- determines the appropriate interface for packet transmission based on destination address matching in the routing table
- prioritizes routes with longer network prefix lengths when multiple matches exist, and
- directs packets through default routes when no specific routing table entries match the destination.

Forwarding decision process

Forwarding decisions are made as follows:

- If the destination does not match an entry in the routing table, the packet is forwarded through the interface specified for the default route. If a default route has not been configured, the packet is discarded.
- If the destination matches a single entry in the routing table, the packet is forwarded through the interface associated with that route.
- If the destination matches more than one entry in the routing table, then the packet is forwarded out of the interface associated with the route that has the longer network prefix length.

Note When a route change occurs, the Threat Defense re-evaluates the forwarding decision of established connections the next time a packet is seen on the flow.

The resulting behavior is determined by your configuration:

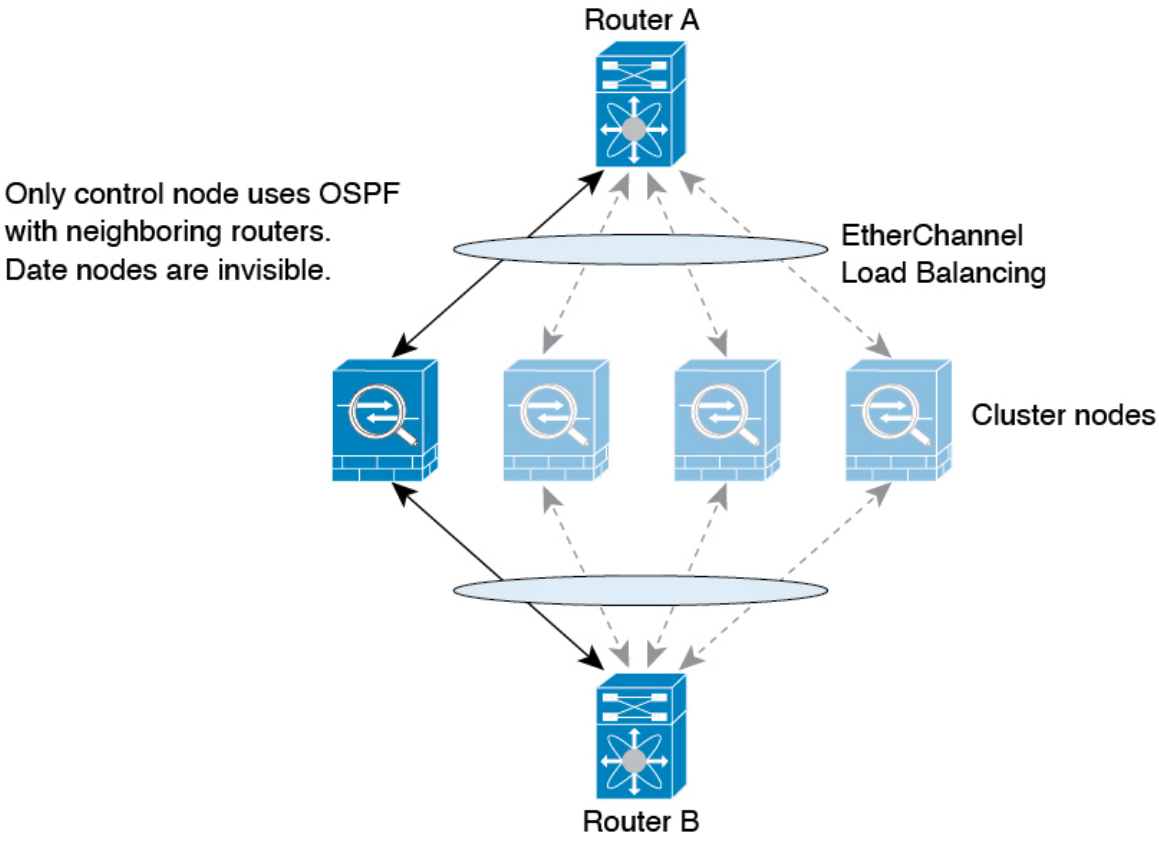
Configuration	Behavior	Outcome
Default (timeout floating-conn 0, no ECMP zone)	Retains the original egress path initially.	If that path can no longer resolve the destination, the flow is torn down after the conn-holddown period (default 15s) rather than waiting for an idle timeout.
Floating-Connection (timeout floating-conn configured)	Identifies a new optimal path on a different interface (outside the same ECMP zone).	The flow is torn down after the floating-conn timeout to allow for a fresh connection. Note: May trigger %FTD-6-110003 syslog messages.
ECMP Zone (Both interfaces in the same ECMP zone)	Dynamically updates the flow's egress interface.	The flow is switched to the new path atomically and non-disruptively.

Longest prefix match example

For example, a packet destined for 192.168.32.1 arrives on an interface with these routes in the routing table:

- 192.168.32.0/24 gateway 10.1.1.2
- 192.168.32.0/19 gateway 10.1.1.3

In this case, a packet destined to 192.168.32.1 is directed toward 10.1.1.2, because 192.168.32.1 falls within the 192.168.32.0/24 network. It also falls within the other route in the routing table, but 192.168.32.0/24 has the longest prefix within the routing table (24 bits verses 19 bits). Longer prefixes are always preferred over shorter ones when forwarding a packet.



Dynamic routing and High availability

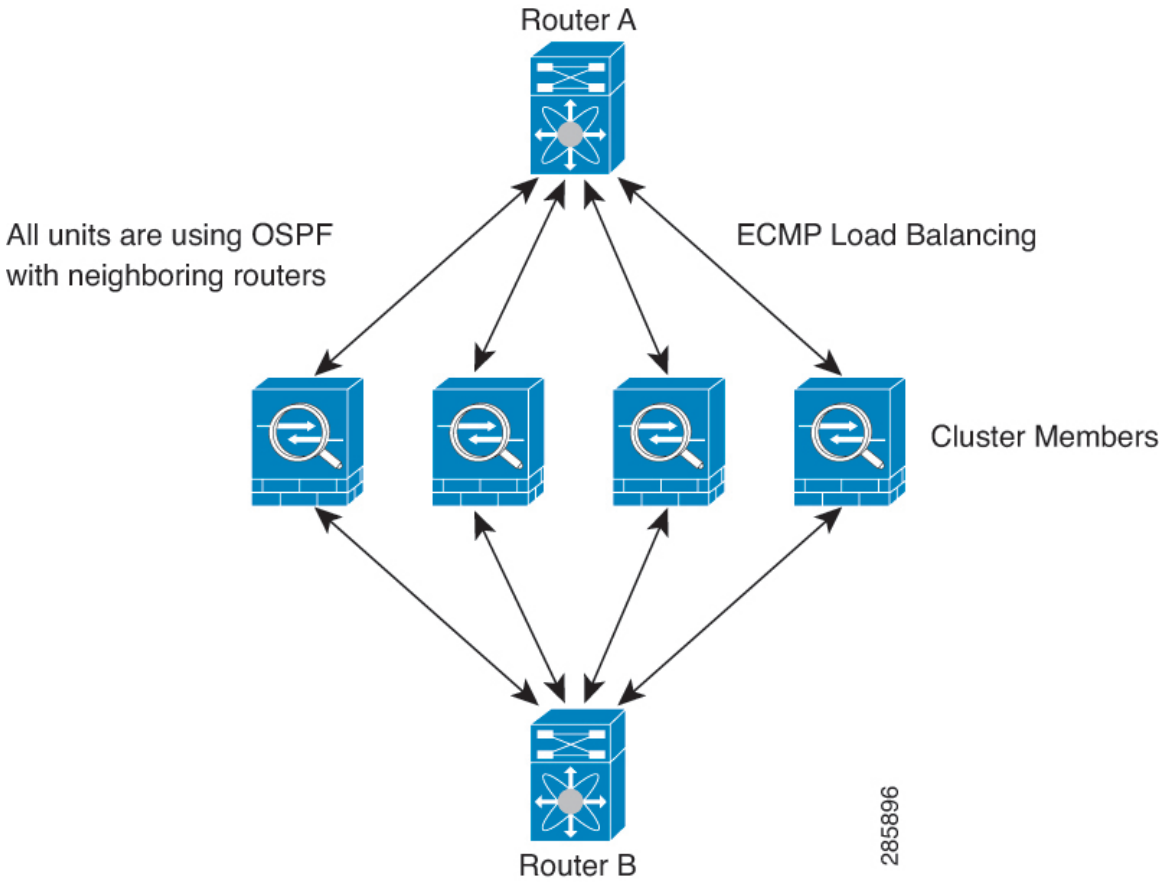
Dynamic routes are synchronized on the standby unit when the routing table changes on the active unit. This means that all additions, deletions, or changes on the active unit are immediately propagated to the standby unit. If the standby unit becomes active in an active/standby ready High availability pair, it will already have an identical routing table as that of the former active unit because routes are synchronized as a part of the High availability bulk synchronization and continuous replication processes.

Dynamic routing in Clustering

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.

Figure 351: Dynamic Routing in Spanned EtherChannel Mode

After the data node learn the routes from the control node, each node makes forwarding decisions independently.



The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

Dynamic routing in individual interface mode

Learn how dynamic routing functions in individual interface mode, where each cluster node operates as a standalone router. Understand how to configure unique router IDs and manage traffic zones to ensure effective load balancing and prevent asymmetric routing in your network environment.

In Individual interface mode, each node runs the routing protocol as a standalone router, and routes are learned by each node independently.

Figure 352: Dynamic Routing in Individual Interface Mode

In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

EIGRP does not form neighbor relationships with cluster peers in individual interface mode.

Note If the cluster has multiple adjacencies to the same router for redundancy purposes, asymmetric routing can lead to unacceptable traffic loss. To avoid asymmetric routing, group all of these node interfaces into the same traffic zone. See Create an ECMP zone, on page 1049.

Routing table for management traffic

The Firewall Threat Defense device includes the following routing tables for from-the-device management traffic:

- Linux Management routing table—Special management traffic sourced from the Management interface such as Firewall Management Center communication, licensing communication, and database updates always uses the Linux Management routing table.
- Data routing table—All from-the-device traffic (as well as all through traffic) uses the data routing table by default. All regular data interfaces are part of this routing table. Most services let you choose a specific interface, so only routes associated with that interface are used.
- Management-only routing table—The Management interface and all data interfaces that you set to management-only are part of this routing table. To send from-the-device traffic from any of these interfaces, you must choose a specific management-only interface when you configure the service. An exception is for DNS lookups and ICMP (ping and traceroute): in these cases, the Firewall Threat Defense will use data and then fall back to management automatically if a route is not found. You can add static routes for management-only interfaces, but not for the special Management interface. The Firewall Threat Defense device automatically adds a default route for Management that forwards traffic to Linux, where a separate route lookup occurs in the Linux routing table. You can add static routes to the Linux routing table that can be used by Management using the Firewall Threat Defense CLI **configure network static-routes** command.

Note The *default* Linux route is set with the **configure network ipv4** or **configure network ipv6** command.

Note For devices that have not yet merged the Management and legacy Diagnostic interfaces, see refer to pre-7.3 versions of this guide.

Equal-cost multi-path routing

The Firewall Threat Defense supports Equal-Cost Multi-Path (ECMP) routing.

ECMP routing implementation

You can have up to 8 equal cost static or dynamic routes per interface. For example, you can configure multiple default routes on the outside interface that specify different gateways.

```
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.3
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.4
```

In this case, traffic is load-balanced on the outside interface between 10.1.1.2, 10.1.1.3, and 10.1.1.4. Traffic is distributed among the specified gateways based on an algorithm that hashes the source and destination IP addresses, incoming interface, protocol, source and destination ports.

ECMP Across Multiple Interfaces Using Traffic Zones

If you configure traffic zones to contain a group of interfaces, you can have up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone. For example, you can configure multiple default routes across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2
route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

Similarly, your dynamic routing protocol can automatically configure equal cost routes. The Firewall Threat Defense load-balances traffic across the interfaces with a more robust load balancing mechanism.

When a route is lost, the device seamlessly moves the flow to a different route.

Routing GRE traffic

In Firewall Threat Defense, Generic Routing Encapsulation (GRE) traffic is managed using bi-directional flows. This means that each GRE session is represented by a single flow entry that handles both inbound and outbound traffic between endpoints. With bi-directional flows, only one route lookup is performed and both directions are mapped to the same interface. As a result, the system cannot make independent routing decisions for each direction, which may lead to sub-optimal routing in some scenarios.

About route maps

Route maps are used when redistributing routes into an OSPF, RIP, EIGRP or BGP routing process. They are also used when generating a default route into an OSPF routing process. A route map defines which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process.

Route map characteristics

Route maps have many features in common with widely known ACLs. These are some of the traits common to both:

- They are an ordered sequence of individual statements, and each has a permit or deny result. Evaluation of an ACL or a route map consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is aborted once the first statement match is found and an action associated with the statement match is performed.
- They are generic mechanisms. Criteria matches and match interpretation are dictated by the way that they are applied and the feature that uses them. The same route map applied to different features might be interpreted differently.

These are some of the differences between route maps and ACLs:

- Route maps are more flexible than ACLs and can verify routes based on criteria which ACLs can not verify. For example, a route map can verify if the type of route is internal.
- Each ACL ends with an implicit deny statement, by design convention. If the end of a route map is reached during matching attempts, the result depends on the specific application of the route map. Route maps that are applied to *redistribution* behave the same way as ACLs: if the route does not match any clause in a route map then the route redistribution is denied, as if the route map contained a deny statement at the end.

Permit and deny clauses

Route maps can have permit and deny clauses. The deny clause rejects route matches from redistribution. You can use an ACL as the matching criterion in the route map.

Route map and ACL clause interaction rules

Because ACLs also have permit and deny clauses, the following rules apply when a packet matches the ACL:

- ACL permit + route map permit: routes are redistributed.
- ACL permit + route map deny: routes are not redistributed.
- ACL deny + route map permit or deny: the route map clause is not matched, and the next route-map clause is evaluated.

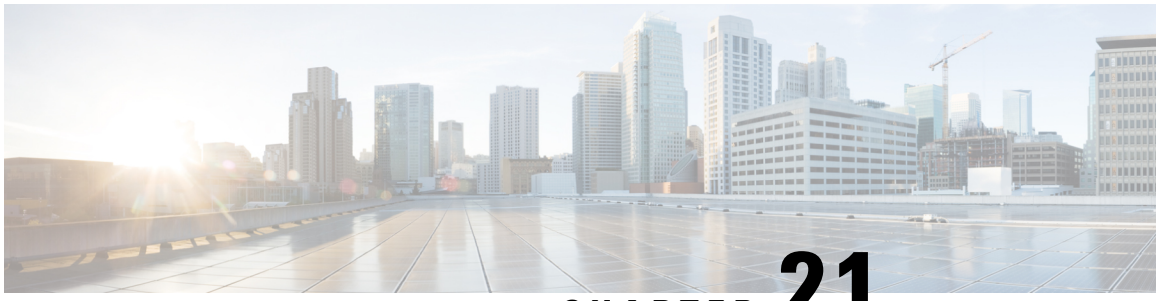
Match and set clause values

Each route map clause has two types of values:

- A match value selects routes to which this clause should be applied.
- A set value modifies information that will be redistributed into the target protocol.

Route map evaluation process

For each route that is being redistributed, the router first evaluates the match criteria of a clause in the route map. If the match criteria succeeds, then the route is redistributed or rejected as dictated by the permit or deny clause, and some of its attributes might be modified by the values set from the set commands. If the match criteria fail, then this clause is not applicable to the route, and the software proceeds to evaluate the route against the next clause in the route map. Scanning of the route map continues until a clause is found that matches the route or until the end of the route map is reached.



A match or set value in each clause can be missed or repeated several times, if one of these conditions exists:

- If several match entries are present in a clause, all must succeed for a given route in order for that route to match the clause (in other words, the logical AND algorithm is applied for multiple match commands).
- If a match entry refers to several objects in one entry, either of them should match (the logical OR algorithm is applied).
- If a match entry is not present, all routes match the clause.
- If a set entry is not present in a route map permit clause, then the route is redistributed without modification of its current attributes.

Note Do not configure a set entry in a route map deny clause because the deny clause prohibits route redistribution—there is no information to modify.

A route map clause without a match or set entry does perform an action. An empty permit clause allows a redistribution of the remaining routes without modification. An empty deny clause does not allow a redistribution of other routes (this is the default action if a route map is completely scanned, but no explicit match is found).

CHAPTER 21

Virtual Routers

This chapter describes underlying concepts about virtual routers and on how virtual routing behaves within the Secure Firewall Threat Defense.

- Virtual routers and virtual routing and forwarding (VRF), on page 991
- Maximum number of virtual routers by device model, on page 997
- Requirements and prerequisites for virtual routers, on page 999
- Guidelines and limitations for virtual routers, on page 999
- Manage virtual routers, on page 1001
- Create a virtual router, on page 1002
- Monitor virtual routers, on page 1006
- Configuration examples for virtual routers, on page 1006
- History for virtual routers, on page 1045

Virtual routers and virtual routing and forwarding (VRF)

A virtual router is a network virtualization feature that

- maintains separate routing tables for groups of interfaces
- provides clean separation in the traffic flowing through the device, and
- implements the "light" version of Virtual Routing and Forwarding, or VRF-Lite, which does not support Multiprotocol Extensions for BGP (MBGP).

Virtual router capabilities and configuration

Virtual routers provide support to two or more distinct customers over a common set of networking equipment. You can also use virtual routers to provide more separation for elements of your own network, for example, by isolating a development network from your general purpose corporate network.

When you create a virtual router, you assign interfaces to the router. You can assign a given interface to one, and only one, virtual router. You would then define static routes, and configure routing protocols such as OSPF or BGP, for each virtual router. You would also configure separate routing processes over your entire network, so that routing tables on all participating devices are using the same per-virtual-router routing process and tables. Using virtual routers, you create logically-separated networks over the same physical network to ensure the privacy of the traffic that runs through each virtual router.

Because the routing tables are separate, you can use the same, or overlapping, address spaces across the virtual routers. For example, you could use the 192.168.1.0/24 address space for two separate virtual routers, supported by two separate physical interfaces.

Note that there are separate management and data routing tables per virtual router. For example, if you assign a management-only interface to a virtual router, then the routing table for that interface is separate from the data interfaces assigned to the virtual router.

Virtual routers and dynamic VTI

You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. You can assign a dynamic VTI to only one virtual router. For more information, refer to Virtual Routers and Dynamic VTI, on page 1368.

Virtual router applications

Virtual router applications are network implementation scenarios that

- isolate networks on shared resources through dedicated routing tables
- enable common security policy management across different departments or networks, and
- provide shared internet access for different departments or networks.

Global and user-defined virtual routers

This reference provides information about global and user-defined virtual routers, including their characteristics and the features supported by each type.

Global virtual routers

For a device with virtual routing capability, system creates a global virtual router by default. The system assigns all interfaces in your network to the global virtual router. A routed interface can belong to either a user-defined virtual router or a global virtual router. When you upgrade Firewall Threat Defense to a version which has virtual router capability, all its existing routing configuration becomes part of the global virtual router.

User-Defined virtual routers

A user-defined virtual router is the one defined by you. You can create more than one virtual router on a device. However, anytime, an interface can be assigned to only one user-defined virtual router. While some of the device features are supported on user-defined virtual routers, few of the features are supported only on the global virtual routers. User-defined virtual routers support route-based site-to-site VPN (static VTI) (static and dynamic VTI).

Supported features and monitoring policies

You can configure these features on the global virtual router only:

- OSPFv3
- RIP

- EIGRP
- IS-IS
- Multicast Routing
- Policy Based Routing (PBR)

ISIS and PBR are supported through Flex Config in Firewall Management Center (see Predefined FlexConfig objects, on page 934). Configure only global virtual router interfaces for these features.

DHCP server auto-configuration uses WINS/DNS server that is learned from an interface. This interface can only be a global virtual router interface.

You can configure these features separately for each user-defined virtual router:

- Static routes and their SLA monitors
- OSPFv2
- BGPv4/v6
- Integrated Routing and Bridging (IRB)
- SNMP

These features are used by the system when querying or communicating with the remote system (from-the-box traffic). These features use interfaces in the global virtual router only. That means, if you configure an interface for the feature, it must belong to the global virtual router. As a rule, anytime, if the system must look up a route to reach an external server for its own management purposes, it does the route lookup in the global virtual router.

- DNS server when used to resolve fully qualified names used in access control rules, or for resolving names for the **ping** command. If you specify **any** as the interface for a DNS server, the system considers interfaces in the global virtual router only.
- AAA server or identity realm when used with VPN. You can configure VPN on interfaces in the global virtual router only. Thus, the external AAA servers that are used for VPN, such as Active Directory, must be reachable through an interface in the global virtual router.

Virtual-router-aware policies

Virtual-router-aware policies are security policies that

- apply to interfaces from a single virtual router only
- use security zones whose memberships are constrained to interfaces assigned to a specific virtual router, and
- prevent policies from affecting all interfaces across all virtual routers when that is not desired.

Virtual router policy behavior

When you create a virtual router, the routing table for that virtual router is automatically separated from the global virtual router or any other virtual router. However, security policies are not automatically virtual-router-aware.

For example, if you write an access control rule that applies to "any" source or destination security zone, then the rule will apply to all interfaces across all virtual routers. This might in fact be exactly what you want. For example, all of your customers might want to block access to the same list of objectionable URL categories.

But, if you need to apply a policy to one of the virtual routers but not others, you need to create security zones that contain interfaces from that single virtual router only. Then, use the virtual-router-constrained security zones in the source and destination criteria of the security policy.

By using security zones whose memberships are constrained to the interfaces assigned to a single virtual router, you can write virtual-router-aware rules in these policies:

- Access control policy.
- Intrusion and file policies.
- SSL decryption policy.
- Identity policy and user-to-IP address mappings. If you use overlapping address spaces in virtual routers, ensure that you create separate realms for each virtual router and apply them correctly in the identity policy rules.

If you use overlapping address spaces in your virtual routers, you should use security zones to ensure that the right policies get applied. For example, if you use the 192.168.1.0/24 address space in two separate virtual routers, an access control rule that simply specifies the 192.168.1.0/24 network will apply to traffic in both virtual routers. If that is not the desired outcome, you can limit the application of the rule by also specifying the source/destination security zones for just one of the virtual routers.

Virtual router interconnection

Virtual router interconnection is a routing mechanism that

- enables traffic routing between virtual routers through route leaking,
- supports both manual static routes and dynamic BGP configurations, and
- allows network segmentation while maintaining controlled inter-segment communication.

Route leaking methods

You can configure the device to route traffic between virtual routers. This process of route leaking can be done manually by setting up static routes or dynamically through BGP settings.

Static route leaking involves manual configuration:

You can configure static routes to route traffic between virtual routers.

For example, if you have the outside interface in the global virtual router, you can set up static default routes in each of the other virtual routers to send traffic to the outside interface. Then, any traffic that cannot be routed within a given virtual router gets sent to the global router for subsequent routing.

Static routes between virtual routers are known as route leaks, because you are leaking traffic to a different virtual router. When you are leaking routes, say, VR1 routes to VR2, you can initiate connections from VR2 to VR1 only. For traffic to flow from VR1 to VR2, you must configure the reverse route. When you create a static route to an interface in another virtual router, you do not need to specify a gateway address. Simply select the destination interface.

For inter-virtual-router routes, the system does destination interface look-up in the source virtual router. Then, it looks up the MAC address of the next hop in the destination virtual router. Thus, the destination virtual router must have either a dynamic (learned) or static route for the selected interface for the destination address.

Configuring NAT rules that use source and destination interfaces in different virtual routers can also allow traffic to route between virtual routers. If you do not select the option for NAT to do a route lookup, the rule will simply send traffic out the destination interface with a NATed address whenever destination translation happens. However, the destination virtual router should have a route for the translated destination IP address so that next-hop lookup can succeed.

Though NAT rule leaks traffic from one virtual router to another, to ensure correct routing, we recommend that you configure a static route leak between these virtual routers for the translated traffic. Without the route leak, sometimes the rule may not match the traffic you expect it to match, and the translation may not be applied.

Virtual routing does not support a cascading or chain of route leaks. For example, assume that your Firewall Threat Defense has VR1, VR2, and VR3 virtual routers; VR3 is directly connected to a network - 10.1.1.0/24. Now, assume you configure a route leak in VR1 for network 10.1.1.0/24 through interface in VR2 and in VR2 define a route leak for 10.1.1.0/24 through VR3. This chain of route leaks will not allow traffic to hop from VR1 to VR2 and then exit from VR3. In case of route leaks, the route lookups first determine egress interface from input Virtual Router's routing table and then looks at the output of Virtual Router's routing table for next hop lookup. From both the lookups, egress interface should match. In our example, the egress interfaces will not be the same and hence the traffic does not pass through.

Use static inter VRF route with caution when the destination network is not a direct-connected subnet of the upstream (outgoing) VR. For example, assume two VRs - VR1 and VR2. While VR1 handles the outgoing traffic which gets the default route from its external peer through BGP or any dynamic routing protocol, and VR2 handles the incoming traffic which is configured with static inter VRF default route with VR1 as the next-hop. When VR1 loses the default route from its peer, VR2 will not able to detect that its upstream (outgoing) VR lost the default route and the traffic is still sent toward VR1 which will eventually get dropped without notifications. In this scenario, we recommend that you configure VR2 with dynamic route leak through BGP.

You can implement an inter-virtual-router route leak by exporting routes from a source virtual router (say VR1) to the source BGP table using route target extended community and then importing the same route target extended community from the source BGP table into the destination BGP table, which in turn is used by the destination virtual router (say, VR2). You can use the route maps for filtering the routes. The routes of global virtual router can also be leaked to user-defined virtual routers and vice versa. The BGP inter-virtual-router route leaking supports both ipv4 and ipv6 prefixes.

For details on configuring BGP route leaking, see Configure BGP route import and export, on page 1125.

BGP route leaking guidelines:

- Ensure that all the routes required for recursion are imported and present in the routing table of the ingress virtual router.
- ECMP is supported per virtual router. Hence, do not configure an ECMP across different virtual routers. The overlapping prefixes imported from different virtual routers cannot form an ECMP. That is, when you attempt to import routes with overlapping addresses from two different virtual routers to other virtual routers (a global virtual router or n user-defined virtual router), only one route (as per BGP best path algorithm, the first route that was advertised) is imported to the respective virtual routing table. For example, if a network 10.10.0.0/24, connected to VR1 is advertised through BGP to a global virtual router first, and later another network with the same address 10.10.0.0/24, connected to VR2 is also advertised through BGP to global virtual router, only the VR1 network route is imported to the global virtual routing table.

- OSPFv3 is not supported on user-defined virtual routers. Hence, do not configure BGPv6 to leak OSPFv3 user-defined virtual routers to global virtual router. However, you can configure BGPv6 to leak OSPFv3 global virtual router routes to user-defined virtual router through redistribution.
- It is recommended to keep VTI interface, protected internal interfaces (loopback interface if supported for VTI) to be part of same virtual router to prevent the need for route leak.

Best practice for overlapping IP addresses

Virtual router creates multiple instances of routing tables that are independent, thereby, the same or overlapping IP addresses can be used without conflicts. Firewall Threat Defense allows the same network to be part of two or more virtual routers. This involves multiple policies to be applied at the interface or at the virtual router level.

Limitations with overlapping IP addresses

When using an overlapping IP address in multiple virtual routers, to ensure proper application of the policy, you have to modify policies or rules for some of the features. Such features require you to use more specific interface either by splitting existing security zone or using new interface group as the need be.

- Network Map—Modify the network discovery policy to exclude some overlapping IP segments to ensure that there is no overlapping IP address being mapped.
- Identity Policy—The identity feed source cannot differentiate among virtual routers; to overcome this limitation, map overlapping address spaces or virtual routers in different realms.
- Access Policy—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.
- Prefilter Policy—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.
- QoS/Rate Limit—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.
- SSL Policy—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.

Unsupported features with overlapping IP addresses

These features are not supported with overlapping IP addresses:

- ISE SGT-based Rule in AC Policy—The static security group tag (SGT) to IP address mappings downloaded from Cisco Identity Services Engine (ISE) are not virtual-router-aware. Set up separate ISE systems per virtual router if you need to create different SGT mappings per virtual router. This is not necessary if you intend to map the same IP addresses to the same SGT number in each virtual router.
- Overlapping DHCP server pools are not supported across virtual routers.
- Events and Analytics—Many of the Firewall Management Center analytics are dependent on network map and identity mappings which cannot differentiate if the same IP address belongs to two different end hosts. Hence, these analytics are not accurate when there are overlapping IP segments existing in same device but different virtual routers.

Other than few exceptions, the routing functions and most of the NGFW and IPS capability does not get impacted by the overlapping IP addresses.

Configuring SNMP on user-defined virtual routers

In addition to supporting SNMP on the management interface and Global virtual router data interfaces, Secure Firewall Threat Defense now allows you to configure SNMP host on user-defined virtual routers.

Summary

The key components involved in configuring SNMP on user-defined virtual routers are:

- Device interfaces: Physical or logical interfaces that need to be configured and enabled
- Virtual router: User-defined virtual router configured on specific interfaces
- SNMP hosts: Network management stations that receive SNMP polling and traps
- Secure Firewall Threat Defense: The target device where configurations are deployed

Workflow

The SNMP configuration on user-defined virtual routers involves these stages:

1. Configure device interfaces.
2. Configure virtual router on an interface.
3. Configure SNMP hosts on a virtual router interface.

Note SNMP is not virtual router-aware. Hence, while configuring SNMP server on the user-defined virtual router, ensure that the network address is not an overlapping IP address.

4. Deploy configurations to Secure Firewall Threat Defense.

   On successful deployment, the SNMP polling and traps are sent to the Network Management Station through the virtual router interface.

Maximum number of virtual routers by device model

The maximum number of virtual routers you can create depends on the device model. The following table shows the maximum supported virtual routers per model. You can confirm the maximum for your system by entering the **show vrf counters** command, which displays the maximum number of user-defined virtual routers for your platform (not including the global virtual router). The numbers below include both user and global routers. For Firepower 4100/9300 devices, these values apply to native mode.

For platforms that support multi-instance capability, such as the Firepower 4100/9300, determine the maximum number of virtual routers per container instance by dividing the maximum virtual routers by the number of cores on the device, and then multiplying by the number of cores assigned to the instance, rounding down to the nearest whole number. For example, if the platform supports a maximum of 100 virtual routers, and it has

70 cores, then each core would support a maximum of 1.43 virtual routers (rounded). Thus, an instance assigned 6 cores would support 8.58 virtual routers, which rounds down to 8, and an instance assigned 10 cores would support 14.3 virtual routers (rounding down, 14).

Device Model	Maximum Virtual Routers
Firepower 1010	5
Firepower 1120	5
Firepower 1140	10
Firepower 1150	10
Firepower 2110	10
Firepower 2120	20
Firepower 2130	30
Firepower 2140	40
Secure Firewall 3105	10
Secure Firewall 3110	15
Secure Firewall 3120	25
Secure Firewall 3130	50
Secure Firewall 3140	100
Firepower 4112	60
Firepower 4115	80
Firepower 4125	100
Firepower 4145	100
Secure Firewall 4215	100
Secure Firewall 4225	100
Secure Firewall 4245	100
Firepower 9300 appliance, all models	100
Firewall Threat Defense Virtual, all platforms	30
ISA 3000	10

Interface guidelines

Configure interfaces for virtual routers according to these guidelines:

- Assign an interface to only one virtual router.
- A virtual router can have any number of interfaces that are assigned to it.
- Assign only routed interfaces with logical names and VTIs to a user-defined virtual router.
- If you want to change a virtual router interface to a non-routed mode, remove the interface from the virtual router, and then change its mode.
- You can assign an interface to a virtual router, either from a global virtual router or from another user-defined virtual router.
- Do not assign these interfaces to a user-defined virtual router:
  - Members of EtherChannel.
  - Members of Redundant interfaces.
  - Members of BVI.
- VTI is a route-based VPN. When the tunnel is established, control the traffic that uses VTI for encryption through routing. Static routing, as well as dynamic routing with BGP, OSPFv2/v3, or EIGRP is supported.

- Do not use interfaces that belong to user-defined virtual routers in policy-based site-to-site or remote access VPNs.
- A dynamic VTI and its corresponding protected network interface must be part of the same virtual router.
- You must map the borrow IP interface and the dynamic VTI to the same virtual router.
- User-defined virtual routers support only BGPv4/v6 and OSPFv2 routing protocols.
- A tunnel source interface can be in a different user-defined virtual router than that associated with the dynamic VTI.

Follow these precautions when moving interfaces between virtual routers:

- If a route using the interface that is being moved or its virtual router is deleted, exist in source or destination virtual router table, remove the routes before the interface movement or virtual router deletion.
- As separate routing tables are maintained for each virtual router, when an interface is moved from one virtual router to another virtual router, be it global or user-defined, the system removes the IP address configured on the interface temporarily. All existing connections on the interface are terminated. Thus, moving interfaces between virtual routers have drastic effect on the network traffic. Hence take precautionary measures before you move interfaces.

Global virtual router guidelines

Consider these guidelines for global virtual routers:

- The interfaces which are named and not part of other virtual routers, are part of the global virtual router.
- Do not remove routed interfaces from global virtual router.
- Do not modify global virtual router.
- Generally, after configuring interfaces, if you un-register and register back to same or another Firewall Management Center, interface configuration is imported back from device. With virtual router support, there is a restriction—the IP address for only global virtual router interfaces is retained.

Clustering guidelines

Consider these limitations when using virtual routers with clustering:

- When the control unit link fails due to failure of its interfaces, the unit removes all leaked routes of its interfaces from the global routing table and propagates the inactive connected and static routes to other units of the cluster. This results in removal of those leaked routes from the routing table in other units. These removal takes place prior to another unit becoming a new control unit, which takes approximately 500 ms. When another unit becomes the new control unit, these routes are learned and added back to the routing tables through BGP convergence. Thus, till the convergence time, approximately one minute, the leaked routes are not available for the routing events to take place.
- When a control role change occurs in a cluster, the leaked routes learnt through BGP is updated with the best ECMP path. However, the non-best ECMP path is removed from the cluster routing table only after the BGP reconvergence timer elapses, that is 210 seconds. Thus, till the BGP reconvergence timer elapse, the old, non-best ECMP path persist as preferred route for routing events.

Additional guidelines

Follow these additional guidelines when configuring virtual routers:

- While configuring BGP for virtual routers, you can redistribute the routes belonging to different protocols within the same virtual routers. For example, OSPF VR2 routes cannot be imported into BGP VR1. You can only redistribute OSPF VR2 into BGP VR2, and then configure a route leak between BGP VR2 and BGP VR1.
- Do not use IPv6 ACL for filtering the routes in the route map. Only prefix list is supported.
- Security Intelligence Policy—The Security Intelligence policy is not virtual-router-aware. If you add an IP address, URL, or DNS name to the block list, it is blocked for all virtual routers. This limitation is applicable on the interface having security zones.
- NAT Rules—Do not mix interfaces in NAT rules. In virtual routing, if the specified source and destination interface objects (interface groups or security zones) have interfaces that belong to different virtual routers, the NAT rule diverts traffic from one virtual router through another virtual router. The NAT does the route lookup in the virtual router table for the inbound interface only. If necessary, define static routes in the source virtual router for the destination interface. If you leave the interface as **any**, the rule applies to all interfaces regardless of virtual router membership.
- DHCP Relay—Interconnecting virtual routers for DHCP relay is not supported. For example, if DHCP relay client is enabled on VR1 interface and DHCP relay server is enabled on VR2 interface, the DHCP requests will not be forwarded outside of VR2 interface.
- Recreating a deleted virtual router—When you recreate a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to recreate a deleted virtual router successively, use a different name for the new virtual router.
- The Threat Defense Snort engine maintains state for each traffic flow and is designed to inspect each flow exactly once. Duplicate or double inspection is unsupported when repeated traffic maps to the same Snort flow key, because the subsequent instance is associated with the existing per-flow state and may be identified as an anomaly.

  This can occur when a flow re-enters the device through a different interface or VLAN, is rerouted by an ACI fabric with different VLAN tags, or traverses VRF cross-VLAN paths. The resulting drop may appear in packet-tracer or capture output as:

  ```
  Drop-reason: (stream) Blocked or blacklisted by the stream preprocessor.
  ```

  If a flow-identifying attribute differs such that the traffic maps to a different Snort flow key, Snort can process the flows independently. However, differences in fields that are not part of the flow key do not create a separate flow.

  From an optimal network architecture perspective, each traffic flow, in both directions, should traverse the Snort engine only once. If duplicate inspection cannot be avoided, use a prefilter or fastpath rule to bypass Snort inspection for the affected flows.

Manage virtual routers

When you click **Manage Virtual Routers** on the Virtual Routers pane, the Manage Virtual Routers page appears. This page displays the existing virtual routers on the device and the associated interfaces. On this page, you can **Add Virtual Router** ( ) to the device. You can also **Edit** ( ) and **Delete** ( ) user-defined

virtual routers. You cannot edit or remove a global virtual router. You can only **View** (🔍) the details of a global virtual router.

Create a virtual router

Create a virtual router to enable network segmentation and manage routing configurations independently within the firewall device.

Virtual routers allow you to segment network traffic and create separate routing domains within a single firewall device, providing enhanced network management and security isolation.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

Step 4 Click **Add Virtual Router** (+).

Step 5 In the Add Virtual Router box, enter a name and description for the virtual router.

Note If you are creating a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to create a deleted virtual router successively, use a different name for the new virtual router.

Step 6 Click **Ok**.

The Routing page appears, displaying the newly created virtual router page.

The virtual router is successfully created and appears in the routing configuration interface, ready for further configuration.

What to do next

- Configure a Virtual Router.

Configure a virtual router

Configure a virtual router to assign interfaces and set up routing policies for network traffic management and routing capabilities on your device.

You can assign interfaces to a user-defined virtual router and configure the routing policies for the device. Though you cannot manually add or remove interfaces for a global virtual router, you can configure the routing policies for the device interfaces.

Before you begin

- To configure routing policies for a user-defined virtual router, add a router. See Create a virtual router, on page 1002.
- All routing configuration settings of a non-virtual routing capable device are also available for a global virtual router. For information on the settings, see Routing Settings.
- Only limited routing protocols are supported for a user-defined virtual router.

Procedure

Step 1 From the **Devices** > **Device Management** page, edit the virtual-router supported device. Navigate to **Routing**.

For information on the modifications to the routing page, see Modifications to the Firewall Management Center web interface routing page.

Step 2 From the drop-down list, select the desired virtual router.

Step 3 In the **Virtual Router Properties** page, modify the description as needed.

Step 4 To add interfaces, select the interface under the **Available Interfaces** box, and then click **Add**.

Remember these guidelines:

- Only interfaces with a logical name are listed under the **Available Interfaces** box. You can edit the interface and provide a logical name in **Interfaces**. Remember to save the changes for the settings to take effect.
- Only interfaces of global virtual routers are available for assigning; the **Available Interfaces** box lists only interfaces that are not assigned to any other user-defined virtual routers. You can assign physical interfaces, subinterfaces, redundant interfaces, bridge groups, VTIs, and EtherChannels to a virtual router, but not their member interfaces. Because the member interfaces cannot be named, they cannot be used in virtual routing.

  You can assign the diagnostic interface to the global virtual router only.

Step 5 To save the interface settings, click **Save**.

Step 6 To configure the routing policy for the virtual router, click the respective names to open the corresponding settings page:

- **OSPF**—Only OSPFv2 is supported on the user-defined virtual router. All other settings for OSPFv2 are as applicable as for a non-virtual-router-aware interface, except that **Interface** allows you to select only the interfaces of the virtual router that you are configuring. You can define the OSPFv3 and OSPFv2 routing policies for a global virtual router. For information on the OSPF settings, see OSPF, on page 1063.
- **RIP**—You can configure RIP routing policies only for a global virtual router. For information on RIP settings, see RIP, on page 1129.
- **BGP**—This page displays the BGP general settings that you have configured in **Settings**:
  - You cannot modify any of those general settings on this page, except for the router ID settings. You can override the router ID settings that were defined in the **Settings** page by editing them on this page.

- To configure other BGP IPv4 or IPv6 settings, you must enable the BGP option in **BGP** page under **General Settings**.
- BGP configuration for both IPv4 and IPv6 address family are supported for global router and the user-defined virtual router.

For information on configuring BGP settings, see BGP, on page 1107.

- **Static Route**—Use this setting to define where to send traffic for a specific destination network. You can also use this setting to create an inter-virtual-router static route. You can create a leak of connected or static route by using the interfaces of user-defined or global virtual routers. **FMC prefixes** to an interface to indicate that it is belonging to another virtual router and can be used for a route leak. For the route leak to be successful, do not specify next hop gateway.

  The Static Route table displays the virtual router whose interface is used for a route leak in the **Leaked from Virtual Router** column. If it is not a route leak, the column displays N/A.

  Irrespective of which virtual router the static route belongs, a Null0 interface is listed along with the interfaces of the same virtual router to which the static route belongs.

  For information on static route settings, see Static and Default Routes, on page 973.

- **Multicast**—You can configure multicast routing policies only for a global virtual router. For information on multicast settings, see Multicast, on page 1137.

Step 7 To save the routing policy settings, click **Save**.

The virtual router is configured with the assigned interfaces and routing policies you specified.

What to do next

- Modify a virtual router.
- Remove a virtual router.

Modify a virtual router

This task allows you to update the configuration settings of virtual routers to meet changing network requirements.

You can modify the description and other routing policies of a virtual router.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

All virtual routers along with the assigned interfaces are displayed in the **Virtual Routers** page.

Step 4 To modify a virtual router, click **Edit** (✎) against the desired virtual router.

Note You cannot modify the general settings of the global virtual router. Hence, edit is not available for the global router; instead a **View** ( ) is provided to view the settings.

Step 5 To save the changes, click **Save**.

The virtual router configuration is updated with your changes.

What to do next

- Remove a virtual router.

Remove Virtual Routers

Remove virtual routers when they are no longer needed or when consolidating routing configurations. This helps maintain a clean and efficient network routing structure.

Virtual routers provide network segmentation and routing isolation. When removing virtual routers, all associated interfaces automatically move to the global virtual router, and all routing policies are deleted.

Before you begin

- You cannot delete the Global virtual router. Hence, the delete option is not available for the Global virtual router.
- You can remove multiple virtual routers at a time.
- All the routing policies of the deleted virtual router are also deleted.
- All the interfaces of the deleted virtual router move to the global virtual router.
- If there are any restrictions on the movement of interfaces, such as overlapping IPs, route conflicts, and so on, you can remove the router only after resolving the conflicts.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

All virtual routers along with the mapped interfaces are displayed in the **Virtual Routers** page.

Step 4 To remove a virtual router, click **Delete** ( ) against the desired virtual router.

Step 5 To remove multiple routers, holding the CTRL key, click the virtual routers that you want to delete. Right-click, and then click **Delete**.

Step 6 To save the changes, click **Save**.

The selected virtual routers are removed from the device configuration. All interfaces from the deleted virtual routers are automatically moved to the global virtual router, and all associated routing policies are permanently deleted.

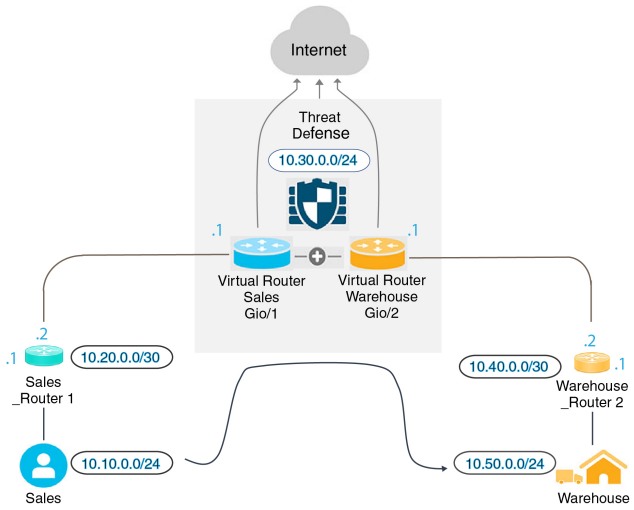
Monitor virtual routers

To monitor and troubleshoot virtual routers, log into the device CLI and use these commands:

- **show vrf**: Displays the details of the virtual routers and their associated interfaces.
- **show route vrf** <*vrf_name*>: Displays the routing details of a virtual router.
- **show run router BGP all**: Displays the BGP routing details of all virtual router.
- **show run router BGP vrf** <*vrf_name*>: Displays the BGP routing details of a virtual router.
- **show crypto ipsec sa/show crypto ikev2 sa**: Displays the details of the tunnel and the associated virtual router.
- You can monitor the tunnels in the Site-to site monitoring dashboard (**Overview > Site to Site VPN**).

  In the **Tunnel Status** widget, hover over a topology, click View and click **Packet Tracer** to view and troubleshoot the threat defense VPN tunnels.

Configuration examples for virtual routers



Route to a distant server through virtual routers

This task enables network separation while maintaining connectivity to servers across different virtual routing domains. You can create multiple virtual routers to maintain separate routing tables for groups of interfaces and interconnect them to reach hosts that are multiple hops away.

In virtual routing, you can create multiple virtual routers to maintain separate routing tables for groups of interfaces, thereby achieve network separation. In some scenarios, you may need to access a server that is reachable only through a separate virtual router. This example provides the procedure that interconnects virtual routers to reach to a host that is multiple hops away.

Consider an example, where a member of the sales department of a garment company wants to look up at the stock maintained by the warehousing department of its factory unit. In a virtual routing environment, you need to leak route between virtual routers where destination (warehousing department) is multiple hops away from sales department. This route leaking is done by adding multihop route leak, where, you configure a static route in Sales virtual router(source) to an interface in Warehouse virtual router (destination). As the destination network is multi-hop away, you also need to configure the Warehouse virtual router with the route to the destination network, namely 10.50.0.0/24.

Figure 353: Interconnecting two virtual routers - an example

Before you begin

This example assumes that you have already configured Sales_Router1 to route traffic from 10.20.0.1/30 interface to 10.50.0.5/24.

Follow these steps to route to a distant server through virtual routers:

Procedure

Step 1 Configure the inside interface (Gi0/1) of the device to be assigned to Sales virtual router.

a) Choose **Devices** > **Device Management**, click the device name, and click **Interfaces**.

b) Edit the Gi0/1 interface.

- **Name**—For this example, VR-Sales.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 10.30.0.1/24.

c) Click **Ok**.

d) Click **Save**.

Step 2 Configure the inside interface (Gi0/2) of the device to be assigned to Warehouse virtual router.

a) Choose **Devices** > **Device Management**, click the device name, and click **Interfaces**.

b) Edit the Gi0/2 interface.

- **Name**—For this example, VR-Warehouse.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.

- **IP Address**—Leave it blank. The system does not allow you to configure interfaces with same IP address (10.30.0.1/24), as you are yet to create user-defined virtual routers.

c) Click **Ok**.
d) Click **Save**.

Step 3 Create Sales and Warehouse virtual routers and assign their interfaces.

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**.
c) Click **Add Virtual Router** and create Sales.
d) Click **Add Virtual Router** and create Warehouse.
e) Select Sales from virtual router drop-down, in **Virtual Router Properties**, add VR-Sales as **Selected Interface** and save.
f) Select Warehouse from virtual router drop-down, in **Virtual Router Properties**, add VR-Warehouse as **Selected Interface** and save.

Step 4 Revisit the VR-Warehouse interface configuration.

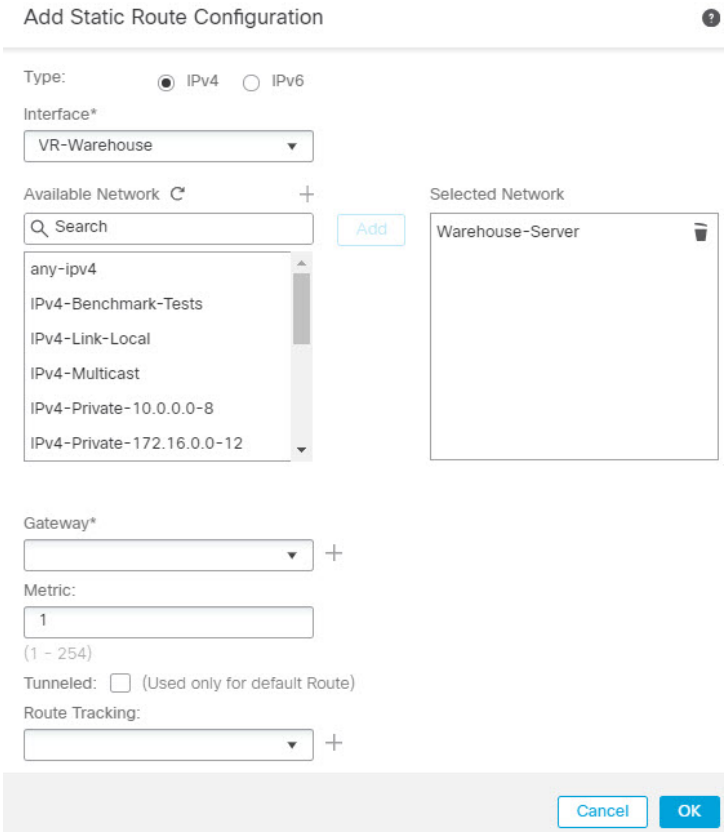
a) Choose **Devices** > **Device Management**, click the device name, and click **Interfaces**.
b) Click **Edit** against VR-Warehouse interface. Specify the IP Address as 10.30.0.1/24. The system now allows you to configure with same IP address of VR-Sales, because the interfaces are seperately assigned to two different virtual routers.
c) Click **Ok**.
d) Click **Save**.

Step 5 Create network objects for the warehouse server—10.50.0.0/24, and for the warehouse gateway— 10.40.0.2/30.

a) Choose **Objects** > **Object Management**.
b) Choose **Add Network** > **Add Object**.

- **Name**—For this example, Warehouse-Server.
- **Network**—Click Network and enter 10.50.0.0/24.

c) Click **Save**.
d) Choose **Add Network** > **Add Object**.



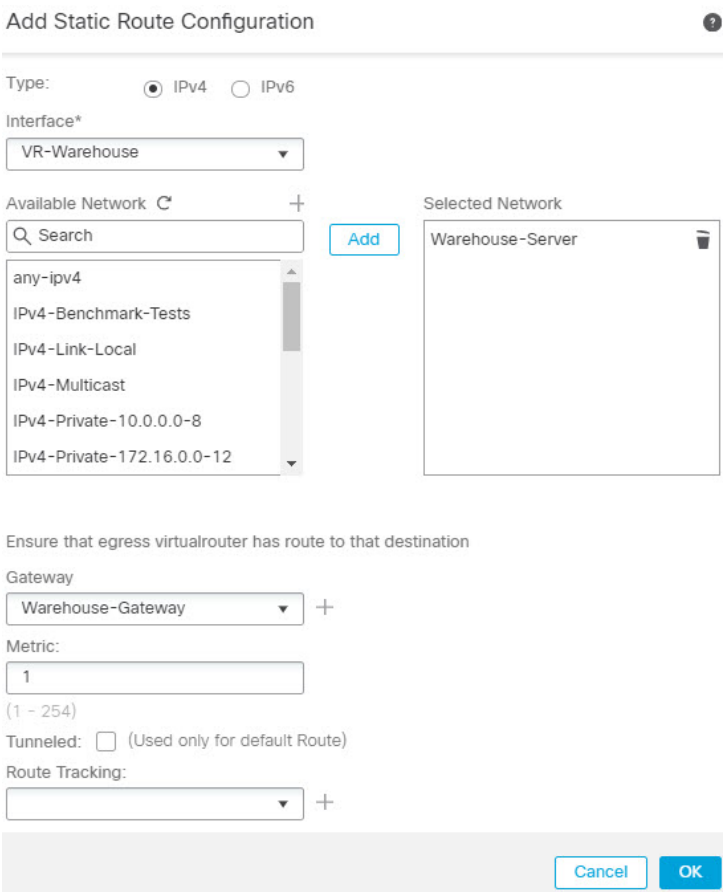
- **Name**—For this example, Warehouse-Gateway.
- **Network**—Click Host and enter 10.40.0.2.

e) Click **Save**.

Step 6 Define the route leak in Sales that points to the VR-Warehouse interface.

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing**.
c) Choose Sales virtual router from the drop-down, and then click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select VR-Warehouse.
- **Network**—Select the Warehouse-Server object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.

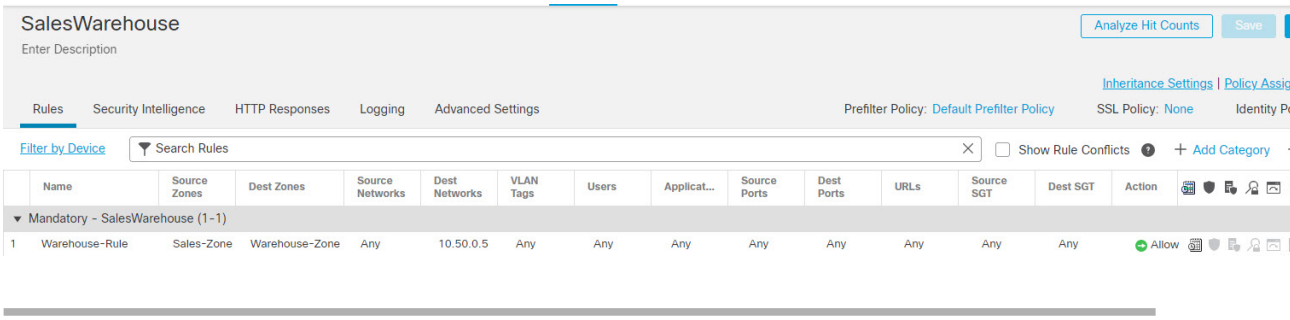


e) Click **Ok**.
f) Click **Save**.

Step 7 In the Warehouse virtual router, define the route that points to the Warehouse Router 2 gateway.

a) Choose Warehouse virtual router from the drop-down, and then click **Static Route**.
b) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select VR-Warehouse.
- **Network**—Select the Warehouse-Server object.
- **Gateway**—Select the Warehouse-Gateway object.



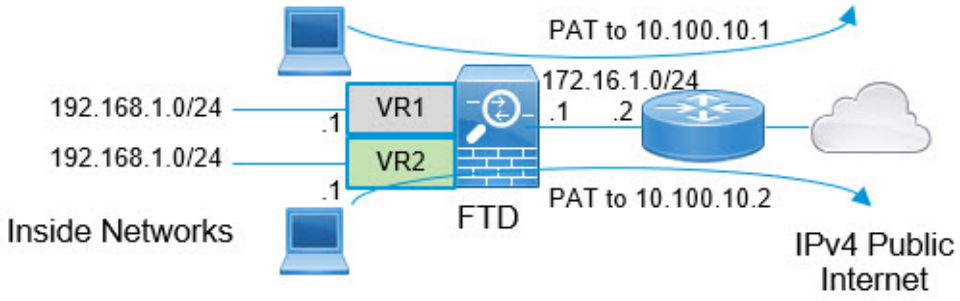
c) Click **Ok**.

d) Click **Save**.

Step 8 Configure access control rule that allows access to the warehouse server. For creating the access control rule, you need to create security zones. Use **Objects** > **Object Management** > **Interface**. Choose **Add** > **Security Zone** and create security zones for VR-Sales and VR-Warehouse; for Warehouse-Server network object, create a Warehouse-Server interface group (Choose **Add** > **Interface Group**).

Step 9 Choose **Policies** > **Access Control heading** > **Access Control** and configure an access control rule to allow traffic from the source interfaces in the Sales virtual router to the destination interfaces in the Warehouse virtual router for the destination Warehouse-Server network object.

For example, if the interfaces in Sales are in the Sales-Zone security zone, and those in Warehouse are in the Warehouse-Zone security zone, the access control rule would look similar to this:



The route leak configuration enables traffic from the Sales virtual router to reach the warehouse server through the Warehouse virtual router. The access control rule allows the required traffic between the security zones.

How to Provide Internet Access with Overlapping Address Spaces

Ensure that endpoints using the same IP address space in different virtual routers can securely access the internet by implementing NAT/PAT policies

When using virtual routers, you can have the same network address for interfaces that reside in separate routers. However, because the IP addresses routed in these separate virtual routers are the same, apply NAT/PAT rules for each interface with separate NAT/PAT pools to ensure that return traffic goes to the correct destination. This example provides the procedure to configure the virtual routers and NAT/PAT rules to manage the overlapping address spaces.

For example, interfaces vr1-inside and vr2-inside on Firewall Threat Defense is defined to use the IP address 192.168.1.1/24, managing endpoints on their segment in the 192.168.1.0/24 network. To allow Internet access from two virtual routers that use the same address space, you need to apply NAT rules separately to the interfaces within each virtual router, ideally using separate NAT or PAT pools. You could use PAT to translate the source addresses in VR1 to 10.100.10.1, and for those in VR2, to 10.100.10.2. The following illustration shows this setup, where the Internet-facing outside interface is part of the global router. You must define the NAT/PAT rules with the source interface (vr1-inside and vr2-inside) explicitly selected—using “any” as the source interface makes it impossible for the system to identify the correct source because the same IP address could exist on two different interfaces.

Note Even if you have some interfaces within virtual routers that does not use overlapping address spaces, define the NAT rule with the source interface to make troubleshooting easier, and to ensure a cleaner separation between traffic from the virtual routers that is Internet-bound.

Procedure

Step 1 Configure the inside interface of the device for VR1:

a) Choose **Devices** > **Device Management**, click the device name, and then click **Interfaces** .

b) Edit the interfaces that you want to assign to VR1:

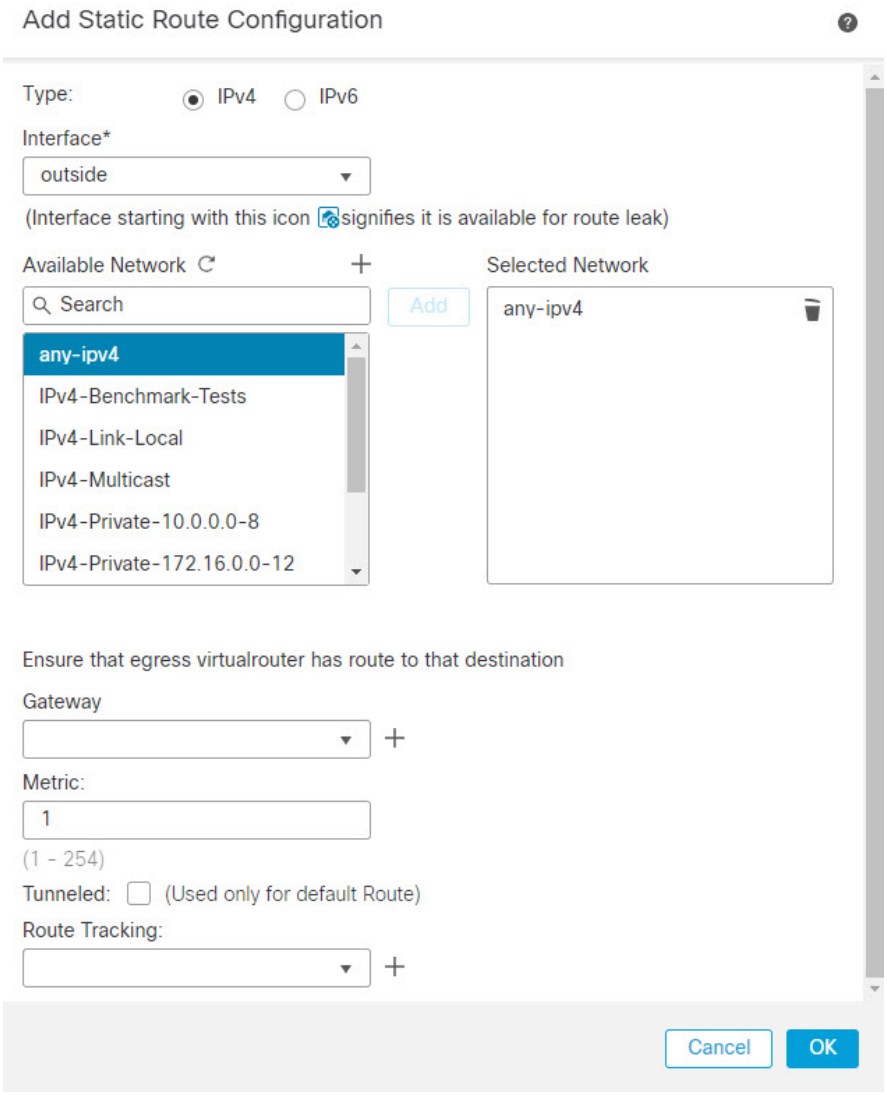
- **Name**—For this example, vr1-inside.
- Select the **Enabled** checkbox.

- In **IPV4**, for **IP Type**, choose **Use Static IP** .
- **IP Address**—Enter 192.168.1.1/24.

c) Click **Ok** .
d) Click **Save** .

Step 2 Configure the inside interface of the device for VR2:

a) Choose **Devices** > **Device Management** , click the device name, and then click **Interfaces** .
b) Edit the interfaces that you want to assign to VR2:



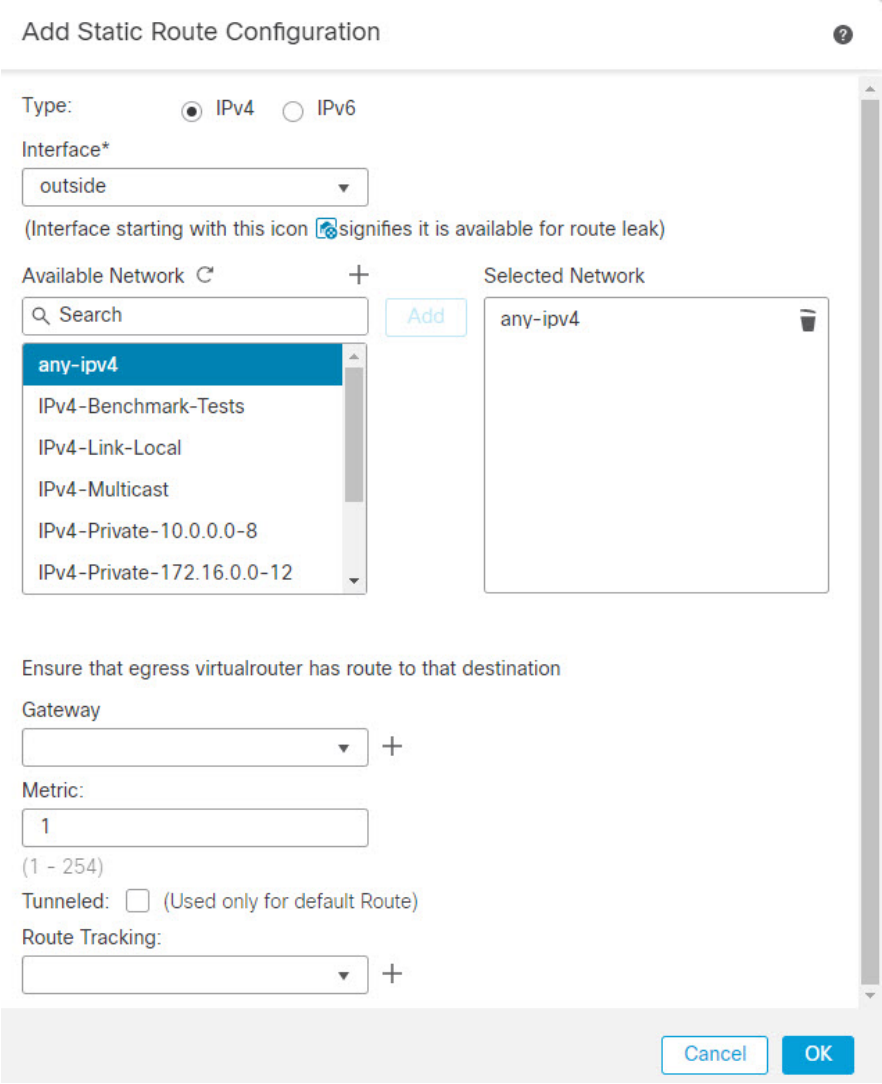
- **Name** —For this example, vr2-inside.
- Select the **Enabled** checkbox.
- In **IPV4** , for **IP Type** , choose **Use Static IP** .
- **IP Address** —Leave it blank. The system does not allow you to configure interfaces with same IP address, as you are yet to create user-defined virtual routers.

c) Click **Ok** .
d) Click **Save** .

Step 3 Configure VR1 and the static default route leak to the outside interface:

a) Choose **Devices** > **Device Management** , and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers** . Click **Add Virtual Router** and create VR1.
c) For VR1, in **Virtual Router Properties** , assign vr1-inside and save.
d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration** , specify the following:

- **Interface** —Select the outside interface of the global router.
- **Network** —Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR1.
- **Gateway** —Leave it blank. When leaking a route into another virtual router, do not provide a Gateway.



f) Click **Ok**.
g) Click **Save**.

Step 4 Configure VR2 and the static default route leak to the outside interface:

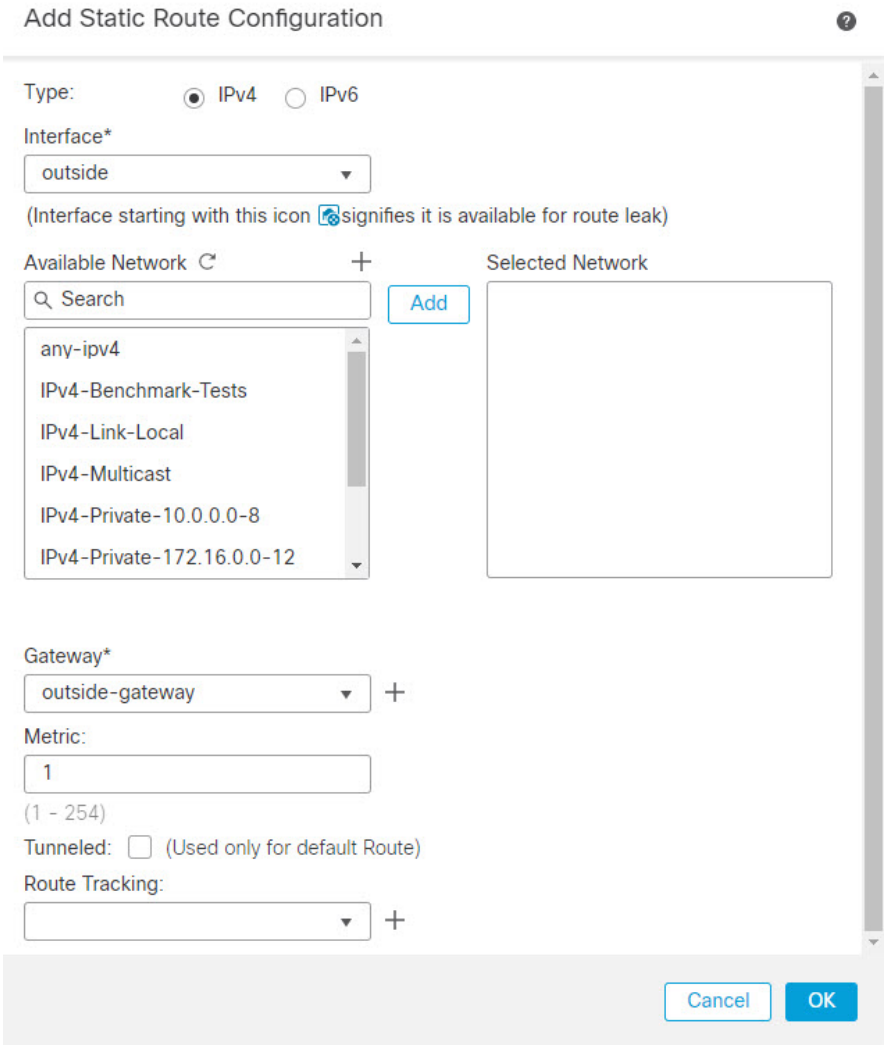
a) Choose **Devices** > **Device Management** , and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VR2.
c) For VR2, in **Virtual Router Properties**, assign vr2-inside and save.
d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration** , specify the following:

- **Interface** —Select the outside interface of the global router.
- **Network** —Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR2.
- **Gateway** —Leave it blank. When leaking a route into another virtual router, do not select the Gateway.

f) Click **Ok**.

g) Click **Save**.

Step 5 Configure IPv4 static default route, namely 172.16.1.2 on the outside interface of the global router:



a) Choose **Devices** > **Device Management** , and edit the Firewall Threat Defense device.

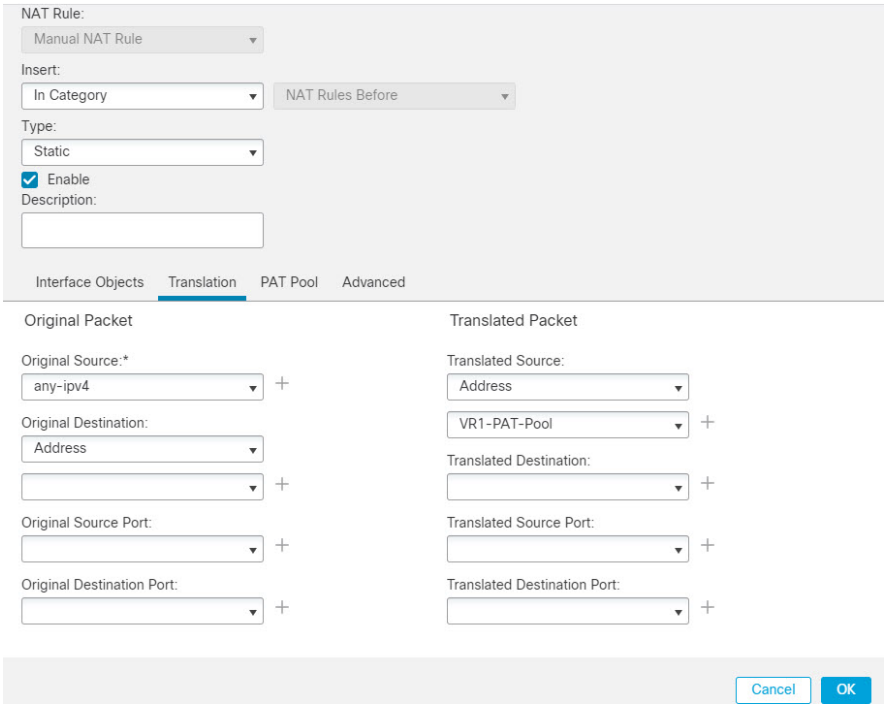
b) Choose **Routing** and edit global router properties.

c) Click **Static Route** .

d) Click **Add Route** . In **Add Static Route Configuration** , specify the following:

- **Interface** —Select the outside interface of the global router.
- **Network** —Select the any-ipv4 object. This will be the default route for any IPv4 traffic.
- **Gateway** —If already created, select the host name from the drop-down. If the object is not yet created, click **Add** and define the host object for the IP address of the gateway at the other end of the network link on the outside interface, in this example, 172.16.1.2. After you create the object, select it in the Gateway field.

e) Click **Ok** .
f) Click **Save** .



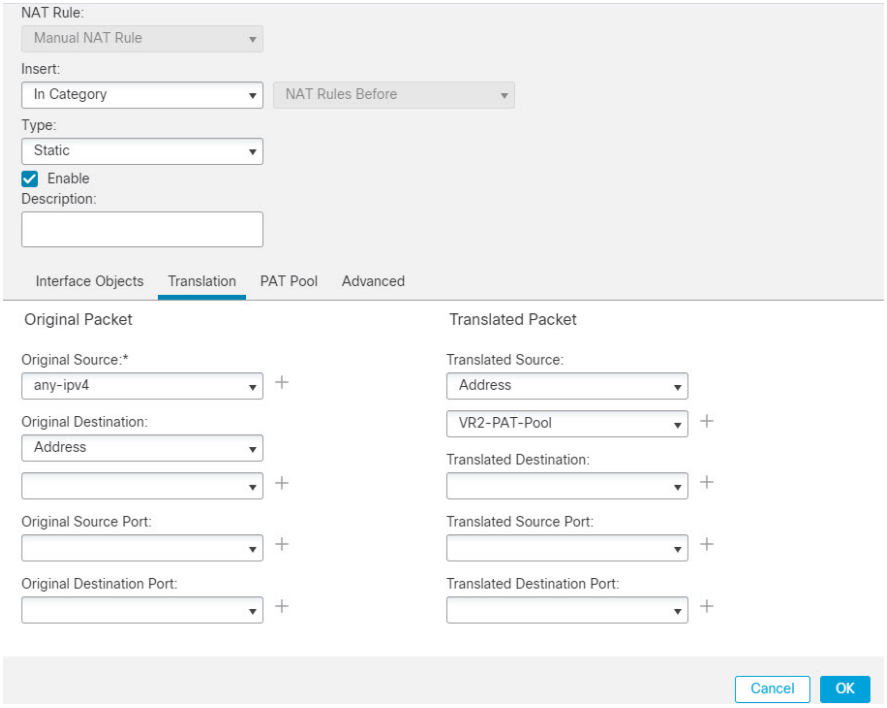
Step 6 Revisit the vr2-inside interface configuration:

a) Choose **Devices** > **Device Management** , click the device name, and then click **Interfaces** .
b) Click **Edit** against vr2-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with same IP address of vr1-inside, because the interfaces are separately assigned to two different virtual routers.
c) Click **Ok** .
d) Click **Save** .

Step 7 Create the NAT rule to PAT inside to outside traffic of VR1 to 10.100.10.1.

a) Choose **Devices** > **NAT**.
b) Click **New Policy** > **Threat Defense NAT**.
c) Enter InsideOutsideNATRule as the NAT policy name, and select the Firewall Threat Defense device. Click **Save** .
d) In InsideOutsideNATRule page, click **Add Rule** and define the following:

- **NAT Rule** —Select Manual NAT Rule.
- **Type** —Select Dynamic.
- **Insert** —Above, if any dynamic NAT rule exists.
- Click **Enabled** .
- In **Interface Objects** , select vr1-interface object and click **Add to Source** (If the object is not available, create one in **Objects** > **Object Management** > **Interface**), and select outside as **Add to Destination** .
- In **Translation** , for **Original Source** , select any-ipv4. For **Translated Source** , click **Add** and define host object VR1-PAT-Pool with 10.100.10.1. Select VR1-PAT-Pool as shown in the figure below:

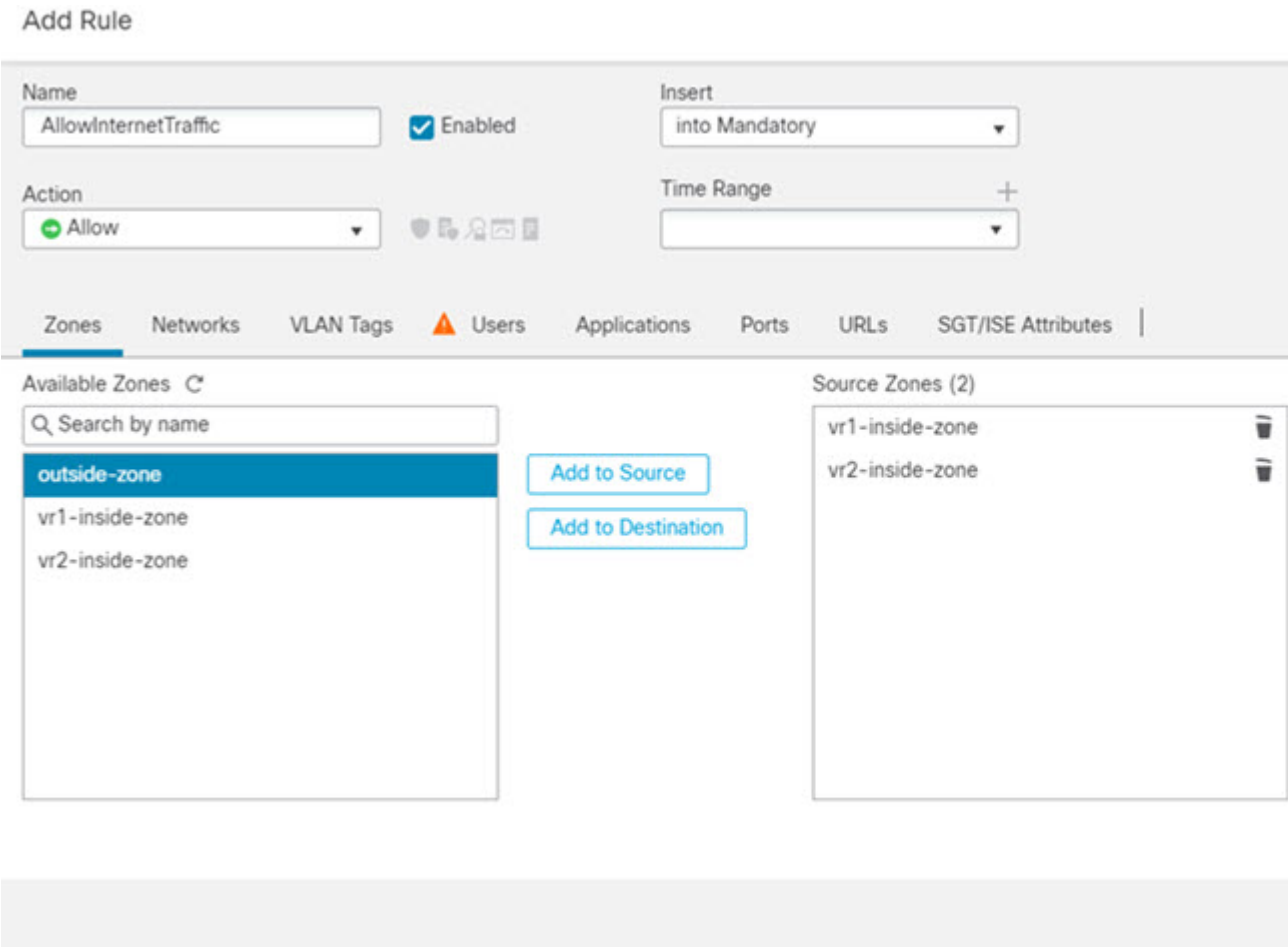


e) Click **Ok** .
f) Click **Save** .

Step 8 Add NAT rule to PAT inside to outside traffic of VR2 to 10.100.10.2.

a) Choose **Devices** > **NAT** .
b) Edit InsideOutsideNATRule to define the VR2 NAT rule:

- **NAT Rule** —Select Manual NAT Rule.
- **Type** —Select Dynamic.
- **Insert** —Above, if any dynamic NAT rule exists.
- Click **Enabled** .

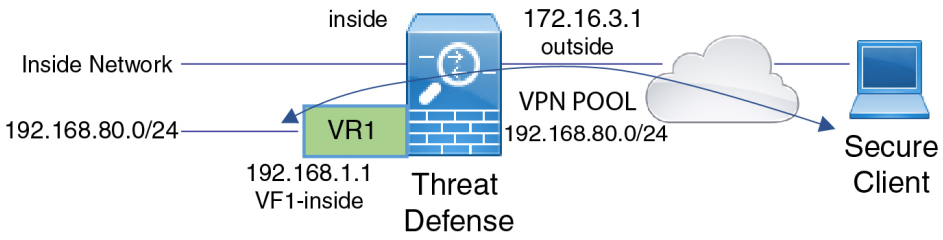


- In **Interface Objects** , select vr2-interface object and click **Add to Source** (If the object is not available, create one in **System** (⚙) > **Configuration** > **Management Interfaces**), and select outside as **Add to Destination** .
- In **Translation** , for **Original Source** , select any-ipv4. For **Translated Source** , click **Add** and define host object VR2-PAT-Pool with 10.100.10.2. Select VR2-PAT-Pool as shown in the figure below:

c) Click **Ok** .
d) Click **Save** .

Step 9 To configure the access control policy that allows traffic from the vr1-inside and vr2-inside interfaces to the outside interface, you need to create security zones. Use **Objects** > **Object Management** > **Interface** . Choose **Add** > **Security Zone** and create security zones for vr1-inside, vr2-inside, and outside interfaces. Choose **Policies** > **Access Control heading** > **Access Control** and configure an access control rule to allow traffic from vr1-inside-zone and vr2- inside-zone to outside-zone.

Assuming that you create zones named after the interfaces, a basic rule that allows all traffic to flow to the Internet will look like the following. You can apply other parameters to this access control policy:



Allow RA VPN access to internal networks in virtual routing

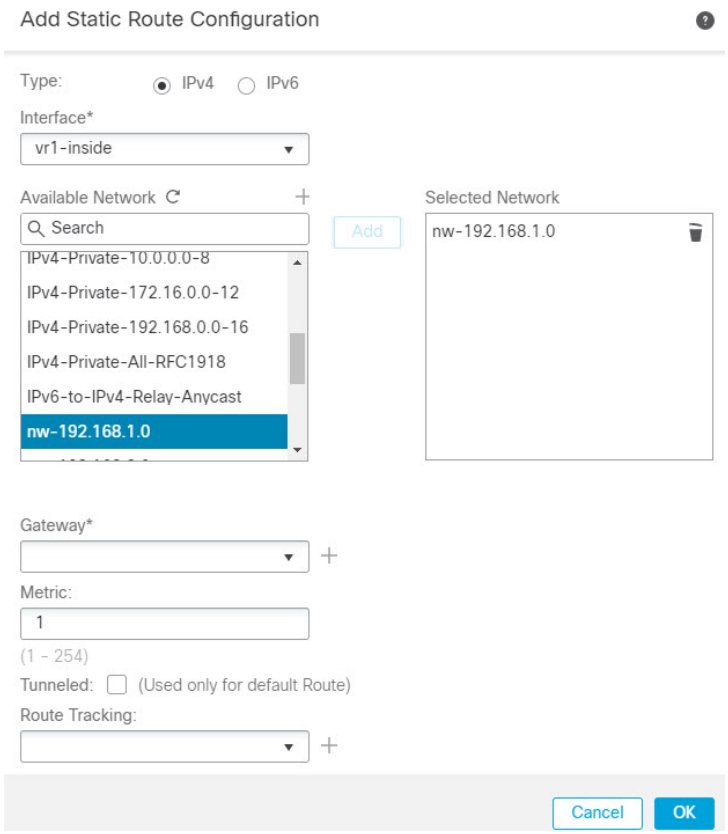
Allow Secure Client users to connect to user-defined virtual router networks by configuring route leaks between the global virtual router and user-defined virtual routers.

On virtual routing-enabled devices, RA VPN is supported only on global virtual router interfaces. This example provides the procedure that allows your Secure Client user to connect to user-defined virtual router networks.

In the following example, the RA VPN (Secure Client) user connects to the outside interface of Firewall Threat Defense at 172.16.3.1, and is given an IP address within the pool of 192.168.80.0/24. The user can access the inside network of only the global virtual router. To allow traffic flow through the network of the user-defined virtual router VR1, namely 192.168.1.0/24, leak the route by configuring the static routes on global and VR1.

Before you begin

This example assumes that you have already configured the RA VPN, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.



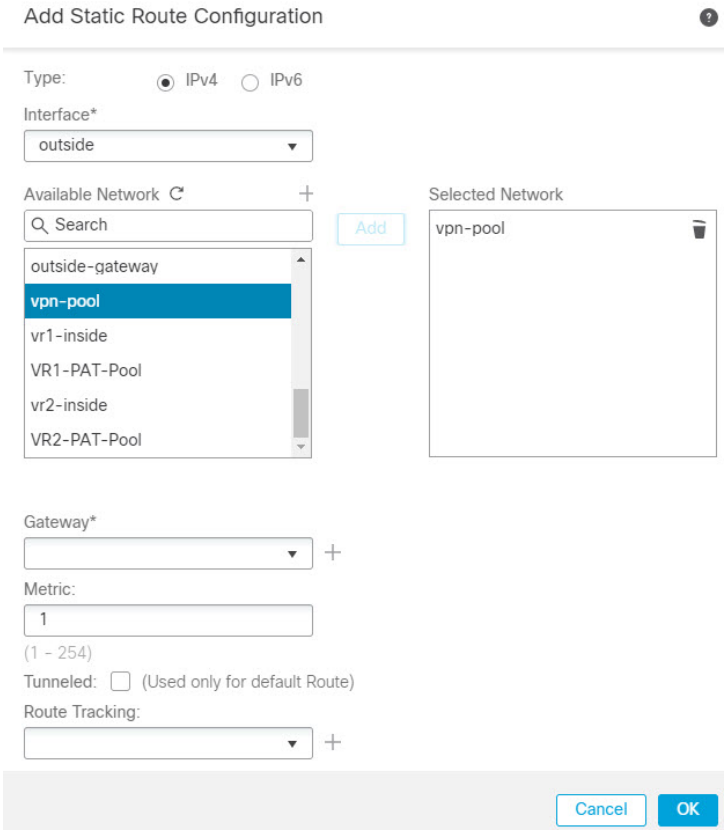
Follow these steps to allow RA VPN access to internal networks in virtual routing:

Procedure

Step 1 Configure route leak from Global virtual router to the user-defined VR1:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Click **Routing**. By default, the Global routing properties page appears.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the VR1 inside interface.
- **Network**—Select the VR1 virtual router network object. You can create one using the **Add Object** option.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.



The route leak allows Secure Client assigned IP addresses in the VPN pool to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click **Ok**.

Step 2 Configure the route leak from VR1 to the Global virtual router:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Click **Routing** and from the drop-down, select VR1.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the outside interface of the global router.
- **Network**—Select the global virtual router network object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.

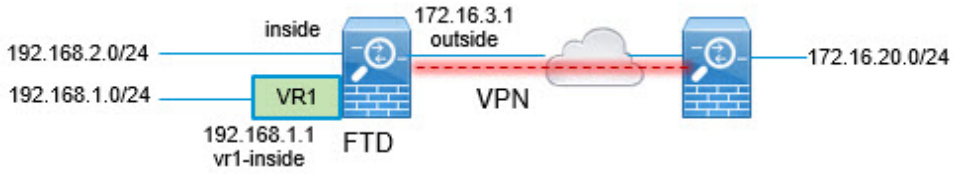
The configured static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections to Secure Client assigned IP addresses in the VPN pool.

e) Click **Ok**.

Secure Client users can now access networks in both the global virtual router and the user-defined VR1 virtual router through the configured route leaks.

What to do next

If RA VPN address pool and the IP addresses in the user-defined virtual router overlap, you must also use static NAT rules on the IP addresses to enable proper routing. Alternatively, you can change your RA VPN address pool so that there is no overlap.



Secure traffic from networks in multiple virtual routers over a site-to-site VPN

This task allows you to secure connections from or to networks hosted within user-defined virtual routers over the site-to-site VPN by configuring route leaking between virtual routers and updating the VPN connection profile.

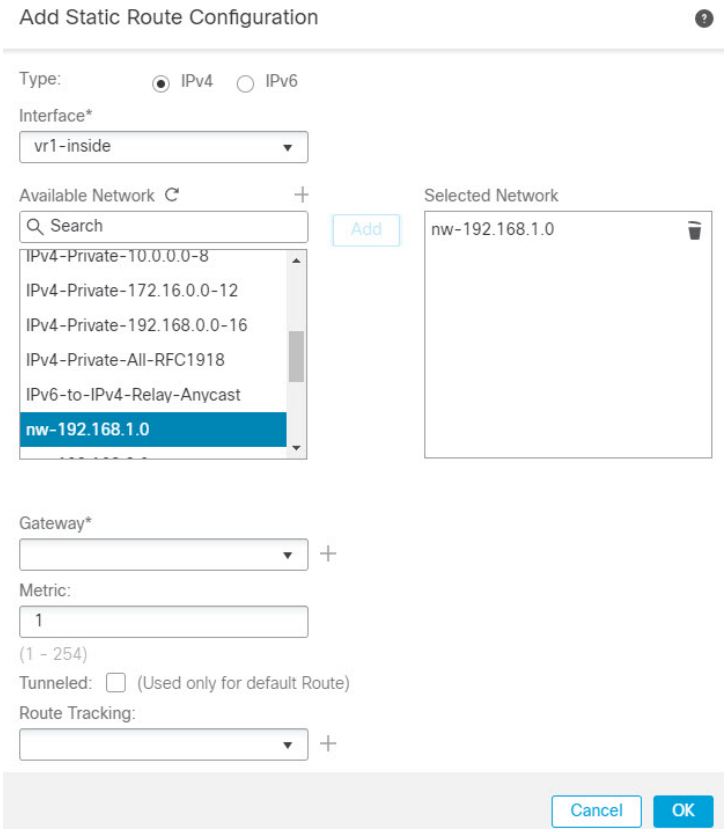
On virtual routing-enabled devices, Site-to-Site VPN is supported only on global virtual router interfaces. You cannot configure it on an interface that belongs to a user-defined virtual router. This procedure allows you to secure the connections from or to networks hosted within user-defined virtual routers over the site-to-site

VPN. You also need to update the site-to-site VPN connection to include the user-defined virtual routing networks.

Let us consider a scenario, where, a site-to-site VPN is configured between a branch office network to a company headquaters network; the Firewall Threat Defense in the branch office having virtual routers. In this case, the site-to-site VPN is defined on the outside interface of the branch office at 172.16.3.1. This VPN includes the inside network 192.168.2.0/24 without extra configuration, because the inside interface is also part of the global virtual router. But, to provide site-to-site VPN services to the 192.168.1.0/24 network, which is part of the VR1 virtual router, you must leak the route by configuring the static routes on global and VR1, and add the VR1 network to the site-to-site VPN configuration.

Before you begin

This example assumes that you have already configured the site-to-site VPN between the 192.168.2.0/24 local network and the 172.16.20.0/24 external network, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.



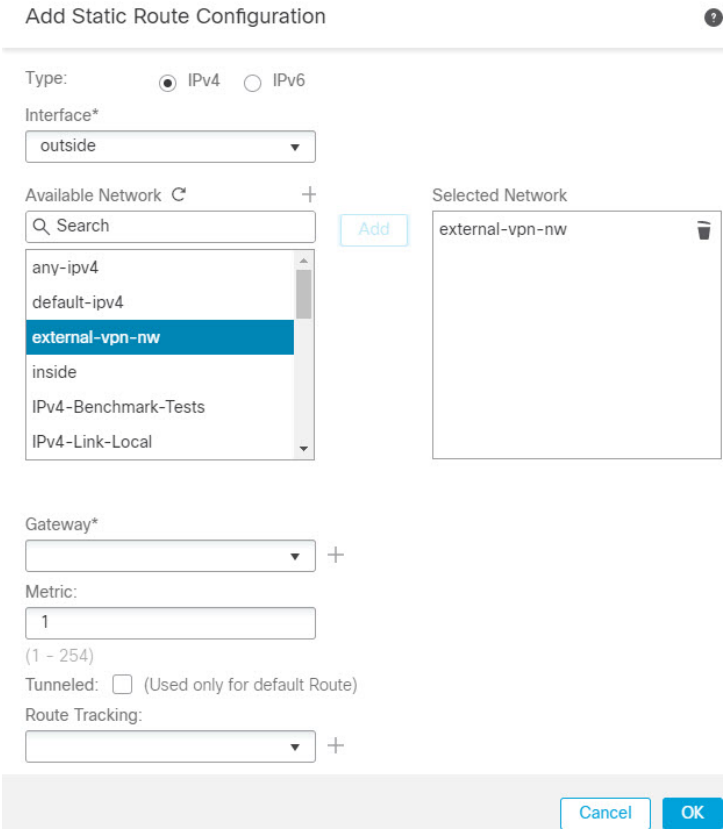
Follow these steps to secure traffic from networks in multiple virtual routers over a site-to-site VPN:

Procedure

Step 1 Configure route leak from the Global virtual router to the user-defined VR1:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Click **Routing**. By default, the Global routing properties page appears.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the VR1 inside interface.
- **Network**—Select the VR1 virtual router network object. You can create one using the **Add Object** option.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.



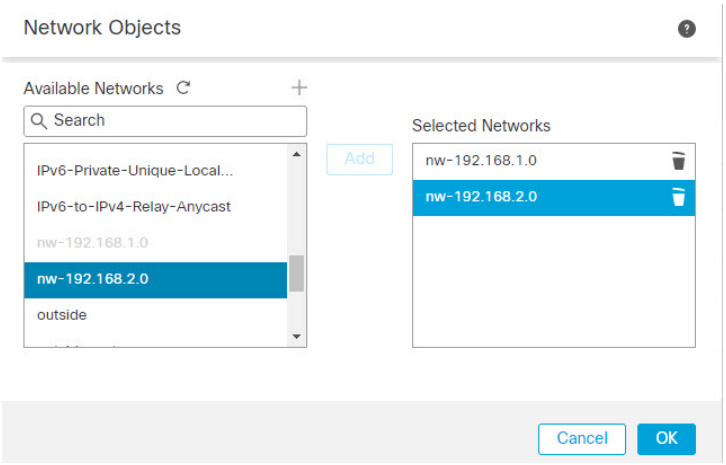
The route leak allows endpoints protected by the external (remote) end of the site-to-site VPN to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click **Ok**.

Step 2 Configure the route leak from VR1 to the Global virtual router:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Click **Routing** and from the drop-down, select VR1.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the outside interface of the global router.
- **Network**—Select the global virtual router network object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.



This static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections that will traverse the site-to-site VPN tunnel. For this example, the remote endpoint that is protecting the 172.16.20.0/24 network.

e) Click **Ok**.

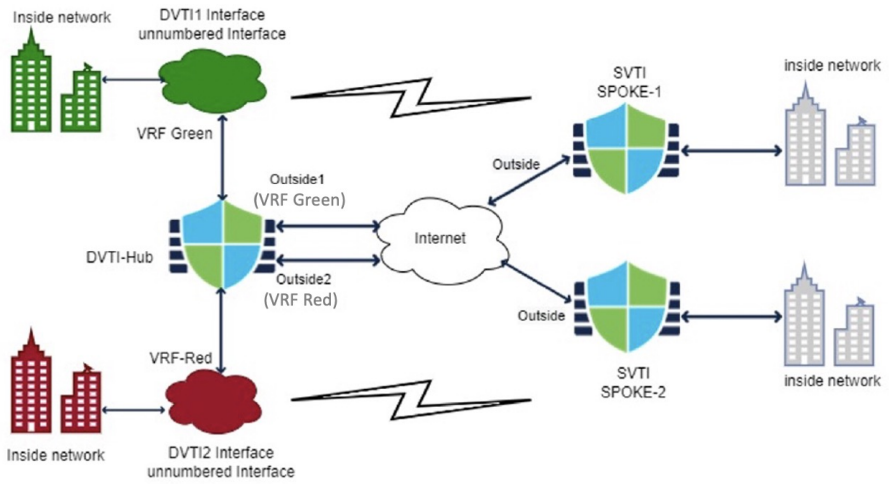
Step 3 Add the 192.168.1.0/24 network to the site-to-site VPN connection profile:

a) Choose **Devices** > **VPN** > **Site to Site**, and edit the VPN Topology.
b) In **Endpoints**, edit Node A endpoint.
c) In **Edit Endpoint**, in the **Protected Networks** field, click **Add New Network Object**.
d) Add the VR1 network object with 192.168.1.0 network:

e) Click **Ok** and save the configuration.

The route leaking configuration allows traffic from networks in user-defined virtual routers to traverse the site-to-site VPN tunnel securely, enabling connectivity between the VR1 network and remote networks protected by the VPN.

Secure traffic from networks with multiple virtual routers over a site-to-site VPN with dynamic VTI



This task enables ISPs to create virtual routers and associate dynamic VTIs with these virtual routers to extend the capabilities of dynamic VTIs in their network. You can associate dynamic VTIs either with global or user-defined virtual routers.

ISPs have different segmented networks for different customers. You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. A single threat defense device can act as a dynamic VTI hub with a global or one or more user-defined virtual routers. Each user-defined virtual router can be one customer network.

Let us consider an example where route-based site-to-site VPNs are configured between two company headquarter networks and their two branch office networks. The ISP's threat defense, a dynamic VTI hub, manages the two company headquarter networks with two user-defined virtual routers: VRF green and VRF red. The dynamic VTI hub establishes a site-to-site VPN between:

- Customer 1 (VRF green) and Branch 1 (SVTI spoke 1)
- Customer 2 (VRF red) and Branch 2 (SVT2 spoke 2)

Figure 354: Site-to-Site VPNs with multiple virtual routers and dynamic VTI

Procedure

Step 1 Configure a dynamic VTI interface on the hub.

a) Choose **Devices** > **Device Management** and edit the threat defense device.
b) Choose **Add Interfaces > Virtual Tunnel Interface**.
c) Select the **Tunnel Type** as **Dynamic**.
d) Specify the interface name as DVTI1 and configure all the parameters for the dynamic VTI.
e) Click **Save**
f) Repeat steps 1a - e to configure the second dynamic VTI on the hub, DVTI2.

Step 2 Configure static VTI on spoke 1.

a) Choose **Devices** > **Device Management** and edit the threat defense device.
b) Select **Add Interfaces > Virtual Tunnel Interface**.
c) Select the **Tunnel Type** as **Static**.
d) Specify the interface name as SVTI spoke-1 and configure all the parameters for the static VTI.
e) Click **Save**
f) Repeat steps 2a - e to configure the static VTI on spoke 2: SVTI spoke-2.

Step 3 Configure a route-based site-to-site VPN between hub and SVTI spoke 1.

a) Choose **Devices** > **VPN** > **Site to Site** and click **+ Site To Site VPN**.
b) Enter a name for the VPN topology in the **Topology Name** field.
c) Choose **Route Based (VTI)** and select **Hub and Spoke** as the network topology.
d) Click the **Endpoints** tab.
e) Configure the hub and the spoke (DVTI1 and SVTI spoke-1) and their routing policies.
f) Configure the **IKE**, **IPsec**, and **Advanced** options for the VPN, if required.
g) Click **Save**.
h) Repeat steps 3a - g to configure the second route-based site-to-site VPN topology between hub (DVTI2) and SVTI spoke 2.

Step 4 Configure the two virtual routers.

a) Choose **Devices** > **Device Management** and edit the threat defense device.
b) Click **Routing**.
c) Click **Manage Virtual Routers**.
d) Click **Add Virtual Router**.

Specify the name as VRF green and provide a description for the virtual router.

e) Repeat steps 4a - d to configure VRF red.

Step 5 Assign all the interfaces to the virtual routers.

a) From the drop-down list, select the virtual router.
b) In the **Virtual Router Properties** page, select the interfaces listed under the **Available Interfaces** box.

Assign the dynamic VTI interface along with the other interfaces.

c) Click **Add**.

Step 6 Repeat steps 5a - c for VRF red.

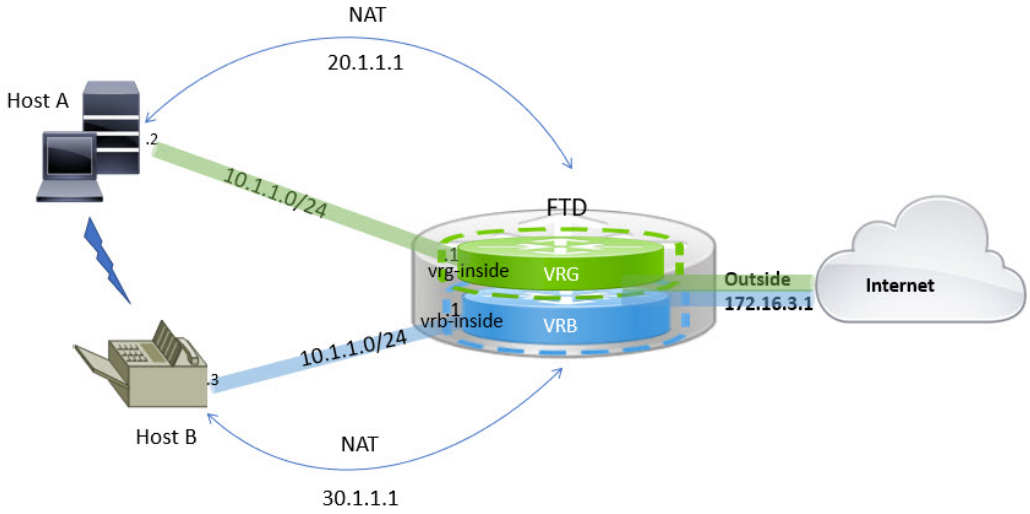
Step 7 Configure the routing policy for the virtual router.

a) From the drop-down list, select the virtual router.
b) Click **Static Route** or one of the dynamic routing protocols.
c) Configure the routing parameters.
d) Click **Save**.

You have successfully configured networks with multiple virtual routers over a site-to-site VPN with dynamic VTI, enabling ISPs to manage different segmented networks for different customers through virtual routers.

What to do next

Select the hub and spoke devices and click **Deploy**. After the deployment, you can monitor the VPN tunnels in the Site-to site monitoring dashboard (**Overview** > **Dashboards** > **Site to Site VPN**).



You can also use the commands listed in Monitor virtual routers, on page 1006 to view and troubleshoot the virtual router.

Route traffic between two overlapping network hosts in virtual routing

Configure NAT rules to manage overlapping network hosts and enable communication between hosts on different virtual routers that have the same network address.

You can configure hosts on the virtual routers that have same network address. If the hosts want to communicate, you can configure twice NAT. This example provides the procedure to configure the NAT rules to manage the overlapping network host.

In the following example, two hosts Host A and Host B belong to different virtual routers: VRG (interface VRG-inside), VRB (interface VRB-inside) respectively with the same subnet 10.1.1.0/24. For both the hosts to communicate, create a NAT policy where, VRG-Host interface object would use a mapped NAT address - 20.1.1.1, and VRB-Host interface object would use a mapped NAT address - 30.1.1.1. Thus, Host A uses 30.1.1.1 to communicate to Host B; Host B uses 20.1.1.1 to reach Host A.

Before you begin

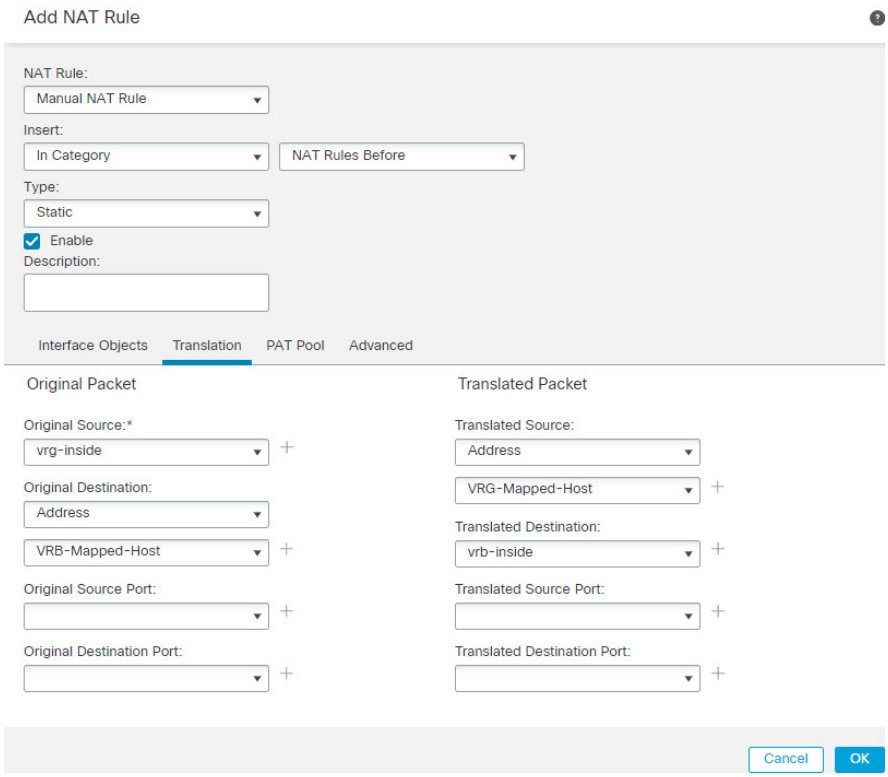
This example assumes that you have already configured:

- VRG-inside and VRB-inside interfaces are associated with virtual routers: VRG and VRB respectively and VRG-inside and VRB-inside interfaces configured with same subnet address (say, 10.1.1.0/24).
- Interfaces zones VRG-Inf, VRB-Inf created with VRG-inside and VRB-inside interfaces respectively.
- Host A in VRG with VRG-inside as default gateway; Host B in VRB with VRB-inside as default gateway.

Follow these steps to route traffic between two overlapping network hosts in virtual routing:

Procedure

Step 1 Create the NAT rule to handle traffic from Host A to Host B. Choose **Devices** > **NAT**.



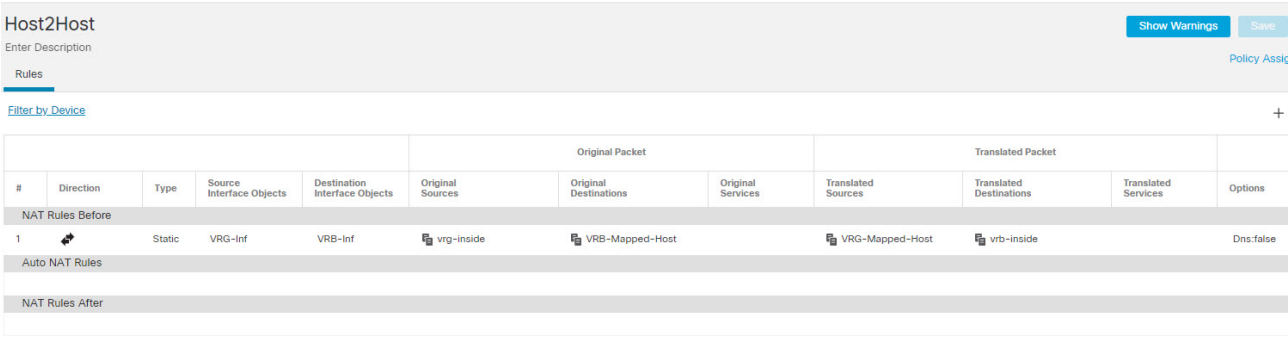
Step 2 Click **New Policy** > **Threat Defense NAT**.

Step 3 Enter a NAT policy name, and select the Firewall Threat Defense device. Click **Save**.

Step 4 In the NAT page, click **Add Rule** and define the following:

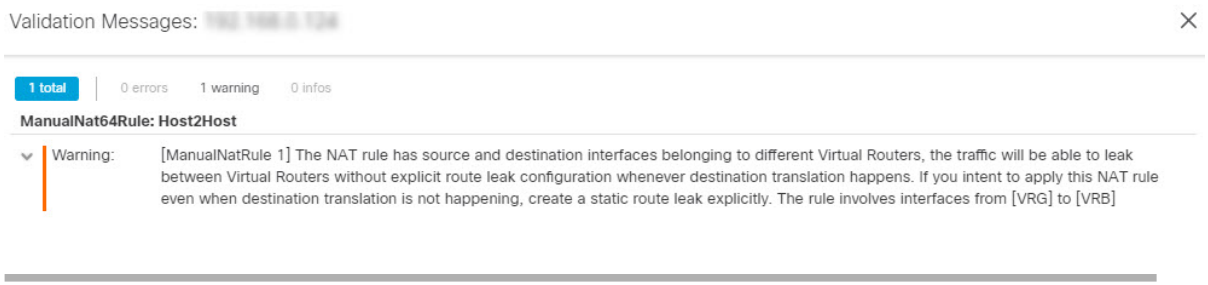
- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRG-Inf object and click **Add to Source** (If the object isn't available, create one in **Objects** > **Object Management** > **Interface**), and select VRB-Inf object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select VRG-inside.

- **Original Destination**, click **Add** and define object VRB-Mapped-Host with 30.1.1.1. Select VRB-Mapped-Host.
- **Translated Source**, click **Add** and define object, VRG-Mapped-Host with 20.1.1.1. Select VRG-Mapped-Host.
- **Translated Destination**, select VRB-inside as shown in the following figure:



When you run the **show NAT detail** command on the Firewall Threat Defense device, you will see an output similar to this:

```
firepower(config-service-object-group)# show nat detail
Manual NAT Policies (Section 1)
1 (2001) to (3001) source static vrg-inside VRG-MAPPED-HOST destination static VRB-MAPPED-HOST
 vrb-inside
translate_hits = 0, untranslate_hits = 0
Source - Origin: 10.1.1.1/24, Translated: 20.1.1.1/24
Destination - Origin: 30.1.1.1/24, Translated: 10.1.1.1/24
```

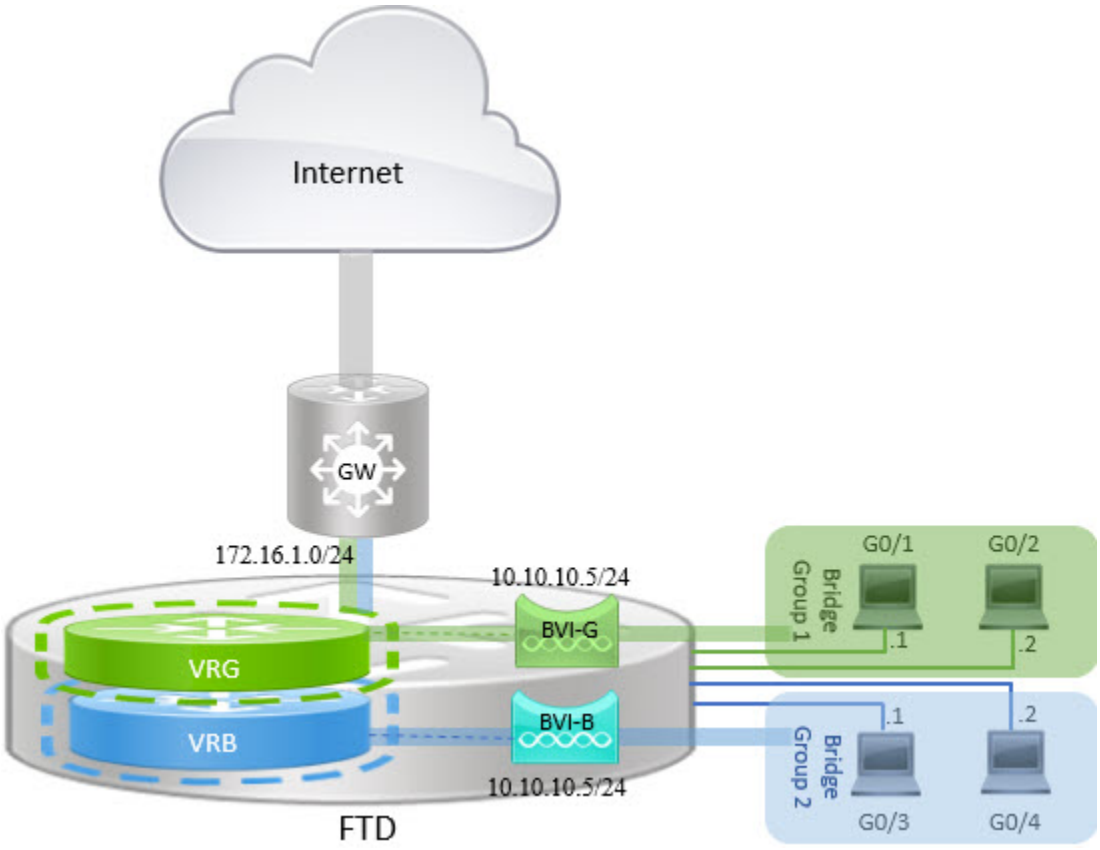


Step 5 Click **Ok**.

Step 6 Click **Save**.

The NAT rule looks like this:

When you deploy the configuration, a warning message appears:



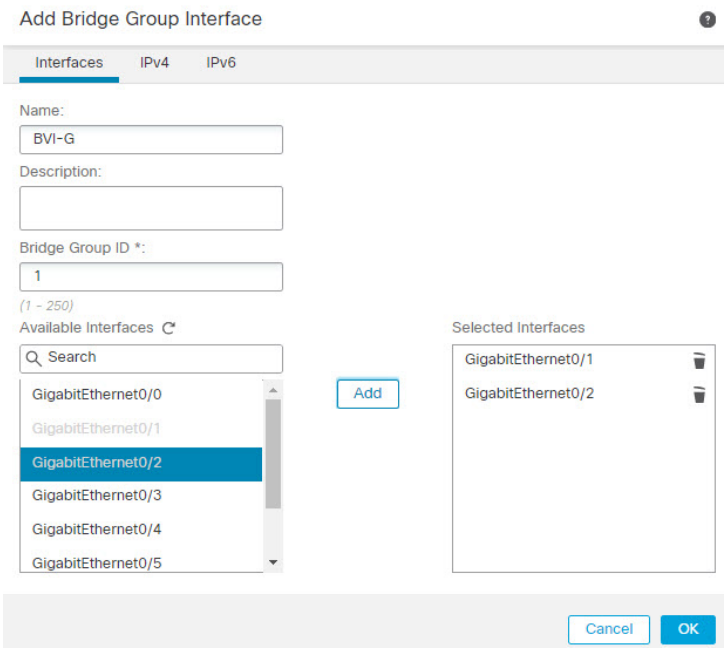
The NAT rule is configured to enable communication between Host A and Host B on overlapping network addresses. Host A uses 30.1.1.1 to communicate with Host B, and Host B uses 20.1.1.1 to reach Host A.

Manage overlapping segments in routed firewall mode with BVI interfaces

This task allows you to deploy single Firewall Threat Defense between multiple overlapping networks transparently and/or deploy the firewall between the hosts of same network by configuring BVI per virtual router.

BVI is a virtual interface within a router that acts like a normal routed interface. It does not support bridging, but represents the comparable bridge group to routed interfaces within the router. All the packets coming in or going out of these bridged interfaces, pass through the BVI interface. The interface number of the BVI is the number of the bridge group that the virtual interface represents.

In the following example, BVI-G is configured in VRG and Bridge Group 1 is the routed interface for interfaces G0/1 and G0/2. Similarly, BVI-B is configured in VRB and Bridge Group 2 is the routed interface for interfaces G0/3 and G0/4. Consider that both BVIs have the same IP subnet address, say 10.10.10.5/24. Because of virtual routers, the network is isolated on the shared resources.



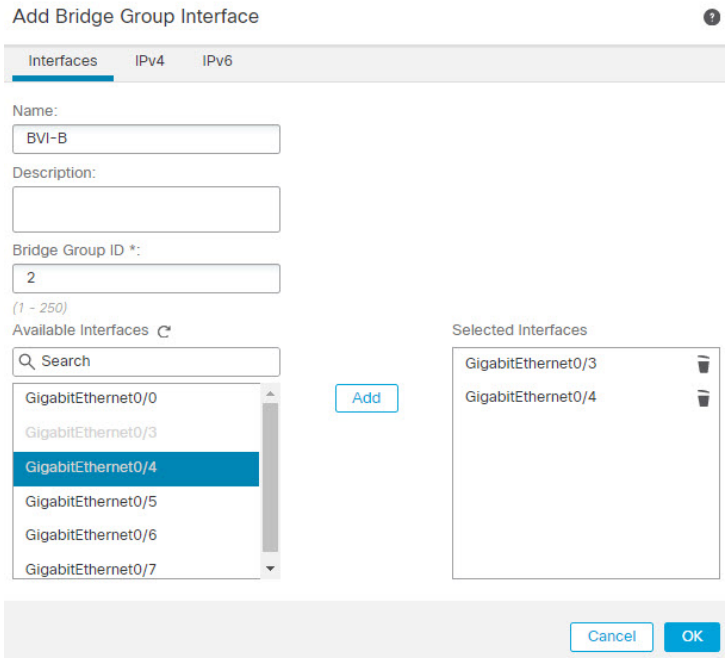
Procedure

Step 1 Choose **Devices** > **Device Management**. Edit the required device.

Step 2 In **Interfaces**, choose **Add Interfaces** > **Bridge Group Interface**.

a) Enter the following details for BVI-G:

- **Name**—For this example, BVI-G.
- **Bridge Group ID**—For this example, 1.
- **Available Interface**—Select the interfaces.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 10.10.10.5/24.



b) Click **Ok**.

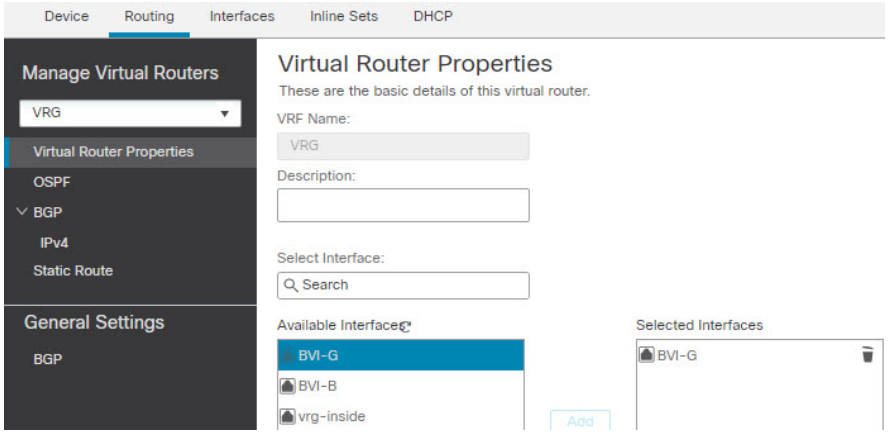
c) Click **Save**.

a) Enter the following details for BVI-B:

- **Name**—For this example, BVI-B.
- **Bridge Group ID**—For this example, 2.
- **Available Interface**—Select the sub interfaces.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave this field empty as the system does not allow two interfaces to have overlapping IP address. You can revisit the Bridge Group and provide the same IP address after aligning it under a virtual router.

b) Click **Ok**.

c) Click **Save**.



Step 3 Create virtual router, say VRG, and select BVI-G as its network:

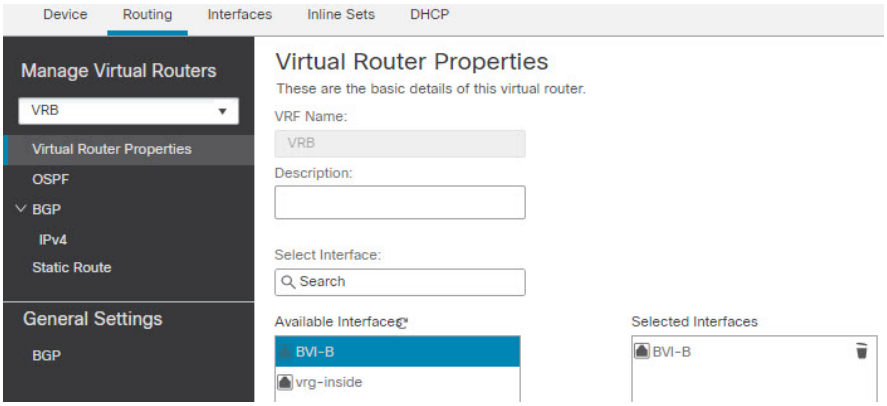
a) Choose **Devices** > **Device Management**.

b) Edit the device, and choose **Routing** > **Manage Virtual Routers**.

c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.

d) In **Virtual Routing Properties**, select **BVI-G** and click **Add**.

e) Click **Save**.



Step 4 Create virtual router, say VRB, and select BVI-B as its network:

a) Choose **Devices** > **Device Management**.

b) Edit the device, and choose **Routing** > **Manage Virtual Routers**.

c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.

d) In **Virtual Routing Properties**, select **BVI-B** and click **Add**.

e) Click **Save**.

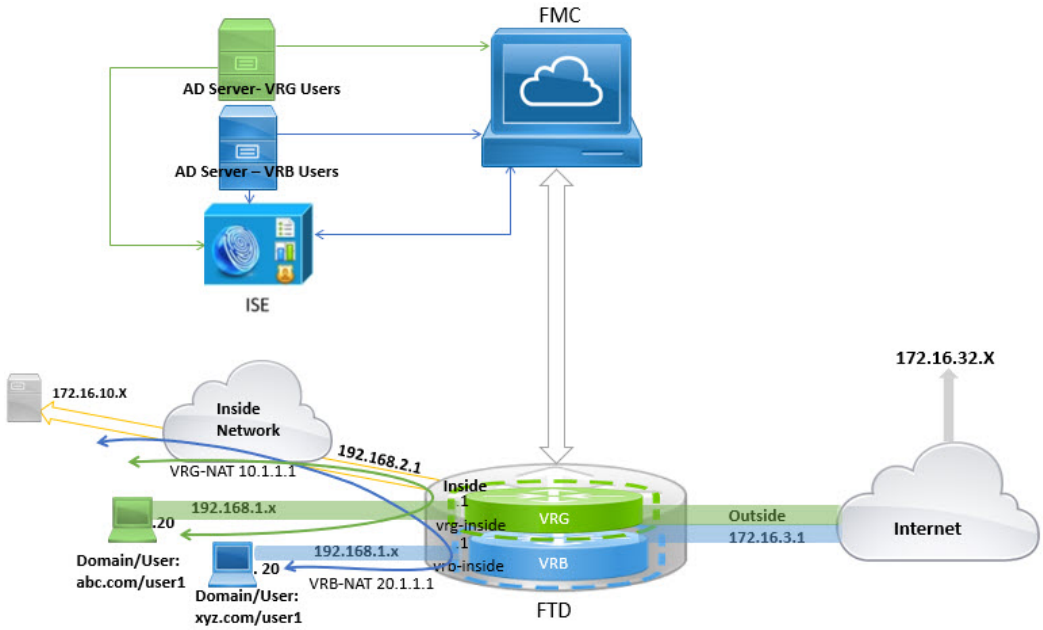
Step 5 Revisit the BVI-B configuration:

a) Choose **Devices** > **Device Management**, edit the device and click **Interfaces**.

b) Click **Edit** against BVI-B interface. Specify the IP Address as 10.10.10.5/24. The system now allows you to configure with same IP address of BVI-G, because the interfaces are seperately assigned to two different virtual routers.

c) Click **Ok**.

d) Click **Save**.



If you want to enable inter-BVI communication, use an external router as default gateway. In overlapping BVI scenarios, as in this example, use twice NAT external router as gateway to establish inter-BVI traffic. When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself. When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify "any" as the interface.

You have successfully configured BVI interfaces per virtual router to manage overlapping segments in routed firewall mode. The virtual routers isolate the network on shared resources, allowing the use of same IP subnet addresses for both BVIs.

Configure user authentication with overlapping networks

This task enables you to configure user authentication in virtual routing environments where multiple virtual routers share overlapping IP addresses and user networks. The configuration allows users from different domains to access shared resources while maintaining proper access control.

In virtual routing, you can configure multiple virtual routers with overlapping IP and overlapping users. In the example, VRG, and VRB are the virtual routers with overlapping IP - 192.168.1.1/24. The users on two different domains are also on overlapping network IP 192.168.1.20. For VRG and VRB users to access the shared server 172.16.10.X, leak routes to the global virtual router. Use source NAT to handle the overlapping IP. For controlling the access from VRG and VRB users, you must set user authentication in Firewall Management Center. Firewall Management Center uses realms, Active Directories, Identity source, and Identity rules and policies for authenticating user identity. Because Firewall Threat Defense does not have direct role in authenticating users, user access is managed only through the access control policy. For controlling traffic from the overlapping users, use Identity policy and rules to create access control policy.

Before you begin

This example assumes that you have:

- Two AD servers for the VRG and VRB users.
- ISE with the two AD servers added.

Follow these steps to configure user authentication with overlapping networks:

Procedure

Step 1 Configure the inside interface of the device for VRG:

a) Choose **Devices** > **Device Management**, click the device name, and then click **Interfaces**.

b) Edit the interfaces that you want to assign to VRG:

- **Name**—For this example, VRG-inside.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 192.168.1.1/24.

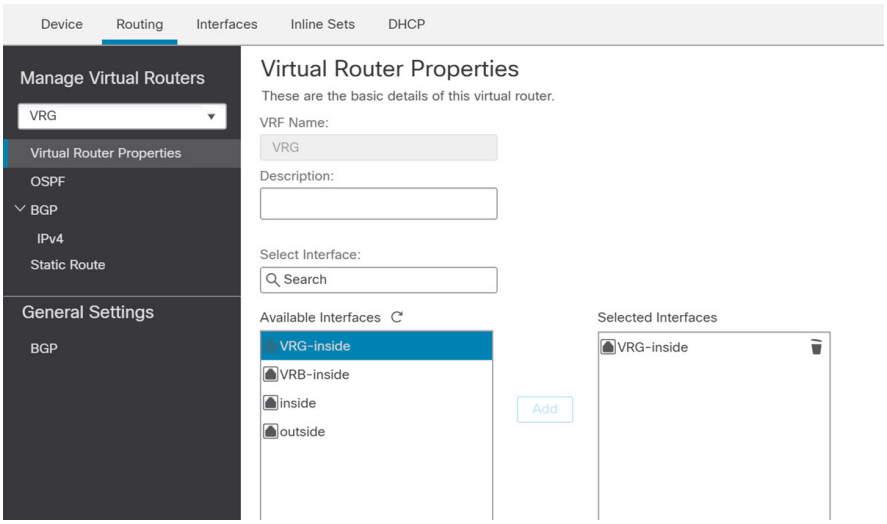
c) Click **Ok**.

d) Click **Save**.

Step 2 Configure the inside interface of the device for VRB:

a) Choose **Devices** > **Device Management** > **Interfaces**.

b) Edit the interfaces that you want to assign to VRB:



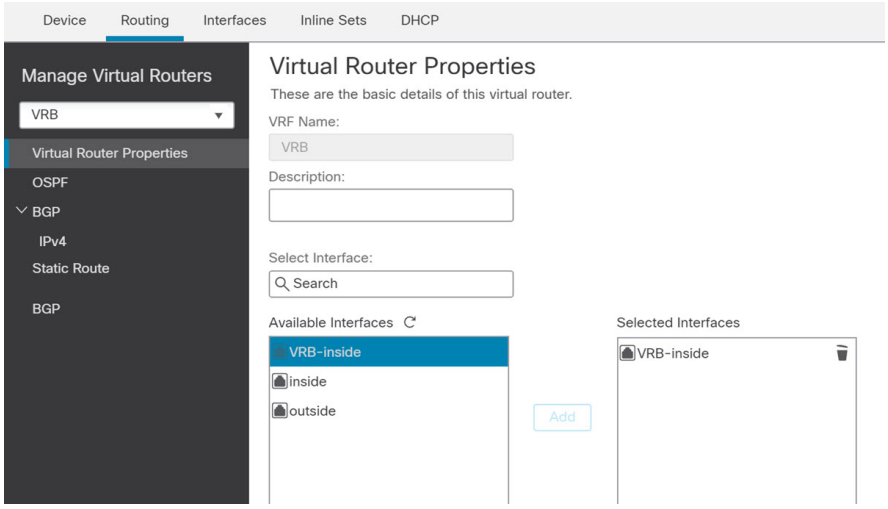
- **Name**—For this example, VRB-inside.

- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave it blank. The system doesn't allow you to configure interfaces with same IP address, as you're yet to create user-defined virtual routers.

c) Click **Ok**.
d) Click **Save**.

Step 3 Configure VRG and the static default route leak to the inside interface of the Global router for the VRG users to access the common server 172.16.10.1:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VRG.
c) For VRG, in **Virtual Router Properties**, assign VRG-inside and save.



d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the inside interface of the global router.
- **Network**—Select the any-ipv4 object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.

f) Click **Ok**.
g) Click **Save**.

Step 4 Configure VRB and the static default route leak to the inside interface of the Global router for the VRB users to access the shared server 172.16.10.x:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VRB.
c) For VRB, in **Virtual Router Properties**, assign VRB-inside and save.

d) Click **Static Route**.

e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the inside interface of the global router.
- **Network**—Select the any-ipv4 object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.

f) Click **Ok**.

g) Click **Save**.

Step 5 Revisit the VRB-inside interface configuration:

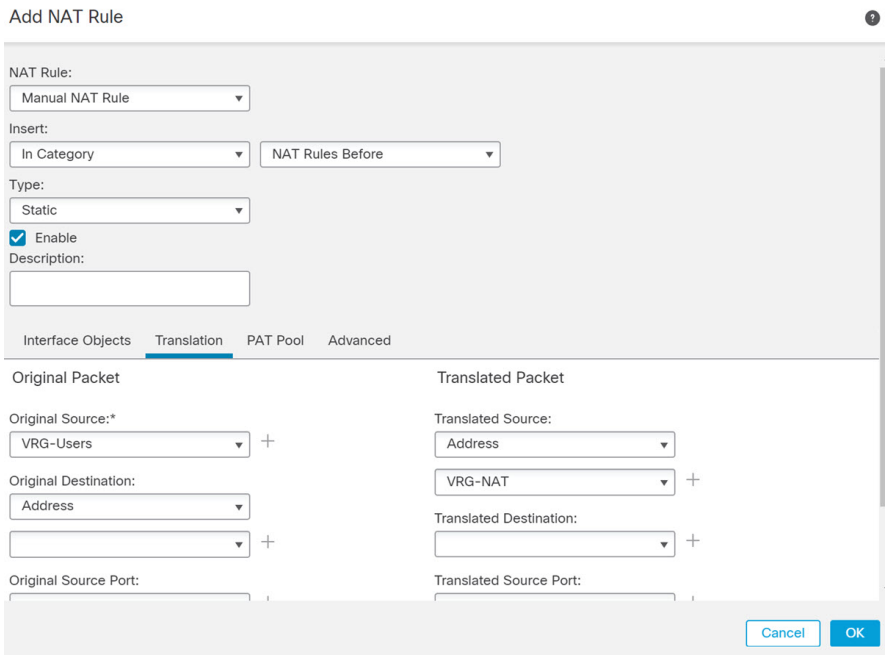
a) Choose **Devices** > **Device Management**, click the device name, and then click **Interfaces**.

b) Click **Edit** against VRB-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with the same IP address as that of VRG-inside, because the interfaces are seperately assigned to two different virtual routers.

c) Click **Ok**.

d) Click **Save**.

Step 6 Add NAT rules for the source objects VRG and VRB. Click **Devices** > **NAT**.

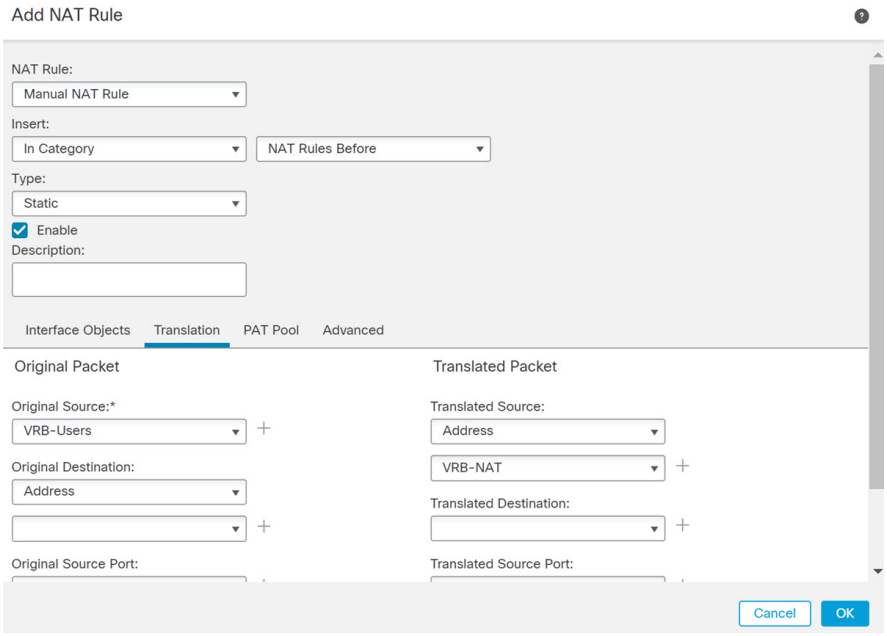


Step 7 Click **New Policy** > **Threat Defense NAT**.

Step 8 Enter a NAT policy name, and select the Firewall Threat Defense device. Click **Save**.

