and
- requires all interfaces in a zone to be of the same type (all inline, passive, switched, or routed).

Zone condition traffic matching

If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

All zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

Security zone conditions in multidomain environments

In a multidomain deployment, a zone created in an ancestor domain can contain interfaces that reside on devices in different domains. When you configure a zone condition in an descendant domain, your configurations apply to only the interfaces you can see.

Network rule conditions

A network condition is a traffic matching criterion that

- controls or decrypts traffic based on source and destination IP addresses using inner packet headers,
- enables administrators to specify exact IP addresses or blocks for granular policy enforcement, and
- can be built using predefined network objects or by manually entering IP addresses or address blocks.

Network rule condition restrictions

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

VLAN tag rule conditions

VLAN tags rule conditions are filtering mechanisms that

- control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic
- use the innermost VLAN tag to filter VLAN traffic, with the exception of prefilter policy which uses the outermost VLAN tag, and
- apply only to inline sets and do not match traffic on firewall interfaces.

VLAN tag rule conditions configuration details

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

DNS policy rule conditions

A DNS policy rule condition is a DNS rule component that

- allows you to control traffic if a DNS list, feed, or category contains the domain name requested by the client,

- must be defined in a DNS rule, and
- applies the configured rule action to traffic regardless of whether you add a global or custom Block or Do Not Block list.

DNS condition behavior

The system applies the configured rule action to the traffic regardless of the list type. For example, if you add the Global Do Not Block List to a rule, and configure a **Drop** action, the system blocks all traffic that should have been allowed to pass to the next phase of inspection.

DNS rules

A DNS rule is a network security mechanism that controls and filters DNS queries and responses within network traffic

Control traffic based on DNS and security zone

Control traffic flow by implementing DNS rules with security zone conditions to manage network access and security policies.

Zone conditions in DNS rules allow you to control traffic by its source security zone. A *security zone* is a grouping of one or more interfaces, which may be located across multiple devices.

Procedure

Step 1 In the DNS rule editor, click **Zones**.

Step 2 Find and select the zones you want to add from the **Available Zones**. To search for zones to add, click the **Search by name** prompt above the **Available Zones** list, then type a zone name. The list updates as you type to display matching zones.

Step 3 Click to select a zone, or right-click and then select **Select All**.

Step 4 Click **Add to Source**, or drag and drop.

Step 5 Click the **DNS** tab and add the lists or feeds that include the DNS names you are controlling. For more information, see Control traffic based on DNS list or feed, on page 2007.

Step 6 Save or continue editing the rule.

The DNS rule is configured with security zone conditions to control traffic based on source security zones and DNS names.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Control traffic based on DNS and network

Control traffic by explicitly specifying the source IP addresses for the traffic you want to manage through DNS rules.

Network conditions in DNS rules allow you to control traffic by its source IP address. You can explicitly specify the source IP addresses for the traffic you want to control.

Procedure

Step 1 In the DNS rule editor, click **Networks**.

Step 2 Find and select the networks you want to add from the **Available Networks**, as follows:

- To add a network object on the fly, which you can then add to the condition, click **Add** (+) above the **Available Networks** list and proceed as described in Create a network object, on page 2388.
- To search for network objects to add, click the **Search by name or value** prompt above the **Available Networks** list, then type an object name or the value of one of the object's components. The list updates as you type to display matching objects.

Step 3 Click **Add to Source**, or drag and drop.

Step 4 Add any source IP addresses or address blocks that you want to specify manually. Click the **Enter an IP address** prompt below the **Source Networks** list; then type an IP address or address block and click **Add**.

Step 5 Click the **DNS** tab and add the lists or feeds that include the DNS names you are controlling. For more information, see Control traffic based on DNS list or feed, on page 2007.

Step 6 Save or continue editing the rule.

The DNS rule is configured with network conditions to control traffic based on the specified source IP addresses and DNS names.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Control traffic based on DNS and VLAN

This task allows you to control VLAN-tagged traffic by configuring VLAN conditions in DNS rules, enabling precise traffic management based on DNS names and VLAN identifiers.

VLAN conditions in DNS rules allow you to control VLAN-tagged traffic. The system uses the innermost VLAN tag to identify a packet by VLAN.

When you build a VLAN-based DNS rule condition, you can manually specify VLAN tags. Alternately, you can configure VLAN conditions with VLAN tag *objects*, which are reusable and associate a name with one or more VLAN tags.

Procedure

Step 1 In the DNS rule editor, select **VLAN Tags**.

Step 2 Find and select the VLANs you want to add from the **Available VLAN Tags**, as follows:

- To add a VLAN tag object on the fly, which you can then add to the condition, click **Add** (+) above the Available VLAN Tags list and proceed as described in Create a VLAN tag object, on page 2456.
- To search for VLAN tag objects and groups to add, click the **Search by name or value** prompt above the **Available VLAN Tags** list, then type either the name of the object, or the value of a VLAN tag in the object. The list updates as you type to display matching objects.

Step 3 Click **Add to Rule**, or drag and drop.

Step 4 Add any VLAN tags that you want to specify manually. Click the **Enter a VLAN Tag** prompt below the **Selected VLAN Tags** list; then type a VLAN tag or range and click **Add**. You can specify any VLAN tag from 1 to 4094; use a hyphen to specify a range of VLAN tags.

Step 5 Click the **DNS** tab and add the lists or feeds that include the DNS names you are controlling. For more information, see Control traffic based on DNS list or feed, on page 2007.

Step 6 Save or continue editing the rule.

The DNS rule is configured with VLAN conditions, allowing the system to control traffic based on both DNS names and VLAN tags.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Control traffic based on DNS list or feed

Control network traffic by applying DNS-based filtering rules using predefined or custom DNS lists and threat intelligence feeds.

Use DNS lists and feeds in security policies to block or allow traffic based on domain reputation and threat intelligence data.

Procedure

Step 1 In the DNS rule editor, click **DNS**.

Step 2 Find and select the DNS lists and feeds you want to add from the **DNS Lists and Feeds**, as follows:

- To add a DNS list or feed on the fly, which you can then add to the condition, click **Add** (+) above the **DNS Lists and Feeds** list and proceed as described in Create custom security intelligence feeds, on page 2428.

- To search for DNS lists, feeds, or categories to add, click the **Search by name or value** prompt above the **DNS Lists and Feeds** list, then type an object name or the value of one of the object's components. The list updates as you type to display matching objects.
- For descriptions of the system-provided threat categories, see Security intelligence categories, on page 1602.

Step 3 Click **Add to Rule**, or drag and drop.

Step 4 Save or continue editing the rule.

The DNS lists and feeds are now configured in your rule and will filter traffic based on the selected criteria.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Requirement: deploy DNS policy configuration changes

After you finish updating your DNS policy configuration, you must deploy it as part of access control configuration.

- Associate your DNS policy with an access control policy, as described in Configure security intelligence, on page 1599.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Cisco umbrella DNS policies

A Cisco Umbrella DNS policy is a security mechanism that

- redirects DNS queries to Cisco Umbrella for domain validation and policy enforcement,
- allows or blocks requests based on domain names and applies DNS-based security policies, and
- provides two lines of protection through local DNS inspection and cloud-based Cisco Umbrella policies.

DNS query redirection process

Cisco Umbrella DNS Connection in the management center helps to redirect DNS queries to Cisco Umbrella. This allows Cisco Umbrella to validate requests, allow or block them based on the domain names, and apply DNS-based security policy on the request. If you use Cisco Umbrella, you must configure the Cisco Umbrella Connection (**Integration** > **Other Integrations** > **Cloud Services** and choose the **Cisco Umbrella Connection**) to redirect DNS queries to Cisco Umbrella.

The Umbrella Connector is part of the system's DNS inspection. If your existing DNS inspection policy map decides to block or drop a request based on your DNS inspection settings, the request is not forwarded to Cisco Umbrella. Thus, you have two lines of protection:

- Your local DNS inspection policy

- Your Cisco Umbrella cloud-based policy

When redirecting DNS lookup requests to Cisco Umbrella, the Umbrella Connector adds an EDNS (Extension mechanisms for DNS) record. An EDNS record includes the device identifier information, organization ID, and client IP address. Your cloud-based policy can use those criteria to control access in addition to the reputation of the FQDN. You can also elect to encrypt the DNS request using DNSCrypt to ensure the privacy of usernames and internal IP addresses.

To redirect DNS requests from the management center to Cisco Umbrella:

1. Configure the Cisco Umbrella connection settings.
2. Create and configure an Umbrella DNS policy.
3. Associate the Umbrella DNS policy with an access control policy.
4. Deploy the changes.

For detailed information about how to set up the Umbrella DNS Connector in the management center, see Configuring the Umbrella DNS Connector for Cisco Secure Firewall Management Center.

Redirect DNS requests to Cisco umbrella

Redirect DNS requests from the device to Cisco Umbrella for enhanced security and DNS filtering capabilities.

Use this procedure when you need to configure DNS redirection to Cisco Umbrella using the Firewall Management Center.

Procedure

Step 1 Ensure that you meet the prerequisites.

Prerequisites for configure the umbrella DNS connector, on page 2010

Step 2 Configure the Cisco Umbrella connection settings.

Configure Cisco umbrella connection settings, on page 2011

Step 3 Create an Umbrella DNS policy.

Create an umbrella DNS policy, on page 2012

Step 4 Configure the Umbrella DNS policy.

Edit Umbrella DNS policies and rules, on page 2012

Step 5 Associate the Umbrella DNS policy with an access control policy.

Associate the umbrella DNS policy with an access control policy, on page 2013

DNS requests from the device are now redirected to Cisco Umbrella for processing and security filtering.

Prerequisites for configure the umbrella DNS connector

This reference provides the prerequisites that must be met before configuring the Umbrella DNS Connector, including minimum platform requirements, account setup, certificate management, and network connectivity requirements.

Table 113: Minimum supported platforms

Product	Version
Secure Firewall Threat Defense	6.6 and above
Secure Firewall Management Center	7.2 and above

- Establish an account with Cisco Umbrella at https://umbrella.cisco.com, and log into Umbrella at http://login.umbrella.com.
- Import the CA certificate from the Cisco Umbrella server to the Firewall Management Center. In Cisco Umbrella, choose **Deployments** > **Configuration** > **Root Certificate** and download the certificate.

  You must import the root certificate to establish the HTTPS connection with the Cisco Umbrella registration server. The certificate needs to be trusted for SSL server validation, which is a non-default option in the Firewall Management Center. Copy and paste this certificate for the device in the Firewall Management Center(**Devices** > **Certificates**).

  When you add the certificate in the management center, ensure that you check the **CA Only** check box.
- Install the certificate on the device.
- Obtain this data from Umbrella:
  - Organization ID
  - Network Device Key
  - Network Device Secret

- Legacy Network Device Token

- Ensure that the Firewall Management Center is connected to the internet.
- Ensure that the base license with the export-controlled feature option is enabled in the Firewall Management Center.
- Ensure that the DNS server is configured to resolve api.opendns.com.
- Ensure that the Firewall Management Center can resolve management.api.umbrella.com for policy configuration.
- Configure the Firewall Threat Defense route to api.opendns.com.

Configure Cisco umbrella connection settings

Configure the token and settings required to register the device with Cisco Umbrella and enable DNS security services.

The Cisco Umbrella Connection settings define the token that is needed to register the device with Cisco Umbrella.

Before you begin

Establish an account with Cisco Umbrella https://umbrella.cisco.com, and then log into Umbrella at https://dashboard.umbrella.com and obtain the required information to establish connection to Cisco Umbrella.

Follow these steps to configure Cisco Umbrella connection settings:

Procedure

Step 1 Choose **Integration** > **Other Integrations** > **Cloud Services** and choose the **Cisco Umbrella Connection**.

Step 2 Obtain the following details and add them to the **General** settings:

- **Organization ID**—A unique number that identifies your organization on Cisco Umbrella. Every Umbrella organization is a separate instance of Umbrella and has its own dashboard. Organizations are identified by their name and their organization ID (Org ID).
- **Network Device Key**—The key to fetch umbrella policy from Cisco Umbrella.
- **Network Device Secret**—The secret to fetch umbrella policy from Cisco Umbrella.
- **Legacy Network Device Token**—An Umbrella Legacy Network Devices API token is issued through the Cisco Umbrella dashboard. Umbrella requires the API token to register a network device.

Step 3 Under **Advanced**, configure the following optional settings:

- **DNSCrypt Public Key**—DNSCrypt authenticates and encrypts the DNS queries between the endpoint and the DNS server. To enable DNScrypt, you can configure the DNScrypt public key for certificate verification. The key is a 32-byte hexadecimal value and is preconfigured to B735:1140:206F:225d:3E2B:d822:D7FD:691e:A1C3:3cc8:D666:8d0c:BE04:bfab:CA43:FB79, which is the public key of the Umbrella Anycast servers.
- **Management Key**—A key to fetch datacenter details from Umbrella cloud for VPN policy.

- **Management Secret**—A secret used to fetch datacenters from Umbrella cloud for VPN.

Step 4 Click **Test Connection**—Test if the Cisco Umbrella Cloud is reachable from the Firewall Management Center. When you provide the required organization ID and network device details, the umbrella connection is created.

Step 5 Click **Save**.

The Cisco Umbrella connection is configured and the device is ready to register with Cisco Umbrella using the specified credentials and settings.

Create an umbrella DNS policy

Create an Umbrella DNS policy to implement DNS-based security controls and filtering for network protection.

Umbrella DNS policies provide DNS security by blocking malicious domains and controlling access to web content through DNS filtering.

Before you begin

Follow these steps to create an Umbrella DNS policy:

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **DNS**.

Step 2 Click **Add DNS Policy** > **Umbrella DNS Policy**.

Step 3 Give the policy a unique **Name** and, optionally, a **Description**.

Step 4 Click **Save**.

The Umbrella DNS policy is created and ready for configuration with DNS security rules.

What to do next

Configure the policy. See Edit Umbrella DNS policies and rules, on page 2012.

Edit Umbrella DNS policies and rules

Edit Umbrella DNS policies and rules to modify protection policies, configure bypass domains, enable DNSCrypt encryption, and adjust connection timeout settings to meet your organization's specific DNS security requirements.

Use this procedure when you need to modify existing Umbrella DNS policies and their associated rules. You can update protection policy settings, configure local domain bypasses, enable encryption options, and adjust timeout parameters to optimize DNS security for your network environment.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **DNS**.

Step 2 In the DNS Policy page, select the Umbrella DNS policy that you want to edit and click **Edit** ( ).

Refresh the Umbrella Protection Policy

If you want to get the latest Umbrella Protection Policy from Cisco Umbrella, click the **Refresh** icon next to **Umbrella Protection Policy Last Updated**.

To configure or modify Umbrella Connection settings for the Management Center, go to **Integration** > **Other Integrations** > **Cloud Services** Choose the **Cisco Umbrella Connection**.

Step 3 In the Umbrella DNS policy editor, select the Umbrella DNS rule and click **Edit** ( ).

Step 4 Configure the rule components, or accept the defaults:

- **Umbrella Protection Policy**—Specify the name of the Cisco Umbrella policy to apply to the device.
- **Bypass Domain**—Specify the name of the local domains for which DNS requests should bypass Cisco Umbrella and instead go directly to the configured DNS servers.

  For example, you can have your internal DNS server resolve all names for the organization's domain name on the assumption that all internal connections are allowed.
- **DNSCrypt**— Enable DNSCrypt to encrypt connections between the device and Cisco Umbrella.

  Enabling DNScrypt starts the key-exchange thread with the Umbrella resolver. The key-exchange thread performs the handshake with the resolver every hour and updates the device with a new secret key. As DNScrypt uses UDP/443, you must ensure that the class map used for DNS inspection includes that port. Note that the default inspection class already includes UDP/443 for DNS inspection.
- **Idle Timeout**—Configure the idle timeout after which a connection from a client to the Umbrella server will be removed if there is no response from the server.

Step 5 Click **Save**.

Your Umbrella DNS policy and rule modifications are saved and ready to be deployed. The updated settings will take effect when the policy is applied to devices.

What to do next

Associate the Umbrella DNS policy with an access control policy. For more information, see Associate the umbrella DNS policy with an access control policy, on page 2013.

Associate the umbrella DNS policy with an access control policy

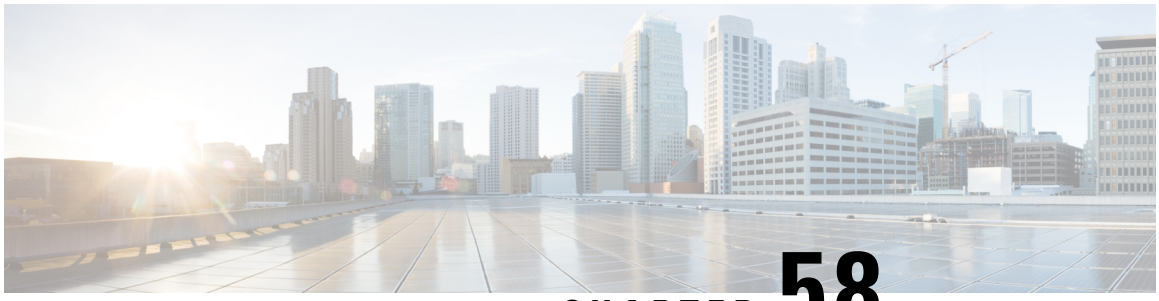
This task associates an Umbrella DNS policy with an access control policy to enable DNS-based security intelligence filtering before deploying the policy on the device.

Before you deploy the Umbrella DNS policy on the device, you must associate it with an access control policy.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control** and select the access policy to edit.

Step 2 Select **Security Intelligence**.



Step 3 From the **Umbrella DNS Policy** drop-down list, select the Umbrella DNS policy.

Step 4 Click **Save**.

The Umbrella DNS policy is now associated with the access control policy and will provide DNS-based security intelligence filtering when deployed.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 135.

CHAPTER 58

File Policies for Network Malware Protection

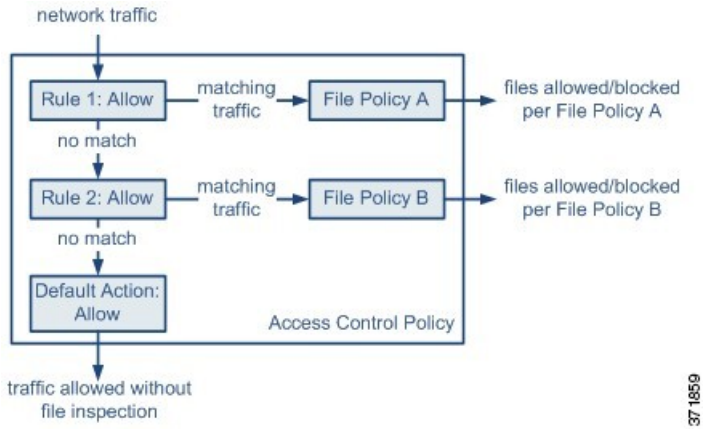
The following topics provide an overview of file control, file policies, file rules, Advanced Malware Protection (AMP), cloud connections, and dynamic analysis connections.

- Network malware protection and file policies, on page 2015
- Prerequisites for file policies, on page 2016
- License requirements for file and malware policies, on page 2017
- Best practices for file policies and malware detection, on page 2017
- Configure malware protection, on page 2021
- Cloud connections for malware protection, on page 2026
- File policies and file rules, on page 2035
- Retrospective disposition changes, on page 2051
- File and malware inspection performance and storage options, on page 2052
- Tune file and malware inspection performance and storage, on page 2053
- (Optional) Malware protection with Secure Endpoint, on page 2054
- History for network malware protection and file policies, on page 2058

Network malware protection and file policies

Advanced Malware Protection (AMP) for Firepower can detect, capture, track, analyze, log, and optionally block the transmission of malware in network traffic. In the Secure Firewall Management Center web interface, this feature is called malware defense, formerly called AMP for Firepower. Advanced Malware Protection identifies malware using managed devices deployed inline and threat data from the Cisco cloud.

You associate file policies with access control rules that handle network traffic as part of your overall access control configuration.



When the system detects malware on your network, it generates file and malware events. To analyze file and malware event data, see the *File/Malware Events and Network File Trajectory* chapter in the *Cisco Secure Firewall Management Center Administration Guide* .

File policies

A file policy is a set of configurations that the system uses to perform malware protection and file control, as part of your overall access control configuration. This association ensures that before the system passes a file in traffic that matches an access control rule's conditions, it first inspects the file. Consider the following diagram of a simple access control policy in an inline deployment.

File policy traffic flow

Consider this diagram of a simple access control policy in an inline deployment.

The policy has two access control rules, both of which use the Allow action and are associated with file policies. The policy's default action is also to allow traffic, but without file policy inspection. In this scenario, traffic is handled as follows:

- Traffic that matches `Rule 1` is inspected by `File Policy A`.
- Traffic that does not match `Rule 1` is evaluated against `Rule 2`. Traffic that matches `Rule 2` is inspected by `File Policy B`.
- Traffic that does not match either rule is allowed; you cannot associate a file policy with the default action.

By associating different file policies with different access control rules, you have granular control over how you identify and block files transmitted on your network.

Prerequisites for file policies

This reference lists the prerequisites necessary for implementing file policies in your network security deployment.

License requirements for file and malware policies

This reference provides the specific license requirements needed to implement various file rule actions and malware detection capabilities in file and malware policies.

To Do This	License Required	File Rule Action
Block or allow all files of a particular type (for example, block all .exe files)	IPS (for Firewall Threat Defense devices) Protection (for Classic devices)	Allow, Block, Block with Reset
Selectively allow or block files based on a judgment that it contains or is likely to contain malware	IPS (for Firewall Threat Defense devices) Protection (for Classic devices) Malware Defense	Malware Cloud Lookup, Block Malware
Store files	IPS (for Firewall Threat Defense devices) Protection (for Classic devices) Malware Defense	Any file rule action with **Store Files** selected

For details about Malware Defense licenses, refer to:

- *Malware Defense Licenses* in the *Cisco Secure Firewall Management Center Administration Guide*

Best practices for file policies and malware detection

In addition to the items described below, follow the steps in Configure malware protection, on page 2021 and referenced topics.

File rule best practices

Consider these guidelines and limitations when configuring file rules:

Prerequisites

- You cannot perform malware analysis on all file types detected by the system. After you select values from the **Application Protocol**, **Direction of Transfer**, and **Action** drop-down lists, the system constrains the list of file types.

- If a file rule is configured with a **Malware Cloud Lookup** or **Block Malware** action and the Firewall Management Center cannot establish connectivity with the AMP cloud, the system cannot perform any configured rule action options until connectivity is restored.

General file rule best practices

- A rule configured to block files in a passive deployment does not block matching files. Because the connection continues to transmit the file, if you configure the rule to log the beginning of the connection, you may see multiple events logged for this connection.
- A policy can include multiple rules. When you create the rules, ensure that no rule is "shadowed" by a previous rule.
- Cisco recommends that you enable **Reset Connection** for the **Block Files** and **Block Malware** actions to prevent blocked application sessions from remaining open until the TCP connection resets. If you do not reset connections, the client session will remain open until the TCP connection resets itself.

Dynamic Analysis

- The file types supported for dynamic analysis are a subset of the file types supported for other types of analysis. To view the file types supported for each type of analysis, navigate to the file rule configuration page, select the **Block Malware** action, and select the checkboxes of interest.

  To ensure that the system examines all file types, create separate rules (within the same policy) for dynamic analysis and for other types of analysis.
- If you are monitoring high volumes of traffic, do **not** store all captured files, or submit all captured files for dynamic analysis. Doing so can negatively impact system performance.

File detection best practices

Consider these notes and limitations when implementing file detection:

Prerequisite

If adaptive profiling is not enabled, access control rules cannot perform file control, including AMP.

General file detection best practices

- If a file matches a rule with an application protocol condition, file event generation occurs after the system successfully identifies a file's application protocol. Unidentified files do not generate file events.
- To detect ISO files, set the "Limit the number of bytes inspected when doing file type detection" option to a value greater than 36870, as described in File and malware inspection performance and storage options, on page 2052.
- .Exe files inside some .rar archives cannot be detected, including possibly rar5.
- If the file disposition is Neutral, it is an unknown disposition.

FTP-Specific considerations

- FTP transfers commands and data over different channels. In a passive or inline tap mode deployment, the traffic from an FTP data session and its control session may not be load-balanced to the same internal resource.

Email protocols considerations

- If the total number of bytes for all file names for files in a POP3, POP, SMTP, or IMAP session exceeds 1024, file events from the session may not reflect the correct file names for files that were detected after the file name buffer filled.
- When transmitting text-based files over SMTP, some mail clients convert newlines to the CRLF newline character standard. Since Mac-based hosts use the carriage return (CR) character and Unix/Linux-based hosts use the line feed (LF) character, newline conversion by the mail client can modify the size of the file. Note that some mail clients default to newline conversion when processing an unrecognizable file type.

File blocking best practices

Consider these notes and limitations for file blocking:

HTTP transfers

- File rules with **Block Files** and **Block Malware** actions block automatic resumption of file download via HTTP by blocking new sessions with the same file, URL, server, and client application detected for 24 hours after the initial file transfer attempt occurs.
- In rare cases, if traffic from an HTTP upload session is out of order, the system cannot reassemble the traffic correctly and therefore will not block it or generate a file event.

End-of-File detection

- If an end-of-file marker is not detected for a file, regardless of transfer protocol, the file will not be blocked by a **Block Malware** rule or the custom detection list. The system waits to block the file until the entire file has been received, as indicated by the end-of-file marker, and blocks the file after the marker is detected.
- If the end-of-file marker for an FTP file transfer is transmitted separately from the final data segment, the marker will be blocked and the FTP client will indicate that the file transfer failed, but the file will actually completely transfer to disk.

SMB or NetBIOS-ssn transfers

- If you transfer a file over NetBIOS-ssn (such as an SMB file transfer) that is blocked with a **Block Files** rule, you may see a file on the destination host. However, the file is unusable because it is blocked after the download starts, resulting in an incomplete file transfer.
- If you create file rules to detect or block files transferred over NetBIOS-ssn (such as an SMB file transfer), the system does not inspect the ongoing file transfers. However, the system inspects the new files that are transferred after you deploy an access control policy invoking the file policy.

- SMB has a functionality called multi-channel which creates multiple parallel sessions with the same IP address and different ports. For a given transaction over multi-channel, the file download is multiplexed across these sessions which is not inspected by the system as a single file.
- Files transferred concurrently in a single TCP or SMB session are not inspected.
- In a cluster environment, if an existing SMB session is moved to a new device due to a cluster role change or a device failure, then the files in any ongoing file transfers may not be inspected.
- Some SMB file transfers between Microsoft Windows systems use very high TCP window size for quick file transfers. To detect or block such file transfers, it is recommended that you increase the value of **Maximum Queued Bytes** and **Maximum Queued Segments** under **Network Analysis Policy** > **TCP Stream Configuration** > **Troubleshooting Options**.

High availability

If you configure Firewall Threat Defense high availability, and failover occurs while the original active device is identifying the file, the file type is not synced. Even if your file policy blocks that file type, the new active device downloads the file.

File policy best practices

Follow these best practices for file policy configuration to ensure proper functionality and optimal performance.

Prerequisites

- For file blocking to work, the NAP policy you apply to the access control policy must be operating in Protection mode, also known as Inline mode.
- You can associate a single file policy with an access control rule whose action is **Allow**, **Interactive Block**, or **Interactive Block with reset**.
- You **cannot** use a file policy to inspect traffic handled by the access control default action.

Encrypted traffic

By default, file inspection of encrypted payloads is disabled. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has file inspection configured.

Attention The File Inpsect preprocessor with the following generator IDs (GIDs) are enabled by default for file/malware policy: GID: 146 and GID: 147.

General file policy best practices

- For a new policy, the web interface indicates that the policy is not in use. If you are editing an in-use file policy, the web interface tells you how many access control policies use the file policy. In either case, you can click the text to jump to the Access Control Policies page.
- Based on your configuration, you can either inspect a file the first time the system detects it, and wait for a cloud lookup result, or pass the file on this first detection without waiting for the cloud lookup result.

- If you enable an access control policy with a file policy that uses either a Malware action or a Store Files option, the computing power and system performance of the device is reduced.
- NEW_OFFICE file type in file policy configuration identifies Microsoft files: DOCX, XLSX, and PPTX. When you apply a policy action to NEW_OFFICE, the action applies uniformly to all three file types—DOCX, XLSX, and PPTX.

  If your security requirements need differentiated handling of Office file formats, such as blocking DOCX documents while permitting XLSX spreadsheets, do not use the NEW_OFFICE aggregate file type. Instead, perform these steps:

  1. Select individual file types (DOCX, XLSX, PPTX) separately in your file policy rule.
  2. Create separate rules with distinct actions for each format you need to control granularly.
  3. Test your policy to ensure each Office format is handled according to your security intent.

  This approach ensures that your file policy aligns with your organization's security posture and prevents unintended blocking of legitimate business traffic.

Configure malware protection

You need to set up your system to protect your network from malicious software by following a series of configuration steps.

Procedure

Step 1 Plan and prepare for malware protection, on page 2022

Step 2 Configure file policies, on page 2023

Step 3 Add file policies to your access control configuration, on page 2023

Step 4 Configure network discovery policies to associate file and malware events with hosts on your network.

(Do not simply turn on network discovery; you must configure it to discover hosts on your network to build a network map of your organization.)

See Network Discovery Policies, on page 2305 and subtopics.

Step 5 Deploy policies to managed devices.

See Deploy configuration changes, on page 135.

Step 6 Test your system to be sure it is processing malicious files as you expect it to.

Step 7 Verify and monitor malware protection, on page 2025

What to do next

- (Optional) To further enhance detection of malware in your network, deploy and integrate Cisco's Secure Endpoint product. Refer to (Optional) Malware protection with Secure Endpoint, on page 2054 and subtopics.
- Understand how to investigate file and malware events.

Refer to *File/Malware Events and Network File Trajectory* in the *Cisco Secure Firewall Management Center Administration Guide*.

Plan and prepare for malware protection

This procedure is the first set of steps in the complete process for configuring your system to provide malware protection.

Procedure

Step 1 Purchase and install licenses.

Refer to License requirements for file and malware policies, on page 2017 and *Licenses* in the *Cisco Secure Firewall Management Center Administration Guide*.

Step 2 Understand how file policies and malware protection fit into your access control plan.

Refer to the chapter Access Control Policies, on page 1569.

Step 3 Understand the file analysis and malware protection tools.

Refer to File rule actions, on page 2042 and subtopics.

Consider also Advanced and archive file inspection options, on page 2036.

Step 4 Determine whether you will use public clouds or private (on-premises) clouds for malware protection (file analysis and dynamic analysis.)

Refer to Cloud connections for malware protection, on page 2026 and subtopics.

Step 5 If you will use private (on-premises) clouds for malware protection: Purchase, deploy, and test those products.

For information, contact your Cisco sales representative or authorized reseller.

Step 6 Configure your firewall to allow communications with your chosen clouds.

Refer to *Security, Internet Access, and Communication Ports* in the *Cisco Secure Firewall Management Center Administration Guide*.

Step 7 Configure connections between Firepower and the malware protection clouds (public or private, as applicable).

- For the AMP cloud, refer to Change AMP options, on page 2031.
- If you have deployed an on-premises Secure Malware Analytics Appliance, see Connect to an on-premises dynamic analysis appliance, on page 2032. (Access to the public Secure Malware Analytics Cloud does not require configuration.)

What to do next

Continue with the next step in the malware protection workflow:

Refer to Configure malware protection, on page 2021.

Configure file policies

File policies are a critical component of the malware protection workflow that allow you to define specific rules and advanced options for file inspection and handling.

Before you begin

Complete the tasks up to this point in the malware protection workflow:

Refer to Configure malware protection, on page 2021.

Procedure

Step 1 Review file policy and file rule restrictions.

Refer to Best practices for file policies and malware detection, on page 2017 and subtopics.

Step 2 Create a file policy.

Refer to Create or edit a file policy, on page 2035.

Step 3 Create rules within your file policy.

Refer to File rules, on page 2040 and subtopics.

Step 4 Configure advanced options.

Refer to Advanced and archive file inspection options, on page 2036.

What to do next

Continue with the next step in the malware protection workflow:

Refer to Configure malware protection, on page 2021.

Add file policies to your access control configuration

An access control policy can have multiple access control rules associated with file policies. You can configure file inspection for any Allow or Interactive Block access control rule, which permits you to match different file and malware inspection profiles against different types of traffic on your network before it reaches its final destination.

Before you begin

Complete the tasks up to this point in the malware protection workflow:

See Configure malware protection, on page 2021.

Procedure

Step 1 Review guidelines for file policies in access control policies. (These are different from the file rule and file policy guidelines.)

Review File and intrusion inspection order, on page 1618.

Step 2 Associate the file policy with an access control policy.

Refer to Configure an access control rule to perform malware protection, on page 2024

Step 3 Assign the access control policy to managed devices.

See Assign access control policy to devices, on page 1583.

What to do next

Continue with the next step in the malware protection workflow:

Refer to Configure malware protection, on page 2021.

Configure an access control rule to perform malware protection

Access control rules with file policies provide comprehensive malware protection by inspecting traffic flows and applying security analysis to files traversing your network.

Caution Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Note Inline normalization is enabled automatically when a file policy is included in an access control rule. For more information, refer to The Inline Normalization Preprocessor.

Before you begin

- Adaptive profiling **must** be enabled (its default state) for access control rules to perform file control, including AMP.
- You must be an Admin, Access Admin, or Network Admin user to perform this task.

Procedure

Step 1 In the access control rule editor (from **Policies > Access Control)**, choose an **Action** of **Allow**, **Interactive Block**, or **Interactive Block with reset**.

Step 2 (Legacy UI only.) Click **Inspection**.

Step 3 Choose a **File Policy** to inspect traffic that matches the access control rule, or choose **None** to disable file inspection for matching traffic.

Step 4 (Optional) Disable logging of file or malware events for matching connections by clicking **Logging** and unchecking **Log Files**.

Note Cisco recommends that you leave file and malware event logging enabled.

Step 5 Save the rule.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Verify and monitor malware protection

Ongoing maintenance is essential for protecting your network.

Before you begin

Configure your system to protect your network from malware.

Refer to Configure malware protection, on page 2021 and referenced procedures.

Procedure

Step 1 Ensure that your system always has the most current and effective protection.

Refer to Maintain your system: file types eligible for dynamic analysis, on page 2034.

Step 2 Configure alerts for malware-related events and health monitoring.

See the *Cisco Secure Firewall Management Center Administration Guide* for information on *Configuring malware defense Alerting* and for information about the following modules:

- Local Malware Analysis
- Security Intelligence
- Threat Data Updates on Devices

- Intrusion and File Event Rate
- AMP for Firepower Status
- Secure Endpoint Status

What to do next

Review "What to do next items" in the malware protection workflow:

Refer to Configure malware protection, on page 2021.

Cloud connections for malware protection

Connections to public or private clouds are required in order to protect your network from malware.

AMP clouds

The Advanced Malware Protection (AMP) cloud is a Cisco-hosted server that uses big data analytics and continuous analysis to provide intelligence that the system uses to detect and block malware on your network.

The AMP cloud provides dispositions FOR possible malware detected IN network traffic by managed devices, as well as data updates FOR local malware analysis and file pre-classification.

If your organization has deployed Secure Endpoint and configured Firepower to import its data, the system imports this data from the AMP cloud, including scan records, malware detections, quarantines, and indications of compromise (IOC).

Cisco offers these options for obtaining data from the Cisco cloud about known malware threats:

- **AMP public cloud**: Your Secure Firewall Management Center communicates directly with the public Cisco cloud. There are three public AMP clouds, in the United States, Europe, and Asia.
- **An AMP private cloud**: An AMP private cloud is deployed on your network and acts as a compressed, on-premises AMP cloud, as well as an anonymized proxy to connect to the public AMP cloud. FOR details, see Cisco AMP private cloud, on page 2028.

  If you integrate with Secure Endpoint, the AMP private cloud has some limitations. See Secure Endpoint and AMP private cloud, on page 2056.

Dynamic analysis cloud

Dynamic analysis cloud options include:

- Secure Malware Analytics Cloud: Public cloud that processes eligible files that you send for dynamic analysis, and provides threat scores and dynamic analysis reports. Firepower supports 200 samples/day FOR Secure Malware Analytics analysis.
- On-premises Secure Malware Analytics Appliance: If your organization's security policy does not allow the system to send files outside of your network, you can deploy an on-premises appliance. This appliance does not contact the public Secure Malware Analytics Cloud.

For more information, refer to Dynamic analysis on-premises appliance (Cisco Secure Malware Analytics), on page 2032.

Configure connections to AMP and Secure Malware Analytics

- AMP cloud connection configurations, on page 2027
- Dynamic analysis connections, on page 2031

AMP cloud connection configurations

These topics describe AMP cloud connection configurations for different scenarios:

- Choose an AMP cloud, on page 2028
- Connect to an AMP private cloud, on page 2029
- Integrate Firepower and Secure Endpoint, on page 2056

Refer these topics:

- Cisco AMP private cloud, on page 2028
- Prerequisites and best practices for AMP cloud connections, on page 2027
- Manage connections to the AMP cloud (public or private), on page 2030

Prerequisites and best practices for AMP cloud connections

This topic lists the prerequisites and best practices for AMP cloud connections.

Prerequisites for AMP cloud connections

- You must be an Admin user to set up the AMP cloud.
- To ensure the Firewall Management Center can communicate with the AMP cloud, see *Security, Internet Access, and Communication Ports* in the *Cisco Secure Firewall Management Center Administration Guide*.

AMP and high availability

Although they share file policies and related configurations, Firewall Management Centers in a high availability pair do not share AMP cloud connections, captured files, file events, and malware events.

Both active and standby Firewall Management Centers must have access to the cloud to ensure continuity of operations and consistent malware dispositions.

These requirements apply to both public and private AMP clouds.

AMP cloud connections and multitenancy

In a multidomain deployment, configure the malware defense connection at the global level. Each Firewall Management Center can have only one malware defense connection.

Choose an AMP cloud

By default, a connection to the United States (US) AMP public cloud is configured and enabled for your system. (This connection appears in the web interface as malware defense and sometimes AMP for Firepower.) You cannot delete or disable an malware defense cloud connection, but you can switch between different geographical AMP clouds, or configure an AMP private cloud connection.

Before you begin

- If you will use an AMP private cloud, refer to Connect to an AMP private cloud, on page 2029 instead of this topic.
- Unless Firepower is integrated with Secure Endpoint, you can configure only one AMP cloud connection. This connection is labeled **AMP for Networks** or **AMP for Firepower**.
- If you have deployed Secure Endpoint and you want to add one or more AMP clouds to integrate that application with Firepower, refer to Integrate Firepower and Secure Endpoint, on page 2056.
- Refer to Prerequisites and best practices for AMP cloud connections, on page 2027.

Procedure

Step 1 Choose **Integration** > **AMP** > **AMP Management**.

Step 2 Click the edit icon to edit the existing cloud connection.

Step 3 From the **Cloud Name** drop-down list, choose the regional cloud nearest to your Secure Firewall Management Center.

APJC is Asia/Pacific/Japan/China.

Step 4 Click **Save**.

What to do next

- If your deployment is a high-availability configuration, refer to Prerequisites and best practices for AMP cloud connections, on page 2027.
- (Optional) Change AMP options, on page 2031.

Cisco AMP private cloud

The Firewall Management Center must connect to the AMP cloud for disposition queries for files detected in network traffic and receipt of retrospective malware events. This cloud can be public or private.

AMP private cloud connection details

Your organization may have privacy or security concerns that make frequent or direct connections between your monitored network and the AMP cloud difficult or impossible. In these situations, you can set up a Cisco AMP Private Cloud. Connecting a Firewall Management Center to an AMP private cloud disables existing direct connections to the public AMP cloud.

All connections to the AMP cloud funnel through the AMP private cloud, which acts as an anonymized proxy to ensure the security and privacy of your monitored network. This includes disposition queries FOR files detected IN network traffic, receiving of retrospective malware events, and so on. The AMP private cloud does not share any of your endpoint data over an external connection.

Note The AMP private cloud does not perform dynamic analysis, nor does it support anonymized retrieval of threat intelligence FOR other features that rely on Cisco Collective Security Intelligence (CSI), such as URL and Security Intelligence filtering.

For information about AMP private cloud (sometimes referred to as "AMPv"), refer to https://www.cisco.com/c/en/us/products/security/fireamp-private-cloud-virtual-appliance/index.html.

Connect to an AMP private cloud

Use this connection when you have a dedicated AMP private cloud infrastructure that provides enhanced security and control over your malware analysis environment. The private cloud connection enables malware detection and analysis while keeping sensitive data within your controlled environment.

Before you begin

- Configure your Cisco AMP private cloud or clouds according to the directions in the documentation for that product. During configuration, note the private cloud host name. You will need this host name in order to configure the connection on the Firewall Management Center.
- Make sure the Firewall Management Center can communicate with the AMP private cloud, and confirm that the private cloud has internet access so it can communicate with the public AMP cloud. See the topics under *Security, Internet Access, and Communication Ports* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Unless your deployment is integrated with Secure Endpoint, each Firewall Management Center can have only one AMP cloud connection. This connection is labeled **AMP for Networks** or **AMP for Firepower**.

  If you integrate with Secure Endpoint, you can configure multiple Secure Endpoint cloud connections.

Procedure

Step 1 Choose **Integration** > **AMP** > **AMP Management**.

Step 2 Click **Add AMP Cloud Connection**.

Step 3 From the **Cloud Name** drop-down list, choose **Private Cloud**.

Step 4 Enter a **Name**.

This information appears in malware events that are generated or transmitted by AMP private cloud.

Step 5 In the **Host** field, enter the private cloud host name that you configured when you set up the private cloud.

Step 6 Click **Browse** next to the **Certificate Upload Path** field to browse to the location of a valid TLS or SSL encryption certificate for the private cloud. For more information, see the AMP private cloud documentation.

Step 7 If you want to use this private cloud for both malware defense and Secure Endpoint, check the **Use for AMP for Firepower** check box.

If you configured a different private cloud to handle malware defense communications, you can clear this check box; if this is your only AMP private cloud connection, you cannot.

In a multidomain deployment, this check box appears only in the Global domain. Each Firewall Management Center can have only one malware defense connection.

Step 8 Click **Register**, confirm that you want to disable existing direct connections to the AMP cloud, and finally confirm that you want to continue to the AMP private cloud management console to complete registration.

Log into the management console and complete the registration process. For further instructions, see the AMP private cloud documentation.

What to do next

In high availability deployments, configure AMP cloud connections on both management centers. These configurations are not synchronized.

Manage connections to the AMP cloud (public or private)

Use the Firewall Management Center to manage connections to public and private AMP clouds used for malware defense or Secure Endpoint or both.

You can delete a connection to a public or private AMP cloud if you no longer want to receive malware-related information from the cloud. Note that deregistering a connection using the Secure Endpoint or AMP private cloud management console does not remove the connection from the system. Deregistered connections display a failed state on the Secure Firewall Management Center web interface.

You can also temporarily disable a connection. When you reenable a cloud connection, the cloud resumes sending data to the system, including queued data from the disabled period.

Caution For disabled connections, the public or private AMP cloud can store malware events, indications of compromise, and so on until you re-enable the connection. In rare cases—for example, with a very high event rate or a long-term disabled connection—the cloud may not be able to store all information generated while the connection is disabled.

In a multidomain deployment, the system displays connections created in the current domain, which you can manage. It also displays connections created in ancestor domains, which you cannot manage. To manage connections in a lower domain, switch to that domain. Each Firewall Management Center can have only one malware defense connection, which belongs to the Global domain.

Procedure

Step 1 Select **Integration** > **AMP** > **AMP Management**.

Step 2 Manage your AMP cloud connections:

- **Delete** — Click **Delete** ( ), then confirm your choice.

- **Enable** or **Disable** — Click the slider, then confirm your choice.

What to do next

In high availability deployments, configure AMP cloud connections on both management centers. These configurations are not synchronized.

Change AMP options

Use this procedure to modify AMP (Advanced Malware Protection) for Networks configuration settings that control automatic signature updates and data sharing with the Cisco cloud.

Procedure

Step 1 Choose **Integration** > **Other Integrations** > **Cloud Services**.

Step 2 Configure these parameters:

Table 114: AMP for networks options

Option	Description
Enable Automatic Local Malware Detection Updates	The local malware detection engine statically analyzes and preclassifies files using signatures provided by Cisco. If you enable this option, the Firewall Management Center checks for signature updates once every 30 minutes.
Share URI from Malware Events with Cisco	The system can send information about the files detected in network traffic to the AMP cloud. This information includes URI information associated with detected files and their SHA-256 hash values. Although sharing is opt-in, transmitting this information to Cisco helps future efforts to identify and track malware.

Step 3 Click **Save**.

Dynamic analysis connections

Dynamic analysis connections are network connections that enable real-time security analysis and threat detection capabilities.

Prerequisites for dynamic analysis

This topic lists the prerequisites to use dynamic analysis.

- You must be an Admin, Access Admin, or Network Admin user, and be in the global domain, to use dynamic analysis.
- With the appropriate license, the system automatically has access to the Secure Malware Analytics Cloud.

- Dynamic analysis requires that managed devices have direct or proxied access to the Secure Malware Analytics Cloud or an on-premises Secure Malware Analytics Appliance on port 443.
- See also Files eligible for dynamic analysis, on page 2047.
- If you will connect to an on-premises Secure Malware Analytics Appliance, see also the prerequisites in Connect to an on-premises dynamic analysis appliance, on page 2032.

View the default dynamic analysis connection

By default, the Secure Firewall Management Center can connect to the public Secure Malware Analytics Cloud for file submission and report retrieval. You can neither configure nor delete this connection.

Procedure

Step 1 Choose **Integration** > **AMP** > **Dynamic Analysis ConnectionsAMP** > **Dynamic Analysis Connections**.

Step 2 Click **Edit** ( ).

Note For information about **Associate** ( ) on the **Integration** > **AMP** > **Dynamic Analysis Connections** page, refer to Enable access to dynamic analysis results in the public cloud, on page 2034.

Dynamic analysis on-premises appliance (Cisco Secure Malware Analytics)

If your organization has privacy or security concerns around submitting files to the public Secure Malware Analytics Cloud, you can deploy an on-premises Secure Malware Analytics Appliance. Like the public cloud, the on-premises appliance runs eligible files in a sandbox environment, and returns a threat score and dynamic analysis report to the system. However, the on-premises appliance does not communicate with the public cloud, or any other system external to your network.

For more information about on-premises Secure Malware Analytics Appliances, see https://www.cisco.com/c/en/us/products/security/threat-grid/index.html.

Connect to an on-premises dynamic analysis appliance

If you install an on-premises Secure Malware Analytics Appliance on your network, you can configure a dynamic analysis connection to submit files and retrieve reports from the appliance. When configuring the on-premises appliance dynamic analysis connection, you register the Secure Firewall Management Center to the on-premises appliance.

Before you begin

- Set up your on-premises Secure Malware Analytics Appliance.

  Documentation for this appliance is available from https://www.cisco.com/c/en/us/support/security/amp-threat-grid-appliances/tsd-products-support-series-home.html.

  For version requirements, refer to the *Cisco Firepower Compatibility Guide*.

- If your Secure Malware Analytics Appliance uses a self-signed public-key certificate, download the certificate from the Secure Malware Analytics Appliance; see the *Administrator's Guide* for your Secure Malware Analytics Appliance for information.

  If you use a certificate signed by a Certificate Authority (CA), the certificate must meet the following requirements:

  - The server key and signed certificate must be installed on the Secure Malware Analytics Appliance. Follow the upload instructions in the *Administrator's Guide* for your Secure Malware Analytics Appliance.
  - If there is a multi-level signing chain of CAs, all required intermediate certificates and the root certificate must be contained in a single file that will be uploaded to the Firewall Management Center.
  - All certificates must be PEM-encoded.
  - The file's newlines must be UNIX, not DOS.

- If you want to connect to the on-premises appliance using a proxy, configure the proxy; refer to *Modify Firewall Management Center Management Interfaces* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Managed devices must have direct or proxied access to the Secure Malware Analytics Appliance on port 443.

Procedure

Step 1 Choose **Integration** > **AMP** > **Dynamic Analysis ConnectionsAMP** > **Dynamic Analysis Connections**.

Step 2 Click **Add New Connection**.

Step 3 Enter a **Name** and enter a **Host**.

Step 4 Next to **Certificate Upload**, click **Browse** to upload the certificate for the on-premises appliance.

If the Secure Malware Analytics Appliance will present a self-signed certificate, upload the certificate you downloaded from that appliance.

If the Secure Malware Analytics Appliance will present a CA-signed certificate, upload the file containing the certificate signing chain.

Step 5 If you want to use a configured proxy to establish the connection, check the check box of **Use Proxy When Available**.

Step 6 Click **Register**.

Step 7 Click **Yes** to display the on-premises Secure Malware Analytics Appliance login page.

Step 8 Enter your username and password to the on-premises Secure Malware Analytics Appliance and click **Sign in**.

Step 9 You have these options:

- If you previously registered the Secure Firewall Management Center to the on-premises appliance, click **Return**.

- If you did not register the Secure Firewall Management Center, click **Activate**.

Enable access to dynamic analysis results in the public cloud

Secure Malware Analytics offers more detailed reporting on analyzed files than is available in the Firewall Management Center. If your organization has a Secure Malware Analytics Cloud account, you can access the Secure Malware Analytics portal directly to view additional details about files sent for analysis from your managed devices. However, for privacy reasons, file analysis details are available only to the organization that submitted the files. Therefore, before you can view this information, you must associate your Firewall Management Center with the files submitted by its managed devices.

Before you begin

You must have a Secure Malware Analytics Cloud account, and have your account credentials ready.

Procedure

Step 1 Select **Integration** > **AMP** > **Dynamic Analysis ConnectionsAMP** > **Dynamic Analysis Connections**.

Step 2 Click **Associate** ( ) in the table row corresponding to the Secure Malware Analytics Cloud.

A Secure Malware Analytics portal window opens.

Step 3 Sign in to the Secure Malware Analytics Cloud.

Step 4 Click **Submit Query**.

Note Do not change the default value in the **Devices** field.

If you have difficulties with this process, contact your Secure Malware Analytics representative at Cisco TAC.

It may take up to 24 hours for this change to take effect.

What to do next

After the association is activated, refer to *Viewing Dynamic Analysis Results in the Cisco Cloud* in the *Cisco Secure Firewall Management Center Administration Guide* .

Maintain your system: file types eligible for dynamic analysis

The list of file types eligible for Dynamic Analysis is determined by the vulnerability database (VDB), which is updated periodically (but no more than once per day.) If you are an Admin user, you can update file types eligible for dynamic analysis.

The supported file types for automatic submission can vary in every release. The currently supported files for automatic submission are:

- PE Executable (32-bit Only)

- EXE
- DLL
- PDF
- MSOLE2 (Microsoft Object Linking and Embedding Compound File)
- DOCX, PPTX, XLSX

Note GZ and ZIP file types are not supported for automatic submission.

Procedure

Step 1 Do one of the following:

- (Recommended) Refer to *Vulnerability Database Update Automation* as discussed in the *Cisco Secure Firewall Management Center Administration Guide*
- Regularly check for new VDB updates, and *Manually Update the VDB* as discussed in the *Cisco Secure Firewall Management Center Administration Guide* when needed.

  If you choose this option, we recommend that you schedule regular reminders to do this.

Step 2 If your file policies specify individual file types instead of the **Dynamic Analysis Capable** file type category, update your file policies to use the newly supported file types.

Step 3 If the list of eligible file types changes, deploy to managed devices.

File policies and file rules

File policies and file rules work together to control file handling and inspection in network traffic.

Create or edit a file policy

File policies allow you to control file transfers and provide malware protection by defining rules that specify which files can be transferred, blocked, or inspected for threats.

Before you begin

If you are configuring policies for malware protection, refer to all required procedures in Configure file policies, on page 2023.

Procedure

Step 1 Select **Policies** > **Access Control heading** > **Malware & File** .

Step 2 Create a new policy, or edit an existing policy.

If you are editing an existing policy: If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Tip To make a copy of an existing file policy, click **Copy** ( ), then type a unique name for the new policy in the dialog box that appears. You can then modify the copy.

Step 3 Add one or more rules to the file policy as described in Create file rules, on page 2050.

Step 4 Optionally, select Advanced and configure advanced options as described in Advanced and archive file inspection options, on page 2036.

Step 5 Save the file policy.

What to do next

- If you are configuring policies for malware protection, see other required procedures in Configure file policies, on page 2023.
- Otherwise:
  - Add the file policy to an access control rule as described in Add file policies to your access control configuration, on page 2023.
  - Deploy configuration changes; see Deploy configuration changes, on page 135.

Advanced and archive file inspection options

The Advanced Settings in the file policy editor provides general options for file analysis and archive file inspection to enhance security policy configuration.

The Advanced Settings in the file policy editor has these general options:

- **First Time File Analysis**—Select this option to analyze first-seen files while AMP cloud disposition is pending. The file must match a rule configured to perform a malware cloud lookup and Spero, local malware, or dynamic analysis. If you deselect this option, files detected for the first time are marked with an Unknown disposition
- **Enable Custom Detection List**—Block files on the custom detection list.
- **Enable Clean List**—If enabled, this policy will allow files that are on the clean list.
- **If AMP Cloud disposition is Unknown, override disposition based upon threat score**—Select an option:
  - If you select **Disabled,** the system will not override the disposition provided by the AMP Cloud.

- If you set a threshold threat score, files with an AMP cloud verdict of Unknown are considered malware if their Dynamic Analysis score is equal to or worse than the threshold.
- If you select a lower threshold value, you increase the number of files treated as malware. Depending on the action selected in your file policy, this can result in an increase of blocked files.
- For numeric threat score ranges, see *Threat Scores and Dynamic Analysis Summary Reports* in the *Cisco Secure Firewall Management Center Administration Guide*.

The Advanced Settings in the file policy editor has these archive file inspection options:

- **Inspect Archives**—Enables inspection of the contents of archive files, for archive files as large as the **Maximum file size to store** advanced access control setting.
- **Block Encrypted Archives**—Blocks password-protected archives.
- **Block Uninspectable Archives**—Blocks archive files with contents that the system is unable to inspect for reasons other than encryption. This usually applies to corrupted files, or those that exceed your specified maximum archive depth.
- **Max Archive Depth**—Blocks nested archive files that exceed the specified depth. The top-level archive file is not considered in this count; depth begins at 1 with the first nested file.

Archive files

Archive files are files that contain other files, such as `.zip` or `.rar` files.

If any individual file in an archive matches a file rule with a block action, the system blocks the entire archive, not just the individual file.

Archive file inspection capabilities

The system provides various options for inspecting archive files.

- **File types**: A complete list of inspectable archive file types appears in the Firewall Management Center web interface on the file rule configuration page. To view that page, see Create file rules, on page 2050. Contained files that can be inspected appears in the same page.
- **File size**: You can inspect archive files as large as the **Maximum file size to store** file policy advanced access control setting.
- **Nested archives**: Archive files can contain other archive files, which can in turn contain archive files. The level at which a file is nested is its *archive file depth*. Note that the top-level archive file is not included in the depth count; depth begins at 1 with the first nested file. The system can inspect up to three levels of nested files beneath the outermost archive file (level 0). You can configure your file policy to block archive files that exceed that depth (or a lower maximum depth that you specify). If you choose not to block files that exceed the maximum archive file depth of 3, when archive files that contain some extractable contents and some contents nested at a depth of 3 or greater appear in monitored traffic, the system examines and reports data only for the files it was able to inspect. All features applicable to uncompressed files (such as dynamic analysis and file storage) are available for nested files inside archive files.
- **Encrypted files**: You can configure the system to block archives whose contents are encrypted or otherwise cannot be inspected.

- **Archives that are not inspected**: If traffic that contains an archive file is on a Security Intelligence Block list or Do Not Block list, or if the top-level archive file's SHA-256 value is on the custom detection list, the system does not inspect the contents of the archive file. If a nested file is blocked, the entire archive is blocked; however, if a nested file is allowed, the archive is not automatically passed (depending on any other nested files and characteristics). .Exe files inside some .rar archives cannot be detected, including possibly rar5.

For details about options for archive file inspection, see Advanced and archive file inspection options, on page 2036.

Archive file dispositions

Archive file dispositions are based on the dispositions assigned to the files inside the archive. All archives that contain identified malware files receive a disposition of `Malware`. Archives without identified malware files receive a disposition of `Unknown` if they contain any unknown files, and a disposition of `Clean` if they contain only clean files.

Table 115: Archive file disposition by contents

Archive File Disposition	Number of Unknown Files	Number of Clean Files	Number of Malware Files
`Unknown`	1 or more	Any	0
`Clean`	0	1 or more	0
`Malware`	Any	Any	1 or more

Archive files, like other files, may have dispositions of `Custom Detection` or `Unavailable` if the conditions for those dispositions apply.

Archive contents and details

If your file policy is configured to inspect archive file contents, you can use the context menu in a table on pages under the Analysis > Files menu, and the network file trajectory viewer to view information about the files inside an archive when the archive file appears in a file event, malware event, or as a captured file.

All file contents of the archive are listed in table form, with a short summary of their relevant information: name, SHA-256 hash value, type, category, and archive depth. A network file trajectory icon appears by each file, which you can click to view further information about that specific file.

Override file disposition using custom lists

Override file disposition using custom lists is a security mechanism that

- allows administrators to correct incorrect file dispositions from the AMP cloud by adding SHA-256 values to specific file lists
- enables treating files as clean or malware regardless of the original cloud disposition, and
- provides per-file policy control without reevaluating the file's disposition on subsequent detection.

File list types and usage

If a file has a disposition in the AMP cloud that you know to be incorrect, you can add the file's SHA-256 value to a file list that overrides the disposition from the cloud:

- To treat a file as if the AMP cloud assigned a clean disposition, add the file to the *clean list*.
- To treat a file as if the AMP cloud assigned a malware disposition, add the file to the *custom detection list*.

On subsequent detection, the device either allows or blocks the file without reevaluating the file's disposition. You can use the clean list or custom detection list per file policy.

Note To calculate a file's SHA-256 value, you must configure a rule in the file policy to either perform a malware cloud lookup or block malware on matching files.

For complete information about using file lists in Firepower, refer to File lists, on page 2377.

Alternatively, if applicable, use Centralized file lists from Secure Endpoint, on page 2039.

Centralized file lists from Secure Endpoint

If your organization has deployed Secure Endpoint, Firepower can use Block and Allow lists created in Secure Endpoint when it queries the AMP cloud for file dispositions.

Requirements for centralized file lists

Your deployment must meet these requirements:

- Your organization must be using the AMP public cloud.
- Your organization has deployed Secure Endpoint.
- You have registered your system to Secure Endpoint using the procedure in Integrate Firepower and Secure Endpoint, on page 2056.

To create and deploy these lists, refer to the documentation or online help for Secure Endpoint.

Note File lists created in Firepower override file lists created in Secure Endpoint.

Manage file policies

The **File Policies** page displays a list of existing file policies along with their last-modified dates. You can use this page to manage your file policies.

Note The system checks for updates to the list of file types eligible for dynamic analysis (no more than once a day). If the list of eligible file types changes, this constitutes a change in the file policy; any access control policy using the file policy is marked out-of-date if deployed to any devices. You must deploy policies before the updated file policy can take effect on the device. See Maintain your system: file types eligible for dynamic analysis, on page 2034.

Procedure

Step 1 Select **Policies** > **Access Control heading** > **Malware & File** .

Step 2 Manage your file policies:

- Compare—Click **Compare Policies**; see Comparing policies.
- **Create**— To create a file policy, click **New File Policy** and proceed as described in Create or edit a file policy, on page 2035.
- **Copy**— To copy a file policy, click **Copy** ( ).

  If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- **Delete**— If you want to delete a file policy, click **Delete** ( ), then click **Yes** and **OK** as prompted.

  If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Deploy—Choose **Deploy** > **Deploy**; see Deploy configuration changes, on page 135.
- **Edit**— If you want to modify an existing file policy, click **Edit** ( ).
- **Report**—Click **Report**( ); Refer to Generate current policy reports, on page 153.

File rules

A file policy, like its parent access control policy, contains rules that determine how the system handles files that match the conditions of each rule. You can configure separate file rules to take different actions for different file types, application protocols, or directions of transfer.

File rule actions

When a file matches a rule, the rule can:

- allow or block files based on simple file type matching
- block files based on disposition (whether or not evaluation indicates that it is malicious)
- store files to the device (For information, see Captured files and file storage, on page 2048)

- submit stored (captured) files for local malware, Spero, or dynamic analysis

In addition, the file policy can:

- automatically treat a file as if it is clean or malware based on entries in the clean list or custom detection list
- treat a file as if it is malware if the file's threat score exceeds a configurable threshold
- inspect the contents of archive files (such as `.zip` or `.rar`)
- block archive files whose contents are encrypted, nested beyond a specified maximum archive depth, or otherwise uninspectable

File rule components

File rules consist of several components that determine how the system detects and handles files transmitted over various application protocols. Understanding these components helps configure effective file detection and inspection policies.

Table 116: File rule components

File Rule Component	Description
application protocol	The system can detect and inspect files transmitted via FTP, HTTP, SMTP, IMAP, POP3, and NetBIOS-ssn (SMB). **Any**, the default, detects files in HTTP, SMTP, IMAP, POP3, FTP, and NetBIOS-ssn (SMB) traffic. To improve performance, you can restrict file detection to only one of those application protocols on a per-file rule basis.
direction of transfer	You can inspect incoming FTP, HTTP, IMAP, POP3, and NetBIOS-ssn (SMB) traffic for downloaded files; you can inspect outgoing FTP, HTTP, SMTP, and NetBIOS-ssn (SMB) traffic for uploaded files. **Tip** Use **Any** to detect files over multiple application protocols, regardless of whether users are sending or receiving.

File Rule Component	Description
file categories and types	The system can detect various types of files. These file types are grouped into basic categories, including multimedia (swf, mp3), executables (exe, torrent), and PDFs. You can configure file rules that detect individual file types, or on entire categories of file types. For example, you could block all multimedia files, or just ShockWave Flash (swf) files. Or, you could configure the system to alert you when a user downloads a BitTorrent (torrent) file. Note that executables include file types that can run macros and scripts, since these can contain malware. For a list of file types the system can inspect, select **Policies** > **Access Control heading** > **Malware & File** , create a temporary new file policy, then click **Add Rule**. Select a file type category and the file types that the system can inspect appear in the **File Types** list. **Note** Frequently triggered file rules can affect system performance. For example, detecting multimedia files in HTTP traffic (YouTube, for example, transmits significant Flash content) could generate an overwhelming number of events.
file rule action	A file rule's action determines how the system handles traffic that matches the conditions of the rule. Depending on the selected action, you can configure whether the system stores the file or performs Spero, local malware, or dynamic analysis on a file. If you select a Block action, you can also configure whether the system also resets the blocked connection. For descriptions of these actions and options, see File rule actions, on page 2042. File rules are evaluated in rule-action, not numerical, order. For details, see File rule actions: evaluation order, on page 2050.

File rule actions

File rules give you granular control over which file types you want to log, block, or scan for malware. Each file rule has an associated action that determines how the system handles traffic that matches the conditions of the rule. To be effective, a file policy must contain one or more rules. You can use separate rules within a file policy to take different actions for different file types, application protocols, or directions of transfer.

File rule actions include these types:

- *Detect Files* rules allow you to log the detection of specific file types to the database, while still allowing their transmission.
- *Block Files* rules allow you to block specific file types. You can configure options to reset the connection when a file transfer is blocked, and store captured files to the managed device.
- *Malware Cloud Lookup* rules allow you to obtain and log the disposition of files traversing your network, while still allowing their transmission.

- *Block Malware* rules allow you to calculate the SHA-256 hash value of specific file types, query the AMP cloud to determine if files traversing your network contain malware, then block files that represent threats.

File rule action options

Depending on the action you select, you have different options:

File Rule Action Option	Block Files capable?	Block Malware capable?	Detect Files capable?	Malware Cloud Lookup capable?
Spero Analysis* for MSEXE	no	yes, you can submit executable files	no	yes, you can submit executable files
Dynamic Analysis*	no	yes, you can submit executable files with Unknown file dispositions	no	yes, you can submit executable files with Unknown file dispositions
Capacity Handling	no	yes	no	yes
Local Malware Analysis*	no	yes	no	yes
Reset Connection	yes (recommended)	yes (recommended)	no	no
Store files	yes, you can store all matching file types	yes, you can store file types matching the file dispositions you select	yes, you can store all matching file types	yes, you can store file types matching the file dispositions you select

* For complete information about these options, refer to Malware protection options, on page 2043 and its subtopics.

Caution Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Malware protection options

The system applies several methods of file inspection and analysis to determine whether a file contains malware.

File inspection sequence

Depending on the options you enable in a file rule, the system inspects files using these tools, in order:

1. Spero analysis, on page 2045 and AMP cloud lookup, on page 2046
2. Local malware analysis, on page 2046
3. Dynamic analysis, on page 2047

For a comparison of these tools, see Comparison of malware protection options, on page 2044.

(You can also, if you choose, block all files based on their file type. For more information, see Block all files by type, on page 2049.)

Refer to information about Cisco's Secure Endpoint product at (Optional) Malware protection with Secure Endpoint, on page 2054 and subtopics.

Comparison of malware protection options

This table details the benefits and drawbacks of each type of file analysis, as well as the way each malware protection method determines a file's disposition.

Analysis Type	Benefit	Limitations	Malware Identification
Spero analysis	Structural analysis of executable files, submits Spero signature to the AMP Cloud for analysis	Less thorough than local malware analysis or dynamic analysis, only for executable files	Disposition changes from Unknown to Malware only on positive identification of malware.
Local malware analysis	Consumes fewer resources than dynamic analysis, and returns results more quickly, especially if the detected malware is common	Less thorough results than dynamic analysis	Disposition changes from Unknown to Malware only on positive identification of malware.
Dynamic analysis	Thorough analysis of unknown files using Secure Malware Analytics	Eligible files are uploaded to the public cloud or an on-premises appliance. It takes some time to complete analysis	Threat score determines maliciousness of a file. Disposition can be based on the threat score threshold configured in the file policy.
Spero analysis and local malware analysis	Consumes fewer resources than configuring local malware analysis and dynamic analysis, while still using AMP cloud resources to identify malware	Less thorough than dynamic analysis, Spero analysis only for executable files	Disposition changes from Unknown to Malware only on positive identification of malware.

Analysis Type	Benefit	Limitations	Malware Identification
Spero analysis and dynamic analysis	Uses full capabilities of AMP cloud in submitting files and Spero signatures	Results obtained less quickly than if using local malware analysis	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes based on configured threat score threshold in the file policy, and from Unknown to Malware if the Spero analysis identifies malware.
Local malware analysis and dynamic analysis	Thorough results in using both types of file analysis	Consumes more resources than either alone	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes from Unknown to Malware if local malware analysis identifies malware, or based on configured threat score threshold in the file policy.
Spero analysis, local malware analysis and dynamic analysis	Most thorough results	Consumes most resources in running all three types of file analysis	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes from Unknown to Malware if Spero analysis or local malware analysis identifies malware, or based on configured threat score threshold in the file policy.
(Block transmission of all files of a specified file type)	Does not require a Malware Defense license (This option is not technically a malware protection option.)	Legitimate files will also be blocked	(No analysis is performed.)

Note Preclassification does not itself determine a file's disposition; it is merely one of the factors that determine whether a file is eligible for Dynamic Analysis.

Spero analysis

Spero analysis examines structural characteristics such as metadata and header information in executable files. After generating a Spero signature based on this information, if the file is an eligible executable file, the device submits it to the Spero heuristic engine in the AMP cloud. Based on the Spero signature, the Spero engine determines whether the file is malware. You can also configure rules to submit files for Spero analysis without also submitting them to the AMP cloud.

Note You cannot manually submit files for Spero analysis.

AMP cloud lookup

For files that are eligible for assessment using Advanced Malware Protection, the Firewall Management Center performs a malware cloud lookup, querying the AMP cloud for the file's disposition based on its SHA-256 hash value.

Performance optimization

To improve performance, the system caches dispositions returned by the cloud and uses the cached disposition for known files rather than querying the AMP cloud. For more information about this cache, see Cached disposition longevity, on page 2046.

Local malware analysis

Local malware analysis allows a managed device to locally inspect executables, PDFs, office documents, and other types of files for the most common types of malware, using a detection rule set provided by the Talos Intelligence Group. Because local analysis does not query the AMP cloud, and does not run the file, local malware analysis saves time and system resources.

Local malware analysis behavior

When the system identifies malware through local malware analysis, it updates the existing file disposition from Unknown to Malware and generates a new malware event. If the system does not identify malware, it does not update the file disposition from Unknown to Clean.

After the system runs local malware analysis, it caches file information such as SHA-256 hash value, timestamp, and disposition, so that if detected again within a certain period of time, the system can identify malware without additional analysis. For more information about the cache, see Cached disposition longevity, on page 2046.

Local malware analysis does not require establishing communications with the Secure Malware Analytics Cloud. However, you must configure communications with the cloud to submit files for dynamic analysis, and to download updates to the local malware analysis ruleset.

Cached disposition longevity

Dispositions returned from an AMP cloud query, associated threat scores, and dispositions assigned by local malware analysis, have a time-to-live (TTL) value. After a disposition has been held for the duration specified in the TTL value without update, the system purges the cached information. Dispositions and associated threat scores have the following TTL values:

TTL values for dispositions and threat scores

Dispositions and associated threat scores have these TTL values:

- Clean — 4 hours
- Unknown — 1 hour
- Malware — 1 hour

If a query against the cache identifies a cached disposition that timed out, the system re-queries the local malware analysis database and the AMP cloud for a new disposition.

Dynamic analysis

Dynamic analysis is a security analysis method that

- automatically submits files for behavioral analysis using Secure Malware Analytics (formerly Threat Grid), Cisco's file analysis and threat intelligence platform,
- runs files in a sandbox environment to analyze behavior and determine maliciousness, and
- returns a threat score indicating the likelihood that a file contains malware.

Dynamic analysis process and capabilities

You can configure your file policy to automatically submit files for dynamic analysis using Secure Malware Analytics (formerly Threat Grid), Cisco's file analysis and threat intelligence platform.

Devices submit eligible files to Secure Malware Analytics (either the public cloud or to an on-premises appliance, whichever you have specified) regardless of whether the device stores the file.

Secure Malware Analytics runs the file in a sandbox environment, analyzes the file's behavior to determine whether the file is malicious, and returns a threat score that indicates the likelihood that a file contains malware. From the threat score, you can view a dynamic analysis summary report with the reasons for the assigned threat score. You can also look in Secure Malware Analytics to view detailed reports for files that your organization submitted, as well as scrubbed reports with limited data for files that your organization did not submit.

For more information about Cisco Secure Malware Analytics, refer to https://www.cisco.com/c/en/us/products/security/threat-grid/index.html

To configure your system to perform dynamic analysis, see the topics under Dynamic analysis connections, on page 2031.

Files eligible for dynamic analysis

A file's eligibility for dynamic analysis depends on the file type, the file size, and the file rule's action.

Additional requirements:

- The system submits only files that match the file rules you configure.
- The file must have a malware cloud lookup disposition of Unknown or Unavailable at the time the file is sent for analysis.
- The system must preclassify the file as potential malware.

Dynamic analysis and capacity handling

Capacity handling is a system feature that temporarily stores files that are otherwise eligible for dynamic analysis if the system is temporarily unable to submit files to the cloud, either because the device cannot communicate with the cloud or because the maximum number of submissions has been reached. The system submits the stored files when the hindering condition has passed.

Storage options

Some devices can store files on the device hard drive or in a malware storage pack. Refer Malware storage packs, on page 2048.

Captured files and file storage

The file storage feature allows you to capture selected files detected in traffic, and automatically store a copy of the file temporarily to a device's hard drive, or, if installed, to the malware storage pack.

File capture and storage capabilities

After your device captures files, you can:

- Store captured files on the device's hard drive for later analysis.
- Download the stored file to a local computer for further manual analysis or archival purposes.
- Manually submit eligible captured files for AMP cloud lookup or dynamic analysis.

Note that once a device stores a file, it will not re-capture it if the file is detected in the future and the device still has that file stored.

Note When a file is detected for the first time on your network, you can generate a file event that represents the file's detection. However, if your file rule performs a malware cloud lookup, the system requires additional time to query the AMP cloud and return a disposition. Due to this delay, the system cannot store this file until the second time it is seen on your network, and the system can immediately determine the file's disposition.

Whether the system captures or stores a file, you can:

- Review information about the captured file from **Analysis** > **Unified Events**, including whether the file was stored or submitted for dynamic analysis, file disposition, and threat score, allowing you to quickly review possible malware threats detected on your network.

  Alternatively, you can also view information about the captured file from **Analysis** > **Files** > **Captured Files**.
- View the file's trajectory to determine how it traversed your network and which hosts have a copy.
- Add the file to the clean list or custom detection list to always treat the file as if it had a clean or malware disposition on future detection.

You configure file rules in a file policy to capture and store files of a specific type, or with a particular file disposition, if available. After you associate the file policy with an access control policy and deploy it to your devices, matching files in traffic are captured and stored. You can also limit the minimum and maximum file sizes to store.

Stored files are not included in system backups.

You can view captured file information under **Analysis** > **Files** > **Captured Files**, and download a copy for offline analysis.

Malware storage packs

A malware storage pack

- provides additional storage capacity for file data when installed in security devices
- allows the primary hard drive to store events and configuration files by dedicating the entire storage pack to captured files, and
- automatically receives stored files from the primary hard drive when installed on devices that already contain file data.

Storage allocation and file management

Based on your file policy configuration, your device may store a substantial amount of file data to the hard drive. You can install a malware storage pack in the device; the system stores files to the malware storage pack, allowing more room on the primary hard drive to store events and configuration files. The system periodically deletes older files. If the device's primary hard drive does not have enough available space, and does not have an installed malware storage pack, you cannot store files.

Caution Do not attempt to install a hard drive that was not supplied by Cisco in your device. Installing an unsupported hard drive may damage the device. Malware storage pack kits are available for purchase **only** from Cisco. Contact Support if you require assistance with the malware storage pack.

Without a malware storage pack installed, when you configure a device to store files, it allocates a set portion of the primary hard drive's space to captured file storage. If you configure capacity handling to temporarily store files for dynamic analysis, the system uses the same hard drive allocation to store these files until it can resubmit them to the cloud.

When you install a malware storage pack in a device and configure file storage or capacity handling, the device allocates the entire malware storage pack for storing these files. The device cannot store any other information on the malware storage pack.

When the allocated space for captured file storage fills to capacity, the system deletes the oldest stored files until the allocated space reaches a system-defined threshold. Based on the number of files stored, you may see a substantial drop in disk usage after the system deletes files.

If a device has already stored files when you install a malware storage pack, the next time you restart the device, any captured files or capacity handling files stored on the primary hard drive are moved to the malware storage pack. Any future files the device stores are stored to the malware storage pack.

For more information on using MSP on the Firepower devices, see the Firepower Hardware Installation Guide for your device.

Block all files by type

If your organization wants to block not only the transmission of malware files, but all files of a specific type, regardless of whether the files contain malware, you can do so.

File type categories and licensing

File control is supported for all file types where the system can detect malware, plus many additional file types. These file types are grouped into basic categories, such as multimedia (swf, mp3), executables (exe, torrent), and PDFs.

Blocking all files based on their type is not technically a malware protection feature; it does not require a Malware Defense license and does not query the AMP cloud.

File rule actions: evaluation order

A file policy will likely contain multiple rules with different actions for different situations. If more than one rule can apply to a particular situation, the evaluation order described in this topic applies. In general, simple blocking takes precedence over malware inspection and blocking, which takes precedence over simple detection and logging.

The order of precedence of file-rule actions is:

- *Block Files*
- *Block Malware*
- *Malware Cloud Lookup*
- *Detect Files*

If configured, TID also impacts action prioritization. For more information, see Threat Intelligence Director - Firewall Management Center action prioritization , on page 2145.

Create file rules

Use this procedure when you need to add file rules to an existing file policy to control file handling and security actions.

Caution Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Before you begin

If you are configuring rules for malware protection, refer to Configure file policies, on page 2023.

Procedure

Step 1 Select **Policies** > **Access Control heading** > **Malware & File** .

Step 2 Click the edit icon to modify an existing file policy.

Step 3 In the file policy editor, click **Add Rule**.

Step 4 Select an **Application Protocol** and **Direction of Transfer** as described in File rule components, on page 2041.

Step 5 Select one or more **File Types**.

The file types you see depend on the selected application protocol, direction of transfer, and action.

You can filter the list of file types in these ways:

- Select one or more **File Type Categories**, then click **All types in selected Categories.**

- Search for a file type by its name or description. For example, type **`Windows`** in the **Search name and description** field to display a list of Microsoft Windows-specific files.

Tip Hover your pointer over a file type to view its description.

Step 6 Select a file rule **Action** as described in File rule actions, on page 2042, with consideration for File rule actions: evaluation order, on page 2050.

The actions available to you depend on the licenses you have installed. Refer to License requirements for file and malware policies, on page 2017.

Step 7 Depending on the action you selected, configure options:

- reset the connection after blocking the file
- store files that match the rule
- enable Spero analysis*
- enable local malware analysis*
- enable dynamic analysis* and capacity handling

* For information about these options, refer to File rule actions, on page 2042 and Malware protection options, on page 2043 and its subtopics.

Step 8 Click **Add.**

Step 9 Click **Save** to save the policy.

What to do next

- If you are configuring policies for malware protection, return to Configure file policies, on page 2023.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Access control rule logging for malware protection

When the system detects a prohibited file (including malware) according to the settings in the file policy, it automatically logs an event to the Secure Firewall Management Center database. If you do not want to log file or malware events, you can disable this logging on a per-access-control-rule basis.

The system also logs the end of the associated connection to the Secure Firewall Management Center database, regardless of the logging configuration of the invoking access control rule.

Retrospective disposition changes

File dispositions can change. For example, as new information is discovered, the AMP cloud can determine that a file that was previously thought to be clean is now identified as malware, or the reverse—that a

malware-identified file is actually clean. When the disposition changes for a file you queried in the past week, the AMP cloud notifies the system so it can automatically take action the next time it detects that file being transmitted. A changed disposition is called a retrospective disposition.

File and malware inspection performance and storage options

Increasing the file sizes can affect the performance of the system.

Table 117: Advanced access control file and malware defense options

Field	Description	Guidelines and Restrictions
Limit the number of bytes inspected when doing file type detection	Specifies the number of bytes inspected when performing file type detection.	0 - 4294967295 (4GB) 0 removes the restriction. The default value is the maximum segment size of a TCP packet (1460 bytes). In most cases, the system can identify common file types using the first packet. To detect ISO files, enter a value greater than 36870.
Allow file if cloud lookup for Block Malware takes longer than (seconds)	Specifies how long the system will hold the last byte of a file that matches a **Block Malware** rule and that does not have a cached disposition, while malware cloud lookup occurs. If the time elapses without the system obtaining a disposition, the file passes. Dispositions of Unavailable are not cached.	0 - 30 seconds Do *not* set this option to 0 without contacting Support. Cisco recommends that you use the default value to avoid blocking traffic because of connection failures.
Do not calculate SHA-256 hash values for files larger than (in bytes)	Prevents the system from storing files larger than a certain size, performing a malware cloud lookup on the files, or blocking the files if added to the custom detection list.	0 - 4294967295 (4GB) 0 removes the restriction. This value must be greater than or equal to **Maximum file size to store (bytes)** and **Maximum file size for dynamic analysis testing (bytes)**.

Maximum file size for advanced file inspection and storage (bytes)	These settings specify:
	• The file size that the system can inspect using these detectors:
	  • Spero analysis
	  • Sandboxing and preclassification
	  • Local malware analysis/ClamAV
	  • Archive inspection
	• The file size that the system can store using a file rule.
		0 - 10485760 (10MB)
		0 disables file storage.
		Must be less than or equal to **Maximum file size to store (bytes)** and **Do not calculate SHA-256 hash values for files larger than (in bytes)**.

Minimum file size for advanced file inspection and storage (bytes)		0 - 10485760 (10MB) 0 disables file storage. Must be greater than or equal to **Minimum file size to store (bytes)**, and less than or equal to **Do not calculate SHA-256 hash values for files larger than (in bytes)**.

Field	Description	Guidelines and Restrictions
Maximum file size for dynamic analysis testing (bytes)	Specifies the minimum file size the system can submit to the AMP cloud for dynamic analysis.	0 -10485760 (10MB) Must be less than or equal to **Maximum file size for dynamic analysis testing (bytes)** and **Do not calculate SHA-256 hash values for files larger than (in bytes)**. The file size for dynamic analysis must be within the limits defined by the minimum and maximum settings for file analysis. The system checks the AMP cloud for updates to the minimum file size you can submit (no more than once a day). If the new minimum size is larger than your current value, your current value is updated to the new minimum, and your policy is marked out-of-date.
Minimum file size for dynamic analysis testing (bytes)	Specifies the maximum file size the system can submit to the AMP cloud for dynamic analysis.	0 -10485760 (10MB) Must be greater than or equal to **Minimum file size for dynamic analysis testing (bytes)**, and less than or equal to **Do not calculate SHA-256 hash values for files larger than (in bytes)**. The file size for dynamic analysis must be within the limits defined by the minimum and maximum settings for file analysis. The system checks the AMP cloud for updates to the maximum file size you can submit (no more than once a day). If the new maximum size is smaller than your current value, your current value is updated to the new maximum, and your policy is marked out-of-date.

Tune file and malware inspection performance and storage

File and malware inspection can impact system performance and storage utilization. Tuning these settings helps ensure optimal security posture while maintaining acceptable system performance.

Before you begin

You must be an Admin, Access Admin, or Network Admin user to perform this task.

Procedure

Step 1 In the access control policy editor, click **Advanced Settings**.

Step 2 Click **Edit** ( ) next to **Files and Malware Settings**.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Set any of the options described in File and malware inspection performance and storage options, on page 2052.

Step 4 Click **OK**.

Step 5 Click **Save** to save the policy.

(Optional) Malware protection with Secure Endpoint

Cisco's Secure Endpoint is a separate malware-protection product that can supplement malware protection provided by the system and be integrated with your Firepower deployment.

Secure Endpoint is Cisco’s enterprise-class Advanced Malware Protection solution that runs as a lightweight connector on individual users' endpoints (computers and mobile devices) to discover, understand, and block advanced malware outbreaks, advanced persistent threats, and targeted attacks.

Benefits of Secure Endpoint

- Configure custom malware detection policies and profiles for your entire organization, as well as perform flash and full scans on all your users' files
- Perform malware analysis, including view heat maps, detailed file information, network file trajectory, and threat root causes
- Configure multiple aspects of outbreak control, including automatic quarantines, application blocking to stop non-quarantined executables from running, and exclusion lists
- Create custom protections, block execution of certain applications based on group policy, and create custom Allowed Applications lists
- Use the Secure Endpoint management console to help you mitigate the effect of malware. The management console provides a robust, flexible web interface where you control all aspects of your Secure Endpoint deployment and manage all phases of an outbreak.

For detailed information about Secure Endpoint, refer to:

- https://www.cisco.com/c/en/us/products/security/amp-for-endpoints/index.html.
- Online help in the Secure Endpoint management console.
- Secure Endpoint documentation available from: http://docs.amp.cisco.com.

Comparison of malware protection: Firepower vs. Secure Endpoint

This table compares the advanced malware protection differences between Firepower malware protection and Secure Endpoint across various features including detection methods, network traffic inspection, malware analysis, mitigation capabilities, and licensing requirements.

Table 118: Advanced malware protection differences by detecting product

Feature	Firepower Malware Protection (malware defense)	Secure Endpoint
File type detection and blocking method (file control)	In network traffic, using access control and file policies	Not supported
Malware detection and blocking method	In network traffic, using access control and file policies	On individual endpoints (end-user computers and mobile devices), using a connector that communicates with the AMP cloud
Network traffic inspected	Traffic passing through a managed device	None; connectors installed on endpoints directly inspect files
Malware intelligence data source	AMP cloud (public or private)	AMP cloud (public or private)
Malware detection robustness	Limited file types	All file types
Malware analysis choices	Firewall Management Center-based, plus analysis in the AMP cloud	Firewall Management Center-based, plus additional options on the Secure Endpoint management console
Malware mitigation	Malware blocking in network traffic, Firewall Management Center-initiated remediations	Secure Endpoint-based quarantine and outbreak control options, Firewall Management Center-initiated remediations
Events generated	File events, captured files, malware events, and retrospective malware events	Malware events
Information in malware events	Basic malware event information, plus connection data (IP address, port, and application protocol)	In-depth malware event information; no connection data
Network file trajectory	Firewall Management Center-based	Firewall Management Center and the Secure Endpoint management console each have a network file trajectory. Both are useful.
Required licenses or subscriptions	Licenses required to perform file control and malware defense	Secure Endpoint subscription. No license is required to bring Secure Endpoint data into Firewall Management Center.

Integrate Secure Firewall with Secure Endpoint

If your organization has deployed Secure Endpoint, you can optionally integrate that product with your Secure Firewall deployment.

Integration with Secure Endpoint does not require a dedicated Secure Firewall license.

Benefits of integrating Firepower and Secure Endpoint

Integrating your Secure Endpoint deployment with your system offers these benefits:

- Centralized Blocked Applications and Allowed Applications lists configured in Secure Endpoint can determine verdicts for file SHAs sent from Firepower to the AMP cloud for disposition.

  Refer to Centralized file lists from Secure Endpoint, on page 2039.

- The system can import malware events detected by Secure Endpoint into Secure Firewall Management Center so you can manage these events along with malware events generated by the system. Imported data for these events includes scans, malware detections, quarantines, blocked executions, and cloud recalls, as well as indications of compromise (IOCs) that Firewall Management Center displays for hosts that it monitors.

  For more information, refer to *Malware Event Analysis with Secure Endpoint* in the *Cisco Secure Firewall Management Center Administration Guide* .

- You can view file trajectory and other details in the Secure Endpoint console.

  For details, refer to *Work with Event Data in the Secure Endpoint Console* in the *Cisco Secure Firewall Management Center Administration Guide* .

Important If you use a Cisco AMP Private Cloud, refer to limitations at Secure Endpoint and AMP private cloud, on page 2056.

Secure Endpoint and AMP private cloud

If you configure a Cisco AMP private cloud to collect Secure Endpoint data on your network, all Secure Endpoint connectors send data to the private cloud, which forwards that data to the Secure Firewall Management Center. The private cloud does not share any of your endpoint data over an external connection.

Private cloud functionality and limitations

The private cloud acts as an anonymized proxy to ensure the security and privacy of your monitored network. This includes importing Secure Endpoint data. The private cloud does not share any of your endpoint data over an external connection.

The integration features that are not available with an AMP private cloud are:

- Use of Blocked Applications and Allowed Applications lists configured in Secure Endpoint. (These lists are used to block or allow files.)
- Visibility in Secure Endpoint of malware events generated from Firepower.

You can configure multiple private clouds to support the capacity you require.

Integrate Firepower and Secure Endpoint

If your organization has deployed Cisco's Secure Endpoint product, you can integrate that application with Firepower to achieve the benefits described in Benefits of integrating Firepower and Secure Endpoint, on page 2055.

When you integrate with Secure Endpoint, you must configure the Secure Endpoint connection even if you already have malware defense (AMP for Firepower) connections configured. You can configure multiple Secure Endpoint cloud connections.

Note Secure Endpoint connections that have not registered successfully do not affect malware defense.

Before you begin

- You must be an Admin user to perform this task.
- If your deployment uses Cisco AMP Private Cloud, refer to limitations at Secure Endpoint and AMP private cloud, on page 2056.
- Secure Endpoint must be set up and working properly on your network.
- The Firewall Management Center must have internet access.
- Make sure your Firewall Management Center and Secure Endpoint can communicate with each other. Refer to *Security, Internet Access, and Communication Ports* in the *Cisco Secure Firewall Management Center Administration Guide*.
- If you are connecting to the AMP cloud after either reimaging or restoring your Firewall Management Center from backup, use the Secure Endpoint management console to remove the previous connection.
- You will need your Secure Endpoint credentials to log in to the Secure Endpoint console during this procedure.

Procedure

Step 1 Choose **Integration** > **AMP** > **AMP Management**.

Step 2 Click **Add AMP Cloud Connection**.

Step 3 From the **Cloud Name** drop-down list, choose the cloud you want to use.

- The AMP cloud closest to the geographical location of your Firewall Management Center.

  APJC is Asia/Pacific/Japan/China.

- For AMP private cloud (AMPv), choose **Private Cloud** and proceed as described in Cisco AMP private cloud, on page 2028.

Step 4 If you want to use this cloud for both malware defense and Secure Endpoint, select the **Use for AMP for Firepower** check box.

If you configured a different cloud to handle malware defense (AMP for Firepower) communications, you can clear this check box; if this is your only AMP cloud connection, you cannot.

Step 5 Click **Register**.

A **Spinning state** () icon indicates that a connection is pending, for example, after you configure a connection on the Firewall Management Center, but before you authorize it using the Secure Endpoint management console. A **Denied** () icon indicates that the cloud denied the connection or the connection failed for another reason.

Step 6 Confirm that you want to continue to the Secure Endpoint management console, then log into the management console.

Step 7 Using the management console, authorize the AMP cloud to send Secure Endpoint data to Firewall Management Center.

Step 8 If you want to restrict the data that the Firewall Management Center receives, select specific groups within your organization for which you want to receive information.

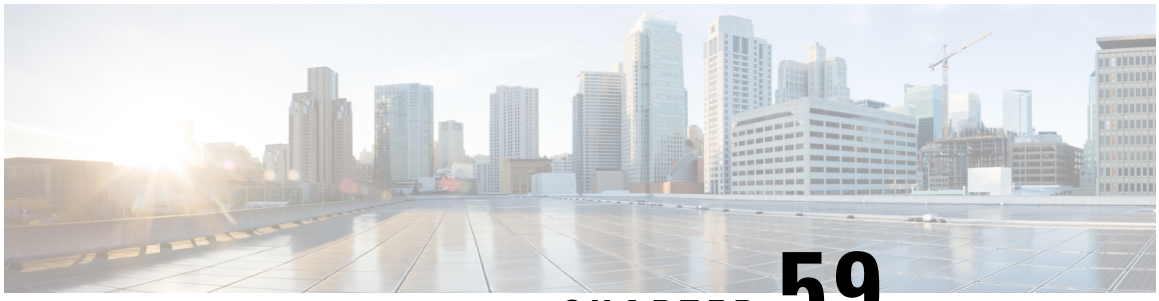
By default, the AMP cloud sends data for all groups. To manage groups, choose **Management** > **Groups** on the Secure Endpoint management console. For detailed information, see the management console online help.

Step 9 Click **Allow** to enable the connection and start the transfer of data.

Clicking **Deny** returns you to the Firewall Management Center, where the connection is marked as denied. If you navigate away from the Applications page on the Secure Endpoint management console, and neither deny nor allow the connection, the connection is marked as pending on the Firewall Management Center's web interface. The health monitor does **not** alert you of a failed connection in either of these situations. If you want to connect to the AMP cloud later, delete the failed or pending connection, then recreate it.

Incomplete registration of the Secure Endpoint connection does not disable the malware defense connection.

What to do next



- In the Secure Endpoint console window, configure settings as needed. For example, define group membership for your management center and assign policies. For information, see the Secure Endpoint online help or other documentation.
- In high availability deployments, configure AMP cloud connections on both management centers. These configurations are not synchronized.
- The default health policy warns you if the Firewall Management Center cannot connect to the Secure Endpoint portal after an initial successful connection, or if the connection is deregistered using the AMP portal.

  Verify that the Secure Endpoint Status monitor is enabled under **System** (⚙) > **Health** > **Policy**.
- To verify that the connection is correctly configured:
  1. On the **Integration** > **AMP** > **AMP Management** page, click the Cloud Name that includes Secure Endpoint in the **Cisco AMP Solution Type** column.
  2. In the Secure Endpoint console window that displays, choose **Accounts > Applications**.
  3. Verify that your Firewall Management Center is on the list.
  4. In the Secure Endpoint console window, choose **Manage > Computers**.
  5. Verify that your Firewall Management Center is on the list.

History for network malware protection and file policies

This reference provides a comprehensive history of changes and updates to network malware protection and file policy features across different software versions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Communication with AMP cloud	7.0	Any	Legacy port 32137 is no longer supported for communicating with the AMP public or private cloud. New/Modified screens: On the **System** > **Integration** > **Cloud Services** page, the **Use Legacy Port 32137 for AMP for Networks** option is no longer available.
Chapter restructure	Changes were made in 6.4 timeframe, but will appear in any version that is republished	Any	Restructured this chapter's content to reduce confusion. Some content was moved to or from the chapter for *File/Malware Events and Network File Trajectory* in the *Cisco Secure Firewall Management Center Administration Guide* .
Moved URL Filtering information to the new URL Filtering chapter	6.3	Any	Moved information about configuring cloud communications for URL Filtering to the new URL Filtering chapter. Made related changes to the structure of the Cisco CSI topics in the chapter.

CHAPTER 59

Dynamic Attributes Connector

The following topics discuss how to configure and use the Dynamic Attributes Connector.

- About the dynamic attributes connector , on page 2061
- How Cisco secure dynamic attributes connector works, on page 2061
- System requirements for the dynamic attributes connector, on page 2063
- Enable the dynamic attributes connector, on page 2063
- Dashboard, on page 2065
- Connectors, on page 2072
- Create dynamic attributes filters, on page 2092
- Manually get a certificate authority (CA) chain, on page 2094
- Dynamic objects in access control rules, on page 2097
- Create dynamic attributes filters, on page 2098
- Dynamic attributes rule conditions, on page 2099
- Create access control rules using dynamic attributes filters, on page 2100
- Dynamic Firewall, on page 2101
- Disable the dynamic attributes connector, on page 2116
- Troubleshoot the Dynamic Attributes Connector, on page 2117
- Recommendation: security requirements for network deployment, on page 2117
- Internet access requirements, on page 2117
- History for the dynamic attributes connector, on page 2119

About the dynamic attributes connector

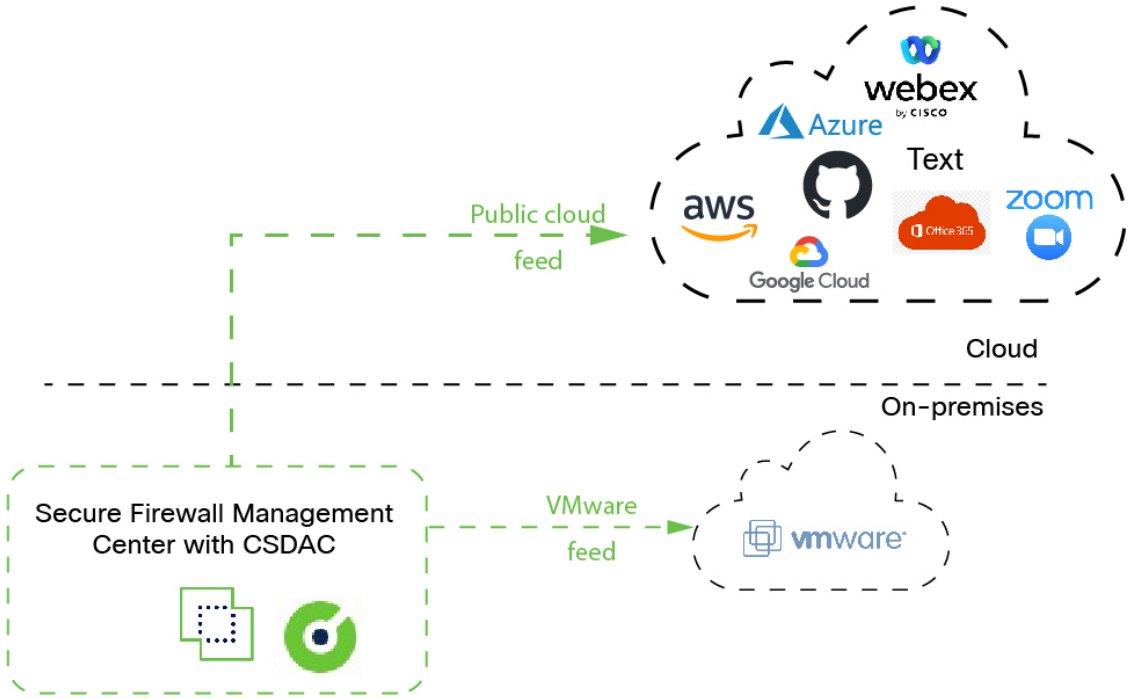
The dynamic attributes connector enables your access control policy to adapt in real time to the changes in public and private cloud workloads and business-critical software-as-a-service (SaaS) applications. It simplifies policy management by keeping rules up to date without tedious manual updates and policy deployment. Customers require policy rules to be defined based on non-network constructs such as VM name or security group, so that firewall policy is persistent even when the IP address or VLAN changes.

How Cisco secure dynamic attributes connector works

This topic discusses the architecture of the dynamic attributes connector.

The system functions by querying cloud services and providing attribute information to the secure management center.

Summary



The key components involved in this process are:

- The system supports certain public cloud providers.

  This topic discusses supported *connectors* (which are the connections to those providers).

- The dynamic attributes connector is provided with Secure Firewall Management Center.

Workflow

These stages describe how the Cisco Secure Dynamic Attributes Connector processes cloud service information:

1. *Connectors* contain the tags and containers to query.

   For example, typically these tags define dynamically allocated network and IP addresses for which you cannot create access control rules. Persisted feeds from the connectors are stored on the dynamic attributes connector for fast access.

2. Tag information is persisted on the dynamic attributes connector where you create *dynamic attributes filters* that define which information is important to use in access control rules.

   For example, if AWS defines networks for the Accounting and Finance Departments virtual machines, you can create a dynamic attributes filter that specifies only the Finance network.

3. The Secure Firewall Management Center receives those dynamic attributes filters as *dynamic objects* and enables you to use them in access control rules.

What's next

Related topics

- Enable the dynamic attributes connector, on page 2063
- Dashboard, on page 2065

System requirements for the dynamic attributes connector

The Dynamic Attributes Connector has specific memory requirements that must be met to ensure proper deployment and operation. These limits apply to both virtual machines and physical machines to avoid deployment issues.

FMCv: Amount of RAM	Secure Firewall Management Center hardware model	Maximum number of (connectors + Azure AD realms)
At least 32 GB	Firepower 1000, Firepower 1600, vFMC	10
At least 64 GB	Firepower 2500, Firepower 2600,vFMC 300	20
At least 128 GB	Firepower 4500, Firepower 4600	30

The preceding limits apply to both virtual machines and physical machines.

The system prevents you from exceeding these limits to avoid deployment issues.

Enable the dynamic attributes connector

Enable the dynamic attributes connector to allow objects from cloud networking products to be used in Secure Firewall Management Center access control rules.

This task discusses how to enable the dynamic attributes connector in the Secure Firewall Management Center. The dynamic attributes connector is an integration that enables objects from cloud networking products to be used in Secure Firewall Management Center access control rules.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not done so already.

Step 2 Click **Integration** > **Dynamic Attributes Connector**.

Step 3 Slide to **Enabled**.

Step 4 The system displays messages when the dynamic attributes connector is enabled.

In the event of errors, try again. If errors persist, contact Cisco TAC.

See Connectors, on page 2072.

Configure networks and subnets for Docker containers

The Dynamic Attributes Connector uses Docker containers to retrieve connector data in the Secure Firewall Management Center . You can change Docker IP addresses and ranges to avoid conflicts with the Secure Firewall Management Center management interface and other network IP addresses.

The Docker daemon used by the dynamic attributes connector requires the following networks:

- `docker0` : Used internally by the Docker daemon.
- IPv6 networks (`vethnumber`): Internal bridge networks used by the dynamic attributes connector .
- Docker bridge networks (`br-number`): Used by dynamic attributes connector connectors.

To change Docker networks and subnets, run the following command as a user with `root` privileges:
`/usr/local/sf/bin/change_docker_subnet.sh -b CIDR-network -s address-pool-size`

- `-b CIDR-network` : Sets a network base address pool in CIDR notation.
- `-s address-pool-size` : Sets a netmask for the network base address to limit the number of addresses and ensure compatibility with available system RAM.

Important The networks you assign to Docker must be in an internal network range and must *not* conflict with networks used by the Secure Firewall Management Center or by other devices in your internal network.