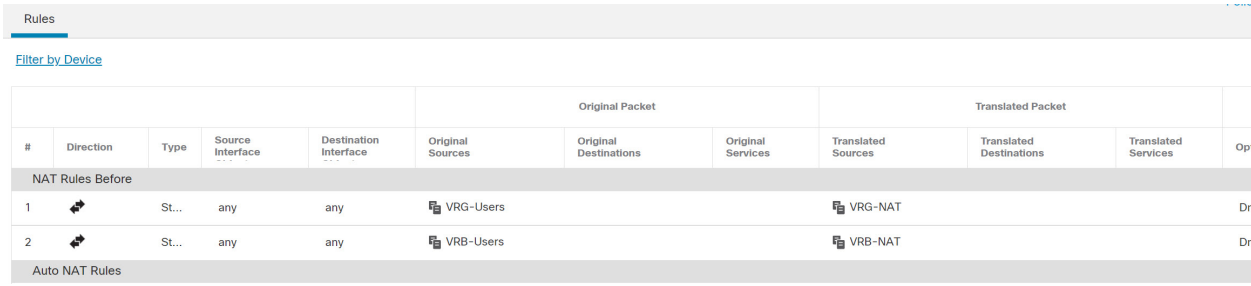
Step 9 In the NAT page, click **Add Rule** and define the following source NAT for VRG:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRG-Inside object and click **Add to Source** (If the object is not available, create one in **Objects** > **Object Management** > **Interface**), and select Global-Inside object and click **Add to Destination**.
- In **Translation**, select the following:



- **Original Source**, select VRG-Users.
- **Translated Source**, click **Add** and define object, VRG-NAT with 10.1.1.1. Select VRG-NAT as shown in the figure:

Step 10 Click **Ok**.



Step 11 In the NAT page, click **Add Rule** and define the following source NAT for VRB:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRB-Inside object and click **Add to Source** (If the object is not available, create one in **Objects** > **Object Management** > **Interface**), and select Global-Inside object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select VRB-Users.
  - **Translated Source**, click **Add** and define object, VRB-NAT with 20.1.1.1. Select VRB-NAT as shown in the figure:

Step 12 Click **Save**.

The NAT rule looks like this:

Step 13 Add the two unique AD servers in Firewall Management Center one for each VRG and VRB users—choose **System** > **Integration** > **Realms**.

Step 14 Click **New Realm** and complete the fields. For detailed information on the fields, see Realm fields, on page 1844.

Step 15 For controlling the access from VRG and VRB users, define 2 Active Directories, see Realm directory and synchronize fields, on page 1848see Create an LDAP realm or an Active Directory realm and realm directory, on page 1860

Step 16 Add ISE in Firewall Management Center—choose **System** > **Integration** > **Identity Sources**.

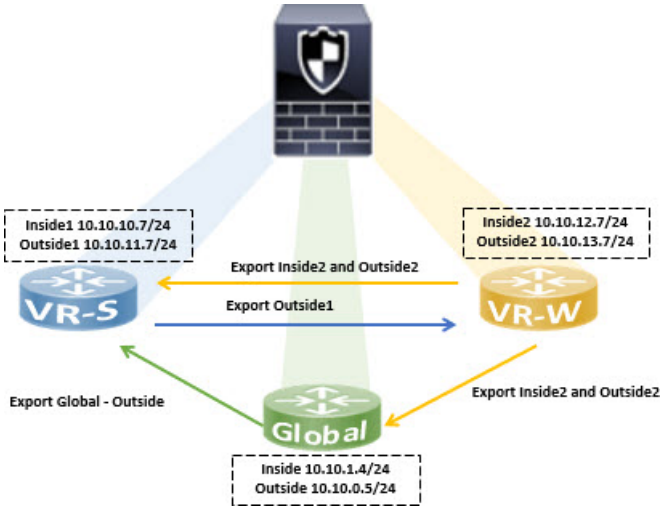
Step 17 Click **Identity Services Engine** and complete the fields. For detailed information on the fields, see Configure ISE/ISE-PIC for user control using a realm, on page 1917.

Step 18 Create Identity policy, rules, and then define access control policy for controlling access of overlapping users from VRG and VRB.

You have successfully configured user authentication for virtual routers with overlapping networks. VRG and VRB users can now access the shared server through proper NAT translation and authentication controls, with distinct identity policies managing access for each user group.

Interconnect virtual routers using BGP

This task enables you to configure BGP settings to leak routes among virtual routers (Global and user-defined virtual routers) by using route targets and route maps to share routes between different virtual routing instances.



You can now configure BGP settings on a device to leak the routes among virtual routers (Global and user-defined virtual routers). The route target of the source virtual router is exported to the BGP table, which, in turn is imported to the destination virtual router. The route map is used to share the Global virtual routes with the user-defined virtual routers and vice versa. Note that all import or export of the routes to the BGP table is configured at the user-defined virtual router, including the Global virtual routes.

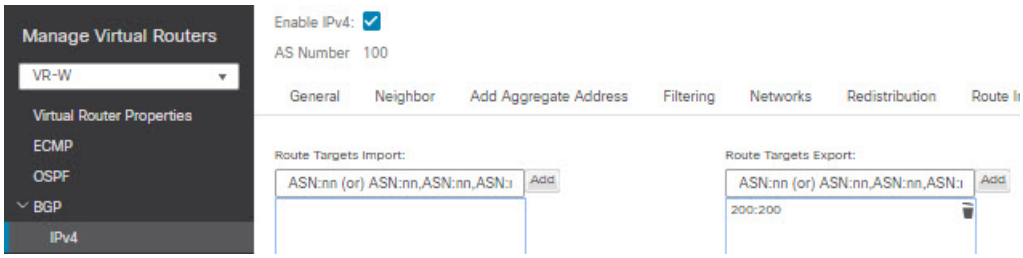
Consider the firewall device of a factory is configured with virtual routers and interfaces:

- Global virtual router is configured with Inside (10.10.1.4/24) and Outside (10.10.0.5/24)
- VR-S (Sales) virtual router is configured with Inside1 (10.10.10.7/24) and Outside1 (10.10.11.7/24)
- VR-W (Warehouse) virtual router is configured with Inside2 (10.10.12.7/24) and Outside2 (10.10.13.7/24)

Assume that you want the routes of warehouse (VR-W) to be leaked with sales (VR-S) and Global, and the outside interface routes of VR-S to VR-W. Similarly, you want the outside interface routes of the Global router to be leaked to sales (VR-S). This example demonstrates the BGP configuration procedure to achieve interconnecting the routers:

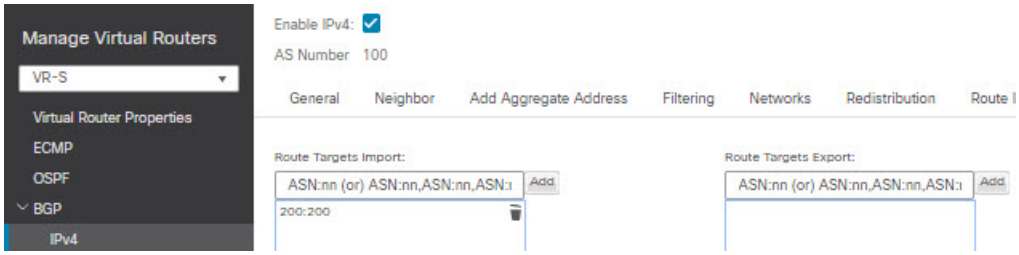
Figure 355: Interconnect virtual routers using BGP settings

Before you begin



- Create the virtual routers—VR-S and VR-W.
- Enable BGP and for each virtual router Configure BGP for redistribution of connected routes.

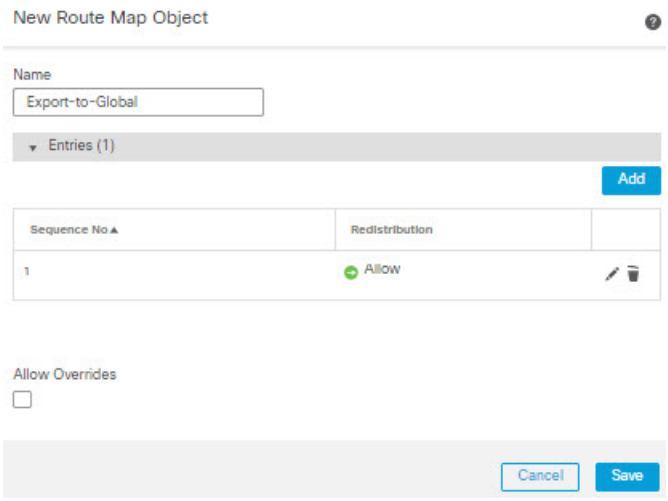
Follow these steps to interconnect virtual routers using BGP:



Procedure

Step 1 Configure VR-W to export its routes tagging them with a route target to VR-S:

a) Choose **Devices** > **Device Management**, edit device, and then click the **Routing** tab.
b) From the virtual router drop-down, select VR-W. Then click **BGP** > **IPv4** > **Route Import/Export**.
c) To leak the VR-W routes to VR-S, tag the routes with a route target, so that the VR-W routes are exported to its BGP table with the route target marked on them. In the **Route Targets Export** field, enter a value, say, *200:200*. Click **Add**:

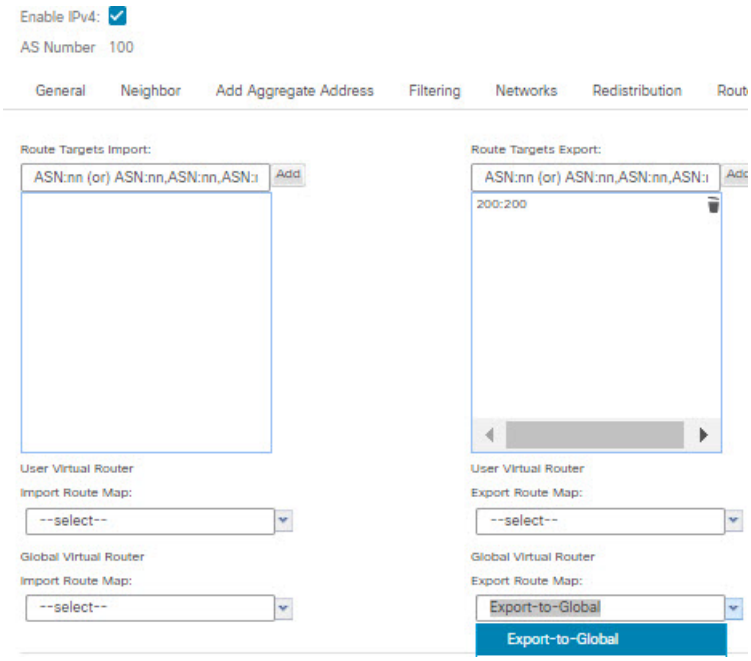


d) From the virtual router drop-down, select VR-S. Then click **BGP** > **IPv4** > **Route Import/Export**.
e) To receive the leaked routes from VR-W, configure the Import Route Target to import the VR-W routes that are marked with the route target from the (peer or redistributed) BGP table. In the **Route Targets Import** field, enter the same route target value that you had configured for VR-W, *200:200*. Click **Add**.

Note If you want to conditionalize routes to be leaked from VR-W, you can specify the match criteria in the route map object, and choose it in the **User Virtual Router Export Route Map**. Similarly, if you want to conditionalize the routes to be imported to VR-S from the BGP table, you can use the **User Virtual Router Import Route Map**. This procedure is explained in Step 3.

Step 2 Configure VR-W to export its routes to the Global virtual router:

a) You need to create a route map that would allow the VR-W routes to be exported to the Global routing table. Choose **Objects** > **Object Management** > **Route Map**.
b) Click **Add Route Map**, give a name, say *Export-to-Global*, and then click **Add**.
c) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list:



d) Click **Save**.

In this example, all the VR-W routes are leaked to the Global routing table. Hence, no match criteria is configured for the route map.

e) Navigate to the **Routing** tab of the device, and select VR-W. Click **BGP** > **IPv4** > **Route Import/Export**.

f) From the **Global Virtual Router Export Route Map** drop-down list, choose Export-to-Global:

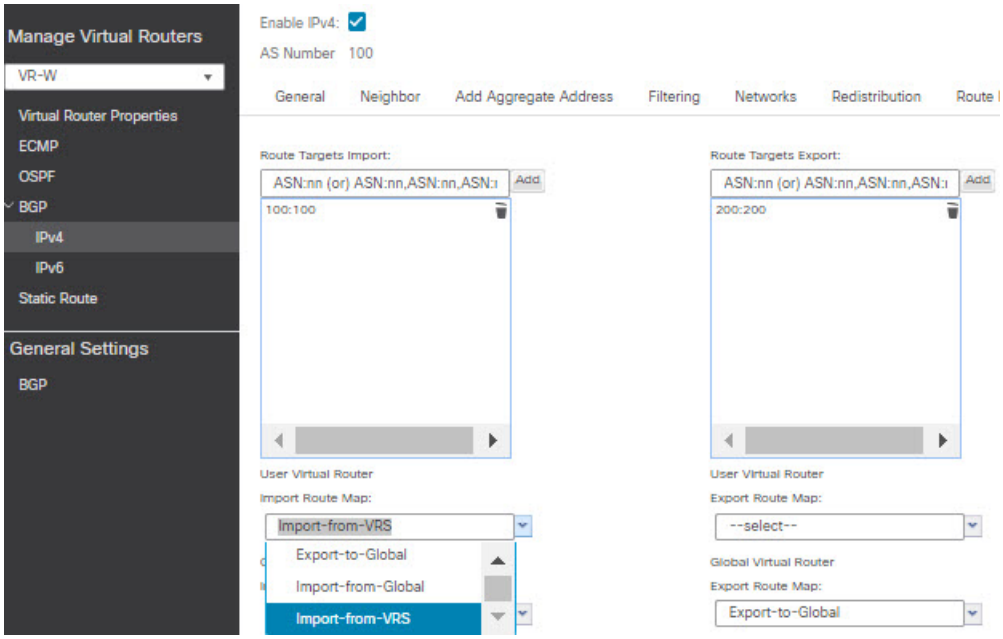
Step 3 To leak only the Outside1 routes of VR-S to VR-W:

a) From the virtual router drop-down, select VR-S and then click **BGP** > **IPv4** > **Route Import/Export**.

b) To leak the VR-S routes to VR-W, tag the routes with a route target, so that the VR-S routes are exported to its BGP table with the route target marked on them. In the **Route Targets Export** field, enter a value, say, *100:100*. Click **Add**.

c) From the virtual router drop-down, select VR-W, and choose **BGP** > **IPv4** > **Route Import/Export**. To receive the leaked routes from VR-S, configure the Import Route Target to import the VR-S routes that are marked with the route target from the (peer or redistributed) BGP table. In the **Route Targets Import** field, enter the VR-S route target value, *100:100*. Click **Add**.

d) Now, you need to conditionalize that only the Outside1 routes of VR-S to be leaked to VR-W. Choose **Objects** > **Object Management** > **Prefix Lists** > **IPv4 Prefix List**. Click **Add IPv4 Prefix List**, give a name, say *VRS-Outside1-Only*, and then click **Add**.



e) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list. Enter the IP Address (first two octets) of the VR-S Outside1 interface and then click **Save**.

f) Create a route map with the match clause with the prefix list. Click **Route Map**. Click **Add Route Map**, give a name, say *Import-from-VRS*, and then click **Add**.

g) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.

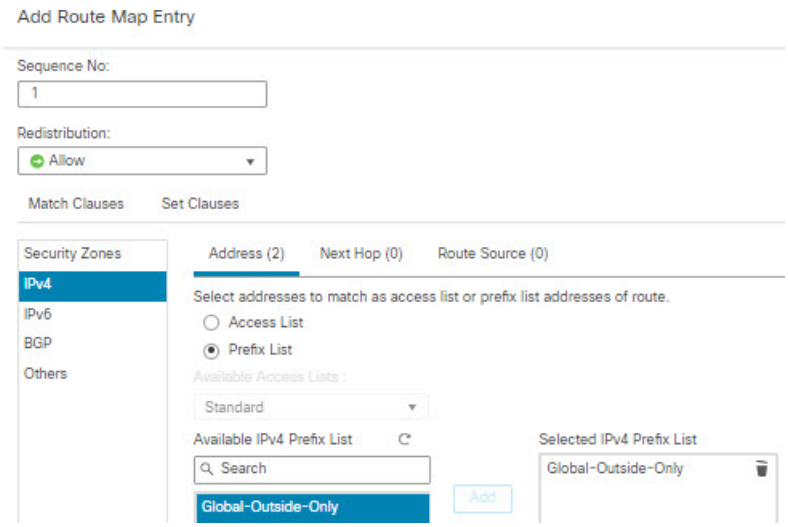
h) In the **Match Clause** tab, click **IPv4**. Under **Address** tab, click **Prefix List**. Under **Available IPv4 Prefix List**, select VRS-Outside1-Only, and then click **Add**.

i) Navigate to the **Routing** tab of the device, and select VR-W. Click **BGP** > **IPv4** > **Route Import/Export**. From the **Global Virtual Router Import Route Map** drop-down list, choose Import-from-VRS:

Step 4 Configure VR-S to import the Outside routes of Global virtual router:

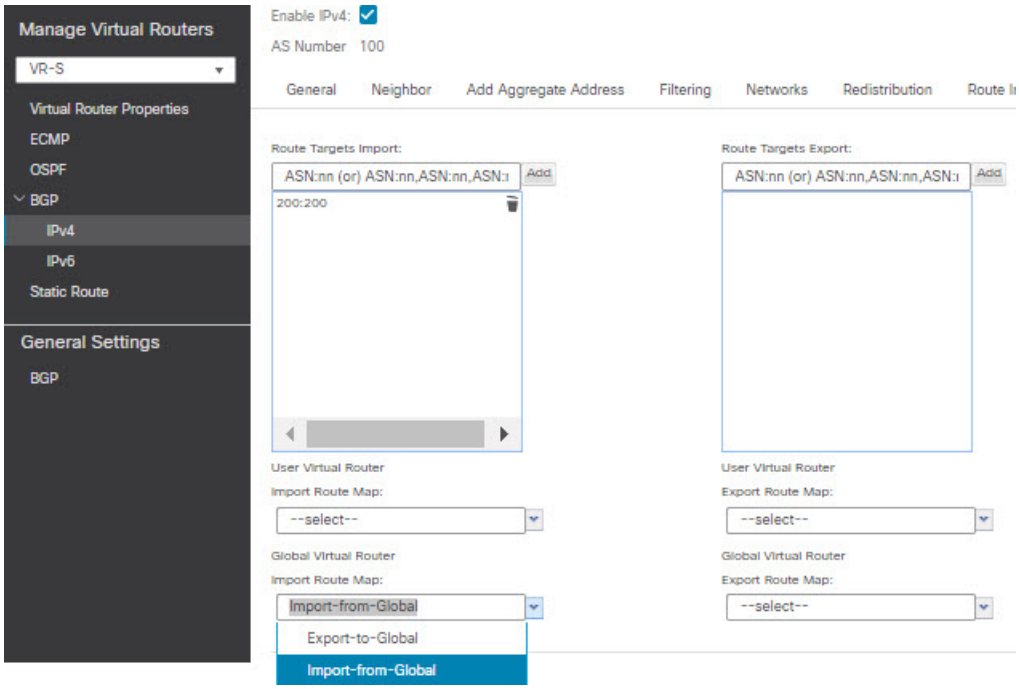
Note To leak routes to or from a Global virtual router, you must configure the source or destination user defined virtual router respectively. Thus, in this example, VR-S is the destination router that imports the routes from Outside interface of the Global virtual router.

a) Choose **Objects** > **Object Management** > **Prefix Lists** > **IPv4 Prefix List**.



b) Click **Add IPv4 Prefix List**, give a name, say *Global-Outside-Only*, and then click **Add**. Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.

c) Enter the IP Address (first two octets) of the Global Outside interface:



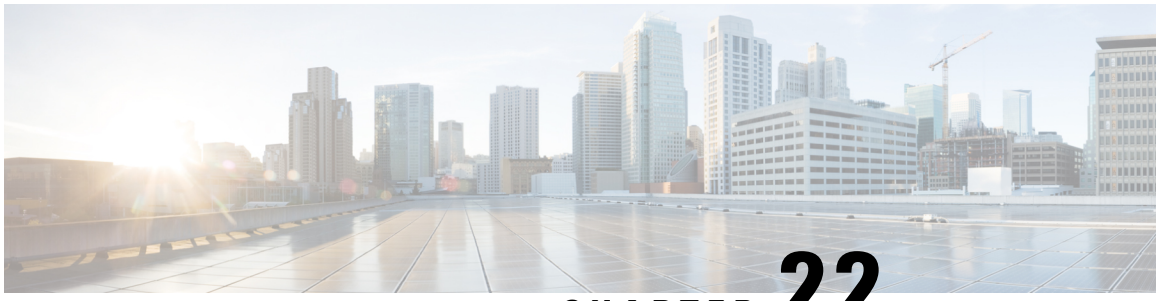
Then click **Save**.

d) Click **Route Map**. Click **Add Route Map**, give a name, say *Import-from-Global*, and then click **Add**.
e) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.
f) In the **Match Clause** tab, click **IPv4**. Under **Address** tab, click **Prefix List**.
g) Under **Available IPv4 Prefix List**, select Global-Outside-Only, and then click **Add**:

Then click **Save**.

h) Navigate to the **Routing** tab of the device, and select VR-S. Click **BGP** > **IPv4** > **Route Import/Export**.
i) From the **Global Virtual Router Import Route Map** drop-down list, choose Import-from-Global:

Step 5 **Save** and **Deploy**.



The BGP configuration is complete and routes are now leaked among the virtual routers according to the configured route targets and route maps. VR-W routes are exported to VR-S and Global, VR-S Outside1 routes are exported to VR-W, and Global Outside routes are imported to VR-S.

History for virtual routers

This reference provides a comprehensive history of virtual router features introduced across different versions, including feature descriptions, minimum version requirements, and implementation details.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Virtual routing with dynamic VTI.	7.4	7.4	You can now configure a virtual router with a dynamic VTI for a route-based site-to-site VPN. New/modified screens: **Devices** > **Device management** > **Edit Device** > **Routing** > **Virtual Router Properties** > **Dynamic VTI interfaces under Available Interfaces** Platform restrictions: Supported only on native mode standalone or high availability devices. Not supported for container instances or clustered devices.
Virtual router support for the ISA 3000.	7.0	7.0	You can configure up to 10 virtual routers on the ISA 3000.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
SNMP support on user-defined virtual routers	7.0	7.0	You can now configure SNMP on user-defined virtual routers.
Bulk removal of virtual routers.	6.7	6.6	You can remove multiple virtual routers from threat defense at a time. New/modified screens: **Devices** > **Device Management** > **Routing** > **Manage Virtual Routers**
Virtual routers and VRF-Lite for threat defense.	6.6	6.6	You can now create multiple virtual routers to maintain separate routing tables for groups of interfaces. Because each virtual router has its own routing table, you can provide clean separation in the traffic flowing through the device. Virtual routers implement the "light" version of Virtual Routing and Forwarding, or VRF-Lite, which does not support Multiprotocol Extensions for BGP (MBGP). The maximum number of virtual routers you can create ranges from five to 100, and depends on the device model.. New/modified screens: **Devices** > **Device Management** edit device **Routing** tab New/modified CLI commands: . • **show VRF** • Added the [**VRF** *name* | **all**] keyword set to these CLI commands, and changed the output to indicate virtual router information where applicable: **clear ospf**, **clear route**, **ping**, **show asp table routing**, **show BGP**, **show ipv6 route**, **show ospf**, **show route**, **show snort counters** Platform restrictions: Not supported on the Firepower 1010 and ISA 3000.

CHAPTER 22

ECMP

Equal Cost Multi-Path (ECMP) is a routing strategy that allows a router to forward packets along multiple paths of equal cost to a destination.

- Enables load balancing across multiple network paths.
- Utilizes routing protocols to determine path cost.
- Increases total available bandwidth for traffic flows.

- ECMP routing methods, on page 1047
- Guidelines and limitations for ECMP, on page 1048
- Manage ECMP zones for virtual routers, on page 1049
- Create an ECMP zone, on page 1049
- Configure an equal cost static route, on page 1050
- Modify an ECMP zone, on page 1051
- Remove an ECMP zone, on page 1052
- Configure ECMP zones on your device, on page 1053
- History for ECMP in Secure Firewall Threat Defense, on page 1056

ECMP routing methods

ECMP is a routing method that

- enables traffic distribution across multiple equal-cost paths,
- supports up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone, and
- uses traffic zones per virtual router to contain a group of interfaces.

Multiple default routes configuration

This example shows multiple default routes configured across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2

route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2

route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

Guidelines and limitations for ECMP

Follow these principles for effective ECMP zone configuration:

Firewall mode limitations

Use ECMP zones only in routed firewall mode.

Interface restrictions

Do not use dVTI or Loopback interfaces with ECMP zones.

ECMP zone configuration limits

Follow these limits when configuring ECMP zones:

- Devices can have a maximum of 256 ECMP zones.
- You can associate only 8 interfaces per ECMP zone.
- An interface can be a member of only one ECMP zone.

Interface management limitations

Do not remove interfaces or delete zones actively used for routing:

- You cannot remove an interface that is associated with an equal cost static route from the ECMP zone.
- You cannot delete an ECMP zone if its interface has equal cost static routes associated with it.

Supported interface types

Use only routed interfaces for ECMP zones. Do not associate these interface types with an ECMP zone:

- BVI interface.
- Member interfaces in an EtherChannel.
- Failover or state link interface.
- Management-only or management-access interfaces.
- Cluster control link interface.
- VNIs.
- VLAN interfaces.
- Interfaces in a remote access VPN configuration with SSL enabled.

Feature compatibility limitations

Consider these feature limitations when using ECMP zones:

- DHCP Relay is not supported on interfaces in an ECMP zone.
- Dual ISP/WAN Firewall Threat Defense Deployment—Create a single ECMP zone for the primary and secondary data interfaces, enabling static routes with identical metric values.

- The Firewall Threat Defense does not support ECMP with NAT in IPsec sessions—a standard IPsec virtual private network (VPN) tunnel does not work with NAT points in the delivery path of IPsec packets.

Manage ECMP zones for virtual routers

The ECMP page lets you manage existing ECMP zones linked with virtual routers. When you click **ECMP** on the **Routing** pane, the ECMP page displays the current ECMP zones, including the associated interfaces, for the selected virtual router. On this page, you can add new ECMP zones to the virtual router. You can also **Edit** ( ) and **Delete** ( ) ECMP zones.

You can perform these actions:

- Create an ECMP zone, on page 1049
- Configure an equal cost static route, on page 1050
- Modify an ECMP zone, on page 1051
- Remove an ECMP zone, on page 1052

Create an ECMP zone

Create an ECMP zone to enable load balancing across multiple equal-cost paths in a virtual router configuration.

ECMP zones are created per virtual router. Only interfaces that belong to the virtual router where the ECMP is being created can be associated with the ECMP zone.

Procedure

Step 1 Navigate to **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 From the virtual router drop-down, select the virtual router in which you want to create the ECMP zone.

You can create ECMP zones in the global virtual router and user-defined virtual routers. For information on creating virtual routers, refer to Create a virtual router, on page 1002.

Step 4 Click **ECMP**.

Step 5 Click **Add**.

Step 6 In the **Add ECMP** box, enter a name for the ECMP zone.

Note The ECMP name must be unique on the routed device.

Step 7 Under the **Available Interfaces** box, select the interface and click **Add**.

- Only interfaces belonging to the virtual router where you are creating the ECMP can be associated with it. Interfaces must have a logical name to be displayed; edit the interface and save to set a logical name.

- From Version 10.0, ECMP is supported on dynamic VTIs (DVTIs) of hub devices in SD-WAN VPN topologies. When enabled on a DVTI, it is automatically added to a system-generated ECMP zone, so DVTIs do not appear under **Available Interfaces**.

Step 8 Click **OK**.

The ECMP page displays your newly created ECMP zone.

Step 9 Click **Save** and **Deploy** the configuration.

You can associate the ECMP zone interfaces with equal cost static route by defining them with same destination and metric value but with a different gateway.

What to do next

- Configure an equal cost static route, on page 1050
- Modify an ECMP zone, on page 1051
- Remove an ECMP zone, on page 1052

Configure an equal cost static route

Configure equal cost static routes to enable load balancing across multiple interfaces with the same destination and metric value within an ECMP zone.

Smart License	Classic License	Supported Devices	Supported Domains	Access
Any	N/A	Firewall Threat Defense and Firewall Threat Defense Virtual	Any	Admin/Network Admin/Security Approver

You can assign interfaces of a virtual router, both global and user-defined, to an ECMP zone for the device.

Before you begin

- To configure an equal cost static route for an interface, ensure that it is associated with an ECMP zone. For more information, refer to Create an ECMP zone, on page 1049.
- All routing configuration settings of a non-VRF-capable device are also available for a global virtual router.
- You cannot define a static route for interfaces with the same destination and metric without associating the interfaces with an ECMP zone.

Procedure

Step 1 From the **Devices** > **Device Management** page, edit the Firewall Threat Defense device. Click the **Routing** tab.

Step 2 From the drop-down list, select the virtual router whose interfaces are associated with an ECMP zone.

Step 3 To configure the equal cost static route for the interfaces, click **Static Route**.

Step 4 Either click **Add Route** to add a new route, or click **Edit** (✎) for an existing route.

Step 5 From the **Interface** drop-down, select the interface that belongs to the virtual router and is associated with an ECMP zone.

Step 6 Select the destination network from the **Available Networks** box and click **Add**.

Step 7 Enter a gateway for the network.

Step 8 Enter a metric value. It can be a number that ranges between 1 and 254.

Step 9 To save the settings, click **Save**.

To configure equal cost static routing, repeat these steps to configure the static route for another interface in the same ECMP zone with the same destination network and metric value. Remember to provide a different gateway.

The equal cost static routes are configured for the interfaces associated with the ECMP zone, enabling load balancing across multiple paths.

What to do next

- Modify an ECMP zone, on page 1051
- Remove an ECMP zone, on page 1052

Modify an ECMP zone

Use this procedure when you need to make changes to an existing ECMP zone configuration on your device.

Follow these steps to modify an ECMP zone:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **ECMP**.

ECMP zones with their associated interfaces appear.

Step 4 To modify an ECMP zone, click **Edit** (✎) next to the desired ECMP zone. In the **Edit ECMP** dialog box, you can make changes to the ECMP name or associated interfaces.

- ECMP Name: Ensure that the ECMP name you enter is unique.
- Interfaces: Add or remove one or more interfaces as needed.

Note An interface must not belong to more than one ECMP zone, and it should not be linked to an equal-cost static route.

Step 5 Click **OK**.

Step 6 Click **Save**.

The ECMP zone shows your updated settings.

What to do next

- Configure an equal cost static route, on page 1050
- Remove an ECMP zone, on page 1052

Remove an ECMP zone

ECMP zones group interfaces for equal-cost multipath routing. You may need to remove an ECMP zone when reconfiguring your network topology or when the zone is no longer required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **ECMP**.

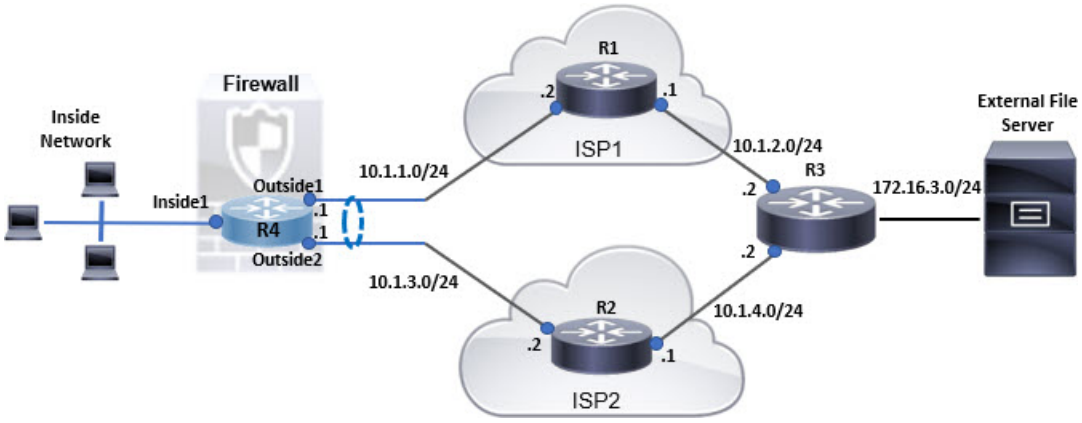
The ECMP zones with associated interfaces appear.

Step 4 To remove an ECMP zone, click **Delete** ( ) next to the ECMP zone.

Note You cannot delete the ECMP zone if it has interfaces associated with equal-cost static routes.

Step 5 Click **Delete** in the confirmation message.

Step 6 Click **Save** to apply changes.



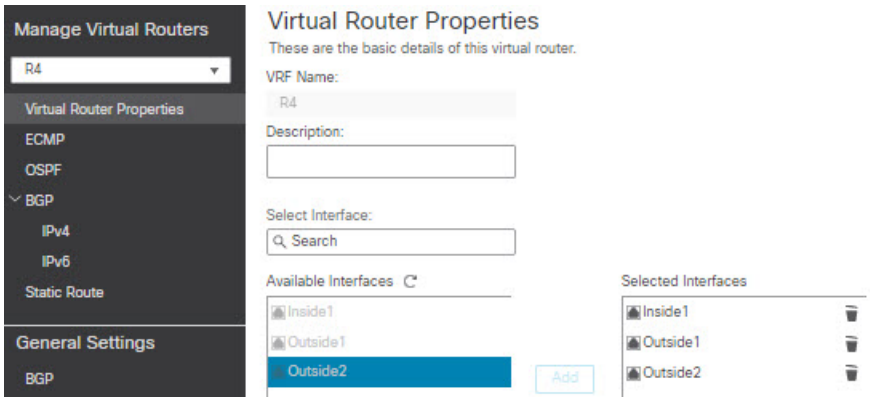
The ECMP zone is removed from the device configuration and is no longer available for routing operations.

Configure ECMP zones on your device

Configure Equal-Cost MultiPath (ECMP) to enable efficient traffic handling through the device with support for asymmetric routing, load balancing, and traffic rerouting when a path becomes unavailable.

This example demonstrates how to use Firewall Management Center to configure ECMP zones on Firewall Threat Defense such that the traffic flowing through the device is handled efficiently. With ECMP configured, Firewall Threat Defense maintains the routing table on a per-zone basis, enabling efficient packet re-routing. Thus, ECMP supports asymmetric routing, load balancing, and traffic rerouting when a path becomes unavailable. In this example, R4 records the two paths to reach the external file server.

Figure 356: Configuration example for ECMP



Follow these steps to configure ECMP on your device:

Procedure

Step 1 Create a virtual router.

Set up a new router on *R4* with interfaces: *Inside1*, *Outside1*, and *Outside2*. For more information, refer to Create virtual router.

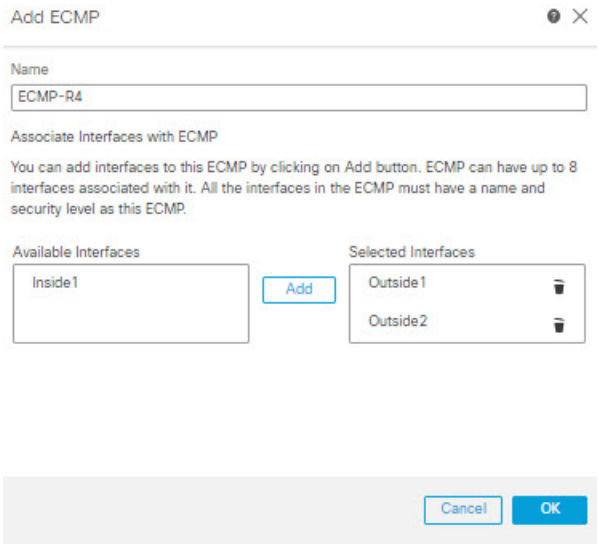


Figure 357: Configuring R4 virtual router

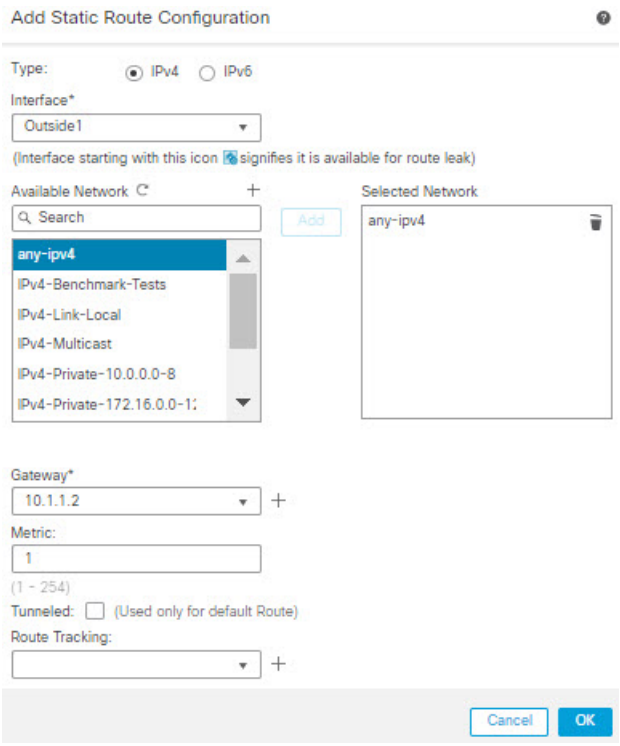
Step 2 Create ECMP zones:

a) In the **Routing** tab, choose R4 user-defined virtual router, and then click **ECMP**.
b) Click **Add**.
c) Enter an ECMP name and from the **Available Interfaces** list, choose *Outside1* and *Outside2*:

Figure 358: Creating ECMP zone



d) Click **OK**.
e) Click **Save**.

Step 3 Create static routes for the zone interfaces:

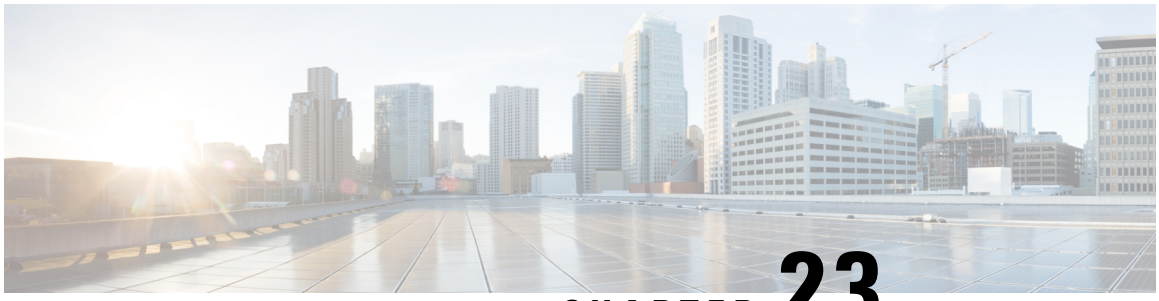
a) In the **Routing** tab, click **Static Route**.
b) From the **Interface** drop-down list, select Outside1.
c) Under **Available Network**, choose any-ipv4 and click **Add**.
d) Specify the next-hop address in the **Gateway** field, 10.1.1.2.

Figure 359: Configuring static route for Outside1

e) Configure the static route for Outside2 by repeating Step 3b through Step 3d.

Ensure that you specify the same metric but different gateways for the static routes:

Figure 360: Configured static routes of ECMP zone interfaces



Step 4 Save and deploy the changes to apply ECMP routing to your device.

Network packets will now utilize efficient routes to reach their destination R3, either through R4>R1>R3 or R4>R2>R3, according to the ECMP algorithm configuration. If the R1>R3 route becomes unavailable, traffic can be rerouted through R2, which helps reduce disruption during path failure. Additionally, return traffic from R3 can arrive on *Outside2* even if the original packet was sent through *Outside1*. When network traffic is heavy, R4 distributes the network load between two specified routes to maintain balanced traffic.

History for ECMP in Secure Firewall Threat Defense

This reference provides the history of Equal-Cost Multi-Path (ECMP) features, focusing on key enhancements introduced in various releases and their implementation specifics.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
ECMP support as Routing Policy	7.1	Any	Secure Firewall Threat Defense supports ECMP routing through FlexConfig policies. Group interfaces into traffic zones to refine ECMP routing in Secure Firewall Management Center. New/modified screens: **Devices** > **Device Management** > **Routing** > **ECMP**

CHAPTER 23

Bidirectional Forwarding Detection Routing

This chapter describes how to configure Firewall Threat Defense to use the Bidirectional Forwarding Detection (BFD) routing protocol.

- BFD routing protocol, on page 1057
- Guidelines for BFD routing, on page 1057
- Configure BFD, on page 1059
- History for BFD routing, on page 1062

BFD routing protocol

A BFD routing protocol is a detection protocol that

- provides fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols
- operates in a unicast, point-to-point mode on top of any data protocol being forwarded between two systems, and
- carries packets in the payload of the encapsulating protocol appropriate for the media and the network.

Why BFD?

BFD provides a consistent failure detection method for network administrators in addition to fast forwarding path failure detection.

Network administrators can use BFD to detect forwarding path failures at a uniform rate, rather than the variable rates for different routing protocol hello mechanisms. This makes network profiling and planning easier, and reconvergence time is consistent and predictable.

Guidelines for BFD routing

Context mode guidelines

BFD is supported on all Firewall Threat Defense platforms and is available in multi-instance mode.

Firewall mode guidelines

BFD is supported in routed firewall mode and not in transparent mode.

Failover and cluster guidelines

- BFD is not supported on failover interfaces.
- In clustering, BFD is supported only on the control node.

Routing and protocol guidelines

- OSPFv2, OSPFv3, IS-IS, BGP IPv4, and BGP IPv6 protocol are supported.

  For BFD support on IS-IS, using FlexConfig CLI configure BFD on IS-IS interfaces (Physical Interfaces, Sub-Interfaces, Port-Channels only):

```
For IPv6
###Flex-config Appended CLI###

router isis
  net 11.1111.0000.0000.0001.00
exit
interface GigabitEthernet x/x
  ipv6 router isis
  isis ipv6 bfd
exit

For IPv4
###Flex-config Appended CLI###

router isis
  net 11.1111.0000.0000.0001.00
exit
interface GigabitEthernet x/x
  isis
  isis bfd
exit
```

  EIGRP protocol is not supported.
- BFD for static routes is not supported. You can configure BFD on interfaces that belong only to virtual routers.
- Only named interfaces are supported.
- BFD on BVI, VTI, and loopback interfaces are not supported.

Single-hop guidelines

- Echo mode is disabled by default. You can enable echo mode on single-hop only.
- Echo mode is not supported for IPv6.
- Use only a single-hop template to configure a single-hop policy.
- Authentication of the single-hop template is optional.
- You cannot configure multiple BFDs on the same interface.

Multi-hop guidelines

- Do not configure the source IP address also as the destination IP address.

- Source and destination address should have same IP type—IPV4 or IPV6.
- Only network objects of host or network type are allowed.
- Use only a multi-hop template to configure a multi-hop policy.
- Authentication is mandatory for the multi-hop template.

Upgrade guidelines

When you upgrade to version 7.3 and the previous version has any FlexConfig BFD policies, the management center displays a warning message during deployment. However, it does not stop the deployment process. After post-upgrade deployment, to manage the BFD policies from the UI (**Device (Edit)** > **Routing** > **BFD**), you must configure BFD policies in the **Device (Edit)** > **Routing** > **BFD** page and remove the configuration from the FlexConfig policy for the device.

Configure BFD

This task enables and configures the Bidirectional Forwarding Detection (BFD) routing policy on your system to provide rapid detection of faults in the forwarding path.

Before you begin

Ensure you have access to the system where you want to configure BFD.

Follow these steps to configure BFD:

Procedure

Step 1 Create Configure a BFD template, on page 2358.

Step 2 Configure BFD policies, on page 1059.

Step 3 Configure BFD support in the BGP neighbor settings; see, Configure BGP Neighbor Settings.

BFD is enabled and configured on your system.

Configure BFD policies

BFD policies are used to provide rapid failure detection for interfaces associated with virtual routers. Configuring BFD templates allows you to monitor connectivity and quickly identify link failures.

- Enable fast failure detection for routing interfaces.
- Support both single-hop and multi-hop BFD configurations.

You can bind a BFD template to an interface belonging to a virtual router, or to a source and destination address pair.

Before you begin

- BFD policy is configurable only on interfaces that belong to virtual routers. See Configure interfaces to a virtual router.

To configure BFD policies, complete these steps.

Procedure

Step 1 From the **Devices** > **Device Management** page, edit the virtual-router supported device. Navigate to **Routing**.

Step 2 From the drop-down list, select the desired virtual router, and then click **BFD**.

Step 3 To configure a BFD on the interface, click the **Single-Hop** tab or **Multi-Hop** tab.

Note For a single-hop policy, the BFD template is configured on an interface; for a multi-hop policy, the BFD template is configured on a source and destination address pair.

Step 4 Click **Add**. To modify the configured BFD policy, click **Edit** ( ).

Note When you edit the interface mapping with BFD template to replace it with a new BFD template, the Firewall Management Center uses a **no** command to remove the template mapping from interface and applies the new template to the interface which causes a BFD flap which may also lead to an OSPFv2, OSPFv3, or BGP flap. However, if the BFD intervals are higher, the BFD flap might not occur. Alternatively, to avoid the flapping, you can delete the existing BFD template mapping; deploy the interface, and then add the new BFD template to the interface and deploy the configuration.

- See Configure a single-hop BFD policy, on page 1060.
- See Configure a multi-hop BFD policy, on page 1061.

After completing this task, BFD policies are configured on the selected interfaces or address pairs.

Configure a single-hop BFD policy

You can configure a single-hop BFD policy only on an interface that belongs to a virtual router. This task is relevant when you need to apply BFD for rapid link failure detection on specific interfaces.

Before you begin

- Create single-hop BFD templates. You cannot configure single-hop BFD policy on interfaces that use a multi-hop template.

Follow these steps to configure a single-hop BFD policy:

Procedure

Step 1 In the **Single-Hop** tab, click **Add** or **Edit**.

Step 2 In the **Add BFD Single-Hop** dialog box, configure the following:

a) The **Interface** drop-down list displays interfaces belonging to virtual routers. Select the interface you want to configure with the BFD policy.

b) The **Template Name** drop-down list displays single-hop templates. Select the template that you want to apply.

If you have not created a single-hop template, use **Add** (+) and create a single-hop BFD template.

Step 3 Click **OK** and **Save** the configuration.

The single-hop BFD policy is applied to the selected interface. The interface will now use the specified BFD template for single-hop operations.

Configure a multi-hop BFD policy

Configure a multi-hop BFD policy to enable monitoring of connectivity between specific source and destination address pairs. This configuration helps to monitor links that traverse multiple hops in your network.

Before you begin

- Create multi-hop BFD templates. You cannot configure multi-hop BFD policy using a single-hop template.

Follow these steps to configure a multi-hop BFD policy:

Procedure

Step 1 In the **Add BFD Multi-Hop** dialog box, configure the following:

a) Click the BFD source address type:**IPv4** or **IPv6** radio button.

b) The **Source Address** drop-down list displays the network objects. Select the source address for the BFD policy; do not choose *any-ipv4* or *any-ipv6*.

If you have not created the required network object, use **Add** (+) and create a host/network object.

Note The created network object's IP type should match with the selected source IP type.

c) The **Destination Address** drop-down list displays network objects. Select the destination address for the BFD; do not choose *any-ipv4* or *any-ipv6*.

If you have not created the required network object, use **Add** (+) and create a host/network object.

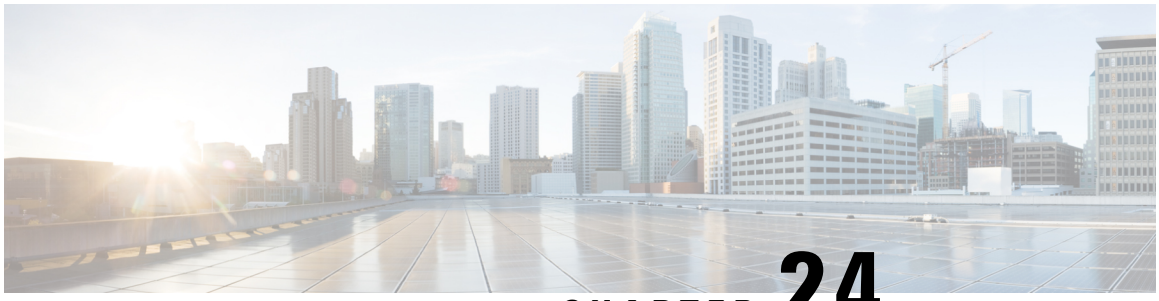
Note The created network object's IP type should match with the selected source IP type.

Attention Do not select the network object that has the same IP address as that of the source address.

d) The **Template Name** drop-down list displays multi-hop templates. Select the template to apply to the BFD policy.

If you have not created a multi-hop template, use **Add** (+) and create a multi-hop BFD template.

Step 2 Click **OK** and **Save** the configuration.



The multi-hop map (table view) is displayed on the **Multi-Hop** tab page.

History for BFD routing

The History table summarizes the introduction and evolution of the BFD routing in Cisco Firewall Management Center across releases, enabling quick tracking of feature availability and changes.

Table 69: Feature history for BFD routing

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
BFD support for IS-IS	7.4	7.4	You can configure BFD on IS-IS interfaces using FlexConfig CLI.
BFD support for OSPF	7.4	7.4	You can enable BFD on interfaces that use OSPF version 2 and OSPF version 3. New/modified screens: • **Configuration** > **Device Setup** > **Routing** > **OSPFv2** • **Configuration** > **Device Setup** > **Routing** > **OSPFv3**
BFD configuration	7.4	7.4	In the previous releases, BFD was configurable on threat defense only through FlexConfig. FlexConfig no longer supports BFD configuration. You can now configure BFD policies for threat defense in the management center UI. In threat defense, BFD is supported only on the BGP protocol. New/modified screens: **Devices** > **Device Management** > **Routing** > **BFD**.

CHAPTER 24

OSPF

This chapter describes how to configure the Firewall Threat Defense to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

- OSPF, on page 1063
- Requirements and prerequisites for OSPF, on page 1067
- Guidelines for OSPF, on page 1067
- OSPFv2 configuration, on page 1070
- OSPFv3 configuration, on page 1083
- History for OSPF, on page 1093

OSPF

This chapter describes how to configure the Firewall Threat Defense to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

OSPF routing

OSPF is an interior gateway routing protocol that

- uses link states rather than distance vectors for path selection,
- propagates link-state advertisements rather than routing table updates, and
- converges more quickly than RIP networks because only LSAs are exchanged instead of the entire routing tables.

OSPF characteristics and features

OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area contains an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

The advantages of OSPF over RIP include these characteristics:

- OSPF link-state database updates are sent less frequently than RIP updates, and the link-state database is updated instantly, rather than gradually, AS stale information is timed out.

- Routing decisions are based on cost, which is an indication of the overhead required to send packets across a certain interface. The Firewall Threat Defense device calculates the cost of an interface based on link bandwidth rather than the number of hops to the destination. The cost can be configured to specify preferred paths.

The disadvantage of shortest path first algorithms is that they require a lot of CPU cycles and memory.

The Firewall Threat Defense device can run two processes of OSPF protocol simultaneously on different sets of interfaces. You might want to run two processes if you have interfaces that use the same IP addresses (NAT allows these interfaces to coexist, but OSPF does not allow overlapping addresses). Or you might want to run one process on the inside and another on the outside, and redistribute a subset of routes between the two processes. Similarly, you might need to segregate private addresses from public addresses.

You can redistribute routes into an OSPF routing process from another OSPF routing process, a RIP routing process, or from static and connected routes configured on OSPF-enabled interfaces.

The Firewall Threat Defense device supports these OSPF features:

- Intra-area, inter-area, and external (Type I and Type II) routes.
- Virtual links.
- LSA flooding.
- Authentication to OSPF packets (both password and MD5 authentication).
- Configuring the Firewall Threat Defense device AS a designated router or a designated backup router. The Firewall Threat Defense device also can be set up AS an ABR.
- Stub areas and not-so-stubby areas.
- Area boundary router Type 3 LSA filtering.

OSPF supports both MD5 and clear text neighbor authentication. Authentication should be used with all routing protocols when possible because route redistribution between OSPF and other protocols (such AS RIP) can potentially be used by attackers to subvert routing information.

If NAT is used, if OSPF is operating on public and private areas, and if address filtering is required, then you need to run two OSPF processes—one process for the public areas and one for the private areas.

A router that has interfaces in multiple areas is called an Area Border Router (ABR). A router that acts AS a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR).

An ABR uses LSAs to send information about available routes to other OSPF routers. Using ABR Type 3 LSA filtering, you can have separate private and public areas with the ASA acting AS an ABR. Type 3 LSAs (inter-area routes) can be filtered from one area to other, which allows you to use NAT and OSPF together without advertising private networks.

Note Only Type 3 LSAs can be filtered. If you configure the Firewall Threat Defense device AS an ASBR in a private network, it will send Type 5 LSAs describing private networks, which will get flooded to the entire AS, including public areas.

If NAT is employed but OSPF is only running in public areas, then routes to public networks can be redistributed inside the private network, either AS default or Type 5 AS external LSAs. However, you need to configure

static routes for the private networks protected by the Firewall Threat Defense device. Also, you should not mix public and private networks on the same Firewall Threat Defense device interface.

You can have two OSPF routing processes, one RIP routing process, and one EIGRP routing process running on the Firewall Threat Defense device at the same time.

OSPF support for fast hello packets

OSPF support for fast hello packets is a feature that

- provides a way to configure the sending of hello packets in intervals less than one second, and
- results in faster convergence in an Open Shortest Path First (OSPF) network.

OSPF fast hello packets configuration prerequisites

OSPF must be configured in the network already or configured at the same time as the OSPF Support for Fast Hello Packets feature.

OSPF hello interval and dead interval

OSPF hello interval and dead interval are configurable time parameters that

- maintain connectivity between OSPF neighbors through regular hello packet exchanges,
- detect neighbor failures when hello packets are not received within the specified timeframes, and
- must be consistent across all routers within the same network to ensure proper operation.

Hello interval and dead interval configuration details

OSPF hello packets are packets that an OSPF process sends to its OSPF neighbors to maintain connectivity with those neighbors. The hello packets are sent at a configurable interval (in seconds). The defaults are 10 seconds for an Ethernet link and 30 seconds for a non broadcast link.

Hello packets include a list of all neighbors for which a hello packet has been received within the dead interval. The dead interval is also a configurable interval (in seconds), and defaults to four times the value of the hello interval. The value of all hello intervals must be the same within a network. Likewise, the value of all dead intervals must be the same within a network.

These two intervals work together to maintain connectivity by indicating that the link is operational. If a router does not receive a hello packet from a neighbor within the dead interval, it will declare that neighbor to be down.

OSPF fast hello packets

OSPF fast hello packets are hello packets that

- are sent at intervals of less than 1 second,
- are achieved by using the OSPF dead-interval command with a dead interval set to 1 second, and
- use a hello-multiplier value set to the number of hello packets sent during that 1 second.

Fast hello packet behavior

When fast hello packets are configured on the interface, these behaviors occur:

- The hello interval advertised in the hello packets that are sent out this interface is set to 0.
- The hello interval in the hello packets received over this interface is ignored.

The dead interval must be consistent on a segment, whether it is set to 1 second (for fast hello packets) or set to any other value. The hello multiplier need not be the same for the entire segment as long as at least one hello packet is sent within the dead interval.

To understand fast hello packets, you should already understand the relationship between OSPF hello packets and the dead interval. See OSPF hello interval and dead interval, on page 1065.

Benefits of OSPF fast hello packets

A fast hello packet is an OSPF protocol feature that

- reduces network convergence time by enabling routers to detect changes in the network faster,
- allows rapid detection of lost neighbors within one second, and
- enhances reliability in LAN environments where neighbor loss may not be detected at the Open Systems Interconnection (OSI) physical or data-link layer.

The benefit of OSPF Fast Hello Packets is that your OSPF network can react swiftly to changes, minimizing downtime and improving overall network stability. This feature is particularly useful in scenarios where routers may not detect lost neighbors via traditional methods, allowing OSPF to maintain accurate routing tables.

If a router on a LAN segment is powered off or disconnected and the physical and data-link layers do not signal neighbor loss, OSPF fast hello packets will detect the neighbor's disappearance within one second.

OSPFv2 and OSPFv3 implementation differences

A protocol distinction is a protocol category that

- prevents backward compatibility between OSPFv2 and OSPFv3,
- requires both OSPF versions to run simultaneously for IPv4 and IPv6 routing, and
- allows OSPFv2 and OSPFv3 to coexist without interacting with each other.

OSPFv3 additional features

OSPFv3 provides additional features that include:

- Protocol processing per link.
- Removal of addressing semantics.
- Addition of flooding scope.
- Support for multiple instances per link.
- Use of the IPv6 link-local address for neighbor discovery and other features.

- LSAs expressed as prefix and prefix length.
- Addition of two LSA types.
- Handling of unknown LSA types.
- Authentication support using the IPsec ESP standard for OSPFv3 routing protocol traffic, as specified by RFC-4552.

Requirements and prerequisites for OSPF

This reference provides the requirements and prerequisites that must be met before configuring OSPF on supported devices.

Guidelines for OSPF

Context mode guidelines

OSPFv2 supports single and multiple context mode.

- OSPFv2 instances cannot form adjacencies with each other across shared interfaces because, by default, inter-context exchange of multicast traffic is not supported across shared interfaces. However, you can use the static neighbor configuration under OSPFv2 process configuration under OSPFv2 process to bring up OSPFv2 neighbourship on a shared interface.
- Inter-context OSPFv2 on separate interfaces is supported.
- **(For point-to-point topology)** In a multiple context mode, you can configure static OSPFv2 neighbors to advertise OSPFv2 routes over a point-to-point, non-broadcast network. For a successful OSPF adjacency formation, when you remove and reconfigure OSPF on a shared interface, execute the commands in this order: Remove the OSPF configuration using **no router <OSPF name>**, and then remove the OSPF point-to-point non-broadcast configuration on the interface using **no OSPF network point-to-point non-broadcast**. When you reconfigure OSPF on the shared interface, configure the OSPF router using **router <OSPF name>**, and then configure the interface with **OSPF network point-to-point non-broadcast**.
- OSPFv3 supports single mode only.

Key chain authentication guidelines

OSPFv2 supports key chain authentication on both single and multiple mode, both in physical and virtual modes. However, in multiple mode, you can configure the key chain only in context mode.

- The rotating keys are applicable only for OSPFv2 protocol. OSPF area authentication with key chain is not supported.
- The existing MD5 authentication without time range in OSPFv2 is still supported along with new rotating keys.
- Though the platform supports SHA1 and MD5 cryptographic algorithms, only MD5 cryptographic algorithm is used for authentication.

Firewall mode guidelines

OSPF supports routed firewall mode only. OSPF does not support transparent firewall mode.

High availability Guidelines

OSPFv2 and OSPFv3 support Stateful High availability.

IPv6 guidelines

OSPFv2 does not support IPv6, while OSPFv3 provides IPv6 support with specific authentication and routing capabilities.

- OSPFv2 does not support IPv6.
- OSPFv3 supports IPv6.
- OSPFv3 uses IPv6 for authentication.
- The Firewall Threat Defense device installs OSPFv3 routes into the IPv6 RIB, provided it is the best route.

OSPFv3 hello packets and GRE

Typically, OSPF traffic does not pass through GRE tunnel. When OSPFv3 on IPv6 is encapsulated inside GRE, the IPv6 header validation for security check such as Multicast Destination fails. The packet is dropped due to the implicit security check validation, as this packet has destination IPv6 multicast.

- You may define a pre-filter rule to bypass GRE traffic. However, with pre-filter rule, inner packets would not be interrogated by the inspection engine.

Clustering guidelines

OSPFv2 and OSPFv3 have specific limitations and behaviors in clustering environments.

- OSPFv3 encryption is not supported. An error message appears if you try to configure OSPFv3 encryption in a clustering environment.
- In Spanned interface mode, dynamic routing is not supported on management-only interfaces.
- In Individual interface mode, make sure that you establish the control and data units as either OSPFv2 or OSPFv3 neighbors.

- In Individual interface mode, OSPFv2 adjacencies can only be established between two contexts on a shared interface on the control unit. Configuring static neighbors is supported only on point-to point-links; therefore, only one neighbor statement is allowed on an interface.
- When a control role change occurs in the cluster, specific behavior occurs based on interface mode. In spanned interface mode, the router process is active only on the control unit and is in a suspended state on the data units. Each cluster unit has the same router ID because the configuration has been synchronized from the control unit. As a result, a neighboring router does not notice any change in the router ID of the cluster during a role change. In individual interface mode, the router process is active on all the individual cluster units. Each cluster unit chooses its own distinct router ID from the configured cluster pool. A control role change in the cluster does not change the routing topology in any way.

Multiprotocol label switching (MPLS) and OSPF guidelines

When a MPLS-configured router sends Link State (LS) update packets containing opaque Type-10 link-state advertisements (LSAs) that include an MPLS header, authentication fails and the appliance silently drops the update packets, rather than acknowledging them. Eventually the peer router will terminate the neighbor relationship because it has not received any acknowledgments.

- Make sure that non-stop forwarding (NSF) is disabled on the appliance to ensure that the neighbor relationship remains stable. Navigate to the **Non Stop Forwarding** page in Firewall Management Center (**Devices** > **Device Management (select the desired device)** > **Routing** > **OSPF** > **Advanced** > **Non Stop Forwarding**). Ensure the **Non Stop Forwarding Capability** boxes are not checked.

These guidelines apply to MPLS environments where opaque LSAs might cause authentication failures.

Note The Firepower 4100/9300 models may have high latency when using MPLS because they lack load balancing across multiple receiving queues.

Bidirectional and forwarding detection (BFD) and OSPF guidelines

You can enable BFD on specific interface types with OSPFv2 and OSPFv3.

- You can enable BFD on OSPFv2 and OSPFv3 interfaces (Physical Interfaces, Sub-Interfaces, and Port-Channels).
- BFD is not supported on VTI Tunnels, DVTI Tunnels, Loopback, Switchport, VNI, VTEP, and IRB interfaces.

Route redistribution guidelines

Route redistribution with prefix lists and between routing domains requires specific configuration considerations.

- Redistribution of route maps with IPv4 prefix list on OSPFv2 is supported. However, redistribution of route maps with IPv6 prefix list on OSPFv3 is not supported. Use an access list in the route map on OSPF for redistribution.
- When OSPF is configured on a device that is a part of EIGRP network or vice versa, ensure that OSPF-router is configured to tag the route (EIGRP does not support route tag yet). When redistributing OSPF into EIGRP and EIGRP into OSPF, a routing loop occurs when there is an outage on one of the links, interfaces, or even when the route originator is down. To prevent the redistribution of routes from one domain back into the same domain, a router can tag a route that belongs to a domain while it is

redistributing, and those routes can be filtered on the remote router based on the same tag. Because the routes will not be installed into the routing table, they will not be redistributed back into the same domain.

Additional guidelines

OSPFv2 and OSPFv3 support various features and have specific limitations in different deployment scenarios.

- OSPFv2 and OSPFv3 support multiple instances on an interface.
- OSPFv3 supports encryption through ESP headers in a non-clustered environment.
- OSPFv3 supports Non-Payload Encryption.
- OSPFv2 supports Cisco NSF Graceful Restart and IETF NSF Graceful Restart mechanisms as defined in RFCs 4811, 4812 & 3623 respectively.
- OSPFv3 supports Graceful Restart mechanism as defined in RFC 5187.
- There is a limit to the number of intra area (type 1) routes that can be distributed. For these routes, a single type-1 LSA contains all prefixes. Because the system has a limit of 35 KB for packet size, 3000 routes result in a packet that exceeds the limit. Consider 2900 type 1 routes to be the maximum number supported.
- For a device using virtual routing, you can configure OSPFv2 and OSPFv3 for a global virtual router. However, you can configure only OSPFv2 for a user-defined virtual router.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.
- OSPFv3 drops the LS update if the packet size exceeds 8190. As a result, the neighbourship is terminated. Hence, configure the switch with the "ospfv3 MTU-ignore" command to avoid neighbourship termination.

OSPFv2 configuration

This section describes the tasks involved in configuring an OSPFv2 routing process. For a device using virtual routing, you can configure OSPFv2 for global as well as for user-defined virtual routers.

Configure OSPF areas, ranges, and virtual links

Complete the configuration of OSPF by defining areas, assigning route summarization ranges, and creating virtual links to connect discontiguous OSPF areas.

You can configure several OSPF area parameters, which include setting authentication, defining stub areas, and assigning specific costs to the default summary route. You can enable up to two OSPF process instances. Each OSPF process has its own associated areas and networks. Authentication provides password-based protection against unauthorized access to an area.

Stub areas are areas into which information on external routes is not sent. Instead, there is a default external route generated by the ABR into the stub area for destinations outside the autonomous system. To take advantage of the OSPF stub area support, default routing must be used in the stub area.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

For a virtual-router-aware device, choose the virtual router from the virtual routers drop-down list.

Step 3 Click **OSPF** and configure the following on the **OSPF** page:

- Check the check box of **Process 1**. You can enable up to two OSPF process instances for each context /virtual router. You must choose an OSPF process to be able to configure the Area parameters.

  If the device is using virtual routing, the ID fields display the unique process IDs generated for the chosen virtual router.

- Choose the **OSPF Role** from the drop-down list, and enter a description for it in the next field. The options are **Internal Router**, **ABR**, **ASBR**, and **ABR & ASBR**. For a description of the OSPF roles, refer to OSPF routing, on page 1063.

Step 4 Select **Area** > **Add**.

You can click **Edit** ( ) , or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 5 Configure the following area options for each OSPF process:

- **OSPF Process**: Choose the process ID. For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Area ID**: Designation of the area for which routes are to be summarized.
- **Area Type**: Choose one of the following:
  - **Normal**: (Default) Standard OSPF area.
  - **Stub**: A stub area does not have any routers or areas beyond it. Stub areas prevent Autonomous System (AS) External LSAs (Type 5 LSAs) from being flooded into the stub area. When you create a stub area, you can prevent summary LSAs (Types 3 and 4) from being flooded into the area by not checking the **Summary Stub** check box.
  - **NSSA**: Makes the area a not-so-stubby area (NSSA). NSSAs accept Type 7 LSAs. You can disable route redistribution by not checking the **Redistribute** check box and checking the **Default Information Originate** check box. You can prevent summary LSAs from being flooded into the area by not checking the **Summary NSSA** check box.
- **Metric Value**: The metric used for generating the default route. The default value is 10. Valid metric values range from 0 through 16777214.
- **Metric Type**: The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Available Network**: Choose one of the available networks and click **Add** , or click **Add** ( ) to add a new network object. For the procedure for adding networks, refer to Networks, on page 2386.

- **Authentication**: Choose the OSPF authentication:
  - **None**: (Default) Disables OSPF area authentication.
  - **Password**: Provides a clear text password for area authentication, which is not recommended where security is a concern.
  - **MD5**: Allows MD5 authentication.
- **Default Cost**: The default cost for the OSPF area, which is used to determine the shortest paths to the destination. Valid values range from 0 through 65535. The default value is 1.
- Click **OK** to save the area configuration.

Step 6 Select **Range** > **Add**.

- Choose one of the available networks and whether to advertise, or
- Click **Add** (+) to add a new network object. For the procedure for adding networks, refer to Networks, on page 2386.
- Click **OK** to save the range configuration.

Step 7 Select **Virtual Link**, click **Add** (+), and configure the following options for each OSPF process:

- **Peer Router**: Choose the IP address of the peer router. To add a new peer router, click **Add** (+). For the procedure for adding networks, refer to Networks, on page 2386.
- **Hello Interval**: The time in seconds between the hello packets sent on an interface. The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. Valid values range from 1 through 65535. The default is 10.

  The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.
- **Transmit Delay**: The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 through 8192. The default is 1.

  LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.
- **Retransmit Interval**: The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 through 65535. The default is 5.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.
- **Dead Interval**: The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The dead interval is an unsigned integer. The default is four times the hello interval, or

40 seconds. The value must be the same for all routers and access servers that are attached to a common network. Valid values range from 1 through 65535.

- **Authentication**: Choose the OSPF virtual link authentication from the following:
  - **None**: (Default) Disables virtual link area authentication.
  - **Area Authentication**: Enables area authentication using MD5. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.
  - **Password**: Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
  - **MD5**: Allows MD5 authentication. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.

Note Ensure to enter only numbers as the MD5 key ID.

  - **Key Chain**: Allows key chain authentication. Click **Add**, and create the key chain, and then click **Save**. For detailed procedure, refer to Create a key chain object, on page 2385. Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.
  - Click **OK** to save the virtual link configuration.

Step 8 Click **Save** on the **Routing** page to save your changes.

OSPF is configured with designated areas, summarized ranges, and any necessary virtual links. Routing updates are generated based on your configuration.

Configure OSPF redistribution

This task enables you to control the redistribution of routes between the OSPF routing processes on your Firewall Threat Defense device.

The Firewall Threat Defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by EIGRP, RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

Before you begin

Follow these steps to configure OSPF redistribution:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 From **OSPF Role** drop-down, choose role.

Step 6 Click **Redistribution** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 7 Configure the following redistribution options for each OSPF process:

- **OSPF Process**: Choose the process ID. For a device using virtual routing, this drop-down list displays the unique process IDs generated for the selected virtual router.
- **Route Type**: Choose one of the following types:
  - **Static**: Redistributes static routes to the OSPF routing process.
  - **Connected**: Redistributes connected routes (routes established automatically by virtue of having the IP address enabled on the interface) to the OSPF routing process. Connected routes are redistributed AS external to the device. You can select whether to use subnets under the Optional list.
  - **OSPF**: Redistributes routes from another OSPF routing process, for example, internal, external 1 and 2, NSSA external 1 and 2, or whether to use subnets. You can select these options under the Optional list.
  - **BGP**: Redistribute routes from the BGP routing process. Add the AS number and whether to use subnets.
  - **RIP**: Redistributes routes from the RIP routing process. You can select whether to use subnets under the Optional list.

Note As a user-defined virtual router does not support RIP, you cannot redistribute routes from RIP.

  - **EIGRP**: Redistribute routes from the EIGRP routing process. Add the AS number and whether to use subnets.

- **Metric Value**: Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

  When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.

- **Metric Type**: The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Tag Value**: Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.

- **RouteMap**: Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add** (+). To add a new route map, refer to Configure Route Map Entry.

Step 8 Click **OK** to save the redistribution configuration.

Step 9 Click **Save** on the Routing page to save your changes.

OSPF redistribution is now configured for the selected OSPF process with the specified route types and parameters.

Configure OSPF Inter-Area filtering

Configure ABR type 3 LSA filtering to control which prefixes are sent between different OSPF areas and restrict other prefixes to their local OSPF area.

ABR type 3 LSA filtering extends the capability of an ABR that is running OSPF to filter type 3 LSAs between different OSPF areas. Once a prefix list is configured, only the specified prefixes are sent from one OSPF area to another OSPF area. All other prefixes are restricted to their OSPF area. You can apply this type of area filtering to traffic going into or coming out of an OSPF area, or to both the incoming and outgoing traffic for that area.

When multiple entries of a prefix list match a given prefix, the entry with the lowest sequence number is used. For efficiency, you may want to put the most common matches or denials near the top of the list by manually assigning them a lower sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.

Before you begin

Follow these steps to configure OSPF inter-area filtering:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **InterArea** > **Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete inter-areas.

Step 6 Configure these inter-area filtering options for each OSPF process:

- **OSPF Process**: For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Area ID**: The area for which routes are to be summarized.
- **PrefixList**: The name of the prefix. To add a new prefix list object, see Step 5.

- **Traffic Direction**: Inbound or outbound. Choose Inbound to filter LSAs coming into an OSPF area, or Outbound to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.

Step 7 Click **Add** (+), and enter a name for the new prefix list, and whether to allow overrides.

You must configure a prefix list before you can configure a prefix rule.

Step 8 Click **Add** to configure prefix rules, and configure these parameters:

- **Action**: Select **Block** or **Allow** for the redistribution access.
- **Sequence No**: The routing sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.
- **IP Address**: Specify the prefix number in the format of IP address/mask length.
- **Min Prefix Length**: (Optional) The minimum prefix length.
- **Max Prefix Length**: (Optional) The maximum prefix length.
- Click **OK** to save the inter-area filtering configuration.

Step 9 Click **Save** on the Routing page to save your changes.

The OSPF inter-area filtering configuration is saved and applied to control LSA distribution between the specified OSPF areas according to the configured prefix lists and traffic direction settings.

Configure OSPF filter rules

Configure OSPF filter rules to improve control of route distribution between OSPF areas by allowing only specified prefixes to be sent from one area to another area while restricting all other prefixes.

You can configure ABR Type 3 LSA filters for each OSPF process. ABR Type 3 LSA filters allow only specified prefixes to be sent from one area to another area and restrict all other prefixes. You can apply this type of area filtering out of a specific OSPF area, into a specific OSPF area, or into and out of the same OSPF area at the same time. OSPF ABR Type 3 LSA filtering improves your control of route distribution between OSPF areas.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Filter Rule** > **Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete filter rules.

Step 6 Configure the following filter rule options for each OSPF process:

- **OSPF Process**: For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Access List**: The access list for this OSPF process. To add a new standard access list object, click **Add** (+) and refer to Configure a standard ACL object, on page 2355.
- **Traffic Direction**: Choose In or Out for the traffic direction being filtered. Choose In to filter LSAs coming into an OSPF area, or Out to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.
- **Interface**: The interface for this filter rule.

Step 7 Click **OK** to save the filter rule configuration.

Step 8 Click **Save** on the Routing page to save your changes.

The OSPF filter rules are configured and saved, enabling controlled route distribution between OSPF areas based on the specified access list and traffic direction settings.

Configure OSPF summary addresses

Configure OSPF summary addresses to decrease the size of the OSPF link-state database by advertising a single route for all redistributed routes that are included for a specified network address and mask.

When routes from other protocols are redistributed into OSPF, each route is advertised individually in an external LSA. However, you can configure the Firewall Threat Defense device to advertise a single route for all the redistributed routes that are included for a specified network address and mask. This configuration decreases the size of the OSPF link-state database. Routes that match the specified IP address mask pair can be suppressed. The tag value can be used as a match value for controlling redistribution through route maps.

Routes learned from other routing protocols can be summarized. The metric used to advertise the summary is the smallest metric of all the more specific routes. Summary routes help reduce the size of the routing table.

Using summary routes for OSPF causes an OSPF ASBR to advertise one external route as an aggregate for all redistributed routes that are covered by the address. Only routes from other routing protocols that are being redistributed into OSPF can be summarized.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Summary Address** > **Add**.

You can click **Edit** (✎) to edit, or use the right-click menu to cut, copy, past, insert, and delete summary addresses.

Step 6 Configure the following summary address options for each OSPF process:

- **OSPF Process**: For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Available Network**: The IP address of the summary address. Select one from the Available networks list and click **Add**, or to add a new network, click **Add** (+). See Networks, on page 2386 for the procedure for adding networks.
- **Tag**: A 32-bit decimal value that is attached to each external route. This value is not used by OSPF itself, but may be used to communicate information between ASBRs.
- **Advertise**: Advertises the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

Step 7 Click **OK** to save the summary address configuration.

Step 8 Click **Save** on the Routing page to save your changes.

The OSPF summary address configuration is saved and the device will advertise a single route for all redistributed routes that are included for the specified network address and mask.

Configure OSPF interfaces and neighbors

You can change some interface-specific OSPFv2 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval, the dead interval, and the authentication key. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

You need to define static OSPFv2 neighbors to advertise OSPFv2 routes over a point-to-point, non-broadcast network. This feature lets you broadcast OSPFv2 advertisements across an existing VPN connection without having to encapsulate the advertisements in a GRE tunnel.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Interface** > **Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 6 Configure the following Interface options for each OSPF process:

- **Interface**: The interface you are configuring.

Note If the device is using virtual routing, this drop-down list displays only those interfaces that belong to the router.

- **Default Cost**: The cost of sending a packet through the interface. The default value is 10.
- **Priority**: The designated router for a network. Valid values range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router.

  When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router. This setting does not apply to interfaces that are configured as point-to-point interfaces.
- **MTU Ignore—OSPF** checks whether neighbors are using the same MTU on a common interface. This check is performed when neighbors exchange DBD packets. If the receiving MTU in the DBD packet is higher than the IP MTU configured on the incoming interface, OSPF adjacency is not established.
- **Database Filter**: Use this setting to filter the outgoing LSA interface during synchronization and flooding. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. In a fully meshed topology, this flooding can waste bandwidth and lead to excessive link and CPU usage. Checking this check box prevents OSPF flooding of the LSA on the selected interface.
- **Database Filter**: Use this setting to filter the outgoing LSA interface during synchronization and flooding. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. In a fully meshed topology, this flooding can waste bandwidth and lead to excessive link and CPU usage. Checking this check box prevents OSPF flooding of the LSA on the selected interface.
- **Hello Interval**: Specifies the interval, in seconds, between hello packets sent on an interface. Valid values range 1–8192 seconds. The default value is 10 seconds.

  The smaller the hello interval, the faster topological changes are detected, but more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface.
- **Transmit Delay**: Estimated time in seconds to send an LSA packet on the interface. Valid values range 1–65535 seconds. The default is 1 second.

  LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.
- **Retransmit Interval**: Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.
- **Dead Interval**: Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range 1–65535.

- **Hello Multiplier**: Specifies the number of Hello packets to be sent per second. Valid values are 3–20.
- **Point-to-Point**: Lets you transmit OSPF routes over VPN tunnels.
- **Authentication**: Choose the OSPF interface authentication from the following:
  - **None**: (Default) Disables interface authentication.
  - **Area Authentication**: Enables interface authentication using MD5. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.
  - **Password**: Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
  - **MD5**: Allows MD5 authentication. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.

Note Enter only letters, numbers, and special characters for the MD5 key ID. Do not enter spaces; spaces are truncated in management center.

  - **Key Chain**:Allows key chain authentication. Click **Add**, and create the key chain, and then click **Save**. For detailed procedure, refer to Create a key chain object, on page 2385. Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.
- **Enable BFD**: Allows you to enable BFD on this interface.
- **Enter Password**: The password you configure if you choose Password as the type of authentication.
- **Confirm Password**: Confirm the password that you chose.

Step 7 Select **Neighbor** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 8 Configure the following parameters for each OSPF process:

- **OSPF Process**: Choose 1 or 2.
- **Neighbor**: Choose one of the neighbors in the drop-down list, or click **Add** () to add a new neighbor; enter the name, description, network, whether to allow overrides, and then click **Save**.
- **Interface**: Choose the interface associated with the neighbor.

Step 9 Click **OK** and click **Save** to save the changes.

OSPF interface and neighbor configuration is completed. The configured parameters are applied to the selected interfaces and neighbors, enabling OSPF routing functionality on the specified network segments.

Configure OSPF Advanced Properties

Enable advanced OSPF features for optimized routing behavior and enhanced protocol reliability.

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, an LSA timer, and graceful restarts.

Graceful Restarts

The Firewall Threat Defense device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv2 by using either using NSF Cisco (RFC 4811 and RFC 4812) or NSF IETF (RFC 3623).

Note NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.
- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF** > **Advanced**.

Step 5 Select **General**, and configure the following:

- **Router ID**: Choose Automatic or IP Address (appears for non-cluster and a cluster in spanned etherchannel mode) or Cluster Pool (appears for a cluster in individual interface mode) for the router ID. If you choose IP address, enter the IP address in the adjacent field. If you choose Cluster Pool, choose the IPv4 cluster pool value in the adjacent drop-down field. For information on creating the cluster pool address, see Configure address pools, on page 2356 .
- **Ignore LSA MOSPF**: Suppresses syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.
- **RFC 1583 Compatible**: Configures RFC 1583 compatibility as the method used to calculate summary route costs. Routing loops can occur with RFC 1583 compatibility enabled. Disable it to prevent routing loops. All OSPF routers in an OSPF routing domain should have RFC compatibility set identically.

- **Adjacency Changes**: Defines the adjacency changes that cause syslog messages to be sent.

  By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.

  - **Log Adjacency Changes**: Causes the Firewall Threat Defense device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.
  - **Log Adjacency Change Details**: Causes the Firewall Threat Defense device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

- **Administrative Route Distance**: Allows you to modify the settings that were used to configure administrative route distances for **inter-area**, **intra-area**, and **external** IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.
- **LSA Group Pacing**: Specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- **Enable Default Information Originate**: Check the **Enable** check box to generate a default external route into an OSPF routing domain and configure the following options:
  - **Always advertise the default route**: Ensures that the default route is always advertised.
  - **Metric Value**: Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  - **Metric Type**: The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  - **RouteMap**: Choose the routing process that generates the default route if the route map is satisfied or click **Add** (+) to add a new one. See Configure Route Map Entry to add a new route map.

Step 6 Click **OK** to save the general configuration.

Step 7 Select **Non Stop Forwarding**, and configure Cisco NSF graceful restart for OSPFv2, for an NSF-capable or NSF-aware device.

Note There are two graceful restart mechanisms for OSPFv2, Cisco NSF and IETF NSF. Only one of these graceful restart mechanisms can be configured at a time for an OSPF instance. An NSF-aware device can be configured as both Cisco NSF helper and IETF NSF helper but a NSF-capable device can be configured in either Cisco NSF or IETF NSF mode at a time for an OSPF instance.

a) Check the **Enable Cisco Non Stop Forwarding Capability** check box.
b) (Optional) Check the **Cancel NSF restart when non-NSF-aware neighboring networking devices are detected** check box if required.
c) (Optional) Make sure the **Enable Cisco Non Stop Forwarding Helper** mode check box is unchecked to disable the helper mode on an NSF-aware device.

Step 8 Configure IETF NSF Graceful Restart for OSPFv2, for an NSF-capable or NSF-aware device: .

a) Check the **Enable IETF Non Stop Forwarding Capability** check box.

b) In the **Length of graceful restart interval (seconds)** field, enter the restart interval in seconds. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.
c) (Optional) Make sure the **Enable IETF nonstop forwarding (NSF) for helper mode** check box is unchecked to disable the IETF NSF helper mode on an NSF-aware device.
d) **Enable Strict Link State advertisement checking**: When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.
e) **Enable IETF Non Stop Forwarding**: Enables non stop forwarding, which allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. OSPF uses extensions to the OSPF protocol to recover its state from neighboring OSPF devices. For the recovery to work, the neighbors must support the NSF protocol extensions and be willing to act as "helpers" to the device that is restarting. The neighbors must also continue forwarding data traffic to the device that is restarting while protocol state recovery takes place.

Advanced OSPF settings are applied. The device now uses customized OSPF general and graceful restart properties for improved routing behavior, syslog management, and protocol resilience.

OSPFv3 configuration

OSPFv3 configuration is a routing process setup that

- enables IPv6 routing functionality on network devices,
- involves multiple configuration tasks to establish the routing process, and
- supports configuration only for global virtual routers in virtual routing environments.

Virtual routing limitations

For a device using virtual routing, you can configure OSPFv3 only for its global virtual router and not for its user-defined virtual router.

Configure OSPFv3 Areas, Route Summaries, and Virtual Links

Use this task to enable OSPFv3, create routing areas, set up route summaries, and configure virtual links for advanced routing scenarios on the Cisco Secure Firewall Management Center (FMC). These steps allow for flexible IPv6 routing and help ensure optimal path calculation and efficient management.

Before you begin

Have admin access to Cisco Secure Firewall Management Center.

- Have admin access to Cisco Secure Firewall Management Center.
- Know the IP addresses and roles for devices to be configured.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Navigate to the **Routing** tab, and click **OSPFv3** in the left pane.

Step 3 By default **Enable Process 1** is selected. You can enable up to two OSPF process instances.

Step 4 Choose the OSPFv3 role from the drop-down list, and enter a description for it. The options are **Internal**, **ABR**, **ASBR**, and **ABR and ASBR**. For descriptions of the OSPFv3 roles, refer to OSPF routing, on page 1063.

Step 5 Select **Area** > **Add**.

Click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete areas.

Select **General**, and configure the following options for each OSPF process:

a) **Area ID**: The area for which routes are to be summarized.
b) **Cost**: The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.
c) **Type**: Specifies Normal, NSSA, or Stub. If you select Normal, there are no other parameters to configure. If you select Stub, you can choose to send summary LSAs in the area. If you select NSSA, you can configure the next three options:

- **Allow Sending summary LSA into this area**: Allows the sending of summary LSAs into the area.
- **Imports routes to normal and NSSA area**: Allows redistribution to import routes to normal and not to stubby areas.
- **Defaults information originate**: Generates a default external route into an OSPFv3 routing domain.

d) **Metric**: Metric used for generating the default route. The default value is 10. Valid metric values range from 0 to 16777214.
e) **Metric Type**: The metric type is the external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route. Click **OK** to save the general configuration.

Step 6 (Not applicable for Internal OSPFv3 Role) Select **Route Summary** > **Add Route Summary**.

Click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete route summaries.

Configure the following route summary options for each OSPF process:

- **IPv6 Prefix/Length**: The IPv6 prefix. To add a new network object, click **Add** ( ). For the procedure for adding networks, refer to, Networks, on page 2386.
- **Cost**: The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.
- **Advertise**: Advertises the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

  Click **OK** to save the route summary configuration.

Step 7 (Not applicable for Internal OSPFv3 Role) Select **Virtual Link**, click **Add Virtual Link** , and configure the following options for each OSPF process:

- **Peer RouterID**: Choose the IP address of the peer router. To add a new network object, click **Add** (+). For the procedure to add networks, refer to Networks, on page 2386.
- **TTL Security**: Enables TTL security check. The value for the hop-count is a number from 1 to 254. The default is 1.

  OSPF sends outgoing packets with an IP header Time to Live (TTL) value of 255 and discards incoming packets that have TTL values less than a configurable threshold. Because each device that forwards an IP packet decrements the TTL, packets received via a direct (one-hop) connection have a value of 255. Packets that cross two hops have a value of 254, and so on. The receive threshold is configured in terms of the maximum number of hops that a packet may have traveled.
- **Dead Interval**: The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The default is four times the hello interval, or 40 seconds. Valid values range from 1 to 65535.

  The dead interval is an unsigned integer. The value must be the same for all routers and access servers that are attached to a common network.
- **Hello Interval**: The time in seconds between the hello packets sent on an interface. Valid values range from 1 to 65535. The default is 10.

  The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.
- **Retransmit Interval**: The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 to 65535. The default is 5.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.
- **Transmit Delay**: The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 to 8192. The default is 1.

  LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

  Click **OK** to save the virtual link configuration.

Step 8 Click **Save** on the **Router** page to save your changes.

Configure OSPFv3 redistribution

Configure OSPFv3 redistribution to control how routes are redistributed between OSPF routing processes and other routing protocols on the Secure Firewall Threat Defense device.

The Secure Firewall Threat Defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by EIGRP, RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

Before you begin

Follow these steps to configure OSPFv3 redistribution:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** > **OSPF**.

Step 3 Select **Redistribution**, and click **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 4 Configure the following redistribution options for each OSPF process:

- **Source Protocol**—The source protocol from which routes are being redistributed. The supported protocols are connected, OSPF, Static, EIGRP, and BGP. If you choose OSPF, you must enter the Process ID in the **Process ID** field. If you choose BGP, you must add the AS number in the **AS Number** field.
- **Metric**—Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

  When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.
- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Tag**—Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.
- **Route Map**—Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add** (). See Configure a route map, on page 2415 for the procedure to add a new route map.
- **Process ID**—The OSPF process ID, either 1 or 2.

Note The Process ID is enabled the OSPFv3 process is redistributing a route learned by another OSPFv3 process.

- **Match**—Enables OSPF routes to be redistributed into other routing domains:

- **Internal** for routes that are internal to a specific autonomous system.
- **External 1**for routes that are external to the autonomous system, but are imported into OSPFv3 AS Type 1 external routes.
- **External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 AS Type 2 external routes.
- **NSSA External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 AS Type 1 external routes.
- **NSSA External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 AS Type 2 external routes.

Step 5 Click **OK** to save the redistribution configuration.

Step 6 Click **Save** on the Routing page to save your changes.

The OSPFv3 redistribution configuration is saved and routes are redistributed according to the specified parameters.

What to do next

Continue with Configure OSPFv3 summary prefixes, on page 1087.

Configure OSPFv3 summary prefixes

Configure OSPFv3 summary prefixes to control route advertisement and suppression based on IPv6 prefix and mask pairs.

You can configure the Firewall Threat Defense device to advertise routes that match a specified IPv6 prefix and mask pair.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** > **OSPFv3**.

Step 3 Select **Summary Prefix** > **Add**.

You can click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete summary prefixes.

Step 4 Configure the following summary prefix options for each OSPF process:

- **IPv6 Prefix/Length**: The IPv6 prefix and prefix length label. Select one from the list or click **Add** ( ) to add a new network object. For the procedure to add networks, refer to Networks, on page 2386.
- **Advertise**: Advertises routes that match the specified prefix and mask pair. Uncheck this check box to suppress routes that match the specified prefix and mask pair.
- (Optional) **Tag**: A value that you can use as a match value for controlling redistribution through route maps.

Step 5 Click **OK** to save the summary prefix configuration.

Step 6 Click **Save** on the Routing page to save your changes.

The OSPFv3 summary prefix configuration is saved and will control route advertisement based on your specified settings.

Configure OSPFv3 interfaces, authentication, and neighbors

Set up OSPFv3 routing, authentication, and neighbor relationships to support IPv6 dynamic network routing.

You can change certain interface-specific OSPFv3 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval and the dead interval. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

For a successful implementation of OSPFv3 authentication with Nexus switches, ensure that you have the compatible version of the switch, for example, Nexus 3000, 7000, and 9000 series switches.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** > **OSPFv3**.

Step 3 Select **Interface** > **Add**.

You can click **Edit** to edit, or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 4 Configure the following interface options for each OSPFv3 process:

- **Interface**: The interface you are configuring.
- **Enable OSPFv3**: Enables OSPFv3.
- **OSPF Process**: Choose 1 or 2.
- **Area**: The area ID for this process.
- **Instance**: Specifies the area instance ID to be assigned to the interface. An interface can have only one OSPFv3 area. You can use the same area on multiple interfaces, and each interface can use a different area instance ID.

Step 5 Select **Properties**, and configuring the following options for each OSPFv3 process:

- **Filter Outgoing Link Status Advertisements**: Filters outgoing LSAs to an OSPFv3 interface. All outgoing LSAs are flooded to the interface by default.
- **Filter Outgoing Link Status Advertisements**: Filters outgoing LSAs to an OSPFv3 interface. All outgoing LSAs are flooded to the interface by default.
- **Disable MTU mismatch detection**: Disables the OSPF MTU mismatch detection when DBD packets are received. OSPF MTU mismatch detection is enabled by default.

- **Flood Reduction**: Changes normal LSAs into Do Not Age LSAs, so that they don't get flooded every 3600 seconds across areas.

  OSPF LSAs are refreshed every 3600 seconds. In large OSPF networks, this can lead to large amounts of unnecessary LSA flooding from area to area.

- **Point-to-Point Network**: Lets you transmit OSPF routes over VPN tunnels. When an interface is configured as point-to-point, non-broadcast, the following restrictions apply:
  - You can define only one neighbor for the interface.
  - You need to manually configure the neighbor.
  - You need to define a static route pointing to the crypto endpoint.
  - If OSPF over a tunnel is running on the interface, regular OSPF with an upstream router cannot be run on the same interface.
  - You should bind the crypto map to the interface before specifying the OSPF neighbor to ensure that the OSPF updates are passed through the VPN tunnel. If you bind the crypto map to the interface after specifying the OSPF neighbor, use the **clear local-host all** command to clear OSPF connections so that the OSPF adjacencies can be established over the VPN tunnel.

- **Broadcast**: Specifies that the interface is a broadcast interface. By default, this check box is checked for Ethernet interfaces. Uncheck this check box to designate the interface as a point-to-point, nonbroadcast interface. Specifying an interface as point-to-point, nonbroadcast lets you transmit OSPF routes over VPN tunnels.

- **Cost**: Specifies the cost of sending a packet on the interface. Valid values for this setting range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router. This setting does not apply to interfaces that are configured as point-to-point, nonbroadcast interfaces.

  When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router.

- **Priority**: Determines the designated router for a network. Valid values range from 0 to 255.

- **Dead Interval**: Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range from 1 to 65535.

- **Hello Interval**: Time period in seconds between OSPF packets that the router will send before adjacency is established with a neighbor. Once the routing device detects an active neighbor, the hello packet interval changes from the time specified in the poll interval to the time specified in the hello interval. Valid values range from 1 to 65535 seconds.

- **Retransmit Interval**: Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.

- **Transmit Delay**: Estimated time in seconds to send a link-state update packet on the interface. Valid values range from 1 to 65535 seconds. The default is 1 second.

- **Enable BFD**: Allows you to enable BFD on this interface.

Step 6 Select **Authentication**, and configure the following options for each OSPFv3 process:

- **Type**: Type of authentication. The available options are Area, Interface, and None. The None option indicates that no authentication is used.
- **Security Parameters Index**: A number from 256 to 4294967295. Configure this if you chose Interface as the type.
- **Authentication**: Type of authentication algorithm. Supported values are SHA-1 and MD5. Configure this if you chose Interface as the type.
- **Authentication Key**: When MD5 authentication is used, the key must be 32 hexadecimal digits (16 bytes) long. When SHA-1 authentication is used, the key must be 40 hexadecimal digits (20 bytes) long.
- **Encrypt Authentication Key**: Enables encryption of the authentication key.
- **Include Encryption**: Enables encryption.
- **Encryption Algorithm**: Type of encryption algorithm. Supported value is DES. The NULL entry indicates no encryption. Configure this if you chose **Include Encryption**.
- **Encryption Key**: Enter the encryption key. The key length must be a hexadecimal string. When AES-256-CBC authentication is used, the key must be 130 hexadecimal digits. Configure this if you chose **Include Encryption**.
- **Encrypt Key**: Enables the key to be encrypted.

Step 7 Click **OK** to save the authentication configuration.

Step 8 Select **Neighbor**, click **Add**, and configure the following options for each OSPFv3 process:

- **Link Local Address**: The IPv6 address of the static neighbor.
- **Cost**: Enables cost. Enter the cost in the **Cost** field, and check the **Filter Outgoing Link State Advertisements** if you want to advertise.
- (Optional) **Poll Interval**: Enables the poll interval. Enter the **Priority** level and the **Poll Interval** in seconds.
- Click **Add** to add the neighbor.

Step 9 Click **OK** to save the Interface configuration.

OSPFv3 interface, authentication, and neighbor settings are configured on the device. OSPFv3 processes will operate according to the specified parameters.

Configure OSPFv3 Advanced Properties

Enable and fine-tune OSPFv3 advanced properties to optimize routing, ensure stability, and automate operations for your device

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, passive OSPFv3 routing, LSA timers, and graceful restarts.

Graceful Restarts

The Firewall Threat Defense device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv3 using graceful-restart (RFC 5187).

Note NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.
- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **OSPFv3** > **Advanced**.

Step 3 For **Router ID**, choose **Automatic** or **IP Address** (appears for non-cluster and a cluster in spanned etherchannel mode) or **Cluster Pool** (appears for a cluster in individual interface mode). If you choose **IP Address**, enter the IPv6 address in the **IP Address** field. If you choose **Cluster Pool**, choose the IPv6 cluster pool value from the **Cluster Pool** down-down list. For information on creating the cluster pool address, refer to Configure address pools, on page 2356.

Check the **Ignore LSA MOSPF** check box if you want to suppress syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.

Step 4 Select **General**, and configure the following:

- **Adjacency Changes**: Defines the adjacency changes that cause syslog messages to be sent.

  By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.

  - **Adjacency Changes**: Causes the Firewall Threat Defense device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.
  - **Include Details**: Causes the Firewall Threat Defense device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

- **Administrative Route Distances**: Allows you to modify the settings that were used to configure administrative route distances for inter-area, intra-area, and external IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.
- **Default Information Originate**: Check the **Enable** check box to generate a default external route into an OSPFv3 routing domain and configure the following options:
  - **Always Advertise**: Will always advertise the default route whether or not one exists.
  - **Metric**: Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  - **Metric Type**: The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  - **Route Map**: Choose the routing process that generates the default route if the route map is satisfied or click **Add** (+) to add a new one. See Configure a route map, on page 2415 to add a new route map.

    Click **OK** to save the general configuration.

Step 5 Select **Passive Interface**, select the interfaces on which you want to enable passive OSPFv3 routing from the **Available Interfaces** list, and click **Add** to move them to the **Selected Interfaces** list.

Passive routing assists in controlling the advertisement of OSPFv3 routing information and disables the sending and receiving of OSPFv3 routing updates on an interface.

Click **OK** to save the passive interface configuration.

Step 6 Select **Timer**, and configure the following LSA pacing and SPF calculation timers:

- **Arrival**: Specifies the minimum delay in milliseconds that must pass between acceptance of the same LSA arriving from neighbors. The range is from 0 to 6000,000 milliseconds. The default is 1000 milliseconds.
- **Flood Pacing**: Specifies the time in milliseconds at which LSAs in the flooding queue are paced in between updates. The configurable range is from 5 to 100 milliseconds. The default value is 33 milliseconds.
- **Group Pacing**: Specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- **Retransmission Pacing**: Specifies the time in milliseconds at which LSAs in the retransmission queue are paced. The configurable range is from 5 to 200 milliseconds. The default value is 66 milliseconds.
- **LSA Throttle**: Specifics the delay in milliseconds to generate the first occurrence of the LSA. The default value is 0 millisecond. The minimum specifies the minimum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds. The maximum specifies the maximum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds.

Note For LSA throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

- **SPF Throttle**: Specifies the delay in milliseconds to receive a change to the SPF calculation. The default value is 5000 milliseconds. The minimum specifies the delay in milliseconds between the first and second SPF calculations. The default value is 10000 milliseconds. The maximum specifies the maximum wait time in milliseconds for SPF calculations. The default value is 10000 milliseconds.

Note For SPF throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

Click **OK** to save the LSA timer configuration.

Step 7 Select **Non Stop Forwarding ngf**, and check the **Enable graceful-restart helper** check box. This is checked by default. Uncheck this to disable the graceful-restart helper mode on an NSF-aware device.

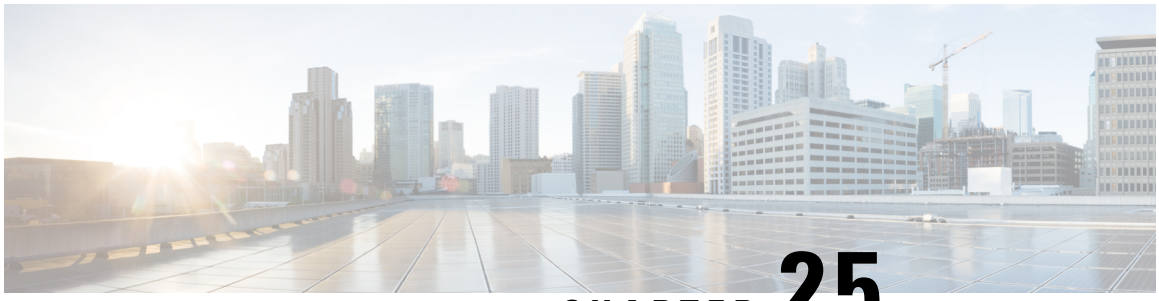
Check the **Enable link state advertisement** check box to enable strict link state advertisement checking.

When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.

Check the **Enable graceful-restart (Use when Spanned Cluster or Failover Configured)** check box and enter the graceful-restart interval in seconds. The range is 1-1800. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.

Click **OK** to save the graceful restart configuration.

Step 8 Click **Save** on the **Routing** page to save your changes.



The device is configured with your OSPFv3 advanced properties. All changes are applied, enhancing routing resilience, logging, and failover handling.

History for OSPF

This reference provides a summary of the key features introduced in OSPF and the versions in which they became available, along with details about their implementation.

Table 70: Feature history for OSPF

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
BFD Support for OSPF v2 and v3	7.4	7.4	You can enable BFD on OSPFv2 and OSPFv3 interfaces. New/modified screens: • **Configuration** > **Device Setup** > **Routing** > **OSPFv2** • **Configuration** > **Device Setup** > **Routing** > **OSPFv3**

CHAPTER 25

EIGRP

EIGRP is a routing protocol that

- enables routers to efficiently exchange information,
- maintain network topology tables, and
- ensures secure data path selection and communication across networks.

EIGRP Operational Overview

This section covers the configuration of the Firewall Threat Defense to perform these routing tasks:

- Route data traffic
- Perform authentication
- Redistribute routing information

- EIGRP routing, on page 1095
- Requirements and prerequisites for EIGRP, on page 1096
- Guidelines and limitations for EIGRP routing, on page 1097
- Configure EIGRP routing on firewall devices, on page 1098
- History for EIGRP, on page 1106

EIGRP routing

An Enhanced Interior Gateway Routing Protocol (EIGRP) is a routing protocol that

- sends updates only when network topology changes, not at regular intervals,
- offers rapid convergence and supports variable-length subnet masks, and
- supports partial updates and multiple network layer protocols.

EIGRP capabilities and operations

EIGRP stores all neighbor routing tables for quick adaptation to alternate routes. If a suitable route does not exist, EIGRP queries its neighbors to discover an alternate route. It propagates these queries through the network to locate a route. EIGRP's support for variable-length subnet masks allows routes to be automatically

summarized on a network boundary. Additionally, EIGRP can be configured to summarize any bit boundary at any interface.

EIGRP sends partial updates when route metrics change, limiting propagation to necessary routers, which minimizes bandwidth use compared to protocols that send periodic full updates.

To learn about routers on attached networks, EIGRP uses neighbor discovery through multicast hello packets to announce their presence on the network. When a new neighbor is detected through hello packets, a topology table exchange occurs.

EIGRP hello packets are normally sent as multicast messages and do not require explicit replies. For manually configured static neighbors, hello packets are sent as unicast messages to the specified neighbor.

Once this neighbor relationship is established, routing updates are exchanged only on topology changes. The relationship persists through regular multicast hello packets, with devices expected to respond within advertised hold times. Hold time is the time within which threat defense can expect to receive a hello packet from that neighbor. If the device does not receive a hello packet within the advertised hold time, it considers the neighbor unavailable.

EIGRP employs mechanisms like neighbor discovery/recovery, Reliable Transport Protocol (RTP), and Diffusing Update Algorithm (DUAL) for route computations. DUAL retains all routes to a destination, selecting the least-cost route for packet forwarding while retaining others in case of network changes. If the main route fails, another route is chosen from the feasible successors. A successor is a neighboring router that is used for packet forwarding that has a least-cost path to a destination. DUAL utilizes a feasibility condition to ensure that the path is not part of a routing loop.

If a feasible successor is not found in the topology table, a route recomputation takes place. During route recomputation, DUAL queries the EIGRP neighbors for a route. The query is propagated to successive neighbors. If a feasible successor is not found, an unreachable message is returned.

During route recomputation, DUAL marks the route as active. By default, threat defense waits for three minutes to receive a response from its neighbors. If the device does not receive a response from a neighbor, the route is marked as stuck-in-active. All routes in the topology table that point to the unresponsive neighbor as a feasible successor are removed.

Requirements and prerequisites for EIGRP

This topic provides the necessary prerequisites and requirements for deploying EIGRP within a Cisco network environment.

Model support

Firewall Threat Defense

Firewall Threat Defense Virtual

Supported domains

Any

User roles

Admin

Network Admin

Guidelines and limitations for EIGRP routing

Firewall mode guidelines

Use routed firewall mode only for EIGRP routing.

Device guidelines

Configure only one EIGRP process per device.

- EIGRP can be configured through management center UI on Firewall Threat Defense version 6.6 and later.

Interface guidelines

Use only routed interfaces with logical names and IP addresses for EIGRP routing processes.

- EIGRP can only incorporate interfaces from the global virtual router. EIGRP can learn, filter, and redistribute routes across routing protocols in the global virtual router.
- Supports physical, EtherChannel, redundant, and subinterfaces only. However, the members of EtherChannel interfaces are not supported.
-
- Passive interfaces cannot be configured as neighbor interfaces.

IP address and network objects support

Use only IPv4 addresses and standard access list objects for EIGRP configuration.

- Ranges, FQDNs, and wildcard masks are not supported.

Redistribution guidelines

Configure route tagging to prevent routing loops when redistributing between EIGRP and OSPF.

- BGP, OSPF, and RIP in the global virtual router can redistribute routes toward EIGRP.
- EIGRP can redistribute to BGP, OSPF, RIP, Static, and Connected in the global virtual router.
- When EIGRP is configured on a device that is a part of an OSPF network or vice versa, ensure that the OSPF router is configured to tag the route (EIGRP does not support route tag).

  When redistributing EIGRP into OSPF and OSPF into EIGRP, a routing loop can occur when there is an outage on one of the links, interfaces, or even when the route originator is down. To prevent the redistribution of routes from one domain back into the same domain, a router can tag a route that belongs to a domain while it is redistributing, and those routes can be filtered on the remote router based on the same tag. Because the routes will not be installed into the routing table, they will not be redistributed back into the same domain.

Deployment process guidelines

Disable and redeploy EIGRP when changing the AS number to prevent deployment failures.

To effectively change the AS number of an existing EIGRP setup, you should disable and redeploy EIGRP configurations to avoid repeated deployments and ensure error-free deployment processes.

Upgrade guidelines

Migrate FlexConfig EIGRP policies to UI management after upgrading to version 7.2 and later.

When you upgrade to version 7.2 and later, and if the previous version includes any FlexConfig EIGRP policies, the management center displays a warning message during deployment. It does not stop the deployment process; a warning message is displayed. After deployment, to manage the EIGRP policies from the UI (**Devices** > **Device Management**, click the **Edit** (✎) icon. Then, click **Routing>EIGRP**), you must redo the configuration in the **EIGRP** page and remove the configuration from FlexConfig. To automate policy creation in the UI, Firewall Management Center provides an option to migrate the policies from FlexConfig to the UI. For more information, refer to Migrate FlexConfig policies, on page 964.

Configure EIGRP routing on firewall devices

Enable EIGRP on a firewall device for efficient routing within an autonomous system.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click the **Routing** tab.

Step 3 Under Global, click **EIGRP**.

Step 4 Check the **Enable EIGRP** check box to enable the EIGRP routing process.

Step 5 In the **AS Number** field, enter the autonomous system (AS) number for the EIGRP process.

Valid values are from 1 to 65535. The AS number identifies the local EIGRP routing domain and must match on EIGRP neighbors.

Step 6 To configure other EIGRP properties, refer to these topics for detailed steps:

a. Configure EIGRP settings, on page 1099.

b. Configure EIGRP neighbors settings, on page 1099.

c. Configure EIGRP filter rules, on page 1100.

d. Configure EIGRP redistribution settings, on page 1101.

e. Configure EIGRP summary address settings, on page 1102.

f. Configure EIGRP interfaces settings, on page 1103.

g. Configure EIGRP advanced settings, on page 1104.

The firewall device is now configured with the base EIGRP process and the designated AS number. It can participate in EIGRP routing after the required interfaces, networks, and related settings are configured.

Configure EIGRP settings

Use this procedure when you need to set up EIGRP routing protocol parameters on your device. EIGRP configuration includes enabling automatic network summarization, selecting networks that participate in the routing process, and configuring passive interfaces that do not exchange routing updates.

Procedure

Step 1 On the **EIGRP** page, click the **Setup** tab.

Step 2 Check the **Auto Summary** check box to enable EIGRP to summarize at network boundaries.

Note Enabling Auto Summary can cause routing problems if you have noncontiguous networks.

Step 3 In the **Available Networks/Hosts** box, select the networks or hosts that should participate in the EIGRP routing process, and then click **Add**. To add a new network object, click **Add** (+). For detailed instructions on adding networks, refer to Networks, on page 2386.

Step 4 To configure passive interfaces, check the **Passive Interface** check box. In EIGRP, a passive interface does not send or receive routing updates.

a) To specify selective interfaces as passive, click the **Selected Interface** radio button. In the **Available Interfaces** box, select the interfaces, and click **Add**.

b) To specify all interfaces as passive, click the **All Interfaces** radio button.

Step 5 Click **Save**.

The EIGRP settings are configured and saved. The routing protocol will operate according to the specified configuration, including automatic summarization behavior, network participation, and passive interface settings.

Configure EIGRP neighbors settings

Define static neighbors for the EIGRP process. This results in unicast hello packets being sent to that neighbor.

Procedure

Step 1 On the **EIGRP** page, click the **Neighbors** tab.

Step 2 Click +**Add**.

Step 3 Select the interface through which the neighbor is available from the **Interface** drop-down list.

Step 4 Select the IP address of the static neighbor from the **Neighbor** drop-down list.

Step 5 To add a new network object, click +. For instructions on adding network objects, refer to Networks, on page 2386.

Step 6 Click **OK**.

Step 7 Click **Save**.

The EIGRP static neighbor is configured, and hello packets are sent as unicast to the specified neighbor through the designated interface.

Configure EIGRP filter rules

Filter rules provide granular control over EIGRP route advertisements and acceptances, allowing you to manage network traffic flow and routing table contents based on specific criteria such as interface or protocol type.

To configure EIGRP filter rules, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Filter Rules** tab.

Step 2 Click **Add**.

Step 3 In the **Add Filter Rules** dialog box, select the direction for the rule from the **Filter Direction** drop-down list:

- **Inbound**: The rule filters routes received in incoming EIGRP updates.
- **Outbound**: The rule filters routes advertised in outgoing EIGRP updates.

Step 4 Under **Type**, choose one of these options:

- To select the interface to which the filtering rule applies, click **Interface**, and then select the interface from the **Select Interface** drop-down list. Select the access list from the **Access List** drop-down list. The list defines the networks that are to be received and suppressed in routing updates. To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2355. Click **OK**.

Note You cannot apply EIGRP filtering rules on VTI interfaces.

- (This option is enabled only if you choose **Outbound** filter direction.) To select the protocol to which the filtering rule applies, click **Protocol** and then select BGP, RIP, Static, Connected, or OSPF from the **Select Protocol** drop-down list. You can specify the relevant **Process ID** for BGP and OSPF protocols. Select the access list from the **Access List** drop-down list. The list defines the networks that are to be received and suppressed in routing updates. To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2355. Click **OK**.

Step 5 Click **Save**.

The EIGRP filter rule is configured and applied to control route filtering based on the specified direction, interface, protocol, and access list criteria.

Configure EIGRP redistribution settings

Define rules to redistribute routes from other routing protocols to the EIGRP routing process to enable route sharing across different routing protocols.

To configure EIGRP redistribution settings, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Redistribution** tab.

Step 2 Click **Add**.

Step 3 In the **Add Redistribution** dialog box, from the **Protocol** drop-down list, select the source protocol from which the routes are being redistributed:

- **BGP**: Redistributes routes discovered by the BGP routing process to EIGRP. Specify the relevant **Process ID**.
- **RIP**: Redistributes routes discovered by the RIP routing process to EIGRP.
- **Static**: Redistributes static routes to the EIGRP routing process. Static routes within a network statement scope automatically redistribute to EIGRP, without additional rules. Specify the metric when redistributing static routes to VTI interfaces in EIGRP. You do not need to specify the metric for static routes pointing to other types of interfaces.
- **Connected**: Redistributes connected routes (routes established automatically by virtue of having IP address enabled on the interface) to the EIGRP routing process. Connected routes that fall within the scope of a network statement are automatically redistributed to EIGRP; you do not need to define a redistribution rule for them.
- **OSPF**: Redistributes routes discovered by the OSPF routing process to EIGRP. Specify the relevant **Process ID**. If you select this protocol, the Match options on this dialog box become available under **Optional OSPF Redistribution**:
  - **Internal**: Routes that are internal to a specific AS.
  - **External1**: Routes that are external to the AS and imported into OSPF as a Type 1 external route.
  - **External2**: Routes that are external to the AS and imported into the selected process as a Type 2 external route.
  - **Nsaa-External1**: Not-So-Stubby Area (NSSA) routes that are external to the AS and imported into the selected process as Type 1 external routes.
  - **Nsaa-External2**: (NSSA) routes that are external to the AS and imported into the selected process as Type 2 external routes.

Note These options are not available when redistributing static, connected, RIP, or BGP routes.

Step 4 Under **Optional Metrics**, enter the relevant values:

- **Bandwidth**: The minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295.
- **Delay Time**: The routing delay in tens of microseconds. Valid values range from 0 to 4294967295.
- **Reliability**: The likelihood of successful packet transmission is expressed as a number 0 through 255. The value 255 indicates 100 percent reliability; 0 means no reliability.
- **Loading**: The effective bandwidth of the route. Valid values range from 1 to 255. 255 indicates 100 percent loading.
- **MTU**: The smallest permissible value for the maximum transmission unit of the path. Valid values range from 1 to 65535.
- **Route Map**: Select the route map object to apply to the redistribution entry from the **Route Map** drop-down list. To create a new route map object, click +. For instructions on adding a new route map, refer to Configure Route Map Entry.

Step 5 Click **OK**.

Step 6 Click **Save**.

The EIGRP redistribution settings have been configured and saved. Routes from the selected source protocol will be redistributed to EIGRP according to the specified rules and metrics.

Configure EIGRP summary address settings

You can configure summary addresses for each interface. If you want to create summary addresses that do not occur at a network boundary, you should manually define them. Alternatively, you can use summary addresses with automatic route summarization disabled. If more specific routes are available in the routing table, EIGRP advertises the summary address with a metric equal to the minimum of all specific routes.

Procedure

Step 1 On the **EIGRP** page, click the **Summary Address** tab.

Step 2 Click +**Add**.

Step 3 From the **Interface** drop-down list, select the interface from which the summary address is advertised.

Step 4 From the **Network** drop-down list, select the network object with a specific IP address and network mask to be summarized. To add a new network, click +. For detailed instructions for adding networks, refer to Networks, on page 2386.

Step 5 In the **Administrative Distance** field, enter the administrative distance of the summary route. Valid values range from 1 to 255.

Step 6 Click **OK**.

Step 7 Click **Save**.

The EIGRP summary address settings are configured and saved. EIGRP will advertise the summary address from the specified interface with the configured administrative distance.

Configure EIGRP interfaces settings

Manage interface settings to optimize routing operations.

To configure EIGRP interface settings, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Interfaces** tab.

Step 2 Click **Add**.

Step 3 Select the appropriate interface from the **Interface** drop-down list.

Step 4 In the **Hello Interval** field, enter the hello interval in seconds for EIGRP packets on an interface. Valid values range from 1 to 65535. The default value is 5 seconds.

Step 5 In the **Hold Time** field, enter the hold time that is advertised by the device in EIGRP hello packets. Valid values range from 1 to 65535. The default value is 15 seconds.

To enable EIGRP split-horizon on the interface, check the **Split Horizon** check box.

Step 6 In the **Delay Time** field, enter the delay time in tens of microseconds. Valid values are from 1 to 16777215.

Note This option is not supported in multi-context mode devices.

Step 7 Specify authentication properties:

- **Enable MD5 Authentication**: Check the check box to use the MD5 hash algorithm for authentication of EIGRP packets.
- **Key Type**: Select one key type from the drop-down list:
  - **None**: Indicates that no authentication is required.
  - **Unencrypted**: Indicates that the key string is a clear text password for authentication.
  - **Encrypted**: Indicates that the key string is an encrypted password for authentication.
  - **Auth Key**: Indicates that the key string is an EIGRP authentication key.
- **Key ID**: The ID of the key that is used to authenticate EIGRP updates. Enter a numerical key identifier. Valid values range from 0 to 255.

- **Key**: An alphanumeric character string up to 17 characters. For an encrypted authentication type, this field should have a minimum of 17 characters.
- **Confirm Key**: Re-enter the key.

Step 8 Click **OK**.

Step 9 Click **Save**.

The EIGRP interface settings that you configured are saved. The interface uses the specified hello interval, hold time, split-horizon setting, delay time, and authentication parameters for EIGRP routing operations.

Configure EIGRP advanced settings

Configure EIGRP advanced settings to optimize routing behavior and performance in your network.

To configure EIGRP advanced settings, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Advanced** tab.

Step 2 Under **Default Route Information**, specify the sending and receiving of default route information in EIGRP updates.

- (Appears for non-cluster and cluster in spanned etherchannel mode)**Router ID (IP Address)**: Enter the ID used to identify the originating router for external routes. If an external route is received with the local router ID, the route is discarded. Specify a global address for the router ID to prevent this issue. Each EIGRP router requires a unique value.
- (Appears only for a cluster in individual interface mode)**IPv4 Address Pool**: Select the relevant cluster pool value (IPv4 address pool object). To create the address pool, refer to Configure address pools, on page 2356.
- **Accept Default Route Info**: Check the check box to configure EIGRP to accept default route information.
  - **Access List**: From the **Access List** drop-down list, specify a standard access list that defines the networks that are allowed and the networks that are not when receiving default route information.

    To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2355.
- **Send Default Route Info**: Check the check box to configure EIGRP to advertise exterior default routing information.
  - **Access List**: From the **Access List** drop-down list, specify a standard access list that defines the networks that are allowed and the networks that are not when sending default route information.

    To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2355.

Step 3 Under **Administrative Distance**, specify:

- **Internal Distance**: Administrative distance for EIGRP internal routes. Internal routes are those that are learned from another entity within the same autonomous system. Valid values range from 1 to 255. The default value is 90.
- **External Distance**: Administrative distance for EIGRP external routes. External routes are those for which the best path is learned from a neighbor external to the autonomous system. Valid values range from 1 to 255. The default value is 170.

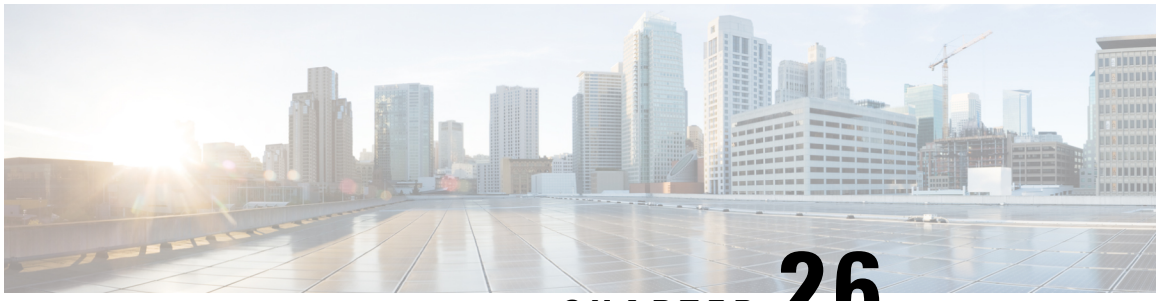
Step 4 Under **Adjacency Changes**, specify:

- **Log Neighbor Changes**: Check the check box to enable the logging of EIGRP neighbor adjacency changes.
- **Log Neighbor Warnings**: Check the check box to enable the logging of EIGRP neighbor warning messages.
- (Optional) Enter the time interval (in seconds) between repeated neighbor warning messages. Valid values range from 1 to 65535. Repeated warnings are not logged if they occur during this interval.

Step 5 Under **Stub**, to enable the device as an EIGRP stub routing process, click one or more of the EIGRP stub routing processes check boxes:

- **Receive only**: Configures the EIGRP stub routing process to receive route information from the neighbor routers but not send route information to the neighbors. If this option is selected, you cannot select any of the other stub routing options.
- **Connected**: Advertises connected routes.
- **Redistributed**: Advertises redistributed routes.
- **Static**: Advertises static routes.
- **Summary**: Advertises summary routes.

Step 6 Under **Default Metrics**, define the default metrics for routes redistributed to the EIGRP routing process:



- **Bandwidth**: The minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295.
- **Delay Time**: The route delay in tens of microseconds. Valid values range from 0 to 4294967295.
- **Reliability**: The likelihood of successful packet transmission expressed as a number from 0 to 255. The value 255 indicates 100 percent reliability; 0 means no reliability.
- **Loading**: The effective bandwidth of the route. Valid values range from 1 to 255; 255 indicates 100 percent loading.
- **MTU**: The smallest allowed value for the maximum transmission unit of the path. Valid values range from 1 to 65535.

EIGRP advanced settings are configured according to your specifications, optimizing routing behavior and performance.

History for EIGRP

This reference provides historical data about EIGRP version compatibility and configuration changes across various releases.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
EIGRP configuration	7.2	Any	In the previous releases, EIGRP was configured on threat defense only through FlexConfig. FlexConfig no longer supports EIGRP configuration. Configuration of EIGRP settings for threat defense is now available in the management center UI. New/modified screens: **Devices** > **Device Management** > **Routing** > **EIGRP**.

CHAPTER 26

BGP

This section describes how to configure the Firewall Threat Defense to route data, perform authentication, and redistribute routing information using the Border Gateway Protocol (BGP).

- BGP, on page 1107
- Requirements and prerequisites for BGP, on page 1111
- Guidelines for BGP, on page 1111
- Configure BGP, on page 1112
- History for BGP, on page 1127

BGP

Border Gateway Protocol (BGP) is an inter- and intra-autonomous system routing protocol that

- operates within and between autonomous systems (networks or groups of networks under common administration with common routing policies),
- exchanges routing information for the Internet, and
- serves as the protocol used between Internet service providers (ISPs).

Routing tables

A routing table is a network database that

- records paths to destination networks based on exchanged routing information
- updates dynamically as neighbors share new or modified routing routes, and
- determines the optimal path to a destination without requiring periodic updates.

BGP attributes for route selection

Routes learned via BGP have several attributes that determine the best path when multiple routes to a destination exist. The most important BGP attributes include:

- Weight: A Cisco-defined attribute that is local to a router. It is not advertised to neighboring routers. Among multiple routes to the same destination, the route with the highest weight is preferred.

- Local preference: This attribute selects an exit point from the local autonomous system (AS) and is shared throughout the local AS. If multiple exit points exist, the one with the highest local preference attribute is chosen for a specific route.
- Multi-exit discriminator: The multi-exit discriminator (MED) or metric attribute is used as a suggestion to an external AS regarding the preferred route into the AS that is advertising the metric. It is referred to as a suggestion because the external AS that is receiving the MEDs may also be using other BGP attributes for route selection. The route with the lower MED metric is preferred.
- Origin: The origin attribute indicates how BGP learned about a particular route. The origin attribute can have one of three possible values and is used in route selection.
  - IGP: The route is interior to the originating AS. This value is set when the network router configuration command is used to inject the route into BGP.
  - EGP: The route is learned via the Exterior Border Gateway Protocol (EBGP).
  - Incomplete: The origin of the route is unknown or learned in some other way. An origin of incomplete occurs when a route is redistributed into BGP.
- AS_PATH: When a route advertisement passes through an autonomous system, the AS number is added to an ordered list of AS numbers that the route advertisement has traversed. Only the route with the shortest AS_PATH list is installed in the IP routing table.
- Next hop: The EBGP next-hop attribute is the IP address that is used to reach the advertising router. For EBGP peers, the next-hop address is the IP address of the connection between the peers. For IBGP, the EBGP next-hop address is carried into the local AS. However, when the next hop is in the same subnet the peering address of the EBGP peer, the next hop is not modified. This behavior is referred to as the third-party next hop.

  Use the **next-hop-self** command when redistributing VPN-advertised routes to IBGP as peers to ensure that the routes are redistributed with the correct next hop IP.
- Community: The community attribute provides a way of grouping destinations, called communities, to which routing decisions (such as acceptance, preference, and redistribution) can be applied. Route maps are used to set the community attribute. The predefined community attributes are as follows:
  - no-export: Do not advertise this route to EBGP peers.
  - no-advertise: Do not advertise this route to any peer.
  - internet: Advertise this route to the Internet community; all routers in the network belong to it.

Note As loop detection is done by scanning the full AS_PATH (as specified in the AS_PATH attribute), and checking that the AS number of the local system does not appear in the AS_PATH. By default, EBGP advertises the learned routes to the same peer to prevent additional CPU cycles on the device in performing loop checks and to avoid delays in the existing outgoing update tasks.

BGP usage scenarios

BGP usage scenarios are network configurations that

- enable ISPs to exchange customer and ISP routes between autonomous systems using External BGP (EBGP),
- allow service providers to exchange routes within an autonomous system using Interior BGP (IBGP), and
- support IPv6 prefix routing over IPv6 networks.

BGP implementation contexts

Customer networks, such as universities and corporations, usually employ an Interior Gateway Protocol (IGP) such as OSPF for the exchange of routing information within their networks. Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

BGP can also be used for carrying routing information for IPv6 prefix over IPv6 networks.

BGP path selection

BGP path selection is a routing process that selects only one path as the best path when BGP receives multiple advertisements for the same route from different sources, puts the selected path in the IP routing table, and propagates the path to its neighbors using specific criteria in order of precedence.

BGP path selection criteria

BGP uses these criteria, in the order presented, to select a path for a destination:

1. If the path specifies a next hop that is inaccessible, drop the update. Otherwise, prefer the path with the largest weight.
2. If the weights are the same, prefer the path with the largest local preference. If the local preferences are the same, prefer the path that was originated by BGP running on this router.
3. If no route was originated, prefer the route that has the shortest AS_PATH. If all paths have the same AS_PATH length, prefer the path with the lowest origin type (where IGP is lower than EGP, and EGP is lower than incomplete).
4. If the origin codes are the same, prefer the path with the lowest MED attribute. If the paths have the same MED, prefer the external path over the internal path.
5. If the paths are still the same, prefer the path through the closest IGP neighbor.
6. Determine if multiple paths require installation in the routing table for BGP multipath, on page 1109.
7. If both paths are external, prefer the path that was received first (the oldest one).
8. Prefer the path with the lowest IP address, as specified by the BGP router ID. If the originator or router ID is the same for multiple paths, prefer the path with the minimum cluster list length.
9. Prefer the path that comes from the lowest neighbor address.

BGP multipath

BGP multipath is a BGP feature that

- allows installation into the IP routing table of multiple equal-cost BGP paths to the same destination prefix,
- enables traffic to the destination prefix to be shared across all installed paths, and
- does not affect best path selection algorithm.

BGP multipath requirements

These paths are installed in the table together with the best path for load-sharing. BGP multipath does not affect best path selection. For example, a router still designates one of the paths as the best path, according to the algorithm, and advertises this best path to its BGP peers.

In order to be candidates for multipath, paths to the same destination need to have these characteristics equal to the best-path characteristics:

- Weight
- Local preference
- AS-PATH length
- Origin code
- Multi Exit Discriminator (MED)
- One of these:
  - Neighboring AS or sub-AS (before the addition of the BGP Multipaths)
  - AS-PATH (after the addition of the BGP multipaths)

Some BGP multipath features put additional requirements on multipath candidates:

- The path should be learned from an external or confederation-external neighbor (eBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric.

These are the additional requirements for internal BGP (iBGP) multipath candidates:

- The path should be learned from an internal neighbor (iBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric, unless the router is configured for unequal-cost iBGP multipath.

BGP inserts up to *n* most recently received paths from multipath candidates into the IP routing table, where *n* is the number of routes to install in the routing table, as specified when you configure BGP multipath. The default value, when multipath is disabled, is 1.

For unequal-cost load balancing, you can also use BGP Link Bandwidth.

Note The equivalent next-hop-self is performed on the best path that is selected among eBGP multipaths before it is forwarded to internal peers.

Requirements and prerequisites for BGP

This reference provides the requirements and prerequisites necessary for configuring BGP on supported devices.

Model support

Firewall Threat Defense

Firewall Threat Defense Virtual

Supported domains

Any

User roles

Admin

Network Admin

Guidelines for BGP

Context mode guidelines

Consider these context mode requirements when implementing BGP.

- Supported in single and multiple context modes.
- Only one Autonomous System (AS) number is supported for all contexts.

Firewall mode guidelines

Does not support transparent firewall mode. BGP is supported only in routed mode.

IPv6 guidelines

Supports IPv6.

Additional guidelines

Consider these additional operational requirements and limitations.

- For BGP, the next hop IP address for the routes is the network IP address and not 0.0.0.0.
- The system does not add a route entry for the IP address received over PPPoE in the CP route table. BGP always looks into the CP route table for initiating the TCP session, hence BGP does not form TCP session.

  Thus, BGP over PPPoE is not supported.
- BGP is not supported on management-only or BVI interfaces.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.

- BGP with PATH MTU (PMTU) can cause adjacency flaps if MTU discovery fails, especially with ECMP routing. Hence, be cautious while using BGP, PMTU, and ECMP as packet drops can occur if MTU discovery fails due to any reason.
- The BGP table of the member unit is not synchronized with the control unit table. Only its routing table is synchronized with the control unit routing table.
- Enable the graceful timeout feature when you use BGP on Firewall Threat Defense devices that are configured in high availability mode. Enabling this feature reduces packet drops that occur due to issues related to BGP convergence.
- When you configure a route-based site-to-site VPN using static or dynamic VTI interfaces, ensure that the TTL hop count is greater than one if you use BGP as the routing protocol.
- On Firewall Threat Defense devices, changing a large number of BGP neighbors from iBGP to eBGP in a single deployment can fail. During deployment, Firewall Management Center can remove and re-create the same peer in immediate succession, and the deployment can fail if the previous peer deletion is still in progress. To avoid this issue, split the changes across multiple deployments. Remove or modify a subset of neighbors, deploy the configuration, and then apply additional neighbor changes in subsequent deployments.

Configure BGP

Configure BGP routing protocol to establish peering relationships and control route advertisement between autonomous systems.

BGP configuration involves multiple components including basic settings, neighbor relationships, route filtering, and redistribution policies.

Procedure

Step 1 Configure basic BGP settings, on page 1113

Step 2 Configure BGP general settings, on page 1115

Step 3 Configure BGP Neighbor Settings, on page 1117

Step 4 Configure BGP aggregate address settings, on page 1121

Step 5 Configure BGPv4 filtering settings, on page 1122

Note The Filtering section is applicable only to IPv4 settings

Step 6 Configure BGP network settings, on page 1123

Step 7 Configure BGP redistribution settings, on page 1123

Step 8 Configure BGP route injection settings, on page 1124

Step 9 Configure BGP route import and export, on page 1125

BGP is configured with all necessary settings, enabling dynamic routing and proper route exchange between autonomous systems.

Configure basic BGP settings

Enable and customize BGP settings to control routing behavior and improve network operations.

You can set many basic settings for BGP.

For a device using virtual routing, the basic settings described in this section must be configured in the **BGP** page under **General Settings**. For more information, refer to Modifications to the Firewall Management Center web interface routing page.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** and do the following:

a) (For a virtual-router-aware device) Under **General Settings**, click **BGP**.

b) Check the **Enable BGP** check box to enable the BGP routing process.

c) In the **AS Number** field, enter the autonomous system (AS) number for the local BGP process. The AS number internally includes multiple autonomous numbers. Valid values are from 1 to 4294967295 or from 1.0 to 65535.65535 when a dot notation is used. The AS number is a uniquely assigned value that identifies each network on the Internet.

d) In the **Router Id** drop-down list, choose **Automatic** or **Manual** (appears for non-cluster and a cluster in spanned etherchannel mode) or **Cluster Pool** (appears for a cluster in individual interface mode). If you choose **Automatic**, the highest-level IP address on the Firewall Threat Defense device is used as the router ID. If you choose **Manual**, enter the IP address in the **IP Address** field. If you choose **Cluster Pool**, enter the cluster pool value in the **Cluster Pool** field. For more information on creating the cluster pool address, refer to Configure address pools, on page 2356..

e) To use a fixed router ID, choose **Manual** and enter an IPv4 address in the **IP Address** field. The default value is **Automatic**. For a virtual router-aware device, you can override the router ID settings in the **Virtual Routers** > **BGP** page.

Step 3 (Optional) Edit the various BGP settings, starting with **General**. The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network. Click **Edit** ( ) to edit the settings in the group:

a) Enter a **Scanning Interval** for BGP routers for next-hop validation. Valid values are from 5 to 60 seconds. The default value is 60.

b) In the **Number of AS numbers in AS_PATH attribute of received routes** field, enter the maximum number of AS numbers allowed in the AS_PATH attribute of received routes. An AS_PATH attribute is a sequence of intermediate AS numbers between source and destination routers that form a directed route for packets to travel. Valid values are between 1 and 254. The default value is **None**.

c) Check the **Log Neighbor Changes** check box to enable logging of BGP neighbor changes (up or down) and resets. This helps in troubleshooting network connectivity problems and measuring network stability. This is enabled by default.

d) Check the **Use TCP path MTU discovery** check box to use the Path MTU determining technique to determine the maximum transmission unit (MTU) size on the network path between two IP hosts. This avoids IP fragmentation. This is enabled by default.

e) Check the **Reset session upon failover** check box to reset the external BGP session immediately upon link failure. This is enabled by default.

f) Check the **Enforce the first AS is peer's AS for EBGP routes** check box to discard incoming updates received from external BGP peers that do not list their AS number as the first segment in the AS_PATH attribute. This prevents a misconfigured or unauthorized peer from misdirecting traffic by advertising a route as if it was sourced from another autonomous system. This is enabled by default.

g) Check the **Use dot notation for AS number** check box to split the full binary 4-byte AS number into two words of 16 bits each, separated by a dot. AS numbers from 1 to 65535 are represented as decimal numbers, and AS numbers greater than 65535 are represented using dot notation. This is disabled by default.

Enter a value for the aggregate timer (in seconds) in the **Aggregate Timer** field. Valid values are 0 or any value between 6 and 60. The default value is 30.

h) Check the **BGP community new format (AA:NN)** check box to configure BGP to display community values in the AA:NN format, where AA represents the autonomous system number, and NN represents the community number, each being 2 bytes long. This format conforms to RFC-1997. By default, BGP communities are displayed as a single 32-bit decimal number.

i) Click **OK**.

Step 4 (Optional) Edit the **Best Path Selection** section:

a) Enter a value for **Default local preference** between 0 and 4294967295. The default value is 100. Higher values indicate higher preference. This preference is sent to all routers and access servers in the local autonomous system.

b) Check the **Allow comparing MED from different neighbors** check box to allow the comparison of Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems. This is disabled by default.

c) Check the **Compare Router ID for identical EBGP paths** check box to compare similar paths received from external BGP peers during the best path selection process and switch the best path to the route with the lowest router ID. This is disabled by default.

d) Check the **Pick the best-MED path among paths advertised by neighbor AS** check box to enable MED comparison among paths learned from confederation peers. The comparison between MEDs is made only if no external autonomous systems are there in the path. This is disabled by default.

e) Check the **Treat missing MED as the least preferred path** check box to consider the missing MED attribute as having a value of infinity, making the path the least desirable; therefore, a path with a missing MED is least preferred. This is disabled by default.

f) Click **OK**.

Step 5 (Optional) Edit the **Neighbor Timers** section:

a) Enter the time interval for which the BGP neighbor remains active after not sending a keepalive message in the **Keepalive interval** field. At the end of this keepalive interval, the BGP peer is declared dead, if no messages are sent. The default value is 60 seconds.

b) Enter the time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Hold time** field. The default value is 180 seconds. Specify a value from 0 to 65535.

c) (Optional) Enter the minimum time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Min Hold time** field. Specify a value from 3 to 65535.

Note A hold time of less than 20 seconds increases the possibility of peer flapping.

d) Click **OK**.

Step 6 In the **Next Hop** section, optionally check the **Address tracking** check box to enable BGP next hop address tracking and enter the **Delay Interval** between checks on updated next-hop routes installed in the routing table. Click **OK**.

Note The **Next Hop** section is applicable only to IPv4 settings.

Step 7 (Optional) Edit the **Graceful Restart** section:

Note This section is available only when the Firewall Threat Defense device is in failover or spanned cluster mode. This is done so that there is no drop in packets in the traffic flow, when one of the devices in the failover setup fails.

a) Check the **Enable Graceful Restart** check box to enable Firewall Threat Defense peers to avoid a routing flap following a switchover.
b) Specify the time duration that Firewall Threat Defense peers will wait to delete stale routes before a BGP open message is received in the **Restart Time** field. The default value is 120 seconds. Valid values are between 1 and 3600 seconds.
c) Enter the time duration that the Firewall Threat Defense will wait before deleting stale routes after an end of record (EOR) message is received from the restarting Firewall Threat Defense in the **Stalepath Time** field. The default value is 360 seconds. Valid values are between 1 and 3600 seconds.
d) Click **OK** and then click **Save**.

Step 8 To view the BGP basic settings, from the virtual routers drop-down, select the desired router, and then click **BGP**.

This page displays the basic settings that are configured in the **Settings** page. You can edit the router ID settings on this page.

Step 9 To edit the router ID settings, modify the IP address in the **IP Address** fields. The modified value overrides the router ID settings that were configured on the **BGP** page under **General Settings**.

The device is configured with basic BGP settings, enabling BGP routing, specifying the AS number, router ID, and any custom parameters you set.

Configure BGP general settings

Configure route maps, administrative route distances, synchronization, next-hop, and packet forwarding for BGP to optimize routing performance in your network.

The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, select the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 In the **General** tab, update the following sections:

a) In the **Setting** section, enter or select a **RouteMap** object and click **OK**.

Note The **RouteMap** field is applicable only to IPv4 settings.

b) In the **Administrative Route Distances** section, update the following as required, and click **OK**:

- **External**: Enter the administrative distance for external BGP routes. Routes are external when learned from an external autonomous system. The range of values for this argument are from 1 to 255. The default value is 20.
- **Internal**: Enter administrative distance for internal BGP routes. Routes are internal when learned from peer in the local autonomous system. The range of values for this argument are from 1 to 255. The default value is 200.
- **Local**: Enter administrative distance for local BGP routes. Local routes are routes originated by the local BGP process, such as networks specified with the network router configuration command or routes redistributed into BGP from another routing process. The range of values for this argument is from 1 to 255. The default value is 200.

c) In the **Routes and Synchronization** section, update the following as required, and click **OK**:

- (Optional) **Generate default routes**: Check the check box of this option to configure default-information originate.
- (Optional) **Summarize subnet routes into network level routes**: Check the check box of this to configure automatic summarization of subnet routes into network-level routes. This check box is applicable only to IPv4 settings.
- (Optional) **Advertise inactive routes**: Check the check box of this to advertise routes that are not installed in the routing information base (RIB).
- (Optional) **Synchronize between BGP and IGP systems**: Check the check box of this to enable synchronization between BGP and your Interior Gateway Protocol (IGP) system. Usually, a BGP speaker does not advertise a route to an external neighbor unless that route is local or exists in the IGP. This feature allows routers and access servers within an autonomous system to have the route before BGP makes it available to other autonomous systems.
- (Optional) **Redistribute IBGP into IGP**: Check the check box of this to configure IBGP redistribution into an interior gateway protocol (IGP), such as OSPF.

d) In the **Forward Packets Over Multiple Paths** section, update the following as required and click **OK**:

- (Optional) **Number of Paths**: Enter the maximum number of Border Gateway Protocol routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.
- (Optional) **IBGP Number of Paths**: Enter the maximum number of parallel internal Border Gateway Protocol (IBGP) routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.

Step 5 Click **Save**.

BGP general settings are configured with your specified route maps, administrative distances, synchronization options, and multi-path forwarding parameters.

Configure BGP Neighbor Settings

Define and customize BGP neighbor connections on your device for efficient routing and advanced peer management.

A BGP router must connect with each of its peers before exchanging updates. These peers are called BGP neighbors. Perform this procedure to define BGP IPv4 or IPv6 neighbors and neighbor settings.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

(For a virtual router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring BGP.

Step 2 Choose **BGP** > **IPv4** or **IPv6**. Click **Neighbor**.

Step 3 Click **Add** to define BGP neighbors and neighbor settings.

a) Enter the BGP neighbor **IP address**. This IP address is added to the BGP neighbor table. When you are configuring BGP IPv6 on static VTI, enter the virtual tunnel IP address of the neighbor. Choose the BGP neighbor **Interface**.

Note The **Interface** field is only applicable to IPv6 settings.

b) Enter the autonomous system to which the BGP neighbor belongs, in the **Remote AS** field. Check the **Enabled address** check box to enable communication with this BGP neighbor. Further neighbor settings will be configured only if the **Enabled address** check box is selected.

c) (Optional) Check the **Shutdown administratively** check box to disable a neighbor or peer group.

d) (Optional) Check the **Configure graceful restart (failover / spanned mode)** check box to enable configuration of the BGP graceful restart capability for this neighbor. After selecting this option, you must check the **Enable graceful restart** check box to specify whether graceful restart should be enabled or disabled for this neighbor.

Note

- The graceful restart is enabled only when the device is in HA mode or when L2 cluster (all nodes from the same network) is configured.
- The graceful restart option for BGPv6 is enabled only on Firewall Threat Defense Version 7.3+.
- If you configure graceful restart only at General Settings and not at BGP IPv6, the global General Settings configuration persists.
- If you configure graceful restart at General Settings and also at BGP IPv6, the global General Settings configuration is overridden by the BGP IPv6 configuration settings.

e) (Optional) To enable configuration of the BFD support for BGP, from the **BFD Fallover** drop-down list, choose the BFD type—single-hop, multi-hop, or auto-detect-hop. This selection registers the BGP neighbor to receive forwarding path detection failure messages from BFD. Choose None if you do not want to have BFD support.

f) (Optional) Enter a **Description** for the BGP neighbor.

g) (Optional) From the **Update Source** drop-down list, choose an interface to source the BGP packets.

You can choose a loopback address as this interface to overcome path failures. You can also choose any physical, port-channel, or a sub-interface.

Step 4 (Optional) In **Filtering Routes**, use access lists, route maps, prefix lists and AS path filters as required, to distribute BGP Neighbor information. Update the following sections:

a) Choose or select the appropriate incoming or outgoing **Access List** to distribute BGP neighbor information.

Note Access lists are only applicable to IPv4 settings.

b) Choose or select the appropriate incoming or outgoing **Route Maps** to apply a route map to incoming or outgoing routes.

c) Choose or select the appropriate incoming or outgoing **Prefix List** to distribute BGP neighbor information.

d) Choose or select the appropriate incoming or outgoing **AS path filter** to distribute BGP neighbor information.

e) Check the check box of **Limit the number of prefixes allowed from the neighbor** to control the number of prefixes that can be received from a neighbor.

- Enter the maximum number of prefixes allowed from a specific neighbor in the **Maximum Prefixes** field.
- Enter the percentage (of maximum) at which the router starts to generate a warning message in the **Threshold Level** field. Valid values are integers between 1 and 100. The default value is 75.

f) Check the **Control prefixes received from the peer** check box to specify additional controls for the prefixes received from a peer. Do one of the following:

- Check the **Terminate peering when prefix limit is exceeded** check box to stop the BGP neighbor when the prefix limit is reached. Specify the interval after which the BGP neighbor will restart in the **Restart interval** field.

- Check the **Give only warning message when prefix limit is exceeded** check box to generate a log message when the maximum prefix limit is exceeded. Here, the BGP neighbor will not be terminated.

g) Click **OK**.

Step 5 (Optional) In **Routes**, specify miscellaneous Neighbor route parameter. Proceed to update the following:

a) Enter the minimum interval (in seconds) between the sending of BGP routing updates in the **Advertisement Interval** field. Valid values are between 1 and 600.

b) Check the **Remove private AS numbers from outbound routing updates** check box to exclude the private AS numbers from being advertised on outbound routes.

c) Check the **Generate default routes** check box to allow the local router to send the default route 0.0.0.0 to a neighbor to use as a default route. Enter or Select the route map that allows the route 0.0.0.0 to be injected conditionally in the **Route map** field.

d) To add conditionally advertised routes, click Add Row +. In the Add Advertised Route dialog box, do the following:

1. Add or choose a route map in the **Advertise Map** field, that will be advertised if the conditions of the exist map or the non-exist map are met.
2. Click **Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.
3. Click **Non-Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.
4. Click **OK**.

Step 6 In **Timers**, check the **Set timers for the BGP peer** check box to set the keepalive frequency, hold time, and minimum hold time.

- **Keepalive interval**: Enter the frequency (in seconds) with which Firewall Threat Defense sends keepalive messages to the neighbor. Valid values are between 0 and 65535. The default value is 60 seconds.
- **Hold time**: Enter the interval (in seconds) after not receiving a keepalive message that Firewall Threat Defense declares a peer dead. Valid values are between 0 and 65535. The default value is 180 seconds.
- **Min hold time**: (Optional) Enter the minimum interval (in seconds) after not receiving a keepalive message that Firewall Threat Defense declares a peer dead. Valid values are between 3 and 65535. The default value is 3 seconds.

Note A hold time of less than 20 seconds increases the possibility of peer flapping.

Step 7 In **Advanced**, update the following:

a) (Optional) Check the **Enable Authentication** check box to enable MD5 authentication on a TCP connection between two BGP peers.

1. Choose an encryption type from the **Enable Encryption** drop-down list.
2. Enter a password in the **Password** field. Reenter the password in the **Confirm Password** field. The password is case-sensitive and can be up to 25 characters long when the service password-encryption

command is enabled and up to 81 characters long when the service password-encryption command is not enabled. The string can contain any alphanumeric characters, including spaces.

Note You cannot specify a password in the format number-space-anything. The space after the number can cause authentication to fail.

b) (Optional) Select the **Send Community attribute to this neighbor** check box to specify that community attributes should be sent to the BGP neighbor
c) (Optional) Select the **Use FTD as next hop for this neighbor** check box to configure the router as the next-hop for a BGP speaking neighbor or peer group.
d) Select the **Disable Connection Verification** check box to disable the connection verification process for eBGP peering sessions that are reachable by a single hop but are configured on a loopback interface or otherwise configured with a non-directly connected IP address. When deselected (default), a BGP routing process will verify the connection of single-hop eBGP peering session (TTL=254) to determine if the eBGP peer is directly connected to the same network segment by default. If the peer is not directly connected to same network segment, connection verification will prevent the peering session from being established.
e) Select **Allow connections with neighbor that is not directly connected** to accept and attempt BGP connections to external peers residing on networks that are not directly connected. (Optional) Enter the time-to-live in the **TTL hops** field. Valid values are between 1 and 255. However, for eBGP multi-hop neighborship configuration, you must enter the **TTL hops** value. Alternatively, select **Limited number of TTL hops to neighbor**, to secure a BGP peering session. Enter the maximum number of hops that separate eBGP peers in the **TTL hops** field. Valid values are between 1 and 254.
f) (Optional) Select the **Use TCP MTU path discovery** check box to enable a TCP transport session for a BGP session.
g) Choose the TCP connection mode from the **TCP Transport Mode** drop-down list. Options are Default, Active, or Passive.
h) (Optional) Enter a **Weight** for the BGP neighbor connection.
i) Select the **BGP Version** that Firewall Threat Defense will accept from the drop-down list. The version can be set to 4-Only to force the software to use only Version 4 with the specified neighbor. The default is to use Version 4 and dynamically negotiate down to Version 2 if requested.

Step 8 Update **Migration**, only if AS migration is considered.

Note The AS migration customization should be removed after transition has been completed.

a) (Optional) Check the **Customize the AS number for routes received from the neighbor** check box to customize the AS_PATH attribute for routes received from an eBGP neighbor.
b) Enter the local autonomous system number in the **Local AS number** field. Valid values are any valid autonomous system number from 1 to 4294967295 or 1.0 to 65535.65535.
c) (Optional) Check the **Do not prepend local AS number to routes received from neighbor** check box to prevent the local AS number from being prepended to any routes received from eBGP peer.
d) (Optional) Check the **Replace real AS number with local AS number in routes received from neighbor** check box to replace the real autonomous system number with the local autonomous system number in the eBGP updates. The autonomous system number from the local BGP routing process is not prepended.

e) (Optional) Check the **Accept either real AS number or local AS number in routes received from neighbor** check box to configure the eBGP neighbor to establish a peering session using the real autonomous system number (from the local BGP routing process) or by using the local autonomous system number.

Step 9 Click **OK**, and then click **Save**.

The BGP neighbor and its associated advanced settings are configured. The device can now establish and manage BGP sessions as specified, ensuring effective routing and network reachability.

Configure BGP aggregate address settings

Route aggregation combines the attributes of several different routes so that only a single route is advertised, reducing the number of routes that need to be advertised.

BGP neighbors store and exchange routing information and the amount of routing information increases as more BGP speakers are configured. Route aggregation is the process of combining the attributes of several different routes so that only a single route is advertised. Aggregate prefixes use the classless interdomain routing (CIDR) principle to combine contiguous networks into one classless SET of IP addresses that can be summarized in routing tables. As a result fewer routes need to be advertised. Use the Add/Edit Aggregate Address dialog box to define the aggregation of specific routes into one route.

Procedure

Step 1 When editing the Firewall Threat Defense device, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Add Aggregate Address**.

Step 5 Enter a value for the aggregate timer (in seconds) in the **Aggregate Timer** field. Valid values are 0 or any value between 6 and 60. The default value is 30.

Step 6 Click ( )**Add** and update the **Add Aggregate Address** dialog box:

a) **Network**: Enter an IPv4 address or select the desired network/hosts objects.
b) **Attribute Map**: (Optional) Enter or select the route map used to SET the attribute of the aggregate route.
c) **Advertise Map**: (Optional) Enter or select the route map used to select the routes to create AS_SET origin communities.
d) **Suppress Map**: (Optional) Enter or select the route map used to select the routes to be suppressed.
e) **Generate AS SET path Information**: (Optional) Check the check box to enable generation of autonomous system SET path information.
f) **Filter all routes from updates**: (Optional) Check the check box to filter all more-specific routes from updates.
g) Click **OK**.

The BGP aggregate address settings are configured and fewer routes need to be advertised due to route aggregation.

What to do next

- For BGPv4 settings, proceed to Configure BGPv4 filtering settings, on page 1122.
- For BGPv6 settings, proceed to Configure BGP network settings, on page 1123.

Configure BGPv4 filtering settings

Configure filtering settings to filter routes or networks received in incoming BGP updates and restrict routing information that the router learns or advertises.

Filtering settings are used to filter routes or networks received in incoming BGP updates. Filtering is used to restrict routing information that the router learns or advertises.

Before you begin

Filtering is only applicable for a BGP IPv4 routing policy.

Follow these steps to configure BGPv4 filtering settings:

Procedure

Step 1 On the Device Management page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4**.

Step 4 Click **Filtering**.

Note The **Filtering** field is applicable only to IPv4 settings.

Step 5 Click (+)**Add** and update the **Add Filter** dialog box:

a) **Access List**: Choose an access control list that defines which networks are to be received and which are to be suppressed in routing updates.

b) **Direction**: (Optional) Choose a direction that specifies if the filter should be applied to inbound updates or outbound updates.

c) **Protocol**: (Optional) Choose the routing process for which you want to filter: None, BGP, Connected, OSPF, RIP, or Static.

d) **Process ID**: (Optional) Enter the process ID for the OSPF routing protocol.

e) Click **OK**.

Step 6 Click **Save**.

BGPv4 filtering settings are configured to filter routes or networks based on the specified access control list and filtering criteria.

Configure BGP network settings

Configure BGP network settings to control which networks are advertised by the BGP routing process and to apply route map filters for network advertisement.

Network settings are used to add networks that will be advertised by the BGP routing process and route maps that will be examined to filter the networks to be advertised.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Networks**.

Step 5 Click **Add** and update the **Add Networks** dialog box:

a) **Network**: Choose the network to be advertised by the BGP routing processes.

Note For a network prefix to be advertised, a route to the device must exist on the routing table.

To add a new network object, refer to Create a network object, on page 2388.

b) (Optional) **Route Map**: Enter or choose a route map that should be examined to filter the networks to be advertised. If not specified, all networks are redistributed. To add a new route map object, refer to Configure a route map, on page 2415.

c) Click **OK**.

Step 6 Click **Save**.

The BGP network settings are configured with the specified networks and route maps for advertisement filtering.

Configure BGP redistribution settings

Configure redistribution settings to define the conditions for redistributing routes from another routing domain into BGP.

Redistribution settings allow you to define the conditions for redistributing routes from another routing domain into BGP.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Redistribution**.

Step 5 Click **Add** and update the **Add Redistribution** dialog:

a) **Source Protocol**: Select the protocol from which you want to redistribute routes into the BGP domain from the Source Protocol drop-down list.

Note User-defined virtual routers do not support redistributing routes from RIP.

b) **Process ID**: Enter the identifier for the selected source protocol. Applies to the OSPF protocol. For devices using virtual routing, this drop-down lists the process ID assigned for the virtual router for which you are configuring the BGP settings.

c) **Metric**: (Optional) Enter a metric for the redistributed route.

d) **Route Map**: Enter or select a route map that should be examined to filter the networks to be redistributed.

If not specified, all networks are redistributed. To create a new route map object, click **Add** (+). For the procedure to add a new route map, see Configure Route Map Entry.

e) **Match**: The conditions used for redistributing routes from one routing protocol to another. The routes must match the selected condition to be redistributed. You can choose one or more conditions. These options are enabled only when OSPF is chosen as the Source Protocol.

- Internal
- External 1
- External 2
- NSSA External 1
- NSSA External 2

f) Click **OK**.

The BGP redistribution settings are configured and routes from the specified source protocol are redistributed into the BGP domain according to the defined conditions.

Configure BGP route injection settings

Configure BGP route injection settings to control which routes are conditionally injected into the BGP routing table based on defined criteria.

Route injection settings allow you to define the routes to be conditionally injected into the BGP routing table.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Route Injection**.

Step 5 Click **Add** and update the **Add Route Injection** dialog box:

a) **Inject Map**: Enter or select the route map that specifies the prefixes to inject into the local BGP routing table. To create a new route map object, click **Add** (+). For the procedure to add a new route map, see Configure Route Map Entry.

b) **Exist Map**: Enter or select the route map containing the prefixes that the BGP speaker will track.

c) **Injected routes will inherit the attributes of the aggregate route**: Check this box to configure the injected route to inherit attributes of the aggregate route.

d) Click **OK**.

Step 6 Click **Save**.

The BGP route injection settings are configured and the specified routes will be conditionally injected into the BGP routing table according to the defined route maps.

Configure BGP route import and export

This task enables you to implement inter-virtual-router route leaking in BGP by importing or exporting routes using route target extended communities, allowing controlled sharing of routes between virtual routers.

In BGP, you can implement an inter-virtual-router route leak by importing or exporting routes using the route target extended community of the destination and source virtual routers respectively. You can use a route map to filter the desired route targets instead of leaking the entire routing table. You can also leak the routes of global virtual router to user-defined virtual routers and vice versa.

- You can configure BGP to leak routes between two user-defined virtual routers using the route target extended communities:
  - Tag the routes with the route targets from the source virtual router using route target export.
  - Import the routes that are matching the route targets into the destination virtual router using route target import.
  - Optionally, you can filter routes from source virtual router or to destination virtual router using export or import route maps respectively. You can configure route map with match extended community list for filtering the routes. Similarly, you can configure route map with set extended community route targets to tag the routes with the route target extended community.
- To import routes from the global virtual router to a user-defined virtual router, specify the IPv4/IPv6 route map in Global Virtual Router Import Route Map to import to the user-defined virtual router.
- To export routes from a user-defined virtual router to the global virtual router, in addition to exporting the route targets, you can also specify the Global Virtual Router Export Route Map to export from the user-defined virtual router.

The BGP inter-virtual-router route leaking supports both IPv4 and IPv6 prefixes.

Before you begin

- Create virtual routers.
- Enable BGP on the virtual router.
- Configure BGP, on page 1112.

Follow these steps to configure BGP route import/export settings:

Procedure

Step 1 On the Device Management page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 (Supported for virtual routers only) Click **Route Import/Export**.

Step 5 In the **Route Targets Import** field, enter the route target extended community that you want to match for the routes to be imported. On deployment, the routes of the destination virtual router that match this value are imported to the source virtual router's BGP table.

Note
- The route target must be in **ASN:nn** format.
- You can enter multiple route targets as comma-separated values.
- This value can range from 0:1 to 65534:65535.

Step 6 In the **Route Targets Export** field, enter the route target extended community to tag the source virtual router's routes with the route target value. On deployment, the routes of the source virtual router are tagged with this value.

Note
- The route target must be in **ASN:nn** format.
- You can enter multiple route targets as comma separated values.
- This value can range from 0:1 to 65534:65535.

Step 7 Route maps help you to narrow down the routes to be shared instead of leaking the entire routing table. Route map filtering is applied on the list of routes that are obtained with the specified route target values:

a) (Optional) Under **User Virtual Router**, choose the route map from the **Import Route Map** drop-down list to filter the routes at the destination virtual router.

Note The user virtual router import route map is effective only when the route targets import is configured.

b) (Optional) Under **User Virtual Router**, choose the route map from the **Export Route Map** drop-down list to filter the routes at the source virtual router before the routes are exported to other virtual routers.

Note You can use the match and set clauses in the route map with the route target extended community lists for filtering based on other criteria or tagging the routes with the route target community values. For more information, refer to Configure a route map, on page 2415.

Step 8 To share the routes between a user-defined virtual router and global virtual router, specify the route map under the **Global Virtual Router**:

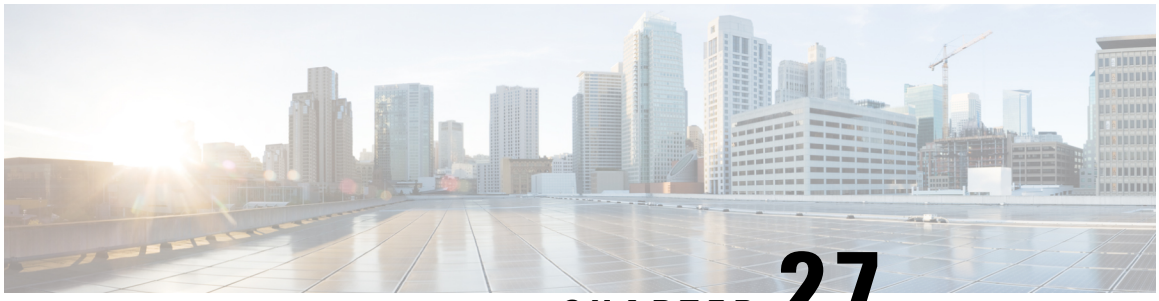
a) To leak the global virtual router routes to the user-defined virtual router, select the route map from the **Import Route Map** drop-down list. The IPv4 or IPv6 route map is imported to the user-defined virtual router.

b) To leak the user-defined virtual router routes to the global virtual router, select the route map from the **Export Route Map** drop-down list. The IPv4 or IPv6 route map is exported to the global virtual router.

Note You must specify the route targets for export apart from specifying the route map.

Note You can use the match clause of the route map object to filter the routes for leaking. For more information, refer to Configure a route map, on page 2415.

Step 9 Follow the procedure (Step 3 to Step 8) to configure relevant BGP route import and export settings for other virtual routers as well. Click **Save**, then **Deploy** to apply your import/export settings.



When the packets flow into the ingress virtual router, BGP imports the routes from the destination virtual routers that have the matching route target value and if a route map is also configured, the routes are further filtered and used to identify the best path routes for routing the packets.

History for BGP

This reference provides the history and version information for BGP features and enhancements, including minimum required versions and implementation details.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Graceful restart support on BGPv6	7.4	Any	You can configure graceful restart on BGPv6 for Secure Firewall Threat Defense version 7.3 and later. New/modified screens: **Routing** > **BGP** > **IPv6** > **Add/Edit Neighbor**.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Loopback interface support for BGP	7.4	Any	You can use a loopback interface for BGP. New/modified screens: **Routing** > **BGP** > **IPv4 or IPv6** > **Add/Edit Neighbor**.
BGP configuration to interconnect virtual routers	7.1	Any	You can configure BGP settings to dynamically leak routes among user-defined virtual routers, and between global virtual router and user-defined virtual routers. The import and export routes feature was introduced to exchange routes among the virtual routers by tagging them with route targets and optionally, filtering the matched routes with route maps. This BGP feature is accessible only when you select a user-defined virtual router. New/modified screens: For a selected user-defined virtual router, **Devices** > **Device Management** > **Routing** > **BGPv4/v6** > **Route Import/Export** tab.
BGPv6 support for user-defined virtual routers	7.1	Any	Secure Firewall Threat Defense now supports configuring BGPv6 on user-defined virtual routers. New/modified screens: For a selected user-defined virtual router, **Devices** > **Device Management** > **Routing** > **BGPv6** page.

CHAPTER 27

RIP

The Routing Information Protocol (RIP) is a distance-vector routing protocol that

- enables devices to exchange routing information,
- supports authentication mechanisms, and
- facilitates redistribution of routing information.

RIP Configuration Constraints

There are constraints when deploying RIP on the Firewall Threat Defense:

- RIP configuration is restricted to the global virtual router and is not supported for user-defined virtual routers.

- RIP, on page 1129
- Requirements and prerequisites for RIP, on page 1132
- Guidelines for RIP, on page 1132
- Configure RIP, on page 1133

RIP

Routing Information Protocol (RIP) is a distance-vector routing protocol that

- uses hop count as the metric for path selection,
- exchanges RIP broadcasts with neighboring devices to dynamically learn and advertise routes, and
- includes four basic components: routing update process, RIP routing metrics, routing stability, and routing timers.

RIP characteristics and versions

RIP is a widely used routing protocol. It sends routing updates at regular intervals and when the network topology changes. These updates provide information about network reachability and the number of hops to each destination..

You can configure RIP with less effort than OSPF, but it generates more network traffic. RIP supports both Version 1 and Version 2.

Secure Firewall Threat Defense device supports both RIP Version 1 and Version 2. RIP Version 1 does not send subnet masks with its updates; Version 2 supports variable-length subnet masks and neighbor authentication to ensure trusted routing information exchanges.

RIP offers simple configuration and adapts to topology changes. In contrast, static routes require manual updates for each change. RIP, however, incurs higher network and processing overhead compared to static routing.

How RIP routing updates work

Summary

Key components in the RIP routing update process include:

- RIP routers: Send and receive routing update messages to maintain network topology information
- Routing tables: Store the best routes to destinations with associated metric values
- Routing update messages: Contain network topology changes and route information
- Metric values: Determine the best path, with routers maintaining only the lowest metric route

Workflow

The process involves these stages:

1. RIP routers send routing-update messages at regular intervals and when the network topology changes.
2. When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop.
3. RIP routers maintain only the best route to a destination, which is the route with the lowest metric value.
4. After updating its routing table, the router immediately begins transmitting routing updates to inform other network routers of the change. These updates occur independently from regularly scheduled RIP router updates.

RIP routing metric

A RIP routing metric is a network measurement that

- calculates the distance between a source and a destination network,
- assigns a hop count value, typically 1, to each hop in a network path from the source to the destination, and
- updates the routing table when new routing data is received, using the sender's IP address as the next hop.

RIP stability features

RIP stability features are routing mechanisms that

- prevent routing loops by setting a limit on the number of hops in a path from source to destination,
- provide stability despite potentially rapid changes in network topology, and
- include split horizon and hold-down mechanisms to prevent incorrect routing information propagation.

Additional stability mechanisms

The maximum number of hops allowed in a path is 15. If a routing update shows a new or changed entry, the system increases the metric value to infinity (16), which makes the network destination unreachable. This stability mechanism limits the maximum diameter of a RIP network to fewer than 16 hops.

RIP timers

RIP timers are network protocol mechanisms that

- regulate RIP performance through timed intervals for routing updates and route management,
- control when routes are marked invalid, placed in holddown, or flushed from the routing table, and
- help prevent network congestion by managing the timing of routing updates across devices.

RIP timer stages

RIP uses numerous timers to regulate its performance. These are the timer stages for RIP:

- Update: The routing-update timer is the interval between periodic routing updates. This is how often the device sends routing updates. Generally, set to 30 seconds, a small random delay added to prevent simultaneous route updates.
- Invalid: Each routing table entry has a route-timeout timer for the last valid update. The route is marked invalid and moves to holddown once the timer expires. The default is 180 seconds (3 minutes).
- Holddown: The period the system waits before accepting any new updates for invalid routes. The default is 180 seconds (3 minutes).
- Flush: The route-flush timer marks the period from when the system receives the last valid update until the route is discarded and removed from the routing table. The default is 240 seconds (4 minutes).

RIP timer sequence when adjacent router interface goes down

When an adjacent router goes down, routing updates stop, and the Invalid and Flush timers start increasing. In the first 180 seconds, nothing will happen. After 180 seconds, the Invalid timer expires, marks the route invalid, and the Holddown timer begins, holding the route for 60 seconds.

If there is no routing update for the adjacent router's status (that is, it is still down), the route enters into the Flush state. In total, the system has waited for 240 seconds from the last update (180 seconds for the Invalid timer and 60 seconds for Holddown timer), and then the system flushes the route. Even if the adjacent router's interface comes up immediately, the system waits for the Holddown timer to complete the 120-second period before accepting updates.

Requirements and prerequisites for RIP

These requirements and prerequisites must be met for configuring RIP on supported firewall models.

Model support

Firewall Threat Defense

Firewall Threat Defense Virtual

Supported domains

Any

User roles

Admin

Network Admin

Guidelines for RIP

IPv6 guidelines

RIP does not support IPv6.

RIP version 2 guidelines

Consider these guidelines for RIP Version 2 configuration:

- If using neighbor authentication, the authentication key and key ID must be the same on all neighbor devices that provide RIP Version 2 updates to the interface.
- With RIP Version 2, the Secure Firewall Threat Defense device transmits and receives default route updates using the multicast address 224.0.0.9. In passive mode, it receives route updates at that address.
- When RIP Version 2 is configured on an interface, the multicast address 224.0.0.9 is registered on that interface. When a RIP Version 2 configuration is removed from an interface, that multicast address is unregistered.

RIP limitations

These are the limitations of RIP:

- The Secure Firewall Threat Defense device cannot pass RIP updates between interfaces.
- RIP Version 1 does not support variable-length subnet masks.
- RIP has a maximum hop count of 15. A route with a hop count greater than 15 is considered unreachable.
- RIP convergence is relatively slow compared to other routing protocols.
- You can only enable a single RIP process on the Secure Firewall Threat Defense device.

Configure RIP

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection.

Use this procedure to define networks, manage redistribution, and apply interface-specific filtering or broadcast parameters.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** and select **RIP** from the table of contents.

Check the **Enable RIP** check box to configure the RIP settings.

Choose the RIP versions for sending and receiving RIP updates from the **RIP Version** drop-down list:

- **Receive Version 1 & 2, Send Version 1**
- **Send & Receive Version 1**
- **Send & Receive Version 2**

Step 3 (Optional) Check the **Generate Default Route** check box to generate a default route for distribution, based on the route map that you specify.

a) Specify a route map name to use for generating default routes, in the **Route Map** field.

Generate the default route 0.0.0.0/0 for distribution when a route map is specified in the **Route Map** field.

Step 4 When you choose Send and Receive Version 2, the **Enable Auto Summary** option is available. When the **Enable Auto Summary** check box is checked, automatic route summarization is enabled. Disable automatic summarization if you must perform routing between disconnected subnets. When automatic summarization is disabled, subnets are advertised.

Note RIP Version 1 always uses automatic summarization—you cannot disable it.

Step 5 Click **Networks**. Define one or more networks for RIP routing. Enter IP address(es), or enter or select the desired Network/Hosts objects. There is no limit to the number of networks you can add to the security appliance configuration. Interfaces belonging to the defined network will participate in the RIP routing. The RIP routing updates will be sent and received only through interfaces on the specified networks. Also, if the network of an interface is not specified, the interface will not be advertised in any RIP updates.

Note RIP only supports IPv4 objects.

Step 6 (Optional) Click **Passive Interface**. Use this option to specify passive interfaces on the appliance, and by extension the active interfaces. The device receives RIP routing broadcasts on passive interfaces, using that

information to populate its routing tables, but does not broadcast routing updates on passive interfaces. Interfaces that are not designated as passive receive and send updates.

Step 7 Click **Redistribution** to manage redistribution routes. These are the routes that are being redistributed from other routing processes into the RIP routing process.

a) Click **Add** to specify redistribution routes.

b) Choose the routing protocol to redistribute into the RIP routing process, in the **Protocol** drop-down list. Available options are **Static**, **Connected**, **OSPF**, **BGP**, and **EIGRP**.

Note For OSPF, specify the process ID in the **Process ID** field. For BGP, specify the AS number in the **AS Number** field. When you choose the Connected option in the **Protocol** drop-down list, you can redistribute directly connected networks into the RIP routing process.

c) (Optional) If you are redistributing OSPF routes into the RIP routing process, you can select specific types of OSPF routes to redistribute in the **Match** drop-down list. Ctrl-click to select multiple types:

- **Internal**: Routes internal to the autonomous system (AS) are redistributed.
- **External 1**: Type 1 routes external to the AS are redistributed.
- **External 2**: Type 2 routes external to the AS are redistributed.
- **NSSA External 1**: Type 1 routes external to a not-so-stubby area (NSSA) are redistributed.
- **NSSA External 2**: Type 2 routes external to an NSSA are redistributed.

Note The default is match Internal, External 1, and External 2.

d) Select the RIP metric type to apply to the redistributed routes in the **Metric** drop-down list. The three choices are:

- **Transparent**: Use the current route metric.
- **Specified Value**: Assign a specific metric value from 0 to 16 in the **Metric Value** field.
- **None**: No metric is specified. Do not use any metric value, to apply to redistributed routes.

Note **None** option is applicable only for **Static** and **Connected** protocols.

e) (Optional) Enter the name of a route map that must be satisfied, in the **Route Map** field before the route can be redistributed into the RIP routing process. Routes are redistributed only if IP address matches an allow statement in the route map address list. To create a new route map object, click **Add** (+). See Configure Route Map Entry for the procedure to add a new route map.

f) Click **OK**.

Step 8 (Optional) Click **Filtering** to manage filters for the RIP policy. In this section, filters are used to prevent routing updates through an interface, control the advertising of routes in routing updates, control the processing of routing updates and filtering sources of routing updates.

a) Click **Add** to add RIP filters.

b) Select the type of traffic to be filtered - Inbound or Outbound in the **Traffic Direction** field.

Note If traffic direction is inbound, you can only define an Interface filter.

c) Specify whether the filter is based on an Interface or a Route, by selecting appropriate option in the **Filter On** field. If you click **Interface**, you can enter or choose the name of the interface on which routing updates are to be filtered. If you click **Route**, you can choose the route type:

- **Static**: Only static routes are filtered.
- **Connected**: Only connected routes are filtered.
- **OSPF**: Only OSPFv2 routes discovered by the specified OSPF process are filtered. Enter the Process ID of the OSPF process to be filtered.
- **BGP**: Only BGPv4 routes discovered by the specified BGP process are filtered. Enter the value in the **Process ID** field.
- **EIGRP**: Only EIGRP routes are filtered.

d) In the **Access List** field, enter or choose the name of one or more access control lists (ACLs) that define the networks to be allowed or removed from RIP route advertisements. To add a new standard access list object, click **Add** (+) and see Configure a standard ACL object, on page 2355.

e) Click **OK**.

Step 9 (Optional) Click **Broadcast** to add or edit interface configurations. Using Broadcast, you can override the global RIP versions to send or receive per interface. You can also define the authentication parameters per interface if you want to implement authentication to ensure valid RIP updates.

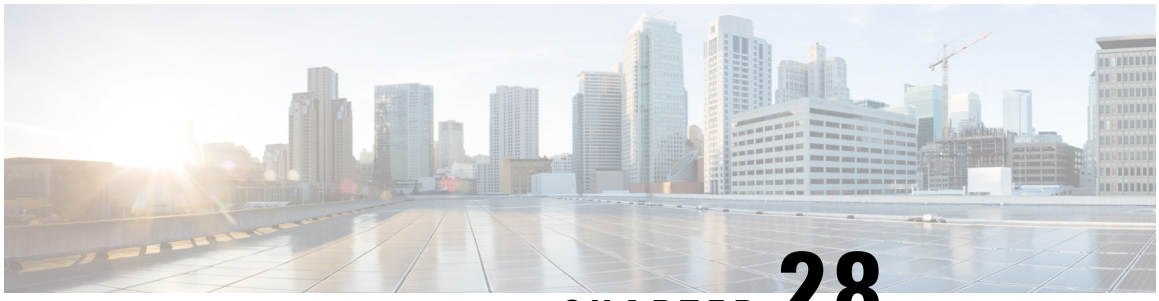
a) Click **Add** to add interface configurations.

b) Enter or choose an interface defined on this appliance in the **Interface** field.

c) In the Send option, select the appropriate boxes to specify sending updates using the RIP **Version 1**, **Version 2**, or both. These options let you override, for the specified interface, the global Send versions specified.

d) In the Receive option, select the appropriate boxes to specify accepting updates using the RIP **Version 1**, **Version 2**, or both. These options let you override, for the specified interface, the global Receive versions specified.

e) Select the **Authentication** used on this interface for RIP broadcasts.



- **None**: No authentication
- **MD5**: Employ MD5
- **Clear Text**: Employ clear-text authentication

If you choose MD5 or Clear Text, you must also provide the following authentication parameters.

- **Key ID**: The ID of the authentication key; valid values are from 0 to 255.

- **Key**: The key used by the chosen authentication method; can contain up to 16 characters.
- **Confirm**: Enter the authentication key again to confirm.

f) Click **OK**.

CHAPTER 28

Multicast

This chapter describes how to configure the Secure Firewall Threat Defense device to use the multicast routing protocol.

- Multicast routing, on page 1137
- Prerequisites for Multicast Routing, on page 1142
- Guidelines for multicast routing, on page 1142
- Configure IGMP features, on page 1143
- Configure PIM features, on page 1149
- Configure multicast routes, on page 1155
- Configure multicast boundary filters, on page 1156

Multicast routing

Multicast routing is a bandwidth-conserving technology that reduces traffic by simultaneously delivering a single stream of information to thousands of corporate recipients and homes. Applications include videoconferencing, corporate communications, distance learning, and distributing software, stock quotes, and news.

Multicast routing applications and protocols

Multicast routing protocols send source traffic to multiple receivers efficiently, without adding extra load on the source or receivers, and use less network bandwidth than other technologies. Multicast packets are replicated in the network by Firewall Threat Defense device enabled with Protocol Independent Multicast (PIM) and other supporting multicast protocols, which results in the most efficient delivery of data to multiple receivers possible.

The Firewall Threat Defense device supports both stub multicast routing and PIM multicast routing. However, you cannot configure both concurrently on a single Firewall Threat Defense device.

Note The UDP and non-UDP transports are both supported for multicast routing. However, the non-UDP transport has no FastPath optimization.

IGMP Protocol

IP hosts use the Internet Group Management Protocol (IGMP) to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IGMP uses group addresses (Class D IP address) as group identifiers. Host group address can be in the range of 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is never assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

Note When you enable multicast routing on the Firewall Threat Defense device, IGMP Version 2 is automatically enabled on all interfaces.

Query Messages to Multicast Groups

The Firewall Threat Defense device sends query messages to discover which multicast groups have members on the networks attached to the interfaces. Members respond with IGMP report messages indicating that they want to receive multicast packets for specific groups. Query messages are addressed to the all-systems multicast group, which has an address of 224.0.0.1, with a time-to-live value of 1.

These messages are sent periodically to refresh the membership information stored on the Firewall Threat Defense device. If the Firewall Threat Defense device discovers that there are no local members of a multicast group still attached to an interface, it stops forwarding multicast packets for that group to the attached network, and it sends a prune message back to the source of the packets.

By default, the PIM designated router on the subnet is responsible for sending the query messages. By default, they are sent once every 125 seconds.

When changing the query response time, by default, the maximum query response time advertised in IGMP queries is 10 seconds. If the Firewall Threat Defense device does not receive a response to a host query within this amount of time, it deletes the group.

Stub multicast routing

Stub multicast routing provides dynamic host registration and facilitates multicast routing.

When configured for stub multicast routing, the Firewall Threat Defense device acts as an IGMP proxy agent. Instead of fully participating in multicast routing, the Firewall Threat Defense device forwards IGMP messages to an upstream multicast router, which sets up delivery of the multicast data. When configured for stub multicast routing, the Firewall Threat Defense device cannot be configured for PIM sparse or bidirectional mode. Enable PIM on the interfaces that participate in IGMP stub multicast routing.

The Firewall Threat Defense device supports both PIM-SM and bidirectional PIM. PIM-SM is a multicast routing protocol that uses the underlying unicast routing information base or a separate multicast-capable routing information base. It builds unidirectional shared trees, each rooted at a single Rendezvous Point (RP) per multicast group. Optionally, it creates shortest-path trees for each multicast source.

PIM multicast routing

Bidirectional PIM is a variant of PIM-SM that builds bidirectional shared trees connecting multicast sources and receivers.

DF election process

Bidirectional trees are built using a Designated Forwarder (DF) election process operating on each link of the multicast topology. With the assistance of the DF, multicast data is forwarded from sources to the Rendezvous Point (RP) and then along the shared tree to receivers. This process does not require source-specific state. The DF election takes place during RP discovery and provides a default route to the RP.

Note If the Firewall Threat Defense device is the PIM RP, use the untranslated outside address of the Firewall Threat Defense device as the RP address.

PIM sparse mode

PIM Sparse Mode (PIM-SM) is a PIM mode that forwards traffic only when specifically requested by receivers. It uses a central Rendezvous Point (RP) to coordinate the multicast traffic forwarding between the multicast source and the destination. RP is a router that serves as the meeting point for the source and the receivers. Multicast sources register with the RP through their first hop router. They send a copy of the multicast traffic to the receivers through the RP.

PIM source specific multicast support

Firewall Threat Defense device can forward source specific multicast traffic (e.g., for groups in the 232.x.x.x range) even though they do not support PIM-SSM configuration or Internet Group Management Protocol version 3 (IGMPv3).

SSM is classified as a data delivery mechanism for one-to-many applications such as IPTV. The SSM model uses a concept of "channels" denoted by an (S,G) pair, where S is a source address and G is an SSM destination address. Subscribing to a channel is achieved by using a group management protocol such as IGMPv3. SSM enables a receiving client, once it has learned about a particular multicast source, to receive multicast streams directly from the source rather than receiving it from a shared Rendezvous Point (RP). Access control mechanisms are introduced within SSM, providing a security enhancement that is not available with current sparse or sparse-dense mode implementations.

Limitation:

- Firewall Threat Defense device cannot act as the last-hop router for SSM multicast because it does not support IGMPv3 (which receivers use to join SSM groups).

  If the Firewall Threat Defense device is the last-hop, it will ignore IGMPv3 join messages from receivers for SSM groups, and SSM forwarding will not work.

- Static multicast routes on Firewall Threat Defense device do not work for SSM range (232.x.x.x).

Workaround:

For Cisco Firewall Threat Defense device firewall to forward SSM-related multicast traffic, you must add a multicast-capable layer 3 device (such as a router or switch) that supports PIM and IGMPv3 on the same network segment as the receivers.

How it Works:

- Receivers register their SSM group joins (IGMPv3) with this layer 3 device.
- This layer 3 device sends PIM join messages towards the Firewall Threat Defense device.
- The Firewall Threat Defense device receives these PIM messages and dynamically learns multicast routes.
- SSM multicast traffic is then properly forwarded by the Firewall Threat Defense device, since it is no longer the last-hop device.

Multicast Bidirectional PIM

Multicast bidirectional PIM is useful for networks that have many sources and receivers talking to each other simultaneously and where each participant can become both the source and receiver of multicast traffic, such as in videoconferencing, Webex meetings, and group chat. When PIM bidirectional mode is used, the RP only creates the (*,G) entry for the shared tree. There is no (S,G) entry. This conserves resources on the RP because state tables for each (S,G) entry are not maintained.

In PIM sparse mode, traffic only flows down the shared tree. In PIM bidirectional mode, traffic flows up and down the shared tree.

PIM bidirectional mode also does not use the PIM register/register-stop mechanism to register sources to the RP. Each source can begin sending to the source at any time. When the multicast packets arrive at the RP, they are forwarded down the shared tree (if there are receivers) or dropped (when there are no receivers). However, there is no way for the RP to tell the source to stop sending multicast traffic.

Design-wise you must think about where to place the RP in your network because it should be somewhere in the middle between the sources and receivers in the network.

PIM bidirectional mode has no Reverse Path Forwarding (RPF) check. Instead it uses the concept of a Designated Forwarder (DF) to prevent loops. This DF is the only router on the segment that is allowed to send multicast traffic to the RP. If there is only one router per segment that forwards multicast traffic, there will be no loops. The DF is chosen using the following mechanism:

- The router with the lowest metric to the RP is the DF.
- If the metric is equal, then the router with the highest IP address becomes the DF.

PIM bootstrap router (BSR)

PIM Bootstrap Router (BSR) is a dynamic Rendezvous Point (RP) selection model that uses candidate routers for RP function and for relaying the RP information for a group.

The RP function includes RP discovery and provides a default route to the RP. It does this by configuring a set of devices as candidate BSRs (C-BSR) which participate in a BSR election process to choose a BSR amongst themselves. Once the BSR is chosen, devices that are configured as candidate Rendezvous Points (C-RP) start sending their group mapping to the elected BSR. The BSR then distributes the group-to-RP mapping information to all the other devices down the multicast tree through BSR messages that travel from PIM router to PIM router on a per-hop basis.

This feature allows networks to learn RPs dynamically. Dynamic RP discovery is essential in large, complex networks where an RP may occasionally go down and come up.

PIM bootstrap router (BSR) terminology

This reference provides definitions for key terminology used in PIM Bootstrap Router (BSR) configurations to help understand the roles and functions of different components in the BSR election and RP advertisement process.

These terms are frequently referenced in the PIM BSR configuration:

- Bootstrap Router (BSR) — A BSR advertises Rendezvous Point (RP) information to other routers with PIM on a hop-by-hop basis. Among multiple Candidate-BSRs, a single BSR is chosen after an election process. The primary purpose of this Bootstrap router is to collect all Candidate-RP (C-RP) announcements in to a database called the RP-set and to periodically send this out to all other routers in the network as BSR messages (every 60 seconds).
- Bootstrap Router (BSR) messages — BSR messages are multicast to the All-PIM-Routers group with a TTL of 1. All PIM neighbors that receive these messages retransmit them (again with a TTL of 1) out of all interfaces except the one in which the messages were received. BSR messages contain the RP-set and the IP address of the currently active BSR. This is how C-RPs know where to unicast their C-RP messages.
- Candidate Bootstrap Router (C-BSR) — A device that is configured as a candidate-BSR participates in the BSR election mechanism. A C-BSR with highest priority is elected as the BSR. The highest IP address of the C-BSR is used as a tiebreaker. The BSR election process is preemptive, for example if a new C-BSR with a higher priority comes up, it triggers a new election process.
- Candidate Rendezvous Point (C-RP) — An RP acts as a meeting place for sources and receivers of multicast data. A device that is configured as a C-RP periodically advertises the multicast group mapping information directly to the elected BSR through unicast. These messages contain the Group-range, C-RP address, and a hold time. The IP address of the current BSR is learned from the periodic BSR messages that are received by all routers in the network. In this way, the BSR learns about possible RPs that are currently up and reachable.

Note The Firewall Threat Defense device does not act as a C-RP, even though the C-RP is a mandatory requirement for BSR traffic. Only routers can act as a C-RP. So, for BSR testing functionality, you must add routers to the topology.

- BSR Election Mechanism — Each C-BSR originates Bootstrap messages (BSMs) that contain a BSR Priority field. Routers within the domain flood the BSMs throughout the domain. A C-BSR that hears about a higher-priority C-BSR than itself suppresses its sending of further BSMs for some period of time. The single remaining C-BSR becomes the elected BSR, and its BSMs inform all the other routers in the domain that it is the elected BSR.

Multicast group concept

Multicast is based on the concept of a group. An arbitrary group of receivers expresses an interest in receiving a particular data stream. This group does not have any physical or geographical boundaries. Hosts can be

located anywhere on the Internet. Hosts that want to receive data sent to a group must join the group using IGMP.

Group membership requirements

Hosts must be a member of the group to receive the data stream.

Multicast Addresses

Multicast addresses specify an arbitrary group of IP hosts that have joined the group and want to receive traffic sent to this group.

Clustering

Multicast routing supports clustering. In Spanned EtherChannel clustering, the control unit sends all multicast routing packets and data packets until fast-path forwarding is established.

After fast-path forwarding is established, data units may forward multicast data packets. All data flows are full flows. Stub forwarding flows are also supported. Because only one unit receives multicast packets in Spanned EtherChannel clustering, redirection to the control unit is common.

Prerequisites for Multicast Routing

Guidelines for multicast routing

Table 71: System requirements

Item	Description
Context mode	Supported in single context mode.
Firewall mode	Supported only in routed firewall mode. Transparent firewall mode is not supported.

Item	Description
IPv6	IPv6 is not supported.
Multicast group	The range of addresses from 224.0.0.0 to 224.0.0.255 is reserved for routing protocols and other topology discovery or maintenance protocols, such as gateway discovery and group membership reporting. Internet multicast routing from the 224.0.0/24 address range is not supported. When multicast routing is enabled for reserved addresses, an IGMP group is not created.
Clustering	In clustering, for IGMP and PIM, this feature is only supported on the primary unit.

Access control configuration

You must configure an access control or prefilter rule on the inbound security zone to allow traffic to the multicast host, such as 224.1.2.3. However, you cannot specify a destination security zone for the rule, or it cannot be applied to multicast connections during initial connection validation.

Interface and protocol management

Ensure proper configuration management when working with PIM-enabled interfaces and multicast routing protocols.

- You cannot disable an interface with PIM configured on it. If you have configured PIM on the interface (see Configure PIM protocol, on page 1149), disabling the multicast routing and PIM does not remove the PIM configuration. You must remove (delete) the PIM configuration to disable the interface.
- Multicast routing is not supported in ECMP.
- Do not configure Firewall Threat Defense to simultaneously be a Rendezvous Point (RP) and a First Hop Router.
- The HSRP standby IP address does not participate in PIM neighborship. If the RP router IP is routed through the HSRP standby IP address, multicast routing does not work in Firewall Threat Defense. To ensure multicast traffic passes through successfully, configure the route for the RP address to use an interface IP address rather than the HSRP standby IP address.
- For a device using virtual routing, you can configure multicast only for its global virtual router and not for its user-defined virtual router.

Configure IGMP features

Configure IGMP features to enable dynamic registration of individual hosts in multicast groups on a particular LAN and to manage multicast traffic efficiently.

IP hosts use IGMP to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IP hosts use IGMP to report their group memberships to directly connected multicast routers. IGMP dynamically registers individual hosts in a multicast group on a specific LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

This section describes how to configure optional IGMP settings on a per-interface basis.

Procedure

Step 1 Enable multicast routing, on page 1144.
Step 2 Configure IGMP protocol, on page 1145.
Step 3 Configure IGMP access groups, on page 1146.
Step 4 Configure IGMP static groups, on page 1147.
Step 5 Configure IGMP join groups, on page 1148.

Enable multicast routing

Enable multicast routing to allow the device to forward multicast traffic using Internet Group Management Protocol (IGMP) and Protocol Independent Multicast (PIM) protocols on all interfaces.

Enabling multicast routing on the Firewall Threat Defense device, enables IGMP and PIM on all interfaces by default. IGMP is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. PIM is used to maintain forwarding tables to forward multicast datagrams.

Note Only the UDP transport layer is supported for multicast routing.

These are the maximum number of entries for specific multicast tables. Any new entries are discarded when these limits are reached.

- Multicast Forwarding Information Base (MFIB): 30,000
- IGMP Groups: 30,000
- PIM Routes: 72,000

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.
Step 3 Check the **Enable Multicast Routing** check box.

Checking this check box enables IP multicast routing on the device. Unchecking it disables IP multicast routing. By default, multicast is disabled. Enabling multicast routing enables multicast on all interfaces.

You can disable multicast on a per-interface basis. This is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the Firewall Threat Defense device from sending host query messages on that interface.

Configure IGMP protocol

Use this task to configures IGMP parameters per-interface. These settings help manage multicast group membership on a Firewall Threat Defense device.

You can configure IGMP parameters per interface, such as the forward interface, query messages, and time intervals.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 Click the **Protocol** tab and click **Add**, or edit an interface.

In the **Add IGMP parameters** dialog box, configure new IGMP parameters to the Firewall Threat Defense device. Use the **Edit IGMP parameters** dialog box to modify the existing parameters.

Step 4 Configure these parameters:

- **Interface**: From the drop-down list, choose the interface for which you want to configure IGMP protocol.
- **Enable IGMP**: Check the check box to enable IGMP.

Note Disabling IGMP on specific interfaces is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the device from sending host query messages on that interface.

- **Forward Interface**: From the drop-down list, choose the specific interface from which you want to forward IGMP messages.

  This configures the Secure Firewall Threat Defense device to act as an IGMP proxy agent and forward IGMP messages from hosts connected on one interface to an upstream multicast router on another interface.

- **Version**: Choose IGMP Version 1 or 2.

  By default, the Firewall Threat Defense device runs IGMP Version 2, which enables several additional features.

Note All multicast routers on a subnet must support the same version of IGMP. The Firewall Threat Defense device does not automatically detect Version 1 routers and switch to Version 1. However, you can have a mix of IGMP Version 1 and 2 hosts on the subnet; the Firewall Threat Defense device running IGMP Version 2 works correctly when IGMP Version 1 hosts are present.

- **Query Interval**: The interval in seconds at which the designated router sends IGMP host-query messages. The range is 1 to 3600. The default is 125.

Note If the Firewall Threat Defense device does not hear a query message on an interface for the specified timeout value, then the device becomes the designated router and starts sending the query messages.

- **Response Time**: The interval in seconds before the Firewall Threat Defense device deletes the group. The range is 1 to 25. The default is 10.

  If the Firewall Threat Defense device does not receive a response to a host query within this amount of time, it deletes the group.

- **Group Limit**: Maximum number of hosts that can join on an interface. The range is 1 to 500. The default is 500.

  You can limit the number of IGMP states resulting from IGMP membership reports on a per-interface basis. Membership reports that exceed the configured limits are not entered in the IGMP cache, and their traffic is not forwarded.

- **Query Timeout**: The period of time in seconds before which the Firewall Threat Defense device takes over as the requester for the interface after the previous requester has stopped. The range is 60 to 300. The default is 255.

Step 5 Click **OK** to save the IGMP protocol configuration.

Configure IGMP access groups

You can control access to multicast groups by using access control lists.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **Access Group**.

Step 3 On **Access Group**, click **Add** or **Edit**.

Use the **Add IGMP Access Group parameters** dialog box to add new IGMP access groups to the Access Group table. Use the **Edit IGMP Access Group parameters** dialog box to change the parameters of an existing access group.

Step 4 Configure the access group options:

a) From the **Interface** drop-down list, choose the interface associated with the access group. You cannot change the associated interface when you are editing an existing access group.

b) Click one of the following:

- **Standard Access List**: From the **Standard Access List** drop-down list, choose the standard ACL or click **Add** (+) to create a new standard ACL. For more information, refer to Configure a standard ACL object, on page 2355.
- **Extended Access List**: From the **Extended Access List** drop-down list, choose the extended ACL or click **Add** (+) to create a new extended ACL. For more information, refer to Configure an extended ACL object, on page 2351.

Step 5 Click **OK** to save the access group configuration.

Configure IGMP static groups

Configure a statically joined IGMP group to enable multicast traffic for that group to be sent to a network segment even when group members cannot report membership or no members exist on the segment.

Sometimes a group member cannot report its membership in the group or there may be no members of a group on the network segment, but you still want multicast traffic for that group to be sent to that network segment. You can have multicast traffic for that group sent to the segment by configuring a statically joined IGMP group. With this method, the Firewall Threat Defense device does not accept the packets itself, but only forwards them. Therefore, this method allows fast switching. The outgoing interface appears in the IGMP cache, but this interface is not a member of the multicast group.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 On **Static Group**, click **Add** or **Edit**.

Use the **Add IGMP Static Group parameters** dialog box to statically assign a multicast group to an interface. Use the **Edit IGMP Static Group parameters** dialog box to change existing static group assignments.

Note The IGMP Static Group enables PIM to send *Join* requests towards the sources or towards the Rendezvous Point (RP), provided, the firewall with this command is the PIM Designated Router (DR) on that interface where the command is applied.

Step 4 Configure the following options:

- From the **Interface** drop-down list, choose the interface to which you want to statically assign a multicast group. If you are editing an existing entry, you cannot change the value.
- From the **Multicast Group** drop-down list, choose the multicast group to which you want to assign the interface, or click **Add** (+) to create a new multicast group. Refer to Creating Network Objects for the procedure.

Step 5 Click **OK** to save the static group configuration.

Configure IGMP join groups

You can configure an interface to be a member of a multicast group.

Configuring the Firewall Threat Defense device to join a multicast group, upstream routers maintain multicast routing table information for that group and keep the group's paths active.

Note Refer to Configure IGMP static groups, on page 1147 if you want to forward multicast packets for a specific group to an interface without the Firewall Threat Defense device accepting those packets as part of the group.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 On **Join Group**, click **Add** or **Edit**.

Use the **Add IGMP Join Group parameters** dialog box to configure the Firewall Threat Defense device to be a member of a multicast group. Use the **Edit IGMP Join Group parameters** dialog box to change existing parameters.

Note The IGMP Join Group enables PIM to send *Join* requests to sources or to the Rendezvous Point (RP) if the firewall with this command is the PIM Designated Router (DR) on that interface.

Step 4 Configure the following options:

- From the **Interface** drop-down list, choose the interface you want to be a member of a multicast group. If you are editing an existing entry, you cannot change the value.
- From the **Join Group** drop-down list, choose the multicast group to which you want to assign the interface, or click **Plus** to create a new multicast group. Refer to Creating Network Objects for the procedure.

Configure PIM features

This section describes how to configure optional PIM settings.

Routers use PIM to maintain forwarding tables to use for forwarding multicast diagrams. Enable multicast routing on the Secure Firewall Threat Defense device, to automatically enable IGMP and PIM on all interfaces.

Note PIM is not supported with PAT. The PIM protocol does not use ports, and PAT only works with protocols that use ports.

Procedure

Step 1 Configure PIM protocol, on page 1149.
Step 2 Configure PIM neighbor filters, on page 1150.
Step 3 Configure PIM bidirectional neighbor filters, on page 1151.
Step 4 Configure PIM rendezvous points, on page 1152.
Step 5 Configure PIM route trees, on page 1153.
Step 6 Configure PIM request filters, on page 1154.
Step 7 Configure multicast boundary filters, on page 1156.

Configure PIM protocol

You can enable or disable PIM on a specific interface.

You can also configure the Designated Router (DR) priority. The DR is responsible for sending PIM register, join, and prune messages to the RP. When there is more than one multicast router on a network segment, the DR is chosen based on DR priority. If multiple devices share the same DR priority, the device with the highest IP address becomes the DR. By default, the Firewall Threat Defense device has a DR priority of 1.

Router query messages are used to choose the PIM DR. The PIM DR is responsible for sending router query messages. By default, router query messages are sent every 30 seconds. Additionally, every 60 seconds, the Firewall Threat Defense device sends PIM join or prune messages.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.
Step 3 Click the **Protocol** tab and click **Add**, or edit an interface.

In the **Add PIM parameters** dialog box, add new PIM parameters for the interface. Use the **Edit PIM parameters** dialog box to change existing parameters.

Step 4 Configure these options:

- **Interface**: From the drop-down list, select the interface for which you want to configure PIM protocol.
- **Enable PIM**: Check the check box to enable PIM.
- **DR Priority**: Set the DR priority value for the selected interface. The router with the highest DR priority on the subnet becomes the designated router.
- **Hello Interval(seconds)**: The interval in seconds at which the interface sends PIM hello messages. The range is 1 to 3600. The default is 30.
- **Join Prune Interval(seconds)**: The interval in seconds at which the interface sends PIM join and prune advertisements. The range is 10 to 600. The default is 60.

Step 5 Click **OK** to save the PIM protocol configuration.

Configure PIM neighbor filters

You can define and filter the routers that become Protocol Independent Multicast (PIM) neighbors.

PIM neighbor filters allow you to define and filter the routers that become Protocol Independent Multicast (PIM) neighbors to:

- Prevent unauthorized routers from becoming PIM neighbors.
- Prevent attached stub routers from participating in PIM.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 Click the **Neighbor Filter** tab and click **Add**, or edit an interface.

In the **Add PIM Neighbor Filter** dialog box, add new PIM neighbor filters to the interface. Use the **Edit PIM Neighbor Filter** dialog box to change existing parameters.

Step 4 Configure these options:

- From the **Interface** drop-down list, choose the interface to which you want to add a PIM neighbor filter.
- From the **Standard Access List** drop-down list, choose a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2355 for the procedure.

Note Choosing **Allow** on the **Add Standard Access List Entry** dialog box lets the multicast group advertisements pass through the interface. Choosing **Block** prevents the specified multicast group advertisements from passing through the interface. When a multicast boundary is configured on an interface, all multicast traffic is prevented from passing through the interface unless permitted with a neighbor filter entry.

Step 5 Click **OK** to save the PIM neighbor filter configuration.

Configure PIM bidirectional neighbor filters

Configure PIM bidirectional neighbor filters to control which neighbor devices participate in the Designated Forwarder (DF) election for bidirectional multicast routing. This helps ensure proper multicast traffic forwarding in the network.

A PIM bidirectional neighbor filter is an ACL that defines the neighbor devices that can participate in the Designated Forwarder (DF) election. If you do not configure a PIM bidirectional neighbor filter for an interface, there are no restrictions. If you configure a PIM bidirectional neighbor filter, only neighbors permitted by the ACL can participate in the DF election process.

Bidirectional PIM allows multicast routers to keep reduced state information. All multicast routers in a segment must be bidirectionally enabled to elect a DF.

When a PIM bidirectional neighbor filter is enabled, the routers permitted by the ACL are considered to be bidirectionally capable. Therefore, the following is true:

- If a permitted neighbor does not support bidirectional mode, the DF election does not occur.
- If a denied neighbor supports bidirectional mode, the DF election does not occur.
- If a denied neighbor does not support bidirectional mode, the DF election can occur.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Multicast Routing** > **PIM**.

Step 3 On **Bidirectional Neighbor Filter**, click **Add** or **Edit**.

Use the **Add PIM Bidirectional Neighbor Filter** dialog box to create ACL entries for the PIM bidirectional neighbor filter ACL. Use the **Edit PIM Bidirectional Neighbor Filter** dialog box to change existing parameters.

Step 4 Configure these options:

- In the **Interface** drop-down list, select the interface for which you want to configure the PIM bidirectional neighbor filter ACL entry.

- From the **Standard Access List** drop-down list, select a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2355 for the procedure.

Note Choosing **Allow** in the **Add Standard Access List Entry** dialog box lets the specified devices participate in the DR election process. Choosing **Block** prevents the specified devices from participating in the DR election process.

Step 5 Click **OK** to save the PIM bidirectional neighbor filter configuration.

Configure PIM rendezvous points

You can configure the Firewall Threat Defense device to serve as a RP to more than one group.

The group range specified in the ACL determines the PIM RP group mapping. If an ACL is not specified, then the RP for the group is applied to the entire multicast group range (224.0.0.0/4). Refer to Multicast Bidirectional PIM, on page 1140 for more information about bidirectional PIM.

These restrictions apply to RPs:

- You cannot use the same RP address twice.
- You cannot specify **All Groups** for more than one RP.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Rendezvous Points**, click **Add** or **Edit**.

Use the **Add Rendezvous Point** dialog box to create a new entry in the Rendezvous Point table. Use the **Edit Rendezvous Point** dialog box to modify existing parameters.

Step 4 Configure these options:

- From the **Rendezvous Point IP address** drop-down list, choose the IP address that you want to add as an RP or click **Add** (+) to create a new network object. Refer to Creating Network Objects for the procedure.
- Check the **Use bi-directional forwarding** check box to enable bidirectional mode for the specified multicast groups. In this mode, if the Firewall Threat Defense device receives a multicast packet and has no directly connected members or PIM neighbors present, it sends a prune message back to the source.
- Click **Use this RP for all Multicast Groups** to use the specified RP for all multicast groups on the interface.
- Click **Use this RP for all Multicast Groups as specified below** to designate the multicast groups to use with the specified RP and then from the **Standard Access List** drop-down list, choose a standard ACL

or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2355 for the procedure.

Step 5 Click **OK** to save the rendezvous point configuration.

Configure PIM route trees

Configure PIM route trees to control whether the Firewall Threat Defense device joins the shortest-path tree or uses the shared tree for multicast traffic routing.

By default, PIM leaf routers join the shortest-path tree immediately after the first packet arrives from a new source. This method reduces delay, but requires more memory than the shared tree. You can configure whether or not the Firewall Threat Defense device should join the shortest-path tree or use the shared tree, either for all multicast groups or only for specific multicast addresses.

The shortest-path tree is used for any group that is not specified in the Multicast Groups table. The Multicast Groups table displays the multicast groups to use with the shared tree. The table entries are processed from the top down. You can create an entry that includes a range of multicast groups, but excludes specific groups within that range by placing deny rules for the specific groups at the top of the table and the permit rule for the range of multicast groups below the deny statements.

Note This behavior is known as Shortest Path Switchover (SPT). We recommend that you always use the Shared Tree option.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Route Tree**, select the path for the route tree:

- Click **Shortest Path** to use the shortest-path tree for all multicast groups.
- Click **Shared Tree** to use the shared tree for all multicast groups.
- Click **Shared tree for below mentioned group** to designate the groups specified in the Multicast Groups table, and then from the **Standard Access List** drop-down list, select a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2355 for the procedure.

Step 4 Click **OK** to save the route tree configuration.

Configure PIM request filters

When the Firewall Threat Defense device is acting as an RP, you can restrict specific multicast sources from registering with it to prevent unauthorized sources from registering with the RP. You can define the multicast sources from which the Firewall Threat Defense device will accept PIM register messages.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Request Filter**, define the multicast sources that are allowed to register with the Firewall Threat Defense device when it acts as an RP:

- From the **Filter PIM register messages using:** drop-down list select **None**, **RouteMap**, or **Access List**.
- If you choose **Access List** from the drop-down list, select an extended ACL or click **Add** (+) to create a new extended ACL. Refer to Configure an extended ACL object, on page 2351 for the procedure.

Note In the **Add Extended Access List Entry** dialog box, select **Allow** from the drop-down list to create a rule that allows the specified source of the specified multicast traffic to register with the Firewall Threat Defense device, or select **Block** to create a rule that prevents the specified source of the specified multicast traffic from registering with the device.

- If you choose **RouteMap**, select a route map from the **Route Map** drop-down list, or click **Add** (+) to create a new route map. Refer to Creating Network Objects for the procedure.

Step 4 Click **OK** to save the request filter configuration.

Configure the Firewall Threat Defense device as a candidate bootstrap router

You can configure the Firewall Threat Defense device as a candidate BSR.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Bootstrap Router**, check the **Configure this FTD as a Candidate Bootstrap Router (C-BSR)** check box to perform the C-BSR setup.

a) From the **Interface** drop-down list, select the interface in the Firewall Threat Defense device from which the BSR address is derived to make it a candidate.

This interface must be enabled with PIM.

b) In the **Hashmask Length** field, enter the length of a mask (32 bits maximum) that is to be ANDed with the group address before the hash function is called. All groups with the same seed hash (correspond) to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. This allows you to configure one RP for multiple groups. The range is 0 to 32.

c) In the **Priority** field, enter the priority of the candidate BSR. The BSR with the larger priority is preferred. If the priority values are the same, the router with the larger IP address is the BSR. The range is 0 to 255. The default value is 0.

Step 4 (Optional) Click **Add** (+) to select an interface on which no PIM BSR messages will be sent or received in the **Configure this FTD as a Border Bootstrap Router (BSR)** section.

- From the **Interface** drop-down list, select the interface on which no PIM BSR messages will be sent or received.

  RP or BSR advertisements are filtered effectively isolating two domains of RP information exchange.

- Check the **Enable Border BSR** check box to enable BSR.

Step 5 Click **OK** to save the bootstrap router configuration.

Configure multicast routes

Configure static multicast routes to separate multicast traffic from unicast traffic. For example, when a path between a source and destination does not support multicast routing, the solution is to configure two multicast devices with a GRE tunnel between them and to send the multicast packets over the tunnel.

When using PIM, the Firewall Threat Defense device expects to receive packets on the same interface where it sends unicast packets back to the source. In some cases, such as bypassing a route that does not support multicast routing, you may want unicast packets to take one path and multicast packets to take another.

Static multicast routes are not advertised or redistributed.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **Multicast Routes** > **Add or Edit**.

Use the **Add Multicast Route Configuration** dialog box to add a new multicast route to the Firewall Threat Defense device. Use the **Edit Multicast Route Configuration** dialog box to change an existing multicast route.

Step 3 Choose an existing network from the **Source Network** drop-down, or click **Add** (+) to add a new network.

Refer to Creating Network Objects for the procedure.

Step 4 To configure an interface to forward the route, click **Interface** and configure the following options:

- From the **Source Interface** drop-down list, choose the incoming interface for the multicast route.

- From the **Output Interface/Dense** drop-down list, choose the destination interface that the route is forwarded through.
- In the **Distance** field, enter the distance of the multicast route. The range is 0 to 255.

Step 5 To configure an RPF address to forward the route, click **Address** and configure the following options:

- In the **RPF Address** field, enter the IP address for the multicast route.
- Enter the multicast route distance in the **Distance** field. The value must be between 0 and 255.

Step 6 Click **OK** to save the multicast routes configuration.

Configure multicast boundary filters

Address scoping defines domain boundary filters so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

You can set up an administratively scoped boundary filter on an interface for multicast group addresses. IANA has designated the multicast address range from 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. The addresses are considered local and are not globally unique.

A standard ACL defines the range of affected addresses. When a boundary filter is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary filter allows the same multicast group address to be reused in different administrative domains.

You can configure, examine, and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary ACL are removed. An Auto-RP group range announcement is permitted and passed by the boundary filter only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

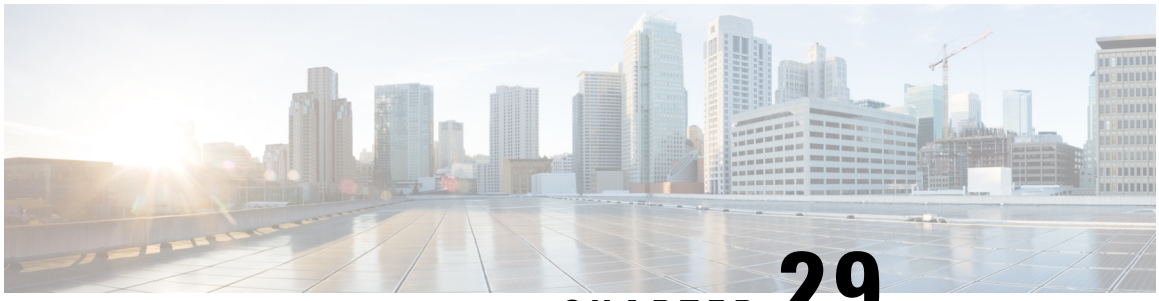
Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **Multicast Boundary Filter**, and then click **Add** or **Edit**.

Use the **Add Multicast Boundary Filter** dialog box to add new multicast boundary filters to the device. Use the **Edit Multicast Boundary Filter** dialog box to change existing parameters.

You can configure a multicast boundary for administratively scoped multicast addresses. A multicast boundary restricts multicast data packet flows and enables reuse of the same multicast group address in different administrative domains. When a multicast boundary is defined on an interface, only the multicast traffic permitted by the filter ACL passes through the interface.



Step 3 From the **Interface** drop-down list, choose the interface for which you are configuring the multicast boundary filter ACL.

Step 4 From the **Standard Access List** drop-down list, choose the standard ACL you want to use, or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2355 for the procedure.

Step 5 Check the **Remove any Auto-RP group range announcement from the Auto-RP packets that are denied by the boundary** check box to filter Auto-RP messages from sources denied by the boundary ACL. If this check box is not checked, all Auto-RP messages are passed.

Step 6 Click **OK** to save the multicast boundary filter configuration.

The multicast boundary filter is configured on the selected interface with the specified standard ACL, restricting multicast traffic according to the filter rules and enabling address reuse across administrative domains.

CHAPTER 29

Policy-Based Routing

This chapter describes how to configure Firewall Threat Defense to support policy-based routing (PBR) through Firewall Management Center's policy-based routing page. The following sections describe policy based routing, guidelines for PBR, and configuration for PBR.

- About policy-based routing, on page 1159
- Licenses for policy-based routing, on page 1161
- Best practices for policy-based routing, on page 1161
- Path monitoring metrics for best path route determination, on page 1163
- Configure policy-based routing policy, on page 1166
- Configure policy-based routing, on page 1169
- Configure PBR with path monitoring, on page 1175
- Useful CLIs for monitoring PBR, on page 1177
- Troubleshoot PBR, on page 1179
- History for policy-based routing, on page 1182

About policy-based routing

Policy-based routing (PBR) extends traditional routing protocols to provide greater control over traffic flow. It enables routing decisions based on criteria beyond destination IP, such as source and destination ports, protocols, and applications. Furthermore, PBR facilitates secure, application-specific traffic breakout in large-scale network deployments.

Policy-based routing characteristics

In traditional routing, packets are routed based on the destination IP address. Changing the routing of specific traffic in a destination-based routing system is difficult. PBR extends and complements the mechanisms provided by routing protocols.

PBR allows you to set the IP precedence. It also allows you to specify a path for certain traffic, such as priority traffic over a high-cost link. With PBR, you can define routing that is based on criteria other than destination network such as source port, destination address, destination port, protocol, applications, or a combination of these objects.

You can use PBR to classify the network traffic based on applications, username, group membership, and security group association. This routing method applies to scenarios involving numerous devices accessing applications and data in large network deployment. In large deployments, network traffic is typically backhauled to a hub as encrypted traffic in a route-based VPN. These topologies often result in issues such as packet

latency, reduced bandwidth, and packet drop. Resolving these issues requires costly, complex deployments and management.

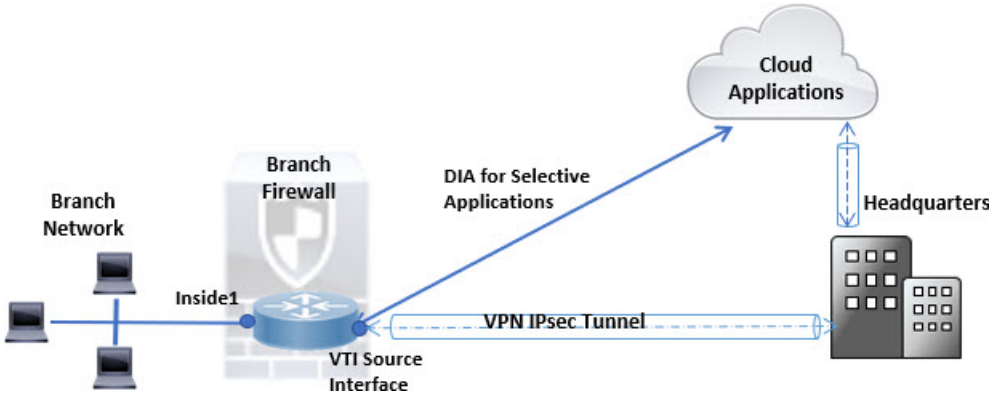
PBR policy enables you to securely break out traffic for specified applications. You can configure PBR policy in the Secure Firewall Management Center user interface to allow the applications to be directly accessed.

Consider a company that has two links between locations: one a high-bandwidth, low-delay expensive link, and the other a low-bandwidth, higher-delay, less-expensive link. While using traditional routing protocols, the higher-bandwidth link gets most, if not all, of the traffic sent across it based on the metric savings obtained by the bandwidth, delay, or both (using EIGRP or OSPF) characteristics of the link. With PBR, you can route higher priority traffic over the high-bandwidth/low-delay link, while sending all other traffic over the low-bandwidth/high-delay link.

These scenarios demonstrate policy-based routing applications:

- **Direct internet access**: In this topology, application traffic from the branch office can be routed directly to the internet instead of through the VPN tunnel connecting to the headquarters. The branch Firewall Threat Defense is configured with an internet exit point. The PBR policy is applied on the ingress interface (*Inside 1*) to identify the traffic based on the applications, user identity (username and group membership), and Security Group Tag (security group association) defined in the ACL. Correspondingly, the traffic is forwarded through the egress interfaces directly to the internet or to the IPsec VPN tunnel.
- **Equal-access and source-sensitive routing**: In this topology, traffic from the HR and Mgmt networks can be configured to go through ISP1 and traffic from Eng network can be configured to go through ISP2. Thus, policy-based routing enables the network administrators to provide equal-access and source-sensitive routing, in this example.
- **Load sharing**: In addition to the dynamic load-sharing capabilities offered by ECMP load balancing, network administrators can now implement policies to distribute traffic among multiple paths based on the traffic characteristics. As an example, in the topology depicted in the Equal-Access Source Sensitive Routing scenario, an administrator can configure policy-based routing to route the traffic from HR network through ISP1 and traffic from Eng network through ISP2 and thus share the load.

Figure 361: Direct internet access scenario



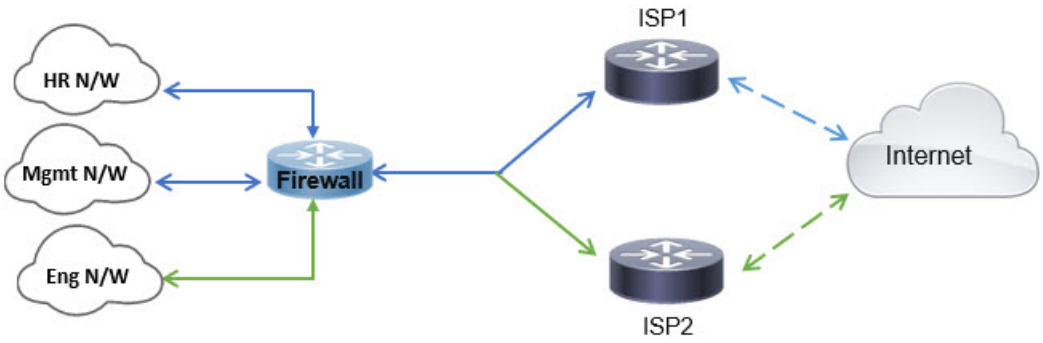


Figure 362: Equal access scenario

Licenses for policy-based routing

Policy-based routing (PBR) has specific licensing requirements depending on the features and services used in your configuration.

- All PBR policy features are supported with the Essentials Firewall Threat Defense smart license.
- Secure Client licensing is required if you are configuring PBR for routing traffic through RA VPN tunnel interface.
- Cisco ISE license is required for ISE usage in PBR policy.

Best practices for policy-based routing

Device guidelines

Ensure proper version compatibility and device-specific configurations when implementing PBR.

- PBR through Firewall Management Center's policy-based routing page is supported only from version 7.1 or later on both the Firewall Management Center and the Firewall Threat Defense device.
- When you upgrade Firewall Management Center or Firewall Threat Defense to version 7.1 or later, the PBR configuration in the device is removed. You must configure PBR again using the PBR page. If the managed device is earlier than version 7.1, you must configure PBR again using FlexConfig with deploy option set to "every time."
- On cluster devices, do not configure application, user identity, and Security Group Tag (SGT) based PBR policies, because they are not supported on cluster devices.

Interface guidelines

Configure appropriate interface types and settings for PBR policies.

- Configure only routed-mode interfaces and non management-only interfaces in the Global virtual router as ingress or egress interfaces for the PBR policy. You cannot configure user-defined virtual router interfaces for the policy.
- The interfaces that you want to define in the policy must have a logical name.

- Configure Static VTIs only as egress interfaces.
- Do not choose Dynamic VTIs for configuring the PBR egress interfaces.

You can apply PBR for managing both IPv4 and IPv6 traffic.

Application-based PBR and DNS configuration

Ensure proper DNS configuration for application-based PBR functionality.

- Application-based PBR uses DNS snooping for application detection. Application detection succeeds only if the DNS requests pass through Firewall Threat Defense in a clear-text format; the DNS traffic is not encrypted.
- You must configure trusted DNS servers for the application detection to succeed.

For more information on configuring DNS servers, refer to Configure DNS server settings, on page 852.

PBR policies not applied for output route look-up

PBR is an ingress-only feature; The system applies PBR only to the first packet of a new incoming connection, at which time the egress interface for the forward leg of the connection is selected. Note that PBR will not be triggered if the incoming packet belongs to an existing connection, or if NAT is applied and NAT chooses the egress interface.

PBR policies not applied for embryonic traffic

An embryonic connection is where the necessary handshake between source and destination has not been made. When a new internal interface is added and a new VPN policy is created using a unique address pool, PBR is applied to the outside interface matches the source of the new client pool. Thus, PBR sends traffic from the client to the next hop on the new interface. However, PBR does not process return traffic from a host until the new internal interface establishes a connection with the client. Thus, the return traffic from the host to the VPN client, specifically, the VPN client response is dropped as there is no valid route. To prevent the response from being dropped, configure a weighted static route with a higher metric on the internal interface.

HTTP-based path monitoring guidelines

Configure HTTP-based path monitoring with appropriate interface types and version considerations.

- Configure HTTP-based path monitoring only on physical, port-channel, subinterfaces, and static tunnel interfaces. Do not configure it on cluster devices.
- HTTP uses only IPv4 to ping applications. IPv4 metrics are applied for routing and forwarding both IPv4 and IPv6 traffic.
- HTTP-based application monitoring is enabled by default in Secure Firewall Management Center version 7.4 and higher. However, when you upgrade from previous versions, this option is not enabled by default. You must manually enable it.

Additional guidelines

Follow these additional configuration considerations for effective PBR implementation.

- All existing configuration restrictions and route map limitations remain in effect.
- When you define the ACL for the policy match criteria, you can select multiple predefined applications from a list to form an Access Control Entry (ACE). In Firewall Threat Defense, the predefined applications

are stored as Network Service objects and the group of applications as Network Service Groups (NSG). You can create a maximum of 1024 such NSGs. The application or network service group is detected through first-packet classification. Currently, you cannot add to or modify the predefined applications list.

- Unicast Reverse Path Forwarding (uRPF) validates the source IP address of packets received on an interface against the routing table and not against the PBR route map. When uRPF is enabled, packets received on an interface through PBR are dropped as they are without the specific route entry. Therefore, when using PBR, ensure you disable uRPF.

Path monitoring metrics for best path route determination

Path monitoring metrics for best path route determination is a dynamic routing method that uses various monitoring approaches, such as ICMP and HTTP, to collect performance metrics and determine the best path.

Path monitoring methods and operation

PBR uses either static cost or path monitoring (dynamic metrics) to route its traffic.

Path monitoring, when configured on interfaces, derive metrics such as round trip time (RTT), jitter, mean opinion score (MOS), and packet loss per interface. These metrics are used to determine the best path for routing PBR traffic.

ICMP-based path monitoring method

The metrics on the interfaces are collected dynamically using ICMP probe messages to the interface's default gateway or a specified remote peer.

HTTP-based path monitoring method

Path monitoring calculates dynamic metrics for each remote peer associated with an interface. HTTP is preferred over ICMP when monitoring multiple applications and determining the best path through a policy on a branch firewall, because:

- HTTP-ping can derive the performance metrics of the path up to the application layer of the server, where the application is hosted.
- Because the application domain is tracked instead of the IP address, you do not need to change the firewall configuration when the application server IP address changes.

Note You can configure both ICMP and HTTP on the same interface. If the destination in the policy matches to any of the domain IP, the corresponding metrics are used. If the destination does not match to any of the configured domains, the metrics from the ICMP are used by PBR to select the outgoing interface.

Default monitoring timers for metric collection

For metric collection and monitoring, the following timers are used:

- The interface monitor average interval is 30 seconds. This interval indicates the frequency to which the probes average.

- The interface monitor update interval is 30 seconds. This interval indicates the frequency at which the average of the collected values are calculated and made available for PBR to determine the best routing path.
- The interface monitor probe interval by ICMP is one second. This interval indicates the frequency at which an ICMP ping is sent.
- The application monitor probe interval by HTTP is 10 seconds. This interval indicates the frequency at which an HTTP ping is sent. Path monitoring uses the last 30 samples of HTTP ping for calculating the average metrics.

Note You cannot configure or modify the interval for any of these timers.

PBR and path monitoring integration

Typically, in PBR, traffic is forwarded through egress interfaces based on the priority value (interface cost) configured on them. From management center version 7.2, PBR uses IP-based path monitoring to collect the performance metrics (RTT, jitter, packet-lost, and MOS) of the egress interfaces. PBR uses the metrics to determine the best path (egress interface) for forwarding the traffic. Path monitoring periodically notifies PBR about the monitored interface whose metric got changed. PBR retrieves the latest metric values for the monitored interfaces from the path monitoring database and updates the data path.

Path monitoring functions only with dynamic metrics, and only if the RTT, jitter, packet-lost, or MOS variables are set on the interfaces. Path monitoring does not function with static metrics—interface cost (cost set in interface).

You must enable path monitoring for the interface and configure the monitoring type. The PBR policy page allows you to specify the desired metric for path determination. See Configure policy-based routing policy, on page 1166.

PBR and HTTP-based path monitoring

From management center version 7.4, PBR can be configured to use HTTP-based path monitoring to collect the performance metrics of the application domains and not just one destination IP address. Path monitoring begins only after a DNS entry for a domain is detected; it does not start immediately when HTTP-based application monitoring is configured. After obtaining the resolved IP address for the domain, path monitoring sends an HTTP request and receives a response. If DNS resolves multiple IP addresses for a domain, path monitoring probes and monitors the application using the first resolved IP address. Path monitoring continues until the IP address changes or until HTTP-based monitoring is disabled.

Based on the HTTP request and response durations, path monitoring computes the performance metrics for the application. Path monitoring sends collected metrics to PBR at regular intervals so that PBR can make routing and forwarding decisions for traffic from the configured ingress interface. If traffic arrives before path monitoring sends metrics to PBR, the routing table determines the traffic flow. Once metrics are available, PBR uses them to make routing decisions for subsequent traffic.

Note Based on the Network Service Groups in the match ACL of the policy, you can apply PBR for multiple domains having multiple IP addresses.

The management center associates applications and NSGs with the egress interface only when the PBR configuration meets these criteria:

- The match ACL contains the monitored applications.
- The PBR policy is configured with any one of the interface ordering values (metric type):
  - Minimal Jitter
  - Maximum Mean Opinion Score
  - Minimal Round-Trip Time
  - Minimal Packet Loss

Configure path monitoring settings

Configure path monitoring to collect metrics such as RTT, jitter, MOS, and packet loss on specified interfaces for effective traffic management and routing optimization.

The PBR policy relies on flexible metrics, such as round-trip time (RTT), jitter, mean opinion score (MOS), and packet loss of the interfaces to identify the best routing path for its traffic. Path monitoring collects these metrics on the specified interfaces. On the **Interfaces** page, you can configure path monitoring settings on interfaces to send ICMP probes or HTTP pings to collect metrics.

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click the **Path Monitoring** tab.

Step 4 To configure ICMP based monitoring of the interface, click the **Enable IP based Monitoring** check box.

Step 5 From the **Monitoring Type** drop-down list, select the relevant option:

- **Auto**—Sends ICMP probes to the IPv4 default gateway of the interface. If the IPv4 gateway does not exist, path monitoring sends the probes to the IPv6 default gateway of the interface.
- **Peer IPv4**—Sends ICMP probes to the specified peer IPv4 address (next-hop IP) for monitoring. If you select this option, enter the IPv4 address in the **Peer IP To Monitor** field.
- **Peer IPv6**—Sends ICMP probes to the specified peer IPv6 address (next-hop IP) for monitoring. If you select this option, enter the IPv6 address in the **Peer IP To Monitor** field.
- **Auto IPv4**—Sends ICMP probes to the default IPv4 gateway of the interface.
- **Auto IPv6**—Send ICMP probes to the default IPv6 gateway of the interface.

Note

- The Auto options are not available for VTI interfaces. You must specify the peer address.
- Only one next-hop is monitored to a destination. That is, you cannot specify more than one peer address to monitor for an interface.

Step 6 By default, the **Enable HTTP based Application Monitoring** check box is selected. All applications selected for path monitoring in the match ACL of the PBR policy are listed, provided this interface is configured as the egress interface in the policy. To disable the HTTP-based monitoring of the interface, clear the check box.

Step 7 Click **Ok**.

Step 8 To save the settings, click **Save**.

Path monitoring is configured on the interface with the specified settings. The system will collect metrics using ICMP probes or HTTP pings based on your configuration to optimize routing paths.

Add path monitoring dashboard

Add the Path Monitoring Dashboard to enable viewing path monitoring metrics with customizable display options through predefined correlations and widget management.

Procedure

Step 1 Choose **System** ( ) > **Health** > **Monitor**.

Step 2 Select the device, and click **Add new dashboard** ( ).

Step 3 Enter a name for the custom dashboard.

Step 4 In the **Metrics** area, click the **Add from predefined correlations** button.

Step 5 From the list, click **Interface - Path metrics**.

By default, all four metrics and an additional metric field are selected to display as widgets in the dashboard.

To exclude any, click **Delete** ( ).

Step 6 Click **Add dashboard**.

Configure policy-based routing policy

This task enables you to configure Policy-Based Routing (PBR) to control traffic routing based on specific criteria rather than relying solely on the routing table.

You can configure the PBR policy on the Policy Based Routing page by specifying the ingress interfaces, match criteria (Extended Access Control List), and egress interfaces.

Before you begin

To use the path monitoring metrics for configuring the traffic forwarding priority over egress interfaces, you must configure the path monitoring settings for the interfaces. See Configure path monitoring settings, on page 1165.

Follow these steps to configure policy-based routing policy:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Policy Based Routing**.

On the Policy Based Routing page, you can view the configured policy. The grid shows ingress interfaces and the combination of the policy-based route access list and egress interfaces.

Step 4 To configure the policy, click **Add**.

Step 5 In the **Add Policy Based Route** dialog box, select the **Ingress Interface** from the drop-down list.

Note You can only select interfaces with logical names that belong to a global virtual router from the drop-down list. You cannot configure a VLAN interface with a logical name as the source (ingress) interface.

Step 6 To specify the match criteria and the forward action in the policy, click **Add**.

Step 7 In the **Add Forwarding Actions** dialog box, do the following:

a) From the **Match ACL** drop-down, choose the extended access control list object. You can predefine the ACL object (see Configure an extended ACL object, on page 2351) or click the **Add** (+) icon to create the object. In the **New Extended Access List Object** box, enter a name, click **Add** to open the **Add Extended Access List Entry** dialog box, where you can define the network, port, user identity, SGT, or application match criteria for the PBR policy.

Note You can either have destination address or application/user identity/SGT defined in an ACE.

To selectively apply PBR on the incoming interface, you can define *Block* criteria in the ACE. When the traffic matches the block rule of the ACE, the traffic is forwarded to the egress interface based on the routing table.

b) From the **Send To** drop-down list:

- To select the configured interfaces, choose **Egress Interfaces**.
- To specify the IPv4/IPv6 next hop addresses, choose **IP Address**. Proceed to Step 7.e, on page 1168

c) If you have selected **Egress Interfaces**, from the **Interface Ordering** drop-down, choose the relevant option:

- By **Interface Priority**—The traffic is forwarded based on the priority of the interfaces. Traffic is routed to the interface with the least priority value first. When the interface is not available, the traffic

is then forwarded to the interface with the next lowest priority value. For example, let us assume that interface1, interface2, and interface3 are configured with priority values *0*,*1*, and *2*, respectively. The traffic is forwarded to interface1. If interface1 becomes unavailable, the traffic is then forwarded to interface2.

Note To configure the priority for the interfaces, click **Configure Interface Priority** on the Policy Based Routing page. In the dialog box, provide the priority number against the interfaces, and then click **Save**. You can also configure the priority for an interface in the Interface Settings.

When the priority value is the same for all the interfaces, the traffic is balanced among the interfaces. By default, the interface priority for PBR is set to 0. Interfaces with the lowest priority value are preferred for traffic forwarding.

- By **Order**—The traffic is forwarded based on the sequence of the interfaces specified here. For example, let us assume that interface1, interface2, and interface3 are selected in this order, interface2, interface3, interface1. The traffic is forwarded first to interface2, then to interface3, regardless of their priority values.
- By **Minimal Jitter**—The traffic is forwarded to the interface that has the lowest jitter value. You need to enable Path Monitoring on the interfaces for PBR to obtain the jitter values.
- By **Maximum Mean Opinion Score**—The traffic is forwarded to the interface that has the maximum mean opinion score (MOS). You need to enable Path Monitoring on the interfaces for PBR to obtain the MOS values.
- By **Minimal Round Trip Time**—The traffic is forwarded to the interface that has the minimal round trip time (RTT). You need to enable Path Monitoring on the interfaces for PBR to obtain the RTT values.
- By **Minimal Packet Loss**—The traffic is forwarded to the interface that has the minimal packet loss. You need to enable Path Monitoring on the interfaces for PBR to obtain the packet loss values.

d) In the **Available Interfaces** box, all the interfaces with their priority values are listed. From the list of interfaces, click the **Add** (+) button to add to the selected egress interfaces. Proceed to Step 8.

Note The selected interface route must be present in the routing table.

e) If you have selected **IP Address**, enter the IP addresses separated by commas in the **IPv4 Addresses** or **IPv6 Addresses** fields. The traffic is forwarded as per the sequence of the specified IP addresses.

Note When multiple next-hop IP addresses are provided, the traffic is forwarded as per the sequence of the specified IP addresses until a valid routable next-hop IP address is found. The configured next-hops should be directly connected.

f) From the **Don't Fragment** drop-down list, select Yes, No, or None. If the DF (Don't Fragment) flag is set to *Yes*, the intermediate routers never perform fragmentation of a packet.To specify the current interface as the default for forwarding, check the **Default Interface** check box.

g) The **IPv4 Settings** and **IPv6 Settings** tabs enable you to specify the recursive and default settings:

Note For a route-map, you can only specify either IPv4 or IPv6 next-hop settings.

- **Recursive**—The route map configuration is applied only when the specified next-hop address and the default next-hop address are found on a directly connected subnet. However, you could use the recursive option, where the next-hop address need not be directly connected. Here, a recursive lookup is performed on the next-hop address, and matching traffic is forwarded to the next-hop used by that route entry according to the current routing path of the router.
- **Default**—If the normal route lookup fails to match traffic, the traffic is forwarded to this specified next-hop IP address.

h) Check the **Peer Address** check box to use the next-hop address as the peer address.

Note You cannot configure a route map with both default next-hop address and peer address.

i) For IPv4 settings, you can check whether the next IPv4 hops of a route map are available under **Verify Availability**—click the **Add** (+) button and add the next-hop IP address entries:

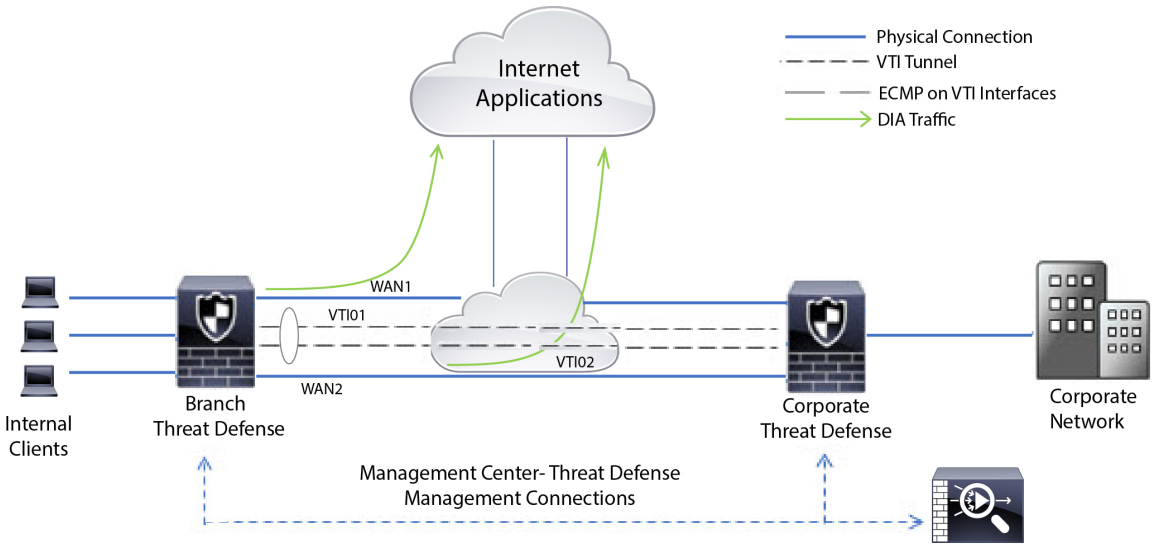
- **IP Address**—Enter the next hop IP address.
- **Sequence**—Entries are assessed in order using the sequence number. Ensure that no duplicate sequence numbers are entered. The valid range is 1 to 65535.
- **Track**—Enter a valid ID. The valid range is 1 to 255.

Step 8 To save the policy, click **Save** and **Deploy**.

The Firewall Threat Defense uses ACLs to match traffic and perform routing actions on the traffic. Typically, you configure a route map that specifies an ACL against which traffic is matched, and then you specify one or more actions for that traffic. With the use of path monitoring, PBR can now select the best egress interface for routing the traffic. Finally, you associate the route map with an interface on which you want to apply PBR on all incoming traffic.

Configure policy-based routing

Configure PBR to enable direct internet access for specific web-based applications, optimize traffic flow, and achieve load balancing between WAN and VTI interfaces.



Consider a typical corporate network scenario where all the branch network traffic passes through a route-based VPN of the corporate network and diverges to the extranet, when required. Accessing web-based applications

through the corporate network to support daily operations may increase network size and maintenance costs. This example illustrates how to configure PBR for direct internet access.

The following figure depicts the topology of a corporate network. The branch network is connected to the corporate network through a route-based VPN. Traditionally, the corporate Firewall Threat Defense is configured to handle both the internal and external traffic of the branch office. With the PBR policy, the branch Firewall Threat Defense is configured with a policy that routes specific traffic to the WAN network instead of the virtual tunnels. The rest of the traffic flows through the route-based VPN, as usual.

This example also illustrates how to configure the WAN and VTI interfaces with ECMP zones to achieve load balancing.

Figure 363: Configuring policy-based routing on Branch Firewall Threat Defense in Firewall Management Center

Before you begin

This example assumes that you have already configured WAN and VTI interfaces for the branch Firewall Threat Defense in Firewall Management Center.

Procedure

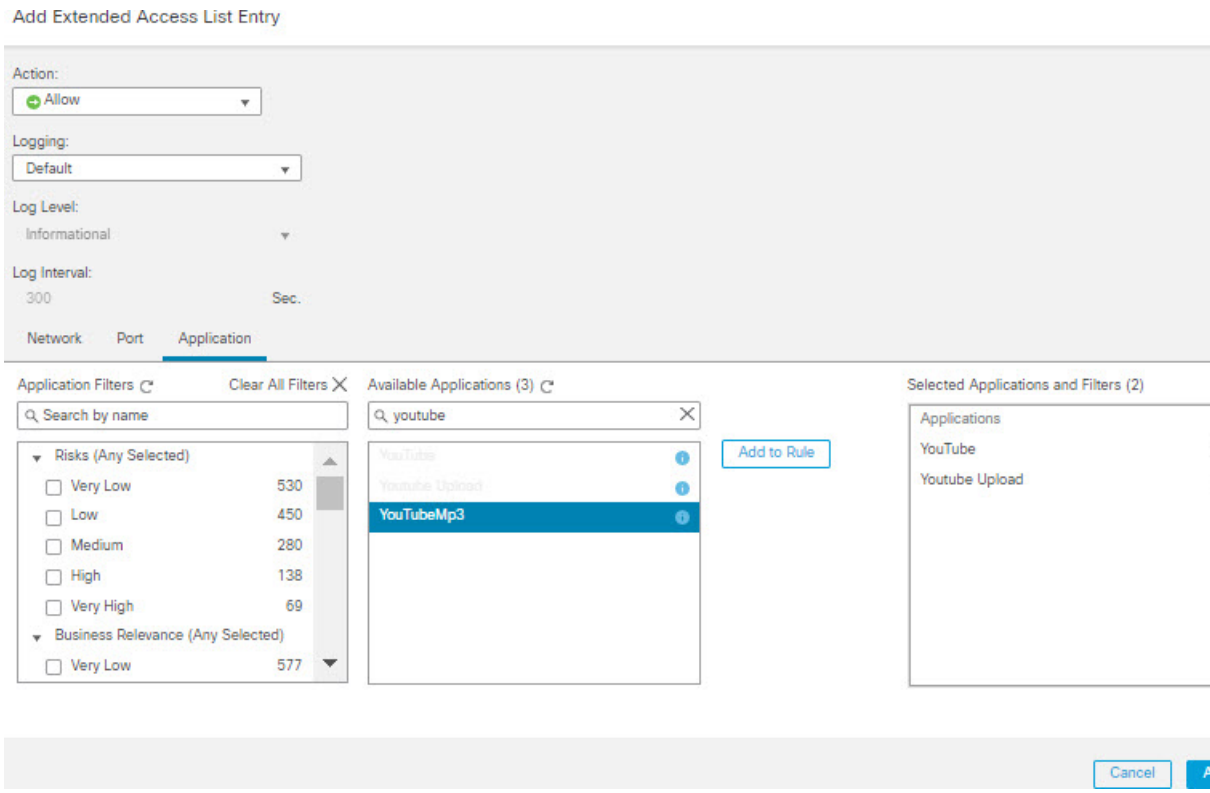
Step 1 Configure policy-based routing for the branch Firewall Threat Defense, select the ingress interfaces:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b) Choose **Routing** > **Policy Based Routing**, and on the **Policy Based Routing** page, click **Add**.

c) In the **Add Policy Based Route** dialog box, select the interfaces (say, *Inside 1*, and *Inside 2*) from the **Ingress Interface** drop-down list.

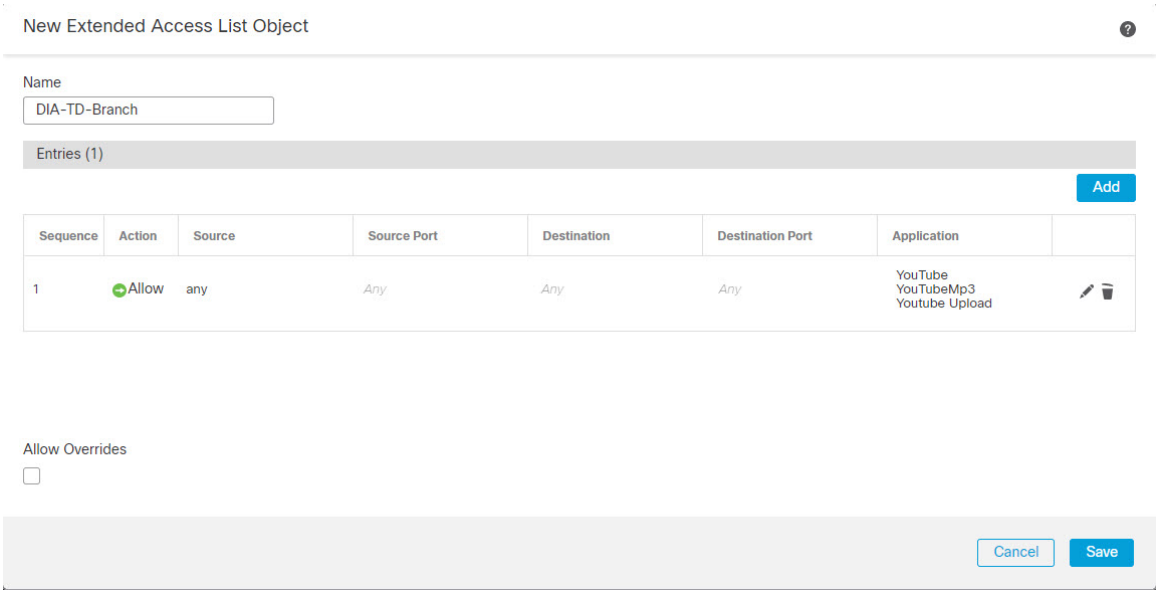
Step 2 Specify the match criteria:



a) Click **Add**.

b) To define the match criteria, click the **Add** (+) button.

c) In **New Extended Access List Object**, enter the name for the ACL (say, *DIA-FTD-Branch*), and click **Add**.



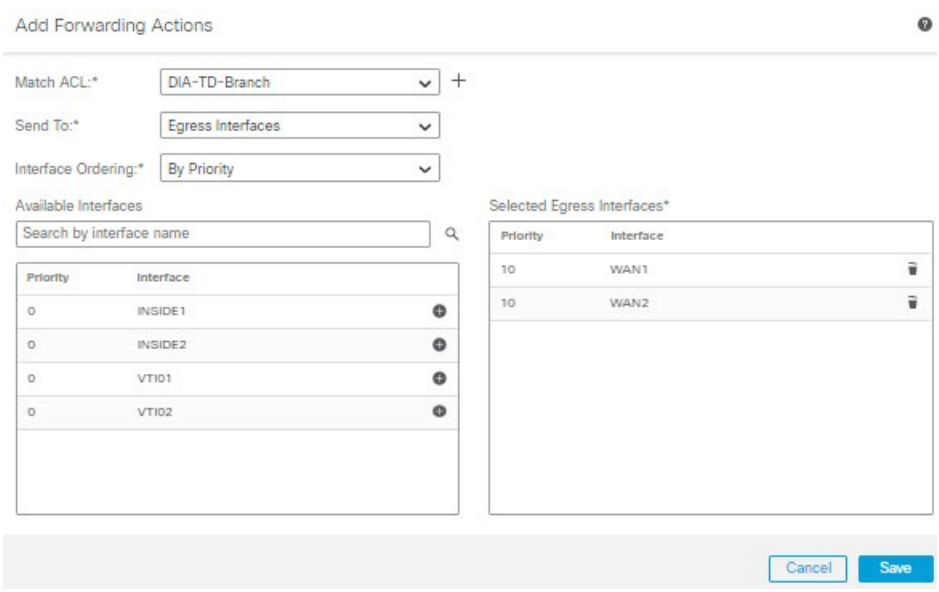
d) In the **Add Extended Access List Entry** dialog box, choose the required web-based applications from the **Application** tab:

Figure 364: Applications tab

On the Firewall Threat Defense, the application group in an ACL is configured as a network service group and each of the applications as a network service object.

Figure 365: Extended ACL

e) Click **Save**.



f) Select *DIA-FTD-Branch* from the **Match ACL** drop-down list.

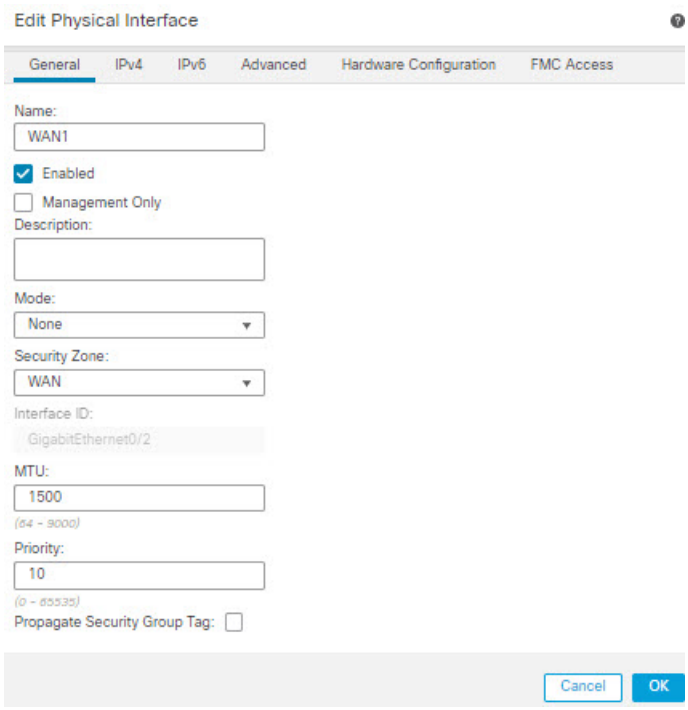
Step 3 Specify the egress interfaces:

a) From the **Send To** and **Interface Ordering** drop-down lists, choose Egress Interfaces, and Interface Priority respectively.

b) Under **Available Interfaces**, click the ⊕ button against the respective interface names to add *WAN1* and *WAN2*:

Figure 366: Configuring policy-based routing

c) Click **Save**.



Step 4 Configure interface priority:

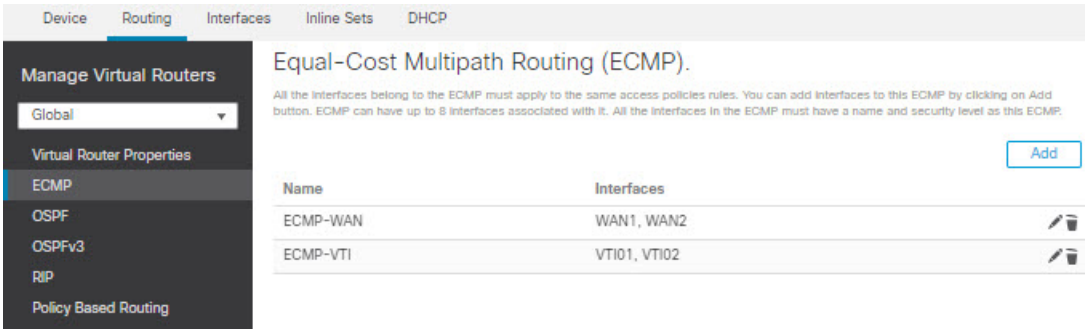
You can set the priority value for the interfaces either in the **Edit Physical Interface** page, or in the **Policy Based Routing** page (**Configure Interface Priority**). In this example, the Edit Physical Interface method is described.

a) Choose **Devices** > **Device Management**, and edit the branch Firewall Threat Defense.

b) Set the priority for the interfaces. Click **Edit** against the interface and enter the priority value:

Figure 367: Setting interface priority

c) Click **Ok** and **Save**.



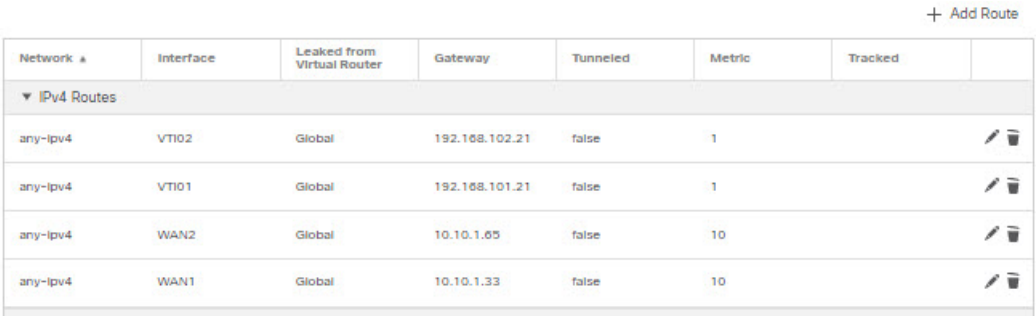
Step 5 Create ECMP zones for load balancing:

a) In the **Routing** page, click **ECMP**.

b) To associate interfaces to the ECMP zone, click **Add**.

c) Select *WAN1* and *WAN 2* and create an ECMP zone—*ECMP-WAN*. Similarly, add *VTI01* and *VTI02* and create an ECMP zone—*ECMP-VTI*:

Figure 368: Associating interfaces with ECMP zone



Step 6 Configure static routes for the zone interfaces for load balancing:

a) In the **Routing** page, click **Static Route**.

b) Click **Add** and specify the static routes for *WAN1*, *WAN2*, *VTI01*, and *VTI02*. Ensure that you specify the same metric value for the interfaces belonging to the same ECMP zones (Step 5):

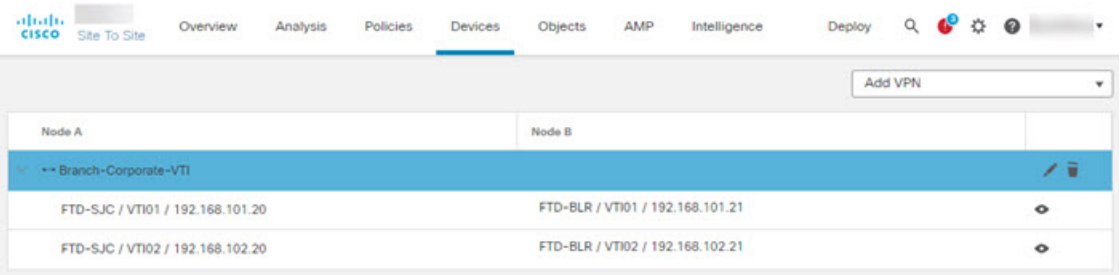
Figure 369: Configuring static routes for ECMP zone interfaces

Note Ensure that the zone interfaces have the same destination address and metric, but different gateway addresses.

Step 7 Configure trusted DNS on the WAN objects of the branch Firewall Threat Defense to ensure secure flow of traffic to the internet:

a) Choose **Devices** > **Platform Settings**, and create a DNS policy on the branch Firewall Threat Defense.

b) To specify the trusted DNS, edit the policy and click **DNS**.



c) To specify the DNS servers for the DNS resolution to be used by WAN objects, in the **DNS Settings** tab, provide the DNS server group details and select WAN from the interface objects.

d) Use the **Trusted DNS Servers** tab to provide specific DNS servers that you trust for the DNS resolution.

Step 8 Click **Save**, and then click **Deploy**.

Any *YouTube* related access requests from the branch inside network *INSIDE1* or *INSIDE2* are routed to *WAN1* or *WAN2* as they would match the *DIA-FTD-Branch* ACL. Any other request, say *google.com*, are routed through *VTI01* or *VTI02* as configured in the Site to Site VPN Settings.

Figure 370: Site to site VPN settings

With the ECMP configured, the network traffic is seamlessly balanced.

Configure PBR with path monitoring

Configure PBR with path monitoring to optimize application traffic routing by dynamically selecting the best egress interface based on performance metrics such as jitter, round-trip time, and packet loss.

This example describes how to configure PBR with path monitoring for the following applications with flexible metrics:

- Audio or video sensitive applications (example, WebEx Meetings) with Jitter.
- Cloud-based application (example, Office365) with RTT.
- Network-based access control (with a specific source and destination) with packet loss.

Before you begin

1. This example assumes that you are aware of the basic configuration steps for PBR.
2. You have configured ingress and egress interfaces with logical names. In this example, the ingress interface is named *Inside1*, and egress interfaces are named *ISP01*, *ISP02*, and *ISP03*.

Follow these steps to configure PBR with path monitoring:

Procedure

Step 1 Path monitoring configuration on interfaces *ISP01*, *ISP02*, and *ISP03*:

For the metrics collection on the egress interfaces, you must enable and configure path monitoring on them.

a) Choose **Devices** > **Device Management**, and edit Firewall Threat Defense.
b) Under the **Interfaces** tab, edit the interface (in our example, *ISP01*)
c) Click the **Path Monitoring** tab, select the **Enable Path Monitoring** check box, and then specify the monitoring type (see Configure path monitoring settings, on page 1165).
d) Click **Ok** and **Save**.
e) Repeat these steps to configure the path monitoring settings for *ISP02* and *ISP03*.

Step 2 Configure policy-based routing for a branch in an organization Firewall Threat Defense, select the ingress interfaces:

a) Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Policy Based Routing**, and on the **Policy Based Routing** page, click **Add**.
c) In the **Add Policy Based Route** dialog box, select *Inside 1* from the **Ingress Interface** drop-down list.

Step 3 Specify the match criteria:

a) Click **Add**.
b) To define the match criteria, click the **Add** (+) button.
c) In **New Extended Access List Object**, enter the name for the ACL (example, *PBR-WebEx*), and click **Add**.
d) In the **Add Extended Access List Entry** dialog box, choose the necessary web-based applications, such as WebEx Meetings) from the **Application** tab.

Remember On Firewall Threat Defense, the application group in an ACL is configured as a network service group and each of the applications as a network service object.

e) Click **Save**.
f) Select *PBR-WebEx* from the **Match ACL** drop-down list.

Step 4 Specify the egress interfaces:

a) From the **Send To** drop-down list, choose Egress Interfaces.
b) From the **Interface Ordering** drop-down list, choose By Minimal Jitter.
c) Under **Available Interfaces**, click the **Right Arrow** (>)button against the respective interface names to add *ISP01*, *ISP02*, and *ISP03*.
d) Click **Save**.

Step 5 Repeat Step 2 and Step 3 to create PBRs for the *Inside1* interface to route Office365 and network-based access control traffic:

a) Create a match criteria object, example *PBR-Office365*, and select the Office365 application from the **Application** tab.
b) From the **Interface Ordering** drop-down list, choose By Minimal Round Trip Time.
c) Specify the egress interfaces *ISP01*, *ISP02*, and *ISP03*, and click **Save**.
d) Now, create a match criteria object, example *PBR-networks*, and specify the source and destination interface in the **Network** tab.
e) From the **Interface Ordering** drop-down list, choose By Minimal Packet Loss.
f) Specify the egress interfaces *ISP01*, *ISP02*, and *ISP03*, and click **Save**.

Step 6 Click **Save**, and then click **Deploy**.

Step 7 To view path monitoring metrics, Choose **Devices** > **Device Management**, and from **More** (⋮) click **Health Monitor**. To view the metric details for the interfaces of the device, you must add the path metrics dashboard. For details, see Add path monitoring dashboard, on page 1166.

The WebEx, Office365, and networks-based ACL traffic are forwarded through the best route derived from the metrics value collected on *ISP01*, *ISP02*, and *ISP03*.

Useful CLIs for monitoring PBR

Run the monitoring commands described in this topic from the Firewall Threat Defense device CLI.

Interface configurations

To view the interface configurations of the device, run the `show run interface` command:

```
> show run interface
!
interface Ethernetl/l
 description Outside ispl handoff
 nameif outside1
 security-level 0
 zone-member ECMP-WAN
 ip address dhcp setroute
 policy-route cost 10
 policy-route path-monitoring 8.8.8.8
 policy-route path-monitoring object-group network-service FMC_NSG_4295470581 policy-route
 path-monitoring object-group network-service FMC_NSG_4295470600
!
interface Ethernet1/2
 description Outside isp2 handoff
 nameif outside2
 security-level 0
 zone-member ECMP-WAN
 ip address 192.133.243.240 255.255.255.192
 policy-route cost 20
 policy-route path-monitoring 8.8.8.8
 policy-route path-monitoring object-group network-service FMC_NSG_4295470581 policy-route
 path-monitoring object-group network-service FMC_NSG_4295470600
!
```

DNS configurations

Application-based routing only uses trusted DNS servers to resolve domains. To view the DNS configurations of the device, run the `show run DNS` command:

```
> show run dns
DNS server-group DefaultDNS
dns trusted-source 10.100.0.5
dns trusted-source 10.200.0.5
```

Route map configurations

When you configure PBR on the device, the Management Center auto-generates the route-map and applies it to the specified ingress interface. To view the route maps of the device, run the `show run route-map` command:

```
> show run route-map
!
route-map FMC_VPN_CONNECTED_DIST_RMAP_1000 permit 10
 match interface inside-employee
 set community 1000
!
route-map FMC GENERATED PBR 1729024850865 permit 5
 match ip address Cloud-storage-apps-acl
  set adaptive-intertace cost outside1 outside2
```

```
!
route-map FMC_GENERATED PBR 1729024850865 permit 10
match ip address Social-media-apps-acl
set adaptive-interface rtt outside1 outside2

!
route-map FMC GENERATED PBR 1729024850865 permit 15
match ip address Conferencing-apps-acl
set adaptive-interface jitter outside1 outside2

!
route-map FMC_GENERATED_PBR_1729024850865 permit 20
match ip address Corp-internal-apps-acl
set adaptive-interface cost outside1_static_vti_1 outside2_static_vti_4
```

Access lists and network service groups configurations

The route-map applied to the ingress interface can reference an extended access control list. To view the details of an access list for PBR, run the `show run access list <access list_name>` command:

```
> show run access-list Cloud-storage-apps-acl
access-list Cloud-storage-apps-acl extended permit ip any object-group-network-service
FMC_NSG_4295470562
```

The network-service objects and object-groups are configured in extended access control lists and referenced in policy-based routing route maps and access control groups. To view the NSG configurations, run the `show object-group network-service <network-service-groups-name>` command. The *network-service-groups-name* is derived from the above show command for an access list.

```
> show object-group network-service FMC_NSG_4295470562
 object-group network-servire FMC_NSG_4295470562 (id=@xfdff0000)
 network-service-member "Box" dynamic

    MOS: 4.39
    Last updated: 12 second(s) ago
    Network Service: Zoom Domain name: zoom.com Remote peer reachable: Yes
    RTT average: 98196 microsecond(s) Jitter: 4120 microseconde)
    Packet loss: 0%
    MOS: 4.34
    Last updated: 12 second(s) ago
```

Troubleshoot PBR

This task helps you debug PBR configuration when packets get dropped by verifying routes, monitoring metrics, and validating interface selection.

When PBR is not working as intended, you need to systematically verify the configuration components including route maps, path monitoring, and interface selection to identify the root cause of packet drops.

Before you begin

Follow these steps to troubleshoot PBR configuration when packets get dropped:

Procedure

Step 1 Check that all essential routes for recursive resolution are present by using the show route or show ipv6 route commands in the appropriate tables.

Unless the route map for the interfaces participating in PBR is updated with correct routes, PBR will not work as intended.

Step 2 Display the remote address that path-monitoring uses to monitor metrics by using the **show running-config interface** command.

Example:

```
interface GigabitEthernet0/0
nameif outside_0
security-level 0
zone-member ecmp-zone
ip address 20.0.0.3 255.255.255.0 -> This is egress interface "show running-config" output,
 the monitored address and cost metric value is determined in this output.
policy-route cost 1
policy-route path-monitoring
20.0.0.4
!
int GigabitEthernet 0/3
!
interface GigabitEthernet0/3
nameif outside_3
security-level 0
ip address 11.1.1.2 255.255.255.0 -> This is ingress interface "show running-config" output,
 the specific route-map will be used by PBR to determine the next route.
policy-route route-map rtt-tes
```

This command shows the monitored address and cost metric values for path monitoring by sending ICMP packets or HTTP pings.

Step 3 Examine the **show path-monitoring** and **show run route-map** outputs for packet loss.

Example:

```
ciscoasa(config)# show path-monitoring
Interface: outside_0  -> The remote address used for ICMP monitoring
Remote peer: 20.0.0.4
Version: 6223
Remote peer reachable: Yes -> If this value turns "No", then the ICMPv4/v6 packet is not
reaching the required remote address.
RTT average: 1920 microsecond(s)
Jitter: 394 microsecond(s)
Packet loss: 0%
MOS: 4.40
Last updated: 17 second(s) ago -> The data should be updated by path monitoring after every
 30 seconds. The 'show route-map' would show the
updated metric values.
Interface: outside_2
Remote peer: 40.0.0.4
Version: 6223
Remote peer reachable: Yes
RTT average: 1935 microsecond(s)
Jitter: 433 microsecond(s)
Packet loss: 0%
MOS: 4.40
Last updated: 17 second(s) ago
```

Example:

```
ciscoasa(config)# show route-map
route-map rtt-test, permit, sequence 10
Match clauses:
Set clauses:
adaptive-interface rtt outside_0 (1920) outside_2 (1935) outside_1 (1971) -> Displays the
metric type (rtt) that is used by the policy route to select the adequate interface to send
 the packet. The interface list where cost of each interface is given. As the metric type
is "rtt" and considering the minimum rtt value, the "outside_0" interface route will be
selected by PBR.
route-map mos-test, permit, sequence 10
Match clauses:
Set clauses:
adaptive-interface mos outside_0 (378) outside_1 (390) outside_2 (440) - > As the metric
type is "mos", considering the maximum value of mos, the "outside_2" interface will be
selected by PBR.
```

The metric types (lost, rtt, jitter, cost) should select the interface with the minimum metric value for routing.

The metric type "mos" should select the interface with the maximum metric value for routing.

Step 4 Use **packet-tracer** command to validate the interface selection based on the metric type defined in the PBR.

Example:

```
packet-tracer input <interface> icmp <src ip address> 8 0 <dst ip
address> detailed
Phase: 3
Type: PBR-LOOKUP
Subtype: policy-route
Result: ALLOW
Elapsed time: 60656 ns
Config:
route-map rtt-test permit 10
match ip address allow_101_1_1_2
set adaptive-interface rtt outside_0 outside_2
Additional Information:
Matched route-map rtt-test, sequence 10, permit
Found next-hop 40.0.0.4 using egress ifc outside_2 -> PBR selects the adequate interface
from adaptiveinterface list given in "rtt-test" route-map.
```

Step 5 Use the **packet-tracer** command similar to the **debug policy-route** command.

When PBR successfully selects the route, the packet tracer output looks like this:

```
pbr: policy based route lookup called for 101.1.1.1/0 to 101.1.1.2/0 proto 1 sub_proto 8
received on
interface outside_3, NSGs, nsg_id=none
pbr: First matching rule from ACL(-1)
pbr: route map rtt-test, sequence 10, permit; proceed with policy routing
pbr: policy based routing applied; egress_ifc = outside_2 : next_hop = 20.0.0.4
```

When PBR is not able to find the adequate route, it falls back to normal route lookup, and the packet tracer output looks like this:

```
pbr: policy based route lookup called for 100.1.1.1/0 to 100.1.1.2/0 proto 1 sub_proto 8
received on interface outside_3, NSGs, nsg_id=none
pbr: First matching rule from ACL(-1)
pbr: route map mos-test, sequence 10, permit; proceed with policy routing
pbr: no route to 100.1.1.2 on adaptive-interface outside_2
pbr: no route to 100.1.1.2 on adaptive-interface outside_1
pbr: no route to 100.1.1.2 on adaptive-interface outside_0
pbr: policy based routing could not be applied; proceeding with normal route lookup
```

When a monitored remote address goes down, and path monitoring marks **Remote peer reachable** as **No** for that address, the PBR displays the a log that excludes the interface from adaptive-interface list.

```
pbr: policy based route lookup called for 100.1.1.1/0 to 101.1.1.2/0 proto 1 sub_proto 8
received on
interface outside_3, NSGs, nsg_id=none
pbr: First matching rule from ACL(-1)
pbr: route map rtt-test, sequence 10, permit; proceed with policy routing
pbr: Path Monitoring Ifc Down : adaptive-interface outside_1 Excluded from PBR routing
pbr: policy based routing applied; egress_ifc = outside_2 : next_hop = 40.0.0.4
```

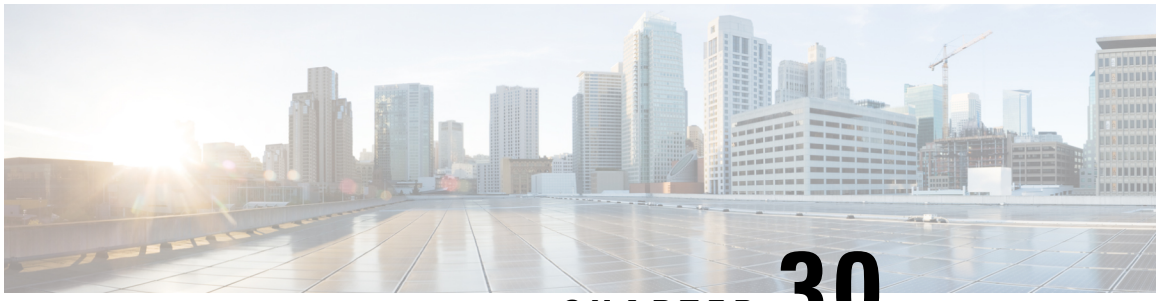
Note The interface becomes eligible for adaptive PBR routing when the interface is reported as reachable in the path monitoring module.

History for policy-based routing

This reference provides a comprehensive history table that summarizes the introduction and evolution of policy-based routing features in Cisco Secure Firewall Management Center across releases, enabling quick tracking of feature availability and changes.

Table 72: History table

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Identity and SGT based PBR Policy	7.4.0	7.4.0	You can now classify the network traffic based on users and user groups, and SGTs in PBR policies. You can select the identity and SGT objects while defining the extended ACLs for the PBR policies. New/modified screens: New tabs added in the extended access list object for configuring the policy-based routing policy: **Objects** > **Object Management** > **Access Control Lists** > **Add Extended** page, **Users** and **Security Group Tag**.
HTTP based Path Monitoring	7.4.0	7.2.0	PBR can now use the performance metrics (RTT, jitter, packet-lost, and MOS) collected by path monitoring through HTTP client on the application domain rather than the metrics on a specific destination IP. HTTP-based application monitoring option is enabled by default for the interface. You can configure a PBR policy with match ACL having the monitored applications and desired metric type for path determination. New/modified screens: New option in Interfaces page for enabling path monitoring: **Devices** > **Device Management** > **Edit Interfaces** > **Path Monitoring** > **Enable HTTP based Application Monitoring** check box.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Dual WAN/ISP Threat Defense Management Support	7.3.0	7.3.0	On a dual WAN-enabled threat defense, a single data interface was configured to communicate with the management center. Now, support to configure a secondary data interface is provided so that the communication channel is sustained when the primary data interface fails. The management center automatically configures PBR to route the SF-Tunnel traffic from the *tapnlp* (internal) interface to one of the available data interfaces based on the priority and SLA metric.
Next-hop settings for PBR route map	7.3.0	7.1.0	You can configure the next-hops for the PBR route-map while enabling packet forwarding actions. New/modified screens: New fields in Add/Edit Forwarding Actions page for configuring egress interfaces: **Device Management** > **Routing** > **Policy Based Routing** > **Add Forwarding Actions** page.
PBR and Path Monitoring	7.2.0	7.2.0	PBR uses path monitoring to collect the performance metrics (RTT, jitter, packet-lost, and MOS) of the egress interfaces. You must enable path monitoring for the interface and configure the monitoring type. You can configure a PBR policy with the desired metric for path determination. New/modified screens: New tab in Interfaces page for enabling path monitoring: **Devices** > **Device Management** > **Edit Interfaces** > **Path Monitoring** tab.
Configure policy based routing from the FMC web interface.	7.1.0	7.1.0	**Upgrade impact. Redo FlexConfigs after upgrade.** You can now configure policy based routing (PBR) from the FMC web interface. This allows you to classify network traffic based on applications and to implement direct internet access (DIA) to send traffic to the internet from a branch deployment. You can define a PBR policy and configure it on ingress interfaces, specifying match criteria and egress interfaces. Network traffic that matches the access control policy is forwarded through the egress interface based on priority or the order as configured in the policy. This feature requires Version 7.1+ on both the FMC and the device. When you upgrade the FMC to Version 7.1+, existing policy based routing FlexConfigs are removed. After you upgrade your devices to Version 7.1+, redo your policy based routing configurations in the FMC web interface. For devices that you do not upgrade to Version 7.1+, redo the FlexConfigs and configure them to deploy "every time." New/modified screens: **Devices** > **Device Management** > **Routing** > **Policy Based Routing**

PART V

Network Policies

- Network Address Translation, on page 1187
- Quality of Service, on page 1313

CHAPTER 30

Network Address Translation

The following topics explain Network Address Translation (NAT) and how to configure it on Firewall Threat Defense devices.