Table 119: Recommended Docker Network Settings

Secure Firewall Management Center model	Recommended -s value	Sample -b value	Dynamic Attributes Connector container addresses used
Firepower 1000, Firepower 1600, vFMC	27 (netmask 255.255.255.224)	172.19.0.0/16	30 IP addresses
Firepower 2500, Firepower 2600, vFMC 300	26 (netmask 255.255.255.192)	192.168.0.0/16	62 IP addresses
Firepower 4500, Firepower 4600	25 (netmask 255.255.255.128)	192.168.0.0/16	126 IP addresses

```
sudo /usr/local/sf/bin/change_docker_subnet.sh -b 172.19.0.0/16 -s 27
        sudo /usr/local/sf/bin/change_docker_subnet.sh -b 192.168.0.0/16 -s 26
        sudo /usr/local/sf/bin/change_docker_subnet.sh -b 192.168.0.0/16 -s 25
```

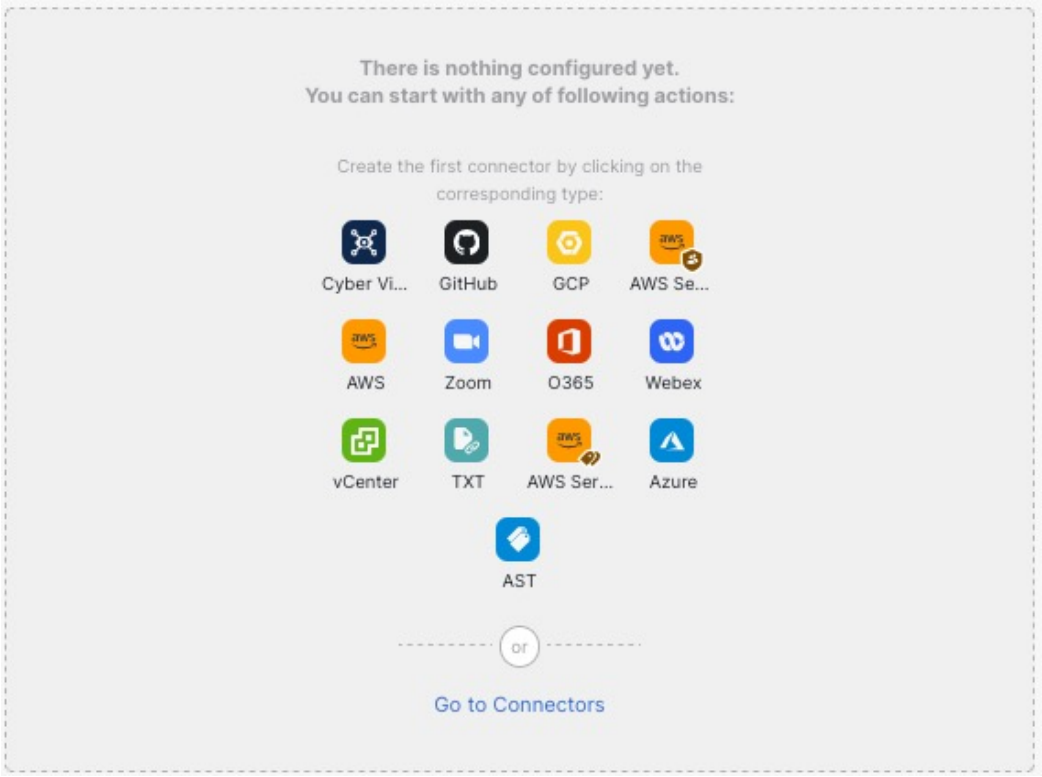
Troubleshooting

Table 120: Common Docker Network Errors

Error	Solution
Pull subnet value can not be greater than size	Change the value of `-s` so it is less than the CIDR network value. For example, INCORRECT: `sudo /usr/local/sf/bin/change_docker_subnet.sh -b 172.19.0.0/16 -s 8` CORRECT: `sudo /usr/local/sf/bin/change_docker_subnet.sh -b 172.19.0.0/16 -s 20`
Docker networks are wrong	Restart the Docker daemon: `sudo pmtool restartbyid docker`
Cannot connect to the Docker daemon `Cannot connect to the Docker daemon at unix:///var/run/docker.sock. Is the docker daemon running?`	Restart Docker: `pmtool restartbyid docker`
Input can't be empty	The `-s` parameter is required.

Dashboard

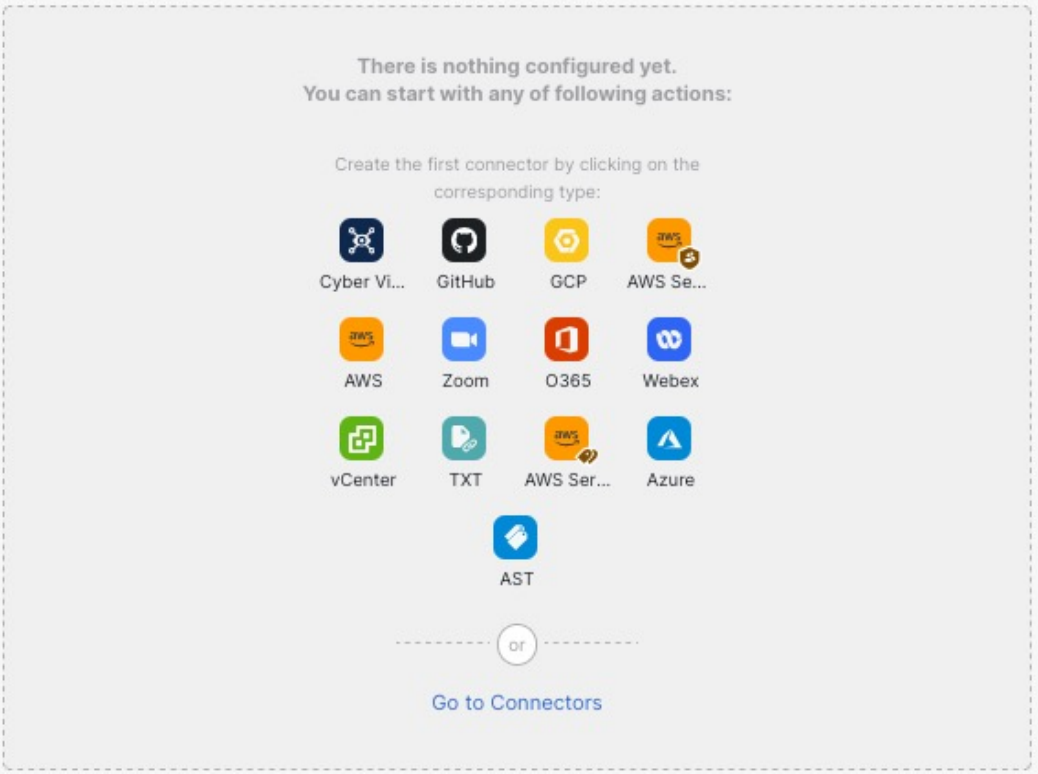
Dashboard capabilities include:



- Add, edit, and delete connectors and dynamic attributes filters.
- See how connectors and dynamic attributes filters are related to each other.
- View warnings and errors.

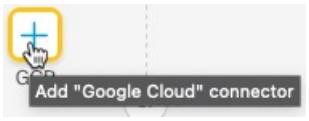
Dashboard access and functionality

To access the dynamic attributes connector dashboard, log in to the Secure Firewall Manager and click **Integration** > **Dynamic Attributes Connector** at the top of the page.



If the dynamic attributes connector is not enabled, move the slider to enable it. This process could take several minutes to complete.

The dynamic attributes connector Dashboard page displays an example of an unconfigured system:



Dashboard of an unconfigured system

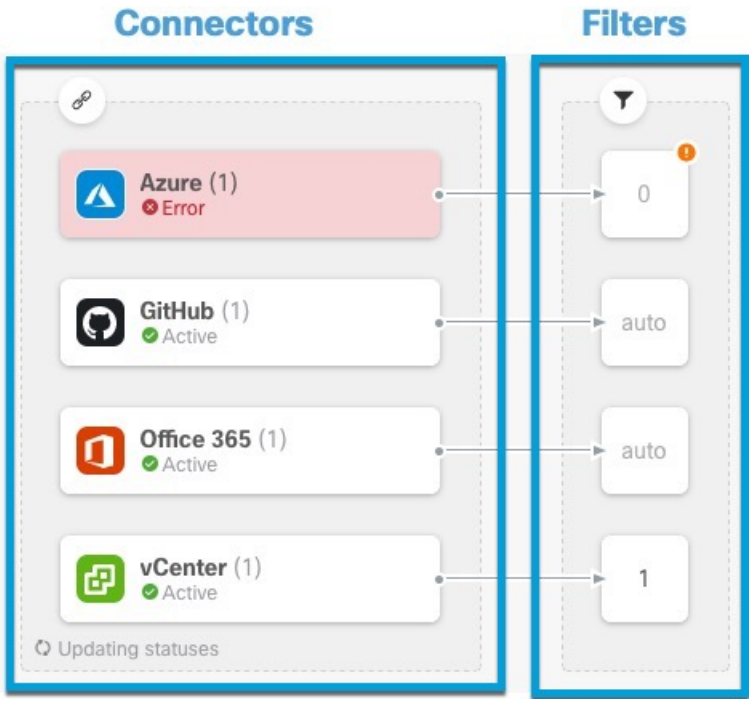
This sample dynamic attributes connector Dashboard page shows how an unconfigured system appears initially.

The Dashboard initially displays all the types of connectors you can configure for your system. You can do any interaction:

- Hover the mouse pointer over a connector and click 

to create a new one.
- Click **Go to Connectors** to add, edit, or delete connectors (good for creating, editing, or deleting multiple connectors at the same time).

  For more information, see Connectors, on page 2072.



Related Topics:

- Dashboard of a configured system, on page 2067
- Add, edit, or delete connectors, on page 2069
- Add, edit, or delete dynamic attributes filters, on page 2070

Dashboard of a configured system

Sample dynamic attributes connector Dashboard page of a configured system displays at-a-glance information about configured connectors, filters, and adapters.

Click an area in the figure to learn more about it or click one of the links that follow the figure.

1 Connectors, on page 2072

2 Create dynamic attributes filters, on page 2092

The Dashboard shows the following (from left to right):

Connectors column	Filters column
List of connectors with a number indicating how many of each type are configured. Connectors collect dynamic attributes that could be sent to the Secure Firewall Manager. Dynamic attributes filters specify what data is sent. Click to view more information about all configured connectors. You can also click the name of a connector to add, edit, or delete connectors; or to view detailed information about them. For more information, see Add, edit, or delete connectors, on page 2069.	List of dynamic attributes filters associated with each connector with a number indicating how many of each filter are associated with a connector. Click to view more information about all configured filters. You can also click the name of a filter to add, edit, or delete filters; or to view detailed information about them. For more information, see Add, edit, or delete dynamic attributes filters, on page 2070.

Note Some connectors, such as Outlook 365 and Azure Service tags, automatically pull available dynamic objects without the need for a dynamic attributes filters. Those connectors display **Auto** in the column.

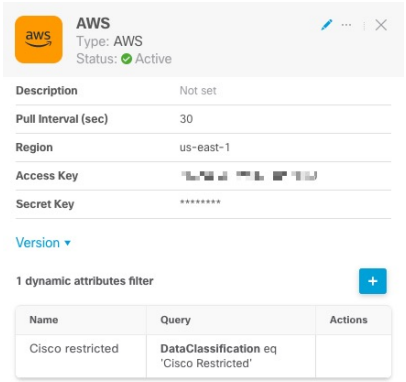
The Dashboard indicates whether or not an object is available. The Dashboard page is refreshed every 15 seconds but you can click **Refresh** ( ) at the top of the page at any time to refresh immediately. If issues persist, check your network connection.

Add, edit, or delete connectors

The Dashboard enables you to manage connectors by viewing, adding, editing, or deleting them. You can also view error information for connectors and troubleshoot issues.

Use the dynamic attributes connector dashboard when you need to manage connectors for your network security infrastructure. The dashboard provides comprehensive options for connector management and troubleshooting.

Procedure



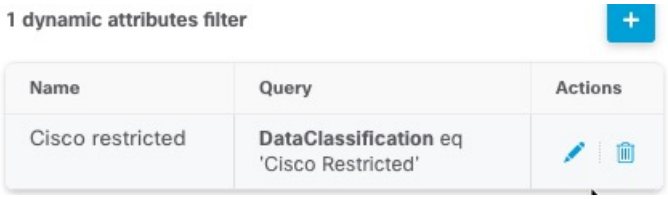
Step 1 Access the connector dashboard and select your desired action.

The Dashboard enables you to view or edit connectors. You can click the name of a connector to view all instances of that connector or you can click  for the following additional options:

- **Go to Connectors** to view all connectors at the same time; you can add, edit, and delete connectors from there.
- **Add Connector** > ***type*** to add a connector of the indicated type.

Step 2 Click any connector in the connectors column ( ) to display more information about it.

An example follows:

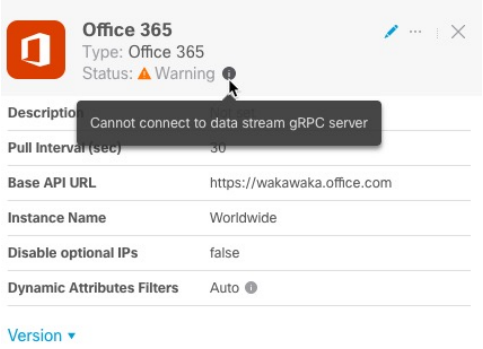


Step 3 Choose from the following management options.

- Click the Edit icon ( ) to edit this connector.
- Click the More icon ( ) for additional options.
- Click to close the panel.
- Click **Version** to display the version of the . You can optionally copy the version to the clipboard if necessary for Cisco TAC.

Step 4 Use the table at the bottom of the panel to add dynamic attributes filters or to edit or delete connectors.

A sample follows:



Click the Add icon ( ) to add a dynamic attributes filter for this connector. For more information, see Create dynamic attributes filters, on page 2092.

Hover the mouse pointer over the Actions column to either edit or delete the indicated connector.

Step 5 To view error information for a connector, click the name of the connector that is displaying the error.

Step 6 In the right pane, click **Information** ( ).

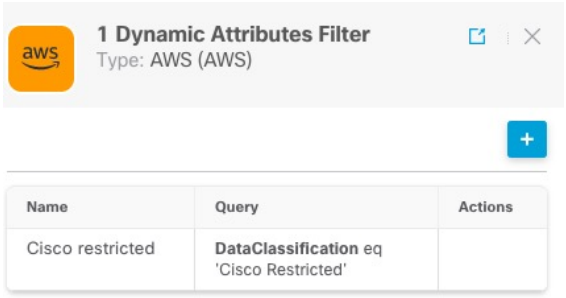
An example follows.

Step 7 To resolve this issue, edit the connector settings as discussed in Create an office 365 connector, on page 2085.

Step 8 If you cannot resolve the issue, click **Version** and copy the version to a text file.

Add, edit, or delete dynamic attributes filters

The dashboard enables you to add, edit, or delete dynamic attributes filters. You can click the name of a filter to view all instances of that filter or you can click for additional options.



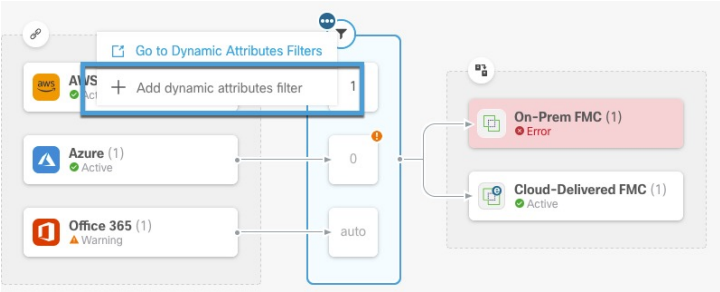
You can click the name of a filter to view all instances of that filter or you can click for the following additional options:

- **Go to Dynamic Attributes Filters** to view all configured dynamic attributes filters. You can add, edit, or delete dynamic attributes filters from there.

- **Add Dynamic Attributes Filters** to add a filter.

For more information about adding dynamic attributes filters, see Create dynamic attributes filters, on page 2092.

An example follows:



Note Some connectors, such as Outlook 365 and Azure Service tags, automatically pull available dynamic objects without the need for a dynamic attributes filters. Those connectors display **Auto** in the column.

You have these options:

- Click a filter instance to view summary information about dynamic attributes filters associated with a connector.
- Click the Add icon ( ) to add a new dynamic attributes filter.

  For more information, see Create dynamic attributes filters, on page 2092.
- Click in the filters column ( ) indicates the indicated connector has no associated dynamic attributes filters. Without associated filters, the connector can send nothing to Firewall Management Center.

  One way to resolve the issue is to click in the filters column and click **Add Dynamic Attributes Filter**. A sample follows.

- Click to add, edit, or delete filters.
- Click to close the panel.

Connectors

A connector is an interface with a cloud service. It retrieves network information from the cloud service to enable the network information to be used in policies on the Secure Firewall Management Center. It supports both air gap mode and network download mode configurations.

Supported connectors

We support these connectors:

Table 121: List of supported connectors by dynamic attributes connector version and platform

CSDAC version	AWS	AWS Security Groups	AWS Service Tags	Azure	Azure Service Tags	Cisco APIC	Cisco Cyber Vision	Cisco Multicl. Defense	Generic text	GitHub	Google Cloud	Microsoft Office 365	Tenable	vCenter	Webex	Zoom
Version 1.1 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	No	No	No	Yes	No	Yes	No	No
Version 2.0 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	No	No	Yes	Yes	No	Yes	No	No

Amazon Web Services connector user permissions and imported data

The dynamic attributes connector imports dynamic attributes from Amazon Web Services (AWS) to Secure Firewall Management Center for use in policies.

Dynamic attributes imported

The connector imports these dynamic attributes from AWS:

- *Tags*, user-defined key-value pairs you can use to organize your AWS EC2 resources.

  For more information, see Tag your EC2 Resources in the AWS documentation

- *IP addresses* of virtual machines in AWS.

Minimum permissions required

The dynamic attributes connector requires a user at minimum with a policy that permits `ec2:DescribeTags`, `ec2:DescribeVpcs`, and `ec2:DescribeInstances` to be able to import dynamic attributes.

Create an AWS user with minimal permissions for the dynamic attributes connector

This task creates a service account with minimum permissions to send dynamic attributes to Secure Firewall Management Center .

For a list of the dynamic attributes that can be sent, refer to Amazon Web Services connector user permissions and imported data, on page 2072.

Before you begin

You must already have set up your Amazon Web Services (AWS) account. For more information about doing that, see this article in the AWS documentation.

Follow these steps to create an AWS user with minimal permissions for the dynamic attributes connector:

Procedure

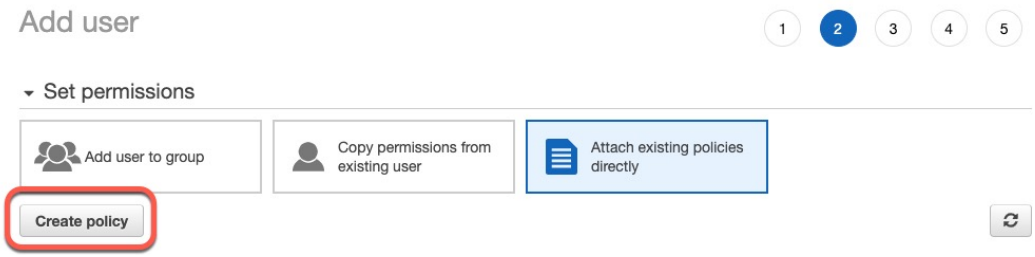
Step 1 Log in to the AWS console as a user with the admin role.

Step 2 From the Dashboard, click **Security, Identity & Compliance** > **IAM**.

Step 3 Click **Access Management** > **Users**.

Step 4 Click **Add Users**.

a) In the **User Name** field, enter a name to identify the user.
b) Click **Access Key - Programmatic Access**.
c) At the Set permissions page, click **Next** without granting the user access to anything. You can grant user access later.
d) Add tags to the user if desired.
e) Click **Create User**.
f) Click **Download .csv** to download the user's key to your computer.



Note This is the only opportunity you have to retrieve the user's key.

g) Click **Close**.

Step 5 At the Identity and Access Management (IAM) page in the left column, click **Access Management** > **Policies**.

Step 6 Click **Create Policy**.

a) On the Create Policy page, click **JSON**.

b) Enter the following policy in the field:

```
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "ec2:DescribeTags",
    "ec2:DescribeInstances",
    "ec2:DescribeVpcs"
   ],
   "Resource": "*"
  }
 ]
}
```

c) Click **Next**.

Step 7 Click **Review**.

On the Review Policy page, enter the requested information and click **Create Policy**.

Step 8 Attach your policy

a) On the Policies page, enter all or part of the policy name in the search field and press Enter.
b) Click the policy you just created.
c) Click **Actions** > **Attach**.
d) If necessary, enter all or part of the user name in the search field and press Enter.
e) Click **Attach Policy**.

What to do next:

Create an AWS connector, on page 2074.

Create an AWS connector

Create a connector to send dynamic objects from AWS to the firewall for use in security policies.

This task discusses how to configure a connector that sends data from AWS to the Secure Firewall Management Center for use in policies.

Before you begin

Create a user with at least the privileges discussed in Create an AWS user with minimal permissions for the dynamic attributes connector, on page 2073.

Follow these steps to create an AWS connector:

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of these actions:

- Add a new connector: click Add icon (), then click the name of the connector.
- Edit or delete a connector: Click **More** (), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter the required information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from AWS.
Region	(Required.) Enter your AWS region code.
Access Key	(Required.) Enter your access key.
Secret Key	(Required.) Enter your secret key.

a) Click **Save**.

The Status column displays **Ok**.

What to do next:

Azure connector—About user permissions and imported data

The dynamic attributes connector imports dynamic attributes from Azure to Secure Firewall Management Center for use in policies.

Dynamic attributes imported

We import these dynamic attributes from Azure:

- *Tags*, key-value pairs associated with resources, resource groups, and subscriptions.

  For more information, see this page in the Microsoft documentation.

- *IP addresses* of virtual machines in Azure.

Minimum permissions required

The dynamic attributes connector requires a user at minimum with the **Reader** permission to be able to import dynamic attributes.

Create an Azure user with minimal permissions for the dynamic attributes connector

Create an Azure service account with minimal permissions to send dynamic attributes to Secure Firewall Management Center.

This task discusses how to set up a service account with minimum permissions to send dynamic attributes to Secure Firewall Management Center. For a list of these attributes, see Azure connector—About user permissions and imported data, on page 2075.

Before you begin

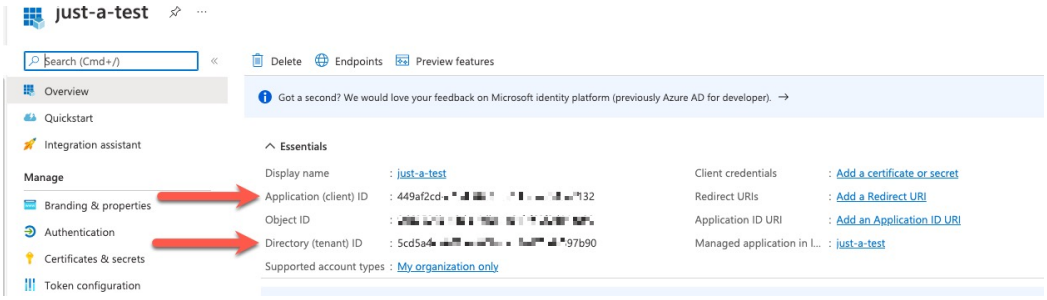
You must already have a Microsoft Azure account. To set one up, see this page on the Azure documentation site.

Follow these steps to create an Azure user with minimal permissions for the dynamic attributes connector:

Procedure

Step 1 Log in to the Azure Portal as the owner of the subscription.

Step 2 Click **Azure Active Directory**.

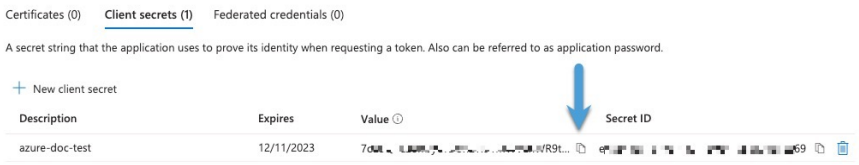


Find the instance of Azure Active Directory for the application you want to set up.

Step 3 Click **Add** > **App registration**.

a) In the **Name** field, enter a name to identify this application.
b) Enter other information on this page as required by your organization.
c) Click **Register**.

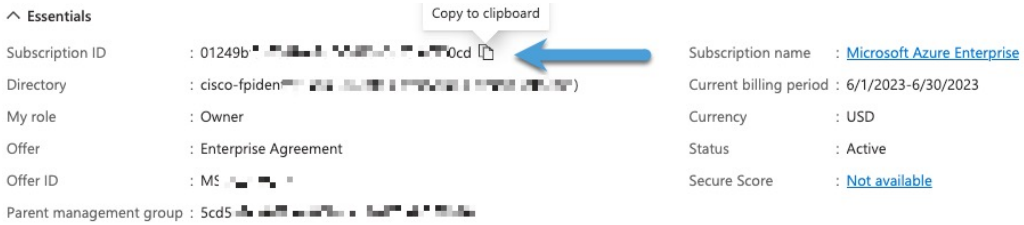
Step 4 On the next page, write down or copy the Client ID (also referred to as *application ID*) and the tenant ID (also referred to as the *directory ID*).



Here is a sample:

Step 5 Next to Client Credentials, click **Add a certificate or secret**.

Step 6 Click **New Client Secret**.

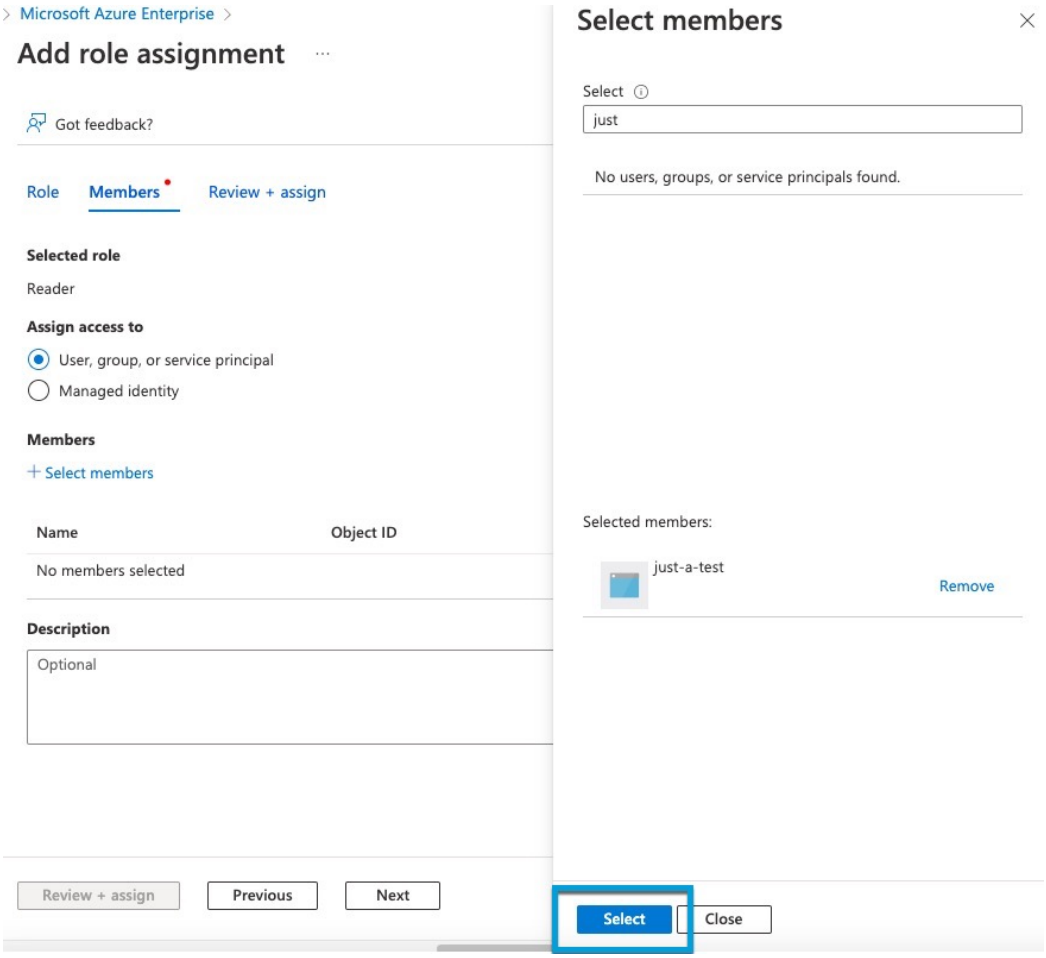


a) Enter the requested information and click **Add**.
b) Copy the value of the **Value** field to the clipboard. This value, *and not the* ***Secret ID***, is the client secret.

Step 7 Go back to the main Azure Portal page and click **Subscriptions**.

a) Click the name of your subscription.

b) Copy the subscription ID to the clipboard.



Step 8 Click **Access Control (IAM)**.

a) Click **Add** > **Add role assignment**.

b) Click **Reader** and click **Next**.

c) Click **Select Members**.

d) On the right side of the page, click the name of the app you registered and click **Select**.

e) Click **Review + Assign** and follow the prompts to complete the action.

Also see Create an Azure connector, on page 2078.

Create an Azure connector

Create a connector to send data from Azure to Secure Firewall Management Center for use in policies.

This connector enables integration between Azure and your security management platform to retrieve dynamic object information for policy implementation.

Before you begin

Create an Azure user with at least the privileges discussed in Create an Azure user with minimal permissions for the dynamic attributes connector, on page 2076.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:

- Add a new connector: click Add icon (), then click the name of the connector.
- Edit or delete a connector: Click **More** (), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from Azure. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Subscription ID	(Required.) Enter your Azure subscription ID.
Tenant ID	(Required.) Enter your tenant ID.
Client ID	(Required.) Enter your client ID.
Client Secret	(Required.) Enter your client secret.

a) Click **Save**.

The Status column displays **Ok**.

Create an Azure service tags connector

Create a connector for Azure service tags to enable use in policies with automatically updated IP addresses from Microsoft.

This topic discusses how to create a connector for Azure service tags to the Secure Firewall Management Center for use in policies. The IP addresses associated with these tags are updated every week by Microsoft.

For more information, see Virtual network service tags on Microsoft TechNet.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:

- Add a new connector: click Add icon (), then click the name of the connector.
- Edit or delete a connector: Click **More** (⋮), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter the required information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from Azure. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Subscription ID	(Required.) Enter your Azure subscription ID.
Tenant ID	(Required.) Enter your tenant ID.
Client ID	(Required.) Enter your client ID.
Client Secret	(Required.) Enter your client secret.

a) Click **Save**.

The Status column displays **Ok**.

Create a generic text connector

Use this task to create a connector that retrieves IP addresses from text files and sends them to the firewall for use in access control rules.

This task discusses how to create an ad hoc list of IP addresses you maintain manually and retrieve at an interval you select (30 seconds by default). You can update the list of addresses anytime you want.

For example, you might have a list of IP addresses for an "allow list" in access control rules and another list of IP addresses for a "block list" in access control rules.

Before you begin

Create text files with IP addresses and put it on a web server that is accessible from the Secure Firewall Management Center . IP addresses can include CIDR notation. The text file must have only one IP address per line.

You can specify up to 10,000 IP addresses per text file.

Follow these steps to create a generic text connector:

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:

- Add a new connector: click Add icon (), then click the name of the connector.
- Edit or delete a connector: Click **More** (), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter the following information:

Item	Description
Name	Enter a name to identify the connector.
Description	(Optional.) Enter a description
Pull Interval	Change the frequency, in seconds, at which the dynamic attributes connector retrieves IP addresses from the text file. The default is 30 seconds. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
URLs	Enter a URL from which to retrieve IP addresses.
Add another URL	(Optional.) Click the link to add more URLs to an existing list.
Certificate	(Optional.) If a certificate chain is required for a secure connection to the web server, you have these options: • Click **Get Certificate** > **Fetch** to automatically fetch the certificate or, if that is not possible, get the certificate manually as discussed in Manually get a certificate authority (CA) chain, on page 2094. • Click **Get Certificate** > **Browse from file** to upload a certificate chain you downloaded previously.

a) Click **Test** and make sure the test succeeds before you save the connector.
b) Click **Save**.
c) Status column displays **Ok**

Create a GitHub connector

Create a GitHub connector that sends data to the Secure Firewall Management Center for use in policies. The IP addresses associated with these tags are maintained by GitHub.

For more information, see About GitHub's IP addresses.

Note Do not change the URL because doing so will fail to retrieve any IP addresses.

Before you begin

You do not have to create a dynamic attributes filters.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:

- Add a new connector: click Add icon (), then click the name of the connector.
- Edit or delete a connector: Click **More** (), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter a **Name** and an optional description.

a) (Optional) In the **Pull Interval** field, change the frequency, in seconds, at which the dynamic attributes connector retrieves IP addresses from GitHub. The default is 21,600 seconds (6 hours).

b) Click **Save**.

The Status column displays **Ok**.

Google cloud connector user permissions and imported data

A Google Cloud connector imports dynamic attributes from Google Cloud to Secure Firewall Management Center for use in policies.

Dynamic attributes imported

The connector imports these dynamic attributes from Google Cloud:

- *Labels*: Key-value pairs assigned to virtual machine instances. Use the labels to organize your Google Cloud resources. For more information, see Creating and Managing Labels in the Google Cloud documentation.
- *Network tags*: Text values assigned to virtual machine instances that help identify groups of instances. For more information, see Creating and Managing Tags in the Google Cloud documentation.

- *IP addresses*: IP addresses associated with virtual machine instances in your Google Cloud project and region.

The dynamic attributes connector requires a user at minimum with the **Basic** > **Viewer** permission to be able to import dynamic attributes.

Create a Google Cloud user with minimal permissions for the dynamic attributes connector

Create a service account with minimum permissions to send dynamic attributes to Secure Firewall Management Center .

This task sets up a service account that provides the minimum permissions necessary for the dynamic attributes connector. For a list of these attributes, see Google cloud connector user permissions and imported data, on page 2082.

Before you begin

You must already have set up your Google Cloud account. For more information about doing that, see Setting Up Your Environment in the Google Cloud documentation.

Procedure

Step 1 Log in to your Google Cloud account as a user with the owner role.

Step 2 Click **IAM & Admin** > **Service Accounts** > **Create Service Account**.

Step 3 Enter the following information:

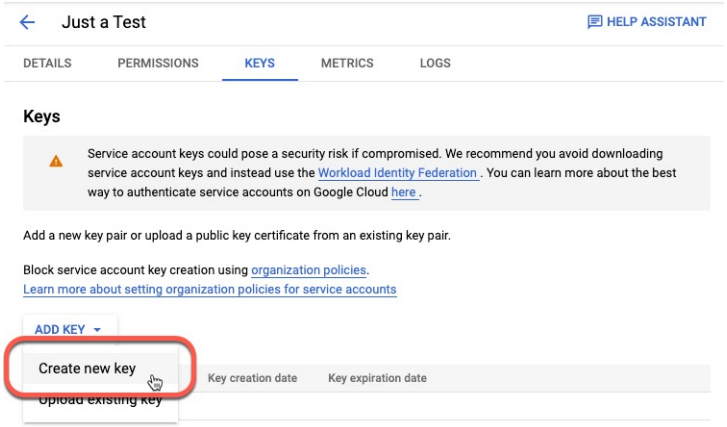
- **Service account name**: A name to identify this account; for example, `CSDAC`.
- **Service account ID**: Should be populated with a unique value after you enter the service account name.
- **Service account description**: Enter an optional description.

For more information about service accounts, see Understanding Service Accounts in the Google Cloud documentation.

Click **Create and Continue**.

Step 4 Follow the prompts on your screen until the Grant users access to this service account section is displayed.

Grant the user the **Basic** > **Viewer** role.



Click **Done**.

A list of service accounts is displayed.

Step 5 Click **More** (⋮) at the end of the row of the service account you created.

Step 6 Click **Manage Keys**.

Step 7 Click **Add Key** > **Create New Key**.

Step 8 Click **JSON**.

Step 9 Click **Create**.

The JSON key is downloaded to your computer.

Keep the key handy when you configure the GCP connector.

See Create a google cloud connector, on page 2084.

Create a google cloud connector

Create a Google Cloud connector to enable data transmission from your Google Cloud environment to the firewall for dynamic security attribute monitoring and management.

The Google Cloud connector allows the firewall to receive real-time data from your Google Cloud infrastructure, enabling dynamic security policies based on cloud resource attributes.

Before you begin

Have your Google Cloud JSON-formatted service account data ready; it's required to set up the connector.

Follow these steps to create a Google Cloud connector:

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit or delete a connector: Click **More** ( ), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from AWS. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
GCP region	(Required.) Enter the GCP region in which your Google Cloud is located. For more information, see Regions and Zones in the Google Cloud documentation.
Service account	Paste the JSON code for your Google Cloud service account.

a) Click **Save**.

The Status column displays **Ok**.

Create an office 365 connector

Create a connector for Office 365 tags to send data to the Secure Firewall Management Center for use in policies.

The IP addresses associated with these tags are updated every week by Microsoft. You do not have to create a dynamic attributes filter to use the data.

For more information, refer to Office 365 URLs and IP address ranges on docs.microsoft.com.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit or delete a connector: Click **More** ( ), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.

Value	Description
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from Azure. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Base API URL	(Required.) Enter the URL from which to retrieve Office 365 information, if it's different from the default. For more information, see Office 365 IP Address and URL web service on the Microsoft documentation site.
Instance name	(Required.) From the list, click an instance name. For more information, see Office 365 IP Address and URL web service on the Microsoft documentation site.
Disable optional IPs	(Required.) Enter **true** or **false**.

Step 5 Click **Save**.

The Status column displays **Ok**.

vCenter connector—About user permissions and imported data

The Dynamic Attributes Connector imports dynamic attributes from vCenter to Secure Firewall Management Center for use in policies.

Dynamic attributes imported

We import these dynamic attributes from vCenter:

- *Operating system*
- *MAC address*
- *IP addresses*
- *NSX tags*

Minimum permissions required

The Dynamic Attributes Connector requires a user at minimum with the **Read Only** permission to be able to import dynamic attributes.

Create a vCenter user with minimal permissions for the dynamic attributes connector

Create a service account with minimum permissions to send dynamic attributes to Secure Firewall Management Center .

This task provides the steps to set up a service account with minimum permissions required for the dynamic attributes connector. For a list of these attributes, see vCenter connector—About user permissions and imported data, on page 2086.

Before you begin

You must already have set up your vCenter Server account. For more information about doing that, see About vCenter Server Installation and Setup in the vCenter documentation.

Follow these steps to create a vCenter user with minimal permissions for the dynamic attributes connector:

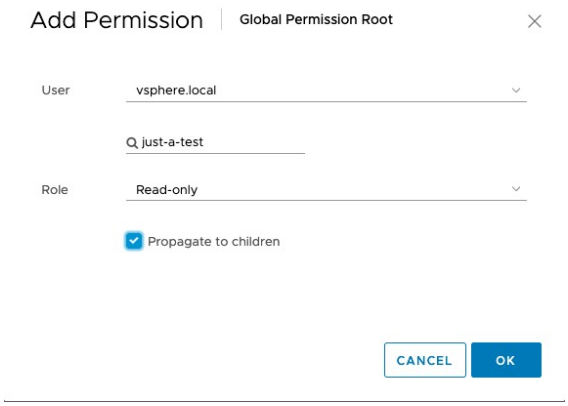
Procedure

Step 1 Log into vCenter as an administrator.

Step 2 Click **Menu** > **Administration**.

Step 3 In the left pane, click **Single Sign On** > **Users and Groups**.

Step 4 From the **Domain** list, click the name of a domain to add the user.



Step 5 Click **Add User**.

a) Enter the requested information and click **Add**.

Step 6 In the left pane, click **Access Control** > **Global Permissions**.

Step 7 Click **Add**(+).

a) From the **User** field, click the name of the vCenter domain in which you created the user.
b) In the search field, enter part of the user's name.
c) From the **Role** list, click **Read-only**.
d) Select the **Propagate to children** check box.

Step 8 Click **OK**.

What to do next

See Create a vCenter connector, on page 2088.

Create a vCenter connector

Create a connector for VMware vCenter to send data to the Secure Firewall Management Center for use in policies.

This connector enables the management center to receive dynamic attribute information from vCenter Server for use in security policies and monitoring.

Before you begin

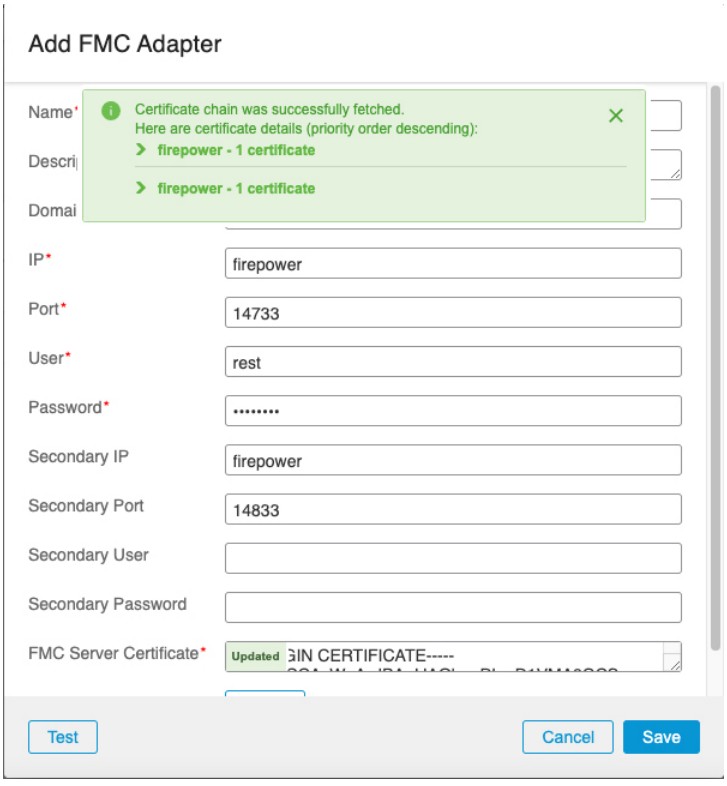
If you use non-trusted certificates to communicate with vCenter, see Manually get a certificate authority (CA) chain, on page 2094.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:



- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit or delete a connector: Click **More** ( ), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Enter an optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from vCenter. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Host	(Required.) Enter any of the following: • vCenter's fully qualified host name • vCenter's IP address • (Optional.) A port *Do not* enter a scheme (such as **`https://`**) or trailing slash. For example, **`myvcenter.example.com`** or **`192.0.2.100:9090`**
User	(Required.) Enter the user name of a user with the Read-only role at minimum. User names are case-sensitive.
Password	(Required.) Enter the user's password.

Value	Description
NSX IP	If you use vCenter Network Security Visualization (NSX), enter its IP address.
NSX User	Enter the user name of an NSX user with the Auditor role at minimum.
NSX Type	Enter **NSX-T**.
NSX Password	Enter the NSX user's password.
vCenter Certificate	You have the following options: • Paste the certificate authority (CA) chain you got as discussed in Manually get a certificate authority (CA) chain, on page 2094. • Click **Fetch** to automatically fetch the certificate or, if that is not possible, get the certificate manually as discussed in Manually get a certificate authority (CA) chain, on page 2094. • Click **Get Certificate** > **Fetch** to automatically fetch the certificate or, if that is not possible, get the certificate manually as discussed in Manually get a certificate authority (CA) chain, on page 2094. • Click **Get Certificate** > **Browse from file** to upload a certificate chain you downloaded previously.

Following is an example of successfully fetching a certificate chain:

Expanding the certificate CA chain at the top of the dialog box displays the certificates similar to the following.

If it's not possible to fetch the certificate this way, you can get the certificate chain manually as discussed in Manually get a certificate authority (CA) chain, on page 2094.

Step 5 Click **Save**.

Create a Webex connector

This task creates a Webex connector that sends IP addresses to the management system for use in policies. The IP addresses associated with these tags are maintained by Webex.

This section discusses how to create a Webex connector that sends data to the Secure Firewall Management Center for use in policies. The IP addresses associated with these tags are maintained by Webex. You do not have to create a dynamic attributes filters.

For more information, see Port Reference for Webex Calling.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit or delete a connector: Click **More** ( ), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from Webex. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Provider Reserved IPs	(Required.) (Required.) Slide to enabled to retrieve any reserved IP addresses.

a) Click **Test** and make sure the test succeeds before you save the connector.
b) Click **Save**.
c) The Status column displays **Ok**.

Create a Zoom connector

Create a Zoom connector that sends data to the Secure Firewall Management Center for use in policies.

The IP addresses associated with these tags are maintained by Zoom. You do not have to create a dynamic attributes filters.

For more information, see Zoom network firewall or proxy server settings.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:

- Add a new connector: click Add icon (), then click the name of the connector.
- Edit or delete a connector: Click **More** (), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter this information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from Zoom. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Provider Reserved IPs	(Required.) Slide to enabled to retrieve any reserved IP addresses.

a) Click **Test** and make sure the test succeeds before you save the connector.
b) Click **Save**.

The Status column displays **Ok**.

Create dynamic attributes filters

Create dynamic attributes filters to expose them as dynamic objects in Secure Firewall Management Center for use in access control policies.

Dynamic attributes filters that you define using the Dynamic Attributes Connector are exposed in the Secure Firewall Management Center as dynamic objects that can be used in access control policies. For example, restrict access to an AWS server for the Finance Department to only members of the Finance group defined in Microsoft Active Directory.

Note You cannot create dynamic attributes filters for Generic Text, Office 365, Azure Service Tags, Webex, or Zoom. These types of cloud objects provide their own IP addresses.

For more information about access control rules, see Create access control rules using dynamic attributes filters, on page 2100.

Before you begin

Connectors, on page 2072

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Click **Integration** > **Dynamic Attributes Connector** > **Dynamic Attributes Filters**.

Step 2 Do any of the following:

- Add a new filter: click **Add** ( ).
- Edit or delete a filter: Click **More** ( ), then click **Edit** or **Delete** at the end of the row.

Step 3 Enter the following information.

Item	Description
Name	Unique name to identify the dynamic filter (as a dynamic object) in a policy and in the Secure Firewall Management Center Object Manager (**External Attributes** > **Dynamic Object**).
Connector	From the list, click the name of a connector to use.
Query	Click Add .

Step 4 To add or edit a query, enter the following information.

Item	Description
Key	Click a key from the list. Keys are fetched from the connector.
Operation	Click one of the following: • **Equals** to exactly match the key to the value. • **Contains** to match the key to the value if any part of the value matches.
Values	Click either **Any** or **All** and click one or more values from the list. Click **Add another value** to add values to your query.

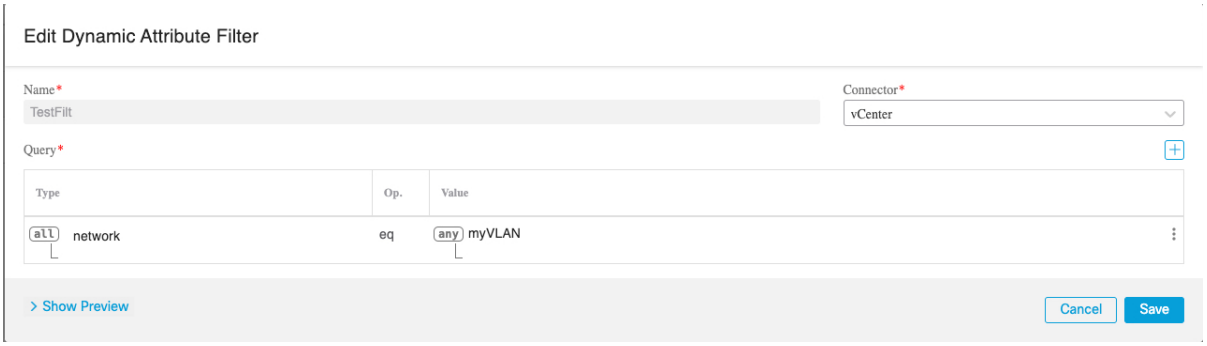
Step 5 Click **Show Preview** to display a list of networks or IP addresses returned by your query.

Step 6 When you're finished, click **Save**.

Step 7 (Optional.) Verify the dynamic object in the Secure Firewall Management Center.

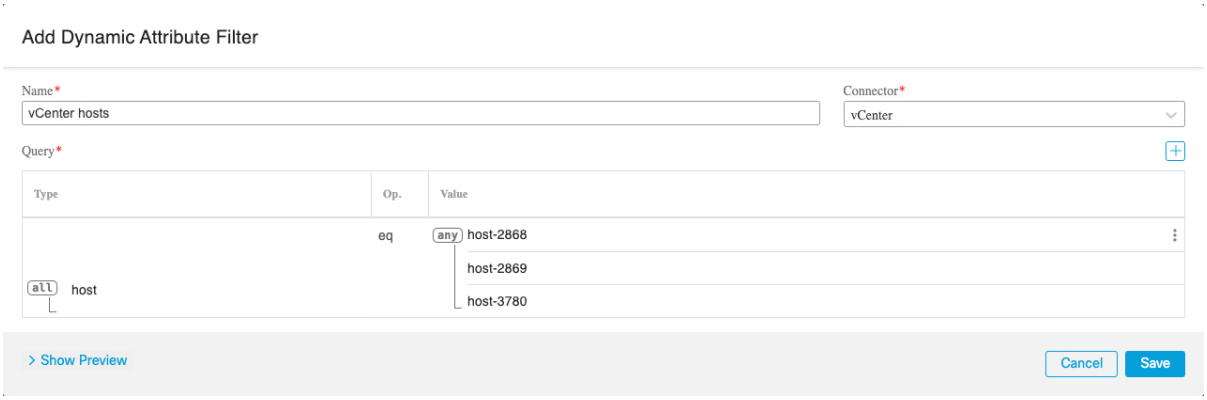
a) Log in to the Secure Firewall Management Center as a user with the Network Admin role at minimum.

b) Click **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.



The dynamic attribute query you created should be displayed as a dynamic object.

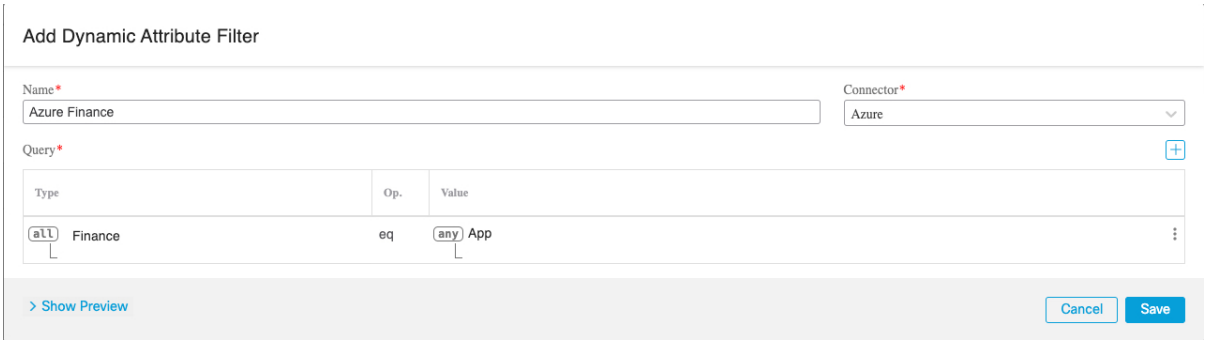
Dynamic attribute filter examples



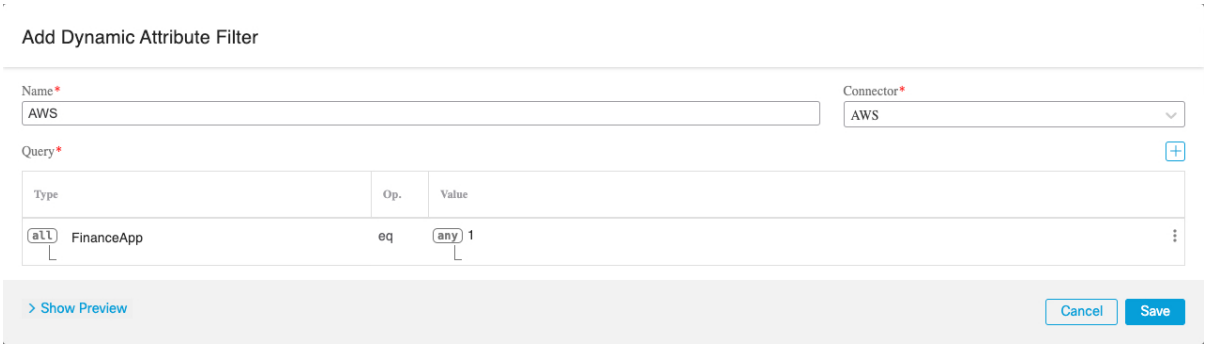
This topic provides some examples of setting up dynamic attribute filters.

Examples: vCenter

This example shows one criterion: a VLAN.



This example shows three criteria that are joined with OR: the query matches any of three hosts.



Example: azure

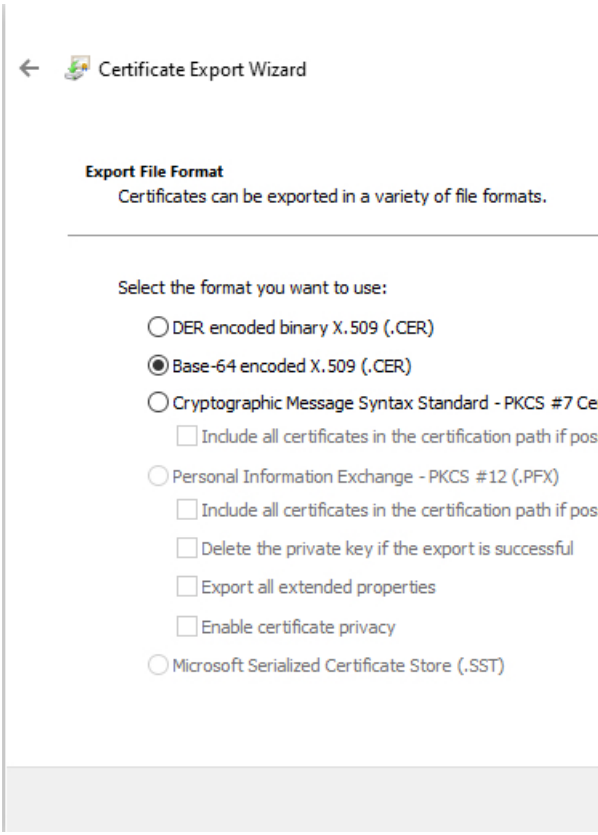
This example shows one criterion: a server tagged as a Finance app.

Example: AWS

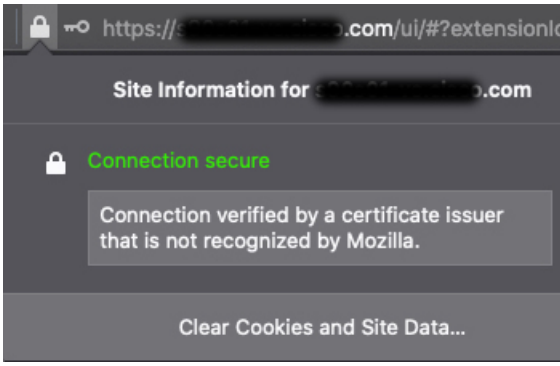
This example shows one criterion: a FinanceApp with a value of 1.

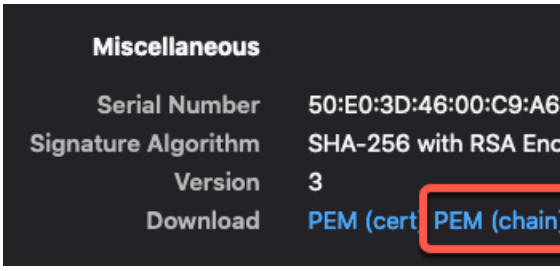
Manually get a certificate authority (CA) chain

If the certificate authority chain is not fetched automatically, use one of these browser-specific procedures to get a certificate chain to securely connect to vCenter or Firewall Management Center .



The *certificate chain* is the root certificate and all subordinate certificates.





Procedure

	Command or Action	Purpose

Step 1	Get a Certificate Chain—Mac (Chrome and Firefox)	**a.** Open a Terminal window.
		b. Enter this command:
		`security verify-cert -P url[:port]`
		where *url* is the URL (including scheme) to vCenter or Firewall Management Center . For example:
		`security verify-cert -P https://myvcenter.example.com`
		If you access vCenter or Firewall Management Center using NAT or PAT, you can add a port as follows:
		`security verify-cert -P https://myvcenter.example.com:12345`
		c. Save the entire certificate chain to a plaintext file.
		• *Include* all `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----` delimiters.
		• *Exclude* any extraneous text (for example, the name of the certificate and any text contained in angle brackets (< and >) as well as the angle brackets themselves.
		d. Repeat these tasks for vCenter Firewall Management Center .

Step 2	Get a Certificate Chain—Windows Chrome	**a.** Log in to vCenter or Firewall Management Center using Chrome. **b.** In the browser address bar, click the lock to the left of the host name. **c.** Click **Certificate**. **d.** Click the **Certification Path** tab. **e.** Click the top (that is, first) certificate in the chain. **f.** Click **View Certificate**. **g.** Click the **Details** tab.

	Command or Action	Purpose
		h. Click **Copy to File**. **i.** Follow the prompts to create a CER-formatted certificate file that includes the entire certificate chain. When you're prompted to choose an export file format, click **Base 64-Encoded X.509 (.CER)**.  Follow the prompts to complete the export. Open the certificate in a text editor. Repeat the process for all certificates in the chain. You must paste each certificate in the text editor in order, first to last. Repeat these tasks for vCenter or Firewall Management Center .
Step 3	Get a Certificate Chain—Windows Firefox	**a.** Log in to vCenter or Firewall Management Center using Firefox.

	Command or Action	Purpose
		b. Click the lock to the left of the host name. **c.** Click the right arrow (**Show connection details**).  **d.** Click **More Information**. **e.** Click **View Certificate**. **f.** If the resulting dialog box has tab pages, click the tab page corresponding to the top-level CA. **g.** Scroll to the Miscellaneous section. **h.** Click **PEM (chain)** in the Download row.  **i.** Save the file. Repeat these tasks for vCenter or Firewall Management Center .

Dynamic objects in access control rules

A *dynamic object* is automatically pushed from the dynamic attributes connector to the Secure Firewall Manager after you create connectors and save a dynamic attributes filter on the connector.

You can use these dynamic objects on the access control rule's **Dynamic Attributes** tab page. You can add dynamic objects as source or destination attributes.

Dynamic object usage examples

In an access control block rule, you can add a Finance dynamic object as a destination attribute to block access to Finance servers by whatever objects match the other criteria in the rule.

Dynamic attributes filter limitations

Note You cannot create dynamic attributes filters for Generic Text, Office 365, Azure Service Tags, Webex, or Zoom. These types of cloud objects provide their own IP addresses.

Create dynamic attributes filters

Create dynamic attributes filters to expose them as dynamic objects in Secure Firewall Management Center for use in access control policies.

Dynamic attributes filters that you define using the Dynamic Attributes Connector are exposed in the Secure Firewall Management Center as dynamic objects that can be used in access control policies. For example, restrict access to an AWS server for the Finance Department to only members of the Finance group defined in Microsoft Active Directory.

Note You cannot create dynamic attributes filters for Generic Text, Office 365, Azure Service Tags, Webex, or Zoom. These types of cloud objects provide their own IP addresses.

For more information about access control rules, see Create access control rules using dynamic attributes filters, on page 2100.

Before you begin

Connectors, on page 2072

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Click **Integration** > **Dynamic Attributes Connector** > **Dynamic Attributes Filters**.

Step 2 Do any of the following:

- Add a new filter: click **Add** ().
- Edit or delete a filter: Click **More** (), then click **Edit** or **Delete** at the end of the row.

Step 3 Enter the following information.

Item	Description
Name	Unique name to identify the dynamic filter (as a dynamic object) in a policy and in the Secure Firewall Management Center Object Manager (**External Attributes** > **Dynamic Object**).
Connector	From the list, click the name of a connector to use.
Query	Click Add .

Step 4 To add or edit a query, enter the following information.

Item	Description
Key	Click a key from the list. Keys are fetched from the connector.
Operation	Click one of the following: • **Equals** to exactly match the key to the value. • **Contains** to match the key to the value if any part of the value matches.
Values	Click either **Any** or **All** and click one or more values from the list. Click **Add another value** to add values to your query.

Step 5 Click **Show Preview** to display a list of networks or IP addresses returned by your query.

Step 6 When you're finished, click **Save**.

Step 7 (Optional.) Verify the dynamic object in the Secure Firewall Management Center.

a) Log in to the Secure Firewall Management Center as a user with the Network Admin role at minimum.

b) Click **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.

The dynamic attribute query you created should be displayed as a dynamic object.

Dynamic attributes rule conditions

Dynamic attributes rule conditions allow you to specify access control rules based on real-time properties such as network objects, device types, locations, and security tags. These conditions determine how access control rules match traffic based on various attributes, optimizing policy flexibility and accuracy.

Types of dynamic attributes

Dynamic attributes include:

- (source or destination) Dynamic objects (such as from the dynamic attributes connector)

The dynamic attributes connector enables you to collect data (such as networks and IP addresses) from cloud providers and send it to the Secure Firewall Management Center so they can be used in access control rules.

For more information about the dynamic attributes connector, see About the dynamic attributes connector , on page 2061.

- (source only) SGT objects contain tags either manually defined or defined in ISE. For more information, see Source and destination security group tag (SGT) matching, on page 1912 and Security group tags, on page 2376.
- (source only) Location IP objects, defined by Cisco ISE
- (source only) Device type objects, defined by Cisco ISE (also referred to as endpoint profile objects)

Combining objects in rules

Dynamic attributes can be used as source criteria and destination criteria in access control rules. Use these guidelines:

- Objects of different types are ANDd together
- Objects of a similar type are ORd together

For example, if you choose source destination criteria SGT 1, SGT 2, and device type 1, the rule matches if device type 1 is detected on either SGT 1 or SGT 2.

If you select both a security group tag, and a dynamic object that lists IP addresses, the rule matches if traffic with the tag originating from, or destined to, one of those IP addresses.

Create access control rules using dynamic attributes filters

Create access control rules using dynamic objects that are based on dynamic attributes filters you have previously configured.

This topic discusses how to create access control rules using dynamic objects (these dynamic objects are named after the dynamic attributes filters you created previously).

To add dynamic attributes filters to DNS policies, see Create basic DNS policies, on page 1997.

Before you begin

Create dynamic attributes filters as discussed in Create dynamic attributes filters, on page 2092.

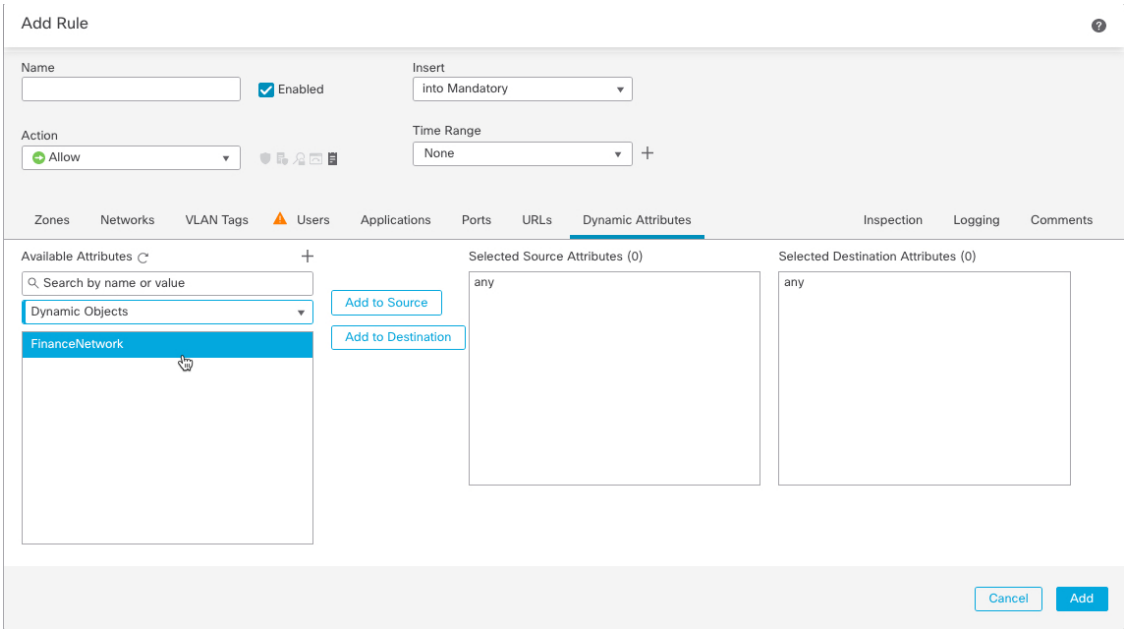
Note You cannot create dynamic attributes filters for Generic Text, Office 365, Azure Service Tags, Webex, or Zoom. These types of cloud objects provide their own IP addresses.

Follow these steps to create access control rules using dynamic attributes filters:

Procedure

Step 1 Log in to the Secure Firewall Management Center

Click **Policies** > **Access Control heading** > **Access Control**.



Step 2 Click **Edit** ( ) next to an access control policy.

Step 3 Click **Add Rule**.

Step 4 Click the **Dynamic Attributes** tab.

Step 5 In the Available Attributes section, from the list, click **Dynamic Objects**.

The following figure shows an example.

This example shows a dynamic object named `APIC Dynamic Attribute` that corresponds to the dynamic attribute filter created in the dynamic attributes connector.

Step 6 Add the desired object to source or destination attributes.

Step 7 Add other conditions to the rule if desired.

See Dynamic attributes rule conditions, on page 2099.

Dynamic Firewall

A dynamic firewall integrates user identity data with user trust data provided by Identity Intelligence to enhance your ability to detect identity-based exploits in your network.

Identity data integration

The dynamic firewall integrates user identity data from Microsoft AD and ISE with user trust data.

Dynamic Firewall

A dynamic firewall integrates identity sources with Identity Intelligence to provide user and device trust information.

Enhanced identity information

Previously, the collected information about users exclusively from the configured identity sources, such as Microsoft Active Directory, the passive identity agent, Cisco Identity Services Engine (Cisco ISE), and so on. This information generally included user name, group, and IP address.

The dynamic firewall enables you to pair user identity with intelligence and use that information in reporting and access control policies.

To use the dynamic firewall, you must:

- Have an Identity Intelligence tenant

  See Duo Identity Security with Cisco Identity Intelligence.

- Enable the Dynamic Attributes Connector
- Set up an identity source:
  - Cisco Identity Services Engine (Cisco ISE)
  - pxGrid Cloud

    pxGrid Cloud combines identity and posture in the same feed

    More information: What is pxGrid?

  In addition to providing authentication information, Cisco ISE and pxGrid Cloud can provide the following:

  - SGT Exchange Protocol (SXP) over TCP binding and directory session information if desired. For more information, see the *Cisco Identity Services Engine Administrator Guide*
  - Posture and mobile device management compliance. For more information, see Compliance.

- Set up an identity realm:
  - Create an LDAP realm or an Active Directory realm and realm directory, on page 1860

The *identity source* provides authentication information (login, logout) as well as posture. The identity source can also provide SXP binding and session directory information if desired.

The *identity realm* provides user, group, and IP address information.

How to configure the dynamic firewall

This topic helps you understand the concepts and options to configure the dynamic firewall discussed in Dynamic Firewall, on page 2102.

Summary

The dynamic firewall integrates an identity source (such as Cisco ISE) with Cisco Identity Intelligence, which provides user trust information to the Secure Firewall Management Center.

1. Configure Cisco Identity Intelligence to collect user trust information.
2. Configure a supported Secure Firewall Management Center identity source.
3. Configure a supported identity realm.
4. Enable the dynamic attributes connector.
5. Configure the dynamic firewall.

Workflow

The following procedure provides a high-level overview of how to configure the dynamic firewall.

1. As a Duo user with the Owner role, provision a Cisco Identity Intelligence tenant.

   You can provision a tenant from Duo Advantage as discussed in *Provision Your Cisco Identity Intelligence Tenant*.

2. In Cisco Identity Intelligence, create an API integration and use the information to set up the dynamic firewall.

   We use Cisco Identity Intelligence to find user and device risk information in your network.

   For more information about Cisco Identity Intelligence, see How-to Guides.

   For more information about this task, see Get required information for Identity Intelligence, on page 2105.

3. (Microsoft Azure AD realm only.) In Identity Intelligence, create a Microsoft Entra ID integration.

   For more information, see Microsoft Entra ID (Azure AD) Data Integration.

4. Create an identity source. (If you already have an identity source, continue with the next step.)

   You can do this in any of the following ways:

   - The Configure Dynamic Firewall dialog box displays **Configure** links to start setting up your identity source.
   - Click **Integration** > **Other Integrations** > **Identity Sources**.

   For more information about creating identity sources, see:

   - Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source
   - Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier)
   - Configuring a pxGrid Cloud identity source

5. Create an identity realm.

   We support the following realms:

   - Create an LDAP realm or an Active Directory realm and realm directory, on page 1860

     Only Microsoft AD is supported; LDAP realms are not supported.

- Create a Microsoft Azure AD (SAML) realm for passive authentication

6. Enable the dynamic attributes connector.

   The dynamic attributes connector is required to use the dynamic firewall. It enables your identity source to integrate with Identity Intelligence to provide enhanced insights into user activity.

   See Enable the dynamic attributes connector, on page 2063.

7. Create the dynamic firewall instance. (If you already have a dynamic firewall instance, continue with the next step.)

   Click **Integration** > **Dynamic Attributes Connector** and click **Configure Dynamic Firewall**.

   See Create a dynamic firewall instance, on page 2107.

8. Associate your identity source with Cisco Identity Intelligence.

   See Associate an identity source with Identity Intelligence, on page 2108.

9. View system-defined filters.

   We create dynamic attributes filters for the following:

   - Untrusted device
   - Trusted device
   - Untrusted user
   - Questionable user

   You can edit or replace these dynamic attributes filters as discussed in Create dynamic attributes filters, on page 2115.

10. View system-defined access control rules.

    We create an access control policy named Dynamic Firewall Policy (or similar) with the following rules:

    - Block an untrusted user from any source network to any destination network.
    - Monitor a questionable user from any source network to any destination network.
    - Block an untrusted device from any source network to any destination network.

    You can edit or delete the access control policy and rules as discussed in View and edit the system-created access control policy, on page 2114.

Enable the dynamic attributes connector

Enable the dynamic attributes connector to allow objects from cloud networking products to be used in Secure Firewall Management Center access control rules.

This task discusses how to enable the dynamic attributes connector in the Secure Firewall Management Center. The dynamic attributes connector is an integration that enables objects from cloud networking products to be used in Secure Firewall Management Center access control rules.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not done so already.

Step 2 Click **Integration** > **Dynamic Attributes Connector**.

Step 3 Slide to **Enabled**.

Step 4 The system displays messages when the dynamic attributes connector is enabled.

In the event of errors, try again. If errors persist, contact Cisco TAC.

See Connectors, on page 2072.

Get required information for Identity Intelligence

Get the necessary credentials and configuration values from Identity Intelligence to enable integration with the dynamic firewall.

This task discusses how to create an API client, which provides all the get required information to set up Identity Intelligence in the dynamic firewall.

If you already have an API client and you know the values of all these parameters, you can skip this procedure and continue with Create a dynamic firewall instance, on page 2107:

- **Client ID**
- **API URL**
- **Token URL**
- **Client Secret**

Before you begin

Integrating with the dynamic firewall requires you to create an *API client integration* in Identity Intelligence.

Among the values you must know about your API client integration is the client secret, which is displayed when you create the API client only. For that reason you might need to create the API integration first.

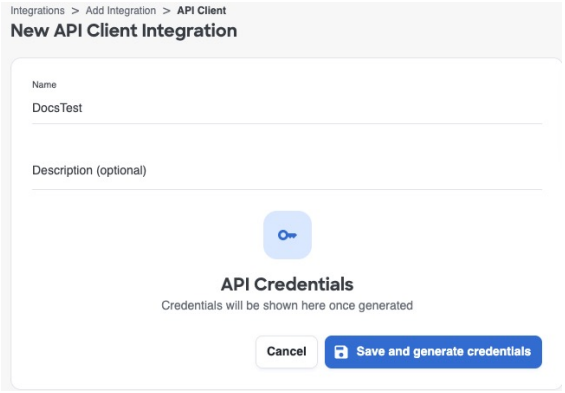
For more information about creating an API cilent integration, see Public API.

Follow these steps to get required information for Identity Intelligence:

Procedure

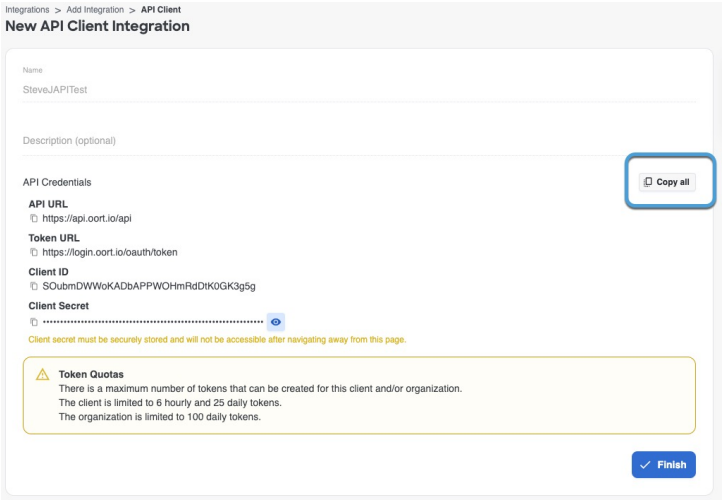
Step 1 Log in to your Identity Intelligence tenant.

Step 2 Click  (**Integrations**).



Step 3 Click **Add Integration**.

Step 4 On the next page, under API Clients, click **Add API Client**.



Step 5 Enter a **Name** and an optional **Description**.

Step 6 Click **Save and Generate Credentials**.

This figure shows an example.

Step 7 On the next page, click **Copy all** as this figure shows.

Step 8 Save the credentials for later use.

Step 9 Click **Finish**.

What to do next

See Create a dynamic firewall instance, on page 2107.

Create an identity source and realm for the dynamic firewall

Before you configure the dynamic firewall, you must configure a supported identity realm and identity source.

Configure an identity realm

These identity realms are supported:

- Create an LDAP realm or an Active Directory realm and realm directory, on page 1860

Only Microsoft AD is supported; LDAP realms are not supported.

- Create a Microsoft Azure AD (SAML) realm for passive authentication

Configure an identity source

These identity sources are supported:

- On-premises Cisco ISE: Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source
- Single or multiple Cisco ISE clusters:
  - Configuring a pxGrid Cloud identity source
  - Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier)

Create a dynamic firewall instance

Create a new instance of the dynamic firewall to establish an association between an identity source and Identity Intelligence.

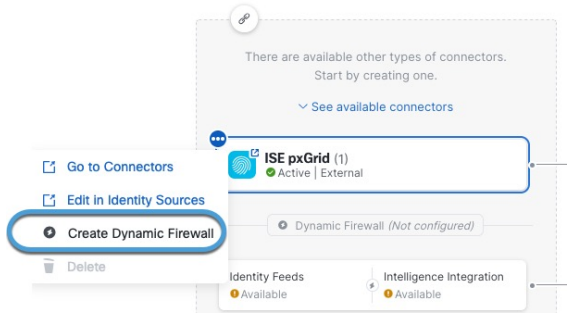
This task discusses how to create a new instance of the dynamic firewall, which is an association between an identity source and Identity Intelligence.

Before you begin

Complete all these steps:

- Enable the dynamic attributes connector as discussed in Enable the dynamic attributes connector, on page 2063.
- Create an identity source:
  - Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source.
  - Create a pxGrid Cloud identity source.

Follow these steps to create a dynamic firewall instance:



Procedure

Step 1 If you have not already done so, log in to the Secure Firewall Management Center.

Step 2 Click **Integrations** > **Dynamic Attributes Connector**.

Step 3 Click next to the name of the identity source with which to add the dynamic firewall.

The following figure shows an example.

Note If you do not see an identity source, create one before continuing:

- Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source
- Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier)
- Configuring a pxGrid Cloud identity source

Step 4 Click **Create Dynamic Firewall**.

Step 5 Continue with Associate an identity source with Identity Intelligence, on page 2108.

Associate an identity source with Identity Intelligence

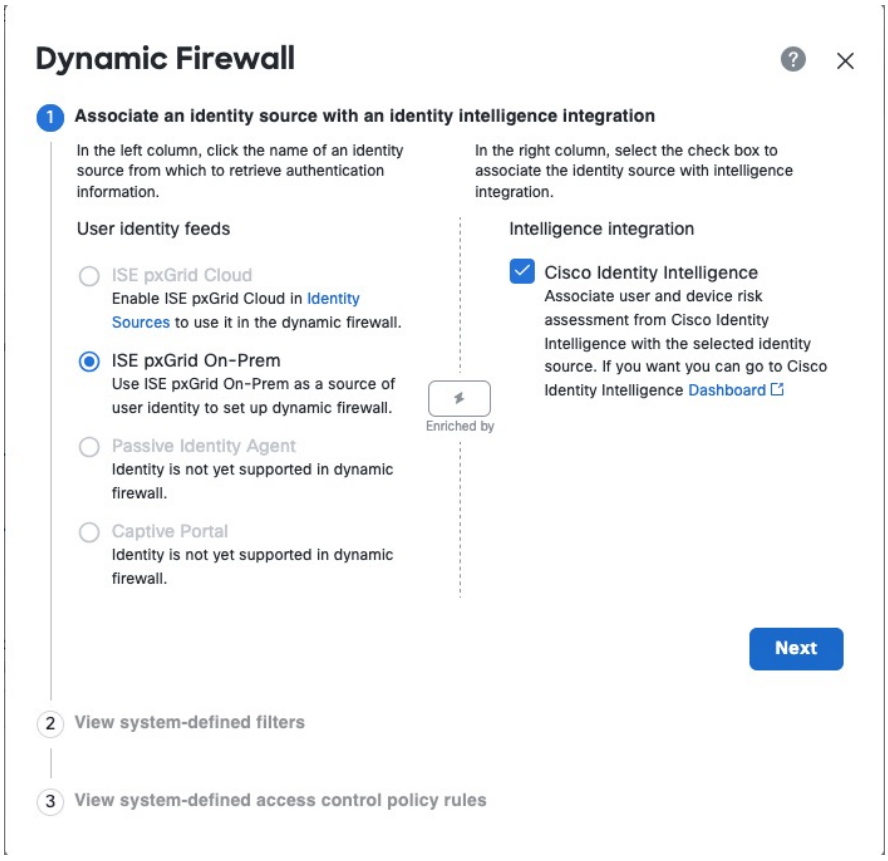
Associate a supported identity source with Identity Intelligence to enable user and device trust ratings for dynamic firewall configuration.

This task discusses how you associate an identity source with Identity Intelligence, which provides user and device trust ratings to the .

For more information, see User Trust Level.

Before you begin

Before you begin, make sure you:



- Understand how the identity realm, identity source, and Identity Intelligence work together as discussed in Dynamic Firewall, on page 2102.
- Completed the tasks discussed in Create a dynamic firewall instance, on page 2107.

Procedure

Step 1 Start with Create a dynamic firewall instance, on page 2107.

Step 2 On the next page, from the left column, click your identity source. Then, in the right column, select the **Cisco Identity Intelligence** check box to add user intelligence, including user and device risk.

The following figure shows an example.

Step 3 Click **Next**.

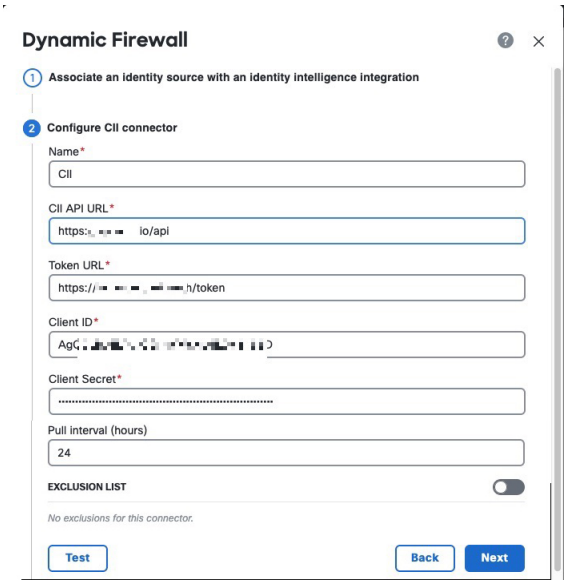
Step 4 Continue with Configure Identity Intelligence, on page 2109.

Configure Identity Intelligence

This task enables integration between the dynamic firewall and Identity Intelligence.

This task discusses how you associate an identity source with Identity Intelligence, which provides user and device risk ratings to the .

Before you begin



Complete the tasks discussed in Associate an identity source with Identity Intelligence, on page 2108.

Procedure

Step 1 Complete the tasks discussed in Associate an identity source with Identity Intelligence, on page 2108.

Step 2 If you selected the **Cisco Identity Intelligence** check box, enter the information you found for Identity Intelligence as described in Get required information for Identity Intelligence, on page 2105.

The following figure shows an example.

Step 3 (Optional.) For Identity Intelligence to consider a specific set of users as trusted, slide **Exclusion List** to **Slider enabled** ( ).

Enter one user name per line in **username@domain.com** format. Users in this list are considered trusted by Identity Intelligence.

Step 4 Click **Test**.

Only if the test succeeds, continue with the next step.

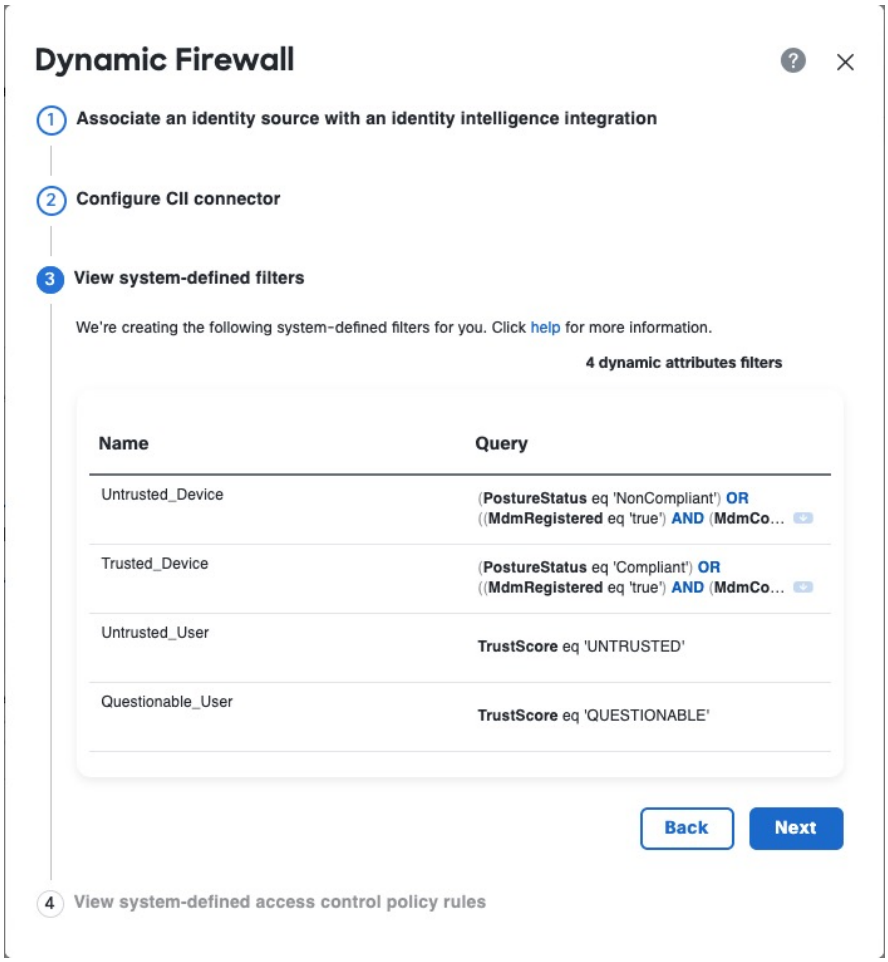
If any errors are displayed, check all of your Identity Intelligence values and try again.

Step 5 Click **Next**.

Step 6 Continue with View system-defined filters, on page 2110.

View system-defined filters

This task allows you to examine and understand the system-defined dynamic attributes filters that are automatically created during the configuration process.



This task discusses how you associate an identity source with Cisco Identity Intelligence, which provides user and device risk ratings to the .

Before you begin

See Configure Identity Intelligence, on page 2109.

Procedure

Step 1 The system displays a set of system-defined dynamic attributes filters, as shown in the following figure.

Step 2 View the system-created filters. Click on any row to expand the filter so you can view the filter and see its details.

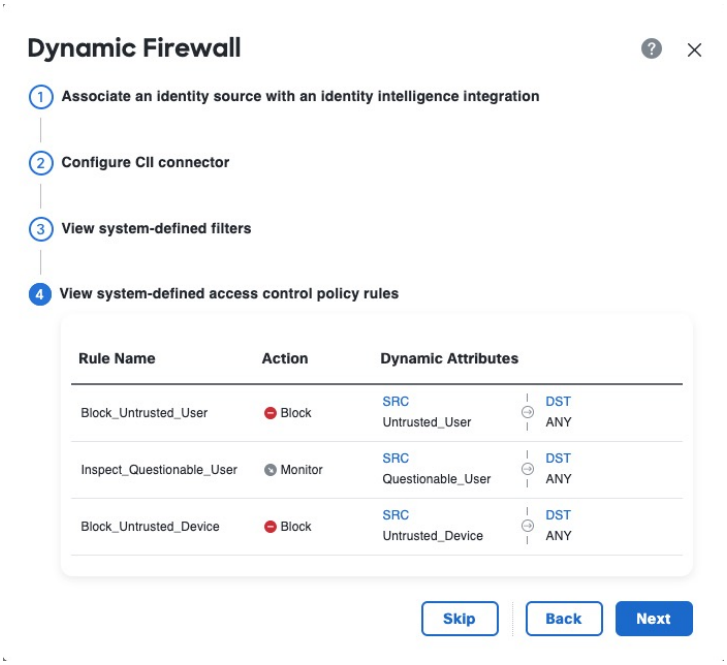
Step 3 Click **Next**.

Step 4 Continue with View system-defined access control rules, on page 2111.

View system-defined access control rules

This task allows you to review and decide whether to create system-defined access control rules for your dynamic firewall instance.

This task discusses access control rules created by the dynamic firewall.

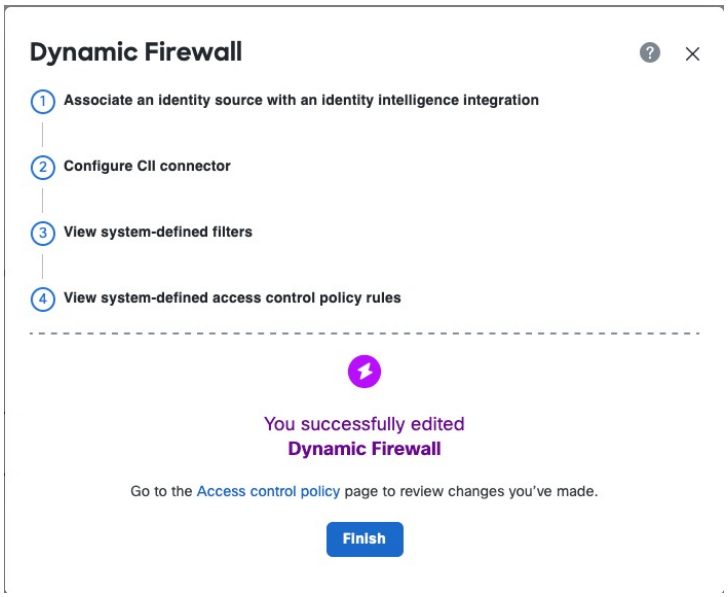


Before you begin

See View system-defined filters, on page 2110.

Procedure

Step 1 View the system-created access control rules.



The following figure shows an example.

Step 2 Choose one of these options:

- Click **Skip** to skip creating these access control rules. You can create your own anytime.
- Click **Next** to create an access control policy named Dynamic Firewall Policy with the rules shown in the preceding figure.
- Click **Back** to return to system-created filters.

Step 3 After you click **Next**, if you created access control rules successfully, the following page is displayed:

Edit the user exclusion list

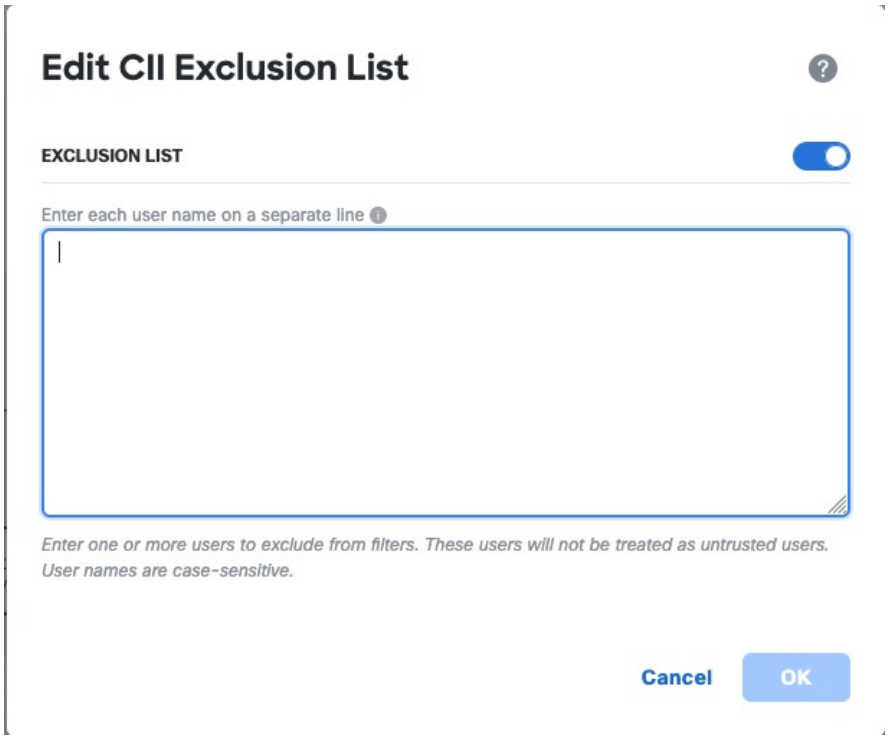
Specify users provided by Identity Intelligence as always being trusted.

You can instruct Identity Intelligence to treat specific users as trusted.

Before you begin

Configure the dynamic firewall as discussed in Create a dynamic firewall instance, on page 2107.

Procedure



Step 1 If you haven't already done so, log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector**.

Step 3 Click next to the name of the identity source.

Step 4 Click **Edit CII Exclusion List**.

The following dialog box is displayed.

Step 5 In the provided field, enter one user name in `username@domain.com` format on a line, press Enter, and enter another user name.

Each user name is considered as trusted by Identity Intelligence.

View and edit the system-created access control policy

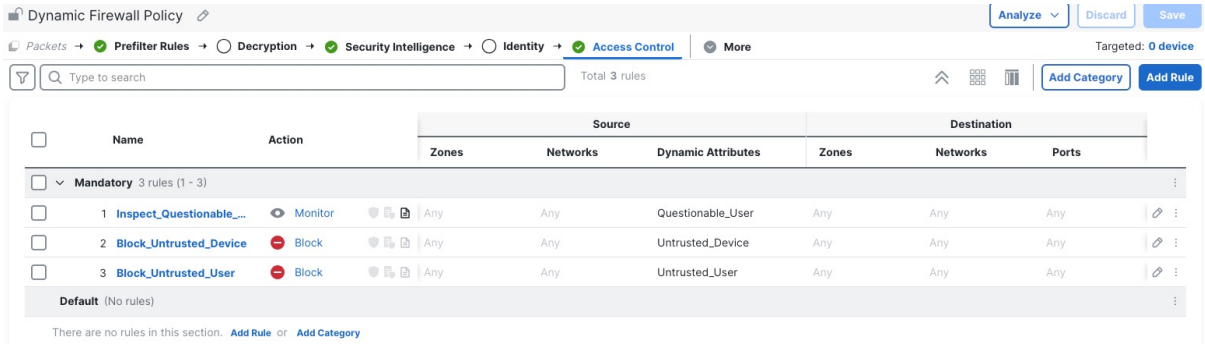
Customize the system-created access control policy by adding devices, changing rules, reordering rules, or deleting rules to meet your specific network security requirements.

This topic discusses how you can edit the system-created access control rules and policy. Initially, the policy isn't associated with any devices but if you want to use it you can add devices, change rules, reorder rules, or delete rules.

Before you begin

Complete the tasks described in View system-defined access control rules, on page 2111.

Follow these steps to view and edit the system-created access control policy:



Procedure

Step 1 If you haven't already done so, log in to the Secure Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Access Control**.

Step 3 Click **Edit** ( ) next to the policy named Dynamic Firewall Policy (or similar).

The following figure shows a sample access control policy.

Note that in this access control policy, only the rule set to monitor questionable users logs anything. To adjust the logging settings, see Logging settings for access control policies, on page 1584.

Step 4 Do any of the following:

- Target the access control policy at devices: Assign access control policy to devices, on page 1583.
- Edit the policy, including adding logging: Manage access control policies, on page 1575.
- Edit access control rules: Access control rule management, on page 1630.
- Set advanced policy options: Configure advanced settings for the access control policy, on page 2170.
- Associate other policies with this access control policy: Associate prefilter, decryption, and identity policies with an access control, on page 1585.

Create dynamic attributes filters

Create dynamic attributes filters that can be used as dynamic objects in access control policies to restrict access based on specific criteria such as group membership.

Dynamic attributes filters that you define using the Dynamic Attributes Connector are exposed in the Secure Firewall Management Center as dynamic objects that can be used in access control policies. For example, you could restrict access to an AWS server for the Finance Department to only members of the Finance group defined in Microsoft Active Directory.

For more information about access control rules, see Create access control rules using dynamic attributes filters, on page 2100.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:

- Add a new filter: click **Add** ( ).

- Edit or delete a filter: Click **More** (⋮), then click **Edit** or **Delete** at the end of the row.

Step 4 Enter the following information.

- **Name**: Unique name to identify the dynamic filter (as a dynamic object) in access control policy and in the Secure Firewall Management Center Object Manager (**External Attributes** > **Dynamic Object**).
- **Connector**: From the list, click the name of a connector to use.
- **Query**: Click Add .

Step 5 To add a query, enter the following information.

- **Key**: Click a key from the list. Keys are fetched from the connector.
- **Operation**: Click one of the following:
  - **Equals** to exactly match the key to the value.
  - **Contains** to match the key to the value if any part of the value matches.
- **Values**: Click either **Any** or **All** and click one or more values from the list. Click **Add another value** to add values to your query.

Step 6 Click **Show Preview** to display a list of networks or IP addresses returned by your query.

When you're finished, click **Save**.

What to do next

Verify the dynamic object in the Secure Firewall Management Center .

1. Log in to the Secure Firewall Management Center as a user with the Network Admin role at minimum.
2. Click **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.

The dynamic attribute query you created should be displayed as a dynamic object.

Disable the dynamic attributes connector

Disable the Dynamic Attributes Connector when you no longer wish to collect dynamic objects from cloud sources.

If you no longer wish to collect dynamic objects from cloud sources, you can disable the Dynamic Attributes Connector in the Secure Firewall Management Center.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not done so already.

Step 2 Click **Integration** > **Dynamic Attributes Connector**.

Step 3 Slide to **Disabled**.

Troubleshoot the Dynamic Attributes Connector

Troubleshoot using the Secure Firewall Management Center

Generate troubleshoot files to diagnose and resolve issues with the Secure Firewall Management Center.

This task discusses how to generate troubleshoot files for the Secure Firewall Management Center.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **System** (⚙) > **Health** > **Monitor**.

Step 3 In the left pane, click **Firewall Management Center**.

Step 4 At the top, click **System & Troubleshooting Details**.

Step 5 Click **Generate Troubleshooting Files**.

Step 6 Provide the files to Cisco TAC or to your Beta coordinator.

Recommendation: security requirements for network deployment

Install the dynamic attributes connector on a protected internal network. Although the dynamic attributes connector is configured to have only the necessary services and ports available, you must make sure that attacks cannot reach it.

If the dynamic attributes connector and the Secure Firewall Management Center reside on the same network, you can connect the Secure Firewall Management Center to the same protected internal network as the dynamic attributes connector.

Take steps to ensure that communications between appliances cannot be interrupted, blocked, or tampered with. Regardless of how you deploy your appliances, inter-system communication is encrypted. However, you must still protect against distributed denial of service (DDoS) or adversary-in-the-middle attacks.

Internet access requirements

By default, the dynamic attributes connector is configured to communicate with the Firepower System over the internet using HTTPS on port 443/tcp (HTTPS). If you do not want the dynamic attributes connector to have direct access to the internet, you can configure a proxy server.

This information details the URLs the dynamic attributes connector use to communicate with the Secure Firewall Management Center and with external servers.

Table 122: Dynamic Attributes Connector access requirements

URL	Reason
https://*fmc-ip***/api/fmc_platform/v1/auth/generatetoken**	Authentication
https://*fmc-ip***/api/fmc_config/v1/domain/***domain-id***/object/dynamicobjects**	GET and POST dynamic objects
https://*fmc-ip***/api/fmc_config/ v1/domain/***domain-id***/object/dynamicobjects/***object-id***/mappings?action=add**	Add mappings
https://*fmc-ip***/api/fmc_config/v1/domain/***domain-id*** /object/dynamicobjects/***object-id***/mappings?action=remove**	Remove mappings

Table 123: Dynamic Attributes Connector vCenter access requirements

URL	Reason
https://*vcenter-ip***/rest/com/vmware/cis/session**	Authentication
https://*vcenter-ip***/rest/vcenter/VM**	GET VM information
https://*NSX-ip***/api/v1/fabric/virtual-machines/***VM-id***	GET NSX-T tag associated with the virtual machine

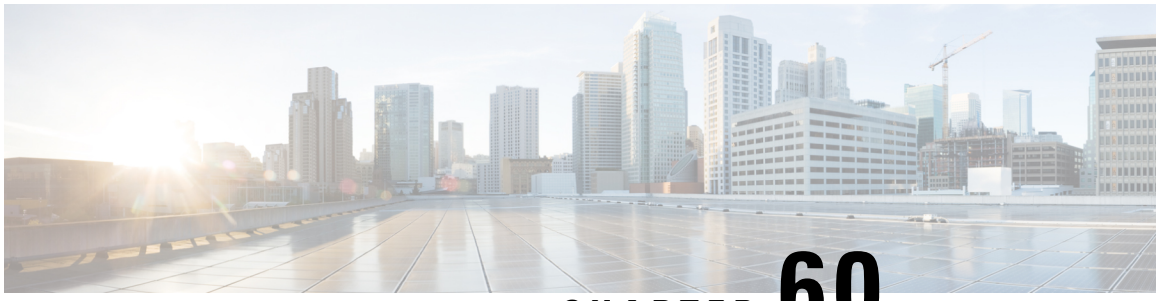
Migration from DockerHub to Amazon ECR

Docker images for the Dynamic Attributes Connector are being migrated from Docker Hub to Amazon Elastic Container Registry (Amazon ECR).

To use the new field packages, you must allow access through your firewall or proxy to all of the following URLs:

- https://public.ecr.aws
- https://csdac-cosign.s3.us-west-1.amazonaws.com
- https://d2glxqk2uabbnd.cloudfront.net
- https://d5l0dvt14r5h8.cloudfront.net

  For more information about Amazon Cloudfront URLs, see EKS Anywhere documentation.



Dynamic Attributes Connector Azure access requirements

The dynamic attributes connector calls built-in SDK methods to GET instance information. These methods internally call https://login.microsoft.com (for authentication) and https://management.azure.com (to GET instance information).

History for the dynamic attributes connector

This document provides the history of features for the dynamic attributes connector, including feature introductions and modifications across different product versions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Dynamic Attributes Connector	7.4.0	7.4.0	This feature is introduced. The Dynamic Attributes Connector is now included in the Secure Firewall Management Center. You can use the dynamic attributes connector to get IP addresses from cloud-based platforms such as Microsoft Azure in access control rules without having to deploy to managed devices. More information: • The dynamic attributes connector included with this product: About the dynamic attributes connector , on page 2061 • The standalone dynamic attributes connector: *Cisco Secure Dynamic Attributes Connector Configuration Guide* New/modified screen: **Integration** > **Dynamic Attributes Connector**

CHAPTER 60

Threat Intelligence Director

The topics in this chapter describe how to configure and use Threat Intelligence Director.

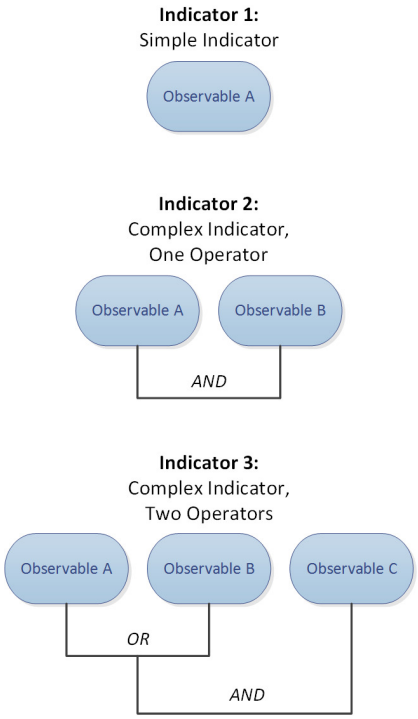
- Secure Firewall Threat Intelligence Director, on page 2121
- Requirements and prerequisites for threat intelligence director, on page 2124
- Set up Threat Intelligence Director, on page 2126
- Analyze Threat Intelligence Director incident and observation data , on page 2136
- View and change Threat Intelligence Director configurations , on page 2148
- Troubleshoot Threat Intelligence Director, on page 2164
- History for Threat Intelligence Director, on page 2166

Secure Firewall Threat Intelligence Director

Secure Firewall Threat Intelligence Director is a threat defense feature that

- operationalizes threat intelligence data to help aggregate intelligence data and configure defensive actions,
- analyzes threats in your environment, and
- supplements other Secure Firewall functionality, offering an additional line of defense against threats.

Threat intelligence data flow and components



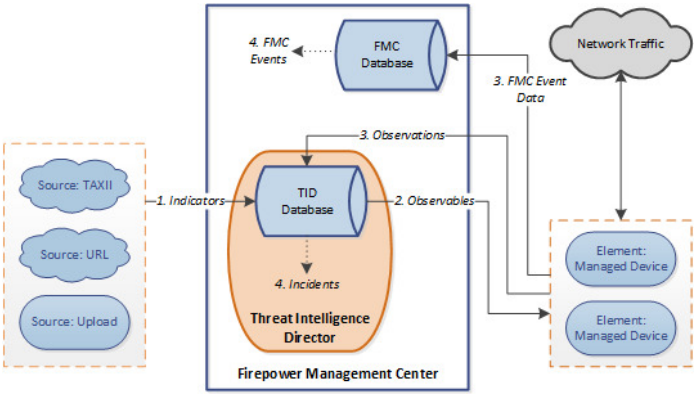
When configured on your hosting platform, Threat Intelligence Director ingests data from threat intelligence *sources* and publishes the data to all configured managed devices (*elements*.) For more information about the hosting platforms and elements supported in this release, refer to Platform, element, and license requirements, on page 2124.