- NAT functions, on page 1187
- NAT basics, on page 1188
- Requirements and prerequisites for NAT policies, on page 1197
- Guidelines for NAT, on page 1197
- Manage NAT policies, on page 1203
- Configure NAT for threat defense, on page 1205
- Translating IPv6 networks, on page 1245
- Monitoring NAT, on page 1258
- Examples for NAT, on page 1259
- History for Firewall Threat Defense NAT, on page 1310

NAT functions

NAT enables private IP networks to connect to the Internet by replacing private IP addresses with public IP addresses. It conserves public addresses by advertising at minimum only one public address for the entire network to the outside world.

Private IP address ranges

Most devices within an IP network are assigned private IP addresses, which are not routable outside the company network due to the shortage of public IPv4 addresses. RFC 1918 defines the private IP address ranges that should not be advertised externally:

- 10.0.0.0 through 10.255.255.255
- 172.16.0.0 through 172.31.255.255
- 192.168.0.0 through 192.168.255.255

One of the primary functions of NAT is to enable private IP networks to access the Internet by translating private IP addresses into legal, routable public addresses. This approach conserves public IP addresses since NAT can be configured to advertise only a single public address for the entire network.

Other functions of NAT include:

- Security: Hides internal IP addresses, discouraging direct attacks.
- IP routing solutions: Handles overlapping IP addresses without conflict.
- Flexibility: Allows internal IP addressing schemes to change without affecting externally visible public addresses.
- Translating between IPv4 and IPv6 (Routed mode only): Supports translating between IPv4 and IPv6, enabling interoperability between different network types.

Note NAT is optional. If NAT is not configured for specific traffic, that traffic will not be translated but will still be subject to normal security policies.

NAT basics

The following topics explain some of the basics of NAT.

NAT terminology

This document uses the following terminology:

- Real address/host/network/interface—The real address is the address that is defined on the host, before it is translated. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the inside network would be the “real” network. Note that you can translate any network connected to the device, not just an inside network. Therefore if you configure NAT to translate outside addresses, “real” can refer to the outside network when it accesses the inside network.
- Mapped address/host/network/interface—The mapped address is the address that the real address is translated to. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the outside network would be the “mapped” network.

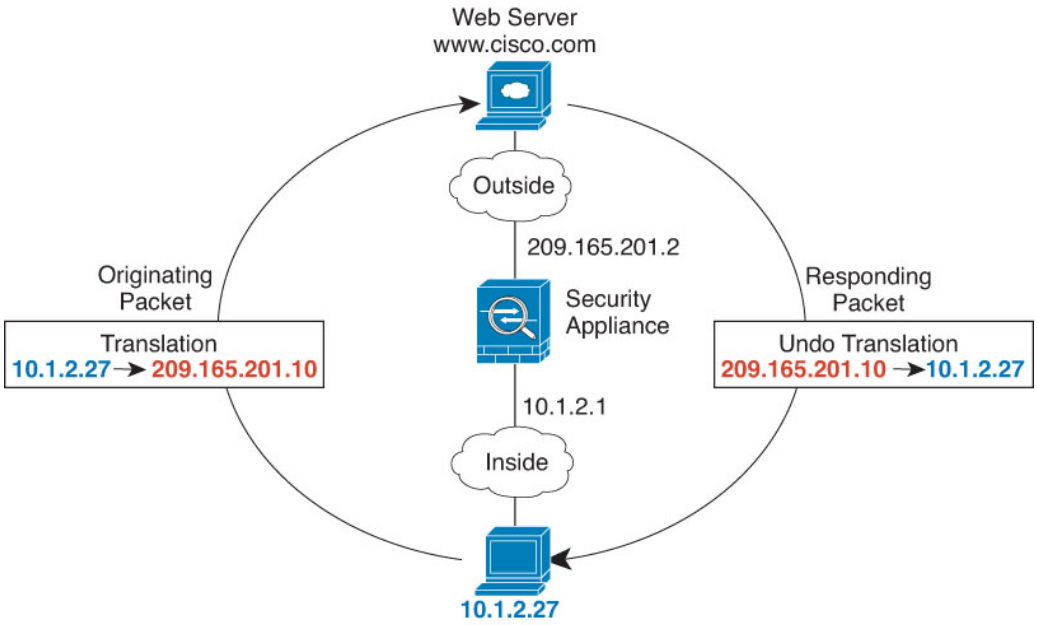
Note During address translation, IP addresses configured for the device interfaces are not translated.

- Bidirectional initiation—Static NAT allows connections to be initiated *bidirectionally*, meaning both to the host and from the host.
- Source and destination NAT—For any given packet, both the source and destination IP addresses are compared to the NAT rules, and one or both can be translated/untranslated. For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address.

NAT types

You can implement NAT using the following methods:

- Dynamic NAT—A group of real IP addresses are mapped to a (usually smaller) group of mapped IP addresses, on a first come, first served basis. Only the real host can initiate traffic. See Dynamic NAT, on page 1210.
- Dynamic Port Address Translation (PAT)—A group of real IP addresses are mapped to a single IP address using a unique source port of that IP address. See Dynamic PAT, on page 1216.
- Static NAT—A consistent mapping between a real and mapped IP address. Allows bidirectional traffic initiation. See Static NAT, on page 1226.
- Identity NAT—A real address is statically translated to itself, essentially bypassing NAT. You might want to configure NAT this way when you want to translate a large group of addresses, but then want to exempt a smaller subset of addresses. See Identity NAT, on page 1235.



NAT in routed and transparent mode

You can configure NAT in both routed and transparent firewall mode. You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. The following sections describe typical usage for each firewall mode.

NAT in routed mode

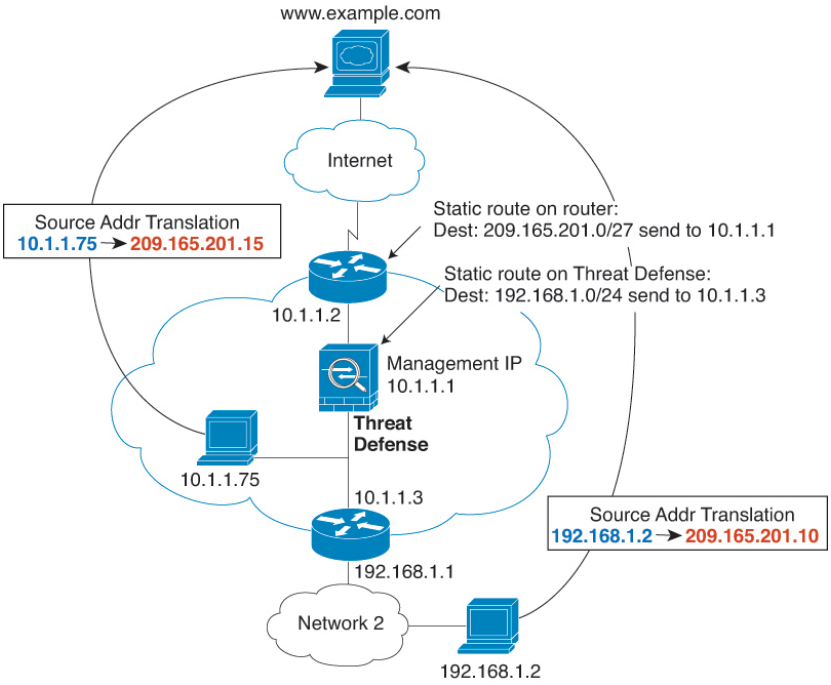
The following figure shows a typical NAT example in routed mode, with a private network on the inside.

Figure 371: NAT Example: Routed Mode

1. When the inside host at 10.1.2.27 sends a packet to a web server, the real source address of the packet, 10.1.2.27, is translated to a mapped address, 209.165.201.10.
2. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the Firewall Threat Defense receives the packet because the Firewall Threat Defense performs proxy ARP to claim the packet.

3. The Firewall Threat Defense then changes the translation of the mapped address, 209.165.201.10, back to the real address, 10.1.2.27, before sending it to the host.

NAT in transparent mode or within a bridge group



Using NAT in transparent mode eliminates the need for the upstream or downstream routers to perform NAT for their networks. It can perform a similar function within a bridge group in routed mode.

NAT in transparent mode, or in routed mode between members of the same bridge group, has the following requirements and limitations:

- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- ARP inspection is not supported. Moreover, if for some reason a host on one side of the Firewall Threat Defense sends an ARP request to a host on the other side of the Firewall Threat Defense, and the initiating host real address is mapped to a different address on the same subnet, then the real address remains visible in the ARP request.
- Translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.

The following figure shows a typical NAT scenario in transparent mode, with the same network on the inside and outside interfaces. The transparent firewall in this scenario is performing the NAT service so that the upstream router does not have to perform NAT.

Figure 372: NAT Example: Transparent Mode

1. When the inside host at 10.1.1.75 sends a packet to a web server, the real source address of the packet, 10.1.1.75, is changed to a mapped address, 209.165.201.15.

2. When the server responds, it sends the response to the mapped address, 209.165.201.15, and the Firewall Threat Defense receives the packet because the upstream router includes this mapped network in a static route directed to the Firewall Threat Defense management IP address.
3. The Firewall Threat Defense then undoes the translation of the mapped address, 209.165.201.15, back to the real address, 10.1.1.1.75. Because the real address is directly-connected, the Firewall Threat Defense sends it directly to the host.
4. For host 192.168.1.2, the same process occurs, except for returning traffic, the Firewall Threat Defense looks up the route in its routing table and sends the packet to the downstream router at 10.1.1.3 based on the Firewall Threat Defense static route for 192.168.1.0/24.

Auto NAT and Manual NAT

You can implement address translation in two ways: *auto NAT* and *manual NAT*.

We recommend using auto NAT unless you need the extra features that manual NAT provides. It is easier to configure auto NAT, and it might be more reliable for applications such as Voice over IP (VoIP). (For VoIP, you might see a failure in the translation of indirect addresses that do not belong to either of the objects used in the rule.)

Auto NAT

All NAT rules that are configured as a parameter of a network object are considered to be *auto NAT* rules. This is a quick and easy way to configure NAT for a network object. You cannot create these rules for a group object, however.

Although these rules are configured as part of the object itself, you cannot see the NAT configuration in the object definition through the object manager.

When a packet enters an interface, both the source and destination IP addresses are checked against the auto NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that sourceA/destinationA should have a different translation than sourceA/destinationB. Use manual NAT for that kind of functionality, where you can identify the source and destination address in a single rule.

Manual NAT

Manual NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that sourceA/destinationA can have a different translation than sourceA/destinationB.

Note For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address. For example, if you configure static NAT with port address translation, and specify the source address as a Telnet server, and you want all traffic going to that Telnet server to have the port translated from 2323 to 23, then you must specify the *source* ports to be translated (real: 23, mapped: 2323). You specify the source ports because you specified the Telnet server address as the source address.

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

Comparing Auto NAT and Manual NAT

The main differences between these two NAT types are:

- How you define the real address.
  - Auto NAT—The NAT rule becomes a parameter for a network object. The network object IP address serves as the original (real) address.
  - Manual NAT—You identify a network object or network object group for both the real and mapped addresses. In this case, NAT is not a parameter of the network object; the network object or group is a parameter of the NAT configuration. The ability to use a network object *group* for the real address means that manual NAT is more scalable.
- How source and destination NAT is implemented.
  - Auto NAT— Each rule can apply to either the source or destination of a packet. So two rules might be used, one for the source IP address, and one for the destination IP address. These two rules cannot be tied together to enforce a specific translation for a source/destination combination.
  - Manual NAT—A single rule translates both the source and destination. A packet matches one rule only, and further rules are not checked. Even if you do not configure the optional destination address, a matching packet still matches one manual NAT rule only. The source and destination are tied together, so you can enforce different translations depending on the source/destination combination. For example, sourceA/destinationA can have a different translation than sourceA/destinationB.
- Order of NAT Rules.
  - Auto NAT—Automatically ordered in the NAT table.
  - Manual NAT—Manually ordered in the NAT table (before or after auto NAT rules).

NAT rule order

Auto NAT and manual NAT rules are stored in a single table that is divided into three sections. Section 1 rules are applied first, then section 2, and finally section 3, until a match is found. For example, if a match is found in section 1, sections 2 and 3 are not evaluated. The following table shows the order of rules within each section.

Note There is also a Section 0, which contains any NAT rules that the system creates for its own use. These rules have priority over all others. The system automatically creates these rules and clears xlates as needed. You cannot add, edit, or modify rules in Section 0.

Table 73: NAT Rule Table

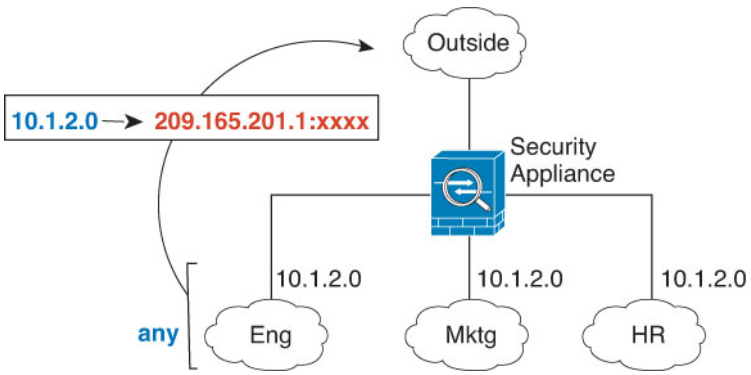
Table Section	Rule Type	Order of Rules within the Section
Section 1	Manual NAT	Applied on a first match basis, in the order they appear in the configuration. Because the first match is applied, you must ensure that specific rules come before more general rules, or the specific rules might not be applied as desired. By default, manual NAT rules are added to section 1. By "specific rules first," we mean: • Static rules should come before dynamic rules. • Rules that include destination translation should come before rules with source translation only. If you cannot eliminate overlapping rules, where more than one rule might apply based on the source or destination address, be especially careful to follow these recommendations. If you do not follow the above recommendation, ensure that accurate routes are configured for the mapped addresses to match the correct NAT rule.
Section 2	Auto NAT	If a match in section 1 is not found, section 2 rules are applied in the following order: **1.** Static rules. **2.** Dynamic rules. **Within each rule type, the following ordering guidelines are used:** **1.** Quantity of real IP addresses—From smallest to largest. For example, an object with one address will be assessed before an object with 10 addresses. **2.** For quantities that are the same, then the IP address number is used, from lowest to highest. For example, 10.1.1.0 is assessed before 11.1.1.0. **3.** If the same IP address is used, then the name of the network object is used, in alphabetical order. For example, abracadabra is assessed before catwoman.
Section 3	Manual NAT	If a match is still not found, section 3 rules are applied on a first match basis, in the order they appear in the configuration. This section should contain your most general rules. You must also ensure that any specific rules in this section come before general rules that would otherwise apply.

For section 2 rules, for example, you have the following IP addresses defined within network objects:

- 192.168.1.0/24 (static)

- 192.168.1.0/24 (dynamic)
- 10.1.1.0/24 (static)
- 192.168.1.1/32 (static)
- 172.16.1.0/24 (dynamic) (object def)
- 172.16.1.0/24 (dynamic) (object abc)

The resultant ordering would be:



- 192.168.1.1/32 (static)
- 10.1.1.0/24 (static)
- 192.168.1.0/24 (static)
- 172.16.1.0/24 (dynamic) (object abc)
- 172.16.1.0/24 (dynamic) (object def)
- 192.168.1.0/24 (dynamic)

NAT interfaces

Except for bridge group member interfaces, you can configure a NAT rule to apply to any interface (in other words, all interfaces), or you can identify specific real and mapped interfaces. You can also specify any interface for the real address, and a specific interface for the mapped address, or vice versa.

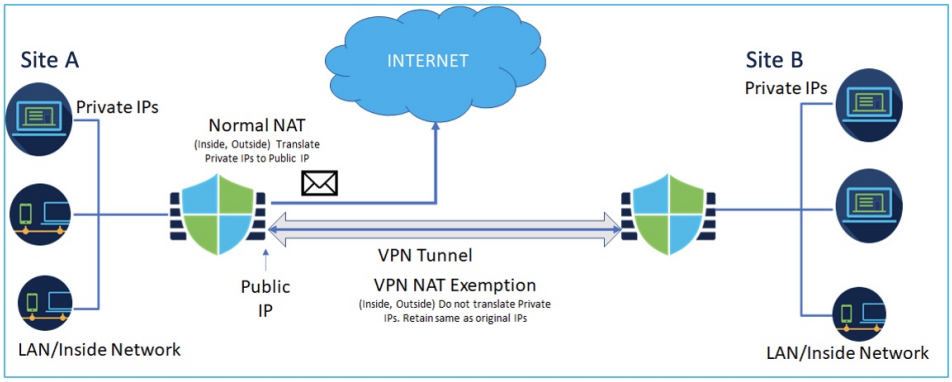
For example, you might want to specify any interface for the real address and specify the outside interface for the mapped address if you use the same private addresses on multiple interfaces, and you want to translate them all to the same global pool when accessing the outside.

Figure 373: Specifying Any Interface

However, the concept of "any" interface does not apply to bridge group member interfaces. When you specify "any" interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. This could result in many similar rules where only one interface is different. You cannot configure NAT for the Bridge Virtual Interface (BVI) itself, you can configure NAT for member interfaces only.

Note You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. When specifying interfaces, you do so indirectly by selecting the interface object that contains the interface.

NAT exemption



When internet edge devices have a site-to-site VPN configured on an interface and also have NAT rules for that interface, you must exempt the VPN traffic from the NAT rules. If you do not exempt the VPN traffic from NAT translation, the traffic gets dropped or is not routed through the VPN tunnel to the remote peer.

NAT exemption allows you to exclude traffic from being translated by NAT rules. When you create a policy-based site-to-site VPN using the Firewall Management Center VPN wizard, you can select the **NAT Exempt** option to create the rules automatically (**Devices** > **VPN** > **Site to Site**). By default, this option is enabled. You can view the NAT exemptions for a device in the NAT policy page (**Devices** > **NAT**, and then click **NAT Exemptions**).

The Firewall Management Center supports NAT exemption for all policy-based site-to-site VPN topology types. For more information, see Configure a policy-based site-to-site VPN, on page 1351.

Consider the following example, which shows a site-to-site VPN tunnel connecting Site A and Site B. For traffic that must go to the Internet, NAT translates the private IPs to a public IP address to access the Internet. For traffic that must go over the VPN tunnel, you must configure NAT exemption for the device in the VPN wizard.

Figure 374: Site-to-site VPN Topology with NAT Exemption

Note that when you upgrade from versions earlier than 7.4, if you have enabled NAT exemption, Firewall Management Center will disable this option. You must enable this option in the policy-based site-to-site VPN wizard.

Configuring routing for NAT

The Firewall Threat Defense device needs to be the destination for any packets sent to the translated (mapped) address.

When sending packets, the device uses the destination interface if you specify one, or a routing table lookup if you do not, to determine the egress interface. For identity NAT, you have the option to use a route lookup even if you specify a destination interface.

The type of routing configuration needed depends on the type of mapped address, as explained in the following topics.

Addresses on the same network as the mapped interface

If you use addresses on the same network as the destination (mapped) interface, the Firewall Threat Defense uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the Firewall Threat Defense does not have to be the gateway for any additional networks. This solution is ideal if the outside network contains an adequate number of free addresses, a consideration if you are using a 1:1 translation like dynamic NAT or static NAT. Dynamic PAT greatly extends the number of translations you can use with a small number of addresses, so even if the available addresses on the outside network is small, this method can be used. For PAT, you can even use the IP address of the mapped interface.

Note If you configure the mapped interface to be any interface, and you specify a mapped address on the same network as one of the mapped interfaces, then if an ARP request for that mapped address comes in on a *different* interface, then you need to manually configure an ARP entry for that network on the ingress interface, specifying its MAC address. Typically, if you specify any interface for the mapped interface, then you use a unique network for the mapped addresses, so this situation would not occur. Configure the ARP table in the ingress interface's **Advanced** settings.

Addresses on a unique network

If you need more addresses than are available on the destination (mapped) interface network, you can identify addresses on a different subnet. The upstream router needs a static route for the mapped addresses that points to the Firewall Threat Defense.

Alternatively for routed mode, you can configure a static route on the Firewall Threat Defense for the mapped addresses using any IP address on the destination network as the gateway, and then redistribute the route using your routing protocol. For example, if you use NAT for the inside network (10.1.1.0/24) and use the mapped IP address 209.165.201.5, then you can configure a static route for 209.165.201.5 255.255.255.255 (host address) to the 10.1.1.99 gateway that can be redistributed.

For transparent mode, if the real host is directly-connected, configure the static route on the upstream router to point to the Firewall Threat Defense: specify the bridge group IP address. For remote hosts in transparent mode, in the static route on the upstream router, you can alternatively specify the downstream router IP address.

The same address as the real address (identity NAT)

The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired. You can also disable proxy ARP for regular static NAT if desired, in which case you need to be sure to have proper routes on the upstream router.

Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues. For example, if you configure a broad identity NAT rule for “any” IP address, then leaving proxy ARP enabled can cause problems for hosts on the network directly connected to the mapped interface. In this case, when a host on the mapped network wants to communicate with another host on the same network, then the address in the ARP request matches the NAT rule (which matches “any” address). The Firewall Threat Defense will then proxy ARP for the address, even though the packet is not actually destined for the Firewall Threat Defense. (Note that this problem occurs even if you have a manual NAT rule; although the NAT rule must match both the source and destination addresses, the proxy ARP decision is made only on the “source” address). If the

Firewall Threat Defense ARP response is received before the actual host ARP response, then traffic will be mistakenly sent to the Firewall Threat Defense.

Requirements and prerequisites for NAT policies

Ensure you meet these requirements for configuring NAT policies:

Supported domains

Any

User roles

You must have one of these user privileges to configure and use NAT policies:

- Admin
- Access Admin
- Network Admin

Guidelines for NAT

The following topics provide detailed guidelines for implementing NAT.

Firewall mode guidelines for NAT

NAT is supported in routed and transparent firewall mode.

However, configuring NAT on bridge group member interfaces (interfaces that are part of a Bridge Group Virtual Interface, or BVI) has the following restrictions:

- When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself.
- When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify “any” as the interface.
- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- You cannot translate between IPv4 and IPv6 networks (NAT64/46) when the source and destination interfaces are members of the same bridge group. Static NAT/PAT 44/66, dynamic NAT44/66, and dynamic PAT44 are the only allowed methods; dynamic PAT66 is not supported. However, you can do NAT64/46 between members of different bridge groups, or between a bridge group member (source) and standard routed interface (destination).

Note You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes.

IPv6 NAT guidelines

NAT supports IPv6 with the following guidelines and restrictions.

- For standard routed mode interfaces, you can also translate between IPv4 and IPv6.
- You cannot translate between IPv4 and IPv6 for interfaces that are members of the same bridge group. You can translate between two IPv6 or two IPv4 networks only. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.
- You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.
- For static NAT, you can specify an IPv6 subnet up to /64. Larger subnets are not supported.
- When using FTP with NAT46, when an IPv4 FTP client connects to an IPv6 FTP server, the client must use either the extended passive mode (EPSV) or extended port mode (EPRT); PASV and PORT commands are not supported with IPv6.

IPv6 NAT best practices

You can use NAT to translate between IPv6 networks, and also to translate between IPv4 and IPv6 networks (routed mode only). We recommend the following best practices:

- NAT66 (IPv6-to-IPv6)—We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only).
- NAT46 (IPv4-to-IPv6)—We recommend using static NAT. Because the IPv6 address space is so much larger than the IPv4 address space, you can easily accommodate a static translation. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only). When translating to an IPv6 subnet (/96 or lower), the resulting mapped address is by default an IPv4-embedded IPv6 address, where the 32-bits of the IPv4 address is embedded after the IPv6 prefix. For example, if the IPv6 prefix is a /96 prefix, then the IPv4 address is appended in the last 32-bits of the address. For example, if you map 192.168.1.0/24 to 201b::0/96, then 192.168.1.4 will be mapped to 201b::0.192.168.1.4 (shown with mixed notation). If the prefix is smaller, such as /64, then the IPv4 address is appended after the prefix, and a suffix of 0s is appended after the IPv4 address. You can also optionally translate the addresses net-to-net, where the first IPv4 address maps to the first IPv6 address, the second to the second, and so on.
- NAT64 (IPv6-to-IPv4)—You may not have enough IPv4 addresses to accommodate the number of IPv6 addresses. We recommend using a dynamic PAT pool to provide a large number of IPv4 translations.

NAT support for inspected protocols

Some application layer protocols that open secondary connections, or that embedded IP addresses in packets, are inspected to provide the following services:

- Pinhole creation—Some application protocols open secondary TCP or UDP connections either on standard or negotiated ports. Inspection opens pinholes for these secondary ports so that you do not need to create access control rules to allow them.

- NAT rewrite— Protocols such as FTP embed IP addresses and ports for the secondary connections in packet data as part of the protocol. If there is NAT translation involved for either of the endpoints, the inspection engines rewrite the packet data to reflect the NAT translation of the embedded addresses and ports. The secondary connections would not work without NAT rewrite.
- Protocol enforcement—Some inspections enforce some degree of conformance to the RFCs for the inspected protocol.

The following table lists the inspected protocols that apply NAT rewrite and their NAT limitations. Keep these limitations in mind when writing NAT rules that include these protocols. Inspected protocols not listed here do not apply NAT rewrite. These inspections include GTP, HTTP, IMAP, POP, SMTP, SSH, and SSL.

Note NAT rewrite is supported on the listed ports only. For some of these protocols, you can extend inspection to other ports using Network Analysis Policies, but NAT rewrite is not extended to those ports. This includes DCERPC, DNS, FTP, and Sun RPC inspection. If you use these protocols on non-standard ports, do not use NAT on the connections.

Table 74: NAT Supported Application Inspection

Application	Inspected Protocol, Port	NAT Limitations	Pinholes Created
DCERPC	TCP/135	No NAT64.	Yes
DNS over UDP	UDP/53	No NAT support is available for name resolution through WINS.	No
ESMTP	TCP/25	No NAT64.	No
FTP	TCP/21	(Clustering) No static PAT.	Yes
H.323 H.225 (Call signaling) H.323 RAS	TCP/1720 UDP/1718 For RAS, UDP/1718-1719	(Clustering) No static PAT. No extended PAT. No NAT64.	Yes
ICMP ICMP Error	ICMP (ICMP traffic directed to a device interface is never inspected.)	No limitations.	No
IP Options	RSVP	No NAT64.	No
NetBIOS Name Server over IP	UDP/137, 138 (Source ports)	No extended PAT. No NAT64.	No
RSH	TCP/514	No PAT. No NAT64. (Clustering) No static PAT.	Yes

Application	Inspected Protocol, Port	NAT Limitations	Pinholes Created
RTSP	TCP/554 (No handling for HTTP cloaking.)	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes
SIP	TCP/5060 UDP/5060	No extended PAT. No NAT64 or NAT46. (Clustering) No static PAT.	Yes
Skinny (SCCP)	TCP/2000	No extended PAT. No NAT64, NAT46, or NAT66. (Clustering) No static PAT.	Yes
SQL*Net (versions 1, 2)	TCP/1521	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes
Sun RPC	TCP/111 UDP/111	No extended PAT. No NAT64.	Yes
TFTP	UDP/69	No NAT64. (Clustering) No static PAT. Payload IP addresses are not translated.	Yes
XDMCP	UDP/177	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes

FQDN destination guidelines

You can specify the translated (mapped) destination in a manual NAT rule using a fully-qualified domain name (FQDN) network object instead of an IP address. For example, you can create a rule based on traffic that is destined for the www.example.com web server.

When using an FQDN, the system obtains the DNS resolution and writes the NAT rule based on the returned address. If you are using multiple DNS server groups, the filter domains are honored and the address is requested from the appropriate group based on the filters. If more than one address is obtained from the DNS server, the address used is based on the following:

- If there is an address on the same subnet as the specified interface, that address is used. If there isn't one on the same subnet, the first address returned is used.
- The IP type for the translated source and translated destination must match. For example, if the translated source address is IPv6, the FQDN object must specify IPv6 as the address type. If the translated source is IPv4, the FQDN object can specify IPv4 or both IPv4 and IPv6. In this case, an IPv4 address is selected.

You cannot include an FQDN object in a network group that is used for manual NAT destination. In NAT, an FQDN object must be used alone, as only a single destination host makes sense for this type of NAT rule.

If the FQDN cannot be resolved to an IP address, the rule is not functional until a DNS resolution is obtained.

Additional guidelines for NAT

- NAT rules apply to through the device traffic only, they do not apply to traffic initiated by the device, such as a RADIUS authentication.
- For interfaces that are members of a bridge group, you write NAT rules for the member interfaces. You cannot write NAT rules for the Bridge Virtual Interface (BVI) itself.
- You cannot write NAT rules for a Virtual Tunnel Interface (VTI), which are used in site-to-site VPN. Writing rules for the VTI's source interface will not apply NAT to the VPN tunnel. To write NAT rules that will apply to VPN traffic tunneled on a VTI, you must use "any" as the interface; you cannot explicitly specify interface names.
- (Auto NAT only.) You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules for an object, you need to create multiple objects with different names that specify the same IP address.
- If a VPN is defined on an interface, inbound ESP traffic on the interface is not subject to the NAT rules. The system allows the ESP traffic for established VPN tunnels only, dropping traffic not associated with an existing tunnel. This restriction applies to ESP and UDP ports 500 and 4500.
- If you define a site-to-site VPN on a device that is behind a device that is applying dynamic PAT, so that UDP ports 500 and 4500 are not the ones actually used, you must initiate the connection from the device that is behind the PAT device. The responder cannot initiate the security association (SA) because it does not know the correct port numbers.
- If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT configuration is used, you can clear the translation table using the **clear xlate** command in the device CLI. However, clearing the translation table disconnects all current connections that use translations.

  If you create a new NAT rule that should apply to an existing connection (such as a VPN tunnel), you need to use **clear conn** to end the connection. Then, the attempt to re-establish the connection should hit the NAT rule and the connection should be NAT'ed correctly.

Note If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the **clear xlate** or **clear conn** commands. This safeguard ensures that the same address is not assigned to multiple hosts.

- You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.
- A network object used in NAT cannot include more than 131,838 IP addresses, either explicitly or implied in a range of addresses or a subnet. Break up the address space into smaller ranges and write separate rules for the smaller objects.

- (Manual NAT only.) When using **any** as the source address in a NAT rule, the definition of "any" traffic (IPv4 vs. IPv6) depends on the rule. Before the Firewall Threat Defense performs NAT on a packet, the packet must be IPv6-to-IPv6 or IPv4-to-IPv4; with this prerequisite, the Firewall Threat Defense can determine the value of **any** in a NAT rule. For example, if you configure a rule from "any" to an IPv6 server, and that server was mapped from an IPv4 address, then **any** means "any IPv6 traffic." If you configure a rule from "any" to "any," and you map the source to the interface IPv4 address, then **any** means "any IPv4 traffic" because the mapped interface address implies that the destination is also IPv4.
- You can use the same mapped object or group in multiple NAT rules.
- The mapped IP address pool cannot include:
  - The mapped interface IP address. If you specify "any" interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), specify the interface name instead of the interface address.
  - The failover interface IP address.
  - (Transparent mode.) The management IP address.
  - (Dynamic NAT.) The standby interface IP address when VPN is enabled.
- Avoid using overlapping addresses in static and dynamic NAT policies. For example, with overlapping addresses, a PPTP connection can fail to get established if the secondary connection for PPTP hits the static instead of dynamic xlate.
- You cannot use overlapping addresses in the source address of a NAT rule and a remote access VPN address pool.
- If you specify a destination interface in a rule, then that interface is used as the egress interface rather than looking up the route in the routing table. However, for identity NAT, you have the option to use a route lookup instead.
- If you use PAT on Sun RPC traffic, which is used to connect to NFS servers, be aware that the NFS server might reject connections if the PAT'ed port is above 1024. The default configuration of NFS servers is to reject connections from ports higher than 1024. The error is typically "Permission Denied." Mapping ports above 1024 happens if you do not select the option to include the reserved ports (1-1023) in the port range of a PAT pool. You can avoid this problem by changing the NFS server configuration to allow all port numbers.
- NAT applies to through traffic only. Traffic generated by the system is not subject to NAT.
- Do not name a network object or group pat-pool, using any combination of upper- or lower-case letters.
- The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.
- You cannot use NAT on the internal payload of Protocol Independent Multicast (PIM) registers.
- (Manual NAT) When writing NAT rules for a dual ISP interface setup (primary and backup interfaces using service level agreements in the routing configuration), do not specify destination criteria in the rule. Ensure the rule for the primary interface comes before the rule for the backup interface. This allows the device to choose the correct NAT destination interface based on the current routing state when the primary ISP is unavailable. If you specify destination objects, the NAT rule will always select the primary interface for the otherwise duplicate rules.

- If you get the ASP drop reason nat-no-xlate-to-pat-pool for traffic that should not match the NAT rules defined for the interface, configure identity NAT rules for the affected traffic so the traffic can pass untranslated.
- If you configure NAT for GRE tunnel endpoints, you must disable keepalives on the endpoints or the tunnel cannot be established. The endpoints send keepalives to the original addresses.
- DHCP and BOOTP share ports UDP/67-68. Because BOOTP is obsolete, writing NAT rules for the bootps port can cause port allocation problems when also running DHCP. Consider using DHCP relay instead for transmitting DHCP requests between network segments.
- In rare cases, return traffic (server to client) with an existing translation (xlate) might be logged as a new flow in Connection Events. This can occur when the client has already terminated the connection and the server sends another packet that reaches the device during the brief interval between connection closure and xlate removal, often due to application behavior or TCP stack cleanup. Because the device removes the xlate only after deleting the connection, a server packet can arrive while the xlate still exists. If no valid connection entry is found, the device logs a separate connection event based on the matched Access Control Policy rule.

Manage NAT policies

NAT converts the IP address of an incoming packet to a different address in the outgoing packet. One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into routable addresses that can be used on the public Internet. NAT keeps track of the translations, also known as xlates, to ensure that return traffic is directed to the correct untranslated host address.

Procedure

Step 1 Choose **Devices** > **NAT**.

Step 2 Manage your NAT policies:

- Create—Click **New Policy** and select **Threat Defense NAT**. Refer to Create NAT policies, on page 1204.
- Copy—Click **Copy** ( ) next to the policy you want to copy. You are prompted to give the copy a new, unique name. The copy includes all policy rules and configurations, but does not include device assignments.
- Report—Click **Report** ( ) for the policy. You are prompted to save the PDF report, which includes policy attributes, device assignments, rules, and object usage information.
- Edit—Click **Edit** ( ) next to the policy you want to edit. Refer to Configure NAT for threat defense, on page 1205.
- Delete—Click **Delete** ( ) next to the policy you want to delete, then click **OK**. When prompted whether to continue, you are also informed if another user has unsaved changes in the policy.

Caution After you have deployed a NAT policy to a managed device, you cannot delete the policy from the device. Instead, you must deploy a NAT policy with no rules to remove the NAT rules already present on the managed device. You also cannot delete a policy that is the last deployed policy on any of its target devices, even if it is out of date. Before you can delete the policy completely, you must deploy a different policy to those targets.

Create NAT policies

Create a NAT policy to define how network addresses are translated between different network segments.

When you create a new NAT policy you must, at minimum, give it a unique name. Although you are not required to identify policy targets at policy creation time, you must perform this step before you can deploy the policy. If you apply a NAT policy with no rules to a device, the system removes all NAT rules from that device.

Procedure

Step 1 Choose **Devices** > **NAT**.

Step 2 Click **New Policy** and from the drop-down list, choose **Threat Defense NAT** for Firewall Threat Defense devices.

Firepower NAT is for older devices that are not covered in this document.

Step 3 Enter a unique **Name**.

Step 4 (Optional) Enter a **Description**.

Step 5 Choose the devices where you want to deploy the policy:

- Choose a device in the **Available Devices** list, and then click **Add to Policy**.

  Alternatively, click and drag a device from the **Available Devices** list to the **Selected Devices** list.

- Remove a device from the **Selected Devices** list by clicking **Delete** ( ) next to the device.

Step 6 Click **Save**.

Configure NAT policy targets

Identify the managed devices that you want to target with your policy while creating or editing a policy and assign NAT policies to identified devices to control NAT behavior. You can search a list of available devices and high-availability pairs, and add them to a list of selected devices.

Procedure

Step 1 Choose **Devices** > **NAT**.

Step 2 Click **Edit** ( ) next to the NAT policy you want to modify.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Click **Policy Assignments**.

Step 4 Do any of the following:

- To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add to Policy**. Alternatively, you can also drag and drop selected devices.
- To remove a device assignment, click **Delete** ( ) next to a device, high-availability pair, or device group in the **Selected Devices** list.

Step 5 Click **OK**.

Configure NAT for threat defense

The NAT policy is a shared policy. Assign it to devices that need similar NAT rules.

Each rule applies to a device if its interface objects (security zones or interface groups) include an interface for that device. When the interface objects include one or more interface for the device, the rule is deployed to the device. You can target subsets of devices within a shared policy by designing interface objects accordingly. Rules using the "any" interface object apply to all devices.

If you change an interface type to one not valid for NAT on an assigned device, the policy marks the interface as deleted. Click **Save** in the NAT policy to automatically remove the interface from the policy.

You can configure multiple NAT policies if groups of your devices require significantly different rules.

Procedure

Step 1 Select **Devices** > **NAT**.

- Click **New Policy** > **Threat Defense NAT** to create a new policy. Give the policy a name, optionally assign devices to it, and click **Save**.

  You can change device assignments later by editing the policy and clicking **Policy Assignments**.

- Click **Edit** ( ) to edit an existing threat defense NAT policy. Note that the page also shows Firepower NAT policies, which are not used by Firewall Threat Defense devices.

  If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Decide what kinds of rules you need.

You can create dynamic NAT, dynamic PAT, static NAT, and identity NAT rules. For an overview, refer to NAT types, on page 1188.

Step 3 Decide which rules should be implemented as manual or auto NAT.

For a comparison of these two implementation options, refer to Auto NAT and Manual NAT, on page 1191.

Step 4 Decide which rules should be custom per device.

Because you can assign a NAT policy to multiple devices, you can configure a single rule on many devices. However, you might have rules that should be interpreted differently by each device, or some rules that should apply to a subset of devices only.

Use interface objects to control on which devices a rule is configured. Then, use object overrides on network objects to customize the addresses used per device.

For detailed information, refer to Customize NAT rules for multiple devices, on page 1207.

Step 5 Create the rules as explained in these sections.

- Dynamic NAT, on page 1210
- Dynamic PAT, on page 1216
- Static NAT, on page 1226
- Identity NAT, on page 1235

Step 6 Do these to manage your NAT policy:

- To edit the policy name or description, click in those fields, type in your changes, and click outside the fields.
- To view only those rules that apply to a specific device, click **Filter by Device** and select the desired device. A rule applies to a device if it uses an interface object that includes an interface on the device.
- To view any warnings or errors in the policy, click **Show Warnings**, then choose a **Device**. Warnings and errors mark configurations that could adversely affect traffic flow or prevent the policy from deploying.
- To change the devices to which the policy is assigned, click the **Policy Assignments** link and modify the selected devices list as desired.
- To change the number of rules displayed on the page, use the **Rows Per Page** drop-down list.

Step 7 Do these to manage your NAT rules:

- To add a rule, click the **Add Rule** button.
- To edit a rule, click the **Edit** ( ) icon next to the rule.
- To delete a rule, click the **Delete** ( ) icon next to the rule.
- To enable or disable a rule, right-click the rule and choose **Enable** or **Disable** from the **State** menu. You can temporarily disable a rule without deleting it using these controls.
- To select more than one rule to enable, disable, or delete, click the checkbox for the rules, or the checkbox in the header, then perform the action.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Customize NAT rules for multiple devices

Because the NAT policy is shared, you can assign a given policy to more than one device. However, you can configure at most one auto NAT rule for a given object. Thus, if you want to configure different translations for an object based on the specific device doing the translation, you need to carefully configure the interface objects (security zones or interface groups) and define network object overrides for the translated address. The interface objects determine on which devices a rule gets configured. The network object overrides determine what IP addresses are used by a given device for that object.

Consider the following scenario:

- FTD-A and FTD-B have inside networks 192.168.1.0/24 attached to the interface named “inside.”
- On FTD-A, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.100.10.10 - 10.100.10.200 range when going to the “outside” interface.
- On FTD-B, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.200.10.10 - 10.200.10.200 range when going to the “outside” interface.

Do these steps to accomplish the above scenario. Although this example rule is for dynamic auto NAT, you can generalize the technique for any type of NAT rule.

Procedure

Step 1 Create the security zones for the inside and outside interfaces.

a) Choose **Objects** > **Object Management**.
b) Select **Interface** from the table of contents and click **Add** > **Security Zone**.

You can use interface groups instead of zones.

c) Configure the inside zone properties.

- **Name**—Enter a name, for example, **inside-zone**.
- **Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
- **Selected Interfaces**—Add the FTD-A/inside and FTD-B/inside interfaces to the selected list.

d) Click **Save**.
e) Click **Add** > **Security Zone** and define the outside zone properties.

- **Name**—Enter a name, for example, **outside-zone**.
- **Interface Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
- **Selected Interfaces**—Add the FTD-A/outside and FTD-B/outside interfaces to the selected list.

f) Click **Save**.

Step 2 Create the network object for the original inside network on the Object Management page.

a) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

b) Configure the inside network properties.

- **Name**—Enter a name, for example, **inside-network**.
- **Network**—Enter the network address, for example, **192.168.1.0/24**.

c) Click **Save**.

Step 3 Create the network object for the translated NAT pool and define overrides.

a) Click **Add Network** > **Add Object**.

b) Configure the NAT pool properties for FTD-A.

- **Name**—Enter a name, for example, **NAT-pool**.
- **Network**—Enter the range of addresses to include in the pool for FTD-A, for example, **10.100.10.10-10.100.10.200**.

c) Select **Allow Overrides**.

d) Click the **Overrides** heading to open the list of object overrides.

e) Click **Add** to open the Add Object Override dialog box.

f) Select FTD-B and **Add** it to the **Selected Devices** list.

g) Click **Override** and change **Network** to **10.200.10.10-10.200.10.200**.

h) Click **Add** to add the override to the device.

By defining an override for FTD-B, whenever the system configures this object on FTD-B, it will use the override value instead of the value defined in the original object.

i) Click **Save**.

Step 4 Configure the NAT rule.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside-zone.
- **Destination Interface Objects** = outside-zone.

Note The interface objects control on which devices the rule is configured. Because in this example the zones contain interfaces for FTD-A and FTD-B only, even if the NAT policy were assigned to additional devices, the rule would be deployed to those 2 devices only.

e) On **Translation**, configure the following:

- **Original Source** = inside-network object.
- **Translated Source** > **Address**= NAT-pool object.

f) Click **Save**.

You now have a single rule that will be interpreted differently for FTD-A and FTD-B, providing unique translations for the inside networks protected by each firewall.

Search and filter the NAT rule table

You can search and filter the NAT rule table to help you find rules that you need to modify or view. When you filter the table, only matching rules are shown. Note that although the rule numbers change to be sequentially 1, 2, and so forth, filtering does not change the actual rule number or the rule's location in the table relative to hidden rules. Filtering simply changes what you can see to help you locate rules that interest you.

When editing the NAT policy, you can use the fields above the table to do these types of search or filter:

- **Filter by Device**—Click **Filter by Device**, then select the devices whose rules you want to see and click **OK**. Whether a rule applies to a device is determined by the rule's interface constraints. If you specify a security zone or interface group for either the source or destination interface, the rule applies to a device if at least one interface for the device is in the zone or group. If a NAT rule applies to any source and any destination interface, then it applies to all devices.

  If you also do a text or multiple-attribute search, the results are constrained to the selected devices.

  To remove this filter, click **Filter by Device** and deselect the devices, or select **All**, and click **OK**.

- **Simple Text Search**—In the **Filter** box, type a string and press Enter. The string is compared to all values in the rules. For example, if you enter "network-object-1," which is the name of a network object, you would get rules that use the object in source, destination, and PAT pool attributes.

  For network and port objects, the string is also compared to the contents of the objects used in the rule. For example, if a PAT pool object includes the range 10.100.10.3-10.100.10.100, searching on either 10.100.10.3 or 10.100.10.100 (or a partial 10.100.10) will include rules that use that PAT pool object. However, the match must be exact: searching on 10.100.10.5 will not match this PAT pool object, even though the IP address is within the object's IP address range.

  To remove the filter, click the **x** on the right side of the Filter box.

- **Multiple-Attribute Search**—If a simple text search gives you too many hits, you can configure multiple values for the search. Click in the **Filter** box to open the list of attributes, then select or enter strings for the attributes you intend to search and click the **Filter** button. These attributes are the same as the ones you would configure within a NAT rule. The attributes are and'ed, so filtered results include only those rules that match all attributes you configured.

  - For binary attributes, such as the rule state (enabled/disabled), whether a PAT pool is configured (enabled/disabled), the direction of the rule (uni/bi), or rule type (static/dynamic), simply check or uncheck the boxes as appropriate. Select both boxes if you do not care about the attribute value. If you deselect both boxes, no rules will match the filter.

- For string attributes, type a full or partial string relevant to that attribute. These will be object names, either for security zones/interface groups, network objects, or port objects. It can also be the network or port object contents, which are matched the same way they are for simple text searches.

To remove the filter, click the **x** on the right side of the Filter box, or click in the Filter box to open the drop-down list, and click the Clear button.

Enable, disable, or delete multiple rules

You can enable or disable manual NAT rules, or delete any NAT rule, one by one. You can also select multiple rules and apply changes to all of them at once. Because enable/disable applies to manual NAT only, if you select a mix of rule types, you can delete them only. Note that when you enable or disable rules, it does not matter if you select some rules that were already enabled or disabled. For example, enabling an already enabled rule simply leaves the rule enabled.

Procedure

Step 1 Select **Devices** > **NAT**, and edit a threat defense NAT policy.

Step 2 (Optional) Filter the NAT rules to locate the ones you want to change.

Filtering is especially useful if you have a large NAT policy. For example, you could search on disabled rules to find ones that need to be enabled.

Step 3 Select the rules you want to change.

- Click the checkbox in the left column of the rule to select (or deselect) individual rules.
- Click the checkbox in the table header to select all the rules on the currently displayed page.

Your selection is preserved as you go from page to page. However, in practice, it makes most sense to perform your actions on the rules selected on a page before going to the next page.

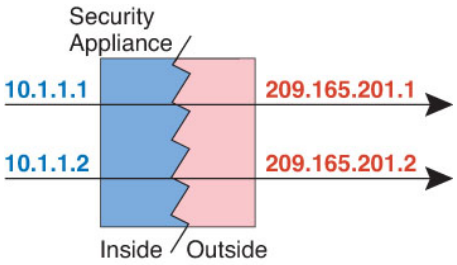
Step 4 Perform the desired action. When selecting multiple rules, you are asked to confirm the action.

Note that these actions are also available on the right-click menu.

- To enable all rules, click **Select Bulk Action** > **Enable**.
- To disable all rules, click **Select Bulk Action** > **Disable**.
- To delete all rules, click **Select Bulk Action** > **Delete**.

Dynamic NAT

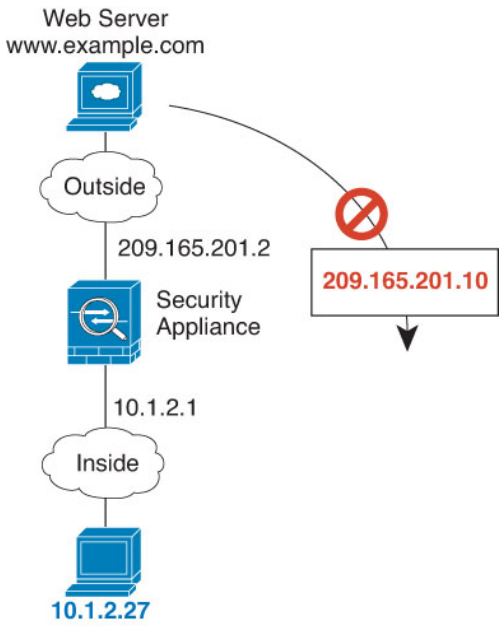
The following topics explain dynamic NAT and how to configure it.



About dynamic NAT

Dynamic NAT translates a group of real addresses to a pool of mapped addresses that are routable on the destination network. The mapped pool typically includes fewer addresses than the real group. When a host you want to translate accesses the destination network, NAT assigns the host an IP address from the mapped pool. The translation is created only when the real host initiates the connection. The translation is in place only for the duration of the connection, and a given user does not keep the same IP address after the translation times out. Users on the destination network, therefore, cannot initiate a reliable connection to a host that uses dynamic NAT, even if the connection is allowed by an access rule.

Note For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the address is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule. A successful connection from a remote host can reset the idle timer for the connection.



The following figure shows a typical dynamic NAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back.

Figure 375: Dynamic NAT

The following figure shows a remote host attempting to initiate a connection to a mapped address. This address is not currently in the translation table; therefore, the packet is dropped.

Figure 376: Remote Host Attempts to Initiate a Connection to a Mapped Address

Dynamic NAT disadvantages and advantages

Dynamic NAT has these disadvantages:

- If the mapped pool has fewer addresses than the real group, you could run out of addresses if the amount of traffic is more than expected.

  Use PAT or a PAT fall-back method if this event occurs often because PAT provides over 64,000 translations using ports of a single address.

- You have to use a large number of routable addresses in the mapped pool, and routable addresses may not be available in large quantities.

The advantage of dynamic NAT is that some protocols cannot use PAT. PAT does not work with the following:

- IP protocols that do not have a port to overload, such as GRE version 0.
- Some multimedia applications that have a data stream on one port, the control path on another port, and are not open standard.

Configure dynamic auto NAT

Use dynamic auto NAT rules to translate addresses to different IP addresses that are routable on the destination network.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.

- **Translated Source**—This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Dynamic**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The network object or group that contains the mapped addresses.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1296.
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure dynamic manual NAT

Use dynamic manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic NAT translates addresses to different IP addresses that are routable on the destination network.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—This can be a network object or group, but it cannot include a subnet. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

Procedure

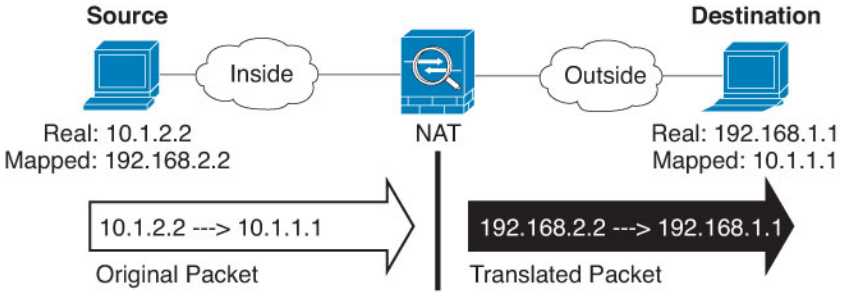
Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** () to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The network object or group that contains the mapped addresses.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the destination service ports for service translation: **Original Destination Port**, **Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

Step 8 (Optional.) On **Advanced**, select the desired options:

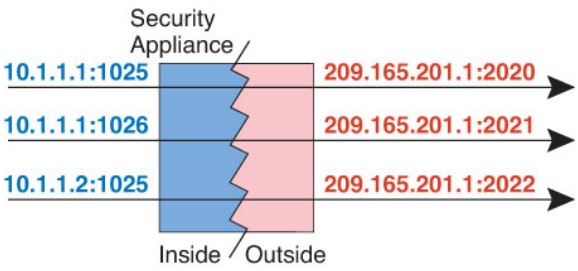
- (For source translation only.) **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1296.
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 9 Click **Save** to add the rule.

Step 10 Click **Save** on the NAT page to save your changes.

Dynamic PAT

The following topics describe dynamic PAT.



About dynamic PAT

Dynamic PAT translates multiple real addresses to a single mapped IP address by translating the real address and source port to the mapped address and a unique port.

Each connection requires a separate translation session because the source port differs for each connection. For example, 10.1.1.1:1025 requires a separate translation from 10.1.1.1:1026.

The following figure shows a typical dynamic PAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back. The mapped address is the same for each translation, but the port is dynamically assigned.

Figure 377: Dynamic PAT

For the duration of the translation, a remote host on the destination network can initiate a connection to the translated host if an access rule allows it. Because the port address (both real and mapped) is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

After the connection expires, the port translation also expires.

Note We recommend that you use different PAT pools for each interface. If you use the same pool for multiple interfaces, especially if you use it for "any" interface, the pool can be quickly exhausted, with no ports available for new translations.

Dynamic PAT disadvantages and advantages

Dynamic PAT lets you use a single mapped address, thus conserving routable addresses. You can even use the Firewall Threat Defense interface IP address as the PAT address.

You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.

Dynamic PAT does not work with some multimedia applications that have a data stream that is different from the control path. For more information, see NAT support for inspected protocols, on page 1198.

Dynamic PAT might also create a large number of connections appearing to come from a single IP address, and servers might interpret the traffic as a DoS attack. You can configure a PAT pool of addresses and use a round-robin assignment of PAT addresses to mitigate this situation.

PAT pool object guidelines

When creating network objects for a PAT pool, follow these guidelines.

For a PAT pool

- Ports are mapped to an available port in the 1024 to 65535 range. You can optionally include the reserved ports, those below 1024, to make the entire port range available for translations.

  When operating in a cluster, blocks of 512 ports per address are allocated to the members of the cluster, and mappings are made within these port blocks. If you also enable block allocation, the ports are distributed according to the block allocation size, whose default is also 512. If you change the cluster unit limit (the size of the cluster), ensure that you clear xlates or reboot the devices so that PAT pools can be appropriately reallocated to the cluster units.

- If you enable block allocation for a PAT pool, port blocks are allocated in the 1024-65535 range only. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host.

- If you use the same PAT pool object in two separate rules, then be sure to specify the same options for each rule. For example, if one rule specifies extended PAT, then the other rule must also specify extended PAT.

- If a host has an existing connection, then subsequent connections from that host use the same PAT IP address. If no ports are available, this can prevent the connection. Use the round robin option to avoid this problem.

- For best performance, limit the number of IP addresses within a PAT pool to 10,000.

For extended PAT for a PAT pool

- Many application inspections do not support extended PAT.
- If you enable extended PAT for a dynamic PAT rule, then you cannot also use an address in the PAT pool as the PAT address in a separate static NAT with port translation rule. For example, if the PAT pool includes 10.1.1.1, then you cannot create a static NAT-with-port-translation rule using 10.1.1.1 as the PAT address.
- If you use a PAT pool and specify an interface for fallback, you cannot specify extended PAT.
- For VoIP deployments that use ICE or TURN, do not use extended PAT. ICE and TURN rely on the PAT binding to be the same for all destinations.
- You cannot use extended PAT on units in a cluster.
- Extended PAT increases memory usage on the device.

For round robin for a PAT pool

- If a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. However, this "stickiness" does not survive a failover. If the device fails over, then subsequent connections from a host might not use the initial IP address.
- IP address "stickiness" is also impacted if you mix PAT pool/round robin rules with interface PAT rules on the same interface. For any given interface, choose either a PAT pool or interface PAT; do not create competing PAT rules.
- Round robin, especially when combined with extended PAT, can consume a large amount of memory. Because NAT pools are created for every mapped protocol/IP address/port range, round robin results in a large number of concurrent NAT pools, which use memory. Extended PAT results in an even larger number of concurrent NAT pools.

Configure dynamic auto PAT

Use dynamic auto PAT rules to translate addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object.
  - **Single PAT address**—Create a network object containing a single host.
  - **PAT pool**—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Dynamic**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Do not select the destination interface IP or a single address as the **Translated Source**.

Step 6 If you are using a PAT pool, select the **PAT Pool** page and do the following:

a) Select **Enable PAT pool**.

b) Select the network object group that contains the addresses for the pool in the **PAT** > **Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.
- **Flat Port Range**, **Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the Firewall Threat Defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.
- **Block Allocation**—To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Step 7 (Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address or PAT pool.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 8 Click **Save** to add the rule.

Step 9 Click **Save** on the NAT page to save your changes.

Configure dynamic manual PAT

Use dynamic manual PAT rules when auto PAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic PAT translates addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object.
  - **Single PAT address**—Create a network object containing a single host.
  - **PAT pool**—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

Procedure

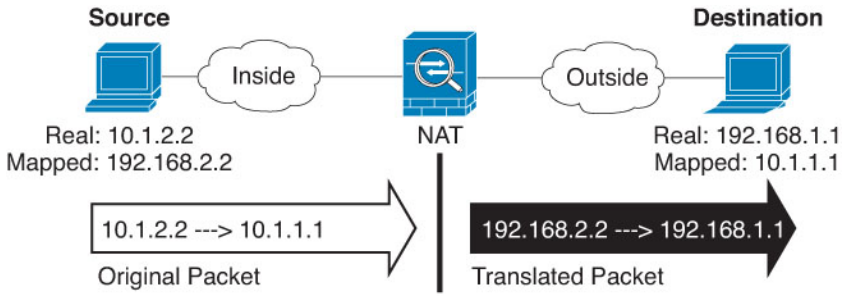
Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Do not select the destination interface IP or a single address as the **Translated Source**.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the destination service ports for service translation: **Original Destination Port**, **Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

Step 8 If you are using a PAT pool, select the **PAT Pool** page and do the following:

a) Select **Enable PAT pool**.

b) Select the network object group that contains the addresses for the pool in the **PAT** > **Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.
- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.
- **Flat Port Range**, **Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the Firewall Threat Defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.
- **Block Allocation**—To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Step 9 (Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 10 Click **Save** to add the rule.

Step 11 Click **Save** on the NAT page to save your changes.

Configure PAT with port block allocation

For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time (see RFC 6888). If you allocate a block of ports, subsequent connections from the host use new randomly-selected ports within the block. If necessary, additional blocks are allocated

if the host has active connections for all ports in the original block. Blocks are freed when the last xlate that uses a port in the block is removed.

The main reason for allocating port blocks is reduced logging. The port block allocation is logged, connections are logged, but xlates created within the port block are not logged. On the other hand, this makes log analysis more difficult.

Port blocks are allocated in the 1024-65535 range only. There are separate blocks for TCP, UDP, and ICMP connections, and these blocks can overlap. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host. You can create a separate NAT rule that does not use block allocation for applications that use low port numbers; for twice NAT, ensure the rule comes before the block allocation rule.

Before you begin

Usage notes for NAT rules:

- You can include the **Use Round Robin Allocation** option, but you cannot include the options for extending PAT uniqueness, using a flat range, including the reserved ports, or falling through to interface PAT. Other source/destination address and port information is also allowed.
- As with all NAT changes, if you replace an existing rule, you must clear xlates related to the replaced rule to have the new rule take effect. You can clear them explicitly or simply wait for them to time out. However, when operating in a cluster, you must reload the cluster so that the units can distribute blocks correctly.

Note If you are switching between a regular PAT and block allocation PAT rule, for object NAT, you must first delete the rule, then clear xlates. You can then create the new object NAT rule. Otherwise, you will see pat-port-block-state-mismatch drops in the **show asp drop** output.

- When you form a cluster while the device that will become the control node has an existing NAT policy that uses PAT pools, PAT port block distribution might not initialize correctly. The control node does not own or distribute the port blocks, and the **show nat pool cluster summary** command might show all port blocks as *RESERVED* on every cluster node.
  - Before forming a cluster, remove any existing NAT policy that uses PAT pools from the device that will become the control node. After cluster formation is complete, reconfigure and deploy the NAT policy.
  - If the cluster is already formed and all port blocks appear as *RESERVED*, delete the affected NAT policy and deploy the change. Then re-create and deploy the policy. Use the **show nat pool cluster summary** command to verify that the port blocks are distributed correctly across the cluster nodes.
- For a given PAT pool, you must specify (or not specify) block allocation for all rules that use the pool. You cannot allocate blocks in one rule and not in another. PAT pools that overlap also cannot mix block allocation settings. You also cannot overlap static NAT with port translation rules with the pool.

Procedure

Step 1 (Optional.) Configure global PAT port block allocation settings.

There are a few global settings that control port block allocation. If you want to change the defaults for these options, you must configure a FlexConfig object and add it to your FlexConfig policy.

a) Select **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object** and create a new object.

b) Configure the block allocation size, which is the number of ports in each block.

xlate block-allocation size *value*

The range is 32-4096. The default is 512. Use the "no" form to return to the default.

If you do not use the default, ensure that the size you choose divides evenly into 64,512 (the number of ports in the 1024-65535 range). Otherwise, there will be ports that cannot be used. For example, if you specify 100, there will be 12 unused ports.

Using the default block-allocation size, a single PAT IP can serve 126 unique, simultaneous users (number of ports 64,512 divided by 512).

c) Configure the maximum blocks that can be allocated per host.

xlate block-allocation maximum-per-host *number*

The limit is per protocol, so a limit of 4 means at most 4 UDP blocks, 4 TCP blocks, and 4 ICMP blocks per host. The range is 1-8, the default is 4. Use the "no" form to return to the default.

d) (Optional.) Enable interim syslog generation.

xlate block-allocation pba-interim-logging *seconds*

By default, the system generates syslog messages during port block creation and deletion. If you enable interim logging, the system generates the following message at the interval you specify. The messages report all active port blocks allocated at that time, including the protocol (ICMP, TCP, UDP) and source and destination interface and IP address, and the port block. You can specify an interval from 21600-604800 seconds (6 hours to 7 days).

%ASA-6-305017: Pba-interim-logging: Active *protocol* block of ports for translation from *real_interface*:*real_host_ip* to *mapped_interface*:*mapped_ip_address*/*start_port_num*-*end_port_num*

Example:

The following example sets the block allocation size to 64, the per-host maximum to 8, and enables interim logging every 6 hours.

```
xlate block-allocation size 64
xlate block-allocation maximum-per-host 8
xlate block-allocation pba-interim-logging 21600
```

e) Select the following options in the FlexConfig object:

- **Deployment** = **Everytime**
- **Type** = **Append**

f) Click **Save** to create the FlexConfig object.

g) Select **Devices** > **FlexConfig**, and create or edit the FlexConfig policy that is assigned to the devices that need to have these settings adjusted.
h) Select your object in the available objects list and click > to move it to the selected objects list.
i) Click **Save**.

You can click **Preview Config**, select one of the target devices, and verify that the xlate commands appear correctly.

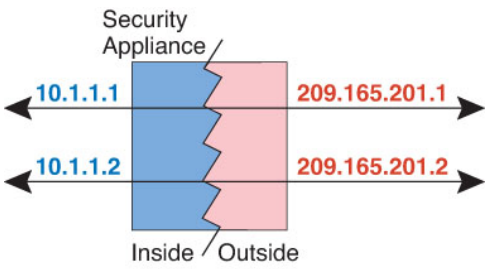
Step 2 Add NAT rules that use PAT pool port block allocation.

a) Select **Devices** > **NAT** and add or edit the threat defense NAT policy.
b) Add or edit a NAT rule and configure at least the following options.

- **Type** = **Dynamic**
- In **Translation** > **Original Source**, select the object that defines the source address.
- On **PAT Pool**, configure the following options:
  - Select **Enable PAT Pool**
  - In **PAT** > **Address**, select a network object or group that defines the pat pool.
  - Select the **Block Allocation** option.

c) Save your changes to the rule and to the NAT policy.

Static NAT



The following topics explain static NAT and how to implement it.

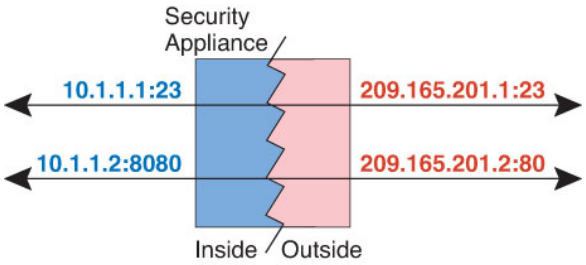
About static NAT

Static NAT creates a fixed translation of a real address to a mapped address. Because the mapped address is the same for each consecutive connection, static NAT allows bidirectional connection initiation, both to and from the host (if an access rule exists that allows it). With dynamic NAT and PAT, on the other hand, each host uses a different address or port for each subsequent translation, so bidirectional initiation is not supported.

The following figure shows a typical static NAT scenario. The translation is always active so both real and remote hosts can initiate connections.

Figure 378: Static NAT

Note You can disable bidirectionality if desired.



Static NAT with port translation

Static NAT with port translation lets you specify a real and mapped protocol and port.

When you specify the port with static NAT, you can choose to map the port and/or the IP address to the same value or to a different value.

The following figure shows a typical static NAT with port translation scenario showing both a port that is mapped to itself and a port that is mapped to a different value; the IP address is mapped to a different value in both cases. The translation is always active so both translated and remote hosts can initiate connections.

Figure 379: Typical Static NAT with Port Translation Scenario

Static NAT-with-port-translation rules limit access to the destination IP address for the specified port only. If you try to access the destination IP address on a different port not covered by a NAT rule, then the connection is blocked. In addition, for manual NAT, traffic that does not match the source IP address of the NAT rule will be dropped if it matches the destination IP address, regardless of the destination port. Therefore, you must add additional rules for all other traffic allowed to the destination IP address. For example, you can configure a static NAT rule for the IP address, without port specification, and place it after the port translation rule.

Note For applications that require application inspection for secondary channels (for example, FTP and VoIP), NAT automatically translates the secondary ports.

Following are some other uses of static NAT with port translation.

Static NAT with Identity Port Translation

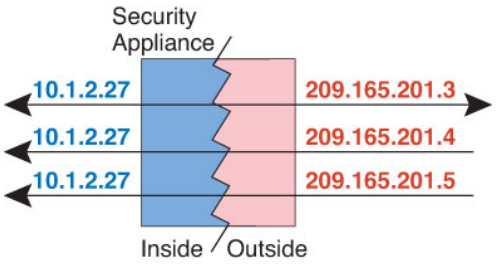
You can simplify external access to internal resources. For example, if you have three separate servers that provide services on different ports (such as FTP, HTTP, and SMTP), you can give external users a single IP address to access those services. You can then configure static NAT with identity port translation to map the single external IP address to the correct IP addresses of the real servers based on the port they are trying to access. You do not need to change the port, because the servers are using the standard ones (21, 80, and 25 respectively).

Static NAT with Port Translation for Non-Standard Ports

You can also use static NAT with port translation to translate a well-known port to a non-standard port or vice versa. For example, if inside web servers use port 8080, you can allow outside users to connect

to port 80, and then undo translation to the original port 8080. Similarly, to provide extra security, you can tell web users to connect to non-standard port 6785, and then undo translation to port 80.

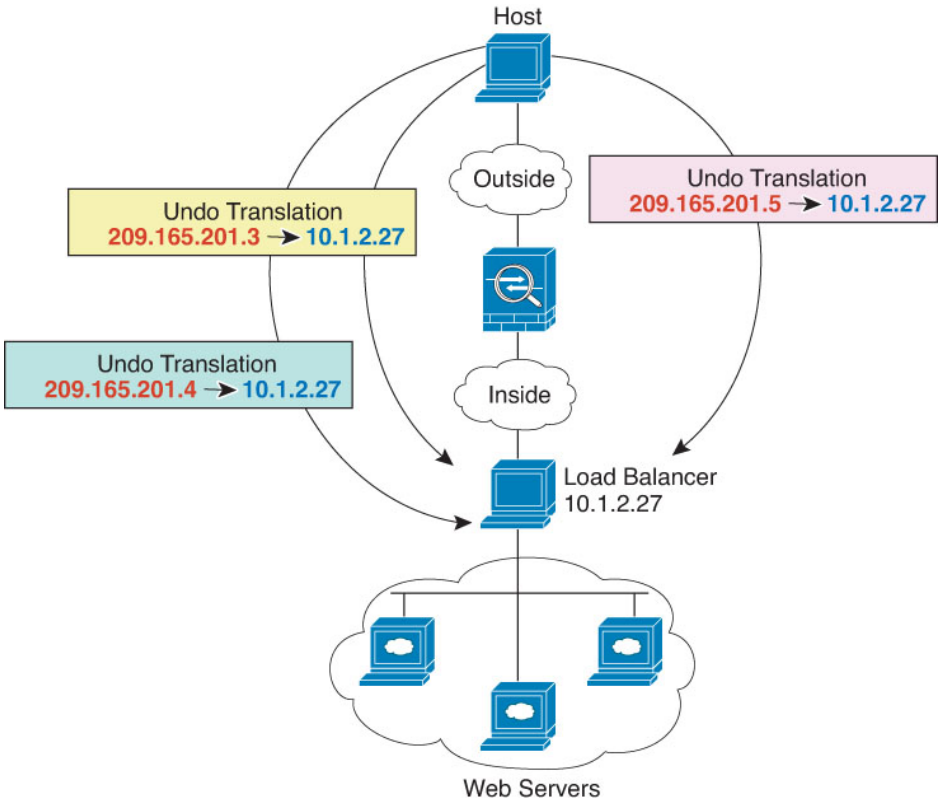
Static Interface NAT with Port Translation



You can configure static NAT to map a real address to an interface address/port combination. For example, if you want to redirect Telnet access for the device's outside interface to an inside host, then you can map the inside host IP address/port 23 to the outside interface address/port 23.

One-to-many static NAT

Typically, you configure static NAT with a one-to-one mapping. However, in some cases, you might want to configure a single real address to several mapped addresses (one-to-many). When you configure one-to-many static NAT, when the real host initiates traffic, it always uses the first mapped address. However, for traffic initiated to the host, you can initiate traffic to any of the mapped addresses, and they will be untranslated to the single real address.

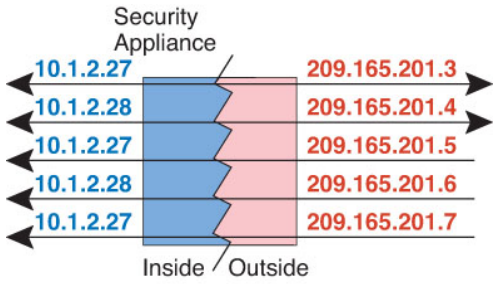


The following figure shows a typical one-to-many static NAT scenario. Because initiation by the real host always uses the first mapped address, the translation of real host IP/first mapped IP is technically the only bidirectional translation.

Figure 380: One-to-Many Static NAT

For example, you have a load balancer at 10.1.2.27. Depending on the URL requested, it redirects traffic to the correct web server.

Figure 381: One-to-Many Static NAT Example



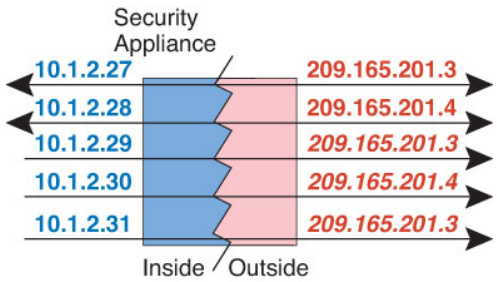
Other mapping scenarios (not recommended)

NAT has the flexibility to allow any kind of static mapping scenario: one-to-one, one-to-many, but also few-to-many, many-to-few, and many-to-one mappings. We recommend using only one-to-one or one-to-many mappings. These other mapping options might result in unintended consequences.

Functionally, few-to-many is the same as one-to-many; but because the configuration is more complicated and the actual mappings may not be obvious at a glance, we recommend creating a one-to-many configuration for each real address that requires it. For example, for a few-to-many scenario, the few real addresses are mapped to the many mapped addresses in order (A to 1, B to 2, C to 3). When all real addresses are mapped, the next mapped address is mapped to the first real address, and so on until all mapped addresses are mapped (A to 4, B to 5, C to 6). This results in multiple mapped addresses for each real address. Just like a one-to-many configuration, only the first mappings are bidirectional; subsequent mappings allow traffic to be initiated *to* the real host, but all traffic *from* the real host uses only the first mapped address for the source.

The following figure shows a typical few-to-many static NAT scenario.

Figure 382: Few-to-Many Static NAT



For a many-to-few or many-to-one configuration, where you have more real addresses than mapped addresses, you run out of mapped addresses before you run out of real addresses. Only the mappings between the lowest real IP addresses and the mapped pool result in bidirectional initiation. The remaining higher real addresses can initiate traffic, but traffic cannot be initiated to them (returning traffic for a connection is directed to the correct real address because of the unique 5-tuple (source IP, destination IP, source port, destination port, protocol) for the connection).

Note Many-to-few or many-to-one NAT is not PAT. If two real hosts use the same source port number and go to the same outside server and the same TCP destination port, and both hosts are translated to the same IP address, then both connections will be reset because of an address conflict (the 5-tuple is not unique).

The following figure shows a typical many-to-few static NAT scenario.

Figure 383: Many-to-Few Static NAT

Instead of using a static rule this way, we suggest that you create a one-to-one rule for the traffic that needs bidirectional initiation, and then create a dynamic rule for the rest of your addresses.

Configure static auto NAT

Use static auto NAT rules to translate addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.

- **Translated Source**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
  - **Address**—Create a network object or group containing hosts, ranges, or subnets. A group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Static**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.

- (Optional.) **Original Port**, **Translated Port**—If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1296. This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure static manual NAT

Use static manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Static NAT translates addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.

- **Address**—Create a network object or group containing hosts, range, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports.

Procedure

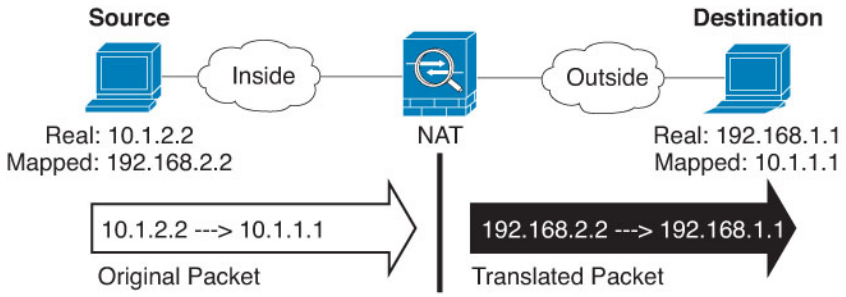
Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Static**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

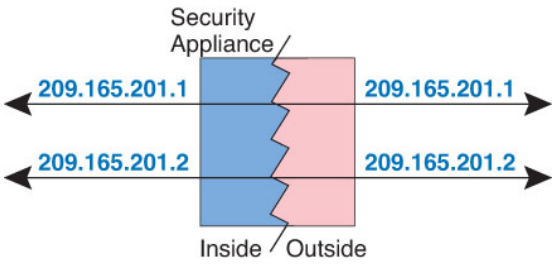
NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port**, **Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port**, **Translated Destination Port**—Defines a port translation for the destination address.

Step 8 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1296. This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Step 9 Click **Save** to add the rule.



Step 10 Click **Save** on the NAT page to save your changes.

Identity NAT

You might have a NAT configuration in which you need to translate an IP address to itself. For example, if you create a broad rule that applies NAT to every network, but want to exclude one network from NAT, you can create a static NAT rule to translate that network to itself.

The following figure shows a typical identity NAT scenario.

Figure 384: Identity NAT

The following topics explain how to configure identity NAT.

Configure identity auto NAT

Use static identity auto NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—A network object or group with the exact same contents as the original source object. You can use the same object.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Static**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Do not configure the **Original Port** and **Translated Port** options for identity NAT.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Do not configure this option for identity NAT.
- **Net to Net Mapping**—Do not configure this option for identity NAT.

- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**— If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure identity manual NAT

Use static identity manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Use static identity NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—The same object or group as the original source. Optionally, you can select a different object that has the exact same contents.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports. You can use the same object for identity NAT.

Procedure

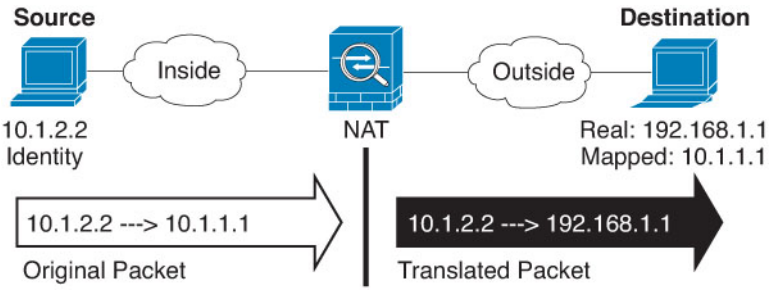
Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Static**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet where you perform identity NAT on the inside host but translate the outside host.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Interface Object** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The same object or group as the original source. Optionally, you can select a different object that has the exact same contents.

- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port**, **Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port**, **Translated Destination Port**—Defines a port translation for the destination address.

Step 8 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**— If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.
- **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Step 9 Click **Save** to add the rule.

Step 10 Click **Save** on the NAT page to save your changes.

NAT rule properties for Firewall Threat Defense

Use network address translation (NAT) rules to translate IP addresses to other IP addresses. You would typically use NAT rules to convert private addresses to publicly routable addresses. The translation can be from one address to another, or you can use port address translation (PAT) to translate many addresses to one or a few addresses, using port numbers to distinguish among the source addresses.

NAT rules include the following basic properties. The properties are the same for auto NAT and manual NAT rules except where indicated.

NAT Type

Whether you want to configure a **Manual NAT Rule** or an **Auto NAT Rule**. Auto NAT translates the source address only, and you cannot make different translations based on the destination address. Because auto NAT is more simple to configure, use it unless you need the added features of manual NAT. For more information on the differences, see Auto NAT and Manual NAT, on page 1191.

Type

Whether the translation rule is **Dynamic** or **Static**. Dynamic translation automatically chooses the mapped address from a pool of addresses, or an address/port combination when implementing PAT. Use static translation if you want to precisely define the mapped address/port.

Enable (Manual NAT only.)

Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page. You cannot disable auto NAT rules.

Insert (Manual NAT only.)

Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Description (Optional. Manual NAT only.)

A description of the purpose of the rule.

The following topics describe the tabs for the NAT rules properties.

Interface objects NAT properties

Interface objects (security zones or interface groups) define the interfaces to which a NAT rule applies. In routed mode, you can use the default "any" for both source and destination to apply to all interfaces of all assigned devices. However, you typically want to select specific source and destination interfaces.

Notes

- The concept of “any” interface does not apply to bridge group member interfaces. When you specify “any” interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. You cannot configure NAT for the bridge virtual interface (BVI) itself, you can configure NAT for member interfaces only.

  If you select interface objects, a NAT rule will be configured on an assigned device only if the device has interfaces included in all selected objects. For example, if you select both source and destination security zones, both zones must contain one or more interface for a given device.

- If more than one interface in an interface object exists on a given device, identical rules are created for each interface. This can become an issue for static NAT rules that include destination translation. Because NAT rules are applied based on first hit rule, only the rule created for the first interface configured for the object matches traffic. When configuring static NAT with destination translation, use interface objects that include at most one interface per device assigned to the NAT policy to ensure you are getting the desired results.

Source Interface Objects, Destination Interface Objects

(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped

interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Translation properties for auto NAT

Use the **Translation** options to define the source addresses and the mapped translated addresses. The following properties apply to auto NAT only.

Original Source (Always required.)

The network object that contains the addresses you are translating. This must be a network object (not a group), and it can be a host, range, or subnet.

You cannot create auto NAT rules for the system-defined any-ipv4 or any-ipv6 objects.

Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.
- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Do not configure a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.
- **Static NAT**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Port, Translated Port (Static NAT only.)

If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary. Do not configure these options for identity NAT.

Translation properties for manual NAT

Use the **Translation** options to define the source addresses and the mapped translated addresses. The following properties apply to manual NAT only. All are optional except as indicated.

Original Source (Always required.)

The network object or group that contains the addresses you are translating. This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can specify **Any** in the rule.

Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.
- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Do not configure a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.
- **Static NAT**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Destination

The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Translated Destination

The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

You can use a network object that specifies a fully-qualified domain name as the translated destination; for more information, see FQDN destination guidelines, on page 1200.

Original Source Port, Translated Source Port, Original Destination Port, Translated Destination Port

The port objects that define the source and destination services for the original and translated packets. You can translate the ports, or select the same object to make the rule sensitive to the service without translating the ports. Keep the following rules in mind when configuring services:

- (Dynamic NAT or PAT.) You cannot do translation on the **Original Source Port** and **Translated Source Port**. You can do translation on the destination port only.
- NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

PAT pool NAT properties

When you configure dynamic NAT, you can define a pool of addresses to use for port address translation using the properties on the **PAT Pool** tab.

Enable PAT Pool

Select this option to configure a pool of addresses for PAT.

PAT

The addresses to use for the PAT pool, one of the following:

- **Address**—The object that defines the PAT pool addresses, either a network object that includes a range, or a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.
- **Destination Interface IP**—Indicates that you want to use the destination interface as the PAT address. For this option, you must select a specific **Destination Interface Object**; you cannot use **Any** as the destination interface. This is another way to implement interface PAT.

Round Robin

To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one

address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

Extended PAT Table

To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.

Flat Port Range; Include Reserved Ports

To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the Firewall Threat Defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.

Block Allocation

To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Advanced NAT properties

When you configure NAT, you can configure properties that provide specialized services in the **Advanced** options. All of these properties are optional: configure them only if you need the service.

Translate DNS replies that match this rule

Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1296. This option is not available if you are doing port translation in a static NAT rule.

Fallthrough to Interface PAT (Destination Interface) (Dynamic NAT only.)

Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address. You also cannot select the option if you configure a PAT pool.

IPv6

Whether to use the IPv6 address of the destination interface for interface PAT.

Net to Net Mapping (Static NAT only.)

For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.

Do not proxy ARP on Destination Interface (Static NAT only.)

Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

Perform Route Lookup for Destination Interface (Static Identity NAT only. Routed mode only.)

If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

Unidirectional (Manual NAT only, static NAT only.)

Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Translating IPv6 networks

In cases where you need to pass traffic between IPv6-only and IPv4-only networks, you need to use NAT to convert between the address types. Even with two IPv6 networks, you might want to hide internal addresses from the outside network.

You can use the following translation types with IPv6 networks:

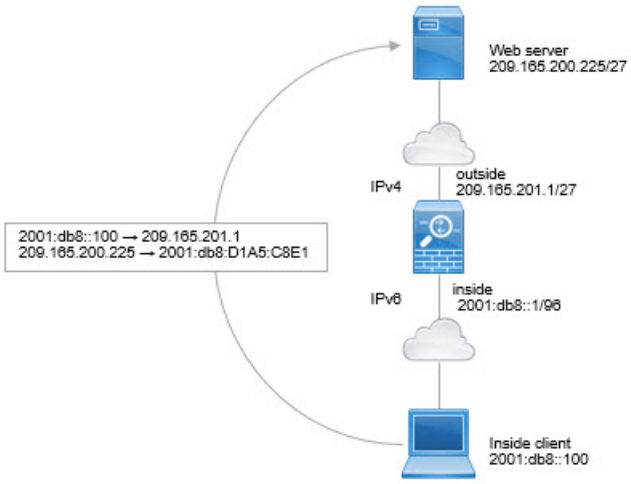
- NAT64, NAT46—Translates IPv6 packets into IPv4 and vice versa. You need to define two policies, one for the IPv6 to IPv4 translation, and one for the IPv4 to IPv6 translation. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

Note NAT46 supports static mappings only.

- NAT66—Translates IPv6 packets to a different IPv6 address. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

Note NAT64 and NAT 46 are possible on standard routed interfaces only. NAT66 is possible on both routed and bridge group member interfaces.

NAT64/46: translating IPv6 addresses to IPv4



When traffic goes from an IPv6 network to an IPv4-only network, you need to convert the IPv6 address to IPv4, and return traffic from IPv4 to IPv6. You need to define two address pools, an IPv4 address pool to bind IPv6 addresses in the IPv4 network, and an IPv6 address pool to bind IPv4 addresses in the IPv6 network.

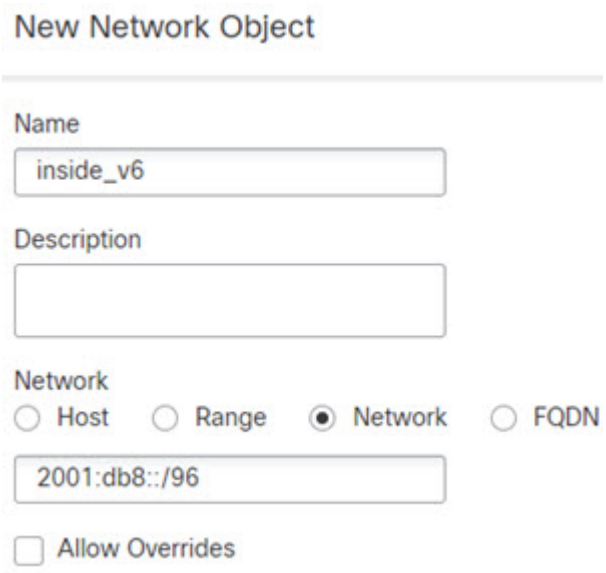
- The IPv4 address pool for the NAT64 rule is normally small and typically might not have enough addresses to map one-to-one with the IPv6 client addresses. Dynamic PAT might more easily meet the possible large number of IPv6 client addresses compared to dynamic or static NAT.
- The IPv6 address pool for the NAT46 rule can be equal to or larger than the number of IPv4 addresses to be mapped. This allows each IPv4 address to be mapped to a different IPv6 address. NAT46 supports static mappings only, so you cannot use dynamic PAT.

You need to define two policies, one for the source IPv6 network, and one for the destination IPv4 network. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

NAT64/46 example: inside IPv6 network with outside IPv4 internet

Following is a straight-forward example where you have an inside IPv6-only network, and you want to convert to IPv4 for traffic sent to the Internet. This example assumes you do not need DNS translation, so you can perform both the NAT64 and NAT46 translations in a single manual NAT rule.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network.



Procedure

Step 1 Create the network object that defines the inside IPv6 network.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:db8::/96.

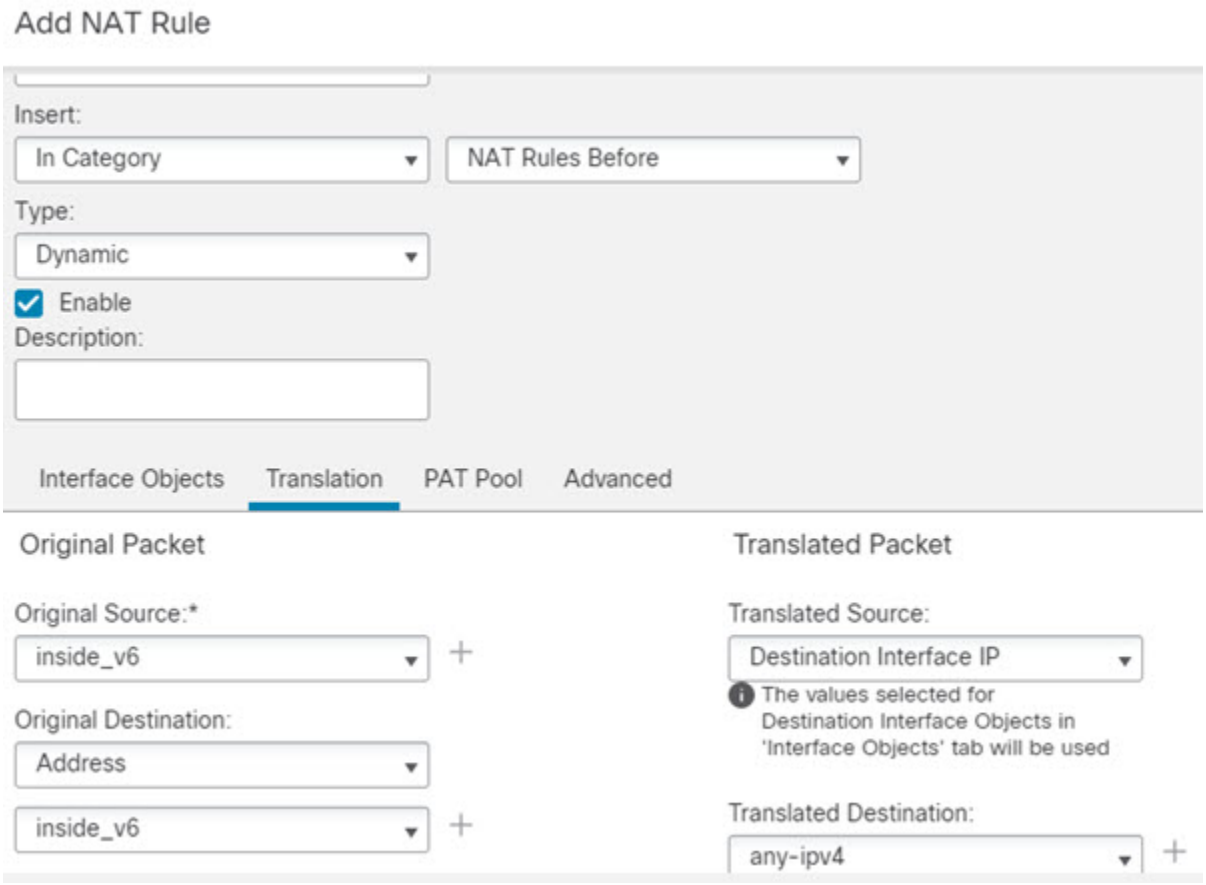
c) Click **Save**.

Step 2 Create the manual NAT rule to translate the IPv6 network to IPv4 and back again.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



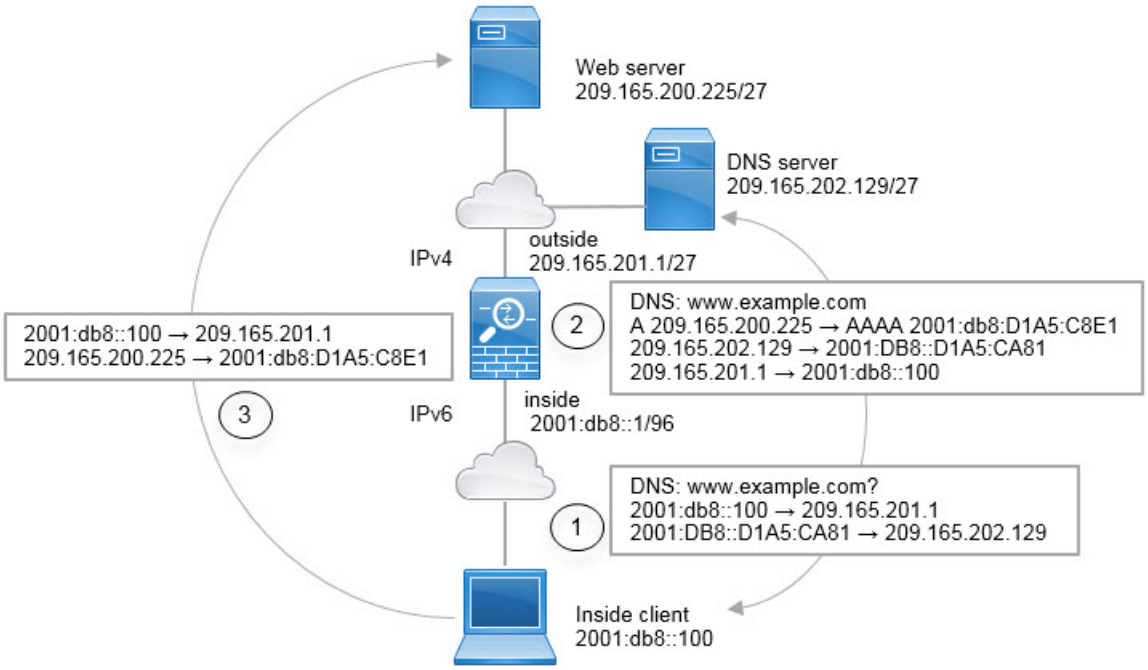
- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** = **Destination Interface IP**.
- **Original Destination** = inside_v6 network object.
- **Translated Destination** = any-ipv4 network object.



f) Click **OK**.

With this rule, any traffic from the 2001:db8::/96 subnet on the inside interface going to the outside interface gets a NAT64 PAT translation using the IPv4 address of the outside interface. Conversely, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method.

g) Click **Save** on the NAT rules page.

NAT64/46 example: inside IPv6 network with outside IPv4 internet and DNS translation

Following is a typical example where you have an inside IPv6-only network, but there are some IPv4-only services on the outside Internet that internal users need.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network. You enable DNS rewrite on the NAT46 rule, so that replies from the external DNS server can be converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.

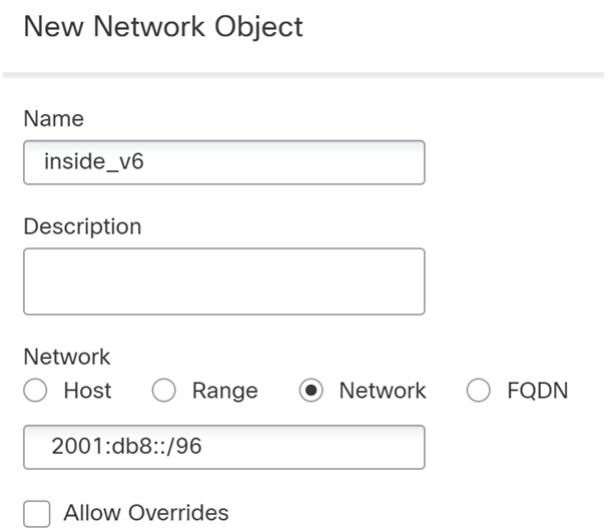
Following is a typical sequence for a web request where a client at 2001:DB8::100 on the internal IPv6 network tries to open www.example.com.

1. The client's computer sends a DNS request to the DNS server at 2001:DB8::D1A5:CA81. The NAT rules make the following translations to the source and destination in the DNS request:
   - 2001:DB8::100 to a unique port on 209.165.201.1 (The NAT64 interface PAT rule.)
   - 2001:DB8::D1A5:CA81 to 209.165.202.129 (The NAT46 rule. D1A5:CA81 is the IPv6 equivalent of 209.165.202.129.)
2. The DNS server responds with an A record indicating that www.example.com is at 209.165.200.225. The NAT46 rule, with DNS rewrite enabled, converts the A record to the IPv6-equivalent AAAA record, and translates 209.165.200.225 to 2001:db8:D1A5:C8E1in the AAAA record. In addition, the source and destination addresses in the DNS response are untranslated:
   - 209.165.202.129 to 2001:DB8::D1A5:CA81
   - 209.165.201.1 to 2001:db8::100
3. The IPv6 client now has the IP address of the web server, and makes an HTTP request to www.example.com at 2001:db8:D1A5:C8E1. (D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225.) The source and destination of the HTTP request are translated:
   - 2001:DB8::100 to a unique port on 209.156.101.54 (The NAT64 interface PAT rule.)
   - 2001:db8:D1A5:C8E1 to 209.165.200.225 (The NAT46 rule.)

The following procedure explains how to configure this example.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

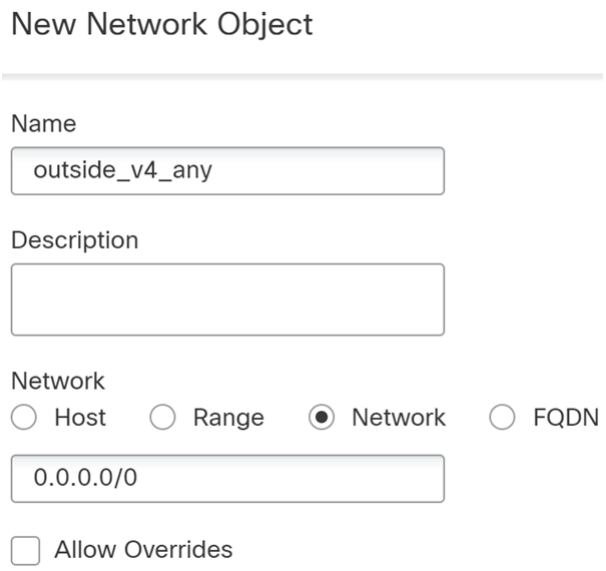


Procedure

Step 1 Create the network objects that define the inside IPv6 and outside IPv4 networks.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.



Name the network object (for example, inside_v6) and enter the network address, 2001:db8::/96.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the outside IPv4 network.

Name the network object (for example, outside_v4_any) and enter the network address 0.0.0.0/0.

e) Click **Save**.

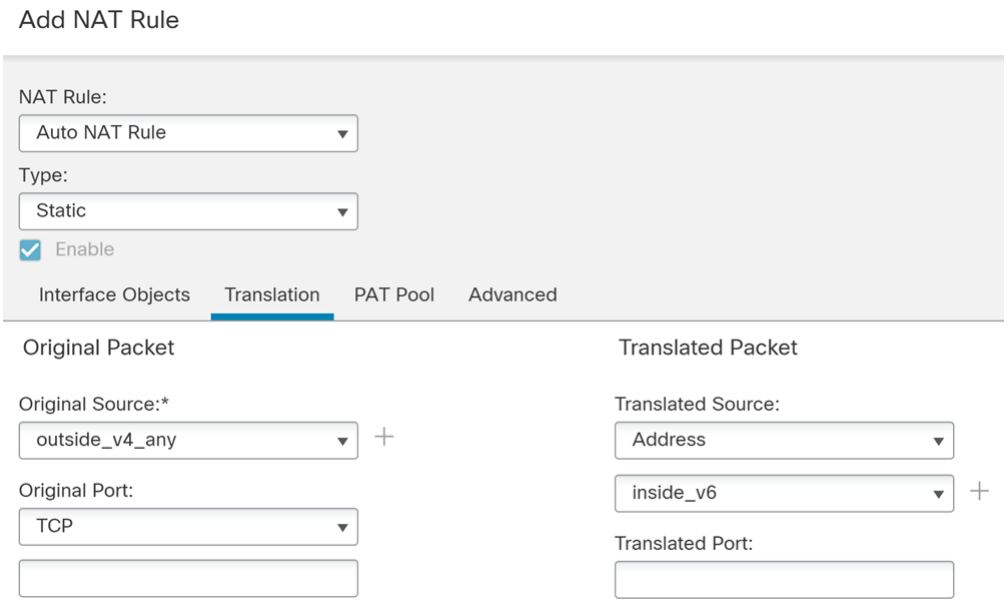
Step 2 Configure the NAT64 dynamic PAT rule for the inside IPv6 network.

Step 3 Configure the static NAT46 rule for the outside IPv4 network.

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

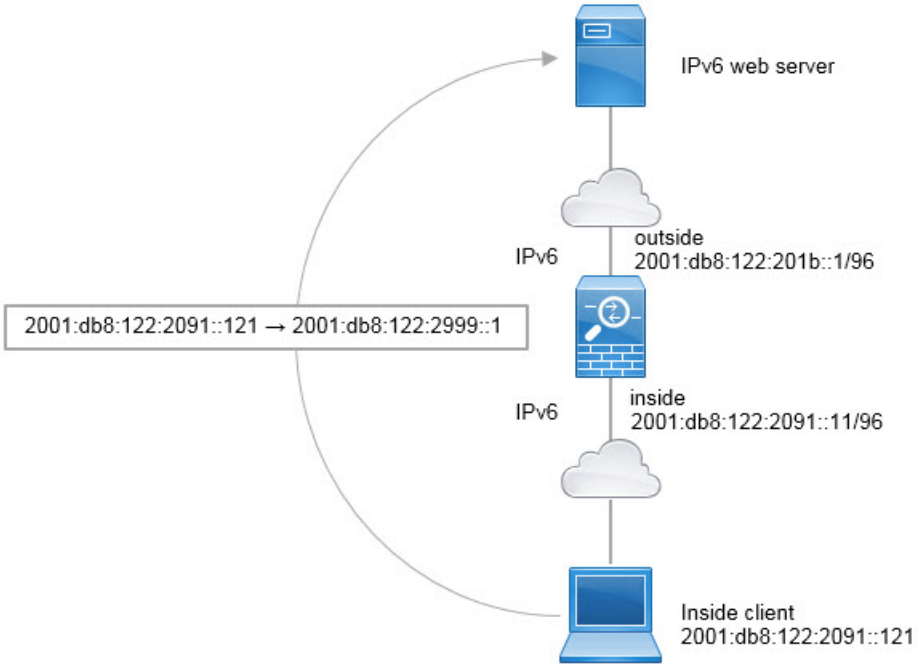
d) On **Translation**, configure the following:

- **Original Source** = outside_v4_any network object.
- **Translated Source** > **Address** = inside_v6 network object.

e) On **Advanced**, select **Translate DNS replies that match this rule**.

f) Click **OK**.

With this rule, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method. In addition, DNS responses are converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.



NAT66: translating IPv6 addresses to different IPv6 addresses

When going from an IPv6 network to another IPv6 network, you can translate the addresses to different IPv6 addresses on the outside network. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

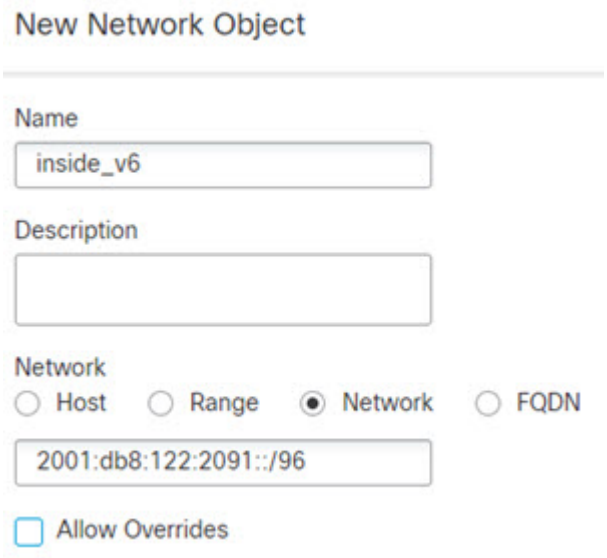
Because you are not translating between different address types, you need a single rule for NAT66 translations. You can easily model these rules using auto NAT. However, if you do not want to allow returning traffic, you can make the static NAT rule unidirectional using manual NAT only.

NAT66 example, static translation between networks

You can configure a static translation between IPv6 address pools using auto NAT. The following example explains how to convert inside addresses on the 2001:db8:122:2091::/96 network to outside addresses on the 2001:db8:122:2999::/96 network.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

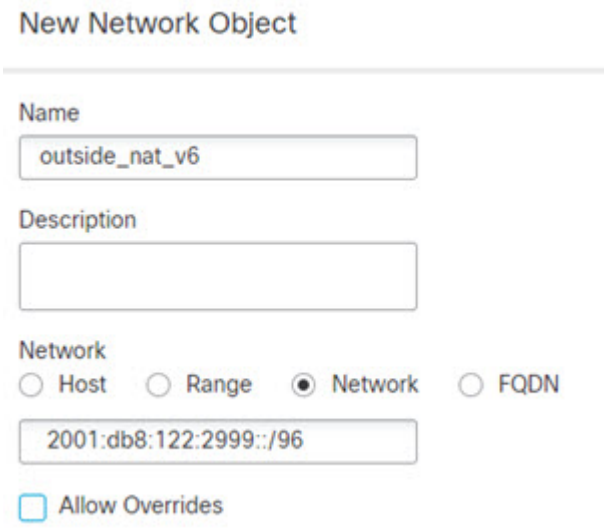


Procedure

Step 1 Create the network objects that define the inside IPv6 and outside IPv6 NAT networks.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.



Name the network object (for example, inside_v6) and enter the network address, 2001:db8:122:2091::/96.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the outside IPv6 NAT network.

Name the network object (for example, outside_nat_v6) and enter the network address 2001:db8:122:2999::/96.

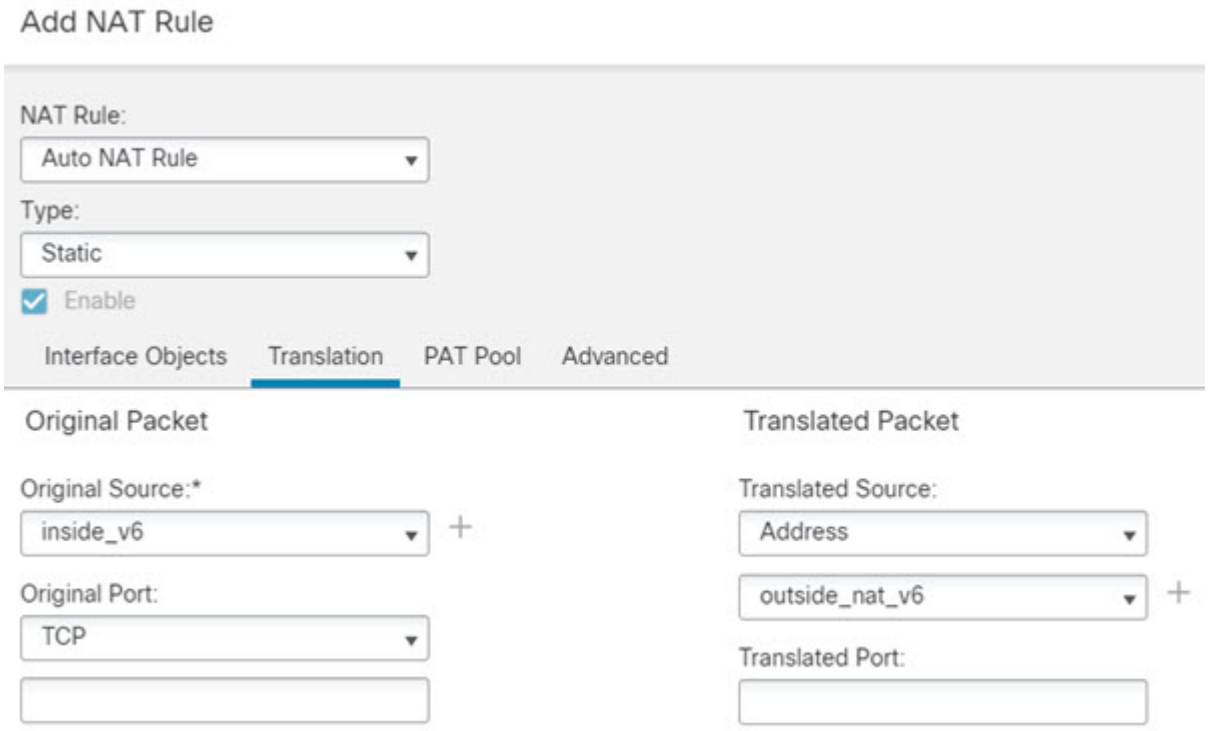
e) Click **Save**.

Step 2 Configure the static NAT rule for the inside IPv6 network.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



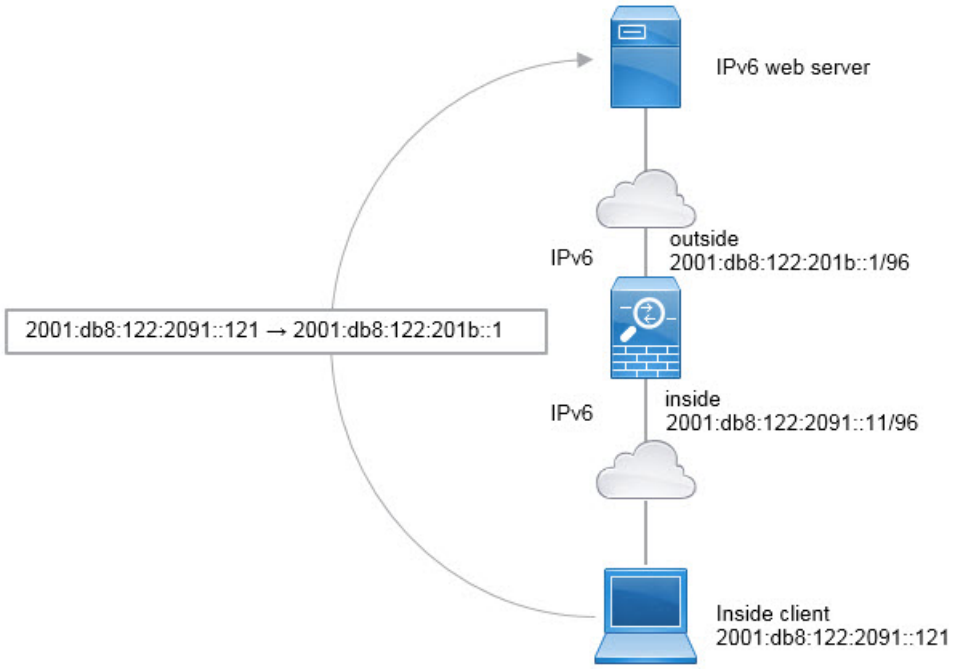
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** > **Address** = outside_nat_v6 network object.



f) Click **OK**.

With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a static NAT66 translation to an address on the 2001:db8:122:2999::/96 network.

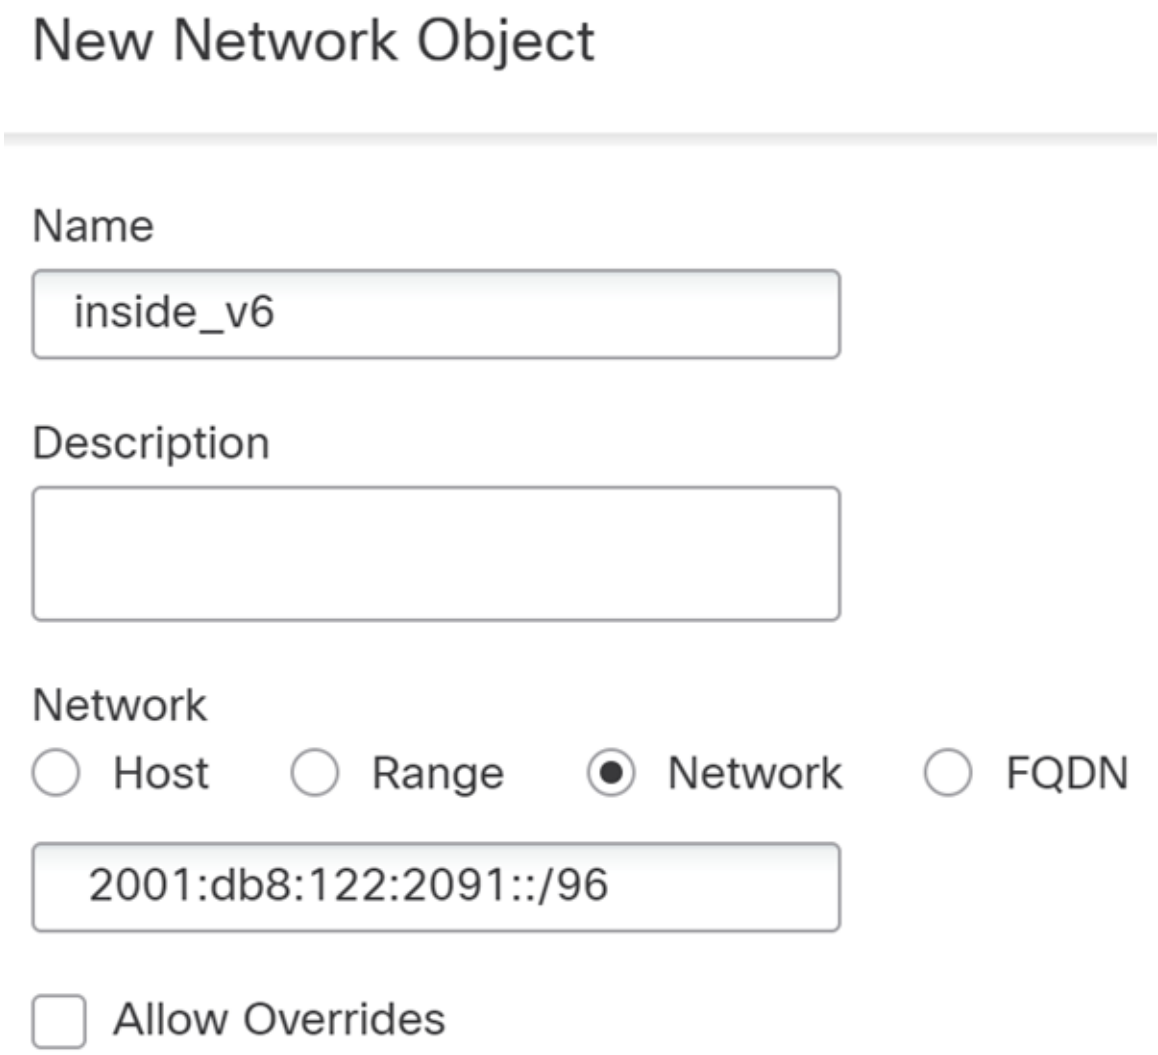
NAT66 example, simple IPv6 interface PAT

A simple approach for implementing NAT66 is to dynamically assign internal addresses to different ports on the outside interface IPv6 address.

When you configure an interface PAT rule for NAT66, all the global addresses that are configured on that interface are used for PAT mapping. Link-local or site-local addresses for the interface are not used for PAT.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.



Procedure

Step 1 Create the network object that defines the inside IPv6 network.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.

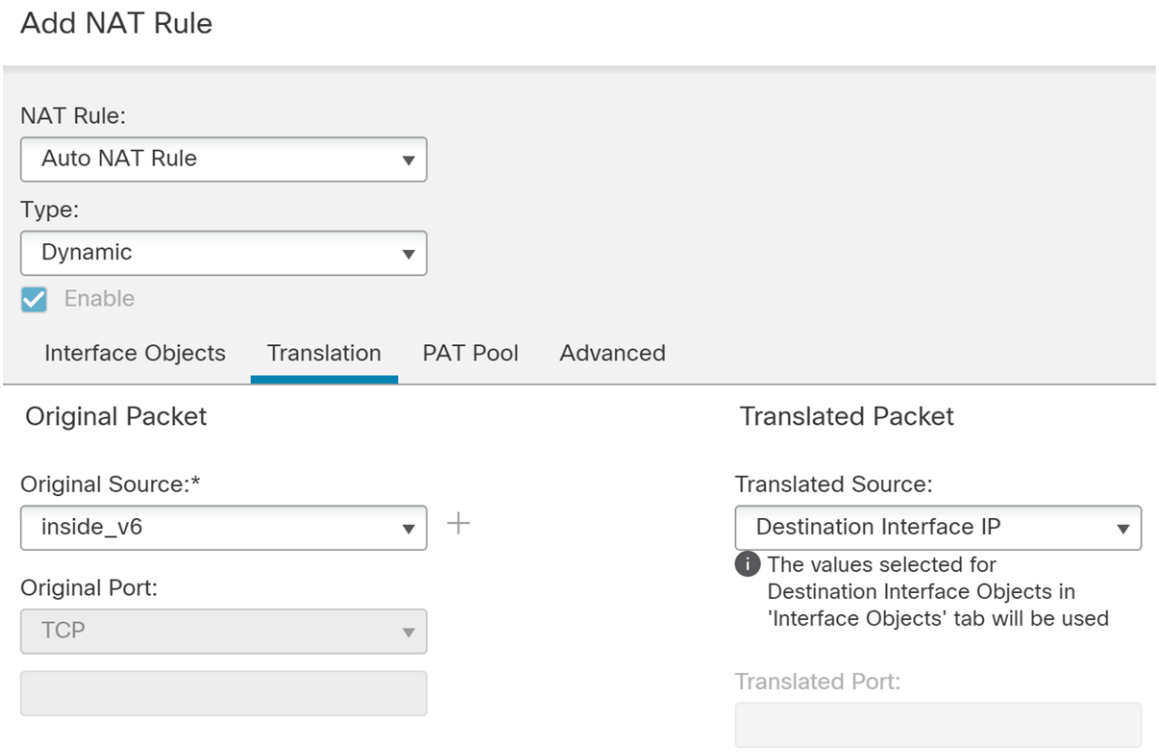
Name the network object (for example, inside_v6) and enter the network address, 2001:db8:122:2091::/96.

c) Click **Save**.

Step 2 Configure the dynamic PAT rule for the inside IPv6 network.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.



d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** = **Destination Interface IP**.

f) On **Advanced**, select **IPv6**, which indicates that the IPv6 address of the destination interface should be used.

g) Click **OK**.

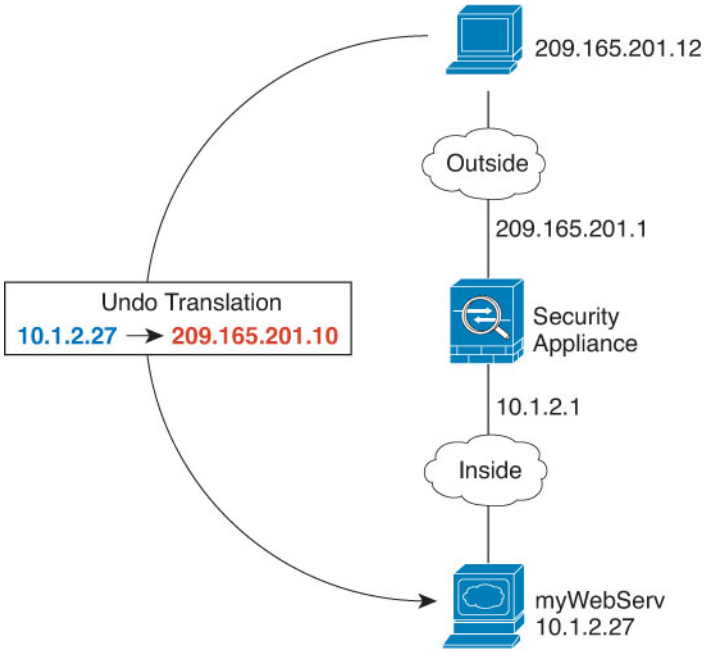
With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a NAT66 PAT translation to one of the IPv6 global addresses configured for the outside interface.

Monitoring NAT

To monitor and troubleshoot NAT connections, log into the device CLI and use the following commands.

- **show nat** displays the NAT rules and per-rule hit counts. There are additional keywords to show other aspects of NAT.
- **show xlate** displays the actual NAT translations that are currently active.
- **clear xlate** lets you remove an active NAT translation. You might need to remove active translations if you alter NAT rules, because existing connections continue to use the old translation slot until the

connection ends. Clearing a translation allows the system to build a new translation for a client on the client's next connection attempt based on your new rules.



Examples for NAT

The following topics provide examples for configuring NAT.

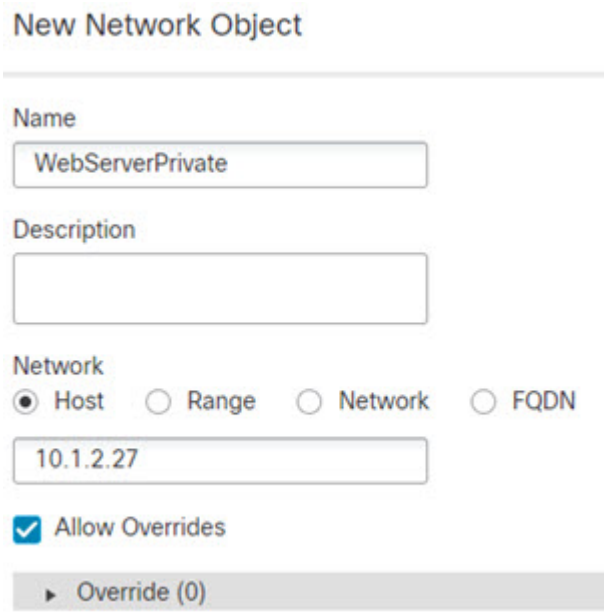
Providing access to an inside web server (static auto NAT)

This example performs static NAT for an inside web server. The real address is on a private network, so a public address is required. Static NAT is necessary so hosts can initiate traffic to the web server at a fixed address.

Figure 385: Static NAT for an inside web server

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

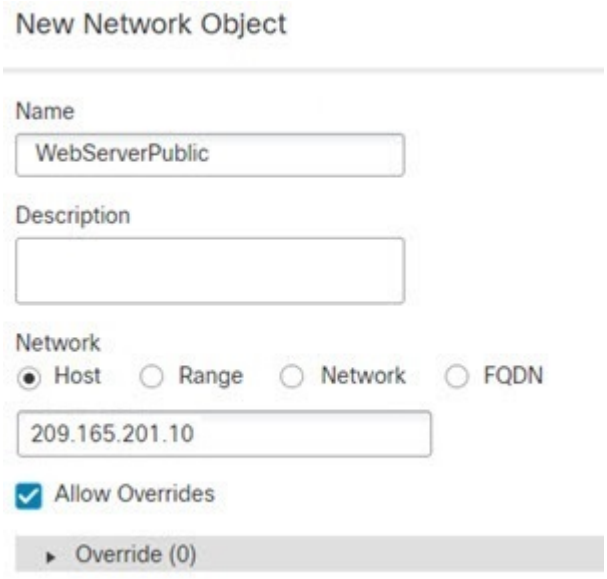


Procedure

Step 1 Create the network objects that define the server's private and public host addresses.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the web server's private address.



Name the network object (for example, WebServerPrivate) and enter the real host IP address, 10.1.2.27.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the public address.

Name the network object (for example, WebServerPublic) and enter the host address 209.165.201.10.

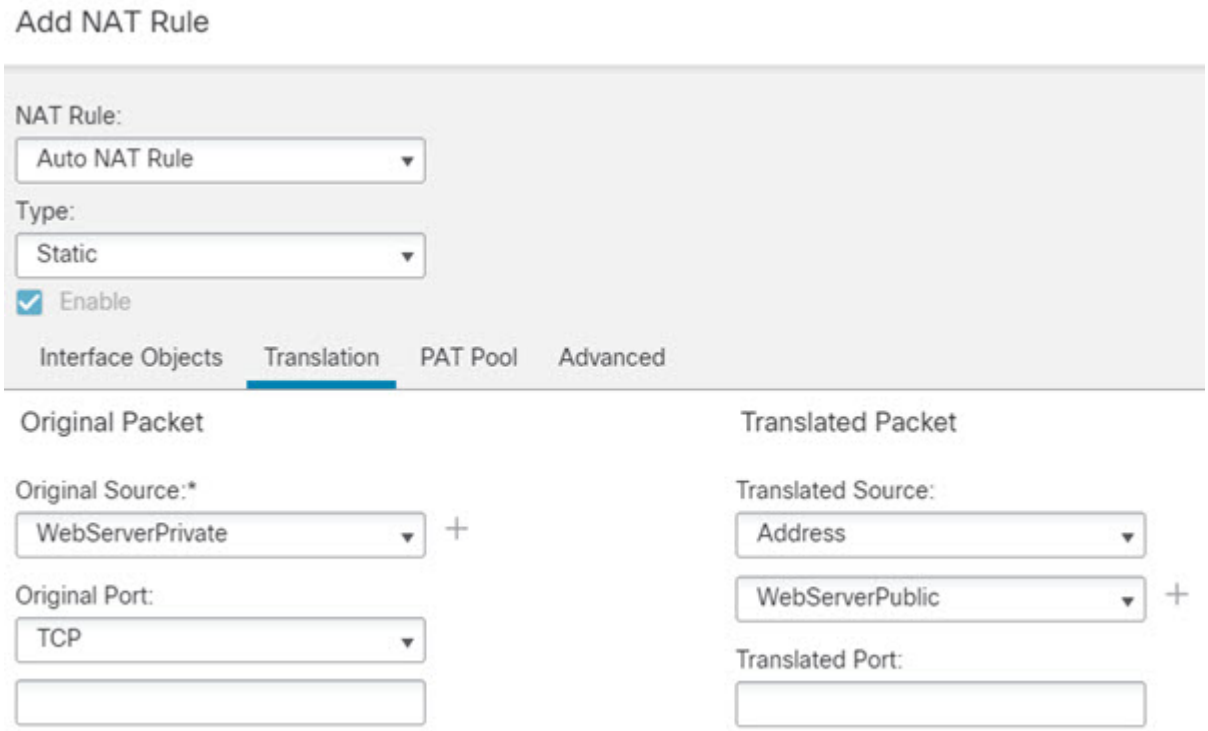
e) Click **Save**.

Step 2 Configure static NAT for the object.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



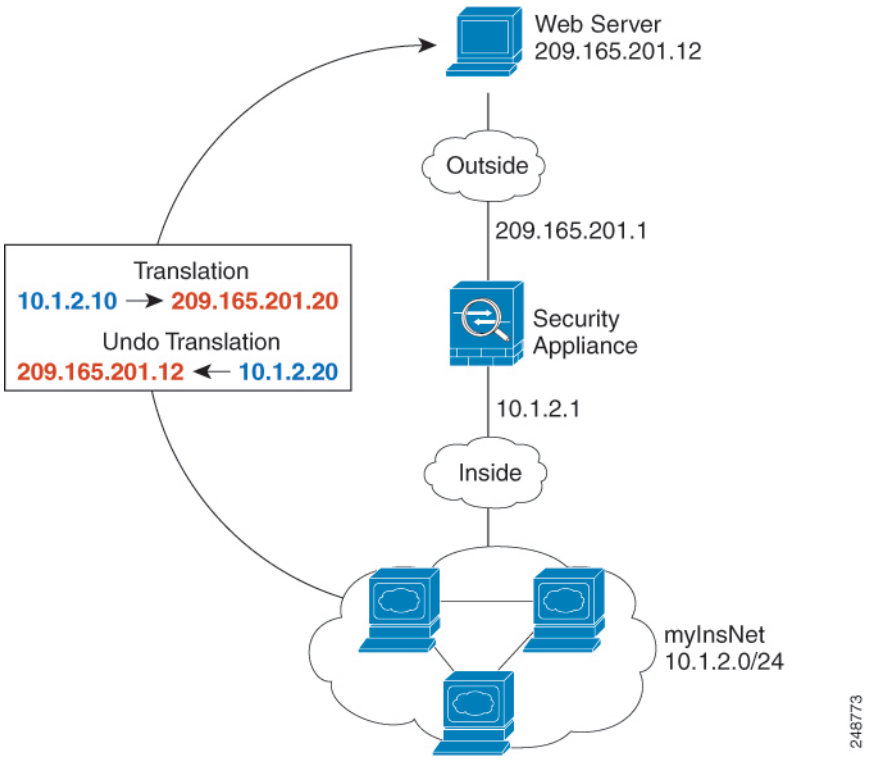
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = WebServerPrivate network object.
- **Translated Source** > **Address** = WebServerPublic network object.



f) Click **Save**.

Step 3 Click **Save** on the NAT rule page.

Dynamic auto NAT for inside hosts and static NAT for an outside web server

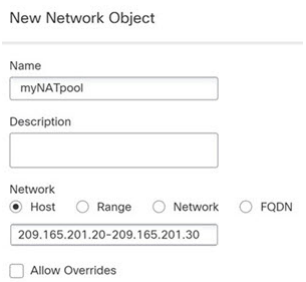
The following example configures dynamic NAT for inside users on a private network when they access the outside. Also, when inside users connect to an outside web server, that web server address is translated to an address that appears to be on the inside network.

Figure 386: Dynamic NAT for Inside, Static NAT for Outside Web Server

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select and click **Add Network** > **Add ObjectObjects** > **Object Management** > **Interface**.

Procedure



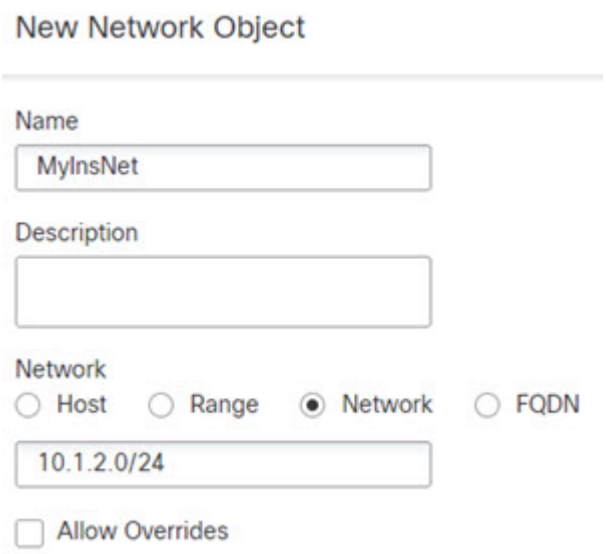
Step 1 Create a network object for the dynamic NAT pool to which you want to translate the inside addresses.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the dynamic NAT pool.

Name the network object (for example, myNATpool) and enter the network range 209.165.201.20-209.165.201.30.

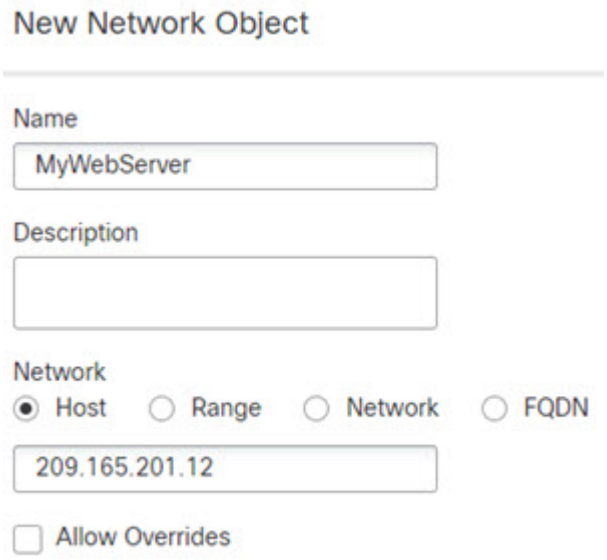


d) Click **Save**.

Step 2 Create a network object for the inside network.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, MyInsNet) and enter the network address 10.1.2.0/24.

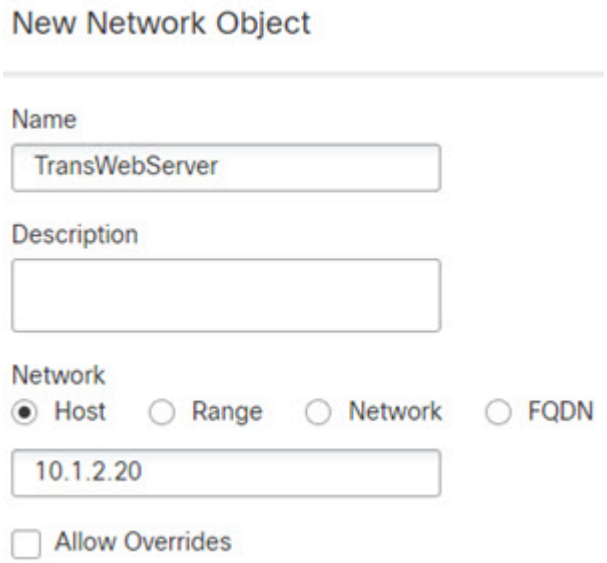


c) Click **Save**.

Step 3 Create a network object for the outside web server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, MyWebServer) and enter the host address 209.165.201.12.