Sources contain *indicators*, which contain *observables*. An indicator conveys all characteristics associated with a threat. Individual observables represent specific characteristics associated with the threat, such as an SHA-256 value.

- **Simple indicators**: Contain a single observable
- **Complex indicators**: Contain two or more observables

Observables and the AND/OR operators between them form an indicator's *pattern*, as illustrated in this example.

Figure 416: Example: indicator patterns



After the observables are published to the elements, the elements monitor traffic and report *observations* to the Firewall Management Center when the system identifies observables in traffic.

The Firewall Management Center collects observations from all elements, evaluates the observations against Threat Intelligence Director indicators, and generates or updates *incidents* associated with the observable's parent indicator(s).

An incident is *fully realized* when an indicator's pattern is fulfilled. An incident is *partially realized* if traffic matches one or more observables in the indicator but not the entire pattern. For more information, see Observation and incident generation, on page 2136.

This diagram shows data flow in a sample system configuration.

Figure 417: Firewall Management Center Data Flow

When a Threat Intelligence Director incident is fully or partially realized, the system takes the configured *action* (monitor, block, partially block, or no action). For details, refer to Factors that affect the action taken, on page 2144.

Threat Intelligence Director and Security Intelligence

Security Intelligence is a threat blocking feature that uses reputation intelligence to quickly block connections to or from IP addresses, URLs, and domains as part of your access control policy.

Security Intelligence uniquely provides access to industry-leading threat intelligence from Talos Intelligence Group. For more information on Security Intelligence, refer to Security intelligence, on page 1595.

Threat Intelligence Director enhances the system's ability to block connections based on security intelligence from third-party sources as follows:

- **Threat Intelligence Director supports additional traffic filtering criteria**—Security Intelligence allows you to filter traffic based on IP address, URL, and (if DNS policy is enabled) domain name. Threat Intelligence Director also supports filtering by these criteria and adds support for filtering on SHA-256 hash values.
- **Threat Intelligence Director supports additional intelligence ingestion methods**—With both Security Intelligence and Threat Intelligence Director, you can import threat intelligence into the system by either manually uploading flat files or configuring the system to retrieve flat files from a third-party host. Threat Intelligence Director provides increased flexibility in managing those flat files. In addition, Threat Intelligence Director can retrieve and ingest intelligence provided in Structured Threat Information eXpression (STIX™) format.
- **Threat Intelligence Director provides granular control of filtering actions**—With Security Intelligence, you can specify filtering criteria by network, URL, or DNS object. Security Intelligence objects, especially lists and feeds, can contain multiple IP addresses, URLs, or DNS domain names, but you can only block or not block based on entire objects, not on individual components of an object. With Threat Intelligence Director, you can configure filtering actions for individual criteria (that is, simple indicators or individual observables).
- **Threat Intelligence Director configuration changes do not require redeployment**—After you modify Security Intelligence settings in the access control policy, you must redeploy the changed configuration to managed devices. With Threat Intelligence Director, after initial deployment of the access control policy to the managed devices, you can configure sources, indicators, and observables without redeploying, and the system automatically publishes new Threat Intelligence Director data to the elements.

For information about what the system does when either Security Intelligence or Threat Intelligence Director could handle a particular incident, refer to Threat Intelligence Director - Firewall Management Center action prioritization , on page 2145.

Performance impact of Threat Intelligence Director

This reference provides information about the performance impacts that may occur when using Threat Intelligence Director with your security infrastructure.

Secure Firewall Management Center

In some cases, you may notice the following:

- The system may experience minor performance issues while ingesting particularly large STIX sources, and ingestion may take longer than expected to finish.
- The system may take up to 15 minutes to publish new or modified Threat Intelligence Director data down to elements.

Managed device

There is no exceptional performance impact. Threat Intelligence Director impacts performance identically to the Secure Firewall Management Center Security Intelligence feature.

Requirements and prerequisites for threat intelligence director

Model support

Any

Supported domains

Any

User roles

Admin

Threat Intelligence Director User

Additional requirements

The following topics explain additional requirements for using Threat Intelligence Director.

Platform, element, and license requirements

This reference provides the specific requirements for hosting platforms, managed elements, and licensing necessary to deploy and operate Threat Intelligence Director in your environment.

Hosting platforms

You can host Threat Intelligence Director on physical and virtual Secure Firewall Management Centers

- running version 6.2.2 or later,
- configured with a minimum of 15 GB of memory, and
- configured with REST API access enabled. See *Enabling REST API Access* in the *Cisco Secure Firewall Management Center Administration Guide*.

Elements

You can use any Secure Firewall Management Center-managed device as a Threat Intelligence Director element if the device is running version 6.2.2 or later.

Licensing

To configure the file policies for SHA-256 observable publishing, you need licensed devices with specific requirements:

- For smart licensed devices:
  - IPS License: For IPv4, IPv6, URL, and DNS detection and observables
  - Malware Defense License: For SHA-256 detection and observables
- For classic licensed devices:
  - Protect License: For IPv4, IPv6, URL, and DNS detection and observables
  - Malware License: For SHA-256 detection and observables

For more information, refer to Configure policies to support Threat Intelligence Director, on page 2127 and the *Licenses* chapter in the *Cisco Secure Firewall Management Center Administration Guide*.

Source requirements

This reference provides the specific requirements for different source types including STIX files and flat files that can be used for threat intelligence indicators.

STIX

Files must be STIX Version 1.0, 1.1, 1.1.1, or 1.2 and adhere to the guidelines in the STIX documentation: http://stixproject.github.io/documentation/suggested-practices/.

STIX files can include complex indicators.

The maximum size for a STIX file is 40 MB when configured via URL download or file upload. If you have STIX files larger than this, we recommend using a TAXII server.

Flat file

Files must be ASCII text files with one observable value on each line.

Flat files include only simple indicators, with one observable for each indicator.

Flat files can be up to 500 MB.

Threat Intelligence Director does **not** support:

- Delimiter characters separating observable values, for example, `observable,` are invalid.
- Enclosing characters around observable values, for example, `"observable"`, are invalid.

Each file should contain only one type of content:

- `SHA-256`—SHA-256 hash values.
- `Domain`—domain names as defined in RFC 1035.
- `URL`—URLs as defined in RFC 1738.

Note Threat Intelligence Director normalizes any URLs that contain port, protocol, or authentication information, and uses the normalized version when detecting indicators. For example, Threat Intelligence Director normalizes any of these URLs:

```
http://example.com/index.htm
http://example.com:8080/index.htm
example.com:8080/index.htm
example.com/index.htm
```

as:

```
example.com/index.htm
```

Or, for example, Threat Intelligence Director normalizes this URL:

```
http://abc@example.com:8080/index.htm
```

as

```
abc@example.com/index.htm/
```

- `IPv4`—IPv4 addresses as defined in RFC 791.

  Threat Intelligence Director does not accept CIDR blocks.

- `IPv6`—IPv6 addresses as defined in RFC 4291.

  Threat Intelligence Director does not accept prefix lengths.

Source content limitations

The system ingests and matches on only the first 1,000 characters of a URL observable.

Set up Threat Intelligence Director

This task establishes a fully functional Threat Intelligence Director deployment by ensuring proper installation requirements, policy configuration, and intelligence source integration.

Setting up Threat Intelligence Director involves configuring multiple components in a specific sequence to ensure optimal threat intelligence capabilities.

Note If you encounter an issue during Threat Intelligence Director configuration or operation, refer to Troubleshoot Threat Intelligence Director, on page 2164.

Procedure

Step 1 Ensure that your installation meets the requirements for running Threat Intelligence Director.

See Platform, element, and license requirements, on page 2124

Step 2 For each managed device, configure the policies required to support Threat Intelligence Director and deploy those policies to the devices.

See Configure policies to support Threat Intelligence Director, on page 2127.

You can configure elements before or after you ingest intelligence data sources.

Step 3 Configure the intelligence sources that you want Threat Intelligence Director to ingest.

See Source requirements, on page 2125 and the topics under Options for ingesting data sources, on page 2128.

Step 4 Publish data to the elements if you have not yet done so.

See Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.

What to do next

- Include Threat Intelligence Director in your regularly scheduled backups. See About backing up and restoring Threat Intelligence Director data, on page 2135.

  If your Secure Firewall Management Center deployment is a high availability configuration, see also *Firewall Management Center High Availability Disaster Recovery* in the *Cisco Secure Firewall Management Center Administration Guide*.

- (Optional) Grant administrative access to Threat Intelligence Director functionality as desired. See User roles with Threat Intelligence Director access, on page 2135 and the *Users* chapter in the *Cisco Secure Firewall Management Center Administration Guide*.

- As needed during operation, fine-tune your configuration. For example, add observables that produce false positive incidents to the Do Not Block list. See View and change Threat Intelligence Director configurations , on page 2148.

Configure policies to support Threat Intelligence Director

This task configures access control policies to publish Threat Intelligence Director data from the Firewall Management Center to your managed devices and maximize observation and event generation.

You must configure access control policies to publish Threat Intelligence Director data from the Firewall Management Center to your managed devices (elements). In addition, we recommend that you configure your access control policies to maximize observation and Firewall Management Center event generation.

For each managed device that you want to support Threat Intelligence Director, perform these steps to configure the associated access control policy.

Elements that are configured to use Threat Intelligence Director after data has been published will automatically receive all currently-published observables.

Procedure

Step 1 Verify that the **Enable Threat Intelligence Director** check box is checked in **General Settings** of the access control policy. To navigate to **General Settings**, choose **Policies** > **Access Control heading** > **Access Control**, and click **Edit** > **More** > **Advanced Settings**. This option is enabled by default.

For more information, see General settings, on page 2172.

Step 2 Add rules that allow (rather than trust) connections to the access control policy if they are not already present. Threat Intelligence Director requires that the access control policy specify at least one rule.

Because Threat Intelligence Director depends on inspection, ensure that you allow traffic, rather than trust it, because the purpose of trusting traffic is to bypass inspection. For more information, see Creating a basic access control policy, on page 1575.

Step 3 If you choose **Intrusion Prevention** as the default action for the access control policy and you want to decrypt traffic for TID detection, associate a decryption policy with the access control policy; see Associate prefilter, decryption, and identity policies with an access control, on page 1585.

Step 4 If you want **SHA-256** observables to generate observations and Secure Firewall Management Center events:

a) Create a file policy containing one or more **Malware Cloud Lookup** or **Block Malware** file rules.

For more information, see Configure file policies, on page 2023.

b) Associate this file policy with one or more rules in the access control policy.

Step 5 If you want **IPv4**, **IPv6**, **URL**, or **Domain Name** observations to generate connection and security intelligence events, enable connection and security intelligence logging in the access control policy:

a) In access control rules where you invoked a file policy, enable **Log at End of Connection** and **File Events: Log Files**, if not already enabled.

For more information, see *Logging Connections with Access Control Rules* in the *Cisco Secure Firewall Management Center Administration Guide*.

b) Verify that default logging (**DNS Policy**, **Networks**, and **URLs**) is enabled in your Security Intelligence settings.

For more information, see *Logging Connections with Security Intelligence* in the *Cisco Secure Firewall Management Center Administration Guide*.

Step 6 Deploy configuration changes; see Deploy configuration changes, on page 135.

What to do next

Complete the remaining action items in Set up Threat Intelligence Director, on page 2126.

Options for ingesting data sources

Choose a configuration option based on the data type and delivery mechanism you want to use.

For more information about these data types, refer to Source requirements, on page 2125.

Table 124: Options for ingesting data sources

Data Type	Ingestion Options
STIX	• Ingest STIX feeds from a TAXII server. Refer to Fetch TAXII feeds to use as sources, on page 2129 • Download STIX data from a URL. Refer to Fetch sources from a URL, on page 2130 • Upload a STIX file. Refer to Upload a local file to use as a source, on page 2132
Flat file	• Download data from a URL. Refer to Fetch sources from a URL, on page 2130 • Upload a flat file. Refer to Upload a local file to use as a source, on page 2132

Fetch TAXII feeds to use as sources

This task establishes TAXII feeds as threat intelligence sources to automatically retrieve STIX data for threat detection and analysis.

TAXII feeds provide structured threat intelligence data that can enhance your security posture by automatically updating threat indicators. If you encounter an issue during TID configuration or operation, see Troubleshoot Threat Intelligence Director, on page 2164.

Before you begin

Before configuring TAXII feeds, ensure your source meets the requirements in Source requirements, on page 2125.

Follow these steps to fetch TAXII feeds to use as sources:

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources**.

Step 2 Click **Add** (+).

Step 3 Choose `TAXII` as the **Delivery** method for the source.

Step 4 Enter information.

- If the host server requires an encrypted connection, configure the **SSL Settings** as described in Configure TLS/SSL settings for a Threat Intelligence Director source, on page 2133.
- You cannot change the **Action** selection for TAXII sources.

`Block` is not an **Action** option for TAXII sources, as STIX data can contain complex indicators, which the system cannot block. Devices (elements) store and take action based on single observables; they cannot take action based on multiple observables.

However, after ingestion, you can block individual observables and simple indicators obtained from the source. For more information, see Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159.

- It may take some time for the list of feeds to load.
- The **Update Every** interval specifies the frequency that Threat Intelligence Director retrieves updates from the TAXII source.

  Set an update frequency that makes sense for how often the data source is updated. For example, if the source is updated 3 times per day, set your update interval to 1440/3 or 480 minutes to regularly capture the latest data.
- After the number of days you specify for **TTL**, Threat Intelligence Director deletes:
  - all indicators for the source that are not included in subsequent source updates.
  - all observables not referenced by a surviving indicator.

Note If the source contains no updates for the number of days specified for TTL and the source checksum remains unchanged, downloads are treated as feeds with no updates. For observables to receive a new TTL value, the source must contain a few updates.

Step 5 If you want to immediately begin publishing to elements, confirm that the **PUBLISH Slider** ( ) is enabled.

When this option is enabled, the system automatically publishes the initial source data and any subsequent changes.

For details, see Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.

Step 6 Click **Save**.

What to do next

- TAXII feeds can contain a lot of data. It may take some time for the system to ingest all of the data. To view ingestion status, refresh the Sources page.
- If you see an error for this source, hover over status for details.
- If you are doing initial Threat Intelligence Director configuration, return to Set up Threat Intelligence Director, on page 2126.

Fetch sources from a URL

Configure a URL source if you want Threat Intelligence Director to fetch files from a host.

If you encounter an issue during TID configuration or operation, refer to Troubleshoot Threat Intelligence Director, on page 2164.

Before you begin

Follow these steps to fetch sources from a URL:

Procedure

Step 1 Make sure your source meets the requirements in Source requirements, on page 2125

Step 2 Choose **Integration** > **Intelligence** > **Sources**.

Step 3 Click **Add** (+).

Step 4 Choose **URL** as the **Delivery** method for the source.

Step 5 Complete the form.

- If you are ingesting a flat file, choose a **Type** that describes the data contained within the source.
- If the host server requires an encrypted connection, configure the **SSL Settings** as described in Configure TLS/SSL settings for a Threat Intelligence Director source, on page 2133.
- For Name: To simplify sorting and handling of incidents based on Threat Intelligence Director indicators, use a consistent naming scheme across sources. For example, <source>-<type>.

  Including the source name simplifies returning to the source for further information or feedback.

  Be sure to enter the name consistently. For example, for a source with IPv4 addresses, you might always use IPV4 (not IPv4 or ipv4 or IP_v4 or IP_V4 or IP-v4 or IP-v4, IP-V4, etc.)
- If you are ingesting a STIX file, **Block** is not an **Action** option, as STIX data can contain complex indicators, which the system cannot block. Devices (elements) store and take action based on single observables; they cannot take action based on multiple observables.

  However, after ingestion, you can block individual observables and simple indicators obtained from the source. For more information, see Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159.
- Set an update frequency that makes sense for how often the data source is updated. For example, if the source is updated three times per day, set your update interval to 1440/3 or 480 minutes to regularly capture the latest data.
- After the number of days you specify for the **TTL** interval, Threat Intelligence Director deletes:
  - all indicators from the source that are not included in subsequent source updates.
  - all observables not referenced by a surviving indicator.

Note If the source contains no updates for the number of days specified for TTL and the source checksum remains unchanged, downloads are treated as feeds with no updates. For observables to receive a new TTL value, the source must contain a few updates.

Step 6 If you want to immediately begin publishing to elements, confirm that the **Publish Slider** () is enabled.

When this option is enabled, the system automatically publishes the initial source data and any subsequent changes.

For details, see Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.

Step 7 Click **Save**.

What to do next

- To view ingestion status, refresh the Sources page. If you see an error, hover over status for details.
- If you are doing initial Threat Intelligence Director configuration, return to Set up Threat Intelligence Director, on page 2126.

Upload a local file to use as a source

This task allows you to manually upload a local STIX or flat file to create threat intelligence indicators in Threat Intelligence Director.

Use this procedure for a one-time manual upload of a local file.

When ingesting a STIX file, Threat Intelligence Director creates a simple or complex indicator from the contents of the STIX file.

When ingesting a flat file, Threat Intelligence Director creates a simple indicator for each observable value in the file.

If you encounter an issue during Threat Intelligence Director configuration or operation, refer to Troubleshoot Threat Intelligence Director, on page 2164

Procedure

Step 1 Make sure your file meets the requirements in Source requirements, on page 2125

Step 2 Choose **Integration** > **Intelligence** > **Sources**.

Step 3 Click **Add** ().

Step 4 Choose **Upload** as the **Delivery** method for the source.

Step 5 Complete the form.

- If you are uploading a flat file, choose a **Type** that describes the data contained within the source.
- For Name: To simplify sorting and handling of incidents based on Threat Intelligence Director indicators, use a consistent naming scheme across sources. For example, <source>-<type>.

  Including the source name simplifies returning to the source for further information or feedback.

  Be sure to enter the name consistently. For example, for a source with IPv4 addresses, you might always use IPV4 (not IPv4 or ipv4 or IP_v4 or IP_V4 or IP-v4 or IP-v4, IP-V4, etc.)

- If you are uploading a STIX file, **Block** is not an **Action** option, because STIX data can contain complex indicators. Devices (elements) store and take action based on single observables; they cannot take action based on multiple observables.

  However, you can block a simple indicator at the indicator or observable level. For more information, see Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159.

- After the number of days you specify for the **TTL** interval, Threat Intelligence Director deletes:
  - all of the source's indicators that are not included in a subsequent upload.
  - all observables not referenced by a surviving indicator.

Note If the source contains no updates for the number of days specified for TTL and the source checksum remains unchanged, downloads are treated as feeds with no updates. For observables to receive a new TTL value, the source must contain a few updates.

Step 6 If you want to immediately begin publishing to elements, confirm that the **Publish Slider** ( ) is enabled.

If you do not publish the source at ingestion, you cannot publish all source indicators at once later; instead, you must publish each observable individually. See Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.

Step 7 Click **Save**.

What to do next

- To view ingestion status, refresh the Sources page. If you see an error, hover over status for details.
- If you are doing initial Threat Intelligence Director configuration, return to Set up Threat Intelligence Director, on page 2126.

Handling of duplicate indicators

If a single indicator is included in multiple sources:

Each instance of the indicator generates an incident, so one encounter with a particular threat may generate multiple incidents.

To avoid future duplicate incidents, pause publishing of all but one of the duplicated indicators. Refer to Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.

Configure TLS/SSL settings for a Threat Intelligence Director source

Configure TLS/SSL settings to establish secure encrypted connections with host servers that require certificate-based authentication.

Configure **SSL Settings** if the host server requires an encrypted connection.

Before you begin

- Configure a `TAXII` or `URL` source, as described in Fetch TAXII feeds to use as sources, on page 2129 or Fetch sources from a URL, on page 2130.

Follow these steps to configure TLS/SSL settings for a Threat Intelligence Director source:

Procedure

Step 1 In the **Edit Source** dialog box, expand the **SSL Settings** section.

Step 2 If your server certificate is self-signed:

a) Enable **Self-Signed CERTIFICATE**.

b) Choose a **SSL Hostname Verification** method.

- `Strict`—Threat Intelligence Director requires the source **URL** to match the hostname provided in the server certificate.

  If the hostname includes a wildcard, TID cannot match more than one subdomain.

- `Browser Compatible`—Threat Intelligence Director requires the source **URL** to match the hostname provided in the server certificate.

  If the hostname includes a wildcard, TID matches all subdomains.

- `Allow All`—Threat Intelligence Director does not require the source **URL** to match the hostname provided in the server certificate.

For example, if `subdomain1.subdomain2.cisco.com` is your source **URL** and `*.cisco.com` is the hostname provided in the server certificate:

- `Strict` hostname verification fails.
- `Browser Compatible` hostname verification succeeds.
- `Allow All` hostname verification ignores the hostname values completely.

c) For **Server CERTIFICATE**:

- If you have access to the PEM-encoded self-signed server certificate, open the certificate in a text editor and copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines. Enter this entire string into the field.
- If you do not have access to the self-signed server certificate, leave the field blank. After you save the source, Threat Intelligence Director retrieves the certificate from the server.

Step 3 If your server requires a user certificate:

a) Enter a **User certificate**:

Open the PEM-encoded certificate in a text editor and copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines. Enter this entire string into the field.

b) Enter a **User PRIVATE KEY**:

Open the PRIVATE KEY file in a text editor and copy the entire block of text, including the `BEGIN RSA PRIVATE KEY` and `END RSA PRIVATE KEY` lines. Enter this entire string into the field.

What to do next

- Take note of the certificate's expiration date. You may want to set a calendar reminder to enter a new server certificate after the current certificate expires.
- Continue configuring the source:
  - Fetch TAXII feeds to use as sources, on page 2129
  - Fetch sources from a URL, on page 2130

User roles with Threat Intelligence Director access

You can use Firewall Management Center user accounts to access the Threat Intelligence Director menus and pages.

The user roles that can access Threat Intelligence Director menus and pages are:

- Accounts with the **Admin** or **Threat Intelligence Director User** user role.
- Accounts with a custom user role containing the **Intelligence** permission.

In addition, you can use Firewall Management Center user accounts with the **Admin**, **Access Admin**, or **Network Admin** user role to enable or disable Threat Intelligence Director in your access control policies.

For more information about user accounts, refer to the *Users for the Firewall Management Center* chapter in the *Cisco Secure Firewall Management Center Administration Guide*.

About backing up and restoring Threat Intelligence Director data

You can use the Firewall Management Center to back up and restore all of the data needed for Threat Intelligence Director: Element data, security intelligence events, connection events, Threat Intelligence Director configurations, and Threat Intelligence Director data. For more information, refer to the *Backup/Restore* chapter in the *Cisco Secure Firewall Management Center Administration Guide*.

Note If you host Threat Intelligence Director on the active Firewall Management Center in a high availability configuration, the system does not synchronize Threat Intelligence Director configurations and Threat Intelligence Director data to the standby Firewall Management Center. We recommend performing regular backups of Threat Intelligence Director data on your active Firewall Management Center so that you can restore the data after failover.

Before you attempt to restore the Threat Intelligence Director data on the active Firewall Management Center, pause synchronization on the active peer. For more information, see *Pausing Communication Between Paired Firepower Management Centers* in the *Cisco Secure Firewall Management Center Administration Guide*.

Table 125: Threat Intelligence Director-Related Backup and Restore File Contents

Threat Intelligence Director-Related File Contents	Backup Selection	Restore Selection
Element data	**Back Up Configuration**	**Restore Configuration Data**
Secure Firewall Management Center event data	**Back Up Events**	**Restore Event Data**
Threat Intelligence Director configurations and Threat Intelligence Director data	**Back Up Threat Intelligence Director**	**Restore Threat Intelligence Director Data**

Analyze Threat Intelligence Director incident and observation data

To analyze incident and observation data generated by Threat Intelligence Director elements, use the Incidents table and Incident Details page.

Observation and incident generation

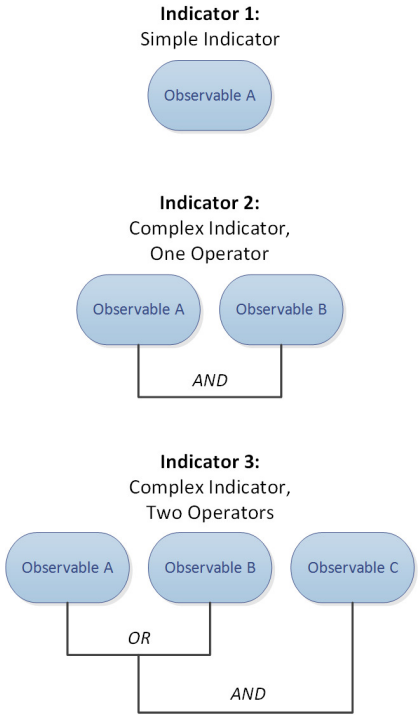
Observation and incident generation is a threat detection process that

- generates an incident when the first observable for an indicator is seen in traffic,
- fully realizes simple indicators after a single observation,
- partially realizes complex indicators until additional observations fulfill their pattern, and
- triggers new incidents for subsequent observations after an incident is fully realized.

How observation and incident generation works

Threat Intelligence Director generates an incident when the first observable for an indicator is seen in traffic. Simple indicators are fully realized after a single observation. Complex indicators are partially realized until one or more additional observations fulfill their pattern. Complex indicators need not necessarily be fulfilled during a single transaction; each observable can be fulfilled separately over time by different transactions.

Note When evaluating an indicator's pattern, Threat Intelligence Director ignores unsupported and invalid objects and observables on the Do Not Block list.



After an incident is fully realized, subsequent observations trigger new incidents.

If a particular indicator exists in multiple sources, you may see duplicate incidents. For more information, see Troubleshoot Threat Intelligence Director, on page 2164.

Incidents are generated only by actual traffic. If there is an observable for URL B, and a user visits URL A which displays a link to URL B, no incident occurs unless the user clicks the URL B link.

Indicator pattern processing example

Figure 418: Indicator patterns

If Threat Intelligence Director ingested the observables from the example above and the observables were seen in order, incident generation would proceed as follows:

1. When the system identifies Observable A in traffic, Threat Intelligence Director:
   - Generates a fully-realized incident for Indicator 1.
   - Generates partially-realized incidents for Indicator 2 and Indicator 3.
2. When the system identifies Observable B in traffic, Threat Intelligence Director:
   - Updates the incident to fully-realized for Indicator 2, since the pattern was fulfilled.
   - Updates the incident to partially-realized for Indicator 3.
3. When the system identifies Observable C in traffic, Threat Intelligence Director:
   - Updates the incident to fully-realized for Indicator 3, since the pattern was fulfilled.
4. When the system identifies Observable A for a second time, Threat Intelligence Director:
   - Generates a new fully-realized incident for Indicator 1.
   - Generates new partially-realized incidents for Indicator 2 and Indicator 3.

View and manage incidents

This task allows you to view and manage incidents to monitor security threats and track investigation progress.

The Incidents page displays summary information for up to 1.1 million of the most recent Threat Intelligence Director incidents. Refer to Incident summary information, on page 2139.

Before you begin

- Configure the feature as described in Set up Threat Intelligence Director, on page 2126.
- Understand observation and incident generation, as described in Observation and incident generation, on page 2136.

Follow these steps to view and manage incidents:

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Incidents**.

Step 2 View your incidents:

- Click **Filter** () to add one or more filters. The default filter duration is six hours. For more information, refer to Filter Threat Intelligence Director data in table views, on page 2156.
- To view the date and time an incident was last updated by Threat Intelligence Director, hover the cursor over the value in the **Last Updated** column.
- To view more information about the indicator associated with the incident, click the text in the **Indicator Name** column. Refer to View and manage indicators, on page 2152.

Step 3 View additional details by clicking a value in the **Incident ID** column.

For an explanation of the details you see, refer to Incident details, on page 2139.

- To view indicator details, click an indicator value (for example, an IP address or SHA-256 value) under the **Indicator** heading in the lower section of the window.
- To view observation details, click the arrow to the left of an observation immediately under the **Observations** heading.
- To view this incident on the Security Intelligence Events page, click the **Events** link in the observation details section.

Step 4 (Optional) Enter descriptive information on the incident details page:

To maximize consistency and usefulness of the options listed, plan ahead and document your naming conventions, category choices, and confidence level criteria.

- Enter any value you like in the following fields: **Name**, **Description**, and **Category**.
- Click a rating level for **Confidence**.

- Indicate the status of your investigation into the incident by choosing a value from the drop-down list in the **Status** field.

Incident summary information

The Incidents page displays summary information for all Threat Intelligence Director incidents.

Table 126: Incident summary information

Field	Description
Last Updated	The number of days since either the system or a user last updated the incident. To view the date and time of the update, hover the cursor over the value in this column.
Incident ID	The unique identifier for the incident. This ID has the format: `<type>-<date>-<number>` • `<type>`—The type of indicator or observable involved in the incident. For simple indicators, this value indicates the observable type: `IP` (IPv4 or IPv6), `URL` (URL), `DOM` (domain), or `SHA` (SHA-256). For complex indicators, this value is `COM`. • `<date>`—The date (*yyyymmdd*) on which the incident was created. • `<number>`—The daily incident number, that is, a number specifying where the incident occurs in the daily sequence of incidents. Note that this sequence starts at 0. For example, `DOM-20170828-10` is the 11th incident created on that day. Next to the identifier, the system displays an icon that indicates whether the incident is **Partially Realized** or **Fully Realized**. For more information, refer to Observation and incident generation, on page 2136.
Indicator Name	The name of the indicator involved in the incident. To view additional information about the indicator, click the value in this column. Refer to View and manage indicators, on page 2152.
Type	The type of indicator involved in the incident. • Indicators that contain a single observable display the data type (`URL`, `SHA-256`, etc.) • Indicators that contain two or more observables display as `Complex`.
Action Taken	The action taken by the system in relation to the incident. For more information, refer to Incident details, on page 2139.
Status	The status of your investigation into the incident. For more information, refer to Incident details, on page 2139.
Delete ( )	Clicking this icon permanently deletes the incident.

Incident details

The Incident Details window displays information about a single Threat Intelligence Director incident. This window is divided into two sections:

• Incident details: Basic information, on page 2140
• Incident details: Indicators and observations, on page 2141

Incident details: Basic information

The upper section of the Incident Details window provides the information described below.

Table 127: Basic incident information fields

Field	Description
Partially-Realized *IncidentID* or **Fully-Realized** *IncidentID*	An icon indicating the status of the incident (partially-realized or fully-realized), as well as the unique identifier for the incident. **Note** When determining the status of an incident, Threat Intelligence Director ignores unsupported and invalid observables and observables on the Do Not Block list.
Opened	The date and time the incident was last updated.
Name	A custom, optional incident name that you enter manually. Tip: If there is information from the source in the Description field (in the bottom part of the window), use information from that field to name the incident.
Description	A custom, optional incident description that you enter manually. Tip: If there is information from the source in the Description field (in the bottom part of the window), use information from that field to describe the incident.
Observations	The number of observations within the incident.
Confidence	An optional rating that you can manually select to indicate the relative importance of the incident.
Action Taken	The action taken by the system: `Monitored`, `Blocked`, or `Partially Blocked`. `Partially Blocked` indicates that the incident contained both `Monitored` and `Blocked` observations. **Note** The **Action Taken** indicates the action taken by the system, not necessarily the action selected in Threat Intelligence Director. For more information, see Threat Intelligence Director - Firewall Management Center action prioritization , on page 2145.
Category	A custom, optional tag or keyword that you manually add to the incident.

Field	Description
Status	A value indicating the current stage of your analysis of the incident. All incidents are `New` until you change the **Status** for the first time. This field is optional. Depending on the needs of your organization, consider using the status values as follows: • `New`—The incident requires investigation, but you have not started investigating. • `Open`—You are currently investigating the incident. • `Closed`—You investigated the incident and took action. • `Rejected`—You investigated the incident and determined there was no action to take.
Delete ( )	Clicking this icon permanently deletes this incident.

Incident details: Indicators and observations

The lower section of the Incident Details window provides an in-depth view of indicator and observation information. This information is organized as **Indicator** fields, the indicator pattern, and **Observations** fields.

Indicator section

When you first view indicator details, this section displays only the indicator name.

Click the indicator name to view the indicator on the Indicators page.

Click the down arrow next to the indicator name to view more indicator details without leaving the incident. Detail fields include:

Table 128: Indicator fields

Field	Description
Description	The indicator description provided by the source.
SOURCE	The source that contained the indicator. Click this link to access full source details.
Expires	The date and time the incident will expire, based on the source's **TTL** value.
Action	The action associated with the indicator. For more information, see Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159.
Publish	The publish setting for the indicator. For more information, see Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.
Download STIX	If the source type is **STIX**, click this button to download the STIX file.

Indicator pattern

The indicator pattern is a graphical representation of the observables and operators that comprise the indicator. Operators link the observables within the indicator. AND relationships are indicated with the **AND** operator. OR relationships are indicated with the **OR** operator OR by a close grouping of several observables.

If an observable in the pattern has already been seen, the observable box is white. If an observable has not already been seen, the observable box is grey.

In the indicator pattern:

- Click the **Add to Do-Not-Block List** button to add the observable to the Do Not Block list. This icon is present in both white and grey observable boxes. For more information, see Adding Threat Intelligence Director observables to the Do Not Block list, on page 2163.
- If you hover the cursor over a white observable box, the system highlights the related observation in the **Observations** section.
- If you click a white observable box, the system highlights the related observation in the **Observations** section, scrolls that observation into view (if multiple observations are present), and expands that observation's detailed display.
- If you hover the cursor over or click a grey observable box in the indicator pattern, there is no change in the **Observations** section. Because the observable is unseen, there are no observation details to display yet.

Observations section

By default, the **Observations** section displays summary information, which includes:

- The type of observable that triggered the observation (for example, **Domain**)
- The data that comprises the observable
- Whether the observation is the first observation or a subsequent observation (for example, **1st** OR **3rd**)

Note If a single observable has been seen three or more times, Threat Intelligence Director displays the first and last observation details. The details for intermediary observations are not available.

- The date AND time of the observation
- The action configured for the observable

If you hover the cursor over an observation in the **Observations** section, the system highlights the related observable in the indicator pattern.

If you click an observation in the **Observations** section, the system highlights the related observable(s) in the indicator pattern and scrolls the first related observable into view (if multiple observables are present). Clicking an observation also expands the details of the observation in the **Observations** section.

Observation details include these fields:

Table 129: Observation detail fields

Field	Description
SOURCE	The source IP address and port for the traffic that triggered the observation.

Field	Description
DESTINATION	The destination IP address and port for the traffic that triggered the observation.
ADDITIONAL INFORMATION	DNS and authentication information related to the traffic that triggered the observation.
Events	This clickable link displays if the observation generated connection, security intelligence, file, or malware events. Click the link to view the events in the Secure Firewall Management Center event table; see *Cisco Secure Firewall Management Center Administration Guide*.

View events for a Threat Intelligence Director observation

View events associated with Threat Intelligence Director observations to analyze security incidents and understand system actions taken.

For more information about the Secure Firewall Management Center events that Threat Intelligence Director observations generate, refer to Threat Intelligence Director observations in Secure Firewall Management Center events, on page 2144.

The system action logged for Threat Intelligence Director-related events can vary, depending on the interaction of Threat Intelligence Director and other Secure Firewall Management Center features. For more information about action prioritization, refer to Threat Intelligence Director - Firewall Management Center action prioritization , on page 2145.

Before you begin

- Configure the feature as described in Set up Threat Intelligence Director, on page 2126.
- Confirm that you enabled event logging required for Threat Intelligence Director in your access control policy, as described in Configure policies to support Threat Intelligence Director, on page 2127.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Incidents**.

Step 2 Click the **Incident ID** value for the incident.

Step 3 Click the observation in the **Indicator** section to display the observation box.

Step 4 Expand the observation box by clicking the arrow in the upper-left corner of the box.

Step 5 Click the **Events** link in the observation information. For more information on the Security Intelligence display, refer to the *Connection and Security Intelligence Events* chapter in the *Cisco Secure Firewall Management Center Administration Guide*.

Threat Intelligence Director observations in Secure Firewall Management Center events

If you fully configure your access control policy, Threat Intelligence Director observations generate specific Secure Firewall Management Center events.

Table 130: Secure Firewall Management Center Events Generated by Observations

Observation Content	Connection Events Table	Security Intelligence Events Table	File Events Table	Malware Events Table
SHA-256	Yes	No	Yes	Yes, if disposition is Malware or Custom Detection.
Domain Name, **URL**, or **IPv4/IPv6**	Yes Threat Intelligence Director-related connection events are identified with a Threat Intelligence Director-related **Security Intelligence Category** value.	Yes Threat Intelligence Director-related security intelligence events are identified with a Threat Intelligence Director-related **Security Intelligence Category** value.	No	No

Factors that affect the action taken

Factors that affect the action taken are system conditions that determine when the system takes action and what action the system takes when it detects traffic that matches a Threat Intelligence Director observable.

Action determination factors

The system considers these factors when determining actions:

- Features like Security Intelligence take action before Threat Intelligence Director does. For details, refer to Threat Intelligence Director - Firewall Management Center action prioritization , on page 2145.
- Generally, the action configured for an observable (which may differ from the action configured for its parent indicator or source) is the action that will be taken.
- Because Structured Threat Information eXpression (STIX) sources can contain complex indicators, the Action setting for the source can be set only to Monitor. However, individual simple indicators or observables contained in a STIX feed or file can be set to Block.
- Action settings for indicators and observables can be inherited or individually configured to override inheritance. Refer to Inheritance in Threat Intelligence Director configurations, on page 2157 and Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159.
- Traffic that might otherwise be actionable might be on a Do Not Block list. For details, refer to Add Threat Intelligence Director observables to a Do Not Block list, on page 2164.
- The configured action is taken for both partially- and fully-realized incidents.
- An incident based on a complex indicator can be partially blocked. This can occur if the indicator includes both monitored and blocked observations.

- The actions the system takes are affected when publishing is paused. Refer to Pausing publishing, on page 2160 and Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.
- Pausing the Threat Intelligence Director feature prevents all actions. After you resume the feature, actionable data may be different from before. For details, refer to Pause Threat Intelligence Director and purge Threat Intelligence Director data from elements, on page 2161.

Threat Intelligence Director - Firewall Management Center action prioritization

If Threat Intelligence Director observable actions conflict with Firewall Management Center policy actions, the system prioritizes actions as follows:

- Security Intelligence Do Not Block
- TID Block
- Security Intelligence Block
- TID Monitor
- Security Intelligence Monitor

Specifically:

Table 131: Threat Intelligence Director URL Observable Action vs. Security Intelligence Action

Setting: Security Intelligence Action	Setting: Threat Intelligence Director Observable Action	Threat Intelligence Director Incidents Field: Action Taken	Security Intelligence Events Fields:		
			Action	Security Intelligence Category	Reason
`Do Not Block`	`Monitor` or `Block`	No TID incident	No Security Intelligence event		
`Block`	`Monitor`	`Blocked`	`Block`	as determined by system analysis; see Security intelligence categories, on page 1602	`URL Block`
	`Block`	`Blocked`	`Block`	`TID URL Block`	`URL Block`
`Monitor`	`Monitor`	`Monitored`	Determined by access control rules processed after Security Intelligence and TID.	`TID URL Monitor`	`URL Monitor`
	`Block`	`Blocked`	`Block`	`TID URL Block`	`URL Block`

Table 132: Threat Intelligence Director IPv4/IPv6 Observable Action vs. Security Intelligence Action

Setting: Security Intelligence Action	Setting: Threat Intelligence Director Observable Action	Threat Intelligence Director Incidents Field: Action Taken	Security Intelligence Events Fields:		
			Action	Security Intelligence Category	Reason
`Do Not Block`	`Monitor` or `Block`	No TID incident	No Security Intelligence event		
`Block`	`Monitor`	No TID incident	`Block`	as determined by system analysis; see Security intelligence categories, on page 1602	`IP Block`
	`Block`	`Blocked`	`Block`	`TID IPv4 Block` `TID IPv6 Block`	`IP Block`
`Monitor`	`Monitor`	`Monitored`	Determined by access control rules processed after Security Intelligence and TID.	`TID IPv4 Monitor` `TID IPv6 Monitor`	`IP Monitor`
	`Block`	`Blocked`	`Block`	`TID IPv4 Block` `TID IPv6 Block`	`IP Block`

Table 133: Threat Intelligence Director Domain Name Observable Action vs. DNS Policy Action

Setting: DNS Policy Action	Setting: Threat Intelligence Director Domain Name Observable Action	Threat Intelligence Director Incidents Field: Action Taken	Security Intelligence Events Fields:		
			Action	Security Intelligence Category	Reason
`Do Not Block`	`Monitor` or `Block`	No TID incident	No Security Intelligence event		

`Drop`, `Domain Not Found`
`Sinkhole—Log`
`Sinkhole—Block and Log`
	`Monitor`	`Blocked`	`Block`	as determined by system analysis; see Security intelligence categories, on page 1602	`DNS Block`

	`Block`	`Blocked`	`Block`	`TID Domain Name Block`	`DNS Block`

Setting: DNS Policy Action	Setting: Threat Intelligence Director Domain Name Observable Action	Threat Intelligence Director Incidents Field: Action Taken	Security Intelligence Events Fields:		
			Action	Security Intelligence Category	Reason
Monitor	Monitor	Monitored	Determined by access control rules processed after Security Intelligence and TID.	TID Domain Name Monitor	DNS Monitor
	Block	Blocked	Block	TID Domain Name Block	DNS Block

Table 134: TID SHA-256 Observable Action vs. Malware Cloud Lookup File Policy

File Disposition	Threat Intelligence Director SHA-256 Observable Action	Action Taken in Threat Intelligence Director Incidents	Action in File Events	Action in Malware Events
Clean	Monitor or Block	Monitored	Malware Cloud Lookup	n/a
Malware	Monitor or Block	Monitored	Malware Cloud Lookup	n/a
Custom	Monitor or Block	Monitored	• Malware Cloud Lookup , if SHA-256 is not in a custom detection list. • Custom Detection , if SHA-256 is in a custom detection list.	• Malware Cloud Lookup , if SHA-256 is not in a custom detection list. • Custom Detection , if SHA-256 is in a custom detection list.
Unknown	Monitor or Block	Monitored	Malware Cloud Lookup	n/a

Note Threat Intelligence Director matching occurs before the system sends a file for dynamic analysis.

Table 135: TID SHA-256 Observable Action vs. Block Malware File Policy

File Disposition	Threat Intelligence Director SHA-256 Observable Action	Action Taken in Threat Intelligence Director Incidents	Action in File Events	Action in Malware Events
Clean or Unknown	Monitor	Monitored	Malware Cloud Lookup	n/a
	Block	Blocked	• TID Block, if SHA-256 is not in a custom detection list. Modified file disposition is Custom. • Custom Detection Block, if SHA-256 is in a custom detection list.	TID Block Modified file disposition is Custom.
Malware or Custom	Monitor	Blocked	Block Malware	Block Malware
	Block	Blocked	• TID Block, if SHA-256 is not in a custom detection list. Modified file disposition is Custom. • Custom Detection Block, if SHA-256 is in a custom detection list.	TID Block Modified file disposition is Custom.

View and change Threat Intelligence Director configurations

Use the following information to review and fine-tune your configuration as needed.

View Threat Intelligence Director status of elements (managed devices)

This task allows you to monitor the status of managed devices and confirm that Threat Intelligence Director is properly enabled on elements.

All devices that are registered to the Firewall Management Center as managed devices appear automatically on the Elements page. All properly configured elements (as specified in Configure policies to support Threat Intelligence Director, on page 2127) will receive all currently published observables, including those ingested before the element was added.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Elements**.

Step 2 To see whether the element is connected and Threat Intelligence Director is enabled, hover over the icon beside the element name.

Note After deploying, it may take up to five minutes for information on this page to update, including the applied access control policy and whether TID is enabled.

View and manage sources

View summary information about all configured sources and manage their settings, including actions, publish status, updates, and deletion.

The Sources page displays summary information about all configured sources. Refer to Source summary information, on page 2150.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources**.

Step 2 View your sources.

- To filter the sources displayed on the page, click **Filter** ( ). For more information, refer to Filter Threat Intelligence Director data in table views, on page 2156.
- To view detailed ingestion status, hover the cursor over the text in the **Status** column. For more information, refer to Source status details, on page 2151.

Step 3 Manage your sources.

- To edit the **Action** setting, refer to Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159. If an action is fixed, it is the only supported action for the source **Type**.

- To edit the **Publish** setting, click **Slider** (). For more information, refer to Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.
- To pause or resume Threat Intelligence Director updating the source, click **Pause Updates** or **Resume Updates**. If you pause updates, updating is paused but existing indicators and observables remain in TID.
- To delete the source, click **Delete** (). The Delete option is unavailable if the source is still processing. Removing a source removes all indicators associated with that source. Associated observables may also be deleted; they are retained if they are associated with indicators remaining in the system.

Source summary information

The Sources page displays summary information for all configured sources. This reference provides brief descriptions of the fields in the summary display. For detailed information on these fields, see descriptions in the relevant configuration topic for the source. Refer to Options for ingesting data sources, on page 2128.

Table 136: Sources summary information

Field	Description
Name	The source name.
Type	The data format of the source, such as**STIX** or **Flat File**.
Delivery	The method Threat Intelligence Director uses to retrieve the source.
Action	The action (**Block** or **Monitor**) that the system is configured to perform on traffic matching the data contained within this source. For more information about Threat Intelligence Director actions, including availability, inheritance, and overriding inheritance, refer to Factors that affect the action taken, on page 2144.
Publish	**On** or **Off** toggle specifying whether Threat Intelligence Director publishes data from the source to registered elements (managed devices configured to support Threat Intelligence Director). Indicators can inherit **Publish** settings from a parent source, and observables can inherit **Publish** settings from a parent indicator. For more information, refer to Inheritance in Threat Intelligence Director configurations, on page 2157.
Last Updated	The date and time Threat Intelligence Director last updated the source.

Field	Description
Status	The current status of the source: • **New**—The source is newly created. • **Scheduled**—The initial download or subsequent update is scheduled, but not yet in progress. • **Downloading**—Threat Intelligence Director is performing the initial download or update refresh. • **Parsing** or **Processing**—Threat Intelligence Director is ingesting the source. • **Completed**—Threat Intelligence Director finished ingesting the source. • **Completed with Errors**—Threat Intelligence Director finished ingesting the source, but some observables are unsupported or invalid. • **Error**—Threat Intelligence Director experienced a problem. If the source is a TAXII or URL source with an **Update Frequency** specified, and updates are not paused, Threat Intelligence Director retries on the next scheduled update. Refresh the page to update the status.
Edit ( )	Clicking this icon allows you to edit settings for the source.
Delete ( )	Clicking this icon permanently deletes the source.

Source status details

When you hover over the **Status** value of a source in the Sources summary page, Threat Intelligence Director provides additional details about the source status.

Data	Description
Status Message	Briefly describes the current status of the source.
Last Updated	Specifies the date and time Threat Intelligence Director last updated the source.
Next Update	For TAXII and URL sources, this value specifies when Threat Intelligence Director will update the source next.

Data	Description
Indicators	Specifies indicator counts. • **Consumed**—The number of indicators Threat Intelligence Director processed during the most recent source update. This number represents all indicators contained in the update, regardless of whether they were ingested or discarded. • **Discarded**—The number of malformed indicators that the system did not add to Threat Intelligence Director during the most recent update. **Note** For `TAXII` sources, Threat Intelligence Director provides separate **Last Update** and **Total** indicator counts, because TAXII updates add incremental data, rather than replacing existing data. For indicators from other source types, Threat Intelligence Director provides only the **Last Update** count, because updates from those sources replace the existing data set entirely. If all observables of an indicator are **Invalid**, Threat Intelligence Director discards the indicator.
Observables	Specifies observable counts. • **Consumed**—The number of observables Threat Intelligence Director processed during the most recent source update. This number represents all observables contained in the update, regardless of whether they were ingested or discarded. • **Unsupported**—The number of unsupported observables that the system did not add to Threat Intelligence Director during the most recent update. For more information about supported observable types, see information about content types in Source requirements, on page 2125. • **Invalid**—The number of invalid observables that the system did not add to Threat Intelligence Director during the most recent update. An observable is invalid if it is improperly constructed. For example, `10.10.10.10.123` is not a valid IPv4 address. **Note** For `TAXII` sources, Threat Intelligence Director provides separate **Last Update** and **Total** observable counts, because TAXII updates add incremental data, rather than replacing existing data. For observables from other source types, Threat Intelligence Director provides only the **Last Update** count, because updates from those sources replace the existing data set entirely.

View and manage indicators

This task enables you to view current indicators and manage their configuration settings including actions and publish status.

Indicators are generated automatically from ingested sources. For more information about the contents of this page, refer to Indicator summary information, on page 2153.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources**.

Step 2 Click **Indicators**.

Step 3 View your current indicators.

- To filter the indicators displayed on the page, click **Filter** (). For more information, refer to Filter Threat Intelligence Director data in table views, on page 2156.
- To view additional details about an indicator, including associated observables, click the indicator name. For more information, refer to Indicator details, on page 2154.
- In the **Incidents** column, click the number to view information about incidents associated with an indicator, or hover the cursor over Incidents to view whether the incidents are fully realized or partially realized.
- To determine whether Threat Intelligence Director finished ingesting an indicator from the source, view the **Status** column.

Step 4 Manage your current indicators.

- To edit the **Action**, refer to Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159. If an action is fixed, that is the only supported action for the source **Type**.
- To edit the **Publish** setting, refer to Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.
- To add one or more observables for an indicator to the Do Not Block list, click the indicator name to access the Indicator Details page. For more information, refer to Adding Threat Intelligence Director observables to the Do Not Block list, on page 2163.

Indicator summary information

The Indicators page displays summary information for all indicators associated with configured sources.

Table 137: Indicators summary information

Field	Description
Type	• Indicators that have a single observable list the data type of that observable (URL, SHA-256, etc.) • Indicators that have two or more observables are listed as **Complex**. Hover over the type to see the specific observable.
Name	The indicator name.
Source	The source that contained the indicator (the parent source).

Field	Description
Incidents	Information about any incidents associated with the indicator: • an icon specifying whether the incident is **Partially** or **Fully** realized • the number of incidents associated with the indicator
Action	The action associated with the indicator. For more information, refer to Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159. Indicators can inherit **Action** settings from a parent source, and observables can inherit **Action** settings from a parent indicator. For more information, refer to Inheritance in Threat Intelligence Director configurations, on page 2157.
Publish	The publish setting for the indicator. For more information, refer to Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161. Indicators can inherit **Publish** settings from a parent source, and observables can inherit **Publish** settings from a parent indicator. For more information, refer to Inheritance in Threat Intelligence Director configurations, on page 2157.
Last Updated	The date and time Threat Intelligence Director last updated the indicator.
Status	The current status of the indicator: • **Pending**—Threat Intelligence Director is ingesting the observables of the indicator. • **Completed**—Threat Intelligence Director successfully ingested all observables for the indicator. • **Completed With Errors**—Threat Intelligence Director finished ingesting the indicator, but some observables are unsupported or invalid.

Indicator details

The Indicator Details page displays indicator and observable data for an incident.

Table 138: Indicator details information

Field	Description
Name	The indicator name.
Description	The indicator description provided by the source.
Source	The source that contained the indicator.
Expires	The date and time the indicator will expire, based on the source's **TTL** value.
Action	The action associated with the indicator. For more information, refer to Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159. Indicators can inherit the **Action** setting from a parent source, and observables can inherit the **Action** setting from a parent indicator. For more information, see Inheritance in Threat Intelligence Director configurations, on page 2157.

Field	Description
Publish	The publish setting for the indicator. For more information, refer to Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161. Indicators can inherit the **Publish** setting from a parent source, and observables can inherit the **Publish** setting from a parent indicator. For more information, refer to Inheritance in Threat Intelligence Director configurations, on page 2157.
Indicator Pattern	The observables and operators that form the indicator's pattern. Operators link the observables within the indicator. AND relationships are indicated with the **AND** operator. OR relationships are indicated with the **OR** operator or by a close grouping of several observables. Optionally, click the **Add to Do-Not-Block List** button to add an observable to the Do Not Block list. For more information, refer to Adding Threat Intelligence Director observables to the Do Not Block list, on page 2163.

View and manage observables

This task allows you to view all successfully ingested observables and perform management operations such as editing actions, modifying publish settings, and adding observables to the Do Not Block list.

The Observables page displays all successfully ingested observables. Refer to Observable summary information, on page 2156.

Before you begin

- Configure one or more sources as described in Fetch TAXII feeds to use as sources, on page 2129, Fetch sources from a URL, on page 2130, or Upload a local file to use as a source, on page 2132.

Follow these steps to view and manage observables:

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources**.

Step 2 Click **Observables**.

Step 3 View your current observables.

- To filter the observables displayed on the page, click **Filter** (). For more information, refer to Filter Threat Intelligence Director data in table views, on page 2156.
- If the information in the **Value** column is cut off, hover over the value.
- To view indicators that contain the observable, click the number in the **Indicators** column. The Incidents page opens with the observable value as the filter. For more information, refer to View and manage indicators, on page 2152.

Step 4 Manage your current observables.

- To edit the **Action**, refer to Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159.

- To edit the **Publish** setting for an observable, refer to Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.
- To change the expiration date for an observable, modify the **TTL** for the parent source. For more information, refer to View and manage sources, on page 2149.
- To add an observable to the Do Not Block list, click the **Add to Do-Not-Block List** button. For more information, refer to Adding Threat Intelligence Director observables to the Do Not Block list, on page 2163.

Observable summary information

The Observables page displays summary information for all ingested observables.

Table 139: Observables summary information

Field	Description
Type	The type of observable data: `SHA-256`, `Domain`, `URL`, `IPv4`, or `IPv6`.
Value	The data that comprises the observable.
Indicators	The number of parent indicators containing the observable.
Action	The action configured for the observable. For more information, refer to Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159. Indicators can inherit **Action** settings from a parent source, and observables can inherit **Action** settings from a parent indicator. For more information, refer to Inheritance in Threat Intelligence Director configurations, on page 2157.
Publish	The publish setting for the observable. Refer to Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161. Indicators can inherit **Publish** settings from a parent source, and observables can inherit **Publish** settings from a parent indicator. For more information, refer to Inheritance in Threat Intelligence Director configurations, on page 2157.
Updated At	The date and time Threat Intelligence Director last updated the observable.
Expires	The date that the observable will be automatically purged from Threat Intelligence Director based on **TTL** for the parent indicator.
Add to Do-Not-Block List button	Clicking this button adds the observable to the Do Not Block list. Refer to Adding Threat Intelligence Director observables to the Do Not Block list, on page 2163.

Filter Threat Intelligence Director data in table views

Filter table views to narrow down and display only the Threat Intelligence Director data that matches your specific criteria.

Use this procedure when you need to focus on specific data within Threat Intelligence Director table views by applying attribute-based filters.

Procedure

Step 1 Choose one of these Threat Intelligence Director table views.

- **Integration** > **Intelligence** > **Incidents**
- **Integration** > **Intelligence** > **Sources**
- **Integration** > **Intelligence** > **Sources**, and click **Indicators**
- **Integration** > **Intelligence** > **Sources**, and click **Observables**

Step 2 Click **Filter** () and choose a filter attribute.

Step 3 Choose or enter a value for that filter attribute.

Filters are case-sensitive.

Step 4 (Optional) To filter by multiple attributes, click **Filter** () and repeat Step 2 and Step 3.

Step 5 To cancel the changes you have made since you last applied the filter, click **Cancel**.

Step 6 Click **Apply** to refresh the table with the filter applied.

Step 7 To remove a filter attribute individually, click **Remove** () next to the filter attribute and click **Apply** to refresh the table.

Inheritance in Threat Intelligence Director configurations

Inheritance in Threat Intelligence Director configurations is a hierarchical configuration mechanism that

- creates indicators and observables as child objects when Threat Intelligence Director ingests intelligence data from a source,
- ensures child objects automatically inherit **Action** and **Publish** settings from their parent configuration on creation, and
- maintains parent-child relationships where indicators inherit from source configurations and observables inherit from parent indicators.

Inheritance relationships

The inheritance hierarchy follows these parent-child relationships:

- An indicator inherits these settings from the parent source. An indicator can only have one parent source.
- An observable inherits these settings from the parent indicators. An observable can have multiple parent indicators.

For more information, refer to:

• Inheritance of TID settings from multiple parents, on page 2158
• Overriding inherited TID settings, on page 2158

Inheritance of TID settings from multiple parents

If an observable has multiple parent indicators, the system compares the inherited settings from all the parents and assigns the most secure option to the observable. Thus:

- **Action**: `Block` is more secure than `Monitor`
- **Publish**: `On` is more secure than `Off`

For example, SourceA might contribute IndicatorA and related ObservableA:

Setting	SourceA	IndicatorA	ObservableA
Action	`Block`	`Block`	`Block`
Publish	`Off`	`Off`	`Off`

If SourceB later contributes IndicatorB, which also includes ObservableA, the system modifies ObservableA in this way:

Setting	SourceB	IndicatorB	ObservableA
Action	`Monitor`	`Monitor`	`Block` (inherited from IndicatorA)
Publish	`On`	`On`	`On` (inherited from IndicatorB)

In this example, ObservableA has two parents: one parent for its **Action** setting and one parent for its **Publish** setting. If you manually edit the settings for the observable and then revert the settings, the system sets the **Action** setting to the IndicatorA value and the **Publish** setting to the IndicatorB value.

Overriding inherited TID settings

An overriding inherited TID setting is a configuration change that

- changes the inherited setting at the child level,
- retains the child object setting despite changes to parent objects, and
- breaks automatic cascading of setting changes from parent to child for that specific setting.

Override behavior and inheritance

To override an inherited setting, change the setting at the child level. Refer to Edit Threat Intelligence Director actions at the source, indicator, or observable Level, on page 2159 and Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161. After you override an inherited setting, the child object retains that setting despite changes to the parent object(s).

At the observable level, you can revert from an override setting to the inherited setting, and the system resumes cascading setting changes automatically from the parent indicator to that observable.

Override inheritance scenarios

For example, you might start with these original settings, with no overrides set:

Setting	SourceA	IndicatorA	ObservableA1	ObservableA2
Publish	Off	Off	Off	Off

If you override the setting for IndicatorA, the settings would be these:

Setting	SourceA	IndicatorA	ObservableA1	ObservableA2
Publish	Off	On	On	On

In this case, any changes to the **Publish** setting for SourceA no longer cascade automatically to IndicatorA. However, inheritance from IndicatorA to ObservableA1 and ObservableA2 continues, because the observable settings are not currently set to override values.

If you later override the setting for ObservableA1:

Setting	SourceA	IndicatorA	ObservableA1	ObservableA2
Publish	Off	On	Off	On

Any changes to the **Publish** setting for IndicatorA no longer cascade automatically to ObservableA1. However, those changes continue to cascade to ObservableA2, because it is not set to an override value.

Edit Threat Intelligence Director actions at the source, indicator, or observable Level

Configure action settings at the source, indicator, or observable level to control how threat intelligence data is handled within your security policies.

Editing the action for a parent sets the action for all children. If you edit the action at the source level, you set the action for all its indicators. If you edit the action at the indicator level, you set the action for all of its observables.

Editing the action for a child interrupts inheritance. If you edit the action at the indicator level, and subsequently edit it at the source level, the indicator's action is retained until you edit the action for the individual indicator. If you edit the action at the observable level, and subsequently edit it at the indicator level, the observable's action is retained until you edit the action for the individual observable. At the observable level, you can revert automatically to the parent indicator's action. For more information about inheritance, refer to Inheritance in Threat Intelligence Director configurations, on page 2157.

You may also want to review other Factors that affect the action taken, on page 2144.

Procedure

Step 1 Choose any of the following:

- **Integration** > **Intelligence** > **Sources**

Note Threat Intelligence Director does not support blocking TAXII sources at the source level. If the TAXII source contains a simple indicator, you can block at the indicator or observable level.

- **Integration** > **Intelligence** > **Sources**, and click **Indicators**

Note Threat Intelligence Director does not support blocking complex indicators. Instead, block individual observables within the complex indicator.

- **Integration** > **Intelligence** > **Sources**, and click **Observables**

Step 2 Use the **Action** dropdown to choose **Monitor** ( ) or **Block** ( ).

Step 3 (Observables only) If you want to resume inheriting the action setting from the parent indicator, click **Revert** next to the **Action** setting for the observable.

Pausing publishing

- If you pause publishing at the feature level, the system purges all Threat Intelligence Director observables stored on your elements. This means that Threat Intelligence Director cannot detect, monitor or block threats. Other security features on your system are not affected.
- If you pause publishing at the source, indicator, or observable level, the system removes the paused Threat Intelligence Director observables from your elements, preventing them from matching traffic.
- If you pause publication for a parent, the system pauses all children. For example, pausing publishing at the source level pauses publishing for all its indicators; pausing publishing at the indicator level pauses publishing for all of its observables.
- Pausing publication for a child interrupts inheritance. If you pause publishing at the indicator level, and subsequently publish at the source level, publishing for the indicator remains paused until you change the individual setting for the indicator. If you pause publishing at the observable level, and subsequently publish at the indicator level, publishing for the observable remains paused until you change the individual setting for the observable. At the observable level, you can revert automatically to the parent indicator's publishing status. For more information about inheritance, see Inheritance in Threat Intelligence Director configurations, on page 2157.
- Publishing for Uploaded sources can only be paused at the indicator level.
- For a comparison of pausing publishing for an observable vs adding the observable to the Do Not Block list, see Adding Threat Intelligence Director observables to the Do Not Block list, on page 2163.
- If you have specified a publish or pause setting for an individual observable or indicator, source updates do not change that setting if the update contains the same observable or indicator.
- Publishing can be disabled on the object management pages. See Modify the observable publication frequency, on page 2162.

- The option on the Sources page to pause updates is not related to publishing data to elements; it applies to updating sources on the Firewall Management Center from feeds.

Pause Threat Intelligence Director and purge Threat Intelligence Director data from elements

This task allows you to pause Threat Intelligence Director operations across all elements and purge existing data when necessary.

Caution This setting pauses publishing to all elements, purges all Threat Intelligence Director observables stored on your elements, and stops inspecting traffic using the Threat Intelligence Director feature.

To disable observables at a more granular level, see Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.

Data on the management center (existing incidents and configured sources, indicators, and observables, and ingestion of sources) is not affected by this setting.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Settings**.

Step 2 Click **Pause**.

What to do next

When you are ready to resume synchronizing Threat Intelligence Director data on your elements and generating observations, manually **Resume** publishing from this page. Existing observables on the management center are published to all elements.

Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level

This task allows you to control the publishing of Threat Intelligence Director data by pausing or enabling publication at the source, indicator, or observable level.

If publishing is enabled at the Source level, the system automatically publishes the initial source data and any subsequent changes including:

- changes from periodic source refreshes
- changes resulting from system action (for example, **TTL** expiration)
- any user-initiated changes (for example, a change in the **Action** setting for an indicator or observable)

Note To purge all Threat Intelligence Director observables at once from your devices (elements), see Pause Threat Intelligence Director and purge Threat Intelligence Director data from elements, on page 2161.

Before you begin

Before pausing publishing, review the ramifications described in Pausing publishing, on page 2160.

Procedure

Step 1 Choose any of these options.

- **Integration** > **Intelligence** > **Sources**
- **Integration** > **Intelligence** > **Sources**, and click **Indicators**
- **Integration** > **Intelligence** > **Sources**, and click **Observables**

Step 2 Locate the **Publish Slider** ( ) and use it to toggle publishing to elements.

Step 3 (Observables only) If you want to resume inheriting the publication setting from the parent indicator, click **Revert** next to the **Publish** setting for the observable.

What to do next

- Wait at least ten minutes for elements to receive changes. Changes involving large sources will take longer.
- (Optional) Change the publication frequency for TID data at the observable level. Refer to Modify the observable publication frequency, on page 2162.

Modify the observable publication frequency

This task allows you to set a custom publication interval for observables to TID elements, replacing the default 5-minute interval.

By default, the system publishes observables to TID elements every 5 minutes. Use this procedure to set this interval to a different value.

Before you begin

- Enable publication of TID data at the observable level. Refer to Pause or publish Threat Intelligence Director data at the source, indicator, or observable Level, on page 2161.

Follow these steps to modify the observable publication frequency:

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence** > **Network Lists and Feeds**.

Step 2 Click **Edit** ( ) next to the **Cisco-TID-Feed**.

Step 3 Choose a value from the **Update Frequency** drop-down list.

- Choose **Disable** to stop publication of observable data to elements.
- Choose any other value to set the interval for observable publication.

Step 4 Click **Save**.

Adding Threat Intelligence Director observables to the Do Not Block list

A Do Not Block list is a security feature that

- exempts observables in indicators from specified actions, allowing traffic to pass without monitoring or blocking,
- ignores listed observables when evaluating traffic in complex indicators while still evaluating other observables, and
- takes precedence over action settings regardless of whether they are inherited or override values.

Do not block list behavior

The Do Not Block list affects simple and complex indicators differently:

- Simple indicators: If you add an observable to the Do Not Block list, traffic passes without monitoring or blocking.
- Complex indicators: Threat Intelligence Director ignores observables on the Do Not Block list when evaluating traffic, but other observables in that indicator are still evaluated.

In a complex indicator that includes Observable 1 and Observable 2 linked by the AND operator:

- If you add Observable 1 to a Do Not Block list, Threat Intelligence Director generates a fully realized incident when Observable 2 is seen.
- If you disable publishing of Observable 1 instead of adding it to the Do Not Block list, Threat Intelligence Director generates a partially-realized incident when Observable 2 is seen.

Note If you add an observable to the Do Not Block list, this always takes precedence over the **Action** setting, whether the setting in the observable is an inherited or override value.

Source updates do not affect the Do Not Block list setting for individual observables if the update contains the same observable.

Add Threat Intelligence Director observables to a Do Not Block list

Adding observables to a Do Not Block list allows you to exempt specific items from being blocked, ensuring legitimate traffic is not inadvertently restricted.

For detailed information about using Do Not Block lists, refer to Adding Threat Intelligence Director observables to the Do Not Block list, on page 2163.

Tip An "Add to Do Not Block List" button ( ) can appear in several places in the web interface. You can add an observable to a Do Not Block list in any of those locations by clicking this button.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources**, and click **Observables**.

Step 2 Navigate to the observable that you want to allow.

Step 3 Click (**Add to Do-Not-Block List**) for that observable.

What to do next

(Optional) If you need to remove an observable from the Do Not Block list, click the button again.

View a STIX source file

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources** , and click **Indicators** .

Step 2 Click the indicator name.

Step 3 Click **Download STIX** .

Step 4 Open the file in a text editor.

Troubleshoot Threat Intelligence Director

This reference describes possible solutions and mitigations for common Threat Intelligence Director issues.

Fetching or uploading flat file sources generates an error

If the system fails to fetch or upload a flat file source, check that the data in the flat file matches the **Type** column on the **Integration** > **Intelligence** > **Sources** page.

TAXII or URL source update generates an error

If a TAXII or URL source update generates a source status error, check that your Server Certificate is not expired. If the certificate has expired, enter a new **Server Certificate** or delete the existing **Server Certificate** so Threat Intelligence Director can retrieve a new certificate. For more information, refer to Configure TLS/SSL settings for a Threat Intelligence Director source, on page 2133.

"Block" action is not available for an indicator or source, only "monitor"

You can change the action for individual observables in the indicator or source.

Threat Intelligence Director table views return "No results"

Table views include the **Sources**, **Indicators**, **Observables**, and **Incidents** pages.

If you do not see data in one of the Threat Intelligence Director table views:

- Check your table filter and consider expanding the time window for the **Last Updated** filter attribute. Refer to Filter Threat Intelligence Director data in table views, on page 2156.
- Verify that you correctly configured your sources. Refer to Options for ingesting data sources, on page 2128.
- Verify that you configured your access control policy and related policies to support Threat Intelligence Director. Refer to Configure policies to support Threat Intelligence Director, on page 2127. For example, if your SHA-256 observables are not generating observations, verify that your deployed access control policy contains one or more access control rules that invoke a **Malware Cloud Lookup** or **Block Malware** file policy.
- Verify that you deployed the Threat Intelligence Director-supporting access control policy and related policies to your elements. Refer to Deploy configuration changes, on page 135.
- Verify that you did not pause Threat Intelligence Director data publication at the feature level. Refer to Pause Threat Intelligence Director and purge Threat Intelligence Director data from elements, on page 2161.

System is experiencing slowness or decreased performance

For more information about performance impact, refer to Performance impact of Threat Intelligence Director, on page 2123.

Secure Firewall Management Center table views do not show Threat Intelligence Director data

If you are publishing observables to your elements but no Threat Intelligence Director data appears in the connection, security intelligence, file, or malware events tables, check the access control and file policies deployed to your elements. For more information, refer to Configure policies to support Threat Intelligence Director, on page 2127.

One or more elements are overwhelmed by Threat Intelligence Director data

If Threat Intelligence Director data is overwhelming one or more of your devices, consider pausing Threat Intelligence Director publishing and purging the data stored on your elements. For more information, refer to Pause Threat Intelligence Director and purge Threat Intelligence Director data from elements, on page 2161.

System is performing a malware cloud lookup instead of a TID block

This is by design. For more information, refer to Threat Intelligence Director - Firewall Management Center action prioritization , on page 2145.

System is performing a security intelligence or DNS policy action instead of a TID action

This is by design. For more information, refer to Threat Intelligence Director - Firewall Management Center action prioritization , on page 2145.

TID is disabled

- Add memory to your appliance. Threat Intelligence Director can only be used on appliances with at least 15 GB of memory.
- Enable REST API access for the Secure Firewall Management Center. For more information, refer to *Enabling REST API Access* in the *Cisco Secure Firewall Management Center Administration Guide*.

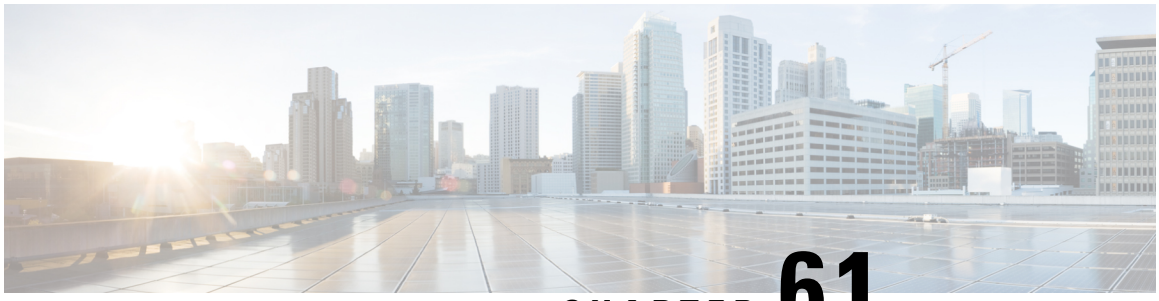
The system does not generate the Threat Intelligence Director incident or take the Threat Intelligence Director action that you expected

- Verify that all of your managed devices are properly enabled and configured for Threat Intelligence Director. Refer to View Threat Intelligence Director status of elements (managed devices), on page 2149 and Configure policies to support Threat Intelligence Director, on page 2127.
- It takes at least 5-10 minutes for changes to be published to elements, and significantly longer if publishing a large data feed.
- Check the action setting for the observable. Refer to View and manage observables, on page 2155.
- For a list of the other factors that influence the Threat Intelligence Director action that the system takes, refer to Factors that affect the action taken, on page 2144.
- Elements (managed devices) may not have the threat data you think they have. Refer to Pausing publishing, on page 2160.

One encounter with a particular threat generates multiple incidents

This can occur if a single indicator is included in multiple sources.

For details, refer to Handling of duplicate indicators, on page 2133.



History for Threat Intelligence Director

This reference provides the complete version history for Threat Intelligence Director features, including implementation details, version requirements, and behavioral changes across different software releases.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Handling of an indicator that is included in multiple STIX feeds	7.1	Any	If STIX feeds contain identical indicators, an indicator is created for each feed, which may lead to multiple incidents being generated for the same indicator. Previously, only the feed that was downloaded last took effect.

Change in action prioritization	6.5	Any	These changes apply if more than one Firepower feature could apply to a particular observable.
			TID blocking/monitoring observable actions now have priority over blocking/monitoring by Security Intelligence.
			Important
			The system still effectively handles traffic as before. Traffic that was previously blocked is still blocked, and monitored traffic is still monitored. This simply changes the component reported in the event as responsible for the action. You may also see more TID incidents generated.
			• If you configure the Block TID observable action, even if the traffic also matches a Security Intelligence Block action:
			  • The Security Intelligence category in the connection event is a variant of TID Block.
			  • The system generates a TID incident with an action taken of Blocked.
			• If you configure the Monitor TID observable action, even if the traffic also matches a Security Intelligence Monitor rule:
			  • The Security Intelligence category in the connection event is a variant of TID Monitor
			  • The system generates a TID incident with an action taken of Monitored.
			Previously, in each of these cases, the system reported the category by analysis and did not generate a TID incident.

Secure Firewall Threat Intelligence Director	6.2.2	Any	Lets you use threat intelligence from external sources to identify and process threats. New screens: A new top-level **Intelligence** menu with multiple tabs. Supported platforms: Secure Firewall Management Center

CHAPTER 61

Advanced Settings for Access Control

Advanced access control policy settings typically require little or no modification. The default settings are appropriate for most deployments.

- Requirements and prerequisites for advanced settings, on page 2169
- Configure advanced settings for the access control policy, on page 2170
- History for advanced settings for the access control policy, on page 2187

Requirements and prerequisites for advanced settings

This reference provides the requirements and prerequisites needed to configure advanced settings for access control policy, including model support, domain compatibility, and user role permissions.

Model support

Any

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin
- You can define custom user roles to differentiate between the intrusion configuration in access control policy and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. The existing pre-defined user roles that included the Modify Access Control Policy permission support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions. The granular permissions are:
  - **Policies** > **Access Control heading** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** allows the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for network analysis and intrusion policies, the configuration of the Security Intelligence policy for the access

control policy, and intrusion actions in the policy default action. If a user has this option only, the user can modify no other part of the policy or rule.

- **Modify Remaining Access Control Policy Configuration** controls the ability to edit all other aspects of the policy.

Configure advanced settings for the access control policy

Configure advanced settings to customize access control policy behavior for specific security requirements and performance optimization.

Advanced access control policy settings typically require little or no modification. The default settings are appropriate for most deployments. Note that many of the advanced preprocessing and performance options in access control policies may be modified by rule updates as described in *Update Intrusion Rules* in the *Cisco Secure Firewall Management Center Administration Guide* .

Caution See Configurations that restart the snort process when deployed or activated, on page 131 for a list of advanced setting modifications that restart the Snort process, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Before you begin

Inheriting settings from a parent policy:

- If the access control policy has a base policy, you can elect to inherit settings from the base policy. Select **Inherit from (*base policy*)** for each setting group where you want to use the parent policy's settings. If you are allowed to configure unique settings for the policy, you must deselect the option to make your edits.
- If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. In this case, inheritance has been configured so that these settings are locked. The settings are read-only.

Follow these steps to configure advanced settings for the access control policy:

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Create or edit an access control policy.

Step 3 Select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 For each settings group, click **Edit** ( ) and configure the settings as needed.

For each feature group, a separate dialog box is opened where you can make your changes. Click **OK** to save any changes.

- **General Settings**—These settings apply broadly to the policy, including URL filtering options. For more information, see General settings, on page 2172.
- **Identity Policy Settings**—Select the policy to be used to implement user identity discovery. You must implement an identity policy to get user or user group information in connection events, or to write access control rules based on users or groups. For more information, see Identity policies, on page 1941.
- **Decryption Policy Settings**—Select the policy to be used when decrypting connections. You must decrypt traffic to apply inspection to encrypted connections.
- **TLS Server Identity Discovery**—Whether to allow the firewall to extract certificate details such as Common Name (CN), Organization, or Subject Alternative Names (SANs) even when TLS 1.3 encryption would normally hide them. This improves policy accuracy without requiring a decryption rule; the original client connection remains encrypted. For more information, see TLS server identity discovery, on page 2173.
- **Prefilter Policy Settings**—Select the policy to be used for statically offloading large flows, implementing early connection blocks, or rezoning plain-text tunnel traffic.
- **Network Analysis and Intrusion Policies**—Advanced network analysis and intrusion policy settings allow you to:
  - Specify the intrusion policy and associated variable set that are used to inspect packets that must pass before the system can determine exactly how to inspect that traffic.
  - Change the access control policy's default network analysis policy, which governs many preprocessing options.
  - Use custom network analysis rules and network analysis policies to tailor preprocessing options to specific security zones, networks, and VLANs.
- **Threat Defense Service Policy**—Use the service policy to apply services to specific traffic classes. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. The service policy rules are applied after the access control rules. For more information, see Service Policies, on page 2191.
- **Files and Malware Settings**—Tune file and malware inspection performance and storage, on page 2053 provides information on performance options for file control and malware defense.
- **Threat Detection**—Configure the portscan detector to detect and prevent portscan activity in all types of traffic to protect networks from eventual attacks. Portscan traffic can be detected efficiently in both allowed and denied traffic. For more information, see Threat Detection, on page 2211.
- **Elephant Flow Settings**—Elephant flows are large, long duration, and fast flows that can cause duress for Snort cores. There are two actions that you can apply on elephant flows to reduce system stress, CPU hogging, packet drops, and so on. These actions are:
  - Bypass any or all applications—This action bypasses flow from Snort inspection.
  - Throttle—This action applies dynamic rate limit policy (10% reduction) on elephant flows.

  For more information, see Configure elephant flow detection, on page 2222.
- **Intelligent Application Bypass Settings**—(Use **Elephant Flow Settings** instead of this option.) Intelligent application bypass (IAB) is an expert-level configuration that specifies applications to bypass or test for bypass if traffic exceeds a combination of inspection performance and flow thresholds.

IAB settings are applicable for Snort2 devices or pre 7.2.0 Snort3 devices. For more information, see Intelligent application bypass, on page 2175.

- **Transport/Network Layer Preprocessor Settings**—Advanced transport and network preprocessor settings apply globally to all networks, zones, and VLANs where you deploy your access control policy. For more information, see Transport/network layer preprocessor settings, on page 2181.
- **Detection Enhancement Settings**—Detection enhancement settings determine whether adaptive profiles are used for application detection and intrusion rules in the access control policy. Typically, the system uses the static settings in your network analysis policy to preprocess and analyze traffic. With adaptive profile updates, the system can adapt processing behavior using host information either detected by network discovery or imported from a third party. For more information, see Detection enhancement settings, on page 2182.
- **Performance Settings**—Settings for improving the performance of your system as it analyzes traffic for attempted intrusions. These settings are very advanced and should be left as defaults by most users. See Performance settings, on page 2184.
- **Latency-Based Performance Settings**—Settings specific to latency-based performance. These settings are very advanced and should be left as defaults by most users. See Latency-based performance settings, on page 2186.

Step 5 Click **Save** to save the changes to the access control policy.

- To get back to the rules list, click **Access Control** in the packet flow line.
- You must deploy the configuration to apply changes to the managed devices.

The advanced settings for the access control policy are configured and saved. The changes will take effect after deployment to the managed devices.

General settings

General settings are advanced configuration options that

- control URL logging and character limits for connection events,
- manage user bypass timeouts for interactive blocking,
- determine URL cache lookup behavior and traffic inspection settings, and
- enable threat intelligence and DNS reputation enforcement features.

General advanced settings configuration options

These are the general advanced settings that you can configure for an access control policy:

- **Maximum URL characters to store in connection events**—Sets the maximum character length of each URL requested by users in end-of-connection events. Disabling or limiting the number of stored URL characters might improve system performance. The default is 1024. The range is 0 to 4096.

  Set the length to 0 to disable URL logging. Storing zero characters does not affect URL filtering. The system filters traffic based on requested URLs even though the system does not record them.

- **Allow an Interactive Block to bypass blocking for (seconds)**—Sets the time allowed for browsing after the user bypasses a URL filtering block. After the timeout expires, the user must bypass the block again. The default is 600 seconds (10 minutes). The range is 0 to 31536000 (8760 hours).

  Setting this value to 0 means the interactive block response is displayed once and the user bypass never expires.

- **Retry URL cache miss lookup**—This setting determines what the system does when it needs to look up a URL's category and reputation in the cloud.

  The first time the system encounters a URL that does not have a locally stored category and reputation, it looks up that URL in the cloud and adds the result to the local data store. This allows faster processing of that URL in the future.

  By default, this setting is enabled. The system momentarily delays the traffic while it checks the cloud for the URL's reputation and category, and uses the cloud verdict to handle the traffic.

  If you disable this setting, when the system encounters a URL that is not in its local cache, the traffic is immediately passed and handled according to the rules configured for uncategorized and reputationless traffic.

  In passive deployments, the system does not retry the lookup, as it cannot hold packets.

- **Enable Threat Intelligence Director**—Whether to use Threat Intelligence Director. Disable this option to stop publishing TID data to your configured devices. The default is enabled. For more information, see Set up Threat Intelligence Director, on page 2126.

- **Enable reputation enforcement on DNS traffic**—Whether to have the system evaluate domain category and reputation early in URL transactions, when the browser looks up the domain name to get the IP address. Enable this option to improve URL filtering performance and efficacy. The default is enabled. For details and additional instructions, see DNS filtering, on page 1665 and subtopics.

- **Inspect traffic during policy apply**—Whether to inspect traffic when you deploy configuration changes unless specific configurations require restarting the Snort process. The default is enabled.

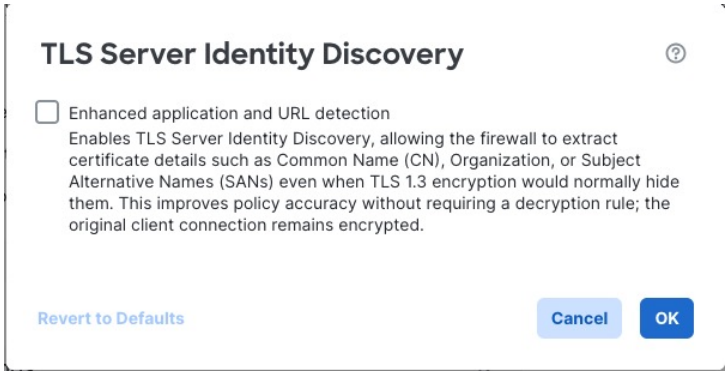
  When this option is enabled, resource demands could result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. The assigned device determines whether traffic drops during this interruption or passes without further inspection. See Snort restart scenarios, on page 127 for more information.

TLS server identity discovery

TLS server identity discovery is an access control policy advanced setting that enables early application detection and URL categorization for encrypted traffic.

TLS server identity discovery configuration

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by RFC 8446, is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate *without* decrypting the entire packet.



You can enable this feature, referred to as *TLS server identity discovery*, when you configure advanced settings for an access control policy. Certain features are not supported, such as STARTTLS traffic, the HTTP CONNECT method, and in a network where another device is already decrypting traffic.

If you enable this option, we recommend you also enable the decryption policy's advanced TLS adaptive server identity probe option as well. Together, these options enable more efficient decryption of TLS 1.3 traffic. For more information, see TLS 1.3 decryption best practices, on page 1743.

When a new connection starts that will be affected by TLS server identity discovery, the Firewall Threat Defense holds the original ClientHello packet to determine the identity of the server to which it connects before continuing. The Firewall Threat Defense device sends a specialized connection from the Firewall Threat Defense to the server. The server's response includes the server certificate, the specialized connection is terminated, and the original connection is evaluated as required by the access control policy.

TLS server identity discovery prioritizes the certificate's Common Name (CN) over the Server Name Indication (SNI).

To enable TLS server identity discovery, click the **Advanced** tab, click **Edit** (✎) for the setting, and select **Early application detection and URL categorization**.

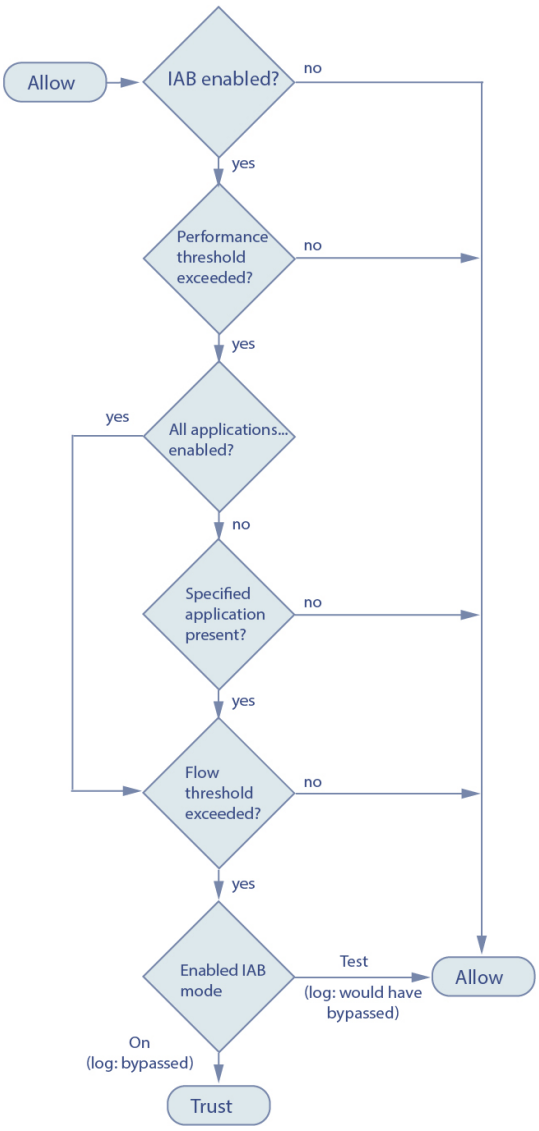
We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. An decryption policy is not required because *traffic is not decrypted* in the process of extracting the server certificate.

Note

- TLS server identity discovery *cannot* be used with any of the following:
  - STARTTLS traffic
  - The HTTP CONNECT method
  - Traffic that is already being decrypted by another device on the network
- Because the certificate is decrypted, TLS server identity discovery can reduce performance depending on the hardware platform.
- TLS server identity discovery is not supported in inline tap mode or passive mode deployments.
- Enabling TLS server identity discovery is supported on any Secure Firewall Threat Defense Virtual version deployed in AWS. TLS server identity is incompatible with certain deployment scenarios that involve Gateway Load Balancer (GWLB). Whether the device initiates a server certificate probe depends on its deployment method with GWLB and the traffic direction.
  - Geneve single-arm flow: The probe *is not initiated* for either east–west or north–south traffic. A connection event **PROBE_FLOW_DROP_BYPASS_PROXY** increments every time the device attempts to extract the server certificate.
  - Geneve dual-arm flow: The probe *is initiated only* for north–south traffic.
- TLS Server Identity Discovery also operates on TLS 1.2 sessions.

Intelligent application bypass

Intelligent application bypass (IAB) is a security feature that



- identifies applications that you trust to traverse your network without further inspection if performance and flow thresholds are exceeded
- implements on traffic allowed by access control rules or the access control policy's default action, before the traffic is subject to deep inspection, and
- can be configured so that when an inspection performance threshold is exceeded, IAB trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.

Additional information

For example, if a nightly backup significantly impacts system performance, you can configure thresholds that, if exceeded, trust traffic generated by your backup application.

A test mode allows you to determine whether thresholds are exceeded and, if so, to identify the application flows that would have been bypassed if you had actually enabled IAB (called *bypass mode*).

This graphic illustrates the IAB decision-making process:

Configure intelligent application bypass

This task enables intelligent application bypass (IAB) to improve system performance by bypassing inspection of specified traffic when performance thresholds are exceeded.

Not all deployments require IAB, and those that do might use it in a limited fashion. Do not enable IAB unless you have expert knowledge of your network traffic, especially application traffic, and system performance, including the causes of predictable performance issues. Before you run IAB in bypass mode, make sure that trusting the specified traffic does not expose you to risk.

Before you begin

IAB settings are applicable for Snort2 devices or pre 7.2.0 Snort3 devices. For Snort 3 devices, use elephant flow detection instead.

Follow these steps to configure intelligent application bypass:

Procedure

Step 1 In the access control policy editor, click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line. Then, click **Edit** ( ) next to **Intelligent Application Bypass Settings**.

Step 2 Set the enabled **State** for IAB.

Turn IAB **Off** or **On**, or enable IAB in **Test** mode.

In test mode, connection events and dashboards tell you what the system would have done if IAB had been on, but traffic is not impacted. Use test mode to check your configuration.

Step 3 Set the **Performance Sample Interval**.

The **Performance Sample Interval** specifies the time in seconds between IAB performance sampling scans, during which the system collects system performance metrics for comparison to IAB performance thresholds. The default is 5 seconds. The range is 1 to 1000 seconds.

Step 4 Select the **Bypassable Applications and Filters**.

Choose from:

- ***X* Applications/Filters**—Click the link and select the applications or application filters whose traffic you want to bypass. You can select by general attributes, specific applications, or both. For example, you could limit bypassable traffic to very low risk applications only.
- **All applications including unidentified applications**—Do not restrict bypass. When an inspection performance threshold is exceeded, IAB trusts all traffic that exceeds any flow bypass threshold, regardless of the application type. This is the default.

Step 5 Configure the performance and flow thresholds.

You must configure at least one **Inspection Performance Thresholds** and one **Flow Bypass Thresholds**. However, all have defaults and you do not need to change the settings if the defaults are appropriate for your network.

When a performance threshold is exceeded, the system examines flow thresholds and, if one threshold is exceeded, trusts the specified traffic. If you enable more than one of either, only one of each must be exceeded.

a) Click **Configure** under **Inspection Performance Thresholds** and configure the options.

Inspection performance thresholds provide intrusion inspection performance limits that, if exceeded, trigger the inspection of flow thresholds. Inspection performance thresholds set to 0 are ignored.

You can configure one or more of these thresholds:

- **Drop Percentage**—The average packets dropped as a percentage of total packets, when packets are dropped because of performance overloads caused by expensive intrusion rules, file policies, decompression, and so on. This does not refer to packets dropped by normal configurations such as intrusion rules.

  Note that specifying an integer greater than 1 activates IAB when the specified percentage of packets is dropped. When you specify 1, any percentage from 0 through 1 activates IAB. This allows a small number of packets to activate IAB.

  The default is 5%. The range is 0 to 100.

- **Processor Utilization Percentage**—Average percentage of processor resources used. The default is 95. The range is 0 to 100.
- **Packet Latency**—The average packet latency in microseconds. The default is 1000. The range is 0 to 1000000.
- **Flow Rate**—The rate at which the system processes flows, measured as the number of flows per second. Note that this option configures IAB to measure flow *rate*, not flow *count*. The default is 0. The range is 0 to 1000000.

b) Click **Configure** under **Flow Bypass Thresholds** and configure the options.

Flow bypass thresholds provide flow limits that, if exceeded, trigger IAB to trust bypassable application traffic in bypass mode or allow application traffic subject to further inspection in test mode. Flow bypass thresholds set to 0 are ignored.

You can configure one or more of these flow bypass thresholds:

- **Bytes per Flow**—The maximum number of kilobytes a flow can include. The default is 500000. The range is 0 to 2147483647.
- **Packets per Flow**—The maximum number of packets a flow can include. The default is 0. The range is 0 to 2147483647.
- **Flow Duration**—The maximum number of seconds a flow can remain open. The default is 0. The range is 0 to 2147483647.
- **Flow Velocity**—The maximum transfer rate in kilobytes per second. The default is 250000. The range is 0 to 2147483647.

Step 6 Click **OK** to save IAB settings.

Step 7 Click **Save** to save the policy.

Intelligent application bypass is configured for the access control policy with the specified performance and flow thresholds.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

IAB logging and analysis

IAB logging and analysis is a monitoring system that

- forces an end-of-connection event. This event logs both bypassed flows and flows that would have been bypassed, regardless of whether you have enabled connection logging
- provides connection events. These events indicate when flows are bypassed in bypass mode or would have been bypassed in test mode, and
- enables custom dashboard widgets and reports based on connection events. These widgets and reports display long-term statistics for bypassed and would-have-bypassed flows.

IAB connection events

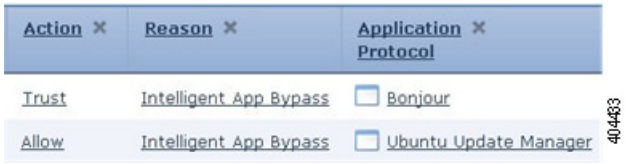
IAB connection events provide specific information about bypassed and would-have-bypassed flows through these key fields:

- Action: When **Reason** includes `Intelligent App Bypass`:
  - **Allow**—indicates that the applied IAB configuration was in test mode and traffic for the application specified by **Application Protocol** remains available for inspection.
  - **Trust**—indicates that the applied IAB configuration was in bypass mode and traffic for the application specified by **Application Protocol** has been trusted to traverse the network without further inspection.
- Reason: `Intelligent App Bypass` indicates that IAB triggered the event in bypass or test mode.
- Application Protocol: This field displays the application protocol that triggered the event.

You can create custom analysis dashboard widgets to display long-term IAB statistics based on connection events. Specify these settings when creating the widget:

- **Preset**: None
- **Table**: Application Statistics
- **Field**: any
- **Aggregate**: either of:
  - IAB Bypassed Connections
  - IAB Would Bypass Connections
- **Filter**: any

You can create custom reports to display long-term IAB statistics based on connection events. Specify these settings when creating the report:



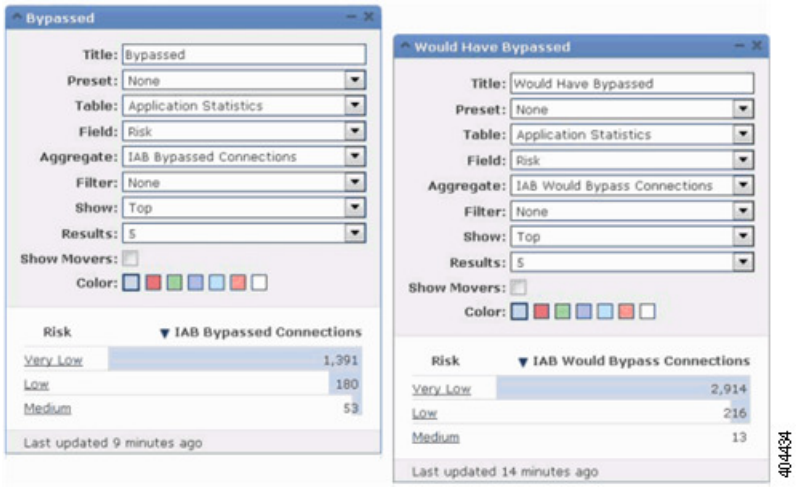
- **Table**: Application Statistics
- **Preset**: None
- **Filter**: any
- **X-Axis**: any
- **Y-Axis**: either of:
  - IAB Bypassed Connections
  - IAB Would Bypass Connections

Connection event examples

In the truncated graphic, some fields are omitted. The graphic shows the **Action**, **Reason**, and **Application Protocol** fields for two connection events resulting from different IAB settings in two separate access control policies.

For the first event, the `Trust` action indicates that IAB was enabled in bypass mode and Bonjour protocol traffic was trusted to pass without further inspection.

For the second event, the `Allow` action indicates that IAB was enabled in test mode, so Ubuntu Update Manager traffic was subject to further inspection but would have been bypassed if IAB had been in bypass mode.



In the truncated graphic, some fields are omitted. The flow in the second event was both bypassed (**Action**: `Trust`; **Reason**: `Intelligent App Bypass`) and inspected by an intrusion rule (**Reason**: `Intrusion Monitor`). The `Intrusion Monitor` reason indicates that an intrusion rule set to **Generate Events** detected but did not block an exploit during the connection. In the example, this happened before the application was detected. After the application was detected, IAB recognized the application as bypassable and trusted the flow.

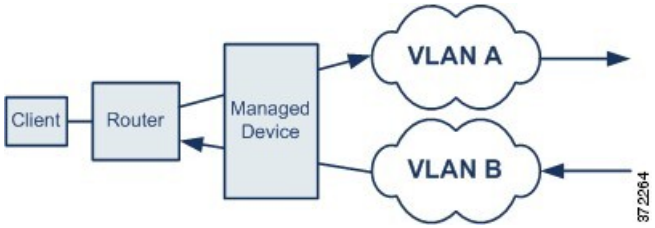
In the custom analysis dashboard widget examples:

- The *Bypassed* example shows statistics for application traffic bypassed because the applications were specified as bypassable and IAB was enabled in bypass mode in the deployed access control policy.
- The *Would Have Bypassed* example shows statistics for application traffic that would have been bypassed because the applications were specified as bypassable and IAB was enabled in test mode in the deployed access control policy.

The graphic shows two abbreviated report examples:

- The *Bypassed* example shows statistics for application traffic bypassed because the applications were specified as bypassable and IAB was enabled in bypass mode in the deployed access control policy.
- The *Would Have Bypassed* example shows statistics for application traffic that would have been bypassed because the applications were specified as bypassable and IAB was enabled in test mode in the deployed access control policy.

Transport/network layer preprocessor settings



Transport/network layer preprocessor settings are access control policy configurations that

- apply globally to all networks, zones, and VLANs where you deploy your access control policy
- control how the system handles VLAN headers, active responses, and connection tracking, and
- affect traffic reassembly and rule processing for transport and network layer communications.

Configuration options

These settings control various aspects of transport and network layer processing:

- **Ignore the VLAN header when tracking connections**—Whether to ignore or include VLAN headers when identifying traffic. Different VLAN tags in traffic traveling in different directions for the same connection can affect traffic reassembly and rule processing. For example, traffic for the same connection could be transmitted over VLAN A and be received over VLAN B. Select this option if the device might see different VLANs for the same connection. This option is off by default.

- **Maximum Active Responses**—For a TCP connection that triggers a preprocessor/intrusion drop rule that is configured to provide an active response, the maximum number of active responses per TCP connection. When additional traffic occurs on a connection where an active response has been initiated, and the traffic occurs more than **Minimum Response Seconds** after a previous active response, the system sends another active response unless the specified maximum has been reached. A setting of 0 disables additional active responses triggered active response rules. The default is no limit. The range is 0 to 25.

Note You have to specifically configure drop rules to provide active responses. For TCP connections, the active response is a RESET packet. For UDP connections, the system sends an ICMP unreachable packet to the source of the connection.

- **Minimum Response Seconds**—Until **Maximum Active Responses** occur, specifies the number of seconds to wait before any additional traffic on a connection where the system has initiated an active response results in a subsequent active response. The default is no limit. The range is 1 to 300.
- **Session Termination Logging Threshold**—Do not modify this option unless instructed to do so by Cisco Technical Support.

  Support might ask you during a troubleshooting call to configure your system to log a message when an individual connection exceeds the specified threshold. Changing the setting for this option will affect performance and should be done only with Support guidance. This option specifies the number of bytes that result in a logged message when the session terminates and the specified number was exceeded. The upper limit is 1GB.

Detection enhancement settings

Detection enhancement settings are adaptive profile configurations that

- determine whether adaptive profiles are used for application detection and intrusion rules in the access control policy
- enable the system to adapt processing behavior using host information either detected by network discovery or imported from a third party, and
- provide control over profile update frequency and network scope for performance optimization.

Detection enhancement setting options

Typically, the system uses the static settings in your network analysis policy to preprocess and analyze traffic. With adaptive profile updates enabled, the system adapts processing behavior using host information detected by network discovery or imported from a third party.

Note To enable adaptive profiles in Snort 3, you must select both the **Enable** and **Enable Profile Updates** options.

The detection enhancement settings include these options:

- **Enable**—You must enable adaptive profiling (its default state) for access control rules to perform application and file control, including malware protection (AMP), and for intrusion rules to use service metadata.
- **Enable Profile Updates**—Profile updates, like the target-based profiles you can configure manually in a network analysis policy, help to defragment IP packets and reassemble streams in the same way as the operating system on the target host. The intrusion rules engine then analyzes the data in the same format as that used by the destination host. Profile updates also compare metadata in an intrusion rule to host information to determine whether a rule should apply for a particular host. For more information, see:

- Adaptive profile updates, on page 2183
- Adaptive profile updates and recommended rules, on page 2184

- **Adaptive Profiles – Attribute Update Interval**—When profile updates are enabled, you can control how frequently in minutes network map data is synced from the management center to its managed devices. The system uses the data to determine what profiles should be used when processing traffic. Increasing the value for this option can improve performance in a large network.
- **Adaptive Profiles – Networks**—Optionally, when profile updates are enabled, you can improve performance by constraining profile updates to a comma-separated list of IP addresses, address blocks, and network variables. If you use a network variable, the system uses the variable's value in the variable set linked to the default intrusion policy for your access control policy. For example, you could enter 192.168.1.101, 192.168.4.0/24, or $HOME_NET. IPv4 and IPv6 are supported.

  The default value (0.0.0.0/0) applies adaptive profile updates to all networks.

Adaptive profile updates

An adaptive profile update is a network analysis feature that

- adapts processing behavior using host information either detected by network discovery or imported from a third party
- switches to the appropriate operating system profile based on the operating system in the host profile for the target host, and
- helps to defragment IP packets and reassemble streams in the same way as the operating system on the target host.

Adaptive profile operation

Typically, the system uses the static settings in your network analysis policy to preprocess and analyze traffic. With adaptive profile updates, the system can adapt processing behavior using host information either detected by network discovery or imported from a third party.

Profile updates, like the target-based profiles you can configure manually in a network analysis policy, help to defragment IP packets and reassemble streams in the same way as the operating system on the target host. The intrusion rules engine then analyzes the data in the same format as that used by the destination host.

Manually configured target-based profiles apply either the default operating system profile you select, or profiles you bind to specific hosts. Profile updates, however, switch to the appropriate operating system profile based on the operating system in the host profile for the target host.

Adaptive profile update scenario

Consider a scenario where you configure profile updates for the 10.6.0.0/16 subnet and set the default IP Defragmentation target-based policy to Linux. The Firewall Management Center where you configure the settings has a network map that includes the 10.6.0.0/16 subnet.

- When the system detects traffic from Host A, which is not in the 10.6.0.0/16 subnet, it uses the Linux target-based policy to reassemble IP fragments.

- When the system detects traffic from Host B, which is in the 10.6.0.0/16 subnet, it retrieves Host B's operating system data from the network map. The system uses a profile based on that operating system to defragment the traffic destined for Host B.

Adaptive profile updates and recommended rules

Adaptive profile updates and recommended rules are security features that

- compare metadata in a rule to host information to determine whether a rule should apply for a particular host
- provide different approaches to rule optimization, with adaptive profiles applying rules dynamically on a packet-by-packet basis while recommended rules provide suggestions for rule state changes, and
- can be used in combination to ensure appropriate rule enablement and efficient rule application for specific traffic.

Feature characteristics and differences

The adaptive profile updates feature is an advanced setting in an access control policy that applies globally to all intrusion policies invoked by that access control policy. The Cisco recommended rules feature applies to the individual intrusion policy where you configure it.

Like recommended rules, profile updates compare metadata in a rule to host information to determine whether a rule should apply for a particular host. However, while recommended rules provide recommendations for enabling or disabling rules using that information, profile updates use the information to apply specific rules to specific traffic.

This table compares the key differences between adaptive profile updates and recommended rules:

Recommended rules require your interaction to implement suggested changes to rule states. Profile updates, on the other hand, do not modify intrusion policies. Treatment of rules based on profile updates happens on a packet-by-packet basis.

Additionally, recommended rules can result in enabling disabled rules. Profile updates, in contrast, only affect the application of rules that are already enabled in intrusion policies. Profile updates never change the rule state.

You can use profile updates and recommended rules in combination. Profile updates use the rule state for a rule when your intrusion policy is deployed to determine whether to include it as a candidate for applying, and your choices to accept or decline recommendations are reflected in that rule state. You can use both features to ensure that you have enabled or disabled the most appropriate rules for each network you monitor, and then to apply enabled rules most efficiently for specific traffic.

Performance settings

Performance settings are access control policy advanced settings that

- tune the performance of your system as it analyzes traffic for attempted intrusions
- apply to Snort and are relevant only if you apply intrusion policies in rules or as the default action, and
- should be changed only if you are a Snort intrusion rule expert, or at the direction of Cisco Technical Support.

Performance setting categories

These settings are organized into separate tabs for each group of settings:

- **Pattern Matching Limits**: The maximum number of events to queue and TCP payload detection options
- **Performance Statistics**: Time range and packet count settings for performance sampling
- **Regular Expression Limits**: PCRE matching and recursion limits
- **Intrusion Event Logging Limits**: Event queue and logging configuration

Pattern Matching Limits include these options:

- **Maximum Pattern States to Analyze Per Packet**: The maximum number of events to queue. The default is 5.
- **Disable Content Checks on Traffic Subject to Future Reassembly**: Whether to detect TCP payload before reassembly. It includes inspection of packets before and after stream reassembly. This process requires more processing overhead and may decrease performance. If the option is not selected, the TCP payload is detected after reassembly. The default is off.

Performance Statistics settings control when the system updates performance statistics. When the number of seconds specified elapses between performance statistics updates, the system verifies it has analyzed the specified number of packets. If it has, the system updates performance statistics. Otherwise, the system waits until it analyzes the specified number of packets.

- **Sample time (seconds)**: The time range for taking a performance sample. The default is 300 seconds.

  Configuring a very low value (for example, 1 second) for the sample time can cause a huge impact on the device; the performance statistics logged on the device can cause disk space issues and affect the operation of the device. Hence, we recommend you do not configure a very low value.

- **Minimum number of packets**: How many packets to consider the minimum for a valid performance statistic. The default is 0.
- **Troubleshooting Options**:
  - **Log Session/Protocol Distribution**: Support might ask you during a troubleshooting call to enable this option to configure the system to calculate the performance statistics only when the Snort process is shut down or restarted.
  - **Summary**: Enable this option only if instructed by Cisco Technical Support.

Regular Expression Limits ensure a minimum level of performance. The default Perl compatible regular expression (PCRE) limits ensure a minimum level of performance. Overriding these limits could increase security but could also significantly impact performance by permitting packet evaluation against inefficient regular expressions.

- **Match Limit State**: The limit for matching regular expressions. You can select **Default Value**, which is 3500, **Unlimited**, or **Custom**. If you select custom, specify the number of times to attempt to match a pattern defined in a PCRE regular expression in **Match Limit**. Specify 0 to completely disable PCRE match evaluations.
- **Match Recursion Limit State**: The limit for matching regular expression recursions. You can select **Default Value**, which is 3500, **Unlimited**, or **Custom**. If you select custom, specify the number of

recursions when evaluating a PCRE regular expression against the packet payload in **Match Recursion Limit**. Specify 0 to completely disable PCRE recursions.

Note For a custom match recursion limit to be meaningful, it must be smaller than the match limit.

Intrusion Event Logging Limits control event queuing and reporting. When the intrusion rules engine evaluates traffic against rules, it places the events generated for a given packet or packet stream in an event queue, then reports the top events in the queue to the user interface. When configuring the intrusion event logging limits, you can specify how many events can be placed in the queue and how many are logged, and select the criteria for determining event order within the queue.

- **Maximum Events Stored Per Packet**: The maximum number of events that can be stored for a given packet or packet stream. The default is 8.
- **Maximum Events Logged Per Packet**: The number of events logged for a given packet or packet stream. This cannot exceed the **Maximum Events Stored Per Packet** value. The default is 5.
- **Prioritize Events Logging By**: The value used to determine event ordering within the event queue. The highest ordered event is reported through the user interface. You can select:
  - **Content Length** (the default), which orders events by the longest identified content match. When events are ordered by content length, rule events always take precedence over decoder and preprocessor events.
  - **Priority**, which orders events in the queue by the event priority.

Latency-based performance settings

Latency-based performance settings are policy configurations that

- use thresholding to manage packet and rule processing performance,
- apply to Snort and are relevant only if you apply intrusion policies in rules or as the default action, and
- are automatically populated by the latest deployed intrusion rule update by default.

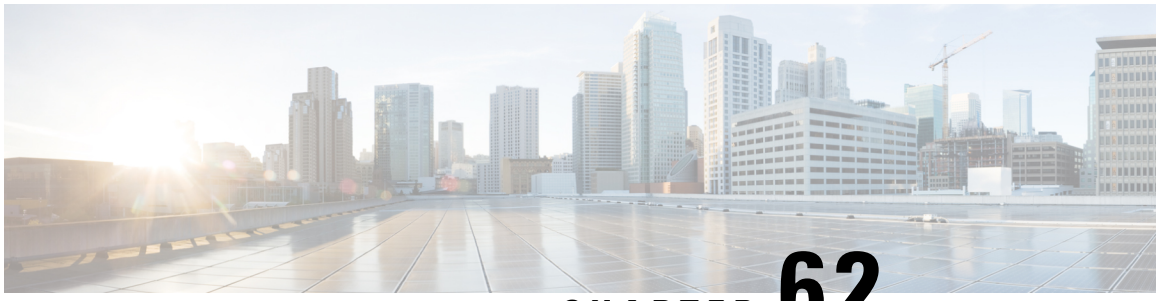
Performance setting behavior

By default, latency-based performance settings for both packet and rule handling are automatically populated by the latest deployed intrusion rule update, and we recommend that you do not change the default. Change these settings only if you are a Snort intrusion rule expert, or at the direction of Cisco Technical Support.

The latency settings that are applied depend on the security level of the network analysis policy (NAP) associated with the access control policy. Generally, this is the default NAP policy. However, if custom network analysis rules are configured, and if any of these specify a NAP policy that is more secure than the default NAP policy, then latency settings are based on the most secure NAP policy among the custom rules. If the default NAP policy or any custom rules invoke a custom NAP policy, then the security level used in the evaluation is the system-provided base policy on which each custom NAP policy is based.

The above is true regardless of whether the effective threshold and/or network analysis configurations are inherited or configured directly in the policy.

Use these settings to tune the latency-based performance of your system:



- **Apply Settings From**: Whether to apply latency-based performance settings from an **Installed Rule Update**, the default, or from your **Custom** settings.
- **Packet Handling**: Packet latency thresholding measures the total elapsed time taken to process a packet by applicable decoders, preprocessors, and rules, and ceases inspection of the packet if the processing time exceeds a configurable threshold. By default, the latency-based performance setting for packet handling is disabled. You may choose to enable it. However, Cisco recommends that you do not change the default value for the threshold setting. Select **Enabled** to turn it on. If you selected **Custom**, also enter the **Threshold** time in microseconds for when inspection of a packet should cease. The default is 256.
- **Rule Handling**: Rule latency thresholding measures the elapsed time each rule takes to process an individual packet, suspends the violating rule along with a group of related rules for a specified time if the processing time exceeds the rule latency threshold a configurable consecutive number of times, and restores the rules when the suspension expires. You can configure these options only if you select **Custom**.
  - **Enabled**: This option is selected automatically if you select custom. If you do not want use this feature, deselect the option. All other settings on this tab require the feature to be enabled.
  - **Threshold (microseconds)**: Specifies the time in microseconds that rules should not exceed when examining a packet. The default is 512.
  - **Consecutive Threshold Violations Before Suspending Rule**: Specifies the consecutive number of times rules can take longer than the time set for threshold to inspect packets before rules are suspended. The default is 3.
  - **Suspension Time**: How long a suspended rule should be suspended. The default is 10.

History for advanced settings for the access control policy

This reference provides a comprehensive history of feature changes by release for advanced settings for the access control policy, helping administrators track the evolution and capabilities of access control policy configurations across different software versions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Improved portscan detection.	7.2	7.2 running Snort 3	With an improved portscan detector, you can easily configure the system to detect or prevent portscans. You can refine the networks you want to protect, set the sensitivity, and so on. For devices running Snort 2 and for devices running Version 7.1 and earlier, continue to use the network analysis policy for portscan detection. New/modified screens: We added **Threat Detection** to the access control policy's Advanced tab. New/Modified commands: **clear threat-detection portscan**, **show threat-detection portscan**.
Bypass inspection or throttle elephant flows on Snort 3 devices.	7.2.0	7.2.0 with Snort 3	You can now detect and optionally bypass inspection or throttle elephant flows. By default, access control policies are set to generate an event when the system sees an unencrypted connection larger than 1 GB/10 sec; the rate limit is configurable. For the Firepower 2100 series, you can detect elephant flows but not bypass inspection or throttle. For devices running Snort 2 and for devices running Version 7.1 and earlier, continue to use Intelligent Application Bypass (IAB). New/modified screens: We added **Elephant Flow Settings** to the access control policy's Advanced tab. For more information, see Elephant Flow Detection.
DNS filtering	7.0.0 6.7.0 (experimental)	Any	If URL filtering is enabled and configured, a new option to enhance category and reputation filtering efficacy is enabled by default for each new access control policy. For more information, see DNS filtering, on page 1665 and subtopics. The Advanced tab of access control policy has a new option under General Settings: **Enable reputation enforcement on DNS traffic**.
TLS server identity discovery	6.7.0	Any	Enable access control policies to evaluate URL and application conditions when a client connects to a TLS 1.3-enabled server. TLS server identity discovery enables these conditions to be evaluated without decrypting traffic. Enabling this feature can impact device performance, depending on model. The Advanced tab page of access control policy has new options: • Warning is displayed on the Advanced tab; moving the slider to the right enables TLS server identity discovery. • New option on the Advanced tab page: **TLS Server Identity Discovery**.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Threat Defense Service Policy.	6.3	Any	You can now configure a Threat Defense Service Policy as part of your access control policy advanced options. You can use Threat Defense Service Policies to apply services to specific traffic classes. Features supported include TCP State Bypass, randomizing TCP sequence numbers, decrementing the time-to-live (TTL) value on packets, Dead Connection Detection, setting a limit on the maximum number of connections and embryonic connections per traffic class and per client, and timeouts for embryonic, half closed, and idle connections. New screen: **Policies** > **Access Control** > **Access Control**, **Advanced** tab, **Threat Defense Service Policy**. Supported platforms: Secure Firewall Threat Defense

CHAPTER 62

Service Policies

- Configure threat defense service policies, on page 2194
- Monitor service policies, on page 2203
- Examples for service policy rules, on page 2204
- History for threat defense service policy, on page 2208

Threat defense service policies

Use Threat Defense service policies to apply services to specific traffic classes. Service policies let you apply different services to different connections entering the device or interface.

For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. A service policy consists of multiple actions or rules applied to an interface or applied globally.

Traffic class types

A traffic class is a combination of the interface and an extended access control list (ACL). The ACL "allow" rules determine which connections are part of the class. Any "denied" traffic in the ACL simply does not have the service applied to it: these connections are not actually dropped. You can use IP addresses and TCP/UDP ports to identify matching connections as precisely as you require.

There are two types of traffic class:

- **Interface-based rules**—If you specify a security zone or interface group in a service policy rule, the rule applies to the ACL "allowed" traffic that goes through any interface that is part of the interface objects.

  Interface-based rules that are applied to the ingress interface always take precedence over global rules for any feature. If an ingress interface-based rule applies to a connection, the system ignores any matching global rule. If no ingress interface or global rule applies, then an interface service rule on the egress interface is applied.

- **Global rules**—These rules apply to all interfaces. If an interface-based rule does not apply to a connection, the global rules are checked and applied to any connections that the ACL "allows." If none apply, then the connections proceed without any services applied.

A given connection can match only one traffic class, either interface-based or global, for a given feature. There should be at most one rule for a given interface object/traffic flow combination.

Service policy rules are applied after access control rules. These services are configured only for connections you are allowing.

Service policy relationships with FlexConfig and other features

Connection-related service policy features are managed separately from other service-rule features, so overlapping traffic classes generally aren't an issue, but they should still be configured carefully.

Service policy feature interactions

Because connection-related service policy features are treated as a separate feature group from other service-rule implemented features, you should not run into problems with overlapping traffic classes. However, please be mindful when configuring these features:

- QoS policy rules: QoS policy rules are implemented using the service policy CLI. These rules are applied before connection-based service policy rules. However, both QoS and connection settings can be applied to the same or overlapping traffic classes.
- FlexConfig policies: You can use FlexConfig policies to implement custom application inspections and NetFlow. Use the **show running-config** command to examine the CLI that already configures service rules, including the **policy-map**, **class-map**, and **service-policy** commands. Netflow and application inspection are compatible with QoS and connection settings, but you need to understand the existing configuration before implementing FlexConfig. Connection settings are applied before application inspections and Netflow.

Note Traffic classes that are created from the Threat Defense service policy are named **class_map_***ACLname*, where *ACLname* is the name of the extended ACL object used in the service policy rule.

Connection settings

Connection settings refer to a variety of features that manage connections through a device.

Connection setting types

Connection settings include these types:

- **Global timeouts for various protocols**—All global timeouts have default values. Change them only if you experience premature connection loss. You configure global timeouts in the Threat Defense platform policy. Select **Devices** > **Platform Settings**.
- **Connection timeouts per traffic class**—You can override the global timeouts for specific types of traffic using service policies. All traffic class timeouts have default values, so you do not have to set them.
- **Connection limits and TCP Intercept**—By default, there are no limits on how many connections can go through (or to) the Firewall Threat Defense. Use service policy rules to set limits on particular traffic classes. This protects servers from denial of service attacks. Particularly, you can set limits on embryonic connections (those that have not finished the TCP handshake), which protects against SYN flooding

attacks. When embryonic limits are exceeded, the TCP Intercept component activates to proxy connections and throttle attacks.

- **Dead connection detection (DCD)**—Enable dead connection detection if you have persistent connections that are valid but often idle. These connections may get closed when they exceed idle timeout settings. Dead connection detection identifies idle but valid connections and keeps them alive by resetting their idle timers. Whenever idle times are exceeded, DCD probes both sides of the connection to see if both sides agree that the connection is valid. The **show service-policy** command output includes counters to show the amount of activity from DCD. You can use the **show conn detail** command to get information about the initiator and responder and how often each has sent probes.
- **TCP sequence randomization**—Each TCP connection has two initial sequence numbers (ISN): one generated by the client and one generated by the server. By default, the Firewall Threat Defense randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions. Randomization prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session. However, TCP sequence randomization effectively breaks TCP SACK (Selective Acknowledgement), as the sequence numbers the client sees are different from what the server sees. You can disable randomization per traffic class if desired.
- **TCP normalization**—The TCP Normalizer protects against abnormal packets. You can configure how some types of packet abnormalities are handled by traffic class. You can configure TCP Normalization using the FlexConfig policy.
- **TCP state bypass**—You can bypass TCP state checking if you use asymmetrical routing in your network.

Requirements and prerequisites for service policies

- You must have one of these user roles: **Admin**, **Access Admin**, or **Network Admin**.
- Assign an access control policy to each target device before you add or edit service-policy rules.
- Create an extended access control list (ACL) for each traffic class. Include **Allow** rules for the connections that should receive the service.
- For interface-based rules, configure the interfaces on the target devices and add them to security zones or interface groups.

Guidelines and limitations for service policies

Service policies apply to routed or switch interfaces only, in either routed or transparent mode. They do not apply to inline set or passive interfaces.

You can configure up to 25 traffic classes for an interface or the global policy.

- Global policy: You can configure up to 25 service policy rules for a given security zone or interface group.
- Interface-based rules: The limit applies to the interfaces themselves, not to each zone or interface group. Because an interface can belong to both a security zone and an interface group, the number of rules allowed for a zone or group might be lower than 25, depending on its member interfaces.

You can have at most one rule for a given interface object/traffic flow combination.

When you make service policy changes to the configuration, all new connections use the new service policy. Existing connections continue to use the policy that was configured at the time of the connection establishment. If you want all connections to immediately use the new policy, you need to disconnect the current connections so they can reconnect using the new policy. Use an SSH or Console CLI session to enter the **clear conn** or **clear local-host** commands.

QoS rules and service policy rules (in the access control policy) are translated to commands on the firewall. This includes creating policy maps. There can be only one policy map per interface. The system automatically combines QoS and service policy configurations in a single policy map per interface.

However, you can also create policy maps manually using FlexConfig. For lower-end firewalls, such as the Secure Firewall 3100, you can create up to 64 policy maps in the configuration. For more powerful firewalls, such as the Firepower 4100, you can create up to 128. Be careful not to exceed this limit, or deployment will fail. You can view the device configuration from the CLI or use the deployment transcript to see how rules are translated to commands.

Configure threat defense service policies

A service policy consists of multiple actions or rules applied to an interface or applied globally. Use Threat Defense service policies to apply services to specific traffic classes.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**, and click **Edit** ( ) for the access control policy whose Threat Defense service policy you want to edit.

Step 2 Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 3 Click **Edit** ( ) in the **Threat Defense Service Policy** group.

A dialog box opens that shows the existing policy. The policy consists of an ordered list of rules, separated between global rules (which apply to all interfaces) and interface-based rules. The table shows the interface object and extended access control list name (which combined defines the traffic class for the rule), and the services applied.

Step 4 Do any of the following:

- Click **Add Rule** to create a new rule. See Configure a service policy rule, on page 2195.
- Click **Edit** ( ) to edit an existing rule. See Configure a service policy rule, on page 2195.
- Click **Delete** ( ) to delete a rule.
- Click a rule and drag it to a new location to move it. You cannot drag rules between the interface and global lists. Instead you must edit the rule to change the interface/global setting. The first rule in the list that matches a connection is applied to the connection.

Step 5 Click **OK** when you are finished editing the policy.

Step 6 Click **Save** on the **Advanced** window. The changes are not saved until you click **Save**.

Configure a service policy rule

Service policy rules allow you to control and customize how network traffic is handled by applying specific services and connection settings to defined traffic classes.

Before you begin

Go to **Objects** > **Object Management** > **Access List** > **Extended** and create an extended access list that defines the traffic to which the rule applies. The rule is applied to any connections that match Allow rules in the extended access list. Define the ACL rules precisely, so that your service policy rule applies to only the traffic that requires the service.

If you are creating an interface-based rule, you must also have configured the interfaces on the assigned devices and added them to security zones or interface groups.

Procedure

Step 1 If you are not already in the Threat Defense service policy dialog box, choose **Policies** > **Access Control heading** > **Access Control**, edit the access control policy, select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, then edit the **Threat Defense Service Policy**.

Step 2 Do any of the following:

- Click **Add Rule** to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The service policy rule wizard opens to step you through the process of configuring the rule.

Step 3 In the **Interface Object** step, select the option that defines the interfaces that will use the policy.

- **Apply Globally**—Select this option to create a global rule, which applies to all interfaces.
- **Select Interface Objects**—Select this option to create an interface-based rule. Then, select the security zones or interface objects that contain the desired interfaces, and click **Add** to move them to the selected list. The service policy rule will be configured on each interface contained in the selected objects; it is not configured on the zone/group itself.

Click **Next** when the interface criterion is complete.

Step 4 In the **Traffic Flow** step, select the extended ACL object that defines the connections to which the rule applies, then click **Next**.

Step 5 In the **Connection Setting** step, configure the services to apply to this traffic class.

- **Enable TCP State Bypass** (TCP connections only)—Implement TCP state bypass. Connections subject to TCP state bypass are not inspected by any inspection engines, and they bypass all TCP state checking and TCP normalization. For detailed information, see Bypass TCP state checks for asymmetrical routing (TCP state bypass), on page 2198.

Note Use TCP state bypass for troubleshooting purposes or when asymmetric routing cannot be resolved. This feature disables multiple security features, which can cause a high number of connections if you do not implement it properly with a narrowly defined traffic class.

- **Randomize TCP Sequence Number** (TCP connections only)—Whether to enable or disable TCP sequence number randomization. Randomization is enabled by default. For more information, see Disable TCP sequence randomization, on page 2202.
- **Enable Decrement TTL** (TCP connections only)—Decrement the time-to-live (TTL) on packets that match the class. If you decrement time to live, packets with a TTL of 1 will be dropped, but a connection will be opened for the session on the assumption that the connection might contain packets with a greater TTL. Note that some packets, such as Open Shortest Path First (OSPF) hello packets, are sent with TTL = 1, so decrementing time to live can have unexpected consequences.

Note If you want the Firewall Threat Defense device to appear on traceroutes, you must configure the decrement TTL option and also set the Internet Control Message Protocol (ICMP) unreachable rate limit in the platform settings policy. See Configure the Firewall Threat Defense device to appear on traceroutes, on page 2207.

- **Connections**—Limits for the number of connections allowed for the entire class. You can configure these options:
  - **Maximum TCP and UDP** (TCP/UDP connections only)—The maximum number of simultaneous connections that are allowed, between 0 and 2000000, for the entire class. For TCP, this count applies to established connections only. The default is 0, which allows unlimited connections. Because the limit is applied to a class, one attacking host can consume all the connections and leave none for the rest of the hosts that are matched to the class. Set the per-client limit to ameliorate this problem.
  - **Maximum Embryonic** (TCP connections only)—The maximum number of simultaneous embryonic TCP connections (those that have not finished the TCP handshake) allowed, between 0 and 2000000. The default is 0, which allows unlimited connections. By setting a non-zero limit, you enable TCP intercept, which protects inside systems from a denial of service (DoS) attack perpetrated by flooding an interface with TCP SYN packets. Also set the per-client options to protect against SYN flooding. For more information, see Protect servers from a SYN flood DoS attack (TCP intercept), on page 2204.
- **Connections Per Client**—Limits for the number of connections allowed for a given client (source IP address). You can configure these options:
  - **Maximum TCP and UDP** (TCP/UDP connections only)—The maximum number of simultaneous connections allowed per client, between 0 and 2000000. For TCP, this includes established, half-open (embryonic), and half-closed connections. The default is 0, which allows unlimited connections. This option restricts the maximum number of simultaneous connections that are allowed for each host that is matched to the class.

- **Maximum Embryonic** (TCP connections only)—The maximum number of simultaneous embryonic TCP connections allowed per client, between 0 and 2000000. The default is 0, which allows unlimited connections. For more information, see Protect servers from a SYN flood DoS attack (TCP intercept), on page 2204.

- **Connections SYN Cookie MSS**—The server maximum segment size (MSS) for SYN-cookie generation for embryonic connections upon reaching the embryonic connections limit, from 48 to 65535 . The default is 1380. This setting is meaningful only if you configure **Maximum Embryonic** for connections or per-client, or both.
- **Connections Timeout**—The timeout settings to apply to the traffic class. These timeouts override the global timeouts defined in the platform settings policy. You can configure these options:
  - **Embryonic** (TCP connections only)—The timeout period until a TCP embryonic (half-open) connection is closed, between 0:0:5 and 1193:00:00. The default is 0:0:30.
  - **Half Closed** (TCP connections only)—The idle timeout period until a half-closed connection is closed, between 0:0:30 and 1193:0:0. The default is 0:10:0. Half-closed connections are not affected by dead connection detection (DCD). Also, the system does not send a reset when taking down half-closed connections.
  - **Idle** (TCP, UDP, ICMP, IP connections)—The idle timeout period after which an established connection of any protocol closes, between 0:0:1 and 1193:0:0. The default is 1:0:0, unless you select the TCP state bypass option, where the default is 0:2:0.
  - **Reset Connection Upon Timeout** (TCP connections only)—Whether to send a TCP RST packet to both end systems after idle connections are removed.
- **Detect Dead Connections** (TCP connections only)—Whether to enable dead connection detection (DCD). Before expiring an idle connection, the system probes the end hosts to determine if the connection is valid. If both hosts respond, the connection is preserved, otherwise the connection is freed. When operating in transparent firewall mode, you must configure static routes for the endpoints. You cannot configure DCD on connections that are also offloaded, so do not configure DCD on connections you are fast-pathing in the prefilter policy. Use the **show conn detail** command in the Firewall Threat Defense CLI to track how many DCD probes have been sent by the initiator and responder.

  Configure these options:
  - **Detection Timeout**—The time duration in hh:mm:ss format to wait after each unresponsive DCD probe before sending another probe, between 0:0:1 and 24:0:0. The default is 0:0:15.

    For systems that are operating in a cluster or high-availability configuration, we recommend that you do not set the interval to less than one minute (0:1:0). If the connection needs to be moved between systems, the changes required take longer than 30 seconds, and the connection might be deleted before the change is accomplished.
  - **Detection Retries**—The number of consecutive failed retries for DCD before declaring the connection dead, from 1 to 255. The default is 5.

Step 6 Click **Finish** to save your changes.

The rule is added to the bottom of the appropriate list, either Interfaces or Global. Global rules are matched in top-down order. Rules in the Interfaces list are matched in top down order for each interface object. Place

rules for narrowly-defined traffic classes above broader rules, to ensure the right services get applied. You can move rules within each list by using drag and drop. You cannot move rules between lists.

Bypass TCP state checks for asymmetrical routing (TCP state bypass)

TCP state bypass allows traffic to bypass stateful inspection checks on Firewall Threat Defense devices.

Implementation considerations

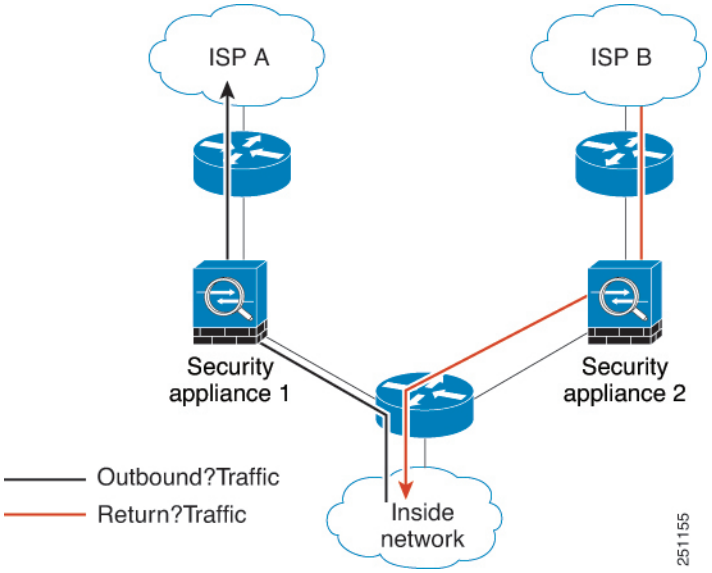
If you have an asymmetrical routing environment in your network, where the outbound and inbound flow for a given connection can go through two different Firewall Threat Defense devices, you need to implement TCP state bypass on the affected traffic.

However, TCP state bypass weakens the security of your network, so you should apply bypass on very specific, limited traffic classes.

The asymmetrical routing problem

The asymmetrical routing problem occurs when return traffic for a connection goes through a different firewall than the outbound traffic. This causes packets to be dropped because they do not match existing connection entries in the fast path table.

Traffic inspection and fast path operation



By default, the Firewall Threat Defense inspects all traffic using the Adaptive Security Algorithm. The Firewall Threat Defense allows or drops traffic based on the security policy. The Firewall Threat Defense maximizes the firewall performance by checking the state of each packet (new connection or established connection). It assigns new connection SYN packets to the session management path. It assigns established connections to the fast path. It assigns packets requiring advanced inspection to the control plane path.

The Firewall Threat Defense allows TCP packets that match existing connections to pass through via the fast path without rechecking every aspect of the security policy. This feature improves performance. However, the fast path establishment method can interfere with asymmetric routing solutions. The method uses SYN packets and performs checks such as TCP sequence number validation. Both outbound and inbound flows of a connection must pass through the same Firewall Threat Defense device.

Asymmetric routing scenario

For example, a new connection goes to Security Appliance 1. The SYN packet goes through the session management path, and an entry for the connection is added to the fast path table. If subsequent packets of this connection go through Security Appliance 1, then the packets match the entry in the fast path, and are passed through. But if subsequent packets go to Security Appliance 2, where no SYN packet went through the session management path, then no entry exists in the fast path for the connection, and Security Appliance 2 drops the packets. The following figure shows an asymmetric routing example where the outbound traffic goes through a different Firewall Threat Defense than the inbound traffic:

Figure 419: Asymmetric routing

If you have asymmetric routing configured on upstream routers and traffic alternates between two Firewall Threat Defense devices, then you can configure TCP state bypass for specific traffic. TCP state bypass alters the way sessions are established in the fast path and disables the fast path checks. This feature treats TCP traffic similarly to a UDP connection: when a non-SYN packet matching the specified networks enters the Firewall Threat Defense device, and there is not a fast path entry, then the packet goes through the session management path to establish the connection in the fast path. Once in the fast path, the traffic bypasses the fast path checks.

Guidelines and limitations for TCP state bypass

TCP state bypass unsupported features

The system does not support these features when you use TCP state bypass:

- Application inspection—Inspection requires both inbound and outbound traffic to go through the same Firewall Threat Defense, so inspection is not applied to TCP state bypass traffic.
- Snort inspection—Inspection requires both inbound and outbound traffic to go through the same device. However, Snort inspection is not automatically bypassed for TCP state bypass traffic. You must also configure a prefilter fastpath rule for the same traffic class for which you configure TCP state bypass. Otherwise, packets might be dropped unexpectedly because the TCP Normalizer is also not engaged.
- TCP Intercept, maximum embryonic connection limit, TCP sequence number randomization—The Firewall Threat Defense does not keep track of the state of the connection, so these features are not applied.
- TCP normalization—The TCP normalizer is disabled.
- TLS server identity discovery cannot be used with TCP state bypass on an inline or inline tap interface.

TCP state bypass NAT guidelines

Because the translation session is established separately for each device, be sure to configure static NAT on both devices for TCP state bypass traffic. If you use dynamic NAT, the address chosen for the session on Device 1 will differ from the address chosen for the session on Device 2.

Configure TCP state bypass

Configure TCP state bypass to handle asymmetrical routing environments where standard TCP state checking would interfere with traffic flow.

To bypass TCP state checking in asymetrical routing environments, carefully define a traffic class that applies only to the affected hosts or networks. Then, enable TCP state bypass on the traffic class using a service policy. You must also configure a corresponding prefilter fastpath policy for the same traffic to ensure that the traffic bypasses inspection.

Because bypass reduces the security of the network, limit its application as much as possible.

Before you begin

Follow these steps to configure TCP state bypass:

Procedure

Step 1 Create the extended ACL that defines the traffic class.

For example, to define a traffic class for TCP traffic from 10.1.1.1 to 10.2.2.2, do the following:

a) Choose **Objects** > **Object Management** > **Access List** > **Extended**.
b) Click **Add Extended Access List**.
c) Enter a **Name** for the object, for example, bypass.
d) Click **Add** to add a rule.
e) Keep **Allow** for the action.
f) Enter 10.1.1.1 beneath the **Source** list and click **Add**. Then, enter 10.2.2.2 beneath the **Destination** list, and click **Add**.
g) Click **Port**, select **TCP (6)** beneath the **Selected Source Ports** list, then click **Add**. Do not enter a port number. Add TCP as the protocol. This will cover all ports.
h) In the Extended Access List Entry dialog box, click **Add** to add the rule to the ACL.
i) In the Extended Access List Object dialog box, click **Save** to save the ACL object.

Step 2 Configure the TCP state bypass service policy rule.

For example, to configure TCP state bypass for this traffic class globally, do the following:

a) Choose **Policies** > **Access Control heading** > **Access Control**, and edit the policy assigned to the devices that require this service.
b) Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** () for the **Threat Defense Service Policy**.
c) Click **Add Rule**.
d) Select **Global** and click **Next**.
e) Select the extended ACL object you created for this rule and click **Next**.
f) Select **Enable TCP State Bypass**.
g) (Optional.) Adjust the **Idle** timeout for bypassed connections. The default is 2 minutes.

h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

Click **OK** to save the changes to the service policy.

Click **Save** on **Advanced** to save the changes to the access control policy.

Step 3 Configure a prefilter fastpath rule for the traffic class.

You cannot use the ACL object in the prefilter rule, so you need to recreate the traffic class either directly in the prefilter rule, or by first creating network objects that define the class.

This procedure assumes that you already have a prefilter policy attached to the access control policy. If you have not created a prefilter policy yet, go to **Policies** > **Prefilter** and first create the policy. You can then follow this procedure to attach it to the access control policy and create the rule.

Keeping with our example, this procedure creates a fastpath rule for TCP traffic from 10.1.1.1 to 10.2.2.2.

a) Choose **Policies** > **Access Control heading** > **Access Control**, and edit the policy that has the TCP bypass service policy rule.
b) Click the link for the **Prefilter Policy**, which is to the left immediately under the policy description.
c) In the Prefilter Policy dialog box, select the policy to assign to the device if the correct one is not already selected. Do not click OK.

Because you cannot add rules to the default prefilter policy, you must choose a custom policy.

d) In the Prefilter Policy dialog box, click **Edit** ( ). This action opens a new browser window where you can edit the policy.
e) Click **Add Prefilter Rule** and configure a rule with these properties.

- **Name**—Any name that you find meaningful will do, such as TCPBypass.
- **Action**—Select **Fastpath**.
- **Interface Objects**—If you configured TCP state bypass as a global rule, leave the default, any, for both source and destination. If you created an interface-based rule, select the same interface objects you used for rule in the **Source Interface Objects** list, and keep any as the destination.
- **Networks**—Add 10.1.1.1 to the **Source Networks** list, and 10.2.2.2 to the **Destination Networks** list. You can either use network objects or manually add the addresses.
- **Ports**—Under **Selected Source Ports**, select TCP(6), **do not enter a port**, and click **Add**. This applies the rule to all TCP traffic, regardless of TCP port number.

f) Click **Add** to add the rule to the prefilter policy.
g) Click **Save** to save your changes to the prefilter policy.

You can now close the prefilter edit window and return to the access control policy edit window.

h) In the access control policy edit window, the Prefilter Policy dialog box should still be open. Click **OK** to save your changes to the prefilter policy assignment.
i) Click **Save** on the access control policy to save the changed prefilter policy assignment, if you changed it.

You can now deploy the changes to the affected devices.

Disable TCP sequence randomization

Disable TCP initial sequence number randomization to prevent issues with data scrambling and to support specific network configurations that require non-randomized sequence numbers.

Each TCP connection has two initial sequence numbers (ISN): one generated by the client and one generated by the server. The Firewall Threat Defense device randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions.

Randomizing the ISN of the protected host prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session. However, TCP sequence randomization effectively breaks TCP SACK (Selective Acknowledgement), as the sequence numbers the client sees are different from what the server sees.

You can disable TCP initial sequence number randomization if data is getting scrambled or if there is another necessity. This is useful in these situations:

- If another in-line firewall is also randomizing the initial sequence numbers, there is no need for both firewalls to be performing this action, even though this action does not affect the traffic.
- If you use eBGP multi-hop through the device, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.
- If you use a WAAS device that requires the device not to randomize the sequence numbers of connections.
- If you enable hardware bypass for the ISA 3000, and TCP connections are dropped when the ISA 3000 is no longer part of the data path.

Procedure

Step 1 Create the extended ACL that defines the traffic class.

For example, to define a traffic class for TCP traffic from any host to 10.2.2.2, do the following:

a) Choose **Objects** > **Object Management** > **Access List** > **Extended**.
b) Click **Add Extended Access List**.
c) Enter a **Name** for the object, for example, preserve-sq-no.
d) Click **Add** to add a rule.
e) Keep **Allow** for the action.
f) Leave the **Source** list empty, enter 10.2.2.2 beneath the **Destination** list, and click **Add**.
g) Click **Port**, select **TCP (6)** beneath the **Selected Source Ports** list, and click **Add**. Do not enter a port number, simply add TCP as the protocol, which will cover all ports.
h) Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.
i) Click **Save** on the Extended Access List Object dialog box to save the ACL object.

Step 2 Configure the service policy rule that disables TCP sequence number randomization.

For example, to disable randomization for this traffic class globally, do the following:

a) Choose **Policies** > **Access Control heading** > **Access Control**, and edit the policy assigned to the devices that require this service.
b) Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** (✎) for the **Threat Defense Service Policy**.

c) Click **Add Rule**.
d) Select **Global** and click **Next**.
e) Select the extended ACL object you created for this rule and click **Next**.
f) Deselect **Randomize TCP Sequence Number**.
g) (Optional.) Adjust the other connection options as needed.
h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

Click **OK** to save the changes to the service policy.

Click **Save** on **Advanced** to save the changes to the access control policy.

You can now deploy the changes to the affected devices.

Monitor service policies

You can monitor service-policy related information using the device CLI. Use these commands to get the information you need.

Commands for monitoring service policies.

- **show conn** [**detail**]

  Shows connection information. Detailed information uses flags to indicate special connection characteristics. For example, the "b" flag indicates traffic subject to TCP state bypass.

  When you use the **detail** keyword, you can see information about dead connection detection (DCD) probing, which shows how often the connection was probed by the initiator and responder. For example, the connection details for a DCD-enabled connection would look like this:

```
TCP dmz: 10.5.4.11/5555 inside: 10.5.4.10/40299,
    flags UO , idle 1s, uptime 32m10s, timeout 1m0s, bytes 11828,
cluster sent/rcvd bytes 0/0, owners (0,255)
  Traffic received at interface dmz
        Locally received: 0 (0 byte/s)
  Traffic received at interface inside
        Locally received: 11828 (6 byte/s)
  Initiator: 10.5.4.10, Responder: 10.5.4.11
  DCD probes sent: Initiator 5, Responder 5
```

- **show service-policy**

  Shows service policy statistics, including dead connection detection (DCD) statistics.

- **show threat-detection statistics top TCP-intercept** [**all** | **detail**]

  View the top 10 protected servers under attack. The **all** keyword shows the history data of all the traced servers. The **detail** keyword shows history sampling data. The system samples the number of attacks 30 times during the rate interval, so for the default 30 minute period, statistics are collected every 60 seconds.

Examples for service policy rules

This section provides examples of service policy rules to help users understand how to configure and implement service policies effectively.

Protect servers from a SYN flood DoS attack (TCP intercept)

This task configures TCP intercept to protect servers from SYN flood denial of service attacks by limiting embryonic connections and enabling monitoring statistics.

A SYN-flooding denial of service (DoS) attack occurs when an attacker sends a series of SYN packets to a host. These packets usually originate from spoofed IP addresses. The constant flood of SYN packets keeps the server SYN queue full, which prevents it from servicing connection requests from legitimate users.

You can limit the number of embryonic connections to help prevent SYN flooding attacks. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination.

When the embryonic connection threshold of a connection is crossed, the Firewall Threat Defense acts as a proxy for the server. It generates a SYN-ACK response to the client SYN request using the SYN cookie method. This approach prevents the connection from being added to the SYN queue of the targeted host. The SYN cookie is the initial sequence number returned in the SYN-ACK that is constructed from MSS, time stamp, and a mathematical hash of other items to essentially create a secret. If the Firewall Threat Defense receives an ACK from the client with the correct sequence number, and within the valid time window, it authenticates the client and allows the connection to the server. The component that performs the proxy is called TCP intercept.

Setting connection limits can protect a server from a SYN flood attack. You can optionally enable TCP intercept statistics and monitor the results of your policy. The following procedure explains the end-to-end process.

Before you begin

- Ensure that you set the embryonic connection limit lower than the TCP SYN backlog queue on the server that you want to protect. Otherwise, valid clients can no longer access the server during a SYN attack. To determine reasonable values for embryonic limits, carefully analyze the capacity of the server, the network, and server usage.
- The number of CPU cores affects the actual number of concurrent and embryonic connections the device can allow. Because each core manages connections, the actual counts can exceed the configured limits. In the worst case, a device with n cores can allow up to n − 1 additional connections of each type.

  For example, on a 4-core device configured for 6 concurrent connections and 4 embryonic connections, the device could allow up to 3 additional connections of each type.

  To find the number of cores for your model, enter the **show CPU core** command in the device CLI.

Procedure

Step 1 Create the extended ACL that defines the traffic class, which is the list of servers you want to protect.

For example, to define a traffic class to protect the web servers with the IP addresses 10.1.1.5 and 10.1.1.6:

a) Choose **Objects** > **Object Management** > **Access List** > **Extended**.
b) Click **Add Extended Access List**.
c) Enter a **Name** for the object, for example, protected-servers.
d) Click **Add** to add a rule.
e) Keep **Allow** for the action.
f) Leave the **Source** list empty, enter 10.1.1.5 beneath the **Destination** list, and click **Add**.
g) Also enter 10.1.1.6 beneath the **Destination** list and click **Add**.
h) Click **Port**, select **HTTP** in the available ports list, and click **Add to Destination**. If your server also supports HTTPS connections, also add that port.
i) Click **Add** to add the rule to the ACL.

Click **Save** to save the ACL object.

Step 2 Configure the service policy rule that sets embryonic connection limits.

For example, to set the total concurrent embryonic limit to 1000 connections, and the per-client limit to 50 connections, do the following:

a) Choose **Policies** > **Access Control heading** > **Access Control**, and edit the policy assigned to the devices that require this service.
b) Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** ( ) for the **Threat Defense Service Policy**.
c) Click **Add Rule**.
d) Select **Global** and click **Next**.
e) Select the extended ACL object you created for this rule and click **Next**.
f) Enter 1000 for **Connections** > **Maximum Embryonic**.
g) Enter 50 for **Connections Per Client** > **Maximum Embryonic**.

(Optional.) Adjust the other connection options as needed.

h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

Click **OK** to save the changes to the service policy.

Click **Save** on **Advanced** to save the changes to the access control policy.

Step 3 (Optional.) Configure the rates for TCP intercept statistics.

TCP intercept uses these options to determine the rate for collecting statistics. All options have default values, so if these rates suit your needs, you can skip this step.

- Rate Interval—The size of the history monitoring window, between 1 and 1440 minutes. The default is 30 minutes. During this interval, the system samples the number of attacks 30 times.
- Burst Rate—The threshold for syslog message generation, between 25 and 2147483647. The default is 400 per second. When the burst rate is exceeded, the device generates syslog message 733104.
- Average Rate—The average rate threshold for syslog message generation, between 25 and 2147483647. The default is 200 per second. When the average rate is exceeded, the device generates syslog message 733105.

If you want to adjust these options, do this:

a) Choose **Objects** > **Object Management** > **FlexConfig** > **Text Object**.

b) Click **Edit** (✎) for the **threat_defense_statistics** system-defined object.
c) Although you can directly change the values, the recommended approach is to open the **Override** section and click **Add** to create a device override.
d) Select the devices to which you will assign the service policy (through the access control policy assignment) and click **Add** to move them to the selected list.
e) Click **Override**.
f) The object must have 3 entries, so click **Count** as needed until you get 3.
g) Enter the values you need, in order from 1-3, as rate interval, burst rate, and average rate. Consult the object description to verify you enter the values in the right order.
h) Click **Add** in the Object Override dialog box.
i) Click **Save** in the Edit Text Object dialog box.

Step 4 Enable TCP intercept statistics.

You must configure a FlexConfig policy to enable TCP intercept statistics.

a) Choose **Devices** > **FlexConfig**.
b) If you already have a policy assigned to the devices, edit it. Otherwise, create a new policy and assign it to the affected devices.
c) Select the **Threat_Detection_Configure** object in the **Available FlexConfig** list and click >>. The object is added to the **Selected Append FlexConfigs** list.
d) Click **Save**.
e) (Optional.) You can verify that you have the right settings by clicking **Preview Config** and selecting one of the devices.

The system generates the CLI commands that will be written to the device during the next deployment. These commands will include those needed for the service policy as well as those needed for threat detection statistics. Scroll to the bottom of the preview to see the appended CLI. The TCP intercept statistics command should look something like this, if you use the default values (line break added for clarity):

```
###Flex-config Appended CLI ###

threat-detection statistics tcp-intercept rate-interval 30
       burst-rate 400 average-rate 200
```

Step 5 You can now deploy the changes to the affected devices.

Step 6 Monitor the TCP intercept statistics from the device CLI using these commands:

- **show threat-detection statistics top TCP-intercept** [**all** | **detail**]—View the top 10 protected servers under attack. The **all** keyword shows the history data of all the traced servers. The **detail** keyword shows history sampling data. The system samples the number of attacks 30 times during the rate interval, so for the default 30 minute period, statistics are collected every 60 seconds.

Note You can use the **shun** command to block attacking host IP addresses. To remove the block, use the **no shun** command.

- **clear threat-detection statistics TCP-intercept**—Erases TCP intercept statistics.

Example:

```
hostname(config)# show threat-detection statistics top tcp-intercept
Top 10 protected servers under attack (sorted by average rate)
Monitoring window size: 30 mins    Sampling interval: 30 secs
<Rank> <Server IP:Port> <Interface> <Ave Rate> <Cur Rate> <Total> <Source IP (Last Attack
Time)>
--------------------------------------------------------------------------------
1    10.1.1.5:80 inside 1249 9503 2249245 <various> Last: 10.0.0.3 (0 secs ago)
2    10.1.1.6:80 inside 10 10 6080 10.0.0.200 (0 secs ago)
```

Configure the Firewall Threat Defense device to appear on traceroutes

Make the Firewall Threat Defense device appear as a hop in traceroute results by decrementing the time-to-live on packets and adjusting ICMP rate limits.

By default, the Firewall Threat Defense device does not appear on traceroutes as a hop. To make it appear, you need to decrement the time-to-live on packets that pass through the device, and increase the rate limit on ICMP unreachable messages. To accomplish this, you must configure a service policy rule and adjust the ICMP platform settings policy.

Note If you decrement time to live, packets with a TTL of 1 will be dropped, but a connection will be opened for the session on the assumption that the connection might contain packets with a greater TTL. Note that some packets, such as OSPF hello packets, are sent with TTL = 1, so decrementing time to live can have unexpected consequences. Keep these considerations in mind when defining your traffic class.

Procedure

Step 1 Create the extended ACL that defines the traffic class for which to enable traceroute reporting.

For example, to define a traffic class for all addresses, but excluding OSPF traffic, do the following:

a) Choose **Objects** > **Object Management** > **Access List** > **Extended**.
b) Click **Add Extended Access List**.
c) Enter a **Name** for the object, for example, traceroute-enabled.
d) Click **Add** to add a rule to exclude OSPF.
e) Change the action to **Block**, click **Port**, select **OSPFIGP (89)** as the protocol beneath the **Destination Ports** list, and click **Add** to add the protocol to the selected list.
f) Click **Add** on the Extended Access List Entry dialog box to add the OSPF rule to the ACL.
g) Click **Add** to add a rule to include all other connections.
h) Keep **Allow** for the action, and leave both the Source and Destination lists empty.
i) Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.

Ensure that the OSPF deny rule is above the Allow Any rule. Drag and drop to move the rules if necessary.

Click **Save** on the Extended Access List Object dialog box to save the ACL object.

Step 2 Configure the service policy rule that decrements the time-to-live value.

For example, to decrement time-to-live globally, do the following:

a) Choose **Policies** > **Access Control heading** > **Access Control**, and edit the policy assigned to the devices that require this service.
b) Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** (✎) for the **Threat Defense Service Policy**.
c) Click **Add Rule**.
d) Select **Global** and click **Next**.
e) Select the extended ACL object you created for this rule and click **Next**.
f) Select **Enable Decrement TTL**.
g) (Optional.) Adjust the other connection options as needed.
h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

Click **OK** to save the changes to the service policy.

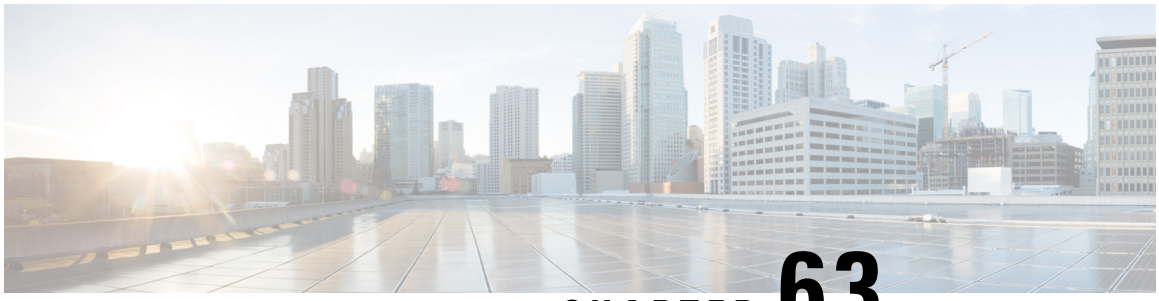
Click **Save** on **Advanced** to save the changes to the access control policy.

You can now deploy the changes to the affected devices.

Step 3 Increase the rate limit on ICMP unreachable messages.

a) Choose **Devices** > **Platform Settings**.
b) If you already have a policy assigned to the devices, edit it. Otherwise, create a new Threat Defense platform settings policy and assign it to the affected devices.
c) Select **ICMP** from the table of contents.
d) Increase the **Rate Limit**, for example, to 50. You might also want to increase the **Burst Size**, for example, to 10, to ensure enough responses are generated within the rate limit.

You can leave the ICMP rules table empty, it is not related to this task.



e) Click **Save**.

Step 4 You can now deploy the changes to the affected devices.

History for threat defense service policy

This reference provides a summary of feature changes by release for the service policy.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Description
Threat Defense Service Policy.	6.3	Any	You can now configure a Threat Defense service policy as part of your access control policy advanced options. You can use Threat Defense service policies to apply services to specific traffic classes. Features supported include TCP state bypass, randomizing TCP sequence numbers, decrementing the time-to-live (TTL) value on packets, dead connection detection, setting a limit on the maximum number of connections and embryonic connections per traffic class and per client, and timeouts for embryonic, half closed, and idle connections. New screen: **Policies** > **Access Control** > **Access Control**, **Advanced** tab, **Threat Defense Service Policy**. Supported platforms: Secure Firewall Threat Defense
Initiator and responder information for dead connection detection (DCD), and DCD support in a cluster.	6.5	Any	If you enable dead connection detection (DCD), you can use the **show conn detail** command to get information about the initiator and responder. Dead connection detection allows you to maintain an inactive connection, and the **show conn** output tells you how often the endpoints have been probed. In addition, DCD is now supported in a cluster. New/Modified commands: **show conn** (output only). Supported platforms: Secure Firewall Threat Defense
Configure the maximum segment size (MSS) for embryonic connections.	7.1	Any	You can configure a service policy to set the server maximum segment size (MSS) for SYN-cookie generation for embryonic connections upon reaching the embryonic connections limit. This is meaningful for service policies where you are also setting embryonic connection maximums. New or changed screens: **Connection Settings** in the Add/Edit Service Policy wizard.

CHAPTER 63

Threat Detection

Threat detection's portscan detector is a mechanism designed to help you detect and prevent portscan activity in all types of traffic to protect networks from eventual attacks. Portscan traffic can be detected efficiently in both allowed and denied traffic.

Portscan is a form of network reconnaissance that is often used by attackers as a prelude to an attack. In a portscan, an attacker determines the types of network protocols or services a host supports and sends specially crafted packets to a targeted host. By examining the packets that the host responds with, the attacker can often determine which ports are open on the host and, either directly or by inference, which application protocols are running on these ports.

- Portscan detection and prevention, on page 2211
- Requirements and prerequisites for threat detection, on page 2213
- Limitations for threat detection configuration, on page 2214
- Best practices for portscan prevention, on page 2214
- Configure portscan detection and prevention, on page 2215
- Monitoring threat detection, on page 2217
- History for threat detection, on page 2219

Portscan detection and prevention

Portscan detection and prevention is a threat detection system that:

- identifies port scan activity and issues events when they are found,
- optionally prevents port scans by automatically blocking scanners, and
- sends you events and also blocks the attacker for a duration that you set.

Pre-defined sensitivity levels for portscan detection

When configuring detection settings, you select from these pre-defined sensitivity levels. Except for custom, each level has pre-set values for each protocol for the number of ports (TCP, UDP), protocols (IP), or hosts (TCP, UDP, IP, ICMP) that must be scanned within a set time interval (expressed in seconds). Also, all types of scans and sweeps are enabled.

Note When counting ports or protocols, threat detection increments the number if the port or protocol in the current packet differs from the previous packet. For example, if you have an application that opens connections in 10 set ports randomly, the total number of ports scanned could mount so quickly that your port number will be exceeded within the interval. The system does not count only unique ports.

Exceeding the number within the interval can indicate a scanning attack. Portscan events are generated only when the port/protocol/host numbers are exceeded for the moving time interval window.

These sensitivity levels determine portscan detection behavior:

- **Low**—This level uses the shortest time window for portscan detection, coupled with high counts for ports, protocols, and hosts. Thus, you should see portscan events for the most aggressive scanners only. Select this sensitivity level to suppress false positives, but remember that some types of port scans, such as slow or filtered scans, might be missed. For more detail on how low sensitivity detection works, see Detection in the low sensitivity level, on page 2213.
- **Medium**—This level uses moderate values for both the interval and port/protocol/host counts. However, very active hosts such as network address translators and proxies might generate false positives. Add such hosts to the ignore scanner list. This is the default sensitivity level and a good place to start.
- **High**—This level uses a much longer time window for portscan detection, coupled with lower counts for ports, protocols, and hosts. With this level, you are most likely to see events for even the least aggressive port scans or sweeps, so you are more likely to notice all attackers. However, this level would likely result in the most portscan events issued, and potentially the highest number of false positives.
- **Custom**—If you want to configure any setting differently than one of the predefined sensitivity levels, or disable a particular type of scan or sweep, the level automatically switches to custom. If you want to adjust the options, first select the level that most closely matches what you want, then edit the values as appropriate.

Table 140: Sensitivity level settings

Setting	Low	Medium	High
Interval (TCP/UDP/IP/ICMP)	60 seconds	90 seconds	600 seconds (10 minutes)
TCP/UDP portscan - Number of Ports	120 seconds	90 seconds	60 seconds
TCP/UDP portsweep - Number of Hosts	180 seconds	150 seconds	100 seconds
IP protocol scan - Number of Protocols	30 seconds	15 seconds	10 seconds
IP protocol sweep - Number of Hosts	25 seconds	20 seconds	10 seconds
ICMP host sweep - Number of Hosts	50 seconds	30 seconds	20 seconds

Detection in the low sensitivity level

When you select the low sensitivity level, the system tracks negative responses for TCP, UDP, and ICMP initial packets. An alert is triggered only when the number of unsuccessful connections exceeds the rejection threshold (10% for low sensitivity) and the port or IP protocol count exceeds the configured threshold. This mitigates false positives.

Low sensitivity level detection behavior

Rejection threshold applies to low sensitivity (or equivalent custom settings) only; it does not apply to other sensitivity levels or their custom equivalents.

When there is a mix of allowed and blocked traffic, the number of rejected ports or hosts is calculated based on the difference between allowed and blocked traffic. In the case of only blocked traffic, the rejection threshold is not considered.

These criteria are not used for UDP/ICMP connections on interfaces configured in inline sets.

Low sensitivity level detection scenarios

In low sensitivity mode, the port count threshold is 120. Thus, the rejection count threshold is 10% of 120, which is 12. Here are examples that show how the system issues portscan events with this configuration:

- An attacker initiates connections with 131 ports of the target and the target positively acknowledges all the initiations. Port count = 131, which is greater than the threshold, but a portscan alert is not triggered because there are no negative acknowledgements.
- An attacker initiates connections with 131 ports of the target and the target positively acknowledges 121 initiations and negatively acknowledges 10 initiations. Port count = 131, which is greater than the threshold, but reject port count = 10, which is lesser than the rejection threshold. Therefore, a portscan alert is not triggered.
- An attacker initiates connections with 134 ports of the target and the target positively acknowledges 121 initiations and negatively acknowledges 13 initiations. Port count = 134, which is greater than the threshold, and reject port count = 13 is also higher than the rejection threshold. Therefore a portscan alert is triggered.

Requirements and prerequisites for threat detection

Model support

Firewall Threat Defense running version 7.2+ and Snort 3.

Supported domains

Any

User roles

Admin

Access Admin

Network Admin

Limitations for threat detection configuration

Threat detection requires Snort 3 and has specific version requirements and configuration interactions that vary by management platform.

- Threat detection requires Snort 3. The managed device must be running version 7.2 or higher. For Snort 2, or devices running versions lower than 7.2, you can configure port scan through the NAP policy. Note that the threat detection feature is not the same as the port scan feature in the NAP policy. If there are non-Snort 3 devices running version 7.2 or higher that are assigned to the access control policy, the threat detection settings are not deployed to those unsupported devices.
- If you configure port scan in the NAP policy on a device running 7.1 or lower, that configuration is not translated to the threat detection feature on upgrade to 7.2. You must manually configure threat detection. Although the NAP and threat detection port scan options are similar, they do not match one-to-one.
- If you configure threat detection, any port scan configuration in the NAP policy is ignored and not configured on the devices that support threat detection.
- The NAP port scan feature for Snort 3 is always ignored for devices running version 7.2 or higher. To configure port scanning, you must use the threat defense settings.
- Threat detection works on traffic that passes through the device only. It does not work on traffic directed to the device.
- In a high availability setup, port scanning statistics are not synchronized to the standby unit. However, blocked hosts are synchronized and continue to be blocked until the duration period expires in case of a failover.
- (Devices running Threat Defense versions 7.2 through 7.7). For nodes in a cluster, detection and prevention happen on the individual cluster node. That is, if node B detects and blocks traffic from a host, node A will not be aware of that action because port scan statistics are not synchronized across cluster nodes.
- For inline sets, or for interfaces that are configured to be part of an equal-cost multipath (ECMP) traffic zone, detection and prevention are done at the zone level. Port scan statistics for a host are accumulated across all interfaces of a zone. Similarly, when a host crosses configured thresholds, it is blocked across all interfaces of the corresponding zone.
- Although the port scan events generated by the threat detection feature are the same as the ones Snort issues for port scan, you do not need to enable port scanning intrusion rules to get the events. Threat detection works regardless of your intrusion policy implementation.

Best practices for portscan prevention

Portscan prevention mode can result in unintended traffic outage. In prevention mode, hosts are blocked from further scanning of networks on all protocols for the configured duration. Review the detection and prevention parameters carefully to ensure legitimate traffic is not blocked.

Before configuring portscan in prevention mode:

- Start using portscan in detection mode.
- Observe the generated portscan events.
- Tune the sensitivity level, monitored networks, ignore scanner list, and ignore target list. If a pre-defined sensitivity level does not work well for your situation, configure custom settings as needed.
- Repeat the process until false positives are eliminated and the event rate represents an accurate picture of port scanning in your network. Ensure that you are comfortable with blocking the remaining identified scanners.

Configure portscan detection and prevention

This task enables threat detection to watch for port scanning activity and optionally automatically block scanners for a period of time.

Portscan is a form of network reconnaissance that is often used by attackers as a prelude to an attack. In a portscan, an attacker determines the types of network protocols or services a host supports and sends specially crafted packets to a targeted host. By examining the packets that the host responds with, the attacker can often determine which ports are open on the host and, either directly or by inference, which application protocols are running on these ports.

You can enable threat detection to watch for port scanning activity and optionally, automatically block scanners for a period of time.

Before you begin

Fully Qualified Domain Name (FQDN), wildcard mask, any, any-ipv4, and any-ipv6 network objects are not supported for portscan configuration. These objects are not shown in the **Monitor**, **Ignore Scanner**, **Ignore Target**, and **Exclude** fields.

Procedure

Step 1 In the access control policy editor, click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line. Then, click **Edit** (✎) next to **Threat Detection**.

Step 2 In the **Threat Detection** window, select the **Portscan mode**:

- **Disable**—Turn off threat detection. This is the default mode. You can click **Revert to Defaults** to return to this unconfigured state.
- **Detection**—Perform portscan detection, but alert on problems only. Do not take action against potential attackers. We suggest you use this mode initially until you fine-tune the threat detection settings to avoid excessive false positives.
- **Prevention**—Perform portscan detection and actively block identified scanners, that is, hosts that are performing the port scan.

Step 3 Configure the **Traffic Selection** options.

The traffic selection options determine which networks are monitored, the type of connections monitored, and whether any scanners or target hosts should be exempted from the monitored networks. By default, the system monitors permitted connections on all networks.

- **Detection On Traffic**—Select the types of connection that will be monitored for portscan activity: **Permitted**, **Denied**, or **All** traffic. The default is **Permitted**.
- **Monitor**—Select the network objects that define the networks to monitor for portscan or sweep activity. The default is any network, IPv4 or IPv6. Use this option to limit scanning to untrusted networks.
- **Ignore Scanner**—Select the network objects that define the hosts or networks, from within the range of the monitored networks, that should be ignored. For example, if you have set up your own scanner to test your network, you can exempt the address of your scanner to avoid unnecessary reporting on the address. Do not include addresses that are outside the monitored networks, as these addresses are already ignored.
- **Ignore Target**—Select the network objects that define the hosts or networks that should be ignored as targets, that is, victims of a portscan or sweep.

Step 4 Click the **Configuration** tab and select the scanning sensitivity level.

The predefined sensitivity levels, **Low**, **Medium**, and **High**, set the port scanning options to values that are increasingly aggressive. For example, if you select low, you would expect to see fewer port scanning events, and you could potentially miss attackers more easily than if you selected medium or high. On the other hand, if you select high, you might see more events and also, potentially, more false positives. The default level is medium. For more information on these levels, see Pre-defined sensitivity levels for portscan detection, on page 2211.

As you select the levels, you can see the related values within the protocol sections: **TCP**, **UDP**, **IP**, and **ICMP**. If you change any of the preset values, or disable a type of scan, the sensitivity mode automatically changes to **Custom**.

Within each protocol section, the options are:

- **Interval**—The time range, in seconds, within which the configured values for portscan or portsweep are exceeded. For example, if you select 90 seconds, and 60 as the number of TCP portscan ports, a scanner would need to try 60 ports on a host within 90 seconds for it to be considered a portscan. The system generates events only if the number of ports, protocols, or hosts (for a portsweep) are exceeded within the specified interval.

  You can specify a range between 30 to 600 seconds. The longer the period, the more likely a host might be identified as a scanner.
- **Portscan** (TCP/UDP)—Select whether to monitor for port scanning against single hosts, and specify the number of ports that must be scanned within the interval to count as a portscan attack. The allowed range is 1-256.
- **Portsweep** (TCP/UDP)—Select whether to monitor for port sweeping against multiple hosts, and specify the number of hosts that must be scanned for a given port within the interval to count as a portsweep attack. The allowed range is 1-256.
- **Protocol Scan** (IP)—Select whether to monitor for protocol scanning against single hosts, and specify the number of protocols that must be scanned within the interval to count as a protocol scan attack. The allowed range is 1-255.
- **Protocol Sweep** (IP)—Select whether to monitor for protocol sweeping against multiple hosts, and specify the number of hosts that must be scanned for a given protocol within the interval to count as a protocol sweep attack. The allowed range is 1-256.

- **Hostsweep** (ICMP)—Select whether to monitor for ICMP host sweeping against multiple hosts, and specify the number of hosts that must be scanned within the interval to count as a hostsweep attack. The allowed range is 1-256.

Step 5 If you selected prevention mode, click the **Prevention** tab and configure the options.

In prevention mode, hosts are automatically blocked from further scanning of networks on all protocols for the configured duration. Review the detection and prevention parameters carefully to ensure legitimate traffic is not blocked.

- **Exclude**—Select the network objects that define the hosts or networks, from within the range of the monitored networks, that should be excluded from automatic blocking. Even if these hosts violate your scanning detection parameters, the system will not block them.
- **Duration**—How long, in seconds, automatically blocked scanner hosts should be prevented from sending traffic of any kind through the device. After the duration period ends, the hosts are automatically cleared and can again send traffic through the device. The allowed range is 600 to 2592000 seconds. The default is 3600 seconds (1 hour).

  If you need to manually unblock a host, SSH to the firewall that is blocking the host and use the **clear threat-detection portscan attacker** command.

Step 6 Click **OK** to save the threat detection settings.

Step 7 Click **Save** to save the access control policy.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 135.

Monitoring threat detection

The following topics explain how to monitor portscan activity.

View portscan alerts

Portscan activity is alerted through the existing portscan-specific intrusion events. Intrusion events with generator ID (GID) 122 and Snort ID from SIDs 1 through 27 are generated. For these events, the *(port_scan)* string is prepended in the event messages. The events include packet information along with packet data containing the statistics that triggered the alert.

To viewportscan events, go to **Analysis** > **Unified Events**.

Alternatively, you can also go to **Analysis** > **Intrusions** > **Events** and view portscan events.

Portscan issues these events regardless of your intrusion policy or NAP configuration. Events are issued only when scanners exceed the number of configured ports, protocols, or hosts for the various types of scan or sweep within the configured time interval for the associated protocol. A port scan from one host generates one event per set interval as soon as the threshold is met. If the same host initiates a new port scan during the same interval, no event is reported.

Table 141: Portscan events

Portscan type	Intrusion event
TCP Regular, Decoy, Distributed Scan	122:1 (port_scan) TCP portscan
TCP Portsweep	122:3 (port_scan) TCP portsweep
TCP Distributed Scan	122:4 (port_scan) TCP distributed portscan
IP Regular, Decoy, Distributed Protocol Scan n	122:9 (port_scan) IP protocol scan
IP Protocol Sweep	122:11 (port_scan) IP protocol sweep
IP Distributed Scan	122:12 (port_scan) IP distributed protocol scan
UDP Regular, Decoy, Distributed Scan	122:17 (port_scan) UDP portscan
UDP Portsweep	122:19 (port_scan) UDP portsweep
UDP Distributed Scan	122:20 (port_scan) UDP distributed portscan
ICMP Sweep	122:25 (port_scan) ICMP sweep
Portscan Block	122:100 (port_scan) host blocked due to portscan activity

Monitor portscan on the firewall

To monitor portscan, log in to the device Command-Line Interface (CLI) and use these commands.

- **show threat-detection portscan** [**attacker** | **target** | **shun**]

  Shows the IP addresses of scanners, those that have been shunned (blocked), and hosts that have been targeted by scans or sweeps.

- **show threat-detection portscan statistics** [**host** [*ipv4_address* | *ipv6_address*]] [**protocol** {**tcp** | **udp** | **IP** | **icmp**}]

  Shows statistics related to the port scan system. You can specify host, protocol, or host and protocol to filter the output to the desired information.

- **clear threat-detection portscan** [**attacker** | **target** | **shun**] [*ipv4_address mask* | *ipv6_address/prefix*]

  Manually unblocks scanners (attackers) or identified targets. Enter the command without parameters to clear all attackers, targets, or shunned hosts.

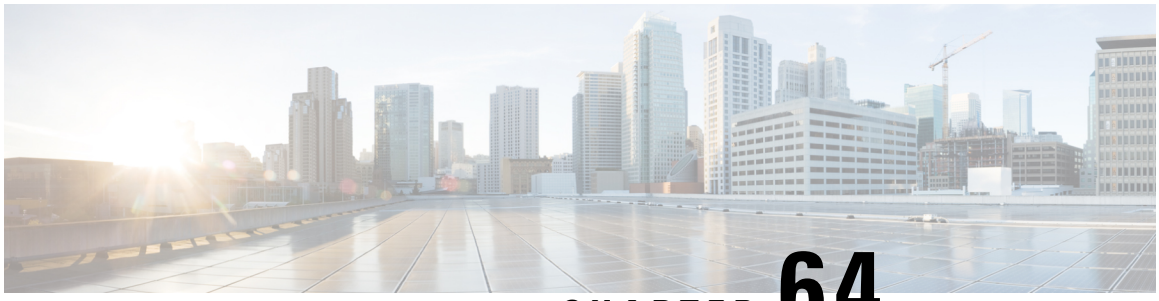
- **clear threat-detection portscan statistics** [**host** [*ipv4_address* | *ipv6_address*]] [**protocol** {**tcp** | **udp** | **IP** | **icmp**}]

  Erases statistics related to portscan, so that you can more clearly see the current state of scanning through this device. Enter the command without parameters to clear all statistics. Alternatively, specify a host, protocol, or host and protocol, to limit the reset to the specified items.

Unblocking a host

If you configure threat detection in prevention mode and the system blocks a host that you know is not an attacker, you can manually unblock the host before the host is automatically unblocked when the duration period expires.

To manually unblock the host, log in to the device CLI where the host is blocked and enter the clear threat-detection portscan attacker command. For example:



```
> clear threat-detection portscan attacker 10.2.0.100 255.255.255.255
1 tracker object deleted and 1 shun entry removed
```

Consider adding the host IP address to the exclude list in the prevention configuration.

History for threat detection

This reference provides a chronological history of changes and enhancements made to the threat detection feature across different software releases.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Description
Improved detection in low sensitivity.	7.4	7.4	The method for identifying port scans and sweeps has been improved when operating in low sensitivity level. Changes are automatic; there are no new configuration settings.
Improved portscan detection.	7.2	7.2 running Snort 3	With an improved portscan detector, you can easily configure the system to detect or prevent portscans. You can refine the networks you want to protect, set the sensitivity, and so on. For devices running Snort 2 and for devices running Version 7.1 and earlier, continue to use the network analysis policy for portscan detection. New/modified screens: We added **Threat Detection** to the access control policy's **Advanced** tab. New/Modified commands: **clear threat-detection portscan**, **show threat-detection portscan**.

CHAPTER 64

Elephant Flow Detection

Elephant flows are extremely large (in total bytes), continuous flows set up by a TCP (or other protocols) flow measured over a network link. By default, elephant flows are those larger than 1 GB/10 seconds. They can cause performance duress in Snort cores. Elephant flows are not numerous, but they can occupy a disproportionate share of the total bandwidth over a period of time. They can lead to problems, such as high CPU utilization, packet drops, and other issues.

From Firewall Management Center 7.2.0 onwards (Snort 3 devices only), you can use the elephant flow feature to detect and remediate elephant flows, which helps to reduce system stress and resolve the mentioned issues.

- Elephant flow detection and remediation, on page 2221
- Elephant flow upgrade from Intelligent Application Bypass, on page 2222
- Configure elephant flow detection, on page 2222
- Use case - Configure Elephant Flow Detection Outcomes, on page 2225

Elephant flow detection and remediation

Elephant flow detection and remediation is a feature that

- detects elephant flows in network traffic,
- applies remediation actions to manage these flows, and
- requires Snort 3 as the detection engine to function.

Remediation actions

These remediation actions can be applied:

- **Bypass elephant flow**—You can configure elephant flow to bypass Snort inspection. If this is configured, Snort does not receive any packet from that flow.
- **Throttle elephant flow**—You can apply rate-limit to the flow and continue to inspect flows. The flow rate is calculated dynamically, and the system reduces the flow rate by 10 percent. Snort sends the verdict (with QoS flow reduced by 10 percent) to the firewall engine. If you choose to bypass all applications, including unidentified applications, you cannot configure the throttle action (rate-limit) for any flow.

Elephant flow upgrade from Intelligent Application Bypass

For devices running 7.2.0 or later, you must configure elephant flow settings under the **Elephant Flow Settings** section in the access control policy (Advanced settings tab) because Intelligent Application Bypass (IAB) is deprecated from version 7.2.0 onwards for Snort 3 devices.

Post-upgrade to 7.2.0 (or later), if you are using a Snort 3 device, the elephant flow configuration settings will be picked and deployed from the **Elephant Flow Settings** section and not from the **Intelligent Application Bypass Settings** section, so if you have not migrated to Elephant Flow configuration settings, your device will lose the elephant flow configuration upon the next deployment.

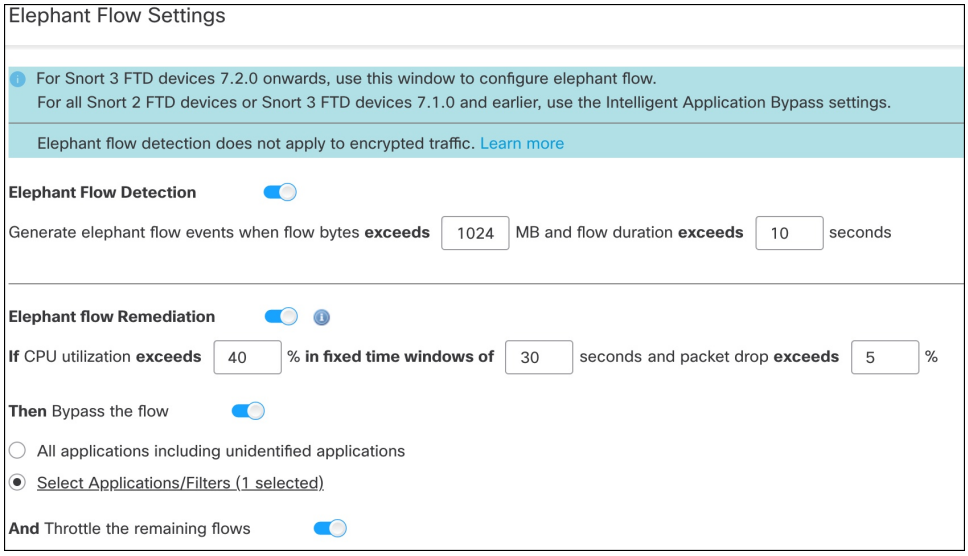
This table shows the IAB or elephant flow configurations that can be applied to version 7.2.0 or later and to version 7.1.0 or earlier that are running Snort 3 or Snort 2 engines.

Firewall Management Center	Firewall Threat Defense	Elephant Flow or IAB Configuration
Firewall Management Center 7.0 or 7.1	Snort 2 device	Configuration from IAB is applicable.
	Snort 3 device	Configuration from IAB is applicable.
Firewall Management Center 7.2.0	Snort 2 device	Configuration from IAB is applicable.
	Snort 3 device (7.1.0 and earlier)	Configuration from IAB is applicable.
	Snort 3 device (7.2.0 and later)	Configuration from Elephant Flow is applicable.

Configure elephant flow detection

Configure elephant flow detection to take actions on elephant flows. This helps resolve issues such as system duress, high CPU utilization, packet drops and related performance problems.

Attention Elephant flow detection is not applicable for prefiltered, trusted, or fast-forwarded flows, which do not process through Snort. As elephant flows are detected by Snort, elephant flow detection is not applicable for encrypted traffic.



Procedure

Step 1 In the access control policy editor, click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line. Then, click **Edit** ( ) next to **Elephant Flow Settings**.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Figure 420: Configure elephant flow detection

Figure 421: Configure elephant flow detection

Step 2 Configure the values for flow bytes and flow duration for the **Elephant Flow Detection** toggle button that is enabled by default.

When they exceed your configured values, elephant flow events are generated.

Step 3 To remediate elephant flows, enable the **Elephant Flow Remediation** toggle button.

Step 4 To set the criteria for remediation of the elephant flow, configure the values for CPU utilization percentage, duration of fixed time windows, and packet drop %.

CPU utilization is calculated per elephant flow and is derived from the flow latency. If the CPU utilization crosses the configured threshold and other configurations, such as fixed time windows and packet drops, are also matched, the elephant flow remediation actions are applied. Similarly, packet drop calculation is based on the packets dropped per CPU. After the packet drop percentage exceeds the configured value on a specific CPU, the remediation actions are applied. For example, consider that configurations are set to the default, that is, CPU utilization of 40%, fixed time window of 30 seconds, and packet drop of 5%. On a specific CPU, if more than 5% of packet drops are detected and the CPU utilization per flow exceeds 40% in the fixed time frame of 30 seconds, then the flows are either bypassed or throttled.

Step 5 Configure the actions for elephant flow remediation when it meets the configured criteria.

a. **Bypass the flow**—Enable this button to bypass Snort inspection for selected applications or filters. Choose from:

- **All applications including unidentified applications**—Select this option to bypass all the application traffic. If you configure this option, you cannot configure the throttle action (rate-limit) for any flow.
- **Select Applications/Filters**—Select this option to select the applications or filters whose traffic you want to bypass; see the topic *Configuring Application Conditions and Filters* in the *Access Control Rules* chapter in the Cisco Secure Firewall Management Center Device Configuration Guide.

b. **Throttle the flow**—Enable this button to apply rate-limit to the flow and continue to inspect flows. Note that you can select the applications or filters to bypass Snort inspection and throttle the remaining flows.

Note Automatic removal of throttle from a throttled elephant flow occurs when the system is out of duress, that is, the percentage of Snort packet drops is less than your configured threshold. Consequently, rate limiting is also removed.

You can also manually remove throttling from a throttled elephant flow, using these threat defense commands:

- **clear efd-throttle <5-tuple/all> bypass**—This command removes throttling from the throttled elephant flow and bypasses Snort inspection.
- **clear efd-throttle <5-tuple/all>**—This command removes throttling from the throttled elephant flow and Snort inspection continues. Elephant flow remediation is skipped after using this command.

For more information about these commands, refer to the Cisco Secure Firewall Threat Defense Command Reference.

Note Taking action on elephant flows (bypass and throttle the flow) is not supported on Cisco Firepower 2100 series devices.

Step 6 In the **Remediation Exemption Rule** section, click **Add Rule** to configure L4 access control list (ACL) rules for flows that must be exempted from remediation.

a) In the **Add Rule** window, use the **Networks** tab to add the network details, that is the source network and the destination network. Use the **Ports** tab to add the source port and the destination port.

If an elephant flow is detected and it matches the rules that are defined, an event is generated with the reason as **Elephant Flow Exempted** in the **Reason** column header of **Connection Events**.

b) In the **Remediation Exemption Rule** section, you can view the flows that are exempt from the remediation action.

c) Click **OK** to save the elephant flow settings.

Step 7 Click **Save** to save the policy.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 135.

After configuring your elephant flow settings, monitor your connection events to see if any flows are detected, bypassed, or throttled. You can view this in the **Reason** field of your connection event. The three reasons for elephant flow connections are:

- Elephant Flow
- Elephant Flow Throttled
- Elephant Flow Trusted

Attention Enabling elephant flow detection alone does not cause generation of connection events for elephant flows. If a connection event is already logged for another reason and the flow is also an elephant flow, then the **Reason** field contains this information. However, to ensure that you are logging all elephant flows, you must enable connection logging in the applicable access control rules.

Refer to Cisco Secure Firewall Elephant Flow Detection for more information.

Use case - Configure Elephant Flow Detection Outcomes

This use case provides a sample scenario for configuring outcomes and system responses that detect elephant flows in network traffic to optimize performance and resource usage.

Elephant flows

An elephant flow is an extremely large network connection that

- consists of long-running connections set up by TCP or other protocols measured over a network link,
- measures larger than 1 GB per 10 seconds by default, and
- can cause performance duress or issues in Snort cores by consuming excessive CPU resources.

Impact on system performance

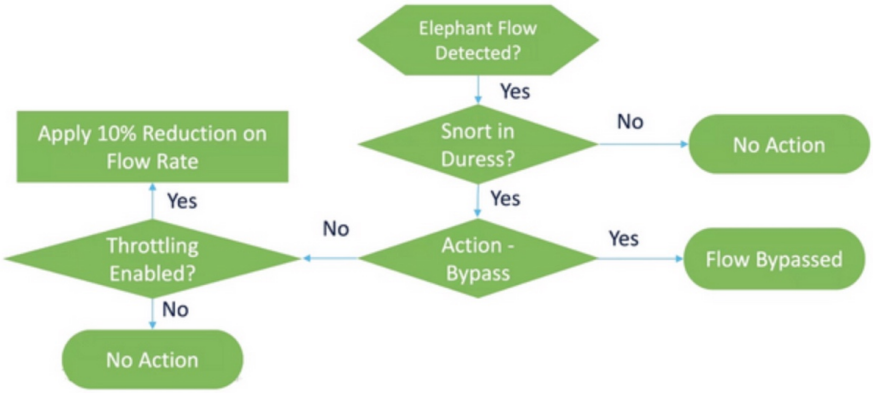
Elephant flows can potentially consume an excessive amount of CPU resources and impact other competing flows for detection resources and cause issues, such as increased latency or packet drops.

Benefits of elephant flow detection and remediation

- Elephant flow configuration allows customization and the option to bypass or even throttle elephant flows.
- You can choose to bypass or throttle flows that are based on your chosen applications to provide Snort inspection of suspect traffic, while bypassing more trusted traffic.
- Elephant flow remediation helps prioritize and free up more bandwidth for your internal applications, depending on your specific requirements.

How elephant flows work

Summary



The key components involved in the elephant flow process are:

- System detection: Monitors for Snort duress conditions based on configured parameters.
- Flow identification: Determines when a flow qualifies as an elephant flow.

- CPU monitoring: Tracks CPU utilization against configured thresholds.
- Bypass action: Allows traffic for trusted applications to pass without Snort inspection.
- Throttle action: Reduces the flow throughput in 10 percent increments until CPU utilization drops below the threshold.

Workflow

Figure 422: Elephant flow workflow

These stages describe how elephant flows are processed:

1. The system continuously monitors traffic flows and applies intrusion policy processing to all flows, including potential elephant flows, ensuring that attacks are detected early in connections.
2. When an elephant flow is detected based on configured parameters, the system evaluates whether a Snort duress condition exists by checking CPU utilization and time window parameters.

   No action is taken unless the system detects a Snort duress condition (performance issue). The system does not throttle or bypass a flow just because it is large.
3. If duress conditions are met, the system determines whether to bypass or throttle the elephant flow based on configuration settings.

   The actions of throttle and bypass are mutually exclusive. This means that you can either bypass or throttle a flow, but not both.
4. For bypass actions, if configured for specific applications only, the system allows trusted application flows to pass without Snort inspection while throttling remaining flows causing duress.

   This ensures that other non-trusted application flows still receive full Snort inspection, although their bandwidth is reduced.
5. For throttle actions, the system reduces flow throughput in 10 percent increments until CPU utilization reduces to below the configured threshold.

Sample business scenarios

In a data center, several activities are happening, such as replication of data between clusters, virtual machine integration, and database backup. Users in an organization could be watching videos on an OTT service or

downloading them. Bandwidth utilization for such activities might result in elephant flows that slow down the network and impact the performance of important tasks. As a network administrator (and depending on your specific requirements), you want visibility into such large flows that are causing bandwidth issues and remediate them.

As an example, let's see how you can configure elephant flow parameters to bypass Snort inspection for WebEx traffic (which your organization uses for real-time video conferencing) and throttle the remaining applications or connections, including videos, movies, and so on.

Prerequisites

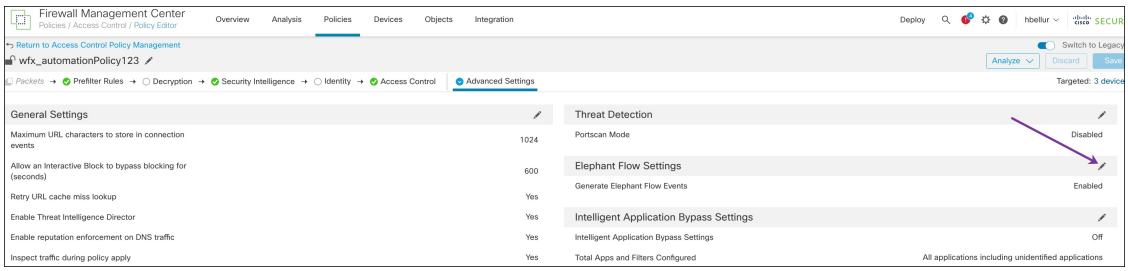
Ensure that you are running management center 7.2.0 or later and that the managed threat defense is also 7.2.0 or later.

When you enable only elephant flow detection, no additional connection events are generated. The system adds the Elephant Flow notation to matching connections that are already logged to the management center. **To log these events, you must enable connection logging in your access control policy.** You can do that for specific rules or add a Monitor rule that logs all connections, including elephant flows.

Configure elephant flow parameters

Configure elephant flow detection and remediation settings to identify high-bandwidth connections, and manage them through bypassing or throttling to maintain optimal system performance during high CPU utilization.

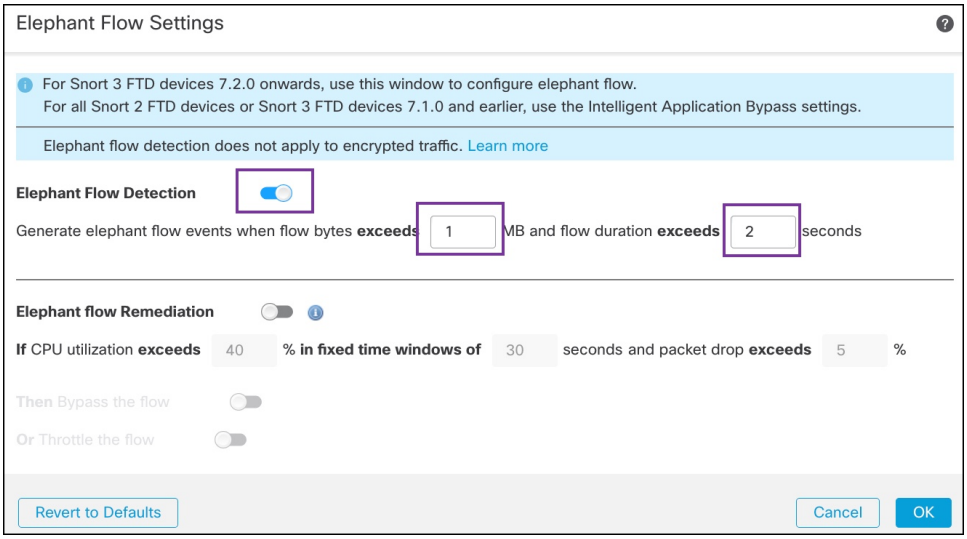
Elephant flows are high-bandwidth, long-duration connections that can impact system performance. By configuring elephant flow parameters, you can detect these flows and apply appropriate remediation actions such as bypassing trusted applications from inspection or throttling flows that cause system duress.



Procedure

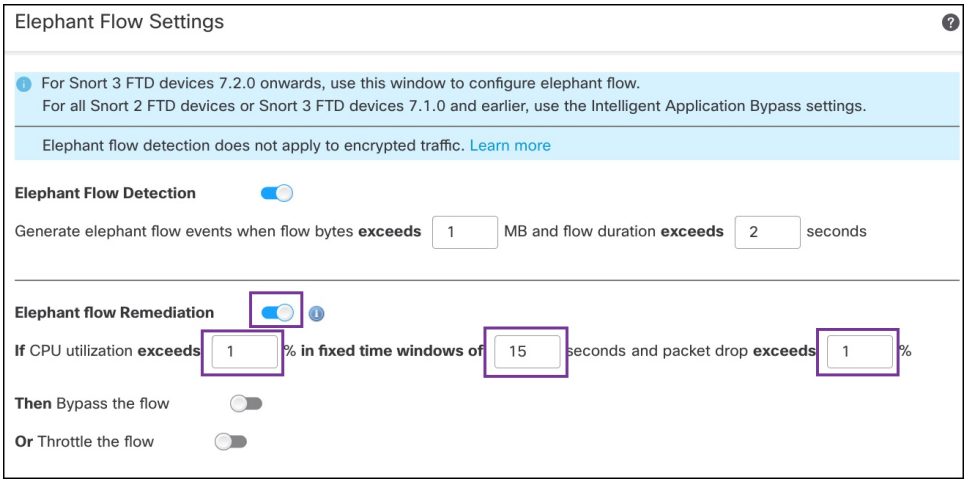
Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** (✎) next to the access control policy that you want to edit.



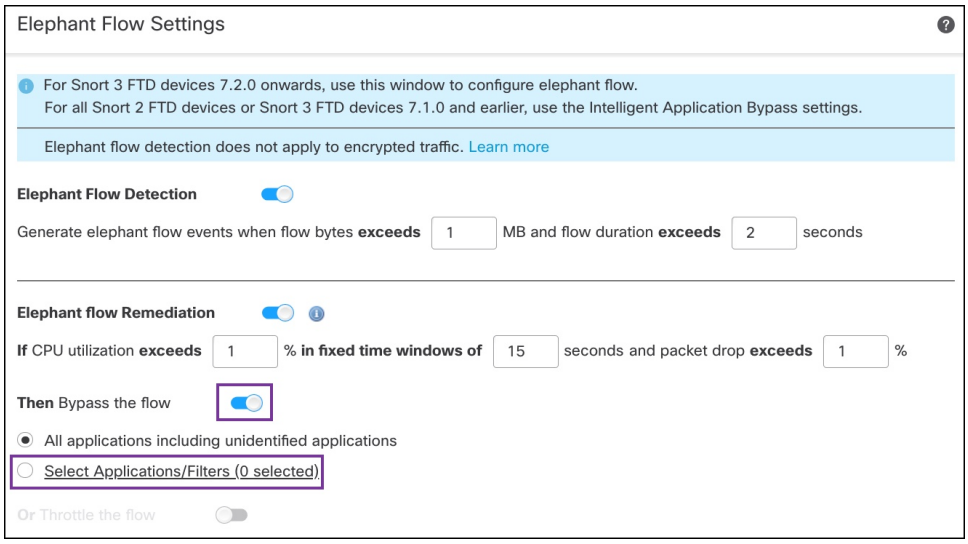
Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 Click **Edit** (✎) next to **Elephant Flow Settings**.

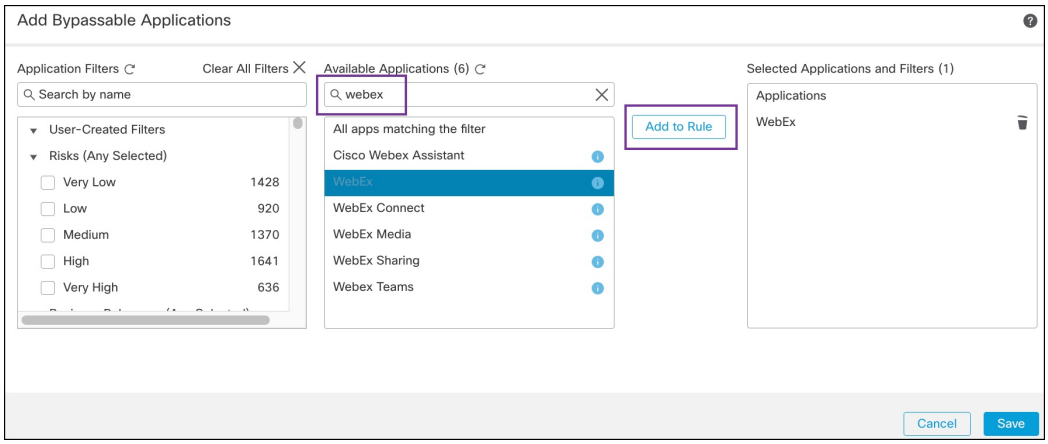


Step 5 The **Elephant Flow Detection** toggle button is enabled by default. The default setting enables detection only and no default action is configured. The detection settings allow you to adjust the flow bytes and duration so that you can identify the elephant flows in your system.

As a test setting, configure the flow bytes and duration parameters, as shown in the following figure.



Step 6 Enable the **Elephant Flow Remediation** toggle button. When an elephant flow is detected, you can choose to bypass or throttle the flow. Bypassing a flow means that the traffic is allowed to pass without Snort inspection. Throttling indicates that the flow throughput is reduced. This rate reduction is done in 10 percent increments until the CPU utilization decreases to less than the configured threshold.



As a test setting, configure the elephant flow remediation parameters as shown in the following figure.

Step 7 Enable the **Bypass the flow** toggle button and click the **Select Applications/Filters** radio button.

Step 8 Under **Application Filters**, search for and select the **WebEx** application, add it to the rule, and click **Save**. This means that WebEx connections are trusted and prioritized. These connections will skip Snort inspection if detected as elephant flows based on the configured parameters.

Step 9 Enable the **Throttle** toggle button to throttle the remaining flows (causing duress). This ensures that all the other flows are slowed down in 10 percent increments until the Snort duress condition is met.

Click **OK** and then **Save**.

What to do next

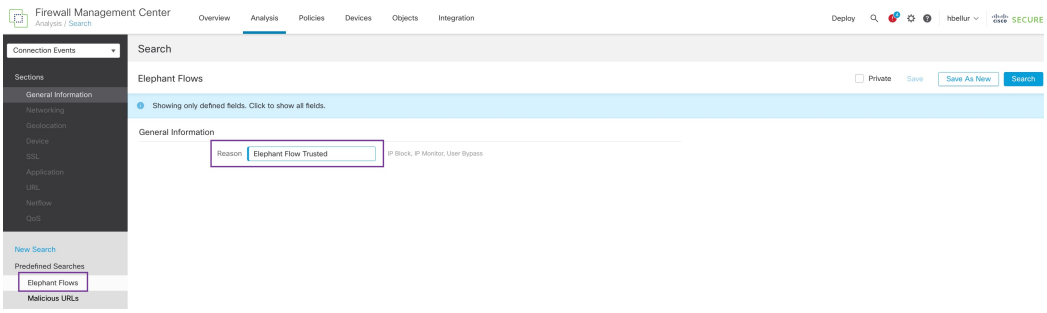
Deploy configuration changes.

View events for elephant flows

This task enables you to monitor elephant flow connection events to track flow detection, bypass, and throttling activities through the Reason field in connection events.

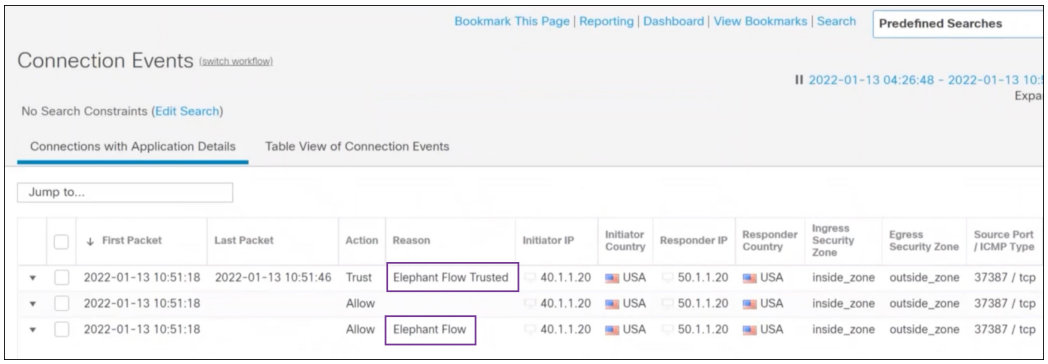
After configuring your elephant flow settings, monitor your connection events to see if any flows are detected, bypassed, or throttled. You can see this information in the **Reason** field of your connection events. The three types for elephant flow connections are:

- Elephant Flow
- Elephant Flow Throttled
- Elephant Flow Trusted



Procedure

Step 1 Choose **Analysis** > **Connections** > **Events**. You can also view the events from the **Unified Events** viewer.



Step 2 In the **Connection Events** page, from the **Predefined Search** drop-down list, choose **Elephant Flows** to display elephant flow events.

Tip To see **Elephant Flow Trusted** or **Elephant Flow Throttled** event types, click the **Edit Search** link on the top-left corner of the page and in the **Reason** field, choose **Elephant Flows** in the left panel. Enter **Elephant Flow Trusted** or **Elephant Flow Throttled**, depending on what you want to search.

Step 3 View the elephant flow that was detected mid-flow and the **Reason** field shows **Elephant Flow**. At the end of the flow, it was bypassed and the **Reason** field shows **Elephant Flow Trusted**.

Configure elephant flow remediation exemption

This task allows you to create exemption rules for specific flows that should not be subject to remediation actions even when detected as elephant flows.

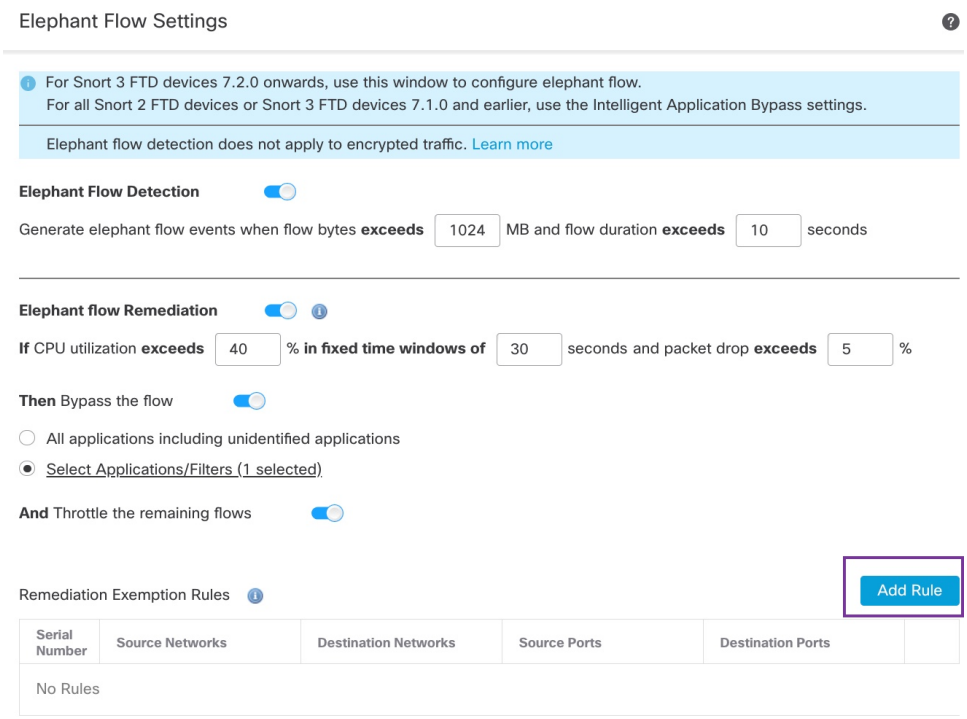
You can configure L4 access control list (ACL) rules for flows that must be exempted from remediation. If a flow is detected as an elephant flow and it matches the rules that are defined, that flow is exempted from remediation.

Before you begin

You must be running management center version 7.4.0 or later and the managed threat defense must also be on version 7.4.0 or later.

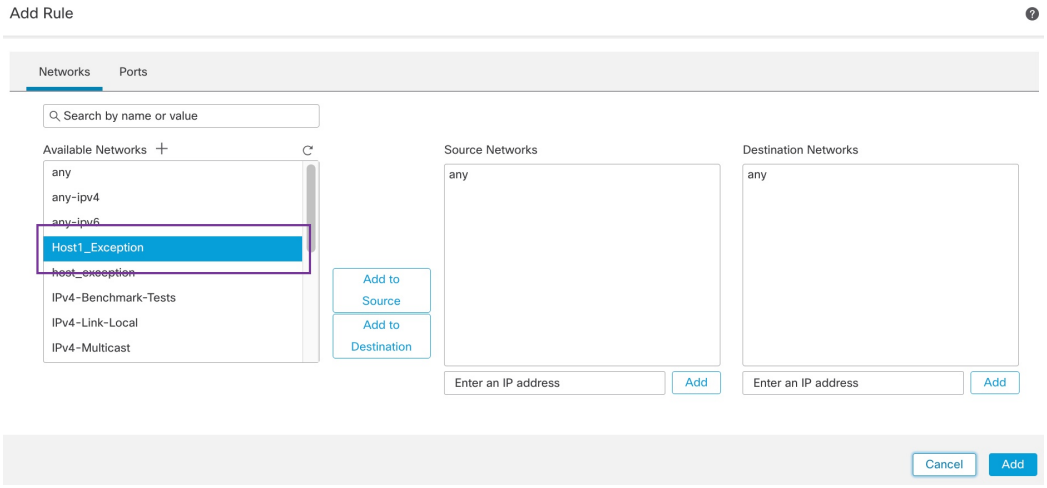
Follow these steps to configure elephant flow remediation exemption.

Procedure



Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

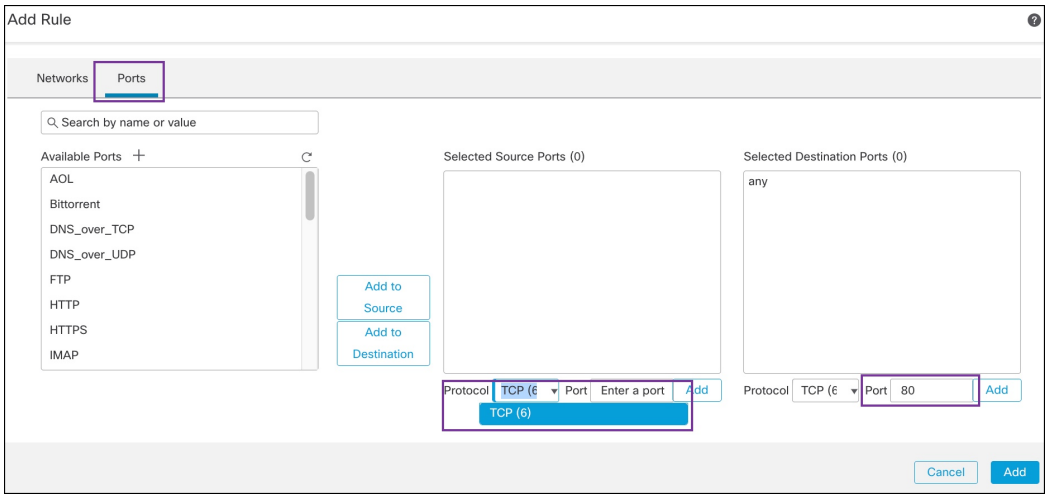
Step 2 Click **Edit** (✎) next to the access control policy you want to edit.