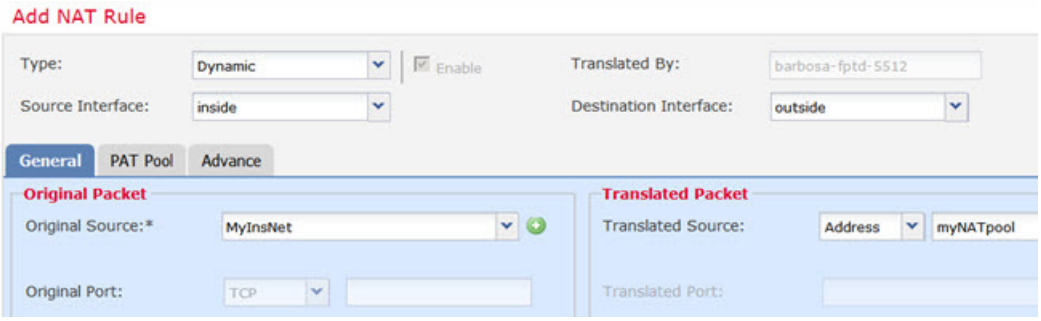
c) Click **Save**.

Step 4 Create a network object for the translated web server address.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, TransWebServer) and enter the host address 10.1.2.20.

c) Click **Save**.



Step 5 Configure dynamic NAT for the inside network using the dynamic NAT pool object.

a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.

Ensure that you are currently in the same leaf domain that includes the device, if you are using domains.

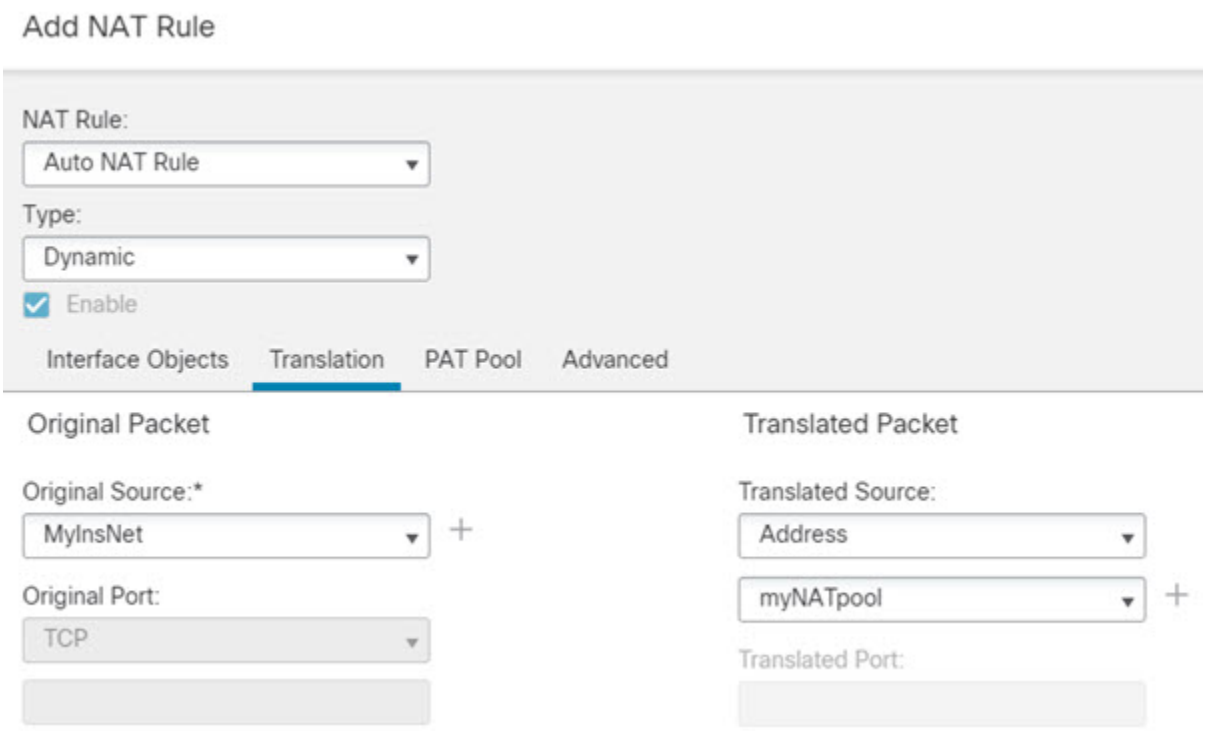
b) Click **Add NAT Rule** > **Add Auto NAT**.
c) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = myInsNet network object.
- **Translated Source** > **Address**= myNATpool network group.

d) Click **Save**.

Step 6 Configure dynamic NAT for the inside network using the dynamic NAT pool object.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:



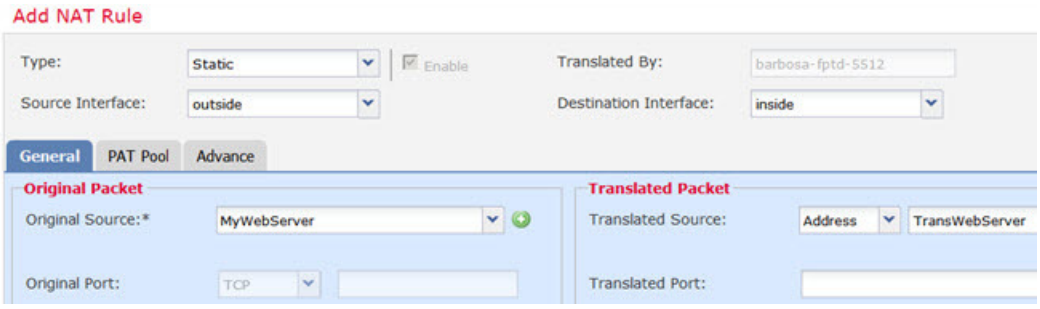
- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = myInsNet network object.
- **Translated Source** > **Address**= myNATpool network group.

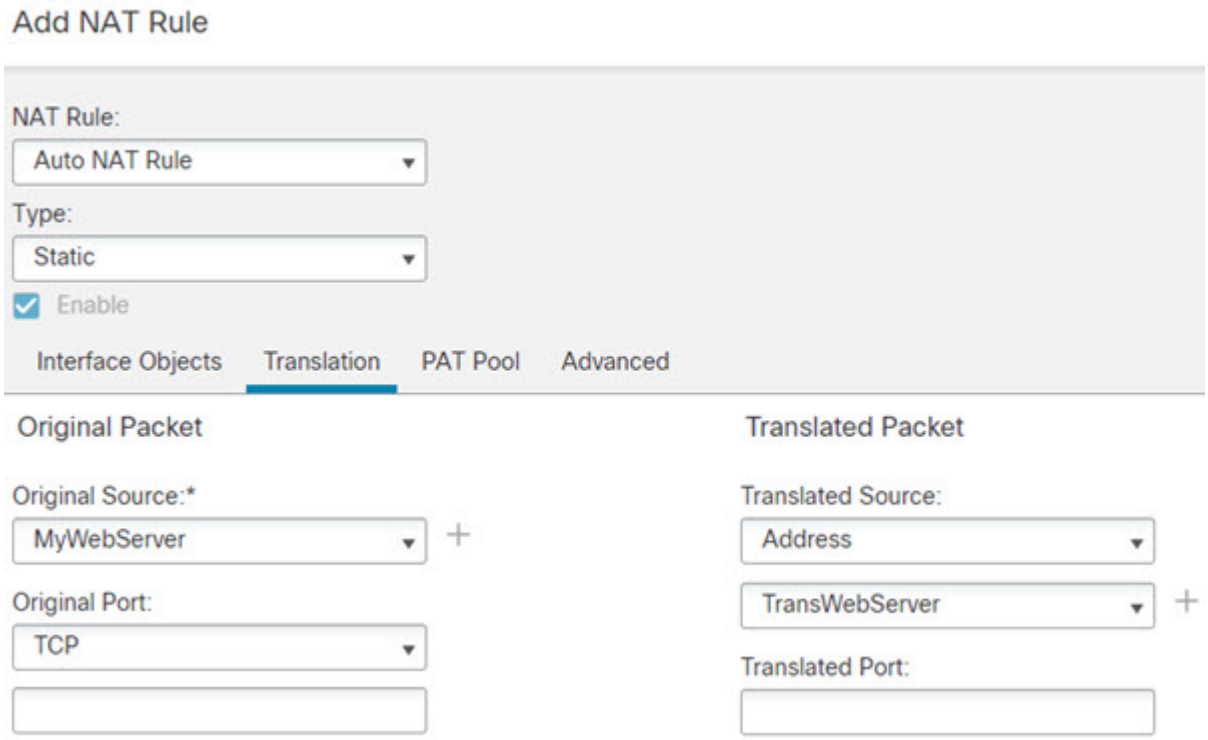


f) Click **Save**.

Step 7 Configure static NAT for the web server.

a) Click **Add NAT Rule** > **Add Auto NAT**.

b) Configure the following properties:

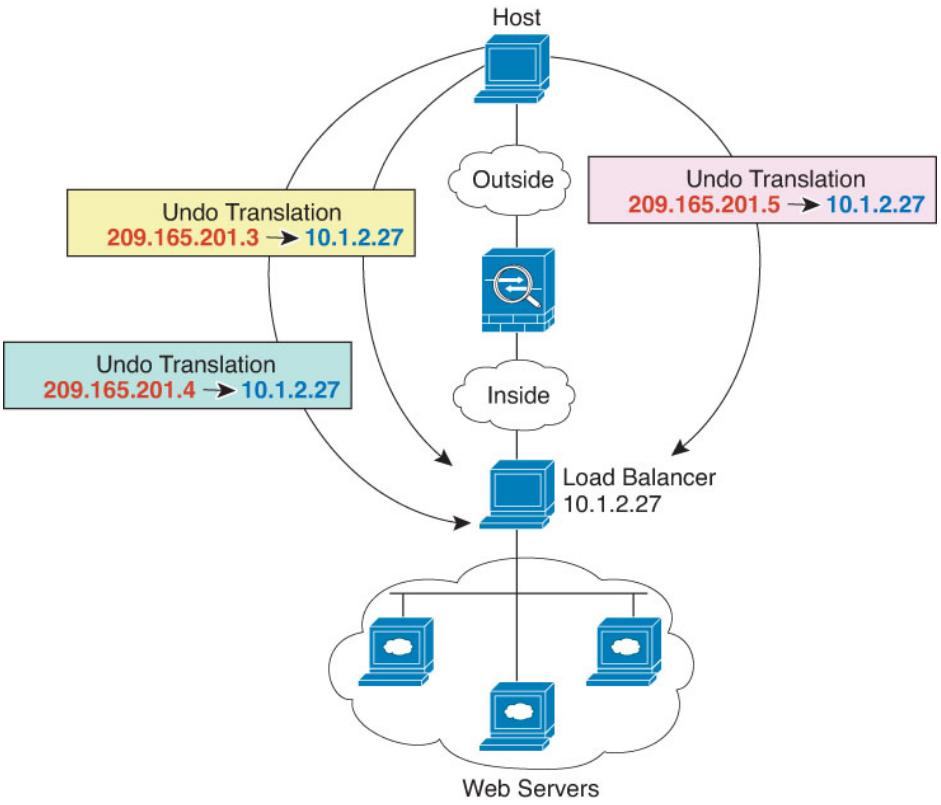


- **Type** = Static.
- **Source Interface** = outside.
- **Destination Interface** = inside.
- **Original Source** = myWebServer network object.
- **Translated Source** > **Address**= TransWebServer network object.

c) Click **Save**.

Step 8 Configure static NAT for the web server.

a) Click **Add Rule**.
b) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Static.
c) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = outside.
   - **Destination Interface Objects** = inside.
d) On **Translation**, configure the following:
   - **Original Source** = myWebServer network object.
   - **Translated Source** > **Address**= TransWebServer network object.



e) Click **Save**.

Step 9 Click **Save** on the NAT rule page.

Configure inside load balancer with multiple mapped addresses

The following example shows an inside load balancer that is translated to multiple IP addresses. When an outside host accesses one of the mapped IP addresses, it is untranslated to the single load balancer address. Depending on the URL requested, it redirects traffic to the correct web server.

Figure 387: Static NAT with One-to-Many for an Inside Load Balancer

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

Procedure

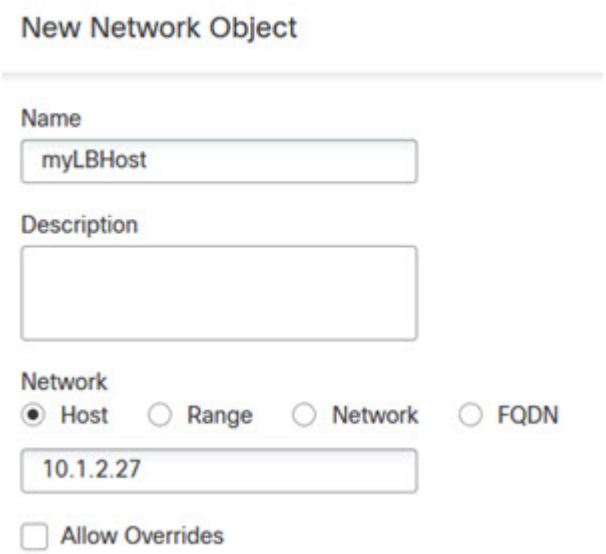
Step 1 Create a network object for the addresses to which you want to map the load balancer.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the addresses.

Name the network object (for example, myPublicIPs) and enter the network range 209.165.201.3-209.165.201.5.



d) Click **Save**.

Step 2 Create a network object for the load balancer.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, myLBHost), enter the host address 10.1.2.27.

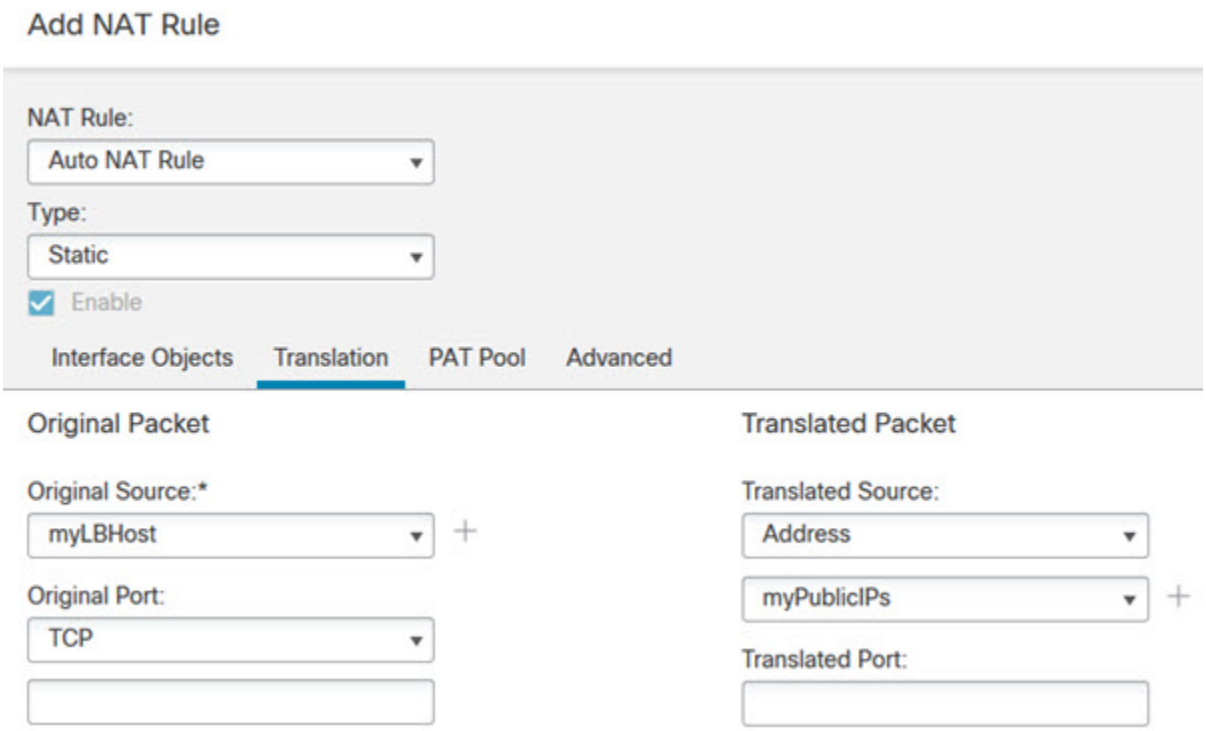
c) Click **Save**.

Step 3 Configure static NAT for the load balancer.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



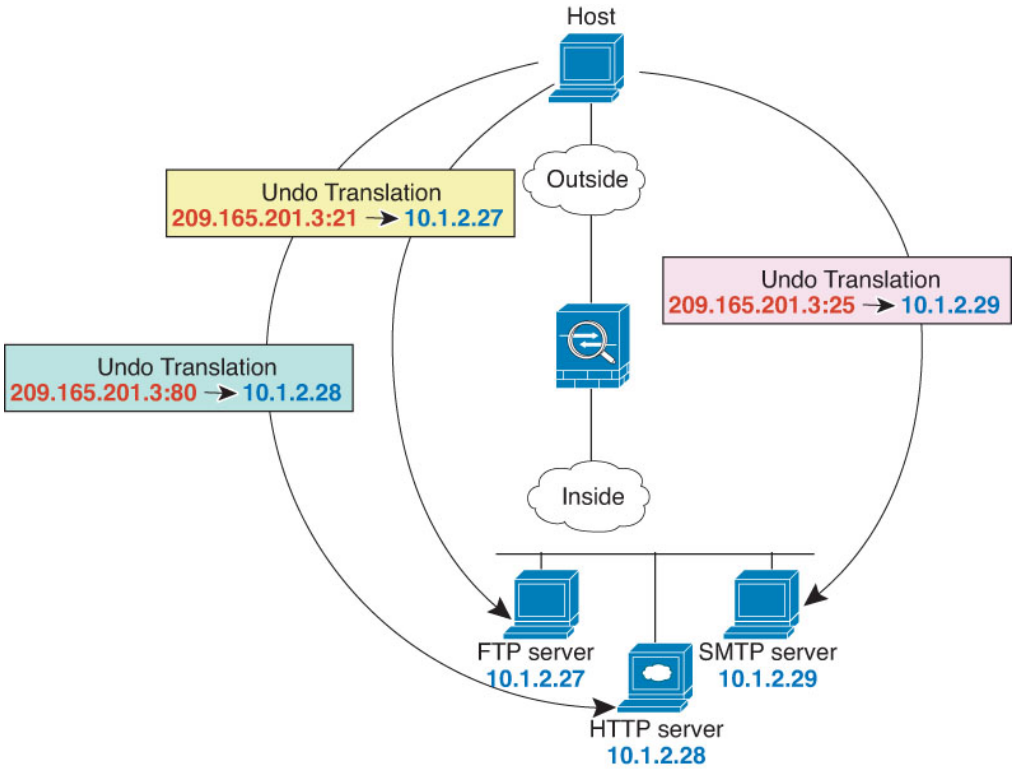
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = myLBHost network object.
- **Translated Source** > **Address** = myPublicIPs network group.



f) Click **Save**.

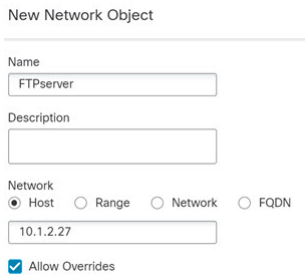
Step 4 Click **Save** on the NAT rule page.

Single address for FTP, HTTP, and SMTP (static auto NAT with port translation)

The following static NAT-with-port-translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT-with-port-translation rules that use the same mapped IP address, but different ports.

Figure 388: Static NAT-with-Port-Translation

Before you begin



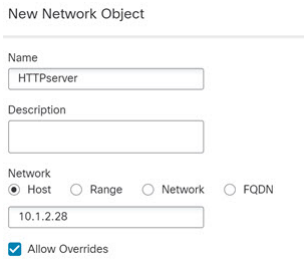
Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select and click **Add Network** > **Add GroupObjects** > **Object Management** > **Interface**.

Procedure

Step 1 Create a network object for the FTP server.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Name the network object (for example, FTPserver), and enter the real IP address for the FTP server, 10.1.2.27.

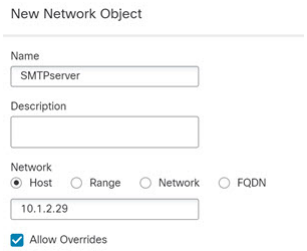


c) Click **Save**.

Step 2 Create a network object for the HTTP server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, HTTPserver), enter the host address 10.1.2.28.

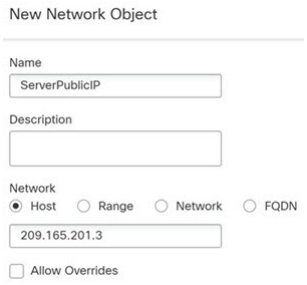


c) Click **Save**.

Step 3 Create a network object for the SMTP server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, SMTPserver), enter the host address 10.1.2.29.



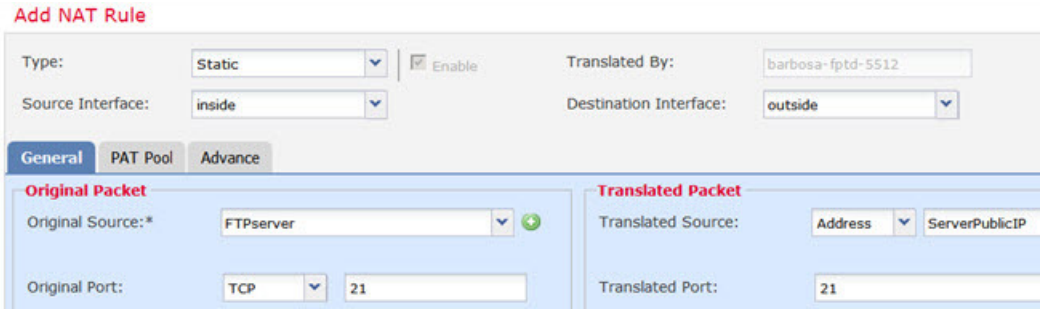
c) Click **Save**.

Step 4 Create a network object for the public IP address used for the three servers.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, ServerPublicIP) and enter the host address 209.165.201.3.

c) Click **Save**.



Step 5 Configure static NAT with port translation for the FTP server, mapping the FTP port to itself.

a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.

Ensure that you are currently in the same leaf domain that includes the device, if you are using domains.

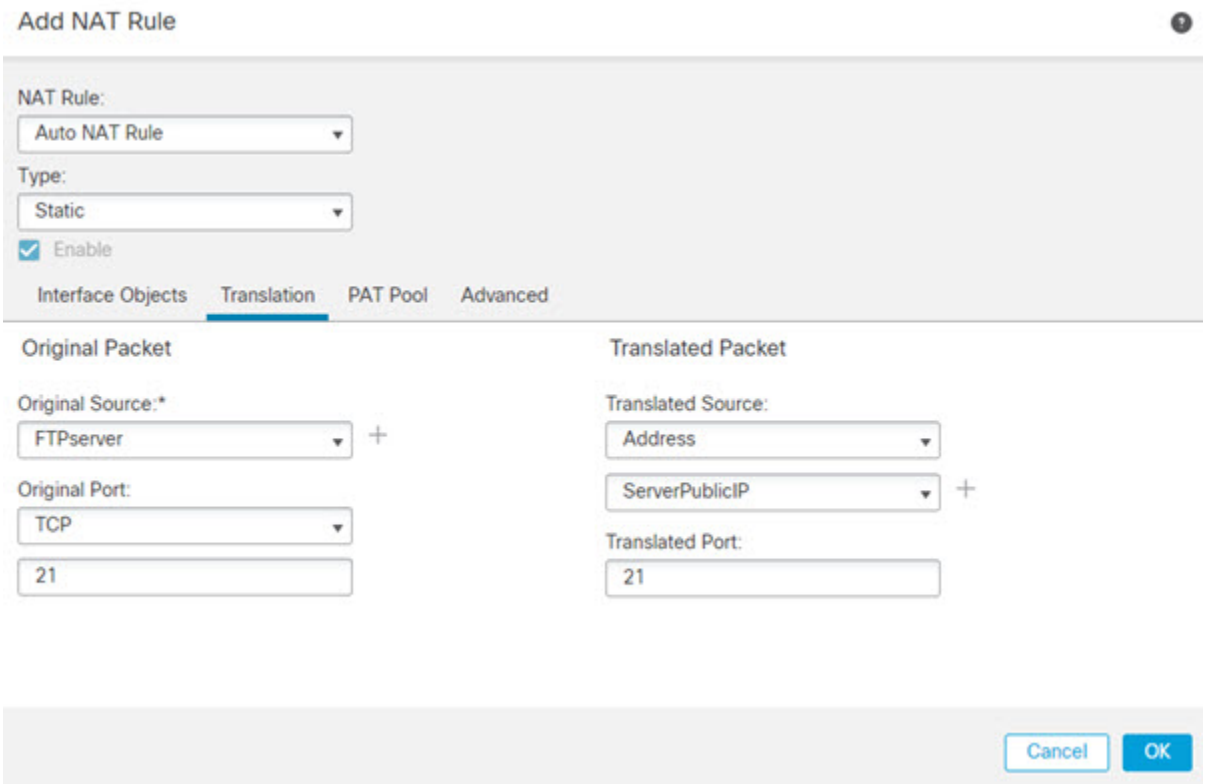
b) Click **Add NAT Rule** > **Add Auto NAT**.
c) Configure the following properties:

- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = FTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 21.
- **Translated Port** = 21.

d) Click **Save**.

Step 6 Configure static NAT with port translation for the FTP server, mapping the FTP port to itself.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:



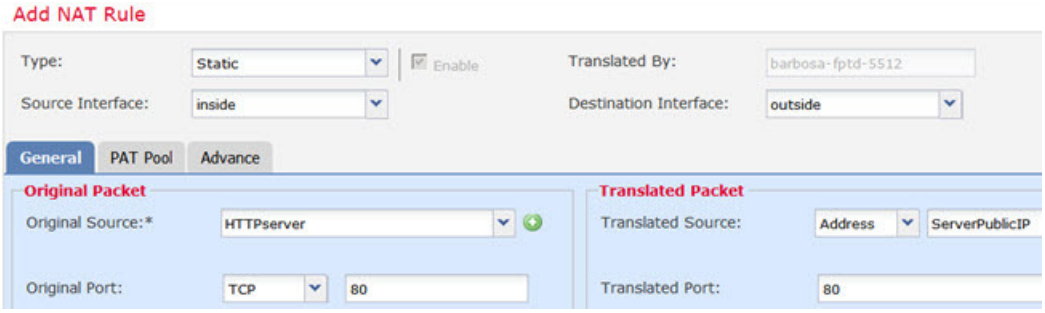
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = FTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 21.
- **Translated Port** = 21.



f) Click **Save**.

Step 7 Configure static NAT with port translation for the HTTP server, mapping the HTTP port to itself.

a) Click **Add NAT Rule** > **Add Auto NAT**.

b) Configure the following properties:

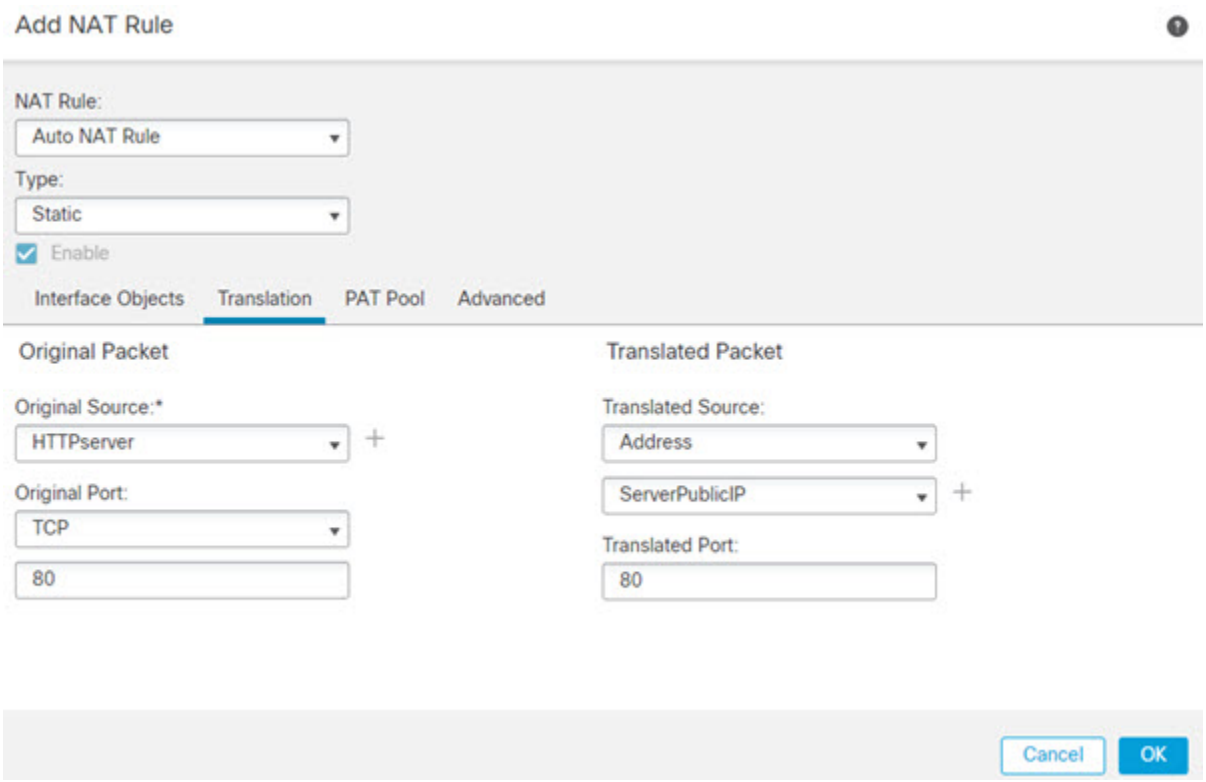
- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = HTTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 80.
- **Translated Port** = 80.

c) Click **Save**.

Step 8 Configure static NAT with port translation for the HTTP server, mapping the HTTP port to itself.

a) Click **Add Rule**.

b) Configure the following properties:



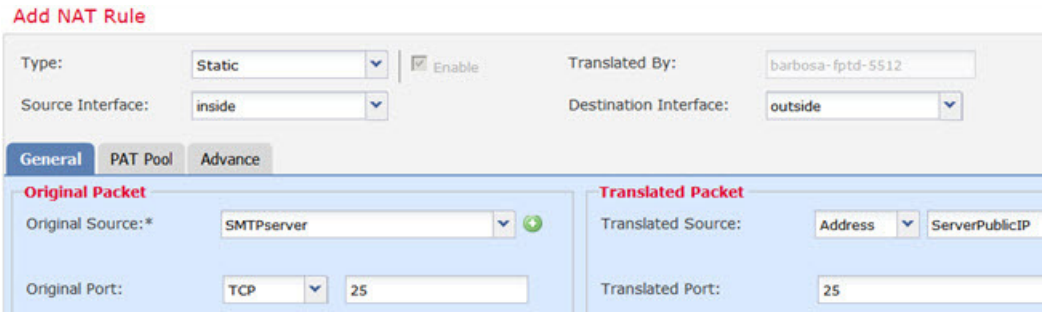
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

d) On **Translation**, configure the following:

- **Original Source** = HTTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 80.
- **Translated Port** = 80.



e) Click **Save**.

Step 9 Configure static NAT with port translation for the SMTP server, mapping the SMTP port to itself.

a) Click **Add NAT Rule** > **Add Auto NAT**.

b) Configure the following properties:

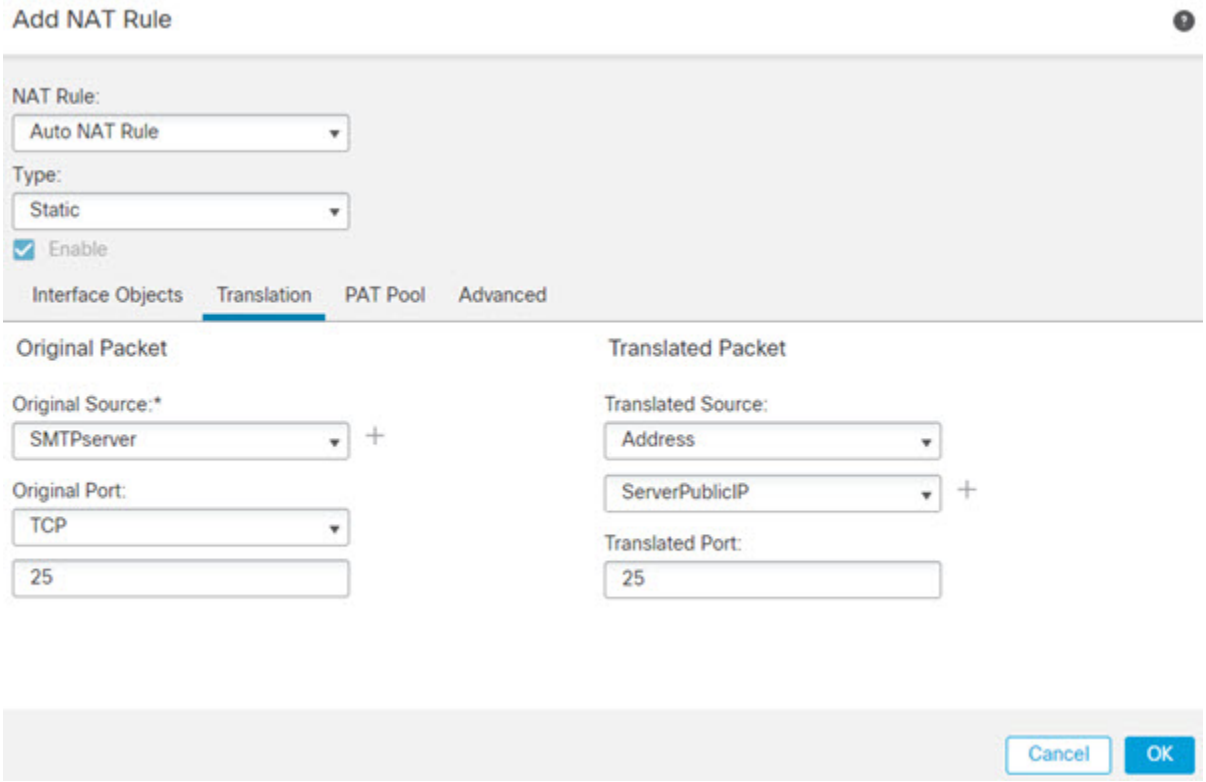
- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = SMTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 25.
- **Translated Port** = 25.

c) Click **Save**.

Step 10 Configure static NAT with port translation for the SMTP server, mapping the SMTP port to itself.

a) Click **Add Rule**.

b) Configure the following properties:



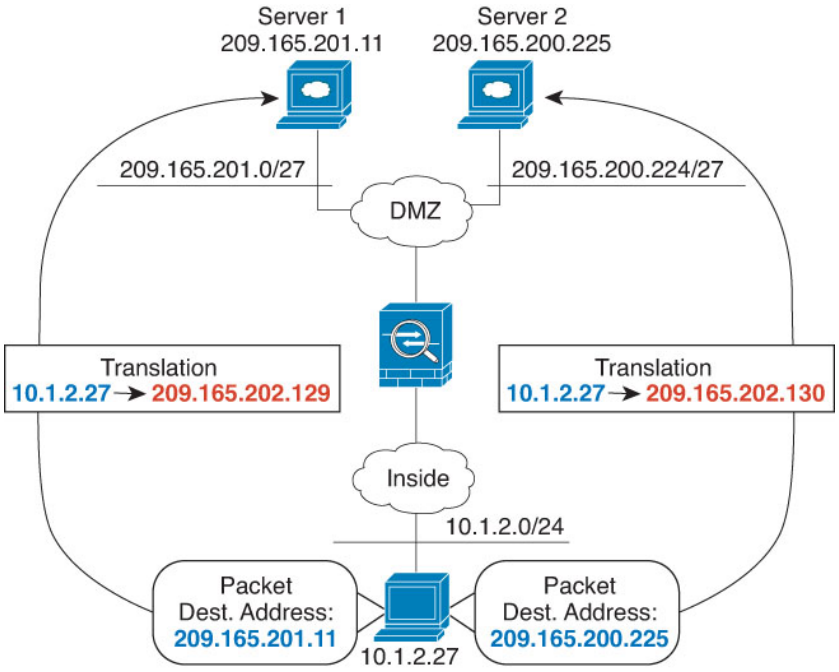
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

d) On **Translation**, configure the following:

- **Original Source** = SMTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 25.
- **Translated Port** = 25.



e) Click **Save**.

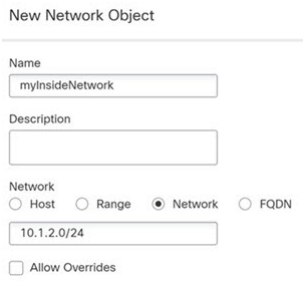
Step 11 Click **Save** on the NAT rule page.

Different translation depending on the destination (dynamic manual PAT)

The following figure shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129:*port*. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130:*port*.

Figure 389: Manual NAT with Different Destination Addresses

Before you begin



Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **dmz**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

Procedure

Step 1 Create a network object for the inside network.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

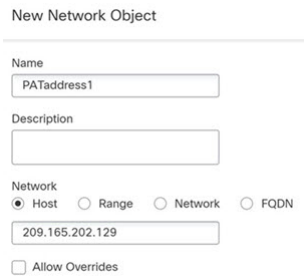
b) Name the network object (for example, myInsideNetwork), and enter the real network address, 10.1.2.0/24.

c) Click **Save**.

Step 2 Create a network object for the DMZ network 1.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, DMZnetwork1) and enter the network address 209.165.201.0/27 (subnet mask of 255.255.255.224).

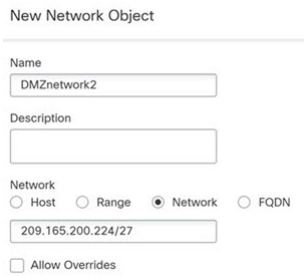


c) Click **Save**.

Step 3 Create a network object for the PAT address for DMZ network 1.

a) Click **Add Network** > **Add Object**.

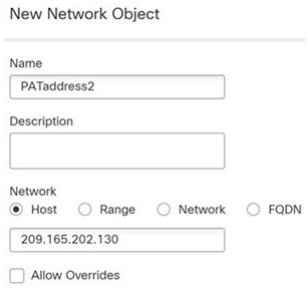
b) Name the network object (for example, PATaddress1) and enter the host address 209.165.202.129.



c) Click **Save**.

Step 4 Create a network object for the DMZ network 2.

a) Click **Add Network** > **Add Object**.



b) Name the network object (for example, DMZnetwork2) and enter the network address 209.165.200.224/27 (subnet mask of 255.255.255.224).

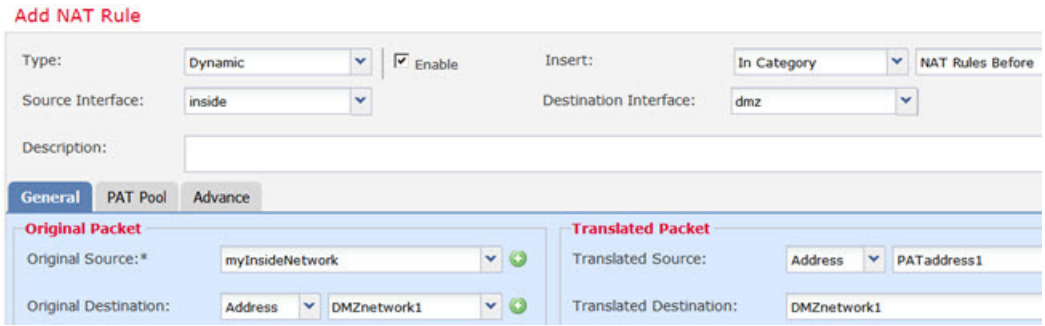
c) Click **Save**.

Step 5 Create a network object for the PAT address for DMZ network 2.

a) Click **Add Network** > **Add Object**.
b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.

c) Click **Save**.

Step 6 Configure dynamic manual PAT for DMZ network 1.



a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.

Ensure that you are currently in the same leaf domain that includes the device, if you are using domains.

b) Click **Add NAT Rule** > **Add Manual NAT**.
c) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress1 network object.
- **Original Destination** > **Address** = DMZnetwork1 network object.
- **Translated Destination** = DMZnetwork1 network object.

Note Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank.

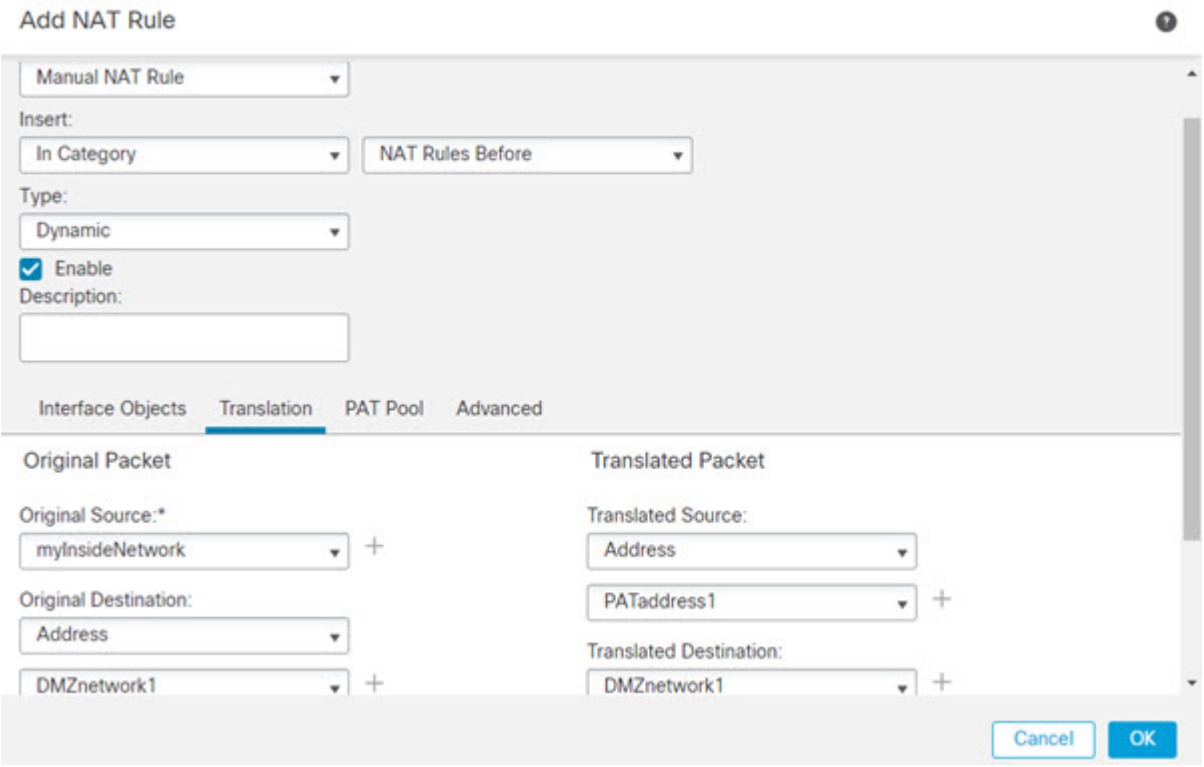
d) Click **Save**.

Step 7 Configure dynamic manual PAT for DMZ network 1.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

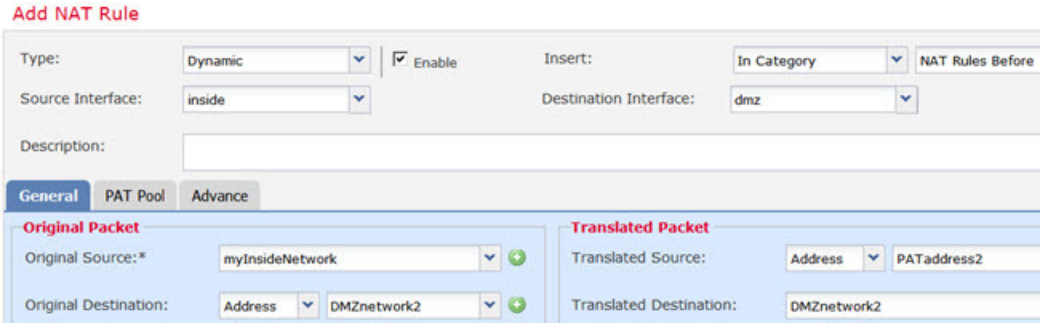


- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

e) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress1 network object.
- **Original Destination** > **Address** = DMZnetwork1 network object.
- **Translated Destination** = DMZnetwork1 network object.

Note Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank.



f) Click **Save**.

Step 8 Configure dynamic manual PAT for DMZ network 2.

a) Click **Add NAT Rule** > **Add Manual NAT**.

b) Configure the following properties:

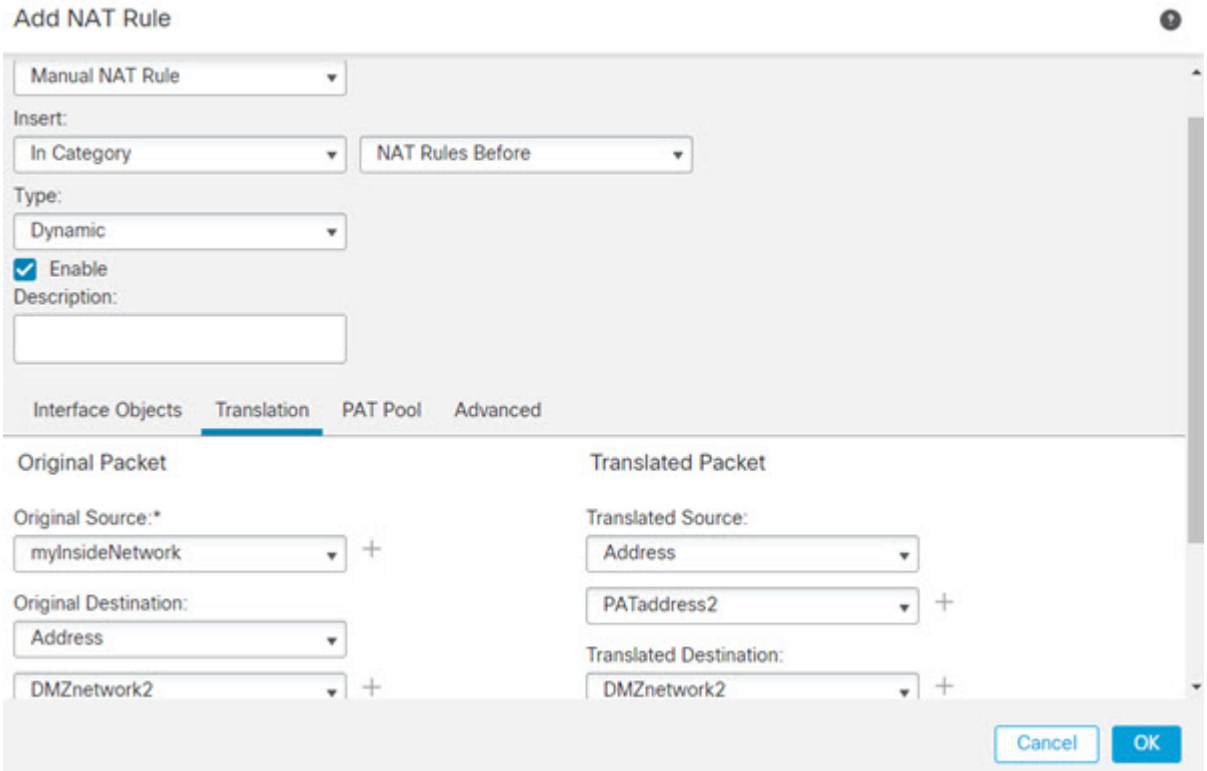
- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress2 network object.
- **Original Destination** > **Address** = DMZnetwork2 network object.
- **Translated Destination** = DMZnetwork2 network object.

c) Click **Save**.

Step 9 Configure dynamic manual PAT for DMZ network 2.

a) Click **Add Rule**.

b) Configure the following properties:



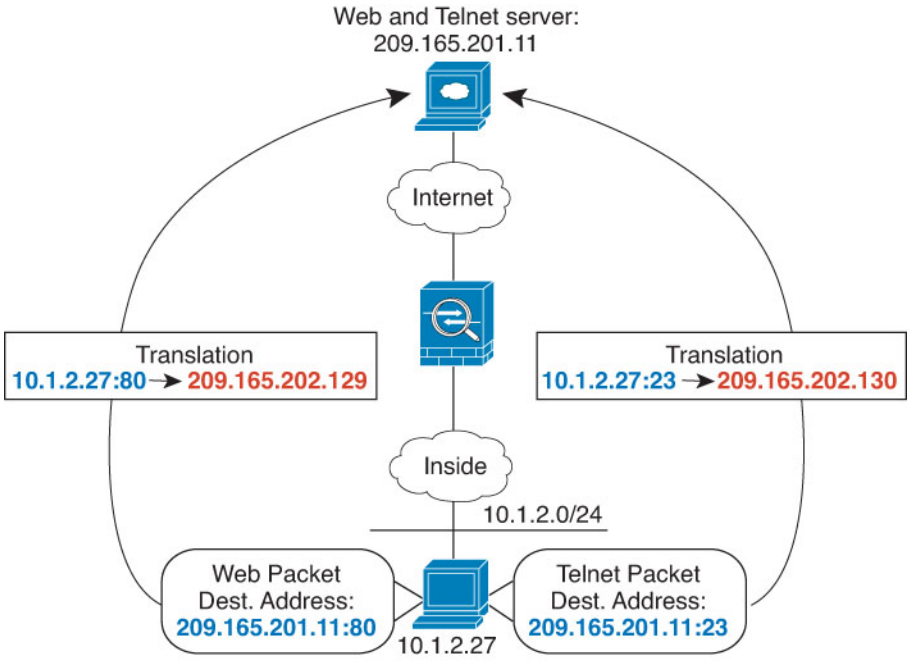
- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

d) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress2 network object.
- **Original Destination** > **Address** = DMZnetwork2 network object.
- **Translated Destination** = DMZnetwork2 network object.



e) Click **Save**.

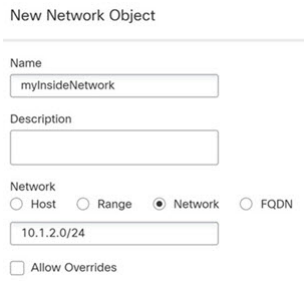
Step 10 Click **Save** on the NAT rule page.

Configure dynamic manual PAT with different destination ports

This illustration displays the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for Telnet services, the real address is translated to 209.165.202.129: *port*. When the host accesses the same server for web services, the real address is translated to 209.165.202.130: *port*.

Figure 390: Manual NAT with Different Destination Ports

Before you begin



Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **dmz**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

Procedure

Step 1 Create a network object for the inside network.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

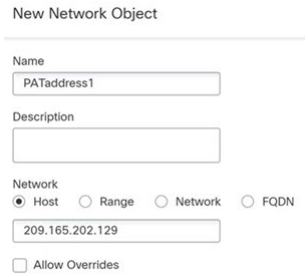
b) Name the network object (for example, myInsideNetwork) and enter the real network address, 10.1.2.0/24.

c) Click **Save**.

Step 2 Create a network object for the Telnet/Web server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, TelnetWebServer) and enter the host address 209.165.201.11.

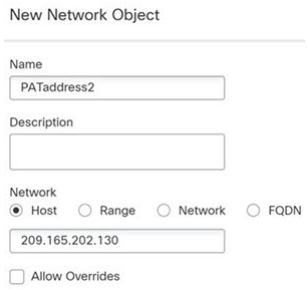


c) Click **Save**.

Step 3 Create a network object for the PAT address when using Telnet.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress1) and enter the host address 209.165.202.129.



c) Click **Save**.

Step 4 Create a network object for the PAT address when using HTTP.

a) Click **Add Network** > **Add Object**.

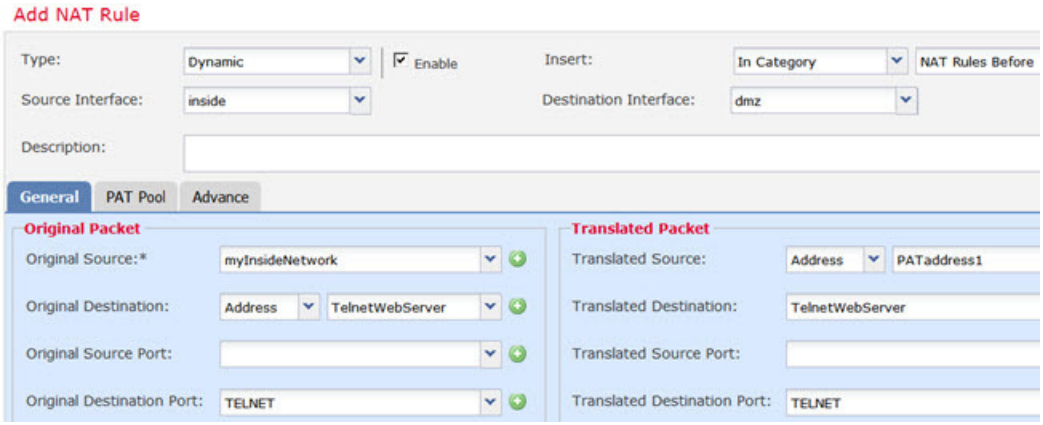
b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.

c) Click **Save**.

Step 5 Configure dynamic manual PAT for Telnet access.

a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.

Ensure that you are currently in the same leaf domain that includes the device, if you are using domains.



b) Click **Add NAT Rule** > **Add Manual NAT**.

c) Configure the following properties:

- **Type** = Dynamic.

- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address** = PATaddress1 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = TELNET port object (system-defined).
- **Translated Destination Port** = TELNET port object (system-defined).

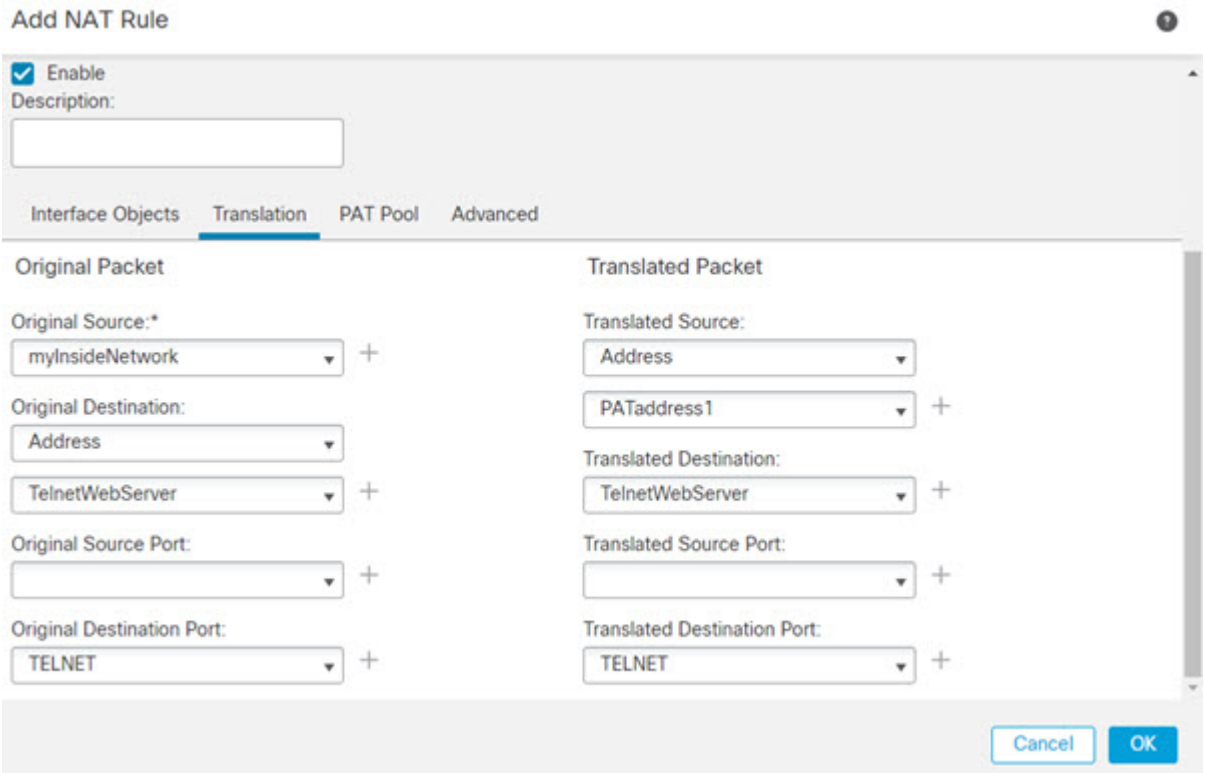
Note Because you do not want to translate the destination address or port, you need to configure identity NAT for them by specifying the same address for the original and translated destination addresses, and the same port for the original and translated port.

d) Click **Save**.

Step 6 Configure dynamic manual PAT for Telnet access.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.



d) On **Interface Objects**, configure the following:

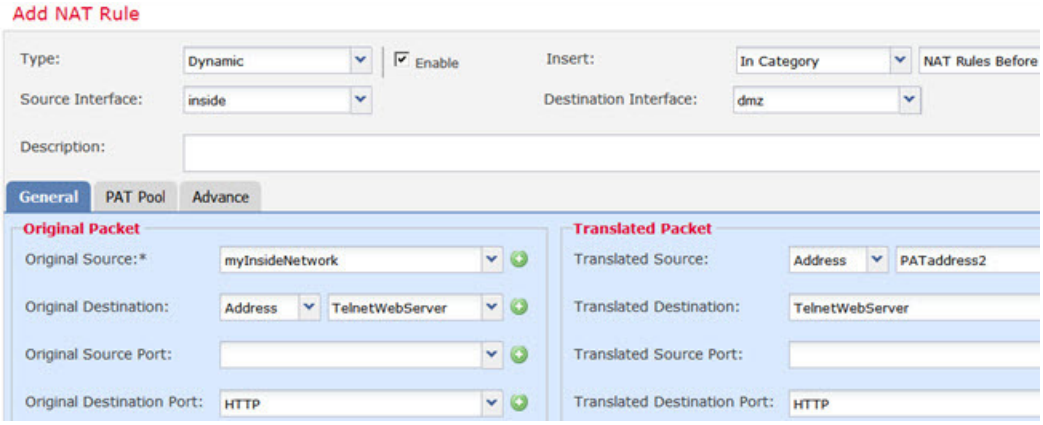
- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

e) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address** = PATaddress1 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = TELNET port object (system-defined).
- **Translated Destination Port** = TELNET port object (system-defined).

Note Because you do not want to translate the destination address or port, you need to configure identity NAT for them by specifying the same address for the original and translated destination addresses, and the same port for the original and translated port.

f) Click **Save**.



Step 7 Configure dynamic manual PAT for web access.

a) Click **Add NAT Rule** > **Add Manual NAT**.

b) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.

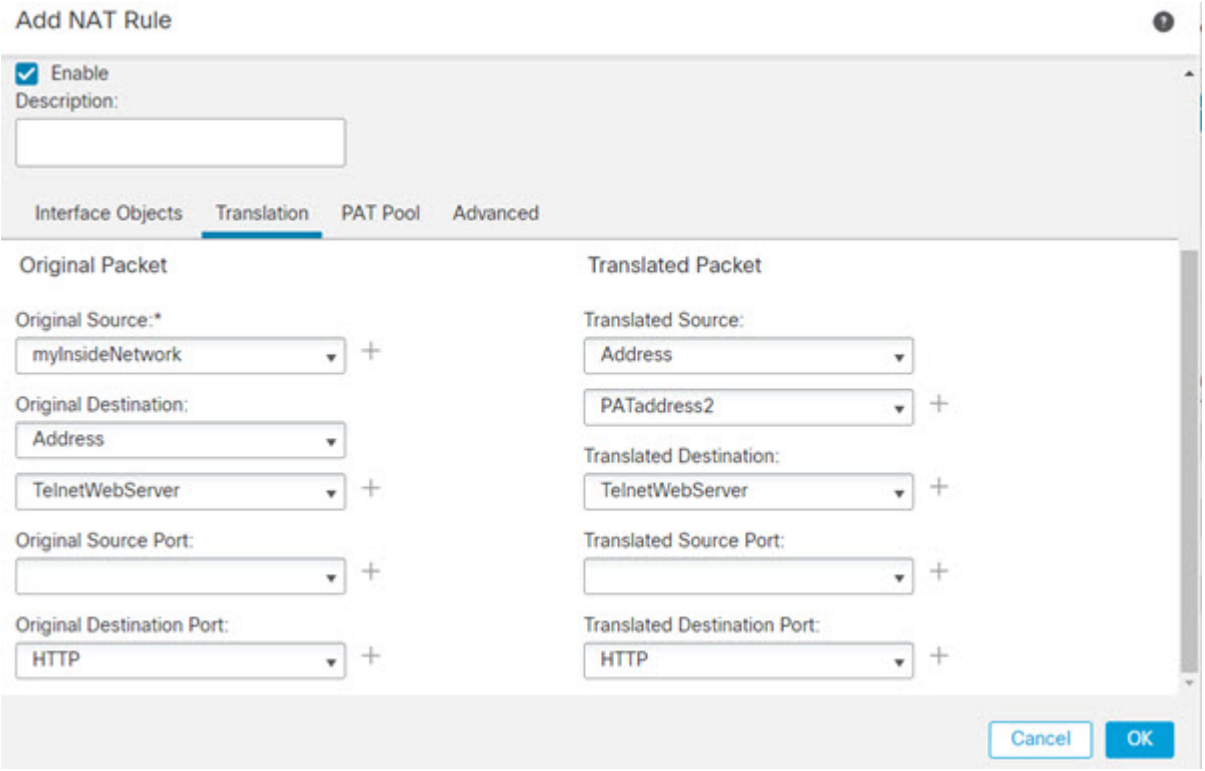
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address** = PATaddress2 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = HTTP port object (system-defined).
- **Translated Destination Port** = HTTP port object (system-defined).

c) Click **Save**.

Step 8 Configure dynamic manual PAT for web access.

a) Click **Add Rule**.

b) Configure the following properties:



- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

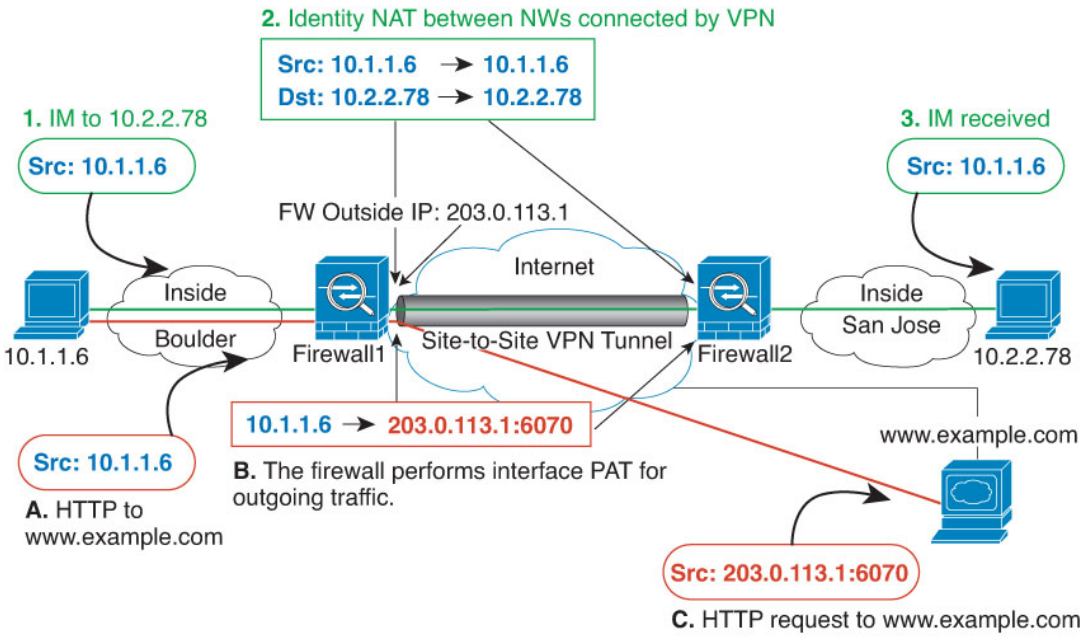
c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

d) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address** = PATaddress2 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = HTTP port object (system-defined).
- **Translated Destination Port** = HTTP port object (system-defined).

e) Click **Save**.



Step 9 Click **Save** on the NAT rule page.

NAT and site-to-site VPN

When you create a policy-based site-to-site VPN using the management center VPN wizard (**Device > Site To Site**), you can select the NAT Exempt option to create the rules automatically. You can view the NAT exemptions for a device in the NAT policy page (**Device > NAT > NAT Exemptions**). If you do not want to configure NAT Exempt in the VPN wizard, you can use the following procedure for NAT exemption.

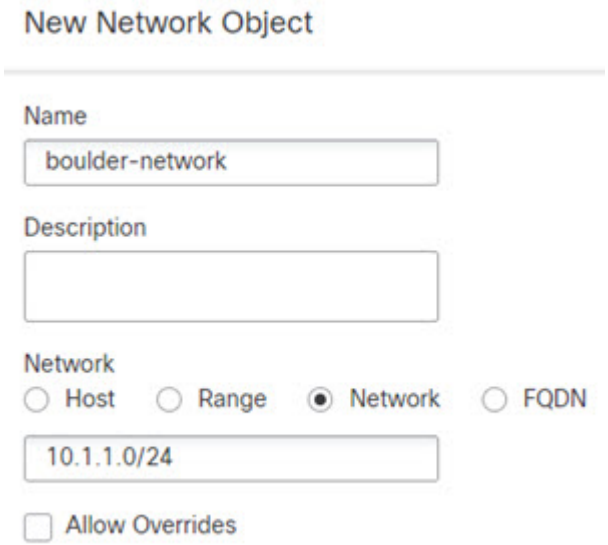
The following figure shows a site-to-site tunnel connecting the Boulder and San Jose offices. For traffic that you want to go to the Internet (for example from 10.1.1.6 in Boulder to www.example.com), you need a public IP address provided by NAT to access the Internet. The below example uses interface PAT rules. However, for traffic that you want to go over the VPN tunnel (for example from 10.1.1.6 in Boulder to 10.2.2.78 in San Jose), you do not want to perform NAT; you need to exempt that traffic by creating an identity NAT rule. Identity NAT simply translates an address to the same address.

Figure 391: Interface PAT and Identity NAT for Site-to-Site VPN

This example explains the configuration for Firewall1 (Boulder).

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the devices in the VPN. In this example, we will assume the interface objects are security zones named **inside-boulder** and **outside-boulder** for the Firewall1 (Boulder) interfaces. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

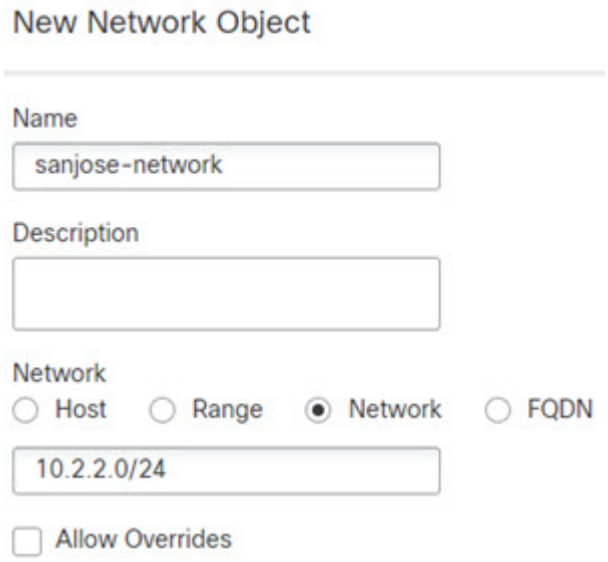


Procedure

Step 1 Create the objects to define the various networks.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Identify the Boulder inside network.



Name the network object (for example, boulder-network) and enter the network address, 10.1.1.0/24.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the inside San Jose network.

Name the network object (for example, sanjose-network) and enter the network address 10.2.2.0/24.

e) Click **Save**.

Step 2 Configure manual identity NAT for the Boulder network when going over the VPN to San Jose on Firewall1 (Boulder).

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

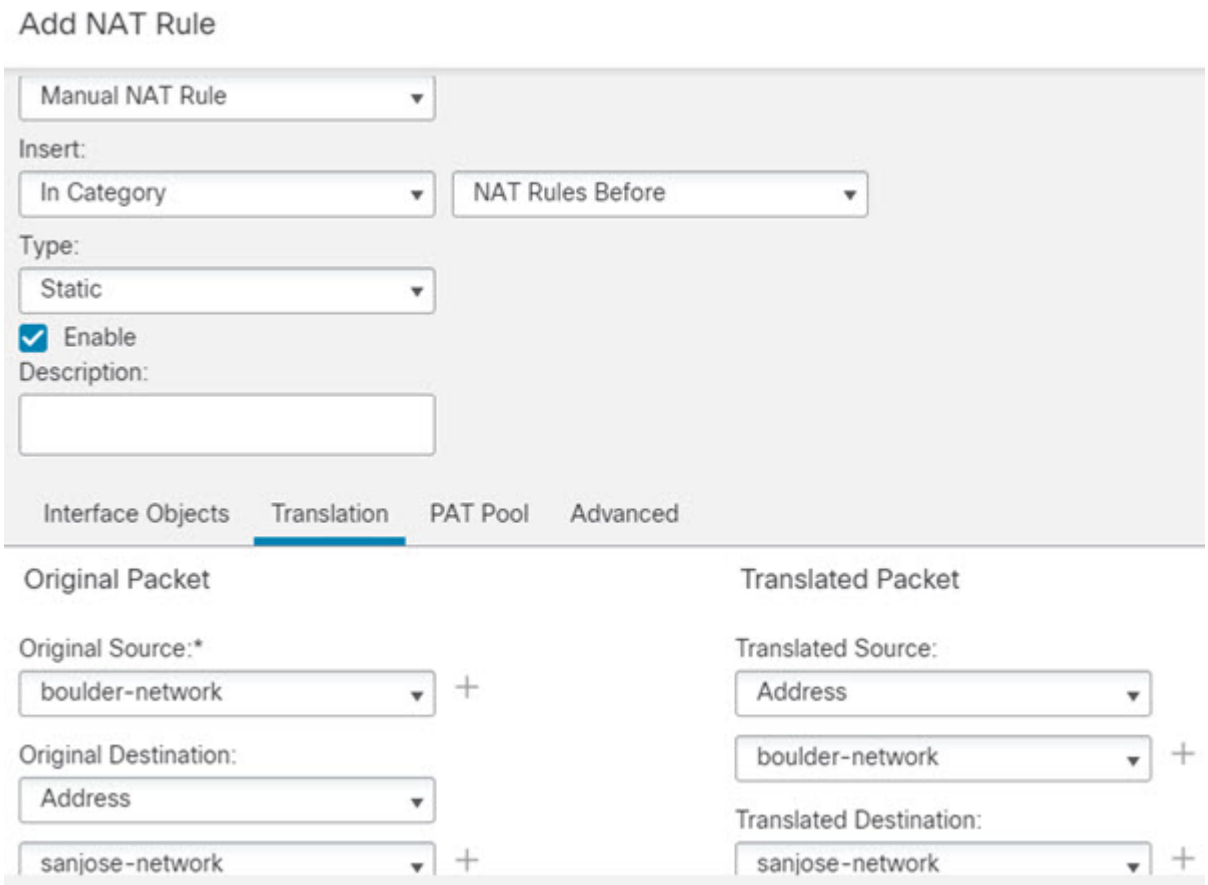
c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.

- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside-boulder.
- **Destination Interface Objects** = outside-boulder.



e) On **Translation**, configure the following:

- **Original Source** = boulder-network object.
- **Translated Source** > **Address** = boulder-network object.
- **Original Destination** > **Address** = sanjose-network object.
- **Translated Destination** = sanjose-network object.

Note Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank. This rule configures identity NAT for both source and destination.

f) On **Advanced**, select **Do not proxy ARP on Destination interface**.

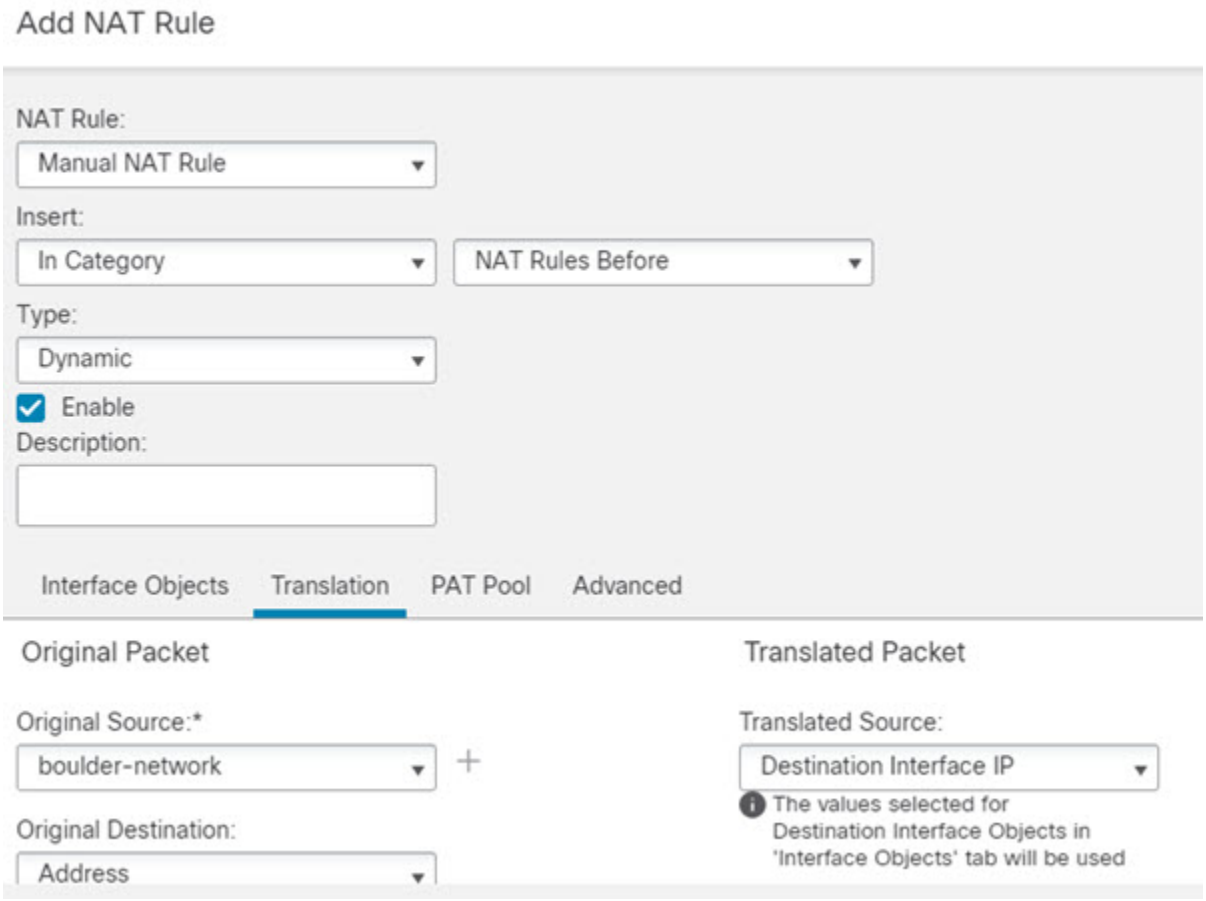
g) Click **Save**.

Step 3 Configure manual dynamic interface PAT when going to the Internet for the inside Boulder network on Firewall1 (Boulder).

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.
- **Insert Rule** = any position after the first rule. Because this rule will apply to any destination address, the rule that uses sanjose-network as the destination must come before this rule, or the sanjose-network rule will never be matched. The default is to place new manual NAT rules at the end of the "NAT Rules Before Auto NAT" section.



c) On **Interface Objects** , configure the following:

- **Source Interface Objects** = inside-boulder.
- **Destination Interface Objects** = outside-boulder.

d) On **Translation** , configure the following:

- **Original Source** = boulder-network object.

- **Translated Source** = **Destination Interface IP**. This option configures interface PAT using the interface contained in the destination interface object.
- **Original Destination** > **Address** = any (leave blank).
- **Translated Destination** = any (leave blank).

e) Click **Save**.

Step 4 If you are also managing Firewall2 (San Jose), you can configure similar rules for that device.

- The manual identity NAT rule would be for sanjose-network when the destination is boulder-network. Create new interface objects for the Firewall2 inside and outside networks.
- The manual dynamic interface PAT rule would be for sanjose-network when the destination is "any."

DNS query and response rewriting using NAT

DNS rewrite is the process of modifying DNS replies so that the IP address returned in the DNS response is replaced with an address that matches the NAT configuration. It is used when a translated address must be

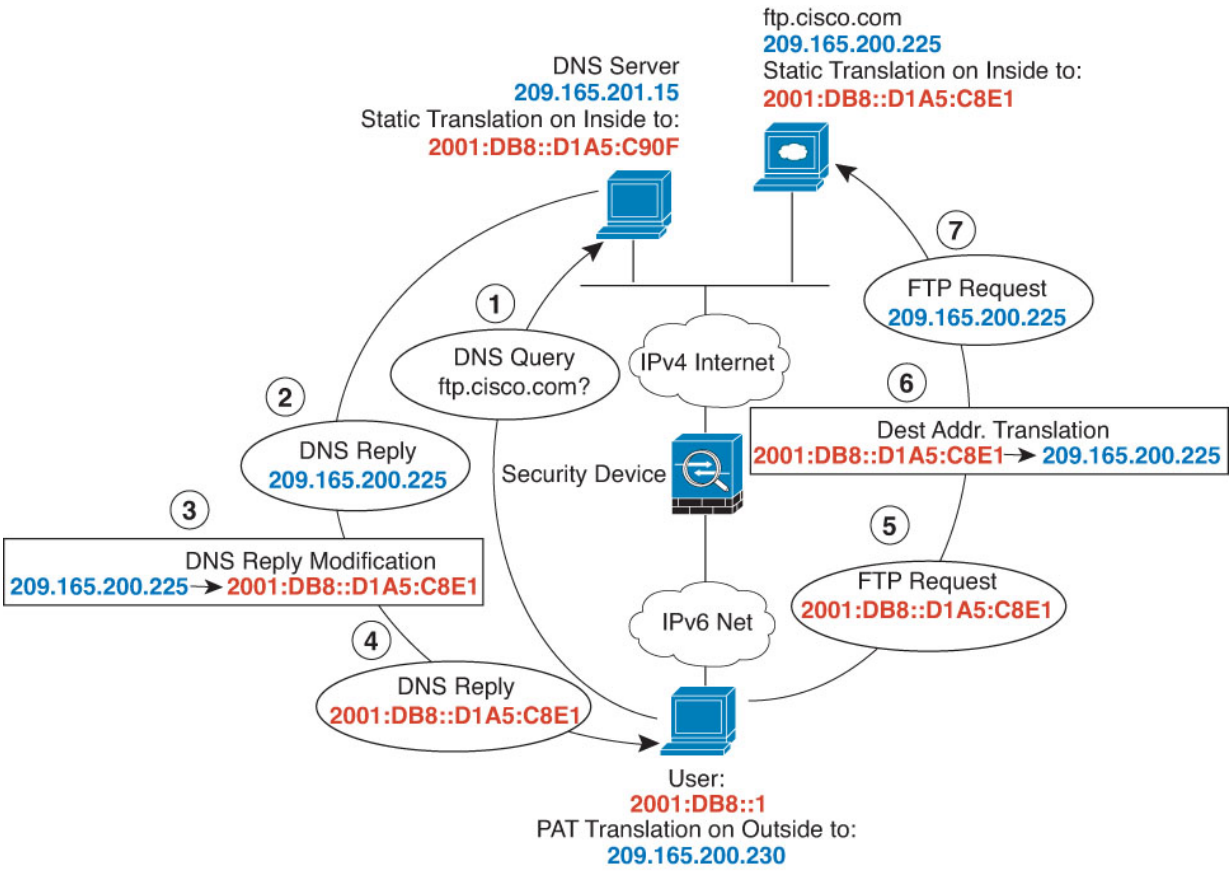
returned to the requester instead of the original address in the DNS record. This function is also known as DNS doctoring.

This feature rewrites the address in DNS queries and replies that match a NAT rule (for example, the A record for IPv4, the AAAA record for IPv6, or the PTR record for reverse DNS queries). For DNS replies traversing from a mapped interface to any other interface, the record is rewritten from the mapped value to the real value. Inversely, for DNS replies traversing from any interface to a mapped interface, the record is rewritten from the real value to the mapped value. This feature works with NAT44,NAT 66, NAT46, and NAT64.

The main circumstances when you would need to configure DNS rewrite on a NAT rule are:

- The rule is NAT64 or NAT46, and the DNS server is on the outside network. You need DNS rewrite to convert between DNS A records (for IPv4) and AAAA records (for IPv6).
- The DNS server is on the outside, clients are on the inside, and some of the fully-qualified domain names that the clients use resolve to other inside hosts.
- The DNS server is on the inside and responds with private IP addresses, clients are on the outside, and the clients access fully-qualified domain names that point to servers that are hosted on the inside.

DNS rewrite has the following limitations:



- DNS rewrite is not applicable for PAT because multiple PAT rules are applicable for each A or AAAA record, and the PAT rule to use is ambiguous.
- If you configure a manual NAT rule, you cannot configure DNS modification if you specify the destination address as well as the source address. These kinds of rules can potentially have a different translation for a single address when going to A vs. B. Therefore, the can not accurately match the IP address inside the DNS reply to the correct twice NAT rule; the DNS reply does not contain information about which source/destination address combination was in the packet that prompted the DNS request.
- You must enable DNS application inspection with DNS NAT rewrite enabled for NAT rules to rewrite DNS queries and responses. By default, DNS inspection with DNS NAT rewrite enabled is globally applied, so you probably do not need to change the inspection configuration.
- DNS rewrite is actually done on the xlate entry, not the NAT rule. Thus, if there is no xlate for a dynamic rule, rewrite cannot be done correctly. The same problem does not occur for static NAT.
- DNS rewrite does not rewrite DNS Dynamic Update messages (opcode 5).

These topics provide examples of DNS rewrite in NAT rules.

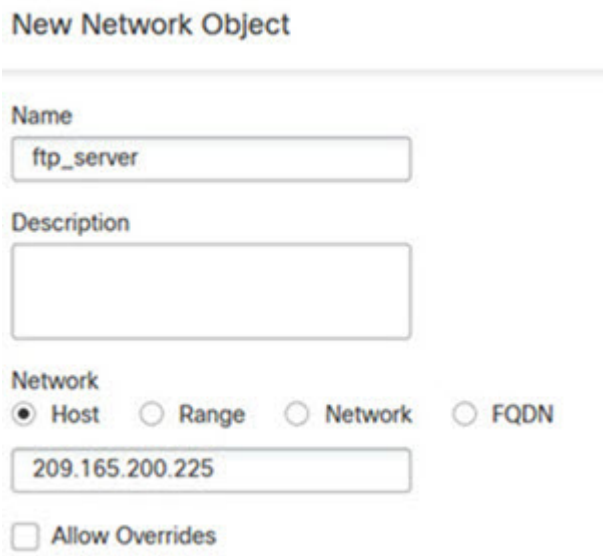
DNS64 reply modification

The following figure shows an FTP server and DNS server on the outside IPv4 network. The system has a static translation for the outside server. In this case, when an inside IPv6 user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.200.225.

Because you want inside users to use the mapped address for ftp.cisco.com (2001:DB8::D1A5:C8E1, where D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225) you need to configure DNS reply modification for the static translation. This example also includes a static NAT translation for the DNS server, and a PAT rule for the inside IPv6 hosts.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

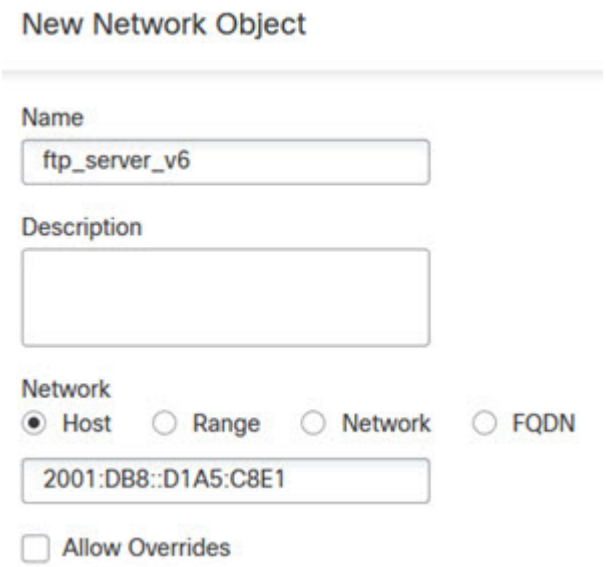


Procedure

Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the real FTP server address.

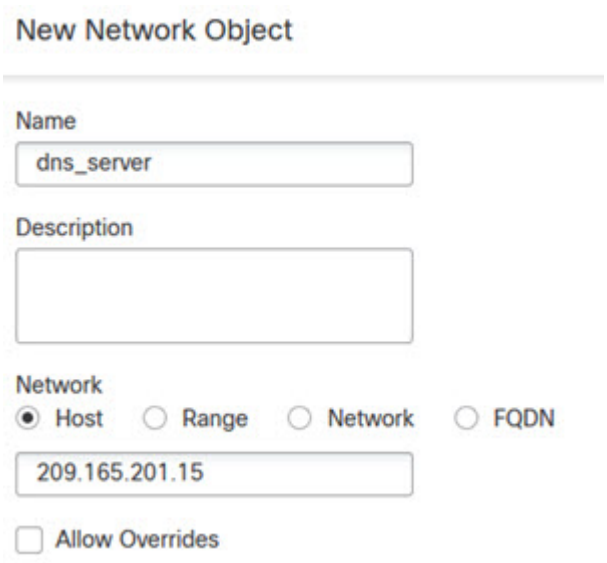


Name the network object (for example, ftp_server) and enter the host address, 209.165.200.225.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the FTP server's translated IPv6 address.

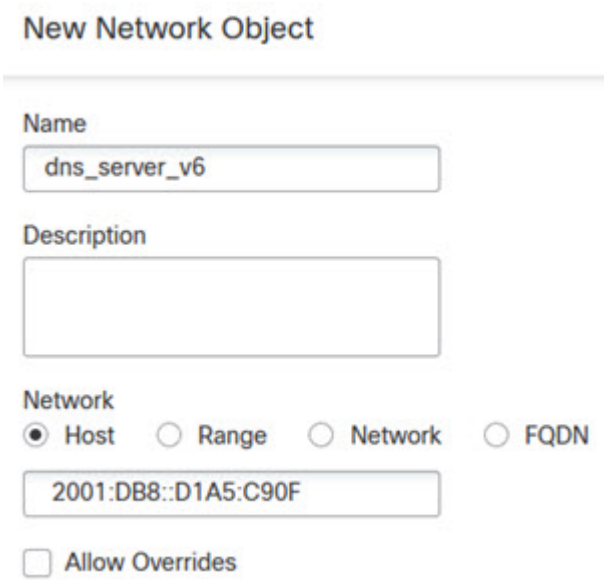
Name the network object (for example, ftp_server_v6) and enter the host address, 2001:DB8::D1A5:C8E1.



e) Click **Save**.

Step 2 Create the network objects for the DNS server.

a) Click **Add Network** > **Add Object** and define the DNS server's real address.

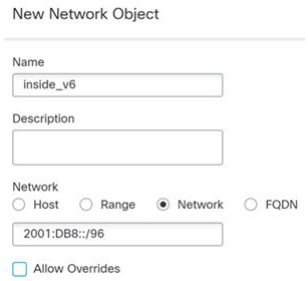


Name the network object (for example, dns_server) and enter the host address, 209.165.201.15.

b) Click **Save**.

c) Click **Add Network** > **Add Object** and define the DNS server's translated IPv6 address.

Name the network object (for example, dns_server_v6) and enter the host address, 2001:DB8::D1A5:C90F (where D1A5:C90F is the IPv6 equivalent of 209.165.201.15).

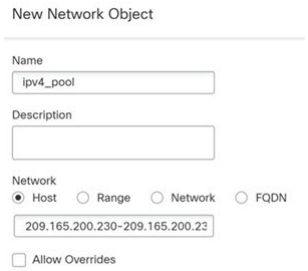


d) Click **Save**.

Step 3 Create the network objects for the inside network.

a) Click **Add Network** > **Add Object** and define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:DB8::/96.



b) Click **Save**.

Step 4 Create the network objects for the PAT pool.

a) Click **Add Network** > **Add Object** and define the IPv4 PAT pool for the inside IPv6 network.

Name the network object (for example, ipv4_pool) and enter the range 209.165.200.230-209.165.200.235.

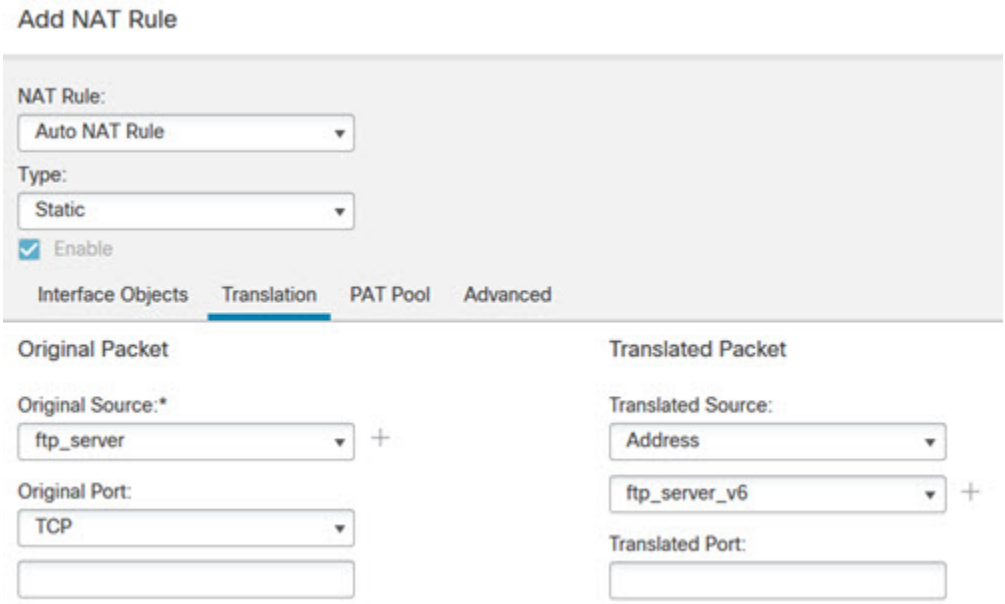
b) Click **Save**.

Step 5 Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_v6 network object.

f) On **Advanced**, select the following options:

- **Translate DNS replies that match this rule**.
- **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

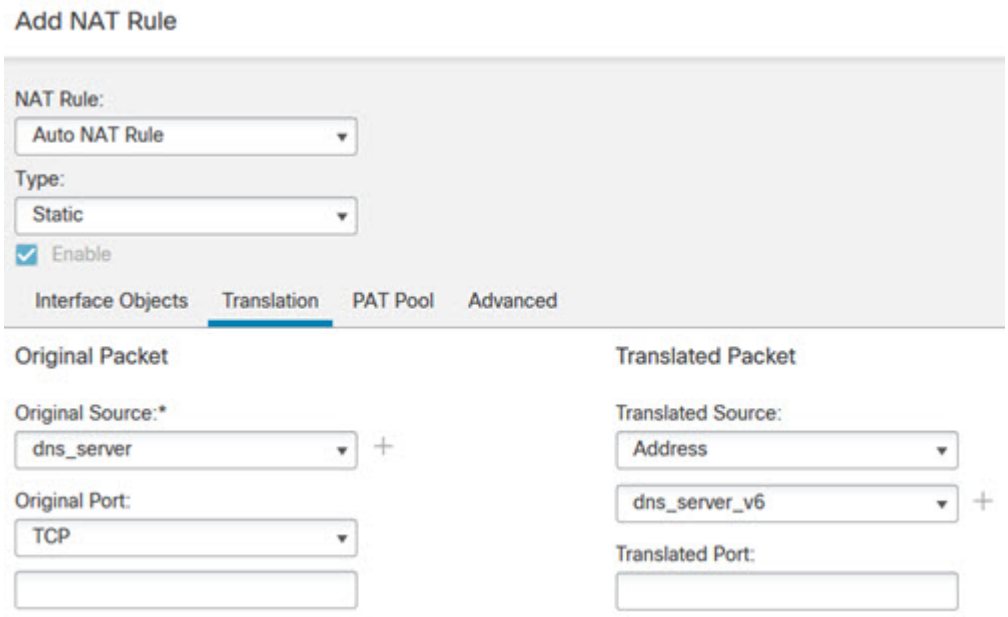
g) Click **OK**.

Step 6 Configure the static NAT rule for the DNS server.

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

d) On **Translation**, configure the following:

- **Original Source** = dns_server network object.
- **Translated Source** > **Address** = dns_server_v6 network object.

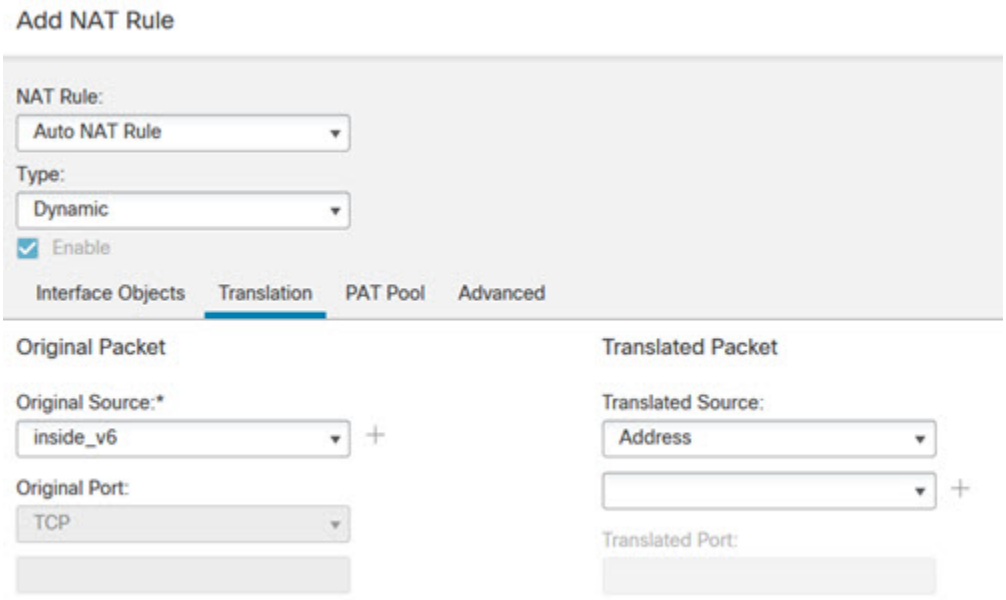
e) On **Advanced**, select **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

f) Click **OK**.

Step 7 Configure the dynamic NAT with a PAT pool rule for the inside IPv6 network.

a) Click **Add Rule**.

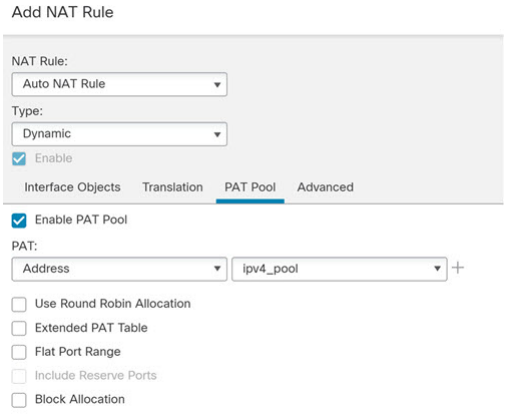
b) Configure the following properties:



- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

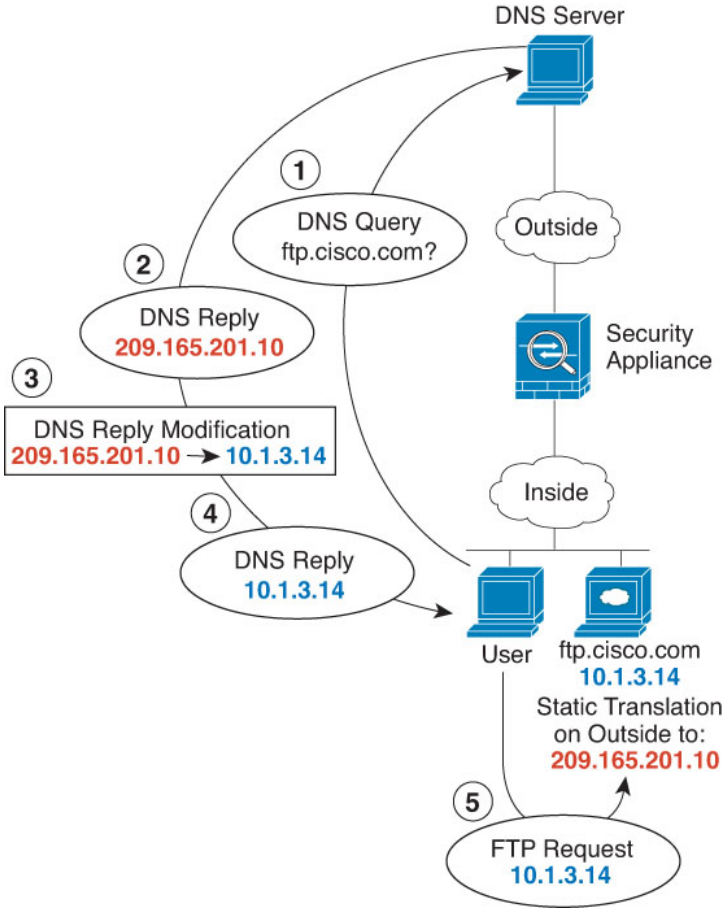


d) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** > **Address** = leave this field empty.

e) On **PAT Pool**, configure the following:

- **Enable PAT Pool** = select this option.
- **Translated Source** > **Address** = ipv4_pool network object.



f) Click **OK**.

Create DNS reply modification with DNS server on outside

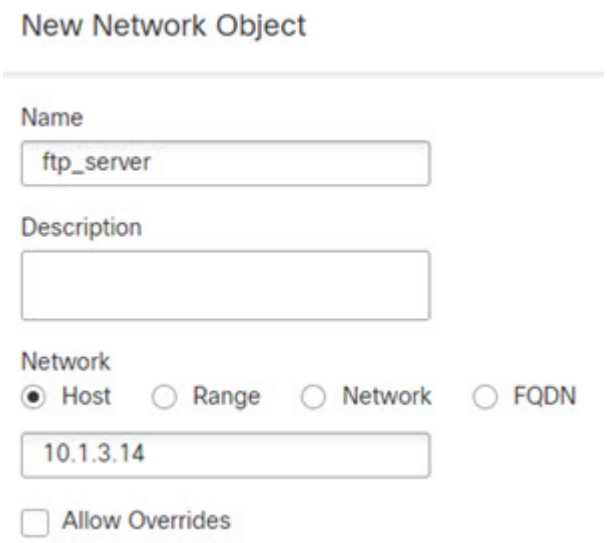
The following figure shows a DNS server that is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure NAT to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network.

In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The system refers to the static rule for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

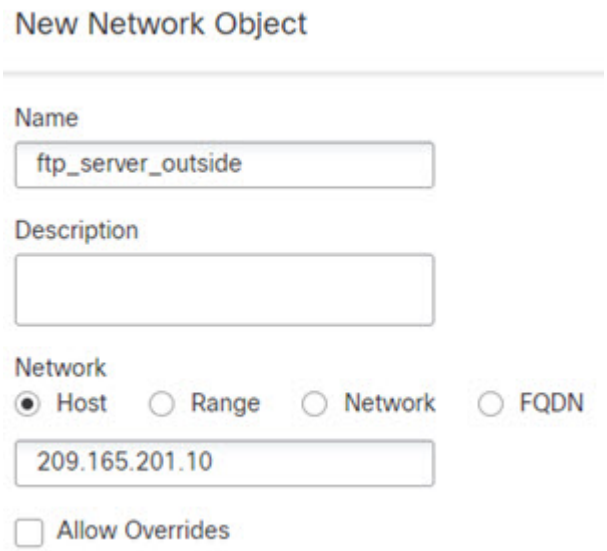


Procedure

Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the real FTP server address.



Name the network object (for example, ftp_server) and enter the host address, 10.1.3.14.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the FTP server's translated address.

Name the network object (for example, ftp_server_outside) and enter the host address, 209.165.201.10.

e) Click **Save**.

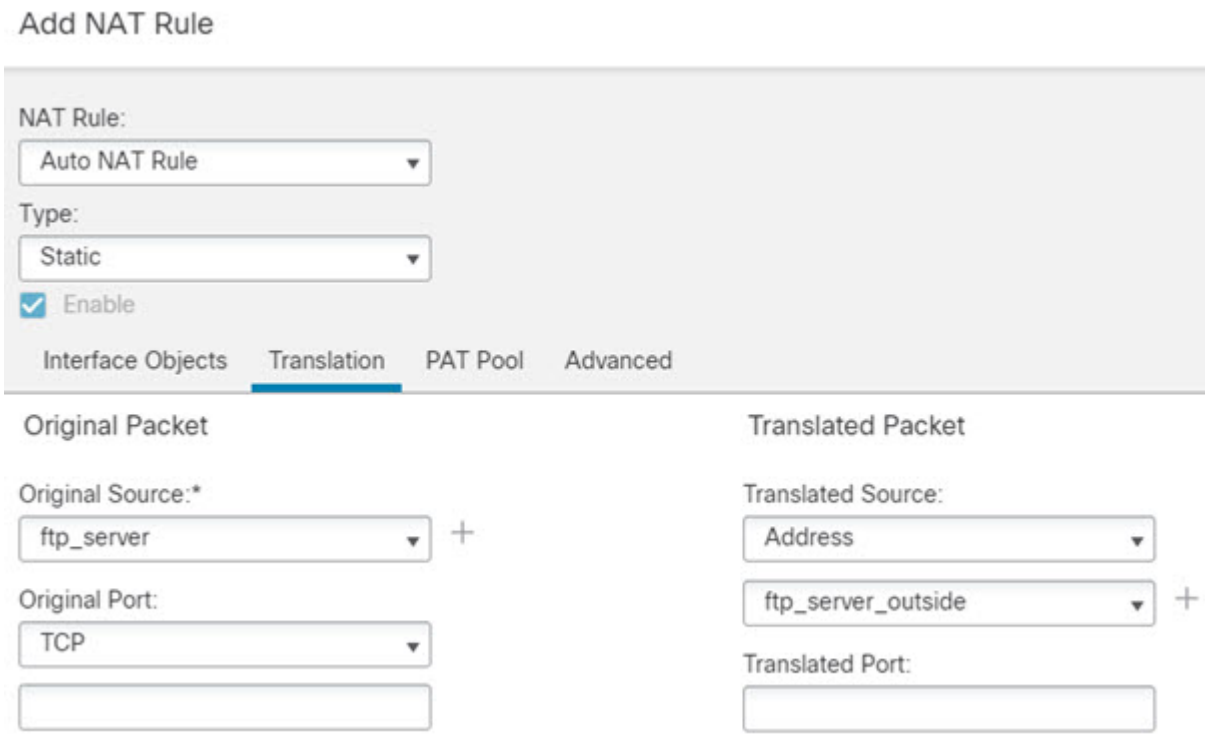
Step 2 Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

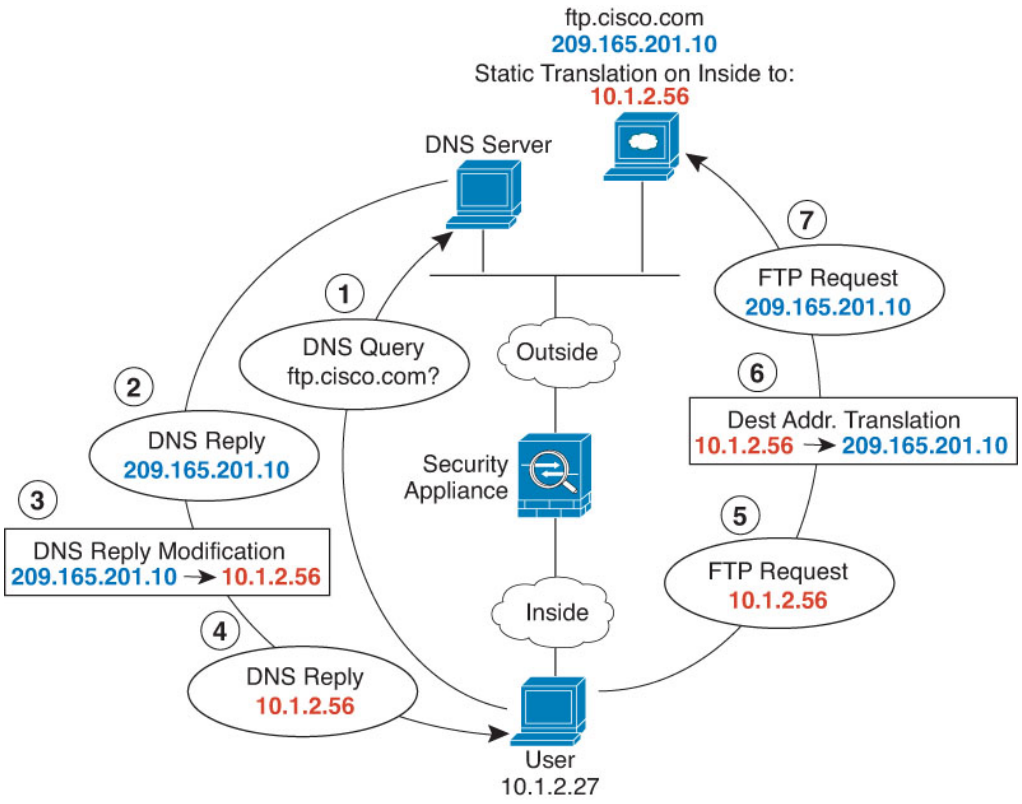


d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_outside network object.



f) On **Advanced**, select **Translate DNS replies that match this rule**.

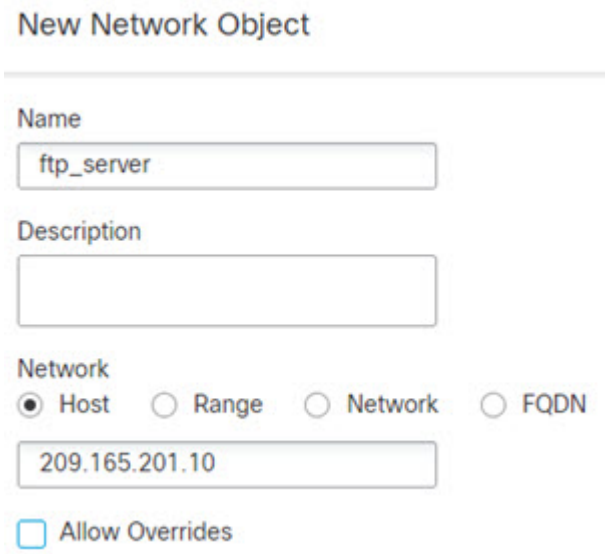
g) Click **OK**.

Configure DNS reply modification with DNS server on host network

The following figure shows an FTP server and DNS server on the outside. The system has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.

Before you begin

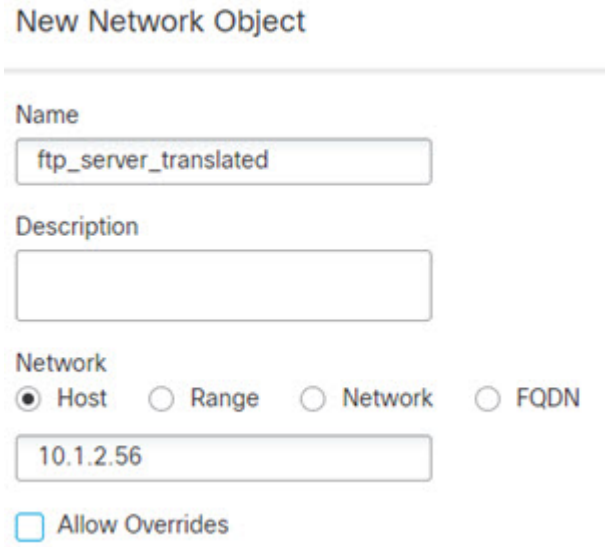
Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.



Procedure

Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.



b) Define the real FTP server address.

Name the network object (for example, ftp_server) and enter the host address, 209.165.201.10.

c) Click **Save**.
d) Click **Add Network** > **Add Object** and define the FTP server's translated address.

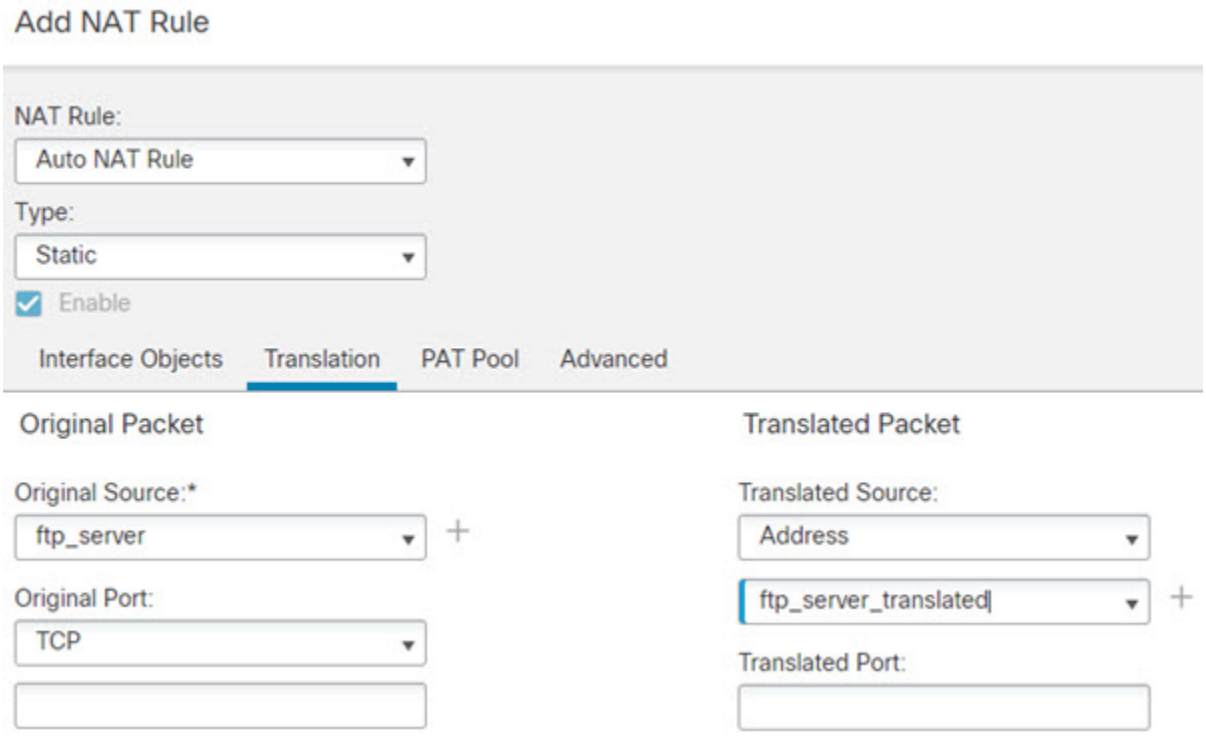
Name the network object (for example, ftp_server_translated) and enter the host address, 10.1.2.56.

e) Click **Save**.

Step 2 Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_translated network object.

f) On **Advanced**, select **Translate DNS replies that match this rule**.

g) Click **OK**.

History for Firewall Threat Defense NAT

This table provides a chronological summary of feature changes and enhancements for the network address translation policy across different software releases.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Creation of network groups while editing NAT rules.	7.2.6 7.4.1	Any	You can create network groups in addition to network objects when you are editing a NAT rule. This feature is not supported in Version 7.3.x or 7.4.0.
Ability to enable, disable, or delete more than one NAT rule at a time.	7.2	Any	You can select multiple NAT rules and enable, disable, or delete them all at the same time. Enable and disable apply to manual NAT rules only, whereas delete applies to any NAT rule.
Manual NAT support for fully-qualified domain name (FQDN) objects as the translated destination.	7.1	Any	You can use an FQDN network object, such as one specifying www.example.com, as the translated destination address in manual NAT rules. The system configures the rule based on the IP address returned from the DNS server.
Changes to PAT address allocation in clustering. The PAT pool **Flat Port Range** option is now enabled by default and it is not configurable.	6.7	Any	The way PAT addresses are distributed to the members of a cluster is changed. Previously, addresses were distributed to the members of the cluster, so your PAT pool would need a minimum of one address per cluster member. Now, the control unit instead divides each PAT pool address into equal-sized port blocks and distributes them across cluster members. Each member has port blocks for the same PAT addresses. Thus, you can reduce the size of the PAT pool, even to as few as one IP address, depending on the amount of connections you typically need to PAT. Port blocks are allocated in 512-port blocks from the 1024-65535 range. You can optionally included the reserved ports, 1-1023, in this block allocation when you configure PAT pool rules. For example, in a 4-node cluster, each node gets 32 blocks with which it will be able to handle 16384 connections per PAT pool IP address compared to a single node handling all 65535 connections per PAT pool IP address. As part of this change, PAT pools for all systems, whether standalone or operating in a cluster, now use a flat port range of 1023 - 65535. Previously, you could optionally use a flat range by including the **Flat Port Range** option in a PAT pool rule. The **Flat Port Range** option is now ignored: the PAT pool is now always flat. You can optionally select the **Include Reserved Ports** option to include the 1 - 1023 port range within the PAT pool. Note that if you configure port block allocation (the **Block Allocation** PAT pool option), your block allocation size is used rather than the default 512-port block. In addition, you cannot configure extended PAT for a PAT pool for systems in a cluster.
Ability to search and filter the Firewall Threat Defense NAT rule table.	6.7	Any	You can now search for rules in Firewall Threat Defense NAT policies to help you find rules based on IP addresses, ports, object names, and so forth. Search results include partial matches. Searching on criteria filters the rule table so only matching rules are displayed. We added a search field above the rule table when you edit Firewall Threat Defense NAT policies.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Carrier grade NAT enhancements.	6.5	Any	For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time (see RFC 6888). New/modified screens: We added the **Block Allocation** option to the NAT PAT Pool tab for Firewall Threat Defense NAT rules.
Support for network range objects in NAT for Firewall Threat Defense.	6.1.0	Any	You can now use network range objects in Firewall Threat Defense NAT rules where appropriate.
Network Address Translation (NAT) for Firewall Threat Defense.	6.0.1	Any	The NAT policy for Firewall Threat Defense was added. New/modified screens: Threat Defense was added as a type of NAT policy to the **Devices** > **NAT** page.

CHAPTER 31

Quality of Service

Quality of Service is a network management feature that:

- enables the policing of network traffic on Firewall Threat Defense devices.
- assists administrators in managing network traffic,
- provides guidelines for rate limiting.

- QoS, on page 1313
- QoS policies, on page 1314
- Requirements and prerequisites for QoS, on page 1314
- Guidelines and limitations for QoS policies, on page 1315
- Rate limiting with QoS policies, on page 1315
- History for QoS, on page 1326

QoS

QoS is a traffic management mechanism that

- rate limits (polices) network traffic that is allowed or trusted by access control
- does not rate limit traffic that was fastpathed and
- is supported only on the routed interfaces of Firewall Threat Defense devices.

QoS interface limitations

QoS is supported only on the routed interfaces of Firewall Threat Defense devices. However, it does not support site-to-site VPN and VTI interfaces.

Logging Rate-Limited Connections

You cannot configure logging for QoS. A connection can be rate limited without being logged. Conversely, a logged connection may not be rate-limited. To view QoS details, you must separately log connection ends in your Firewall Management Center database. See *Other Connections You Can Log* in the *Cisco Secure Firewall Management Center Administration Guide* for more information.

Connection events for rate-limited connections show how much traffic was dropped and the specific QoS configurations that applied. You can view this information in event views (workflows), dashboards, and reports.

QoS policies

A QoS policy is a configuration mechanism that

- governs rate limiting on managed devices
- can target multiple devices with each device having one deployed QoS policy at a time, and
- contains up to 63 QoS rules that handle network traffic in specified order.

QoS policy characteristics

QoS policies have these key characteristics:

-
- The system matches traffic to QoS rules in the order specified. The system rate limits traffic according to the first rule where all rule conditions match the traffic. Traffic not matching any of the rules is not rate limited.
- QoS rules can be limited by source or destination (routed) interfaces. The system enforces rate limiting *independently* on *each* of those interfaces and does not support an aggregate rate limit for a set of interfaces.
-
- You can independently rate limit download and upload traffic based on the connection initiator.

Note A device can have no more than 255 rules, including QoS rules. Exceeding this number causes a deployment warning necessitating a reduction in the number of rules..

Note QoS operates independently and is not subordinate to a main access control configuration. However, the access control and QoS policies deployed to the same device share identity configurations. For more infomration, see Associate prefilter, decryption, and identity policies with an access control, on page 1585.

Requirements and prerequisites for QoS

This reference provides the requirements and prerequisites for implementing QoS, including supported models, domains, and user roles.

Model support

Firewall Threat Defense

Supported domains

Any

User roles

Admin

Access Admin

Network Admin

Guidelines and limitations for QoS policies

QoS rules and service policy rules (in the access control policy) are translated into firewall commands. There can be only one policy map per interface as the system combines QoS and service policy configurations automatically.

However, you can also create policy maps manually using FlexConfig. For lower-end firewalls, such as the Secure Firewall 3100, you can create up to 64 policy maps using FlexConfig. For more powerful firewalls, such as the Firepower 4100, you can create up to 128 policy maps. Ensure not to exceed this limit to prevent deployment failures. You can check the device configuration using the CLI or the deployment transcript to see how rules are translated into commands.

Rate limiting with QoS policies

To perform policy-based rate limiting, configure and deploy QoS policies to managed devices. Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Procedure

Step 1 Choose **Devices** > **QoS**.

Step 2 Click **New Policy** to create a new QoS policy and, optionally assign target devices; see Create a QoS policy, on page 1316.

You can also **Copy** ( ) or **Edit** ( ) an existing policy.

Step 3 Configure QoS rules; see Configuring QoS rules, on page 1318 and QoS rule conditions, on page 1320.

The QoS policy editor lists each rule in evaluation order and displays a summary of the rule conditions and rate limiting configurations. Use the right-click menu to manage rules, including moving, enabling, and disabling them.

This feature is helpful in larger deployments. You can **Filter by Device** to display only the rules that affect a specific device or group of devices. You can also search for rules, and the system matches text entered in the **Search Rules** field to rule names and condition values, including objects and object groups.

Note Properly creating and ordering rules is a complex but essential to effective deployment. Careful planning is necessary to prevent rules from preempting each other, requiring additional licenses, or containing invalid configurations. Icons in the interface represent comments, warnings, and errors. If issues exist, click **Show Warnings** to display a list. For more information, see Best practices for access control rules, on page 1625.

Step 4 Click **Policy Assignments** to identify which managed devices the policy targets; see Set target devices for a QoS policy , on page 1317.

Verify your choices, if you identified target devices during policy creation.

Step 5 Save the QoS policy.

Step 6 Since this feature must allow some packets to pass, configure your system to examine those packets.

Step 7 Deploy configuration changes; see Deploy configuration changes, on page 135.

The QoS policy is configured and deployed to the target devices, enabling policy-based rate limiting for network traffic.

Create a QoS policy

Create a QoS policy to establish the foundation for implementing rate limiting and traffic management rules on network devices.

The new QoS policy you create will not perform any rate limiting unless rules are added.

Procedure

Step 1 Choose **Devices** > **QoS**.

Step 2 Click **New Policy**.

Step 3 Enter a **Name** and, optionally, a **Description**.

Step 4 (Optional) Choose the **Available Devices** where you want to deploy the policy, then click **Add to Policy**, or drag and drop to the **Selected Devices**. To narrow the devices that appear, type a search string in the **Search** field.

Devices must be assigned before policy deployment.

Step 5 Click **Save**.

A new QoS policy is created and ready for configuration with rate limiting rules.

What to do next

- Configure and deploy the QoS policy; see Rate limiting with QoS policies, on page 1315.

Set target devices for a QoS policy

Before you begin

Ensure you are logged into the QoS policy editor and have the necessary access rights to configure system policies.

A QoS policy can target multiple devices, but each device can have one deployed QoS policy at a time.

Procedure

Step 1 In the QoS policy editor, click **Policy Assignments**.

Step 2 Build your target list:

- Add—Choose one or more **Available Devices**, then either click **Add to Policy** or drag and drop into the list of **Selected Devices**.
- Delete—Click **Delete** ( ) next to a single device, or choose multiple devices, right-click, then choose **Delete Selected**.
- Search—Enter a search string in the search field. Click **Clear** ( ) to clear the search.

Step 3 Click **OK** to save policy assignments.

Step 4 Click **Save** to save the policy.

The QoS policy is successfully configured with assigned target devices and is ready for deployment.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Filter QoS rules by device

You can filter the list of QoS policy rules based on the device to which the rules apply. A rule's interface constraints determine if the rule affects a device.

Tip Hover your pointer over a rule criterion to see its value. If the criterion represents an object with device-specific overrides, the system displays the override value when you filter the rules list by that device. If the criterion represents an object with domain-specific overrides, the system displays the override value when you filter the rules list by devices in that domain.

Procedure

Step 1 In the policy editor, click **Rules**, then click **Filter by Device**.
A list of targeted devices and device groups appears.

Step 2 Check one or more check boxes to display only the rules that apply to those devices or groups. Or, check **All** to reset and display all of the rules.

Step 3 Click **OK**.

A message appears next to the button showing the filter used. To remove the filter, click the X in the message. Alternatively, select **All** in the Filter by device dialog box.

The QoS rules list displays only the rules that apply to the selected devices or device groups. It simplifies the process of reviewing and managing device-specific QoS policies.

Configuring QoS rules

QoS rules enable you to control and rate limit network traffic on specific interfaces by configuring rule properties, conditions, and traffic limits.

When you create or edit a rule, use the upper portion of the rule editor to configure general rule properties. Use the lower portion of the rule editor to configure rule conditions and comments.

Procedure

Step 1 On Rules of the QoS policy editor:

- Add Rule—Click **Add Rule**.
- Edit Rule—Click **Edit** ( ).

Step 2 Enter a **Name**.

Step 3 Configure rule components:

- Enabled—Specify whether the rule is **Enabled**.
- Apply QoS On—Select the interfaces you want to rate limit, either **Interfaces in Destination Interface Objects** or **Interfaces in Source Interface Objects**. Your choice must correspond with a populated interface constraint (not **any**).
- Traffic Limit Per Interface—Enter a **Download Limit** and an **Upload Limit** in Mbits/sec. The default value of **Unlimited** prevent matching traffic from being rate limited in that direction.
- Conditions—Click the corresponding condition you want to add. You must configure a source or destination interface condition, corresponding to your choice for **Apply QoS On**.
- Comments—Click **Comments**. To add a comment click **New Comment**, enter a comment, and click **OK**. You can edit or delete this comment until you save the rule.

For detailed information on rule components, see QoS rule components, on page 1319.

Step 4 Save the rule.

Step 5 In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste.

Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

Step 6 Click **Save** to save the policy.

The QoS rule you created or modified is saved to the policy and configured with your set traffic limits and conditions.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Best practices for access control rules, on page 1625

QoS rule components

QoS rules consist of several key components that control traffic rate limiting and filtering behavior. Understanding these components helps you configure effective quality of service policies.

QoS rules include these main components:

- State (Enabled/Disabled): Controls whether the rule is active and enforced by the system.
- Interfaces (Apply QoS On): Specifies which interfaces the rate limiting applies to.
- Traffic Limit Per Interface: Sets the rate limiting values for matching traffic.
- Conditions: Defines the traffic criteria that must be matched for the rule to apply.
- Comments: Provides documentation and change tracking for the rule.

State (Enabled/Disabled)

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

Interfaces (apply QoS on)

You cannot save a QoS rule that rate limits all traffic. For each QoS rule, apply QoS on one of the options:

- Interfaces in Source Interface Objects—Rate limits traffic through the rule's source interfaces. If you choose this option, you must add at least one source interface constraint (cannot be **any**).
- Interfaces in Destination Interface Objects—Rate limits traffic through the rule's destination interfaces. If you choose this option, you must add at least one destination interface constraint (cannot be **any**).

Traffic limit per interface

A QoS rule enforces rate limiting *independently* on *each* interface specified with the Apply QoS On option. Aggregate rate limits cannot be applied to a group of interfaces.

You can rate limit traffic by Mbits per second. The default value of **Unlimited** prevents matching traffic from being rate limited.

You can independently rate limit download and upload traffic. The system determines download and upload directions based on the connection initiator.

If you specify a limit greater than the interface's maximum throughput, the system does not rate limit matching traffic. Maximum throughput may be affected by an interface's hardware configuration, which you specify in each device's properties (**Devices** > **Device Management**).

Conditions

Conditions specify the specific traffic that the rule handles. You can configure each rule with multiple conditions. Traffic must meet all conditions to match the rule. Each condition type has its own tab in the rule editor. For more information, see QoS rule conditions, on page 1320.

Comments

Each time you save changes to a rule, add comments. You might summarize the overall configuration for users, or note any changes made and the reasons.

In the policy editor, the system displays how many comments a rule has. In the rule editor, use the Comments tab to view existing comments and add new ones.

QoS rule conditions

Conditions specify the traffic the rule handles. You can configure each rule with multiple conditions. All conditions must be met for traffic to match the rule. Each condition type has its own tab in the rule editor. You can rate limit traffic using these conditions.

Custom SGT rule conditions, on page 1325

Interface rule conditions

An interface rule condition is a network traffic control that

- controls traffic by its source and destination interfaces,
- uses predefined interface objects called security zones or interface groups to build interface conditions, and
- improves system performance by constraining rules to specific interfaces.

Interface rule condition characteristics

Interface objects segment your network by grouping interfaces across multiple devices to manage and classify traffic flow. For more information, refer to Interfaces, on page 2383.

QoS rules can be applied only on routed interfaces.

Note Constraining rules by interface is one of the best ways to improve system performance. If a rule excludes all of a device's interfaces, that rule does not affect that device's performance.

Network rule conditions

A network condition is a traffic matching criterion that

- controls or decrypts traffic based on source and destination IP addresses using inner packet headers,
- enables administrators to specify exact IP addresses or blocks for granular policy enforcement, and
- can be built using predefined network objects or by manually entering IP addresses or address blocks.

Network rule condition restrictions

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

User rule conditions

A user rule condition is a traffic matching mechanism that

- matches traffic based on whether the user initiating the connection or the group to which they belong
- can be configured for users in Microsoft Active Directory realms only, and
- enables policy enforcement based on user identity and group membership.

Special identities users

In addition to configuring users and groups for configured realms, you can set policies for the special identities users:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.

User rule condition example

Configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

Application rule conditions

Application rule conditions are application awareness and control mechanisms that

- identify and classify applications through IP traffic analysis
- enable control with organized filters
- require one enabled detector for each condition.

Application filters and control benefits

System-provided *application filters* help perform control by organizing applications according to basic characteristics, such as type, risk, business relevance, category, and tags. You can also create reuseable, user-defined filters using combinations of system-provided filters, or custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled, the system automatically enables all available system-provided detectors, or the most recently modified user-defined detector. For more information about application detectors, see Application detectors, on page 2284.

You can utilize both application filters and individually specified applications to ensure complete coverage. Understand the application's requirements to effectively order access control rules.

Application filters help you to quickly configure application control effectively. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

The system characterizes detected applications using several criteria which form effective filters.

Table 75: Application characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email applications are clients. MPEG video and Facebook are web applications.

Characteristic	Description	Example
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged `high bandwidth` and `displays ads`.

Best practice: use application-based rules over port-based rules

Use application filtering criteria instead of port filtering to target traffic. Applications can be configured to use unique ports to bypass access control blocks.

Port conditions allow you to control traffic by its source and destination ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

The traditional method targets applications by using port specifications, but applications can manipulate unique ports to bypass these controls

Application filtering is recommended for applications to avoid blocking legitimate applications, like Firewall Threat Defense, that dynamically open separate channels for control and data flow. Port-based access control rules could block such applications, impacting desirable operations.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP).

- For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).
- If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

Port, protocol, and ICMP code rule conditions (concept)

A port, protocol, and ICMP code rule condition is a traffic matching criterion that

- matches traffic based on source and destination ports
- supports TCP, UDP, ICMP, and other protocols that do not use ports, and
- controls traffic flow in access control and other policy rules.

Port condition types

Port conditions match traffic based on the source and destination ports. Depending on the rule type, "port" can represent any of these types:

- TCP and UDP—Control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP (6) /22.
- ICMP—Control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—Control traffic using other protocols that do not use ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best practices for port-based rules

Specifying ports is the traditional method used to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Use application filtering criteria when possible; however, note that application filtering is unavailable in prefilter rules.

Use application filtering for FTP and similar applications that open separate channels for control and data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly and could result in blocking desirable connections.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching non-TCP traffic with port conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although configuring port conditions can match non-TCP traffic, restrictions apply:

- Access control rules—For Classic devices, match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, add only network-based conditions: zone, IP address, port, and VLAN tag. The system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For Firewall Threat Defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support only TCP port conditions.
- IMCP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies, sent in response to ICMP echo requests, are ignored. To match any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

Recommendation: use URL conditions for website access control

Use URL conditions to control the websites that users on your network can access.

For complete information, see URL filtering with category and reputation, on page 1652.

Custom SGT rule conditions

A custom SGT rule condition is a traffic filtering mechanism that

- Use manually created SGT objects to filter traffic. Do not rely on ISE SGTs from a server.
- Correspond to the SGT attributes on the traffic to be controlled.
- Exclude user control considerations when using custom SGT traffic.

SGT traffic control without ISE configuration

If you do not configure ISE or ISE-PIC as an identity source, you can control traffic using Security Group Tags (SGTs) that were **not** assigned by ISE. SGTs specify traffic source privileges in a trusted network.

ISE SGT versus custom SGT rule conditions

Certain rules allow you to control traffic based on assigned SGT. The rule type and identity source configuration determine whether ISE-assigned SGTs or custom SGTs are used to match traffic with assigned SGT attributes.

Condition Type	Requires	SGTs Listed in Rule Editor
ISE SGT	ISE identity source	SGTs obtained by querying the ISE server, automatically updated metadata
Custom SGT	No ISE or ISE-PIC identity source	Static SGT objects you create

Note If using ISE SGTs to match traffic, any packet will match an ISE SGT rule if the SGT associated with the packet source IP address is recognized in ISE, even without an assigned SGT attribute.

Autotransition from custom Security Group Tags to ISE Security Group Tags

An autotransition from custom Security Group Tags (SGTs) to ISE Security Group Tags is a system process that automatically adjusts rule configuration when you configure ISE/ISE-PIC as an identity source after creating rules with custom Security Group Tags.

System behavior during autotransition

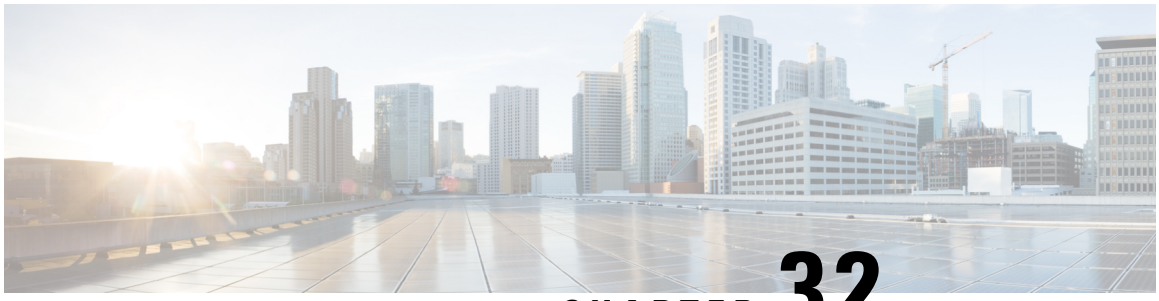
If you create rules that match custom SGTs, then configure ISE or ISE-PIC as an identity source, the system will:

- Disable **Security Group Tag** options: The system retains existing SGT objects, but you cannot modify them or add new ones.
- Retain existing rules: Existing rules with custom SGT conditions remain, but they do not match traffic, and you cannot add more custom SGT conditions.