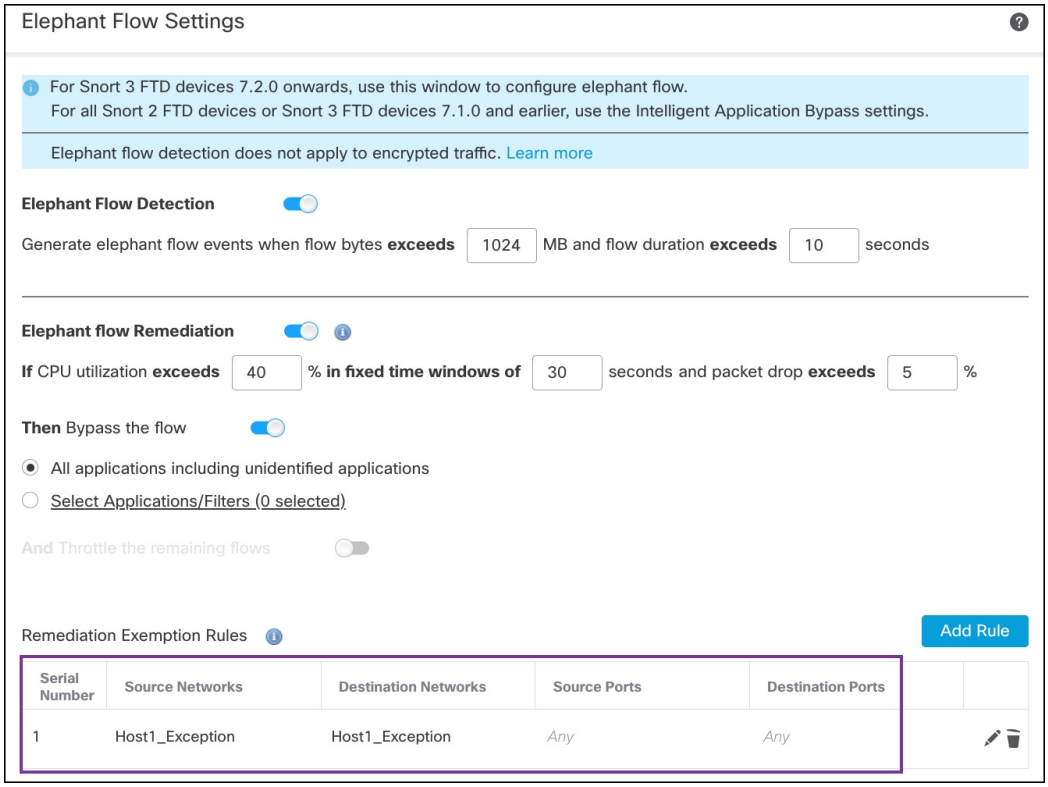
Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 Click **Edit** (✎) next to **Elephant Flow Settings**. Ensure that you have configured the elephant flow detection and remediation parameters. See Configure elephant flow parameters, on page 2227.

Step 5 Click the **Add Rule** button next to **Remediation Exemption Rules**.



Step 6 From the list of **Available Networks**, choose the configured host to exempt from elephant flow remediation. For the purposes of this example, we have created a host called "Host1_Exception."



Step 7 Click **Add to Source** or **Add to Destination** as needed to add this host to the source or destination.

Step 8 Click the **Ports** tab.

a) For the source port, choose **Protocol** as TCP, enter **80** as the destination port, then click **Add**.

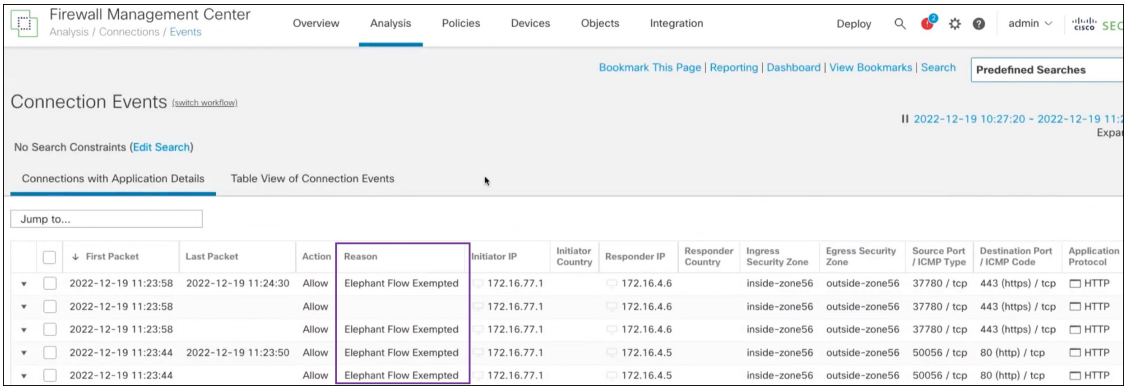
b) Click **OK**.

Step 9 Click **Save**.

What to do next

Deploy configuration changes.

View events for elephant flow remediation exemption



This task allows you to monitor and review elephant flows that have been exempted from remediation to understand network traffic patterns and exemption reasons.

Elephant flows are high-volume network connections that may require special handling. When these flows are exempted from remediation, you can view the exemption events to track and analyze the decision.

Procedure

Step 1 Choose **Analysis** > **Connections** > **Events**. You can also view the events from the **Unified Events** viewer.

Step 2 View the elephant flows that were exempted from remediation. The **Reason** field shows **Elephant Flow Exempted**.

- Elephant Flow Detection

PART XII

Network Discovery

- Network discovery overview, on page 2237
- Host identity sources, on page 2247
- Application detection, on page 2283
- Network Discovery Policies, on page 2305

CHAPTER 65

Network discovery overview

Network discovery is the automated process for identifying active devices and their connections within a network to maintain an accurate inventory.

- Detection of host, application, and user data, on page 2237
- Host and application detection fundamentals, on page 2238

Detection of host, application, and user data

Detection of host, application, and user data is a network monitoring capability that

- collects host and application data using host identity sources and application detectors according to network discovery policy settings,
- gathers user data through user identity sources according to network discovery and identity policy configurations, and
- enables comprehensive network asset mapping, forensic analysis, behavioral profiling, access control, and vulnerability mitigation.

Host, application, and user data collection

The system uses *network discovery* and *identity* policies to collect host, application, and user data for traffic on your network. The system analyzes discovery and identity data to create a detailed map of network assets, perform forensic analysis, behavioral profiling, access control, and respond to potentials vulnerabilities and hazards to your organization.

The system collect various types of data to enhance network security and performance analytics:

- Host and Application Data: Collected by host identity sources and application detectors according to the settings in your network discovery policy. Managed devices observe traffic on the network segments you specify.

  For more information about fundamentals of host and application data, refer to Host and application detection fundamentals, on page 2238
- User Data: Collected by user identity sources according to the settings in your network discovery and identity policies. Use the data for user awareness and user control.

  For more information about user identity, refer to User identity, on page 1819.

Logging discovery and identity data allows you to take advantage of many features in the system, including:

- Viewing the network map, which is a detailed representation of your network assets and topology that you can view by grouping hosts and network devices, host attributes, application protocols, or vulnerabilities.
- Performing application and user controls using access control rules with application conditions, realm conditions, user conditions, user group conditions, and ISE attribute conditions.
- Viewing complete profiles for detected hosts.
- Monitoring network assets and user activity through dashboards.
- Viewing detailed information on the discovery events and user activity.

  Logging and using NetFlow connections, if applicable.
- Associate hosts, servers, and clients with susceptible exploits to identify and mitigate vulnerabilities.

  Evaluate the impact that intrusion events have on your network, and tune intrusion rule states so that they provide maximum protection for your network assets.
- Receiving alerts by email, SNMP trap, or syslog when the system generates either an intrusion event with a specific impact flag, or a specific type of discovery event.
- Monitoring your organization's compliance with an allow list of allowed operating systems, clients, application protocols, and protocols.
- Creating correlation policies with rules that trigger and generate correlation events when the system generates discovery events or detects user activity.

Host and application detection fundamentals

The network discovery policy is a feature that serves multiple purposes. You can:

- enable device identification,
- monitor network devices and services, and
- configure detection settings to track performance.

For more information on host and application detection, refer to Host data collection overview, on page 2247 and Application detection, on page 2283.

Passive detection of operating system and host data

Passive detection is a network mapping method that

- analyzes network traffic and any exported NetFlow data to populate the network map,
- provides contextual information about network assets, such as operating systems and running applications, and
- serves as the system's default detection method.

Operating system determination process

If traffic from a monitored host does not offer conclusive evidence of the host's operating system, the network map displays the most likely operating system. For example, a NAT device may appear to be running several operating systems because of the hosts "behind" the NAT device. To make this most-likely determination, the system uses a confidence value it assigns to each detected operating system, and the amount of corroborating data among detected operating systems.

Note The system does not consider reported "`unknown`" applications and operating systems in its determination.

If passive detection inaccurately identifies your network assets, consider the placement of your managed devices. You can also augment the system's passive detection capabilities with custom operating-system fingerprints and custom application detectors. Or, you can use *active detection*, which is not based on traffic analysis, but instead allows you to directly update the network map using scan results or other information sources.

Active detection of operating system and host data

Active detection is a network discovery capability that

- adds host information collected by active sources to network maps,
- discovers operating systems and applications on hosts using tools like Nmap Scanner, and
- allows active addition of host input data to network maps.

Host input data is categorized into:

- *User input data*—Data added through the system user interface, permitting modification of the host's operating system or application identity.
- *Host import input data*—Data imported using a command line utility.

Identity retention and priority behavior

The system retains one identity for each active source. For example, when you run an Nmap scan instance, previous results are updated with the new scan data. However, replacing scan results with data from a client whose results are imported through the command line, the system retains both the identities. The system then uses the priorities set in the network discovery policy to determine which active identity to use as the current identity.

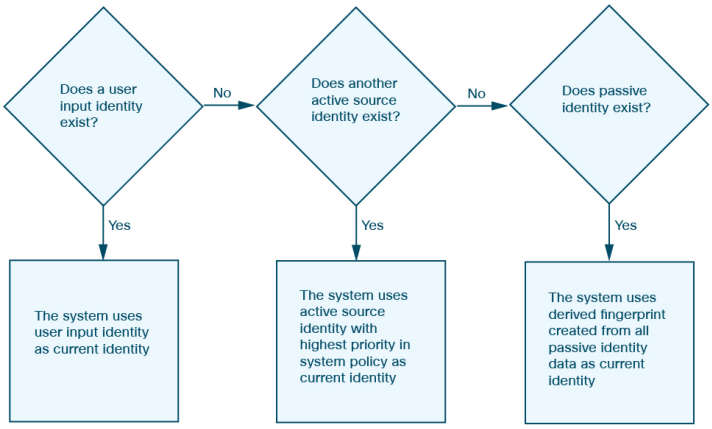
User input supersedes other identities, regardless of the source. For example, if UserA sets the operating system through the host profile, and then UserB changes that definition through the host profile, the definition set by UserB is retained. User input overrides all other active sources and is used as the current identity if it exists.

Current identities for applications and operating systems

A *current identity* is an identity determination for an application or operating system that

- represents the identity that the system finds most likely to be correct,

- is used for vulnerability assignments and impact assessments, and
- is determined by source priorities when multiple identities exist for the same host.



Current identity uses

The system uses the current identity for an operating system or application for these purposes:

- Assign vulnerabilities to a host
- Assess impact
- Evaluate correlation rules relating to operating system identifications, host profile qualifications, and compliance allow lists
- Display in the Hosts and Servers table views in workflows
- Display in the host profile
- Calculate the operating system and application statistics on the Discovery Statistics page

The system uses source priorities to determine which active identity should be used as the current identity for an application or operating system.

Figure 423: Current identity determination process

The database may retain information from multiple sources for an operating system or for a specific application on a host.

The system treats an operating system or application identity as the current identity when the source for the data has the highest source priority. Possible sources have this priority order:

1. User
2. Scanner and application (set in the Network Discovery Policy)
3. Managed devices
4. NetFlow records

If a new higher priority application identity has less detail than the current identity, it will not override the current application identity.

In addition, when an identity conflict occurs, the resolution of the conflict depends on settings in the network discovery policy or on your manual resolution.

Operating system assignment as current identity

For example, if a user sets the operating system to Windows 2003 Server on a host, Windows 2003 Server becomes the current identity and attacks targeting Windows 2003 Server vulnerabilities on that host are given a higher impact. The vulnerabilities listed for that host in the host profile include Windows 2003 Server vulnerabilities.

Current user identities

A current user identity is a system determination that:

- identifies the last authoritative user login as the current user when multiple users log into the same host
- assumes only one user is logged into any given host at a time
- records the first login for a user on a specific host and disregards subsequent logins by the same user, and
- reports the last user detected by the server to the Firewall Management Center when multiple users are logged in through remote sessions.

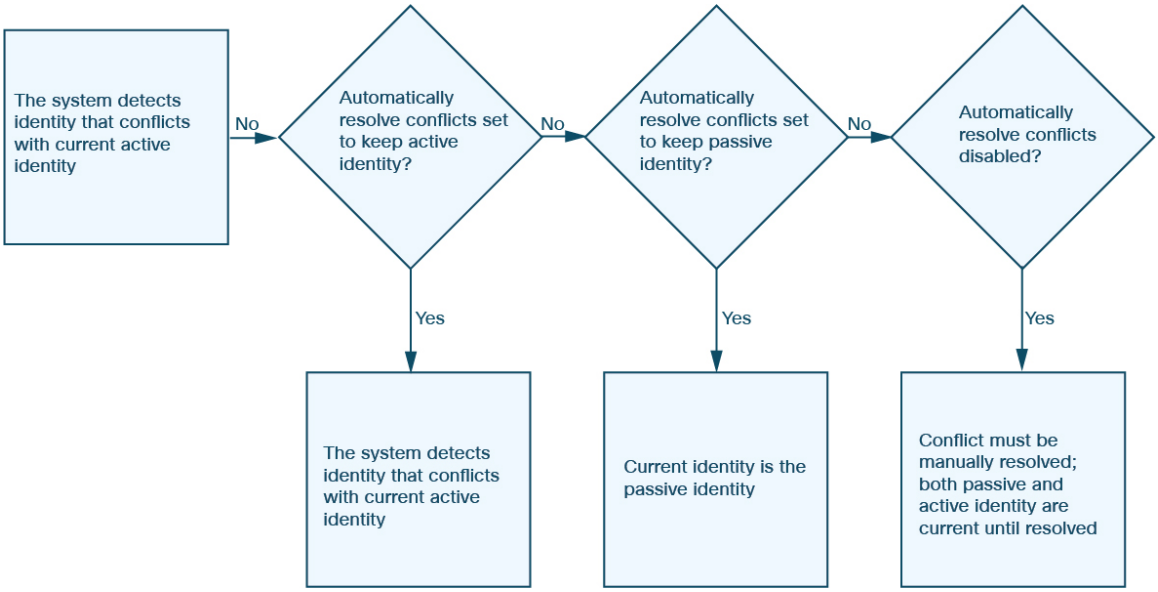
User login tracking behavior

The system uses specific rules to determine current user identity:

- When the system detects multiple logins to the same host by different users, the system assumes that only one user is logged into any given host at a time, and that the current user of a host is the last authoritative user login. If only non-authoritative user logins have been logged into the host, the last non-authoritative user login is considered the current user. If multiple users are logged in through remote sessions, the last user reported by the server is the user reported to the Firewall Management Center.
- When the system detects multiple logins to the same host by the same user, the system records the first time that a user logs into a specific host and disregards subsequent logins. If an individual user is the only person who logs into a specific host, the only login that the system records is the original login.
- If another user logs into that host, however, the system records the new login. Then, if the original user logs in again, his or her new login is recorded.

Application and operating system identity conflicts

An *identity conflict* is a system condition that



- occurs when the system reports a new passive identity that conflicts with the current active identity and previously reported passive identities
- results in both conflicting identities being listed as current and used for impact assessment until the conflict is resolved, and
- can be resolved automatically by choosing to always use the passive identity or always use the active identity.

Identity conflict behavior and resolution

When an identity conflict exists for the identity of the host's operating system or one of the applications on the host, the system lists both conflicting identities as current and uses both for impact assessment until the conflict is resolved.

A user with Administrator privileges can resolve identity conflicts automatically by choosing to always use the passive identity or always use the active identity. Unless you disable automatic resolution of identity conflicts, identity conflicts are always automatically resolved.

A user with Administrator privileges can also configure the system to generate an event when an identity conflict occurs. That user can then set up a correlation policy with a correlation rule that uses an Nmap scan as a correlation response. When an event occurs, Nmap scans the host to obtain updated host operating system and application data.

Operating system identity conflict scenario

The previous passive identity for an operating system is reported as Windows 2000, then an active identity of Windows XP becomes current. Next, the system detects a new passive identity of Ubuntu Linux 8.04.1. The Windows XP and the Ubuntu Linux identities are in conflict.

NetFlow data

NetFlow data is a collection of network flow statistics that

- provides statistics on packets flowing through a router through a Cisco IOS application
- is available on Cisco networking devices and can also be embedded in Juniper, FreeBSD, and OpenBSD devices, and
- stores records of flows in a database on the device called the NetFlow cache when NetFlow is enabled on a network device.

NetFlow data processing and usage

A flow, called a *connection* in the system, is a sequence of packets that represents a session between a source and destination host, using specific ports, protocol, and application protocol. The network device can be configured to export this NetFlow data. In this documentation, network devices configured in this way are called *NetFlow exporters*.

Managed devices can be configured to collect records from NetFlow exporters, generate unidirectional end-of-connection events based on the data in those records, and finally send those events to the Firewall Management Center to be logged in the connection event database. You can also configure the network discovery policy to add host and application protocol information to the database based on the information in NetFlow connections.

You can use this discovery and connection data to supplement the data gathered directly by your managed devices. This is especially useful if you have NetFlow exporters monitoring networks that your managed devices cannot monitor.

Requirements for using NetFlow data (principle)

NetFlow device configuration

Before you configure the system to analyze NetFlow data, you **must** enable the NetFlow feature on the routers or other NetFlow-enabled network devices you plan to use. Configure the devices to broadcast NetFlow data to a destination network where the sensing interface of a managed device is connected.

NetFlow version and field specifications

The system can parse both NetFlow version 5 and NetFlow version 9 records. NetFlow exporters **must** use one of those versions if you export data. Ensure the exported NetFlow templates and records contain specific fields like IN_BYTES, IN_PKTS, PROTOCOL, among others. If your NetFlow exporters are using version 9, which you can customize, you **must** make sure that the exported templates and records contain these fields, in any order:

- IN_BYTES (1)
- IN_PKTS (2)
- PROTOCOL (4)
- TCP_FLAGS (6)
- L4_SRC_PORT (7)
- IPV4_SRC_ADDR (8)
- L4_DST_PORT (11)
- IPV4_DST_ADDR (12)
- LAST_SWITCHED (21)
- FIRST_SWITCHED (22)
- IPV6_SRC_ADDR (27)
- IPV6_DST_ADDR (28)

Managed device deployment

Your deployment must include at least one managed device that can monitor NetFlow exporters. Connect at least one sensing interface on that managed device to a network for collecting exported NetFlow data. The system does not support the direct collection due to lack of IP addresses on sensing interfaces.

Sampled NetFlow considerations

Sampled NetFlow feature available on some network devices collects NetFlow statistics on only a subset of packets that pass through the devices. While enabling this feature improves CPU utilization, it may affect the NetFlow data collected for system analysis.

Differences between NetFlow and managed device data

NetFlow and managed device data differences are analytical distinctions that

- result from converting exported NetFlow records into connection logs and host and application protocol data rather than directly analyzing traffic,
- affect statistics on detected connections, operating system information, and application data, and
- impact the identification of connection initiators and responders.

Key differences in data collection and analysis

The traffic represented by NetFlow data is not directly analyzed. Instead, it converts exported NetFlow records into connection logs and host and application protocol data.

As a result, there are several differences between converted NetFlow data and the discovery and connection data gathered directly by your managed devices. You should keep these differences in mind when performing analysis that requires:

- Statistics on the number of detected connections
- Operating system and other host-related information (including vulnerabilities)
- Application data, including client information, web application information, and vendor and version server information
- Knowing which host in a connection is the initiator and which is the responder

Network discovery policy versus access control policy:

You configure NetFlow data collection, including connection logging, using rules in the network discovery policy. Contrast this with connection logging for connections detected by managed devices, which you configure per access control rule.

Types of connection events:

- Because NetFlow data collection is linked to networks rather than access control rules, you do not have granular control over which NetFlow connections the system logs.
- NetFlow data cannot generate Security Intelligence events.
- NetFlow-based connection events can be stored in the connection event database only; you cannot send them to the system log or an SNMP trap server.

Number of connection events generated per monitored session:

For connections detected directly by managed devices, you can configure the access control rule to log a bidirectional connection event at the beginning or end of a connection, or both.

In contrast, because exported NetFlow records contain unidirectional connection data, the system generates at least two connection events for each NetFlow record it processes. This also means that a summary's connection count is incremented by two for every connection based on NetFlow data, providing an inflated count of the number of connections that are actually occurring on your network.

Because the NetFlow exporter outputs records at regular intervals, even during an ongoing connection, long-running sessions can result in multiple exported records, each of which generates a connection event. For example, if the NetFlow exporter exports every five minutes, and a particular connection lasts twelve minutes, the system generates six connection events for that session:

- One pair of events for the first five minutes
- One pair for the second five minutes
- A final pair when the connection is terminated

Host and operating system data:

Hosts added to the network map from NetFlow data do not have operating system, NetBIOS, or host type (host vs network device) information. However, using the host input feature, you can manually set a host's operating system identity.

Application data:

For connections detected directly by managed devices, the system can identify application protocols, clients, and web applications by examining the packets in the connection.

When the system processes NetFlow records, the system uses a port correlation in `/etc/sf/services` to extrapolate application protocol identity. However, there is no vendor or version information for those application protocols, nor do connection logs contain information on client or web applications used in the session. You can, however, manually provide this information using the host input feature.

Note that a simple port correlation means that application protocols running on non-standard ports may be unidentified or misidentified. Additionally, if no correlation exists, the system marks the application protocol as `unknown` in connection logs.

Vulnerability mappings:

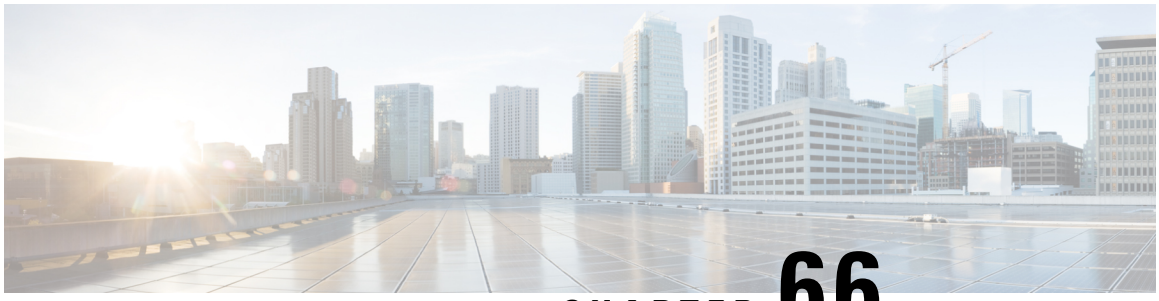
The system cannot map vulnerabilities to hosts monitored by NetFlow exporters, unless you use the host input feature to manually set either a host's operating system identity or an application protocol identity. Note that because there is no client information in NetFlow connections, you cannot associate client vulnerabilities with hosts created from NetFlow data.

Initiator and responder information in connections:

For connections detected directly by managed devices, the system can identify which host is the initiator, or source, and which is the responder, or destination. However, NetFlow data does not contain initiator or responder information.

When the System processes NetFlow records, it uses an algorithm to determine this information based on the ports each host is using, and whether those ports are well-known:

- If both or neither port being used is a well-known port, the system considers the host using the lower-number port to be the responder.
- If only one of the hosts is using a well-known port, the system considers that host to be the responder.



For this purpose, a well-known port is any port that is either numbered from 1 to 1023,or any port that the system considers a server port, regardless of number.

NetFlow byte counts

Connection events based on unidirectional NetFlow records contain only one byte count, which the system assigns to either **Initiator Bytes** or **Responder Bytes**, depending on the port-based algorithm. The system sets the other field to 0. Note that if you are viewing connection summaries (aggregated connection data) of NetFlow records, both fields may be populated.

NetFlow-only connection event fields

A small number of fields are present only in connection events generated from NetFlow records; refer to *Information Available in Connection Event Fields* in the *Cisco Secure Firewall Management Center Administration Guide*.

CHAPTER 66

Host identity sources

These topics provide information on host identity sources.

- Host data collection overview, on page 2247
- Requirements and prerequisites for host identity sources, on page 2248
- Determine which host operating systems the system can detect, on page 2248
- Identifying host operating systems, on page 2249
- Custom fingerprinting, on page 2249
- Host input data, on page 2257
- Nmap scanning, on page 2264
- History for host identity sources, on page 2282

Host data collection overview

Host data collection is a passive monitoring mechanism that

- compares specific packet header values and other unique data from network traffic against established definitions called *fingerprints*,
- determines information about the hosts on your network, and
- identifies network topology and system characteristics through traffic analysis.

Host information collected

The system determines this information about hosts on your network:

- The number and types of hosts (including network devices such as bridges, routers, load balancers, and NAT devices).
- Basic network topology data, including the number of hops from the discovery point on the network to the hosts.
- The operating systems running on the hosts.
- Applications on the hosts and users associated with these applications.

If the system cannot identify a host's operating system, you can create custom client or server fingerprints. The system uses these fingerprints to identify new hosts. You can map fingerprints to systems in the

vulnerability database (VDB) to allow the appropriate vulnerability information to be displayed whenever a host is identified using the custom fingerprint.

Note In addition to collecting host data from monitored network traffic, the system can collect host data from exported NetFlow records, and you can actively add host data using Nmap scans and the host input feature.

Requirements and prerequisites for host identity sources

This topic provides the necessary requirements and prerequisites to manage host identity sources:

Requirement	Details
Model support	Any.
Supported domains	Any, with the exception of custom fingerprinting, which is Leaf only.
User roles	• Admin • Discovery Admin, except for third-party data and custom mappings.

Determine which host operating systems the system can detect

To verify the exact operating systems that the system can fingerprint, you can view the list of available fingerprints during the process of creating a custom operating system fingerprint. This helps you understand which operating systems the system is capable of identifying.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Create Custom Fingerprint**.

Step 4 In the **OS Vulnerability Mappings** section, view the options available in the drop-down lists. These options represent the operating systems that the system can fingerprint.

What to do next

For more information, refer to Identifying host operating systems, on page 2249.

Identifying host operating systems

If the system does not correctly identify a host operating system (for example, it shows in the Host Profile as Unknown or is incorrectly identified), try the strategies listed here.

Procedure

Try one of these strategies:

- Check the Network Discovery Identity Conflict Settings.
- Create a custom fingerprint for the host.
- Run an Nmap scan against the host.
- Import data into the network map, using the host input feature.
- Manually enter operating system information.

Custom fingerprinting

The system includes operating system *fingerprints* that the system uses to identify the operating system on each host it detects. However, sometimes the system cannot identify a host operating system or misidentifies it because no fingerprints exist that match the operating system. To correct this problem, you can create a *custom fingerprint*. This fingerprint provides a pattern of operating system characteristics unique to the unknown or misidentified operating system and supplies the name of the operating system for identification purposes

Operating system identification and vulnerability mapping

If the system cannot match the operating system of a host, it cannot identify the vulnerabilities for the host, because the system derives the list of vulnerabilities for each host from its operating system fingerprint. For example, if the system detects a host running Microsoft Windows, it adds a stored Microsoft Windows vulnerability list to the host's profile based on the detected operating system.

As an example, if you have several devices on your network running a new beta version of Microsoft Windows, the system cannot identify that operating system or map vulnerabilities to the hosts. However, knowing that the system has a list of vulnerabilities for Microsoft Windows, you may want to create a custom fingerprint for one of the hosts to help identify the other hosts running the same operating system. You can include a mapping of the vulnerability list for Microsoft Windows in the fingerprint to associate it with each host that matches the fingerprint.

When you create a custom fingerprint, the Firewall Management Center lists the set of vulnerabilities associated with that fingerprint for any hosts running the same operating system. If the custom fingerprint does not contain any vulnerability mappings, the system uses the fingerprint to assign the custom operating system information you provide. When the system sees new traffic from a previously detected host, it updates the

host with the new fingerprint information. The system also uses the new fingerprint to identify any new hosts with that operating system the first time they are detected.

Before you create a custom fingerprint, determine why the host is not being identified correctly to decide whether custom fingerprinting is a viable solution.

You can create two types of fingerprints with the system:

- Client fingerprints, which identify operating systems based on the SYN packet that the host sends when it connects to a TCP application running on another host on the network.
- Server fingerprints, which identify operating systems based on the SYN-ACK packet that the host uses to respond to an incoming connection to a running TCP application.

Note If both a client and server fingerprint match the same host, the client fingerprint is used.

After creating fingerprints, you must activate them before the system can associate them with hosts.

Manage fingerprints

After a fingerprint is created and activated, you can edit a fingerprint to make changes or add vulnerability mappings.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

If the system is waiting for data to create a fingerprint, it refreshes the page every 10 seconds until the fingerprint is created.

Step 3 Manage your custom fingerprints using these options:

- **Activate/Deactivate**: Activate or deactivate a fingerprint as described in Activate and deactivate fingerprints, on page 2250.
- **Create**: Create fingerprints as described in Create a custom fingerprint for clients, on page 2252 and Create a custom fingerprint for servers, on page 2254.
- **Edit**: Edit a fingerprint as described in Edit an active fingerprint, on page 2251 and Edit an inactive fingerprint, on page 2252.
- **Delete**: Click **Delete** ( ) next to the fingerprint you want to delete, and click **OK** to confirm. You can only delete deactivated fingerprints.

Activate and deactivate fingerprints

You must activate a custom fingerprint before the system can use it to identify hosts. After the new fingerprint is activated, the system uses it to re-identify previously discovered hosts and discover new hosts.

If you want to stop using a fingerprint, you can deactivate it. Deactivating a fingerprint prevents the system from using it, but the fingerprint remains on the system. When you deactivate a fingerprint, the operating system is marked as unknown for hosts that use the fingerprint. If these hosts are detected again and match a different active fingerprint, they are then identified by that active fingerprint.

Deleting a fingerprint removes it from the system completely. After deactivating a fingerprint, you can delete it.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

Step 3 Click the slider next to the fingerprint you want to activate or deactivate.

Note The activate option is only available if the fingerprint you created is valid. If the slider is not available, try creating the fingerprint again.

Edit an active fingerprint

If a fingerprint is *active*, you can modify the fingerprint name, description, and custom operating system display. You can also map additional vulnerabilities to it.

You can modify the fingerprint name, description, custom operating system display, and map additional vulnerabilities to it.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Edit** ( ) next to the fingerprint you want to edit.

Step 4 Modify the fingerprint name, description, and custom OS display, if necessary.

Step 5 If you want to delete a vulnerability mapping, click **Delete** next to the mapping in the **Pre-Defined OS Product Maps** section of the page.

Step 6 If you want to add additional operating systems for vulnerability mapping, choose the **Product** and, if applicable, **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** and then click **Add OS Definition**.

The vulnerability mapping is added to the **Pre-Defined OS Product Maps** list.

Step 7 Click **Save**.

Edit an inactive fingerprint

If a fingerprint is *inactive*, you can modify all elements of the fingerprint and resubmit it to the Secure Firewall Management Center. This includes all properties you specified when creating the fingerprint, such as fingerprint type, target IP addresses and ports, vulnerability mappings, and so on.

When you edit and submit an inactive fingerprint, the system resubmits it. If it is a client fingerprint, you must resend traffic to the appliance before activating it. Note that you can choose only a single vulnerability mapping for an inactive fingerprint. After you activate the fingerprint, you can map additional operating systems and versions to its vulnerabilities list.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Edit** ( ) next to the fingerprint you want to edit.

Step 4 Make changes to the fingerprint as necessary:

- If you are modifying a client fingerprint, refer to Create a custom fingerprint for clients, on page 2252.
- If you are modifying a server fingerprint, refer to Create a custom fingerprint for servers, on page 2254.

Step 5 Click **Save**.

What to do next

If you modified a client fingerprint, remember to send traffic from the host to the appliance gathering the fingerprint.

Create a custom fingerprint for clients

Client fingerprints identify the operating system by analyzing the SYN packet a host sends when it connects to a TCP application on another network host.

If the Firewall Management Center does not have direct contact with monitored hosts, you can specify a device that is managed by the Firewall Management Center and is closest to the host you intend to fingerprint when specifying client fingerprint properties.

Before you begin

Before you begin the fingerprinting process, obtain these details about the host you want to fingerprint:

- The number of network hops between the host and the Firewall Management Center or the device you use to obtain the fingerprint. (Cisco strongly recommends that you directly connect the Firewall Management Center or the device to the same subnet that the host is connected to.)
- The network interface (on the Firewall Management Center or the device) that is connected to the network where the host resides.
- The actual operating system vendor, product, and version of the host.
- Access to the host in order to generate client traffic.

Procedure

Step 1 Choose **Policies** > **Network Discovery**. Click **Custom Operating Systems**, and then **Create Custom Fingerprint**.

Step 2 From the **Device** drop-down list, choose the Firewall Management Center or the device that you want to use to collect the fingerprint. Then, enter a **Fingerprint Name**, **Fingerprint Description** and from the **Fingerprint Type** list, choose **Client**.

Step 3 In the **Target IP Address** field, enter an IP address of the host you want to fingerprint.

Note The fingerprint is based exclusively on traffic to and from the specified host IP address. Traffic from other IP addresses assigned to the host is not included.

Step 4 In the **Target Distance** field, enter the number of network hops between the host and the device that you chose earlier to collect the fingerprint.

Caution This must be the actual number of physical network hops to the host, which may or may not be the same as the number of hops detected by the system.

Step 5 From the **Interface** list, choose the network interface that is connected to the network segment where the host resides.

Note Use the management interface or any other available network interfaces that is configured as the sensing interface on your device to perform fingerprint collection. If you do not know which interface is the sensing interface on your device, refer to the *Installation Guide* for the specific model you are using to fingerprint.

Step 6 If you want to display custom information in the host profile for fingerprinted hosts (or if the host you want to fingerprint does not reside in the **OS Vulnerability Mappings** section), choose **Use Custom OS Display** and provide the values you want to display for these fields:

- In the **Vendor String** field, enter the operating system's vendor name. For example, the vendor for Microsoft Windows would be Microsoft.
- In the **Product String** field, enter the operating system's product name. For example, the product name for Microsoft Windows 2000 would be Windows.
- In the **Version String** field, enter the operating system's version number. For example, the version number for Microsoft Windows 2000 would be 2000.

Step 7 In the OS Vulnerability Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping.

You must specify **Vendor** and **Product** values in this section if you want to use the fingerprint to identify vulnerabilities for matching hosts or if you do not assign custom operating system display information.

To map vulnerabilities for all versions of an operating system, specify only the **Vendor** and **Product** values.

Note Not all options in the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** drop-down lists may apply to the operating system you choose. In addition, if no definition appears in a list that matches the operating system you want to fingerprint, you can leave these values empty. Be aware that if you do not create any OS vulnerability mappings in a fingerprint, the system cannot use the fingerprint to assign a vulnerabilities list with hosts identified by the fingerprint.

Example:

If you want your custom fingerprint to assign the list of vulnerabilities from Redhat Linux 9 to matching hosts, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the major version.

Example:

To add all versions of the Palm OS, you would choose **PalmSource, Inc.** from the **Vendor** list, **Palm OS** from the **Product** list, and leave all other lists at their default settings.

Step 8 Click **Create**.

The status briefly shows `New`, then switches to `Pending`, where it remains until traffic is seen for the fingerprint. Once traffic is seen, it switches to `Ready`.

The Custom Fingerprint status page refreshes every ten seconds until it receives data from the host in question.

Step 9 Using the IP address you specified as the target IP address, access the host you are trying to fingerprint and initiate a TCP connection to the appliance.

To create an accurate fingerprint, traffic **must** be seen by the appliance collecting the fingerprint. If you are connected through a switch, traffic to a system other than the appliance may not be seen by the system.

Example:

Access the web interface of the Firewall Management Center from the host you want to fingerprint or SSH into the Firewall Management Center from the host. If you are using SSH, use the command below, where localIPv6address is the IPv6 address specified in step 7 that is currently assigned to the host and DCmanagementIPv6address is the management IPv6 address of the Firewall Management Center. The Custom Fingerprint page should then reload with a “Ready” status.

```
ssh -b localIPv6address DCmanagementIPv6address
```

Create a custom fingerprint for servers

Server fingerprints identify operating systems based on the SYN-ACK packet that the host uses to respond to an incoming connection to a running TCP application.

Before you begin, you should obtain this information about the host you want to fingerprint:

- The number of network hops between the host and the appliance you use to obtain the fingerprint. Cisco strongly recommends that you directly connect an unused interface on the appliance to the same subnet that the host is connected to.
- The network interface (on the appliance) that is connected to the network where the host resides.
- The actual operating system vendor, product, and version of the host.

- An IP address that is not currently in use and is authorized on the network where the host is located.

Tip If the Firewall Management Center does not have direct contact with monitored hosts, you can specify a managed device that is closest to the host you intend to fingerprint when specifying server fingerprint properties.

Procedure

Step 1 Choose **Policies** > **Network Discovery**. Click **Custom Operating Systems** and then, click **Create Custom Fingerprint**.

Step 2 From the **Device** list, choose the Firewall Management Center or the managed device that you want to use to collect the fingerprint and enter a **Fingerprint Name**. Enter a **Fingerprint Description** and from the **Fingerprint Type** list, choose **Server** to display the server fingerprinting options. In the **Target IP Address** field, enter an IP address of the host you want to fingerprint.

Note that the fingerprint will only be based on traffic to and from the host IP address you specify, not any of the host's other IP addresses (if it has any).

Caution You can capture IPv6 fingerprints only with appliances running Version 5.2 and later.

Step 3 In the **Target Distance** field, enter the number of network hops between the host and the device that you chose earlier to collect the fingerprint.

Caution This must be the actual number of physical network hops to the host, which may or may not be the same as the number of hops detected by the system.

Step 4 From the **Interface** list, choose the network interface that is connected to the network segment where the host resides.

Caution Cisco recommends that you do **not** use the sensing interface on a managed device for fingerprinting for several reasons. First, fingerprinting does not work if the sensing interface is on a span port. Also, if you use the sensing interface on a device, the device stops monitoring the network for the amount of time it takes to collect the fingerprint. You can, however, use the management interface or any other available network interfaces to perform fingerprint collection. If you do not know which interface is the sensing interface on your device, refer to the *Installation Guide* for the specific model you are using to fingerprint.

Step 5 Click **Get Active Ports**. In the **Server Port** field, enter the port that you want the device chose to collect the fingerprint to initiate contact with, or choose a port from the **Get Active Ports** drop-down list.

You can use any server port that you know is open on the host (for instance, 80 if the host is running a web server).

Step 6 In the **Source IP Address** field, enter an IP address that should be used to attempt to communicate with the host.

You should use a source IP address that is authorized for use on the network but is not currently being used, for example, a DHCP pool address that is currently not in use. This prevents you from temporarily knocking another host offline while you create the fingerprint.

You should exclude that IP address from monitoring in your network discovery policy while you create the fingerprint. Otherwise, the network map and discovery event views will be cluttered with inaccurate information about the host represented by that IP address.

Step 7 In the **Source Subnet Mask** field, enter the subnet mask for the IP address you are using. If the **Source Gateway** field appears, enter the default gateway IP address that should be used to establish a route to the host. If you want to display custom information in the host profile for fingerprinted hosts or if the fingerprint name you want to use does not exist in the OS Definition section, choose **Use Custom OS Display** in the Custom OS Display section.

Provide the values you want to appear in host profiles for these fields:

- In the **Vendor String** field, enter the operating system's vendor name. For example, the vendor for Microsoft Windows would be Microsoft.
- In the **Product String** field, enter the operating system's product name. For example, the product name for Microsoft Windows 2000 would be Windows.
- In the **Version String** field, enter the operating system's version number. For example, the version number for Microsoft Windows 2000 would be 2000.

Step 8 In the OS Vulnerability Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping.

You must specify a Vendor and Product name in this section if you want to use the fingerprint to identify vulnerabilities for matching hosts or if you do not assign custom operating system display information.

To map vulnerabilities for all versions of an operating system, specify only the vendor and product name.

Note Not all options in the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** drop-down lists may apply to the operating system you choose. In addition, if no definition appears in a list that matches the operating system you want to fingerprint, you can leave these values empty. Be aware that if you do not create any OS vulnerability mappings in a fingerprint, the system cannot use the fingerprint to assign a vulnerabilities list with hosts identified by the fingerprint.

Example:

If you want your custom fingerprint to assign the list of vulnerabilities from Redhat Linux 9 to matching hosts, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Example:

To add all versions of the Palm OS, you would choose **PalmSource, Inc.** from the **Vendor** list, **Palm OS** from the **Product** list, and leave all other lists at their default settings.

Click **Create**.

Step 9 Click **Create**.
The Custom Fingerprint status page refreshes every ten seconds and should reload with a "Ready" status.

Note If the target system stops responding during the fingerprinting process, the status shows an `ERROR: No Response` message. If you see this message, submit the fingerprint again. Wait three to five minutes (the time period may vary depending on the target system), click **Edit** ( ) to access the Custom Fingerprint page, and then click **Create**.

What to do next

Activate the fingerprint as described in Activate and deactivate fingerprints, on page 2250.

Host input data

You can augment the network map by importing network map data from third parties. You can also use the host input feature by modifying operating system or application identities or deleting application protocols, protocols, host attributes, or clients using the web interface.

The system may reconcile data from multiple sources to determine the current identity of an operating system or application.

All data except third-party vulnerabilities is discarded when the affected host is removed from the network map. For more information on setting up scripts or import files, see the *Firepower System Host Input API Guide*.

To include imported data in impact correlations, you must map the data to the operating system and application definitions in the database.

Requirements for using third-party data

You can import discovery data from third-party systems on your network. However, to enable features where intrusion and discovery data are used together, such as Cisco recommendations, adaptive profile updates, or impact assessment, you should map as many elements of it as possible to corresponding definitions. Consider the following requirements for using third-party data:

- If you have a third-party system that has specific data on your network assets, you can import that data using the host input feature. However, because third parties may name the products differently, you must map the third-party vendor, product, and versions to the corresponding Cisco product definition. After you map the products, you must enable vulnerability mappings for impact assessment in the Firewall Management Center configuration to allow impact correlation. For versionless or vendorless application protocols, you need to map vulnerabilities for the application protocols in the Firewall Management Center configuration.
- If you import patch information from a third party and you want to mark all vulnerabilities fixed by that patch as invalid, you must map the third-party fix name to a fix definition in the database. All vulnerabilities addressed by the fix will then be removed from hosts where you add that fix.
- If you import operating system and application protocol vulnerabilities from a third party and you want to use them for impact correlation, you must map the third-party vulnerability identification string to vulnerabilities in the database. Note that although many clients have associated vulnerabilities, and clients

are used for impact assessment, you cannot import and map third-party client vulnerabilities. After the vulnerabilities are mapped, you must enable third-party vulnerability mappings for impact assessment in the Firewall Management Center configuration. To cause application protocols without vendor or version information to map to vulnerabilities, an administrative user must also map vulnerabilities for the applications in the Firewall Management Center configuration.

- If you import application data and you want to use that data for impact correlation, you must map the vendor string for each application protocol to the corresponding Cisco application protocol definition.

Third-party product mappings

When you add data from third parties to the network map through the user input feature, you must map the vendor, product, and version names used by the third party to the Cisco product definitions. Mapping the products to Cisco definitions assigns vulnerabilities based on those definitions.

Similarly, if you are importing patch information from a third party, such as a patch management product, you must map the name for the fix to the appropriate vendor and product and the corresponding fix in the database.

Map third-party products

If you import data from a third party, you must map the Cisco product to the third-party name to assign vulnerabilities and perform impact correlation using that data. Mapping the product associates Cisco vulnerability information with the third-party product name, which allows the system to perform impact correlation using that data.

If you import data using the host input import feature, you can also use the AddScanResult function to map third-party products to operating system and application vulnerabilities during the import.

For example, if you import data from a third party that lists Apache Tomcat as an application and you know it is version 6 of that product, you could add a third-party map where:

- **Vendor Name** is set to `Apache`.
- **Product Name** is set to `Tomcat`.
- **Apache** is chosen from the **Vendor** drop-down list.
- **Tomcat** is chosen from the **Product** drop-down list.
- **6** is chosen from the **Version** drop-down list

This mapping would cause any vulnerabilities for Apache Tomcat 6 to be assigned to hosts with an application listing for Apache Tomcat.

Note that for versionless or vendorless applications, you must map vulnerabilities for the application types in the Secure Firewall Management Center configuration. Although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot import and map third-party client vulnerabilities.

Tip If you have already created a third-party mapping on another Secure Firewall Management Center, you can export it and then import it onto this Firewall Management Center. You can then edit the imported mapping to suit your needs.

Follow these steps to map third-party products:

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **User Third-Party Mappings**.

Step 3 You have two choices:

- **Create**: To create a new map set, click **Create Product Map Set**.
- **Edit**: To edit an existing map set, click **Edit** ( ) next to the map set you want to modify. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Mapping Set Name**.

Step 5 Enter a **Description**.

Step 6 You have two choices:

- **Create**: To map a third-party product, click **Add Product Map**.
- **Edit**: To edit an existing third-party product map, **Edit** ( ) next to the map set you want to modify. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 7 Enter the **Vendor String**, **Product String**, and **Version String** used by the third-party product.

Step 8 In the Product Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping from the **Vendor**, **Product**, **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** fields.

Example:

If you want a host running a product whose name consists of third-party strings to use the vulnerabilities from Red Hat Linux 9, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Step 9 Click **Save**.

Map third-party product fixes

Mapping a fix name to a set of fixes in the database allows you to import data from a third-party patch management application and apply the fix to specified hosts. When the fix name is imported to a host, the system marks all vulnerabilities addressed by the fix as invalid for that host.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **User Third-Party Mappings**.

Step 3 You have two choices:

- Create — To create a new map set, click **Create Product Map Set**.

- Edit — To edit an existing map set, click **Edit** ( ) next to the map set you want to modify. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Mapping Set Name**.

Step 5 Enter a **Description**.

Step 6 You have two choices:

- Create — To map a third-party product, click **Add Fix Map.**
- Edit — To edit an existing third-party product map, click **Edit** ( ) next to it. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 7 Enter the name of the fix you want to map in the **Third-Party Fix Name** field.

Step 8 In the **Product Mappings** section, choose the operating system, product, and versions you want to use for fix mapping from these fields:

- **Vendor**
- **Product**
- **Major Version**
- **Minor Version**
- **Revision Version**
- **Build**
- **Patch**
- **Extension**

Example:

If you want your mapping to assign the fixes from Red Hat Linux 9 to hosts where the patch is applied, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Step 9 Click **Save** to save the fix map.

Map third-party vulnerabilities

To add vulnerability information from a third party to the VDB, you must map the third-party identification string for each imported vulnerability to any existing SVID, Bugtraq, or SID. After you create a mapping for the vulnerability, the mapping works for all vulnerabilities imported to hosts in the network map and allows impact correlation for those vulnerabilities.

You must enable impact correlation for third-party vulnerabilities to allow correlation to occur. For versionless or vendorless applications, you must also map vulnerabilities for the application types in the Secure Firewall Management Center configuration.

Although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot use third-party client vulnerabilities for impact assessment.

Tip If you have already created a third-party mapping on another Secure Firewall Management Center, you can export it and then import it onto this Firewall Management Center. You can then edit the imported mapping to suit your needs.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **User Third-Party Mappings**.

Step 3 You have two choices:

- Create — To create a new vulnerability set, click **Create Vulnerability Map Set**.
- Edit — To edit an existing vulnerability set, click **Edit** ( ) next to the vulnerability set. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Click **Add Vulnerability Map**.

Step 5 Enter the third-party identification for the vulnerability in the **Vulnerability ID** field.

Step 6 Enter a **Vulnerability Description**.

Step 7 Optionally:

- Enter a Snort ID in the **Snort Vulnerability ID Mappings** field.
- Enter a legacy vulnerability ID in the **SVID Mappings** field.
- Enter a Bugtraq identification number in the **Bugtraq Vulnerability ID Mappings** field.

Step 8 Click **Add**.

Custom product mappings

A custom product mapping is a network configuration feature that - ensures servers input by a third party are associated with the appropriate Cisco definitions - applies to all servers or clients on monitored hosts that have the mapped vendor strings, and - enables mapping vulnerabilities for all servers in the network map with a particular vendor string instead of explicitly setting the vendor, product, and version for the server.

Create custom product mappings

Custom product mappings allow you to manually create mappings when the system cannot automatically map a server to a vendor and product in the VDB. When you activate a custom product mapping, the system maps vulnerabilities for the specified vendor and product to all servers in the network map where that vendor string occurs.

Note Custom product mappings apply to all occurrences of an application protocol, regardless of the source of the application data (such as Nmap, the host input feature, or the system itself). However, if third-party vulnerability mappings for data imported using the host input feature conflicts with the mappings you set through a custom product mapping, the third-party vulnerability mapping overrides the custom product mapping and uses the third-party vulnerability mapping settings when the input occurs.

You create lists of product mappings and then enable or disable use of several mappings at once by activating or deactivating each list. When you specify a vendor to map to, the system updates the list of products to include only those made by that vendor.

After you create a custom product mapping, you must activate the custom product mapping list. After you activate a list of custom product mappings, the system updates all servers with occurrences of the specified vendor strings. For data imported through the host input feature, vulnerabilities update unless you have already explicitly set the product mappings for this server.

If, for example, your company modifies the banner for your Apache Tomcat web servers to read `Internal Web Server`, you can map the vendor string `Internal Web Server` to the vendor **Apache** and the product **Tomcat**, then activate the list containing that mapping, all hosts where a server labeled `Internal Web Server` occurs have the vulnerabilities for Apache Tomcat in the database.

Tip You can use this feature to map vulnerabilities to local intrusion rules by mapping the SID for the rule to another vulnerability.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **Custom Product Mappings**, and then **Create Custom Product Mapping List**.

Step 3 Enter a **Custom Product Mapping List Name**.

Step 4 Click **Add Vendor String**.

Step 5 In the **Vendor String** field, enter the vendor string that identifies the applications that should map to the chosen vendor and product values.

Step 6 Choose the vendor you want to map to from the **Vendor** drop-down list.

Step 7 Choose the product you want to map to from the **Product** drop-down list.

Step 8 Click **Add** to add the mapped vendor string to the list.

Step 9 Optionally, repeat steps 4 to 8 as needed to add additional vendor string mappings to the list.

Step 10 Click **Save**.

What to do next

- Activate the custom product mapping list. For more information, see Activate and deactivate custom product mappings, on page 2263.

Edit custom product mapping lists

You can modify existing custom product mapping lists by adding or removing vendor strings or changing the list name.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **Custom Product Mappings**.

Step 3 Click **Edit** ( ) next to the product mapping list you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Make changes to the list as described in Create custom product mappings, on page 2261.

Step 5 When you finish, click **Save**.

Activate and deactivate custom product mappings

Activating custom product mappings allows you to enable or disable use of an entire list of custom product mappings at once, providing centralized control over application detection across your network.

After you activate a custom product mapping list, each mapping on that list applies to all applications with the specified vendor string, whether detected by managed devices or imported through the host input feature.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **Custom Product Mappings**.

Step 3 Click the slider next to the custom product mapping list to activate or deactivate it.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Configure the host input client

The host input feature allows you to update the Firewall Management Center's network map from a client program running on another appliance. For example, you can add or delete hosts from the network map, or update the host OS and service information. For more information, see the *Firepower System Host Input API Guide*.

Before you can run a remote client, you must add the client to the Firewall Management Center's peers database from the Host Input Client page. You must also copy the authentication certificate generated by the Firewall

Management Center to the client. After completing these steps the client can connect to the Firewall Management Center.

In a multidomain deployment, you can create a client in any domain. The authentication certificate allows the client to submit network map updates for any leaf domains associated with the client certificate's domain. If you create a certificate for an ancestor domain (or if your certificate domain later becomes an ancestor domain after adding descendant domains), any clients using that certificate must specify a target leaf domain with every transaction, as described in the *Firepower System Host Input API Guide*.

The Host Input Client shows only clients associated the current domain, so if you want to download or revoke a certificate, switch to the domain where the client was created.

This connection uses TLS 1.2.

Before you begin

Follow these steps to configure the host input client:

Procedure

Step 1 Choose **Integration** > **Other Integrations**.

Step 2 Click **Host Input Client**.

Step 3 Click **Create Client**.

Step 4 In the **Hostname** field, enter the host name or IP address of the host running the host input client.

Note If you have not configured DNS resolution, use an IP address.

Step 5 If you want to encrypt the certificate file, enter a password in the **Password** field.

Step 6 Click **Save**.
The host input service allows the host to access port 8307 on the Firewall Management Center and creates an authentication certificate to use during client-server authentication.

Step 7 Click **Download** ( ) next to the certificate file.

Step 8 Save the certificate file to the directory used by your client for SSL/TLS authentication.

Step 9 To revoke access for a client, click **Delete** ( ) next to the host you want to remove.

Nmap scanning

The system builds network maps through passive analysis of traffic on your network. Information obtained through this passive analysis can occasionally be incomplete, depending on system conditions. However, you can actively scan a host to obtain complete information.

If a host has a server running on an open port but the server has not received or sent traffic during the time that the system has been monitoring your network, the system does not add information

about that server to the network map. If you scan the host using an active scanner, you can detect the server.

You can use Nmap, an open source active scanner, to explore your network and audit its security.

When you scan a host using Nmap, the system:

- Adds servers found on previously undetected open ports are added to the Servers list in the host profile. The host profile lists any servers detected on filtered or closed TCP ports or on UDP ports in the **Scan Results** section. By default, Nmap scans more than 1660 TCP ports.

  If the system recognizes a server identified in an Nmap scan and has a corresponding server definition, the system maps the names Nmap uses for servers to the corresponding Cisco server definitions.

- Compares the results of the scan to over 1500 known operating system fingerprints to determine the operating system and assigns scores to each. The operating system assigned to the host is the operating system fingerprint with the highest score.

  The system maps Nmap operating system names to Cisco operating system definitions.

- Vulnerabilities are assigned to the host for any added servers and operating systems.

Note

- A host must exist in the network map before Nmap can append its results to the host profile.
- If the host is deleted from the network map, any Nmap scan results for that host are discarded.

Tip Scanning options like port scans can put a heavy load on networks with low bandwidth. Run these scans when your network traffic is low.

For more information on the underlying Nmap technology used to scan, refer to the Nmap documentation at http://insecure.org/.

Nmap remediation options

You define the settings for an Nmap scan by creating an Nmap remediation. An Nmap remediation can be used in a correlation policy, initiated on demand, or scheduled for a specific time.

Note Nmap-supplied server and operating system data remain static until you run another Nmap scan. If you plan to scan a host for operating system and server data using Nmap, schedule regular scans to keep Nmap-supplied data and server data up-to-date.

Table 142: Nmap remediation options

Option	Description	Corresponding Nmap option
Scan which addresses from the event?	When you use an Nmap scan as a response to a correlation rule, select one of the following options to control which address in the event is scanned: that of the source host, the destination host, or both: • **Scan Source and Destination Addresses** scans the hosts represented by the source IP address and the destination IP address in the event. • **Scan Source Address Only** scans the host represented by the event's source IP address. • **Scan Destination Address Only** scans the host represented by the event's destination IP address.	N/A
Scan types	Select how Nmap scans ports: • The **TCP Syn** scan connects quickly to thousands of ports without using a complete TCP handshake. This option allows you to scan quickly in stealth mode on hosts where the `admin` account has raw packet access or where IPv6 is not running, by initiating TCP connections but not completing them. If a host acknowledges the Syn packet sent in a TCP Syn scan, Nmap resets the connection. • The **TCP Connect** scan uses the `connect()` system call to open connections through the operating system on the host. You can use the TCP Connect scan if the `admin` user on the Firewall Management Center or managed device does not have raw packet privileges on a host or you are scanning IPv6 networks. In other words, use this option in situations where the TCP SYN scan cannot be used. • The **TCP ACK** scan sends an ACK packet to check whether ports are filtered or unfiltered. • The **TCP Window** scan works in the same way as a TCP ACK scan but can also determine whether a port is open or closed. • The **TCP Maimon** scan identifies BSD-derived systems using a FIN/ACK probe.	**TCP Syn**: `-sS` **TCP Connect**: `-sT` **TCP ACK**: `-sA` **TCP Window**: `-sW` **TCP Maimon**: `-sM`
Scan for UDP ports	Enable this option to scan UDP ports as well as TCP ports. Scanning UDP ports may be time consuming, so avoid using this option if you want to scan quickly.	`-sU`

Option	Description	Corresponding Nmap option
Use port from event	If you plan to use the remediation as a response in a correlation policy, enable to cause the remediation to scan only the port specified in the event that triggers the correlation response. • Select **On** to scan the port in the correlation event, rather than the ports you specify during Nmap remediation configuration. If you scan the port in the correlation event, note that the remediation scans the port on the IP addresses that you specify during Nmap remediation configuration. These ports are also added to the remediation's dynamic scan target. • Select **Off** to scan only the ports you specify Nmap remediation configuration. You can also control whether Nmap collects information about operating system and server information. Enable the **Use Port From Event** option to scan the port associated with the new server.	N/A
Scan from reporting detection engine	Enable this option to scan a host from the appliance where the detection engine that reported the host resides. • To scan from the appliance running the reporting detection engine, select **On**. • To scan from the appliance configured in the remediation, select **Off**.	N/A
Fast port scan	Enable this option to scan only the TCP ports listed in the `nmap-services` file located in the `/var/sf/nmap/share/nmap/nmap-services` directory on the device that does the scanning, ignoring other port settings. You cannot use this option with the **Port Ranges and Scan Order** option. • To scan only the ports listed in the `nmap-services` file located in the `/var/sf/nmap/share/nmap/nmap-services` directory on the device that does the scanning, ignoring other port settings, select **On**. • To scan all TCP ports, select **Off**.	`-F`
Port ranges and scan order	Set the specific ports you want to scan and the order in which you want to scan them using Nmap port specification syntax. Note that you cannot use this option with the **Fast Port Scan** option.	`-p`
Probe open ports for vendor and version information	Enable to detect server vendor and version information. If you probe open ports for server vendor and version information, Nmap obtains server data that it uses to identify servers. Nmap then replaces the Cisco server data for that server. • Select **On** to scan open ports on the host for server information to identify server vendors and versions. • Select **Off** to continue using Cisco server information for the host.	`-sV`

Option	Description	Corresponding Nmap option
Service version intensity	Select the intensity of Nmap probes for service versions. • To use more probes for higher accuracy with a longer scan, select a higher number. • To use fewer probes for less accuracy with a faster scan, select a lower number.	`--version-intensity` <intensity>
Detect operating system	Enable to detect operating system information for the host. If you configure detection of the operating system for a host, Nmap scans the host and uses the results to create a rating for each operating system that reflects the likelihood that the operating system is running on the host. • Select **On** to scan the host for information to identify the operating system. • Select **Off** to continue using Cisco operating system information for the host.	`-O`
Treat all hosts as online	Enable to skip the host discovery process and run a port scan on every host in the target range. Note that when you enable this option, Nmap ignores settings for **Host Discovery Method** and **Host Discovery Port List**. • To skip the host discovery process and run a port scan on every host in the target range, select **On**. • To perform host discovery using the settings for **Host Discovery Method** and **Host Discovery Port List** and skip the port scan on any host that is not available, select **Off**.	`-PN`
Host discovery method	Select to perform host discovery for all hosts in the target range, over the ports listed in the **Host Discovery Port List**, or if no ports are listed, over the default ports for that host discovery method. Note that if you also enabled **Treat All Hosts As Online**, however, the **Host Discovery Method** option has no effect and host discovery is not performed. Select the method to be used when Nmap tests to see if a host is present and available: • The **TCP SYN** option sends an empty TCP packet with the SYN flag set and recognizes the host as available if a response is received. TCP SYN scans port 80 by default. Note that TCP SYN scans are less likely to be blocked by a firewall with stateful firewall rules. • The **TCP ACK** option sends an empty TCP packet with the ACK flag set and recognizes the host as available if a response is received. TCP ACK also scans port 80 by default. Note that TCP ACK scans are less likely to be blocked by a firewall with stateless firewall rules. • The **UDP** option sends a UDP packet and assumes host availability if a port unreachable response comes back from a closed port. UDP scans port 40125 by default.	**TCP SYN**: `-PS` **TCP ACK**: `-PA` **UDP**: `-PU`

Option	Description	Corresponding Nmap option
Host discovery port list	Specify a customized list of ports, separated by commas, that you want to scan when doing host discovery.	port list for host discovery method
Default NSE scripts	Enable to run the default set of Nmap scripts for host discovery and server and operating system and vulnerability detection. or a list of default scripts, refer to https://nmap.org/nsedoc/categories/default.html. • To run the default set of Nmap scripts, select **On**. • To skip the default set of Nmap scripts, select **Off**.	`-sC`
Timing template	Select the timing of the scan process; the higher the number you select, the faster and less comprehensive the scan.	**0**: `T0` (paranoid) **1**: `T1` (sneaky) **2**: `T2` (polite) **3**: `T3` (normal) **4**: `T4` (aggressive) **5**: `T5` (insane)

Nmap scanning guidelines

While active scanning can obtain valuable information, overuse of a tool such as Nmap may overload your network resources or even crash important hosts. When you use any active scanner, create a scanning strategy to scan only the hosts and ports you need.

Selecting appropriate scan targets

When you configure Nmap, you can create scan targets that identify which hosts you want to scan. A scan target includes a single IP address, a CIDR block, an octet range of IP addresses, an IP address range, or a list of IP addresses or ranges to scan. You can also select the ports on the host or hosts.

You can specify targets in various ways:

- For IPv6 hosts: An exact IP address (for example, `2001:DB8:1::178:ABCD`).
- For IPv4 hosts:
  - An exact IP address (for example, `192.168.x.x`) or a list of IP addresses separated by commas or spaces.
  - An IP address block using CIDR notation (for example, `192.168.1.0/24` scans the 254 hosts between 192.168.x.x and 192.168.x.x, inclusive).
  - An IP address range using octet range addressing (for example, `198.51.0-255.1-254` scans all addresses in the 198.51.x.x range, except those that end in .0 and or .255).
  - An IP address range using hyphenation (for example, `192.168.x.x-192.168.x.x` scans the six hosts between 192.168.x.x and 192.168.x.x, inclusive).

- A list of addresses or ranges separated by commas or spaces (for example, `192.168.1.0/24, 194.168.1.0/24` scans the 254 hosts between 192.168.x.x and 192.168.x.x, inclusive and the 254 hosts between 194.168.x.x and 194.168.x.x, inclusive).

Ideal scan targets for Nmap scans include hosts with operating systems that the system is unable to identify, hosts with unidentified servers, or hosts recently detected on your network. Remember that Nmap results cannot be added to the network map for hosts that do not already exist in the network map.

Caution

- Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans.
- If a host is deleted from the network map, any Nmap scan results are discarded.
- Make sure you have permission to scan your targets. Scanning Nmap hosts not owned by you or your company may be illegal.

Selecting appropriate ports to scan

For each scan target you configure, you can select the ports you want to scan. You can designate individual port numbers, port ranges, or a series of port numbers and port ranges to identify the exact set of ports that should be scanned on each target.

By default, Nmap scans TCP ports 1 through 1024. If you plan to use the remediation as a response in a correlation policy, you can configure the remediation to scan only the port specified in the event that triggers the correlation response. If you run remediation on demand, or as a scheduled task, or if you do not use the port from the event, you can use other port options to determine which ports are scanned. You can choose to scan only the TCP ports listed in the `nmap-services` file, ignoring other port settings. You can also scan UDP ports in addition to TCP ports. Scanning for UDP ports may take longer. Use this option only if you do not require a quick scan. To select the specific ports or range of ports to scan, use Nmap port specification syntax to identify ports.

Setting host discovery options

You can decide whether to perform host discovery before starting a port scan for a host, or you can assume that all the hosts you plan to scan are online. If you choose not to treat all hosts as online, you can choose what method of host discovery to use and, if needed, customize the list of ports scanned during host discovery. Host discovery does not probe the ports listed for operating system or server information; it uses the response over a particular port only to determine whether a host is active and available. If you perform host discovery and a host is not available, Nmap does not scan ports on that host.

Example: Use Nmap to resolve unknown operating systems

This example walks through an Nmap configuration designed to resolve unknown operating systems. For a complete look at Nmap configuration, see Manage Nmap scanning, on page 2272.

If the system cannot determine the operating system on a host on your network, you can use Nmap to actively scan the host. Nmap uses the information it obtains from the scan to rate the possible operating systems. It then uses the operating system that has the highest rating as the host operating system identification.

Using Nmap to challenge new hosts for operating system and server information deactivates the system's monitoring of that data for scanned hosts. If you use Nmap to discover the host and server operating system

for hosts marked as unknown by the systems, you may identify groups of similar hosts. You can then create a custom fingerprint using one of these hosts to associate the fingerprint with the operating system you identified through Nmap scan. Whenever possible, create a custom fingerprint rather than inputting static data through a third-party source like Nmap because the custom fingerprint allows the system to continue to monitor the host operating system and update it as needed.

Procedure

Step 1 Configure a scan instance as described in Add an Nmap scan instance, on page 2273.

Step 2 Create an Nmap remediation using the following settings:

- Enable **Use Port From Event** to scan the port associated with the new server.
- Enable **Detect Operating System** to detect operating system information for the host.
- Enable **Probe open ports for vendor and version information** to detect server vendor and version information.
- Enable **Treat All Hosts as Online**, because you know the host exists.

Step 3 Create a correlation rule that triggers when the system detects a host with an unknown operating system.

The rule should trigger when **a discovery event occurs** and **the OS information for a host has changed** and it meets the following conditions: **OS Name is unknown**.

Step 4 Create a correlation policy that contains the correlation rule.

Step 5 In the correlation policy, add the Nmap remediation you created in step 2 as a response to the rule you created in step 3.

Step 6 Activate the correlation policy.

Step 7 Purge the hosts on the network map to force network discovery to restart and rebuild the network map.

Step 8 After a day or two, search for events generated by the correlation policy.

Analyze the Nmap results for the operating systems detected on the hosts to see if there is a particular host configuration on your network that the system does not recognize.

Step 9 If you find hosts with unknown operating systems whose Nmap results are identical, create a custom fingerprint for one of those hosts and use it to identify similar hosts in the future.

Example: Using Nmap to respond to new hosts

This example walks through an Nmap configuration designed to respond to new hosts. For a complete look at Nmap configuration, see Manage Nmap scanning, on page 2272.

When the system detects a new host in a subnet where intrusions may be likely, you may want to scan that host to make sure you have accurate vulnerability information for it.

You can accomplish this by creating and activating a correlation policy that detects when a new host appears in this subnet, and that launches a remediation that performs an Nmap scan on the host.

Procedure

Step 1 Configure a scan instance as described in Add an Nmap scan instance, on page 2273.

Step 2 Create an Nmap remediation using the following settings:

- Enable **Use Port From Event** to scan the port associated with the new server.
- Enable **Detect Operating System** to detect operating system information for the host.
- Enable **Probe open ports for vendor and version information** to detect server vendor and version information.
- Enable **Treat All Hosts as Online**, because you know the host exists.

Step 3 Create a correlation rule that triggers when the system detects a new host on a specific subnet.

The rule should trigger when **a discovery event occurs** and **a new host is detected**.

Step 4 Create a correlation policy that contains the correlation rule.

Step 5 In the correlation policy, add the Nmap remediation you created in step 2 as a response to the rule you created in step 3.

Step 6 Activate the correlation policy.

Step 7 When you are notified of a new host, check the host profile to see the results of the Nmap scan and address any vulnerabilities that apply to the host.

After you activate the policy, you can periodically check the remediation status view (**Analysis** > **Correlation** > **Status**) to see when the remediation launched. The remediation's dynamic scan target should include the IP addresses of the hosts it scanned as a result of the server detection. Check the host profile for those hosts to see if there are vulnerabilities that need to be addressed for the host, based on the operating system and servers detected by Nmap.

Caution If you have a large or dynamic network, detection of a new host may be too frequent an occurrence to respond to using a scan. To prevent resource overload, avoid using Nmap scans as a response to events that occur frequently. In addition, note that using Nmap to challenge new hosts for operating system and server information deactivates Cisco monitoring of that data for scanned hosts.

Manage Nmap scanning

To use Nmap scanning, you must, at minimum, configure an Nmap scan instance and an Nmap remediation. Configuring an Nmap scan target is optional.

Procedure

Step 1 Configure the Nmap scan:

- Add an Nmap scan instance as described in Add an Nmap scan instance, on page 2273.
- Create an Nmap remediation as described in Create an Nmap remediation, on page 2276.
- Optionally, add an Nmap scan target as described in Add an Nmap scan target, on page 2275.

Step 2 Run the Nmap scan:

- Run an on-demand Nmap scan as described in Run an on-demand Nmap scan, on page 2279.
- Configure automatic Nmap scans as described in *Nmap Scan Automation* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Schedule automatic Nmap scans as described in *Scheduling an Nmap Scan* in the *Cisco Secure Firewall Management Center Administration Guide*.

What to do next

- Monitor the Nmap scan in progress by viewing the related task; see *Viewing Task Messages* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Optionally, refine the scan:
  - Edit an Nmap scan instance as described in Edit an Nmap scan instance, on page 2274.
  - Edit an Nmap scan target as described in Edit an Nmap scan target, on page 2276.
  - Edit an Nmap remediation as described in Edit an Nmap remediation, on page 2278.

Add an Nmap scan instance

You can set up a separate scan instance for each Nmap module that you want to use to scan your network for vulnerabilities. You can set up scan instances for the local Nmap module on the Secure Firewall Management Center and for any devices you want to use to run scans remotely. The results of each scan are always stored on the Firewall Management Center where you configure the scan, even if you run the scan from a remote device. To prevent accidental or malicious scanning of mission-critical hosts, you can create a blacklist for the instance to indicate the hosts that should never be scanned with the instance.

You cannot add a scan instance with the same name as any existing scan instance.

Procedure

Step 1 Access the list of Nmap scan instances using either of the following methods:

- Choose **Policies** > **Actions** > **Instances**.
- Choose **Policies** > **Actions** > **Scanners**.

Step 2 Add the remediation:

- If you accessed the list via the first method above, locate the Add a New Instance section, choose the Nmap Remediation module from the drop-down list, and click **Add**.
- If you accessed the list via the second method above, click **Add Nmap Instance**.

Step 3 Enter an **Instance Name**.

Step 4 Enter a **Description**.

Step 5 Optionally, in the **Exempted hosts** field, specify any hosts or networks that should *never* be scanned with this scan instance, using the following syntax:

- For IPv6 hosts, an exact IP address (for example, `2001:DB8::fedd:eeff`)
- For IPv4 hosts, an exact IP address (for example, `192.168.1.101`) or an IP address block using CIDR notation (for example, `192.168.1.0/24` scans the 254 hosts between `192.168.1.1` and `192.168.1.254`, inclusive)
- Note that you cannot use an exclamation mark (!) to negate an address value.

Note If you specifically target a scan to a host that is in a blacklisted network, that scan will not run.

Step 6 Optionally, to run the scan from a remote device instead of the Firewall Management Center, specify the IP address or name of the device as it appears in the Information page for the device in the Firewall Management Center web interface, in the **Remote Device Name** field.

Step 7 Click **Create**.
When the system is done creating the instance, it displays it in edit mode.

Step 8 Optionally, add an Nmap remediation to the instance. To do so, locate the Configured Remediations section of the instance, click **Add**, and create a remediation as described in Create an Nmap remediation, on page 2276.

Step 9 Click **Cancel** to return to the list of instances.

Note If you accessed the list of Nmap scan instances via the **Scanners** option, the system does not display the instance you added unless you also added a remediation to the instance. To view any instances to which you have not yet added remedations, use the **Instances** menu option to access the list.

Edit an Nmap scan instance

When you edit a scan instance, you can view, add, and delete remediations associated with the instance. If you no longer need the Nmap module in this scan instance, delete the Nmap scan instance. When you delete a scan instance, you also remove any remediations that use this instance.

Procedure

Step 1 To access the list of Nmap scan instances, use one of these methods:

- Choose **Policies** > **Actions** > **Instances**.
- Choose **Policies** > **Actions** > **Scanners**.

Step 2 Click **View** ( ) next to the instance you want to edit.

Step 3 Make changes to the scan instance settings as described in Add an Nmap scan instance, on page 2273.

Step 4 Click **Save**.

Step 5 Click **Done**.

What to do next

- To add a new remediation to the scan instance; refer to Create an Nmap remediation, on page 2276.
- To edit a remediation associated with the instance; refer to Edit an Nmap remediation, on page 2278.
- To delete a remediation associated with the instance; refer to Run an on-demand Nmap scan, on page 2279.
- You can delete the scan instance by clicking **Delete** ( ) next to it.

Add an Nmap scan target

Create and save scan targets that identify the hosts and ports you want to target when you perform an on-demand or a scheduled scan, so that you do not have to construct a new scan target every time.

A scan target includes a single IP address or a block of IP addresses. It also specifies the ports on the host or hosts. For Nmap targets, you can also use Nmap octet range addressing or IP address ranges. For more information on Nmap octet range addressing, see the Nmap documentation at https://insecure.org/.

Note

- Scans for targets containing a large number of hosts can take a long time. As a workaround, scan fewer hosts at a time.
- Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans. If a host is deleted from the network map, any Nmap scan results are discarded.

Procedure

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Targets**.

Step 3 Click **Create Scan Target**.

Step 4 In the **Name** field, enter the name you want to use for this scan target.

Step 5 In the **IP Range** text box, specify the host or hosts you want to scan using the syntax described in Nmap scanning guidelines, on page 2269.

Note If you use a comma in a list of IP addresses or ranges in a scan target, the comma converts to a space when you save the target.

Step 6 In the **Ports** field, specify the ports you want to scan.

You can enter any of these values from 1 to 65535:

- A port number.
- A list of ports separated by commas.
- A range of port numbers separated by a dash.
- Range of port numbers separated by dashes, and commas.

Step 7 Click **Save**.

Edit an Nmap scan target

Edit a remediation's dynamic scan target to exclude a specific IP address, but the IP address was added to the target because the host was involved in a correlation policy violation that launched the remediation.

Delete a scan target if you no longer want to scan the hosts listed in it.

Procedure

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Targets**.

Step 3 Click **Edit** ( ) next to the scan target you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Make modifications as necessary. For more information, see Add an Nmap scan target, on page 2275.

Step 5 Click **Save**.

Step 6 Delete the scan target by clicking **Delete** ( ) next to it.

Create an Nmap remediation

An Nmap remediation can only be created by adding it to an existing Nmap scan instance. You can use the remediation as a response in a correlation policy, run it on demand, or schedule it to run at a specific time.

Nmap-supplied server and operating system data remains static until another Nmap scan is run. To keep data updated, regularly schedule scans if you plan to scan a host using Nmap. If a host is deleted from the network map, any existing Nmap scan results are discarded.

For general information about Nmap functionality, refer to the Nmap documentation at https://insecure.org.

Before you begin

Add an Nmap scan instanceas described in Add an Nmap scan instance, on page 2273 .

Procedure

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Click **View** ( ) next to the instance to which you want to add the remediation.

Step 3 In the Configured Remediations section, click **Add**.

Step 4 Enter a **Remediation Name**.

Step 5 Enter a **Description**.

Step 6 If you plan to use this remediation in response to a correlation rule that triggers on an intrusion event, a connection event, or a user event, configure the **Scan Which Address(es) From Event?** option.

Tip If you plan to use this remediation in response to a correlation rule that triggers on a discovery event or a host input event, by default the remediation scans the IP address of the host involved in the event; you do not need to configure this option.

Note Do **not** assign an Nmap remediation as a response to a correlation rule that triggers on a traffic profile change.

Step 7 Configure the **Scan Type** option.

Step 8 To scan UDP ports in addition to TCP ports, choose **On** for the **Scan for UDP ports** option.

Tip A UDP portscan takes more time than a TCP portscan. To speed up your scans, leave this option disabled.

Step 9 If you plan to use this remediation in response to correlation policy violations, configure the **Use Port From Event** option.

Step 10 If you plan to use this remediation in response to correlation policy violations and want to run the scan using the appliance running the detection engine that detected the event, configure the **Scan from reporting detection engine** option.

Step 11 Configure the **Fast Port Scan** option.

Step 12 In the **Port Ranges and Scan Order** field, enter the ports you want to scan by default, using Nmap port specification syntax, in the order you want to scan those ports.

Use this format:

- Specify values from 1 to 65535.
- Separate ports using commas or spaces.
- Use a hyphen to indicate a port range.
- When scanning for both TCP and UDP ports, preface the list of TCP ports you want to scan with a T and the list of UDP ports with a U.

Note The **Use Port From Event** option overrides this setting when the remediation is launched in response to a correlation policy violation, as described in step 8.

Example:

To scan ports 53 and 111 for UDP traffic, then scan ports 21-25 for TCP traffic, enter **U:53,111,T:21-25**.

Step 13 To probe open ports for server vendor and version information, configure **Probe open ports for vendor and version information**.

Step 14 If you choose to probe open ports, set the number of probes used by choosing a number from the **Service Version Intensity** drop-down list.

Step 15 To scan for operating system information, configure **Detect Operating System** settings.

Step 16 To determine whether host discovery occurs and whether port scans are only run against available hosts, configure **Treat All Hosts As Online**.

Step 17 To set the method you want Nmap to use when it tests for host availability, choose a method from the **Host Discovery Method** drop-down list.

Step 18 If you want to scan a custom list of ports during host discovery, enter a list of ports appropriate for the host discovery method you chose, separated by commas, in the **Host Discovery Port List** field.

Step 19 Configure the **Default NSE Scripts** option to control whether to use the default set of Nmap scripts for host discovery and server, operating system, and vulnerability discovery.

Tip See https://nmap.org/nsedoc/categories/default.html for the list of default scripts.

Step 20 To set the timing of the scan process, choose a timing template number from the **Timing Template** drop-down list.

Choose a higher number for a faster, less comprehensive scan and a lower number for a slower, more comprehensive scan.

Step 21 Click **Create**.
When the system is done creating the remediation, it displays it in edit mode.

Step 22 Click **Done** to return to the related instance.

Step 23 Click **Cancel** to return to the instance list.

Edit an Nmap remediation

Edit an Nmap remediation to modify scan settings or remove it when it is no longer required.

Modifications you make to Nmap remediations do not affect scans in progress. The new settings take effect when the next scan starts. Delete an Nmap remediation if you no longer need it.

Procedure

Step 1 Access the list of Nmap scan instances using one of these methods:

- Choose **Policies** > **Actions** > **Instances**.
- Choose **Policies** > **Actions** > **Scanners**.

Step 2 Access the remediation you want to edit by performing one of these actions:

- If you accessed the list via the first method above, click **View** ( ) next to the relevant instance, and then click it again next to the remediation you want to edit in the Configured Remediations section.
- If you accessed the list via the second method above, click **View** ( ) next to the remediation you want to edit.

Step 3 Make any necessary modifications as described in Create an Nmap remediation, on page 2276.

Step 4 Click **Save** if you want to save your changes, or click **Done** to exit without saving.

Step 5 Delete the remediation by clicking **Delete** ( ) next to it.

Run an on-demand Nmap scan

You can launch on-demand Nmap scans whenever needed. You can specify the target for an on-demand scan by entering the IP addresses and ports you want to scan or by choosing an existing scan target.

Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans. If a host is deleted from the network map, any Nmap scan results are discarded.

Before you begin

Optionally, add an Nmap scan target; for more information, refer to Add an Nmap scan target, on page 2275 section.

Procedure

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 Next to the Nmap remediation you want to use to perform the scan, click **Scan** ( ).

Step 3 To scan using a saved scan target, choose a target from the **Saved Targets** drop-down list, and click **Load**.

Step 4 In the **IP Range(s)** field, specify the IP address for hosts you want to scan or modify the loaded list.

Note

- For hosts with IPv4 addresses, you can specify multiple IP addresses separated by commas or use CIDR notation. You can also negate IP addresses by preceding them with an exclamation point (!).
- For hosts with IPv6 addresses, use an exact IP address. Ranges are not supported.

Step 5 In the **Ports** field, specify the ports you want to scan or modify the loaded list.

You can enter a port number, a list of ports separated by commas, or a range of port numbers separated by a dash.

Step 6 Click **Scan Now**.

What to do next

- Monitor the task status; see *Viewing Task Messages* in the *Cisco Secure Firewall Management Center Administration Guide*.

Nmap scan results

You can manage, monitor, and analyze Nmap scan data to gain insights into your network configuration.

Nmap scan result viewing options

You can monitor Nmap scans in progress. You can import results from scans previously performed through the system, or import results performed outside the system. You can also view and analyze scan results.

You can view scan results that you create using the local Nmap module as a rendered page in a pop-up window. You can also download the Nmap results file in raw XML format.

You can also view operating system and server information detected by Nmap in host profiles and in the network map. If a scan of a host produces server information for servers on filtered or closed ports, or if a scan collects information that cannot be included in the operating system information or the servers section, the host profile includes those results in an Nmap Scan Results section.

View Nmap scan results

You can view the scan results in tabular format after the Nmap scan is completed and use the results view to find specific information.

When an Nmap scan is complete, you can view a table of scan results.

You can customize the results view depending on the information you are looking for. The page you see when you access scan results differs, based on the workflow. The predefined workflow includes a table view of scan results. You can also create a custom workflow that displays only the information that matches your specific needs.

You can download and view the Nmap results using the Nmap Version 1.01 DTD, available at http://insecure.org.

You can also clear scan results.

Procedure

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Scan Results**.

Step 3 You have the following choices:

- Adjust the time range as described in *Event Time Constraints* in the *Cisco Secure Firewall Management Center Administration Guide*.

- To use a different workflow, including a custom workflow, click **(switch workflows)** by the workflow title.
- To view the scan results as a rendered page in a pop-up window, click **View** next to the scan job.
- To save a copy of the scan results file so that you can view the raw XML code in any text editor, click **Download** next to the scan job.
- To sort scan results, click the column title. Click the column title again to reverse the sort order.
- To constrain the columns that appear, click **Close** ( ) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**.

Tip To hide or show other columns, check or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, Click the expand arrow to expand the search constraints, then click the column name under **Disabled Columns**.

- To drill down to the next page in the workflow, see *Using Drill-Down Pages* in the *Cisco Secure Firewall Management Center Administration Guide*.
- To configure scan instances and remediations, click **Scanners** in the toolbar and see Manage Nmap scanning, on page 2272.
- To navigate within and between workflow pages, see *Workflow Page Navigation Tools* in the *Cisco Secure Firewall Management Center Administration Guide*.
- To navigate to other event views to view associated events, choose the name of the event view you want to see from the **Jump to** drop-down list.
- To search for scan results, enter your search criteria in the appropriate fields.

Nmap scan results fields

When you run an Nmap scan, the Firewall Management Center collects the scan results in a database. The following table describes the fields in the scan results table that can be viewed and searched.

Table 143: Scan results fields

Field	Description
Start Time	The date and time that the scan that produced the results started.
End Time	The date and time that the scan that produced the results ended.
Target	The IP address (or host name, if DNS resolution is enabled) of the scan target for the scan that produced the results.
Scan Type	Either `Nmap` or the name of the third-party scanner to indicate the type of the scan that produced the results.

Field	Description
Scan Mode	The mode of the scan that produced the results: • `On Demand`: results from scans run on demand. • `Imported`: results from scans on a different system and imported onto the Firewall Management Center. • `Scheduled`: results from scans run as a scheduled task.
Results	The results of the scan.
Domain	The domain of the scan target. This field is only present in a multidomain deployment.

Import Nmap scan results

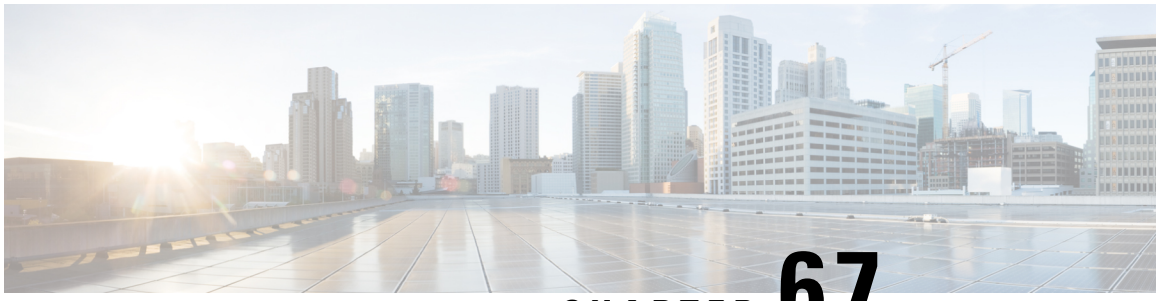
You can import XML results files created by an Nmap scan performed outside of the system. You can also import XML results files that you previously downloaded from the system. To import Nmap scan results, the results file must be in XML format and adhere to the Nmap Version 1.01 DTD. For more information on creating Nmap results and on the Nmap DTD, refer to the Nmap documentation at https://insecure.org.

A host must already exist in the network map before Nmap can append its results to the host profile.

Procedure

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Import Results**.



Step 3 Click **Browse** to navigate to the results file.

Step 4 After you return to the Import Results page, click **Import** to import the results.

History for host identity sources

This reference provides the version history for Host Identity Sources features, including security improvements and version compatibility information.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Security improvement to the host input data feature	6.5	Any	TLS 1.2 is now used for communication between your Firewall Management Center and the host input client. The topic Configure the host input client, on page 2263has been updated with this information.

CHAPTER 67

Application detection

Application detection is a process that

- identifies network traffic by application type,
- classifies network traffic to facilitate granular management, and
- enhances security.

Application detection provides administrators visibility into network usage patterns and enhances control over network management and policy enforcement.

- Application detection, on page 2283
- Requirements and prerequisites for application detection, on page 2289
- Custom application detectors, on page 2289
- View or download detector details, on page 2298
- Sort the detector list, on page 2299
- Filter the detector list, on page 2299
- Navigate to other detector pages, on page 2301
- Activate and deactivate detectors, on page 2301
- Edit custom application detectors, on page 2302
- Deleting detectors, on page 2303

Application detection

Application detection is a system capability that

- analyzes IP traffic to identify commonly used applications on your network,
- provides application awareness crucial for application control, and
- identifies applications according to characteristics specified in detectors.

Application detection types and sources

The system detects three types of applications:

- *application protocols* such as HTTP and SSH, representing communications between hosts
- *clients* such as web browsers and email clients, representing software running on the host

- *web applications* such as MPEG video and Facebook, representing the content or requested URL for HTTP traffic

The system identifies applications in network traffic according to the characteristics specified in the detector. For example, applications may be identified using ASCII patterns in packet headers. SSL protocol detectors use session information to identify the applications.

Application detectors come from two sources:

- *System-provided detectors* detect web applications, clients, and application protocols based on system software version and VDB. Professional Services can import individual detectors. Release notes provide information on updated detectors.
- *Custom application protocol detectors* are user-created to detect web applications, clients, and application protocols.

Implied application protocol detection, infers the existence of an application protocol based on client detection.

You can identify applications only if they originate from monitored network hosts as defined in your network discovery policy. If an internal host accesses an FTP server at an unmonitored remote site, the system does not identify the application protocol as FTP. However, if a remote or internal host accesses an FTP server on a monitored host, the system can identify the application protocol.

If the system identifies the client used by a monitored host to connect to a non-monitored server, it identifies the client's application protocol. However, it does not add this protocol to the network map. Client sessions must include a response from the server to occur for application detection.

The system characterizes each application that it detects; see Application rule conditions, on page 1322. The system uses these characteristics to create groups of applications, called *application filters*. Application filters are used to perform access control and to constrain search results and data used in reports and dashboard widgets.

You can also supplement application detector data using exported NetFlow records, Nmap active scans, and the host input feature.

Related Topics

Application detectors, on page 2284

Application detectors

An application detector is a tool used in network analysis that

- identifies commonly used applications on your network by analyzing traffic patterns,
- provides customizable detection capabilities through different detector types, and
- operates only when active to analyze application traffic.

Application detector types and characteristics

Application detectors identify commonly used applications on your network. Use the Detectors page (**Policies** > **Application Detectors**) to view the detector list and customize detection capabilities.

Modify a detector or change its state (active or inactive) based on its type. The system uses only active detectors to analyze application traffic.

Note

- Cisco-provided detectors may change with system and VDB updates. Refer to the release notes for updates.
- For firepower application identification, we intentionally do not list the ports. The application's associate ports are not reported for any of Cisco's applications because most of the applications are port-agnostic. Our platform's detection capabilities can identify services running at any port in the network.

- *Internal detectors* are a special category of detectors for client, web application, and application protocol traffic. Internal detectors are delivered with system updates and are always on.

  If an application matches internal detectors for client-related activity and no specific client detector exists, it reports a generic client.
- *Client detectors* detect client traffic and are delivered via VDB or system update. These detectors are provided for import by Cisco Professional Services. You can activate and deactivate client detectors. You can export a client detector only if you import it.
- *Web application detectors* detect web applications in HTTP traffic payloads and are delivered via VDB or system update. Web application detectors are always on.
- *Port-based application protocol detectors* use well-known ports to identify network traffic. They are delivered via VDB or system update, or are provided for import by Cisco Professional Services. You can activate and deactivate application protocol detectors, and view a detector definition to use it as the basis for a custom detector.
- *Firepower-based application protocol detectors* analyze network traffic using Firepower application fingerprints and are delivered via VDB or system update. You can activate and deactivate application protocol detectors.
- *Custom application detectors* are pattern-based. They detect patterns in packets from client, web application, or application protocol traffic. You have full control over imported and custom detectors.

Identification of application protocols in the web interface

This table shows how the web interface system identifies application protocols:

Table 144: System identification of application protocols

Identification	Description
Application protocol name	The Firewall Management Center lists the protocol name if it is: • Positively identified by the system • Identified using NetFlow data and a correlation exists in `/etc/sf/services` • Manually identified using the host input feature • Identified by Nmap or an active source

Identification	Description
`pending`	The Firewall Management Center identifies an application protocol as `pending` if the system can neither positively nor negatively identify the application. The system usually needs to collect and analyze more connection data to identify a pending application. In the Application Details and Servers tables and in the host profile, the `pending` status appears only where specific application protocol traffic is detected, not inferred from detected client or web application traffic.
`unknown`	The Firewall Management Center identifies an application protocol as `unknown` if: • the application does not match any of the system's detectors. • the application protocol was identified using NetFlow data, but no port-application protocol correlation exists in `/etc/sf/services`. • Snort has closed the session, but the session still persists in the device. Here, the traffic is allowed to pass through the firewall, but the application is not detected.
blank	All available detected data has been examined, but no application protocol was identified. In the Application Details and Servers tables and in the host profile, the application protocol is left blank for generic client traffic without HTTP connections.

Implied application protocol detection from client detection

Implied application protocol detection is a process that

- occurs when the system can identify the client used by a monitored host to access a non-monitored server,
- allows the Firewall Management Center to infer that the connection uses the application protocol that corresponds with the client, and
- provides application protocol information for connections where monitored hosts access non-monitored servers.

Consequences of implied application protocol detection

This process has these consequences:

- The system does not generate a New TCP Port or New UDP Port event for these servers, preventing their appearance in the Servers table. Additionally, the detection of these application protocols cannot trigger discovery event alerts or correlation rules.
- The application protocol is not associated with a host. Its details cannot be viewed in host profiles, its server identity is not set, and its information is not used in host profile qualifications for traffic profiles or correlation rules. In addition, the system does not associate vulnerabilities with hosts based on this type of detection.

You can trigger correlation events when application protocol information is present in a connection. You can also use the application protocol information in connection logs to create connection trackers and traffic profiles.

Host limits and discovery event logging

The system generates a discovery event when it detects a client, server, or web application, unless the associated host has reached its maximum number of clients, servers, or web applications.

Each host profile displays up to 16 clients, 100 servers, and 100 web applications.

Actions that depend on the detection of clients, servers, or web applications are not affected by this limit. Access control rules set to activate on a server will continue to log connection events.

Special considerations for application detection

Special considerations for application detection are network traffic analysis requirements that

- define specific conditions needed for accurate detection of certain application protocols,
- address limitations in detecting encrypted or proxy-based traffic, and
- establish rules for identifying applications that use referral mechanisms or certificate-based identification.

Application-specific detection requirements

Different applications require specific detection approaches:

- **SFTP**: To detect SFTP traffic, the same rule must also detect SSH.
- **Squid**: The system identifies Squid server traffic when either the system detects a connection from a host on your monitored network to a Squid server where proxy authentication is enabled, or the system detects a connection from a Squid proxy server on your monitored network to a target system, like the the destination server where the client is requesting information or another resource.

The system cannot identify Squid service traffic if:

- proxy authentication is disabled, or
- the Squid proxy server is configured to strip through header fields from its HTTP responses

SSL application detection:

The system uses session information from a Secure Socket Layers (SSL) session to identify the application protocol, client application, or web application in the session.

When the system detects an encrypted connection, it marks that connection as either a generic HTTPS connection or as a specific secure protocols, like SMTPS, when applicable. When the system detects an SSL session, it adds `SSL client` to the **Client** field in connection events for the session. If it identifies a web application for the session, the system generates discovery events for the traffic.

For SSL application traffic, managed devices can also detect the common name from the server certificate and match that against a client or web application from an SSL host pattern. When the system identifies a specific client, it replaces `SSL client` with the name of the client.

Because the SSL application traffic is encrypted, the system can use only information in the certificate for identification, not application data within the encrypted stream. For this reason, SSL host patterns can sometimes only identify the company that authored the application, so SSL applications produced by the same company may have the same identification.

In some instances, such as when an HTTPS session is launched from within an HTTP session, managed devices detect the server name from the client certificate in a client-side packet.

To enable SSL application identification, you must create access control rules that monitor responder traffic. Those rules must have either an application condition for the SSL application or URL conditions using the URL from the SSL certificate. For network discovery, the responder IP address does not have to be in the networks to monitor in the network discovery policy; the access control policy configuration determines whether the traffic is identified. To identify detections for SSL applications, you can filter by the `SSL protocol` tag, in the application detectors list or when adding application conditions in access control rules.

Referred web applications:

Web servers sometimes refer traffic to other websites, which are often advertisement servers. To help you understand referred traffic on your network, the system lists the referring web application in the **Web Application** field for the referred sessio eventsn. The VDB contains a list of known referred sites. When the system detects traffic from one of those sites, the referring site is stored with the event for that traffic. For example, if an advertisement accessed via Facebook is actually hosted on Advertising.com, the detected Advertising.com traffic is associated with the Facebook web application. The system can also detect referring URLs in HTTP traffic, such as when a website provides a simple link to another site; in this case, the referring URL appears in the HTTP Referrer event field.

In events, if a referring application exists, it is listed as the web application for the traffic, while the URL is that for the referred site. In the example above, the web application for the connection event for that traffic would be Facebook, but the URL would be Advertising.com. A referred application may appear as the web application if no referring web application is detected, if the host refers to itself, or if there is a chain of referrals. In the dashboard, connection and byte counts for web applications include sessions where the web application is associated with traffic referred by that application.

Note When creating a rule for referred traffic, add a condition for the referred application instead of the referring application. To block Advertising.com traffic referred from Facebook, for example, add an application condition to your access control rule specific to Advertising.com.

Disable application detection in Snort 3

Disable application detection in Snort 3 by removing application rules and related policies that enable application monitoring.

Note Snort 3 is now at parity with Snort 2, with respect to enabling AppID inspection exclusively on particular network subnets that are defined in the Network Discovery policy filters **if** no other configuration in the AC policy requires AppID to monitor all traffic.

Snort 3 always enables application detection for all networks by default.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**, click edit policy and delete the application rules.

Step 2 Choose **Policies** > **Access Control heading** > **Decryption**, click delete to delete the SSL policy.

Step 3 Choose **Policies** > **Network Discovery**, click delete to delete the network discovery policy.

Step 4 Choose **Policies** > **Access Control heading** > **Access Control**, click **Edit** ( ) to the policy you want to edit and then click the **Security Intelligence** > **URLs** tab to delete the URLs Allow or Block list.

Step 5 As you cannot delete default DNS rules, choose **Policies** > **Access Control heading** > **DNS**, click edit, and uncheck the enabled box to disable the DNS policy.

Step 6 In the access control policy, under the **Advanced** settings, disable the *Enable Threat Intelligence Director* and the *Enable reputation enforcement on DNS traffic* options.

Step 7 Save and deploy the access control policy.

Application detection is disabled in Snort 3, stopping any network monitoring for application identification.

Requirements and prerequisites for application detection

This reference provides the requirements and prerequisites for application detection, including model support, supported domains, and required user roles.

Model support

Any.

Supported domains

Any

User roles

- Discovery Admin

Custom application detectors

A custom application detector is a network monitoring tool that

- provides the system with information needed to identify custom applications on your network
- can be created as a custom web application, client, or application protocol detector, and
- is determined by your selections in the **Protocol**, **Type**, and **Direction** fields.

Custom application detector requirements and limitations

The system detects application protocols in server traffic when client sessions include a responder packet from the server. For UDP traffic, the system designates the server as the source of the responder packet.

If you have already created a detector on another Firewall Management Center, you can export it and then import it onto this Firewall Management Center. You can then edit the imported detector to suit your needs.

You can export and import both custom detectors and those provided by Cisco Professional Services. However, you **cannot** export or import any other type of Cisco-provided detectors.

Custom application detector and user-defined application fields

Use these fields to configure custom application detectors and user-defined applications.

Custom application detector fields: general

You should use these fields to configure basic and advanced custom application detectors.

Table 145: General custom application detector fields

Field	Description
Application Protocol	The application protocol you want to detect. This can be a system-provided application or a user-defined application. If you want the application to be available for exemption from active authentication (configured in your identity rules), you should select or create an application protocol with the **`User-Agent Exclusion`** tag.
Description	A description for the application detector.
Name	A name for the application detector.
Detector Type	The type of detector, **`Basic`** or **`Advanced`**. Basic application detectors are created in the web interface as a series of fields. Advanced application detectors are created externally and uploaded as custom .lua files.

Custom application detector fields: detection patterns

Use these fields to configure the detection patterns for basic custom application detectors.

Table 146: Detection pattern fields

Field	Description
Direction	The source of the traffic the detector should inspect, **`Client`** or **`Server`**.
Offset	The location in a packet, in bytes from the beginning of the packet payload, where the system should begin the pattern search. Because packet payloads start at byte 0, calculate the offset by subtracting 1 from the number of bytes you want to move forward from the beginning of the packet payload. For example, to look for the pattern in the fifth bit of the packet, type `4` in the **Offset** field.
Pattern	The pattern string associated with the **Type** you selected.
Ports	The port of the traffic the detector should inspect.

Field	Description
Protocol	The protocol you want to detect. Your protocol selection determines whether the **Type** or the **URL** field displays. The protocol (and, in some cases, your subsequent selections in the **Type** and **Direction** fields) determine the type of application detector you create: web application, client, or application protocol.
Type	The type of pattern string you entered. The options you see are determined by the **Protocol** you selected. If you selected **`RTMP`** as the protocol, the **URL** field displays instead of the **Type** field. **Note** If you select **`User Agent`** as the **Type**, the system automatically sets the **Tag** for the application to **`User-Agent Exclusion`**.
URL	Either a full URL or a section of a URL from the swfURL field within the C2 message of a RTMP packet. This field displays instead of the **Type** field when you select **`RTMP`** as the **Protocol**. **Note** The detector assumes that the string you enter is a complete section of the URL. For example, entering **`cisco.com`** would match **`www.cisco.com/support`** and **`www.cisco.com`**, but not **`www.wearecisco.com`**.

Table 147: Application detector types by protocol and configuration

Detector Type	Protocol	Type or Direction
Web Application	HTTP	**Type** is **`Content Type`** or **`URL`**
	RTMP	Any
	SSL	Any
Client	HTTP	**Type** is **`User Agent`**
	SIP	Any
	TCP or UDP	**Direction** is **`Client`**
Application Protocol	TCP or UDP	**Direction** is **`Server`**

Table 148: Pattern string types and characteristics

Type Selection	String Characteristics
`ASCII`	The string is ASCII encoded.
`Common Name`	The string is the value in the commonName field within the server response message.
`Content Type`	The string is the value in the content-type field within the server response header.

Type Selection	String Characteristics
Hex	The string is in hexadecimal notation.
Organizational Unit	The string is the value in the organizationName field within the server response message.
SIP Server	The string is the value in the From field within the message header.
SSL Host	The string is the value in the server_name field within the ClientHello message.
URL	The string is a URL. **Note** The detector assumes that the string you enter is a complete section of the URL. For example, entering **cisco.com** would match **www.cisco.com/support** and **www.cisco.com**, but not **www.wearecisco.com**.
User Agent	The string is the value in the user-agent field within the GET request header. It is also available for the SIP protocol and indicates that the string is the value in the User-Agent field within the SIP message header.

User-defined application fields

Use these fields to configure user-defined applications within basic and advanced custom application detectors.

Table 149: User-defined application configuration fields

Field	Description
Business Relevance	The likelihood that the application is used within the context of your organization's business operations, as opposed to recreationally: **Very High**, **High**, **Medium**, **Low**, or **Very Low**. Select the option that best describes the application.
Categories	A general classification for the application that describes its most essential function.
Description	A description for the application.
Name	A name for the application.
Risk	The likelihood that the application is used for purposes that might be against your organization's security policy: **Very High**, **High**, **Medium**, **Low**, or **Very Low**. Select the option that best describes the application.
Tags	One or more predefined tags that provide additional information about the application. If you want an application to be available for exemption from active authentication (configured in your identity rules), you must add the **User-Agent Exclusion** tag to your application.

Configure custom application detectors

Configure custom application detectors to identify specific applications and protocols not covered by the default detectors, enabling more accurate traffic analysis and control.

Configure basic or advanced custom application detectors.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click **Create Custom Detector**.

Step 3 Enter a **Name** and a **Description**.

Step 4 Choose an **Application Protocol** from the application drop-down list.

You have these options:

- If you are creating a detector for an existing application protocol (for example, if you want to detect a particular application protocol on a non-standard port), select the application protocol from the drop-down list.
- If you are creating a detector for a user-defined application, follow the procedure outlined in Create a user-defined application, on page 2294.

Step 5 Click **Detector Type** as **Basic** or **Advanced** and click **OK**.

Step 6 Configure **Detection Patterns** or **Detection Criteria** or **Encrypted Visibility Engine Process Assignments**:

- If you are configuring a basic detector, specify preset **Detection Patterns** as described in Specifying detection patterns in basic detectors, on page 2295.
- If you are configuring an advanced detector, specify custom **Detection Criteria** as described in Specify detection criteria in advanced detectors, on page 2296.
- If you are configuring an encrypted visibility engine (EVE) detector, specify custom EVE process assignments as described in *Specifying EVE Process Assignments* section in this chapter.

Caution Advanced custom detectors are complex; ensure your knowledge of .lua files is adequate. Incorrect configuration can negatively impact performance or detection.

Step 7 Optionally, use **Packet Captures** to test the new detector as described in Testing a custom application protocol detector, on page 2298.

Step 8 Click **Save**.

Note If you include the application in an access control rule, the detector is automatically activated and cannot be deactivated while it's in use.

The custom application detector is created and is ready for activation in access control rules and policies.

What to do next

Activate the detector as described in Activate and deactivate detectors, on page 2301.

Related Topics

Custom application detector and user-defined application fields, on page 2290

Create a user-defined application

Creating an application protocol detector to identify traffic that is not recognized by default system detectors. Applications, categories, and tags created here can be used in access control rules and application filters.

Caution Creating a user-defined application immediately restarts the Snort process without going through the deploy process. The system warns that continuing will restart the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Before you begin

Begin configuring your custom application protocol detector as described in Configure custom application detectors, on page 2293.

Follow these steps to create a user-defined application:

Procedure

Step 1 On the **Create A Custom Application Detector** dialog box, click **Add** (+) next to the **Application** field.

Step 2 Type a **Name**.

Step 3 Type a **Description**.

Step 4 Select a **Business Relevance**.

Step 5 Select a **Risk**.

Step 6 Click **Add** next to Categories to add a category and type a new category name, or select an existing category from the **Categories** drop-down list.

Step 7 (Optional) Click **Add** next to Tags to add a tag and type a new tag name, or select an existing tag from the **Tags** drop-down list.

Step 8 Click **OK**.

The user-defined application is created and is ready to be configured as part of your custom application protocol detector.

What to do next

Continue configuring your custom application protocol detector as described in Configure custom application detectors, on page 2293. You must save and activate the detector before the system can use it to analyze traffic.

Related Topics

Custom application detector and user-defined application fields, on page 2290

Specifying detection patterns in basic detectors

Configure a custom application protocol detector to search application protocol packet headers for a specific pattern string. You can also configure detectors to search for multiple patterns; requiring the application protocol traffic to match all patterns for positive identification.

Application protocol detectors can search for ASCII or hexadecimal patterns, using any offset.

Before you begin

Configure your custom application protocol detector as described in Configure custom application detectors, on page 2293.

Follow these steps to specify detection patterns in basic detectors:

Procedure

Step 1 On the **Create Detector** page, in the **Detection Patterns** section, click **Add**.

Step 2 Choose protocol type from the **Application** drop-down list.

Step 3 Choose pattern type from the **Type** drop-down list.

Step 4 Type a **Pattern** string that matches the **Type** you specified.

Step 5 Optionally, type the **Offset** (in byte).

Step 6 Optionally, to identify application protocol traffic based on the port it uses, type a port from 1 to 65535 in the **Port(s)** field. To use multiple ports, separate them by commas.

Step 7 Click a **Direction**: `Client` or `Server`.

Step 8 Click **OK**.

Tip If you want to delete a pattern, click **Delete** ( ) next to the pattern you want to delete.

The detection pattern is successfully added to your custom application protocol detector configuration.

What to do next

Continue configuring your custom application protocol detector as described in Configure custom application detectors, on page 2293. You must save and activate the detector before the system can use it to analyze traffic.

Related Topics

Specify detection criteria in advanced detectors, on page 2296

Specify detection criteria in advanced detectors

Upload a custom .lua file to specify detection criteria for advanced custom application detectors.

Caution

- Advanced custom detectors are complex and require outside knowledge to construct valid .lua files. Incorrectly configured detectors could have a negative impact on performance or detection capability.
- Do not upload .lua files from untrusted sources.

Custom .lua files contain your custom application detector settings. Creating custom .lua files requires advanced knowledge of the lua programming language and experience with Cisco's C-lua API. Cisco strongly recommends you use these references to prepare .lua files:

- Third-party instruction and reference material for the lua programming language
- The Open Source Detectors Developers Guide: https://www.snort.org/downloads
- OpenAppID Snort community resources: http://blog.snort.org/search/label/openappid

Note The system does not support .lua files that reference system calls or file I/O.

Before you begin

- Begin configuring your custom application protocol detector as described in Configure custom application detectors, on page 2293.
- Prepare to create a valid .lua file by downloading and studying the .lua files for comparable detectors. For more information about downloading detector files, refer to View or download detector details, on page 2298.
- Create a valid .lua file that contains your custom application detector settings.

Follow these steps to specify detection criteria in advanced detectors:

Procedure

Step 1 On the **Create Detector** page for an advanced custom application detector, in the **Detection Criteria** section, click **Add**.

Step 2 Click **Browse...** to navigate to the `.lua` file and upload it.

Step 3 Click **OK**.

The .lua file is uploaded and the detection criteria are specified for your advanced custom application detector.

What to do next

Continue configuring your custom application protocol detector as described in Configure custom application detectors, on page 2293. You must save and activate the detector before the system can use it to analyze traffic.

Related Topics

Specifying detection patterns in basic detectors, on page 2295

Specifying EVE process assignments

Configure custom application detectors to map processes detected by the encrypted visibility engine (EVE) to applications.

Before you begin

Configure your custom application protocol detector as described in the relevant section on Configure custom application detectors, on page 2293.

Follow these steps to specify EVE process assignments:

Procedure

Step 1 On the Create Detector page, in the Encrypted Visibility Engine Process Assignments section, click **Add**.

Step 2 Enter the **Process Name** and **Minimum Process Confidence** value.

Note You can enter text in the **Process Name** field, and this is case-sensitive. The value should match the exact process name detected by EVE. The **Minimum Process Confidence** value ranges from 0 to 100. This is the number displayed in the **Encrypted Visibility Process Confidence Score** field in Connection Events.

For information about the **Encrypted Visibility Process Confidence Score** field, refer to the section *Connection and Security Intelligence Event Fields* in the Cisco Firepower Management Center Administration Guide.

Step 3 Click **Save**.

Step 4 In the Application Detector listing page, activate the detector that you created. For more information, refer to Activate and deactivate detectors, on page 2301. When you activate the detector, the system pushes the detector files to all the FTDs registered on the Firewall Management Center.

Your EVE process assignments are set for your custom application detector, effectively mapping processes to the specified applications.

What to do next

Continue the configuration of your custom application protocol detector as described in Configure custom application detectors, on page 2293 to enable system traffic analysis.

Testing a custom application protocol detector

Test a custom application protocol detector against packet capture (pcap) files to verify that the detector accurately identifies the intended application traffic before deploying it in your network environment.

If you have a packet capture (pcap) file that contains packets with traffic from the application protocol you want to detect, test it using a custom application protocol detector. Use a simple pcap file free of unnecessary traffic.

Pcap files must be 256 KB or smaller. If you test your detector with a larger pcap file, the Firewall Management Center automatically truncates it and tests the incomplete file. You must fix the unresolved checksums in a pcap before using the file to test a detector.

Before you begin

Configure your custom application protocol detector as described in Configure custom application detectors, on page 2293.

Follow these steps to test a custom application protocol detector:

Procedure

Step 1 On the Create Detector page, in the **Packet Captures** section, click **Add**.

Step 2 Browse to the pcap file in the pop-up window and click **OK**.

Step 3 Click **Evaluate** next to the pcap file to test your detector against the contents of the pcap file. The system displays a message shwoing if the test was successful.

Step 4 Optionally, repeat steps 1 to 3 to test the detector against additional pcap files.

Tip To delete a pcap file, click **Delete** ( ) next to the file you want to delete.

The system evaluates your custom application protocol detector against the chosen pcap files and displays test results indicating the detector's success in identifying traffic.

What to do next

Continue configuring your custom application protocol detector as described in Configure custom application detectors, on page 2293. You must save and activate the detector before the system can use it to analyze traffic.

View or download detector details

Use the detectors list to view details for all application detectors and to download details for custom application detectors, supporting network security analysis and configuration management.

Procedure

Step 1 To view application detector details, choose from the available options:

- Refer to the *Cisco Firepower Application Detector Reference* for the relevant VDB version at https://www.cisco.com/c/en/us/support/security/defense-center/products-technical-reference-list.html
- a. Select **Policies** > **Application Detectors**.

  b. Filter the list to find a particular detector.

  c. Click **Information** ( )

Step 2 To download detector details for a custom application detector, click **Download** ( ).

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have the necessary permissions.

You can access application detector information either through the reference documentation or the management interface and download custom detector details.

Sort the detector list

Organize detectors in a specific order to make them easier to locate and manage by sorting the detector list.

By default, the Detectors page lists detectors alphabetically by name. An up or down arrow placed next to a column heading shows the sort direction.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click the appropriate column heading.

The detector list is sorted according to the selected column, with an arrow indicator showing the sort direction.

Filter the detector list

Use filters to narrow down the detector list. Focus on specific types of detectors or detector characteristics relevant to your analysis or configuration needs.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Expand one of the filter groups described in Filter groups for the detector list, on page 2300 and select the check box next to a filter. To select all filters in a group, right-click the group name and select **Check All**.

Step 3 If you want to remove a filter, click **Remove** (×) in the name of the filter in the **Filters** field or disable the filter in the filter list. To remove all filters in a group, right-click the group name and select **Uncheck All**.

Step 4 If you want to remove all filters, click **Clear all** next to the list of filters applied to the detectors.

The system updates the detector list displaying only those detectors that match your selected criteria.

Filter groups for the detector list

You can use several filter groups, separately or in combination, to filter the list of detectors.

Name

Locate detectors using string-matching in names or descriptions. All alphanumeric and special characters are allowed.

Custom filter

Locates detectors using custom filters set up on the object management page.

Author

Filter detectors based on their creator, such as:

- Individual user: Custom detectors created or imported by a user
- Cisco: All detectors provided by Cisco, *except* imported add-on detectors (you are the author for any detector that you import)
- **Any User**: Detectors not provided by Cisco.

State

Filters detectors based on their status, either **Active** or **Inactive**.

Type

Filters detectors by type, as described in Application detectors, on page 2284.

Protocol

Identifies detectors based on the inspected traffic protocol.

Category

Finds detectors based on the application categories they target.

Tag

Locates detectors by the tags assigned to applications.

Risk

Filters detectors based on the application risk levels: **Very High**, **High**, **Medium**, **Low**, and **Very Low**.

Business relevance

Filters detectors according to the business relevance of applications: **Very High**, **High**, **Medium**, **Low**, and **Very Low**.

Navigate to other detector pages

Detector pages display large amounts of data across multiple pages. Use the navigation controls to move efficiently between pages.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 If you want to view the next page, click **Right Arrow** ( ).

Step 3 If you want to view the previous page, click **Left Arrow** ( ).

Step 4 If you want to view a different page, type the page number and press Enter.

Step 5 If you want to jump to the last page, click **Right End Arrow** ( ).

Step 6 If you want to jump to the first page, click **Left End Arrow** ( ).

You can now navigate efficiently between detector pages using the available navigation controls.

Activate and deactivate detectors

Activate detectors to analyze network traffic or deactivate unused detectors to improve performance.

You must activate a detector before you can use it to analyze network traffic. By default, all Cisco-provided detectors are activated.

You can activate multiple application detectors for each port to enhance detection.

If you include an application in an access control rule in a policy and that policy is deployed without an active detector for that application, one or more detectors automatically activate. You cannot deactivate a detector while an application is in use in a deployed policy if doing so leaves no active detectors for that application.

Tip For improved performance, deactivate any application protocol, client, or web application detectors you do not intend to use.

Caution Activating or deactivating a system or custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click the slider next to the detector you want to activate or deactivate. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Note Some application detectors are required by other detectors. If you deactivate one of these detectors, a warning appears to indicate that the detectors that depend on it are also disabled.

The detector activation status changes immediately. When you activate or deactivate a system or custom application detector, the Snort process automatically restarts.

Edit custom application detectors

Use this procedure to modify the custom application detectors already configured in your system.

Before you begin

Follow these steps to edit custom application detectors:

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click **Edit** ( ) next to the detector you want to modify. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Make changes to the detector as described in Configure custom application detectors, on page 2293.

Step 4 Choose an appropriate saving options based on the state of the detector:

- To save an inactive detector, click **Save**.
- To save an inactive detector as a new, inactive detector, click **Save as New**.
- To save an active detector and immediately start using it, click **Save and Reactivate**.

Caution Saving and reactivating a custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing will restart the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

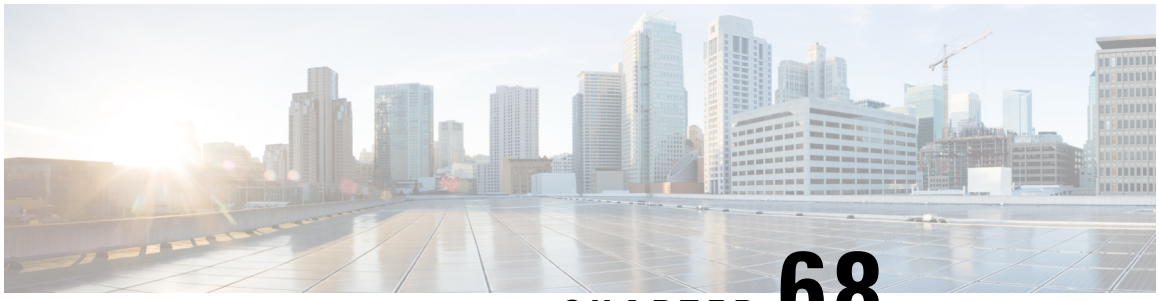
- To save an active detector as a new, inactive detector, click **Save as New**.

The custom application detector is modified and saved based on your selected option.

Deleting detectors

You can delete custom detectors as well as individually imported add-on detectors provided by Cisco Professional Services. You cannot delete any of the other Cisco-provided detectors, though you can deactivate many of them.

Note While a detector is in use in a deployed policy, you cannot delete the detector.



Caution Deleting an activated custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click **Delete** ( ) next to the detector you want to delete. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Click **OK**.

CHAPTER 68

Network Discovery Policies

The following topics describe how to create, configure, and manage network discovery policies:

- Network discovery policies overview, on page 2305
- Requirements and prerequisites for network discovery policies, on page 2306
- Network discovery customization, on page 2306
- Network discovery rules, on page 2307
- Configure advanced network discovery options, on page 2316
- Troubleshoot your network discovery strategy, on page 2325

Network discovery policies overview

The network discovery policy on the Firewall Management Center controls how the system collects data on the network assets of your organization and which network segments and ports are monitored.

Discovery rule configuration

Discovery rules in the policy specify which networks and ports you monitor to collect discovery data from traffic, and the zones where you deploy the policy. Within a rule, choose whether to discover hosts, applications, and non-authoritative users. Create rules to exclude networks and zones from discovery that you do not want to monitor. Set up discovery for data from NetFlow exporters as needed. You can also restrict which protocols on your network are used for discovering user data.

By default, the network discovery policy has a single rule that discovers applications from all observed traffic without excluding any networks, zones, or ports. Host and user discovery is not enabled, nor is NetFlow exporter monitoring. The policy is deployed automatically to managed devices when you register them to the Firewall Management Center. To collect host or user data, add or modify discovery rules and deploy the policy to a device.

If you want to adjust the scope of network discovery, you can create additional discovery rules and modify or remove the default rule.

The access control policy for each managed device determines which traffic you permit and, therefore, the traffic you can monitor with network discovery. If you block certain traffic with access control, the system does not examine that traffic for host, user, or application activity. For example, when you block access to social networking applications in an access control policy, discovery data is not collected on those applications.

Enable traffic-based user detection in your discovery rules to detect non-authoritative users based on login activity in traffic across specific application protocols. Disable discovery in certain protocols across all rules

if necessary. Disabling some protocols helps prevent reaching the user limit for your Firewall Management Center model and reserves user count for other protocols.

Use advanced network discovery settings to control what data is logged, how discovery data is stored, which indications of compromise (IOC) rules are active, how you map vulnerabilities for impact assessment, and how you resolve conflicting discovery data from multiple sources.

You can also add sources for host input and NetFlow exporters to monitor.

Requirements and prerequisites for network discovery policies

The following requirements and prerequisites apply to network discovery policies:

Requirement	Description
Model support	Any
Supported domains	Only Leaf domains are supported
User roles	• Admin • Discovery Admin

Network discovery customization

The information about your network traffic collected by the system is most valuable to you when the system can correlate this information to identify the hosts on your network that are most vulnerable and most important.

As an example, if you have several devices on your network running a customized version of SuSE Linux, the system cannot identify that operating system and so cannot map vulnerabilities to the hosts. However, knowing that the system has a list of vulnerabilities for SuSE Linux, you may want to create a custom fingerprint for one of the hosts that can then be used to identify the other hosts running the same operating system. You can include a mapping of the vulnerability list for SuSE Linux in the fingerprint to associate that list with each host that matches the fingerprint.

Customization capabilities

The system also allows you to input host data from third-party systems directly into the network map, using the host input feature. However, third-party operating system or application data does not automatically map to vulnerability information. If you want to see vulnerabilities and perform impact correlation for hosts using third-party operating system, server, and application protocol data, you must map the vendor and version information from the third-party system to the vendor and version listed in the vulnerability database (VDB). You also may want to maintain the host input data on an ongoing basis. Note that even if you map application data to system vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

If the system cannot identify application protocols running on hosts on your network, you can create user-defined application protocol detectors that allow the system to identify the applications based on a port or a pattern. You can also import, activate, and deactivate certain application detectors to further customize the application detection capability.

You can also replace detection of operating system and application data using scan results from the Nmap active scanner or augment the vulnerability lists with third-party vulnerabilities. The system may reconcile data from multiple sources to determine the identity for an application.

Configure the network discovery policy

Configure the Network Discovery Policy to establish how the system identifies and monitors network resources, user traffic, and host operating systems in your environment.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Configure the following components of your policy:

- Discovery rules — See Configure network discovery rules, on page 2308.
- Traffic-based detection for users — See Configure Traffic-Based user detection, on page 2315.
- Advanced network discovery options — See Configure advanced network discovery options, on page 2316.
- Custom operating system definitions (fingerprints) — See Create a custom fingerprint for clients, on page 2252 and Create a custom fingerprint for servers, on page 2254.

Network discovery rules

Network discovery rules allow you to tailor the information discovered for your network map to include only the specific data you want. Rules in your network discovery policy are evaluated sequentially. You can create rules with overlapping monitoring criteria, but doing so may affect your system performance.

Network discovery rule behavior

When you exclude a host or a network from monitoring, the host or network does not appear in the network map and no events are reported for it. However, when the host discovery rules for the local IP are disabled, the detection engine instances are impacted by a higher processing load, as it builds data from each flow afresh rather than using the existing host data.

We recommend that you exclude load balancers (or specific ports on load balancers) and NAT devices from monitoring. These devices may create excessive and misleading events, filling the database and overloading the Firewall Management Center. For example, a monitored NAT device might exhibit multiple updates of its operating system in a short period of time. If you know the IP addresses of your load balancers and NAT devices, you can exclude them from monitoring.

Tip The system can identify load balancers and NAT devices by examining your network traffic.

In addition, if you need to create a custom server fingerprint, you should temporarily exclude from monitoring the IP address that you are using to communicate with the host you are fingerprinting. Otherwise, the network

map and discovery event views will be cluttered with inaccurate information about the host represented by that IP address. After you create the fingerprint, you can configure your policy to monitor that IP address again.

Cisco also recommends that you **not** monitor the same network segment with NetFlow exporters and managed devices. Although ideally you should configure your network discovery policy with non-overlapping rules, the system does drop duplicate connection logs generated by managed devices. However, you **cannot** drop duplicate connection logs for connections detected by both a managed device and a NetFlow exporter.

Configure network discovery rules

You can configure discovery rules to tailor the discovery of host and application data to your needs.

Tip In most cases, we recommend restricting discovery to the addresses in RFC 1918.

Before you begin

- Make sure you are logging connections for the traffic where you want to discover network data ; see *Best Practices for Connection Logging* in the *Cisco Secure Firewall Management Center Administration Guide*.
- If you want to collect exported NetFlow records, add a NetFlow Exporter as described in Add NetFlow exporters to a network discovery policy, on page 2321.
- If you will want to view discovery performance graphs, you must enable hosts, users, and applications in your discovery rule. Note that this may impact system performance.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Add Rule**.

Step 3 Set the **Action** for the rule as described in Actions and discovered assets, on page 2309.

Step 4 Set optional discovery parameters:

- Restrict the rule action to specific networks; see Restrict the monitored network, on page 2310.
- Restrict the rule action to traffic in specific zones; see Configuring zones in network discovery rules, on page 2313.
- Exclude ports from monitoring; see Exclude ports in network discovery rules, on page 2312.
- Configure the rule for NetFlow data discovery; see Configure rules for NetFlow data discovery, on page 2310.

Step 5 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Actions and discovered assets

When you configure a discovery rule, you must select an action for the rule. The effect of that action depends on whether you are using the rule to discover data from a managed device or from a NetFlow exporter.

The table describes what assets are discovered by rules with the specified action settings in those two scenarios.

Table 150: Discovery rule actions

Action	Option	Managed Device	NetFlow Exporter
Exclude	--	Excludes the specified network from monitoring. If the source or destination host for a connection is excluded from discovery, the connection is recorded but discovery events are not created for excluded hosts.	Excludes the specified network from monitoring. If the source or destination host for a connection is excluded from discovery, the connection is recorded but discovery events are not created for excluded hosts.
Discover	Hosts	Adds hosts to the network map based on discovery events. (Optional, unless user discovery is enabled, then required.)	Adds hosts to the network map and logs connections based on NetFlow records.
Discover	Applications	Adds applications to the network map based on application detectors. Note that you cannot discover hosts or users in a rule without also discovering applications.	Adds application protocols to the network map based on NetFlow records and the port-application protocol correlation in `/etc/sf/services`.
Discover	Users	Adds users to the users table and logs user activity based on traffic-based detection on the user protocols configured in the network discovery policy.	n/a
Log NetFlow Connections	--	n/a	Logs NetFlow connections only. Does not discover hosts or applications.

If you want the rule to monitor managed device traffic, application logging is required. If you want the rule to monitor users, host logging is required. If you want the rule to monitor exported NetFlow records, you cannot configure it to log users, and logging applications is optional.

Note The system detects connections in exported NetFlow records based on the **Action** settings in the network discovery policy. The system detects connections in managed device traffic based on access control policy settings.

Monitored networks

A discovery rule causes discovery of monitored assets only in traffic to and from hosts in the specified networks. For a discovery rule, discovery occurs for connections that have at least one IP address within the networks specified, with events generated only for IP addresses within the networks to monitor. The default discovery rule discovers applications from all observed traffic (`0.0.0.0/0` for all IPv4 traffic, and `::/0` for all IPv6 traffic).

If you configure a rule to handle NetFlow discovery and log only connections data, the system also logs connections to and from IP addresses in the specified networks. Note that network discovery rules provide the only way to log NetFlow network connections.

You can also use network object or object groups to specify the networks to monitor.

Restrict the monitored network

Network discovery rules require at least one network to be specified for monitoring purposes. This task enables you to define which networks should be included in the discovery process.

Every discovery rule must include at least one network.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Add Rule**.

Step 3 Click **Networks**, if it is not already open.

Step 4 Add network objects to the Available Networks list as described in Create network objects during discovery rule configuration, on page 2311.

If you modify a network object used in the network discovery policy, the changes do not take effect for discovery until you deploy the configuration changes.

Step 5 Specify a network:

- Choose a network from the **Available Networks** list. If the network does not immediately appear on the list, click **Reload** ( ).
- Enter the IP address into the text box below the Available Networks label.

Step 6 Click **Add**.

Step 7 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure rules for NetFlow data discovery

The system can use data from NetFlow exporters to generate connection and discovery events, and to add host and application data to the network map.

If you choose a NetFlow exporter in a discovery rule, the rule is limited to discovery of NetFlow data for the specified networks. Choose the NetFlow device to monitor before you configure other aspects of rule behavior, as the available rule actions change when you choose a NetFlow device. You cannot configure port exclusions for monitoring NetFlow exporters.

Before you begin

- Add NetFlow-enabled devices to the network discovery policy; see Add NetFlow exporters to a network discovery policy, on page 2321.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Add Rule**.

Step 3 Choose **NetFlow Device**.

Step 4 From the **NetFlow Device** drop-down list, choose the IP address of the NetFlow exporter to be monitored.

Step 5 Specify the type of NetFlow data you want the system managed device to collect:

- Connection only — Choose `Log NetFlow Connections` from the **Action** drop-down list.
- Host, Application, and Connection — Choose `Discover` from the **Action** drop-down list. The system automatically checks the **Hosts** check box and enables collection of connection data. Optionally, you can check the **Application** check box to collect application data.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Create network objects during discovery rule configuration

You can add new network objects to the list of available networks that appears in a discovery rule by adding them to the list of reusable network objects and groups.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 In **Networks**, click **Add Rule**.

Step 3 Click **Add** (+) next to **Available Networks**.

Step 4 Create a network object as described in Create a network object, on page 2388.

Step 5 Finish adding the network discovery rule as described in Configure network discovery rules, on page 2308.

Port exclusions

Just as you can exclude hosts from monitoring, you can exclude specific ports from monitoring.

Port exclusion use cases

Port exclusions are useful in these scenarios:

- Load balancers can report multiple applications on the same port in a short period of time. You can configure your network discovery rules so that they exclude that port from monitoring, such as excluding port 80 on a load balancer that handles a web farm.
- Your organization may use a custom client that uses a specific range of ports. If the traffic from this client generates excessive and misleading events, you can exclude those ports from monitoring. Similarly, you may decide that you do not want to monitor DNS traffic. In that case, you could configure your rules so that your discovery policy does not monitor port 53.

When adding ports to exclude, you can decide whether to use a reusable port object from the Available Ports list, add ports directly to the source or destination exclusion lists, or create a new reusable port and then move it into the exclusion lists.

Note You cannot exclude ports in rules handling NetFlow data discovery.

Exclude ports in network discovery rules

Excluding ports in network discovery rules allows you to prevent the system from monitoring traffic on specific source and destination ports, helping to optimize network discovery performance and focus on relevant traffic patterns.

You cannot exclude ports in rules handling NetFlow data discovery.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Add Rule**.

Step 3 Click **Port Exclusions**.

Step 4 Optionally, add port objects to the Available Ports list as described in Create port objects during discovery rule configuration, on page 2313.

Step 5 Exclude specific source ports from monitoring, using either of these methods:

- Choose a port or ports from the **Available Ports** list and click **Add to Source**.
- To exclude traffic from a specific source port without adding a port object, under the **Selected Source Ports** list, choose a **Protocol**, enter a **Port** number (a value from 1 to 65535), and click **Add**.

Step 6 Exclude specific destination ports from monitoring, using either of these methods:

- Choose a port or ports from the **Available Ports** list and click **Add to Destination**.
- To exclude traffic from a specific destination port without adding a port object, under the **Selected Destination Ports** list, choose a **Protocol**, enter a **Port** number, and click **Add**.

Step 7 Click **Save** to save the changes you made.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Create port objects during discovery rule configuration

You can add new port objects to the list of available ports that appears in a discovery rule by adding them to the list of reusable port objects and groups that can be used anywhere in the system.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 In Networks, click **Add Rule**.

Step 3 Click **Port Exclusions**.

Step 4 To add a port to the Available Ports list, click **Add** (+).

Step 5 Enter **Name**.

Step 6 In the **Protocol** field, specify the protocol of the traffic you want to exclude.

Step 7 In the **Port** field, enter the ports you want to exclude from monitoring.

You can specify a single port, a range of ports using the dash (-), or a comma-separated list of ports and port ranges. Allowed port values are from 1 to 65535.

Step 8 Click **Save**.

Step 9 If the port does not immediately appear on the list, click **Refresh**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Zones in network discovery rules

To improve performance, discovery rules can be configured so that the zones in the rule include the sensing interfaces on your managed devices that are physically connected to the networks-to-monitor in the rule.

Unfortunately, you may not always be kept informed of network configuration changes. A network administrator may modify a network configuration through routing or host changes without informing you, which may make it challenging to stay on top of proper network discovery policy configurations. If you do not know how the sensing interfaces on your managed devices are physically connected to your network, leave the zone configuration as the default. This default causes the system to deploy the discovery rule to all zones in your deployment. (If no zones are excluded, the system deploy the discovery policy to all zones.)

Configuring zones in network discovery rules

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Add Rule**.

Step 3 Click **Zones**.

Step 4 Choose a zone or zones from the **Available Zones** list.

Step 5 Click **Save** to save the changes you made.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Traffic-based detection identity sources

Traffic-based detection is the only non-authoritative identity source supported by the system. When configured, managed devices detect LDAP, AIM, POP3, IMAP, Oracle, SIP (VoIP), FTP, HTTP, MDNS, and SMTP logins on the networks you specify. The data gained from traffic-based detection can be used only for user awareness. Unlike authoritative identity sources, you configure traffic-based detection in your network discovery policy as described in Configure Traffic-Based user detection, on page 2315.

Traffic-based detection limitations

- Traffic-based detection interprets only Kerberos logins for LDAP connections as LDAP authentications. Managed devices cannot detect encrypted LDAP authentications using protocols such as SSL or TLS.
- Traffic-based detection detects AIM logins using the OSCAR protocol only. They cannot detect AIM logins using TOC2.
- Traffic-based detection cannot restrict SMTP logging. This is because users are not added to the database based on SMTP logins; although the system detects SMTP logins, the logins are not recorded unless there is already a user with a matching email address in the database.

Traffic-based detection also records failed login attempts. A failed login attempt does not add a new user to the list of users in the database. The user activity type for detected failed login activity detected by traffic-based detection is **Failed User Login**.

Note The system cannot distinguish between failed and successful HTTP logins. To see HTTP user information, you must enable **Capture Failed Login Attempts** in the traffic-based detection configuration.

Caution Enabling or disabling non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Traffic-based detection data

When a device detects a login using traffic-based detection, it sends the following information to the Firewall Management Center to be logged as user activity:

- The user name identified in the login.
- The time of the login.

- The IP address involved in the login, which can be the IP address of the user's host (for LDAP, POP3, IMAP, and AIM logins), the server (for HTTP, MDNS, FTP, SMTP and Oracle logins), or the session originator (for SIP logins).
- The user's email address (for POP3, IMAP, and SMTP logins).
- The name of the device that detected the login.

If the user was previously detected, the Firewall Management Center updates that user's login history. Note that the Firewall Management Center can use the email addresses in POP3 and IMAP logins to correlate with LDAP users. This means that, for example, if the Firewall Management Center detects a new IMAP login, and the email address in the IMAP login matches that for an existing LDAP user, the IMAP login does not create a new user; rather, it updates the LDAP user's history.

If the user was previously undetected, the Firewall Management Center adds the user to the users database. Unique AIM, SIP, and Oracle logins always create new user records, because there is no data in those login events that the Firewall Management Center can correlate with other login types.

The Firewall Management Center does **not** log user activity or user identities in the following cases:

- If you configured the network discovery policy to ignore that login type
- If a managed device detects an SMTP login, but the users database does not contain a previously detected LDAP, POP3, or IMAP user with a matching email address

The user data is added to the users table.

Traffic-based detection strategies

You can restrict the protocols where user activity is discovered to reduce the total number of detected users so you can focus on users likely to provide the most complete user information. Limiting protocol detection helps minimize user name clutter and preserve storage space on your Firewall Management Center.

Consider these factors when selecting traffic-based detection protocols:

- Obtaining user names through protocols such as AIM, POP3, and IMAP may introduce user names not relevant to your organization due to network access from contractors, visitors, and other guests.
- AIM, Oracle, and SIP logins may create extraneous user records. This occurs because these login types are not associated with any of the user metadata that the system obtains from an LDAP server, nor are they associated with any of the information contained in the other types of login that your managed devices detect. Therefore, the Firewall Management Center cannot correlate these users with other types of users.

Configure Traffic-Based user detection

Configure traffic-based user detection to automatically enable host discovery and monitor user login activities across various protocols in your network.

When you enable traffic-based user detection in a network discovery rule, host discovery is automatically enabled. For more information about traffic-based detection, see Traffic-based detection identity sources, on page 2314.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Users**.

Step 3 Click **Edit** ( ).

Step 4 Check the check boxes for protocols where you want to detect logins, or clear check boxes for protocols where you do not want to detect logins. Then choose whether you want to **Capture Failed Login Attempts**.

Step 5 Click **Save**.

Traffic-based user detection is configured for the selected protocols, enabling the system to monitor user login activities and automatically discover hosts in your network.

What to do next

Caution Enabling or disabling non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

- Configure network discovery rules to discover users as described in Configure network discovery rules, on page 2308.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure advanced network discovery options

The **Advanced** section of the network discovery policy allows you to configure policy-wide settings. You can define which events are detected, how long discovery data is retained, how often it is updated, which vulnerability mappings are used for impact correlation, and how operating system and server identity conflicts are resolved. In addition, you can add host input sources and NetFlow exporters to allow import of data from other sources.

Note Database event limits for discovery and user activity events are set in system configuration.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** ( ) or **Add** ( ) next to the setting you want to modify:

- Data Storage Settings — Update the settings as described in Configure network discovery data storage, on page 2323.
- Event Logging Settings — Update the settings as described in Configure network discovery event logging, on page 2324.
- General Settings — Update the settings as described in Configuring network discovery general settings, on page 2318.
- Identity Conflict Settings — Update the settings as described in Configure network discovery identity conflict resolution, on page 2319.
- Indications of Compromise Settings — Update the settings as described in Enable indications of compromise rules, on page 2321.
- NetFlow Exporters — Update the settings as described in Add NetFlow exporters to a network discovery policy, on page 2321.
- OS and Server Identity Sources — Update the settings as described in Add network discovery OS and server identity sources, on page 2324.
- Vulnerabilities to use for Impact Assessment — Update the settings as described in Enable network discovery vulnerability impact assessment, on page 2320.

Step 4 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Network discovery general settings

The general settings control how often the system updates network maps and whether server banners are captured during discovery.

Capture banners

Select this check box if you want the system to store header information from network traffic that advertises server vendors and versions (“banners”). This information can provide additional context to the information gathered. You can access server banners collected for hosts by accessing server details.

Update interval

The interval at which the system updates information (such as when any of a host's IP addresses was last seen, when an application was used, or the number of hits for an application). The default setting is 3600 seconds (1 hour).

Note Setting a lower interval for update timeouts provides more accurate information in the host display, but generates more network events.

Configuring network discovery general settings

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **General Settings**.

Step 4 Update the settings as described in Network discovery general settings, on page 2317.

Step 5 Click **Save** to save the general settings.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Network discovery identity conflict settings

The system identifies the operating system and applications running on a host by matching fingerprints for operating systems and servers against patterns in traffic. It collects fingerprint information from several sources to give you reliable operating system and server identity information.

The system uses all passive data to derive operating system identities and assign a confidence value.

By default, unless there is an identity conflict, identity data added by a scanner or third-party application overrides identity data detected by the system. You can use the Identity Sources settings to rank scanner and third-party application fingerprint sources by priority. The system retains one identity for each source, but only data from the highest priority third-party application or scanner source is used as the current identity.

Note User input data overrides scanner and third-party application data, regardless of priority.

An identity conflict occurs when the system detects an identity that conflicts with an existing identity from active scanner, third-party application sources listed in the Identity Sources settings, or a system user. By default, identity conflicts are not automatically resolved and you must resolve them through the host profile or by rescanning the host or re-adding new identity data to override the passive identity. However, you can set your system to automatically resolve the conflict by keeping either the passive identity or the active identity.

Generate identity conflict event

Specifies whether the system generates an event when an identity conflict occurs.

Automatically resolve conflicts

From the **Automatically Resolve Conflicts** drop-down list, choose one of these options:

- **Disabled** if you want to force manual conflict resolution of identity conflicts.

- **Keep Passive Identity** if you want the system to use the passive fingerprint when an identity conflict occurs.
- **Keep Active Identity** if you want the system to use the current identity from the highest priority active source when an identity conflict occurs.

Configure network discovery identity conflict resolution

Network discovery may encounter conflicts when multiple sources provide different information about the same network device or host. Configure these settings to define how the system resolves such conflicts.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** ( ) next to **Identity Conflict Settings**.

Step 4 Update the settings in the Edit Identity Conflict Settings pop-up window as described in Network discovery identity conflict settings, on page 2318.

Step 5 Click **Save** to save the identity conflict settings.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Network discovery vulnerability impact assessment options

You can configure how the system performs impact correlation with intrusion events.

Your choices are:

- Check the **Use Network Discovery Vulnerability Mappings** check box if you want to use system-based vulnerability information to perform impact correlation.
- Check the **Use Third-Party Vulnerability Mappings** check box if you want to use third-party vulnerability references to perform impact correlation. For more information, see the *Firepower System Host Input API Guide*.

You can check either or both of the check boxes. If the system generates an intrusion event and the host involved in the event has servers or an operating system with vulnerabilities in the selected vulnerability mapping sets, the intrusion event is marked with the Vulnerable (level 1: red) impact icon. For any servers which do not have vendor or version information, note that you need to enable vulnerability mapping in the Firewall Management Center configuration.

If you clear both check boxes, intrusion events will **never** be marked with the Vulnerable (level 1: red) impact icon.

Related Topics

Map third-party vulnerabilities, on page 2260

Enable network discovery vulnerability impact assessment

Configure network discovery vulnerability impact assessment. This configuration determines which vulnerabilities are evaluated when you assess the potential impact of security threats on your network assets.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Vulnerabilities to use for Impact Assessment**.

Step 4 Update the settings in the Edit Vulnerability Settings pop-up window as described in Network discovery vulnerability impact assessment options, on page 2319.

Step 5 Click **Save** to save the vulnerability settings.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Indications of compromise

An indication of compromise (IOC) tag is a security detection marker that

- signifies a host is likely compromised by malicious means,
- is generated based on IOC rules that correlate network and host activity, and
- specifies the nature and type of potential compromise, aiding investigation and remediation.

IOC tagging conditions

The Firewall Management Center can tag the host and user involved when one of these things occurs:

- The system correlates data gathered about your monitored network and its traffic, using intrusion, connection, Security Intelligence, and file or malware events, and determines that a potential IOC has occurred.
- The Firewall Management Center can import IOC data from your Secure Endpoint deployments via the AMP cloud. Because this data examines activity on a host itself, such as actions taken by or on individual programs, it can provide insights into possible threats that network-only data cannot. For your convenience, the Firewall Management Center automatically obtains any new IOC tags that Cisco develops from the AMP cloud.

To configure this feature, refer to Enable indications of compromise rules, on page 2321.

You can also write correlation rules against host IOC data and compliance allow lists that account for IOC-tagged hosts.

To investigate and work with tagged IOCs, see *Cisco Secure Firewall Management Center Administration Guide*.

Enable indications of compromise rules

Tip To disable IOC rules for individual hosts or their associated users, see the *Discovery Events* chapter in the *Cisco Secure Firewall Management Center Administration Guide*.

Before you begin

Because IOC rules trigger based on data provided by other components of the system and by Secure Endpoint, those components must be correctly licensed and configured for IOC rules to set IOC tags. Enable the system features associated with the IOC rules you plan to enable, such as intrusion detection and prevention (IPS) and Advanced Malware Protection (AMP). If an IOC rule's associated feature is not enabled, no relevant data is collected and the rule cannot trigger.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Indications of Compromise Settings**.

Step 4 To toggle the entire IOC feature off or on, click the slider next to **Enable IOC**.

Step 5 To globally enable or disable individual IOC rules, click the slider in the rule's **Enabled** column.

Step 6 Click **Save** to save your IOC rule settings.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Add NetFlow exporters to a network discovery policy

Use this procedure to add NetFlow exporters.

Note You cannot delete an exporter if it is currently in use in a disocvery rule.

Before you begin

- Review prerequisites: Refer to Requirements for using NetFlow data (principle), on page 2243.
- Configure NetFlow exporters: Refer to NetFlow data, on page 2242.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Add** (+) next to **NetFlow Devices**.

Step 4 Enter the **IP Address** of the exporter.

Step 5 Click **Save**.

What to do next

- Configure a network discovery rule to monitor NetFlow traffic: Refer to Configure network discovery rules, on page 2308.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Network discovery data storage settings

Discovery data storage settings include the host limit and timeout settings.

When host limit reached

The number of hosts a Secure Firewall Management Center can monitor, and therefore store in the network map, depends on its model. The **When Host Limit Reached** option controls what happens when you detect a new host after you reach the host limit. You can:

Drop hosts

The system drops the host that has remained inactive for the longest time, then adds the new host. This is the default setting.

Don't insert new hosts

The system does not track any newly discovered hosts. Only after the host count falls below the limit does the system resume tracking new hosts. This can occur if an administrator increases the domain's host limit, manually deletes hosts from the network map, or the system identifies hosts as timed out due to inactivity.

Table 151: Reaching the host limit with multitenancy

Setting	Domain Host Limit Set?	Domain Host Limit Reached	Ancestor Domain Host Limit Reached
Drop hosts	yes	Drops oldest host in the constrained domain.	Drops the oldest host among all descendant leaf domains configured to drop hosts. If no host can be dropped, does not add the host.
	no	n/a	Drops the oldest host among all descendant leaf domains configured to drop hosts and that share the general pool.
Don't insert new hosts	yes or no	Does not add the host.	Does not add the host.

Host timeout

The amount of time that passes, in minutes, before the system drops a host from the network map due to inactivity. The default setting is 10080 minutes (one week). Individual host IP and MAC addresses can time out individually, but a host does not disappear from the network map unless all its associated addresses time out.

To avoid premature timeout of hosts, make sure that the host timeout value is longer than the update interval in the network discovery policy general settings.

Server timeout

The amount of time that passes, in minutes, before the system drops a server from the network map due to inactivity. The default setting is seven days (10,080 minutes).

To avoid premature timeout of servers, make sure that the service timeout value is longer than the update interval in the network discovery policy general settings.

Client application timeout

The amount of time that passes, in minutes, before the system drops a client from the network map due to inactivity. The default setting is 10080 minutes (one week).

To ensure optimal performance, set the client timeout value to exceed the update interval in the network discovery policy general settings.

Related Topics

Host limits, on page 1830

Configure network discovery data storage

Configure network discovery data storage settings to control how the system stores and manages network discovery information, including retention policies and storage limits.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Network Discovery Data Storage Settings**.

Step 4 Update the settings in the Data Storage Settings dialog as described in Network discovery data storage settings, on page 2322.

Step 5 Click **Save** to save the data storage settings.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure network discovery event logging

The Event Logging Settings control whether discovery and host input events are logged. If you do not log an event, you cannot retrieve it in event views or use it to trigger correlation rules.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Event Logging Settings**.

Step 4 Check or clear the check boxes next to the discovery and host input event types you want to log in the database , described in the *Discovery Events* chapter of the *Cisco Secure Firewall Management Center Administration Guide*.

Step 5 Click **Save** to save the event logging settings.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Add network discovery OS and server identity sources

In **Advanced** section of the network discovery policy, add new active sources or change the priority or timeout settings for existing sources.

Adding a scanner to this page does not add the full integration capabilities that exist for the Nmap scanners, but does allow integration of imported third-party application or scan results.

If you import data from a third-party application or scanner, make sure that you map vulnerabilities from the source to the vulnerabilities detected in your network.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** ( ) next to **OS and Server Identity Sources**.

Step 4 To add a new source, click **Add Source**.

Step 5 Enter a **Name**.

Step 6 Choose the input source **Type** from the drop-down list:

- Choose **Scanner** if you plan to import scan results using the AddScanResult function.
- Choose **Application** if you do not plan to import scan results.

Step 7 To indicate the duration of time that should elapse between the addition of an identity to the network map by this source and the deletion of that identity, choose **Hours**, **Days**, or **Weeks** from the **Timeout** drop-down list and enter the appropriate duration.

Step 8 Optionally:

- To promote a source and cause the operating system and application identities to be used in favor of sources below it in the list, choose the source and click the up arrow.
- To demote a source and cause the operating system and application identities to be used only if there are no identities provided by sources above it in the list, choose the source and click the down arrow.
- To delete a source, click **Delete** ( ) next to the source.

Step 9 Click **Save** to save the identity source settings.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Related Topics

Map third-party vulnerabilities, on page 2260

Troubleshoot your network discovery strategy

Before you make any changes to the system's default detection capabilities, you should analyze what hosts are not being identified correctly and why, so you can decide what solution to implement.

Are your managed devices correctly placed?

If network devices such as load balancers, proxy servers, or NAT devices reside between the managed device and the unidentified or misidentified host, place a managed device closer to the misidentified host rather than using custom fingerprinting. Custom fingerprinting is not recommended in this scenario.

Do unidentified operating systems have a unique TCP stack?

If the system misidentifies a host, you should investigate why the host is misidentified to help you decide between creating and activating a custom fingerprint or substituting Nmap or host input data for discovery data.

Caution If you encounter misidentified hosts, contact your support representative before creating custom fingerprints.

- If a host is running an operating system that is not detected by the system by default and does not share identifying TCP stack characteristics with existing detected operating systems, you should create a custom fingerprint.
- For example, if you have a customized version of Linux with a unique TCP stack that the system cannot identify, you would benefit from creating a custom fingerprint, which allows the system to identify the host and continuing monitoring it, rather than using scan results or third-party data, which require you to actively update the data yourself on an ongoing basis.
- Note that many open source Linux distributions use the same kernel, and as such, the system identifies them using the Linux kernel name. If you create a custom fingerprint for a Red Hat Linux system, you may see other operating systems (such as Debian Linux, Mandrake Linux, Knoppix, and so on) identified as Red Hat Linux, because the same fingerprint matches multiple Linux distributions.
- Do not use a fingerprint in every situation.

  For example:

  - A modification may have been made to a host's TCP stack so that it resembles or is identical to another operating system.
  - If an Apple Mac OS X host is altered, making its fingerprint identical to a Linux 2.4 host, causing the system to identify it as Linux 2.4 instead of Mac OS X. If you create a custom fingerprint for the Mac OS X host, it may cause all legitimate Linux 2.4 hosts to be erroneously identified as Mac OS X hosts. In this case, if Nmap correctly identifies the host, you could schedule regular Nmap scans for that host.

Third-party data integration

If you import data from a third-party system using host input, you must map the vendor, product, and version strings that the third party uses to describe servers and application protocols to the Cisco definitions for those products. Note that even if you map application data to system vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

- The system may reconcile data from multiple sources to determine the current identity for an operating system or application.
- For Nmap data, you can schedule regular Nmap scans. For host input data, you can regularly run the Perl script for the import or the command line utility. However, note that active scan data and host input data may not be updated with the frequency of discovery data.

Can the system identify all applications?

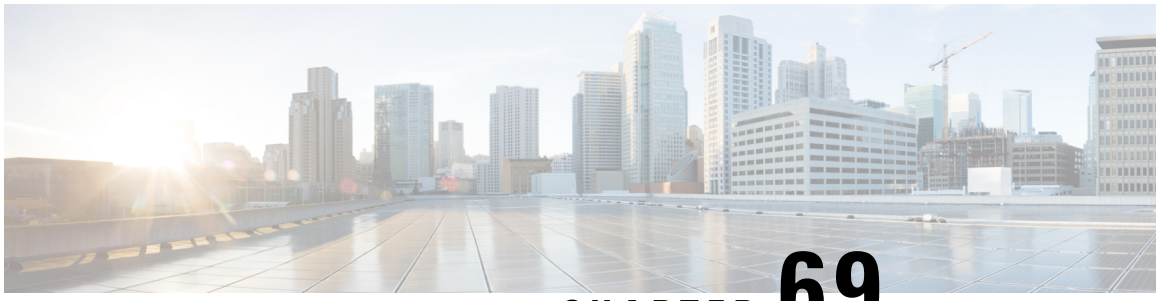
If a host is correctly identified by the system but has unidentified applications, create a user-defined detector to provide the system with port and pattern matching information to help identify the application.

If the system correctly identifies a host but cannot identify some applications, create a user-defined detector that provides the system with port and pattern matching information. This will help the system identify the application.

Have you applied patches that fix vulnerabilities?

If the system correctly identifies a host but does not reflect applied fixes, you can use the host input feature to import patch information. When you import patch information, you must map the fix name to a fix in the database.

Do you want to track third-party vulnerabilities?



If you have vulnerability information from a third-party system that you want to use for impact correlation, you can map the third-party vulnerability identifiers for servers and application protocols to vulnerability identifiers in the Cisco database and then import the vulnerabilities using the host input feature. For more information on using the host input feature, see the *Firepower System Host Input API Guide*. Note that even if you map application data to system vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

Objects

An object is a configuration element that

- associates a name with a value for increased flexibility and ease of use in the web interface,
- enables reuse of configurations across policies, rules, event searches, reports, and dashboards, and
- can be managed, grouped, and overridden as needed within the system.

Object management and usage

The system uses named objects to simplify configuration and management. Use the object manager to create and manage objects. Many configurations that use objects also allow you to create objects as needed. The object manager enables you to:

- View the policies, settings, and other objects where a network, port, VLAN, or URL object is used; see View objects and their usage, on page 2338.
- Group objects to reference multiple objects with a single configuration; see Object groups, on page 2340.
- Override object values for selected devices; see Object overrides, on page 2342.

After editing an object used in an active policy, you must redeploy the changed configuration for your changes to take effect. You cannot delete an object that is in use by an active policy.

Note The system configures an object on a managed device only when a policy assigned to that device uses the object. If you remove an object from all policies assigned to a given device, the object is also removed from the device configuration on the next deployment, and subsequent changes to the object are not reflected in the device configuration.

Object types

This table lists the objects you can create in the system, and indicates whether each object type can be grouped or configured to allow overrides.

Object type	Groupable?	Allows overrides?
Network	yes	yes
Port	yes	yes

Object type	Groupable?	Allows overrides?
Interface: • Security Zone • Interface Group	no	no
Tunnel Zone	no	no
Application Filter	no	no
VLAN Tag	yes	yes
External Attribute: Security Group Tag (SGT) and Dynamic Object	no	no
URL	yes	yes
Geolocation	no	no
Time Range	no	no
Variable Set	no	no
Security Intelligence: Network, DNS, and URL lists and feeds	no	no
Sinkhole	no	no
File List	no	no
Cipher Suite List	no	no
Distinguished Name	yes	no
Public Key Infrastructure (PKI): • Internal and Trusted CA • Internal and External Certs	yes	no
Key Chain	no	yes
DNS Server Group	no	no
SLA Monitor	no	no
Prefix List: IPv4 and IPv6	no	yes
Route Map	no	yes
Access List: Standard and Extended	no	yes
AS Path	no	yes
Community List	no	yes

Object type	Groupable?	Allows overrides?
Policy List	no	yes
FlexConfig: Text and FlexConfig objects	no	yes

Objects and multi-tenancy

In a multidomain deployment, you can create objects in Global and descendant domains with the exception of Security Group Tag (SGT) objects, which you can create only in the Global domain. The interface shows objects created in the current domain, which you can edit. It also presents objects created in ancestor domains, which you cannot edit, except for security zones and interface groups.

Note Security zones and interface groups are tied to device interfaces, which you configure at the leaf level. Administrators in descendant domains can view and edit security zones and groups created in ancestor domains. Subdomain users can add and delete interfaces from ancestor zones and groups, but cannot delete or rename these zones or groups.

Object names must be unique within the domain hierarchy. The system may identify a conflict with the name of an object you cannot view in your current domain.

For objects that support grouping, you can group objects in the current domain with objects inherited from ancestor domains.

Object overrides allow you to define device-specific or domain-specific values for certain types of object, including network, port, VLAN tag, and URL. In a multidomain deployment, you can define a default value for an object in an ancestor domain, but allow administrators in descendant domains to add override values for that object.

Use the object manager

The object manager provides capabilities for creating and managing objects and object groups, viewing them in paginated lists, filtering results, and refreshing the displayed information.

- The object manager enables creation and management of objects and object groups.
- The object manager displays 20 objects or groups per page. If you have more than 20 of any type of object or group, use the navigation links at the bottom of the page to view additional pages. You can also go to a specific page or click **Refresh** ( ) to refresh your view.
- Access the page using **Objects** > **Object Management**. You can alternatively access the page using **Objects** > **Other FTD Objects**.
- By default, objects and groups are listed alphabetically by name. You can filter objects by name or value.

Import objects

Import objects into the system by uploading a properly formatted comma-separated values file. This task enables bulk addition of supported object types, streamlining object management.

Objects can be quickly imported into the system using a properly formatted CSV file. Up to 1000 objects can be imported in a single operation. The format and required columns vary depending on object type.

Object TYPE	Rules

Individual object	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • DN
	• Both NAME and DN column entries are mandatory to import an entry.
	• You can import individual objects directly into an existing distinguished NAME object group.

Network object	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • DESCRIPTION
	  • TYPE
	  • VALUE
	  • LOOKUP
	• To import a host, range, or network object type, provide entries for both NAME and VALUE columns.
	• For an FQDN object, specify "FQDN" in the TYPE column entry, and enter "IPv4," "IPv6," or "IPv4/IPv6" in the LOOKUP column entry.
	• If you leave the LOOKUP column entry for the FQDN object empty, the system saves the object with ipv4_ipv6 as the VALUE.

Object TYPE	Rules

PORT	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • PROTOCOL
	  • PORT
	  • ICMPCODE
	  • ICMPTYPE
	• The NAME column entry is mandatory.
	• The PORT column entry is mandatory for 'tcp' and 'udp' PROTOCOL types.
	• The ICMPCODE and ICMPTYPE column entries are mandatory for 'icmp' and 'icmp6' PROTOCOL types.

URL	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • DESCRIPTION
	  • URL
	• You must provide entries for the NAME and URL columns to import an object.

VLAN TAG	• The column header must be mentioned in capital letters.
	• The file must have these columns headers:
	  • NAME
	  • DESCRIPTION
	  • TAG
	• The NAME and TAG column entries are mandatory to import an entry.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose one of these object types from the left pane:

- **Distinguished Name** > **Individual Objects**
- **Network Object**
- **PORT**
- **URL**
- **VLAN TAG**

Step 3 Choose **Import Object** from the **Add [Object TYPE]** drop-down list.

Note If you have selected **Individual Objects** in the previous step, click **Import**.

Step 4 Click **Browse**.

Step 5 Locate and select the comma-separated file on your system.

Step 6 Click **Open**.

Note While importing **Distinguished Name** objects, you can optionally check the **Add imported Distinguished Name objects to the below object group** check box and select the group name from the drop-down box to import the objects directly to an existing distinguished name object group.

Step 7 Click **Import**.

Edit objects

Edit network objects and groups to update their settings or manage variable sets as required for your deployment.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose an object type from the list; see Objects, on page 2332.

Step 3 Click **Edit** ( ) next to the object you want to edit.

If **View** ( ) appears instead, the object belongs to an ancestor domain and has been configured not to allow overrides, or you do not have permission to modify the object.

Step 4 Modify the object settings as desired.

Step 5 If you are editing a variable set, manage the variables in the set; see Manage variables, on page 2452.

Step 6 For objects that can be configured to allow overrides:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344. You can change this setting only for objects that belong to the current domain.

- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2344.

Step 7 Click **Save**.

Step 8 If you are editing a variable set, and that set is in use by an access control policy, click **Yes** to confirm that you want to save your changes.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

View objects and their usage

This task enables you to view where objects are used within your system, helping you understand object dependencies and usage across policies and settings.

You can view usage details of objects on the Object Management page. Firewall Management Center provides this functionality for many object types. However, some object types are not supported.

Before you begin

No prerequisites are required to view object usage details.

Follow these steps to view objects and their usage:

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose one of the following supported object types:

- Access List > Extended
- Access List > Standard
- AS Path
- Community List
- Interface
- Network
- Policy List
- Port
- Prefix List > IPv4 Prefix List
- Prefix List > IPv6 Prefix List
- Route Map

- SLA Monitor
- URL
- VLAN Tag

Step 3 Click the **Find Usage** ( ) icon next to the object.

The Object Usage window displays a list of all the policies, objects, and other settings where the object is in use. Click any of the listed items to know more about the object usage. For policies and some other settings where the object is used, you can click the corresponding links to visit the respective UI pages.

After completing these steps, you will be able to see where each object is used within your system, allowing you to manage and audit object usage efficiently.

Filter objects or object groups

Use this task when working with large configurations or when you need to identify and manage unused objects or object groups.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Enter your filter criteria in the **Filter** field.

The page updates as you type to display matching items.

You can use these wildcards:

- The asterisk (*) matches zero or more occurrences of a character.
- The caret (^) matches content at the beginning of a string.
- The dollar sign ($) matches content at the end of a string.

Step 3 To identify and review unused objects or object groups, check the **Show Unused Object** check box.

Note

- If an object is a part of an unused object group, the object is considered as used. However, the unused object group is displayed when the **Show Unused Object** check box is checked.
- The **Show Unused Object** check box is available only for network, port, URL, and VLAN tag object types.

Object groups

An object group is a configuration grouping that

- enables referencing multiple objects with a single configuration,
- allows objects and object groups to be used interchangeably in the web interface, and
- supports grouping of network, port, VLAN tag, URL, and PKI objects.

Object group usage and management

The system allows you to use objects and object groups interchangeably in the web interface. For example, anywhere you would use a port object, you can also use a port object group.

Network object groups can be nested. You can add a network object group to another network object group, up to 10 levels deep.

Objects and object groups of the same type cannot have the same name.

Edit an object group used in a policy, such as a network object group in an access control policy. Then, re-deploy the configuration for your changes to take effect.

Deleting a group does not delete the objects in the group; only their association with each other. Additionally, you cannot delete a group that is in use in an active policy. For example, you cannot delete a VLAN tag group that is used in a VLAN condition in a saved access control policy.

Object references and literal entries in object groups

Object groups can contain either object references or literal entries.

- Object references are links to existing Host/Network Objects. When the original object is modified (for example, an IP address change), all object groups containing references to that object are automatically updated to reflect the change.
- Literal entries are manually created entries within an object group. Unlike object references, literal entries are independent configuration entities and are not dynamically linked to existing Host/Network Objects. Therefore, changes made to a Host/Network Object do not propagate to object groups containing literal entries.

For example, an administrator may manually add a literal entry with the same name and IP address as an existing Host/Network Object. Although the entries appear identical, the literal entry remains independent of the original object. If the original Host/Network Object is modified, only object groups containing a reference to that object are updated.

Modifying a Host/Network Object updates only those object groups that contain a reference to that object. Object groups containing literal entries continue to display their original configuration unless the literal entries are manually modified.

Group reusable objects

Group reusable objects to simplify configuration and management in Secure Firewall Management Center.

- Organize object types such as Network, Port, URL, VLAN Tag, Distinguished Name, and PKI into groups for easier policy application.

This task is relevant when you need to manage multiple reusable objects and apply them efficiently in firewall policies.

Grouping objects allows for streamlined configuration and reduces manual effort when deploying or updating policies.

- Use this task when creating or editing object groups for policy deployment in Secure Firewall Management Center.

Before you begin

No explicit prerequisites are stated. Ensure you have access to Secure Firewall Management Center and the necessary permissions to manage objects.

- Identify the object types you want to group before starting the task.

Follow these steps to group reusable objects:

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 If the object type you want to group is **Network**, **Port**, **URL**, or **VLAN Tag**:

a) Choose the object type from the list of object types.
b) Choose **Add Group** from the **Add [Object Type]** drop-down list.

Step 3 If the object type you want to group is **Distinguished Name**:

a) Expand the **Distinguished Name** node.
b) Choose **Object Groups**.
c) Click **Add Distinguished Name Group**.

Step 4 If the object type you want to group is **PKI**:

a) Expand the **PKI** node.
b) Choose one of the following:
   - **Internal CA Groups**
   - **Trusted CA Groups**
   - **Internal Cert Groups**
   - **External Cert Groups**
c) Click **Add [Object Type] Group**.

Step 5 Enter a unique **Name**.

Step 6 Choose one or more objects from the list, and click **Add**.

You can also:

- Use the filter field **Search** ( ) to search for existing objects to include, which updates as you type to display matching items. Click **Reload** ( ) above the search field or click **Clear** ( ) in the search field to clear the search string.

- Click **Add** (+) to create objects on the fly if no existing objects meet your needs.

Step 7 Optionally for **Network**, **Port**, **URL**, and **VLAN Tag** groups:

- Enter a **Description**.
- Check the **Allow Overrides** check box to allow overrides for this object group; see Allow object overrides, on page 2344.

Step 8 Click **Save**.

After completing these steps, the object group is created and available for use in firewall policies. You can reference the group in active policies and deploy configuration changes as needed.

What to do next

- If an active policy references your object group, deploy configuration changes; see Deploy configuration changes, on page 135.

Object overrides

An object override is a configuration mechanism that

- enables the definition of alternate values for objects, which the system applies to specified devices,
- lets administrators create a smaller set of shared policies that can be used across devices without losing the flexibility to modify policies for individual devices, and
- allows modifications to an object for devices or domains that require different definitions.

Object override usage and supported object types

Administrators can create an object whose definition works for most devices and use overrides to specify modifications for those devices needing different definitions. You may also need to override an object for all devices. This approach allows you to create a single policy that applies everywhere. Object overrides allow you to use fewer shared policies and customize them for individual devices when necessary.

You can target overrides to a specific domain. The override value applies to all devices in that domain unless you set a device-specific override. The object manager enables selection of objects that can be overridden and allows listing device-level or domain-level overrides for each object.

Supported object types for overrides include:

- Network
- Port
- VLAN tag
- URL
- SLA Monitor

- Prefix List
- Route Map
- Access List
- AS Path
- Community List
- Policy List
- Cert Enrollment (PKI)
- Key Chain

In the object manager, the **Override** column flags objects that support overrides:

- Green checkmark: Overrides can be created, and none have been added yet.
- Red X: Overrides are not supported for the object.
- Number: Indicates the count of overrides added for the object (for example, "2" means two overrides have been defined).

Object override example

For example, to deny ICMP traffic to different departments, each connected to a different network, you can define an access control policy that includes a network object called Departmental Network. By enabling overrides for this object, it's possible to create policy variations on each relevant device that specify the actual network associated with that device.

Manage object overrides

Object overrides are used when you need to adjust the behavior of reusable objects for specific use cases, such as applying different values in different domains or policies. Use this task when you want to add, allow, delete, or edit object overrides in the Secure Firewall Management Center.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose from the list of object types; see Objects, on page 2332.

Step 3 Click **Edit** ( ) next to the object you want to edit.

If **View** ( ) appears instead, the object belongs to an ancestor domain and has been configured not to allow overrides, or you do not have permission to modify the object.

Step 4 Manage the object overrides:

- Add—Add object overrides; see Add object overrides, on page 2344.
- Allow—Allow object overrides; see Allow object overrides, on page 2344.
- Edit—Edit object overrides; see Edit an object override, on page 2345.
- Delete—In the object editor, click **Delete** ( ) next to the override you want to remove.

Step 5 Click **Save**.

Allow object overrides

Enable the Allow Overrides option for an object so that you can specify override values as required for different use cases.

Procedure

Step 1 In the object editor, check the **Allow Overrides** check box.

Step 2 Click **Save** to apply your changes.

What to do next

Add object override values; see Add object overrides, on page 2344.

Add object overrides

Add or adjust object overrides so that network objects or groups can have different values assigned in specific domains or to specific devices, making configuration more flexible without modifying the base object.

Use this task when you need to assign different settings or values to the same object across multiple domains or devices—for example, when different parts of your organization require different configurations for the same network object.

Before you begin

Ensure that object overrides are allowed in your environment. See Allow object overrides, on page 2344.

Procedure

Step 1 In the object editor, expand the **Override** section.

Step 2 Click **Add**.

Step 3 On **Targets**, choose domains or devices in the **Available Devices and Domains** list and click **Add**.

Step 4 On the Override tab, enter a **Name**.

Step 5 Optionally, enter a **Description**.

Step 6 Enter an override value.

Example:

```
For a network object, enter a network value.
```

Step 7 Click **Add**.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Edit an object override

This task enables you to edit the description and value of an existing object override to update its configuration as needed.

You can modify the description and the value of an existing override, but you cannot modify the existing target list. Add a new override with new targets to replace the existing override.

Procedure

Step 1 In the object editor, expand the **Override** section.

Step 2 Click **Edit** ( ) next to the override you want to modify.

Step 3 Optionally, modify the **Description**.

Step 4 Modify the override value.

Step 5 Click **Save** to save the override.

Step 6 Click **Save** to save the object.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

AAA servers

An AAA server is a network authentication, authorization, and accounting component that

- enables centralized management of user credentials
- supports policy enforcement, and
- provides accounting for user activities.

Add a RADIUS server group

RADIUS Server Group objects contain one or more references to RADIUS servers. These servers are used to authenticate users logging in through Remote Access VPN connections.

You can apply these objects to compatible Firewall Threat Defense devices.

Before you begin

Note You cannot override RADIUS Server Group Objects.

Procedure

Step 1 Select **Objects** > **Object Management** > **AAA Server** > **RADIUS Server Group**.

All currently configured RADIUS Server Group objects will be listed. Use the filter to narrow down the list.

Step 2 Choose and edit a listed RADIUS Server Group object, or add a new one.

See Configure RADIUS server options, on page 2347 and RADIUS server group configuration options, on page 2346 to configure this object.

Step 3 Click **Save**.

RADIUS server group configuration options

The configuration options for a RADIUS server group enable integration with identity policies and VPN authentication. This topic lists each option and describes its purpose, required settings, and usage notes.

Navigation path

Objects > **Object Management** > **AAA Server** > **RADIUS Server Group**. Choose and edit a configured RADIUS Server Group object or add a new one.

Fields

- **Name** and **Description**—Enter a name and optionally, a description to identify this RADIUS Server Group object.
- **Group Accounting Mode**—Defines how accounting messages are sent to the RADIUS servers. Choose one of these:
  - **Single**—Sends accounting messages to a single server (default).
  - **Multiple**—Sends accounting messages to all servers in the group simultaneously.
- **Retry Interval**—Sets the interval (1–10 seconds) between attempts to contact RADIUS servers.
- **Realms**(Optional)—Specify the Active Directory (AD) realm associated with this RADIUS server group. The selected realm is referenced in identity policies to determine VPN authentication identity sources

for relevant traffic flows. This realm effectively provides a bridge from the identity policy to this RADIUS server group. If no realm is associated with this RADIUS server group, the RADIUS server group cannot be reached to determine the VPN authentication identity source for a traffic flow in an identity policy.

Note This field is mandatory if you use remote access VPN with User Identity and RADIUS as the identity source.

- **Enable authorize only**—If the group is used only for authorization or accounting (not authentication), enable authorize-only mode. This mode omits the RADIUS server password from Access-Request messages; the configured password for individual RADIUS servers is ignored.
- **Enable interim account update** and **Interval**—Enables the generation of interim accounting update messages to notify the RADIUS server of newly assigned IP addresses. The Interval option sets the period (1 to 120 hours; default is 24 hours) between updates.
- **Enable Dynamic Authorization** and **Port**— Enables the RADIUS dynamic authorization or change of authorization (CoA) services for this RADIUS server group. Specify the listening port for RADIUS CoA requests in the **Port** field. The valid range is 1024 to 65535 and the default value is 1700. Once defined, the corresponding RADIUS server group will be registered for CoA notification and it listens to the port for the CoA policy updates from the Cisco Identity Services Engine (ISE).
- **Merge Downloadable ACL with Cisco AV Pair ACL**—Enables merging a downloadable access control list (dACL) with a Cisco attribute-value (AV) pair ACL.

  A downloadable ACL defines and updates access control lists in Cisco ISE. Administrators can then download the updated ACLs to all applicable controllers. For more information about using dACLs in Cisco ISE, see the chapter on Segmentation, section on authorization policies, in the *Cisco ISE Administrator Guide*.

  A Cisco AV pair ACL can be utilized to define specific authentication, authorization, and accounting elements for each individual session. For more information about using dACLs in Cisco ISE, see the chapter on Segmentation, section on authorization profile settings, in the *Cisco ISE Administrator Guide*.

  If you select **Merge Downloadable ACL with Cisco AV Pair ACL**, you can choose the following options:

  - **After Cisco AV Pair ACL**—Place downloadable ACL entries after AV pair entries.
  - **Before Cisco AV Pair ACL**—Place downloadable ACL entries before AV pair entries.

- **RADIUS Servers**—For server-specific configuration options, see Configure RADIUS server options, on page 2347.

Related Topics

Add a RADIUS server group, on page 2346

Configure RADIUS server options

Use this topic to configure a RADIUS server, including authentication, accounting, connectivity, and security settings.

Navigation path

Objects > **Object Management** > **AAA Server** > **RADIUS Server Group**. Choose and edit a listed RADIUS Server Group object, or add a new one. In the RADIUS Server Group dialog, choose and edit a RADIUS Server or add a new server.

Fields

- **IP Address/Hostname**—Specify the hostname or IP address (IPv4 or IPv6) of the RADIUS server that receives authentication requests. Only one server may be selected. To add servers, add more RADIUS Server entries to the RADIUS Server Group list.
- **RADIUS Server-Enabled Message Authenticator**—Message authenticators safeguard server-to-client communication and are required for a secure connection between your RADIUS server and firewall devices. Disabling message authenticators may expose your firewalls to potential attacks.

  Your RADIUS server must support and be configured for Message-Authenticator. Requires Firewall Threat Defense Version 7.0.7+, 7.2.10+, or 7.4.3+. For the Firepower 4100/9300, this feature may require an FXOS upgrade; for minimum builds, see *Cisco Secure Firewall Threat Defense Compatibility Guide*.
- **Authentication Port**—The port on which RADIUS authentication and authorization are performed. The default is 1812.
- **Key** and **Confirm Key**—Enter the shared secret to encrypt data between the managed device (client) and the RADIUS server.

  The key is a case-sensitive, alphanumeric string of up to 127 characters. Special characters are permitted.

  Enter the same key in this field and on the RADIUS server. Enter the shared secret again in the Confirm field.
- **Accounting Port**—Enter the port number for RADIUS accounting. The default port is 1813.
- **Timeout**—Specify the session timeout for authentication.

  Set the timeout value to 60 seconds or more for RADIUS two-factor authentication. The default timeout value is 10 seconds.
- **Connect Using** —Select the method to connect the device to a RADIUS server using either a route lookup or a specific interface.
  - Click the **Routing** radio button to use the routing table.
  - Click the **Specific Interface** radio button and choose a security zone/interface group or the Management interface (the default) from the drop-down list. If you want to use Management, you must choose it specifically; it is not available when using a route lookup. You cannot specify any other management-only interface as the RADIUS source.You can also choose a loopback interface group.
- **Redirect ACL**—Select the redirect ACL from the list or add a new one.

  Use the ACL name from the device to control redirected traffic. The Redirect ACL name here must be the same as the *redirect-ACL* name in ISE server. When you configure the ACL object, ensure that you select Block action for ISE and DNS servers, and Allow action for the rest of the servers.

Add a single sign-on server

Add a single sign-on (SSO) server to integrate SAML-based authentication for remote access VPN users. This task enables secure user authentication through your identity provider.

Use this task when you need to configure SAML single sign-on for remote access VPN, allowing users to authenticate using an external identity provider. You typically need to perform this configuration when you integrate with SAML IdPs, such as Microsoft Azure.

Before you begin

Obtain the following from your SAML identity provider:

- Identity Provider Entity ID URL
- Sign-in URL
- Sign-out URL
- Identity provider certificate and enroll the certificate in Firewall Threat Defense using the Firewall Management Center web interface (**Devices** > **Certificates**)

For more information, see Configuring a SAML Single Sign-On Authentication, on page 1508.

Follow these steps to add a single sign-on server:

Procedure

Step 1 Choose **Objects** > **Object Management** > **AAA Server** > **Single Sign-on Server**.

Step 2 Click **Add Single Sign-on Server** and provide the following details:

Field	Description
Name	Enter the name for the SAML single sign-on server object.
Identity Provider Entity ID	Enter the URL that the SAML IdP defines to uniquely identify a service provider. Enter the URL for a metadata XML page that describes how the SAML Issuer responds to requests.
SSO URL	Enter the URL for signing in to the SAML identity provider server.
Logout URL	Enter the URL for signing out of the SAML identity provider server.
Base URL	Enter the URL that redirects users back to Firewall Threat Defense after the identity provider authenticates them. This should be the access interface URL configured for the Firewall Threat Defense remote access VPN.

Field	Description
Identity Provider Certificate	Enter the IdP certificate enrolled into the Firewall Threat Defense to verify the signed messages. Select an identity provider certificate from the list or click **Add** to create a new certificate enrollment object. For more information, see Manage Firewall Threat Defense certificates, on page 2483. You must enroll all of the Microsoft Azure registered application CA certificates as Trustpoints on the Firewall Threat Defense. The Microsoft Azure SAML identity provider is configured on Firewall Threat Defense for the initial application. All connection profiles are mapped to the configured MS Azure SAML identity provider. For each of the MS Azure applications (other than the default), you can choose the required trustpoint(CA certificate) in the connection profile configuration of the remote access VPN. For details, see Configure AAA Settings for Remote Access VPN, on page 1439.
Service Provider Certificate	Firewall Threat Defense certificate, which will be used to sign the requests and build circle of trust with IdP. If you have not enrolled internal Firewall Threat Defense certificates, click + to add and enroll a certificate. For more information, see Manage Firewall Threat Defense certificates, on page 2483.
Request Signature	Select the encryption algorithm to sign the SAML single sign-on requests. The signatures are listed from weakest to strongest: SHA1, SHA256, SHA384, SHA512. Select None to disable encryption.
Request Timeout	Specify how long users can complete the single sign-on request (SAML assertion validity duration). The SAML IdP has two time outs: *NotBefore* and *NotOnOrAfter*. The Firewall Threat Defense validates if its current time is within the time range of (lower limit) *NotBefore* and (upper limit) the smaller of *NotBefore* plus *timeout* and *NotOnOrAfter*. Thus, if you set a timeout longer than the IdP's *NotOnOrAfter* timeout, the specified timeout is ignored and the *NotOnOrAfter* timeout is selected. If the sum of the specified timeout and the *NotBefore* timeout is less than the *NotOnOrAfter* time, Firewall Threat Defense timeout overrides the timeout. The timeout range is 1-7200 seconds; the default is 300 seconds.
Enable IdP only accessible on Internal Network	Select this option if the SAML IdP resides on the internal network. Firewall Threat Defense acts as a gateway and establishes communication between the users and IdP using an anonymous webvpn session.
Request IdP re-authentication on Login	Select this option to authenticate user at each login even if the previous IdP session is valid.
Allow Overrides	Select this check box to allow overrides for this single sign-on server object.

Step 3 Click **Save**.

The single sign-on server is added and configured for SAML authentication. Users can now authenticate to the remote access VPN using the specified identity provider.

Access lists

An access list is a traffic selection object that

- identifies and selects traffic to which a service will apply
- is used when configuring features such as route maps for Firewall Threat Defense devices, and
- distinguishes between allowed and blocked traffic, where blocked traffic is excluded from the service but not necessarily dropped altogether.

Types of access lists

You can configure these types of ACL:

- Extended: Identifies traffic based on source and destination address and ports. Supports IPv4 and IPv6 addresses, which you can mix in a given rule.
- Standard: Identifies traffic based on destination address only. Supports IPv4 only.

Each access list is composed of one or more access control entries (ACEs), or rules. The order of ACEs is important.

1. When the ACL is evaluated, a packet is tested against each ACE in the order listed.
2. After a match is found, no more ACEs are checked.
3. Place more specific rules at the top of an ACL for correct behavior.

Place the most specific rules at the top of the ACL so it works as expected

Configure an extended ACL object

Configure extended ACL objects to define traffic classification rules based on source and destination addresses, protocols, ports, application groups, or IPv6 traffic. This enables granular control over network traffic for security and policy enforcement.

Use extended ACL objects when you want to match traffic based on source and destination addresses, protocol and port, application group, or if the traffic is IPv6. These objects are useful for policy-based routing and direct internet access scenarios, and provide flexibility in defining access control entries for various network requirements.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Access List** > **Extended** from the table of contents.

Step 2 Do one of the following:

- Click **Add Extended Access List** to create a new object.
- Click **Edit** ( ) to edit an existing object.

Step 3 In the **New Extended Access List Object** dialog box, enter a name for the object (no spaces allowed) and configure the access control entries:

a) Do one of the following:

- Click **Add** to create a new entry.
- Click **Edit** ( ) to edit an existing entry.

b) Select the **Action**, whether to Allow (match) or Block (not match) the traffic criteria.

Note The **Logging**, **Log Level**, and **Log Interval** options are used for access rules only (ACLs attached to interfaces or applied globally). Because ACL objects are not used for access rules, leave these values at their defaults.

c) Configure the source and destination addresses on the **Network** tab using any of the following techniques:

- Select the desired network objects or groups from the Available list and click **Add to Source** or **Add to Destination**. You can create new objects by clicking the + button above the list. You can mix IPv4 and IPv6 addresses.
- Type an address in the edit box below the source or destination list and click **Add**. You can specify a single host address (such as 10.100.10.5 or 2001:DB8::0DB8:800:200C:417A), or a subnet (in 10.100.10.0/24 or 10.100.10.0 255.255.255.0 format, or for IPv6, 2001:DB8:0:CD30::/60).

d) Click the **Port** tab and configure the service using any of the following techniques.

- Select the desired port objects from the Available list and click **Add to Source** or **Add to Destination**. You can create new objects by clicking the + button above the list. The object can specify TCP/UDP ports, ICMP/ICMPv6 message types, or other protocols (including “any”). However, the source port, which you typically would leave empty, accepts TCP/UDP only. You cannot select port groups.

  For TCP/UDP, note that you must use the same protocol in both the source and destination fields, if you specify both. For example, you cannot specify a UDP source port and a TCP destination port.
- Type or select a port or protocol in the edit box below the source or destination list and click **Add**.

Note To get an entry that applies to all IP traffic, select a destination port object that specifies “all” protocols.

e) Click the **Application** tab and choose the applications that are to be grouped for the direct internet access policy.

Important

- You cannot configure applications for cluster devices. Hence, this tab is not applicable for cluster devices.
- Use extended ACL with applications only in policy-based routing. Do not use it in other policies as its behavior is unknown and not supported. Ensure migration of the realm/ISE configuration for policy-based routing that uses User Identity and SGT in extended ACL.

Note

- The **Available Applications** list displays a fixed set of pre-defined applications. This list is a subset of the applications that are available on the Access Control policy as only they can be detected by their first packet (FQDN end-points resolved to IP addresses and port). The application definitions are updated through the VDB updates and are pushed to Firewall Threat Defense during subsequent deployments.
- User-defined custom applications or group of applications are not supported.
- Currently, Firewall Management Center neither supports user-defined custom applications or group of applications nor allows you to modify the pre-defined applications list.
- You can use the filter options provided under the **Application Filters** to refine this list.

f) Click the **Users** tab and choose the users, user groups, or both that are to be classified for the Policy Based Routing (PBR).

Important

Use extended ACL with users, user groups, or both only for Policy Based Routing. Do not use it in other policies as its behavior is unknown and not supported.

Note

- The **Available Realms** list displays the configured active directory/LDAP realms. For information on creation of realm and managing them, see Create an LDAP realm or an Active Directory realm and realm directory, on page 1860 and Manage a realm, on page 1876 respectively.

  Note Local realms and Azure AD realms are not supported.

- The **Available Users** list displays the downloaded users and user groups of the selected AD/LDAP realms. To download the users, user groups, or both, navigate to **Integrations** > **Other Integrations** > **Realms**, and then click **Download** against the relevant active directory/LDAP realms.

  Note Threat defense can support a maximum of 512 user groups and 64000 user-IP mappings.

- The user to IP mapping and user group membership information are updated and pushed to the Firewall Threat Defense from the Firewall Management Center during the user login or logouts, and changes in the group memberships.

g) Click the **Security Group Tag** tab and choose the source SGT tags to be classified for the direct internet access policy.

Important Use extended ACL with SGTs only for Policy Based Routing. Do not use it in other policies as its behavior is unknown and not supported.

Note

- The **Available Security Group Tags** list displays the configured security group tags. You can choose to use the ISE SGTs or create custom SGTs.
- To use ISE SGTs, ensure that ISE is integrated with Firewall Management Center with **Session Directory Topic** and SXP Topic subscribed.

  Note The supported ISE versions are 3.2, 3,1, 3.0, and 2.7 patch 2+.

- For information on creating custom SGTs, see Create a security group tag object, on page 2376.

h) Select the required application, and click **Add to Rule**.

Note

- Do not configure destination networks and applications in the extended ACL object.
- The selected applications (Network Service objects) in each of the access control entries, form a Network Service Group (NSG) and this group is deployed on the Firewall Threat Defense. The NSG is used in direct internet access to classify traffic based on the match with the selected application group.

i) Click **Add** to add the entry to the object.

Troubleshooting Tips

If necessary, click and drag the entry to move it up or down in the rule order to the desired location. Repeat the process to create or edit additional entries in the object.

Step 4 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.

Step 5 Click **Save**.

Configure a standard ACL object

Use standard ACL objects when you only need to match traffic based on destination IPv4 address. Extended ACLs allow more granularity if needed.

Procedure

Step 1 Select **Objects** > **Object Management** > **Access List** > **Standard** from the table of contents.

Step 2 Do one of the following:

- Click **Add Standard Access List** to create a new object.
- Click **Edit** (✎) to edit an existing object.

Step 3 In the **New Standard Access List Object** dialog box, enter a name for the object (no spaces allowed), and configure the access control entries:

a) Do one of the following:

- Click **Add** to create a new entry.
- Click **Edit** (✎) to edit an existing entry.

b) For each access control entry, configure the following properties:

- **Action**—Whether to allow (match) or block (not match) the traffic criteria.
- **Network**—Add the IPv4 network objects or groups that identify the destination of the traffic.

c) Click **Add** to add the entry to the object.

d) If necessary, click and drag the entry to move it up or down in the rule order to the desired location.

Repeat the process to create or edit additional entries in the object.

Step 4 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.

Step 5 Click **Save**.

Configure address pools

You can configure IP address pools for both IPv4 and IPv6 that can be used for clustering or for VPN remote access profiles.

Procedure

Step 1 Select **Objects** > **Object Management** > **Address Pools**.

Step 2 Click **IPv4 Pools** and then **Add IPv4 Pools**, and configure the following fields.

- **Name**—Enter the name of the address pool. It can be up to 64 characters.
- **Description**—Add an optional description for this pool.
- **IP Address**—Enter a range of addresses available in the pool. Use dotted decimal notation and a dash between the beginning and the end address, for example: 10.10.147.100-10.10.147.177.
- **Mask**—Identifies the subnet on which this IP address pool resides.
- **Allow Overrides**—Check this check box to enable object overrides. Click the expand arrow to show the **Overrides** table. You can add a new override by clicking **Add**. See Object overrides, on page 2342 for more information.

Step 3 Click **Save**.

Step 4 Click **IPv6 Pools** and then **Add IPv6 Pools**, and configure the following fields.

- **Name**—Enter the name of the address pool. It can be up to 64 characters
- **Description**—Add an optional description for this pool.
- **IPv6 Address**—Enter the first IP address available in the configured pool and the prefix length in bits. For example: 2001:DB8::1/64.
- **Number of Addresses**—Identifies the number of IPv6 addresses, starting at the Starting IP Address, that are in the pool.
- **Allow Overrides**—Check this check box to enable overrides. Click the expand arrow to show the **Overrides** table. You can add a new override by clicking **Add**. See Object overrides, on page 2342 for more information.

Step 5 Click **Save**.

Create an application filter

An application filter is a reusable object that allows you to organize and manage applications efficiently for use in policies that require application matching.

An application filter does these:

- Simplifies application control and policy management.
- Groups applications based on type, risk, business relevance, category, and tags.
- Supports policies such as access control, QoS, intelligent application bypass, and decryption.

Application filter configuration options

- Use the system-provided filters to find applications. Select the desired applications and click **Add to Rule**.
- To remove an application from the filter, click the delete icon next to it.
- Click the info icon next to an application to view its information.

For detailed information on application characteristics, refer to Application rule conditions, on page 1322.

Configure an AS PATH object

Enable control over BGP routing updates and filtering by specifying a sequence of autonomous system (AS) numbers.

An AS Path is a mandatory attribute to set up BGP. It is a sequence of AS numbers through which a network can be accessed. AS path is a sequence of intermediate AS numbers between source and destination routers that form a directed route for packets to travel. Neighboring autonomous systems (ASes) use BGP to exchange and update messages about how to reach different AS prefixes. After each router makes a new local decision on the best route to a destination, it sends the route and associated path information, including distance metrics and path attributes, to its peers. As this information travels through the network, each router along the path prepends its unique AS number to a list of ASes in the BGP message. This list is the route's AS-PATH.

An AS path, along with an AS prefix, provides a specific handle for a one-way transit route through the network. Use the Configure AS Path page to create, copy, and edit autonomous system (AS) path policy objects. Create AS path objects to use when configuring route maps, policy maps, or BGP Neighbor Filtering. An AS path filter allows you to filter the routing update message by using regular expressions.

You can use this object with Firewall Threat Defense devices.

Procedure

Step 1 Choose **Objects** > **Object Management** > **AS Path** from the table of contents.

Step 2 Click **Add AS PATH**.

Step 3 Enter a name for the AS PATH object in the **Name** field. Valid values are between 1 and 500.

Step 4 Click **Add** on the **New AS PATH Object** window.

a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.

b) Specify the regular expression that defines the AS PATH filter in the **Regular Expression** field.

c) Click **Add**.

Step 5 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.

Step 6 Click **Save**.

Configure a BFD template

Configure a BFD template to define BFD interval values and authentication settings for single-hop or multi-hop sessions. This enables flexible and reusable BFD configurations across interfaces.

The BFD template specifies a set of BFD interval values. BFD interval values as configured in the BFD template are not specific to a single interface. You can also configure authentication for single-hop and multi-hop sessions. Echo mode is disabled by default. You can enable Echo mode on single-hop only.

Before you begin

No prerequisites are required to configure a BFD template.

Procedure

Step 1 Choose **Objects** > **Object Management** > **BFD Template**.

Step 2 Click **Add BFD Template** or **Edit**.

Note If you are editing a template, you cannot modify its name and type.

Step 3 On the **Template** tab, configure the following:

- **Template Name**—The name of this BFD template. You must assign a name in order to configure the rest of the parameters in the template. The template name cannot have spaces and cannot have only numbers.
- **Type**—Click the **Single-Hop** or **Multi-Hop** radio button.
- **Enable Echo**—(Optional) Enables Echo for the single-hop template.

If the Echo function is not negotiated, BFD control packets are sent at a high rate to meet the detection time. If the Echo function is negotiated, BFD control packets are sent at a slower, negotiated rate and self-directed echo packets are sent at a high rate. We recommend that you use Echo mode, if possible.

Step 4 On the **Interval** tab, configure the following:

a) From the **Interval Type** drop-down list, select **Microseconds** or **Milliseconds**.

b) In the **Multiplier** field, enter the value to be used for computing the hold down time. This value indicates the number of consecutive BFD control packets that must be missed from a BFD peer before BFD declares that the peer is unavailable and the Layer 3 BFD peer is informed of the failure. The range is 3 to 50. The default is 3.

c) In the **Minimum Transmit** field, enter the minimum transmit interval capability. The range is 50 to 999 milliseconds or 50000 to 999000 microseconds.

d) In the **Minimum Receive** field, enter the minimum receive interval capability. The range is 50 to 999 milliseconds or 50000 to 999000 microseconds.

Step 5 On the **Authentication** tab, configure the following:

- **Authentication Type**—Select **NONE**, **md5**, **meticulous-sha-1**, **meticulous-md5**, or **sha-1** from the drop-down list.
- **Encrypted Password**—(Optional) Enables encryption of the authentication password.
- **Password**—The authentication password that must be sent and received in the packets using the routing protocol being authenticated. The valid value is a string containing 1 to 29 uppercase and lowercase alphanumeric characters, except that the first character cannot be a digit or a digit followed by a whitespace. For example, '1password' or '0 password' is invalid.
- **Key ID**—The shared key ID that matches the key value. The range is 0 to 255.

Step 6 Click **OK**.

Step 7 Click **Apply** to save the BFD template configuration.

The BFD template is configured with the specified interval values, authentication settings, and echo mode options. The template can now be applied to interfaces as needed.

Cipher suite lists

A cipher suite list is an object that

- contains several cipher suites,
- enables negotiation of SSL or TLS encrypted sessions, and
- can be used in SSL rules to control encrypted traffic based on the negotiated cipher suite.

Usage of cipher suite lists in SSL rules

You can use cipher suites and cipher suite lists in SSL rules to control encrypted traffic. These rules evaluate whether the client and server negotiated the SSL session using that cipher suite. If you add a cipher suite list to an SSL rule, and if an SSL session negotiates with any cipher suite from the list, the rule matches the session.

Note You can use cipher suites in the web interface wherever you use cipher suite lists. However, you cannot add, change, or remove cipher suites.

Create a cipher suite list

Create a custom cipher suite list to control which cipher suites are available for use in your environment.

Use this task when defining or updating the set of cipher suites to align with security policies or updated encryption standards.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Cipher Suite List** from the list of object types.

Step 2 Click **Add Cipher Suites**.

Step 3 Enter a **Name**.

Step 4 Choose one or more cipher suites from the **Available Ciphers** list.

Step 5 Click **Add**.

Step 6 Optionally, click **Delete** ( ) next to any cipher suites in the **Selected Ciphers** list that you want to remove.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Configure a community list

Configure a community list to group BGP destinations that share common attributes for route tagging and policy enforcement. This task enables you to create, copy, and edit community list policy objects for use in route maps or policy maps.

Community lists allow marking sets of prefixes for common routing policies, such as filtering or assigning local preference.

A community is an optional transitive BGP attribute used for route tagging. Communities are numerical values assigned to prefixes. They are advertised to neighbors. Upstream providers use these markers to apply routing policies, such as filtering or modifying attributes.

Use the Configure Community Lists page to create, copy, and edit community list policy objects. You can use this object with Firewall Threat Defense devices.

Community lists are used in match clauses of route maps and consist of ordered matching statements. Each destination is compared against the rules. The system stops processing further rules when it finds a match.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Community List** from the table of contents.

Step 2 Click **Add Community List**.

Step 3 In the **Name** field, specify a name for the community list object.

Step 4 Click **Add** on the **New Community List Object** window.

Step 5 Select the **Standard** radio button to indicate the community rule type.

Standard community lists are used to specify well-known communities and community numbers.

Note You cannot have entries using Standard and entries using Expanded community rule types in the same Community List object.

a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
b) In the **COMMUNITIES** field, specify a community number. Valid values can be from 1 to 4294967295 or from 0:1 to 65534:65535.
c) Select the appropriate **Route Type**.

- Internet—Select to specify the Internet well-known community. Routes with this community are advertised to all peers (internal and external).
- No Advertise—Select to specify the no-advertise well-known community. Routes with this community are not advertised to any peer (internal or external).
- No Export—Select to specify the no-export well-known community. Routes with this community are advertised to only peers in the same autonomous system or to only other sub-autonomous systems within a confederation. These routes are not advertised to external peers.

Step 6 Select the **Expanded** radio button to indicate the community rule type.

Expanded community lists filter communities with regular expressions, which specify patterns used to match community attributes.

a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
b) Specify the regular expression in the **Expressions** field.

Step 7 Click **Add**.

Step 8 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.

Step 9 Click **Save**.

Configure an extended community list

Create an extended community list to organize destinations by shared attributes, enabling precise BGP route filtering and policy object use.

An extended community is a larger group of destinations that share some common attribute. The BGP extended community list has attributes that can be used to mark a set of prefixes that share a common attribute. These markers are used in the match clause of a route map to filter the routes for implementing route leaks among virtual routers. You can also define policy list objects with the extended community list for filtering. Matching statements are organized in an ordered list within the extended community list. Routes are matched against the rules until a match is found with the specified route target (standard rule type) or regular expression

(expanded rule type). Create and edit extended community list policy objects using the Extended Community page.

Note The extended community lists are applicable only for configuring import or export of routes.

You can use this object with Firewall Threat Defense devices.

Procedure

Step 1 Select **Objects** > **Object Management** > **Community List** > **Extended Community**, and then click **Add Extended Community List**.

Step 2 In the **Name** field, specify a name for the extended community list object. You can enter up to 80 characters for the name.

Step 3 Select the extended community rule type:

- To specify one or more route targets, click the **Standard** radio button .
- To specify regular expressions, click the **Expanded** radio button.

Note Use either Standard or Expanded extended community rule type in each Extended Community List object.

Step 4 Click **Add**.

Step 5 If you have selected **Standard** as the extended community rule type, specify the following:

a) In the **Sequence No** field, enter the order in which you want the rule to be executed.

The sequence number must be unique in the list.

b) From the **Action** drop-down list, if you want to permit routes that have matching route target that is specified here, select **Allow**; if you want to deny routes that have matching route target that is specified here, select **Block**.

c) In the **Route Target** field, specify a route target.

- You can add a single route target or a set of route targets separated by commas in a single entry. For example, *1:2,1:4,1:6*.
- Valid values can be from 1:1 to 65534:65535.
- You can have a maximum of 8 route targets in an entry.
- You cannot have redundant route target set across multiple entries. For example, say you want to configure *seq1* with *1:200,100:100,1:300* route targets, and *seq2* with *1:300,100:100,1:200* route targets. This results in redundant route target set and cannot be deployed.

Step 6 If you have selected **Expanded** as the extended community rule type, specify the following:

a) In the **Sequence No** field, enter the order in which you want the rule to be executed.

The sequence number must be unique in the list.

b) From the **Action** drop-down list, if you want to permit routes that have matching regular expression that is specified here, select **Allow**; if you want to deny routes that have matching regular expression that is specified here, select **Block**.

c) Specify the regular expression in the **Expressions** field.

- You can add a single route target or a set of route targets separated by a space in a single entry. For example, *^((16) | (18)):(.)$*.
- You can add a maximum of 16 regular expressions to an entry.
- You cannot have redundant regular expression set across multiple entries. For example, say you want to configure *seq1* with *^((16) | (18)):(.)$ ^4_[0-9]*$* route targets, and *seq2* with *^4_[0-9]*$ ^((16) | (18)):(.)$* route targets. This results in redundant regular expression set and cannot be deployed.

For details on BGP regular expressions, see here.

Step 7 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.

Step 8 Click **Save**.

The extended community list can be referenced in the match clause of the Route Map object or Policy List object:

- In the Route Map object, the name of the extended community list is displayed in the **Add Route Map Entry** > **Match Clause** > **BGP** > **Community List** > **Add Extended Community List** dialog. For more details on configuring BGP settings in a route map, see Configure a route map, on page 2415.
- In the Policy List object, the name of the extended community list is displayed in the **Add Policy List** > **Community Rule** > **Add Extended Community List** dialog. For more details on configuring BGP settings in a policy list, see Configure a policy list, on page 2409.

DHCP IPv6 pools

A DHCP IPv6 pool is a configuration element that

- defines a range of IPv6 addresses for DHCP assignment,
- is referenced when configuring DHCPv6 services, and
- enables address allocation to IPv6 clients.

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature (Enable the IPv6 prefix delegation client, on page 703), you can configure the Firewall Threat Defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the Firewall Threat Defense by defining a DHCP IPv6 Pool and assigning it to the DHCPv6 server. The Firewall Threat Defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the Firewall Threat Defense received using Prefix Delegation.

To add a pool, see Create a DHCP IPv6 pool, on page 833.

Distinguished names

A distinguished name is a certificate attribute that

- represents the subject or issuer for a public key certificate,
- can be used in rules to control encrypted traffic based on certificate negotiation, and
- consists of attributes such as country code, common name, organization, and organizational unit.

A *distinguished name group* is a named collection of existing distinguished name objects.

Distinguished name attributes and usage

Distinguished name objects and distinguished name groups can be used in TLS/SSL rules to control encrypted traffic based on whether the client and server negotiated the TLS/SSL session using a server certificate with the distinguished name as subject or issuer.

A distinguished name can include a country code, common name, organization, and organizational unit. In most cases, the certificate includes only a common name. For example, the common name in the certificate for `https://www.cisco.com` is `cisco.com`. The certificate can include multiple Subject Alternative Names (SANs). You can use these names as distinguished names (DNs) in a rule condition. For detailed information about SANs, see RFC 5280, section 4.2.1.6.

The format of a distinguished name object that references a common name is `CN=`*`name`*. If you add a DN rule condition without `CN=`, the system prepends `CN=` before saving the object.

The system uses Server Name Indication (SNI) to match the DN in the TLS/SSL rule whenever possible.

You can also add a distinguished name with one of each of the attributes listed in this table, separated by commas.

Table 152: Distinguished name attributes

Attribute	Description	Allowed Values
C	Country Code	two alphabetic characters
CN	Common Name	up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces
O	Organization	up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces
OU	Organizational Unit	up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces

DN rule conditions

- When the system first detects an encrypted session to a new server, DN data is not available for ClientHello processing. As a result, the first session might not be decrypted.

If the server requests TLS 1.3, the setting for TLS server identity discovery can help by making sure the server certificate is known before making decryption policy decisions. For more information, see TLS server identity discovery, on page 2173.

- You *cannot* configure a distinguished name condition if you also choose the **Decrypt - Known Key** action. Because that action requires you to choose a server certificate to decrypt traffic, the certificate already matches the traffic.

Wildcard examples

You can define one or more asterisks (*****) as wildcards in an attribute. In a common name attribute, you can define one or more asterisks per domain name label. Wildcards match only in that label, but you can define multiple labels with wildcards. See this table for examples.

Table 153: Common name attribute wildcard examples

Attribute	Matches	Does not match
CN=*ample.com	example.com	mail.example.com example.text.com ampleexam.com
CN=exam*.com	example.com	mail.example.com example.text.com ampleexam.com
CN=*xamp*.com	example.com	mail.example.com example.text.com ampleexam.com
CN=*.example.com	mail.example.com	www.myhost.example.com example.com example.text.com ampleexam.com

Note The DN object `CN=amp.cisco.com` would *not* match a CN like `CN=auth.amp.cisco.com`, which is why wildcards are recommended in these cases.

For more information and examples, see Conditions for distinguished name rules in decryption policies, on page 1765.

Related Topics

Conditions for distinguished name rules in decryption policies, on page 1765

Create a distinguished name object

Enables you to create distinguished name objects, which uniquely identify and reference network entities within Secure Firewall Management Center.

Distinguished name objects are used to specify unique identifiers for certificates or access policies. Perform this task when configuring objects that require a distinguished or common name for identification.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **Distinguished Name** node, and choose **Individual Objects**.

Step 3 Click **Add Distinguished Name**.

Step 4 Enter a **Name**.

Step 5 In the **DN** field, enter a value for the distinguished name or common name. You have the following options:

- If you add a distinguished name, you can include one of each attribute listed in Distinguished names, on page 2364 separated by commas.
- If you add a common name, you can include multiple labels and wild cards.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

DNS server groups

A DNS server group is a network configuration object that

- contains multiple Domain Name System (DNS) servers
- resolves fully qualified domain names (FQDNs), such as `www.example.com`, to IP addresses, and
- enables efficient domain name resolution within a network.

Create a DNS server group object

Create and manage a group of DNS servers for use in network policies to simplify DNS server assignments.

DNS server group objects allow you to define multiple DNS servers that can be referenced by other configuration elements. Use this task to centralize DNS server assignments for interfaces or policies.

Procedure

Step 1 Choose **Objects** > **Object Management** > **DNS Server Group** from the network objects list.

Step 2 Click **Add DNS Server Group**.

Step 3 Enter a **Name**.

Step 4 Optionally, enter the **Default Domain** that will be used to append to the host names that are not fully-qualified.

This setting is only used for the default server group.

Step 5 The default **Timeout** and **Retries** values are pre-populated. Change these values if necessary.

- Retries—Specify how many times (0 to 10) to retry contacting DNS servers if there is no response. Default is 2.
- Timeout—Specify how many seconds (1 to 30) to wait before trying the next DNS server. Default is 2 seconds; this timeout doubles with each retry.

Step 6 Enter the **DNS Servers** IP addresses (IPv4 or IPv6), separated by commas. *(Maximum of 6 servers per group.)*

Step 7 Click **Save**.