If you configure ISE, it is recommended to delete or disable existing rules with custom Security Group Tag conditions and use ISE attribute conditions to match traffic with Security Group Tag attributes.

History for QoS

This reference provides a chronological history of QoS feature updates, including version information and implementation details.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Deprecated: priority-queue with FlexConfig.	7.2.5	7.2.5	FlexConfig was used to configurethe priority-queue in threat defense. This command was removed.
Ability to specify handling of URLs having unknown reputation.	6.7.0	Any	For details, see History for URL filtering, on page 1678. New/modified screens: QoS rule editor
Rate limit increased.	6.2.1	Any	Raised the maximum rate limit from 1,000 Mbps to 100,000 Mbps. New/modified screens: QoS rule editor
Custom SGT and original client network filtering.	6.2.1	Any	Rate limit traffic using custom Security Group Tags (SGTs) and original client network information (XFF, True-Client-IP, or custom-defined HTTP headers). New/modified screens: QoS Rule Editor
QoS (rate limiting) introduced.	6.1.0	Any	FTD can rate limit (police) network traffic that is either allowed or trusted by access control. New/modified screens: **Devices** > **QoS**

CHAPTER 32

Secure Connections Overview

A virtual private network (VPN) connection establishes a secure tunnel between endpoints over a public network such as the Internet.

This chapter applies to Remote Access and Site-to-site VPNs on Secure Firewall Threat Defense devices. It describes the Internet Protocol Security (IPsec), the Internet Security Association and Key Management Protocol (ISAKMP, or IKE) and SSL standards that are used to build site-to-site and remote access VPNs.

- VPN types, on page 1329
- VPN basics, on page 1330
- VPN packet flow, on page 1333
- IPsec flow offload, on page 1333
- VPN licensing, on page 1334
- VPN encryption and performance, on page 1334
- Deprecated hash algorithms, encryption algorithms, and Diffie-Hellman modulus groups, on page 1339
- VPN topologies, on page 1340

VPN types

VPN types are network connection categories that

- provide secure, encrypted connections between remote locations and private networks
- support deployment models including remote access and site-to-site configurations, and
- use various protocols including SSL and IPsec for establishing secure tunnels.

Supported VPN connection types

The Firewall Management Center supports these types of VPN connections:

- Remote Access VPNs in Firewall Threat Defense devices.

  Remote access VPNs provide secure, encrypted connections, or tunnels, between remote users and your company's private network. These connection use two devices: a VPN endpoint device, which is a workstation or mobile device with VPN client capabilities, and a VPN headend device, or secure gateway, at the edge of the corporate private network.

  Secure Firewall Threat Defense devices can be configured to support Remote Access VPNs over SSL or IPsec IKEv2 by the Firewall Management Center. When acting as secure gateways, these devices

authenticate remote users, authorize access, and encrypt data to provide secure connections to your network. Only these devices support remote access VPN connections, managed by the Firewall Management Center.

Secure Firewall Threat Defense secure gateways support the Secure Client full tunnel client. This client is required to provide secure SSL IPsec IKEv2 connections for remote users. This client automatically installs when a connection is established, so network administrators do not need to manually install or configure it on remote computers. It is the only client supported on endpoint devices.

- Site-to-site VPNs in Firewall Threat Defense devices.

  A site-to-site VPN connects networks in different geographic locations. You can create site-to-site IPsec connections between managed devices, and between managed devices and other Cisco or third-party peers. These peers can use either IPv4 and IPv6 addresses. Site-to-site tunnels are built using the Internet Protocol Security (IPsec) protocol suite and IKEv1 or IKEv2. After the VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel.

VPN basics

A VPN is a secure networking technology that

- uses tunneling to create secure connections between remote users and private corporate networks over public TCP/IP networks such as the Internet
- employs IPsec-based technologies with ISAKMP (IKE) and IPsec tunneling standards to build and manage tunnels, and
- enables bidirectional data transfer through tunnel endpoints that encapsulate and unencapsulate packets.

VPN tunnel management capabilities

ISAKMP and IPsec accomplish these tunnel management functions:

- Negotiate tunnel parameters.
- Establish tunnels.
- Authenticate users and data.
- Manage security keys.
- Encrypt and decrypt data.
- Manage data transfer across the tunnel.
- Manage data transfer inbound and outbound as a tunnel endpoint or router.

A device in a VPN functions as a bidirectional tunnel endpoint. It can receive plain packets from the private network, encapsulate them, create a tunnel, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets from the public network, unencapsulate them, and send them to their final destination on the private network.

After the site-to-site VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel. A connection consists of the IP addresses

and hostnames of the two gateways, the subnets behind them, and the method the two gateways use to authenticate to each other.

VPN deployments use two primary device types:

- Hubs: Devices that enable secure VPN connectivity to and from one or more remote branch devices or spokes. Hubs also act as a gateway for spokes to communicate with each other.
- Spokes: Devices that connect over VPN to a hub to securely access the corporate resources behind the hub. Spokes communicate with each other through the hub.

Internet Key Exchange (IKE)

Internet Key Exchange (IKE) is a key management protocol that

- authenticates IPsec peers
- negotiates and distributes IPsec encryption keys, and
- automatically establishes IPsec security associations (SAs).

IKE negotiation phases and policies

The IKE negotiation comprises two phases:

- Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2.
- During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec.

Each phase uses proposals to negotiate a connection.

An IKE policy is a set of algorithms that two peers use to secure the IKE negotiation between them. IKE negotiation begins when each peer agrees on a common IKE policy. This policy defines security parameters to protect subsequent IKE negotiations. IKEv1 policies contain a single set of algorithms and a modulus group. In an IKEv2 policy, you can select multiple algorithms and modulus groups for peers to choose from during the Phase 1 negotiation. You may create a single IKE policy, or create multiple policies to give higher priority to preferred options. For site-to-site VPNs, you can create an IKE policy. IKEv1 and IKEv2 each support a maximum of 20 IKE policies, each with a different set of values. Assign a unique priority to each policy that you create. A lower priority number indocates a higher priority for the policy.

To define an IKE policy, specify:

- A unique priority (1 to 65,543, with 1 being the highest priority).
- An encryption method for the IKE negotiation to protect the data and ensure privacy.
- A Hashed Message Authentication Codes (HMAC) method (called integrity algorithm in IKEv2) to verify the sender's identity, and to confirm that the message is unchanged during transit.
- For IKEv2, a separate pseudorandom function (PRF) used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption. The options are the same as those used for the hash algorithm.
- A Diffie-Hellman group to determine the strength of the encryption key determination algorithm. The device uses this algorithm to derive the encryption and hash keys.

- An authentication method, to ensure the identity of the peers.
- A limit to the time the device uses an encryption key before replacing it.

When IKE negotiation begins, the initiating peer sends all its policies to the remote peer. The remote peer searches for a match with its own policies, in priority order. IKE policies match if both peers use the same encryption, hash (integrity and PRF for IKEv2), authentication, and Diffie-Hellman values. The SA lifetime must be less than or equal to the lifetime in the policy sent. If the lifetimes are not identical, the shorter value from the remote peer policy applies. By default, the Secure Firewall Management Center deploys an IKEv1 policy with the lowest priority for all VPN endpoints to ensure a successful negotiation.

IPsec

IPsec is a secure method for setting up a VPN that:

- provides data encryption at the IP packet level,
- transmits data over a public network through tunnels, which are secure, logical communication paths between two peers, and
- secures traffic that enters an IPsec tunnel by a combination of security protocols and algorithms.

With IPsec, data is transmitted over a public network through tunnels.

IPsec proposal policy components

An IPsec proposal policy defines the settings for IPsec tunnels. An IPsec proposal includes one or more crypto maps that are applied to the VPN interfaces in the devices. A crypto map combines all the components required to set up IPsec security associations, including:

- A proposal (or transform set) combines security protocols and algorithms that secure traffic in an IPsec tunnel. During the IPsec security association (SA) negotiation, peers search for a matching proposal. Apply the selected proposal to create an SA that protects data flows in the crypto map's access list and secures VPN traffic. There are separate IPsec proposals for IKEv1 and IKEv2. In IKEv1 proposals (or transform sets), you set one value for each parameter. In IKEv2 proposals, you can configure multiple encryption and integration algorithms for a single proposal.
- A crypto map combines all components required to set up IPsec security associations (SA), including IPsec rules, proposals, remote peers, and other parameters that are necessary to define an IPsec SA. When two peers try to establish an SA, they must each have at least one compatible crypto map entry.

  Dynamic crypto map policies are used in site-to-site VPNs when an unknown remote peer tries to start an IPsec security association with the local hub. The hub does not initiate the security association negotiation. Dynamic crypto policies allow remote peers to exchange IPsec traffic with a local hub, even if the hub does not know the remote peer's identity. A dynamic crypto map policy creates a crypto map entry before configuring all parameters. IPsec negotiation then dynamically configures the missing parameters to match a remote peer's requirements.

  Dynamic crypto map policies are applicable to both hub-and-spoke and point-to-point VPN topologies. To apply dynamic crypto map policies, specify a dynamic IP address for one of the peers in the topology and ensure that the dynamic crypto-map is enabled on this topology. In a full mesh VPN topology, you can apply only static crypto map policies.

Note Simultaneous IKEv2 dynamic crypto map is not supported for the same interface for both remote access and site-to-site VPNs in a Firewall Threat Defense device.

VPN packet flow

VPN packet flow is a security process that

- requires explicit permission through access control before allowing traffic to pass through,
- decrypts incoming tunnel packets before sending them to the Snort process,
- processes outgoing packets through Snort before encryption, and
- blocks tunnel traffic to the public source when the tunnel is down.

Access control requirements

Access control identifies the protected networks for each endpoint node of a VPN tunnel and determines which traffic is allowed to pass through the Firewall Threat Defense device and reach the endpoints. For remote access VPN traffic, a group policy filter or an access control rule must be configured to permit VPN traffic flow.

IPsec flow offload

IPsec flow offload is a performance optimization feature that

- offloads IPsec connections to field-programmable gate array (FPGA) or specialized hardware components after initial setup
- improves device performance by handling pre-decryption, decryption, pre-encryption, and encryption processing in hardware, and
- is enabled by default on supporting device models while allowing system software to handle inner flow security policies.

IPsec flow offload characteristics

After the initial setup of an IPsec site-to-site VPN or remote access VPN security association (SA), IPsec connections are offloaded to the field-programmable gate array (FPGA) in the device. This process improves device performance.

Offloaded operations include pre-decryption and decryption processing on ingress and egress. The system software applies your security policies for traffic within the inner flow.

IPsec flow offload applies to these device types:

- Secure Firewall 3100
- Secure Firewall 4200

IPsec flow offload is also used when the device's VTI loopback interface is enabled.

By default, the system enables IPsec flow offload on supported device models. To change the configuration, use FlexConfig to implement the **flow-offload-ipsec** command. For more information, refer to the ASA command reference.

VPN licensing

You do not need any specific license to enable VPN on a Firewall Threat Defense device, it is available by default.

The Firewall Management Center determines whether to allow or block the usage of strong encryption in the Firewall Threat Defense device based on the export-controlled functionality in the device. You can enable this functionality when you register with the Cisco Smart License Manager. If you are using the evaluation license, or you did not enable export-controlled functionality, you cannot use strong encryption. Choose **System** (⚙) > **Licenses** > **Smart Licenses** to verify this functionality in Firewall Management Center.

If you created your VPN configurations with an evaluation license and later upgraded your license to a smart license with export-controlled functionality, check and update your encryption algorithms to use stronger encryption so that the VPNs function properly. Do not use DES-based encryption, as it is not supported.

VPN encryption and performance

When you configure VPN tunnel encryption, provide sufficient protection and maintain efficiency by balancing security and performance.

Because a VPN tunnel typically traverses a public network, most likely the Internet, you need to encrypt the connection to protect the traffic. You define the encryption and other security techniques with IKE policies and IPsec proposals. Using stronger tunnel encryption may lower system performance.

If your device license allows strong encryption, you can choose from a range of encryption and hash algorithms and Diffie-Hellman groups. This document does not provide specific guidance on which options you should choose. If you operate within a larger corporation or other organization, there might already be defined standards that you need to meet. If not, take the time to research the options.

Comply with security certification requirements

Review your certification requirements and the available options to plan your VPN configuration. Many VPN settings have options that allow you to comply with various security certification standards.

Decide encryption algorithms for VPN policies

When deciding which encryption algorithms to use for the IKE policy or IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN.

- For IKEv2, you can configure multiple encryption algorithms. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order.
- For IKEv1, you can select a single option only.

- For IPsec proposals, the algorithm is used by the Encapsulating Security Protocol (ESP), which provides authentication, encryption, and anti-replay services. ESP is IP protocol type 50. In IKEv1 IPsec proposals, the algorithm name is prefixed with ESP-.

If your device license qualifies for strong encryption, you can choose from the available encryption algorithms. If you are not qualified for strong encryption, you can select DES only.

Strong encryption license considerations

Note If you are qualified for strong encryption, before upgrading from the evaluation license to a smart license, check and update your encryption algorithms for stronger encryption so that the VPN configuration works properly. Choose AES-based algorithms. DES is not supported if you are registered using an account that supports strong encryption. After registration, you cannot deploy changes until you remove all uses of DES.

Available encryption algorithms

- AES-GCM—(IKEv2 only) Advanced Encryption Standard in Galois or Counter Mode is a block cipher mode that provides confidentiality and data-origin authentication. It offers greater security than AES.

  AES-GCM offers three different key strengths: 128-bit, 192-bit, and 256-bit keys. Longer keys increase security but reduce performance. NSA Suite B, a set of cryptographic algorithms that devices must support to meet federal cryptographic strength standards, requires GCM.

- AES—Advanced Encryption Standard is a symmetric cipher algorithm that provides greater security than DES and is computationally more efficient than 3DES. AES offers three different key strengths: 128-bit, 192-bit, and 256-bit keys. Longer keys increase security but reduce performance.

- DES—Data Encryption Standard, which encrypts using 56-bit keys, is a symmetric secret-key block algorithm. If your license account does not meet the requirements for export controls, this is your only option.

- Null, ESP-Null—A null encryption algorithm provides authentication without encryption. This method is not secure; use at your own discretion.

Decide which hash algorithms to use

In IKE policies, the hash algorithm creates a message digest to ensure your messages remain secure. In IKEv2, you can choose one hash algorithm for integrity and another for the pseudo-random function (PRF).

In IPsec proposals, the Encapsulating Security Protocol (ESP) uses the hash algorithm for authentication. In IKEv2 IPsec proposals, this is called the integrity hash. In IKEv1 IPsec proposals, the algorithm name has the ESP- prefix and an -HMAC suffix.

The system arranges your settings from the most secure to the least secure and negotiates with the peer in that order. For IKEv1, select only one option.

Select a hash algorithm that meets your security and performance needs:

- SHA (Secure Hash Algorithm)—The standard SHA (SHA1) produces a 160-bit digest.

  These SHA-2 options provide increased security and are available for IKEv2 configurations. Choose one if you require NSA Suite B cryptography compliance.

- SHA256—Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.
- SHA384—Specifies the Secure Hash Algorithm SHA 2 with the 384-bit digest.
- SHA512—Specifies the Secure Hash Algorithm SHA 2 with the 512-bit digest.

- Null or None (NULL, ESP-NONE)—(IPsec Proposals only) AUse a null hash algorithm only for testing purposes. If you select one of the AES-GCM options as the encryption algorithm, choose the null integrity algorithm. For these encryption standards, the integrity hash is ignored even if you choose a non-null option.

Decide which Diffie-Hellman modulus group to use

You can use Diffie-Hellman key derivation algorithms to generate IPsec security association (SA) keys. Each group has a different size modulus. A larger modulus increases security but requires more processing time. You must have a matching modulus group on both peers.

For AES encryption, use Diffie-Hellman (DH) Group 5 or higher to support the large key sizes required by AES. IKEv1 policies do not support all of the groups.

To implement the NSA Suite B cryptography specification, use IKEv2 and select one of the elliptic curve Diffie-Hellman (ECDH) options: 19, 20, or 21. Elliptic curve options and groups that use a 2048-bit modulus reduce exposure to attacks such as Logjam.

For IKEv2, you can configure multiple groups. The system orders the settings from the most secure to the least secure, then negotiates with the peer using that order. For IKEv1, you can select only a single option.

- 14—Diffie-Hellman Group 14: 2048-bit modular exponential (MODP) group. Considered good protection for 192-bit keys.
- 15—Diffie-Hellman Group 15: 3072-bit MODP group.
- 16—Diffie-Hellman Group 16: 4096-bit MODP group.
- 19—Diffie-Hellman Group 19: National Institute of Standards and Technology (NIST) 256-bit elliptic curve modulo a prime (ECP) group.
- 20—Diffie-Hellman Group 20: NIST 384-bit ECP group.
- 21—Diffie-Hellman Group 21: NIST 521-bit ECP group.
- 31—Diffie-Hellman Group 31: Curve25519 256-bit EC Group.

Decide VPN authentication methods

A VPN authentication method is a security mechanism that

- validates the identity of peers in a VPN connection
- enables secure communication between network devices, and
- ensures that only authorized devices can establish VPN connections.

Available authentication methods

VPNs support two primary authentication methods:

- **Preshared keys**: A secret key shared between two peers and used by IKE during the authentication phase. The same shared key must be configured at each peer or the IKE SA cannot be established.
- **Digital certificates**: Use RSA key pairs to sign and encrypt IKE key management messages. Certificates provide proof of communication between two peers.

VPN type support varies by authentication method.

Table 76: VPN authentication method support

VPN Type	Preshared Keys	Digital Certificates
Site-to-site IKEv1 and IKEv2	Supported	Supported
Remote Access (SSL and IPsec IKEv2)	Not supported	Supported

When you use digital certificate authentication, you need a Public Key Infrastructure (PKI) defined for peers to obtain digital certificates from a Certification Authority (CA). CAs manage certificate requests and issue certificates to participating network devices, providing centralized key management for all participating devices.

Preshared keys are difficult to manage for large networks. CAs make it easier to manage and scale your IPsec network. With a CA, you do not need to configure keys between all encrypting devices. Register each device with the CA to request its certificate. Devices with their own certificates and the CA's public key can authenticate other devices within the CA's domain.

Pre-shared keys

A pre-shared key is a secret key that

- enables you to share authentication credentials between two peers
- is used by IKE in the authentication phase, and
- must be configured identically on each peer or the IKE SA cannot be established.

Key configuration options

To configure pre-shared keys, select either a manual key or an automatically generated key. Specify this key in the IKEv1 or IKEv2 options. When you deploy your configuration, the key is configured on all devices in the topology.

PKI infrastructure and digital certificates

A PKI infrastructure is a centralized key management system that

- provides defined policies, procedures, and roles supporting public key cryptography
- generates, verifies, and revokes public key certificates, commonly known as digital certificates, and
- manages key pairs consisting of public and private keys for VPN endpoints to sign and encrypt messages.

Public key cryptography and certificate components

In public key cryptography, each endpoint of a connection has a key pair consisting of both a public and a private key. The key pairs are used by the VPN endpoints to sign and encrypt messages. The keys act as complements, and anything encrypted with one of the keys can be decrypted with the other, securing the data flowing over the connection.

Generate a general-purpose RSA, ECDSA, or EDDSA key pair for signing and encryption. Alternatively, generate separate key pairs for each purpose. Separate signing and encryption keys help to reduce key exposure. SSL uses a key for encryption, while IKE uses a key for signing. Separate keys for each purpose minimize exposure.

Certificates also ensure non-repudiation by providing proof that communication between two peers occurred.

You can obtain CA certificates by:

- Using the Simple Certificate Enrollment Protocol (SCEP) or Enrollment over Secure Transport (EST) to retrieve the CA's certificate from the CA server
- Manually copying the CA's certificate from another participating device

Trustpoints represent the object representation of a CA and associated certificates. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

A PKCS#12, or PFX, file holds the server certificate, any intermediate certificates, and the private key in one encrypted file. This type of file may be imported directly into a device to create a trustpoint.

A CA may also revoke certificates for peers that no longer participate in your network. Revoked certificates are either managed by an Online Certificate Status Protocol (OCSP) server or are listed in a certificate revocation list (CRL) stored on an LDAP server. A peer may check these before accepting a certificate from another peer.

Digital certificates or identity certificates

When you use digital certificates as the authentication method for VPN connections, peers are configured to obtain digital certificates from a Certificate Authority (CA). CAs are trusted authorities that sign certificates to verify their authenticity, thereby guaranteeing the identity of the device or user.

Digital certificates contain these components:

- The digital identification of the owner for authentication, such as name, serial number, company, department, or IP address.
- A public key needed to send and receive encrypted data to the certificate owner.
- The secure digital signature of a CA.

The certificate enrollment process includes these steps:

1. CA servers manage public CA certificate requests and issue certificates to participating network devices as part of a PKI.
2. Each participating device enrolls individually with a CA server, which validates identities and creates an identity certificate.
3. Each participating peer sends their identity certificate to the other peer to validate their identities and establish encrypted sessions with the public keys contained in the certificates.

Certificate enrollment

Using a PKI improves the manageability and scalability of your VPN because you do not have to configure preshared keys between all encrypting devices. Instead, enroll each participating device with a CA server, which validates identities and creates an identity certificate for the device. After completing enrollment, each participating peer sends its identity certificate to the other peer to validate their identities and establish encrypted sessions with the public keys contained in the certificates. For more information about enrolling Firewall Threat Defense device certificates, refer to Certificate enrollment objects, on page 2400.

Certificate authority certificates

In order to validate a peer's certificate, each participating device must retrieve the CA's certificate from the server. A CA certificate is used to sign other certificates. It is self-signed and called a root certificate. This certificate contains the CA's public key, which you use to decrypt and validate the CA's digital signature and the contents of the received peer's certificate.

To obtain the CA certificate:

- Use the Simple Certificate Enrollment Protocol (SCEP) or Enrollment over Secure Transport (EST) to retrieve the CA's certificate from the CA server
- Manually copy the CA's certificate from another participating device

Trustpoints

Once enrollment is complete, a trustpoint is created in the managed device. It is the object representation of a CA and associated certificates. A trustpoint includes the identity of the CA, CA-specific parameters, and one enrolled identity certificate.

PKCS#12 file

A PKCS#12 file, or PFX file holds the server certificate, intermediate certificates, and the private key in one encrypted file. This type of file may be imported directly into a device to create a trustpoint.

Revocation checking

A CA may also revoke certificates for peers that no longer participate in your network. Revoked certificates are either managed by an Online Certificate Status Protocol (OCSP) server or are listed in a certificate revocation list (CRL) stored on an LDAP server. A peer may check these before accepting a certificate from another peer.

Deprecated hash algorithms, encryption algorithms, and Diffie-Hellman modulus groups

Update your VPN configuration to use supported DH and encryption algorithms before upgrading to Firewall Threat Defense 6.70 or later.

- Update your IKE proposals and IPSec policies to match the ones supported in Firewall Threat Defense 6.70 or later.
- Deploy the configuration changes after updating to supported algorithms.

Support has been removed for these less secure ciphers from Firewall Threat Defense Version 6.70:

- **Diffie-Hellman GROUP 5** is deprecated for IKEv1 and IKEv2.
- Diffie-Hellman groups 2 and 24 have been removed.
- **Encryption algorithms**: 3DES, AES-GMAC, AES-GMAC-192, and AES-GMAC-256 have been removed.

Note **DES** continues to be supported in evaluation mode or for users who do not satisfy export controls for strong encryption.

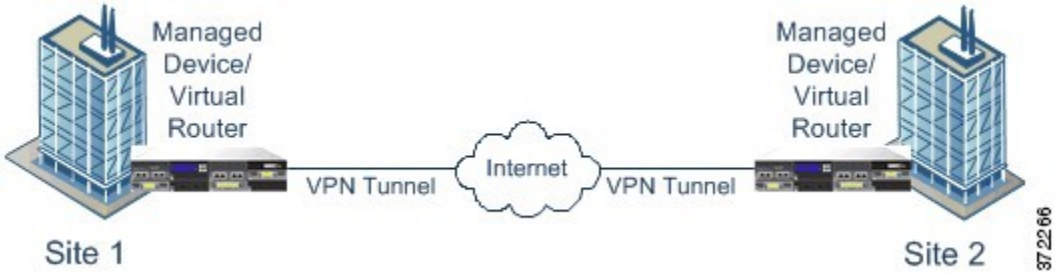
NULL is removed in IKEv2 policy, but supported in both IKEv1 and IKEv2 IPsec transform-sets.

VPN topologies

When you create a new VPN topology you must give it a unique name, specify a topology type, and select the IKE version. You can select from three types of topologies, each containing a group of VPN tunnels:

- Point-to-point (PTP) topologies establish a VPN tunnel between two endpoints.
- Hub and spoke topologies establish a group of VPN tunnels connecting a hub endpoint to a group of spoke endpoints.
- Full mesh topologies establish a group of VPN tunnels among a set of endpoints.

There is no default pre-shared key for VPN authentication. You must define a pre-shared key manually or let the system generate it automatically. When choosing automatic, the Secure Firewall Management Center generates a pre-shared key and assigns it to all the nodes in the topology.



Point-to-point VPN topologies

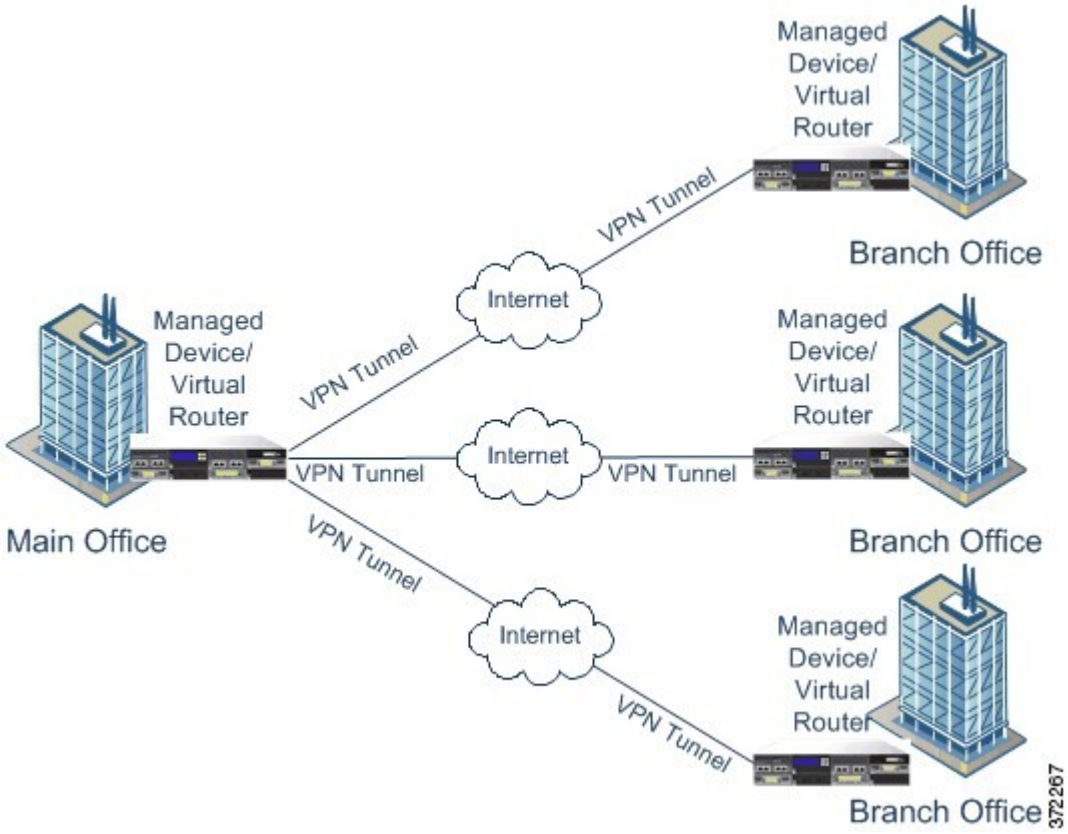
A point-to-point VPN topology is a network configuration that

- enables two endpoints to communicate directly with each other
- allows you to configure the two endpoints as peer devices, and
- permits either device to start the secured connection.

This diagram displays a typical point-to-point VPN topology.

Figure 392: Point-to-point VPN topology

Hub and spoke VPN topology



A hub and spoke VPN topology is a network architecture that

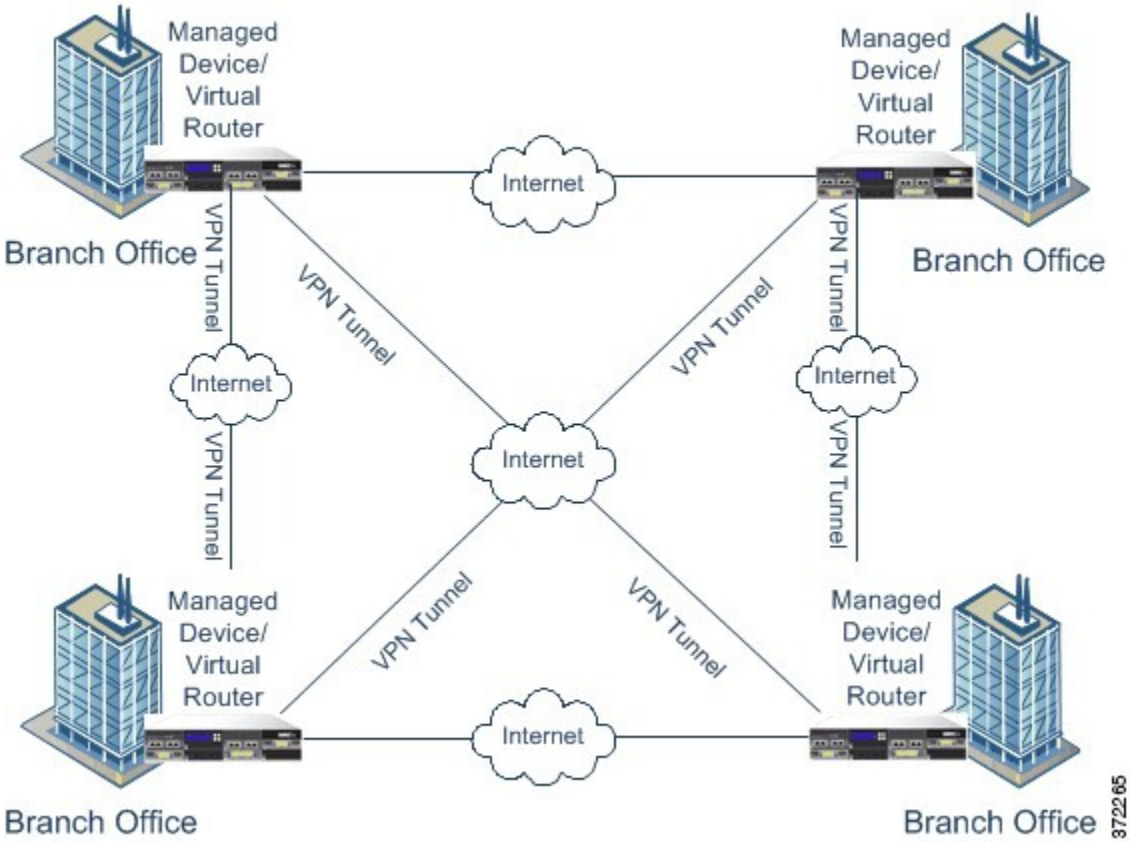
- connects a central endpoint (hub node) with multiple remote endpoints (spoke nodes)
- establishes each connection between the hub node and an individual spoke endpoint as a separate VPN tunnel, and
- enables hosts behind any of the spoke nodes to communicate with each other through the hub node.

The hub and spoke topology commonly represent a VPN that connects an organization's main and branch office locations using secure connections over the Internet or other third-party network. These deployments provide all employees with controlled access to the organization's network. Typically, the hub node is located at the main office. Spoke nodes are located at branch offices and start most of the traffic.

This diagram displays a typical hub and spoke VPN topology.

Figure 393: Hub and spoke VPN topology diagram

Full mesh VPN topology



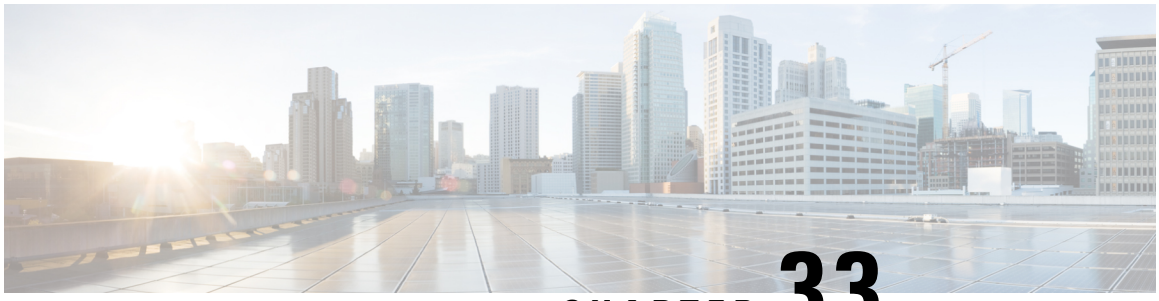
A full mesh VPN topology is a network configuration that

- allows all endpoints to communicate with every other endpoint by an individual VPN tunnel
- offers redundancy so that when one endpoint fails, the remaining endpoints can still communicate with each other, and
- commonly represents a VPN that connects a group of decentralized branch office locations.

The number of VPN-enabled managed devices you deploy in this configuration depends on the level of redundancy you require.

This diagram displays a typical full mesh VPN topology.

Figure 394: Full mesh VPN topology



Implicit topologies

Implicit topologies are complex VPN network configurations that

- combine elements from the three main VPN topologies (full mesh, hub-and-spoke, and point-to-point)
- create more advanced network architectures than individual topology types, and
- provide customized connectivity solutions for specific network requirements.

Types of implicit topologies

- **Partial mesh**: A network where some devices use a full mesh topology, while others form either hub-and-spoke or point-to-point connections with some fully meshed devices. The partial mesh does not offer the redundancy found in a full mesh but costs less to implement. Peripheral networks use partial mesh topologies to connect to a fully meshed backbone.
- **Tiered hub-and-spoke**: A network of hub-and-spoke topologies where devices act as a hub in some topologies and as a spoke in others. Spoke groups can send traffic to their closest hub.
- **Joined hub-and-spoke**: A combination of two topologies (hub-and-spoke, point-to-point, or full mesh) that connect to form a point-to-point tunnel. For example, a joined hub-and-spoke topology could comprise two hub-and-spoke topologies, with the hubs acting as peer devices in a point-to-point topology.

- Configure virtual tunnel interfaces, on page 1364
- Deploy a SASE tunnel on Umbrella, on page 1388
- Monitor site-to-site topologies, on page 1395
- History for site-to-site VPN, on page 1400

Site-to-site VPN

A site-to-site VPN is a secure, encrypted VPN tunnel between two networks in different geographic locations. After the VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel. You can create site-to-site IPsec connections between managed devices, and between managed devices and other Cisco or third-party peers.

Site-to-site VPN features

Secure Firewall Threat Defense site-to-site VPN supports these features:

- IPsec IKEv1 & IKEv2 protocols.
- Certificates and automatic or manual preshared keys for authentication.
- IPv4 & IPv6 addresses. All combinations of inside and outside are supported.
- Static and dynamic interfaces.
- HA environments for both Firewall Management Center and Firewall Threat Defense.
- VPN alerts when the tunnel goes down and tunnel statistics.
- IKEv1 and IKEv2 back-up peer configuration for point-to-point extranet and hub-and-spoke VPNs.
- Extranet device as hub in 'Hub and Spokes' deployments.

- Dynamic IP address for a managed endpoint pairing with extranet device in 'Point to Point' deployments and for extranet device as an endpoint.

VPN topologies

VPN topology configuration requires specifying a unique name, a topology type, IKE version selection, and authentication method. The Secure Firewall Management Center configures site-to-site VPNs on Firewall Threat Defense devices only.

You can select from three types of topologies, containing one or more VPN tunnels:

- Point-to-point (PTP) deployments establish a VPN tunnel between two endpoints.
- Hub and Spoke deployments establish a group of VPN tunnels connecting a hub endpoint to a group of spoke nodes.
- Full Mesh deployments establish a group of VPN tunnels among a set of endpoints.

In the Secure Firewall Management Center, site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. Policies and proposals are sets of parameters that define the characteristics of a site-to-site VPN, such as the security protocols and algorithms that are used to secure traffic in an IPsec tunnel. Several policy types may be required to define a full configuration image that can be assigned to a VPN topology.

For authentication of VPN connections, configure a preshared key in the topology, or a trustpoint on each device. Preshared keys allow for a secret key, used during the IKE authentication phase, to be shared between two peers. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

IPsec and IKE

In the Secure Firewall Management Center, site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. Policies and proposals are sets of parameters that define the characteristics of a site-to-site VPN, such as the security protocols and algorithms that are used to secure traffic in an IPsec tunnel. Several policy types may be required to define a full configuration image that can be assigned to a VPN topology.

Authentication

For authentication of VPN connections, configure a preshared key in the topology, or a trustpoint on each device. Preshared keys allow for a secret key, used during the IKE authentication phase, to be shared between two peers. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

Extranet Devices

Each topology type can include extranet devices, devices that you don't manage in Firewall Management Center. These include:

- Cisco devices that Secure Firewall Management Center supports, but for which your organization isn't responsible. Such as spokes in networks managed by other organizations within your company, or a connection to a service provider or partner's network.
- Non-Cisco devices. You can't use Secure Firewall Management Center to create and deploy configurations to non-Cisco devices.

Add non-Cisco devices, or Cisco devices not managed by the Secure Firewall Management Center, to a VPN topology as "Extranet" devices. Also specify the IP address of each remote device.

Guidelines for configuring site-to-site VPN in Secure Firewall Threat Defense devices

General guidelines

- Site-to-site VPN supports ECMP zone interfaces.
- Configure all nodes in a topology with either crypto ACL or a protected network. You cannot configure a topology with crypto ACL on one node and protected network on another.
- Configure a VPN connection across domains by using an extranet peer for the endpoint not in the current domain.
- You can backup Firewall Threat Defense VPNs using the Firewall Management Center backup.
- Configure unique local IKE identity for all tunnels across all your VPN topologies.
- Ensure that IKE ports 500 and 4500 are not already in use and that no active PAT translations exist on those ports before configuring a site-to-site VPN. Configuring a site-to-site VPN on ports that are already in use will cause the service to fail to start.
- When configuring a site-to-site VPN between two devices managed by the same Firewall Management Center, do not configure the devices as backup peers. Instead, configure one of the peer devices in the topology as an extranet device.
- If a spoke is part of multiple topologies with the same hub, for the Local Tunnel (IKE) Identity, we recommend that you use Key ID instead of an IP address.

  If the spoke uses an IP address as its local identity, the hub creates only one tunnel group. The spoke is then mapped to a specific virtual template interface, so the connection works with only one topology.

Limitations for configuring site-to-site VPN in Threat Defense devices

General limitations

- IKEv1 does not support CC/UCAPL-compliant devices. IKEv2 is recommended for these devices.
- VPN does not support network objects with a 'range' option.
- Firewall Threat Defense VPNs do not support PDF export and policy comparison.
- Tunnel status is not updated realtime, but at an interval of five minutes in the Firewall Management Center.
- You cannot use the double quote character (") in pre-shared keys, replace it if already in use.

Crypto ACL limitations

- Firewall Management Center supports only point-to-point VPN with crypto ACL and does not support tunnel health events.

- Firewall Management Center does not verify the device interface address verification for transport mode when you select a crypto ACL.
- There is no support for automatic mirror ACE generation. Mirror ACE generation for the peer is a manual process on either side.

Topology management limitations

- You cannot move a VPN topology between domains.
- There is no per-tunnel or per-device edit option for Firewall Threat Defense VPNs, you can edit only the whole topology.

Types of site-to-site VPN topologies

This table provides an overview of the different site-to-site VPN topology options available for secure network connectivity configuration.

Site-to-Site VPN Topology	Description	More Information
Route-Based VPN	Configure secure traffic dynamically between peers in a network based on routing over Virtual Tunnel Interfaces (VTIs).	Create a route-based site-to-site VPN, on page 1373
Policy-Based VPN	Configure secure traffic between peers in a network based on a static policy using protected networks.	Configure a policy-based site-to-site VPN, on page 1351
SASE Topology	Configure an IPsec IKEv2 tunnel from a Firewall Threat Defense device to an Umbrella Secure Internet Gateway (SIG). This tunnel forwards all internet-bound traffic to Umbrella SIG for inspection and filtering.	Configure a SASE tunnel for Umbrella, on page 1392

License requirements for site-to-site VPN

This topic lists the license requirements for setting up various types of site-to-site VPN connections.

License requirements for policy-based and route-based VPN

With the Essentials license, you can set up policy-based and route-based VPNs on your Firewall Threat Defense devices.

Depending on whether export-controlled functionality is enabled in your Smart License account, Firewall Management Center determines whether to allow or block the usage of strong crypto on devices. To verify if export-controlled functionality is enabled for your Smart License account, choose **System** (⚙) > **Licenses** > **Smart Licenses**.

Note If you use an evaluation license, or if you have not enabled the export-controlled functionality, you cannot use strong encryption for your VPN connections.

License requirements for deploying a SASE tunnel on Umbrella

To deploy SASE tunnels on Umbrella from Firewall Management Center, you must enable your Smart License account with the export-controlled functionality. If this functionality is not enabled, you can only create a SASE topology, you cannot deploy tunnels on Umbrella.

Prerequisites for site-to-site VPN

Supported interfaces

Topology Type	Interface Type

Policy-Based	• Physical interfaces
	  • Non-management
	  • Interface Mode must be either Routed or None
	• Subinterface interfaces
	• Redundant interfaces
	• Etherchannel interfaces
	• VLAN interfaces

Route-Based	Static Virtual Tunnel Interfaces

Note The maximum number of supported security associations (SA) depends on the maximum VPN peers for your platform. For more information about maximum VPN peers, refer the data sheet of the Secure Firewall Threat Defense device.

General prerequisites

- You must have administrator privileges.
- You must be in a leaf domain to perform the site-to-site VPN configurations.

Manage site-to-site VPNs

You can view, create, modify, and deploy site-to-site VPN configurations and manage their deployment status.

The **Site-to-Site VPN** page provides a snapshot of site-to-site VPN tunnels. You can view the status of the tunnels and filter the tunnels based on the device, topology, or tunnel type. The page lists 20 topologies per page and you can navigate between pages to view more topology details. You can click individual VPN topologies to expand and view details of the endpoints.

Before you begin

For certificate authentication of your site-to-site VPNs, you must prepare the devices by allocating trustpoints as described in Certificates, on page 2481.

Procedure

Select **Devices** > **VPN** > **Site to Site** to manage your Firewall Threat Defense site-to-site VPN configurations and deployments.

The page lists the site-to-site VPNs topologies and indicates the status of tunnels using color codes:

- Active (Green)–There is an active IPsec Tunnel.
- Unknown (Amber)–No tunnel establishment event has been received from the device yet.
- Down (Red)–There are no active IPsec tunnels.
- Deployment Pending–Topology has not been deployed on the device yet.

Choose one of these actions:

- **Refresh**—View the updated status of the VPNs.
- **Add**—Create new policy based or route-based Site to Site VPNs.
- **Edit**—Modify the settings of an existing VPN topology.

Note You cannot edit the topology type after you initially save it. To change the topology type, delete the topology and create a new one.

Two users shouldn't edit the same topology simultaneously; however, the web interface doesn't prevent simultaneous editing.

- **Delete**—To delete a VPN deployment, click **Delete** ( ).
- Deploy—Choose **Deploy** > **Deploy**; see Deploy configuration changes, on page 135.

Note Some VPN settings are validated only during deployment. Be sure to verify that your deployment was successful.

Configure a policy-based site-to-site VPN

Configure a policy-based site-to-site VPN to establish secure communication channels between network endpoints using crypto maps and specified network topologies.

Procedure

Step 1 Choose **Devices > Site To Site**. Then click **+ Site To Site VPN**, or edit a listed VPN topology.

Step 2 Enter a unique **Topology Name** and click the **Policy Based (Crypto Map)** radio button, and choose the **Network Topology** for this VPN.

Step 3 Choose the IKE versions to use during IKE negotiations. Check the **IKEv1** or **IKEv2** check box.

Default is IKEv2. Select either or both options as appropriate; select IKEv1 if any device in the topology doesn't support IKEv2.

You can also configure a backup peer for point-to-point extranet VPNs. For more information, see Firewall Threat Defense VPN endpoint options, on page 1352.

Step 4 Required: Add Endpoints for this VPN deployment by clicking **Add** (+) for each node in the topology.

Configure each endpoint field as described in Firewall Threat Defense VPN endpoint options, on page 1352.

- For Point to point, configure **Node A** and **Node B**.
- For Hub and Spoke, configure a **Hub Node** and **Spoke Nodes**
- For Full Mesh, configure multiple **Nodes**

Step 5 (Optional) Specify non-default IKE options for this deployment as described in Firewall Threat Defense VPN IKE options, on page 1356

Step 6 (Optional) Specify non-default IPsec options for this deployment as described in Firewall Threat Defense VPN IPsec options, on page 1358

Step 7 (Optional) Specify non-default Advanced options for this deployment as described in Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1360 and click **Save**.

The policy-based site-to-site VPN is configured with the specified endpoints, IKE settings, and topology options.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 135.

Note Some VPN settings are validated only during deployment. Be sure to verify that your deployment was successful.

If you get an alert that your VPN tunnel is inactive even when the VPN session is up, follow the VPN troubleshooting instructions to verify and ensure that your VPN is active.

Firewall Threat Defense VPN endpoint options

Devices > Site To Site. Then click **+ Site To Site VPN**, or edit a listed VPN topology. Click the **Endpoints** tab.

Fields

Device

Choose an endpoint node for your deployment:

- A Firewall Threat Defense device managed by this Firewall Management Center
- A Firewall Threat Defense high availability container managed by this Firewall Management Center
- An **Extranet** device, any device (Cisco or third party) not managed by this Firewall Management Center .

Device Name

For extranet devices only, provide a name for this device. We recommend naming it such that it is identifiable as an unmanaged device.

Interface

If you chose a managed device as your endpoint, choose an interface on that managed device.

For 'Point to Point' deployments, you can also configure an endpoint with dynamic interface. An endpoint with a dynamic interface can pair only with an extranet device and can’t pair with an endpoint, which has a managed device.

You can configure device interfaces at **Devices** > **Device Management Add/Edit device** > **Interfaces**.

IP Address

- If you choose an extranet device, a device not managed by the Firewall Management Center, specify an IP address for the endpoint.

  For an extranet device, select **Static** and specify an IP address or select **Dynamic** to allow dynamic extranet devices.

- If you chose a managed device as an endpoint, choose a single IPv4 address or multiple IPv6 addresses from the drop-down list. These IP addresses are already assigned to this interface on the managed device.
- All endpoints in a topology must have the same IP addressing scheme. IPv4 tunnels can carry IPv6 traffic and vice versa. The **Protected Networks** define which addressing scheme the tunneled traffic uses.
- If the managed device is a high-availability container, choose from a list of interfaces.

This IP is Private

Check the check box if the endpoint resides behind a firewall with network address translation (NAT).

Note Use this option only when the peer is managed by the same Firewall Management Center and don’t use this option if the peer is an extranet device.

Public IP address

If you checked the **This IP is Private** check box, specify a public IP address for the firewall. If the endpoint is a responder, specify this value.

Connection Type

Specify the allowed negotiation as bidirectional, answer-only, or originate-only. Supported combinations for the connection type are:

Table 77: Connection Type Supported Combinations

Remote Node	Central Node
Originate-Only	Answer-Only
Bi-Directional	Answer-Only
Bi-Directional	Bi-Directional

Certificate Map

Choose a preconfigured certificate map object, or click **Add** (+) to add a certificate map object. The certificate map defines what information is necessary in the received client certificate to be valid for VPN connectivity. See Certificate map objects, on page 2457 for details.

Protected Networks

Caution Hub and Spoke topology—To avoid traffic drop for a dynamic crypto map, ensure that you don't select the protected network *any* for both the endpoints.

If the protected network is configured as *any*, on both the endpoints, the crypto ACL that works upon the tunnel is not generated.

Defines the networks that are protected by this VPN endpoint. Select the networks by selecting the list of Subnet/IP Address that define the networks that are protected by this endpoint. Click **Add** (+) to select from available Network Objects or add new Network Objects. See Create a network object, on page 2388 . Access control lists are generated from the choices made here.

- **Subnet/IP Address (Network)** —VPN endpoints can't have the same IP address and protected networks in a VPN endpoint pair cannot overlap. If protected networks for an endpoint contain IPv4 or IPv6 entries, the other endpoint's protected network must have at least one entry of the same type (IPv4 or IPv6). If it doesn't, the other endpoint's IP address must be of the same type and not overlap with the entries in the protected network. (Use /32 CIDR address blocks for IPv4 and /128 CIDR address blocks for IPv6.) If both of these checks fail, the endpoint pair is invalid.

Note By default, **Reverse Route Injection is enabled** check box is enabled in Firewall Management Center.

Subnet/IP Address (Network) remains the default selection.

When you've selected Protected Networks as *Any* and observe default route traffic being dropped, disable the Reverse Route Injection. Choose **VPN** > **Site to Site** . Edit a VPN and then click **IPsec** > **Enable Reverse Route Injection** . Deploy the configuration changes to remove set reverse-route (Reverse Route Injection) from the crypto map configuration and remove the VPN-advertised reverse route that causes the reverse tunnel traffic to be dropped.

- **Access List (Extended)** —An extended access list provides the capability to control the type of traffic that will be accepted by this endpoint, like GRE or OSPF traffic. Traffic may be restricted either by address or port. Click **Add** (+) to add access control list objects.

Note Access Control List is supported only in the point to point topology.

Enable NAT Traversal

Check this check box to allow seamless communication between the peer Firewall Threat Defense devices when there are NAT devices between these devices. For hub and spoke topologies, this option is available only for the spoke. You can uncheck this check box to disable this feature for an endpoint. This parameter is a per peer setting for an endpoint within a topology.

To view or configure the global NAT Traversal (NAT-T) setting, in the **Add/Edit VPN Topology** dialog box:

1. Click the **Advanced** tab.
2. In the left navigation pane, click **Tunnel** .
3. Under **NAT Settings**, the **Keepalive Messages Traversal** is a global setting that enables NAT-T for all endpoints within a topology.

Exempt VPN traffic from network address translation

Check this check box to exempt the VPN traffic from the Network Address Translation (NAT) rules.

If you do not exempt the VPN traffic from the NAT rules, the traffic gets dropped or is not routed through the VPN tunnel to the remote device. After you enable this option, you can view the NAT exemptions for the device in the NAT policy page (**Devices** > **NAT** , and click **NAT Exemptions**).

Inside interfaces directly connected to the internal network

Specify the security zone or interface group for the inside interface(s) where the protected networks reside. By default, the inside interface is any.

Click + to configure one or more interfaces from a security zone or an interface group that can map to one or more inside interfaces. Ensure that the interface type of the security zone or an interface group is Routed.

Advanced Settings

Enable Dynamic Reverse Route Injection —Reverse Route Injection (RRI) enables routes to be automatically inserted into the routing process, for the networks and hosts protected by a remote tunnel endpoint. Dynamic RRI routes are created only upon the successful establishment of IPsec security associations (SA's).

Note

- Dynamic RRI is supported only on IKEv2, and not supported on IKEv1 or IKEv1 + IKEv2.
- Dynamic RRI isn't supported on originate-only peer, Full Mesh topology, and Extranet peer.
- In Point-to-Point, only one peer can have dynamic RRI enabled.
- Between Hub and Spoke, only one of the endpoints can have dynamic RRI enabled.
- Dynamic RRI cannot be combined with a dynamic crypto map.

Send Local Identity to Peers —Select this option to send local identity information to the peer device. Select one of the following **Local Identity Configuration** from the list and configure the local identity:

- **IP address**—Use the IP address of the interface for the identity.
- **Auto**—Use the IP address for pre-shared key and Cert DN for certificate-based connections.
- **Email ID**—Specify the email ID to use for the identity. The email address can be up to 127 characters.
- **Hostname**—Use the fully qualified hostname.
- **Key ID**—Specify the key-id to use for the identity. The key ID must be fewer than 65 characters.

The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows Firewall Threat Defense to have multiple IPsec tunnels behind a NAT to connect to the Cisco Umbrella Secure Internet Gateway (SIG).

For information about configuring a unique tunnel ID on Umbrella, see **Cisco Umbrella SIG User Guide**.

VPN Filter—Select an extended access list from the list or click **Add** to create a new extended access list object to filter the site-to-site VPN traffic.

The VPN filter provides more security and filters site-to-site VPN data using an extended access list. The extended access list object selected for the VPN filter lets you filter pre-encrypted traffic before entering the VPN tunnel and decrypted traffic that exits a VPN tunnel. The **sysopt permit-vpn** option, when enabled, would bypass the access control policy rules for the traffic coming from the VPN tunnel. When the **sysopt permit-vpn** option is enabled, the VPN filter helps in identifying and filtering the site-to-site VPN traffic.

Note The VPN filter is supported only on point to point, and hub and spoke topologies. It isn't supported on mesh topology.

For hub and spoke topology, you can choose to override the hub VPN filter on the spoke endpoints in case a different VPN filter needs to enabled on a specific tunnel.

Select the **Override VPN Filter on the Hub** option to override the hub VPN filter on the spokes. Select the **Remote VPN Filter** extended access list object or create an access list to override.

Note For an extranet device as a spoke, only the **Override VPN filter on the Hub** option is available.

For more information about sysopt permit-VPN, see Firewall Threat Defense advanced site-to-site VPN tunnel options , on page 1362 .

Firewall Threat Defense VPN IKE options

For the versions of IKE you have chosen for this topology, specify the **IKEv1/IKEv2 Settings**.

Note Settings in this dialog apply to the entire topology, all tunnels, and all managed devices.

Devices > Site To Site. Then click **+ Site To Site VPN**, or edit a listed VPN topology. Click the **IKE** tab.

Fields

Policy

Choose the required IKEv1 or IKEv2 policy objects from the predefined list or create new objects to use. You can choose multiple IKEv1 and IKEv2 policies. IKEv1 and IKEv2 support a maximum of 20 IKE policies, each with a different set of values. Assign a unique priority to each policy that you create. The lower the priority number, the higher the priority.
We recommend that you do NOT use values such as 10, 20 and so on because the default IKEv2 policy for remote access VPN can have these values as its priority value. Before deployment, verify that the priority values of the IKE policies (site-to-site and remote access VPN) do NOT conflict.

Note When upgrading from Version 7.4.x or earlier—where the IKEv2 policy priority field is optional—to Version 7.6.x or later—where it is mandatory—leaving the priority field blank may lead to IKEv2 policy configuration issues and affect network traffic. To avoid these problems, ensure that a priority value is set for all IKEv2 policies either before or after the upgrade.

For details, see IKE policies, on page 2470

Authentication Type

Site-to-site VPN supports two authentication methods, pre-shared key and certificate. For an explanation of the two methods, see Decide VPN authentication methods, on page 1336.

Note In a VPN topology that supports IKEv1, the **Authentication Method** specified in the chosen IKEv1 Policy object becomes the default in the IKEv1 **Authentication Type** setting. These values must match, otherwise, your configuration will error.

- **Pre-shared Automatic Key**—The Firewall Management Center automatically defines the pre-shared key for this VPN. Specify the **Pre-shared Key Length**, the number of characters in the key. The range is 1 to 27.

  The character " (double quote) isn't supported as part of pre-shared keys. If you've used " in a pre-shared key, ensure that you change the character after you upgrade to Secure Firewall Threat Defense 6.30 or higher.

- **Pre-shared Manual Key**—Manually assign the pre-shared key for this VPN. Specify the **Key** and then reenter the same to **Confirm Key**.

  When you choose this option for IKEv2, the **Enforce hex-based pre-shared key only** check box appears, check if desired. If enforced, you must enter a valid hex value for the key, an even number of 2-256 characters, using numerals 0-9, or A-F.

- **Certificate**—When you use certificates as the authentication method for VPN connections, peers obtain digital certificates from a CA server in your PKI infrastructure, and trade them to authenticate each other.

  In the **Certificate** field, select a preconfigured certificate enrollment object. This enrollment object generates a trustpoint with the same name on the managed device. The certificate enrollment object should be associated with and installed on the device, post which the enrollment process is complete, and then a trustpoint is created.

  A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one enrolled identity certificate.

  Before you select this option, note these requirements:

  - Ensure you've enrolled a certificate enrollment object on all the endpoints in the topology—A certificate enrollment object contains the Certification Authority (CA) server information and enrollment parameters that are required for creating Certificate Signing Requests (CSRs) and obtaining Identity Certificates from the specified CA. Certificate Enrollment Objects are used to enroll your managed devices into your PKI infrastructure, and create trustpoints (CA objects) on devices that support VPN connections. For instructions on creating a certificate enrollment object, see Add certificate enrollment objects, on page 2402, and for instructions on enrolling the object on the endpoints see one of these as applicable:
    - Install a certificate using self-signed enrollment, on page 2486
    - Install a certificate using EST enrollment, on page 2487
    - Install a certificate using SCEP enrollment, on page 2487
    - Install a certificate using manual enrollment, on page 2488
    - Install a certificate using a PKCS12 file, on page 2489

Note For a site-to-site VPN topology, ensure that the same certificate enrollment object is enrolled in all the endpoints in the topology. For further details, see the table below.

- Refer to this table to understand the enrollment requirement for different scenarios. Some of the scenarios require you to override the certificate enrollment object for specific devices. See Manage object overrides, on page 2343 to understand how to override objects.

Certificate Enrollment Types	Device identity certificate for all endpoints is from the same CA		Device identity certificate for all endpoints is from different CAs
	Device-specific parameters are NOT specified in the certificate enrollment object	Device-specific parameters are specified in the certificate enrollment object	
Manual	No override required	Override required	Override required
EST	No override required	Override required	Override required
SCEP	No override required	Override required	Override required
PKCS	Override required	Override required	Override required
Self-signed	NOT applicable	NOT applicable	NOT applicable

- Understand the VPN certificate limitations mentioned in Secure Firewall Threat Defense VPN certificate guidelines and limitations, on page 2481.

Note If you use a Windows Certificate Authority (CA), the default application policies extension is **IP security IKE intermediate**. If you use this default setting, you must select the **Ignore IPsec Key Usage** option in the Advanced Settings section on the **Key** tab in the **PKI Certificate Enrollment** dialog box for the object you select. Otherwise, the endpoints can't complete the site-to-site VPN connection.

Firewall Threat Defense VPN IPsec options

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in Configure Endpoints for a Point to Point Topology and click the **IPsec** tab.

Note Settings in this dialog apply to the entire topology, all tunnels, and all managed devices.

Crypto-Map Type

A crypto map combines all the components required to set up IPsec security associations (SA). When two peers try to establish an SA, they must each have at least one compatible crypto map entry. IPsec security negotiation uses the proposals defined in the crypto map entry to protect the data flows specified by that crypto map's IPsec rules. Choose static or dynamic for this deployment's crypto-map:

- **Static**—Use a static crypto map in a point-to-point or full mesh VPN topology.

- **Dynamic**—Dynamic crypto-maps essentially create a crypto map entry without all the parameters configured. The missing parameters are later dynamically configured (as the result of an IPsec negotiation) to match a remote peer's requirements.

  Dynamic crypto map policies are applicable to both hub-and-spoke and point-to-point VPN topologies. To apply these policies, specify a dynamic IP address for one of the peers in the topology and ensure that the dynamic crypto-map is enabled on this topology. In a full mesh VPN topology, you can apply only static crypto map policies.

IKEv2 Mode

For IPsec IKEv2 only, specify the encapsulation mode for applying ESP encryption and authentication to the tunnel. This determines what part of the original IP packet has ESP applied.

- **Tunnel mode**—(default) Encapsulation mode is set to tunnel mode. Tunnel mode applies ESP encryption and authentication to the entire original IP packet (IP header and data), hiding the ultimate source and destination addresses and becoming the payload in a new IP packet.

  The major advantage of tunnel mode is that you don't need to modify the end systems to receive the benefits of IPsec. This mode allows a network device, such as a router, to act as an IPsec proxy. That is, the router performs encryption on behalf of the hosts. The source router encrypts packets and forwards them along the IPsec tunnel. The destination router decrypts the original IP datagram and forwards it onto the destination system. Tunnel mode also protects against traffic analysis; with tunnel mode, an attacker can only determine the tunnel endpoints and not the true source and destination of the tunneled packets, even if they are the same as the tunnel endpoints.

- **Transport preferred**—Encapsulation mode is set to transport mode with an option to fall back to tunnel mode if the peer doesn't support it. In transport mode only the IP payload is encrypted, and the original IP headers are left intact. Therefore, the admin must select a protected network that matches the VPN interface IP address.

  This mode has the advantages of adding only a few bytes to each packet and allowing devices on the public network to see the final source and destination of the packet. With transport mode, you can enable special processing (for example, QoS) on the intermediate network based on the information in the IP header. However, the layer 4 header is encrypted, which limits examination of the packet.

- **Transport required**— Encapsulation mode is set to transport mode only, falling back to tunnel mode is allowed. If the endpoints can't successfully negotiate transport mode, due to one endpoint not supporting it, the VPN connection is not made.

Proposals

Click **Edit** ( ) to specify the proposals for your chosen IKEv1 or IKEv2 method. Select from the available **IKEv1 IPsec Proposals** or **IKEv2 IPsec Proposals** objects, or create and then select a new one. See Configure an IKEv1 IPsec proposal object, on page 2469 and Configure an IKEv2 IPsec proposal object, on page 2470 for details.

Enable Security Association (SA) Strength Enforcement

Enabling this option ensures that the encryption algorithm used by the child IPsec SA isn't stronger (in terms of the number of bits in the key) than the parent IKE SA.

Enable Reverse Route Injection

Reverse Route Injection (RRI) enables static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint.

Enable Perfect Forward Secrecy

Whether to use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the Modulus Group list.

Modulus Group

The Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. For a full explanation of the options, see Decide which Diffie-Hellman modulus group to use, on page 1336.

Lifetime Duration

The number of seconds a security association exists before expiring. The default is 28,800 seconds.

Lifetime Size

The volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before it expires. The default is 4,608,000 kilobytes. Infinite data isn't allowed.

ESPv3 Settings

Validate incoming ICMP error messages

Choose whether to validate ICMP error messages received through an IPsec tunnel and destined for an interior host on the private network.

Enable 'Do Not Fragment' Policy

Define how the IPsec subsystem handles large packets that have the do-not-fragment (DF) bit set in the IP header.

Policy

- Copy DF bit—Maintains the DF bit.
- Clear DF bit—Ignores the DF bit.
- Set DF bit—Sets and uses the DF bit.

Enable Traffic Flow Confidentiality (TFC) Packets

Enable dummy TFC packets that mask the traffic profile which traverses the tunnel. Use the **Burst**, **Payload Size**, and **Timeout** parameters to generate random length packets at random intervals across the specified SA.

Note You can enable dummy Traffic Flow Confidentiality (TFC) packets at random lengths and intervals on an IPsec security association (SA). You must have an IKEv2 IPsec proposal set before enabling TFC.

Enabling TFC packets prevents the VPN tunnel from being idle. Thus the VPN idle timeout configured in the group policy doesn't work as expected when you enable the TFC packets.

Firewall Threat Defense advanced site-to-site VPN deployment options

The sections describe the advanced options you can specify in your site-to-site VPN deployment. These settings apply to the entire topology, all tunnels, and all managed devices.

Firewall Threat Defense VPN advanced IKE options

Advanced > IKE > ISAKAMP settings

IKE Keepalive

Enable or disables IKE Keepalives. You can set this option to EnableInfinite so that the device never starts the keepalive monitoring itself.

Threshold
Specifies the IKE keep alive confidence interval. This interval is the number of seconds allowing a peer to idle before beginning keepalive monitoring. The minimum and default interval is 10 seconds; the maximum interval is 3600 seconds.

Retry Interval
Specifies number of seconds to wait between IKE keep alive retries. The default is 2 seconds, the maximum is 10 seconds.

Identity Sent to Peers:
Choose the identity that the peers will use to identify themselves during IKE negotiations:

- **autoOrDN**(default)—Determines IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication (not supported).
- **ipAddress**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
- **hostname**—Uses the fully qualified domain name of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.

Note Enable or disable this option for all your VPN connections.

Peer Identity Validation
During IKE tunnel establishment, the peer provides its identity: either an IP address, a Fully Qualified Domain Name (FQDN), or a Distinguished Name (DN). It also presents a certificate, which contains none, some, or all of these fields.

If IKE peer identity validation is enabled, the Firewall Threat Defense compares the peer's identity to the respective field in the certificate to see if the information matches. If the information matches, then the peer's identity is validated and the Firewall Threat Defense establishes the tunnel. If the information does not match, the tunnel is not established.

- **Do not check**—Firewall Threat Defense does not validate the peer identity.
- **Required**—Firewall Threat Defense validates the peer identity.
- **If supported by cert**—Firewall Threat Defense validates the peer identity only if the peer provides a certificate.

Enable Aggressive Mode
Select this negotiation method for exchanging key information if the IP address isn't known and DNS resolution might not be available on the devices. Negotiation is based on hostname and domain name.

Enable Notification on Tunnel Disconnect
Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA does not match the traffic selectors for that SA. This notification is disabled by default.

Advanced > IKE > IKEv2 security association (SA) settings

More session controls are available for IKE v2 that limit the number of open SAs. By default, there's no limit to the number of open SAs.

Cookie Challenge
Whether to send cookie challenges to peer devices in response to SA initiate packets, which can help thwart denial of service (DoS) attacks. The default is to use cookie challenges when 50% of the available SAs are in negotiation. Select one of these options:

- Custom
- Never (default)
- Always

Threshold to Challenge Incoming Cookies
The percentage of the total allowed SAs that are in-negotiation. This triggers cookie challenges for any future SA negotiations. The range is zero to 100%.

Number of SAs Allowed in Negotiation
Limits the maximum number of SAs that can be in negotiation at any time. If used with Cookie Challenge, configure the cookie challenge threshold lower than this limit for an effective cross-check.

Maximum number of SAs Allowed
Limits the number of allowed IKEv2 connections. Default is unlimited.

Enable Notification on Tunnel Disconnect
Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA doesn't match the traffic selectors for that SA. Sending this notification is disabled by default.

Firewall Threat Defense VPN advanced IPsec options

Advanced > IPsec > IPsec Settings

The advanced IPsec settings include these configuration options:

- **Enable Fragmentation Before Encryption**: This option lets traffic travel across NAT devices that don't support IP fragmentation. It doesn't impede the operation of NAT devices that do support IP fragmentation.
- **Path Maximum Transmission Unit Aging**: Check to enable Path Maximum Transmission Unit (PMTU) Aging, the interval to reset the PMTU of a Security Association (SA).
- **Value Reset Interval**: Enter the number of minutes at which the PMTU value of an SA is reset to its original value. The range is 10 to 30 minutes, default is unlimited.

Firewall Threat Defense advanced site-to-site VPN tunnel options

This topic lists the advanced site-to-site VPN tunnel options.

Navigation path

Devices > Site To Site, then click **+ Site To Site VPN**, or edit a listed VPN Topology. Click the **Advanced** tab, and select **Tunnel** in the navigation pane.

Tunnel options

Only available for Hub and Spoke, and Full Mesh topologies. This section doesn't appear for Point to Point configurations.

- **Enable Spoke to Spoke Connectivity through Hub**—Disabled by default. Choosing this field enables the devices on each end of the spokes to extend their connection through the hub node to the other device.

NAT settings

- **Keepalive Messages Traversal**—Enabled by default. This parameter is a global setting that enables NAT-T for all endpoints within a topology. Check this check box to enable keepalive messages for NAT traversal. NAT traversal keepalive is used for the transmission of keepalive messages when there's a device (middle device) located between a VPN-connected hub and spoke, and that device performs NAT on the IPsec flow.

  NAT traversal allows seamless communication between the peer Firewall Threat Defense devices when there are NAT devices between these devices. For hub and spoke topologies, this option is available only for the spoke.

  If you select this option, configure the **Interval**, in seconds, between the keepalive signals sent between the spoke and the middle device to indicate that the session is active. The value can be from 5 to 3600 seconds. The default is 20 seconds. You can disable this feature for an endpoint in a topology when you add it using the VPN wizard (**Enable NAT Traversal** check box in the **Add Endpoint** dialog box).

Access control for VPN traffic

Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)—By default, the Firewall Threat Defense applies access control policy inspection on the decrypted traffic. Enable this option to bypass the ACL inspection. The Firewall Threat Defense still applies the VPN Filter ACL and authorization ACL downloaded from the AAA server to the VPN traffic.

Enable or disable the option for all your VPN connections. If you disable this option, ensure that the traffic is allowed by the access control policy or prefilter policy.

Note For route-based VPNs, **sysopt permit-vpn** does not work. You must always create access control rules to allow route-based VPN traffic.

Certificate map settings

- **Use the certificate map configured in the Endpoints to determine the tunnel**—If this option is enabled (checked), the tunnel is determined by matching the contents of the received certificate to the certificate map objects configured in the endpoint nodes.
- **Use the certificate OU field to determine the tunnel**—Indicates that if a node isn't determined based on the configured mapping (the above option) if selected, then use the value of the organizational unit (OU) in the subject distinguished name (DN) of the received certificate to determine the tunnel.

- **Use the IKE identity to determine the tunnel**—Indicates that if a node isn't determined based on a rule matching or taken from the OU (the above options) if selected, then the certificate-based IKE sessions are mapped to a tunnel based on the content of the phase1 IKE ID.
- **Use the peer IP address to determine the tunnel**—Indicates that if a tunnel isn't determined based on a rule matching or taken from the OU or IKE ID methods (the above options) if selected, then use the established peer IP address.

Configure virtual tunnel interfaces

Firewall Management Center supports a routable logical interface called the Virtual Tunnel Interface (VTI).

Virtual tunnel interfaces

A virtual tunnel interface is a routable logical interface that

- does not require static mapping of IPsec sessions to a physical interface
- associates the IPsec tunnel endpoint with a virtual interface, and
- supports static and dynamic routing policies.

Virtual tunnel interface capabilities

Firewall Management Center supports VTIs as an alternative to policy-based VPN. VTIs support route-based VPN with IPsec profiles attached to the end of each tunnel. VTIs use static or dynamic routes. The device encrypts or decrypts the traffic from or to the tunnel interface and forwards it according to the routing table. Deployments become easier, and having VTI which supports route-based VPN with dynamic routing protocol also satisfies many requirements of a virtual private cloud. Firewall Management Center enables you to easily migrate from crypto-map based VPN configuration to VTI-based VPN.

You can configure route-based VPN with static or dynamic VTI using the site-to-site VPN wizard. Traffic is encrypted using static route, BGP, OSPFv2/v3, or EIGRP.

You can create a routed security zone, add VTI interfaces to it, and define access control rules for the decrypted traffic control over the VTI tunnel.

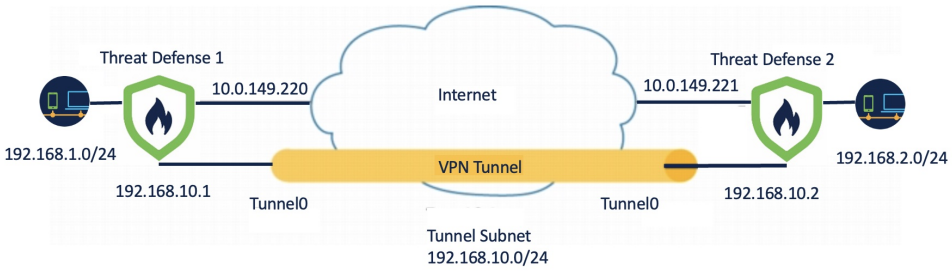
There are two types of VTI interfaces: static VTI and dynamic VTI.

You can create VTI-based VPNs between:

- Two Firewall Threat Defense devices.
- A Firewall Threat Defense and public cloud.
- One Firewall Threat Defense and another Firewall Threat Defense with service provider redundancy.
- A Firewall Threat Defense and any other device with VTI interfaces.
- A Firewall Threat Defense and another device with policy-based VPN configuration.

For more information, see Static VTI, on page 1365 and Dynamic VTI, on page 1366.

Static VTI



A static VTI is a virtual tunnel interface that

- uses tunnel interfaces to create a tunnel that is always-on between two sites
- requires defining a physical interface as a tunnel source, and
- supports a maximum of 1024 VTIs per device.

To create a static VTI interface in the Management Center, see Add a VTI interface, on page 1371.

The figure shows a VPN topology using static VTIs.

Figure 395: Static VTI VPN topology

On Threat Defense 1:

- Static VTI IP address is 192.168.10.1
- Tunnel source is 10.0.149.220
- Tunnel destination is 10.0.149.221

On Threat Defense 2:

- Static VTI IP address is 192.168.10.2
- Tunnel source is 10.0.149.221
- Tunnel destination is 10.0.149.220

Benefits of SVTI

Static VTI provides these benefits:

- Minimizes and simplifies configuration.

  You do not have to track all remote subnets for a crypto map access list, and configure complex access lists or crypto maps.

- Provides a routable interface.

  Supports IP routing protocols such as BGP, EIGRP, and OSPFv2/v3, and static routes.

- Supports backup VPN tunnels
- Supports load balancing using ECMP.

- Supports virtual routers.
- Provides differential access control for VPN traffic.

  You can configure a VTI with a security zone and use it in an AC policy. This configuration:

  - Allows you to classify and differentiate VPN traffic from clear-text traffic and permit VPN traffic selectively.
  - Provides differential access-control for VPN traffic across different VPN tunnels.

Dynamic VTI

A dynamic VTI is a VPN interface that

- uses a virtual template for dynamic instantiation and management of IPsec interfaces
- dynamically generates a unique virtual access interface for each VPN session
- supports multiple IPsec security associations and accepts multiple IPsec selectors proposed by the spoke.

Benefits of dynamic VTI

- Minimizes and simplifies configuration.

  You do not have to configure complex access lists or crypto maps.
- Simplifies management.
  - Easily manage peer configuration for large enterprise hub and spoke deployments.
  - Use only one dynamic VTI for multiple spokes, instead of configuring one static VTI per spoke.
- Provides a routable interface.

  Supports IP routing protocols such as BGP, EIGRP, and OSPFv2/v3.
- Simplifies scaling

  Addition of new spokes does not require any additional VPN configuration on the hub. You may need to update NAT and routing configurations depending upon the setup.
- Support for backup VPN tunnels.
- Supports dynamic spokes.

  You do not have to update the hub configuration for spoke's DHCP IP address changes.
- Conserves IP addresses.
  - Uses the IP unnumbered interface functionality to borrow the IP address from another physical or loopback interface.
  - All virtual access interfaces associated to a dynamic VTI use the same IP address.
- Supports virtual routers.
- Provides differential access control for VPN traffic.

You can configure a VTI with a security zone and use it in an AC policy. This configuration:

- Allows you to classify and differentiate VPN traffic from clear-text traffic and permit VPN traffic selectively.
- Provides differential access-control for VPN traffic across different VPN tunnels.

How Does the Firewall Management Center Create a Dynamic VTI Tunnel for a VPN Session

When a spoke initiates a tunnel request with the hub:

1. The spoke initiates an IKE exchange with the hub for a VPN connection.
2. The hub authenticates the spoke.
3. The Firewall Management Center assigns a dynamic virtual template on the hub for the spoke.

   The virtual template dynamically generates a virtual access interface on the hub. This interface is unique for the VPN session with the spoke.
4. The hub establishes a dynamic VTI tunnel with the spoke using the virtual access interface.
   a. The hub and spoke exchange traffic over the tunnel using:
      - Specific traffic proposed by the spokes over IKE exchanges.
      - BGP/OSPF/EIRGP protocols over the IPsec tunnel.
   b. After the VPN session ends, the tunnel disconnects and the hub deletes the corresponding virtual access interface.

To create a dynamic VTI interface in the Firewall Management Center, see Add a VTI interface, on page 1371.

To configure a route-based site-to-site VPN using dynamic VTI, see Configure dynamic VTI for a route-based site-to-site VPN, on page 1384.

Virtual Routers and Dynamic VTI

You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. You can assign a dynamic VTI to only one virtual router.

A virtual router associated with:

- A dynamic VTI is called an Indoor VRF (IVRF).
- A tunnel source interface is known as Front Door VRF (FVRF).

A dynamic VTI and its corresponding protected network interface must be part of the same virtual router. You must map the borrow IP interface and the dynamic VTI to the same virtual router. A tunnel source interface can be part of multiple virtual routers.

To configure virtual routers using dynamic VTI for a route-based site-to-site VPN, refer to Configure a virtual router with dynamic VTI, on page 1384.

For more information about a configuration example, refer to Secure traffic from networks with multiple virtual routers over a site-to-site VPN with dynamic VTI, on page 1025

Guidelines for virtual tunnel interfaces

General configuration guidelines

- VTIs are only configurable in IPsec mode.
- Dynamic VTI supports only Firewall Threat Defense devices from Version 7.3.
- You can use static, BGP, EIGRP IPv4, OSPFv2/v3 routes for traffic using the tunnel interface.
- In an HA configuration with dynamic routing, the standby device cannot access the known subnets through the VTI tunnels as these tunnels are created with the active IP address.
- For static and dynamic VTI, ensure that you don't use the borrow IP interface as the tunnel source IP address for any VTI interface.
- When you configure a route-based site-to-site VPN using static or dynamic VTI interfaces, ensure that the value of the TTL hop is more than one if you use BGP.
- If NAT has to be applied, the IKE and ESP packets are encapsulated in the UDP header.
- Ensure that you remove unused transform sets from route-based IKE VPN configurations. If you have unused transform sets, the VPN tunnels may not come up and encapsulation and decapsulation will not happen. Use **show run crypto** and **show VPN-sessiondb detail l2l** commands to view the transform sets.

IPv6 address guidelines

- VTI supports IPv6 addresses.
- You can use an IPv6 address for the tunnel source interface and use the same address as the tunnel endpoint.

- The Firewall Management Center supports the following combinations of VTI IP (or internal networks IP version) over public IP versions: IPv6 over IPv6, IPv4 over IPv6, IPv4 over IPv4, and IPv6 over IPv4.
- VTI supports static and dynamic IPv6 addresses as the tunnel source and destination.
- The tunnel source interface can have IPv6 addresses and you can specify the tunnel endpoint address. If you don't specify the address, by default, the device uses the first IPv6 global address in the list as the tunnel endpoint.

IKE support and guidelines

- Static VTI supports IKE v1 and v2.
- Dynamic VTI supports only IKE version v2, and uses IPsec for sending and receiving data between the tunnel's source and destination.
- IKE and IPsec security associations are re-keyed continuously regardless of data traffic in the tunnel. This ensures that VTI tunnels are always up.
- Tunnel group name must match what the peer sends as its IKEv1 or IKEv2 identity.
- For IKEv1 in LAN-to-LAN tunnel groups, you can use names which aren't IP addresses, if the tunnel authentication method is digital certificates and/or the peer is configured to use aggressive mode.

MTU behavior

- MTU for VTIs is automatically set based on the underlying physical interface.
- For dynamic VTI, the virtual access interface inherits MTU from the configured tunnel source interface. If you don't specify the tunnel source interface, the virtual access interface inherits the MTU from the source interface from which the device accepts the VPN session request.

VTI scaling and guidelines

- Configure a maximum of 1024 static and dynamic VTIs in a device.

  While calculating the VTI count, consider nameif subinterfaces, portchannel configurations, and platform VLAN limitations.
- If you configure more than 400 VTIs in a device in a high-availability setup, configure 45 seconds as the unit holdtime.

Routing protocol support

VTI supports multiple routing protocols for different IP versions.

- VTI supports IPv6 BGP.
- VTI supports IPv4 EIGRP.
- VTI supports IPv4 and IPv6 OSPF.

ECMP configuration guidelines

- Configure spokes' static VTIs in an ECMP zone to load balance application traffic. If you do not configure the ECMP zone, the remaining paths act as backup paths when the primary path goes down.
- You can associate VTI interfaces with ECMP zones and configure ECMP static routes to achieve these benefits:

- Load balancing (Active/Active VTIs)—Connection can flow over any of the parallel VTI tunnels.
- Seamless connection migration—When a VTI tunnel becomes unreachable, the flows are seamlessly migrated to another VTI interface that is configured in the same zone.
- Asymmetric routing—Forward traffic flow through one VTI interface and configure the reverse traffic flow through another VTI interface.

For information on configuring ECMP, see ECMP routing methods, on page 1047.

Access control rule guidelines

- By default, all traffic sent through a VTI is encrypted.
- Access control rules can be applied on a VTI interface to control traffic through VTI.
- For route-based VPNs, Bypass Access Control policy for decrypted traffic (**sysopt connection permit-VPN**) does not work. You must always create access control rules to allow route-based VPN traffic.

Crypto map guidelines

- If you use dynamic crypto maps and dynamic VTIs in your site-to-site VPNs, only the dynamic VTI tunnels will come up. This behaviour occurs because both the crypto maps and dynamic VTIs try to use the default tunnel group. We recommend that you migrate your site-to-site VPNs to dynamic VTIs or use static crypto maps with their own tunnel-groups.
- VTI and crypto map configurations can coexist on the same physical interface if the peer address configured in the crypto map and the tunnel destination for the VTI are different.

Topology guidelines

- Dynamic VTI supports only the hub and spoke topology in the management center.
- We recommend that you configure only a single hub for a route-based hub and spoke topology. To configure a topology with multiple hubs for a set of spokes, with one hub as the backup hub, configure multiple topologies with a single hub and the same set of spokes.

Dynamic VTI and virtual router guidelines

- A dynamic VTI and its corresponding protected network interface must be part of the same virtual router.
- You must map the borrow IP interface and the dynamic VTI to the same virtual router.
- User-defined virtual routers support only BGPv4/v6 and OSPFv2 routing protocols.
- A tunnel source interface can be in a different user-defined virtual router than that associated with the dynamic VTI.

Firewall mode guideline

Configure VTI only in routed mode.

Limitations for Virtual Tunnel Interfaces

This topic lists the limitations for configuring Virtual Tunnel Interfaces in Management Center.

General limitations

- VTIs do not support clustering.
- VTI tunnel interfaces are not supported for SNMP or Syslog in Platform Settings.

Static VTI limitations

- Only 20 unique IPSec profiles are supported.
- In policy-based routing, you can configure VTI only as an egress interface.
- You cannot configure a VTI interface as a network interface for a remote access VPN policy.

Dynamic VTI limitations

- Dynamic VTI does not support ECMP , VRF in multi-instance, Clustering, IKEv1, or QoS.
- If a spoke has a dynamic IP address and a hub has a dynamic VTI behind a NAT, the tunnel status will be unknown.
- For a dynamic extranet, when multiple spokes establish a connection, the site-to-site monitoring dashboard does not show the individual tunnels.
- If you configure a hub with dynamic VTI behind NAT with dynamic spokes, the VPN monitoring data will not be accurate.
- You cannot configure a VTI interface as a network interface for a remote access VPN policy.

Backup VTI limitations

- Flow resiliency across tunnel failovers isn't supported. For example, the clear text TCP connection gets lost after a tunnel failover, and you need to reinitiate any FTP transfer that took place during the failover.
- Certificate authentication isn't supported in backup VTI.

Add a VTI interface

For configuring a route-based site-to-site VPN, you must create a VTI interface on the devices at both the nodes of the VTI tunnel.

When you specify the tunnel type as dynamic and configure the related parameters, the Firewall Management Center generates a dynamic virtual template. The virtual template dynamically generates the virtual access interface that is unique for each VPN session.

Before you begin

Configure a loopback interface for redundancy of static and dynamic VTI VPN tunnels. For more information, see Configure a loopback interface, on page 662.

For a Secure Firewall 1200/3100/4200device, IPsec flow offload is also used when the device's VTI loopback interface is enabled.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click the **Edit** icon next to the device on which you want to create a VTI interface.

Step 3 Choose **Add Interfaces > Virtual Tunnel Interface**.

In the **Add Virtual Tunnel Interface** dialog box, configure these parameters:

a) Select the **Tunnel Type** as **Static** or **Dynamic**, and enter the name and description for the interface. By default, the interface is enabled.

b) (Optional) Choose a security zone from the **Security Zone** drop-down list to add the static VTI or dynamic VTI interface to that zone. In the **Priority** field, enter the priority to load balance the traffic across multiple VTIs.

If you want to perform traffic inspection based on a security zone, add the VTI interface to the security zone and configure an access control (AC) rule. To permit the VPN traffic over the tunnel, you need to add an AC rule with this security zone as the source zone.

The priority range is from 0 to 65535. The lowest number has the highest priority. This option is not applicable for dynamic VTI.

c)

d) Depending on the tunnel type, do one of the following:

- For a dynamic VTI, enter a unique ID in the range of 1 to 10413 in the **Template ID** field.
- For a static VTI, enter a unique tunnel ID in the range of 0 to 10413 in the **Tunnel ID** field.

e) (Optional for dynamic VTI) Choose the tunnel source interface from the **Tunnel Source** drop-down list.

The VPN tunnel terminates at this interface, a physical or loopback interface. Choose the IP address of the interface from the drop-down list. You can select the IP address irrespective of the IPsec tunnel mode. In case of multiple IPv6 addresses, select the address that you want to use as the tunnel endpoint.

f) Under **IPSec Tunnel Mode**, click the **IPv4** or **IPv6** radio button to specify the traffic type over the IPsec tunnel.

g) Under **IP Address**:

- **Configure IP**: Enter the IPv4 or IPv6 address for the static VTI interface. You cannot configure an IP address for a dynamic VTI interface. Use the **Borrow IP** field for the dynamic VTI interface.
- **Borrow IP (IP unnumbered)**: Choose a physical or loopback interface from the drop-down list, the VTI interface inherits this IP address.

  Ensure that you use an IP address different from the tunnel source IP address. You can use this option for a static or dynamic VTI interface.

  Click Add + to configure a loopback interface. The loopback interface helps to overcome path failures. If an interface goes down, you can access all interfaces through the IP address assigned to the loopback interface.

Step 4 Click **OK**.

Step 5 Click **Save**.

Create a route-based site-to-site VPN

You can configure a route-based site-to-site VPN for the following two topologies:

- **Point to Point**: Configure VTIs on both nodes of the tunnel and use the wizard to configure the VPN.
- **Hub and Spoke**: Configure VTIs on the hub and the spokes. Configure the hub with a dynamic VTI and spokes with static VTIs.

You can configure an extranet device as the hub and managed devices as spokes. You can configure multiple hubs and spokes, and also configure backup hubs and spokes.

- For extranet hubs and spokes, you can configure multiple IPs as backup.
- For managed spokes, you can configure a backup static VTI interface along with the primary VTI interface.

For more information on VTI, see Virtual tunnel interfaces, on page 1364.

Note All references to VTI stands for static VTI and dynamic VTI, unless mentioned.

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site**.

Step 2 Click **+ Site To Site VPN**.

Step 3 Enter a name for the VPN topology in the **Topology Name** field.

Step 4 Choose **Route Based (VTI)** and do one of the following:

- Select **Point to Point** as the network topology. To configure endpoints for a route-based **Point to Point** topology, refer to Configure endpoints for a point-to-point VPN topology, on page 1374.
- Select **Hub and Spoke** as the network topology. To configure endpoints for a route-based **Hub and Spoke** topology, refer to Configure endpoints for a hub and spoke topology, on page 1376.

Step 5 (Optional) Specify the **IKE**, **IPsec**, and **Advanced** options and click **Save**.

For more information, refer to these topics:

- Firewall Threat Defense VPN IKE options, on page 1356
- Firewall Threat Defense VPN IPsec options, on page 1358
- Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1360

What to do next

After you configure VTI interfaces and VTI tunnel on both the devices, you must configure:

- A routing policy to route the VTI traffic between the devices over the VTI tunnel. For more information, see Configure routing and AC policies for VTI, on page 1385.
- An access control rule to allow encrypted traffic. Choose **Policies** > **Access Control**.

Configure endpoints for a point-to-point VPN topology

Configure these parameters to configure endpoints for a route-based site-to-site VPN for the **Point to Point** topology nodes:

Before you begin

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in Create a route-based site-to-site VPN, on page 1373 and click the **Endpoints** tab.

Procedure

Step 1 Under **Node A**, in the **Device** drop-down menu, select the name of the registered device (Firewall Threat Defense) or extranet as the first endpoint of your VTI tunnel.

For an extranet peer, specify the following parameters:

a. Specify the name of the device.

b. Enter the primary IP address in the **Endpoint IP address** field. If you configure a backup VTI, add a comma and, specify the backup IP address.

c. Click **OK** .

After configuring the above parameters for the extranet hub, specify the pre-shared key for the extranet in the **IKE** tab.

Note The AWS VPC has **AES-GCM-NULL-SHA-LATEST** as the default policy. If the remote peer connects to AWS VPC, select **AES-GCM-NULL-SHA-LATEST** from the **Policy** drop-down list to establish the VPN connection without changing the default value in AWS.

Step 2 For a registered device, you can specify the VTI interface for Node A from the **Virtual Tunnel Interface** drop-down list.

The selected tunnel interface is the source interface for Node A and the tunnel destination for Node B.

If you want to create a new interface on Node A, click the Add + icon and configure the fields as described in Add a VTI interface, on page 1371 .

If you want to edit the configuration of an existing VTI, select the VTI in the **Virtual Tunnel Interface** drop-down field and click **Edit VTI**.

Step 3 If your Node A device is behind a NAT device, check the **Tunnel Source IP is Private** check box. In the **Tunnel Source Public IP Address** field, enter the tunnel source public IP address.

Step 4 **Send Local Identity to Peers** —Select this option to send local identity information to the peer device. Select one of the following **Local Identity Configuration** from the list and configure the local identity:

- **IP address** —Use the IP address of the interface for the identity.
- **Auto** —Use the IP address for pre-shared key and Cert DN for certificate-based connections.
- **Email ID** —Specify the email ID to use for the identity. The email ID can be up to 127 characters.
- **Hostname** —Use the fully qualified hostname.
- **Key ID** —Specify the key-id to use for the identity. The key ID must be fewer than 65 characters.

The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows Firewall Threat Defense to have multiple IPsec tunnels behind a NAT to connect to a Cisco Umbrella Secure Internet Gateway (SIG).

For information about configuring a unique tunnel ID on Umbrella, see **Cisco Umbrella SIG User Guide** .

Step 5 (Optional) Click **Add Backup VTI** to specify an extra VTI as the backup interface and configure the parameters.

Note Ensure that both peers of the topology do not have the same tunnel source for the backup VTI. A device cannot have two VTIs with the same tunnel source and tunnel destination; hence, configure a unique tunnel source and tunnel destination combination.

Though the virtual tunnel interface is specified under Backup VTI, the routing configuration determines which tunnel to be used as primary or backup.

Step 6 Under **Additional Configuration** , do the following:

- To route traffic to the VTI, click **Routing Policy** . Firewall Management Center displays the **Devices** > **Routing** page.

  You can configure the Static, BGP, OSPF v2/v3, or EIGRP routing for the VPN traffic.

- To permit VPN traffic, click **AC Policy** . Firewall Management Center displays the access control policy page of the device. Proceed to add an allow/block rule specifying the security zone of the VTI. If you configure a backup VTI, ensure to include the backup tunnel to the same security zone as that of the primary VTI. No specific settings are required for the backup VTI in the AC policy page.

Step 7 Expand **Advance Settings** to configure additional configurations for the device. For more information, see Configure advanced settings for a point-to-point topology in a route-based VPN, on page 1376 .

Step 8 Repeat the above procedure for Node B and click **OK** .

What to do next

- (Optional) Specify the **IKE** options for the deployment as described in Firewall Threat Defense VPN IKE options, on page 1356.
- (Optional) Specify the **IPsec** options for the deployment as described in Firewall Threat Defense VPN IPsec options, on page 1358.

- (Optional) Specify the **Advanced** options for the deployment as described in Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1360.
- Click **Save**.
- To route traffic to the VTI, choose **Devices** > **Device Management** , edit the threat defense device and click the **Routing** tab.

  You can configure the static routes, or use BGP, OSPF v2/v3, or EIGRP for routing the VPN traffic.
- To permit VPN traffic, choose **Policies** > **Access Control heading** > **Access Control**. Add a rule specifying the security zone of the VTI. For a backup VTI, ensure that you include the backup VTI in the same security zone as that of the primary VTI.

Configure advanced settings for a point-to-point topology in a route-based VPN

Configure advanced settings to enhance the functionality and security of a point-to-point topology in a route-based VPN beyond the basic configuration parameters.

Before you begin

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in Configure endpoints for a point-to-point VPN topology, on page 1374 and expand **Advance Settings**.

Procedure

Step 1 Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.

Step 2 Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the spokes and peers.

Step 3 Choose one of the following from the **Connection Type** drop-down list:

Answer Only: The device can only respond when a peer device initiates a connection, it can't initiate any connection.

Bidirectional: The device can initiate or respond to a connection. This is the default option.

Configure endpoints for a hub and spoke topology

You can create a route-based site-to-site VPN using dynamic VTI only for hub and spoke topologies. The hub can use only a dynamic VTI and the spokes can use only static VTI interfaces. You can also configure an extranet device as a hub.

Configure these parameters to configure endpoints for a route-based site-to-site VPN for the **Hub and Spoke** topology nodes:

Before you begin

Configure the basic parameters for a hub and spoke topology in a route-based VPN as described in Create a route-based site-to-site VPN, on page 1373 and click the **Endpoints** tab.

Procedure

Step 1 Under **Hub Nodes**:

a) Click Add + to configure the hub node in the **Add Endpoint** dialog box.

b) Choose a hub from the **Device** drop-down list.

For an extranet hub, configure these parameters:

1. Enter the name of the device.
2. Enter the primary IP address. If you configure a backup VTI, add a comma, and then specify the backup IP address.
3. Click **OK**.

After configuring the above parameters for the extranet hub, specify the pre-shared key for the extranet in the **IKE** tab.

Note The AWS VPC has **AES-GCM-NULL-SHA-LATEST** as the default policy. If the remote peer connects to AWS VPC, select **AES-GCM-NULL-SHA-LATEST** from the **Policy** drop-down list to establish the VPN connection without changing the default value in AWS.

c) Choose a dynamic VTI from the **Dynamic Virtual Tunnel Interface** drop-down list.

Tunnel source configuration is mandatory for a dynamic VTI as the management center needs this information to determine the tunnel destination of the spoke.

Click Add + to add a new dynamic VTI. We recommend that you configure the Borrow IP for the dynamic interface from a loopback interface.

If you want to edit an existing dynamic VTI, select the interface, and click **Edit VTI**.

d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box and configure the tunnel source IP address in the **Tunnel Source Public IP Address** field.

e) Click **Routing Policy** to configure the routing policy for the hub.

f) Click **AC Policy** to configure the access control policy.

g) Expand **Advance Settings** to configure additional configurations on the hub. For more information, see Configure advanced settings for hub and spokes in a route-based VPN, on page 1379 .

h) Click **OK**.

Step 2 Under **Spoke Nodes**:

a) Click Add + to configure the spoke in the **Add Endpoint** dialog box.

b) Choose a spoke from the **Device** drop-down list.

For an extranet spoke, configure these parameters:

1. Enter the name of the device.
2. In **Endpoint IP Address**, choose one of these options:
   - **Static**: Enter the IP address of the device, and the backup IP address, if required.

- **Dynamic**: Choose this option to dynamically assign the IP addresses for the extranet spokes.

3. Click **OK**.

c) Choose a static VTI from the **Static Virtual Tunnel Interface** drop-down list.

Click Add + to add a new static VTI. Tunnel IP of the static VTI is auto populated, ensure that this IP address is unique for the spoke.

If you want to edit an existing static VTI, select the interface, and click **Edit VTI**.

d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box. The management center needs the tunnel source interface address to configure the tunnel destination IP address on the spokes. In the **Tunnel Source Public IP Address** field, enter the tunnel source public IP address.

e) (Optional) **Send Local Identity to Peers** —Check this check box to send the local identity information to the peer device. Choose one of the following parameters from the **Local Identity Configuration** drop-down list and configure the local identity:

- **IP address**—Use the IP address of the interface for the identity.
- **Auto**—Use the IP address for pre-shared key and Cert DN for certificate-based connections.
- **Email ID**—Specify the email ID to use for the identity. The email ID can be up to 127 characters.
- **Hostname**—Use the fully qualified hostname.
- **Key ID**—Specify the key-id to use for the identity. The key ID must be less than 65 characters.

The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows Firewall Threat Defense to have multiple IPsec tunnels behind a NAT to connect to the Cisco Umbrella Secure internet Gateway (SIG).

For more information about configuring a unique tunnel ID on Umbrella, see *Cisco Umbrella SIG User Guide* .

f) (Optional) Click **Add Backup VTI** to specify an extra VTI interface as the backup interface.

Note Ensure that both peers of the topology do not have backup VTI configured on the same tunnel source. For instance, if Peer A is having two VTIs (primary and a backup) configured with a single tunnel source interface, say, 10.10.10.1/30, then Peer B also can't have its 2 VTIs with a single tunnel source IP, say 20.20.20.1/30.

Though the virtual tunnel interface is specified under backup VTI, the routing configuration determines which tunnel to be used as primary or backup.

g) Click **Routing Policy** to configure the routing policy for the spoke.

h) Click **AC Policy** to configure the access control policy.

i) Expand **Advance Settings** to configure additional configurations on the spoke and click **OK** . For more information, see Configure advanced settings for hub and spokes in a route-based VPN, on page 1379.

What to do next

1. (Optional) Specify the **IKE** options for the deployment as described in Firewall Threat Defense VPN IKE options, on page 1356.
2. (Optional) Specify the **IPsec** options for the deployment as described in Firewall Threat Defense VPN IPsec options, on page 1358.
3. (Optional) Specify the **Advanced** options for the deployment as described in Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1360.
4. Click **Save**.

Configure advanced settings for hub and spokes in a route-based VPN

After configuring basic parameters for a hub and spoke in a route-based VPN, you can configure additional advanced settings to optimize the VPN topology's functionality and performance.

Before you begin

Configure the basic parameters for a hub and spoke in a route-based VPN as described in Configure endpoints for a hub and spoke topology, on page 1376 and expand **Advance Settings**.

Procedure

Step 1 Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.

For a hub, you must check this check box if you use BGP as the routing protocol. This configuration ensures that the loopback IP address is shared in the BGP routing table.

For a spoke, this option is enabled by default.

Step 2 Add the **Protected Networks** to define the networks protected by the VPN endpoint. Click Add + to select a protected network.

For a hub, configure the protected networks behind the hub. This information and the spoke's protected network generate the spoke access list.

You cannot create a static route for a virtual access interface on a hub with dynamic VTI. The hub creates and deletes these interfaces dynamically during tunnel establishment and termination.

For a spoke, configure the spoke's protected network.

To enable static routing for the spokes, after you configure the endpoints for your topology, click the **IPsec** tab and check the **Enable Reverse Route Injection** check box.

You do not need this option if you use BGP, OSPF, or EIGRP.

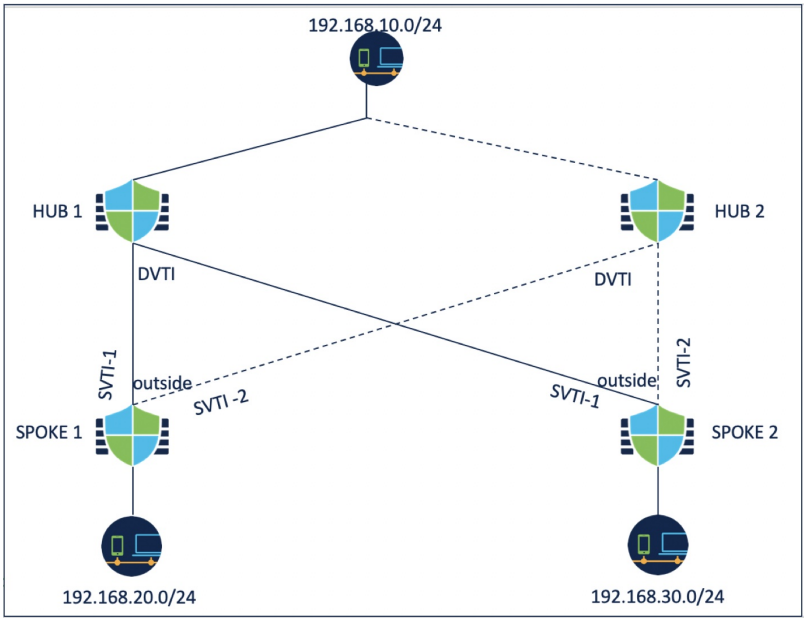
Step 3 Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the spokes and peers.

For a hub: During an IKE exchange, the hub advertises the dynamically created virtual access interfaces to the spokes, and the spokes advertise their VTI IP addresses to the hub.

For a spoke: By default, this option is enabled.

Step 4 In the **Connection Type** drop-down list, choose one of the following:

Answer Only: The device can only respond when a peer device initiates a connection, it can't initiate any connection.



Bidirectional: The device can initiate or respond to a connection. This is the default option.

Configure multiple hubs in a route-based VPN

You can configure a topology with multiple hubs for a set of spokes. With one hub as the backup hub, you can configure multiple topologies with a single hub and the same set of spokes.

In this example, there are two hubs connected to the same set of spokes. Hub 1 is the primary hub and Hub 2 is the secondary hub. To configure this network in the Firewall Management Center, you must configure two route-based hub and spoke topologies:

- Topology 1: Hub 1 connected to spoke 1 and spoke 2.
- Topology 2: Hub 2 connected to spoke 1 and spoke 2.

To configure topology 1:

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site** and click **+ Site To Site VPN**.

Step 2 Enter a name for the VPN topology in the **Topology Name** field.

Step 3 Choose **Route Based (VTI)** and do one of these topologies:

- Select **Point to Point** as the network topology. To configure endpoints for a route-based **Point to Point** topology, see Configure endpoints for a point-to-point VPN topology, on page 1374.

- Select **Hub and Spoke** as the network topology. To configure endpoints for a route-based **Hub and Spoke** topology, see Configure endpoints for a hub and spoke topology, on page 1376.

Step 4 Configure the IKE version and click the **Endpoints** tab.

Step 5 Under **Hub Nodes**:

a) Click Add + to add the hub.
b) Choose Hub 1 from the **Device** drop-down list.
c) Choose a dynamic VTI from the **Dynamic Virtual Tunnel Interface** drop-down list or click Add + to add a new dynamic VTI.

We recommend that you configure the Borrow IP for the dynamic interface from a loopback interface.

d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box and configure the tunnel source IP address in the **Tunnel Source Public IP Address** field.
e) Click **Routing Policy** to configure the routing policy for the hub. You can configure dynamic routing using BGP.
f) Expand **Advance Settings**. You can configure these advanced settings for the hub to enable IKEv2 routing, which can be used if you do not use dynamic routing.

- (Optional) Check the **Send Virtual Tunnel Interface IP to the peers** check box.
- Check the **Allow incoming IKEv2 routes from the peers** check box for the hub to accept routes from the spokes and update the routing table.
- Choose **Connection Type** as Bidirectional from the drop-down list.

g) Click **OK**.

Step 6 Under **Spoke Nodes**:

a) Click Add + to add a spoke.
b) Choose Spoke 1 from the **Device** drop-down list.
c) Choose SVTI-1 as the static VTI for the spoke from the **Static Virtual Tunnel Interface** drop-down list or click Add + to add a new static VTI.

Choose the outside interface as the tunnel source of SVTI-1. Tunnel IP of SVTI-1 is autopopulated, ensure that this IP address is unique for spoke 1 across peers in both the topologies.

d) Expand **Advance Settings**. If you do not use dynamic routing, you can configure these settings to enable IKEv2 routing for the spoke.

- Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.
- Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the peers.
- Choose **Connection Type** as Bidirectional from the drop-down list.

e) Click **OK**.
f) Repeat steps 5a to 5e to add spoke 2. Configure SVTI-1 as the static VTI of spoke 2.

Step 7 Configure the IKE and IPSec parameters as required or use the default values.

What to do next

1. Configure topology 2 with hub 2, spoke 1, and spoke 2.

   Configure SVTI-2 as the static VTI of spoke 1 and SVTI-2 as the static VTI of spoke 2 (refer the above illustration). Tunnel source for SVTI-2 should be the same outside interface.

2. For each spoke, configure the routing policy. For more information, see Configure routing for multiple hubs in a route-based VPN, on page 1382.

3. Verify the configuration and tunnel statuses. For more information, see Verify multiple hubs configuration in a route-based VPN, on page 1383.

Configure routing for multiple hubs in a route-based VPN

Configure dynamic routing using BGP on both hub and spoke devices, and implement Policy Based Routing on spokes to enable proper traffic routing in a route-based VPN topology with multiple hubs.

Before you begin

Configure topology 1 and 2 as explained in Configure multiple hubs in a route-based VPN, on page 1380.

Procedure

Step 1 Configure dynamic routing for the hub using BGP.

a) Choose **Devices** > **Device Management**, and click **Edit** ( ) then click the **Routing** tab.
b) In the left pane, choose **General Settings** > **BGP**.
c) Check the **Enable BGP** check box and enter the **AS number**.

   You can configure the other fields AS per your requirement.

d) Click **Save**.
e) On the left pane, choose **BGP** > **IPv4**.
f) Check the **Enable IPv4** check box.
g) Click the **Neighbor** tab, click **Add** and configure these parameters.

   1. **IP Address**: Enter the tunnel interface IP address of Spoke 1.
   2. **Remote AS**: AS number of Spoke 1.
   3. Check the **Enabled Address** check box.
   4. Click **OK**.

   Repeat the above steps to add Spoke 2 as a neighbor.

h) Click **Save**.
i) Click the **Networks** tab and click **Add** to advertise the network behind the hub to the peers.

Step 2 Configure dynamic routing for the spokes using BGP.

The BGP configuration for the spokes is similar to that of the hub except for these differences:

- Configure Hub 1 and Hub 2 AS the neighbors for both the spokes and use the tunnel interface IP address of the hubs.

- When you configure networks, use the network behind each spoke.

Step 3 Configure Policy Based Routing on the spokes.

a) In the left pane, choose **Policy Based Routing** and click **Add**.
b) Choose the **Ingress Interface** from the drop-down list.
c) Click **Add** to configure a Match ACL.

For example, for spoke 1, source network is 192.168.20.0/24 and destination network is 192.168.10.0/24.

d) Choose Egress Interfaces from the **Send to** drop-down list.
e) Choose Order from the **Interface Ordering** drop-down list.
f) Select the SVTI-1 and SVTI-2 interfaces AS the egress interfaces.
g) Click **Save**.

If you want to use the hubs as a load-balancing pair, you must configure ECMP.

Step 4 Deploy the configurations on the hub and spokes.

What to do next

Verify the configurations and tunnel statuses. For more information, see Verify multiple hubs configuration in a route-based VPN, on page 1383.

Verify multiple hubs configuration in a route-based VPN

To verify the multiple hub configurations and the tunnel statuses.

- After the deployment, check the tunnel status in the dashboards.
- Use **Packet Trace**r from the **Site-to-Site VPN dashboard** to verify the selected path of the traffic (hub 1 or hub 2).
- Use these show commands for each endpoint to verify the configurations:
  - **show run route-map**
  - **show run access-list**
  - **show route-map**
  - **show route**

Route traffic through a backup VTI tunnel

A backup VTI tunnel ensures traffic continuity by providing an alternative path when the primary VTI tunnel fails to route traffic in route-based VPN configurations.

You can deploy the backup VTI tunnel in these scenarios:

- Both peers having service provider redundancy backup.

  In this case, there are two physical interfaces, acting as the tunnel sources for the two VTIs of the peers.
- Only one of the peers has service provider redundancy backup.

In this case, there's an interface backup on only one side of the peer and on the other end, there is only one tunnel source interface.

Before you begin

Ensure that you review the guidelines and limitations. For more information, refer to Guidelines for virtual tunnel interfaces, on page 1368.

Procedure

Step 1 Create the VTI interface.

For more information, refer to Add a VTI interface, on page 1371

Step 2 In the **Add Endpoint** dialog box of the **Create New VPN Topology** wizard, click **Add Backup VTI** to configure the respective backup interface for each peer.

For more information, refer to

- Configure endpoints for a point-to-point VPN topology, on page 1374
- Configure endpoints for a hub and spoke topology, on page 1376

Step 3 Choose **Devices > Device Management**, and edit the threat defense device and click **Routing** to configure the routing policy.

Step 4 Choose **Policies > Access Control** to configure the access control policy.

Configure dynamic VTI for a route-based site-to-site VPN

To configure dynamic VTI for a route-based site-to-site VPN in the Management Center:

Step	Do This	More Information
1	Create a dynamic VTI interface on the hub.	Add a VTI interface, on page 1371
2	Create static VTI interfaces on the spokes.	Add a VTI interface, on page 1371
3	Create a route-based site-to-site VPN.	Create a route-based site-to-site VPN, on page 1373
4	Configure the routing policy and the access control policy.	Configure endpoints for a hub and spoke topology, on page 1376

Configure a virtual router with dynamic VTI

To configure a virtual router with dynamic VTI for a route-based site-to-site VPN in the Management Center:

Step	Do This	More Information
1	Create a route-based site-to-site VPN with a dynamic VTI interface on the hub and static VTI(s) on the spoke(s).	Create a route-based site-to-site VPN, on page 1373
2	Create a virtual router.	Create a virtual router, on page 1002
3	Assign the interfaces to the virtual router.	Configure a virtual router, on page 1002
4	Configure routing policies for the hub and spoke.	Configure endpoints for a hub and spoke topology, on page 1376
5	Configure access control policies for the hub and spoke.	Configure endpoints for a hub and spoke topology, on page 1376

Configure routing and AC policies for VTI

After you configure VTI interfaces and the VTI tunnel on both the devices, you must configure these parameters:

- A routing policy to route VTI traffic between the devices over the VTI tunnel.
- An access control rule to allow encrypted traffic.

Procedure

Step 1 Configure routing for VTI interfaces.

For the VTI interfaces, you can configure static route or routing protocols such AS BGP, EIGRP, OSPF/OSPFv3.

a. Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b. Click **Routing**.

c. Configure static route, or BGP, EIGRP, OSPF/OSPFv3.

Routing	Parameters	More Information
Static Route	• **Interface**—Select the VTI interface. For a backup tunnel, select the backup VTI interface. • **Selected Network**—Remote peer's protected network. • **Gateway**—Remote peer's tunnel interface IP address. For a backup tunnel, select the remote peer's backup tunnel interface IP address. • **Metric**—For a backup tunnel, configure a different metric to handle the failover of the traffic flow over the backup tunnel. **Note** DVTI does not support static routes.	Add a static route, on page 977

BGP	• Under **General Settings** > **BGP**, enable BGP, provide the AS number of the local device, and add Router ID (if you choose Manual).
	• Under **BGP**, enable IPv4/IPv6 and click the **Neighbor** tab to configure the neighbors.
	  • **IP Address**—Remote peer's VTI interface IP address. For a backup tunnel, add a neighbor with the remote peer's backup VTI interface IP address.
	  • **Remote AS**—Remote peer's AS number.
	• Click the **Redistribution** tab, select the **Source Protocol** AS Connected to enable connected route redistribution.
		Configure BGP, on page 1112

Routing	Parameters	More Information
EIGRP	• Enable EIGRP, provide the AS number of the local device, and select the networks or hosts that participate in the EIGRP routing process. • Click the **Neighbors** tab and define the static neighbors for the EIGRP process. • To advertise summary addresses from a VTI interface, click the **Summary Address** tab, choose the VTI interface from the **Interface** drop-down. From the **Network** drop-down, choose the network to be summarized. • Click the **Interfaces** tab to configure the interface-specific EIGRP routing properties for the VTI interface. To enable EIGRP split-horizon on the interface, check the **Split Horizon** check box. You can also configure the **Hold Time** that is advertised by the device in the EIGRP hello packets.	Configure EIGRP routing on firewall devices, on page 1098
OSPF	• Check the **Process 1** check box, and choose the OSPF role. • Click the **Interface** tab and choose a VTI interface.	OSPFv2 configuration, on page 1070
OSPFv3	• Check the **Process 1** and **Enable Process 1** check boxes, and choose the OSPFv3 role. • Click the **Interface** tab and choose a VTI interface.	OSPFv3 configuration, on page 1083

Step 2 Add an access control rule to the access control policy on the device to allow encrypted traffic between the VTI tunnels with these settings:

a. Create the rule with the Allow action.

b. Select the VTI security zone of the local device AS the source zone and the VTI security zone of the remote peer AS the destination zone.

c. Select the VTI security zone of the remote peer AS the source zone and the VTI security zone of the local device AS the destination zone.

For more information about configuring an access control rule, see Create and edit access control rules, on page 1631.

View virtual tunnel interface details

You can view details of dynamic and static VTIs of route-based VPNs on the device. For every VPN topology, you can also view details of all the dynamically generated virtual access interfaces associated with each dynamic VTI.

Before you begin

- Supported device for static VTIs: Firewall Threat Defense Version 7.0 and later
- Supported device for dynamic VTIs: Firewall Threat Defense Version 7.3 and later

Procedure

Step 1 Choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click the **Virtual Tunnels** tab.

For each VTI, you can view details such as name, IP address, IPsec mode, tunnel source interface details, topology, and remote peer IP. You can also view if path monitoring is enabled for each interface.

Deploy a SASE tunnel on Umbrella

Guidelines for configuring SASE tunnels on Umbrella

SASE topology supports:

- Only PSK-based authentication
- IKEv2
- High availability

General configuration guidelines

- Firewall Management Center does not discover tunnels created directly on Umbrella or by other applications.

- You can add only devices managed by the Firewall Management Center as endpoints for the SASE topology. You cannot add extranet devices.

  For high availability pairs, the HA pair names appear in the endpoint list.

- If you check the **Deploy configuration on threat defense nodes** check box in the wizard, the Umbrella SASE topology configuration is deployed on the Firewall Threat Defense only after the tunnels are deployed on Umbrella.

  The Firewall Management Center requires the local tunnel ID to deploy the Umbrella configuration in Firewall Threat Defense. Umbrella generates the complete tunnel ID (*<prefix>@<umbrella generated ID>*-umbrella.com) only after the Firewall Management Center deploys the tunnel on Umbrella.

- After a Firewall Threat Defense HA switchover, the SASE topology will not appear in the site-to-site monitoring/VPN summary dashboard. We recommend that you bring the tunnel down using the **VPN-sessiondb logoff index** command and bring it up using packet tracer.

Version migration guideline (Pre-version 7.3)

You must create new SASE topologies in version 7.3 and delete the existing SASE topologies because Firewall Management Center does not recognize topologies using Umbrella data center as an extranet hub created before version 7.3 as SASE topologies.

Deployment status and monitoring guideline

You can track the tunnel deployment status in three places:

- Cisco Umbrella Configuration dialog box of the wizard
- Notifications page under the Deployments and Tasks tabs
- Site to Site VPN Monitoring dashboard

Tunnel deletion guidelines

- You cannot edit or delete a SASE topology while deployment to Umbrella is in progress.
- When you delete a tunnel from Firewall Management Center and if it is unable to delete the tunnel from Umbrella, you must manually delete it by logging into Umbrella.

Limitations for configuring SASE tunnels on Umbrella

SASE topology does not support these features:

- Clustering
- Certificate-based authentication
- IKEv1

Deploy a SASE tunnel on Umbrella

This section provides instructions to deploy a SASE tunnel on Umbrella from a Firewall Threat Defense device using the Firewall Management Center.

Step	Do This	More Info
1	Review the guidelines and limitations.	Guidelines for configuring SASE tunnels on Umbrella, on page 1388
2	Ensure that you meet the prerequisites.	Prerequisites for configuring Umbrella SASE tunnels, on page 1390
3	Configure Cisco Umbrella connection settings.	• Configure Cisco Umbrella Connection Settings • Map Management Center Umbrella parameters and Cisco Umbrella API keys, on page 1390
4	Configure a SASE tunnel on Umbrella.	Configure a SASE tunnel for Umbrella, on page 1392
5	View the status of the SASE tunnel.	View SASE tunnel status, on page 1394

Prerequisites for configuring Umbrella SASE tunnels

License prerequisites

- You must have a Cisco Umbrella Secure Internet Gateway (SIG) Essentials subscription.
- You must enable your Smart License account with the export-controlled features to deploy tunnels on Umbrella from the Firewall Management Center. If this license is not enabled, you can only create a SASE topology. You cannot deploy tunnels on Umbrella.

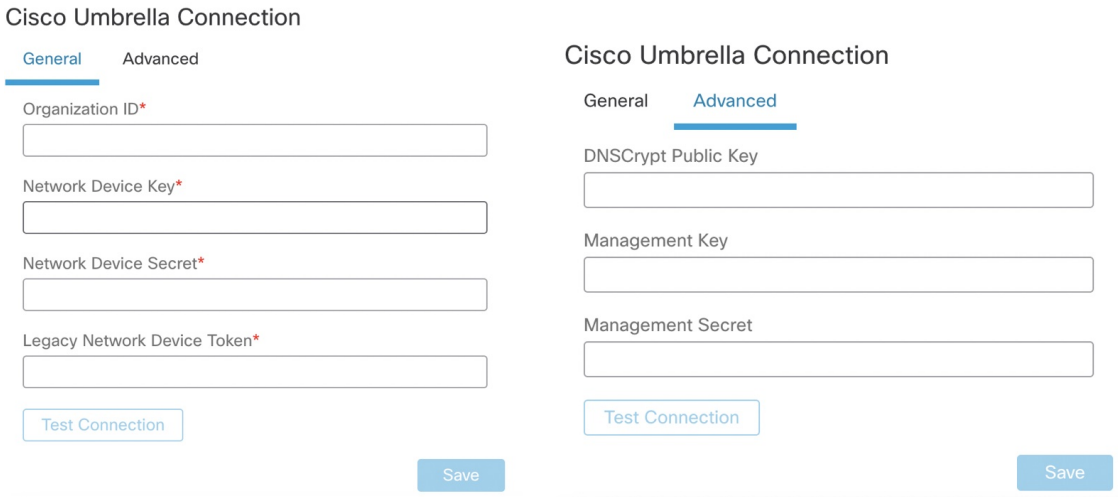
General prerequisites

- You must establish an account with Cisco Umbrella at https://umbrella.cisco.com, log into Umbrella at http://login.umbrella.com, and obtain the required information to establish connection to Cisco Umbrella.
- You must register Cisco Umbrella with the Firewall Management Center and configure the management key and the management secret in the Cisco Umbrella Connection Settings. The management center requires the management key and management secret to fetch the datacenter details from the Cisco Umbrella cloud. You must also configure the Organization ID, Network Device Key, Network Device Secret, and the Legacy Network Device Token in the Cisco Umbrella Connection Settings.

  For more information, refer to:

  - Configure Cisco Umbrella Connection Settings
  - Map Management Center Umbrella parameters and Cisco Umbrella API keys, on page 1390

- Ensure that Umbrella data center is reachable from the Firewall Threat Defense.
- You can deploy a tunnel only between Cisco Umbrella and a Firewall Threat Defense version 7.1.0 and later.



Map Management Center Umbrella parameters and Cisco Umbrella API keys

To register Cisco Umbrella with the Firewall Management Center and configure the Umbrella parameters in the Firewall Management Center, you must complete these steps:

1. Log in to Cisco Umbrella.

2. Choose **Admin** > **API Keys** > **Legacy Keys**.
3. Generate and copy the required API keys.
4. Use the API keys to configure the Cisco Umbrella connection parameters in the Firewall Management Center.

This figures show the parameters that you must configure in the Cisco Umbrella Connection in the Firewall Management Center. DNScrypt Public Key is an optional parameter.

This figure shows the Cisco Umbrella API keys that you must use to register the Cisco Umbrella with the Firewall Management Center.

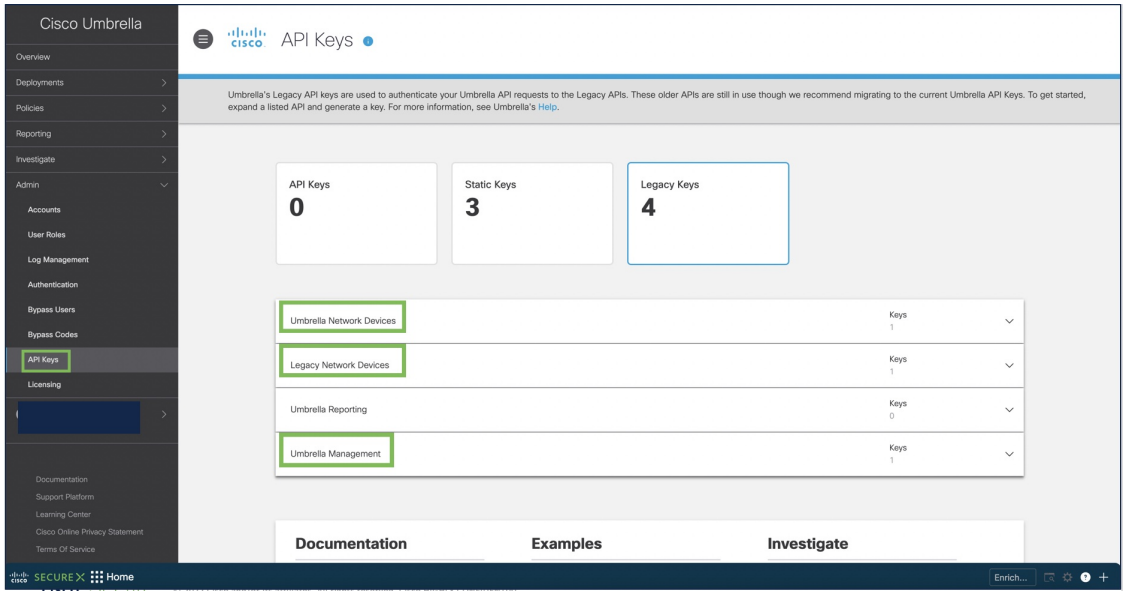


Table 78: Map Firewall Management Center Umbrella Parameters and Cisco Umbrella API Keys

Management Center Parameter	Cisco Umbrella API Keys
Network Device Key Network Device Secret	Umbrella Network Devices
Legacy Network Device Token	Legacy Network Devices
Management Key Management Secret	Umbrella Management

Configure a SASE tunnel for Umbrella

Configure a SASE tunnel to establish secure connectivity between threat defense devices and Cisco Umbrella data centers for cloud-delivered security services.

SASE (Secure Access Service Edge) tunnels provide secure connections to Umbrella data centers, enabling cloud-based security functions. These tunnels use IKEv2 with pre-shared keys for authentication and static VTI interfaces for routing traffic.

Before you begin

Ensure that you review the prerequisites and guidelines in Prerequisites for configuring Umbrella SASE tunnels, on page 1390 and Guidelines for configuring SASE tunnels on Umbrella, on page 1388.

Follow these steps to configure a SASE tunnel for Umbrella:

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site**, click **+SASE Topology** and enter a unique **Topology Name**.

Step 2 **Pre-shared Key**: This key is auto-generated according to the Umbrella PSK requirements. For a single topology, the pre-shared key is common for all threat defense spokes and Umbrella.

The device and Umbrella share this secret key, and IKEv2 uses it for authentication. If you want to configure this key, it must be between 16 and 64 characters in length, include at least one uppercase letter, one lowercase letter, one numeral, and have no special characters. Each topology must have a unique pre-shared key. If a topology has multiple tunnels, all the tunnels have the same pre-shared key.

Step 3 Choose a data center from the **Umbrella Data center** drop-down list. (Configure routing on the Firewall Threat Defense to ensure reachability of the umbrella DC from the Firewall Threat Defense.)

Step 4 Click **Add** to add a Firewall Threat Defense node.

a) Choose a Firewall Threat Defense from the **Device** drop-down list.

Only devices managed by the Firewall Management Center appear in the list. For high availability pairs, the HA pair names appear in the endpoint list.

b) Choose a static VTI interface from the **VPN Interface** drop-down list.

To create a new static VTI interface, click Add +. The **Add Virtual Tunnel Interface** dialog box appears with the following pre-populated default configurations.

- Tunnel Type is static.

- Name is <*tunnel_source interface logical name*>+ static_vti +<*tunnel ID*>. For example, outside_static_vti_2.
- Tunnel ID is auto-populated with a unique ID.
- Tunnel Source Interface is auto-populated with an interface with an 'outside' prefix.
- IPsec tunnel mode is IPv4.
- IP address is from the 169.254.x.x/30 private IP address range.

c) Enter a prefix for the local tunnel ID in the **Local Tunnel ID** field.

The prefix can have a minimum of eight characters and a maximum of 100 characters. Umbrella generates the complete tunnel ID (<*prefix*>@<*umbrella generated ID*>-umbrella.com) after the management center deploys the tunnel on Umbrella. The management center then retrieves and updates the complete tunnel ID and deploys it on the threat defense device. Each tunnel has a unique local tunnel ID.

d) Click **Save** to add the endpoint device to the topology.

You can add multiple endpoints in a SASE topology.

Step 5 Click **Next** to view the summary of the Umbrella SASE tunnel configuration.

- **Endpoints** pane: Displays the summary of the configured endpoints.
- **Encryption Settings** pane: Displays the default IKEv2 policies and IKEv2 IPsec transform sets for the topology.

Step 6 Check the **Deploy configuration on threat defense nodes** check box to trigger deployment of the network tunnels to the threat defense. This deployment occurs after the tunnels are deployed on Umbrella. Local tunnel ID is required for the threat defense deployment.

Step 7 Click **Save**.

This action:

a. Saves the topology in the management center.

b. Triggers deployment of the network tunnels to the Umbrella.

c. Triggers deployment of the network tunnels to the threat defense devices, if the option is enabled. This action commits and deploys all the updated configurations and policies, including non-VPN policies, since the last deployment on the device.

d. Opens the **Cisco Umbrella Configuration** window and displays the status of the tunnel deployment on Umbrella. For more details, see View SASE tunnel status, on page 1394.

What to do next

For the interesting traffic intended to flow through the SASE tunnel, configure a PBR policy with a specific match criteria to send the traffic through the VTI interface.

Ensure that you configure a PBR policy for each endpoint of the SASE topology.

View SASE tunnel status

After configuring Umbrella SASE topology, you need to monitor the tunnel deployment status and verify that the configuration has been successfully pushed to Umbrella.

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site**.

Step 2 Click **+SASE Topology**.

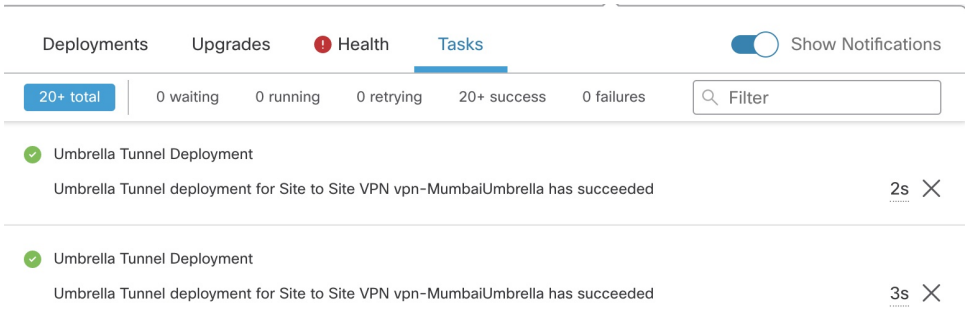
Step 3 Enter a unique **Topology Name**, **Pre-shared Key**, choose a data center, add a device, and click **Next**.

Step 4 View the summary of the Umbrella SASE Tunnel configuration and click **Save**.

The **Cisco Umbrella Configuration** window appears.

You can view the topology details such as name, data center, data center IP address, start, and end time of the tunnel deployment.

You can view the deployment status of the tunnels on Umbrella. The different tunnel deployment statuses are:



- Pending: The management center hasn't pushed the configuration to Umbrella.
- Success: The management center successfully configured a tunnel on Umbrella.
- In Progress: The management center is deploying the tunnel on Umbrella.
- Failure: The management center couldn't configure a tunnel on Umbrella.

If the status appears as pending, or failure, use the transcript to troubleshoot the tunnel creation. Click the **Transcript** button to view the transcript details such as the APIs, request payload, and the response received from Umbrella.

Step 5 Click **Umbrella Dashboard** to view the network tunnels in Cisco Umbrella.

Step 6 View the Umbrella tunnel deployment status in:

- The **Notifications** page under the **Deployments** and **Tasks** tabs.

- The **Site to Site** VPN dashboard (**Overview** > **Dashboards** > **Site to Site VPN**).

The dashboard provides a summary of the site to site VPN topologies including the Umbrella SASE topologies. You can view the tunnels between the peer devices and the status of each tunnel. You can also troubleshoot any problems with the tunnel deployment using CLI commands and packet tracer.

Monitor site-to-site topologies

This section provides information about the different ways to monitor your site-to-site topologies.

Monitor site-to-site VPNs using Site-to-Site VPN summary page

You can view a summary of your site-to-site VPN topologies in the **Site-to-Site VPN Summary** page. For each topology, you can view details such as VPN type, network topology, VPN interfaces, VPN devices, and tunnel statuses.

You can edit or delete the topology using the edit and delete buttons. For SASE topology VPNs, you have options to deploy, edit and delete any topology.

Monitor site-to-site VPNs using Site-to-Site VPN dashboard

Choose **Overview** > **Dashboards** > **Site to Site VPN** to open the site to site dashboard.

The **Site-to-Site VPN** dashboard provides a snapshot and status of the site-to-site VPN tunnels. You can view the list of tunnels between peer devices and the status of each tunnel: Active, Inactive, or No Active Data. You can filter the data in the table according to the topology, device, and status. The dashboard shows live data and you can also configure the refresh interval.

Benefits of the dashboard

The dashboard provides these benefits:

- Identify problematic VPN tunnels and troubleshoot them.
- Verify connectivity between the site-to-site VPN peers devices.
- Monitor the health of the VPN tunnels to provide uninterrupted VPN connectivity between sites.
- Use Packet tracer to troubleshoot VPN tunnels.

Widgets of the dashboard

- **Tunnel Status**—A table listing the tunnel status of the site-to-site VPNs , including the SASE tunnels for Umbrella, configured using the Firewall Management Center. For more information, refer to Tunnel status widget, on page 1396.
- **Tunnel Summary**—Aggregated status of the tunnels in a donut graph.
- **Topology**—Status of tunnels summarized by topology.

Status of VPN tunnels

The different VPN tunnel statuses that you can view in the Site-to-Site dashboard are:

- **Inactive**—A policy-based (crypto map-based) VPN tunnel is inactive if all the IPSec tunnels are down. A VTI or and SASE topology VPN tunnel is down if the tunnel encounters any configuration or connectivity issues.
- **Active**—In the Firewall Management Center, policy-based site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. A policy-based VPN tunnel is in the Active state if the Firewall Management Center identifies interesting traffic through the tunnel after the deployment. An IKE tunnel is up only if a minimum of one IPsec tunnel is up.

  Route-based VPN (VTI) and SASE topology VPN tunnels do not require interesting traffic to be in the Active state. They are in the Active state if they are configured and deployed without errors.
- **No Active Data**—Policy-based and SASE topology VPN tunnels remain in the No Active Data state until there is a traffic flow event through the tunnel for the first time. The No Active Data state also lists the policy-based and route-based VPNs that have been deployed with errors.

Important notes about tunnel statuses in Firewall Management Center

- The VPN statuses in the Firewall Management Center are event-based. The Firewall Management Center does not initiate status updates. Hence, there might be mismatches between the tunnel statuses in the dashboard and the Firewall Threat Defense . You can view the correct status in the **CLI Details** tab of the **Tunnel Status** widget.
- When a Firewall Threat Defense switches over to a secondary Firewall Threat Defense , there is a mismatch between the status of the VPN tunnels in the Firewall Management Center and the Firewall Threat Defense . When the device switches back to the primary device, the correct tunnel status appears.
- The Firewall Management Center does not update the tunnel status of Firewall Threat Defense devices earlier than 7.3 after the devices reboot. We recommend that you bring the tunnel down using the command **vpn-sessiondb logoff index** and bring it up using the packet tracer.