What to do next

Assign the configured DNS server group to interface objects in the DNS platform settings. For more information, see Configure DNS server settings, on page 852.

External attributes

Dynamic objects

A dynamic object is a network object that

- specifies one or many IP addresses retrieved using REST API calls or the Dynamic Attributes Connector from cloud sources,
- can be used in access control rules without deploying dynamic changes, and
- automatically updates object values on managed devices after being pushed by the Dynamic Attributes Connector.

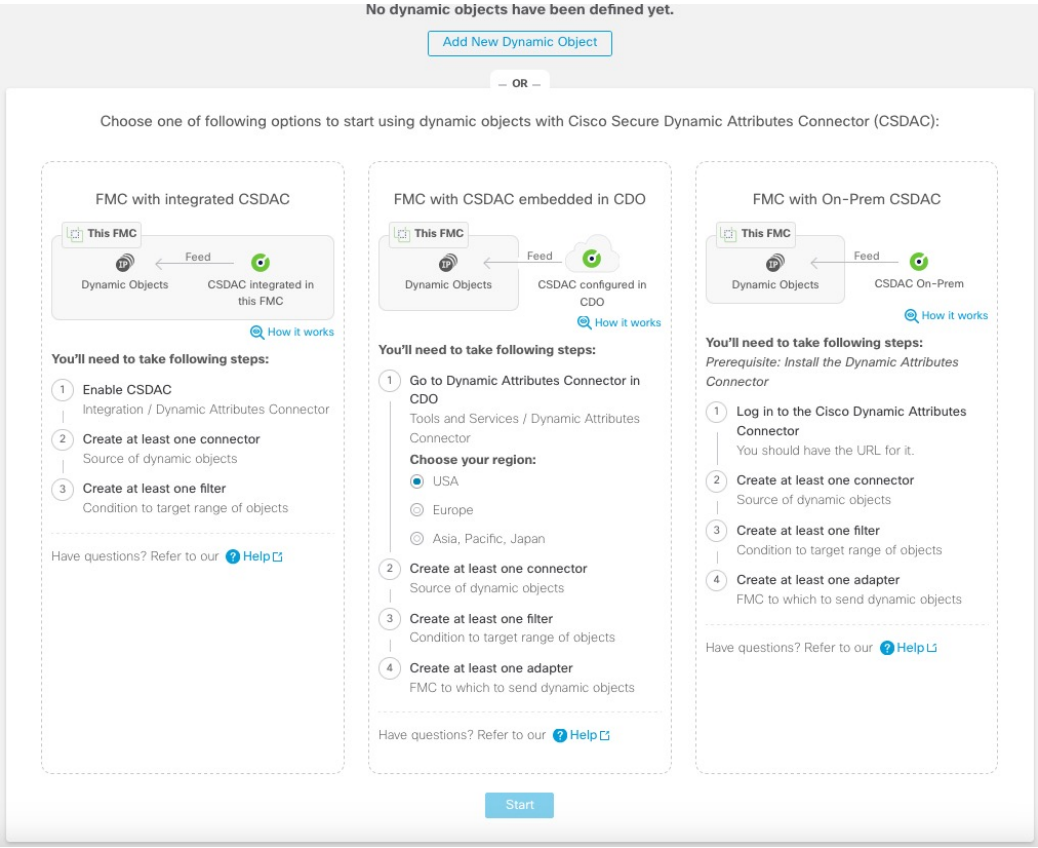
Kinds of dynamic objects

There are these kinds of dynamic objects:

- Connector-created dynamic objects: The system pushes dynamic objects created using the dynamic attributes connector to the Firewall Management Center as soon as you create them. The system updates them at regular intervals.

- API-created dynamic objects have the following characteristics:
  - Are IP addresses, with or without classless inter-domain routing (CIDR), that can be used in access control rules much like a network object.
  - Do not support fully-qualified domain names or address ranges.
  - You must update these objects using an API.

For more information about API-created dynamic objects, see API-created dynamic objects, on page 2375.



Note Unlike most other objects, dynamic objects do not have to be deployed to managed devices to take effect. Add a dynamic object to the **Dynamic Attributes** tab in a rule and deploy the rule. The object values are automatically updated on the managed device as soon as possible after being pushed by the Dynamic Attributes Connector.

Create dynamic objects for the first time

This topic explains how to create dynamic objects for the first time, describes the informational page displayed when no dynamic objects exist, and outlines the steps to begin the configuration process using the secure firewall manager or dynamic attributes connector.

The page available at **Objects** > **Object Management** > **External Attributes** > **Dynamic Object** is displayed as follows if you have not configured any dynamic objects yet.

If you have already created some dynamic objects, see Dynamic objects page features, on page 2374.

To use this page:

- Select the section that matches how you plan to deploy the dynamic attributes connector.

  Deployment method and outcome:

Method	Outcome
Cloud-Delivered Firewall Management Center with CSDAC Embedded	Access dashboard and configure within application
Cloud-Delivered Firewall Management Center with or CSDAC	Download connector and follow guided configuration
Management Center with Integrated CSDAC	Enable and configure connector within on-prem manager

- Click **How it works** to view diagrams and get more help with that type of deployment.

  The following topics provide more information.

  - Create dynamic objects with embedded Dynamic Attributes Connector, on page 2370
  - Dynamic objects with Security Cloud Control, on page 2371
  - Create dynamic objects with on-premises Dynamic Attributes Connector, on page 2372

- Click **Start** to begin the configuration process in the related application:

- If you clicked the **FMC with Integrated CSDAC** method, **Start** takes you to **Objects** > **Object Management** > **External Attributes** > **Dynamic Object** where you can enable and configure the Dynamic Attributes Connector.

  For more information, see Enable the dynamic attributes connector, on page 2063.

- If you clicked the **FMC with CSDAC embedded in** Security Cloud Control method, **Start** starts Security Cloud Control.

  For more information, see the guide titled *Managing Firewall Threat Defense with Cloud-delivered Firewall Management Center in Security Cloud Control*.

- If you clicked the **FMC with On-Prem CSDAC** method, **Start** enables you to download the Dynamic Attributes Connector if you have not done so already.

  For more information, see the *Cisco Secure Dynamic Attributes Connector Configuration Guide*.

Create dynamic objects with embedded Dynamic Attributes Connector

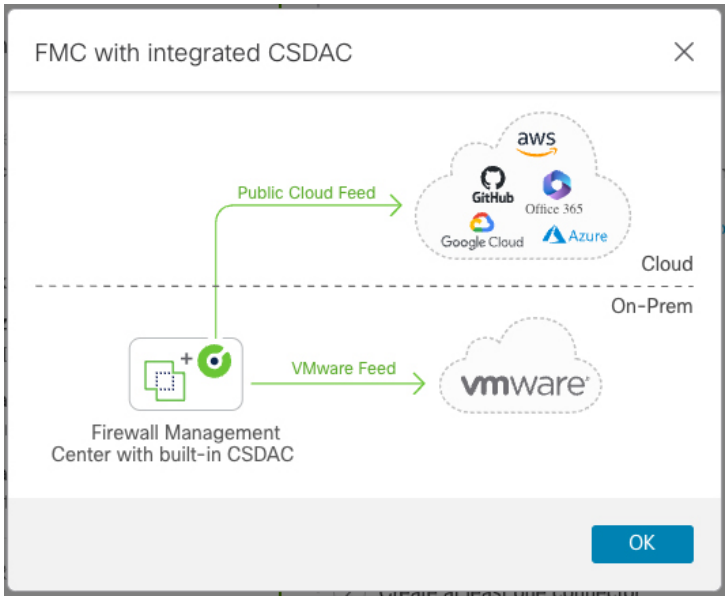
A dynamic object is a firewall configuration element that

- enables integration with the embedded Dynamic Attributes Connector
- allows retrieval of IP addresses from cloud services, and
- supports use in access control and DNS rules within the Secure Firewall Management Center.

Integration and configuration details

The Dynamic Attributes Connector is already integrated with the Secure Firewall Management Center (**Integration** > **Dynamic Attributes Connector**).

To use the dynamic attributes connector included with the secure firewall manager, enable it (Integration > Dynamic Attributes Connector), configure connectors that receive dynamic objects, and set up dynamic attributes filters that determine what dynamic objects are sent to this secure firewall manager.



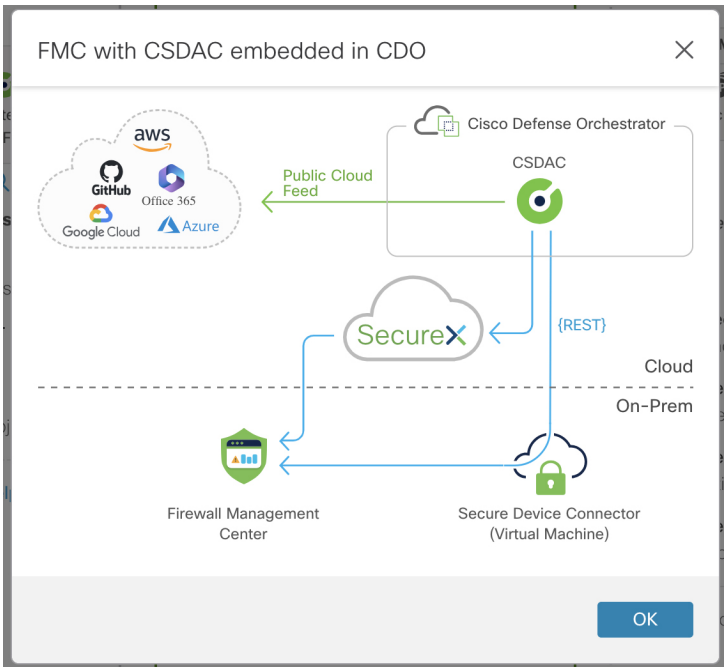
To use this type of deployment:

1. Enable the Dynamic Attributes Connector as discussed in Enable the dynamic attributes connector, on page 2063.
2. Configure connectors, which retrieve IP addresses from cloud services.

   For more information, see Connectors, on page 2072.
3. Configure dynamic attributes filters, which determine what IP addresses to send to the management center.

   For more information, see Create dynamic attributes filters, on page 2092.
4. View your dynamic objects at **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.
5. Use dynamic objects in access control rules (**Policies** > **Access Control heading** > **Access Control**, then click the **Dynamic Attributes** tab).

Figure 424: Dynamic attributes connector integration



Dynamic objects with Security Cloud Control

A dynamic object is a network management feature that

- enables the retrieval of IP addresses from cloud services using connectors,
- allows you to create dynamic attributes filters to determine which objects are sent, and
- supports integration with secure firewall management centers through adapters.

This page is displayed if you configure the Dynamic Attributes Connector provided with Security Cloud Control.

The diagram includes details about configuring Security Cloud Control that are not discussed in this guide. For more information, see Secure Device Connector (SDC) or SecureX and Security Cloud Control.

To use this type of deployment:

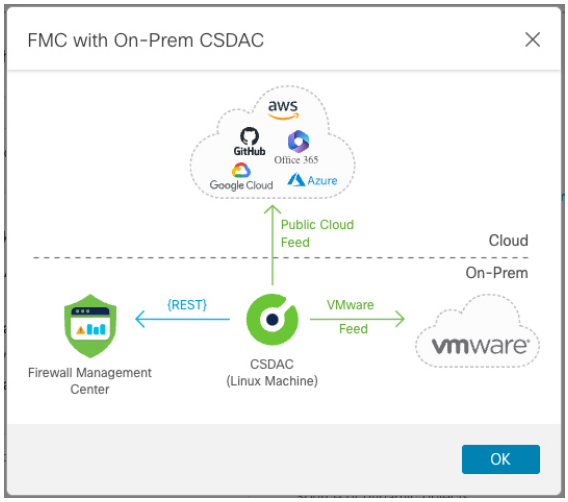
1. Configure connectors to retrieve IP addresses from cloud services. For instructions, see Connectors, on page 2072.
2. Define dynamic attribute filters to specify which IP addresses are sent to the management center.

   For more information, see Create dynamic attributes filters, on page 2092.
3. Set up adapters to send IP addresses to a Secure Firewall Management Center or Cloud-Delivered Firewall Management Center.

   For more information, see the section on creating adapters in the *Cisco Security Cloud Control: Secure Firewall Threat Defense Management*.
4. Log in to the Secure Firewall Management Center that you defined as an adapter.

   If the Secure Firewall Management Center is managed by Security Cloud Control, access the **Cloud-Delivered FMC**.
5. View your dynamic objects at **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.
6. Use dynamic objects in access control rules (**Policies** > **Access Control heading** > **Access Control**, then click the **Dynamic Attributes** tab).

Create dynamic objects with on-premises Dynamic Attributes Connector



A dynamic object deployment is a configuration method that

- installs the Dynamic Attributes Connector on a supported Linux virtual machine,

- configures connectors, adapters, and dynamic attributes filters to retrieve and send IP addresses to a management center, and
- enables use of dynamic objects in access control and DNS rules.

This page appears if you indicated that you are configuring the on-premises Dynamic Attributes Connector to send dynamic objects to a Secure Firewall Management Center or Cloud-Delivered Firewall Management Center.

Figure 425: Dynamic attributes connector configuration

The on-premises Dynamic Attributes Connector can send dynamic objects to a Secure Firewall Management Center or Cloud-Delivered Firewall Management Center.

To use this type of deployment, complete these steps:

1. Install the Dynamic Attributes Connector on a supported Linux virtual machine.
2. Configure connectors, which retrieve IP addresses from cloud services.

   For more information, see the section on creating connectors in the *Cisco Secure Dynamic Attributes Connector Configuration Guide*.
3. Configure adapters, which send IP addresses to a Secure Firewall Management Center or Cloud-Delivered Firewall Management Center.

   For more information, see the section on creating adapters in the *Cisco Secure Dynamic Attributes Connector Configuration Guide*.
4. Configure dynamic attributes filters, which determine what IP addresses to send to the management center.

   For more information, see the section on configuring dynamic attributes filters in the *Cisco Secure Dynamic Attributes Connector Configuration Guide*.
5. You can view your dynamic objects at **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.
6. Use dynamic objects in access control rules (**Policies** > **Access Control heading** > **Access Control**, then click the **Dynamic Attributes** tab).

For more information, see the *Cisco Secure Dynamic Attributes Connector Configuration Guide*.

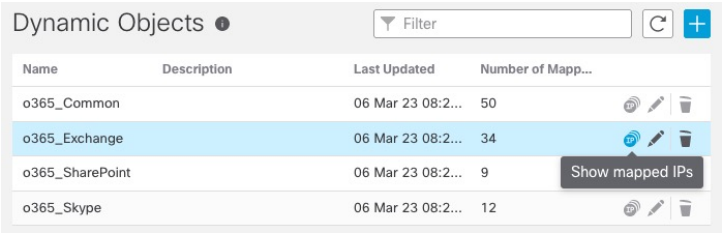
Dynamic objects page features

The Dynamic Objects page displays all dynamic objects created using the API or the Cisco Secure Dynamic Attributes Connector. You can edit, delete, or view IP address mappings on this page. The page enables you to view or download IP addresses associated with each object.

The page available at **Objects** > **Object Management** > **External Attributes** > **Dynamic Object** is displayed similar to this if you have already configured some dynamic objects.

This page displays information about each dynamic object and enables you to view or download IP addresses associated with that object. For more information, see Dynamic object mappings, on page 2374.

Dynamic object mappings



A dynamic object mapping is a configuration feature that

- enables connectors to send IPs matching dynamic attribute filters to the Firewall Management Center,
- allows users to view or download a current list of mapped IP addresses, and
- updates IP addresses dynamically over time to reflect changes in access control rules.

Mapped IP address information

If you configured dynamic objects through the API or by using the dynamic attributes connector, the connectors send IPs that match dynamic attribute filters to the Firewall Management Center at regular intervals.

To view or download a current list of these IP addresses, click **Show Mapped IDs** in the Firewall Management Center, as illustrated.

IP addresses are added dynamically over time. Review the mapped IP addresses regularly, especially if the access control rules do not behave as expected.

Related topics

- API-created dynamic objects, on page 2375
- About the dynamic attributes connector , on page 2061

API-created dynamic objects

An API-created dynamic object is a network object that

- specifies one or more IP addresses retrieved using REST API calls or the Dynamic Attributes Connector,
- can be used in access control rules without deploying dynamic changes to the objects, and
- updates IP addresses from cloud sources.

For more information about the dynamic attributes connector, see the *Cisco Secure Dynamic Attributes Configuration Guide* (link to guide).

Differences between dynamic objects and network objects

- Dynamic objects created using the dynamic attributes connector are pushed to the Firewall Management Center as soon as they are created. These objects are then updated at regular intervals.
- API-created dynamic objects:
  - are IP addresses, with or without classless inter-domain routing (CIDR), that can be used in access control rules much like a network object,
  - do not support fully-qualified domain names or address ranges, and
  - must be updated using an API.

Add or edit an API-created dynamic object

This task enables you to add or edit a dynamic object using the API, allowing you to group IP addresses for use in access control rules. Dynamic objects help automate address management and streamline policy configuration.

A dynamic object is a group of IP addresses, with or without classless inter-domain routing (CIDR). You can use dynamic objects in access control rules much like a network object. This procedure is relevant when you need to manage dynamic address groups via the API instead of manually creating static objects.

Note This procedure is not necessary if you use the Dynamic Attributes Connector because it automatically creates dynamic objects for you.

Before you begin

Consult the *Firepower Management Center REST API Quick Start Guide* for information about how to use the object services REST API to populate the IP object with an address. Dynamic objects do not require deployment.

Follow these steps to add or edit an API-created dynamic object:

Procedure

Step 1 Click **Objects** > **Object Management**.

Step 2 Click **External Attributes** > **Dynamic Objects**.

Step 3 Click **Add Dynamic Object** or **Edit** ( ).

Step 4 Enter a **Name** for the object and an optional **Description**.

Step 5 From the **Type** list, click **IP**.

What to do next

If necessary, update the dynamic object using the API. Deployment is not required.

Security group tags

A security group tag is a network security object that

- specifies a single SGT value,
- is used in rules to control traffic with SGT attributes not assigned by Cisco ISE, and
- cannot be grouped or overridden.

Related Topics

Autotransition from custom SGTs to ISE SGTs
Custom SGT conditions
ISE SGTs versus custom SGT rule conditions

Create a security group tag object

This task allows you to add a security group tag object to enforce network access policies based on SGT.

You can create security group tag objects only in the global domain. A Control license is required for Classic devices. Any Smart License provides coverage for Smart Licensed devices.

Before you begin

- Disable ISE or ISE-PIC connections because custom SGT objects cannot be created if either is used as an identity source.

  Click **Integration** > **Other Integrations** > **Identity Sources**, click **None**, then click **Save**.

- See Best practices for ISE/ISE-PIC integration, on page 1914 for guidelines for using the identity source.

Follow these steps to create a security group tag object:

Procedure

Step 1 Click **Objects** > **Object Management**.

Step 2 Click **External Attributes** > **Security Group Tag**.

Step 3 Click **Add Security Group Tag**.

Step 4 Enter a **Name**.

Step 5 Optionally, enter a **Description**.

Step 6 In the **Tag** field, enter a single SGT.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

File lists

A file list is a threat management feature that

- allows you to manually specify files using unique SHA-256 hash values,
- overrides AMP cloud verdicts to improve detection accuracy within your environment, and
- supports categorization into clean or custom detection lists, enabling precise control over file treatment.

If you use malware defense and the AMP cloud incorrectly identifies a file's disposition, you can add the file to a file list to improve future detection. Specify these files using SHA-256 hash values. You can add up to 10,000 unique SHA-256 values in each file list.

File list categories

File lists are organized into two predefined categories.

- **Clean list**: If you add a file to this list, the system treats it as if the AMP cloud assigned a clean disposition.
- **Custom detection list**: If you add a file to this list, the system treats it as if the AMP cloud assigned a malware disposition.

Because you manually specify the blocking behavior for the files included in these lists, the system does not query the AMP cloud for these files' dispositions. You must configure a rule in the file policy with either the **Malware Cloud Lookup** or **Block Malware** action and a matching file type to calculate a file's SHA value.

Caution Do **not** include malware on the clean list. The clean list overrides both the AMP cloud disposition and the custom detection list.

Source files for file lists

Source files allow you to add multiple SHA-256 values to a file list by uploading a comma-separated value (CSV) file. The system validates the contents and populates the file list with valid SHA-256 values. Upload source files must meet the following requirements:

- The source file must be a simple text file with a .CSV extension.
- Any header must start with a pound sign; it is treated as a comment and will not be uploaded.

- Each entry should contain a single SHA-256 value followed by a description, and must end with either LF or CR+LF newline character.
- The system ignores any additional information present in the entry.

Note the following behaviors and limitations:

- Deleting a source file from the file list also removes all associated SHA-256 hashes from the list.
- You cannot upload multiple files to a file list if the upload would result in more than 10,000 distinct SHA-256 values in the list.
- The system truncates descriptions exceeding 256 characters to the first 256 characters when uploading. If the description contains commas, you must use an escape character (`\,`). If no description is provided, the source file name is used instead.
- All non-duplicate SHA-256 values are added to the file list. If a SHA-256 value already exists, it is not modified by subsequent uploads. Any threat name or description is derived from the individual SHA-256 value in related events.
- Invalid SHA-256 values in a source file are not uploaded.
- If multiple uploaded source files contain entries for the same SHA-256 value, the system uses the most recent value.
- If a source file contains multiple entries for the same SHA-256 value, the system uses the last entry.
- You cannot edit a source file directly within the object manager. To make changes, edit your local source file, delete the existing file from the system, then upload the revised file.
- The number of entries associated with a source file refers to the number of distinct SHA-256 values. Deleting a source file decreases the file list's SHA-256 entries by the number of valid entries in the deleted file.

Add individual SHA-256 values to file lists

Add unique SHA-256 values to file lists to enhance file detection and management within the system.

You must have the Malware Defense license for this procedure.

Adding SHA-256 values identifies files for detection and prevents duplicates by ensuring only unique values are included.

Before you begin

- Right-click a file or malware event from the event view, choose **Show Full Text** in the context menu, and copy the full SHA-256 value for pasting into the file list.

Follow these steps to add individual SHA-256 values to file lists:

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **File List** from the list of object types.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to add a file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 Choose `Enter SHA Value` from the **Add by** drop-down list.

Step 5 Enter a description of the source file in the **Description** field.

Step 6 Enter or paste the file's entire value in the **SHA-256** field. The system does not support matching partial values.

Step 7 Click **Add**.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Note After configuration changes are deployed, the system no longer queries the AMP cloud for files on the list.

Upload an individual file to a file list

You must have the Malware Defense license for this procedure.

If you have a copy of the file you want to add to a file list, you can upload the file to the Secure Firewall Management Center for analysis. The system automatically calculates the file's SHA-256 value on upload. No file size limit applies for SHA-256 calculation.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **File List** from the list of object types.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to add a file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 From the **Add by** drop-down list, choose **Calculate SHA**.

Step 5 (Optional) Enter a description of the file in the **Description** field. If you leave this field blank, the file name becomes the description during upload.

Step 6 Click **Browse**, and choose a file to upload.

Step 7 Click **Calculate and Add SHA** to upload the file and calculate the SHA-256 value.

Step 8 Click **Save**.

After completing these steps, the file is uploaded, its SHA-256 value is calculated, and the file is added to the selected file list for analysis.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Note After you deploy configuration changes, the system no longer queries the AMP cloud for files on the list.

Upload source files to file lists

This task enables you to upload source files to file lists, allowing for efficient management and use of file data within the system.

You must have the Malware Defense license for this procedure.

Use this task when you need to add values from a source file to an existing file list in the system.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Click **File List**.

Step 3 Click **Edit** ( ) next to the file list where you want to add values from a source file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 In the **Add by** drop-down list, choose `List of SHAs`.

Step 5 (Optional) Enter a description of the source file in the **Description** field. If you do not enter a description, the system uses the file name.

Step 6 Click **Browse** to browse to the source file, then click **Upload and Add List**.

Step 7 Click **Save**.

After you complete these steps, the system uploads the source file and adds its values to the selected file list.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Note After you deploy the policies, the system stops querying the AMP cloud for files on the list.

Edit SHA-256 values in file lists

You must have the Malware Defense license for this procedure.

You can edit or delete individual SHA-256 values on a file list. However, you cannot directly edit a source file within the object manager. To make changes, first modify your source file, delete the copy on the system, and then upload the modified file.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Click **File List**.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to modify a file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 You can:

- Click **Edit** ( ) next to the SHA-256 value you want to change, and modify the **SHA-256** or **Description** values as desired.
- Click **Delete** ( ) next to the SHA-256 value you want to delete.

Step 5 Click **Save** to update the file entry in the list.

Step 6 Click **Save** to save the file list.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Note After configuration changes are deployed, the system no longer queries the AMP cloud for files on the list.

Download source files from a file list

This task allows you to download source files from file lists, enabling you to obtain files for analysis or operational needs.

You must have the Malware Defense license for this procedure.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **File List** from the list of object types.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to download a source file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 Next to the source file you want to download, click **View** ( ).

Step 5 Click **Download SHA List** and follow the prompts to save the source file.

Step 6 Click **Close**.

FlexConfig objects

A FlexConfig object is a configuration element that

- provides customized configuration of features on Firewall Threat Defense devices
- enables configuration of features not otherwise available through Secure Firewall Management Center, and
- uses policy objects in FlexConfig policies to customize device behavior.

FlexConfig object types

You can configure these types of objects for FlexConfig.

- **Text objects** define free-form text strings used as variables in a FlexConfig object. These objects can have a single value or multiple values. Several predefined text objects are included in FlexConfig objects. To customize device behavior, edit the contents of the text object when using a FlexConfig object. When editing a predefined object, create device overrides for each device instead of changing the default values. This helps prevent configuration issues for other users who use the same FlexConfig object. For information on configuring text objects, see Configure FlexConfig text objects, on page 950.
- **FlexConfig objects** include device configuration commands, variables, and scripting language instructions. During deployment, the system processes these instructions to create configuration commands with customized parameters for the target devices. You can add instructions at the beginning (prepended) of the configuration or at the end (appended), based on your requirements. Append any FlexConfig that depends on Secure Firewall Management Center-configured objects (for example, a network object) to the configuration deployment. This ensures the necessary objects are configured before the FlexConfig refers to them. For more information on configuring FlexConfig objects, see Configure FlexConfig objects, on page 945.

Geolocation objects

A geolocation object is a network policy element that

- represents one or more countries or continents identified as the source or destination of traffic on your monitored network,

- can be used in various places in the system's web interface, including access control policies, SSL policies, remote access VPN, and event searches, and
- enables you to write access control rules that block traffic to or from certain countries.

Geolocation database updates

To ensure that you are using up-to-date information to filter your network traffic, we strongly recommend that you regularly update your Geolocation Database (GeoDB).

Create a geolocation object

Create a geolocation object to define groups of countries and continents for use in security policies.

Use geolocation objects in access control and policy rules to manage network traffic based on geographic criteria.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Geolocation** from the list of object types.

Step 3 Click **Add Geolocation**.

Step 4 Enter a **Name**.

Step 5 Select the countries and/or continents to include.

- Selecting a continent includes all countries within that continent, including future additions via GeoDB updates.
- You can select any combination of countries and continents.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Interfaces

An interface is a network connection point that

- can be assigned to a *security zone*, an *interface group*, or both,
- enables application of security policies based on zones or groups, and
- supports flexible traffic control between different network segments.

Security zone and interface group assignments

Each interface can be assigned to a *security zone*, an *interface group*, or both. Apply your security policy based on zones or groups. For example, assign the "inside" interface to the "inside" zone and the "outside" interface to the "outside" zone. Configure the access control policy to allow traffic from inside to outside and block traffic from outside to inside. Some policies support only security zones. Other policies support both zones and groups.

For more information about interface objects, see Security zones and interface groups, on page 607.

To add interface objects, see Create security zone and interface group objects, on page 610.

Key chains

Key chains help you rotate authentication keys for IGP peers to enhance data security, prevent unauthorized users from guessing routing protocol authentication keys, and maintain uninterrupted, secure communication by allowing overlapping key lifetimes.

Key chain authentication and key management

Use rotating keys in key chains, with a duration of 180 days or less, to protect your devices and data. Rotating keys apply only to the OSPFv2 protocol.

Note Only the MD5 cryptographic algorithm is used for authentication.

Each key in a key chain has two lifetimes:

- Accept lifetime: The time interval within which the device accepts the key during key exchange with another device.
- Send lifetime: The time interval within which the device sends the key during key exchange with another device.

During a key's send lifetime, the device sends routing update packets using that key. If the key is not within the accept lifetime, the device does not accept communication from other devices.

If lifetimes are not configured, the system treats the configuration as using an MD5 authentication key without defined timelines.

When configuring authentication for routing protocols that provide key chains, configure the keys in your key chain with overlapping lifetimes to prevent losing secure communication if no active key is available.

Key selection in a key chain is determined as follows:

- When a key chain has more than one valid key, OSPF selects the key with the longest lifetime.
- The system prefers a key with an infinite lifetime.
- If keys have the same lifetime, then key with the higher key ID is preferred.

Create a key chain object

Create key chain objects that securely manage and organize authentication keys for devices on your network.

Use this task when you need to define and manage key chains for secure authentication. Key chains enable secure key exchange, helping prevent unauthorized access and ensuring reliable communication between devices.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Key Chain** from the list of object types, and then click **Add Key Chain**.

Step 3 In the Add Key Chain Object dialog box, do the following:

a. Enter a name for the key chain in the **Name** field.

The name must start with an underscore or letter, followed by alphanumeric characters or one of the following special characters: hyphen, underscore, plus sign, or period.

b. Add a key to the key chain, click **Add**.

c. Specify the key identifier (between 0 and 255; use 0 only to signal an invalid key) in the **Key ID** field.

d. The **Algorithm** field and the **Crypto Encryption Type** field displays the supported algorithm and the encryption type, namely MD5 and Plain Text.

e. Enter the password in the **Crypto Key String** field and confirm it in the appropriate field. Passwords can be up to 80 characters and must not be a single digit or start with a digit followed by a space (e.g., "0 pass" or "1" are invalid).

f. Set the **Accept Lifetime** and **Send Lifetime** values to define the time intervals for key exchange. The times default to UTC. When specifying start and end lifetimes, ensure that the start is earlier than the end and is never left blank if the end is entered.

g. Click **Add** to create keys. Create at least two keys with overlapping lifetimes to prevent loss of secure communication.

Repeat steps 3b to 3g to create keys.

Step 4 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2344.

Step 5 Click **Save**.

After you save, you can use the key chain object in device authentication and secure communication configurations.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Networks

A network object is a network entity that

- represents one or more IP addresses,
- can be used in access control policies, network variables, identity rules, network discovery rules, event searches, and reports, and
- is filtered automatically to show only valid objects for each configuration option.

Network object types

You can define a network object as one of these types:

- **Host**: A single IP address.

  IPv4 example:

  `209.165.200.225`

  IPv6 example:

  `2001:DB8::0DB8:800:200C:417A` or `2001:DB8:0:0:0DB8:800:200C:417A`

- **Range**: A range of IP addresses.

  IPv4 example:

  `209.165.200.225-209.165.200.250`

  IPv6 example:

  `2001:db8:0:cd30::1-2001:db8:0:cd30::1000`

- **Network**: An address block, also known as a subnet.

  IPv4 example:

  `209.165.200.224/27`

  IPv6 example:

  `2001:DB8:0:CD30::/60`

Note Security Intelligence ignores IP address blocks using a `/0` netmask.

- **FQDN**: A single fully-qualified domain name (FQDN). You can limit FQDN resolution to IPv4 address only, IPv6 address only, or both types. FQDNs must begin and end with a digit or letter. They can contain only letters, digits, and hyphens internally.

Example:

```
www.example.com
```

Note You can use FQDN objects in access control rules and prefilter rules, or manual NAT rules, only. The rules match the IP address obtained for the FQDN through a DNS lookup. To use an FQDN network object, ensure you have configured the DNS server settings in DNS server groups, on page 2366 and the DNS platform settings in Configure DNS server settings, on page 852.

You *cannot* use FDQN network objects in identity rules.

- **Group**: A group of network objects or other network object groups. You can create nested groups by adding a network object group to another. Nesting is supported up to 10 levels.

Note You can add up to 100 network literals in a network object. Each nested network object group contains up to 100 network literals.

Network wildcard masks

A network wildcard mask is an IP address mask that

- uses a discontinuous mask of bits to define network objects,
- enables you to create network objects with expanded subnet IP addresses, and
- appears as **Network Wildcard** in the **Type** column of the network object list.

Network wildcard mask usage and support

You can create and manage wildcard mask objects from the Network Wildcard Mask page in **Objects** > **Object Management** .

Standard network objects use contiguous masks, while wildcard network objects use discontinuous masks.

This table shows examples of IP addresses and indicates whether they are considered network wildcard objects:

Table 154: Network wildcard mask examples

Example IP address	Network wildcard?	Object type
192.0.0.0/8	No	Network
10.10.0.0/255.255.0.0	No	Network
10.10.0.10/255.255.0.255	Yes	Network Wildcard
72.0.240.10/255.255.240.255	Yes	Network Wildcard

Note Network wildcard objects and groups containing network wildcard objects are allowed only when configuring these policies:

- Prefilter policy
- Access control policy
- NAT policy

Guidelines and limitations

- To create network wildcard objects, in the Firewall Management Center UI, choose **Objects** > **Object Management** > **Network** and click **Add Network** and then **Add Object**. Select the **Network** option and enter the value as expanded subnet mask fotmat, such as 10.0.10.10 or 255.255.0.255.
- Features supported: Object override, group object support, group object override, wildcard literals, and wildcard object import.
- Network wildcard objects are supported only for IPv4 addresses.
- Network wildcard objects are supported from Firewall Management Center and Firewall Threat Defense versions 7.1 onwards.
- Network wildcard objects are supported only for Snort-3.

Create a network object

Create network objects to define network addresses, address ranges, or groups that can be used in security policies and access rules.

Network objects allow you to efficiently manage and reuse network definitions across your security policies. This task is relevant when you need to add, clone, or modify network objects in your management center.

Procedure

Step 1 Choose **Objects** > **Object Management**, and then Choose **Network** from the list of object types.

Step 2 Choose **Add Object** from the **Add Network** drop-down menu.

Step 3 Alternatively, you can clone an existing network object and edit the parameters to create a new network object. Click the **Clone** icon on the existing network object that you want to clone.

Step 4 Enter a **Name** and optionally, enter a **Description**.

Step 5 In the **Network** field, select the required option and enter an appropriate value; see Networks, on page 2386.

Note You can add up to 100 network literals in a network object. Additionally, each nested network object group can contain a maximum of 100 network literals.

Step 6 (FQDN objects only) Select the DNS resolution from the **Lookup** drop-down menu to determine whether you want the IPv4, IPv6, or both IPv4 and IPv6 addresses associated with the FQDN.

Step 7 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2344.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Import network objects

For details on importing network objects, see Import objects, on page 2334.

PKI objects

PKI objects are public key certificates and paired private keys that

- represent the security components required to support your deployment
- consist of certificate authority certificates for internal and trusted CA objects
- consist of server certificates for internal and external certificate objects, and
- contain private keys paired with certificates for internal objects.

PKI object usage for applications and SSL rules

PKI objects support various security configurations across your network deployment.

You can use PKI objects for these applications:

- ISE/ISE-PIC identity source: Use trusted certificate authority objects and internal certificate objects to configure a connection to ISE/ISE-PIC as an identity source.
- Captive portal authentication: Use internal certificate objects to authenticate the identity of your captive portal device when connecting to users' web browsers.
- Secure LDAP or AD connections: Use trusted certificate authority objects to configure realms for secure connections to LDAP or AD servers.

If you use PKI objects in SSL rules, you can match traffic encrypted with:

- the certificate in an external certificate object
- a certificate either signed by the CA in a trusted CA object, or within the CA's chain of trust

If you use PKI objects in SSL rules, you can decrypt:

- outgoing traffic by re-signing the server certificate with an internal CA object
- incoming traffic using the known private key in an internal certificate object

You can manually input certificate and key information, upload a file containing that information, or in some cases, generate a new CA certificate and private key.

When you view a list of PKI objects in the object manager, the system displays the certificate's Subject distinguished name as the object value. Hover your pointer over the value to view the full certificate Subject distinguished name. To view other certificate details, edit the PKI object.

Note The Firewall Management Center and managed devices encrypt all private keys stored in internal CA objects and internal certificate objects with a randomly generated key before saving them. If you upload private keys that are password protected, the appliance decrypts the key using the user-supplied password, then reencrypts it with the randomly generated key before saving it.

PKI objects for certificate enrollment

A certificate enrollment object is a PKI configuration item that

- contains the Certification Authority (CA) server information and enrollment parameters required for creating Certificate Signing Requests (CSRs)
- obtains identity certificates from the specified CA, and
- may include certificate revocation information.

Internal certificate authority objects

An internal certificate authority object is a security certificate object that

- represents the CA public key certificate of a CA your organization controls
- consists of the object name, CA certificate, and paired private key, and
- can be used in SSL rules to decrypt outgoing encrypted traffic by re-signing the server certificate with the internal CA.

Internal certificate authority object usage and management

You can create an internal certificate authority object in these ways:

- import an existing RSA-based or elliptic curve-based CA certificate and private key
- generate a new self-signed RSA-based CA certificate and private key
- generate an unsigned RSA-based CA certificate and private key. You must submit a certificate signing request (CSR) to another CA to sign the certificate before using the internal CA object.

Note If you reference an internal CA object in a **Decrypt - Resign** SSL rule and the rule matches an encrypted session, the user's browser may warn that the certificate is not trusted while negotiating the SSL handshake. To avoid this, add the internal CA object certificate to either the client or domain list of trusted root certificates.

After you create an internal CA object containing a signed certificate, you can download the CA certificate and private key. The system encrypts downloaded certificates and private keys with a user-provided password.

Whether system-generated or user-created, you can modify the internal CA object name, but cannot modify other object properties.

You cannot delete an internal CA object that is in use. Additionally, after you edit an internal CA object used in an SSL policy, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

CA certificates and private key import

A CA certificate and private key import is a security configuration process that

- enables uploading of X.509 v3 CA certificates and private keys,
- supports files encoded in DER or PEM formats, and
- validates that the certificate and key are properly paired before saving the object.

Supported file formats and import details

You can configure an internal CA object by importing an X.509 v3 CA certificate and private key. You can upload files encoded in one of these supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the private key file is password-protected, you can supply the decryption password. If the certificate and key are encoded in the PEM format, you can also copy and paste the information.

The system only allows you to upload files that contain proper certificate or key information. It also ensures the certificate and key are paired with each other. The system validates the pair before saving the object.

Note If you configure a rule with the **Decrypt - Resign** action, the rule matches traffic based on the referenced internal CA certificate's encryption algorithm type, in addition to any configured rule conditions. You must upload an elliptic curve-based CA certificate to decrypt outgoing traffic encrypted with an elliptic curve-based algorithm, for example.

Import a CA certificate and private key

Use this task when you need to add a new internal CA to your Secure Firewall Management Center for certificate management.

Administrators typically perform this task during initial setup or when updating trusted certificate authorities. It is relevant for those managing PKI infrastructure within Secure Firewall Management Center.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Click **Import CA**.

Step 4 Enter a **Name**.

Step 5 Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.

Step 6 Above the **Key** field, click **Browse** to upload a DER or PEM-encoded paired private key file.

Step 7 If the uploaded file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Generate a new CA certificate and private key

Generate a self-signed RSA-based CA certificate and accompanying private key by configuring an internal CA object.

Use this task to establish a trusted CA for your environment. The CA certificate enables secure signing and validation of other certificates and will be valid for ten years, with the **Valid From** date starting one week before creation.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Click **Generate CA**.

Step 4 Enter a **Name**.

Step 5 Enter your identification attributes.

Step 6 Click **Generate self-signed CA**.

Signed certificates

A signed certificate is a digital security credential that

- is obtained from a certificate authority (CA)
- enables configuration of an internal CA object, and
- allows referencing the internal CA object in an SSL rule if it contains a signed certificate.

Certificate configuration steps

You can configure an internal CA object by obtaining a signed certificate from a CA. This process consists of these actions:

- Provide identification information to configure the internal CA object. This action generates an unsigned certificate, produces a paired private key, and creates a certificate signing request (CSR) to a specified CA.
- Upload the signed certificate issued by the CA to the internal CA object. The internal CA object now contains a signed certificate instead of the unsigned certificate.

Only reference an internal CA object in an SSL rule if it contains a signed certificate.

Create an unsigned CA certificate and CSR

Create an unsigned CA certificate and generate a certificate signing request (CSR) to enable secure certificate management in Secure Firewall Management Center.

Perform this task when you need to generate a new unsigned CA certificate and CSR, typically for setting up internal certificate authorities or renewing certificates for secure communications. Always complete this task before uploading a signed certificate issued by a certificate authority.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Click **Generate CA**.

Step 4 Enter a **Name**.

Step 5 Enter the identification attributes.

Step 6 Click **Generate CSR**.

Step 7 Copy the CSR to submit to a CA.

Step 8 Click **OK**.

What to do next

- Upload a signed certificate issued by a CA as described in Upload a signed certificate issued in response to a CSR, on page 2394

Upload a signed certificate issued in response to a CSR

Perform this task after receiving a signed certificate from a certificate authority (CA) in response to a CSR generated by the system. Once uploaded, the certificate is available for referencing in SSL rules.

Before you begin

Obtain the signed certificate file (DER or PEM-encoded X.509 v3 CA certificate) that was issued in response to the CSR.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Click **Edit** (✎) next to the CA object containing the unsigned certificate awaiting the CSR.

Step 4 Click **Install Certificate**.

Step 5 Click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.

Step 6 If the uploaded file is password protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 7 Click **Save** to upload a signed certificate to the CA object.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

CA certificates and private key downloads

A CA certificate and private key download is a security operation that

- enables you to back up or transfer a CA certificate and its paired private key by downloading a file from an internal CA object,
- requires the system to decrypt the private key before creating the downloadable file, and
- uses a password provided by the user to encrypt the downloaded file for secure storage.

Encryption and storage of downloaded CA certificates and private keys

When you download a CA certificate and its private key, the system decrypts the private key before generating the file. Provide a password to encrypt the downloaded file. This helps keep it safe during storage and transfer. The system also encrypts the private key in the CA object with a randomly generated key before saving it to disk.

Caution Store downloaded key information in a secure location.

Caution If you download private keys as part of a system backup, they are decrypted and stored in the unencrypted backup file.

Download a CA certificate and private key

Obtain a CA certificate and private key required for certificate backup, migration, or integration within your secure firewall environment.

You can download CA certificates for both the current domain and ancestor domains. Use this task when you need to obtain the CA certificate and private key for backup, migration, or integration purposes.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Select the internal CA object whose certificate and private key you want to download. Click **Edit** ( ).

Step 4 Click **Download**.

Step 5 Enter an encryption password in the **Password** and **Confirm Password** fields.

Step 6 Click **OK**.

Trusted certificate authority objects

A trusted certificate authority object is a security configuration item that

- represents a CA public key certificate belonging to a trusted CA,
- consists of the object name and CA public key certificate, and
- can be used in SSL policy, realm configurations, and integration with ISE or ISE-PIC.

Usage scenarios for trusted certificate authority objects

You can use trusted certificate authority objects and groups in the following configurations:

- SSL policy: Control traffic encrypted with a certificate signed either by the trusted CA, or any CA within the chain of trust.
- Realm configurations: Establish secure connections to LDAP or Active Directory (AD) servers.
- ISE or ISE-PIC connection: Select trusted certificate authority objects for the pxGrid Server CA and MNT Server CA fields.

After you create the trusted CA object, you can modify the name and add certificate revocation lists (CRL), but cannot modify other object properties. There is no limit on the number of CRLs you can add to an object. If you want to modify a CRL you have uploaded to an object, you must delete the object and recreate it.

Note Adding a CRL to an object has no effect when the object is used in your ISE or ISE-PIC integration configuration.

You cannot delete a trusted CA object that is in use. Additionally, after you edit a trusted CA object that is in use, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

Trusted CA objects

A trusted CA object is a security object that:

- enables configuration of an external CA object by uploading an X.509 v3 CA certificate
- supports uploading files encoded in DER or PEM formats, and
- requires the system to validate the certificate before saving the object.

You can upload a file encoded in one of these supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the file is password-protected, you must supply the decryption password. If the certificate is encoded in the PEM format, you can also copy and paste the certificate information.

You can upload a CA certificate only if the file contains proper certificate information; the system validates the certificate before saving the object.

Add a trusted CA object

Add a trusted CA object so the system can validate certificates issued by a Certificate Authority (CA).

Use this task when you need to import a new trusted CA certificate into the system, such as when enabling secure communications or integrating with external certificate authorities.

Before you begin

- Have the DER or PEM-encoded X.509 v3 CA certificate file available.
- If the file is password-protected, ensure you have the password ready.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Trusted CAs**.

Step 3 Click **Add Trusted CAs**.

Step 4 Enter a **Name**.

Step 5 Click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.

Step 6 If the file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 7 Click **Save**.

The trusted CA object is added and available for use in certificate validation processes.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Certificate revocation lists in trusted CA objects

A certificate revocation list is a security file that

- can be uploaded to a trusted CA object
- enables control of encrypted traffic based on whether the issuing CA has revoked a certificate, and
- supports files encoded in Distinguished Encoding Rules (DER) or Privacy-enhanced Electronic Mail (PEM) formats.

Certificate revocation list usage in trusted CA objects

You can upload CRLs to a trusted CA object. If you reference that trusted CA object in an SSL policy, you can control encrypted traffic based on whether the CA that issued the session encryption certificate subsequently revoked the certificate.

Supported file formats for CRLs include:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

After you add the CRL, you can view the list of revoked certificates. If you want to modify a CRL you have uploaded to an object, you must delete the object and recreate it.

You can upload only files that contain a proper CRL. There is no limit to the number of CRLs you can add to a trusted CA object. However, you must save the object each time you upload a CRL, before adding another CRL.

Note Adding a CRL to an object has no effect when the object is used in your ISE/ISE-PIC integration configuration.

Add a certificate revocation list to a trusted CA object

Add a certificate revocation list (CRL) to a trusted certificate authority (CA) object. This step ensures that revoked certificates are recognized during certificate validation.

Add a CRL to a trusted CA object to ensure that Secure Firewall Management Center validates client certificates against a list of revoked certificates.

Note Adding a CRL to an object has no effect when the object is used in your ISE/ISE-PIC integration configuration.

Before you begin

Ensure you have a DER or PEM-encoded CRL file available for upload.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Trusted CAs**.

Step 3 Click **Edit** ( ) next to a trusted CA object.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Click **Add CRL** and upload your DER or PEM-encoded CRL file.

Step 5 Click **OK** to save the changes.

The certificate revocation list is added to the trusted CA object, updating it with the new CRL information.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

External certificate objects

An external certificate object is a certificate management item that

- represents a server public key certificate that does not belong to your organization,
- consists of the object name and certificate, and
- can be used in SSL rules to control traffic that is encrypted with the server certificate. For example, you can upload a self-signed server certificate that you trust, but cannot verify by using a trusted CA certificate.

Supported certificate formats

You can configure an external certificate object by uploading an X.509 v3 server certificate. The supported file formats include:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

The system validates the file before saving the object, ensuring your certificate is correctly processed. If the certificate is encoded in the PEM format, you can also copy and paste the information.

Add external certificate objects

Add external certificate objects to facilitate secure certificate management and integration with external systems.

Use this task when you need to import and manage external X.509 v3 server certificates in Secure Firewall Management Center for PKI integration.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **External Certs**.

Step 3 Click **Add External Cert**.

Step 4 Enter a **Name**.

Step 5 Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 server certificate file.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Internal certificate objects

An internal certificate object is a server public key certificate representation that

- belongs to your organization and consists of the object name, public key certificate, and paired private key
- supports SSL rule traffic decryption using the known private key, and
- enables authentication for ISE connections and captive portal configurations.

Internal certificate object usage and configuration

You can use internal certificate objects and groups in:

- your SSL rules to decrypt traffic incoming to one of your organization's servers using the known private key.
- your ISE/ISE-PIC connection. Select an internal certificate object for the **MC Server Certificate** field.
- your captive portal configuration to authenticate the identity of your captive portal device when connecting to users' web browsers. Select an internal certificate object for the **Server Certificate** field.

You can configure an internal certificate object by uploading an X.509 v3 RSA-based or elliptic curve-based server certificate and paired private key. You can upload a file in one of these supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the file is password-protected, you must supply the decryption password. If the certificate and key are encoded in the PEM format, you can also copy and paste the information.

You can upload only files that contain proper certificate or key information, and that are paired with each other. The system validates the pair before saving the object.

After you create the internal certificate object, you can modify the name, but cannot modify other object properties.

You cannot delete an internal certificate object that is in use. Additionally, after you edit an internal certificate object that is in use, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

Add internal certificate objects

Add and manage internal certificate objects for secure handling of server certificates and associated private keys within the system.

Use this task when you need to upload and manage DER or PEM-encoded X.509 v3 server certificates and their corresponding private keys for internal use. This is typically required for secure communication and authentication within your environment.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal Certs**.

Step 3 Click **Add Internal Cert**.

Step 4 Enter a **Name**.

Step 5 Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 server certificate file.

Step 6 Above the **Key** field, or click **Browse** to upload a DER or PEM-encoded paired private key file.

Step 7 If the uploaded private key file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 8 Click **Save**.

Certificate enrollment objects

A certificate enrollment object is a PKI configuration item that

- contains the Certification Authority (CA) server information and enrollment parameters required for creating Certificate Signing Requests (CSRs)
- obtains identity certificates from the specified CA, and
- may include certificate revocation information.

Certificate enrollment object reference information

Trustpoints let you manage and track CAs and certificates. A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one, enrolled identity certificate.

This section describes how to use and manage certificate enrollment objects in your PKI infrastructure.

- Certificate enrollment objects are used to enroll managed devices into your PKI infrastructure and create trustpoints (CA objects) on devices that support VPN connections.
- To manage certificate enrollment objects, go to **Objects** > **Object Management** > **PKI** > **Certificate Enrollment**. The following information is shown:
  - Existing certificate enrollment objects are listed in the **Name** column. Use the search field (the magnifying glass) to filter the list.
  - The enrollment type of each object is shown in the **Type** column. These enrollment methods can be used:
    - **Self Signed**—The managed device generates its own self signed root certificate.
    - **EST**—Enrollment over Secure Transport is used by the device to obtain an identity certificate from the CA.
    - **SCEP**—(Default) Simple Certificate Enrollment Protocol (SCEP) is used by the device to obtain an identity certificate from the CA.
    - **Manual**—The process of enrolling is carried out manually by the administrator.
    - **PKCS12 File**—Import a PKCS12 file on a Threat Defense managed device that supports VPN connectivity. A PKCS#12, or PFX or P12 file holds the server certificate, any intermediate certificates, and the private key in one encrypted file. Enter the **Passphrase** value for decryption.
  - The **Override** column indicates whether the object allows overrides (a green check mark) or not (a red X). If a number is displayed, it is the number of overrides in place. Use the Override option to customize the object settings for each device that is part of the VPN configuration. Overriding makes each device's trustpoint details unique. Typically the Common Name or Subject is overridden for each device in the VPN configuration. See Object overrides, on page 2342 for details and procedures on overriding objects of any type.
  - **Edit** a previously created certificate enrollment object by clicking on the edit icon (a pencil). Editing can only be done if the enrollment object is not associated with any managed devices. Refer to the adding instructions for editing a certificate enrollment object. Failed enrollment objects can be edited.
  - **Delete** a previously created certificate enrollment object by clicking on the delete icon (a trash can). You cannot delete a certificate enrollment object if it is associated with any managed device.

1. Define parameters for CA authentication and enrollment in a certificate enrollment object. Specify shared parameters and use the override facility to specify unique object settings for different devices.
2. Associate and install this object on each managed device that requires the identity certificate. On the device, it becomes a trustpoint.

   When a certificate enrollment object is associated with and then installed on a device, the process of certificate enrollment starts immediately. The process is automatic for self-signed, SCEP, EST, and

PKCS12 file enrollment types, meaning it does not require any additional administrator action. Manual certificate enrollment requires extra administrator action.

3. Specify the created trustpoint in your VPN configuration.

Press ( )**Add Cert Enrollment** to open the **Add Cert Enrollment** dialog and configure a certificate enrollment object, see Add certificate enrollment objects, on page 2402. Then install the certificate on each managed, headend device.

For more information on PKI, digital certificates, and certificate enrollment see PKI infrastructure and digital certificates, on page 1337.

Add certificate enrollment objects

Add certificate enrollment objects to manage device trustpoints and enable secure certificate enrollment for Firewall Threat Defense devices.

- Support multiple enrollment protocols, including SCEP, EST, Manual, and PKCS12 file import.

Use these objects to enable secure certificate management and device trustpoint enrollment. You must have Admin or Network Admin privileges to do this task.

Procedure

Step 1 Open the **Add Certificate Enrollment** dialog:

- Directly from Object Management: In the **Objects** > **Object Management** > **PKI** > **Certificate Enrollment** from the navigation pane, and click **Add Certificate Enrollment**.
- While configuring a managed device: In the **Devices** > **Certificates** screen, choose **Add** > **Add New Certificate** and click ( ) for the **Certificate Enrollment** field.

Step 2 Enter the **Name**. When enrollment is complete, this name is used as the trustpoint name on the managed devices with which it is associated. Click the **CA Information** tab, and then choose the **Enrollment Type**.

- **Self-Signed Certificate**—The managed device, acting as a CA, generates its own self-signed root certificate. No other information is needed in this pane.

Note When enrolling a self-signed certificate you must specify the Common Name (CN) in the certificate parameters.

- **EST**—Enrollment over Secure Transport protocol. Specify the EST information. See EST enrollment configuration options in Certificate Enrollment Object , on page 2404.
- **SCEP**—(Default) Simple Certificate Enrollment Protocol. Specify the SCEP information. See Certificate Enrollment Object SCEP options , on page 2405.
- **Manual**
  - **CA Only**—Check this check box to create only the CA certificate from the selected CA. An identity certificate will not be created for this certificate.

    If you do not select this check box, a CA certificate is not mandatory. You can generate the CSR without having a CA certificate and obtain the identity certificate.

- **CA Certificate**—Paste the CA certificate in the PEM format in the box. You can also obtain a CA certificate by copying it from another device.

  You can leave this box empty if you choose to generate a CSR without the CA certificate.

- **PKCS12 File**—Import a PKCS12 file on a Firewall Threat Defense managed device that supports VPN connectivity. A PKCS#12, or PFX, file holds a server certificate, intermediate certificates, and a private key in one encrypted file. Enter the **Passphrase** value for decryption.

Step 3 **Skip Check for CA flag in basic constraints of the CA Certificate**—Check this check box if you want to skip checking the basic constraints extension and the CA flag in a trustpoint certificate.

Step 4 **Validation Usage**—Choose from the options to validate the certificate during a VPN connection:

- **IPsec Client**—Validate an IPsec client certificate for a site-to-site VPN connection.
- **SSL Client**—Validate an SSL client certificate during a remote access VPN connection attempt.
- **SSL Server**—Select to validate an SSL server certificate, such as a Cisco Umbrella server certificate.

Step 5 (Optional) Click the **Certificate Parameters** tab and specify the certificate contents. Refer to Certificate Enrollment Object certificate parameters in certificate requests , on page 2406.

This information is placed in the certificate and is readable by any party who receives the certificate from the router.

Step 6 (Optional) Click the **Key** tab and specify the Key information. Refer to Certificate Enrollment Object key options , on page 2407.

Step 7 (Optional) Click the **Revocation** tab and specify the revocation options: Refer to Certificate Enrollment Object revocation options , on page 2408.

Step 8 **Allow Overrides** of this object if desired.

When you allow overrides in the PKCS12 certificate enrollment object, update the**Passphrase** for the certificate on the device where you override it.

See Object overrides, on page 2342 for a full description of object overrides.

Step 9 Click **Save**.

What to do next

Associate and install the enrollment object on a device to create a trustpoint on that device.

Related Topics

Install a certificate using self-signed enrollment, on page 2486
Install a certificate using EST enrollment, on page 2487
Install a certificate using SCEP enrollment, on page 2487
Install a certificate using manual enrollment, on page 2488
Install a certificate using a PKCS12 file, on page 2489

Add a certificate enrollment

A valid IdP certificate ensures that your system can securely authenticate users through an identity provider. This is essential for secure communications and compliance.

Procedure

Step 1 Enter the **Name**.

Step 2 Paste the certificate information in the **IdP Certificate** field in PEM format.

Note If the certificate is dependent on a root or intermediate certificate, you must install the dependent certificates. See Certificates, on page 2481.

Step 3 Click **Save**.

EST enrollment configuration options in Certificate Enrollment Object

This topic describes the EST enrollment options and the required fields for configuring EST certificate enrollment in the Secure Firewall Management Center.

Secure Firewall Management Center navigation path

Objects > **Object Management** > **PKI** > **Certificate Enrollment**. Click **Add Certificate Enrollment** to open the **Add Certificate Enrollment** dialog, and select the **CA Information** tab.

Fields

Enrollment Type—set to **EST**.

Note
- EST enrollment type does not support EdDSA key.
- EST's ability to auto-enroll a device when its certificate expires is not supported.

Enrollment URL—Enter the URL of the CA server to which devices should attempt to enroll.

Use an HTTPS URL in the form of **https://CA_name:port**, where *CA_name* is the host DNS name or IP address of the CA server. The *port* number is mandatory.

Username—The username required to access the CA server.

Password / Confirm Password—The password required to access the CA server.

Fingerprint—Optionally, enter the fingerprint of the CA server certificate. Verifying the fingerprint helps ensure you are connecting to the legitimate CA server and not a substitute. Enter the fingerprint in hexadecimal format. If the fingerprint does not match, the certificate is rejected. Obtain the fingerprint directly from the CA server.

Source Interface—The interface that interacts with the CA server. By default, the diagnostic interface is displayed. To configure a data interface as the source interface, choose the respective security zone or interface group object.

Ignore EST Server Certificate Validations—By default, EST server certificate validation is enabled. Check the check box to ignore Firewall Threat Defense validating EST server certificate.

Certificate Enrollment Object SCEP options

This topic describes the SCEP enrollment options and fields available when adding a certificate enrollment object in Secure Firewall Management Center.

Secure Firewall Management Center navigation path

Objects > **Object Management** > **PKI** > **Certificate Enrollment**. Click **Add Certificate Enrollment** to open the **Add Certificate Enrollment** dialog, and select the **CA Information** tab.

Fields

Enrollment Type—Set to **SCEP**.

Enrollment URL—Enter the URL of the CA server to which devices should attempt to enroll.

Use an HTTP URL in the format **`http://CA_name:port,`** . The CA_name is the DNS name or IP address of the CA server, and the port number is mandatory.

Note If the SCEP Server is referred with hostname/FQDN, configure the DNS Server using FlexConfig object.

If the CA cgi-bin script location at the CA is not the default (/cgi-bin/pkiclient.exe) include the nonstandard script location in the URL, in the form of http://CA_name:port/script_location, where script_location is the full path to the CA scripts.

Challenge Password / Confirm Password—The password used by the CA server to validate the identity of the device. You can obtain the password by contacting the CA server directly or by entering the following address in a web browser: **`http://URLHostName/certsrv/mscep/mscep.dll`**. Because the password is valid for only 60 minutes, deploy it as soon as possible after creation.

Retry Period—The interval (in minutes) between certificate request attempts. Values range from 1 to 60 minutes. The default is 1 minute.

Retry Count—The number of retries that should be made if no certificate is issued on the first request. Value can be 1 to 100. The default is 10.

CA Certificate Source—Specifies how the CA certificate will be obtained.

- **Retrieve Using SCEP** (default and only supported option)—Retrieve the certificate from the CA server using the Simple Certificate Enrollment Process (SCEP). Using SCEP requires a connection between your device and the CA server. Ensure a network route exists between your device and the CA server before beginning enrollment.

Fingerprint—When retrieving the CA certificate using SCEP, you may enter the fingerprint for the CA server. Using the fingerprint to verify the authenticity of the CA server's certificate helps prevent an unauthorized party from substituting a fake certificate in place of the real one. Enter the **Fingerprint** for the CA server in hexadecimal format. If the value you enter does not match the fingerprint on the certificate, the certificate is rejected. Obtain the CA's fingerprint by contacting the server directly, or by opening: **`http://<URLHostName>/certsrv/mscep/mscep.dll`**.

Certificate Enrollment Object certificate parameters in certificate requests

When sending a certificate request to a CA server, you can specify additional information that is placed into the certificate and is viewable by recipients. All information should follow the standard LDAP X.500 format.

Secure Firewall Management Center navigation path

Objects > **Object Management** > **PKI** > **Certificate Enrollment**. Click **Add Certificate Enrollment** to open the **Add Certificate Enrollment** dialog box, and select the **Certificate Parameters** tab.

Fields

Field	Description
Include FQDN	Whether to include the device's fully qualified domain name (FQDN) in the certificate request. You can select from these options: • **Use Device Hostname as FQDN** • **Don't use FQDN in certificate** • **Custom FQDN**—Select this and then specify it in the **Custom FQDN** field that displays.
Include Device's IP Address	Specify the interface whose IP address you want to include in the certificate request.
Common Name (CN)	Specify the X.500 common name to include in the certificate. **Note** When enrolling a self-signed certificate you must specify the Common Name (CN) in the certificate parameters.
Organization Unit (OU)	Specify the name of the organization unit (for example, a department name) to include in the certificate.
Organization (O)	Specify the organization or company name to include in the certificate.
Locality (L)	Specify the state or province to include in the certificate.
State (ST)	The state or province to include in the certificate.
County Code (C)	The country to include in the certificate. These codes conform to ISO 3166 country abbreviations, for example "US" for the United States of America.
Email (E)	Specify the email address to include in the certificate.
Include Device's Serial Number	Specify whether to include the device's serial number in the certificate. The CA uses the serial number to authenticate certificates or to later associate a certificate with a particular device. If you are unsure, include the serial number, because it is useful for debugging purposes.

Certificate Enrollment Object key options

This topic describes the available key options and their settings when adding certificate enrollment and selecting the Key tab in the Certificate Enrollment Object dialog box.

Secure Firewall Management Center navigation path

Objects > **Object Management** > **PKI** > **Certificate Enrollment**, and click **Add Certificate Enrollment** to open the **Add Certificate Enrollment** dialog box, and select the **Key** tab.

Fields

- **Key Type**: Choose RSA, ECDSA, EdDSA.

Note

- EdDSA is not supported for EST enrollment type.
- EdDSA is supported only in Site-to-Site VPN topologies.
- EdDSA is not supported as an identity certificate for Remote Access VPN.

- **Key Name**: Specifies the name of the key pair. If the key pair already exists, this field refers to the existing name. If not, it defines the name for a new key pair to be generated during enrollment. If no name is specified, the fully qualified domain name (FQDN) key pair is used instead.
- **Key Size**: When generating a new key pair, defines the desired key size (modulus) in bits. The recommended size is 2048 bits. Larger modulus sizes offer more security but require more time (a minute or more when larger than 512 bits) to generate and process.

Important

- On Firewall Management Center and Firewall Threat Defense Versions 7.0 and higher, you cannot enroll certificates with RSA key sizes smaller than 2048 bits and keys using SHA-1 with the RSA Encryption algorithm.
- You can use the PKI Enrollment of Certificates with Weak-Crypto to allow certificates with SHA-1 and smaller key size.
- You cannot generate RSA keys with sizes smaller than 2048 bits for Firewall Threat Defense 7.0, even when you enable the weak-crypto option.

- **Advanced Settings**: Select **Ignore IPsec Key Usage** if you do not want to validate values in the key usage and extended key usage extensions of IPsec remote client certificates. You can suppress key usage checking on IPsec client certificates. By default, this option is not enabled.

Note For site-to-site VPN connection, if you use a Windows Certificate Authority (CA), the default Application Policies extension is **IP security IKE intermediate**. If you are using this default setting, you must select the **Ignore IPsec Key Usage** option for the object you select. Otherwise, the endpoints cannot complete the site-to-site VPN connection.

Enroll PKI certificates with weak-crypto

Certificates that use weak cryptography (such as SHA-1 signatures or RSA keys smaller than 2048 bits) have restricted support on Firewall Management Center and Firewall Threat Defense devices. This reference details the conditions under which weak-crypto certificates may be enrolled and the required steps for enabling their use.

SHA-1 hashing signature algorithm, and RSA key sizes that are smaller than 2048 bits for certification are not supported on Firewall Management Center and Firewall Threat Defense Version 7.0 and later. You cannot enroll certificates with RSA key sizes that are smaller than 2048 bits.

To override these restrictions on Firewall Management Center 7.0 managing Firewall Threat Defenses running Versions earlier than 7.0, use the enable weak-crypto option on the Firewall Threat Defense. Do not permit weak-crypto keys, because, such keys are not as secure as the ones with larger key sizes.

Note Firewall Threat Defense 7.0 or later does not support generating RSA keys with sizes smaller than 2048 bits even when you permit weak-crypto.

To enable weak-crypto on the device, navigate to the **Devices** > **Certificates** page. Click the **Enable Weak-Crypto**() button provided against the Firewall Threat Defense device. When the weak-crypto option is enabled, the button changes to . By default, the weak-crypto option is disabled.

Note When a certificate enrollment fails due to weak cipher usage, the Firewall Management Center displays a warning message prompting you to enable the weak-crypto option. Similarly, when you turn on the enable weak-crypto button, the Firewall Management Center displays a warning message before enabling weak-crypto configuration on the device.

Upgrade earlier versions to Firewall Threat Defense 7.0

When you upgrade to Firewall Threat Defense 7.0, the existing certificate configurations are retained. However, if those certificates have RSA keys smaller than 2048 bits and use SHA-1 encryption algorithm, they cannot be used to establish VPN connections. You must either procure a certificate with RSA key size of at least 2048 bits or enable the permit weak-crypto option for VPN connections.

Certificate Enrollment Object revocation options

Specify whether to check the revocation status of a certificate by choosing and configuring the method. Revocation checking is off by default. The system does not check either method (CRL or OCSP).

Secure Firewall Management Center navigation path

Objects > **Object Management** > **PKI** > **Certificate Enrollment**, and click () **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **Revocation** tab.

Fields

- **Enable Certificate Revocation Lists**—Check to enable CRL checking.

- **Use CRL distribution point from the certificate**—Check to obtain the revocation lists distribution URL from the certificate.
- **Use static URL configured**—Check this to add a static, predefined distribution URL for revocation lists. Then add the URLs.

  CRL Server URLs—Specify the URL of the LDAP server from which the CRL can be downloaded.

  URLs must start with **`http://`**. Include a port number in the URL. Enclose IPv6 addresses in square brackets, for example: *http://[0:0:0:0:0.18:0a01:7c16]*.

- **Enable Online Certificate Status Protocol (OCSP)**—Check to enable OCSP checking.

  OCSP Server URL—The URL of the OCSP server checking for revocation if you require OCSP checks.

  URLs must start with **`http://`**. Enclose IPv6 addresses in square brackets, for example: *http://[0:0:0:0:0.18:0a01:7c16]*.

- **Consider the certificate valid if revocation information cannot be reached**—Checked by default. Uncheck if you do not want to allow this.

Configure a policy list

Configure a policy list to group and manage multiple match statements for use in route maps. This allows for efficient policy management and flexible routing decisions.

Use the Configure Policy List page to create, copy, and edit policy list objects. You can create policy list objects to use when you are configuring route maps. When a policy list is referenced within a route map, all of the match statements in that policy list are evaluated and processed. With a route map, you can configure two or more policy lists. A policy list can coexist with other match and set statements that are configured in the same route map but outside the policy list. When multiple policy lists perform matching within a route map entry, only the incoming attribute is matched by all policy lists.

You can use this object with Firewall Threat Defense devices.

Procedure

Step 1 Select **Objects** > **Object Management** > **Policy List**.

Step 2 Click **Add Policy List**. Specify these values:

a. Enter a name for the policy list object in the **Name** field. Object names are not case-sensitive.

b. Select whether to allow or block access for matching conditions from the **Action** drop-down list.

Step 3 Enter the details in each of these tabs:

Tabs	Details
Interface	Use this tab to distribute routes that have their next hop out of one of the interfaces specified. In the **Zones/Interfaces** list, add the zones that contain the interfaces through which the device communicates with the management station. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zone/Interface** list and click **Add**. The host will be configured on a device only if the device includes the selected interfaces or zones.
Address	Use this tab to redistribute any routes that have a destination address that is permitted by a standard access list or prefix list. Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.
Next Hop	Use this tab to redistribute any routes that have a next hop router address passed by one of the access lists or prefix lists specified. Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.
Route Source	Use this tab to redistribute routes that have been advertised by routers and access servers at the address specified by the access lists or prefix list. Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.
AS Path	Use this tab to match a BGP autonomous system path. If you specify more than one AS path, then the route can match either AS path.
Community Rule	Use this tab to enable matching of the BGP community or extended community with the specified community list objects or the extended community list objects respectively. If you specify more than one rule, the routes are verified against the rules until a matching permit or deny is met. **a.** To specify a community list to the rule, click **Edit** ( ) given in the **Selected Community List** field. The community lists appear under **Available Community List**. Select the required list, click **Add**, and then click **Ok**. To enable matching the BGP community exactly with the specified community, check the **Match the specified community exactly** check box. **b.** To add the extended community list, click **Edit** ( ) given in the **Selected Extended Community List** field. The extended community lists appear under the **Available Extended Community List**. Select the required list, click **Add**, and then click **Ok**. **Note** The extended community lists are applicable only for configuring import or export of routes.

Tabs	Details
Metric & tag	Use this tab to match the metric and security group tag of a route. **a.** Enter the metric values to use for matching in the **Metric** field. You can enter multiple values, separated by commas. This setting allows you to match any routes that have a specified metric. The metric values can range from 0 to 4294967295. **b.** Enter the tag values to use for matching in the **Tag** field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified security group tag. The tag values can range from 0 to 4294967295.

Step 4 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.

Step 5 Click **Save**.

Ports

A port object is a network configuration element that

- represents different protocols, such as TCP, UDP, ICMP, and others, in distinct ways
- can specify protocol numbers, port numbers or ranges, and optional type and code for certain protocols, and
- is used to define access and monitoring rules within the system's web interface.

Port object representations and usage

Port objects represent protocols differently depending on their type.

- **TCP and UDP**: Port objects represent these transport layer protocols by specifying the protocol number, and may include an associated port or port range. For example: `TCP(6)/22`.
- **ICMP and ICMPv6 (IPv6-ICMP)**: Port objects represent these Internet layer protocols by specifying the protocol number and optional type and code. For example: `ICMP(1):3:3`.

  Restrict an ICMP or IPV6-ICMP port object by type and, if needed, code. Learn more about ICMP types and codes at:

  - ICMP Types and Codes: http://www.iana.org/assignments/ICMP-parameters/ICMP-parameters.xml
  - ICMPv6 Types and Codes: http://www.iana.org/assignments/icmpv6-parameters/icmpv6-parameters.xml

- **Other protocols**: Port objects can represent protocols that do not use ports.

The system provides default port objects for well-known ports. Default objects are read-only and always available for use. You can create custom port objects or groups in addition to the default ones.

Port objects and groups can be used throughout the system's web interface in access control policies, identity rules, network discovery rules, port variables, and event searches. For example, you can configure a network

discovery policy to exclude monitoring ports used by a custom client if it generates excessive or misleading events.

Guidelines for using port objects

- You cannot add any protocol other than TCP or UDP for source port conditions in access control rules.
- Set source and destination port conditions in a rule using only one transport protocol.
- Add only supported protocols to a port object group used in a source port condition so that the rule takes effect on the managed device when you deploy the configuration.
- To add a destination port, create a port object using only TCP or only UDP ports for the source port condition in a rule. Similarly, to add a source port, create a port object using only TCP or only UDP ports as the destination port condition.

Create port objects

Create port objects to specify protocol and port information for network traffic management in Secure Firewall Management Center.

Use this task to add or modify port objects in access control or other security policies within Secure Firewall Management Center. Port objects allow you to specify which network traffic is allowed or blocked based on protocol and port criteria. They are critical when you set up or update security rules.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Port** from the object types list.

Step 3 Choose **Add Object** from the **Add Port** drop-down list.

Alternatively, clone an existing port object and edit its parameters to create a new port object. Click the **Clone** icon on the existing port object that you want to clone.

Step 4 Enter a **Name**.

Step 5 Choose a **Protocol**.

Step 6 Depending on the protocol you chose, constrain by **Port**, or choose an ICMP **Type** and **Code**.

You can enter ports from `1` to `65535`. Use a hyphen to specify a port range. You must constrain the object by port if you chose to match **All** protocols, using the **Other** drop-down list.

Step 7 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2344.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Import port objects

To import port objects, refer to Import objects, on page 2334.

Prefix lists

A prefix list is a route filtering object that

- defines IPv4 and IPv6 address ranges
- is used when configuring route maps, policy maps, OSPF filtering, or BGP neighbor filtering, and
- enables control over which routes are permitted or denied.

Configure an IPv6 prefix list

Use IPv6 prefix lists in Firewall Threat Defense devices to specify which IPv6 routes are allowed or blocked during redistribution. This enhances routing policy control for protocols such as OSPF and BGP.

Procedure

Step 1 Select **Objects** > **Object Management** > **Prefix Lists** > **IPv6 Prefix List** from the table of contents.

Step 2 Click **Add Prefix List**.

a. Enter a name for the prefix list object in the **Name** field

b. Click **Add**.

Step 3 Select the appropriate action, Allow or Block, from the **Action** drop-down list to indicate the redistribution access.

Step 4 Enter a unique number that indicates the position a new prefix list entry will have in the list of prefix list entries already configured for this object, in the **Sequence No.** field. If left blank, the sequence number will default to five more than the largest sequence number currently in use.

Step 5 Specify the IPv6 address in the IP address/mask length format in the **IP address** field. The mask length must be a valid value between 1 and 128.

Step 6 Enter the minimum prefix length in the **Minimum Prefix Length** field and the maximum prefix length in the **Maximum Prefix Length** field.

The minimum prefix length value must be greater than the mask length and less than or equal to the Maximum Prefix Length, if specified.

If the Minimum Prefix Length is present, the maximum prefix length value must be greater than or equal to it. If the Minimum Prefix Length is not specified, the maximum value must be greater than the mask length.

Step 7 Click **Add**.

Step 8 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.

Step 9 Click **Save**.

Configure an IPv4 prefix list

Use the Configure IPv4 Prefix list page to manage prefix list objects. These objects can be used when configuring route maps, policy maps, OSPF filtering, or BGP neighbor filtering.

You can use this object with Firewall Threat Defense devices.

Procedure

Step 1 Select **Objects** > **Object Management** > **Prefix Lists** > **IPv4 Prefix List** from the table of contents.

Step 2 Click **Add Prefix List**.

a. Enter a name for the prefix list object in the **Name** field

b. Click **Add**.

Step 3 Select the appropriate action, Allow or Block, from the **Action** drop-down list to indicate the redistribution access.

Step 4 Enter a unique number in the **Sequence No.** field to specify the position of the new prefix list entry. If the field is left blank, the system assigns a sequence number that is five higher than the largest one currently in use.

Step 5 Specify the IPv4 address in the IP address/mask length format in the **IP address** field. The mask length must be a valid value between 1 and 32.

Step 6 Enter the minimum prefix length in the **Minimum Prefix Length** field and the maximum prefix length in the **Maximum Prefix Length** field.

The minimum prefix length value must be greater than the mask length and less than or equal to the Maximum Prefix Length, if specified.

If the Minimum Prefix Length is present, the maximum prefix length value must be greater than or equal to it. If the Minimum Prefix Length is not specified, the maximum value must be greater than the mask length.

Step 7 Click **Add**.

Step 8 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.

Step 9 Click **Save**.

Configure a route map

Route maps are used to manage route redistribution between routing protocols and to control default route generation. Route maps can specify which routes are permitted or denied and apply rules for matching route attributes.

You can use this object with Firewall Threat Defense devices.

Configure a route map to create or edit route map entries in a Route Map object.

Before you begin

A Route Map can use one or more of these objects. It is not mandatory to add all of them. Create and use any of these objects as required to configure your route map.

- Add ACLs.
- Add Prefix Lists.
- Add AS Path.
- Add Community Lists.
- Add Extended Community Lists.

Note The extended community lists apply only to configuring import or export of routes.

- Add Policy Lists.

Procedure

Step 1 Select **Objects** > **Object Management** > **Route Map**.

Step 2 Click **Add Route Map**.

Step 3 Click **Add** on the **New Route Map Object** window.

Step 4 In the **Sequence No.** field, enter a number, from 0 through 65535, that indicates the position a new route map entry has in the list of route maps entries already configured for this route map object.

Note We recommend that you number clauses in intervals of at least 10 to reserve numbering space in case you want to insert clauses in the future.

Step 5 Select Allow or Block from the **Redistribution** drop-down list, to indicate the redistribution access.

Step 6 Click the **Match Clauses** tab to match routes or traffic based on the following criteria, which you select in the table of contents:

- **Security Zones** —Match traffic based on the (ingress/egress) interfaces. You can select zones and add them, or type in interface names and add them.
- **IPv4**— Match IPv4 (routes/traffic) based on the following criteria; select the tab to define the criteria.
  a. Click the **Address** tab to match routes based on the route address. For IPv4 addresses, choose whether to use an Access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
  b. Click the **Next Hop** tab to match routes based on the next hop address of a route. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
  c. Click the **Route Source** tab to match routes based on the advertising source address of the route. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
- **IPv6** —Match IPv6 (routes/traffic) based on the route address, next-hop address or advertising source address of route.
- **BGP**—Match BGP (routes/traffic) based on the following criteria; select the tab to define the criteria.
  a. Click the **AS Path** tab to enable matching the BGP autonomous system path access list with the specified path access list. If you specify more than one path access list, then the route can match either path access list.
  b. Click the **Community List** tab to enable matching of the BGP community or extended community with the specified community list objects or the extended community list objects respectively.
     - To specify a community list to the rule, click **Edit** ( ) given in the **Selected Community List** field. The community lists appears under **Available Community List**. Select the required list, click **Add**, and then click **Ok**. For information on how to create community list objects, see Configure a community list, on page 2360
     - To add the extended community list, click **Edit** ( ) given in the **Selected Extended Community List** field. The extended community lists appears under the **Available Extended Community List**. Select the required list, click **Add**, and then click **Ok**. For information on how to create extended community list objects, see Configure an extended community list, on page 2361.

     To enable matching the BGP community exactly with the specified community list objects, check the **Match the specified community exactly** check box. This option is not applicable for the extended community list.

Note If you specify more than one rule, the routes are verified against the rules until a matching permit or deny condition is met. Any route that does not match at least one Match community will not be advertised for outbound route maps.

  c. Click the **Policy List** tab to configure a route map to evaluate and process a BGP policy. When multiple policy lists perform matching within a route map entry, all policy lists match on the incoming attribute only.

- **Others** —Match routes or traffic based on the following criteria.

a. Enter the metric values to use for matching in the **Metric Route Value** field, to enable matching the metric of a route. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified metric. The metric values can range from 0 to 4294967295.

b. Enter the tag values to use for matching in the **Tag Values** field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified security group tag. The tag values can range from 0 to 4294967295.

c. Check the appropriate **Route Type** option to enable matching of the route type. Valid route types are External1, External2, Internal, Local, NSSA-External1, and NSSA-External2. You can choose more than one route type from the list.

Step 7 Click the **Set Clauses** tab to set routes/traffic based on the following criteria, which you select in the table of contents:

- **Metric Values**—Set either Bandwidth, all of the values or none of the values.

  a. Enter a metric value or bandwidth in Kbits per second in the **Bandwidth** field. Valid values are an integer value in the range from 0 to 4294967295.

  b. Select to specify the type of metric for the destination routing protocol, from the **Metric Type** drop-down list. Valid values are: internal, type-1, or type-2.

- **BGP Clauses** —Set BGP routes based on the following criteria; select the tab to define the criteria.

  a. Click the **AS Path** tab to modify an autonomous system path for BGP routes.

     1. Enter an AS path number in the **Prepend AS Path** field to prepend an arbitrary autonomous system path string to BGP routes. Usually the local AS number is prepended multiple times, increasing the autonomous system path length. If you specify more than one AS path number then the route can prepend either AS number.

     2. Enter an AS path number in the **Prepend Last AS to AS Path** field to prepend the AS path with the last AS number. Enter a value for the AS number from 1 to 10.

     3. Check the **Convert route tag into AS path** check box to convert the tag of a route into an autonomous system path.

  b. Click the **Community List** tab to set the community attributes:

     Under **Specific Community**:

     1. Click the **None** radio button, to remove the community attribute from the prefixes that pass the route map.

     2. Click the **Specific Community** radio button, to enter a community number, if applicable. Valid values are from 1 to 4294967295.

     3. Check the **Add to existing communities** check box, to add the community to the already existing communities.

     4. Select the **Internet**, **No-Advertise**, or **No-Export** check-boxes to use one of the well-known communities.

     Under **Specific Extended Community**, in the **Route Target** field, enter the route target number in *ASN:nn* format:

- You can enter values that ranges from 1:1 to 65534:65535.

  You can add a single route target or a set of route targets separated by commas in a single entry. For example, *1:2,1:4,1:6*.

- You can have a maximum of 8 route targets in an entry.
- You cannot have redundant route target entries across route maps.

c. Click the **Others** tab to set additional attributes.

1. Check the **Set Automatic Tag** check-box to automatically compute the tag value.
2. Enter a preference value for the autonomous system path in the **Set Local Preference** field. Enter a value between 0 and 4294967295.
3. Enter a BGP weight for the routing table in the **Set Weight** field. Enter a value between 0 and 65535.
4. Select to specify the BGP origin code. Valid values are **Local IGP** and **Incomplete**.
5. In the IPv4 Settings section, specify a next hop IPv4 address of the next hop to which packets are output. It need not be an adjacent router. If you specify more than one IPv4 address then the packets can output at either IP address.

   Select to specify an IPv4 prefix list in the **Prefix List** drop-down list.
6. In the IPv6 Settings section, specify a next hop IPv6 address of the next hop to which packets are output. It need not be an adjacent router. If you specify more than one IPv6 address, then the packets can output at any of the IP addresses.

   Select to specify an IPv6 prefix in the **Prefix List** drop-down list.

Step 8 Click **Add**.

If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.

Step 9 Click **Save**.

After completing these steps, the route map is configured and ready for use in route redistribution and policy enforcement. The route map entries and associated match and set clauses are applied AS specified.

What to do next

Review the route map configuration to ensure that all required match and set clauses are correctly defined. Make any necessary adjustments to optimize routing policies.

- Monitor route redistribution and verify that routes are processed according to the configured route map.

Security intelligence

Security Intelligence is a traffic filtering mechanism that

- uses collections of IP addresses, domain names, and URLs to quickly filter traffic that matches entries
- requires the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types), and
- operates through lists and feeds that are grouped into DNS, Network, and URL categories.

Security intelligence components

Security Intelligence *lists* and *feeds* are collections of IP addresses, domain names. You can use these to quickly filter traffic that matches an entry on a list or feed.

- A list is a static collection that you manage manually.
- A feed is a dynamic collection that updates on an interval over HTTP or HTTPS.

Security Intelligence lists/feeds are grouped into:

- DNS (Domain names)
- Network (IP addresses)
- URLs

System-provided feeds:

Cisco provides these feeds as Security Intelligence objects:

- Security Intelligence feeds updated regularly with the latest threat intelligence from Talos:
  - Cisco-DNS-and-URL-Intelligence-Feed (under DNS Lists and Feeds)
  - Cisco-Intelligence-Feed (for IP addresses, under Network Lists and Feeds)

  You cannot delete the system-provided feeds, but you can change the frequency of (or disable) their updates.
- Cisco-TID-Feed (under Network Lists and Feeds)

  This feed is not used in the Security Intelligence tab of the access control policy.

  Instead, you must enable and configure Secure Firewall Threat Intelligence Director to use this feed. The feed is a collection of TID observables data.

  Use this object to configure the frequency of data publication to TID elements.

  For more information, see Threat Intelligence Director, on page 2121.

Predefined global Block and Do Not Block lists:

The system includes predefined global Block lists and Do Not Block lists for domains (DNS), IP addresses (Networks), and URLs.

These lists are empty until you populate them. To build these lists, see Global and domain security intelligence lists, on page 2420.

By default, access control and DNS policies use these lists as part of Security Intelligence.

Custom feeds:

You can use third-party feeds or use a custom internal feed to easily maintain an enterprise-wide Block list in a large deployment with multiple Secure Firewall Management Center appliances.

See Custom security intelligence feeds, on page 2428.

Custom lists:

Custom lists can augment and fine-tune feeds and the global lists.

See Custom Security Intelligence lists, on page 2430.

Security Intelligence lists and feeds usage locations:

- IP address and address blocks—Use Block and Do Not Block lists in access control policies, as part of Security Intelligence.
- Domain Names—Use Block and Do Not Block lists in DNS policies, as part of Security Intelligence.
- URLs—Use Block and Do Not Block lists in access control policies, as part of Security Intelligence. You can also use URL lists in access control and QoS rules, whose analysis and traffic handling phases occur after Security Intelligence.

Modify security intelligence objects

This topic explains how to add or delete entries on a Block list, Do Not Block list, feed, or sinkhole object. It also describes the edit capabilities and redeployment requirements for each object type.

The table summarizes the editing options and redeployment requirements for various security intelligence object types.

Object Type	Edit Capabilities	Requires Redeploy After Edit?
Custom Block and Do Not Block lists	Upload new and replacement lists using the object manager.	No
Default (but custom-populated) Block lists and Do Not Block lists: Global, descendant, and domain-specific	Add entries using the context menu or delete entries using the object manager.	No
System-provided Intelligence Feeds	Disable or change update frequency using the object manager.	No
Custom feeds	Fully modify using the object manager.	No
Sinkhole	Fully modify using the object manager.	Yes

Global and domain security intelligence lists

A security intelligence list helps you manage firewall policies by

- lets you manage lists of connections to block or exempt,

- applies your policies consistently across global and domain contexts, and
- enables further threat evaluation without the need to redeploy firewall policies.

Security intelligence list reference information

The Firewall Management Center includes Global Block and Do Not Block lists, so you can use Security Intelligence to consistently block or exempt connections, allowing evaluation by other threat detection processes you configure.

Access control and DNS policies use these Global lists by default, and they apply to all security zones. If you want, you can turn these lists off for individual policies.

- Global Block list: Lets you block specified connections in all security zones.
- Do-Not-Block list: Lets you exempt specified connections from blocking so you can further evaluate threats.

Note These options apply only to Security Intelligence. Security Intelligence does not block traffic already fastpathed. Adding an item to a Security Intelligence Do Not Block list does not mean matching traffic is trusted or fastpathed. For more information, see Security intelligence, on page 1595.

Global and domain security intelligence lists example

For example, if you notice a set of routable IP addresses in intrusion events associated with exploit attempts, you can immediately block those IP addresses. Although it may take a few minutes for your changes to propagate, you do not have to redeploy.

Security intelligence lists and multitenancy

A security intelligence list is a multitenancy feature that

- enables the creation of block or do not block lists that apply to specific subdomains,
- supports descendant domain lists that aggregate the lists of a domain's descendants, and
- allows administrators at or above a domain to populate lists, while only domain-specific administrators can remove items.

Domain lists and descendant domain lists

Domain lists are block or do not block lists whose contents apply to a particular subdomain. The global lists are domain lists for the global domain. Each subdomain has its own named lists, and their contents apply only to that subdomain.

For example, a subdomain named Company A owns these lists:

- Domain Block list - Company A and Domain Do Not Block list - Company A
- Domain Block list for DNS - Company A, Domain Do Not Block list for DNS - Company A
- Domain Block list for URL - Company A, Domain Do Not Block list for URL - Company A

Any administrator at or above the current domain can populate these lists. You can use the context menu to add an item to the block or do not block list in the current and all descendant domains. However, only an administrator in the associated domain can remove an item from a domain list.

For example, a global administrator could add the same IP address to the block list in the global domain and Company A's domain, but not in Company B's domain. This action would add the same IP address to:

- Global Block list (removable only by global administrators)
- Domain Block list - Company A (removable only by Company A administrators)

A descendant domain list is a do not block list or block list that aggregates the domain lists of the current domain's descendants. Leaf domains do not have descendant domain lists.

Descendant domain lists are useful because a higher-level domain administrator can enforce general security intelligence settings, while subdomain users can add items to a block or do not block list in their own deployment.

For example, the global domain has these descendant domain lists:

- Descendant Block lists - Global, Descendant Do Not Block lists - Global
- Descendant Block lists for DNS - Global, Descendant Do Not Block lists for DNS - Global
- Descendant Block lists for URL - Global, Descendant Do Not Block lists for URL - Global

Note Descendant domain lists do not appear in the object manager because they are symbolic aggregations, not hand-populated lists. They appear where you can use them: in access control and DNS policies.

Add entries to global security intelligence lists

Add entries to global Security Intelligence lists to control access and improve threat detection by blocking or exempting specific IP addresses, domains, and URLs.

When reviewing events and dashboards, you can instantly block future traffic involving IP addresses, domains, and URLs that appear in those events by adding them to a predefined Block list.

Similarly, if Security Intelligence is blocking traffic that you want evaluated by threat detection processes subsequent to Security Intelligence blocking, you can add IP addresses, domains, and URLs from events to a predefined Do-Not-Block list.

Traffic is evaluated against entries on these lists during the Security Intelligence phase of threat detection.

For more information about these lists, see Global and domain security intelligence lists, on page 2420.

Before you begin

Because adding an entry to a Security Intelligence list affects access control, you must have one of the following user roles:

- Administrator
- Network Admin or Access Admin, plus Security Analyst and Security Approver
- A custom role with both "Modify Access Control Policy" and "Deploy Configuration to Devices" permissions

- Verify that these lists are used in the policies where you expect them to be effective.

Procedure

Step 1 Navigate to an event that includes an IP address, domain, or URL that you want to always block using Security Intelligence, or exempt from Security Intelligence blocking.

Step 2 Right-click the IP address, domain, or URL and choose the appropriate option.

Item Type	Context Menu Option
IP address	Add IP to Block List Add IP to Do-Not-Block List These options add the IP address to the respective lists for Networks.
URL	Add URL to Global Block List for URL Add URL to Global Do-Not-Block List for URL
Domain of a URL in the URL field	Add Domain to Global Block List for URL Add Domain to Global Do-Not-Block List for URL
Domain in the DNS Query field	Add Domain to Global Block List for DNS Add Domain to Global Do-Not-Block List for DNS

What to do next

You do not need to redeploy for these changes to take effect.

If you want to delete an item from a list, see Delete entries from global security intelligence lists, on page 2423.

Delete entries from global security intelligence lists

Update your security intelligence lists by removing entries that should no longer be blocked or allowed. This helps you maintain accurate and effective security intelligence lists.

Note To add entries to these lists, see Add entries to global security intelligence lists, on page 2422.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence**.

Step 2 Click the appropriate option:

- **Network Lists and Feeds** (for IP addresses)
- **DNS Lists and Feeds** (for domain names)
- **URL Lists and Feeds**

Step 3 Click the pencil beside the Global Block or Global Do-Not-Block list.

Step 4 Click the trash button beside the entry to delete.

List and feed updates for security intelligence feeds

A list and feed update is a security intelligence mechanism that performs the following functions:

- Replaces the existing list or feed file with the contents of the new file.
- Does not merge contents of existing and new files.
- If a corrupt or unrecognizable feed is downloaded, the system keeps using previous feed data. This is not true for the first download. If the system recognizes at least one entry in the feed, it uses only the entries it can recognize.

Feed update frequency and device polling

- Each feed updates the Firewall Management Center every two hours by default; you can modify this frequency.
- When the Firewall Management Center receives updates, it immediately passes them to your managed devices.
- Your managed devices poll the Firewall Management Center every 30 minutes for changes. You cannot change this polling frequency.
- For Secure Firewall 200, updates are downloaded once a day, not every 30 minutes.

To modify feed update intervals, see Change the update frequency for security intelligence feeds, on page 2424.

Change the update frequency for security intelligence feeds

Set the intervals at which Security Intelligence feeds are updated in the system. Adjusting the update frequency ensures that threat data is refreshed according to your organization's needs.

You can specify the intervals at which the Firewall Management Center updates Security Intelligence Feeds.

For details about feed updates, see List and feed updates for security intelligence feeds, on page 2424.

Before you begin

No explicit prerequisites are stated. Ensure you have access to the system interface where Security Intelligence feeds are managed.

Follow these steps to change the update frequency for Security Intelligence feeds:

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **Security Intelligence** node, then choose the feed type whose frequency you want to change.

The system-provided URL feed is combined with the domain feed under **DNS Lists and Feeds**.

Step 3 Next to the feed you want to update, click **Edit** ( ).

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 Edit the **Update Frequency**.

Step 5 Click **Save**.

The Security Intelligence feed will update at the new interval you specified. The system will retrieve threat data according to the configured frequency.

Custom security intelligence lists and feeds

This reference describes custom Security Intelligence lists and feeds.

List custom lists and feeds requirements

Each custom list or feed must be a simple text file no larger than 500 MB. List files must have the `.txt` extension. Include one entry or comment per line—for example, one IP address, one URL, or one domain name per line.

List and feed formatting

Each custom list or feed must be a simple text file no larger than 500 MB. List files must have the `.txt` extension. Include one entry or comment per line—for example, one IP address, one URL, or one domain name per line.

Tip The number of entries is limited by the maximum file size. For example, a URL list with no comments and an average URL length of 100 characters (including Unicode representations and newlines) can support more than 5.24 million entries.

- In a DNS list entry, you can use an asterisk (`*`) wildcard character for a domain label. All labels match the wildcard. Example: `www.example.*` matches `www.example.com` and `www.example.co`.
- Comment lines must start with the pound (`#`) character.
- Comments are removed during upload. Files you download contain only the entries, not the comments.

Feed requirements

- When configuring a feed, specify its location using a URL; the URL cannot be Punycode-encoded.
- For feed update intervals of 30 minutes or less, you must provide an MD5 URL to prevent frequent downloads of unchanged feeds. If your feed server does not provide an MD5 URL, use a download interval of at least 30 minutes.
- If you use an MD5 checksum, store it in a simple text file. The file should contain only the checksum. Do not add comments to the file.

List URL syntax and matching criteria for URL lists and feeds

Security Intelligence URL lists and feeds, including custom lists and feeds and entries in the global Block list and Do Not Block list, can include hostnames, URLs, slashes for exact matches, wildcards, and IP addresses, each with specific matching behavior.

- Hostnames

  For example, **`www.example.com`**.

- URLs
  - **`example.com`** matches **`example.com`** and all subdomains, including:
    - **`www.example.com`**
    - **`eu.example.com`**
    - **`example.com/abc`**
    - **`www.example.com/def`**
  - Does not match:
    - **`example.co.uk`**
    - **`examplexyz.com`**
    - **`example.com.malicious-site.com`**
  - When a feed or list includes a single entry, every URL that ends with those domains is identified and blocked
  - Example feed:

    If you add `www.netflix.com, www.amazon.*, org, edu, www.hulu.*` to the feed, these are blocked:
    - `http://www.amazon.in`
    - `http://www.rajiv.org/`
    - `http://www.edu.edu/`
    - `http://www.edu.org/`
    - `http://org.org/`

- `http://edu.edu`

- You can also include an entire URL path, such as **`https://www.cisco.com/c/en/us/products/security/firewalls/index.html`**

- Custom feeds with embedded credentials:

  You can create a custom URL, Network, and DNS feeds, including the username and password inside the URL (for example: **`https://admin:password@server.domain.com/list.txt`**).

Note If your password contains special characters (such as a colon (:) or an at sign (@)), transmission would fail. Ensure that your passwords do not contain these special characters, or use encoded passwords.

- A slash at the end of a URL to specify an exact match

  `example.com/` matches only **`example.com`**; it does not match **`www.example.com`** or any other URL.

- A wildcard (*) to represent any domain in a URL

  - An asterisk can represent a complete domain string separated by dots, but not a partial domain string, and not any part of the URL following the first slash.

    Valid examples:

    - **`*.example.com`**
    - **`www.*.com`**
    - **`example.*`**

      (This will match **`example.com`** and **`example.org`** and **`example.de`**, for example, but not **`example.co.uk`**)

    - **`*.example.*`**
    - **`example.*/`**

    Invalid examples:

    - **`example*.com`**
    - **`example.com/*`**

- IP addresses (IPv4)

  - For IPv6 addresses, or to use ranges or CIDR notation, use the Security Intelligence Network object.
  - You can include one or more wildcards representing an octet, for example 10.10.10.* or 10.10.*.*.

See also Custom Security Intelligence lists, on page 2430.

Custom security intelligence feeds

A custom security intelligence feed is a threat intelligence source that

- enables augmentation of system-provided intelligence feeds with regularly updated reputable block lists and do not block lists from the internet,
- supports configuration of internal feeds for updating multiple Secure Firewall Management Center appliances using a single source list, and
- allows use of MD5 checksums to determine if a feed requires downloading, reducing unnecessary updates for large or internal feeds.

Security intelligence feed management

Custom or third-party Security Intelligence feeds allow you to augment the system-provided intelligence feeds with other regularly updated reputable block lists and do not block lists on the internet. You can also set up an internal feed, which is useful if you want to update multiple Secure Firewall Management Center appliances in your deployment using one source list.

You can configure the system to use an MD5 checksum to determine whether to download an updated feed. If the checksum has not changed since the last download, the system does not need to re-download it. Using MD5 checksums is especially helpful for internal feeds that are large.

Note You cannot add address blocks to block or do not block lists using a `/0` netmask in a Security Intelligence feed. If you want to monitor or block all traffic targeted by a policy, use an access control rule with the **Monitor** or **Block** rule action and specify`any` for the **Source Networks** and **Destination Networks**.

Note The system does **not** perform peer SSL certificate verification when downloading custom feeds, nor does the system support the use of certificate bundles or self-signed certificates to verify the remote peer.

If you want strict control over when the system updates a feed from the internet, you can disable automatic updates for that feed. However, automatic updates ensure that the data is always current and relevant.

When you manually update Security Intelligence feeds, the system updates all feeds, including the system-provided intelligence feeds.

See complete requirements at List custom lists and feeds requirements, on page 2425.

Create custom security intelligence feeds

Configure security intelligence feeds to enhance your device's ability to detect and respond to threats by importing external or custom threat data sources.

You must have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Use this task when you need to add new threat intelligence feeds for IP, DNS, or URL data to your security device.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence** node, then choose a feed type you want to add.

Step 2 Click the option appropriate to the feed type you chose:

- **Add Network Lists and Feeds** (for IP addresses)
- **Add DNS Lists and Feeds**
- **Add URL Lists and Feeds**

Step 3 Enter a **Name** for the feed.

Step 4 Choose **Feed** from the **Type** drop-down list.

Step 5 Enter a **Feed URL**.

Step 6 Enter an **MD5 URL**.

- The MD5 URL is used to check if the feed content has changed since the last update and is required for update intervals shorter than 30 minutes.
- If your feed provider does not supply an MD5 URL, set the update interval to at least 30 minutes.

Step 7 Choose an **Update Frequency**.

Step 8 Click **Save**.
Unless you disabled feed updates, the system downloads and verifies the feed.

Update custom security intelligence feeds manually

Manually updating Security Intelligence feeds allows you to ensure that your deployment uses the most current threat intelligence data for filtering network traffic.

You must have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Before you begin

At least one device must already be added to the management center.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence**.

Step 2 Click **Update Feeds**, then confirm.

Step 3 Click **OK**.

After the Secure Firewall Management Center downloads and verifies the feed updates, it communicates any changes to its managed devices. Your deployment begins filtering traffic using the updated feeds.

Custom Security Intelligence lists

A custom Security Intelligence list is a static list that

- contains IP addresses, address blocks, URLs, or domain names that you manually upload to the system,
- enables you to augment and fine-tune feeds or global lists for the managed devices of a single Firewall Management Center, and
- is useful when you need to override or supplement existing feed behavior without removing the entire feed from a policy.

Formatting requirements for custom Security Intelligence lists

- Netmasks for address blocks must be integers from `0` to `32` for IPv4 or from `0` to `128` for IPv6.
- Encode Unicode in domain names using Punycode format. The encoding is not case sensitive.
- Characters in domain names are not case sensitive.
- Unicode in URLs must be percent-encoded.
- Characters in URL subdirectories are case sensitive.
- List entries that start with the number sign (`#`) are treated as comments.
- For more information about formatting requirements, see the List custom lists and feeds requirements, on page 2425.

Matching requirements for custom Security Intelligence lists

- If you add a higher-level domain to a URL or DNS list, any sub-level domains also match. For example, if you add `example.com` to a DNS list, `www.example.com` and `test.example.com` also match.
- DNS lookups (forward or reverse) are not performed on DNS or URL list entries. For example, if you add `http://198.51.100.2` to a URL list, the list matches only that exact address and not any domain it resolves to.

Note You cannot add address blocks to a Block or Do Not Block list using a `/0` netmask in a Security Intelligence list. To monitor or block all traffic targeted by a policy, use an access control rule with the **Monitor** or **Block** action, and set the **Source Networks** and **Destination Networks** to `any`.

Examples for customizing Security Intelligence lists

- If a global feed blocks access to a vital resource but is otherwise useful, you can upload a custom list to allow access to that resource without disabling the feed entirely.
- You can supplement an existing feed by adding URLs or domains relevant to your organization.

Upload new custom security intelligence lists to the Secure Firewall Management Center

To modify a Security Intelligence list, you must make your changes to the source file and upload a new copy. You cannot modify the file's contents using the web interface. If you do not have access to the source file, download a copy from the system.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence** node, then choose a list type.

Step 2 Click the option appropriate to the list you chose above:

- **Add Network Lists and Feeds** (for IP addresses)
- **Add DNS Lists and Feeds**
- **Add URL Lists and Feeds**

Step 3 Enter a **Name**.

Step 4 From the **Type** drop-down list, choose **List**.

Step 5 Click **Browse** to browse to the list `.txt` file, then click **Upload**.

Step 6 Click **Save**.

What to do next

You do not need to redeploy these changes to take effect. If you want to delete an entry from the list, see Delete entries from global security intelligence lists, on page 2423.

Update custom security intelligence lists

Modify, add, or remove entries from your security intelligence lists in Secure Firewall Management Center. Update your lists when new threats emerge or when you need to refine your firewall's response to known risks. Perform this task as part of routine security maintenance or to update your firewall based on new threat intelligence.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence** node, then choose a list type.

Step 2 Next to the list you want to update, click **Edit** ( ).

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 To edit the list, click **Download** and save the list as a text file using your browser's prompts.

Step 4 Change the list as needed.

Step 5 On the Security Intelligence pop-up window, click **Browse** to browse to the modified list, then click **Upload**.

Step 6 Click **Save**.

What to do next

These changes take effect without redeployment. If you want to delete an entry from the list, see Delete entries from global security intelligence lists, on page 2423.

Sinkhole objects

A sinkhole object is a network security object that

- represents either a DNS server that gives non-routable addresses for all domain names within the sinkhole
- can represent an IP address that does not resolve to a server, and
- requires assignment of both an IPv4 address and an IPv6 address.

Sinkhole object usage in DNS policy rules

You can reference the sinkhole object within a DNS policy rule to redirect matching traffic to the sinkhole.

Create a sinkhole object

Create a sinkhole object to redirect or block suspicious traffic for enhanced threat detection and analysis.

Use this task when you need to configure a sinkhole object for traffic redirection or blocking to maintain security.

Before you begin

Ensure you have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Procedure

Step 1 Choose **Objects** > **Object Management** > **Sinkhole**.

Step 2 Click **Add Sinkhole**.

Step 3 Enter a **Name**.

Step 4 Enter the **IPv4 Address** and **IPv6 Address** of your sinkhole.

Step 5 You have these options:

- To redirect traffic to a sinkhole server, choose **Log Connections to Sinkhole**.
- To redirect traffic to a non-resolving IP address, choose **Block and Log Connections to Sinkhole**.

Step 6 (Optional) From the **Type** drop-down list, assign an Indication of Compromise (IoC) type for the sinkhole object, if needed.

Step 7 Click **Save**.

Configure an SLA monitor

Configure an SLA monitor to define a connectivity policy to a monitored address and track the availability of a route. This helps ensure that the route is periodically checked and replaced with a backup route if it becomes unavailable.

An Internet Protocol Service Level Agreement (SLA) monitor defines a connectivity policy to a monitored address and tracks the availability of a route. The monitor periodically checks the route by sending ICMP echo requests. If requests time out, the route is removed from the routing table and replaced with a backup route. SLA monitoring jobs start immediately after deployment and continue to run unless you remove the SLA monitor from the device configuration. The SLA Monitor Object is used in the Route Tracking field of an IPv4 Static Route Policy.

Note IPv6 routes do not support SLA monitors via route tracking.

Procedure

Step 1 Select **Objects** > **Object Management** > **SLA Monitor**.

Step 2 Click **Add SLA Monitor** and enter these values:

Fields	Details
Name	Enter a name for the object.
Description	Enter a description for the object.
Frequency	Enter the frequency of ICMP echo request transmissions, in seconds. Valid values range from 1 to 604800 seconds (7 days). The default is 60 seconds. **Note** The frequency cannot be less than the timeout value; you must convert frequency to milliseconds to compare the values.
SLA Monitor ID	Enter the ID number of the SLA operation. Values range from 1 to 2147483647. You can create a maximum of 2000 SLA operations on a device. Each ID number must be unique to the policy and the device configuration.
Threshold	Enter the amount of time that must pass after an ICMP echo request before a rising threshold is declared, in milliseconds. Valid values range from 0 to 2147483647 milliseconds. The default is 5000 milliseconds. The threshold value identifies events that exceed the defined value, which you can use to evaluate the proper timeout value. However, the threshold does not serve as a direct indicator of the reachability of the monitored address. **Note** The threshold value should not exceed the timeout value.

Fields	Details
Timeout	Enter the amount of time that the SLA operation waits for a response to the ICMP echo requests, in milliseconds. Values range from 0 to 604800000 milliseconds (7 days). The default is 5000 milliseconds. If a response is not received from the monitored address within the amount of time defined in this field, the static route is removed from the routing table and replaced by the backup route. **Note** The timeout value cannot exceed the frequency value (adjust the frequency value to milliseconds to compare the numbers).
Data Size	Enter the size of the ICMP request packet payload, in bytes. Values range from 0 to 16384 bytes. The default is 28 bytes, which creates a total ICMP packet of 64 bytes. Do not set this value higher than the maximum allowed by the protocol or the Path Maximum Transmission Unit (PMTU). For purposes of reachability, you might need to increase the default data size to detect PMTU changes between the source and the target. A low PMTU can affect session performance and, if detected, might indicate that the secondary path should be used.
ToS	Enter a value for type of service (ToS) defined in the IP header of the ICMP request packet. Values range from 0 to 255. The default is 0. This field contains information such as delay, precedence, reliability, and so on. It can be used by other devices on the network for policy routing and features such as committed access rate.
Number of Packets	Enter the number of packets that are sent. Values range from 1 to 100. The default is 1 packet. **Note** Increase the default number of packets if you are concerned that packet loss might falsely cause the Secure Firewall Threat Defense device to believe that the monitored address cannot be reached.
Monitored Address	Enter the IP address that is being monitored for availability by the SLA operation.

Step 3 The **Available Zones** list displays both zones and interface groups. In the **Zones/Interfaces** list, add the zones or interface groups that contain the interfaces through which the device communicates with the management station. To specify a single interface, you need to create a zone or the interface groups for the interface; see Create security zone and interface group objects, on page 610. The host will be configured on a device only if the device includes the selected interfaces or zones.

Step 4 Click **Save**.

After completing these steps, the SLA monitor is configured and begins tracking the availability of the specified route. If the monitored address becomes unreachable, the route is removed from the routing table and replaced with a backup route.

Time ranges

A time range is a configuration object that

- defines specific time periods,
- enables use of these periods to determine when rules apply, and
- supports integration with time-based ACLs.

Time range objects allow you to specify periods for rule enforcement.

Note Time-based ACLs is supported in Snort 3 also from Firewall Management Center 7.0 onwards.

Create a time range object

Establish a time range object so policies apply only during specified periods, enabling precise control of network traffic.

If you want a policy to apply only during a specified time range, create a time range object and specify that object in the policy. This object works on Firewall Threat Defense devices only.

You can specify time range objects only in certain policy types, which are listed in this topic.

Note The timezone represents the device's local time and is used only for applying the time ranges in rules in the policies that support the time ranges. The timezone does not change the configured time of the device. To verify the configuration, in the Firewall Threat Defense CLI, use the **show time-range timezone** and **show time** commands (see the *Cisco Secure Firewall Threat Defense Command Reference* guide). In addition, the timezone of a chassis overrides the management center timezone.

Before you begin

Time ranges operate based on the time zone associated with the device that processes the traffic. By default, this is UTC. To change the time zone associated with a device, go to **Devices** > **Platform Settings**.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Time Range** from the list of object types.

Step 2 Click **Add Time Range**.

Step 3 Enter the object name and specify the desired time periods.

- If you see a red error box around the object name you have entered, mouse over the **Name** field to see naming restrictions.
- All times are in UTC, unless you specify a time zone for the device in **Devices** > **Platform Settings**.

- Enter times using a 24-hour clock; for example, enter 13:30 for 1:30 PM.
- To specify a single continuous range, such as typical weekend hours (Fridays at 5pm through Mondays at 8am, including evenings and nights), choose Range Type **Range**.
- To specify part of multiple days, such as Monday through Friday from 8am to 5pm (excluding evenings, nights, and early mornings every day), choose Range Type **Daily Interval**.
- You may specify up to 28 periods per object.
- For multiple noncontiguous times of day or different hours for different days, create multiple recurring intervals. For example, to apply a policy at all times other than standard working hours, create a single time range object with the following two recurring intervals:
  - A Daily Interval for Monday through Friday from 5pm through 8am, and
  - A Range recurring interval for Friday at 5pm through Monday at 8am.

Step 4 Click **Save**.

What to do next

Configure time ranges in any of these:

- Access control rules
- Prefilter rules
- Tunnel rules
- VPN group policy

In a VPN group policy object, specify the time range object using the **Access Hours** field. For details, see Configure a group policy object, on page 2461 and Advanced group policy option fields and values, on page 2467.

Time zones

A time zone is a configuration object that

- specifies the local time zone for a managed device
- is used only for applying time ranges in rules in policies that support time ranges, such as access control, prefilter, and VPN group policies), and
- defaults to UTC if not assigned to a device.

Device support and usage of time zones

- Time zone objects are supported only for Firewall Threat Defense devices.
- Time-based ACLs is supported in Snort 3 also from Firewall Management Center 7.0 onwards.

Tunnel zones

A tunnel zone is a network object that

- represents certain types of plaintext, passthrough tunnels that you explicitly tag for special analysis,
- is not an interface object, and
- can be used as an interface constraint in some configurations.

For detailed information, see Using tunnel zones to apply access control at the tunnel level, on page 1970.

URLs

A URL object is a configuration element that

- defines a single URL or IP address for use within access control policies, event searches, and Security Intelligence configurations,
- can be used in multiple locations throughout the system's web interface to specify what traffic is filtered or monitored, and
- provides distinct matching behavior compared to URL group objects, which define multiple URLs or addresses.

URL object configuration guidelines

Important For best practices for using this and similar options in Security Intelligence configurations and for URL rules in access control and QoS policies, see Manual URL filtering options, on page 1668.

When creating URL objects, consider the following guidelines:

- If the URL does not include a path (no / characters), the match is based only on the server's hostname. If a path is included (one or more / characters), the entire URL string is used for a substring match.
- A URL is considered a match if:
  - the string appears at the beginning of the URL,
  - the string follows a dot,
  - the string contains a dot at the beginning,
  - or the string follows the :// characters.
- The system ignores the encryption protocol (HTTP or HTTPS). Blocking a website applies to both unless an application condition targets a specific protocol. Specify URLs without the protocol (use example.com, not http://example.com).
- To match HTTPS traffic in access control rules, use the subject common name from the public key certificate. Do not include subdomain information. The subject common name in certificates may differ

from the web site's domain (for example, youtube.com uses *.google.com). Use SSL Decryption policy to decrypt HTTPS traffic for consistent URL filtering results.

- URL objects will not match HTTPS traffic if the browser resumes a TLS session, as certificate information may not be available, which can lead to inconsistent results.
- When using URL objects as aliases in remote access VPN policies, ensure the URL is 128 characters or less.
- Do not use manual URL filtering to block or allow individual web pages or parts of sites (that is, URL strings with / characters), as servers can be reorganized and pages moved to new paths.

URL object matching examples

For example, ign.com matches ign.com or www.ign.com, but not versign.com. Use example.com rather than http://example.com when specifying a URL object.

Create a URL object

Use this task when you need to define a new URL object in the Secure Firewall Management Center for use in access control or other security policies.

Procedure

Step 1 Choose **Objects** > **Object Management** > **URL** from the list of object types.

Step 2 Choose **Add Object** from the **Add URL** drop-down list.

Step 3 Enter a **Name**.

Step 4 (Optional) Enter a **Description**.

Step 5 Enter the **URL** or IP address.

Step 6 (Optional) Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2344.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Variable sets

A variable set is a configuration group that

- collects and manages variables used in intrusion rules and policies
- allows customization of predefined and user-defined variables, and
- enables linking of variable sets to intrusion policies for flexible network security management.

Variable set management and usage

Variables represent values commonly used in intrusion rules to identify source and destination IP addresses and PORTS. You can also use variables in intrusion policies to represent IP addresses in rule suppressions, adaptive profile updates, and dynamic rule states.

Tip Preprocessor rules can trigger events regardless of the hosts defined by network variables used in intrusion rules.

You use variable sets to manage, customize, and group your variables. You can use the default variable set provided by the system or create your own custom sets. Within any set you can modify predefined default variables and add and modify user-defined variables.

Most of the shared object rules and standard text rules that the system provides use predefined default variables to define networks and port numbers. For example, the majority of the rules use the variable `$HOME_NET` to specify the protected network and the variable `$EXTERNAL_NET` to specify the unprotected (or outside) network. In addition, specialized rules often use other predefined variables. For example, rules that detect exploits against web SERVERS use the `$HTTP_SERVERS` and `$HTTP_PORTS` variables.

Rules are more effective when variables more accurately reflect your network environment. At a minimum, you should modify default variables in the default set. By ensuring that a variable such as `$HOME_NET` correctly defines your network and `$HTTP_SERVERS` includes all web SERVERS on your network, processing is optimized and all relevant systems are monitored for suspicious activity.

To use your variables, you link variable sets to intrusion policies associated with access control rules or with the default action of an access control policy. By default, the default variable set is linked to all intrusion policies used by access control policies.

Adding a variable to any set adds it to all sets; that is, each variable set is a collection of all variables currently configured on your system. Within any variable set, you can add user-defined variables and customize the value of any variable.

Initially, the system provides a single, default variable set comprised of predefined default values. Each variable in the default set is initially set to its default value, which for a predefined variable is the value set by the Talos Intelligence Group and provided in rule updates.

Although you can leave predefined default variables configured to their default values, Cisco recommends that you modify a subset of predefined variables.

You could work with variables only in the default set, but in many cases you can benefit most by adding one or more custom sets, configuring different variable values in different sets, and perhaps even adding new variables.

When using multiple sets, it is important to remember that the *current value* of any variable in the default set determines the *default value* of the variable in all other sets.

When you select **Variable Sets** on the Object Manager page, the object manager lists the default variable set and any custom sets you created.

On a freshly installed system, the default variable set is comprised only of the default variables predefined by Cisco.

Each variable set includes the default variables provided by the system and all custom variables you have added from any variable set. Note that you can edit the default set, but you cannot rename or delete the default set.

Caution Importing an access control or an intrusion policy overwrites existing default variables in the default variable set with the imported default variables. If your existing default variable set contains a custom variable not present in the imported default variable set, the unique variable is preserved.

Variable sets in intrusion policies

A variable set is a configuration group that

- links to intrusion policies used in an access control policy,
- provides variable values for enabled intrusion rules, and
- affects deployment status when modified.

Deployment status for variable sets in intrusion policies

By default, the system links the default variable set to all intrusion policies used in an access control policy. When you deploy an access control policy that uses an intrusion policy, intrusion rules that you have enabled in the intrusion policy use the variable values in the linked variable set.

When you modify a custom variable set used by an intrusion policy in an access control policy, the system reflects the status for that policy as out-of-date on the Access Control Policy page. You must re-deploy the access control policy to implement changes in your variable set. When you modify the default set, the system reflects the status of all access control policies that use intrusion policies as out-of-date, and you must re-deploy all access control policies to implement your changes.

Variables

A variable is a configuration element that

- can be provided by the system or created by users
- is categorized as default, customized, or advanced, and
- enables flexible management of network addresses and ports in rule creation.

Variable categories

Variables are grouped into three categories: default, customized, and advanced.

- **Default variables** are provided by the system. You cannot rename or delete a default variable, and you cannot change its default value. However, you can create a customized version of a default variable.
- **Customized variables** are variables you create. These variables can include:
  - *customized default variables*

    When you edit the value for a default variable, the system moves the variable from the Default Variables area to the Customized Variables area. Variable values in the default set determine the default values of variables in custom sets. If you customize a default variable in the default set, the system changes the default value of the variable in all other sets.
  - *user-defined variables*

    You can add and delete your own variables, customize their values within different variable sets, and reset customized variables to their default values. When you reset a user-defined variable, it remains in the Customized Variables area.

    User-defined variables can be one of these types:
    - *network* variables specify the IP addresses of hosts in your network traffic.
    - *port* variables specify TCP or UDP ports in network traffic, including the value `any` for either type.
- **Advanced variables** are provided by the system under specific conditions. These variables have a very limited deployment.

Variable usage examples

For example, if you create custom standard text rules, you might also want to add your own user-defined variables to more accurately reflect your traffic or as shortcuts to simplify the rule creation process. Alternatively, if you create a rule that you want to inspect traffic in the "demilitarized zone" (or DMZ) only, you can create a variable named `$DMZ` whose value lists the server IP addresses that are exposed. You can then use the `$DMZ` variable in any rule written for this zone.

List predefined default variables

By default, the system provides a single default variable set, which is comprised of predefined default variables. The Talos Intelligence Group uses rule updates to provide new and updated intrusion rules and other intrusion policy elements, including default variables. Because many intrusion rules from the system use predefined default variables, set appropriate values for these variables. You can modify the values for these default variables in any or all variable sets, depending on how you use variable sets to identify traffic on your network.

Caution Importing an access control or an intrusion policy overwrites existing default variables in the default variable set with the imported default variables. If your existing default variable set contains a custom variable not present in the imported default variable set, the unique variable is preserved.

This table describes the variables provided by the system and indicates which variables you typically would modify. For assistance determining how to tailor variables to your network, contact Professional Services or Support.

Table 155: System-Provided variables

Variable Name	Description	Modify?
`$AIM_SERVERS`	Defines known AOL Instant Messenger (AIM) SERVERS, and is used in chat-based rules and rules that look for AIM exploits.	Not required.
`$DNS_SERVERS`	Defines Domain Name Service (DNS) SERVERS. If you create a rule that affects DNS SERVERS specifically, you can use the `$DNS_SERVERS` variable as a destination or source IP address.	Not required in current r
`$EXTERNAL_NET`	Defines the network that the system views as the unprotected network, and is used in many rules to define the EXTERNAL network.	Yes, you should adequat `$HOME_NET` and then excl `$HOME_NET` as the value f `$EXTERNAL_NET`.
`$FILE_DATA_PORTS`	Defines non-encrypted ports used in intrusion rules that detect files in a network stream.	Not required.
`$FTP_PORTS`	Defines the ports of FTP SERVERS on your network, and is used for FTP server exploit rules.	Yes, if your FTP SERVE ports other than the defa (you can view the defaul the web interface).
`$GTP_PORTS`	Defines the data channel ports where the packet decoder extracts the payload inside a GTP (General Packet Radio Service [GPRS] Tunneling Protocol) PDU.	Not required.
`$HOME_NET`	Defines the network that the associated intrusion policy monitors, and is used in many rules to define the internal network.	Yes, to include the IP add your internal network.
`$HTTP_PORTS`	Defines the ports of web SERVERS on your network, and is used for web server exploit rules.	Yes, if your web SERVE ports other than the defa (you can view the defaul the web interface).
`$HTTP_SERVERS`	Defines the web SERVERS on your network. Used in web server exploit rules.	Yes, if you run HTTP SE
`$ORACLE_PORTS`	Defines Oracle database server ports on your network, and is used in rules that scan for attacks on Oracle databases.	Yes, if you run Oracle SI
`$SHELLCODE_PORTS`	Defines the ports you want the system to scan for shell code exploits, and is used in rules that detect exploits that use shell code.	Not required.
`$SIP_PORTS`	Defines the ports of SIP SERVERS on your network, and is used for SIP exploit rules.	Not required.

Variable Name	Description	Modify?
$SIP_SERVERS	Defines SIP SERVERS on your network, and is used in rules that address SIP-targeted exploits.	Yes, if you run SIP SI should adequately de $HOME_NET and then i $HOME_NET as the val $SIP_SERVERS.
$SMTP_SERVERS	Defines SMTP SERVERS on your network, and is used in rules that address exploits that target mail SERVERS.	Yes, if you run SMTI
$SNMP_SERVERS	Defines SNMP SERVERS on your network, and is used in rules that scan for attacks on SNMP SERVERS.	Yes, if you run SNM
$SNORT_BPF	Identifies a legacy advanced variable that appears only when it existed on your system in a software release before Version 5.3.0 that you subsequently upgraded to Version 5.3.0 or greater.	No, you can only view variable. You cannot recover it after deleti
$SQL_SERVERS	Defines database SERVERS on your network, and is used in rules that address database-targeted exploits.	Yes, if you run SQL S
$SSH_PORTS	Defines the ports of SSH SERVERS on your network, and is used for SSH server exploit rules.	Yes, if your SSH SEI ports other than the d (you can view the de the web interface).
$SSH_SERVERS	Defines SSH SERVERS on your network, and is used in rules that address SSH-targeted exploits.	Yes, if you run SSH S you should adequatel $HOME_NET and then i $HOME_NET as the val $SSH_SERVERS.
$TELNET_SERVERS	Defines known Telnet SERVERS on your network, and is used in rules that address Telnet server-targeted exploits.	Yes, if you run Telne
$USER_CONF	Provides a general tool that allows you to configure one or more features not otherwise available via the web interface. Conflicting or duplicate $USER_CONF configurations will halt the system.	No, only as instructed description or with th Support.

Network variables

A network variable is a configuration element that

- represents IP addresses for use in intrusion rules, intrusion policy rule suppressions, dynamic rule states, and adaptive profile updates
- differs from network objects and network object groups by being specific to intrusion policies and intrusion rules, and
- enables specification of host IP addresses in various configurations within an intrusion policy.

Network variable usage and configuration

Network variables can be used to specify the IP addresses of hosts on the network in the following configurations:

- Intrusion rules: The **Source IPs** and **Destination IPs** fields restrict packet inspection to traffic originating from or destined to specific IP addresses.
- Suppressions: The **Network** field in source or destination intrusion rule suppressions suppresses intrusion event notifications when a specific IP address or range triggers an intrusion rule or preprocessor.
- Dynamic rule states: The **Network** field in dynamic rule states identifies when too many matches for an intrusion rule or preprocessor occur within a given time period.
- adaptive profile updates: The**Networks** field identifies hosts where packet fragment and TCP stream reassembly is improved in passive deployments.

When variables are used in these fields, the variable set linked to an intrusion policy determines the variable values applied to network traffic handled by the related access control policy.

A variable can include any combination of the following network configurations:

- network variables, network objects, and network object groups selected from the available networks list,
- individual network objects added from the New or Edit Variable page, which can then be used in variables or other configurations,
- literal single IP addresses or address blocks; multiple literal IP addresses and address blocks may be included individually, supporting both IPv4 and IPv6 addresses.

  When specifying IPv6 addresses, any addressing convention defined in RFC 4291 may be used.

The default value for included networks in any variable is `any`, which indicates any IPv4 or IPv6 address. The default value for excluded networks is `none`, meaning no network. If you specify the address `::`, it means any IPv6 address when included, or no IPv6 addresses when excluded.

Adding networks to the excluded list negates those addresses and blocks; all addresses except the excluded ones can be matched.

For example, excluding `192.168.1.1` specifies any IP address other than 192.168.1.1. Excluding `2001:db8:ca2e::fa4c`specifies any IP address except 2001:db8:ca2e::fa4c.

Exclusions can be made with any combination of literal or available networks. For instance, excluding both `192.168.1.1` and `192.168.1.5` matches any IP address other than 192.168.1.1 or 192.168.1.5.

Keep these points in mind when you add or edit network variables:

- The value `any` cannot be logically excluded, as it would mean no address; for example, it is not possible to add a variable with the value `any` to the exclusion list.
- Network variables identify traffic for specific intrusion rule and intrusion policy features; preprocessor rules can trigger events regardless of the hosts defined by network variables.
- Excluded values must resolve to a subset of included values; for example, including the address block 192.168.5.0/24 and excluding 192.168.6.0/24 is not valid.

Port variables

A port variable is a network configuration element that

- represents TCP and UDP ports you can use in the **Source Port** and **Destination Port** header fields in intrusion rules,
- is specific to intrusion rules and differs from port objects and port object groups, and
- can be used to restrict packet inspection to packets originating from or destined to specific TCP or UDP ports.

Port variable configuration details

Port variables are linked to intrusion policies associated with access control rules or policies, determining the values for these variables in the network traffic where you deploy the access control policy.

When configuring a port variable, you can include:

- any combination of port variables and port objects that you select from the list of available ports (excluding port object groups, which cannot be added to variables),
- individual port objects that you add while creating or editing a variable, which can also be reused for other variables,
- and single literal port values as well as port ranges (ranges must use a dash, e.g., 80-90; colon-separated ranges are supported for backward compatibility but not for new variables).

  You can list multiple literal port values and ranges by adding each individually in any combination.

Port variable configuration has these important considerations:

- The default value for included ports in any variable is `any`, indicating all ports or port ranges. The default for excluded ports is `none`, indicating no ports.

Tip To create a variable with the value `any`, name and save the variable without adding a specific value.

- You cannot exclude the value `any` from a variable, as that would result in no ports being matched.
- Adding ports to an excluded list prevents matching on those specified ports or port ranges. The system matches any port except those excluded.
- Excluded values must be a subset of the included values. For example, if you include the port range 10-50, you cannot exclude port 60.

Advanced variables

An advanced variable is a configuration mechanism that

- enables you configure of features not available through the web interface
- includes the USER_CONF variable as your primary advanced variable, and
- allows you to enter custom instructions or lines up to the maximum character length.

User_CONF variable details

The USER_CONF variable provides a general tool that allows configuration of one or more features not otherwise available via the web interface.

Caution Do **not** use the advanced variable USER_CONF to configure an intrusion policy feature unless you are instructed to do so in the feature description or by Support. Conflicting or duplicate configurations will halt the system.

When editing USER_CONF, you can type up to 4096 characters on a single line. The line wraps automatically. You can include any number of valid instructions or lines until you reach either the 8192-character maximum length for a variable or a physical limit, such as disk space. Use the backslash (\) character as a line continuation after any complete argument in a command directive.

Resetting USER_CONF empties it.

Variable resets

A variable reset is a configuration action that

- returns a variable to its default value on the variable set new or edit variables page,
- applies different reset behaviors depending on whether the variable is in a default or custom set, and
- affects the value used in any intrusion policy where the variable set is linked.

Variable reset values

You can reset a variable to its default value on the variable set new or edit variables page. This table summarizes the basic principles of resetting variables.

Table 156: Variable reset values

Resetting this variable type...	In this set type...	Resets it to...
default	default	the rule update value
user-defined	default	`any`
default or user-defined	custom	the current default set value (modified or unmodified)

When you reset a variable in a custom set, you return it to the current value for that variable in the default set.

If you reset or change a variable in the default set, you update the default value in all custom sets. If the reset icon is unavailable, you cannot reset the variable because it has no customized value in the set. If you have not customized the variable in a custom set, changing it in the default set also updates any intrusion policy where you have linked the variable set.

Note Before you modify a variable in the default set, check how this change affects any intrusion policy that uses the variable in a linked custom set, especially if you have not customized the variable value in the custom set.

You can hover your pointer over the **Reset** icon in a variable set to see the reset value. If the customized value and the reset value match, you are in one of these situations:

- you are in the custom or default set where you added the variable with the value `any`.
- you are in the custom set where you added the variable with an explicit value and elected to use the configured value as the default value.

Variable sets

A variable set is a configuration grouping that

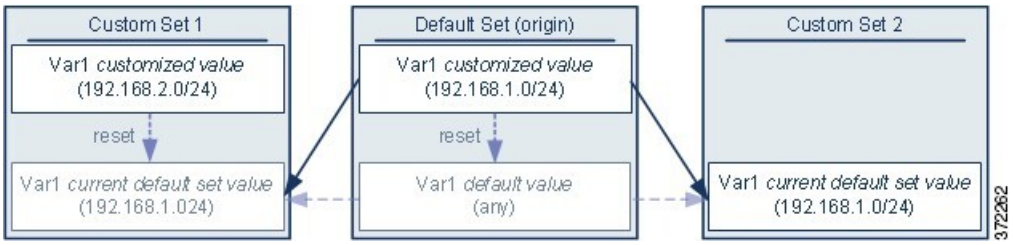
- allows variables to be managed collectively across multiple sets
- enables the addition of variables to all sets simultaneously, and
- provides options for using configured or default values when adding variables.

Variable set behavior

When you add a variable to a variable set, it is also added to all other sets. If you add a variable from a custom set, decide if you want to use the configured value as the customized value in the default set.

- **If you use the configured value** (for example, 192.168.0.0/16), the variable is added to the default set using the configured value as a customized value with a default value of `any`. The current value in the default set determines the default value in other sets. Therefore, the initial default value in other custom sets is the configured value (which in this example is 192.168.0.0/16).
- **If you do not use the configured value**, the variable is added to the default set using only the default value `any` and, consequently, the initial, default value in other custom sets is `any`.

Examples: Adding user-defined variables to default sets



A user-defined variable addition is a configuration action that

- enables adding a variable, such as Var1, to a default set with a specific value (like 192.168.1.0/24),
- allows customization of the variable value in any set, and
- ensures that resetting the variable in the default set resets its default value to `any` across all sets.

Set interactions and variable customization

The diagram below illustrates how adding and customizing user-defined variables affects default and custom sets.

Figure 426: Set interaction diagram

Customizing the value of `Var1` in a custom set overrides the default value. For example, if `Var1` is customized in `Custom Set 1`, it takes on a new value, while in `Custom Set 2`, if `Var1` is not customized, it retains the default value (e.g., `192.168.1.0/24`). Resetting the user-defined variable in the default set updates its default value to `any` in all sets.

Further, when `Var1` in `Custom Set 2` is not updated, customizing or resetting `Var1` in the default set updates its current value in `Custom Set 2`, affecting any intrusion policy linked to the variable set.

Note While the interactions are the same for user-defined variables and default variables, resetting a default variable in the default set resets it to the value configured by Cisco in the current rule update, not `any`.

Customizing user-defined variable values

In Custom Set 1, the customized value `192.168.2.0/24` of `Var1` overrides the default value, while in Custom Set 2, `Var1` retains the default value `192.168.1.0/24` unless customized.

Resetting default variables in default sets

Although not shown in the example, note that interactions between sets are the same for user-defined variables and default variables except that resetting a default variable in the default set resets it to the value configured by Cisco in the current rule update.

Examples: User-defined variables in custom sets

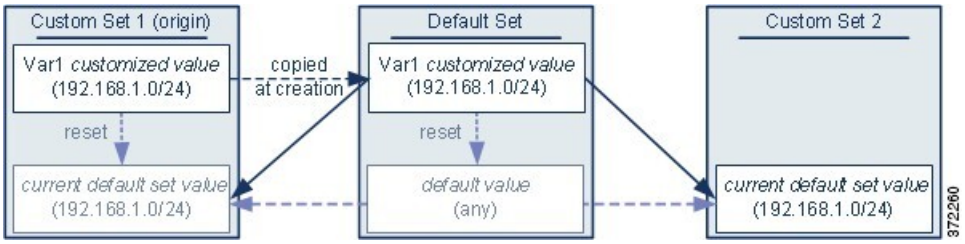
A user-defined variable in a custom set is a configuration element that:

- enables you to add variables to custom sets,
- allows you to choose whether the configured value becomes the default for other sets, and
- affects how variable values and interactions propagate across sets.

Variable set interactions and default value behavior

When you add a user-defined variable to a custom set, you are prompted to decide if the configured value should be used as the default value for other sets. The examples illustrate the outcomes of each choice.

- Choosing to use the configured value as the default copies the value to the default set as a customized value, with a default value of `any`.



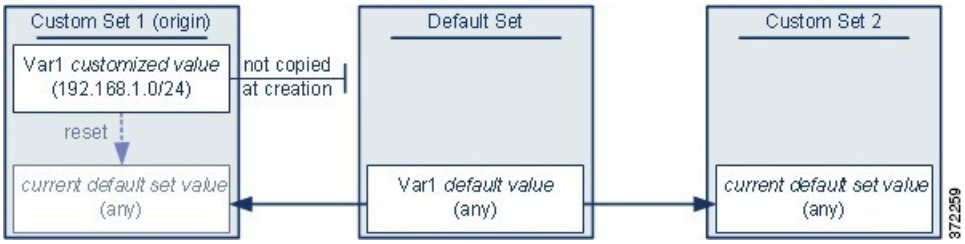
- Choosing not to use the configured value as the default adds the variable to all sets with a default value of `any`, allowing customization in any set.

Note Further customizing or resetting a variable in the default set updates the current, default value in other sets, which can affect any intrusion policy linked to the variable set.

Examples of adding user-defined variables to custom sets

The first example shows adding `Var1` with the value `192.168.1.0/24` to Custom Set 1 and electing **to use** the configured value as the default for other sets.

Figure 427: Variable set interaction when using the configured value as default



Except for the origin of `Var1` from Custom Set 1, this example is identical to adding `Var1` to the default set. Adding the customized value `192.168.1.0/24` for `Var1` to Custom Set 1 copies the value to the default set as a customized value with a default value of `any`. Thereafter, `Var1` values and interactions are the same as if you had added `Var1` to the default set. Further customizing or resetting `Var1` in the default set updates the current, default value of `Var1` in Custom Set 2, affecting any intrusion policy linked to the variable set.

Adding a variable and not using the configured value as default

The second example shows adding `Var1` with the value `192.168.1.0/24` to `Custom Set 1`, but electing **not to use** the configured value as the default in other sets.

Figure 428: Variable set interaction when not using the configured value as default

This approach adds `Var1` to all sets with a default value of `any`. After adding `Var1`, you can customize its value in any set. An advantage of this approach is that, by not initially customizing `Var1` in the default set, you decrease your risk of customizing the value in the default set and inadvertently changing the current value in a set such as Custom Set 2 where you have not customized `Var1`.

Nesting variables

A nesting variable is a configuration element that

- can include other variables as part of its definition
- does not support circular nesting, and
- does not support nested, negated variables.

Valid nested variables

In this example, SMTP_SERVERS, HTTP_SERVERS, and OTHER_SERVERS are valid nested variables.

Variable	Type	Included Networks	Excluded Networks
SMTP_SERVERS	customized default	10.1.1.1	—
HTTP_SERVERS	customized default	10.1.1.2	—
OTHER_SERVERS	user-defined	10.2.2.0/24	—
HOME_NET	customized default	10.1.1.0/24 OTHER_SERVERS	SMTP_SERVERS HTTP_SERVERS

Invalid nested variable

In this example, HOME_NET is an invalid nested variable because the nesting of HOME_NET is circular; that is, the definition of OTHER_SERVERS includes HOME_NET, so you would be nesting HOME_NET in itself.

Variable	Type	Included Networks	Excluded Networks
SMTP_SERVERS	customized default	10.1.1.1	—
HTTP_SERVERS	customized default	10.1.1.2	—
OTHER_SERVERS	user-defined	10.2.2.0/24 HOME_NET	—
HOME_NET	customized default	10.1.1.0/24 OTHER_SERVERS	SMTP_SERVERS HTTP_SERVERS

Unsupported nested, negated variable

Because nested, negated variables are not supported, do not use the variable NONCORE_NET to represent IP addresses outside your protected networks.

Variable	Type	Included Networks	Excluded Networks
HOME_NET	customized default	10.1.0.0/16 10.2.0.0/16 10.3.0.0/16	—
EXTERNAL_NET	customized default	—	HOME_NET
DMZ_NET	user-defined	10.4.0.0/16	—
NOT_DMZ_NET	user-defined	—	DMZ_NET
NONCORE_NET	user-defined	EXTERNAL_NET NOT_DMZ_NET	—

Alternative to unsupported nested, negated variable

As an alternative to the example above, you could represent IP addresses that are outside of your protected networks by creating the variable NONCORE_NET to represent IP addresses outside your protected networks.

Variable	Type	Included Networks	Excluded Networks
HOME_NET	customized default	10.1.0.0/16 10.2.0.0/16 10.3.0.0/16	—
DMZ_NET	user-defined	10.4.0.0/16	—
NONCORE_NET	user-defined	—	HOME_NET DMZ_NET

Manage variable sets

Manage variable sets to organize and control the variables used by your devices. This task helps you add, edit, delete, or filter variable sets as needed for device configuration.

Variable sets are used to efficiently manage collections of variables crucial for device configuration. To use variable sets, you must have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Procedure

Step 1 Choose **Objects** > **Object Management** > **Variable Set**.

Step 2 Manage your variable sets:

- Add — If you want to add a custom variable set, click **Add Variable Set**; see Create a variable set, on page 2452.
- Delete — If you want to delete a custom variable set, click **Delete** ( ) next to the variable set, then click **Yes**. You cannot delete the default variable set or variable sets belonging to ancestor domains.

Note Variables created in a variable set you delete are not deleted or otherwise affected in other sets.

- Edit — If you want to edit a variable set, click **Edit** ( ) next to the variable set you want to modify; see Edit objects, on page 2337.
- Filter — If you want to filter variable sets by name, begin entering a name; as you type, the page refreshes to display matching names. If you want to clear name filtering, click **Clear** ( ) in the filter field.
- Manage Variables — To manage the variables included in variable sets, see Manage variables, on page 2452.

Create a variable set

Variable sets allow you to define and group variables for use in Secure Firewall Management Center. Use this task when you need to create a new set of variables for policy configuration or reuse.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Variable Set**.

Step 2 Click **Add Variable Set**.

Step 3 Enter a **Name**.

Step 4 (Optional) Enter a **Description**.

Step 5 Manage the variables in the set; see Manage variables, on page 2452.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Manage variables

Configure variable sets to control device policies and manage variables for Secure Firewall Management Center.

- You can display, add, delete, edit, or reset variables as required for your environment.

To manage variables in Secure Firewall Management Center, you must have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Procedure

Step 1 Choose **Objects** > **Object Management** > **Variable Set**.

Step 2 Click **Edit** ( ) next to the variable set you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Manage your variables:

- Display — If you want to display the complete value for a variable, hover your pointer over the value in the **Value** column next to the variable.
- Add — If you want to add a variable, click **Add**; see Add variables, on page 2454.
- Delete — Click **Delete** ( ) next to the variable. If you have saved the variable set since adding the variable, click **Yes** to confirm that you want to delete the variable.

  You *cannot* delete these:

  - default variables
  - user-defined variables that are used by intrusion rules or other variables
  - variables belonging to ancestor domains

- Edit — Click **Edit** ( ) next to the variable you want to edit; see Edit variables values in a variable set, on page 2455.
- Reset — If you want to reset a modified variable to its default value, click **Reset** next to a modified variable. If reset is dimmed, one of these is true:
  - The current value is already the default value.
  - The configuration belongs to an ancestor domain.

Tip Hover your pointer over an active reset to display the default value.

Step 4 Click **Save** to save the variable set. If the variable set is in use by an access control policy, click **Yes** to confirm that you want to save your changes.

The current value in the default set determines the default value in all other sets. If you modify or reset a variable in the default set, the current value changes in other sets where you have not customized the default value.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Add variables

Add variables to a variable set so you can define reusable network or port values for use in policies.

Use variables in device policies to enable flexible, reusable configurations that simplify network management.

Before you begin

Ensure you have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Procedure

Step 1 In the variable set editor, click **Add**.

Step 2 Enter a unique variable **Name**.

Step 3 From the **Type** drop-down list, choose either **Network** or **Port**.

Step 4 Define the values for the variable:

- To include or exclude specific networks or ports, select them and click **Include** or **Exclude**. If there is overlap, excluded addresses or ports always take precedence over included ones.
- To add literal values, enter a single IP address, address block, port, or port range. If you need to add more than one value, repeat this action.
- To remove any items from included or excluded lists, select the item and click **Delete** ( ) next to the item.
- You may use a combination of literal values, existing variables, objects, or network object groups when specifying included or excluded items for network variables.

Step 5 Save the variable.

- If adding a new variable from a custom set, choose whether to add it as a customized value in the default set or as a default value of `any` in the default and other custom sets.

Step 6 Save the variable set.

- Any access control policy linked to the variable set will display an out-of-date status until changes are deployed.

The variable is added to the variable set and is available for use in policies. Any access control policy linked to the variable set displays an out-of-date status until you deploy the changes.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

Edit variables values in a variable set

You must have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

You can edit both custom and default variables.

You cannot change the **Name** or **Type** values in an existing variable.

Procedure

Step 1 In the variable set editor, click **Edit** ( ) next to the variable you want to modify.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 2 Modify the variable:

- If you want to move items from the list of available networks or ports to the list of included or excluded items, you can select one or more items and then drag and drop, or click **Include** or **Exclude**.

Tip If addresses or ports overlap between the included and excluded lists for a network or port variable, the excluded addresses or ports take precedence.

- Enter a single literal value, then click **Add**. For network variables, you can enter a single IP address or address block. For port variables, you can add a single port or port range, separating the upper and lower values with a hyphen (-). Repeat this step as needed to enter multiple literal values.
- If you want to remove an item from the included or excluded lists, click **Delete** ( ) next to the item.

Note The list of items to include or exclude can be comprised of any combination of literal strings and existing variables, objects, and network object groups in the case of network variables.

Step 3 Click **Save** to save the variable.

Step 4 Click **Save** to save the variable set. If the variable set is in use by an access control policy, click **Yes** to confirm that you want to save your changes. Your changes are saved, and any access control policy the variable set is linked to displays an out-of-date status.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

VLAN tags

A VLAN tag is a network identifier that

- represents a single VLAN or a range of VLAN tags,
- can be grouped with other VLAN tag objects to create tag groups, and

VLAN tag usage

You can use VLAN tag objects and groups in various places in the system's web interface, such as rules and event searches. For example, you could write an access control rule that applies only to a specific VLAN.

Create a VLAN tag object

Use this task when you need to add or manage VLAN tag objects in your Secure Firewall Management Center. VLAN tag objects are referenced in access control and other policies to match specific VLAN tags or ranges.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VLAN Tag**.

Step 2 Choose **Add Object** from the **Add VLAN Tag** drop-down list.

Step 3 Enter a **Name**.

Step 4 Enter a **Description**.

Step 5 Enter a value in the **VLAN Tag** field. Use a hyphen to specify a range of VLAN tags.

Step 6 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2344.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2344.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy configuration changes, on page 135.

VPN

You can use the following VPN objects on Firewall Threat Defense devices. To use these objects, you must have Admin privileges, and your Smart License account must satisfy export controls. You can configure these objects in leaf domains only.

Certificate map objects

A certificate map object is a configuration element that

- contains a named set of certificate matching rules,
- associates a received certificate with a remote access VPN connection profile, and
- matches rules in priority order, ending when the first rule results in a match.

Certificate map object reference information

Remote access VPN policies use certificate map objects to map certificates to connection profiles. If a received certificate matches the rules in a certificate map, the system associates the connection with the specified profile.

Both certificate map objects and connection profiles are components of a remote access VPN policy.

- The rules are matched in the order shown in the UI.
- Matching ends when the first rule within the certificate map object results in a match.

Navigation path for certificate map objects:

- **Objects** > **Object Management** > **VPN** > **Certificate Map**

Fields in certificate map objects:

- **Name**: Identifies this object so it can be referred to from other configurations, such as remote access VPN.
- **Mapping criteria**: Specifies the contents of the certificate to evaluate. If the certificate satisfies these rules, the user is mapped to the connection profile containing this object.
  - **Field**: Select the field for the matching rule according to the subject or issuer of the client certificate.

    If you set the **Field** to *Alternative Subject* or *Extended Key Usage*, the component remains fixed as *Whole Field*.
  - **Component**: Select the component of the client certificate to use for the matching rule.

Note **SER (Serial Number) component**: Ensure you specify the serial number for the subject field. The certificate map only matches with a serial number attribute in the subject name.

  - **Operator**: Select the operator for the matching rule:
    - Equals: The certificate component must match the entered value. If they do not match exactly, the connection is denied.
    - Contains: The certificate component must contain the entered value. If the component does not contain the value, the connection is denied.

- Does not equal: The certificate component cannot equal the entered value. For example, for a selected certificate component of country and an entered value of US, if the client country value equals US, then the connection is denied.
- Does not contain: The certificate component cannot contain the entered value. For example, for a selected certificate component of country and an entered value of US, if the client country value contains US, the connection is denied.

- **Value**: The value of the matching rule. The value entered is associated with the selected component and operator.

Configure Certificate Maps, on page 1460

Secure Client custom attributes objects

Custom attributes objects enable Secure Client (formerly AnyConnect) to configure features such as Per App VPN, allow or defer upgrade, and dynamic split tunneling. You define the attribute type, then assign one or more named values for this type. In Secure Firewall Management Center, you create custom attributes objects, add them to a group policy, and associate the policy with a remote access VPN to enable features for VPN clients.

Supported features using custom attributes objects

Firewall Threat Defense supports these features using custom attribute objects:

- **Per App VPN**—You can specify which applications may use the VPN tunnel. The system identifies these apps and tunnels only the allowed applications.
- **Allow or defer upgrade**—You can delay downloading Secure Client updates. When a client update becomes available, you can prompt users to upgrade or defer the update.
- **Dynamic Split Tunneling**—You can configure policies to selectively include or exclude IP addresses or networks from the VPN tunnel. Create a custom attribute and add it to a group policy to achieve this.

For step-by-step instructions to configure Secure Client custom attributes, see Configure custom attributes for Secure Client, on page 2458.

For details about the specific custom attributes to configure for a feature, see the *Cisco Secure Client (including AnyConnect) Administrator Guide* for the Secure Client release you are using.

Configure custom attributes for Secure Client

Use this task when you need to configure custom attributes for Secure Client clients, such as Per App VPN, update deferment, or dynamic split tunneling, in Secure Firewall Management Center.

This is relevant for environments where device management and application-specific VPN rules are required, and when deploying secure client features that depend on custom attribute objects.

Applicable when integrating MDM-enrolled devices and advanced VPN features.

Before you begin

Ensure that you have done these steps before adding a custom attribute object for Per App VPN:

- Per App VPN must be properly configured via MDM and each device must be enrolled to the MDM server.
- Create a base64 encoded string for each app using the Cisco Secure Client Enterprise Application Selector Tool.
  1. Download the Cisco Secure Client Enterprise Application Selector Tool from here.
  2. Open the Application Selection Tool and select the mobile platform from the drop-down menu located on the upper left.
  3. Add rule by entering friendly name and App ID; the other fields are optional.
  4. On the menu bar, click **Policy**. The encoded base64 rule appears.
  5. Select and copy the policy string, and save it to use later when you create the Secure Client Custom Attributes object.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **Custom Attribute**.

Step 2 Click **Secure Client Custom Attribute**.

Step 3 Enter a **Name** and optionally a **Description** for the attribute.

Step 4 Select an attribute from the **Secure Client Attribute** drop-down list:

- **Per App VPN**—Select this option and specify the base64 encoded string in the **Attribute Value** box.
- **Allow Defer Update**—Select one of these options and specify the required information to allow or defer Secure Client update:
  - **Show the prompt until user takes action**—Display the prompt to the VPN user until the user chooses to allow or defer the VPN client update.
  - **Show the prompt until times out**—Choose this option to display the prompt for a specified duration and specify the duration in the **Timeout** box.
  - **Do not show the prompt and take automatic action**—Choose this option to automatically allow or defer the VPN update.
  - **Default Action**—Select the default action to be taken when the user does not respond, or when you want to configure an automatic action without the user's intervention. You can choose to update the Secure Client or postpone the update.
  - **Minimum Version**—Specify the minimum Secure Client version to be present on the client system to allow or defer the update.
- **Dynamic Split Tunneling**—Select this option to include or exclude IP addresses or networks from the VPN tunnel.
  - **Include domains**—Specify domain names that will be included in the remote access VPN tunnel.
  - **Exclude domains**—Specify domain names that will be excluded from the remote access VPN tunnel.

Step 5 Select the **Allow Overrides** check box to enable object overrides.

Step 6 Click **Save**.
The custom attributes object is added to the list.

What to do next

Associate the custom attributes with a group policy. See Add custom attributes to your group policy, on page 2460.

Add custom attributes to your group policy

Add custom attributes to a group policy to enable their use with remote access VPN connections. You can assign advanced VPN features to users based on their group policy membership.

To use Secure Client custom attributes with remote access VPN connections, you must associate them with the appropriate group policy. This enables you to offer advanced VPN customization to users based on their group policy membership.

Procedure

Step 1 Select **Objects** > **Object Management** > **VPN** > **Group Policy**.

Step 2 Add a new group policy or edit an existing group policy.

Step 3 Click **Secure Client** > **Custom Attributes**.

Step 4 Click **Add**.

Step 5 Select the **Secure Client Attribute**: Per App VPN, Allow Defer Update, or Dynamic Split Tunneling.

Step 6 Select a **Custom Attribute Object** from the list.

Note Click Add (+) to create a new custom attribute object for the selected Secure Client attribute. You can also create a custom attribute object at **Objects** > **Object Management** > **VPN** > **Custom Attribute**. See Configure custom attributes for Secure Client, on page 2458.

Step 7 Click **Add** to save the attributes to the group policy, and then click **Save** to save the changes to the group policy.

Related Topics

Group policy options for Secure Client, on page 2464

Firewall Threat Defense group policy objects

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience. For example, in the group policy object, you configure general attributes such as addresses, protocols, and connection settings.

Group policy object assignment and licensing

The group policy applied to a user is determined when the VPN tunnel is established. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile.

Note There is no group policy attribute inheritance on the Firewall Threat Defense. A group policy object is used, in its entirety, for a user. The group policy object identified by the AAA server upon login is used, or, if that is not specified, the default group policy configured for the VPN connection is used. The provided default group policy can be set to your default values, but will only be used if it is assigned to a connection profile and no other group policy has been identified for the user.

To use group objects, you must have one of these Secure Client licenses associated with your Smart License account with Export-Controlled Features enabled:

- Secure Client VPN Only
- Secure Client Advantage
- Secure Client Premier

Configure a group policy object

Group policy objects are used to manage and enforce security and access policies for remote access VPN connections.

See Firewall Threat Defense group policy objects, on page 2460.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **Group Policy**.

Previously configured policies are listed including the system default. Depending on your level of access, you may edit, view, or delete a group policy.

Step 2 Click **Add Group Policy** or choose a current policy to edit.

Step 3 Enter a **Name** and optionally a **Description** for this policy.

The name can be up to 64 characters. Spaces are allowed. The description can be up to 1,024 characters.

Step 4 Specify the **General** parameters for this Group Policy as described in Group policy general options, on page 2462.

Step 5 Specify the **Secure Client** parameters for this Group Policy as described in Group policy options for Secure Client, on page 2464.

Step 6 Specify the **Advanced** parameters for this Group Policy as described in Advanced group policy option fields and values, on page 2467.

Step 7 Click **Save**.
The new Group Policy is added to the list.

What to do next

Add the group policy object to a remote access VPN connection profile.

Group policy general options

This topic describes the general options available when configuring a group policy, including navigation, VPN protocol selection, IP address pool assignment, banner configuration, DNS/WINS settings and split tunneling options.

Navigation path

Objects > **Object Management** > **VPN** > **Group Policy**, click **Add Group Policy** or choose an existing policy to edit, then select the **General** tab.

VPN protocols fields

Specify the types of Remote Access VPN tunnels (**SSL** or **IPsec IKEv2**) you want to apply for this group policy.

IP address pools

- Specifies the IPv4 address assignment based on address pools designated for user groups in Remote Access VPN.
- You can assign IP addresses from specific pools for identified user groups using RADIUS/ISE for authorization.
- You can enforce policy for users or user groups in non-identity-aware systems by configuring the Group Policy as the RADIUS Authorization attribute (GroupPolicy/Class).

Example: Select a specific address pool for contractors and enforce policy for restricted access to the internal network using those addresses.

The Firewall Threat Defense device assigns IPv4 address pools to the clients in this order:

1. RADIUS attribute for IPv4Address Pool
2. RADIUS attribute for Group Policy
3. Address Pool in Group Policy mapped to a Connection Profile
4. IPv4Address Pool in Connection Profile

Limitations:

- IPv6 address pool is not supported.
- A maximum of six IPv4 address pools can be configured in a Group Policy.
- Deployment failures may occur when address pools in use are modified. Before making any changes to the address pools, you must log off all users.
- If you rename address pools or configure overlapping address pools, deployment may fail. To address this, first remove the old address pool, then deploy the changed address pool.

  Troubleshooting commands :

- `show ip local pool <address-pool-name>`
- `show vpn-sessiondb detail anyconnect`
- `vpn-sessiondb loggoff all noconfirm`

Banner fields

Specifies the banner text to present to users at login. You can enter up to 491 characters in the banner. By default, no value is configured. The IPsec VPN client supports full HTML for the banner, however, the Secure Client supports only partial HTML. To ensure that the banner displays properly to remote users, use the /n tag for IPsec clients and the <BR> tag for SSL clients.

DNS/WINS fields

Domain Naming System (DNS) and Windows Internet Naming System (WINS) servers. Used for Secure Client name resolution.

- **Primary DNS Server** and **Secondary DNS Server**—Choose or create a Network Object which defines the IPv4 or IPv6 addresses of the DNS servers you want this group to use.
- **Primary WINS Server** and **Secondary WINS Server**—Choose or create a Network Object containing the IP addresses of the WINS servers you want this group to use.
- **DHCP Network Scope**—Choose or create a Network Object containing a routable IPv4 address on the same SUBNET as the desired pool, but not within the pool. The DHCP server determines which SUBNET this IP address belongs to and assigns an IP address from that pool. If not set properly, deployment of the VPN policy fails.

  If you configure DHCP servers for the address pool in the connection profile, the DHCP scope identifies the subnets to use for the pool for this group. The DHCP server must also have addresses in the same SUBNET identified by the scope. The scope allows you to select a subset of the address pools defined in the DHCP server for this specific group.

  If you do not define a network scope, the DHCP server assigns IP addresses in the order of the address pools configured. It goes through the pools until it identifies an unassigned address.

  We recommend using the IP address of an interface whenever possible for routing purposes. For example, if the pool is 10.100.10.2-10.100.10.254, and the interface address is 10.100.10.1/24, use 10.100.10.1 as the DHCP scope. Do not use the network number. Use DHCP only for IPv4 addressing. If the address you choose is not an interface address, you might need to create a static route for the scope address.

  LINK-SELECTION (RFC 3527) and SUBNET-SELECTION (RFC 3011) are currently not supported.
- **Default Domain**—Name of the default domain. Specify a top-level domain, for example, example.com.

Split tunneling fields

Split tunneling directs some network traffic through the VPN tunnel (encrypted) and the remaining network traffic outside the VPN tunnel (unencrypted or “in the clear”).

- **IPv4 Split Tunneling / IPv6 Split Tunneling**—By default, split tunneling is not enabled. For both IPv4 and IPv6 it is set to **Allow all traffic over tunnel**. Left as is, all traffic from the endpoint goes over the VPN connection.

To configure split tunneling, choose the **Tunnel networks specified below** or **Exclude networks specified below** policy, and then configure an access control list for that policy.

- **Split Tunnel Network List Type**—Choose the type of Access List you are using. Then choose or create a **Standard Access List** or **Extended Access List**. See Access lists, on page 2351 for details.

Note From Version 7.4, the **Standard Access List** option is disabled by default. Use the **Extended Access List** option to add an access list.

- **DNS Request Split Tunneling**—Also known as Split DNS. Configure the DNS behavior expected in your environment.

  By default, split DNS is not enabled and set to **Send DNS request as per split tunnel policy**. Choosing **Always send DNS request over tunnel** forces all DNS requests to be sent over the tunnel to the private network.

  To configure split DNS, choose **Send only specified domains over tunnel**, and enter the list of domain names in the **Domain List** field. These requests are resolved through the split tunnel to the private network. All other names are resolved using the public DNS server. Enter up to 10 entries in the list of domains, separated by commas. The entire string can be no longer than 491 characters.

Related Topics

Configure a group policy object, on page 2461

Group policy options for Secure Client

This topic lists and describes the specifications and configuration fields for group policy Secure Client VPN operation. This includes navigation steps, profile fields, management profile settings, client modules, SSL settings, connection options, and custom attributes.

These specifications apply to the operation of the Secure Client VPN.

Navigation

Objects > **Object Management** > **VPN** > **Group Policy**. Click **Add Group Policy** or choose a current policy to edit., and then select the **Secure Client** tab.

Profile fields

Profile—Choose or create a file object containing the Secure Client Profile. See File objects, on page 2474 for object creation details.

The Secure Client Profile is a group of configuration parameters stored in an XML file. The Secure Client software uses it to configure the connection entries that appear in the client's user interface. These parameters (XML tags) also configure settings to enable more Secure Client features.

Use the GUI-based Secure Client Profile Editor, an independent configuration tool, to create the Secure Client Profile. See the *Secure Client Profile Editor* chapter in the appropriate release of the Cisco Secure Client (including AnyConnect) Administrator Guide for details.

Management profile fields

Management VPN Tunnel—Provides always-on connectivity to the corporate network when the endpoint is powered up, regardless of the user's VPN connection status.

Management VPN Profile—The Management Profile file contains settings for enabling and establishing Management VPN Tunnel on endpoint.

The Standalone Management VPN Tunnel profile editor can be used to create a new profile file or modify an existing file. You can download the profile editor from Cisco Software Download Center.

For more information about adding a profile file, see File objects, on page 2474.

Client modules fields

Cisco Secure Client VPN Only offers enhanced security through various built-in modules. These modules provide services such as web security, network visibility into endpoint flows, and off-network roaming protection. Each module includes a custom client profile.

The following Secure Client modules are optional and you can configure these modules to be downloaded when a VPN user downloads Secure Client:

- **AMP Enabler**—Deploys advanced malware protection (AMP) for endpoints.
- **DART**—Captures a snapshot of system logs and other diagnostic information, which can be sent to the Cisco TAC for troubleshooting.
- **ISE Posture**—Uses the OPSWAT library to perform posture checks to assess an endpoint's compliance.
- **Network Access Manager**—Provides 802.1X (Layer 2) and device authentication for access to both wired and wireless networks.
- **Network Visibility**—Enhances the enterprise administrator's ability to do capacity and service planning, auditing, compliance, and security analytics.
- **Start Before Login**—Forces the user to connect to the enterprise infrastructure over a VPN connection before logging on to Windows by starting Secure Client before the Windows login dialog box appears.
- **Umbrella Roaming Security**—Provides DNS-layer security when no VPN is active.
- **Web Security**—Enforces web security policies and blocks malicious content.

Click **Add** and select the following for each client module:

- **Client Module**—Select the Secure Client module from the list.
- **Profile to download**—Choose or create a file object containing the Secure Client Profile. See File objects, on page 2474 for object creation details.
- **Enable module download**—Select to enable endpoints to download the client module along with the profile. If not selected, the endpoints can download only the client profile.

Use the GUI-based Secure Client Profile Editor, an independent configuration tool to create a client profile for each module. Download the Secure Client Profile Editor from Cisco Software Download Center. See the *Secure Client Profile Editor* chapter in the appropriate release of the Cisco Secure Client (including AnyConnect) for details.

SSL settings fields

- **SSL Compression**—Determines if data compression is enabled, and specifies the method to use (Deflate or LZS). SSL Compression is disabled by default.

  Data compression speeds up transmission rates, but also increases the memory requirement and CPU usage for each user session. Thereby, decreasing the overall throughput of the security appliance.

- **DTLS Compression**—Specifies whether to compress Datagram Transport Layer Security (DTLS) connections for this group using LZS. DTLS Compression is disabled by default.

- **MTU Size**—TSpecifies the maximum transmission unit (MTU) size for SSL VPN connections established by Cisco Secure Client VPN Only. The default is 1406 bytes; the valid range is 576 to 1462 bytes.

  - **Ignore DF Bit**—Whether to ignore the Don't Fragment (DF) bit in packets that need fragmentation. Allows the forced fragmentation of packets that have the DF bit set, allowing them to pass through the tunnel.

Connection settings fields

- **Enable Keepalive Messages between Secure Client and VPN gateway** and its **Interval** setting.—Determines whether peers exchange keepalive messages to demonstrate availability for sending and receiving data in the tunnel. By default, this feature is enabled. Keepalive messages are transmitted at set intervals. If enabled, enter the time interval (in seconds) that the remote client waits between sending IKE keepalive packets. The default interval is 20 seconds, the valid range is 15 to 600 seconds.

- **Enable Dead Peer Detection** and its **Interval** settings.—Dead Peer Detection (DPD) ensures that the VPN secure gateway or client quickly detects when the peer is no longer responding and the connection has failed. Default is enabled for both the gateway and the client. DPD messages transmit at set intervals. If enabled, enter the time interval (in seconds) that the remote client waits between sending DPD messages. The default interval is 30 seconds, the valid range is 5 to 3600 seconds.

- **Enable Client Bypass Protocol**—Allows you to configure how the secure gateway manages IPv4 traffic (when it is expecting only IPv6 traffic), or how it manages IPv6 traffic (when it is expecting only IPv4 traffic).

  After the Secure Clientconnects to the headend, the headend assigns the VPN connection an IPv4 address, an IPv6 address, or both. If the headend assigns only one type of address, you can configure the Client Bypass Protocol to either drop network traffic for which an IP address was not assigned (default, disabled, not checked), or allow that traffic to bypass the headend and be sent from the client unencrypted (“in the clear”; enabled, checked).

  For example, if the secure gateway assigns only an IPv4 address to the Secure Client connection and the endpoint is dual-stacked. When the endpoint attempts to reach an IPv6 address, if Client Bypass Protocol is disabled, the IPv6 traffic is dropped; however, if Client Bypass Protocol is enabled, the IPv6 traffic is sent from the client in the clear.

- **SSL rekey**—Enables the client to rekey the connection, renegotiating the crypto keys and initialization vectors, increasing the security of the connection. This is disabled by default. When enabled, the renegotiation can be done at a specified interval and rekey the existing tunnel or create a new tunnel by setting the following fields:

  - **Method**—Available when SSL rekey is enabled. Create a **New Tunnel** (default), or renegotiate, the **Existing Tunnel**'s specifications.

- **Interval**—Available when SSL rekey is enabled. Set to a default of 4 minutes with a range of 4-10080 minutes (1 week).

- **Client Firewall Rules**—Use the Client Firewall Rules to configure firewall settings for the VPN client's platform. Rules are based on criteria such as source address, destination address, and protocol. Extended Access Control List building block objects are used to define the traffic filter criteria. Choose or create an Extended ACL for this group policy. Define a **Private Network Rule** to control data flowing to the private network, a **Public Network Rule** to control data flowing "in the clear", outside of the established VPN tunnel, or both.

Note Ensure that the ACL contains only TCP/UDP/ICMP/IP ports and source network as any, any-ipv4 or any-ipv6.

Only VPN clients running Microsoft Windows can use these firewall settings.

Custom attributes fields

Custom attributes are used by the Secure Client to configure features such as Per App VPN, Allow or defer upgrade, and Dynamic split tunneling. Click **Add** to add custom attributes to the group policy.

1. Select the **Secure Client Attrinute**: Per App VPN, Allow Defer Update, or Dynamic Split Tunneling.
2. Select a **Custom Attribute Object** from the list.

Note Click Add (+) to create a new custom attribute object for the selected Secure Client attribute. You can also create a custom attribute object at **Objects** > **Object Management** > **VPN** > **Custom Attribute**. See Configure custom attributes for Secure Client, on page 2458.

3. Click **Add** to save the attributes to the group policy, and then click **Save** to save the changes to the group policy.

Related Topics

Configure a group policy object, on page 2461

Advanced group policy option fields and values

The advanced group policy includes options and attributes for configuring VPN access and session behavior. This reference describes where to locate advanced settings, outlines attributes related to traffic filtering, and summarizes session control fields and their allowed values.

Navigation path

Objects > **Object Management** > **VPN** > **Group Policy**. Click **Add Group Policy** or choose a current policy to edit. Then select the **Advanced** tab.

Traffic filter fields

- **Access List Filter**—Filters consist of rules that determine whether to allow or block tunneled data packets coming through the VPN connection. You set rules using criteria such as source address, destination address, and protocol.

  The VPN filter applies only to initial connections. It does not control secondary connections, such as a SIP media connection, that are opened during application inspection.

  Use Extended Access Control List building block objects to define traffic filter criteria. Choose or create an Extended ACL for this group policy.

- **Restrict VPN to VLAN**—Also called "VLAN mapping," this parameter specifies the egress VLAN interface for sessions to which this group policy applies. The ASA forwards all group traffic to the VLAN you select.

  Use this attribute to assign a VLAN to the group policy to simplify access control. You can assign a value to this attribute instead of using ACLs to filter session traffic. The drop-down list shows only the VLANs that are configured in this ASA. Allowed values range from 1 to 4094. The default value is Unrestricted.

Session settings fields

- **Access Hours**—Choose or create a time range object. This object specifies the range of time this group policy is available to be applied to a remote access user. See Time ranges, on page 2435 for details.
- **Simultaneous Logins Per User**—Specifies the maximum number of simultaneous logins allowed for a user. The default value is 3. If the minimum value is set to 0, logins are disabled and users cannot access the VPN. If you allow several simultaneous connections, security may be compromised and performance reduced.
- **Maximum Connection Time / Alert Interval**—Specifies the maximum user connection time in minutes. At the end of this time, the system disconnects the user. The minimum is 1 minute). The Alert interval lets you display a message to the user before the maximum connection time is reached.
- **Idle Timeout / Alert Interval**—Specifies this user's idle timeout period in minutes. If there is no communication activity on the user connection in this period, the system stops the connection. The minimum time is 1 minute. The default is 30 minutes. The Alert interval lets you display a message to the user before the idle time is reached.

Configure a group policy object, on page 2461

Firewall Threat Defense IPsec proposals

IPsec Proposals (or Transform Sets) are used when configuring VPN topologies. During the IPsec security association negotiation with ISAKMP, both peers must agree on the same proposal to protect the data flow.

IPsec proposal types and negotiation

IPsec proposals are categorized based on the IKE version: IKEv1 or IKEv2.

- For an IKEv1 IPsec proposal (Transform Set), select the mode for IPsec operation and define the required encryption and authentication types. Select only one option for each algorithm. To support multiple combinations in a VPN, create multiple IKEv1 IPsec proposal objects.

- For an IKEv2 IPsec proposal, select all encryption and hash algorithms allowed in the VPN. During IKEv2 negotiations, the peers negotiate and use the most appropriate options supported by both devices.

Both IKEv1 and IKEv2 IPsec proposals use the Encapsulating Security Protocol (ESP), which provides authentication, encryption, and antireplay services. ESP uses IP protocol type 50.

Note We recommend that you use both encryption and authentication on IPsec tunnels.

Configure an IKEv1 IPsec proposal object

Use this task when you need to create or modify IKEv1 IPsec proposal objects in Secure Firewall Management Center. Proposal objects define the cryptographic parameters for VPN connections and are required for establishing secure tunnels between firewalls or security gateways.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **IKEv1 IPsec Proposal** and then **VPN** > **IPsec IKev1 Proposal** from the table of contents.

Previously configured Proposals are listed including system defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a Proposal.

Step 2 Choose **Add IPsec IKEv1 Proposal** to create a new Proposal.

Step 3 Enter a **Name** for this proposal.

The name of the policy object can be up to 128 characters.

Step 4 Enter a **Description** for this Proposal.

Provide a description of the policy object that is up to 1024 characters.

Step 5 Choose the **ESP Encryption** method. The Encapsulating Security Protocol (ESP) encryption algorithm for this Proposal.

For IKEv1, select one of the options. When deciding which encryption and Hash Algorithms to use for the IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN. For a full explanation of the options, see Decide encryption algorithms for VPN policies, on page 1334.

Step 6 Select an option for **ESP Hash**.

For a full explanation of the options, see Decide which hash algorithms to use, on page 1335.

Step 7 Click **Save**
The new Proposal is added to the list.

Configure an IKEv2 IPsec proposal object

Use this task when you need to define or update the cryptographic settings for IKEv2 IPsec VPN tunnels on your Secure Firewall Management Center. This is relevant when setting up new VPNs or adjusting security policies to meet organizational requirements.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **IKEv2 IPsec Proposal** from the table of contents.

Previously configured proposals are listed including system defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a Proposal.

Step 2 Choose **Add IKEv2 IPsec Proposal** to create a new proposal.

Step 3 Enter a **Name** for this proposal.

The policy object name can be up to 128 characters.

Step 4 Enter a **Description** for this proposal.

The policy object description can contain up to 1,024 characters.

Step 5 Click **ESP Hash**, the hash or integrity algorithm to use in the proposal for authentication.

Note Firewall Threat Defense does not support IPSec tunnels with NULL encryption. Make sure that you do not choose NULL encryption for IPSec IKEv2 proposal.

For IKEv2, select all the options you want to support for **ESP Hash**. For a full explanation of the options, see Decide which hash algorithms to use, on page 1335.

Step 6 Click **ESP Encryption** . Select the Encapsulating Security Protocol (ESP) encryption algorithm for this proposal.

For IKEv2, click Select to open a dialog box where you can select all of the options you want to support. When deciding which encryption and hash algorithms to use for the IPsec proposal, choose only algorithms supported by the devices in the VPN. For a full explanation of the options, see Decide encryption algorithms for VPN policies, on page 1334.

Step 7 Click **Save**.
The new proposal is added to the list.

IKE policies

A IKE policy is a key management policy that

- defines security parameters and algorithms used to authenticate IPsec peers,
- negotiates and distributes IPsec encryption keys, and

- establishes secure communications by negotiating security associations in IPsec VPNs.
- The Internet Key Exchange (IKE) protocol manages authentication, key negotiation, and automatic establishment of IPsec security associations (SAs).
- IKE negotiation occurs in two phases:
  - Phase 1 negotiates a security association between two IKE peers, enabling secure communication in Phase 2.
  - Phase 2 establishes SAs for applications, such as IPsec.
- Both phases use proposals to negotiate connections. An IKE proposal is a set of algorithms that two peers use to secure negotiation.
- IKE negotiation starts with peers agreeing on a shared IKE policy, which defines the security parameters to protect future negotiations.
- For IKEv1, proposals include a single set of algorithms and a modulus group; multiple, prioritized policies can be created to match remote peers.
- For IKEv2, you can select multiple algorithms and modulus groups in one policy.
- Peers choose proposals during Phase 1 negotiation, enabling creation of a single IKE proposal but consideration of multiple prioritized options.
- For IKEv2, the policy object does not specify authentication; other policies must define authentication requirements.
- An IKE policy is required when you configure a site-to-site IPsec VPN. .

Configure an IKEv1 policy object

Use the IKEv1 Policy page to create, edit, or delete IKEv1 policy objects. These policy objects specify settings such as encryption, authentication, priority, and other parameters necessary for establishing secure VPN tunnels.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **IKEv1 Policy** from the table of contents.

Previously configured policies are listed including system-defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a proposal.

Step 2 (Optional) Click **Add IKEv1 Policy** to create a new policy object. Then, enter a **Name** for this policy. The policy object name can be up to 128 characters. Optionally, you can enter the description. The policy object description can contain up to 1,024 characters.

Step 3 Enter the **Priority** value of the IKE policy.

The priority value determines the order of the IKE policy compared by the two negotiating peers when attempting to find a common security association (SA). If the remote IPsec peer does not support the parameters selected in your first priority policy, it tries to use the parameters defined in the next lowest priority. Valid values range from 1 to 65,535. The lower the number, the higher the priority. If you leave this field blank,

Management Center assigns the lowest unassigned value starting with 1, then 5, then continuing in increments of 5.

Step 4 Select the **Encryption** method.

When deciding which encryption and Hash Algorithms to use for the IKEv1 policy, your choice is limited to algorithms supported by the peer devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. For IKEv1, select one of the options. For a full explanation of the options, see Decide encryption algorithms for VPN policies, on page 1334.

Step 5 Select the **Hash** Algorithm that creates a Message Digest, which is used to ensure message integrity.

When deciding which encryption and Hash Algorithms to use for the IKEv1 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. For a full explanation of the options, see Decide which hash algorithms to use, on page 1335.

Step 6 Select the **Diffie-Hellman Group**.

The Diffie-Hellman group to use for encryption. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the group that you want to allow in the VPN. For a full explanation of the options, see Decide which Diffie-Hellman modulus group to use, on page 1336.

Step 7 Enter the **Lifetime** of the security association (SA), in seconds. You can specify a value from 120 to 2,147,483,647 seconds. The default is 86400.

When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

Step 8 Select the **Authentication Method** to use between the two peers.

- **Preshared Key**—Preshared keys allow for a secret key to be shared between two peers and to be used by IKE during the authentication phase. If one of the participating peers is not configured with the same preshared key, the IKE SA cannot be established.
- **Certificate**—When you use Certificates as the authentication method for VPN connections, peers obtain digital certificates from a CA server in your PKI infrastructure, and trade them to authenticate each other.

Note In a VPN topology that supports IKEv1, the **Authentication Method** specified in the chosen IKEv1 Policy object becomes the default in the IKEv1 **Authentication Type** setting. These values must match, otherwise, your configuration will error.

Step 9 Click **Save**
The new IKEv1 policy is added to the list.

Configure an IKEv2 policy object

Use the IKEv2 policy dialog box to create, delete, and edit an IKEv2 policy object. These policy objects contain the parameters required for IKEv2 policies.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **IKEv2 Policy** from the table of contents.

Previously configured policies are listed including system defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a policy.

Step 2 Click **Add IKEv2 Policy** to create a new policy. Then, enter a **Name** for this policy. The policy object name can be up to 128 characters. Optionally, enter the description. The description can be up to 1024 characters.

Step 3 Enter the **Priority**.

The priority value of the IKE proposal. The priority value determines the order of the IKE proposals compared by the two negotiating peers when attempting to find a common security association (SA). If the remote IPsec peer does not support the parameters selected in your first priority policy, it tries to use the parameters defined in the next lowest priority policy. Valid values range from 1 to 65535. The lower the number, the higher the priority. If you leave this field blank, Management Center assigns the lowest unassigned value starting with 1, then 5, then continuing in increments of 5.

Step 4 Enter the **Lifetime** of the security association (SA), in seconds. You can specify a value from 120 to 2,147,483,647 seconds. The default is 86400.

When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

Step 5 Select algorithms for these methods:

a. Click **Integrity Algorithms** portion of the Hash Algorithm used in the IKE policy. The Hash Algorithm creates a Message Digest, which is used to ensure message integrity.

When deciding which encryption and Hash Algorithms to use for the IKEv2 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. Select all the algorithms that you want to allow in the VPN.For a full explanation of the options, see Decide which hash algorithms to use, on page 1335.

b. Click **Encryption Algorithm** used to establish the Phase 1 SA for protecting Phase 2 negotiations.

When deciding which encryption and Hash Algorithms to use for the IKEv2 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. Select all the algorithms that you want to allow in the VPN. For a full explanation of the options, see Decide encryption algorithms for VPN policies, on page 1334.

c. Click **PRF Algorithm**.

The pseudorandom function (PRF) portion of the Hash Algorithm used in the IKE policy. In IKEv1, the Integrity and PRF algorithms are not separated, but in IKEv2, you can specify different algorithms for these elements. Select all of the algorithms that you want to allow in the VPN. For a full explanation of the options, see Decide which hash algorithms to use, on page 1335.

d. Click **Diffie-Hellman Group** for encryption.

A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the groups that you want to allow in the VPN. For a full explanation of the options, see Decide which Diffie-Hellman modulus group to use, on page 1336.

Step 6 Click **Save**.
If a valid combination of choices has been selected the new IKEv2 policy is added to the list. If not, errors are displayed and you must make changes accordingly to successfully save this policy.

Secure client customizations

A Secure Client customization is a configuration object that

- represents files used to customize Secure Client,
- enables deployment of customizations to the VPN headend, and
- allows threat defense to distribute customizations to endpoints when users connect from Secure Client.

Supported secure client customizations

Secure Client customization objects represent files used to modify Secure Client. Secure Client supports these types of customizations:

- GUI text and messages
- Icons and images
- Scripts
- Binaries
- Custom installer transforms
- Localized installer transforms

For more information about configuring Secure Client customizations, see Customize Cisco Secure Client, on page 1472.

File objects

File objects are configuration element that

- represent files used in configurations, typically for remote access VPN policies
- can contain Secure Client Profile and Secure Client Image files, and
- are created, edited, and managed through the Add and Edit File Object dialog boxes.

File object management and usage

File objects are used to manage files for remote access VPN policies and are associated with profiles and images for deployment to endpoints.

File objects can be created and edited using the Add and Edit File Object dialog boxes. They are used in configurations for remote access VPN policies and can contain Secure Client Profile and Secure Client Image files.

Create profiles for each AnyConnect module and Secure Client Management VPN using independent profile editors. Deploy these profiles to meet administrator-defined end user requirements and authentication policies on endpoints Secure Client only. This makes preconfigured network profiles available to end users

When you create a file object, the Firewall Management Center makes a copy of the file in its repository. When you back up the database, these files are included. If you restore the database, the files are restored as well. To use a file in a file object, upload it through the management center interface, not directly to the file repository.

When you deploy configurations that specify a file object, the associated file is downloaded to the device in the appropriate directory.

You can take these actions for each file object:

- **Download**: Download the Secure Client file.
- **Edit**: Modify the file object details.
- **Delete**: Delete the Secure Client file object. When you delete a file object, the associated file is not deleted from the file repository, only the object is deleted.

Navigation path

Objects > **Object Management** > **VPN** > **Secure Client File**.

Fields

- **Name**: Enter the name of the file to identify the file object; you can add up to 128 characters.
- **File Name**: Click **Browse** to select the file. The file name and full path of the file are added when you select the file.
- **File Type**: Choose the file type corresponding to the file you have selected. These file types are available:

File Types	Details
Secure Client Image	Select when you add the Secure Client image you have downloaded from the Cisco Software Download Center. You can associate any new or additional Secure Client images to the remote access VPN policy. You can also remove unsupported or end-of-life client packages that are no longer required.
Secure Client VPN Profile	Choose for the Secure Client VPN profile file. The profile file is created using the GUI-based Secure Client Profile Editor, an independent configuration tool. See the *Secure Client Profile Editor* chapter in the appropriate release of the Cisco Secure Client (including AnyConnect) User Guide for details.

File Types	Details
Secure Client Management VPN Profile	Select when you add a profile file for the Secure Client management VPN tunnel. Download the Secure Client **VPN Management Tunnel Standalone Profile Editor** from Cisco Software Download Center if you have not done already and create a profile with required settings for the Secure Client management VPN tunnel.
AMP Enabler Service Profile	The profile is used for the Secure Client The AMP Enabler and this profile are deployed to endpoints from Firewall Threat Defense when a user connects to the VPN using remote access.
Feedback Profile	You can add a Customer Experience Feedback profile and select this type to receive information about the features and modules customers have enabled and use.
ISE Posture Profile	Choose if you are adding a profile file for the Secure Client ISE Posture module.
NAM Service Profile	Configure and add the NAM profile file using the Network Access Manager profile editor.
Network Visibility Service Profile	Profile file for Secure Client Network Visibility module. You can create the profile using the NVM profile editor.
Umbrella Roaming Security Profile	You must select this file type if you are deploying the Umbrella Roaming Security module using the .json file created using the profile editor.
Web Security Service Profile	Select this option when you add a profile file for the Web security module.
HostScan Posture Package	Select when you add a Secure Firewall Posture Package file. This file is used while configuring a Dynamic Access Policy (DAP) to collect information about the operating system, anti-virus, anti-spyware, and firewall software installed on the endpoints.
Secure Client External Browser Package	For selecting an external browser package file for SAML single sign-on web authentication. You can add the package file when a new version of the external package file is available. For more information, see Configure AAA Settings for Remote Access VPN, on page 1439.
Description	Add an optional description.

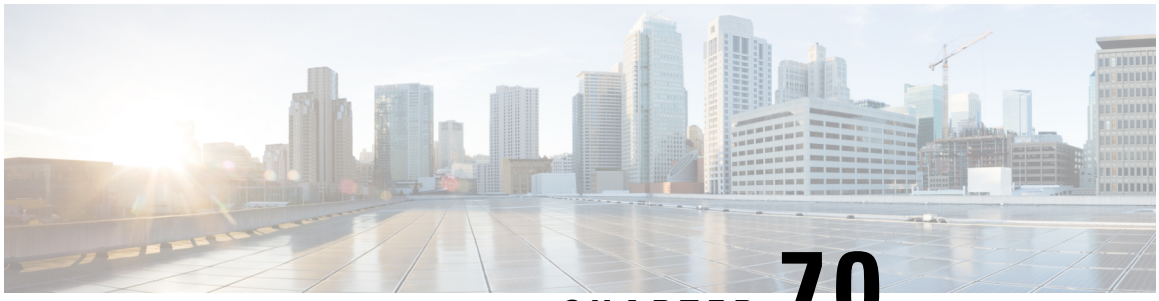
History for object management



This reference provides a history of object management features, enhancements, and changes across releases, including details and supported platforms for each feature.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Merged ACL and AV ACL	7.4.1	Any	New/modified screens: **Objects** > > **Object Management** > **RADIUS Server Group** > **Add RADIUS Server Group** > **Merge Downloadable ACL with Cisco AV Pair ACL** New CLI commands: • **sh run AAA-server AAA-server ISE-Server protocol RADIUS merge-dacl after-avpair** • **sh run AAA-server AAA-server ISE-Server protocol RADIUS merge-dacl before-avpair**
Secure Client Customization	Any	7.4	You can now customize Secure Client and deploy these customizations to the VPN headend. The threat defense distributes these customizations to the endpoint when an end user connects from the Secure Client.
IPv6 support for CRL and OCSP urls	Any	7.4	You can now configure IPv6 OCSP and CRL URLs.
Loopback and Management type interface group objects	Any	7.4	You can now create interface group objects that include only management-only interfaces or only loopback interfaces. You can then use these groups for management features such as DNS servers, HTTP access, or SSH. Loopback groups are supported for any feature that supports loopback interfaces. Note that DNS does not support management interfaces. New/Modified screens: **Objects** > **Object Management** > **Interface** > **Add** > **Interface Group**
Loopback interface support for AAA	Any	7.4	You can use a loopback interface group for configuring a RADIUS server. New/Modified screens: **Objects** > **Object Management** > **AAA Server** > **RADIUS Server Group**
Clone network and port objects	Any	7.4	You can now clone network and port objects. In the object manager (**Objects** > **Object Management**), click the new **Clone** icon next to a port or network object. You can then change the new object's properties and save it using a new name.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
DHCP IPv6 Pool	Any	7.3	The Firewall Threat Defense now supports a light DHCPv6 stateless server when using the DHCPv6 Prefix Delegation client. The Firewall Threat Defense provides other information such as the domain name to SLAAC clients when they send Information Request (IR) packets to the Firewall Threat Defense. The Firewall Threat Defense only accepts IR packets and does not assign addresses to the clients. New/Modified screens: • **Devices** > **Device Management** > **Interfaces** > **Add/Edit Interfaces** > **IPv6** > **DHCP** • **Objects** > **Object Management** > **DHCP IPv6 Pool** New/Modified commands: **show ipv6 DHCP**
BFD Template	Any	7.3	In the previous releases, BFD was configurable on threat defense only through FlexConfig. FlexConfig no longer supports BFD configuration. You can now configure BFD policies for threat defense in the management center UI. Hence, the BFD Template object was introduced. New/modified screens: • **Devices** > **Device Management** > **Routing** > **BFD**. • **Objects** > **Object Management** > **BFD Template**
New Applications tab for policy based routing	Any	7.1	A new tab for selecting the applications for configuring direct internet access policy (policy based routing) was introduced in the extended access list object. New/Modified Screens: New option to select applications when configuring **Object** > **Object Management** > **Access List** > **Extended** page. Supported platforms: Secure Firewall Management Center
New Extended Community List object and	Any	7.1	Extended community list object was introduced to be used in policy list and route map objects. The extended community list object is applicable only for importing or exporting routes in BGP route leaking support for virtual routers. New/Modified Screens: New object for configuring policy list and route maps **Object** > **Object Management** > **Community list** > **Extended Community** page. Supported platforms: Secure Firewall Management Center

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Enhancements to Policy List object and Route Map object	Any	7.1	Options to select the newly introduced Extended Community List objects in policy list and route maps. New/Modified Screens: New options for configuring policy list and route maps **Object** > **Object Management** > **Policy List** > **Community rule** tab, and **Object** > **Object Management** > **Route Map** > **BGP** > **Community List** tab. Supported platforms: Secure Firewall Management Center
Time-based ACL support for Snort 3	Any	7.0	Time-based rules in access control and prefilter policies are supported in Snort 3 as well. Supported platforms: Firewall Threat Defense
EST for certificate enrollment	Any	7.0	Support for Enrollment over Secure Transport for certificate enrollment was provided. New/Modified Screens: New enrollment options when configuring **Objects** > **PKI** > **Cert Enrollment** > **CA Information** tab. Supported platforms: Secure Firewall Management Center
Support for EdDSA certificate type	Any	7.0	A new certificate key type- EdDSA was added with a key size of 256. New/Modified Screens: New certificate key options when configuring **Objects** > **PKI** > **Cert Enrollmet** > **Key** tab. Supported platforms: Secure Firewall Management Center
Restrictions on ciphers and key sizes	Any	7.0	Certificates having SHA-1 with RSA Encryption signature algorithm, and RSA key sizes smaller than 2048 bits are not supported. To override these restrictions on existing certificates, you can enable the weak-crypto option on Firewall Threat Defense. However, you cannot generate RSA keys with sizes smaller than 2048 bits. New/Modified Screens: New toggle button when configuring **Devices** > **Certificates**. Supported platforms: Secure Firewall Management Center
Security Intelligence feed options	Any	6.7	New update frequency options (5 and 15 minutes) for custom Security Intelligence feeds. Update frequencies of less than 30 minutes require an MD5 URL, to prevent unnecessary downloads if the feed has not changed. New/Modified Screens: New frequency choices when configuring **Security Intelligence** > **Network Lists and Feeds**. Supported platforms: Secure Firewall Management Center

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Bulk upload of objects using a comma-separated-values (csv) file	Any	6.7	Objects can be imported from a comma-separated-values file. Up to 1000 objects can be imported in one attempt. New/Modified Screens: The following object types have a new **Import Object** option in the **Add [Object Type]** drop-down list. • **Distinguished Name** > **Individual Objects** • **Network Object** • **Port** • **URL** • **VLAN Tag** Supported platforms: Secure Firewall Management Center
See the policies in which interface objects are used	Any	6.6	See the policies in which interface objects are used. New/Modified Screens: The **Interface** object page in **Object** > **Object management** has a new **Find** button. Supported platforms: Secure Firewall Management Center
Time zone objects introduced	Any	6.6	You can assign time zones to Firewall Threat Defense devices, for use when applying time-based policies. New/Modified Screens: New **Time Zone Object** in **Object** > **Object management**. Supported platforms: Secure Firewall Management Center
Time-based objects can now be used in access control and prefilter policies	Any	6.6	Use time range objects in conjunction with new time zone objects for applying time-based rules in access control and prefilter policies. You can specify an absolute or recurring time or time range for a rule to be applied. The rule is applied based on the time zone of the device that processes the traffic.
View Object Details from prefilter rule page	Any	6.6	Feature introduced: Option to view details for an object or object group when viewing prefilter rules. New options: Right-clicking a value in any of the following columns in the prefilter rule list offers options to view object details: Source Networks, Destination Networks, Source Port, Destination Port, and VLAN Tag. Supported platforms: Secure Firewall Management Center

Requirements and prerequisites for certificates

This topic outlines the domain and role-based access requirements for certificate management.

Requirement	Supported values
Supported domains	Any
User roles	• Admin • Network Admin

Secure Firewall Threat Defense VPN certificate guidelines and limitations

Certificate enrollment guidelines

When a PKI enrollment object is associated with and then installed on a device, the certificate enrollment process starts immediately. The process is automatic for self-signed and SCEP enrollment types; it does not require any additional administrator's action. Manual certificate enrollment requires administrator's action.

- When a PKI enrollment object is associated with and then installed on a device, the certificate enrollment process starts immediately. The process is automatic for self-signed and SCEP enrollment types; it does not require any additional administrator's action. Manual certificate enrollment requires administrator's action.
- When importing identity certificates into Firewall Threat Defense devices, the expiration date of the certificate must not exceed February 6, 2106. Ensure that all certificates used within devices have expiration dates earlier to February 6, 2106 to avoid issues during certificate import or renewal.
- When the certificate enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your VPN Authentication Method.
- Firewall Threat Defense devices support certificate enrollment using Microsoft Certificate Authority(CA) Service, and CA Services provided on Cisco Adaptive Security Appliances(ASA) and Cisco IOS Router.
- Firewall Threat Defense devices cannot be configured as a certificate authority (CA).
- Ensure that only valid and properly functioning certificates are assigned to VPN or Remote Access VPN policies to prevent blocking deployments or causing validation errors. If a certificate is marked as failed but not referenced by any VPN policy, deployments will proceed with a warning rather than a failure. This practice helps maintain smooth deployment operations and avoids interruptions caused by certificate issues.

Guidelines for certificates and multitenancy

Firewall Threat Defense devices support certificate enrollment using Microsoft CA Service, as well as CA services provided by Cisco Adaptive Security Appliances and Cisco IOS Routers.

Supported certificate enrollment services:

Certificate enrollment domains

- Certificate enrollment can be done in a **child domain** or a **parent domain**.
- When enrollment is done from a **parent domain**, the certificate enrollment object must also be in the same domain.
- If the trustpoint on a device is overridden in the child domain, the overridden value will be deployed on the device.

Enrollment visibility and behavior in leaf domains

- When certificate enrollment is done on a device in a **leaf domain**, the enrollment will be visible to the parent domain or another child domain.
- Adding additional certificates in a leaf domain is possible.

Certificate enrollment restrictions and permissions

- Once a device has certificates enrolled in one domain, it will be allowed to be enrolled in any other domain. The certificates can be added in the other domain.

Device movement between domains

- When you move a device from one domain to another, the certificates also get moved accordingly. You will receive an alert to delete the enrollments on these devices.

Manage Firewall Threat Defense certificates

This task enables you to manage certificates on devices including viewing certificate status, enrolling new certificates, and performing certificate operations such as export and re-enrollment.

See PKI infrastructure and digital certificates, on page 1337 for an introduction to Digital Certificates.

See Certificate enrollment objects, on page 2400 for a description of the objects used to enroll and obtain certificates on managed devices.

Procedure

Step 1 Select **Devices** > **Certificates**.

You can see the following columns for each device listed on this screen:

- **Name**—Lists the devices that already have trustpoints associated with them. Expand the device to see the list of associated trustpoints.
- **Domain**—Displays the certificates that are enrolled in a specific domain.
- **Enrollment Type**—Displays the type of enrollment used for a trustpoint.
- **Status**—Provides the status of the **CA Certificate** and **Identity Certificate**. You can view the certificate contents, when `Available`, by clicking the magnifying glass.

  When you view the CA certificate information, you can view the hierarchy of all the certifying authorities, which issued your CA certificate. If the enrollment fails, click status to view the failure message.
- Click **Enable weak-crypto** on the right to enable weak cipher usage in certificates. When you click the toggle button, you get a warning to confirm before enabling weak ciphers. Click **Yes** to enable weak ciphers.

Note When a certificate enrollment fails due to weak cipher usage, you get a prompt to enable the weak cipher. You can choose to enable weak cipher when you need to use weak encryption.

- The additional column lists icons to perform the following tasks:
  - **Export Certificate**—Click to export and download a copy of the certificate. You can choose to export the PKCS12 (Complete Certificate Chain) or the PEM (Identity Certificate Only) format.

    You must provide a pass phrase to export a PKCS12 certificate format to import the file later.
  - **Re-enroll certificate**—Re-enroll an existing certificate.
  - **Refresh certificate status**—Refresh a certificate to synchronize the device certificate status to the Firewall Management Center.
  - **Delete certificate**—Delete all the associated certificates for a trustpoint.

Step 2 Choose **(+) Add** to associate and install an enrollment object on a device.

When a certificate enrollment object is associated with and then installed on a device, the process of certificate enrollment starts immediately. The process is automatic for self-signed and SCEP enrollment types, meaning it does not require any additional administrator action. Manual certificate enrollment requires extra administrator action.

Note The certificate enrollment on a device does not block the user interface and the enrollment process gets executed in the background, enabling the user to perform certificate enrollment on other devices in parallel. The progress of these parallel operations can be monitored on the same user interface. The respective icons display the certificate enrollment status.

Automatically update CA bundles

You can set the management center to automatically update the CA certificates through CLI commands. By default, the CA certificates are automatically updated when you install or upgrade to version 7.0.5.

Note In an IPv6-only deployment, the automatic update of CA certificates may fail, because, some of the Cisco servers do not support IPv6. In such cases, force update the CA certificates using the **configure cert-update run-now force** command.

Procedure

Step 1 Log into the FMC CLI using SSH, or, if virtual, open the VM console.

Step 2 You can verify whether the CA certificates in the local system are the latest or not:

configure cert-update test

This command compares the CA bundle on the local system with the latest CA bundle (from the Cisco server). If the CA bundle is up to date, no connection check is executed and the test result is displayed as the one below:

Example:

```
> configure cert-update test
Test succeeded, certs can safely be updated or are already up to date.
```

If the CA bundle is out of date, the connection check is executed on the downloaded CA bundle and the test result is displayed.

Example:

When the connection check fails:

```
> configure cert-update test
Test failed, not able to fully connect.
```

Example:

When the connection check succeeds, or the CA bundle is already up to date:

```
> configure cert-update test
Test succeeded, certs can safely be updated or are already up to date.
```

Step 3 (Optional) To instantly update the CA bundles:

configure cert-update run-now

Example:

```
>configure cert-update run-now
Certs have been replaced or was already up to date.
```

When you execute this command, the CA certificates (from the Cisco server) are verified for SSL connectivity. If the SSL connectivity check fails for even one of the Cisco servers, the process is terminated.

Example:

```
> configure cert-update run-now
Certs failed some connection checks.
```

To proceed with the update despite connection failures, use the **force** keyword.

Example:

```
> configure cert-update run-now force
Certs failed some connection checks, but replace has been forced.
```

Step 4 If you do not want the CA bundles to be automatically updated, disable the configuration:

configure cert-update auto-update disable

Example:

```
> configure cert-update auto-update disable
Autoupdate is disabled
```

Step 5 To re-enable the automatic update of CA bundles:

configure cert-update auto-update enable

Example:

```
> configure cert-update auto-update enable
```

```
Autoupdate is enabled and set for every day at 12:18 UTC
```

When you enable the automatic update on the CA certificates, the update process is executed daily at a system-defined time.

Step 6 (Optional) View the status of automatic update of CA certificates:

show cert-update

Example:

```
> show cert-update
Autoupdate is enabled and set for every day at 09:34 UTC
CA bundle was last modified 'Thu Sep 15 16:12:35 2022'
```

Install a certificate using self-signed enrollment

Install a self-signed certificate to establish secure VPN connections by creating an identity certificate directly on the managed device.

Procedure

Step 1 On the **Devices** > **Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.

Step 2 Choose a device from the **Device** drop-down list.

Step 3 Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the type Self-Signed from the drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2402.

Step 4 Press **Add** to start the Self Signed, automatic, enrollment process.

For self signed enrollment type trustpoints, the **CA Certificate** status will always be displayed, since the managed device is acting as its own CA and does not need a CA certificate to generate its own Identity Certificate.

The **Identity Certificate** will go from InProgress to Available as the device creates its own self signed identity certificate.

Step 5 Click the magnifying glass to view the self-signed Identity Certificate created for this device.

What to do next

When enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your Site to Site and Remote Access VPN Authentication Method.

Install a certificate using EST enrollment

Use EST enrollment to automatically obtain and install identity certificates on devices from a Certificate Authority (CA).

Before you begin

Note Using EST enrollment establishes a direct connection between the managed device and the CA server. So be sure your device is connected to the CA server before beginning the enrollment process.

Note EST's ability to auto-enroll a device when its certificate expires is not supported.

Follow these steps to install a certificate using EST enrollment:

Procedure

Step 1 On the **Devices** > **Certificates** screen, click **Add** to open the **Add New Certificate** dialog.

Step 2 Choose a device from the **Device** drop-down list.

Step 3 Associate a certificate enrollment object with this device in one of the following ways:

- Choose the EST certificate enrollment object from the **Cert Enrollment** drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2402.

Step 4 Click **Add** to enroll the certificate on the device.

The **Identity Certificate** will go from `InProgress` to `Available` as the device obtains its identity certificate using EST from the specified CA. Sometimes, a manual refresh might be required to obtain the identity certificate.

Step 5 Click the magnifying glass to view the Identity Certificate created and installed on this device.

Install a certificate using SCEP enrollment

Install a certificate using SCEP enrollment to enable secure authentication for VPN connections and other security features on your device.

Before you begin

Note Using SCEP enrollment establishes a direct connection between the managed device and the CA server. So be sure your device is connected to the CA server before beginning the enrollment process.

Follow these steps to install a certificate using SCEP enrollment:

Procedure

Step 1 On the **Devices** > **Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.

Step 2 Choose a device from the **Device** drop-down list.

Step 3 Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the type SCEP from the drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2402.

Step 4 Press **Add**, to start the automatic enrollment process.

For SCEP enrollment type trustpoints, the **CA Certificate** status will transition from InProgress to Available as the CA Certificate is obtained from the CA server and installed on the device.

The **Identity Certificate** will go from `InProgress` to `Available` as the device obtains its identity certificate using SCEP from the specified CA. Sometimes, a manual refresh might be required to obtain the identity certificate.

Step 5 Click the magnifying glass to view the Identity Certificate created and installed on this device.

What to do next

When enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your Site to Site and Remote Access VPN Authentication Method.

Install a certificate using manual enrollment

Manual enrollment allows you to obtain and install an identity certificate on a managed device by generating a certificate signing request (CSR) and working with your PKI CA server to obtain the corresponding identity certificate.

Procedure

Step 1 On the **Devices** > **Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.

Step 2 Choose a device from the **Device** drop-down list.

Step 3 Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the type Manual from the drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2402.

Step 4 Press **Add** to start the enrollment process.

Step 5 Execute the appropriate activity with your PKI CA Server to obtain an identity certificate.

a) Click **Identity Certificate** warning to view and copy the CSR.

b) Execute the appropriate activity with your PKI CA Server to obtain an identity certificate using this CSR.

This activity is completely independent of the Secure Firewall Management Center or the managed device. When complete, you will have an Identity Certificate for the managed device. You can place it in a file.

c) To finish the manual process, install the obtained identity certificate onto the managed device.

Return to the Secure Firewall Management Center dialog and select **Browse Identity Certificate** to choose the identity certificate file.

Note Ensure not to choose a binary certificate (PKCS12, DER, and alike) file because Firewall Threat Defense does not support them.

Step 6 Select **Import** to import the Identity Certificate.

The Identity Certificate status will be `Available` when the import complete.

Step 7 Click the magnifying glass to view the **Identity Certificate** for this device.

What to do next

When enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your Site to Site and Remote Access VPN Authentication Method.

Install a certificate using a PKCS12 file

Install a certificate using a PKCS12 file to enable secure authentication and encrypted communications on managed devices.

Procedure

Step 1 Go to **Devices** > **Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.

Step 2 Choose a pre-configured managed device from the **Device** drop down list.

Step 3 Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the PKCS type from the drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2402.

Step 4 Press **Add**.

The CA Certificate and Identity Certificate status will go from `In Progress` to `Available` as it installs the PKCS12 file on the device.

Note When you upload the PKCS12 file for the first time, the file is stored in Firewall Management Center as part of the CertEnrollment object. For any failed enrollments due to a wrong passphrase or failed deployment, retry enrolling the PKCS12 certificate without uploading the file again. Also, whenever you modify the certificate enrollment object to permit overrides, you must update the **Passphrase** for the certificate for a sucessful enrollment. A PKCS12 file size should not be larger than 24K.

Step 5 Once `Available`, click the magnifying glass to view the Identity Certificate for this device.

What to do next

The certificate (trustpoint) on the managed device is named the same as the PKCS#12 file. Use this certificate in your VPN authentication configuration.

Troubleshoot Threat Defense certificates

See Secure Firewall Threat Defense VPN certificate guidelines and limitations, on page 2481 to determine if variations in your certificate enrollment environment may be causing a problem.

Certificate expiration monitoring
CA server connectivity

Ensure there is a route to the CA Server from the device. If the CA Server's host name is given in the Enrollment Object, use Flex Config to configure DNS appropriately to reach the server. Alternatively, use the IP Address of the CA Server.

Microsoft 2012 CA server template configuration

If you are using a Microsoft 2012 CA Server, the default IPsec Template is not accepted by the managed device and must be changed.

To configure a working template, follow these steps as you use MS CA documentation as a reference.

1. Duplicate the IPsec (Offline Request) template.
2. In **Extensions** > **Application policies**, select *IP security end system*, instead of the *IP security IKE intermediate*.
3. Set the permissions and the template name.
4. Add the new template and change the registry settings to reflect the new template name.

Default keyring certificate regeneration

On the Firewall Management Center, you might receive this health alert related to the Firewall Threat Defense device:

`Code - F0853; Description - default Keyring's certificate is invalid, reason: expired`

Solution: In such cases, use the following command to regenerate the default certificate in CLISH CLI:

```
> system support regenerate-security-keyring default
```

CA certificate configuration errors

A red cross appears in the CA certificate status with this error:

Error: `Fail to configure CA certificate`

Solution: See Troubleshoot Certificate Error on FMC.

Certificate verification in .pfx files

To check the list of the certificates in a .pfx file, use tools such as `certutil` or `openssl`. You can see the whole chain with ID certificate, SubCA certificate, and CA certificate (if any).

- `certutil -dump cert.pfx`
- `openssl pkcs12 -info -in cert.pfx`

Identity certificate import errors

Error: `Identity certificate import required`

Solution: See Troubleshoot Certificate Error "Identity certificate import required" on FMC.

Self-signed certificates hostname behavior in Threat Defense high-availability environments

In a Threat Defense HA configuration, the secondary unit adopts the primary unit's hostname. When you break the HA pair, you must perform these actions:

- Manually update the hostname on the secondary unit to its unique identifier
- Perform a certificate re-enrollment to ensure that the certificate accurately reflects the unit's identity.

History for certificates

This table lists the certificate feature history and enhancements introduced in different software versions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Support for OCSP and CRL IPv6 URL	7.4	Any	You can now add IPv6 OCSP and CRL URLs for certificate authentication (revocation checking). The IPv6 addresses must be enclosed in square brackets.
Enhancements to Manual Enrollment	6.7	Any	You can now create only a CA certificate without an identity certificate. You can also generate a CSR without a CA certificate and obtain an identity certificate from the CA.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
PKCS CA Chain	6.7	Any	You can view and manage the chain of certifying authorities (CAs) issuing your certificates. You can also export a copy of the certificates.