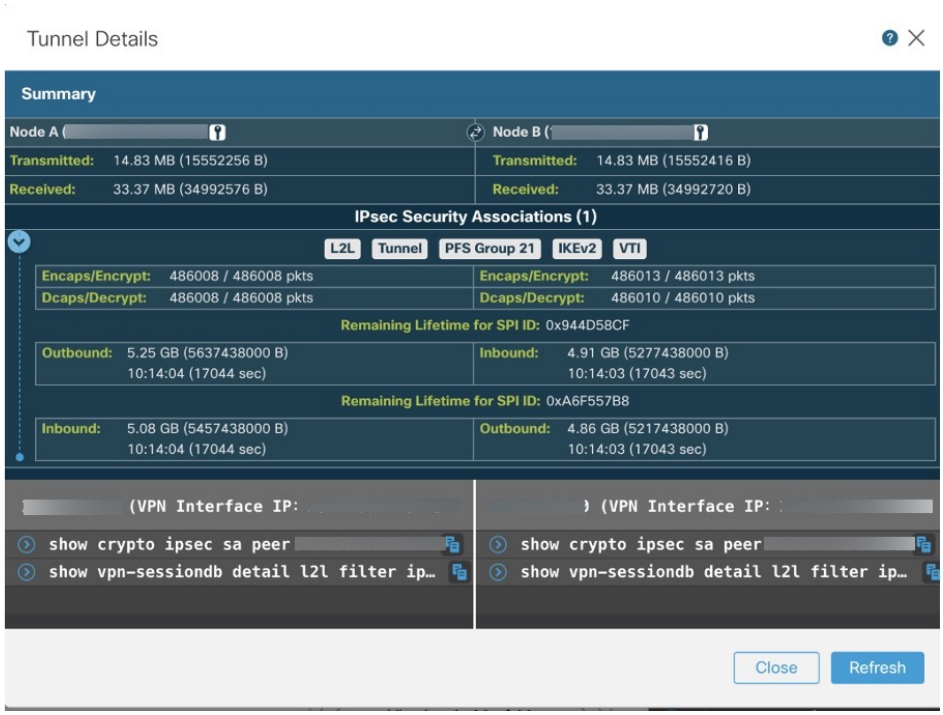
Limitations of the dashboard

- The table shows the list of site-to-site , including SASE topology, VPNs that are deployed. It does not show the tunnels that are created and not deployed.
- The table does not show the information about the backup tunnels of policy-based VPNs and backup VTIs.
- For cluster deployments, the table does not show director change in real-time data. It shows only the director information that existed when the VPN was deployed. The director change reflects in the table only after the tunnel AM redeployed after the change.

Tunnel status widget

This widget lists the site-to-site VPNs, including SASE topology VPN, configured using the Firewall Management Center and their tunnel statuses.

Features of the widget



Hover over a topology and click **View** ( ) to view these details about the topology:

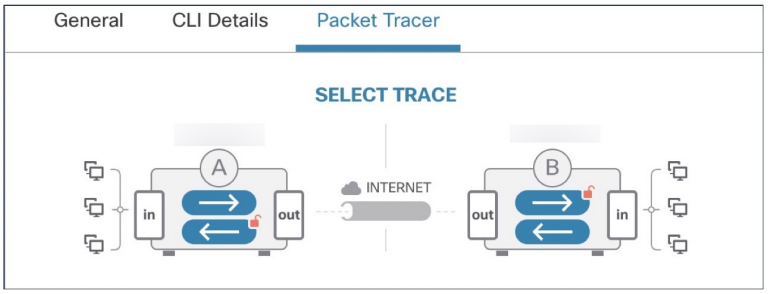
- **General**—Displays more information about the nodes such as IP address and interface name.
- **CLI Details**—Displays the CLI outputs for the following commands:
  - **show crypto ipsec sa peer**: Displays the IPsec SAs built between Node A and B.
  - **show vpn-sessiondb l2l filter ipaddress** : Displays information about VPN sessions.

  For an extranet device, no command output appears.

  Important details about the IKE and IPsec sessions, derived from the above command outputs, appear in a summarized, and user-friendly format. You can view the details of both nodes at a time. The icon next to the node name specifies the authentication type: preshared key or client certificate. The details include IKE statistics per tunnel and IPsec SA statistics as shown below:

Figure 396: Tunnel Status > View > CLI Details

- **Packet Tracer**—Use packet tracer to troubleshoot the VPN tunnels.



Packet Tracer

Packet tracer allows you to troubleshoot VPN tunnels between two threat defense devices. You can check if the VPN connection between device A and device B is up. This tool performs these actions:

- Injects a packet into the device and tracks the packet flow from the ingress to the egress ports.
- Simulates traffic after you configure the ingress interfaces of the devices along with the protected networks.

- Evaluates the packet against modules such as flow and route lookups, ACLs, protocol inspection, NAT, and QoS.

Figure 397: Packet Tracer

For each device, the tool runs an encrypted trace and a decrypted trace (packet is treated as decrypted VPN traffic). You can run four different traces between the ingress and egress ports of the devices. Click the individual encrypt and decrypt options to enable or disable the trace.

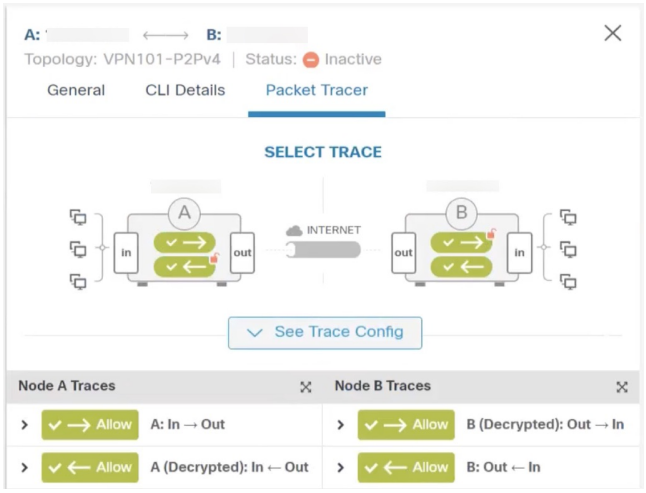
When you run the trace, the tool executes the trace sequentially in the following order:

1. Encrypted trace of A.
2. Decrypted trace of B.
3. Encrypted trace of B.
4. Decrypted trace of A.

After the trace completes, you can view the output of the trace with the results of each module.

Note You cannot run a decrypt trace for route-based (VTI-based) VPNs.

To run the Packet Tracer:



1. Click **See Detailed Config** to view the VPN interface name, VPN interface IP address, VTI interface name, and the VTI Interface IP address.
2. (Optional) Choose a protocol from the **Protocol** drop-down list. You can choose ICMP/8/0, TCP, or UDP.

   ICMP/8/0 is the default option. If you choose ICMP/8/0, 8 indicates the ICMP type as Echo Request and 0 indicates the ICMP code. If you choose TCP or UDP, choose the destination port from the **Destination Port** drop-down list. The range is from 0 to 65535.
3. Choose the ingress interface for both the devices on which to trace the packet from the **Ingress Interface** drop-down lists.
4. Enter an IP address from the same subnet as the ingress interface in the **Protected Network IP Address** fields.
5. Click **Trace Now**.

   After you initiate the trace, you can view if the trace is successful or not for each module. If the tunnel is down, the path appears in red. If the tunnel is up, the path appears in green. If a tunnel is down, click

Re-trace to run the tool again. For a crypto-map based VPN, when the tunnel is inactive with no interesting traffic, the initial trace can be red. Click **Re-trace** to run the trace again.

Figure 398: Packet Tracer after a Successful Trace

Extranet Nodes: You can initiate a packet trace for VPN tunnels with one node as an extranet. For an extranet node, you cannot choose the ingress interface. The remaining steps for the packet trace are the same. You can't run trace on the extranet side.

For example, if Node A is a managed threat defense and Node B is an extranet:

- Configure the ingress interface for node A.
- Configure the protected network for Node A and B.
- Click **Trace Now**. The traces appear for Node A and not for Node B.

Site-to-site VPN connection event monitoring

The site-to-site VPN connection event allows you to know if the VPN encrypts or do not encrypts the connection and helps you to troubleshoot connectivity issues, especially in multi-hop VPN deployments. The event dashboard of the Firewall Management Center displays the IP address of the VPN peer (peer's IKE address) which encrypts or decrypts the traffic and displays the VPN action.

The VPN actions displayed are:

- If the connection is decrypted by the VPN, the column **Decrypt Peer** displays the IP address of the peer's address from where the flow was received and displays **Decrypt** as the VPN action.
- If the connection is encrypted by the VPN, the column **Encrypt Peer** displays the IP address of the VPN peer to which the flow is sent and displays **Encrypt** as the VPN action.
- If the VPN server cascades the connection, it gets decrypted on one tunnel and gets re-encrypted on another tunnel. In this case, both **Encrypt Peer** and **Decrypt Peer** IP addresses get appears in the event. The column **VPN Action** displays **VPN Routing** as the action to indicate that the connection transit through the VPN server.

If you enable the **Bypass Access Control Policy for decrypted traffic (sysopt permit-VPN)** option, the system bypasses the access control policy and do not log events for decrypted traffic. This option is disabled by default and all decrypted traffic in the VPN tunnel undergoes ACL inspection.

View site-to-site VPN connection events

Access the connection event viewer of the Firewall Management Center to know if the VPN encrypts or do not encrypts the connection traffic and to retrieve the VPN peer details.

Before you begin

Ensure that you enable logging of connection events at the beginning of connection and at the end of connection in the access control rule.

Procedure

Step 1 Choose **Analysis** > **Connections** > **Events**.

Step 2 Click **Table View of Connection Events** tab.

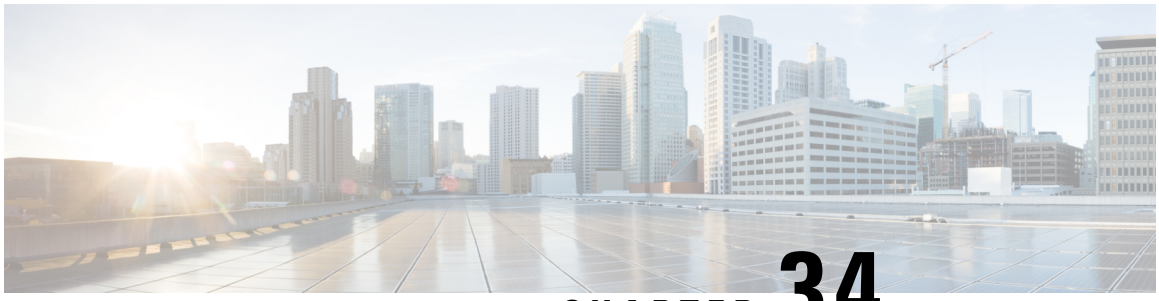
Step 3 In the table view of events, multiple fields are hidden by default. To change the fields that appear, click the **x** icon in any column name to display a field chooser.

Step 4 Choose these columns:

- Decrypt Peer
- Encrypt Peer
- VPN Action

Step 5 Click **Apply**.

See *Connection and Security-Related Connection Events* in the Secure Firewall Management Center Administration Guide for more information on the connection events.



History for site-to-site VPN

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
View Virtual Tunnel Information	7.4.1	Any	You can view details of dynamic and static VTIs of route-based VPNs on the device. For every VPN topology, you can also view details of all the virtual access interfaces of the dynamic VTIs. New/Modified screens: **Device** > **Device Management** > **Edit a device** > **Interfaces** and click the **Virtual Tunnels** tab.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
IPsec flow offload	7.4	Any	IPsec flow offload is automatically enabled on the VTI loopback interface on Secure Firewall 3100 and Secure Firewall 4200 devices.
Umbrella SASE Topology	7.3	Any	You can configure an Umbrella SASE topology and deploy IPsec IKEv2 tunnels between a threat defense device and Umbrella. This tunnel forwards all internet-bound traffic to the Umbrella Secure Internet Gateway (SIG) for inspection and filtering.
Support for Dynamic Virtual Tunnel Interface	7.3	Any	You can create a dynamic VTI and use it to configure a route-based site-to-site VPN in a hub and spoke topology.
EIGRP IPv4 support for VTI	7.3	Any	Static and dynamic VTI interfaces support EIGRP IPv4 routing protocol.
OSPFv2/v3 IPv4/v6 support for VTI	7.3	Any	Static and dynamic VTI interfaces support OSPFv2/v3 IPv4/v6 routing protocol.
Packet Tracer in Site to Site VPN Monitoring Dashboard	7.3	Any	Use the packet tracer tool in the site-to-site VPN monitoring dashboard to troubleshoot the threat defense VPN tunnels. New/Modified screens: **Overview** > **Dashboards** > **Site to Site VPN**
Remote Access VPN Dashboard	7.3	Any	Use the Remote Access VPN dashboard to monitor real-time data from active remote access VPN sessions on the devices. New/Modified screens: **Overview** > **Dashboards> Remote Access VPN**
IPsec flow offload	7.2	Any	On the Secure Firewall 3100, IPsec flows are offloaded by default. After the initial setup of an IPsec site-to-site VPN or remote access VPN security association (SA), IPsec connections are offloaded to the field-programmable gate array (FPGA) in the device, which should improve device performance. You can change the configuration using FlexConfig and the **flow-offload-ipsec** command.
Site-to-Site VPN Filter	7.1	Any	You can control site-to-site VPN traffic by using an access control policy.
Local tunnel ID support	7.1	Any	For each endpoint on a site-to-site VPN, you can configure a unique tunnel ID to be shared with the peers.
Multiple IKE Policy Support	7.1	Any	You can add multiple IKEv1 and IKEv2 policy objects for each endpoint.
Site-to-Site VPN Monitoring Dashboard	7.1	Any	Use the Site-to-Site VPN Monitoring dashboard to view and monitor the status of site-to-site VPN tunnels.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Backup virtual tunnel interfaces (VTI) for route-based site-to-site VPN.	7.0	Any	When you configure a site-to-site VPN that uses virtual tunnel interfaces, you can select a backup VTI for the tunnel. Specifying a backup VTI provides resiliency, so that if the primary connection goes down, the backup connection might still be functional. For example, you could point the primary VTI to the endpoint of one service provider, and the backup VTI to the endpoint of a different service provider. You can add a backup VTI in the site-to-site VPN wizard by selecting route-based as the VPN type for a point-to-point connection.
Enhance the number of VTI from 100 per interface to 1024 per device	7.0	Any	Support for maximum number of VTIs is enhanced from 100 per physical interface to 1024 VTIs per device.
IPv6 Support	7.0	Any	You can configure IPv6 addressed VTIs. While only static IPv6 address is supported as the tunnel source and destination, IPv6 BGP isn't supported over VTI.
Removal and deprecation of weak ciphers	6.7	Any	Support has been removed for less secure ciphers. We recommend that you update your VPN configuration before you upgrade to Firewall Threat Defense 6.70 to supported DH and encryption algorithms to ensure the VPN works correctly. Update your IKE proposals and IPSec policies to match the ones supported in Firewall Threat Defense 6.70 and then deploy the configuration changes. These less secure ciphers have been removed or deprecated in Firewall Threat Defense 6.70 onwards: • **Diffie-Hellman Group 5** is deprecated for IKEv1 and removed for IKEv2 • Diffie-Hellman groups 2 and 24 have been removed. • **Encryption algorithms**: 3DES, AES-GMAC, AES-GMAC-192, AES-GMAC-256 have been removed. **Note** **DES** is supported in evaluation mode or for users who do not satisfy export controls for strong encryption. **NULL** is removed in IKEv2 policy, but supported in both IKEv1 and IKEv2 IPsec transform-sets.
Dynamic RRI support	6.7	Any	Dynamic Reverse Route Injection is supported with IKEv2 based static crypto maps.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Backup peer for site-to-site VPN	6.6	Any	You can use the Firewall Management Center to add a backup peer to a site-to-site VPN connection. For example, if you have two ISPs, you can configure the VPN connection to fail over to the backup ISP if the connection to the first ISP becomes unavailable. New/modified pages: **Devices** > **VPN** > **Site to Site**. When adding or editing a point to point or hub and spoke FTD VPN topology to add an endpoint, the **IP Address** field supports comma-separated backup peers.

CHAPTER 34

SD-WAN

This chapter describes the SD-WAN capabilities supported in Management Center.

- SD-WAN capabilities, on page 1405
- SD-WAN features, on page 1406
- Use cases for SD-WAN capabilities, on page 1407
- Monitor SD-WAN topologies, on page 1408

SD-WAN capabilities

SD-WAN capabilities are software-defined networking features that

- replace traditional WAN routers and are agnostic to WAN transport technologies
- provide dynamic, policy-based, application path selection across multiple WAN connections, and
- support service chaining for additional services such as WAN optimization and firewalls.

SD-WAN capabilities in Secure Firewall

As organizations expand their operations across multiple branch locations, ensuring secure and streamlined connectivity becomes paramount. Deploying a secure branch network infrastructure involves complex configurations, which can be time-consuming and prone to configuration errors if not handled properly. However, organizations can overcome these challenges by leveraging Management Center and Threat Defense devices for a simplified and secure branch deployment.

By integrating Secure Firewall as a foundational component of the branch network architecture, organizations can establish a strong security baseline while simplifying the deployment process. This approach enables organizations to enforce unified security policies, optimize traffic routing, and ensure resilient connectivity.

Some of the SD-WAN capabilities supported on the Cisco Secure Firewall include:

- **Simplified management:**
  - SASE: Umbrella auto tunnel deployment
  - Dynamic VTI (DVTI) hub spoke topology simplification
- **Application awareness:**
  - Direct Internet Access (DIA) for public cloud and guest user

- Policy based routing (PBR) using applications as a match criteria
- Local tunnel ID support for Umbrella

- **Increased usable bandwidth:**
  - ECMP support for load balancing across multiple ISPs and VTIs
  - Application-based load balancing using PBR

- **High availability with near zero network downtime:**
  - Dual ISP configuration
  - Optimal path selection based on application-based interface monitoring.

- **Secure elastic connectivity:**
  - Route-based (VTI) VPN tunnels between headquarters (hub) and branches (spokes)
  - IPv4 and IPv6 BGP, IPv4 and IPv6 OSPF, and IPv4 EIGRP over VTI
  - DVTI hubs that support spokes with static or dynamic IP

SD-WAN features

This table lists the SD-WAN features of Management Center, including their introduction releases and links to detailed information.

Feature	Introduced in	More Information
Application monitoring using SD-WAN Summary dashboard	Release 7.4.1	SD-WAN summary dashboard, on page 1408
SD-WAN Summary Dashboard	Release 7.4	SD-WAN summary dashboard, on page 1408
Policy-based routing with user identity and SGTs	Release 7.4	Policy-Based Routing, on page 1159
Policy-based routing using HTTP path monitoring	Release 7.4	Policy-Based Routing, on page 1159
Loopback interface support for VTIs	Release 7.3	Loopback interfaces, on page 661
Support for dynamic VTI (DVTI) with site-to-site VPN	Release 7.3	Dynamic VTI, on page 1366
Umbrella auto tunnel	Release 7.3	Deploy a SASE Tunnel on Umbrella

Feature	Introduced in	More Information
Support for IPv4 and IPv6 BGP, IPv4 and IPv6 OSPF, and IPv4 EIGRP for VTIs	Release 7.3	BGP, on page 1107 OSPF, on page 1063 EIGRP, on page 1095
Route-based site-to-site VPN with hub and spoke topology	Release 7.2	Create a route-based site-to-site VPN, on page 1373
Policy-based routing with path monitoring	Release 7.2	Policy-Based Routing, on page 1159
Site to Site VPN Monitoring Dashboard	Release 7.1	Monitor Site-to-Site VPNs Using Site-to-Site VPN Dashboard
Direct Internet Access/Policy Based Routing	Release 7.1	Policy-Based Routing, on page 1159
Equal-Cost-Multi-Path (ECMP) zone with WAN interfaces	Release 7.1	ECMP, on page 1047
ECMP zone with VTI interfaces	Release 7.1	ECMP, on page 1047
Backup VTI for route-based site-to-site VPN	Release 7.0	Route traffic through a backup VTI tunnel, on page 1383
Support for static VTI (SVTI) with site-to-site VPN	Release 6.7	Static VTI, on page 1365

Use cases for SD-WAN capabilities

Use the Cisco Secure Firewall Threat Defense SD-WAN Design and Deployment Guide to design and deploy SD-WAN architectures using Firewall Threat Defense and Firewall Management Center. This guide explains design principles, configuration workflows, and best practices.

Use these guides for detailed instructions for the primary use cases leveraging the SD-WAN capabilities supported by Cisco Secure Firewall.

- Simplify Branch to Hub Communication using Dynamic Virtual Tunnel Interface (DVTI)
- Route Application Traffic from the Branch to the Internet Using Direct Internet Access (DIA)
- Secure Internet Traffic Using Umbrella Auto Tunnel
- Empower Remote Workers with Secure Connectivity: DIA, Umbrella Auto Tunnel, and DVTI in Action
- Set Up SD-WAN Branch Office with Dual ISPs Using Registration Key and Device Templates
- Set Up SD-WAN Branch Office with Dual ISPs Using Serial Numbers and Device Template

Monitor SD-WAN topologies

This section provides information about the different ways to monitor your SD-WAN topologies.

SD-WAN summary dashboard

The SD-WAN Summary dashboard (**Overview** > **Dashboards** > **SD-WAN Summary**) provides a snapshot of your WAN devices and their interfaces. This dashboard helps you to:

- Identify issues with the underlay and overlay (VPN) topologies.
- Troubleshoot VPN issues using the existing **Health Monitoring**, **Device Management**, and **Site-to-Site Monitoring** pages.
- Monitor application performance metrics of WAN interfaces. The threat defense steers application traffic based on these metrics.

For clusters, this dashboard displays application performance metrics of only the control node and not the data nodes.

WAN device criteria

A WAN device must meet one of these criteria:

- The device must be a VPN peer.
- The device must have WAN interface.

WAN interface criteria

A WAN interface must meet one of these criteria:

- The interface has IP address-based path monitoring enabled on it.
- The interface has a Policy Based Routing (PBR) policy with at least one application configured to monitor it.

For more information about PBR policy and path monitoring, see Policy-Based Routing, on page 1159.

Uplink decisions

Click **Uplink Decisions** to view the **VPN Troubleshooting** page. You can view syslogs with ID: 880001. These syslogs show the threat defense interfaces through which it steers traffic based on the configured PBR policy.

To view the above syslogs and to view the data on this dashboard, ensure that you review Prerequisites for using SD-WAN summary dashboard, on page 1408.

Prerequisites for using SD-WAN summary dashboard

Ensure that you review these prerequisites before using the SD-WAN summary dashboard.

General prerequisites

- You must be an Admin, Security Analyst, or Maintenance user to view this dashboard.
- Threat Defense devices must be Version 7.2 or later.
- Enable IP-based path monitoring and HTTP-based application monitoring on the WAN interfaces.

  To do this:

  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click the edit icon adjacent to the interface that you want to edit.
  4. Click the **Path Monitoring** tab.
  5. Check the **Enable IP based Monitoring** check box.
  6. Check the **Enable HTTP based Application Monitoring** check box.
  7. Click **OK**.

- Configure a PBR policy with at least one application configured to monitor it:

  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click **Routing**.
  4. In the left pane, click **Policy Based Routing**.
  5. Click **Add**.
  6. From the **Ingress Interface** drop-down list, choose an interface.
  7. Click **Add** to configure a forwarding action.
  8. Configure the parameters.
  9. Click **Save**.

- To view syslogs when you click **Uplink Decisions**, you must:
  - Choose **Devices** > **Platform Settings** and create or edit a threat defense policy.
  - In the left pane, click **Syslog**.
  - Click the **Logging Setup** tab.
  - Check the **Enable Logging** check box to turn on the data plane system logging for the threat defense device.
  - Click the **All Logs** radio button to enable logging of all the troubleshooting syslog messages.

    or

    Click the **VPN Logs** radio button to enable logging of only the VPN troubleshooting messages.
  - Click **Save**.

Prerequisites to view application performance metrics in the dashboard

- Threat Defense devices must be Version 7.4.1.
- Enable data collection from the SD-WAN module in the health policy.
  1. Choose **System** (⚙) > **Health** > **Policy**.
  2. Click the **Edit health policy** icon.
  3. In the **Health Modules** tab, under **SD-WAN**, click the **SD-WAN Monitoring** toggle button.
- Configure applications for the PBR policies.
  1. Choose **Objects** > **Object Management** > **Access List** > **Extended**.
  2. Click the edit icon adjacent to the access list and add the applications for the PBR policy.
- Configure the forwarding action for the policy with one of the four application metrics.
  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click **Routing**.
  4. In the left pane, click **Policy Based Routing**.
  5. Click the edit icon adjacent to the policy that you want to edit.
  6. In the **Edit Policy Based Route** dialog box, click the edit icon adjacent to the corresponding ACL.
  7. In the **Edit Forwarding Actions** dialog box, from the **Interface Ordering** drop-down list, choose one of these options:
     - **Minimal Jitter**
     - **Maximum Mean Opinion Score**
     - **Minimal Round-Trip Time**
     - **Minimal Packet Loss**

     If you choose **Interface Priority** or **Order**, application monitoring is not enabled on the interface.
- Configure ECMP on the WAN interfaces:
  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click **Routing**.
  4. In the left pane, click **ECMP**.
  5. Click **Add** and specify a name for the ECMP zone.
  6. Click **Add** to move interfaces from **Available Interfaces** to **Selected Interfaces**.
  7. Click **OK**.

- Ensure that traffic passes through the interface.
- Enable DNS inspection on each WAN device so that the Threat Defense device can do DNS snooping, and configure the trusted DNS servers:
  1. Choose **Devices** > **Platform Settings**.
  2. Click the edit icon adjacent to the threat defense policy that you want to edit.
  3. In the left pane, click **DNS**.
  4. Click the **DNS Settings** tab.
  5. Check the **Enable DNS name resolution by device** check box.
  6. Click the **Trusted DNS Servers** tab.
  7. Do one of these options:
     - Click the **Trust Any DNS server** toggle button.
     - Under **Specify DNS Servers**, click **Edit** to add trusted DNS servers.

Monitor WAN devices and interfaces using the SD-WAN summary dashboard

The SD-WAN Summary dashboard has these widgets under the **Overview** tab:

- Top applications, on page 1411
- WAN connectivity, on page 1411
- VPN topology, on page 1412
- interface throughput, on page 1412
- Device inventory, on page 1412
- WAN device health, on page 1412

Top applications

This widget displays the top 10 applications ranked according to throughput.

You can choose a time range for the widget data from the **Show Last** drop-down list. The range is 15 minutes to two weeks.

WAN connectivity

This widget provides a summary of the WAN interfaces statuses. It shows the number of WAN interfaces that are in the **Online**, **Offline** or **No Data** states. Note that you cannot monitor subinterfaces using this widget.

Click **View All Interfaces** to view more details about the interfaces in the health monitor page.

If a WAN interface is in the **Offline** or **No Data** state, you can troubleshoot it from the health monitor page:

1. In the **Monitoring** pane, expand **Devices**.
2. Click the corresponding WAN device to view the device-specific health details.

3. Click the **Interface** tab to view the interface status and aggregate traffic statistics for a specific time.

   Alternatively, you can click **View System & Troubleshoot Details**. The health monitor page is displayed with all the necessary details.

VPN topology

This widget provides a summary of the site-to-site VPN tunnel statuses. It shows the number of **Active**, **Inactive**, and **No Active Data** VPN tunnels.

Click **View All Connections** to view the VPN tunnel details in the **Site-to-site VPN Monitoring** dashboard.

If the tunnels are in the **Inactive** or **No Active Data** state, you can troubleshoot using the **Site-to-site VPN Monitoring** dashboard. In the **Tunnel Status** widget, hover your cursor over a topology, click **View** ( ) and do one of these actions:

- Click the **CLI Details** tab to view the details of the VPN tunnels.
- Click the **Packet Tracer** tab to use the packet tracer tool for the topology.

interface throughput

This widget monitors the average throughput of the WAN interfaces during the chosen time period.

The interface throughput is classified into four bands. These details aid in cost planning and resourcing. You can choose a time range for the widget data from the **Show Last** drop-down list. The range is from 15 minutes to two weeks.

Click **View Health Monitoring** to view more details about the interface in the health monitor page.

Device inventory

This widget lists all the managed WAN devices and groups them according to the model.

Click **View Device Management** to view more details about the device in the **Device Management** page.

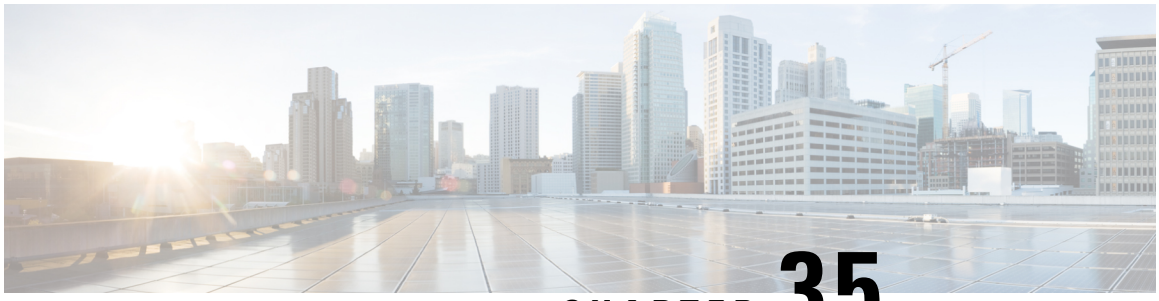
WAN device health

This widget displays the device count according to the health of the WAN devices. You can view the number of devices with errors, warnings, or those that are in **Disabled** state.

Click **View Health Monitoring** to view the alarms, and quickly identify, isolate, and resolve issues.

If the health of a device is affected, you can troubleshoot it from the health monitor page.

1. In the **Monitoring** pane, expand **Devices**.
2. Click the corresponding WAN device to view the device-specific health details.
3. Click **View System & Troubleshoot Details**. The health monitor page is displayed with all the necessary details.



A device can be in **Disabled** state for multiple reasons, including these:

- Management interface is disabled.
- Device is powered off.
- Device is being upgraded.

Monitor application performance metrics of WAN interfaces using SD-WAN summary dashboard

You can monitor application performance metrics of WAN interfaces using the **Application Monitoring** tab of the SD-WAN Summary dashboard. These metrics include Jitter, Round Trip Time (RTT), Mean Opinion Score (MOS), and Packet Loss.

By default, the metrics data is refreshed every 5 minutes. You can change the refresh time; the range is from 5 to 30 minutes. You can view the metrics in tabular and graphical formats. For each WAN interface, the latest metric value appears in the table. For graphical data, you can choose a time interval of up to 24 hours to view the metrics data for the corresponding WAN interfaces.

CHAPTER 35

Remote Access VPN

Remote Access virtual private network (VPN) allows individual users to connect to your network from a remote location using a computer or other supported devices connected to the Internet. This allows mobile workers to connect from their home networks or a public Wi-Fi network, for example.

The following topics explain how to configure remote access VPN for your network.

- Remote Access VPN Overview, on page 1415
- License Requirements for Remote Access VPN, on page 1421
- Requirements and Prerequisites for Remote Access VPN, on page 1421
- Guidelines and Limitations for Remote Access VPNs, on page 1422
- Configuring a New Remote Access VPN Connection, on page 1425
- Create a Copy of an Existing Remote Access VPN Policy, on page 1435
- Set Target Devices for a Remote Access VPN Policy, on page 1435
- Associate Local Realm with Remote Access VPN Policy, on page 1436
- Additional Remote Access VPN Configurations, on page 1436
- Customizing Remote Access VPN AAA Settings, on page 1490
- Advanced Secure Client Configurations, on page 1511
- Remote Access VPN Examples, on page 1519
- Monitor Remote Access VPNs, on page 1524
- History for Remote Access VPNs, on page 1526

Remote Access VPN Overview

Secure Firewall Threat Defense provides secure gateway capabilities that support remote access SSL and IPsec-IKEv2 VPNs. The full tunnel client, Secure Client, provides secure SSL and IPsec-IKEv2 connections to the security gateway for remote users. When the client negotiates an SSL VPN connection with Firewall Threat Defense, it connects using Transport Layer Security (TLS) or Datagram Transport Layer Security (DTLS)

Secure Client is the only client supported on endpoint devices for remote VPN connectivity to Firewall Threat Defense devices. The client gives remote users the benefits of an SSL or IPsec-IKEv2 VPN client without the need for network administrators to install and configure clients on remote computers. The Secure Client for Windows, Mac, and Linux is deployed from the secure gateway upon connectivity. The Secure Client apps for Apple iOS and Android devices are installed from the platform app store.

Use the Remote Access VPN policy wizard to set up SSL and IPsec-IKEv2 remote access VPNs with basic capabilities. Then, enhance the policy configuration as you want and deploy it to your Firewall Threat Defense secure gateway devices.

Remote Access VPN Features

The following table describes the features of Secure Firewall Threat Defense remote access VPN:

Table 79: Remote access VPN features

	Description
Secure Firewall Threat Defense remote access VPN features	• SSL and IPsec-IKEv2 remote access using the Secure Client. • Secure Firewall Management Center supports all combinations such as IPv6 over an IPv4 tunnel. • Configuration support on both Firewall Management Center and Firewall Device Manager. Device-specific overrides. • Support for both Secure Firewall Management Center and Firewall Threat Defense HA environments. • Support for multiple interfaces and multiple AAA servers. • Rapid Threat Containment support using RADIUS CoA or RADIUS dynamic authorization. • Support for DTLS v1.2 protocol with Cisco Secure Client version 4.7 or higher. • Secure Client modules support for additional security services for remote access VPN connections. • VPN load balancing.

	Description
AAA features	• Server authentication using self-signed or CA-signed identity certificates. • AAA username and password-based remote authentication using RADIUS server or LDAP or AD. • RADIUS group and user authorization attributes, and RADIUS accounting. • Double authentication support using an additional AAA server for secondary authentication. • NGFW Access Control integration using VPN Identity. • LDAP or AD authorization attributes using Secure Firewall Management Center web interface. • Support for single sign-on using SAML 2.0. • Support for multiple identity provider trustpoints with Microsoft Azure that can have multiple applications for the same Entity ID, but a unique identity certificate.
VPN tunneling features	• Address assignment. • Split tunneling. • Split DNS. • Client Firewall ACLs. • Session Timeouts for maximum connect and idle time.
Remote access VPN monitoring features	• New VPN Dashboard Widget showing VPN users by various characteristics such as duration and client application. • Remote access VPN events including authentication information such as username and OS platform. • Tunnel statistics available using the Firewall Threat Defense Unified CLI.

Secure Client Components

Secure Client Deployment

Your remote access VPN policy can include the Secure Client Image and the Secure Client Profile for distribution to connecting endpoints. Or, the client software can be distributed using other methods. See the *Deploy Cisco Secure Client* chapter in the Cisco Secure Client (including AnyConnect) Administrator Guide, Release 5.

Without a previously installed client, remote users enter the IP address in their browser of an interface configured to accept SSL or IPsec-IKEv2 VPN connections. Unless the security appliance is configured to redirect http:// requests to https://, remote users must enter the URL in the form https://*address*. After the user enters the URL, the browser connects to that interface and displays the login screen.

After a user logs in, if the secure gateway identifies the user as requiring the VPN client, it downloads the client that matches the operating system of the remote computer. After downloading, the client installs and configures itself, establishes a secure connection, and either remains or uninstalls itself (depending on the security appliance configuration) when the connection stops. In the case of a previously installed client, after login, the Firewall Threat Defense security gateway examines the client version and upgrades it as necessary.

Secure Client Operation

When the client negotiates a connection with the security appliance, the client connects using Transport Layer Security (TLS), and optionally, Datagram Transport Layer Security (DTLS). DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

When an IPsec-IKEv2 VPN client initiates a connection to the secure gateway, negotiation consists of authenticating the device through Internet Key Exchange (IKE), followed by user authentication using IKE Extended Authentication (Xauth). The group profile is pushed to the VPN client and an IPsec security association (SA) is created to complete the VPN.

Secure Client Profile and Editor

The Secure Client Profile is a group of configuration parameters, stored in an XML file that the VPN client uses to configure its operation and appearance. These parameters (XML tags) include the names and addresses of host computers and settings to enable more client features.

You can configure a profile using the Secure Client Profile Editor. This editor is a convenient GUI-based configuration tool that is available as part of the Secure Client software package. It is an independent program that you run outside of the Firewall Management Center.

Remote Access VPN Authentication

Remote Access VPN Server Authentication

Secure Firewall Threat Defense secure gateways always use certificates to identify and authenticate themselves to the VPN client endpoint.

While you use the Remote Access VPN Policy Wizard, you can enroll the selected certificate on the targeted Firewall Threat Defense device. In the wizard, under **Access & Certificate** phase, select “Enroll the selected certificate object on the target devices” option. The certificate enrollment gets automatically initiated on the specified devices. As you complete the remote access VPN policy configuration, you can view the status of

the enrolled certificate under the device certificate homepage. The status provides a clear standing as to whether the certificate enrollment was successful or not. Your remote access VPN policy configuration is now fully completed and ready for deployment.

Obtaining a certificate for the secure gateway, also known as PKI enrollment, is explained in Certificates, on page 2481. This chapter contains a full description of configuring, enrolling, and maintaining gateway certificates.

Remote Access VPN Client AAA

For both SSL and IPsec-IKEv2, remote user authentication is done using usernames and passwords only, certificates only, or both.

Note If you are using client certificates in your deployment, they must be added to your client's platform independent of the Secure Firewall Threat Defense or Secure Firewall Management Center. Facilities such as SCEP or CA Services are not provided to populate your clients with certificates.

AAA servers enable managed devices acting as secure gateways to determine who a user is (authentication), what the user is permitted to do (authorization), and what the user did (accounting). Some examples of the AAA servers are RADIUS, LDAP/AD, TACACS+, and Kerberos. For Remote Access VPN on Firewall Threat Defense devices, AD, LDAP, and RADIUS AAA servers are supported for authentication.

Refer to the section Understanding Policy Enforcement of Permissions and Attributes to understand more about remote access VPN authorization.

Before you add or edit the remote access VPN policy, you must configure the Realm and RADIUS server groups you want to specify. For more information, see Create an LDAP realm or an Active Directory realm and realm directory, on page 1860 and Add a RADIUS server group, on page 2346.

Without DNS configured, the device cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames, it can only resolve IP addresses.

The login information provided by a remote user is validated by an LDAP or AD realm or a RADIUS server group. These entities are integrated with the Secure Firewall Threat Defense secure gateway.

Note If users authenticate with remote access VPN using Active Directory as the authentication source, users must log in using their username; the format `domain\username` or `username@domain` fails. (Active Directory refers to this username as the *logon name* or sometimes as `sAMAccountName`.) For more information, see User Naming Attributes on MSDN.

If you use RADIUS to authenticate, users can log in with any of the preceding formats.

Once authenticated via a VPN connection, the remote user takes on a *VPN Identity*. This VPN Identity is used by *identity policies* on the Secure Firewall Threat Defense secure gateway to recognize and filter network traffic belonging to that remote user.

Identity policies are associated with access control policies, which determine who has access to network resources. It is in this way that the remote user blocked or allowed to access your network resources.

For more information, see the Identity policies, on page 1941 and Access Control Policies, on page 1569 sections.

Related Topics

Configure AAA Settings for Remote Access VPN, on page 1439

Understanding Policy Enforcement of Permissions and Attributes

The Secure Firewall Threat Defense device supports applying user authorization attributes (also called user entitlements or permissions) to VPN connections from an external authentication server and/or authorization AAA server (RADIUS) or from a group policy on the Firewall Threat Defense device. If the Firewall Threat Defense device receives attributes from the external AAA server that conflicts with those configured on the group policy, then attributes from the AAA server always take the precedence.

The Firewall Threat Defense device applies attributes in the following order:

1. **User attributes on the external AAA server**—The server returns these attributes after successful user authentication and/or authorization.
2. **Group policy configured on the Firepower Threat Defense device**—If a RADIUS server returns the value of the RADIUS Class attribute IETF-Class-25 (OU= group-policy) for the user, the Firewall Threat Defense device places the user in the group policy of the same name and enforces any attributes in the group policy that are not returned by the server.
3. **Group policy assigned by the Connection Profile (also known as Tunnel Group)**—The Connection Profile has the preliminary settings for the connection, and includes a default group policy applied to the user before authentication.

Note The Firewall Threat Defense device does not support inheriting system default attributes from the default group policy, *DfltGrpPolicy*. The attributes on the group policy assigned to the connection profile are used for the user session, if they are not overridden by user attributes or the group policy from the AAA server as indicated above.

Related Topics

Configure AAA Settings for Remote Access VPN, on page 1439

Understanding AAA Server Connectivity

LDAP, AD, and RADIUS AAA servers must be reachable from the Firewall Threat Defense device for your intended purposes: user-identity handling only, VPN authentication only, or both activities. AAA servers are used in remote access VPN for the following activities:

- **User-identity handling**— the servers must be reachable over the Management interface.

  On the Firewall Threat Defense, the Management interface has a separate routing process and configuration from data interfaces.

- **VPN authentication**—the servers must be reachable over a data interface or the Management interface.

  To use the Management interface, you must explicitly select Management as the source interface. Other management-only interfaces cannot be used.

To use the same AAA servers for both activities, we recommend specifying the Management interface as the source interface.

For more information about various interfaces, see Regular Firewall Interfaces, on page 649.

After deployment, use the following CLI commands to monitor and troubleshoot AAA server connectivity from the Firewall Threat Defense device:

- **show aaa-server** to display AAA server statistics.
- **show network** and **show network-static-routes** to view the Management interface default route and static routes.
- **show route** to view data traffic routing table entries.
- **ping system** and **traceroute system** to verify the path to the AAA server through the Management interface.
- **ping interface** *ifname* and **traceroute** *destination* to verify the path to the AAA server through the data interfaces.
- **test aaa-server authentication** and **test aaa-server authorization** to test authentication and authorization on the AAA server.
- **clear aaa-server statistics** *groupname* or **clear aaa-server statistics protocol** *protocol* to clear AAA server statistics by group or protocol.
- **aaa-server** *groupname* **active host** *hostname* to activate a failed AAA server, or **aaa-server** *groupname* **fail host** *hostname* to fail a AAA server.
- **debug ldap level**, **debug aaa authentication**, **debug aaa authorization**, and **debug aaa accounting**.

License Requirements for Remote Access VPN

Threat Defense License

Firewall Threat Defense remote access VPN requires Strong Encryption and one of the following licenses for Secure Client:

- Secure Client Advantage
- Secure Client Premier
- Secure Client VPN Only

Guidelines and Limitations for Remote Access VPNs

Remote Access VPN Policy Configuration

- You can add a new remote access VPN policy only by using the wizard. You must proceed through the entire wizard to create a new policy; the policy will not be saved if you cancel before completing the wizard.
- Two users must **not** edit a remote access VPN policy at the same time; however, the web interface does not prevent simultaneous editing. If this occurs, the last saved configuration persists.
- Moving a Secure Firewall Threat Defense device from one domain to another domain is not possible if remote access VPN policy is assigned to that device.
- Remote access VPN does not support SSL while using ECMP. We recommend that you use IPsec-IKEv2.
- Remote access VPN does not support clustering.
- Remote access VPN connectivity could fail if there is a misconfigured Firewall Threat Defense NAT rule.
- If you are using DHCP to provide IP addresses to the client, and the client cannot obtain an address, check the NAT rules. Any NAT rule that applies to the RA VPN network should include the route lookup option. Route lookup can help ensure the DHCP requests are sent to the DHCP server through an appropriate interface.
- Whenever IKE ports 500/4500 or SSL port 443 is in use or when there are some PAT translations that are active, the Secure Client IPSec-IKEv2 or SSL remote access VPN cannot be configured on the same port as it fails to start the service on those ports. These ports must not be used on the Firewall Threat Defense device before configuring remote access VPN policy.
- While configuring remote access VPNs using the wizard, you can create in-line certificate enrollment objects, but you cannot use them to install the identity certificate. Certificate enrollment objects are used for generating the identity certificate on the Firewall Threat Defense device being configured as the remote access VPN gateway. Install the identity certificate on the device before deploying the remote access VPN policy to the device.

  For more information about how to install the identity certificate based on the certificate enrollment object, see Use the object manager, on page 2334.
- The ECMP zone interfaces can be used in remote access VPN with IPsec enabled.
- The ECMP zone interfaces cannot be used in remote access VPN with SSL enabled. Deployment of remote access VPN (SSL enabled) configuration fails if all the remote access VPN interfaces that belong to security zones or interface groups also belong to one or more ECMP zones. However, if only some of the remote access VPN interfaces belonging to the security zones or interface groups also belongs to one or more ECMP zones, deployment of the remote access VPN configuration succeeds excluding those interfaces.
- After you change the remote access VPN policy configurations, re-deploy the changes to the Firewall Threat Defense devices. The time it takes to deploy configuration changes depends on multiple factors such as complexity of the policies and rules, type and volume of configurations you send to the device, and memory and device model. Before deploying remote access VPN policy changes, review the Best practices for deploying configuration changes, on page 133.

- Issuing commands such as **curl** against the RA VPN headend is not directly supported, and might not have desirable results. For example, the headend does not respond to HTTP HEAD requests.
- Firewall Threat Defense does not accept remote access VPN sessions if the third-party client sends a null user agent.
- You can configure browser proxy using FlexConfig.
- When **Bypass Access Control policy for decrypted traffic** is disabled on a Firewall Threat Defense and ISE issues a DACL, traffic is first matched against the ACP: if permitted, it proceeds to DACL checking; if denied, it bypasses DACL matching.

Concurrent VPN Sessions Capacity Planning (Firewall Threat Defense Virtual Models)

The maximum concurrent VPN sessions are governed by the installed Firewall Threat Defense Virtual smart-licensed entitlement tier, and enforced via a rate limiter. There is a maximum limit to the number of concurrent remote access VPN sessions allowed on a device based on the licensed device model. This limit is designed so that system performance does not degrade to unacceptable levels. Use these limits for capacity planning.

Device Model	Maximum Concurrent Remote Access VPN Sessions
Firewall Threat Defense Virtual5	50
Firewall Threat Defense Virtual10	250
Firewall Threat Defense Virtual20	250
Firewall Threat Defense Virtual30	250
Firewall Threat Defense Virtual50	750
Firewall Threat Defense Virtual100	10,000

Concurrent VPN Sessions Capacity Planning (Hardware Models)

The maximum concurrent VPN sessions are governed by platform-specific limits and have no dependency on the license. There is a maximum limit to the number of concurrent remote access VPN sessions allowed on a device based on the device model. This limit is designed so that system performance does not degrade to unacceptable levels. Use these limits for capacity planning.

Device Model	Maximum Concurrent Remote Access VPN Sessions
Firepower 1010	75
Firepower 1120	150
Firepower 1140	400
Firepower 2110	1500
Firepower 2120	3500
Firepower 2130	7500

Device Model	Maximum Concurrent Remote Access VPN Sessions
Firepower 2140	10,000
Secure Firewall 3110	3000
Secure Firewall 3120	6000
Secure Firewall 3130	15,000
Secure Firewall 3140	20,000
Firepower 4100, all models	10,000
Firepower 9300 appliance, all models	20,000
ISA 3000	25

For capacity of other hardware models, contact your sales representative.

Note The Firewall Threat Defense device denies the VPN connections once the maximum session limit per platform is reached. The connection is denied with a syslog message. Refer the syslog messages %ASA-4-113029 and %ASA-4-113038 in the syslog messaging guide. For more information, see Cisco Secure Firewall ASA Series Syslog Messages.

Controlling Cipher Usage for VPN

To prevent use of ciphers greater than DES, pre-deployment checks are available at the following locations in the Firewall Management Center:

Devices > **Platform Settings**, click **Edit** and then **SSL**.

Devices > **VPN** > **Remote Access**, click **Edit**, and then from **Advanced** drop-down list, choose **IPsec**.

For more information about SSL settings and IPsec, see Configure SSL settings, on page 884 and Configure Remote Access VPN IPsec/IKEv2 Parameters, on page 1471.

Authentication, Authorization, and Accounting

Configure DNS on each device in the topology in to use remote access VPN. Without DNS, the device cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames; it can only resolve IP addresses.

You can configure DNS using the **Platform Settings**. For more information, see Configure DNS server settings, on page 852 and DNS server groups, on page 2366.

Client Certificates

If you are using client certificates in your deployment, they must be added to your client's platform independent of the Secure Firewall Threat Defense or Secure Firewall Management Center. Facilities such as SCEP or CA Services are not provided to populate your clients with certificates.

Unsupported Features of Secure Client

The only supported VPN client is the Cisco Secure Client. No other clients or native VPNs are supported. Clientless VPN is not supported for VPN connectivity; it is only used to deploy the Secure Client using a web browser.

Note Using multiple Secure Client packages on Firewall Threat Defense devices can increase memory usage and affect the device's performance. We recommend that you do not use multiple Secure Client packages on low-end threat defense devices to avoid continuous reboots because of memory exhaustion.

The following Secure Client features are not supported when connecting to a Firewall Threat Defense secure gateway:

- TACACS, Kerberos (KCD Authentication and RSA SDI), and SDI.

Configuring a New Remote Access VPN Connection

This section provides instructions to configure a new remote access VPN policy with Secure Firewall Threat Defense devices as VPN gateways and Cisco Secure Client as the VPN client.

Step	Do This	More Info
1	Review the guidelines and prerequisites.	Guidelines and Limitations for Remote Access VPNs, on page 1422 Prerequisites for Configuring Remote Access VPN, on page 1426
2	Create a new remote access VPN policy using the wizard.	Create a New Remote Access VPN Policy, on page 1426
3	Update the access control policy deployed on the device.	Update the Access Control Policy on the Secure Firewall Threat Defense Device, on page 1429
4	(Optional) Configure a NAT exemption rule if NAT is configured on the device.	(Optional) Configure NAT Exemption, on page 1430
5	Configure DNS.	Configure DNS, on page 1431
6	Add Secure Client Profile.	Add Secure Client Profile XML File, on page 1431
7	Deploy the remote access VPN policy.	Deploy configuration changes, on page 135
8	(Optional) Verify the remote access VPN policy configuration.	Verify the Configuration, on page 1434

Prerequisites for Configuring Remote Access VPN

- Deploy Secure Firewall Threat Defense devices and configure Secure Firewall Management Center to manage the device with required licenses with export-controlled features enabled. For more information, see VPN licensing, on page 1334.
- Configure the certificate enrollment object that is used to obtain the identity certificate for each Firewall Threat Defense device that act as a remote access VPN gateway.
- Configure any AD or LDAP realms being used by remote access VPN policies.
- Ensure that the AAA server is reachable from the Firewall Threat Defense device. Configure routing (**Devices** > **Device Management**, click the **Edit** icon. From the left pane, choose **Routing**) to ensure connectivity to the AAA servers.

  For remote access VPN double authentication, ensure that both the primary and secondary authentication servers are reachable from the Firewall Threat Defense device.
- Purchase and enable one of the following Cisco Secure Client licenses: Secure Client Advantage, Secure Client Premier, or Secure Client VPN Only to enable the Firewall Threat Defense remote access VPN.
- Download the latest Secure Client image files from Cisco Software Download Center.

  On your Secure Firewall Management Center web interface, go to **Objects** > **Object Management** > **VPN** > **Secure Client File** and add the new Secure Client image files.
- Create a security zone or interface group that contains the network interfaces that users will access for VPN connections. See Interfaces, on page 2383.
- Download the Secure Client Profile Editor from Cisco Software Download Center to create the Secure Client profile. You can use the standalone profile editor to create a new or modify an existing Secure Client profile.

Create a New Remote Access VPN Policy

The Remote Access VPN Policy Wizard guides you to quickly and easily set up remote access VPNs with basic capabilities. You can further enhance the policy configuration by specifying additional attributes as you want and deploy it to your Secure Firewall Threat Defense secure gateway devices.

Before you begin

- Ensure that you complete all the prerequisites listed in Prerequisites for Configuring Remote Access VPN, on page 1426.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Add** to create a new remote access VPN policy with basic policy configuration, using the Remote Access VPN Policy wizard.

You must proceed through the entire wizard to create a new policy; the policy is not saved if you cancel before you complete the wizard.

Step 3 Select the target devices and protocols.

The Firewall Threat Defense devices that you select here functions as your remote access VPN gateways for the VPN client users.

You can select Firewall Threat Defense devices when you create a remote access VPN policy or change them later. See Set Target Devices for a Remote Access VPN Policy, on page 1435.

You can select **SSL** or **IPSec-IKEv2**, or both the VPN protocols. Firewall Threat Defense supports both the protocols to establish secure connections over a public network through VPN tunnels.

Note Firewall Threat Defense does not support IPSec tunnels with NULL encryption. If you have selected IPSec-IKEv2, make sure that you do not choose NULL encryption for IPSec IKEv2 proposal. See Configure an IKEv2 IPsec proposal object, on page 2470.

For SSL settings, see Configure SSL settings, on page 884.

Step 4 Click **Next**.

Step 5 Configure the **Connection Profile** and **Group Policy** settings.

A connection profile specifies a set of parameters that define how the remote users connect to the VPN device. The parameters include settings and attributes for authentication, address assignments to VPN clients, and group policies. Firewall Threat Defense device provides a default connection profile named *DefaultWEBVPNGroup* when you configure a remote access VPN policy.

For more information, see Configure Connection Profile Settings, on page 1436.

Step 6 Configure the **Authentication, Authorization & Accounting** settings.

For information about configuring,

- AAA settings, see Configure AAA Settings for Remote Access VPN, on page 1439
- LDAP attribute maps, see Configuring LDAP Attribute Mapping, on page 1462
- SAML 2.0 single sign-on authentication, see Configuring a SAML Single Sign-On Authentication, on page 1508

Step 7 Configure the **Client Address Assignment** settings.

Client IP address can be assigned from AAA server, DHCP server and IP address pools. When multiple options are selected, IP address assignment is done in the order of AAA server, DHCP server, and IP address pool. Assignment of client IP addresses from the AAA server is supported only for realm and RADIUS authorization. Ensure that realm or RADIUS server is configured to provide client IP address.

Step 8 Configure the **Group Policy** settings.

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience for VPN users. You configure attributes such as user authorization profile, IP addresses, Secure Client settings, VLAN mapping, and user session settings and so on using the group policy. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile. For more information, see Configuring Group Policies, on page 1461.

Step 9 Click **Next**.

Step 10 Select the **Secure Client Image** that the VPN users will use to connect to the remote access VPN.

The Secure Client provides secure SSL or IPSec (IKEv2) connections to the Secure Firewall Threat Defense device for remote users with full VPN profiling to corporate resources. After the remote access VPN policy is deployed on the Firewall Threat Defense device, VPN users can enter the IP address of the configured device interface in their browser to download and install the Secure Client.

For information about configuring the client profile and client modules, see Group policy options for Secure Client, on page 2464.

Step 11 Click **Next**.

Step 12 Configure **Network Interface for Incoming VPN Access**.

Interface objects segment your network to help you manage and classify traffic flow. A security zone object simply groups interfaces. These groups may span multiple devices; you can also configure multiple zones interface objects on a single device. There are two types of interface objects:

- Security zones—An interface can belong to only one security zone.
- Interface groups—An interface can belong to multiple interface groups (and to one security zone).

(Optional) Check the **Enable DTLS on member interfaces** check box, if required. DTLS is applicable only for SSL protocol.

Step 13 Configure **Device Certificates**.

Device certificate (also called Identity certificate) identifies the VPN gateway to the remote access clients. Select a certificate which is used to authenticate the VPN gateway. From the **Certificate Enrollment** drop-down list, choose a certificate or click + to add a certificate to authenticate the VPN gateway.

Step 14 Configure **Access Control for VPN Traffic** .

By default, all decrypted traffic in the VPN tunnel is subjected to the Access Control Policy. Check the **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** check box to bypass decrypted traffic from the Access Control Policy. This option bypasses the Access Control Policy inspection, but VPN filter ACL and authorization ACL downloaded from AAA server are still applied to VPN traffic.

Note If you select this option, you need not update the access control policy for remote access VPN as specified in Update the Access Control Policy on the Secure Firewall Threat Defense Device, on page 1429.

Step 15 Click **Next**.

Step 16 View the **Summary** of the remote access VPN policy configuration.

The Summary page displays all the remote access VPN settings you have configured so far and provides links to the additional configurations that need to be performed before deploying the remote access VPN policy on the selected devices.

Click **Back** to make changes to the configuration, if required.

Step 17 Click **Finish** to complete the basic configuration for the remote access VPN policy.

When you complete the Remote Access VPN Policy Wizard, the policy listing page appears. Later, set up DNS configuration, configure access control for VPN users, and enable NAT exemption (if necessary) to complete a basic remote access VPN Policy configuration.

What to do next

Use the Remote Access VPN dashboard (**Overview** > **Dashboards** > **Remote Access VPN**) to monitor real-time data from active remote access VPN sessions on the devices. You can quickly determine problems related to user sessions and mitigate the problems for your network and users. For more information, see Remote Access VPN Dashboard, on page 1524.

Update the Access Control Policy on the Secure Firewall Threat Defense Device

Before deploying the remote access VPN policy, you must update the access control policy on the targeted Secure Firewall Threat Defense device with a rule that allows VPN traffic. The rule must allow all traffic coming in from the outside interface, with source as the defined VPN pool networks and destination as the corporate network.

Note If you have selected the **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** option on the Access Interface tab, you need not update the access control policy for remote access VPN.

Enable or disable the option for all your VPN connections. If you disable this option, make sure that the traffic is allowed by the access control policy or pre-filter policy.

For more information, see Configure Access Interfaces for Remote Access VPN, on page 1455.

Before you begin

Complete the remote access VPN policy configuration using the Remote Access VPN Policy wizard.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** on the access control policy that you want to update.

Step 3 Click **Add Rule** to add a new rule.

Step 4 Specify the **Name** for the rule and select **Enabled**.

Step 5 Select the **Action**, **Allow** or **Trust**.

Step 6 Select the following on the **Zones** tab:

a) Select the outside zone from Available Zones and click **Add to Source**.

b) Select the inside zone from Available Zones and click **Add to Destination**.

Step 7 Select the following on the **Networks** tab:

a) Select the inside network (inside interface and/or a corporate network) from Available networks and click **Add to Destination**.

b) Select the VPN address pool network from **Available Networks** and click **Add to Source Networks**.

Step 8 Configure other required access control rule settings and click **Add**.

Step 9 Save the rule and access control policy.

(Optional) Configure NAT Exemption

NAT exemption exempts addresses from translation and allows both translated and remote hosts to initiate connections with your protected hosts. Like identity NAT, you do not limit translation for a host on specific interfaces; you must use NAT exemption for connections through all interfaces. However, NAT exemption enables you to specify the real and destination addresses when determining the real addresses to translate (similar to policy NAT). Use static identity NAT to consider ports in the access list.

When you configure static identity NAT for remote access or site-to-site VPN, you must configure NAT with the route lookup option. Without route lookup, the Firewall Threat Defense sends traffic out of the interface specified in the NAT command, regardless of what the routing table says. For example, you do not want the Firewall Threat Defense to send the DHCP scope traffic through an incorrect interface; it will never return to the interface IP address. The route lookup option lets the Firewall Threat Defense send, or intercept, the traffic directly on the interface IP address instead of through the interface. For traffic from the VPN client to a host on the inside network, the route lookup option will still result in the correct egress interface (inside), so normal traffic flow is not affected.

Before you begin

Check if NAT is configured on the targeted devices where remote access VPN policy is deployed. If NAT is enabled on the targeted devices, you must define a NAT policy to exempt VPN traffic.

Procedure

Step 1 On your Secure Firewall Management Center web interface, click **Devices** > **NAT**.

Step 2 Select a NAT policy to update or click **New Policy** > **Threat Defense NAT** to create a NAT policy with a NAT rule to allow connections through all interfaces.

Step 3 Click **Add Rule** to add a NAT rule.

Step 4 On the Add NAT Rule window, select the following:

a) Select the NAT Rule as **Manual NAT Rule**.

b) Select the Type as **Static**.

c) Click **Interface Objects** and select the Source and destination interface objects.

Note This interface object must be the same as the interface selected in the remote access VPN policy.

For more information, see Configure Access Interfaces for Remote Access VPN, on page 1455.

a) Click **Translation** and select the source and destination networks:

- **Original Source** and **Translated Source**
- **Original Destination** and **Translated Destination**

Step 5 On the Advanced tab, select **Do not proxy ARP on Destination Interface**.

Do not proxy ARP on Destination Interface—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router.

Step 6 Click **OK**.

Configure DNS

Configure DNS on each Firewall Threat Defense device in order to use remote access VPN. Without DNS, the devices cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames. It can only resolve IP addresses.

Procedure

Step 1 Configure DNS server details and domain-lookup interfaces using the Platform Settings. For more information, see Configure DNS server settings, on page 852 and DNS server groups, on page 2366.

Step 2 Configure split-tunnel in group policy to allow DNS traffic through remote access VPN tunnel if the DNS server is reachable through VNP network. For more information, see Configure a group policy object, on page 2461.

Add Secure Client Profile XML File

The Secure Client Profile is a group of configuration parameters stored in an XML file that the client uses to configure its operation and appearance. These parameters (XML tags) include the names and addresses of host computers and settings to enable more client features.

You can create the Secure Client Profile using the Secure Client Profile Editor, a GUI-based configuration tool that is available as part of the Secure Client software package. It is an independent program that you run outside of the Firewall Management Center. For more information about Secure Client Profile Editor, see Cisco Secure Client (including AnyConnect) Administrator Guide.

Before you begin

A Secure Firewall Threat Defense remote access VPN policy requires assignment of the Secure Client Profile to the VPN clients. You can attach the client profile to a group policy.

Download the Secure Client Profile Editor from Cisco Software Download Center.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy which you want to update.

Step 3 Click **Edit** on the connection profile to which you want to add the Secure Client profile.

Step 4 Click **Edit Group Policy**. If you choose to add a new group policy, click **Add**.

Step 5 Choose **Secure Client** > **Profile**.

Step 6 Choose a profile from the **Client Profile** drop-down list. If you choose to add a new client profile, click **Add** and do the following:

a) Specify the profile **Name**.

b) Click **Browse** and select the Secure Client Profile XML file.

Note For two-factor authentication, make sure that the timeout is set to 60 seconds or more in the Secure Client profile.

c) Click **Save**.

Step 7 Save your changes.

(Optional) Configure Split Tunneling

Split tunnel allows VPN connectivity to a remote network across a secure tunnel and also to a network outside VPN tunnel. Configure split tunneling if you want to allow your VPN users to access an outside network while they remain connected to the remote access VPN. To configure a split-tunnel list, you must create a Standard Access List or Extended Access List.

For more information, see Configuring Group Policies, on page 1461.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy for which you want to configure split tunneling.

Step 3 Click **Edit** on the required connection profile.

Step 4 Click **Add** to add a group policy or click **Edit Group Policy**.

Step 5 Choose **General** > **Split Tunneling**.

Step 6 From the **IPv4 Split Tunneling** or **IPv6 Split Tunneling** list, select **Exclude networks specified below** and then select the networks that you want to exclude from VPN traffic.

The default setting allows all traffic over the VPN tunnel.

Step 7 Click **Standard Access List** or **Extended Access List**, and select an access list from the drop-down or add a new one.

Step 8 If you choose to add a new standard or extended access list, do the following:

a) Specify the **Name** for the new access list and click **Add**.

b) Choose **Allow** from the **Action** drop-down.

c) Select the network traffic that you want to allow over the VPN tunnel and click **Add**.

Step 9 Save your changes.

Related Topics

Access lists, on page 2351

(Optional) Configure Dynamic Split Tunneling

Dynamic split tunneling allows you to fine-tune split tunneling based on DNS domain names. You can configure domains that must be included or excluded in the remote access VPN tunnel. Excluded domains are not blocked. Instead, traffic to those domains is kept outside the VPN tunnel. For example, you could send traffic to Cisco WebEx on the public Internet, thus freeing bandwidth in your VPN tunnel for traffic that is targeted to servers within your protected network. For more information about configuring this feature, see Configure AnyConnect Dynamic Split Tunnel on FTD Managed by FMC.

Before you begin

You can configure this feature using the Firewall Management Center and Firewall Threat Defense from versions 7.0 or later. If you have an older version of the Firewall Management Center, you can configure it using FlexConfig as instructed in the Advanced AnyConnect VPN Deployments for Firepower Threat Defense with FMC.

Procedure

Step 1 Configure the group policy to use Dynamic Split Tunnel.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click **Edit** on the remote access VPN policy for which you want to configure dynamic split tunneling.
c) Click **Edit** on the required connection profile.
d) Click **Edit Group Policy**.

Step 2 Configure the Secure Client custom attribute in the **Add/Edit Group Policy** dialog box.

a) Click the Secure Client tab.
b) Click **Custom Attributes** and click **+**.
c) Choose **Dynamic Split Tunneling** from the **Secure Client Attribute** drop-down list.
d) Click **+** to create a new custom attribute object.
e) Enter the name for the custom attribute object.
f) **Include domains**—Specify domain names that will be included in the remote access VPN tunnel.

You can include domains in the tunnel that will be excluded based on IP addresses.

g) **Exclude domains**—Specify domain names that will be excluded from the remote access VPN.

Excluded domains are not blocked, traffic to these domains is kept outside the VPN tunnel.

h) Click **Save**.
i) Click **Add**.

Step 3 Verify the configured custom attribute and click **Save** to save the group policy.

Step 4 Click **Save** to save the connection profile.

Step 5 Click **Save** to save the remote access VPN policy.

What to do next

1. Deploy the configuration to Firewall Threat Defense.
2. Verify the configured dynamic split tunnel configuration on the Firewall Threat Defense and the Secure Client. For more information, see Verify Dynamic Split Tunneling Configuration, on page 1434.

Verify Dynamic Split Tunneling Configuration

On the Firewall Threat Defense

Use the following commands to verify the dynamic split tunneling configuration:

- **show running-config webvpn**
- **show running-config anyconnect-custom-data**
- **show running-config group-policy** *<group-policy-name>*

On the Secure Client

Click the Statistics () icon and choose **VPN > Statistics**. You can confirm the domains under the Dynamic Split Exclusion/Inclusion category.

Verify the Configuration

Procedure

Step 1 Open a web browser on a machine on the outside network.

Step 2 Enter the URL of the Firewall Threat Defense remote access VPN gateway device.

Step 3 Enter the username and password when prompted, and click **Logon**.

Note Connection to the VPN establishes automatically if you install Secure Client on the system.

The VPN prompts you to download Secure Client if Secure Client is not installed.

Step 4 Download Secure Client if it is not installed and connect to the VPN.
The Secure Client installs itself. On successful authentication, you establish connection to the Secure Firewall Threat Defense remote access VPN gateway. The remote access VPN enforces the applicable identity or QoS policy according to your VPN policy configuration.

Create a Copy of an Existing Remote Access VPN Policy

You can copy an existing remote access VPN policy to create a new one with all the settings, including the connection profiles and access interfaces. You can then assign devices to the new policy and deploy the VPN on the assigned devices as required.

Note Users with read-only permission for remote access VPN cannot create copy of the VPN. Users with read-only privileges in the domain can copy the remote access VPNs.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Copy** on the policy that you want to copy.

Step 3 Specify a **Name** for the new remote access VPN.

Step 4 Click **OK**.

What to do next

To assign devices to the new policy, see Set Target Devices for a Remote Access VPN Policy, on page 1435.

Set Target Devices for a Remote Access VPN Policy

After you create remote access VPN policy, you can assign the policy to threat defense devices.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** ( ) next to the remote access VPN policy that you want to edit.

Step 3 Click **Policy Assignments**.

Step 4 Do any of the following:

- To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add**. You can also drag and drop the available devices to select.
- To remove a device assignment, click **Delete** ( ) next to a device, high-availability pair, or device group in the **Selected Devices** list.

Step 5 Click **OK**.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Associate Local Realm with Remote Access VPN Policy

You can associate local realm to remote access VPN policy to enable local user authentication.

For information about creating and managing realms, see Manage a realm, on page 1876.

For information about configuring local user authentication for remote access VPNs, see Configure AAA Settings for Remote Access VPN, on page 1439.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** ( ) next to the remote access VPN policy that you want to edit.

Step 3 Click the link next to **Local Realm**.

Step 4 Select the **Local Realm Server** from the list, or click **Add** to add a new local realm.

Step 5 Click **OK**.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Additional Remote Access VPN Configurations

Configure Connection Profile Settings

Remote Access VPN policy contains the connection profiles targeted for specific devices. These policies pertain to creating the tunnel itself, such as, how AAA is accomplished, and how addresses are assigned (DHCP or Address Pools) to VPN clients. They also include user attributes, which are identified in group policies configured on the Firewall Threat Defense device or obtained from a AAA server. A device also provides a default connection profile named *DefaultWEBVPNGroup*. The connection profile that is configured using the wizard appears in the list.

If you decide to grant different rights to different groups of VPN users, then you can add specific connection profiles for each of the user groups and maintain multiple connection profiles in your remote access VPN policy.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Select a **Connection Profile** and click **Edit**.

Step 4 (Optional) If you choose to add new connection profile, click **Add**.

Step 5 Configure IP Addresses for VPN Clients.
Configure IP Addresses for VPN Clients, on page 1437

Step 6 (Optional) Update AAA Settings for remote access VPNs.
Configure AAA Settings for Remote Access VPN, on page 1439

Step 7 (Optional) Create or update Aliases.
Create or Update Aliases for a Connection Profile, on page 1454

Step 8 Save your changes.

Configure IP Addresses for VPN Clients

Client address assignment allows you to assign IP addresses for the remote access VPN users.

You can assign IP Address for remote VPN clients from the local IP address pools, DHCP Servers, and AAA servers. The AAA servers are assigned first, followed by others. Configure the **Client Address Assignment** policy in the **Advanced** tab to define the assignment criteria. The IP pools defined in this connection profile will only be used if no IP pools are defined in group policy associated with the connection profile, or the system default group policy **DfltGrpPolicy**.

IPv4 Address Pools—SSL VPN clients receive new IP addresses when they connect to the Firewall Threat Defense device. Address pools define a range of addresses that remote clients can receive. You can add a maximum of six pools for IPv4 and IPv6 addresses each.

Note You can use the IP address from the existing IP pools in the Firewall Management Center or create a new pool using the **Add** option. Also, you can create an IP pool in Firewall Management Center using the **Objects** > **Object Management** > **Address Pools** path. For more information, see Configure address pools, on page 2356.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.
Existing remote access policies are listed.

Step 2 Select a remote access VPN policy and click the edit icon.

Step 3 Select the connection profile that you want to update and click the edit icon.

Step 4 Under the **Client Address Assignment** tab, do the following:

Step 5 Click + next to **Address Pools**:

a) Click + next to **Address Pools** to add IP addresses, and select **IPv4** or **IPv6** to add the corresponding address pool. Select the IP address pool from **Available Pools** and click **Add**.

Note If you share your remote access VPN policy among multiple Secure Firewall Threat Defense devices, bear in mind that all devices share the same address pool unless you use device-level object overrides to replace the global definition with a unique address pool for each device. Unique address pools are required to avoid overlapping addresses in cases where the devices are not using NAT.

b) Click + next to **Available Pools** in the **Address Pools** window to add a new IPv4 or IPv6 address pool. When you choose the IPv4 pool, provide a starting and ending IP address. When you choose to include a new IPv6 address pool, enter **`Number of Addresses`** in the range 1-16384. Select the **Allow Overrides** option to avoid conflicts with IP address when objects are shared across many devices. For more information, see Configure address pools, on page 2356.

c) Click **OK**.

If you plan to edit the IP address pools, we recommend that you perform the following steps during a maintenance window:

1. Unassign the device from the remote access VPN.
2. Select the device and click **Deploy**.

   This deployment removes all the remote access VPN configurations from the device, terminates the remote access VPN sessions, the sessions are not reestablished.
3. Click the edit icon next to the IP address pools to edit it, edit any other remote access VPN configurations, if required, on the Firewall Management Center.
4. Assign the device to the updated remote access VPN policy.
5. Deploy the configurations on the device.

   The remote access VPN clients can connect to the device after the maintenance window.

Step 6 Click + next to **DHCP Servers** to add DHCP servers:

Note The DHCP server address can be configured only with IPv4 address.

a) Specify the name and DHCP (Dynamic Host Configuration Protocol) server address as network objects. Click **Add** to choose the server from the object list. Click **Delete** to delete a DHCP server.

b) Click **Add** in the **New Objects** page to add a new network object. Enter the new object name, description, network, and select the **Allow Overrides** option as applicable. For more information, see Create a network object, on page 2388 and Allow object overrides, on page 2344.

c) Click **OK**.

Step 7 Click **Save**.

Related Topics

Configure Connection Profile Settings, on page 1436

Configure AAA Settings for Remote Access VPN

Before you begin

- Ensure that the required machine and user certificates are deployed on the endpoints. For information about Firewall Threat Defense certificates, see Manage Firewall Threat Defense certificates, on page 2483.
- Configure Secure Client profiles with required certificates. For more information, see *Cisco Secure Client (including AnyConnect) Administrator Guide*.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Select a connection profile to update AAA settings, click **Edit** and then choose**AAA**.

Step 4 Select the following for **Authentication**:

- **Authentication Method**—Determines how a user is identified before being allowed access to the network and network services. It controls access by requiring valid user credentials, which are typically a username and password. It may also include the certificate from the client. Supported authentication methods are **AAA only**, **Client Certificate only**, and **AAA + Client Certificate**.

  When you select the **Authentication Method** as:

  - **AAA Only**—If you select the **Authentication Server** as **RADIUS**, by default, the Authorization Server has the same value. Select the **Accounting Server** from the drop-down list. Whenever you select **AD** and **LDAP** from the Authentication Server drop-down list, you must select the **Authorization Server** and **Accounting Server** manually.
  - **SAML**—Each user is authenticated using the SAML single sign-on server. For more information, see Single Sign-On Authentication with SAML 2.0, on page 1506.

    Override Identity Provider Certificate—Select to override the primary identity provider certificate of the SAML provider with an IdP certificate specific to a connection profile or SAML application. Select the IdP certificate from the drop-down.

    Microsoft Azure can support multiple applications for the same entity ID. Each application (mapped to a different connection profile) requires a unique certificate. If you want to retain an existing entity ID for the single-sign-on object in current connection profile and use a different IdP certificate, you can select this option.

    This enables support for multiple SAML applications per Microsoft Azure SAML identity provider.

    The primary identity certificate is configured in the single sign-on server object.

    For information about configuring a single sign-on server object, see Add a single sign-on server, on page 2349.

    Choose your **SAML Login Experience** to configure a browser for SAML web authentication:

    - **VPN client embedded browser**—Choose this option to use the browser embedded with the VPN client for web authentication. The authentication applies to the VPN connection only.

- **Default OS Browser**—Choose this option to configure the operating system that default or native browser that supports WebAuthN (FIDO2 standard for web authentication). This option enables single sign-on(SSO) support for web authentication methods such as biometric authentication.

  The default browser requires an external browser package for web authentication. The package Default-External-Browser-Package is configured by default. You can change the default external browser package by editing a remote access VPN policy and selecting the file under **Advanced** and choose **AnyConnect Client ImagesSecure Client Image**s, then click **Package File**.

  You can also add a new package file by selecting. **Objects** > **Object Management** > **VPN** > **Secure Client File** and then click **Add Secure Client File**.

- **Client Certificate Only**—Each user is authenticated with a client certificate. The client certificate must be configured on VPN client endpoints. By default, the user name is derived from the client certificate fields CN and OU. If the user name is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.

  Select **Enable multiple certificate authentication** to authenticate the VPN client using the machine and user certificates.

  If have enabled multiple certificate authentication, you can select one of the following certificates to map the username and authenticate the VPN user:

  - **First Certificate**—Select this option to map the username from the machine certificate sent from the VPN client.
  - **Second Certificate**—Select this option to map the username from the user certificate sent from the client.

Note If you do not enable multiple certificate authentication, the user certificate (second certificate) is used for authentication by default.

  If you select the **Map specific field** option, which includes the username from the client certificate, the **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

  The primary and Secondary fields pertaining to the **Map specific field** option contain these common values:

  - C (Country)
  - CN (Common Name)
  - DNQ (DN Qualifier)
  - EA (Email Address)
  - GENQ (Generational Qualifier)
  - GN (Given Name)

- I (Initial)
- L (Locality)
- N (Name)
- O (Organisation)
- OU (Organisational Unit)
- SER (Serial Number)
- SN (Surname)
- SP (State Province)
- T (Title)
- UID (User ID)
- UPN (User Principal Name)

- **Client Certificate & AAA**— Each user is authenticated with both a client certificate and AAA server. Select the required certificate and AAA configurations for authentication.

  Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

- **Client Certificate & SAML**— Each user is authenticated with both a client certificate and SAML server. Select the required certificate and SAML configurations for authentication.
  - **Allow connection only if username from certificate and SAML are the same**—Select to allow VPN connection only if the username from the certificate matches the SAML single sign-on username.
  - **Use username from client certificate for Authorization**—When you choose the option to pick username from client certificate for authorization, you must configure the fields to pick from the client certificate.

    You can choose to map a specific filed as the username or use the entire distinguished name (DN) for authorization:
    - **Map specific field**— Select to include the username from the client certificate; the **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively.
    - **Use entire DN as username**— The system automatically retrieves the user identity for authorization.

  You can also create a Dynamic Access Policy (DAP) to match user-specific SAML assertion attributes or username to DAP certificate attributes. See Configure AAA criteria settings for a DAP record, on page 1535.

- **Authentication Server**—Authentication is the way a user is identified before being allowed access to the network and network services. Authentication requires valid user credentials, a certificate, or both. You can use authentication alone, or with authorization and accounting.

Select an authentication server from the list if you have added a server already or else create an authentication server:

- **LOCAL**—Use a local database from the Firewall Threat Defense for user authentication. To configure local authentication, Firewall Threat Defense must be Version 7.0 and later.
  - **Local Realm**—Select a local realm or click **Add** to configure a realm. See Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.
- **Realm**—Configure an LDAP or AD realm. See Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.
- **RADIUS Server Group**—Add a RADIUS server group object with RADIUS servers. See Add a RADIUS server group, on page 2346.
- **Single Sign-On Server**—Create a single sign-on server object for SAML authentication. See Add a single sign-on server, on page 2349.

Fallback to LOCAL Authentication— The user is authenticated using the local database and the VPN tunnel can be established even if the AAA server group is unavailable, provided that the local database is configured.

- **Use secondary authentication** — Secondary authentication is configured in addition to primary authentication to provide additional security for VPN sessions. Secondary authentication is applicable only to **AAA only** and **Client Certificate & AAA** authentication methods.

  Secondary authentication is an optional feature that requires a VPN user to enter two sets of username and password on the Secure Client login screen. You can also configure to pre-fill the secondary username from the authentication server or client certificate. Remote access VPN authentication is granted only if both primary and secondary authentications are successful. VPN authentication is denied if any one of the authentication servers is not reachable or one authentication fails.

  You must configure a secondary authentication server group (AAA server) for the second username and password before configuring secondary authentication. For example, you can set the primary authentication server to an LDAP or Active Directory realm and the secondary authentication to a RADIUS server.

Note By default, secondary authentication is not required.

Authentication Server— Secondary authentication server to provide secondary username and password for VPN users.

- **Fallback to LOCAL Authentication**— This user is authenticated using the local database and the VPN tunnel can be established even if the AAA server group is unavailable, provided that the local database is configured.

Select the following under **Username for secondary authentication**:

- **Prompt**: Prompts the users to enter the username and password while logging on to VPN gateway.
- **Use primary authentication username**: The username is taken from the primary authentication server for both primary and secondary authentication; you must enter two passwords.
- **Map username from client certificate**: Prefills the secondary username from the client certificate.

  If you have enabled multiple certificate authentication, you can select one of the following certificates:

- **First Certificate**— Select this option to map the username from the machine certificate sent from the VPN client.
- **Second Certificate**— Select this option to map the username from the user certificate sent from the client.
- If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity.

  See **Authentication Method** descriptions for more information about primary and secondary field mapping.
- **Prefill username from certificate on user login window**: Prefills the secondary username from the client certificate when the user connects via Secure Client.
  - **Hide username in login window**: The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.

- **Use secondary username for VPN session**: The secondary username is used for reporting user activity during a VPN session.

Step 5 Select the following for **Authorization**:

- **Authorization Server**—After authentication is complete, authorization controls the services and commands available to each authenticated user. Authorization works by assembling a set of attributes that describe what the user is authorized to perform, their actual capabilities, and restrictions. When you do not use authorization, authentication alone provides the same access to all authenticated users. Authorization requires authentication.

  To know more about how remote access VPN authorization works, see Understanding Policy Enforcement of Permissions and Attributes, on page 1420.

  When a RADIUS Server is configured for user authorization in the connection profile, the remote access VPN system administrator can configure multiple authorization attributes for users or user-groups. The authorization attributes that are configured on the RADIUS server can be specific for a user or a user-group. Once users are authenticated, these specific authorization attributes are pushed to the Firewall Threat Defense device.

Note The AAA server attributes obtained from the authorization server override the attribute values that may have been previously configured on the group policy or the connection profile.

- Check **Allow connection only if user exists in authorization database** if desired.

  When enabled, the system checks the username of the client must exist in the authorization database to allow a successful connection. If the username does not exist in the authorization database, then the connection is denied.

- When you select a realm as the Authorization Server, you must configure an LDAP attribute map. You can choose a single server for authentication and authorization or a different servers. Click **Configure LDAP Attribute Map** to add LDAP attribute maps for authorization.

Note Firewall Threat Defense does not support SAML Identity Provider as the Authorization server. If the Active Directory behind the SAML Identity Provider is reachable via Firewall Management Center and Firewall Threat Defense, you can configure authorization following these steps:

- Add realm for the AD Server. See Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.
- Select the realm object as the Authorization Server in remote access VPN connection profile.
- Configure LDAP attribute map for the selected realm.

For information about configuring LDAP attribute maps, see Configuring LDAP Attribute Mapping, on page 1462.

Step 6 Select the following for **Accounting**:

- **Accounting Server**—Accounting is used to track the services that users are accessing and the amount of network resources they are consuming. When AAA accounting is activated, the network access server reports user activity to the RADIUS server. Accounting information includes when sessions start and stop, usernames, the number of bytes that pass through the device for each session, the services used, and the duration of each session. This data can then be analyzed for network management, client billing, or auditing. You can use accounting alone or together with authentication and authorization.

  Specify the RADIUS Server Group object that will be used to account for the remote access VPN session.

Step 7 Select the following **Advanced Settings**:

- **Strip Realm from username**—Select to remove the realm from the username before passing the username on to the AAA server. For example, if you select this option and provide *domain\username*, the domain is stripped off from the username and sent to AAA server for authentication. By default this option is unchecked.
- **Strip Group from username**—Select to remove the group name from the username before passing the username on to the AAA server. By default this option is unchecked.

Note A realm is an administrative domain. Enabling these options allows the authentication to be based on the username alone. You can enable any combination of these options. However, you must select both check boxes if your server cannot parse delimiters.

- **Password Management**—Enable managing the password for the remote access VPN users. Select to notify ahead of the password expiry or on the day the password expires.

Step 8 Click **Save**.

RADIUS Server Attributes for Secure Firewall Threat Defense

The Firewall Threat Defense device supports applying user authorization attributes (also called user entitlements or permissions) to VPN connections from the external RADIUS server that are configured for authentication and/or authorization in the remote access VPN policy.

Note Secure Firewall Threat Defense devices support attributes with vendor ID 3076.

The following user authorization attributes are sent to the Firewall Threat Defense device from the RADIUS server.

- RADIUS attributes 146 and 150 are sent from Firewall Threat Defense devices to the RADIUS server for authentication and authorization requests.
- All three (146, 150, and 151) attributes are sent from Firewall Threat Defense devices to the RADIUS server for accounting start, interim-update, and stop requests.

Table 80: RADIUS Attributes Sent from Secure Firewall Threat Defense to RADIUS Server

Attribute	Attribute Number	Syntax, Type	Single or Multi-valued	Description or Value
Connection Profile Name or Tunnel Group Name	146	String	Single	1-253 characters
Client Type	150	Integer	Single	2 = Secure Client SSL VPN, 6 = Secure Client IPsec VPN (IKEv2)
Session Type	151	Integer	Single	1 = Secure Client SSL VPN, 2 = Secure Client IPsec VPN (IKEv2)

Table 81: Supported RADIUS Authorization Attributes

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
Access-Hours	Y	1	String	Single	Name of the time range, for example, Busine

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
Access-List-Inbound	Y	86	String	Single	Both of the Access-List attributes take the name ACL that is configured on the Firewall Threat D device. Create these ACLs using the Smart CLI E Access List object type (select **Device** > **Advan Configuration** > **Smart CLI** > **Objects**). These ACLs control traffic flow in the inbound entering the Firewall Threat Defense device) or o (traffic leaving the Firewall Threat Defense devi direction.
Access-List-Outbound	Y	87	String	Single	
Address-Pools	Y	217	String	Single	The name of a network object defined on the Fi Threat Defense device that identifies a subnet, wh be used as the address pool for clients connectin remote access VPN. Define the network object **Objects** page and then associate the network obj a group policy or a connection profile.
Allow-Network-Extension-Mode	Y	64	Boolean	Single	0 = Disabled 1 = Enabled
Authenticated-User-Idle-Timeout	Y	50	Integer	Single	1-35791394 minutes
Authorization-DN-Field	Y	67	String	Single	Possible values: UID, OU, O, CN, L, SP, C, EA, GN, SN, I, GENQ, DNQ, SER, use-entire-name
Authorization-Required		66	Integer	Single	0 = No 1 = Yes
Authorization-Type	Y	65	Integer	Single	0 = None 1 = RADIUS 2 = LDAP
Banner1	Y	15	String	Single	Banner string to display for Cisco VPN remote a sessions: IPsec IKEv1, Secure Client SSL-TLS/DTLS/IKEv2, and Clientless SSL
Banner2	Y	36	String	Single	Banner string to display for Cisco VPN remote a sessions: IPsec IKEv1, Secure Client SSL-TLS/DTLS/IKEv2, and Clientless SSL. The string is concatenated to the Banner1 string , if con
Cisco-IP-Phone-Bypass	Y	51	Integer	Single	0 = Disabled 1 = Enabled
Cisco-LEAP-Bypass	Y	75	Integer	Single	0 = Disabled 1 = Enabled
Client Type	Y	150	Integer	Single	1 = Cisco VPN Client (IKEv1) 2 = Secure Clien VPN 3 = Clientless SSL VPN 4 = Cut-Through- = L2TP/IPsec SSL VPN 6 = Secure Client IPsec (IKEv2)
Client-Type-Version-Limiting	Y	77	String	Single	IPsec VPN version number string
DHCP-Network-Scope	Y	61	String	Single	IP Address

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
Extended-Authentication-On-Rekey	Y	122	Integer	Single	0 = Disabled 1 = Enabled
Framed-Interface-Id	Y	96	String	Single	Assigned IPv6 interface ID. Combines with Framed-IPv6-Prefix to create a complete ass address. For example: Framed-Interface-ID= combined with Framed-IPv6-Prefix=2001:0db the assigned IP address 2001:0db8::1:1:1:1.
Framed-IPv6-Prefix	Y	97	String	Single	Assigned IPv6 prefix and length. Combines Framed-Interface-Id to create a complete ass address. For example: prefix 2001:0db8::/64 with Framed-Interface-Id=1:1:1:1 gives the 2001:0db8::1:1:1:1. You can use this attribut an IP address without using Framed-Interfac assigning the full IPv6 address with prefix le for example, Framed-IPv6-Prefix=2001:0db
Group-Policy	Y	25	String	Single	Sets the group policy for the remote access V You can use one of the following formats: • *group policy name* • OU=*group policy name* • OU=*group policy name*;
IE-Proxy-Bypass-Local		83	Integer	Single	0 = None 1 = Local
IE-Proxy-Exception-List		82	String	Single	New line (\n) separated list of DNS domains
IE-Proxy-PAC-URL	Y	133	String	Single	PAC address string
IE-Proxy-Server		80	String	Single	IP address
IE-Proxy-Server-Policy		81	Integer	Single	1 = No Modify 2 = No Proxy 3 = Auto detec Concentrator Setting
IKE-KeepAlive-Confidence-Interval	Y	68	Integer	Single	10-300 seconds

Table 82: RADIUS Attributes Sent to Secure Firewall Threat Defense

Attribute	Attribute Number	Syntax, Type	Single or Multi-valued	Description or Value
Address-Pools	217	String	Single	The name of a network object defined on the Firewall Threat Defense device that identifies a subnet, which will be used as the address pool for clients connecting to the remote access VPN. Define the network object on the **Objects** page.
Banner1	15	String	Single	The banner to display when the user logs in.
Banner2	36	String	Single	The second part of the banner to display when the user logs in. Banner2 is appended to Banner1.

Attribute	Attribute Number	Syntax, Type	Single or Multi-valued	Description or Value
Downloadable ACLs	Cisco-AV-Pair	merge-dacl {before-avpair | after-avpair}		Supported via Cisco-AV-Pair configuration.
Filter ACLs	86, 87	String	Single	Filter ACLs are referred to by ACL name in the RADIUS server. It requires the ACL configuration to be already present on the Firewall Threat Defense device, so that it can be used during RADIUS authorization. 86=Access-List-Inbound 87=Access-List-Outbound
Group-Policy	25	String	Single	The group policy to use in the connection. You must create the group policy on the remote access VPN **Group Policy** page. You can use one of the following formats: • *group policy name* • OU=*group policy name* • OU=*group policy name*;
Simultaneous-Logins	2	Integer	Single	The number of separate simultaneous connections the user is allowed to establish, 0 - 2147483647.
VLAN	140	Integer	Single	The VLAN on which to confine the user's connection, 0 - 4094. You must also configure this VLAN on a subinterface on the Firewall Threat Defense device.

You must set the values of the IE-Proxy-Server-Method attribute returned from ISE to one of the following:

- IE_PROXY_METHOD_PACFILE: 8
- IE_PROXY_METHOD_PACFILE_AND_AUTODETECT: 11
- IE_PROXY_METHOD_PACFILE_AND_USE_SERVER: 12
- IE_PROXY_METHOD_PACFILE_AND_AUTODETECT_AND_USE_SERVER: 15

Firewall Threat Defense will deliver a proxy setting only if one of the above values is used for the IE-Proxy-Server-Method attribute.

Create or Update Aliases for a Connection Profile

Aliases contain alternate names or URLs for a specific connection profile. Remote access VPN administrators can enable or disable the Alias names and Alias URLs. VPN users can choose an Alias name when they connect to the Secure Firewall Threat Defense device. Aliases names for all connections configured on this device can be turned on or off for display. You can also configure the list of Alias URLs, which your endpoints

can select while initiating the remote access VPN connection. If users connect using the Alias URL, system will automatically log them using the connection profile that matches the Alias URL.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the policy that you want to modify.

Step 3 Click **Edit** on the connection profile for which you want to create or update aliases.

Step 4 Click **Aliases**.

Step 5 To add an Alias name, do the following:

a) Click **Add** under **Alias Names**.
b) Specify the **Alias Name**.
c) Select the **Enabled** check box in each window to enable the aliases.
d) Click **OK**.

Step 6 To add an Alias URL, do the following:

a) Click **Add** under **URL Alias**.
b) Select the **Alias URL** from the list or create a new URL object. For more information see Create a URL object, on page 2438.
c) Select the **Enabled** check box in each window to enable the aliases.
d) Click **OK**.

Step 7 Save your changes.

Configure Connection Profile Settings, on page 1436

Configure Access Interfaces for Remote Access VPN

The **Access Interface** table lists the interface groups and security zones that contain the device interfaces. These are configured for remote access SSL or IPsec IKEv2 VPN connections. The table displays the name of each interface group or security-zone, the interface trustpoints used by the interface, and whether Datagram Transport Layer Security (DTLS) is enabled.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Click the **Access Interface** tab.

Step 4 To add an access interface, click + and specify values for the following in the **Add Access Interface** dialog box:

a) **Access Interface**—Select the interface group or security zone to which the interface belongs.

The interface group or security zone must be a Routed type. Other interface types are not supported for remote access VPN connectivity.

b) Associate the **Protocol** object with the access interface by selecting the following options:

- **Enable IPSet-IKEv2**—Select this option to enable **IKEv2** settings.
- **Enable SSL**—Select this option to enable **SSL** settings.
  - Select **Enable Datagram Transport Layer Security**.

    When selected, it enables Datagram Transport Layer Security (DTLS) on the interface and allows the AnyConnect VPN module of Cisco Secure Client to establish an SSL VPN connection using two simultaneous tunnels—an SSL tunnel and a DTLS tunnel.

    Enabling DTLS avoids the latency and bandwidth problems associated with certain SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

    To configure SSL settings, and TLS and DTLS versions, see Configure SSL settings, on page 885.

    To configure SSL settings for the AnyConnect VPN module of Cisco Secure Client, see Group policy options for Secure Client, on page 2464.
  - Select the **Configure Interface Specific Identity Certificate** check box and select **Interface Identity Certificate** from the drop-down list.

    If you do not select the Interface Identity Certificate, the **Trustpoint** will be used by default.

    If you do not select the Interface Identity Certificate or Trustpoint, the **SSL Global Identity Certificate** will be used by default.

c) Click **OK** to save the changes.

Step 5 Select the following under **Access Settings**:

- **Allow Users to select connection profile while logging in**—If you have multiple connection profiles, check this check box to allow user to select the correct connection profile during login. You must select this option for **IPsec-IKEv2** VPNs.

Step 6 Use the following options to configure **SSL Settings**:

- **Web Access Port Number**—The port to use for VPN sessions. The default port is 443.
- **DTLS Port Number**—The UDP port to use for DTLS connections. The default port is 443.
- **SSL Global Identity Certificate**— The selected **SSL Global Identity Certificate** will be used for all the associated interfaces if the **Interface Specific Identity Certificate** is not provided.

Step 7 For **IPsec-IKEv2 Settings**, select the **IKEv2 Identity Certificate** from the list or add an identity certificate.

Step 8 Under the **Access Control for VPN Traffic** section, select the following option if you want to bypass access control policy:

- **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** — Decrypted traffic is subjected to Access Control Policy inspection by default. Enabling the Bypass Access Control policy for decrypted traffic option bypasses the ACL inspection, but VPN Filter ACL and authorization ACL downloaded from AAA server are still applied to VPN traffic.

Note If you select this option, you need not update the access control policy for remote access VPN as specified in Update the Access Control Policy on the Secure Firewall Threat Defense Device, on page 1429.

Step 9 Click **Save** to save the access interface changes.

Configure Advanced Options for Remote Access VPN

Cisco Secure Client Image

Secure Client Image

The Secure Client provides secure SSL or IPsec (IKEv2) connections to the Firewall Threat Defense device for remote users with full VPN profiling to corporate resources. Without a previously-installed client, remote users can enter the IP address of an interface configured to accept clientless VPN connections in their browser to download and install the Secure Client. The Firewall Threat Defense device downloads the client that matches the operating system of the remote computer. After downloading, the client installs and establishes a secure connection. In case of a previously installed client, when the user authenticates, the Firewall Threat Defense device, examines the version of the client, and upgrades the client if necessary.

The Remote Access VPN administrator associates any new or additional Secure Client images to the VPN policy. The administrator can unassociate the unsupported or end of life client packages that are no longer required.

The Secure Firewall Management Center determines the type of operating system by using the file package name. If the user renamed the file without indicating the operating system information, the valid operating system type must be selected from the list box.

Download the Secure Client image file by visiting Cisco Software Download Center.

Related Topics

Adding a Secure Client Image to the Secure Firewall Management Center, on page 1457

Adding a Secure Client Image to the Secure Firewall Management Center

You can upload the Secure Client image to the Secure Firewall Management Center by using the **Secure Client File** object. For more information, see File objects, on page 2474. For more information about the client image, see Cisco Secure Client Image, on page 1457.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**, choose and edit a listed remote access policy, then choose the **Advanced** tab.

Step 2 Click **Add** to add a Secure Client image.

Step 3 Click **Add** in the **Available Secure Client Images** portion of the **Secure Client Images** dialog.

Step 4 Enter the **Name** and **Description**(optional) for the available Secure Client Image.

Step 5 Click **Browse**, locate and select the client image that you want to upload.

Step 6 Click **Save** to upload the image to the Firewall Management Center.

When you upload the client image to the Secure Firewall Management Center, the operating system information for the image appears automatically.

Step 7 To change the order of client images, Click **Show Re-order buttons** and move the client image up or down.

Update Secure Client Image for Remote Access VPN Clients

When new Secure Client updates are available in Cisco Software Download Center, you can download the packages manually and add them to the remote access VPN policy so that the new client packages are upgraded on the VPN client systems according to their operating systems.

Before you begin

Instructions in this section help you update new Secure Client images to remote access VPN clients connecting to Secure Firewall Threat Defense VPN gateway. Ensure that the following configurations are complete before updating your Secure Client images:

- Download the latest Secure Client image files from Cisco Software Download Center.
- On your Secure Firewall Management Center web interface, go to **Objects** > **Object Management** > **VPN** > **Secure Client File** and add the new Secure Client image files.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy that you want to update.

Step 3 From **Advanced** drop-down menu, choose **AnyConnect Client ImagesSecure Client Image** and then click **Add**.

Step 4 Select a client image file from **Available Secure Client Images** and click **Add**.

If the required client image is not listed, click **Add** to browse and upload an image.

Step 5 Click **OK**.

Step 6 Save the remote access VPN policy.
After the remote access VPN policy changes are deployed, the new Secure Client images are updated on the Secure Firewall Threat Defense device that is configured as the remote access VPN gateway. When a new VPN user connects to the VPN gateway, the user gets the new Secure Client image to download depending on the operating system of the client system. For existing VPN users, the Secure Client image gets updated in their next VPN session.

Add a Cisco Secure Client External Browser Package to the Secure Firewall Management Center

If you have the Secure Client external browser package image on your local disk, use this procedure to upload the same to the Secure Firewall Management Center. After you upload the external browser package, you can update the external browser package for your remote access VPN connections.

You can upload the external browser package file to the Secure Firewall Management Center by using the **Secure Client File** object. For more information, see File objects, on page 2474.

Points to Remember

- Only one external browser package can be added to the Firewall Threat Defense device.
- After the external browser package is added to the Firewall Management Center, the browser is pushed to the Firewall Threat Defense only after the external browser is enabled in the remote access VPN configuration.

Procedure

Step 1 On the Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**, choose and edit a listed remote access policy, then choose the **Advanced** tab.

Step 2 Click **Add** in the **Secure Client External Browser Package** portion of the **Secure Client Images** page.

Step 3 Enter the **Name** and **Description** for the Secure Client package.

Step 4 Click **Browse** and locate the external browser package file to upload.

Step 5 Click **Save** to upload the image to the Secure Firewall Management Center.

Note If you want to update the remote access VPN connection with an existing external browser package, select the file from the **Package File** drop-down.

Step 6 Save the remote access VPN policy.

Remote Access VPN Address Assignment Policy

The Firewall Threat Defense device can use an IPv4 or IPv6 policy for assigning IP addresses to Remote Access VPN clients. If you configure more than one address assignment method, the Firewall Threat Defense device tries each of the options until it finds an IP address.

IPv4 or IPv6 Policy

You can use the IPv4 or IPv6 policy to address an IP address to remote access VPN clients. You must try with the IPv4 policy to begin and later followed by IPv6 policy.

- **Use Authorization Server**—Retrieves the address from an external authorization server on a per-user basis. If you are using an authorization server that has IP address configured, we recommend using this method. Address assignment is supported by RADIUS-based authorization server only. It is not supported for AD/LDAP. This method is available for both IPv4 and IPv6 assignment policies.

- **Use DHCP**—Obtains IP addresses from a DHCP server configured in a connection profile. You can also define the range of IP addresses that the DHCP server can use by configuring DHCP network scope in the group policy. If you use DHCP, configure the server in the **Objects** > **Object Management** > **Network** pane. This method is available for IPv4 assignment policies.

  For more information about DHCP network scope configuration, see Group policy general options, on page 2462.

- **Use an internal address pool**—Internally configured address pools are the easiest method of address pool assignment to configure. If you use this method, create the IP address pools in the **Objects** > **Object Management** > **Address Pools** pane and select the same in the connection profile. This method is available for both IPv4 and IPv6 assignment policies.

- **Allow reuse an IP address so many minutes after it is released**—Delays the reuse of an IP address after its return to the address pool. Adding a delay helps to prevent problems firewalls can experience when an IP address is reassigned quickly. By default, the delay is set to zero. If you want to extend the delay, enter the number of minutes in the range of 0–480 to delay the IP address reassignment. This configurable element is available for IPv4 assignment policies.

Configure Connection Profile Settings, on page 1436
Remote Access VPN Authentication, on page 1418

Configure Certificate Maps

Certificate maps let you define rules matching a user certificate to a connection profile based on the contents of the certificate fields. Certificate maps provide certificate authentication on secure gateways.

The rules or the certificate maps are defined in Certificate map objects, on page 2457.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Choose **Advanced** > **Certificate Maps**.

Step 4 Select the following options from the **General Settings for Connection Profile Mapping** pane:

Selections are priority-based, matching continues down the list of options when the first selection does not match. Matching is complete when the rules are satisfied. If the rules are not satisfied, the default connection profile listed at the bottom of this page is used for the connection. Select any, or all of the following options to establish authentication and to determine which connection profile (tunnel group) must be mapped to the client.

- **Use Group URL if Group URL and Certificate Map match different Connection profiles**
- **Use the configured rules to match a certificate to a Connection Profile**—Enable this to use the rules defined in the Connection Profile Maps.

Note Configuring a certificate mapping implies certificate-based authentication. The remote user will be prompted for a client certificate regardless of the configured authentication method.

Step 5 Under the **Certificate to Connection Profile Mapping** section, click **Add Mapping** to create certificate to connection profile mapping for this policy.

a) Choose or create a **Certificate Map Name** object.
b) Select the **Connection Profile** that want to use if the rules in the certificate map object are satisfied.
c) Click **OK** to create the mapping.

Step 6 Click **Save**.

Configuring Group Policies

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience. For example, in the group policy object, you configure general attributes such as addresses, protocols, and connection settings.

The group policy applied to a user is determined when the VPN tunnel is established. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile.

Note There is no group policy attribute inheritance on the Firewall Threat Defense. A group policy object is used, in its entirety, for a user. The group policy object identified by the AAA server upon login is used, or, if that is not specified, the default group policy configured for the VPN connection is used. The provided default group policy can be set to your default values, but will only be used if it is assigned to a connection profile and no other group policy has been identified for the user.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Choose **Advanced** > **Group Policies** > **Add**.

Step 4 Select group policies from the **Available Group Policy** list and click **Add**. You can select one or more group policies to associate with this remote access VPN policy.

Step 5 Click **OK** to complete the group policy selection.

Step 6 Save your changes.

Configure a group policy object, on page 2461

Configuring LDAP Attribute Mapping

An LDAP attribute name maps LDAP user or group attribute name to a Cisco-understandable name. The attribute map equates attributes that exist in the Active Directory (AD) or LDAP server with Cisco attribute names. You can map any standard LDAP attribute to a well-known vendor specific attribute (VSA). You can map one or more LDAP attributes to one or more Cisco LDAP attributes. When the AD or LDAP server returns authentication to the Firewall Threat Defense device during remote access VPN connection establishment, the Firewall Threat Defense device can use the information to adjust how the Secure Client completes the connection.

When you want to provide VPN users with different access permissions or VPN content, you can configure different VPN policies on the VPN server and assign these policy-sets to each user based on their credentials. You can achieve this in Firewall Threat Defense by configuring LDAP authorization, with LDAP attribute maps. In order to use LDAP to assign a group policy to a user, you must configure a map that maps an LDAP attribute.

An LDAP attribute map consists of three components:

- **Realm**—Specifies the name for the LDAP attribute map; the name is generated based on the selected realm.
- **Attribute Name Map**—Maps the LDAP user or group attribute name to Cisco-understandable name.
- **Attribute Value Map**—Maps value in the LDAP user or group attribute to the value of a Cisco attribute for the selected name mapping.

The group policies that are used in an LDAP attribute map get added to the list of group policies in the remote access VPN configuration. Removing a group policy from the remote access VPN configuration also removes the associated LDAP attribute mapping.

In versions 6.4 to 6.6, you can configure LDAP attribute maps only using FlexConfig. For more information, see Configure AnyConnect Modules and Profiles Using FlexConfig.

In versions 7.0 and later, you can use the following procedure:

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Click **Advanced** > **LDAP Attribute Mapping**.

Step 4 Click **Add**.

Step 5 On the Configure LDAP Attribute Map page, select a **Realm** to configure the attribute map.

Step 6 Click **Add**.

You can configure multiple attribute maps. Each attribute map requires that you configure a name map and value maps.

Note Ensure that you follow these guidelines while creating an LDAP attribute map:

- Configure at least one mapping for an LDAP attribute; multiple mappings with the same LDAP attribute name is not allowed.
- Configure a minimum of one name map to create an LDAP attribute map.
- You can remove any LDAP attribute map if the attribute map is not associated with any connection profile in the remote access VPN configuration.
- Use the correct spelling and capitalization in the LDAP attribute map for ***both*** the Cisco and LDAP attribute names and values.

a) Specify the **LDAP Attribute Name** and then select the required **Cisco Attribute Name** from the list.
b) Click **Add Value Map** and Specify the **LDAP Attribute Value** and **Cisco Attribute Value**.

Repeat this step to add more value maps.

Step 7 Click **OK** to complete LDAP attribute map configuration.

Step 8 Click **Save** to save the changes to the LDAP attribute mapping.

Example

For a detailed example, see Configure RA VPN with LDAP Authentication and Authorization for FTD.

Configuring VPN Load Balancing

About VPN Load Balancing

VPN load balancing in Firewall Threat Defense allows you group two or more devices logically and distribute remote access VPN sessions among the devices equally. VPN load balancing shares Secure Client VPN sessions among the devices in a load balancing group.

VPN load balancing is based on simple distribution of traffic without taking into account throughput or other factors. A VPN load-balancing group consists of two or more Firewall Threat Defense devices. One device acts as the director, and the other devices are member devices. Devices in a group do not need to be of the exact same type, or have identical software versions or configurations. Any Firewall Threat Defense device that supports remote access VPN can participate in a load balancing group. Firewall Threat Defense supports VPN load balancing with Secure Client SAML authentication.

All active devices in a VPN load-balancing group carry session loads. VPN load balancing directs traffic to the least-loaded device in the group, distributing the load among all devices. It makes efficient use of system resources and provides increased performance and high availability.

Components of VPN Load Balancing

Following are the components of VPN load balancing:

- **Load-balancing group**—A virtual group of two or more Firewall Threat Defense devices to share the VPN sessions.

  A VPN load-balancing group can consist of Firewall Threat Defense devices of the same release or of mixed releases; but the device must support remote access VPN configuration.

  See Configure Group Settings for VPN Load Balancing, on page 1465 and Configure Additional Settings for Load Balancing, on page 1465.

- **Director**—One device from the group acts a director. It distributes the load among other members in the group and participate is serving the VPN sessions.

  The director monitors all devices in the group, keeps track of how loaded each device is, and distributes the session load accordingly. The role of director is not tied to a physical device; it can shift among devices. For example, if the current director fails, one of the member devices in the group takes over that role and immediately becomes the new director.

- **Members**—Devices other than the director in a group are called members. They participate in load balancing and share the remote access VPN connections.

  Configure Settings for Participating Devices, on page 1466.

Prerequisites for VPN Load Balancing

- **Certificates**—Firewall Threat Defense's certificate must contain the IP addresses or FQDN of the director and members to which the connection is redirected. Or else, the certificate will be deemed untrusted. The certificate must use Subject Alternate Name (SAN) or wildcard certificate
- **Group URL**—Add the group URL for VPN load-balancing group IP address to the connection profiles. Specify a group URL to eliminate the need for the user to select a group at login.
- **IP Address Pool**—Choose unique IP address pool for member devices, and override the IP pool in Firewall Management Center for each of the member devices.
- Devices that are behind Network Address Translation (NAT) can also be part of a load balancing group.

Guidelines and Limitations for VPN Load Balancing

- VPN load balancing is disabled by default. You must explicitly enable VPN load balancing.
- Only the Firewall Threat Defense devices that are co-located can be added to a load-balancing group.
- A load-balancing group must have a minimum of two Firewall Threat Defense devices.
- Devices in Firewall Threat Defense high availability can participate in a load-balancing group.
- Devices that are behind Network Address Translation (NAT) can also be part of a load balancing group.
- When a member or a director device goes down, remote access VPN connections that are served by that device will be dropped. You must initiate the VPN connection again.
- Identity certificate on each device must have Subject Alternate Name (SAN) or wildcard.

Configure Group Settings for VPN Load Balancing

You can enable VPN load balancing and configure group settings that are applicable to all the members of the load-balancing group. When you create the group, you can configure participation settings for load balancing.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy that you want to update.

Step 3 Click **Advanced** > **Load Balancing**.

Step 4 Click the **Enable Load balancing between member devices** toggle button to enable load balancing. The **Edit Group Configuration** page opens. Group parameters apply to all devices under the load-balancing group.

Step 5 Specify the **Group IPv4 Address** and **Group IPv6 Address** as applicable.

The IP address that you specify here is for the entire load-balancing group and the director opens this IP address for incoming VPN connections.

Step 6 Select the **Communication Interface** for the load-balancing group. Click **Add** to add an interface group or security zone.

Communication interface is a private interface through which the director and members share information about their load.

Step 7 Enter the **UDP Port** for communication between the director and members in a group. The default port is 9023.

Step 8 Enable the **IPsec Encryption** toggle button to activate IPsec encryption for the communication between the director and members.

Enabling the encryption establishes an IPsec tunnel between the director and members using a pre-shared key.

When you upgrade or downgrade Firewall Threat Defense devices with the **IPsec Encryption** option enabled, ensure there is no configuration mismatch between the Firewall Management Center and the Firewall Threat Defense to prevent deployment failures.

Step 9 Enter **Encryption Key** for IPsec encryption and confirm the encryption key.

Step 10 Click **OK**.

Configure Additional Settings for Load Balancing

The additional settings for VPN load balancing include FQDN and IKEv2 redirection.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy that you want to update.

Step 3 Click **Advanced** > **Load Balancing**.

Step 4 Turn on the **Enable Load balancing between member devices** toggle button to enable load balancing if not done already.

Step 5 Click **Settings**.

Step 6 Turn on the **Send FQDN to peer devices instead of IP** toggle button to enable redirection using a fully qualified domain name.

By default, Firewall Threat Defense sends only IP addresses in VPN load balancing redirection to a client.

Step 7 Select one of the **IKEv2 Redirect** phases:

- **Redirect during SA authentication**
- **Redirect during SA initialization**

Step 8 Click **OK**.

Step 9 Save your changes.

Configure Settings for Participating Devices

The device participation settings determine how the devices share load in VPN load balancing. Configure a participating device by enabling VPN load balancing on the device and defining device-specific properties. These values vary from device to device. You can provide a priority number for the devices participating in load balancing. A higher priority number gives the device a better chance to become the director over other devices. But you cannot select a device to be the director of the group.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** next to the remote access VPN policy that you want to modify.

Step 3 Click **Advanced** > **Load Balancing**.

Step 4 Turn on the **Enable Load balancing between member devices** toggle button to enable load balancing if you have not enabled already.

Step 5 Configure **Device Participation** settings:

The **Device Participation** section lists all the target devices of the selected remote access VPN configuration. You can configure these devices to share the load of the incoming VPN sessions.

a) Turn on the **Load Balancing** toggle button to enable load balancing for a device and then click **Edit**.
b) Enter the device **Priority**.

By default, the device priority is set to 5. You can choose a number from 1 trough 10.

c) Specify the **IPv4 NAT** or **IPv6 NAT** address for VPN interface IP address if the device is behind NAT.
d) Click **OK**.

Step 6 Click **Save** to save the remote access VPN policy settings.

Configuring IPsec Settings for Remote Access VPNs

The IPsec settings are applicable only if you selected IPsec as the VPN protocol while configuring your remote access VPN policy. If not, you can enable IKEv2 using the Edit Access Interface dialog box. See Configure Access Interfaces for Remote Access VPN, on page 1455 for more information.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 From the list of available VPN policies, select the policy for which you want to modify the settings.

Step 3 Click **Advanced**.

The list of IPsec settings appears in a navigation pane on the left of the screen.

Step 4 Use the navigation pane to edit the following IPsec options:

a) **Crypto Maps**—The Crypto Maps page lists the interface groups on which IKEv2 protocol is enabled. Crypto Maps are auto generated for the interfaces on which IKEv2 protocol is enabled. To edit a Crypto Map, see Configure Remote Access VPN Crypto Maps, on page 1467. You can add or remove interface groups to the selected VPN policy in **Access Interface**. See Configure Access Interfaces for Remote Access VPN, on page 1455 for more information.

b) **IKE Policy**—The IKE Policy page lists all the IKE policy objects applicable for the selected VPN policy when Secure Client endpoints connect using the IPsec protocol. See IKE Policies in Remote Access VPNs, on page 1469 for more information. To add a new IKE policy, see Configure an IKEv2 policy object, on page 2472. Firewall Threat Defense supports only Secure Client IKEv2 clients. Third-party standard IKEv2 clients are not supported.

c) **IPsec/IKEv2 Parameters**—The IPsec/IKEv2 Parameters page enables you to modify the IKEv2 session settings, IKEv2 Security Association settings, IPsec settings, and NAT Transparency settings. See Configure Remote Access VPN IPsec/IKEv2 Parameters, on page 1471 for more information.

Step 5 Click **Save**.

Configure Remote Access VPN Crypto Maps

Crypto maps are automatically generated for the interfaces on which IPsec-IKEv2 protocol has been enabled. You can add or remove interface groups to the selected VPN policy in **Access Interface**. See Configure Access Interfaces for Remote Access VPN, on page 1455 for more information.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 From the list of available VPN policies, select the policy for which you want to modify the settings.

Step 3 Click the **Advanced** > **Crypto Maps**, and select a row in the table and click **Edit** to edit the Crypto map options.

Step 4 Select **IKEv2 IPsec Proposals** and select the transform sets to specify which authentication and encryption algorithms will be used to secure the traffic in the tunnel.

Step 5 Select **Enable Reverse Route Injection** to enable static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint.

Step 6 Select **Enable Client Services** and specify the port number.

The Client Services Server provides HTTPS (SSL) access to allow the Secure Client Downloader to receive software upgrades, profiles, localization and customization files, CSD, SCEP, and other file downloads required by the client. If you select this option, specify the client services port number. If you do not enable the Client Services Server, users will not be able to download any of these files that the Secure Client might need.

Note You can use the same port that you use for SSL VPN running on the same device. Even if you have an SSL VPN configured, you must select this option to enable file downloads over SSL for IPsec-IKEv2 clients.

Step 7 Select **Enable Perfect Forward Secrecy** and select the **Modulus group**.

Use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the **Modulus Group** list.

Modulus group is the Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the modulus group that you want to allow in the remote access VPN configuration:

- 1—Diffie-Hellman Group 1 (768-bit modulus).
- 2—Diffie-Hellman Group 2 (1024-bit modulus).
- 5—Diffie-Hellman Group 5 (1536-bit modulus, considered good protection for 128-bit keys, but group 14 is better). If you are using AES encryption, use this group (or higher).
- 14—Diffie-Hellman Group 14 (2048-bit modulus, considered good protection for 128-bit keys).
- 19—Diffie-Hellman Group 19 (256-bit elliptical curve field size).
- 20—Diffie-Hellman Group 20 (384-bit elliptical curve field size).
- 21—Diffie-Hellman Group 21 (521-bit elliptical curve field size).
- 24—Diffie-Hellman Group 24 (2048-bit modulus and 256-bit prime order subgroup).

Step 8 Specify the **Lifetime Duration (seconds)**.

The lifetime of the security association (SA), in seconds. When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations will be. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

You can specify a value from 120 to 2147483647 seconds. The default is 28800 seconds.

Step 9 Specify the **Lifetime Size (kbytes)**.

The volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before it expires.

You can specify a value from 10 to 2147483647 kbytes. The default is 4,608,000 kilobytes. No specification allows infinite data.

Step 10 Select the following **ESPv3 Settings**:

- **Validate incoming ICMP error messages**—Choose whether to validate ICMP error messages received through an IPsec tunnel and destined for an interior host on the private network.
- **Enable 'Do Not Fragment' Policy**—Define how the IPsec subsystem handles large packets that have the do-not-fragment (DF) bit set in the IP header, and select one of the following from the **Policy** list:
  - Copy—Maintains the DF bit.
  - Clear—Ignores the DF bit.
  - Set—Sets and uses the DF bit.
- Select **Enable Traffic Flow Confidentiality (TFC) Packets**— Enable dummy TFC packets that mask the traffic profile which traverses the tunnel. Use the **Burst**, **Payload Size**, and **Timeout** parameters to generate random length packets at random intervals across the specified SA.

Note Enabling traffic flow confidentiality (TFC) packets prevents the VPN tunnel from being idle. Thus the VPN idle timeout configured in the group policy does not work as expected when you enable the TFC packets. See Advanced group policy option fields and values, on page 2467.

  - Burst—Specify a value from 1 to 16 bytes.
  - Payload Size—Specify a value from 64 to 1024 bytes.
  - Timeout—Specify a value from 10 to 60 seconds.

Step 11 Click **OK**.

Interfaces, on page 2383

IKE Policies in Remote Access VPNs

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs). The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection. An IKE proposal is a set of algorithms that two peers use to secure the negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters are used to protect subsequent IKE negotiations.

Note Firewall Threat Defense supports only IKEv2 for remote access VPNs.

Unlike IKEv1, in an IKEv2 proposal, you can select multiple algorithms and modulus groups in one policy. Since peers choose during the Phase 1 negotiation, this makes it possible to create a single IKE proposal, but consider creating multiple, different proposals to give higher priority to your most desired options. For IKEv2, the policy object does not specify authentication, other policies must define the authentication requirements.

An IKE policy is required when you configure a remote access IPsec VPN.

Configuring Remote Access VPN IKE Policies

The IKE Policy table specifies all the IKE policy objects applicable for the selected VPN configuration when Secure Client endpoints connect using the IPsec protocol. For more information, see IKE Policies in Remote Access VPNs, on page 1469.

Note Firewall Threat Defense supports only IKEv2 for remote access VPNs.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 From the list of available VPN policies, select the policy for which you want to modify the settings.

Step 3 Click **Advanced** > **IKE Policy**.

Step 4 Click **Add** to select from the available IKEv2 policies, or add a new IKEv2 policy and specify the following:

- **Name**—Name of the IKEv2 policy.
- **Description**—Optional description of the IKEv2 policy
- **Priority**—The priority value determines the order of the IKE policy compared by the two negotiating peers when attempting to find a common security association (SA).
- **Lifetime**— Lifetime of the security association (SA), in seconds
- **Integrity**—The Integrity Algorithms portion of the Hash Algorithm used in the IKEv2 policy.
- **Encryption**—The Encryption Algorithm used to establish the Phase 1 SA for protecting Phase 2 negotiations.
- **PRF Hash**—The pseudorandom function (PRF) portion of the Hash Algorithm used in the IKE policy. In IKEv2, you can specify different algorithms for these elements.
- **DH Group**—The Diffie-Hellman group used for encryption.

Step 5 Click **Save**.

Configure Remote Access VPN IPsec/IKEv2 Parameters

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 From the list of available VPN policies, select the policy for which you want to modify the settings.

Step 3 Click **Advanced** > **IPsec**> **IPsec/IKEv2 Parameters**.

Step 4 Select the following for **IKEv2 Session Settings**:

- **Identity Sent to Peers**—Choose the identity that the peers will use to identify themselves during IKE negotiations:
  - **Auto**—Determines the IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication (not supported).
  - **IP address**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
  - **Hostname**—Uses the fully qualified domain name (FQDN) of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.
- **Enable Notification on Tunnel Disconnect**—Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA does not match the traffic selectors for that SA. Sending this notification is disabled by default.
- **Do not allow device reboot until all sessions are terminated**—Check to enable waiting for all active sessions to voluntarily terminate before the system reboots. This is disabled by default.

Step 5 Select the following for **IKEv2 Security Association (SA) Settings**:

- **Cookie Challenge**—Whether to send cookie challenges to peer devices in response to SA initiated packets, which can help thwart denial of service (DoS) attacks. The default is to use cookie challenges when 50% of the available SAs are in negotiation. Select one of these options:
  - **Custom**—Specify **Threshold to Challenge Incoming Cookies**, the percentage of the total allowed SAs that are in-negotiation. This triggers cookie challenges for any future SA negotiations. The range is zero to 100%. The default is 50%.
  - Always— Select to send cookie challenges to peer devices always.
  - Never— Select to never send cookie challenges to peer devices.
- **Number of SAs Allowed in Negotiation**—Limits the maximum number of SAs that can be in negotiation at any time. If used with Cookie Challenge, configure the cookie challenge threshold lower than this limit for an effective cross-check. The default is 100 %.
- **Maximum number of SAs Allowed**—Limits the number of allowed IKEv2 connections.

Step 6 Select the following for **IPsec Settings**:

- **Enable Fragmentation Before Encryption**—This option lets traffic travel across NAT devices that do not support IP fragmentation. It does not impede the operation of NAT devices that do support IP fragmentation.

- **Path Maximum Transmission Unit Aging**—Check to enable PMTU (Path Maximum Transmission Unit) Aging, the interval to Reset PMTU of an SA (Security Association).
- **Value Reset Interval**—Enter the number of minutes at which the PMTU value of an SA (Security Association) is reset to its original value. Valid range is 10 to 30 minutes, default is unlimited.

Step 7 Select the following for **NAT Settings**:

- **Keepalive Messages Traversal**—Select whether to enable NAT keepalive message traversal. NAT traversal keepalive is used for the transmission of keepalive messages when there is a device (middle device) located between a VPN-connected hub and spoke, and that device performs NAT on the IPsec flow. If you select this option, configure the interval, in seconds, between the keepalive signals sent between the spoke and the middle device to indicate that the session is active. The value can be from 10 to 3600 seconds. The default is 20 seconds.
- **Interval**—Sets the NAT keepalive interval, from 10 to 3600 seconds. The default is 20 seconds.

Step 8 Click **Save**.

Customize Cisco Secure Client

You can configure the Secure Client customizations using the management center and deploy them to the VPN headend. The threat defense device distributes these customizations to the endpoint when a user connects from the Secure Client. Administrators can customize the following elements at the endpoint:

Table 83: Secure Client Customizations Available in Management Center

Customization	Description	More Info
GUI text and messages	Customize or localize Secure Client GUI text and informational/error messages.	Customize and Localize Secure Client GUI Text and Messages, on page 1476
Icons and images	Customize the logo, images, or icons of the Secure Client GUI.	Customize Secure Client Icons and Images, on page 1477
Scripts	Deploy scripts on the endpoint devices when a client establishes or disconnects a VPN session.	Deploy Scripts on Endpoint Devices Using Secure Client, on page 1478
Binaries	Deploy custom applications using Secure Client APIs.	Deploy Custom Applications Using Cisco Secure Client APIs, on page 1480
Custom Installer Transforms	Customize the Secure Client installer.	Customize the Secure Client Installer, on page 1481
Localized Installer Transforms	Localize the Secure Client installer.	Localize the Client Installer, on page 1481

Overview of the customization file

The customization file is an XML-based configuration object in the Threat Defense device that controls the visual appearance and layout of Secure Client to remote VPN users. It defines:

- Branding—logos and color schemes
- Page structure—logon page and portal layout
- Content elements—titles, banners, and button labels
- Messaging—error messages and other user-facing text

By default, a Threat Defense device has two customization objects:

- Template: A blank XML template file that you can update to add the required customizations. You cannot delete this file.
- DfltCustomization: An XML file with a set of URLs and basic customization to bring up the Secure Client. This is the default customization file.

  To view these customization files, run the **show import webvpn customization** command on the Threat Defense device:

```
FTD(config)# show import webvpn customization
Template
DfltCustomization
```

Customize the customization file

To update the **Template** XML file:

1. Export the file to disk0. You can rename the file, if required.

```
FTD(config)# export webvpn customization Template disk0:ABCTemplate
```

2. Copy the XML file to a remote PC.
3. Edit the XML file with the required customizations and copy it back to disk0.
4. Import the file to the Threat Defense device.

```
FTD(config)# import webvpn customization ABCTemplate disk0:ABCTemplate
```

5. Verify the customization files in the device.

```
FTD(config)# show import webvpn customization
Template
DfltCustomization
ABCTemplate
```

Note You can also update the **DfltCustomization** file using the same procedure as above. You can also rename this file.

Upload the customization file to Management Center

1. Choose **Objects** > **Object Management** > **VPN** > **Secure Client File** and click **Add Secure Client File**.

2. In the **Add Secure Client File** dialog box, configure these parameters:
   a. In the **Name** file, enter the name of the customization file.
   b. From the **File Type** drop-down list, choose **Secure Client VPN Profile**.
   c. Click **Browse**, locate and select the customization file that you want to upload.
   d. Click **Save**.
3. Choose **Devices** > **VPN** > **Remote Access**.
4. Click the edit icon next to the remote access VPN policy.
5. Click the **Advanced** tab.
6. In the left pane, click **Group policies**.
7. Click **+** to add a group policy.
8. In the **Add Group Policy** dialog box, configure these parameters:
   a. Enter a **Name** and optionally a **Description** for this policy.
   b. Click the **Secure Client** tab, and from the **Client Profile** drop-down list, choose the customization file.
   c. Click **Save**.
9. Choose this group policy as the selected policy in the **Group Policy** dialog box, click **OK**, and click **Deploy**.

Guidelines and Limitations for Secure Client Customizations

Guidelines

- Ensure that you import the xml file to the object defined as `DfltCustomization`. When you import the customization object, the Firewall Management Center checks the XML code for validity.

  For example:

  ```
  hostname# import webvpn customization DfltCustomization
  disk0:/csm/defaultcustomizationwebvpn.xml
  ```

- Add the Windows Cisco Secure Client headend deployment package to the remote access VPN policy before deploying customization commands. This package must be included when supporting Windows, MacOS, or Linux clients.

General Limitations

- If there are any customizations earlier than 7.4 configured directly on the threat defense using the CLI, the management center removes these customizations during deployment.
- No clustering support.

Table 84: Limitations for Secure Client Customizations

Customization	Limitations

GUI Text and Message Customizations	• You must restart Secure Client before you use this customization.
	• No support for right-to-left languages.
	• Some strings are truncated in the GUI due to hardcoded field lengths.
	• Some messages are hardcoded in the client. For example:
	  • Status messages (during an update)
	  • Untrusted server messages
	  • Deferred update messages
	• Localization is version-specific.
	If an Administrator created a translation table based on a template of an old Secure Client version, the new messages do not appear to the remote users. The Administrator must merge the latest template with the translation table so that the table has the new messages. You can use third-party tools like Get text to perform the merge.

Icons and Images Customizations	• You must restart Secure Client before you use this customization. • The customization object names must match the Secure Client GUI filenames. File names are different for each operating system and are case-sensitive. For more information about the filenames, extensions, and sizes for each OS, see the Cisco Secure Client Administrator Guide. • Images do not appear properly if the image size is not correct. The management center or the threat defense device does not verify the image size. • MacOS does not support customization of Secure Client images and icons.
Deploy Customized Scripts	• Secure Client runs only one OnConnect and one OnDisconnect script; however, these scripts may launch other scripts. • Scripts can only execute functions that the user has the right to invoke. • You cannot launch the OnConnect script from the Start Before Logon (SBL) GUI.
Deploy Custom Applications Using Cisco Secure Client APIs (Binaries)	• After you use this customization, if you deploy an updated version of the Secure Client on the management center, the client will download the update and replace your custom UI.

Customization	Limitations
Customize the Client Installer	• This customization is available only for Windows.

Customize and Localize Secure Client GUI Text and Messages

You can customize the Secure Client GUI text and the informational/error messages. You also can customize the GUI text and all messages to appear in a preferred language.

Customize GUI Text and Messages

To customize the GUI text or messages, you can edit the messages in the message file. You can update the messages to include more details in the error messages. For example:

- Modify any label in the login dialog box such as **Password** to **Domain Password**.
- Add your support contact details in the error messages.

Localize GUI Text and Messages

Threat defense devices use translation tables to translate the labels and user messages displayed in the Secure Client. When a user connects to the remote access VPN, the Secure Client identifies the locale set on the endpoint and downloads the translation file. Threat defense devices support 128 locales. By default, Secure Client is installed in English.

- For Cisco Secure Client 5.0, the default localization files for various languages are part of the application.
- For AnyConnect Clients 4.x, you can download the localization files for a few languages from Cisco.com and upload them to the management center.

How to Customize Secure Client GUI Text and Messages

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Get the base template or translation file either from the Secure Client package or from Cisco.com. For example, AnyConnect.po.

Step 2 Use a text editor to add the translations or customize the labels or messages.

Step 3 Update the **msgstr** string corresponding to each **msgid**.

Step 4 Save the file.

Step 5 Create a new Secure Client Customization object.

a) Choose **Objects** > **Object Management** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization.
d) From the **Customization Type** drop-down list, choose **GUI Text and Messages**.
e) From the **Language** drop-down list, choose a language for which you are adding the translation.

f) Click **Browse** and select the translation file. The supported file extensions are .po, .mo, and .txt.

Step 6 Add the customization to the remote access VPN policy.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click the edit icon of the remote access VPN policy.
c) Click **Advanced > Secure Client Customizations > Localization**.
d) Click **+** to select the translation file.
e) Click **Add**.
f) Click **OK**.

Step 7 Click **Save**.

Step 8 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Verify the Secure Client customizations. For more information, see Verify Secure Client Customizations, on page 1482.

Customize Secure Client Icons and Images

You can customize the logo, images, and icons of the Secure Client GUI using the management center.

To customize the logo, images, and icons of the Secure Client GUI, you must create a Secure Client customization object in the management center. The name of this customization object must match the Secure Client GUI filename. File names are different for each operating system and are case-sensitive. For more information about the filenames, extensions, and sizes for each OS, see the Cisco Secure Client Administrator Guide.

For example, if you want to replace the corporate logo for Windows clients, you must create a customization object with the name as `company_logo` and add this customization object to the remote access VPN policy. If you use a different name for the customization object, the Secure Client installer does not change the component. However, if you deploy your own executable to customize the GUI, the customization object can have any name.

Location of all images files:

- Windows: **%PROGRAMFILES%\Cisco\Cisco Secure Client\res**
- Linux: **/opt/cisco/secureclient/resources** or **/opt/cisco/anyconnect/resources**
- macOS: Not supported

Note When the remote access VPN connection is established, the logo or images are downloaded to the client directory. Ensure that you restart the client for the updated logo or images to appear in your client.

How to Customize Secure Client Images and Icons

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Create the icons or images using the correct extensions, and sizes.

Images do not appear properly if the image size is not correct. The management center or the threat defense device does not verify the image size.

For more information about the filenames, extensions, and sizes, see the Cisco Secure Client Administrator Guide.

Step 2 Create a new Secure Client Customization object.

a) Choose **Objects** > **Object Management** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization object.

Ensure that the customization object name matches the Secure Client GUI filenames. For more information about the filenames, see the Cisco Secure Client Administrator Guide.

d) From the **Customization Type** drop-down list, choose **Icon and Images**.
e) From the **Platform** drop-down list, choose a platform.
f) Click **Browse** and select the file. The supported file extensions are .png, .ico, and .jpeg.
g) Repeat the steps from 2a - f to add multiple icons and images.

Step 3 Add the customization object to the remote access VPN policy.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click the edit icon of the remote access VPN policy.
c) Click **Advanced > Secure Client Customizations > Icons and Images**.
d) Click **+** to select the file.
e) Click **Add**.
f) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Verify the Secure Client customizations. For more information, see Verify Secure Client Customizations, on page 1482.

Deploy Scripts on Endpoint Devices Using Secure Client

Secure Client lets you download and run scripts when the following events occur:

- Establishment of a new client VPN session with the threat defense. The script triggered by this event is an OnConnect script because it requires this filename prefix. Reconnection of the VPN session does not trigger this script.
- Disconnection of a client VPN session with the threat defense. The script triggered by this event is an OnDisconnect script because it requires this filename prefix.

These scripts run asynchronously and do not delay the connection establishment or disconnection. They can be of any extension and must be executable on the endpoint. Secure Client identifies the OnConnect and OnDisconnect scripts by the filename. It looks for a file whose name begins with OnConnect or OnDisconnect regardless of the file extension.

Some examples of this feature are:

- Refresh the group policy upon VPN connection.
- Mount a network drive upon a VPN connection.
- Unmount a network drive upon a VPN disconnection.

To enable scripts, check the **Enable Scripting** option in the VPN profile. By default, the client does not launch scripts. The client does not require the script to be written in a specific language. It requires an application that can run the script to be installed on the client computer. For the client to launch the script, the script must run from the command line.

Secure Client can only launch scripts after the user logs in and establishes a VPN session. You cannot launch the OnConnect script from the Start Before Logon (SBL) GUI. You must check the **Enable Post SBL On Connect Script** option in the VPN profile to trigger the scripts once the user logs in. Secure Client is a 32-bit application. When the scripts run on a 64-bit Windows version, they use the 32-bit version of cmd.exe.

How to Add Customized Scripts for Secure Client

Before you begin

1. Configure a remote access VPN.
2. Enable scripting in the VPN profile.
3. Add the VPN profile to the remote access VPN group policy.

Procedure

Step 1 Create OnConnect and OnDisconnect scripts for a platform.

Step 2 Create a new Secure Client Customization object.

a) Choose **Objects** > **Object Management** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization.
d) From the **Customization Type** drop-down list, choose **Scripts**.
e) From the **Platform** drop-down list, choose a platform.
f) Select one of the following:

- **On Connect**: To select an OnConnect script.

- **On Disconnect**: To select an OnDisconnect script.

g) Click **Browse** and select the script you want to execute on the endpoint.

Step 3 Add the customization to the remote access VPN policy.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click the edit icon of the remote access VPN policy.
c) Click **Advanced > Secure Client Customizations > Localization**.
d) Click **+** to select the translation file.
e) Click **Add**.
f) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Verify the Secure Client customizations. For more information, see Verify Secure Client Customizations, on page 1482.

Deploy Custom Applications Using Cisco Secure Client APIs

For Windows, Linux, or MacOs machines, you can create and deploy a custom client that uses the Secure Client APIs. You can use this client binary file to replace the Secure Client GUI or CLI binary files.

Your executable can call any resource files such as logo images that you import to the management center. When you deploy your own executable, you can use any filenames for your resource files.

The following table lists the filenames of the client executable files for the different operating systems:

Table 85: Filenames of the Secure Client Executable Files

Client OS	Client GUI File	Client CLI File
Windows	vpnui.exe	vpncli.exe
Linux	vpnui	vpn
MacOS	Not supported by the management center deployment. However, you can deploy an executable for the macOS that replaces the client GUI using other means, such as Altiris Agent.	vpn

How to Deploy Custom Applications Using Cisco Secure Client API

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Create the custom application using the Cisco Secure Client APIs.

Step 2 Create a new Secure Client Customization object.

a) Choose **Objects** > **Object Management** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization.
d) From the **Customization Type** drop-down list, choose **Binary**.
e) From the **Platform** drop-down list, choose a platform.
f) Click **Browse** and select the custom application.

Step 3 Add the customization to the remote access VPN policy.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click the edit icon of the remote access VPN policy.
c) Click **Advanced > Secure Client Customizations > Binaries**.
d) Click **+** to select the translation file.
e) Click **Add**.
f) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Customize the Secure Client Installer

You can customize the Secure Client GUI by creating a custom transform that deploys with the client installer program. You can import the transform to the management center and deploy it to the threat defense device. The threat defense deploys this transform to the endpoint using the client installer program.

Note This customization is available only for Windows.

Localize the Client Installer

You can translate the messages displayed by the Cisco Secure Client installer. The management center uses a transform to translate the messages displayed by the installer. The transform alters the installation but leaves the original security-signed MSI intact. These transforms only translate the installer screens and do not translate the client GUI screens.

Every release of Cisco Secure Client includes a localized transform that administrators can upload to the management center whenever they upload Cisco Secure Client packages with new software. If you use our localization transform, ensure that you update them with the latest release from Cisco.com whenever you upload a new Cisco Secure Client package.

How to Customize or Localize the Client Installer

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Create a customized or localized transform.

Step 2 Create a new Secure Client Customization object.

a) Choose **Objects** > **Object Management** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization.
d) From the **Customization Type** drop-down list, choose **Customized Installer Transform** or **Localized Installer Transform**.
e) From the **Platform** drop-down list, choose a platform.
f) Click **Browse** and select the transform.

Step 3 Add the customization to the remote access VPN policy.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click the edit icon of the remote access VPN policy.
c) Click **Advanced > Secure Client Customizations > Custom Installer Transforms** or **Localized Installer Transforms**.
d) Click **+** to select the transform.
e) Click **Add**.
f) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Verify Secure Client Customizations

Validate the Deployment

After the deployment is complete, validate the deployment in the management center. Click the **Transcript Details** ( )) icon to verify the commands generated for the customizations.

Examples

1. The example below shows the transcript details of a GUI text and messages customization: Secure Client en_us localization with customized prompts.

```
import webvpn translation-table AnyConnect language en-us disk0:/AnyConnect_en-us.po
```

2. The example below shows the transcript details of customized icons and images: customization of the Secure Client logo to ABC logo.

```
import webvpn AnyConnect-customization type resource platform win name company_logo.png
 disk0:/company_logo.png
```

3. The example below shows the transcript details of the customized OnConnect and OnDisconnect scripts. The On connect script mounts the network drive and the On disconnect script unmounts the network drive.

```
import webvpn AnyConnect-customization type binary platform win name
  scripts_OnConnect_mount.bat disk0:/mount.bat
import webvpn AnyConnect-customization type binary platform win name
  scripts_OnDisconnect_unmount.bat disk0:/unmount.bat
```

Verify Customizations Using Threat Defense Commands

Use the following commands on the threat defense to verify the customizations:

- **show import webvpn translation-table detailed**: Shows the available translation tables.

```
HQ-FTD# show import webvpn translation-table detailed
 Translation Tables' Templates:
   AnyConnect           ia4DaAXNSvl5pZboQRGJcs9KMXY=
   customization
 Translation Tables:
   fr                   customization        BWWodsOt1PbvDvYOp8hLb3W7a64=
   ja                   customization        lNvUk1+qTLNZyNrBcApMQPHnm1M=
   ru                   customization        UqyKyUAcjR+xTGUtdiIFnoIiW5U=
```

- **show import webvpn AnyConnect-customization detailed**: Shows the details of the Secure Client customizations.

```
HQ-FTD# show import webvpn AnyConnect-customization detailed
OEM resources for AnyConnect client:
  linux-64/binary/scripts_OnConnect_conn.sh           w6+n7z80D/8AR+ul2f7DvTmcDTw=
  linux-64/binary/scripts_OnDisconnect_discon.sh      jx5LJC2XBEmEkGeww59CAkszvnI=
  linux-64/resource/company-logo.png                  GsfBDroqGSQEEwuBDS/3DJNVv88=
  win/binary/scripts_OnConnect_mount.bat              dzjfsLYYft/XMlPlzskKl+Wv1bw=
  win/binary/scripts_OnDisconnect_unmount.bat         k6xlKhF1l2IRyJu08+sdYXgKNgM=
  win/resource/company_logo.png                       cmEvxwqvtaS+Pz/6sb9n3NZudS4=
```

Verify Customizations in Secure Client

- In Secure Client, click the **Message History** tab to verify that the customizations are downloaded.

  Use the DART tool to view the client-side diagnostics.

Table 86: Verifying the Customizations in Secure Client

Customization	Verification
GUI text and message customizations	• Verify if Secure Client has the language localization or customized files in the following locations: • Windows: %ProgramData%\Cisco\Cisco AnyConnect Secure Mobility Client\l10n\<language-code>\LC_MESSAGES (AnyConnect versions 4.9 and earlier) • Windows: %ProgramData%\Cisco\Cisco Secure Client\l10n\<language-code>\LC_MESSAGES (Secure Client versions 5.0 and later) • For Mac OS and Linux: /opt/cisco/anyconnect/l10n/<LANGUAGE-CODE>/LC_MESSAGES /opt/cisco/secureclient/l10n/<LANGUAGE-CODE>/LC_MESSAGES • Verify the contents of the localized or customized file and confirm if they have the customized or localized strings. For example: AnyConnect.mo
Image and icon customizations	• Verify if Secure Client has the customized files in the following locations: • Windows: %PROGRAMFILES%\ Cisco\Cisco AnyConnect Secure Mobility Client\res\ (AnyConnect versions 4.10 and earlier) • Windows: %PROGRAMFILES%\ Cisco\Cisco Secure Client\UI\res (Cisco Secure Client 5.0 and above) • Linux: /opt/cisco/anyconnect/resources or /opt/cisco/secureclient/resources • Verify the content of the customized icon or image file.
Customized OnConnect and OnDisconnect scripts	• Verify if the customized scripts are in the following locations: • Windows: %ProgramData%\Cisco\Cisco Secure Client\Script (Cisco Secure Client 5.0 and above) • Windows: %ProgramData%\Cisco\ Cisco AnyConnect Secure Mobility Client\Script (AnyConnect versions 4.9 and earlier) • Mac OS and Linux: /opt/cisco/anyconnect/script or /opt/cisco/secureclient/vpn/script • Verify the script.

Configure Secure Client Management VPN Tunnel

A management VPN tunnel provides connectivity to the corporate network whenever a client system is powered up, without the VPN users having to connect to the VPN. This helps organizations keep their endpoints up-to-date with software patches and updates. Management tunnel disconnects when the user-initiated VPN tunnel is established.

This section provides information about configuring Secure Client management VPN tunnel on Firewall Threat Defense. Configuring the Secure Client management tunnel on Firewall Threat Defense using the Firewall Management Center web interface requires the following settings:

- A **Connection profile** with certificate-based authentication and a group URL.
- **Secure Client management VPN profile file**, configured a server with group URL and backup servers if required.
- A **Group policy** with the management VPN profile, split tunneling with explicitly included networks, client bypass protocol, and no banner.

For detailed instructions on configuring the Secure Client Management VPN tunnel, see Configuring Secure Client Management VPN Tunnel on Firewall Threat Defense, on page 1486.

Requirements and Prerequisites for Secure Client Management VPN Tunnel

Software and Configuration Requirements

Ensure that you have the following before you configure the Secure Client Management tunnel on using the Firewall Threat Defense using the Firewall Management Center web interface:

- Ensure that you are using Firewall Threat Defense and Firewall Management Center versions 6.7.0 or above.
- Download the Secure ClientSecure Client VPN Webdeploy package 4.7 or above and upload it to Firewall Threat Defense remote access VPN.
- Ensure that the certificate authentication is configured in the connection profile.
- Ensure that no banner is configured in the group policy.
- Check the split tunneling configuration in the management tunnel-group policy.

Certificate Requirements

- Firewall Threat Defense must have a valid identity certificate for remote access VPN and the root certificate from the local certifying authority (CA) must be present on the Firewall Threat Defense.
- Endpoints connecting to the management VPN tunnel must have a valid identity certificate.
- CA certificate for Firewall Threat Defense's identity certificate must be installed on the endpoints and the CA certificate for the endpoints must be installed on the Firewall Threat Defense.
- The identity certificate issued by the same local CA must be present in the Machine store.

  Certificate Store (For Windows) and/or in System Keychain (For macOS).

Limitations of Secure Client Management VPN Tunnel

- Secure Client Management VPN Tunnel supports only certificate authentication, it does not support AAA-based authentication.
- Public or private proxy settings are not supported.
- Secure Client upgrade and AnyConnect module download are not supported when the management VPN tunnel is connected.

Configuring Secure Client Management VPN Tunnel on Firewall Threat Defense

Procedure

Step 1 **Create a remote access VPN policy configuration using the wizard**:

For information about configuring a remote access VPN, see Configuring a New Remote Access VPN Connection, on page 1425.

Step 2 **Configure connection profile settings for management VPN tunnel**:

Note It is advisable to create a new connection profile to be used only for Secure Client management VPN tunnel.

a) Edit the remote access VPN policy you have created.
b) Select and edit the connection profile that will be used for management VPN tunnel.
c) From **AAA** drop-down menu, choose **Authentication Method** and click **Client Certificate Only**. Configure the authorization and accounting settings as required.
d) Click the **Aliases** tab of the connection profile.
e) Click **Add (+)** under URL Aliases and **URL Alias** for the connection profile.
f) Click **Enabled** to enable the URL.
g) Click **OK** and then click **Save** to save the connection profile settings.

For more information about connection profile settings, see Configure Connection Profile Settings, on page 1436.

Step 3 **Create a management tunnel profile using the Secure Client profile editor**:

a) Download the Secure Client **VPN Management Tunnel Standalone Profile Editor** from Cisco Software Download Center if you have not done already.
b) Create a management tunnel profile with the required settings for your VPN users and save the file.
c) Configure a server in the Server List with the group URL you have configured in the connection profile.

For information about creating a management profile using the Profile Editor, see the *Cisco Secure Client (including AnyConnect) Administrator Guide*.

Step 4 **Create a management tunnel object**:

a) On your Secure Firewall Management Center web interface, navigate to **Objects** > **Object Management** > **VPN** > **Secure Client File**
b) Click **Add Secure Client File**.

c) Specify the **Name** for the Secure Client file.
d) Click **Browse** and select the management tunnel profile file you have saved.
e) Click the **File Type** drop-down and select **Secure Client Management VPN Profile**.
f) Click **Save**.

Note You an also create the management tunnel object when you create or update Secure Client settings for a group policy. See Group policy options for Secure Client, on page 2464.

Step 5 **Associate a management profile with a group policy and configure group policy settings**:

You must add the management VPN profile to the group policy associated with the connection profile used for the management tunnel VPN connection. When the user connects, the management VPN profile is downloaded along with the user VPN profile already mapped to the group policy, enabling the management VPN tunnel feature.

Caution **No Banner**: Check and ensure that no banner is configured in the group policy settings. You can check the banner settings under **Group Policy** > **General Settings** > **Banner**.

a) Edit the connect profile you have created for management VPN tunnel.
b) Click **Edit Group Policy** > **Secure Client** > **Management Profile Edit Group Policy** and choose **AnyConnect Secure Client**, then click **Management Profile**.
c) Click the **Management VPN Profile** drop-down and select the management profile file object you have created.

Note You can also click + and add a new Secure Client Management VPN Profile object.

d) Click **Save**.

Step 6 **Configure split tunneling in group policy**:

a) Click **Edit Group Policy** and then choose **General**, then click **Split Tunneling**.
b) From the IPv4 or IPv6 split tunneling drop-down, select **Tunnel networks specified below**.
c) Select the Split Tunnel Network List Type: **Standard Access List** or **Extended Access List**, and then select the required access list to allow the traffic over the management VPN tunnel.
d) Click **Save** to save the split tunnel settings.

Secure Client Custom Attribute

Secure Client Management VPN tunnel requires split include tunneling configuration by default. If you are configuring Secure Client custom attribute in the group policy to deploy the management VPN tunnel with split tunneling to tunnel all, you can do so using FlexConfig because Firewall Management Center 6.7 web interface does not support Secure Client custom attribute .

The following is an example command for Secure Client custom attribute:

```
webvpn
 anyconnect-custom-attr ManagementTunnelAllAllowed description ManagementTunnelAllAllowed
anyconnect-custom-data ManagementTunnelAllAllowed true true
```

```
group-policy MGMT_Tunnel attributes
 anyconnect-custom ManagementTunnelAllAllowed value true
```

Step 7 **Deploy, verify, and monitor the remote access VPN policy**:

a) Deploy the management VPN tunnel configuration to Firewall Threat Defense.

Note Client systems must connect to the Firewall Threat Defense remote access VPN once to download the management tunnel VPN profile to the client machines.

b) You can verify the Secure Client management VPN tunnel at **AnyConnect Secure Mobility ClientSecure Mobility Client** and choose **VPN**, then click **Statistics**.

You can also check the management VPN session details on the Firewall Threat Defense command prompt using the **show vpn-sessiondb anyconnect** command.

c) On your Firewall Management Center web interface, click **Analysis** to view the management tunnel session information.

Firewall Threat Defense group policy objects, on page 2460

Multiple Certificate Authentication

Multiple certificate based authentication gives the ability to have the Firewall Threat Defense validate the machine or device certificate, to ensure the device is a corporate-issued device, in addition to authenticating the user's identity certificate to allow VPN access using the Secure Client during SSL or IKEv2 EAP phase.

The multiple certificates option allows certificate authentication of both the machine and user via certificates. Without this option, you could only do certificate authentication of either machine or the user, but not both.

Guidelines and Limitations of Multiple Certificate Authentication

Note When you configure multiple certificate authentication, ensure that you set the value of **AutomaticCertSelection** to true in the Cisco Secure Client Profile settings.

- Multiple certificate authentication currently limits the number of certificates to two.
- Secure Client must indicate support for multiple certificate authentication. If that is not the case then the gateway uses one of the legacy authentication methods or fails the connection. Secure Client version 4.4.04030 or later supports Multi-Certificate based authentication.
- Secure Client supports only RSA-based certificates.
- Only SHA256, SHA384, and SHA512 based certificate are supported during the Secure Client aggregate authentication.

- Certificate authentication cannot be combined with SAML authentication.

Configuring Multiple Certificate Authentication

Before you begin

Before you configure multiple certificate authentication, ensure that you have configured the certificate enrollment object that is used to obtain the identity certificate for each Firewall Threat Defense device. For more information, see Certificate map objects, on page 2457.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select the remote access VPN policy and click **Edit**.

Note If you have not configured a remote access VPN, click **Add** to create a new remote access VPN policy.

Step 3 Select and **Edit** a connection profile to configure multiple certificate authentication.

Step 4 Click **AAA** settings and select **Authentication Method** > **Client Certificate Only** or **Client Certificate & AAA**.

Note Select the **Authentication Server** if you have selected the Client Certificate & AAA authentication method

Step 5 Select the **Enable multiple certificate authentication** checkbox.

Step 6 Choose one of the certificates to **Map username from client certificate**:

- **First Certificate**— Select this option to map the username from the machine certificate sent from the VPN client.
- **Second Certificate**— Select this option to map the username from the user certificate sent from the client.

The username sent from the client is used as the VPN session username when certificate only authentication is enabled. When AAA and certificate authentication is enabled, VPN session username will be based on prefill option.

Note If you select the **Map specific field** option, which includes the username from the client certificate, the **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively.

If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields that can be used as the identifier when matching users to a connection profile DN rules are used for enhanced certificate authentication.

If you have selected the Client Certificate & AAA authentication, select the **Prefill username from certificate on user login window** option to prefill the secondary username from the client certificate when the user connects via AnyConnect VPN module of Cisco Secure Client.

- **Hide username in login window**: The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.

Step 7 Configure the required AAA settings and connection profile settings for the remote access VPN.

Step 8 Save the connection profile and remote access VPN configuration and deploy it on your Firewall Threat Defense device.

Customizing Remote Access VPN AAA Settings

This section provides information about customizing your AAA preferences for remote access VPNs. For more information, see Configure AAA Settings for Remote Access VPN, on page 1439.

Authenticate VPN Users via Client Certificates

You can configure remote access VPN authentication using client certificate when you create a new remote access VPN policy using the wizard or by editing the policy later.

Before you begin

Configure the certificate enrollment object that is used to obtain the identity certificate for each Firewall Threat Defense device that acts as a VPN gateway.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access policy and click **Edit**; or click **Add** to create a new remote access VPN policy.

Step 3 For a new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click **Edit**.

Step 4 Click **AAA** > **Authentication Method** > **Client Certificate Only**.

With this authentication method, the user is authenticated using a client certificate. You must configure the client certificate on VPN client endpoints. By default, the user name is derived from client certificate fields CN and OU respectively. If the user name is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.

If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display the following default values, respectively: **CN (Common Name)** and **OU (Organisational Unit)**. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields, that can be used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

- Primary and Secondary fields pertaining to the **Map specific field** option contain these common values:
  - C (Country)
  - CN (Common Name)
  - DNQ (DN Qualifier
  - EA (Email Address)
  - GENQ (Generational Qualifier)
  - GN (Given Name)
  - I (Initial)
  - L (Locality)
  - N (Name)
  - O (Organisation)
  - OU (Organisational Unit)
  - SER (Serial Number)
  - SN (Surname)
  - SP (State Province)
  - T (Title)
  - UID (User ID)
  - UPN (User Principal Name)
- Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

For more information, see Configure AAA Settings for Remote Access VPN, on page 1439.

Step 5 Save your changes.

Configure Connection Profile Settings, on page 1436

Add certificate enrollment objects, on page 2402

Configure VPN User Authentication via Client Certificate and AAA Server

When you configure remote access VPN authentication to use both client certificate and authentication server, VPN client authentication is done using both the client certificate validation and AAA server.

Before you begin

- Configure the certificate enrollment object that you use to obtain the identity certificate for each Firewall Threat Defense device that acts as a VPN gateway.
- Configure the RADIUS server group object and any AD or LDAP realms to use in the remote access VPN policy configuration.
- Ensure that the AAA Server is reachable from the Secure Firewall Threat Defense device for the remote access VPN configuration to work.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy for which you want to update the authentication or click **Add** to create new one.

Step 3 If you choose to create new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click **Edit**.

Step 4 Go to **AAA** and from the **Authentication Method** drop-down, choose **Client Certificate & AAA**.

- When you select the **Authentication Method** as:

  Client Certificate & AAA—Both types of authentication are done.

  - **AAA**—If you select the **Authentication Server** as **RADIUS**, by default, the Authorization Server has the same value. Select the **Accounting Server** from the drop-down list. Whenever you select **AD** and **LDAP** from the Authentication Server drop-down list, you must manually select the **Authorization Server** and **Accounting Server** respectively.
  - **Client Certificate**—Authenticates the user with client certificate. You must configure client certificate on the VPN client endpoints. By default, the username is derived from client certificate fields CN & OU respectively. If you use any other field in the client profile to specify the username, use **Primary Field** and **Secondary Field** to map appropriate fields.

    If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields that can be used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

    Primary and Secondary fields pertaining to the **Map specific field** option contains these common values:

- C (Country)
- CN (Common Name)
- DNQ (DN Qualifier
- EA (Email Address)
- GENQ (Generational Qualifier)
- GN (Given Name)
- I (Initial)
- L (Locality)
- N (Name)
- O (Organisation)
- OU (Organisational Unit)
- SER (Serial Number)
- SN (Surname)
- SP (State Province)
- T (Title)
- UID (User ID)
- UPN (User Principal Name)

- Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

For more information, see Configure AAA Settings for Remote Access VPN, on page 1439.

Step 5 Save your changes.

Manage Password Changes over VPN Sessions

Password management allows remote access VPN policy administrator to configure the notification settings for the remote access VPN users on their password expiry. Password management is available in AAA settings with authentication methods AAA Only and Client Certificate & AAA. For more information, see Configure AAA Settings for Remote Access VPN, on page 1439.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy that you want to update.

Step 3 Click **Edit** on the connection profile that includes AAA settings.

Step 4 Choose **AAA** > **Advanced Settings** > **Password Management**.

Step 5 Check the **Enable Password Management** check-box and select one of the following:

- Notify User - days ahead of password expiry and specify the number of days in the box.
- Notify user on the day of password expiration.

Step 6 Save your changes.

Related Topics

Send Accounting Records to the RADIUS Server

Accounting records in remote access VPN help the VPN administrator track the services that users access and the amount of network resources that they consume. Accounting information includes when user session start and stop, username, the number of bytes that pass through the device for each session, the service used, and the duration of each session.

You can use accounting alone or together with authentication and authorization. When you activate AAA accounting, the network access server reports the user activity to the configured accounting server. You can configure a RADIUS server as the accounting server so that the Firewall Management Center sends all the user activity information to the RADIUS server.

Note You can use the same RADIUS server or separate RADIUS servers for authentication, authorization, and accounting in remote access VPN AAA settings.

Before you begin

- Configure a RADIUS group object with RADIUS servers to receive authentication requests or accounting records. For more information, see RADIUS server group configuration options, on page 2346.
- Ensure that the RADIUS server is reachable from the Firewall Threat Defense device. Configure routing on your Secure Firewall Management Center at **Devices** > **Device Management**, and click **Edit** (✎). Then, click the **Routing** tab to ensure connectivity to the RADIUS server.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access policy for which you want to configure RADIUS server, or create new remote access VPN policy.

Step 3 Click **Edit** on the connection profile that includes AAA settings and choose **AAA**.

Step 4 Select the RADIUS server from the **Accounting Server** drop-down.

Step 5 Save your changes.

Delegating Group Policy Selection to Authorization Server

The group policy applied to a user is determined when the VPN tunnel is being established. You can select a group policy for a connection profile while creating a remote access VPN policy using the wizard or update the connection policy for connection profiles later. However, you can configure the AAA (RADIUS) server to assign the group policy or it is obtained from the current connection profile. If the Firewall Threat Defense device receives attributes from the external AAA server that conflicts with those configured on the connection profile, then attributes from the AAA server always take the precedence.

You can configure ISE or the RADIUS Server to set the Authorization Profile for a user or user-group by sending IETF RADIUS Attribute 25 and map to the corresponding group policy name. You can configure specific group policy to a user or user group to push a Downloadable ACL, set a banner, Restrict VLAN, and configure the advanced option of applying an SGT to the session. These attributes are applied to all users that are part of that group when the VPN connection is established.

For more information, see the Configure Standard Authorization Policies section of Cisco Identity Services Engine Administrator Guide and RADIUS Server Attributes for Secure Firewall Threat Defense, on page 1445.

Figure 399: Remote Access VPN Group Policy Selection by AAA Server

Related Topics

Configure a group policy object, on page 2461
Configure Connection Profile Settings, on page 1436

Override the Selection of Group Policy or Other Attributes by the Authorization Server

When a remote access VPN user connects to the VPN, the group policy and other attributes configured in the connection profile are assigned to the user. However, the remote access VPN system administrator can delegate the selection of group policy and other attributes to the authorization server by configuring ISE or the RADIUS Server to set the Authorization Profile for a user or user-group. Once users are authenticated, these specific authorization attributes are pushed to the Firewall Threat Defense device.

Before you begin

Ensure that you configure a remote access VPN policy with RADIUS as the authentication server.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access policy and click **Edit**.

Step 3 Select RADIUS or ISE as the authorization server if not configured already.

Step 4 Select **Advanced** > **Group Policies** and add the required group policy. For detailed information about a group policy object, see Configure a group policy object, on page 2461.

You can map only one group policy to a connection profile; but you can create multiple group policies in a remote access VPN policy. These group policies can be referenced in ISE or the RADIUS server and configured to override the group policy configured in the connection profile by assigning the authorization attributes in the authorization server.

Step 5 Deploy the configuration on the target Firewall Threat Defense device.

Step 6 On the authorization server, create an Authorization Profile with RADIUS attributes for IP address and downloadable ACLs.

When the group policy is configured in the authorization server selected for remote access VPN, the group policy overrides the group policy configured in the connection profile for the remote access VPN user after the user is authenticated.

Related Topics

Configure a group policy object, on page 2461

Deny VPN Access to a User Group

When you do not want an authenticated user or user group to be able to use VPN, you can configure a group policy to deny VPN access. You can configure a group policy in a remote access VPN policy and reference it in the ISE or RADIUS server configuration for authorization.

Before you begin

Ensure that you have configured remote access VPN using the Remote Access Policy wizard and configured authentication settings for the remote access VPN policy.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access policy and click **Edit**.

Step 3 Select **AdvancedGroup Policies**.

Step 4 Select a group policy and click **Edit** or add a new group policy.

Step 5 Select **AdvancedSession Settings** and set **Simultaneous Login Per User** to 0 (zero).
This stops the user or user group from connecting to the VPN even once.

Step 6 Click **Save** to save the group policy and then save the remote access VPN configuration.

Step 7 Configure ISE or the RADIUS server to set the Authorization Profile for that user/user-group to send IETF RADIUS Attribute 25 and map to the corresponding group policy name.

Step 8 Configure the ISE or RADIUS server as the authorization server in the remote access VPN policy.

Step 9 Save and deploy the remote access VPN policy.

Related Topics

Configure Connection Profile Settings, on page 1436

Restrict Connection Profile Selection for a User Group

When you want to enforce a single connection profile on a user or user group, you can choose to disable the connection profile so that the group alias or URLs are not available for the users to select when they connect using the AnyConnect VPN module of Cisco Secure Client.

For example, if your organization wants to use specific configurations for different VPN user groups such as mobile users, corporate-issued laptop users, or personal laptop users, you can configure connection a profile specific to each of these user groups and apply the appropriate connection profile when the user connects to the VPN.

The AnyConnect VPN module of Cisco Secure Client, by default, shows a list of the connection profiles (by connection profile name, alias, or alias URL) configured in Firewall Management Center and deployed on Firewall Threat Defense. If custom connection profiles are not configured, AnyConnect VPN module of Cisco Secure Client shows the *DefaultWEBVPNGroup* connection profile. Use the following procedure to enforce a single connection profile for a user group.

Before you begin

- On your Secure Firewall Management Center web interface, configure remote access VPN using the remote access VPN policy wizard with Authentication Method as 'Client Certificate Only' or 'Client Certificate + AAA'. Choose the username fields from the certificate.
- Configure ISE or RADIUS server for authorization and associate the group policy with the authorization server.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access policy and click **Edit**.

Step 3 Select **Access Interfaces** and disable **Allow users to select connection profile while logging in**.

Step 4 Click **Advanced Certificate Maps**.

Step 5 Select **Use the configured rules to match a certificate to a Connection Profile**.

Step 6 Select the **Certificate Map Name** or click the **Add** icon to add a certificate rule.

Step 7 Select the **Connection Profile**, and click **Ok**.
With this configuration, when a user connects from the AnyConnect VPN module of Cisco Secure Client, the user will have the mapped connection profile and will be authenticated to use the VPN.

Update the Secure Client Profile for Remote Access VPN Clients

Secure Client Profile is an XML file that contains an administrator-defined end user requirements and authentication policies to be deployed on a VPN client system as part of Secure Client. It makes the preconfigured network profiles available to end users.

You can use the GUI-based Secure Client Profile Editor, an independent configuration tool, to create them. The standalone profile editor can be used to create a new or modify existing Secure Client profile. You can download the profile editor from Cisco Software Download Center.

See the Secure Client Profile Editor chapter in the appropriate release of the Cisco Secure Client (including AnyConnect) Administrator Guide for details.

Before you begin

- Ensure that you have configured remote access VPN using the Remote Access Policy wizard and deployed the configuration on Firewall Threat Defense device. See Create a New Remote Access VPN Policy, on page 1426.
- On your Secure Firewall Management Center web interface, go to **Objects** > **Object Management** > **VPN** > **Secure Client File** and add the new Secure Client image.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access VPN policy and click **Edit**.

Step 3 Select the connection profile that includes the client profile to be edited, and click **Edit**.

Step 4 Click **Edit Group Policy** > **Secure Client** > **Profiles**.

Step 5 Select the client profile XML file from the list or click **Add** to add a new client profile.

Step 6 Save the group policy, connection profile, and then the remote access VPN policy.

Step 7 Deploy the changes.
Changes to the client profile will be updated on the VPN clients when they connect to the remote access VPN gateway.

RADIUS Dynamic Authorization

Secure Firewall Threat Defense has the capability to use RADIUS servers for user authorization of VPN remote access and firewall cut-through-proxy sessions using dynamic access control lists (ACLs) or ACL names per user. To implement dynamic ACLs for dynamic authorization or RADIUS Change of Authorization (RADIUS CoA), you must configure the RADIUS server to support them. When the user tries to authenticate, the RADIUS server sends a downloadable ACL or ACL name to the Firewall Threat Defense. Access to a given service is either permitted or denied by the ACL. Secure Firewall Threat Defense deletes the ACL when the authentication session expires.

RADIUS Server Attributes for Secure Firewall Threat Defense, on page 1445

Configuring RADIUS Dynamic Authorization

Before you begin:

- Only one interface can be configured in the security zone or interface group if it is referred in a RADIUS Server.
- A dynamic authorization enabled RADIUS server requires Secure Firewall Threat Defense 6.3 or later for the dynamic authorization to work.
- Interface selection in RADIUS server is not supported on Secure Firewall Threat Defense 6.2.3 or earlier versions. The interface option will be ignored during deployment.
- Firewall Threat Defense posture VPN does not support group policy change through dynamic authorization or RADIUS change of authorization (CoA).

Step 7	Deploy the configuration changes.	Deploy configuration changes, on page 135

Two-Factor Authentication

You can configure two-factor authentication for the remote access VPN. With two-factor authentication, the user must supply a username and static password, plus an additional item such as an RSA token or a passcode. Two-factor authentication differs from using a second authentication source in that two-factor is configured on a single authentication source, with the relationship to the RSA server tied to the primary authentication source.

Secure Firewall Threat Defense supports RSA tokens and Duo Push authentication requests to Duo Mobile for the second factor in conjunction with any RADIUS or AD server as the first factor in the two-factor authentication process.

Configuring RSA Two-Factor Authentication

About this task:

You can configure the RADIUS or AD server as the authentication agent in the RSA server, and use the server in Secure Firewall Management Center as the primary authentication source in the remote access VPN.

When using this approach, the user must authenticate using a username that is configured in the RADIUS or AD server, and concatenate the password with the one-time temporary RSA token, separating the password and token with a comma: *password*,*token*.

In this configuration, it is typical to use a separate RADIUS server (such as one supplied in Cisco ISE) to provide authorization services. You would configure the second RADIUS server as the authorization and, optionally, accounting server.

Before you begin:

Ensure that the following configurations are complete before configuring RADIUS two-factor authentication on Secure Firewall Threat Defense:

On the RSA Server

- Configure RADIUS or Active Directory server as an authentication agent.
- Generate and download the configuration (*sdconf.rec*) file.
- Create a token profile, assign the token to the user, and distribute the token to the user. Download and install the token on the remote access VPN client system.

For more information, see RSA SecureID Suite documentation.

On the ISE Server

- Import the configuration (*sdconf.rec*) file generated on the RSA server.
- Add the RSA server as the external identity source and specify the shared secret.

	Do This	More Info
Step 1	Log on to your Secure Firewall Management Center web interface.	

	Do This	More Info
Step 2	Create a RADIUS server group.	RADIUS server group configuration options, on page 2346
Step 3	Create a RADIUS Server object within the new RADIUS server group, with RADIUS or AD server as the host and with a timeout of 60 seconds or more.	RADIUS server group configuration options, on page 2346 **Note** The RADIUS or AD server must be the same server that is configured as the authentication agent in RSA server. For two-factor authentication, make sure that the timeout is updated to 60 seconds or more in the Secure Client Profile XML file as well.
Step 4	Configure a new remote access VPN policy using the wizard or edit an existing remote access VPN policy.	Create a New Remote Access VPN Policy, on page 1426
Step 5	Select RADIUS as the authentication server and then select the newly-created RADIUS server group as the authentication server.	Configure AAA Settings for Remote Access VPN, on page 1439
Step 7	Deploy the configuration changes.	Deploy configuration changes, on page 135

Configuring Duo Two-Factor Authentication

About this task:

You can configure the Duo RADIUS server as the primary authentication source. This approach uses the Duo RADIUS Authentication Proxy. (You cannot use a direct connection with the Duo Cloud Service over LDAPS.)

For the detailed steps to configure Duo, see https://duo.com/docs/cisco-firepower.

You would then configure Duo to forward authentication requests directed to the proxy server to use another RADIUS server, or an AD server, as the first authentication factor, and the Duo Cloud Service as the second factor.

When using this approach, the user must authenticate using a username that is configured on both the Duo Cloud or web server, and the associated RADIUS server. The user must enter the password configured in the RADIUS server, followed by one of the following Duo codes:

- **Duo-passcode**. For example, *my-password*,123456.
- **push**. For example, *my-password*,**push**. Use push to tell Duo to send a push authentication to the Duo Mobile app, which the user must have already installed and registered.
- **sms**. For example, *my-password*,**sms**. Use **sms** to tell Duo to send an SMS message with a new batch of passcodes to the user's mobile device. The user's authentication attempt will fail when using **sms**. The user must then re-authenticate and enter the new passcode as the secondary factor.
- **phone**. For example, *my-password*,**phone**. Use **phone** to authenticate using phone callback.

For more information on login options with examples, see https://guide.duo.com/anyconnect.

Before you begin:

Before configuring two-factor authentication with Duo Authentication Proxy on Firewall Threat Defense, ensure that you complete the following configurations:

- Configure a working primary authentication (RADIUS or AD) for your remote access VPN users before you begin to deploy Duo.
- Install Duo proxy service on a Windows or Linux machine within your network to integrate Duo with Secure Firewall Threat Defense remote access VPN. This Duo proxy server also acts as a RADIUS server.

  Download and install the most recent Duo authentication proxy from the following location:

  - **Windows**: https://dl.duosecurity.com/duoauthproxy-latest.exe
  - **Linux**: https://dl.duosecurity.com/duoauthproxy-latest-src.tgz
  - Verify the checksum at https://duo.com/docs/checksums#duo-authentication-proxy.

- Configure Duo authentication file `authproxy.cfg`. Follow instructions on the https://duo.com/docs/cisco-firepower#configure-the-proxy page to configure the authentication configuration settings.

  The `authproxy.cfg` configuration file must contain the details for RADIUS or ISE server, Firewall Threat Defense device, Duo proxy server details, Integration Key, Secret key, and API host details.
- Ensure that you have the right API host information in the `authproxy.cfg` file.
- Configure other required settings such as secondary authentication factor in the newly installed Duo proxy server at **Duo Security Server** > **Duo Admin Panel** > **Applications** > **CISCO RADIUS VPN**.

Table 89: Procedure

	Do This	More Info
Step 1	Log on to your Secure Firewall Management Center web interface.	
Step 2	Create a RADIUS server group.	RADIUS server group configuration options, on page 2346
Step 3	Create a RADIUS Server object within the new RADIUS server group with Duo proxy server as the host with a timeout of 60 seconds or more.	Configure RADIUS server options, on page 2347 **Note** For two-factor authentication, make sure that the timeout is updated to 60 seconds or more in the Secure Client Profile XML file as well.
Step 4	Configure a new remote access VPN policy using the wizard or edit an existing remote access VPN policy.	Create a New Remote Access VPN Policy, on page 1426
Step 5	Select RADIUS as the authentication server and then select the RADIUS server group created with the Duo proxy server as the authentication server.	Configure AAA Settings for Remote Access VPN, on page 1439

Step 7	Deploy the configuration changes.	Deploy configuration changes, on page 135

Secondary Authentication

Secondary authentication or double authentication in Secure Firewall Threat Defense adds an additional layer of security to remote access VPN connections by using two different authentication servers. With secondary authentication enabled, the Secure Client VPN users must provide two sets of credentials to login to the VPN gateway.

Secure Firewall Threat Defense remote access VPN supports secondary authentication in AAA Only and Client Certificate & AAA authentication methods.

Figure 400: Remote Access VPN Secondary or Double Authentication

Related Topics

Configure Remote Access VPN Secondary Authentication, on page 1504

Configure Remote Access VPN Secondary Authentication

When remote access VPN authentication is configured to use both client certificate and authentication sever, VPN client authentication is done using both the client certificate validation and AAA server.

Before you begin

- Configure two authentication (AAA) servers— the primary and secondary authentication servers, and required identity certificates. The authentication servers can be RADIUS server, and AD or LDAP realms.
- Ensure that the AAA servers are reachable from the Secure Firewall Threat Defense device for the remote access VPN configuration to work. Configure routing (at **Devices** > **Device Management**, click **Edit** (). Then, click **Device > Routing**) to ensure connectivity to the AAA servers.

Procedure

Step 1 On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access** .

Step 2 Select a remote access policy and click **Edit**; or click **Add** to create a new remote access VPN policy.

Step 3 For a new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click **Edit**.

Step 4 Click **AAA** > **Authentication Method**, **AAA** or **Client Certificate & AAA**.

- When you select the **Authentication Method** as:

  Client Certificate & AAA—Authentication is done using both client certificate and AAA server.

  - **AAA**—If you select the **Authentication Server** as **RADIUS**, by default, the Authorization Server has the same value. Select the **Accounting Server** from the drop-down list. Whenever you select **AD** and **LDAP** from the Authentication Server drop-down list, you must manually select the **Authorization Server** and **Accounting Server** respectively.
  - Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

- **Use secondary authentication** — Secondary authentication is configured in addition to primary authentication to provide additional security for VPN sessions. Secondary authentication is applicable only to **AAA only** and **Client Certificate & AAA** authentication methods.

  Secondary authentication is an optional feature that requires a VPN user to enter two sets of username and password on the Secure Client login screen. You can also configure to pre-fill the secondary username from the authentication server or client certificate. Remote access VPN authentication is granted only if both primary and secondary authentications are successful. VPN authentication is denied if any one of the authentication servers is not reachable or one authentication fails.

  You must configure a secondary authentication server group (AAA server) for the second username and password before configuring secondary authentication. For example, you can set the primary authentication server to an LDAP or Active Directory realm and the secondary authentication to a RADIUS server.

Note By default, secondary authentication is not required.

Authentication Server— Secondary authentication server to provide secondary username and password for VPN users.

Select the following under **Username for secondary authentication**:

- **Prompt**: Prompts the users to enter the username and password while logging on to VPN gateway.
- **Use primary authentication username**: The username is taken from the primary authentication server for both primary and secondary authentication; you must enter two passwords.
- **Map username from client certificate**: Prefills the secondary username from the client certificate.
  - If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity.

    See **Authentication Method** descriptions for more information about primary and secondary field mapping.
  - **Prefill username from certificate on user login window**: Prefills the secondary username from the client certificate when the user connects via Secure Client.
    - **Hide username in login window**: The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.
- **Use secondary username for VPN session**: The secondary username is used for reporting user activity during a VPN session.

For more information, see Configure AAA Settings for Remote Access VPN, on page 1439.

Configure Connection Profile Settings, on page 1436

Single Sign-On Authentication with SAML 2.0

About SAML Single Sign-On Authentication

Security Assertion Markup Language (SAML) is an open standard for logging users into applications using their sessions in another context. Organizations already know the identity of users when users log in to their Active Directory (AD) domain or the intranet. They use this identity information to log in users to other applications, such as web-based applications using SAML. Individual applications do not need to store credentials and users do not have to remember and manage different sets of credentials for individual applications. SAML single sign-on (SSO) works by transferring the user's identity from one place (the identity provider) to another (the service provider).

SAML Single Sign-On with Secure Firewall Threat Defense

The Secure Firewall Threat Defense device supports SAML 2.0 single sign-on (SSO) authentication for remote access VPN connections using the Secure Client. You need the following to configure SAML 2.0 SSO on Secure Firewall Threat Defense:

- **Identity Provider (IdP)**—The Duo Access Gateway acts as the identity provider to perform user authentication and issues assertions.
- **Service Provider (SP)**—The Firewall Threat Defense device acts as the service provider and obtains the authentication assertion from the identity provider.

- **VPN Client**—The Secure Client performs SAML 2.0 authentication via the embedded browser.

Guidelines and Limitations for SAML 2.0

- Firewall Threat Defense supports the following signatures for SAML authentication:
  - SHA1 with RSA and HMAC
  - SHA2 with RSA and HMAC
- Firewall Threat Defense supports SAML 2.0 Redirect-POST binding , which is supported by all SAML IdPs.
- The Firewall Threat Defense functions as a SAML SP only. It cannot act as an Identity Provider in gateway mode or peer mode.
- You can enforce an access policy on a SAML-authenticated user if you have an associated identity policy with an AD realm matching the SAML domain. However, it does not work for Azure AD SAML because it requires additional mapping from the tenant ID of the Azure AD to an associated realm ID on the threat defense device.
- Having SAML authentication attributes available in DAP evaluation (similar to RADIUS attributes sent in RADIUS auth response from AAA server) is not supported. Firewall Threat Defense supports SAML enabled group policy on DAP policy; however, you cannot check the username attribute while using SAML authentication, because the username attribute is masked by the SAML Identity provider.
- Firewall Threat Defense administrators need to ensure clock synchronization between the Firewall Threat Defense and the SAML IdP for proper handling of authentication assertions and proper timeout behavior.
- Firewall Threat Defense administrators have the responsibility to maintain a valid signing certificate on both Firewall Threat Defense and IdP considering the following:
  - The IdP signing certificate is mandatory when configuring an IdP on the Firewall Threat Defense.
  - The Firewall Threat Defense does not do a revocation check on the signing certificate received from the IdP.
- In SAML assertions, there are NotBefore and NotOnOrAfter conditions. The Firewall Threat Defense SAML configured timeout interacts with these conditions as follows:
  - Timeout overrides NotOnOrAfter if the sum of NotBefore and timeout is earlier than NotOnOrAfter.
  - If NotBefore + timeout is later than NotOnOrAfter, then NotOnOrAfter takes effect.
  - If the NotBefore attribute is absent, the Firewall Threat Defense denies the login request. If the NotOnOrAfter attribute is absent and SAML timeout is not set, Firewall Threat Defense denies the login request.
- Firewall Threat Defense does not work with Duo in a deployment using an internal SAML, which forces the Firewall Threat Defense to proxy for the client to authenticate, due to the FQDN change that occurs during challenge/response for Two-factor authentication (push, code, password).
- When using SAML with Secure Client, follow these guidelines:
  - Untrusted server certificates are not allowed in the embedded browser.
  - The embedded browser SAML integration is not supported in CLI or SBL modes.

- SAML authentication established in a web browser is not shared with Secure Client and vice versa.
- Depending on the configuration, various methods are used when connecting to the headend with the embedded browser. For example, while Secure Client might prefer an IPv4 connection over an IPv6 connection, the embedded browser might prefer IPv6, or vice versa. Similarly, Secure Client may fall back to no proxy after trying proxy and getting a failure, while the embedded browser may stop navigation after trying proxy and getting a failure.
- You must synchronize your Firewall Threat Defense's Network Time Protocol (NTP) server with the IdP NTP server in order to use the SAML feature.
- You cannot access internal servers with SSO after logging in using an internal IdP.
- The SAML IdP NameID attribute determines the user's username and is used for authorization, accounting, and VPN session database.

- SAML does not support Start Before Logon (SBL).
- Multiple attributes received with a SAML assertion are not supported.
- A firewall uses the Identity Provider Entity ID as the SAML object name from the single sign-on server object created in the Firewall Management Center (**Objects** > **Object Management** > **AAA Server** > **Single Sign-on Server**). Hence, you cannot use multiple SAML objects with the same Identity Provider Entity ID on a single firewall.

Configuring a SAML Single Sign-On Authentication

Before you begin

Ensure that you have done the following before you configure SAML single sign-on with Firewall Threat Defense remote access VPN:

- Create an account with Duo.
- Download and install the Duo Access Gateway.
- Obtain the following from your SAML identity provider (Duo).
  - Identity Provider Entity ID URL
  - Sign-in URL
  - Sign-out URL
  - Identity provider certificate
- Create a SAML single sign-on server object. For more information, see Add a single sign-on server, on page 2349.

Note You can create a single sign-on server object in the **Connection Profile** settings when you create a new policy using the Remote Access VPN policy Wizard.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** next to the remote access VPN policy for which you want to configure SAML authentication. If you want to create a new policy, click **Add**.

Step 3 Click **Edit** on the connection profile that you want to modify.

Step 4 Choose **AAA** settings and select **SAML** from the **Authentication Method** drop-down.

Step 5 Choose the required SAML single sign-on server as the **Authentication Server**.

Step 6 Configure the required settings for the remote access VPN.

Step 7 Save and deploy the remote access VPN policy on your Firewall Threat Defense device.

Configure AAA Settings for Remote Access VPN, on page 1439

Configuring SAML Authorization

About SAML Authorization

SAML authorization supports user attributes delivered in SAML assertions within the AAA and Dynamic Access Policy (DAP) frameworks. You can configure the SAML assertion attributes on the Identity Provider as name-value pairs which then parses as strings. The attributes received are made available to DAP so that they can be used when defining selection criteria within a DAP record. The SAML assertion *cisco_group_policy* is used to determine the Group Policy to be applied to the VPN session.

Dynamic Access Policy Attribute Representation

In the DAP table, the DAP attributes are represented in the following format:

```
aaa.saml.name = "value”
```

Example, *aaa.saml.department = ”finance"*

This attribute can be used in DAP selection as follows:

```
<attr>
<name>aaa.saml.department</name>
<value>finance</value>
<operation>EQ</operation>
</attr>
```

Multi-Valued Attributes

Multi-valued attributes are also supported in DAP and the DAP table is indexed :

```
aaa.saml.name.1 = "value”
aaa.saml.name.2 = "value"
```

Active Directory memberOf Attributes

The Active Directory (AD) memberOf attribute receives a special processing that is consistent with the way it is handled through an LDAP query.

Group names are represented by the CN attribute of the DN.

Example Attributes received from the authorization server:

```
memberOf = "CN=FTD-VPN-Group,OU=Users,OU=TechspotUsers,DC=techspot,DC=us"
 memberOf = "CN=Domain Admins,OU=Users,DC=techspot,DC=us”
```

Dynamic Access Policy attributes:

```
aaa.saml.memberOf.1 = "FTD-VPN-Group”
aaa.saml.memberOf.2 = "Domain Admins"
```

Interpretation of the cisco_group_policy Attribute

A group-policy can be specified by a SAML assertion attribute. When an attribute "cisco_group_policy" is received by the Firewall Threat Defense, the corresponding value is used to select the connection group-policy

Configure SAML Authorization

Before you begin

Ensure that you have configured a single sign-on server like DUO and completed the required Identity Provider (IdP) and Service Provider (SP) settings.

For more information, see Single Sign-On Authentication with SAML 2.0, on page 1506.

Procedure

Step 1 Configure a single sign-on server object if not configured already.

a) Choose **Objects** > **Object Management** > **AAA Server** > **Single Sign-on Server**.
b) Click **Add Single Sign-on Server**.
c) Enter the single sign-on server details and click **Save**.

For more information, see Add a single sign-on server, on page 2349.

Step 2 Configure SAML authentication in the remote access VPN connection profile.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click **Edit** on the remote access VPN policy for which you want to configure SAML authorization or create a new policy.
c) Edit the required connection profile and select **AAA**.
d) Select the single sign-on server object from the **Authentication Server** drop-down.
e) Save the remote access VPN configuration.

Step 3 Match a SAML criteria in DAP policy.

a) Select **Devices** > **VPN** > **Dynamic Access Policy**.
b) Create a new DAP or edit an existing one.
c) Create a DAP record or edit and existing record.
d) Click **AAA Criteria** > **SAML Criteria** > **Add SAML Criteria**.
e) Create a SAML criteria based on the SAML assertions returned by the SSO server.

Step 4 Deploy the remote access VPN configuration.

Advanced Secure Client Configurations

Configure Secure Client Modules on a Firewall Threat Defense

Secure Client can integrate with various Cisco endpoint security solutions and offer enhanced security using different Secure Client modules.

You can use the managed headend Firewall Threat Defense to distribute and manage Secure Client modules to the endpoints. When a user connects to the Firewall Threat Defense, it downloads and installs Secure Client and the required modules on the endpoint.

In version 6.7 and later, you can use the headend Firewall Threat Defense, managed by a Firewall Management Center, to distribute and manage Secure Client modules to the endpoints. These modules then integrate with the corresponding Cisco endpoint security solution.

In versions 6.4 to 6.6, you can enable these modules and profiles on a Firewall Threat Defense using FlexConfig. For more information, see Configure AnyConnect Modules and Profiles Using FlexConfig.

Benefits

If you use a Firewall Threat Defense to distribute and manage Secure Client modules to the endpoints, you can easily perform the following tasks:

- Distribute and manage Secure Client modules and profiles on each endpoint.
- Upgrade Secure Client on each endpoint.

Types of Secure Client Modules

AMP Enabler

Use this module to deploy Secure Endpoint, on endpoints. The module pushes Secure Endpoint to endpoints from a server hosted locally within the enterprise. This module provides an additional security agent that detects potential malware threats in the network, removes these threats, and protects the enterprise.

In Cisco Secure Client 5.0, AMP Enabler is only for macOS. Cisco Secure Client for Windows offers full integration with Cisco Secure Endpoint.

ISE Posture

Use this module to perform endpoint posture checks such as antivirus, antispyware, operating system and so on using Cisco Identity Services Engine (ISE) and assess the endpoint's compliance. ISE provides next generation identity and access control policy. ISE Posture performs a client-side evaluation. The client receives the posture requirement policy from the headend, performs the posture data collection, compares the results against the policy, and sends the assessment results back to the headend.

Network Visibility

Use this module to monitor the endpoint application usage using the Network visibility module. You can uncover potential behavior anomalies and make informed network design decisions. It enhances the enterprise administrator's ability to do capacity and service planning, auditing, compliance, and security analytics. You can share the usage data with NetFlow analysis tools such as Cisco Stealthwatch.

Umbrella Roaming Security

Use this module for a DNS-layer security using the Cisco Umbrella Roaming Security service. Cisco Umbrella provides content filtering, multiple policies, robust reporting, active directory integration, and much more.

Web Security

Use this module to enable Cisco Secure Web Appliance (SWA), powered by Cisco Talos. This module protects the endpoint by blocking risky sites and testing unknown sites before allowing users to access them. It can deploy web security either through the on-prem WSA or the cloud-based Cisco Cloud Web Security. This module is not part of the AnyConnect package from release 4.5 and in Secure Client 5.0.

Network Access Manager

This module provides a secure layer 2 network and performs device authentication to access wired and wireless networks. Network Access Manager manages user and device identity and the network access protocols required for secure access.

Network Access Manager is not supported on macOS or Linux.

Start Before Login

Start Before Login (SBL) allows users to establish their VPN connection to the enterprise infrastructure before logging onto Windows. After the SBL module installation, you must enable SBL in the Secure Client VPN profile and add it to the remote access VPN group policy.

DART

Diagnostics and Reporting Tool (DART) collates system logs and other diagnostic information to troubleshoot AnyConnect installation and connection problems. You can send this data to Cisco TAC for troubleshooting.

By default, DART is not enabled in new RA VPN group policies for 6.7 and later versions. In 6.6 and earlier versions, DART is enabled by default.

Feedback

The customer experience feedback (CEF) module provides information about which features and modules you use and have enabled. This information gives an insight into the user experience so that Cisco can continue to improve the quality, reliability, performance, and user experience of the Cisco Secure Client. Secure Client does not download the Feedback module to the endpoint. The feedback data is sent to the Cisco Feedback Server.

Prerequisites for Configuring Secure Client Modules

- Configure the associated products depending on the module that you are going to use.
- Download the following Secure Client-related packages from Cisco Software Download Center to your local host.

- Cisco Secure Client Headend Deployment Package for the required platforms.

  This package is for the headend and contains all the Secure Client modules. For Windows, the filename is cisco-secure-client-win-5.0.03076-webdeploy-k9.pkg.

- Profile Editor: Create profiles for the modules that require profiles.

  Secure Client needs a Secure Client profile for some of the modules. A profile contains configurations to enable the modules and connect to the corresponding security services. The profile editor supports only Windows.

  The following table lists if the modules require a client profile:

Secure Client Module	Requires a Client Profile
AMP Enabler	Yes
ISE Posture	Yes
Network Access Manager	Yes
Network Visibility Module	Yes
Umbrella Roaming Secure Module	Yes
Feedback	Yes
Web Security	Yes
DART	No
Start Before Login	No

- Licensing
  - You need one of the following Secure Client licenses: Secure Client Premier, Secure Client Advantage, or Secure Client VPN Only
  - Your Firewall Management Center Essentials license must allow export-controlled functionality.

    Choose **System** (⚙) > **Licenses** > **Smart Licenses** to verify this functionality in the management center.

Guidelines for Configuring Secure Client Modules

- All Secure Client modules are supported from AnyConnect 4.8 and later, and Secure Client 5.0.
- Different modules support profiles with different file extensions. The following table lists the modules and the supported file extensions of their profiles:

Table 90: Supported File Extensions of Profiles

Module	File Extension
AMP Enabler	*.xml, *.asp

Module	File Extension
Feedback	*.xml
ISE Posture	*.xml, *.isp
Network Access Manager	*.xml, *.nsp
Network Visibility	*.xml, *.nvmsp
Umbrella Roaming Security	*.xml, *.json
Web Security	*.xml, *.wsp, *.wso

- You can add only one entry per client module. You can edit or delete an entry for a module.
- If you plan to use ISE posture and Network Access Manager modules on a Windows OS, you must install Network Access Manager before you use the ISE Posture module.
- If you enable the Umbrella Roaming Security module, ensure that you disable the **Always send DNS requests over tunnel** option under split tunnelling in the VPN group policy.
- If you want to use SBL, then you must enable SBL in the Secure Client VPN profile.

Install Secure Client Modules using a Firewall Threat Defense

Before you begin

Ensure that you review the Prerequisites for Configuring Secure Client Modules, on page 1512 and Guidelines for Configuring Secure Client Modules, on page 1513 topics.

Procedure

Step 1 The administrator creates profiles, if needed, for the required Secure Client modules.

Step 2 The administrator uses the Firewall Management Center to:

a) Configure the modules and add the profiles in the remote access VPN group policy.

b) Deploy the configuration on the Firewall Threat Defense.

Step 3 The user uses Secure Client to initiate a VPN connection to the Firewall Threat Defense.

Step 4 The Firewall Threat Defense authenticates the user.

Step 5 The Secure Client checks for updates.

Step 6 The Firewall Threat Defense distributes the Secure Client modules and the profiles on the endpoint.

What to do next

Configure a Remote Access VPN Group Policy with Secure Client Modules, on page 1515.

Configure a Remote Access VPN Group Policy with Secure Client Modules

To install and update the Secure Client modules on the endpoint using a Firewall Threat Defense managed by a Firewall Management Center, you must update the remote access VPN group policy with the Secure Client module configurations.

Before you begin

Ensure that you have configured a remote access VPN policy in the Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access VPN policy and click **Edit**.

Step 3 Select a connection profile and click **Edit**.

Step 4 Click **Edit Group Policy**.

Step 5 Click the **Secure Client** tab.

Step 6 Click **Client Modules**.

Step 7 Click **+**.

Step 8 Choose a module from the **Client Module** drop-down list.

Step 9 Choose a profile for the module from the **Profile to download** drop-down list or click **+** to add a profile.

Step 10 Check the **Enable module download** check box to download the module on the endpoint.

Step 11 Click **Add**.

Step 12 Repeat steps 7 to 11 if you want to add more modules.

Step 13 Click **Save**.

What to do next

1. Deploy the configuration on the threat defense.
2. Launch the Secure Client, select the VPN profile, and connect to the VPN. Secure Client installs the configured modules on it.
3. Verify the configuration. For more information, see Verify Secure Client Modules Configuration, on page 1515.

Verify Secure Client Modules Configuration

On the Firewall Threat Defense

Use the following commands on the Firewall Threat Defense to view the profiles and the Secure Client modules configuration:

- **show disk0:**- View the profiles and their configuration.
- **show run webvpn** - View details of the Secure Client configurations.

- **show run group-policy <ravpn_group_policy_name>** - View details of the RA VPN group policy for Secure Client.
- **show vpn-sessiondb anyconnect** - View details of the active Secure Client VPN sessions.

On the Endpoint

1. Use the Secure Client to establish a VPN connection to the Firewall Threat Defense.
2. Verify if the configured modules are downloaded and installed as part of the Secure Client.
3. Verify if the configured profiles, if any, are available in the locations documented in Profile Locations for all Operating Systems.

On the Firewall Management Center

You can monitor remote access VPN active sessions on the Firewall Management Center using the Remote Access VPN dashboard (**Overview** > **Dashboards** > **Remote Access VPN**). You can quickly determine problems related to user sessions and mitigate the problems for your network and users.

Configure Application-Based (Per App VPN) Remote Access VPN on Mobile Devices

When you use Secure Client to establish a VPN connection from a mobile device, all the traffic including the traffic from personal applications is routed through the VPN.

For mobile devices that run on Android or iOS, you can restrict the applications that use the VPN tunnel. This application-based remote access VPN is called Per App VPN. To use Per App VPN, you must install and configure a third-party Mobile Device Manager (MDM) application. You must define the list of approved applications that can be used over the VPN tunnel in the MDM. You can enable Per App VPN on the Firewall Threat Defense headend so that your MDM can apply your policies on mobile devices.

Benefits

Benefits of restricting the remote access VPN to approved applications include:

- Performance—Limits VPN traffic over the corporate network and frees up resources of the VPN headend.
- Protection—Protects the corporate VPN tunnel from unapproved malicious applications on the mobile device.

Prerequisites and Licensing for Configuring Per App VPN Tunnels

Prerequisites

- Install and configure a third-party Mobile Device Manager (MDM).

  You must configure the applications that will be allowed in the VPN in the MDM itself, not on the Firewall Threat Defense headend device.

- Download the Cisco AnyConnect Enterprise Application Selector from Cisco Software Download Center.

  You need this tool to define the Per App VPN policy.

Licensing

- Secure Client Premier, or Secure Client Advantage.
- Essentials license must allow export-controlled functionality.

  To verify this functionality in the Firewall Management Center, choose **System** (⚙) > **Licenses** > **Specific Licenses**.

Determine the Application IDs for Mobile Applications

Before configuring the Firewall Threat Defense headend to allow application-based VPN from mobile devices, you must determine which applications should be allowed in the tunnel.

We strongly recommend that you configure the per-app policy in the MDM on the user's mobile device. This simplifies the headend configuration. If you decide to configure the list of allowed applications on the headend, you must determine the application IDs for each application on each type of endpoint.

The application ID, called the bundle ID in iOS, is a reverse DNS name. You can use an asterisk as a wildcard. For example, *.* indicates all applications, com.cisco.* indicates all Cisco applications.

To determine the application IDs:

- **Android**—Go to Google Play in a web browser and select the Apps category. Click (or hover over) an application that you want to allow, then look at the URL. The app id is in the URL, on the **id=** parameter. For example, the following URL is for Facebook Messenger, so the app id is com.facebook.orca.

  https://play.google.com/store/apps/details?id=com.facebook.orca

  For applications that are not available through Google Play, such as your own applications, download a package name viewer application to extract the app ID. There are many of these applications available, one of them should provide what you need, but Cisco does not endorse any of them.

- **iOS**—There is no straight-forward way to get the bundle ID. Following is one way to find it:

  1. Use a desktop web browser such as Chrome to search for the application name.
  2. In the search results, look for the link to download the app from the Apple App Store. For example, Facebook Messager would be similar to:

     https://apps.apple.com/us/app/messenger/id454638411
  3. Copy the number after the **id** string. In this example, **454638411**.
  4. Open a new browser window, and add the number to the end of the following URL:

     https://itunes.apple.com/lookup?id=

     For this example: https://itunes.apple.com/lookup?id=454638411
  5. You will be prompted to download a text file, usually named 1.txt. Download the file.
  6. Open the file in a text editor such as WordPad, and search for bundleId. For example:

     "bundleId":"com.facebook.Messenger",

     In this example, the bundle ID is com.facebook.Messenger. Use this as the app ID.

Once you have your list of application IDs, you can configure the policy as explained in .

Configure Application-Based VPN Tunnels

After you install and configure your MDM software, you can enable Per App VPN on the Firewall Threat Defense headend device. Once enabled on the headend, your MDM software will control which applications are tunneled over the VPN to the corporate network.

Before you begin

- Ensure that you have a remote access VPN policy in the Firewall Management Center.
- Configure Per App VPN using MDM and enroll each device to the MDM server.
- Download the Cisco AnyConnect Enterprise Application Selector.

Procedure

Step 1 Use the Cisco AnyConnect Enterprise Application Selector to define the Per App VPN policy.

We recommend that you create a simple **Allow All** policy, and define the allowed applications in the MDM. However, you can specify a list of applications to allow and control the list from the headend. If you want to include specific applications, create a separate rule for each application, using a unique name and the application's app ID. For more information on getting the app IDs, see Determine the Application IDs for Mobile Apps.

To create an **Allow All** policy that supports both Android and iOS platforms using the AnyConnect Enterprise Application Selector:

a) Choose **Android** from the drop-down list as the platform type and configure the following options:
   - **Friendly Name**—Enter a name for the policy. For example, Allow_All.
   - **App ID**—Enter *.* to match all possible applications.
   - Leave the other options.

b) Choose **iOS** from the drop-down list as the platform type and configure the following options:
   - **Friendly Name**—Enter a name for the policy. For example, Allow_All.
   - **App ID**—Enter *.* to match all possible applications.
   - Leave the other options.

c) Choose **Policy > View Policy** to get the base64 encoded string for the policy.

   This string contains an encrypted XML file that allows the Firewall Threat Defense to see the policies. Copy this value. You need this string when you configure Per App VPN on the Firewall Threat Defense.

Step 2 Use the Firewall Management Center to enable the Per App on the Firewall Threat Defense headend device.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Select a remote access VPN policy and click **Edit**.
c) Select a connection profile and click **Edit**.
d) Click **Edit Group Policy**.
e) Click the **Secure Client** tab.

f) Click **Custom Attributes** and click +.
g) Choose **Per App VPN** from the **Secure Client Attribute** drop-down list.
h) Choose an object from the **Custom Attribute Object** drop-down list or click + to add an object.

When you add a new custom attribute object for Per App VPN, enter the name, description, and the base64 encoded policy string from the Cisco AnyConnect Enterprise Application Selector.

i) Click **Save**.
j) Click **Add** and click **Save**.

Step 3 Deploy your changes on the Firewall Management Center.

What to do next

1. Launch the Secure Client, select the VPN profile, and connect to the VPN.
2. Verify the configuration. For more information, see Verify Per App Configuration, on page 1519.

Verify Per App Configuration

On the Firewall Threat Defense

Use the following commands on the Firewall Threat Defense to view the Per App configuration:

- **show run webvpn**
- **show run group-policy <ravpn_group_policy_name>**
- **show run anyconnect-custom-data**

On the Endpoint

After the endpoint establishes a VPN connection with the Firewall Threat Defense:

1. Click the **Statistics** icon of the Secure Client.
2. **Tunnel Mode** will be “Application Tunnel” instead of “Tunnel All Traffic.”
3. **Tunneled Apps** will list the applications you enabled for tunneling in the MDM.

Remote Access VPN Examples

How to Limit Secure Client Bandwidth Per User

This section provides instructions to limit the maximum bandwidth that the VPN users consume when they connect using the Secure Client to Secure Firewall Threat Defense remote access VPN gateway. You can limit the maximum bandwidth by using a Quality of service (QoS) policy in Firewall Threat Defense, to ensure that a single user or group or users do not take over the entire resource. This configuration lets you give priority to critical traffic, prevent bandwidth hogging, and manage the network. If a When traffic exceeds the maximum rate, the Firewall Threat Defense drops the excess traffic.

Step	Do This	More Info
1	Create and set up a realm.	Create an LDAP realm or an Active Directory realm and realm directory, on page 1860
2	Create a QoS policy and QoS rule for the user or group available in the newly created realm.	• See Create a QoS policy, on page 1316 to create a QoS policy. • See Configuring QoS rules, on page 1318 to create a QoS rule.
3	Configure remote access VPN policy and select the newly created realm for user authentication.	Create a New Remote Access VPN Policy, on page 1426
4	Deploy the remote access VPN policy.	Deploy configuration changes, on page 135

How to Use VPN Identity for User-Id Based Access Control Rules

Step	Do This	More Info
1	Create and set up a realm.	Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.
2	Create an identity policy and add an identity rule.	• See Create an identity policy, on page 1943 to create an identity policy. • See Create an identity rule, on page 1952 to create an identity rule.
3	Associate the identity policy with an access control policy.	Associate prefilter, decryption, and identity policies with an access control, on page 1585
4	Configure remote access VPN policy and select the newly created realm for user authentication.	Create a New Remote Access VPN Policy, on page 1426
5	Deploy the remote access VPN policy.	Deploy configuration changes, on page 135

Configure Firewall Threat Defense Multiple Certificate Authentication

Multiple Certificate-based Authentication

Multiple certificate-based authentication allows the Firewall Threat Defense to validate the machine or device certificate. Multiple certificates can be enabled for certificate-based authentication in the remote access VPN connection profile. It can be combined with AAA authentication. The multiple certificates option in the remote access VPN connection profile allows certificate authentication of both the machine and user via certificates. This ensures that the device is a corporate-issued device, in addition to authenticating the user's identity certificate to allow RA VPN access. The administrator can choose if the username for the session should be taken from the machine certificate or user certificate.

When multiple certificate-based authentication is configured, two certificates are obtained from the VPN client:

- **First Certificate** —Machine certificate to authenticate the endpoint.
- **Second Certificate**—User certificate to authenticate the VPN user.

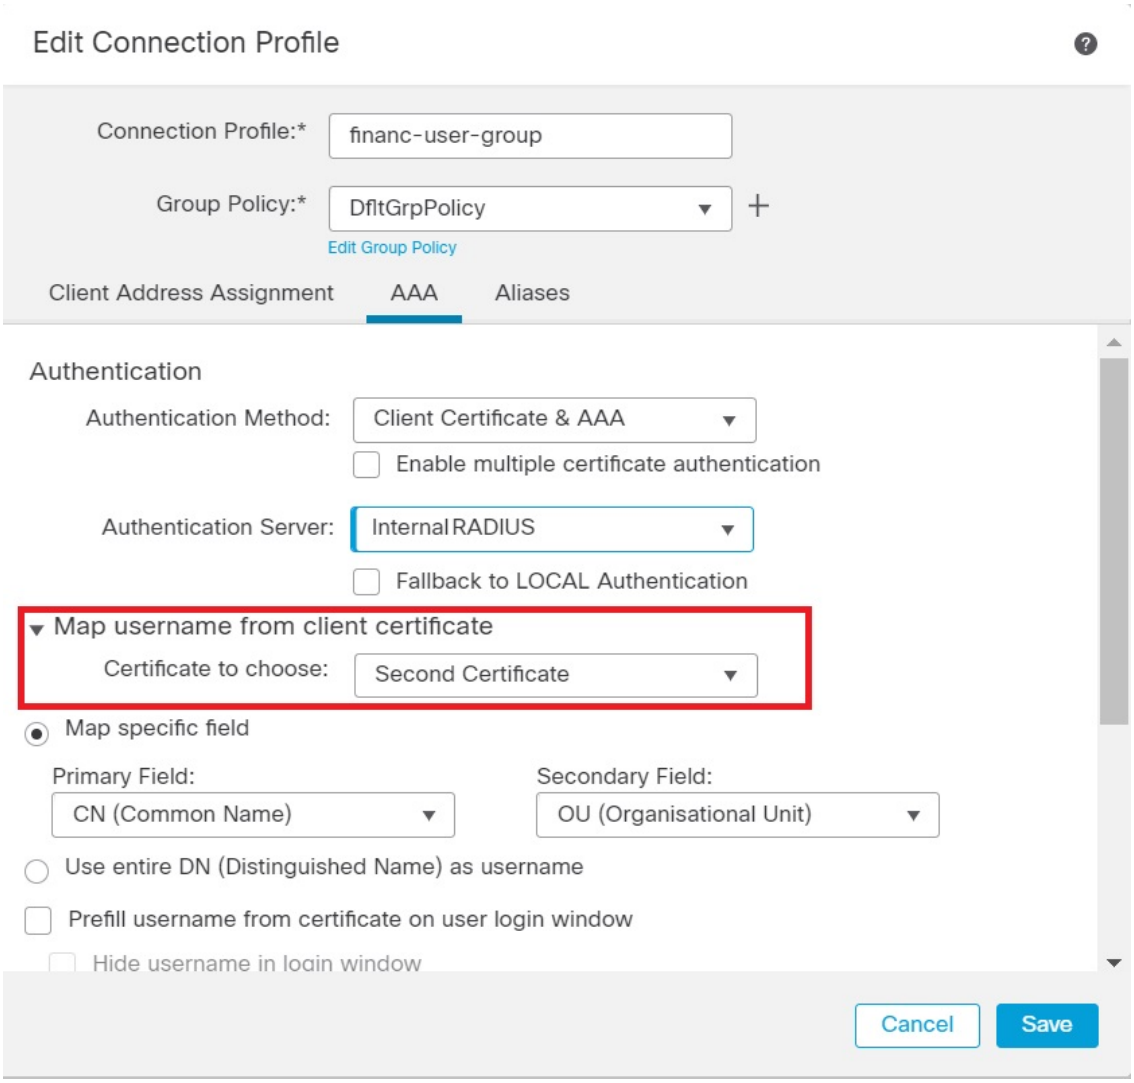
For detailed information about Firewall Threat Defense certificates, see Manage Firewall Threat Defense certificates, on page 2483.

Limitations

- Multiple certificate authentication currently limits the number of certificates to two.
- Secure Client supports only RSA-based certificates.
- Only SHA256, SHA384, and SHA512 based certificates are supported during the Secure Client aggregate authentication.
- Certificate authentication cannot be combined with SAML authentication.

Pre-fill Username from Certificate

The Pre-fill username option allows a field from the certificates to be parsed and used for subsequent AAA authentication (primary and secondary). When two certificates are used for authentication, the Administrator can choose the certificate from which the username should be derived for the prefill functionality. By default, username for prefill is retrieved from the User certificate (second certificate received from Secure Client). The prefilled username is used as the VPN session username when the Certificate Only authentication method is enabled. When AAA and certificate authentication is enabled, VPN session username will be based on the pre-fill option.



Configure Multiple Certificate Authentication for Remote Access VPN

1. On your Secure Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.
2. Edit an existing remote access policy, or create a new one and then edit.

   See Create a New Remote Access VPN Policy, on page 1426.
3. Select the connection profile to configure multiple certificate authentication, and click **Edit**.

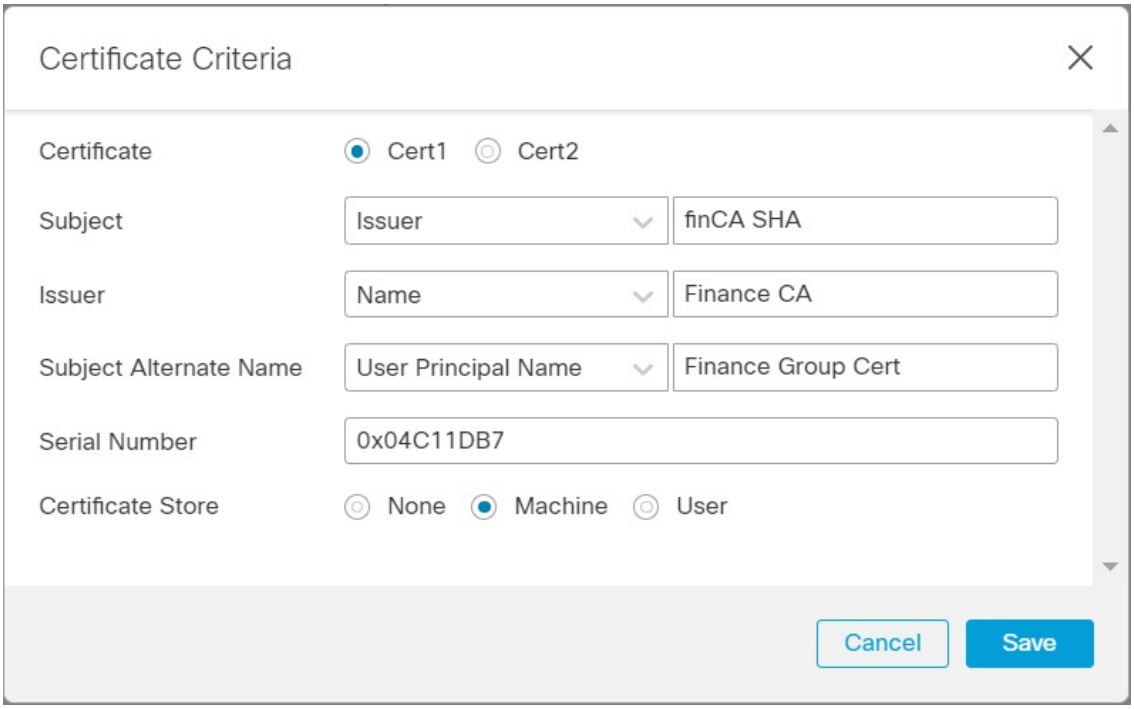
   See Configure Connection Profile Settings, on page 1436.
4. Choose **AAA**, and then select an **Authentication Method**:

Figure 401:

- **Client Certificate Only**—User is authenticated using client certificate. Client certificate must be configured on VPN client endpoints. By default, the username is derived from client certificate fields CN & OU respectively. In case, the username is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.
- **Client Certificate & AAA**—User is authenticated using both the types of authentication, AAA and client certificate.

5. Select **Enable multiple certificate authentication**.
6. Select **Map username from client certificate** and select a certificate from the **Certificate to choose** drop-down to choose the username for the VPN session from the machine certificate or user certificate.
   - **First Certificate** —Map the username from the Machine Certificate.
   - **Second Certificate**—Map the username from the User certificate to authenticate the VPN user.

7. Configure the required connection profile settings and remote access VPN settings.
8. Save the connection profile and remote access VPN policy. Deploy the remote access VPN on Firewall Threat Defense.



For information about remote access VPN AAA settings, see Configure AAA Settings for Remote Access VPN, on page 1439.

Certificate Configuration in DAP

You can also configure certificate criteria attributes in a DAP record. The user and machine certificate received from the VPN client during multiple-certificate authentication is loaded into dynamic access policy (DAP) to allow policies to be configured based on the field of the certificate. You can make policy decisions based on the fields of a certificate used to authenticate that connection attempt.

1. Choose **Devices** > **VPN** > **Dynamic Access Policy**.
2. Edit an existing DAP policy or create a new one and then edit the policy.
3. Choose an existing DAP record, or create a new one and then edit the record.
4. Select **Endpoint Criteria** > **Certificate**.
5. Select the Match Criteria **All** or **Any**.
6. Click **Add** to add certificate attributes.

Figure 402:

7. Select the certificate, **Cert1** or **Cert2**.
8. Select the **Subject** and specify the certificate subject value.

9. Select the **Issuer** and specify the certificate issuer name.
10. Select the **Subject Alternate Name** and specify the alternate name for the subject.
11. Specify the **Serial Number**.
12. Select the **Certificate Store**: None, Machine, or User.

    This option adds a condition to check for the store from which the certificate is picked on the endpoint.
13. Click **Save** to complete the certificate criteria settings.

    Configure the required DAP record settings and then associate the DAP with the remote access VPN.

For more information about DAP, see Dynamic Access Policies , on page 1531.

Monitor Remote Access VPNs

Remote Access VPN Dashboard

Remote Access Virtual Private Network (RA VPN) allows remote users to securely connect to your network. The RA VPN dashboard allows you to monitor real-time data from active RA VPN sessions on the devices. You can quickly determine problems related to user sessions and mitigate the problems for your network and users.

RA VPN dashboard (**Overview** > **Dashboards** > **Remote Access VPN**) provides a snapshot of the active RA VPN sessions on the threat defense devices managed by the Firewall Management Center.

The dashboard provides:

- Visualization of active user sessions based on their location.
- Detailed information about the active user sessions.
- Mitigation of user session problems by terminating sessions, if required.
- Distribution of active user sessions per device, encryption type, Secure Client version, operating system, and connection profile.
- Device identity certificate expiration details of the devices.

The dashboard has the following widgets:

- Active Sessions (Tabular View)
- Active Sessions (Map view)
- Sessions
- Device Identity Certificates

Active Sessions (Tabular View)

This widget provides a tabular view of the active RA VPN users connected. You can view details of the active RA VPN sessions such as username, assigned IP, public IP, login time, VPN gateway (threat defense device), client application, client operating system, connection profile, and group policy. You can use the filter to

narrow down your search based on the different criteria. You can also perform the following actions on the individual sessions:

- Terminate a session of a specific user.
- Terminate all sessions of a specific user connected to a specific VPN gateway.
- Terminate all sessions that are connected to a specific VPN gateway.

If a client device supports dual address stack and the RA VPN configuration on the Firewall Threat Defense device allows IPv4 and IPv6 address pools, when a client establishes an RA VPN session with the headend device, it assigns an IPv4 and an IPv6 address to the client's tunnel interface. The RA VPN session has two IP addresses, an IPv4 and an IPv6 address on the threat defense device. The Firewall Management Center shows two sessions for the same user, one with an IPv4 address and another with an IPv6 address, and the session count is two.

Hence, even when there is only a single RA VPN session from a user as per **show vpn-sessiondb l2l filter ipaddress** command on the device, the Firewall Management Center shows two different sessions.

Active Sessions (Map View)

This widget shows an interactive heat map to visualize the location of the users connected through RA VPN sessions on the devices.

- Countries that have user sessions appear in shades of blue.
- Legend of the map provides a scale that indicates the correlation between the number of sessions in a country and the shade of blue for the country.
- Hover the mouse pointer over the map to view the country name and the total number of active user sessions.
- Zoom in, zoom out, and reset options are available.

Sessions

This widget allows you to monitor real-time data from active RA VPN sessions on the devices. You can filter and view the distribution of active RA VPN sessions according to:

- Device: Displays the number of sessions per device.
- Encryption Type: Displays the number of Secure Client SSL or IPsec sessions.
- Secure Client Version: Displays the sessions per Secure Client version.
- Operating System: Displays the sessions per operating systems. For example, Windows, Linux, Mac, Mobile OS, and so on.
- Connection Profile: Displays the sessions per connection profile.

Device Identity Certificates

This widget provides information about the identity certificate expiry of the RA VPN gateways. You can view expired certificates and certificates that are due for expiry within a month. Click **View Details** to view the certificates in the **Devices** > **Certificates** page.

VPN Session and User Information

The system generates events that communicate the details of user activity on your network, including VPN-related activity. The system monitoring capabilities enable you to determine quickly whether remote access VPN problems exist and where they exist. You can then apply this knowledge and use your network management tools to reduce or eliminate problems for your network and users. Optionally, you can log out remote access VPN users as needed.

Viewing Remote Access VPN Active Sessions

Analysis > **Users heading** > **Active Sessions**

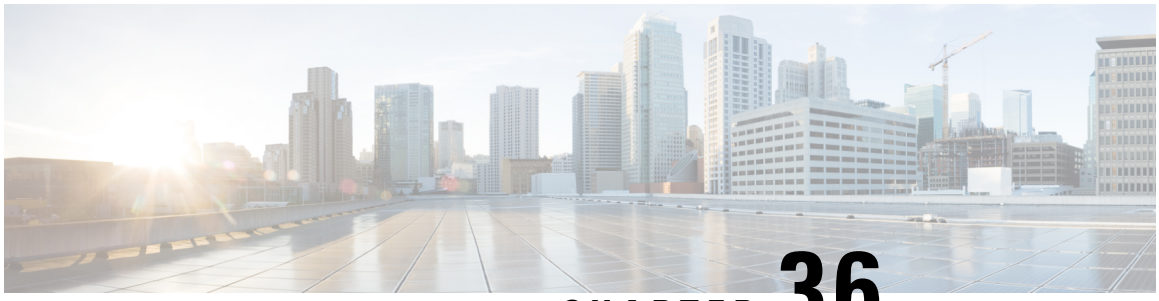
Lets you view the currently logged-in VPN users at any given point in time with supporting information such as the user name, login duration, authentication type, assigned/public IP address, device details, client version, endpoint information, throughput, bandwidth consumed group policy, tunnel group and so on. The system allows you to filter current user information, log users out, and delete users from the summary list.

Note If you configure your VPN in a high-availability deployment, the device name displayed against active VPN sessions can be the primary or secondary device that identified the user session.

Viewing Remote Access VPN User Activity

Analysis > **Users heading** > **User Activity**

Lets you view the details of user activity on your network. The system logs historical events and includes VPN-related information such as connection profile information, IP address, geolocation information, connection duration, throughput, and device information.



History for Remote Access VPNs

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
IPsec flow offload on the VTI loopback interface	7.4	Any	On the Secure Firewall 3100 and Secure Firewall 4200 devices, IPsec flow offload is enabled automatically on the VTI loopback interface.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Secure Client Customizations	7.4	Any	You can configure Secure Client customizations and deploy them to the VPN headend. The threat defense distributes these customizations to the endpoint when a user connects from the Secure Client: • GUI text and messages • Icons and images • Scripts • Binaries • Customized Installer Transforms • Localized Installer Transforms New/Modified Screens: • **Objects** > **Object Management** > **VPN** > **Secure Client Customization** • **Devices** > **Remote Access** > **Advanced** > **Secure Client Customization**
WAN Summary Dashboard	7.4	Any	The WAN Summary dashboard provides a snapshot of your WAN devices and their interfaces. New/Modified Screen: **Overview** > **Dashboard** > **WAN Summary**
Remote Access VPN dashboard	7.3	Any	The Remote Access VPN (RA VPN) dashboard that allows you to monitor real-time data from active remote access VPN sessions on the devices. So that you can quickly determine problems related to user sessions and mitigate the problems for your network and users. New/Modified Screen: **Overview** > **Dashboards** > **Remote Access VPN**
SAML with Certificate Support	7.2	Any	We have updated the remote access VPN configuration wizard to support user authentication with Certificate and SAML. You can configure a remote access VPN to authenticate machine or user certificate before a SAML authentication is initiated.
IPsec flow offload.	7.2	Any	On the Secure Firewall 3100, IPsec flows are offloaded by default. After the initial setup of an IPsec site-to-site VPN or remote access VPN security association (SA), IPsec connections are offloaded to the field-programmable gate array (FPGA) in the device, which should improve device performance. You can change the configuration using FlexConfig and the **flow-offload-ipsec** command.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Multiple IDP trustpoint support	7.1	Any	Secure Firewall Management Center supports multiple identity provider trustpoints with Microsoft Azure that can have multiple applications for the same Entity ID, but a unique identity certificate.
AnyConnect VPN SAML External Browser	7.1	Any	You can now configure AnyConnect VPN SAML External Browser to enable additional authentication choices, such as password less authentication, WebAuthN, FIDO, SSO, U2F, and an improved SAML experience due to the persistence of cookies. When you use SAML as the primary authentication method for a remote access VPN connection profile, you can elect to have the AnyConnect client use the client's local browser instead of the AnyConnect embedded browser to perform the web authentication. This option enables single sign-on (SSO) between your VPN authentication and other corporate logins. Also choose this option if you want to support web authentication methods, such as biometric authentication and Yubikeys, that cannot be performed in the embedded browser. We updated the remote access VPN connection profile wizard to allow you to configure the **SAML Login Experience**.
Multi-Certificate Authentication	7.0	Any	Secure Firewall Management Center now supports multiple certificate-based authentication for Firewall Threat Defense to validate the machine or device certificate, to ensure that the device is a corporate-issued device in addition to authenticating the user's identity certificate to allow VPN access using AnyConnect client.
VPN Load balancing	7.0	Any	VPN load balancing logically group two or more devices and distributes remote access VPN sessions among the grouped devices equally without considering throughput and other traffic parameters.
AnyConnect Custom Attributes	7.0	Any	Secure Firewall Management Center now supported AnyConnect custom attributes and provides an infrastructure to configure the AnyConnect client feature without adding hard-coded support for these features on Firewall Threat Defense.
Local User Authentication	7.0	Any	You can now configure and manage users locally on Firewall Threat Defense using the Secure Firewall Management Center web interface, and configure the local users for primary and secondary remote access VPN authentication.
Selective Policy Deployment	7.0	Any	You can now choose to include or exclude changes to remote access VPN and site-to-site VPN configurations during the deployment.
Support for AnyConnect Modules Configuration	6.7	Any	Secure Firewall Management Center now supports configuring AnyConnect modules and profiles for additional security.
Support for LDAP Authorization	6.7	Any	You can configure LDAP authorization for remote access VPN using the Secure Firewall Management Center.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
SAML single sign-on support for remote access VPN	6.7	Any	You can configure a SAML 2.0 server as the single sign-on authentication server for remote access VPNs.
AnyConnect Management VPN tunnel support	6.7	Any	Firewall Threat Defense remote access VPN supports configuring AnyConnect Management VPN tunnel that allows VPN connectivity to endpoints when the corporate endpoints are powered on, without the VPN users connecting to the VPN.
Support for Datagram Transport Layer Security (DTLS) 1.2	6.6	Any	DTLS 1.2 is now part of the default SSL cipher group and it can be configured along with TLS 1.2.

CHAPTER 36

Dynamic Access Policies

Dynamic access policies (DAP) enable you to configure authorization that addresses the dynamics of VPN environments. You create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. These attributes address issues of multiple group membership and endpoint security.

- Firewall Threat Defense dynamic access policies, on page 1531
- Prerequisites for dynamic access policy, on page 1533
- Guidelines and limitations for dynamic access policies, on page 1533
- Configure a Dynamic Access Policy (DAP), on page 1534
- Associate dynamic access policy with remote access VPN, on page 1544
- History for dynamic access policy, on page 1544

Firewall Threat Defense dynamic access policies

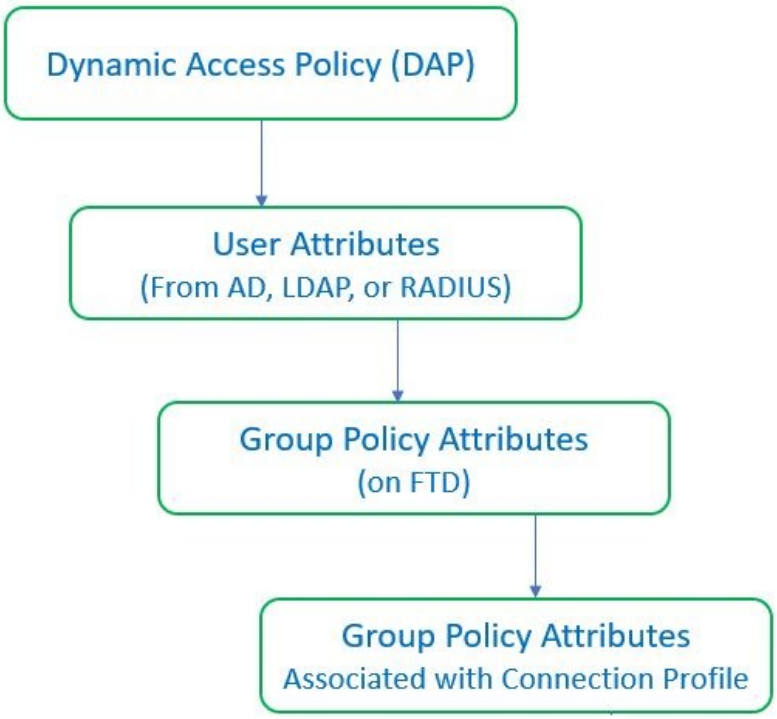
A Secure Firewall Threat Defense dynamic access policy is a collection of access control attributes that

- addresses issues of multiple group memberships and endpoint security in VPN environments
- grants access to particular users for particular sessions according to defined policies, and
- adapts to dynamic environments with multiple variables affecting each VPN connection.

Dynamic access policy operation

VPN gateways operate in dynamic environments. Multiple variables can affect each VPN connection. For example, intranet configurations that frequently change, the various roles each user inhabits within an organization, and log in attempts from remote access sites with different configurations and levels of security. The task of authorizing users is much more complicated in a VPN environment than it is in a network with a static configuration.

You can create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. The Firewall Threat Defense device generates a DAP during user authentication by selecting or aggregating attributes from one or more DAP records. The device then selects these DAP records based on the endpoint security information of the remote device and AAA authorization information for the authenticated user. Then the device applies the DAP record to the user tunnel or session.



Hierarchy of policy enforcement of permissions and attributes in a Firewall Threat Defense device

The Firewall Threat Defense device supports applying user authorization attributes, also called user entitlements or permissions, to VPN connections. The attributes are applied from a DAP on the Firewall Threat Defense, external authentication server and/or authorization AAA server (RADIUS) or from a group policy on the Firewall Threat Defense device.

If the Firewall Threat Defense device receives attributes from all sources, the device evaluates, merges, and applies the attributes to the user policy. If there are conflicts between attributes coming from the DAP, the AAA server, or the group policy, the attributes from the DAP always take precedence.

The Firewall Threat Defense device applies attributes in this order:

Figure 403: Policy enforcement flow

1. **DAP attributes on the FTD**—The DAP attributes take precedence over all others.
2. **User attributes on the external AAA server**—The server returns these attributes after successful user authentication and/or authorization.
3. **Group policy configured on the FTD**—If a RADIUS server returns the value of the RADIUS Class attribute IETF-Class-25 (OU= group-policy) for the user, the Firewall Threat Defense device places the user in the group policy of the same name and enforces any attributes in the group policy that are not returned by the server.

4. **Group policy assigned by the Connection Profile (also known as Tunnel Group)**—The Connection Profile has the preliminary settings for the connection, and includes a default group policy that is applied to the user before authentication.

Note The Firewall Threat Defense device does not support inheriting system default attributes from the default group policy, *DfltGrpPolicy*. For the user session, the device uses the attributes on the group policy that you assign to the connection profile, unless the user attributes or the group policy from the AAA server overrides them.

Prerequisites for dynamic access policy

This reference provides the licensing prerequisites that must be met before configuring Dynamic Access Policy features.

Licensing prerequisites

- Firewall Threat Defense must have at least one of these Secure Client licenses:
  - Secure Client Premier
  - Secure Client Advantage
  - Secure Client VPN Only
- The Firewall Threat Defense Essentials license must allow export-controlled functionality.

General prerequisite

Ensure that you have the Secure Firewall Posture package before you configure the dynamic access policy. You can add the Secure Firewall Posture file at **Objects** > **Object Management** > **VPN** > **Secure Client File**.

Guidelines and limitations for dynamic access policies

Consider these guidelines and limitations when implementing Dynamic Access Policies:

- Matching of AAA attributes in a DAP will work only if a AAA server is configured to return the correct attributes when authenticating or authorizing a remote access VPN session.
- Minimum Secure Client and Secure Firewall Posture package version supported for DAP is 4.6. But it is highly recommended to use the latest version of Secure Client.
- DAP does not support clustering or multi-instance mode.
- DAP condition with an assigned IPv4 or IPv6 address does not work for local authentication.

Configure a Dynamic Access Policy (DAP)

Create a dynamic access policy

Create a dynamic access policy to enable conditional access control for VPN users based on their endpoint security posture and compliance status.

Dynamic access policies evaluate endpoint attributes and security posture to determine appropriate access permissions for VPN users. These policies work in conjunction with posture assessment packages to enforce security compliance.

Before you begin

Ensure that you have the Secure Firewall Posture package before you configure the dynamic access policy. You can add the Secure Firewall Posture file at **Objects** > **Object Management** > **VPN** > **Secure Client File**.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**, and click **Create Dynamic Access Policy**.

Step 2 Specify the **Name** for the DAP policy and an optional **Description**.

Step 3 Choose the **HostScan Package** from the drop-down list.

Step 4 Click **Save**.

What to do next

To configure DAP record, see Create Dynamic Access Policy Record

Create a dynamic access policy record

A dynamic access policy (DAP) can contain multiple DAP records, where you configure user and endpoint attributes. You can prioritize the DAP records within a DAP so that the Firewall Threat Defense device can select and sequence the required criteria when a user attempts VPN connection.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Edit an existing dynamic access policy or click **Create Dynamic Access Policy** to create a new one and then edit the policy.

Step 3 Click **Create DAP Record**.

Step 4 Click the **General** tab.

Step 5 Specify the **Name** for the DAP record.

Step 6 Enter the **Priority** for the DAP record.

The lower the number, the higher the priority.

Step 7 Select one of these actions to take when a DAP record matches:

- **Continue**—Applies access policy attributes to the session. If any, the next DAP record (next policy line with less priority) is then evaluated.
- **Terminate**—Terminates the session.
- **Quarantine**—Quarantines the connection.

Step 8 Check the **Display User Message on Criterion Match** check-box and add the user message.

The Firewall Threat Defense displays this message to the user when the DAP record matches.

Step 9 Check the **Apply a Network ACL on Traffic** check box and select the access control list from the drop-down.

Step 10 Check the **Apply one or more Secure Client Custom Attributes** check box and select the custom attributes object from the drop-down.

Step 11 Click **Save**.

Configure AAA criteria settings for a DAP record

Configure AAA criteria settings to specify the conditions under which DAP records are selected and applied to user sessions based on AAA authorization and posture assessment information.

DAP complements AAA services by providing a limited set of authorization attributes that can override the attributes that AAA provides. The Firewall Threat Defense device selects DAP records based on the AAA authorization information for the user and posture assessment information for the session. The Firewall Threat Defense device can choose multiple DAP records depending on this information, which it then aggregates to create DAP authorization attributes.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Edit an existing DAP policy or create a new one and then edit the policy.

Step 3 Select a DAP record or create a new one, and edit the DAP record.

Step 4 Click **AAA Criteria**.

Step 5 Select one of the **Match criteria between sections**.

- Any—Matches any of the criteria.
- All—Matches all the criteria.
- None—Matches none of the set criteria.

Step 6 Click **Add** to add the required **Cisco VPN Criteria**.

Cisco VPN criteria include attributes for group policy, assigned IPv4 address, assigned IPv6 address, connection profile, username, username 2, and SCEP required.

a) Select an attribute and specify the **Value**.
b) Click **Add another criteria** to add more criteria.
c) Click **Save**.

Step 7 Select **LDAP Criteria**, **RADIUS Criteria**, or **SAML Criteria** and specify the **Attribute ID** and **Value**.

Step 8 Click **Save**.

Configure endpoint attribute selection criteria in DAP

Endpoint attributes contain information about the endpoint system environment, posture assessment results, and applications. A Firewall Threat Defense device dynamically generates a collection of endpoint attributes during session establishment and stores these attributes in a database that is associated with the session. Each DAP record specifies the endpoint selection attributes that must be satisfied for the Firewall Threat Defense device to choose it for a session. The Firewall Threat Defense device selects only DAP records that satisfy every condition configured.

Note When using remote Access VPN with DAP or Secure Firewall Posture (formerly HostScan) and change of authorization (CoA), endpoint attribute checks differ between initial authentication and CoA-triggered authorization.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**, and click **Create Dynamic Access Policy**.

Step 2 Create or edit a DAP record.

Step 3 Click **Endpoint Criteria** and configure attributes such as anti-malware, device, Secure Client, NAC, application, personal firewall, operating system, process, registry, file, and certificate authentication.

Note You can create multiple instances of each type of endpoint attribute. There is no limit for the number of endpoint attributes for each DAP record.

Step 4 Click **Save**.

Add an anti-malware endpoint attribute to a DAP record

Add anti-malware endpoint attributes to a DAP to control access based on the presence and configuration of anti-malware software on client devices.

Anti-malware endpoint attributes allow you to create access policies that verify client devices have appropriate anti-malware protection before granting network access.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Anti-Malware**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add the anti-malware attributes.

In the **Anti-Malware** dialog box, configure these parameters:

a) Check the **Installed** check box to indicate whether the selected endpoint attribute and its accompanying qualifiers are installed or not installed.
b) In **Real Time Scanning**, choose **Enabled** or **Disabled** to activate or deactivate real-time malware scanning.
c) Choose the anti-malware vendor from the **Vendor** drop-down list.
d) Choose the anti-malware description from the **Product Description** drop-down list.
e) Choose the **Version** of the anti-malware product.
f) Specify the number of days since the **Last Update**.

You can indicate that an anti-malware update must occur in less than (<) or more than (>) the number of days you specify.

g) Click **Save**.

Add a device endpoint attribute to a DAP record

Add device endpoint attributes to a DAP to control access based on specific device characteristics such as hostname, MAC address, BIOS serial number, or port configuration.

Device endpoint attributes allow you to create policies that evaluate device-specific criteria to determine access permissions. These attributes help enforce security policies based on device identity and configuration.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Device**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add application attributes.

In the **Device** dialog box, configure these parameters:

Select the = or ≠ operator to check the attribute to be equal to or not equal to the value you enter for these attributes:

- **Host Name**—Hostname of the device. Use the computer's host name only, not the fully qualified domain name (FQDN).
- **MAC Address**—MAC address of the network interface card you are testing for. The address must be in the format xxxx.xxxx.xxxx where x is a hexadecimal character.
- **BIOS Serial Number**—BIOS serial number value of the device you are testing for. The number format is manufacturer-specific.
- **Port Number**—Listening port number of the device.
- **Secure Desktop Version**—Version of the Secure Firewall Posture image running on the endpoint.
- **OPSWAT Version**—The OPSWAT client version.
- **Privacy Protection**—None, Cache cleaner, Secure Desktop.
- **TCP/UDP Port Number**—TCP or UDP port in the listening state.

Step 6 Click **Save**.

Add Secure Client endpoint attributes to a DAP record

Add specific endpoint attributes to a Dynamic Access Policy (DAP) record to control client access based on Secure Client characteristics such as client version, platform, and device identifiers.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Secure Client**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add the attributes.

In the **Secure Client** dialog box, configure these parameters:

Select the **=** or **≠** operator to check the attribute to be equal to or not equal to the value you enter.

a) Specify the **Client Version**.
b) Choose the platform from the **Platform** drop-down list.
c) Choose the platform version from the **Platform Version** drop-down list.
d) Specify the **Device Type** and **Device Unique ID**.
e) Add the **MAC Addresses**.

Note The MAC Address must be in the format XX-XX-XX-XX-XX-XX, where each X is a hexadecimal character. You can click **Add another MAC Address** to add more addresses.

f) Click **Save**.

Add NAC endpoint attributes to a DAP record

You can configure Network Access Control (NAC) endpoint attributes within a DAP (Dynamic Access Policy) record to evaluate endpoint posture status based on a defined criteria.

NAC endpoint attributes in DAP records help determine access permissions based on endpoint posture compliance. You can specify whether endpoints must match all criteria or any criteria, and define specific posture token strings for evaluation.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **NAC**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add NAC attributes.

Step 6 In the **NAC** dialog box, set the operator to be equal to **=** or not equal to **≠** the posture status.

Step 7 Choose one of these options from the **Posture Status** drop-down list:

- Compliant
- Non-Compliant
- Unknown

Step 8 Click **Save**.

Add an application attribute to a DAP record

This task allows you to define application-specific criteria within a DAP record to control access based on the type of remote access client.

Application attributes in DAP records help determine access policies by evaluating the client application type used for remote connections. You can configure these attributes to match all or any specified criteria.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Application**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add application attributes.

Step 6 In the **Application** dialog box, choose equals (=) or does not equal (≠) and specify the **Client Type** to indicate the type of remote access connection. Choose from one of these options:

- Clientless
- Cut-Through-Proxy
- Secure Client
- IPsec
- L2TP
- IPsec-IKEv2-Generic-RA

Step 7 Click **Save**.

Add a personal firewall endpoint attribute to a DAP record

Adding personal firewall endpoint attributes to a DAP allows you to control network access based on whether client devices have specific firewall software installed, enabled, and meeting version requirements.

Personal firewall endpoint attributes help enforce security policies by ensuring that connecting devices meet firewall protection standards before granting network access.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Personal Firewall**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add personal firewall attributes.

In the **Personal Firewall** dialog box, configure these parameters:

a) Click **Installed** to indicate whether the personal firewall endpoint attribute and its accompanying qualifiers (fields below the Name/Operation/Value column) are installed or not installed.
b) Select **Enabled** or **Disabled** to activate or deactivate firewall protection.
c) Choose the name of the firewall vendor from the **Vendor** drop-down list.
d) Choose the firewall description from the **Product Description** drop-down list.
e) Select the equals (=) or does not equal (≠) operator and choose the **Version** of the personal firewall product.
f) Click **Save**.

Add an operating system endpoint attribute to a DAP record

Operating system endpoint attributes help create granular access policies by identifying and filtering client devices based on their operating system characteristics. This is useful for implementing different access levels or restrictions based on device types.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Operating System**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add endpoint attributes.

In the **Operating System** dialog box, configure these parameters:

a) Select the equals (=) or does not equal (≠) operator and then choose the operating system from the **Operating System** drop-down list.
b) Select the equals (=) or does not equal (≠) operator and then specify the operating system version in the **Version** field.
c) Click **Save**.

Add a process endpoint attribute to a DAP

Configure process endpoint attributes to define specific criteria for device access policy enforcement based on running processes.

Process endpoint attributes allow you to create device access policies based on specific processes running on endpoints. This helps ensure that only devices with approved processes can access network resources.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Process**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add process attributes.

In the **Process** dialog box, configure these parameters:

a) Select **Exists** or **Does not exist**.
b) Specify the **Process Name**.
c) Click **Save**.

Add a registry endpoint attribute to a DAP record

Registry endpoint attributes allow you to define specific registry keys that the system scans during posture assessment to determine endpoint compliance status.

Scanning for registry endpoint attributes applies to Windows operating systems only.

Before you begin

Before configuring a registry endpoint attribute, define the registry key for which you want to scan in the Secure Firewall Posture window for Cisco Secure Desktop.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Registry**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add registry attributes.

In the **Registry** dialog box, configure these parameters:

a) Select the **Entry Path** for the registry and specify the path.
b) Choose the existence of the registry, **Exists** or **Does not exist**.
c) Select the registry **Type** from the list.
d) Select the equals (**=**) or does not equal (**≠**) operator and enter the **Value** of the registry key.
e) Select **Case insensitive** to disregard the case of the registry entry while scanning.
f) Click **Save**.

Add a file endpoint attribute to a DAP record

You can configure file endpoint criteria within a DAP (Device Access Policy) record to specify file attributes used for posture assessment and device authorization.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **File**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add file attributes.

In the **File** dialog box, configure these parameters:

a) Specify the **File Path**.
b) Select **Exists** or **Does not exist** to indicate the presence of the file.
c) Select less than (**<**) or greater than (**>**) and specify the **Last Modified** days for the file.

d) Select the equal to (=) or not equal to ≠ operator and enter the **Checksum**.
e) Click **Save**.

Add certificate authentication attributes to a DAP record

Adding certificate authentication attributes to a DAP allows you to control access based on specific certificate fields such as subject, issuer, and serial number.

You can index each certificate to allow referencing to any of the received certificates, by the configured rules. Based on these certificate fields, you can configure DAP rules to allow or disallow connection attempts.

Note This configuration is applicable only for certificates used with multiple certificate authentication. It does not apply for single client certificate authentication.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.
Step 2 Create or edit a DAP record.
Step 3 Click the **Endpoint Criteria** tab and click **Multiple Certificate Authentication**.
Step 4 Select the **Match criteria** as **All** or **Any**.
Step 5 Click + to add certification authentication criteria.

In the **Multiple Certificate Authentication Criteria** dialog box, configure these parameters:

a) Select **Cert1** or **Cert2** certificate.
b) Select the **Subject** and specify the subject value.
c) Select the **Issuer** and specify the issuer value.
d) Select the **Subject Alternate Name** and specify the subject value.
e) Specify the **Serial Number**.
f) Choose the **Certificate Store** as **None**, **Machine**, or **User**.

The VPN client sends the certificate store information.

g) Click **Save**.

Configure advanced settings for DAP

This task allows you to configure selection criteria for DAP records using Lua scripts when the standard AAA AND endpoint attribute areas are insufficient for your requirements.

You can use the **Advanced** tab for adding selection criteria other than what is possible in the AAA AND endpoint attribute areas. For example, while you can configure the Firewall Threat Defense to use AAA attributes that satisfy any, all, OR none of the specified criteria, the endpoint attributes are cumulative, AND

must satisfy all. To let the security appliance employ one endpoint attribute OR another, you must create appropriate logical expressions in Lua AND enter them here.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.
Step 2 Create or edit a DAP record.
Step 3 Click the **Advanced** tab.
Step 4 Select **AND** OR **OR** as the match criteria to use in the DAP configuration.
Step 5 Add the Lua script in the **Lua script for advanced attribute matching** field.
Step 6 Click **Save**.

Associate dynamic access policy with remote access VPN

You can associate Dynamic Access Policy (DAP) with remote access VPN policy for the dynamic access policy attributes to match during VPN session authentication and authorization. You can then deploy the remote access VPN on the Firewall Threat Defense.

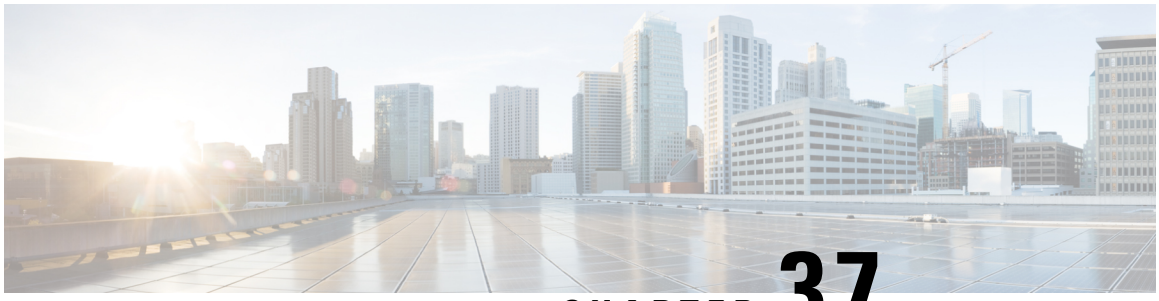
Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.
Step 2 Click **Edit** next to the remote access VPN policy to which you want to associate dynamic access policy.
Step 3 Click the link in remote access VPN to select the dynamic access policy.
Step 4 Select the policy from the **Dynamic Access Policy** drop-down or click **Create a new Dynamic Access Policy** to configure a new dynamic access policy.
Step 5 Click **OK**.
Step 6 Click **Save** to save the remote access VPN policy.

When the remote access VPN user tries to connect, the VPN checks the configured dynamic access policy records and attributes. VPN creates a dynamic access policy based on the matching dynamic access policy records and takes appropriate action on the VPN session.

History for dynamic access policy

This reference provides the version history for dynamic access policy features, including when they were introduced and what changes were made in each release.



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Dynamic Access Policy	7.0	Any	The feature was introduced.

PART VII

Zero Trust Network Access

- Zero Trust Network Access Overview, on page 1549

CHAPTER 37

Zero Trust Network Access Overview

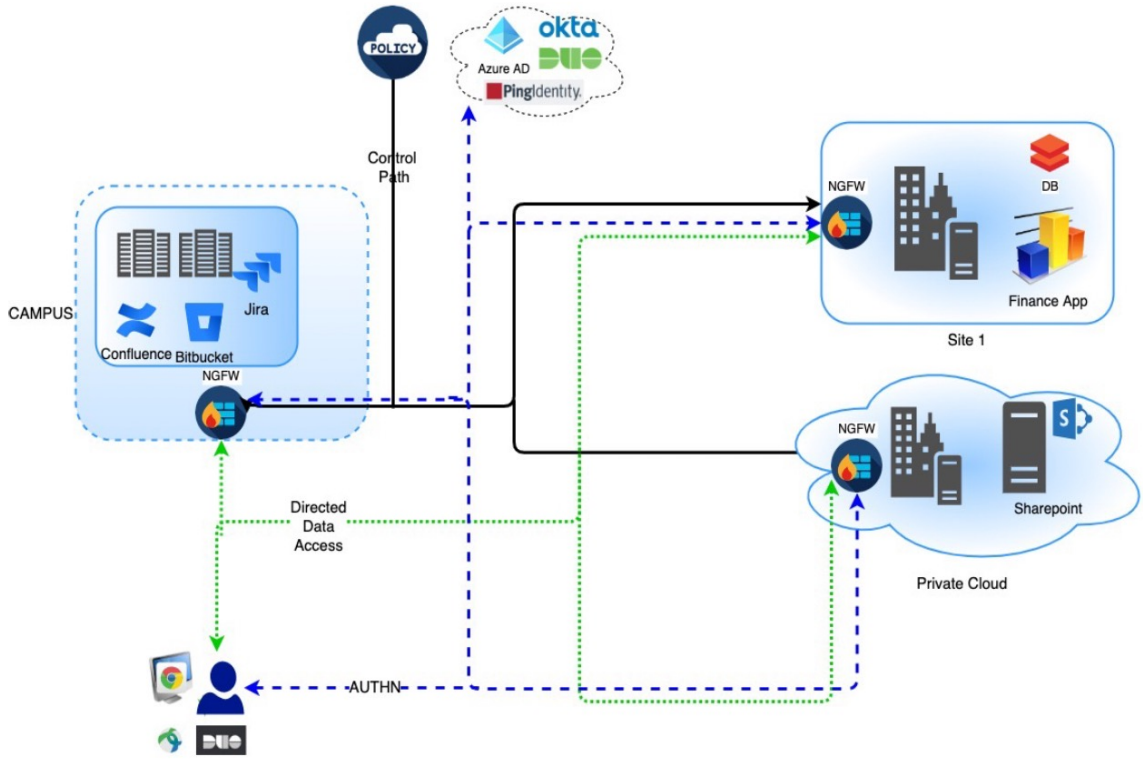
Zero Trust Network Access (ZTNA) secures internal resources by verifying user identity and device posture to grant least-privilege access. Organizations implement either browser-based Clientless ZTNA for web applications or agent-based Universal ZTNA for comprehensive, protocol-wide support using existing threat defense infrastructure.

- Zero Trust Access, on page 1549
- History for zero trust network access, on page 1564

Zero Trust Access

Zero Trust Access is based on Zero Trust Access principles. Zero Trust Access is a zero trust security model that eliminates implicit trust. The model grants the least privilege access after verifying the user, the context of the request, and after analyzing the risk if access is granted.

Zero Trust Access enables you to authenticate and authorize access to protected web-based resources and applications from inside (on-premises) or outside (remote) the network using an external Security Assertion Markup Language (SAML) identity provider (IdP) policy.



The features are:

- Supports multiple SAML-based identity providers such as Duo, Azure Active Directory (Azure AD), Okta, and other identity providers.
- Client applications such as Cisco Secure Client are not required on the endpoint (client devices) for secure access.
- Access and authentication is through the browser.
- Supports only TLS web applications.
- Client device posture is supported through agents such as Duo Health, using which the posture of the device can be evaluated against a policy in Duo, and access can be provided based on the same. The same functionality can be performed in conjunction with third-party identity providers that support posture evaluation with their agents such as Okta or PingID.
- Supports HTTP-Redirect SAML binding.
- Supports application groups that make it easier to enable zero trust access protection on a set of applications.
- Leverages threat defense intrusion and malware protection on zero trust application traffic.

You can use the Secure Firewall Management Center web interface to create a Zero Trust Application Policy that allows you to define private applications and assign threat policies to them. The policy is application specific where the administrator decides the inspection levels based on the threat perception for that application.

How Threat Defense Works with Zero Trust Access

Figure 404: Threat Defense Deployment

1. Using a browser, a remote or on-prem user sends a HTTPS request to connect to an application from an endpoint.
2. The HTTPS request is intercepted by the firewall that protects the application.
3. The firewall redirects the user to application's configured IdP for authentication.

Note In the figure, each firewall protects a set of web applications. The user can directly access the applications behind the firewall after authentication and authorization.

4. After the authentication and authorization process is complete, the firewall allows the user to access the application.

Zero trust network access

Zero Trust Network Access (ZTNA) provides secure, segmented application access by requiring explicit authorization for every connection. This approach reduces the attack surface and simplifies secure migrations without adding devices.

Key characteristics

ZTNA uses your existing Threat Defense deployment as an enforcement point for application access, enabling segmented and per-application authorization. ZTNA establishes individual tunnels for both remote and on-premises users.

ZTNA hides the network from users and ensures that they can only access applications for which they have been explicitly authorized. Authorization for one application does not provide implicit access to other applications, which significantly reduces the attack surface. In other words, every access to an application or a resource must be explicitly authorized.

You can adopt a more secure access model by adding zero trust access functionality to Threat Defense. This eliminates the need to install or manage additional devices in the network.

Components of a Clientless Zero Trust Network Access Configuration

A new configuration consists of a Zero Trust Application Policy, Application Group, and Applications.

- **Zero Trust Application Policy**— Consists of application groups, and grouped or ungrouped applications. Security Zones and Security Controls settings are associated at a global level for all the ungrouped applications and group of applications.

  A global port pool is assigned to the policy, by default. A unique port is automatically assigned from this pool to each private application that is configured.

  Zero Trust Application policy consists of application groups, and grouped or ungrouped applications.

- **Application Groups**—Consists of a logical group of applications that share SAML authentication settings and can optionally share Security Zones and Security Controls settings.

  Application Groups inherit the Security Zones and Security Controls settings from the global policy and can override the values.

  When an Application Group is created, the same SAML IdP configuration can be used for authenticating multiple applications. Applications that are part of an Application Group inherit the Application Group's SAML configuration. This eliminates the need to configure the SAML settings for each application. After the Application Group is created, new applications can be added to it without configuring the IdP for it.

  When an end user tries to access an Application that is part of group, the user is authenticated to the Application Group for the first time. When the user tries to access other applications that are part of the same Application Group, the user is provided access without being redirected again to the IdP for authentication. This prevents overloading the IdP with requests for application access and optimizes the usage of the IdP if a limit is enabled.

- **Applications**—There are two types:

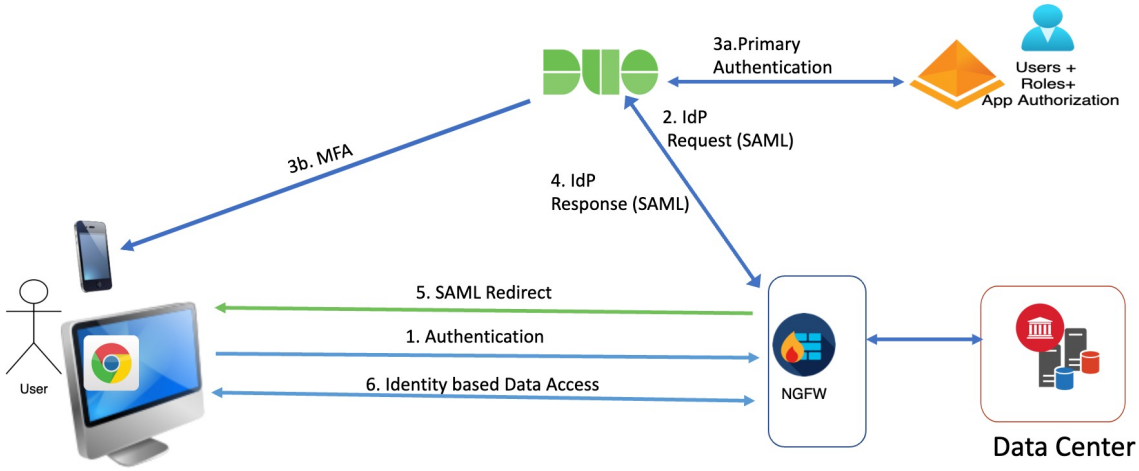
  - **Ungrouped Applications**— Are standalone applications. SAML settings must be configured for every application. The applications inherit the Security Zones and Security Controls settings from the global policy and can be overridden by the application.

- **Grouped Applications**— Are multiple applications that are grouped under an Application Group. The SAML settings are inherited from the Application Group and cannot be overridden. However, the Security Zones and Security Controls settings can be overridden for each application.

The following certificates are required for the configuration:

- **Identity Certificate**—This certificate is used by Firewall Threat Defense to masquerade as the applications. Firewall Threat Defense behaves as a SAML Service Provider (SP). This certificate must be a wildcard or Subject Alternative Name (SAN) certificate that matches the FQDN of the private applications. It is a common certificate for all applications protected by Firewall Threat Defense. Upload the public key from the same certificate to the identity provider (IDP), designating it as the SP certificate. The identity provider uses this certificate to verify the authentication request it receives. By default, Firewall Threat Defense signs the SAML authentication request before sending it to IDP. You cannot disable authentication request signing, and it is not configurable.
- **IdP Certificate**—The IdP provides a certificate for each defined Application or Application Group. This certificate must be configured so that Firewall Threat Defense can verify the IDP's signature on incoming SAML assertions.

Note IdP certificates are commonly included within the metadata file; otherwise, users are required to have the IdP certificate readily available during the configuration of applications.



- **Application Certificate**—The encrypted traffic from user to the application is decrypted by Firewall Threat Defense using this certificate for the purpose of inspection.

Note This certificate is required to verify the cookies in the header to authorize connections, even if we are not conducting an IPS/Malware inspection.

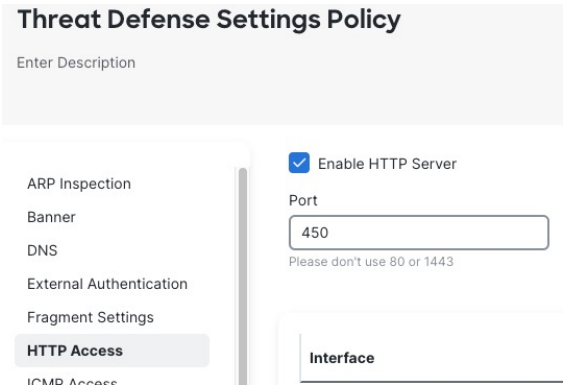
Clientless Zero Trust Network Access Workflow

This figure depicts the Zero Trust Access workflow.

Figure 405: Clientless Zero Trust Network Access Workflow

The workflow is as follows:

1. User types the application URL in the browser.
   - If the HTTPS request is valid, the user is redirected to the mapped port (Step 6).
   - If the HTTPS request is invalid, the user is sent for authentication per application (Step 2).
2. The user is redirected to the configured identity provider (IdP).
3. **a.** The user is redirected to the configured primary authentication source.
   b. The user is challenged with the configured secondary multi-factor authentication, if any.
4. The IdP sends a SAML response to threat defense. The user ID and other necessary parameters are retrieved from the SAML response through the browser.
5. The user is redirected to the application.
6. The user is allowed access to the application after validation is successful.



Limitations for Clientless Zero Trust Network Access

- Supports only TLS-enabled web applications. All traffic must be decrypted.
- Supports only SAML identity providers.
- IPv6 is not supported.

  NAT66, NAT64, and NAT46 scenarios are not supported.
- Clientless zero trust network access is available on Firewall Threat Defense only if Snort 3 is enabled.
- By default, the Firewall Threat Defense device uses port 443 for secure communications. Because this is the same port used by TLS-enabled applications likely to be configured for zero trust network access, you must change the device's HTTP server port.

Go to **Devices** > **Platform Settings**, then edit the Threat Defense Settings policy for the device, click **HTTP Access**, select the **Enable HTTP Server** check box, and enter a port other than 443 in the field. When you're finished, click **Save** in the upper right corner of the page.

The following figure shows an example.

- All hyperlinks in protected web applications must have a relative path and are not supported on individual mode clusters.
- Protected web applications running on a virtual host or behind internal load balancers must use the same external and internal URL.
- Not supported on applications with strict HTTP Host Header validation enabled.
- If the application server hosts multiple applications and serves content based on the Server Name Indication (SNI) header in the TLS Client Hello, the external URL of the zero trust application configuration must match the SNI of that specific application.

Prerequisites for Zero Trust Application Policy

Prerequisite Type	Description
Licensing	• Smart license account with export-controlled features • (Optional) IPS and Threat licenses—It is required if security controls are used.
Configurations	Create a wildcard or Subject Alternative Name (SAN) certificate that matches the FQDN of private applications. For more information, see Add certificate enrollment objects, on page 2402.
	Create a security zone through which access to private applications are regulated. For more information, see Create security zone and interface group objects, on page 610.

Manage Zero Trust Application Policies

You can create, edit, and delete zero trust application policies.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Manage the zero trust access policies:

- Create—Click **New Policy**. See Create a Zero Trust Application Policy, on page 1555
- Edit—Click **Edit** ( ). See Edit a Zero Trust Application Policy, on page 1560
- Report—Click **Report** ( ).
- Delete—Click **Delete** ( ).

Step 3 Click **Save**.

What to do next

Ensure that there are no warnings before you deploy the configuration to threat defense. To deploy configuration changes, see Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Create a Zero Trust Application Policy

This tasks configures a Zero Trust Application Policy.

Before you begin

Ensure that you complete all the prerequisites listed in Prerequisites for Zero Trust Application Policy, on page 1554.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**.

Step 2 Click **Add Policy**.

Step 3 In the **General** section, enter the policy name in the **Name** field. The description field is optional.

Step 4 Enter a domain name in the **Domain Name** field.

Ensure that the domain name is added to the DNS. The domain name resolves to the Firewall Threat Defense gateway interface from where the application is accessed. The domain name is used to generate the ACS URL for all private applications in an Application Group.

Step 5 Choose an existing certificate from the **Identity Certificate** drop-down list.

Click the **Add** (+) icon to configure a certificate enrollment object. For more information, see Add certificate enrollment objects, on page 2402.

Step 6 Choose a security zone from the **Security Zones** drop-down list.

Click the **Add** (+) icon to add a new security zone.

To add security zones, see Create security zone and interface group objects, on page 610.

Step 7 In the **Global Port Pool** section, a default port range is displayed. Modify, if required. Port values range from 1024 to 65535. A unique port from this pool is assigned to each private application.

Note This port range should avoid any conflicts with the existing NAT range.

Step 8 (Optional) In the **Security Controls** section, you can add an Intrusion or Malware and File policy:

- **Intrusion Policy**—Choose a default policy from the drop-down list or click the **Add** (+) icon to create a new custom intrusion policy. For more information, see Creating a Custom Snort 3 Intrusion Policy topic in the latest version of the Cisco Secure Firewall Management Center Snort 3 Configuration Guide.
- **Variable Set**—Choose a default variable set from the drop-down list or click the **Add** (+) icon to create a new variable set. For more information, see Create a variable set, on page 2452.

Note To use variable sets, you must have the Secure Firewall Threat Defense IPS license for your managed devices.

- **Malware and File Policy**—Choose an existing policy from the drop-down list. Click the **Add** (+) icon to create a new malware and file policy. For more information, see Manage file policies, on page 2039.

Step 9 Click **Save** to save the policy.

What to do next

1. Create an Application Group. See Create an Application Group, on page 1557.
2. Create an Application. See Create an Application, on page 1558.
3. Associate a Zero Trust Application Policy with a device. See Set Targeted Devices for Zero Trust Access Policy, on page 1560
4. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Create an Application Group

Before you begin

Create a Zero Trust Application Policy, on page 1555

Procedure

Step 1 Click **Add Application Group**.

Step 2 In the **Application Group** section, type the name in the **Name** field and click **Next**.

Step 3 In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the values of the **Entity ID** and **Assertion Consumer Service (ACS) URL** fields or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

Step 4 In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using any one of the methods:

- **XML File Upload**—Choose a file or drag and drop the XML file.

  The details of the **Entity ID**, **Single Sign-On URL**, and **IdP Certificate** are displayed.

- **Manual Configuration**—Perform these steps:
  - **Entity ID**—Enter the URL that is defined in the SAML IdP to identify a service provider uniquely.
  - **Single Sign-On URL**—Enter the URL for signing into the SAML identity provider server.
  - **IdP Certificate**—Choose the certificate of the IdP enrolled in threat defense to verify the messages signed by the IdP.

    Click the **Add** (+) icon to configure a new certificate enrollment object. For more information, see Add a certificate enrollment, on page 2403.

- **Configure Later**—In the event you do not have the IdP metadata, you can configure it later.

Click **Next**.

Step 5 In the **Re-authentication Interval** section, enter the value in the **Timeout Interval** field and click **Next**.

The re-authentication interval allows you to provide a value that determines when a user must authenticate again.

Step 6 In the **Security Zones and Security Controls** section, the security zones and threat settings are inherited from the parent policy. You can override these settings. Click **Next**.

Step 7 Review the configuration summary. Click **Edit** to modify the details in any of the sections. Click **Finish**.

Step 8 Click **Save**.

The Application Group is created and is displayed on the Zero Trust Application page.

What to do next

1. Create an Application, on page 1558.

2. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Create an Application

Use this task to create a Grouped or Ungrouped Application.

Before you begin

1. Create a Zero Trust Application Policy, on page 1555.
2. Create an Application Group, on page 1557 (required only for Grouped Applications).

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Choose the policy.

Step 3 Click **Add Application**.

Step 4 In the **Application Settings** section, complete the following fields.

- **Application Name**—Enter the application name.
- **External URL**—Enter the URL that is used by the user to access the application.
- **Application URL**—By default, the external URL is used as the Application URL. Uncheck the **Use External URL as Application URL** check box to specify a different URL.

  If Threat Defense uses an internal DNS, the Application URL must match an entry within that DNS to ensure it resolves to the application.

- **Application Certificate**—Choose the certificate for the private application. Click the **Add** (+) icon to configure an internal certificate object. For more information, see Add internal certificate objects, on page 2400.
- **IPv4 Source Translation**—Choose the source network for NAT from the list. Click **Add** (+) to create a network object. For more information, see Networks, on page 2386.

  This Network Object or Object Group is used to translate a public network source IPv4 address of an incoming request to a routable IPv4 address inside the corporate network.

Note Only object or object groups of type Host or Range are supported.

- **Application Group**—Choose the Application Group from the drop-down list. See Create an Application Group, on page 1557.

Note This field is not applicable for an ungrouped application.

Step 5 Click **Next**.

Step 6 Depending on the type of application:

- For a Grouped Application, the **SAML Service Provider (SP) Metadata**, **SAML Identity Provider (IdP) Metadata** , and **Re-authentication Interval** are inherited from the Application Group and do not need to be configured by the user.
- For an Ungrouped Application, perform these steps:

  a. In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the **Entity ID**, **Assertion Consumer Service (ACS) URL** of the IdP, or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

  b. In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using any one of the methods:

  - **XML File Upload**—Choose a file or drag and drop the XML file.

    The details of the **Entity ID**, **Single Sign-On URL**, and **IdP Certificate** are displayed.

  - **Manual Configuration**—Perform these steps:
    - **Entity ID**—Enter the URL that is defined in the SAML IdP to identify a service provider uniquely.
    - **Single Sign-On URL**—Enter the URL for signing into the SAML identity provider server.
    - **IdP Certificate**—Choose the certificate of the IdP enrolled in threat defense to verify the messages signed by the IdP.

      Click the **Add** (+) icon to configure a new certificate enrollment object. For more information, see Add a certificate enrollment, on page 2403.

  - **Configure Later**—If you do not have the IdP metadata, you can configure it later.

  Click **Next**.

  c. In the **Re-authentication Interval** section, enter the value in the **Timeout Interval** field and click **Next**. The reauthentication interval allows you to provide a value that determines when a user must authenticate again.

Step 7 In the **Security Zones and Security Controls** section, the security zones and threat settings are inherited from the parent policy or application group. You can override these settings. Click **Next**.

Step 8 Review the configuration summary. Click **Edit** to modify the details in any of the sections. Click **Finish**.

Step 9 Click **Save**.

The application is listed on the Zero Trust Application page and enabled by default.

What to do next

1. Set Targeted Devices for Zero Trust Access Policy, on page 1560.
2. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Set Targeted Devices for Zero Trust Access Policy

Each Zero Trust Application policy can target multiple devices; each device can have one deployed policy at a time.

Before you begin

1. Create a Zero Trust Application Policy, on page 1555.
2. Create an Application Group, on page 1557.
3. Create an Application, on page 1558.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Choose the policy.

Step 3 Click **Targeted Devices**.

Step 4 Choose the devices where you want to deploy the policy using any one of the methods:

- Choose a device in the **Available Devices** list and click >> or the **Add** (⊕) icon.
- To remove a device from the **Selected Devices** list, choose a device and click << or the **Delete** ( ) icon.

Step 5 Click **Apply** to save policy assignments.

Step 6 Click **Save** to save the policy.

What to do next

Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Edit a Zero Trust Application Policy

You can edit the settings of a Zero Trust Application Policy, Application Group, or Application.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Click **Edit** (✎) next to the Zero Trust Application Policy you want to edit.

Step 3 Edit your Zero Trust Application Policy.

You can change the following settings or perform these actions:

- Name and Description—Click **Edit** (✎) next to the policy name, make your changes, and click **Apply**.
- To modify the policy settings:
  - Click **Settings**
  - Modify the settings as required.

Important Editing the domain name for the SAML ACS URL interrupts application access.

  - Click **Save**.

- To modify the Application Group settings:
  - Click **Applications**.
  - Click **Edit** (✎) next to the Application Group you want to edit.
  - In each section, click **Edit** to modify the settings, as required

Important Editing the Application Group name interrupts application access.

  - Click **Apply** after you modify the settings in a section.
  - Click **Finish**.
  - Click **Save**.

- To modify the Application settings:
  - Click **Applications**.
  - Click **Edit** (✎) next to the Application you want to edit.
  - In each section, click **Edit** to modify the settings, as required.

Important Editing the Application name interrupts application access.

  - Click **Apply** after you modify the settings in a section.

- Click **Finish**.
- Click **Save**.

- To enable, disable, or delete multiple Applications, choose the Applications, click the required bulk action, and click **Save**.

Note These actions are also available in the right-click menu.

- To enable all Applications, click **Bulk Actions** > **Enable**.
- To disable all Applications, click **Bulk Actions** > **Disable**.
- To delete all Applications, click **Bulk Actions** > **Delete**.

- Click **Return to Zero Trust Application** to return to the policy page.

What to do next

Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Monitor Zero Trust Sessions

Connection Events

After a Zero Trust Application Policy is deployed, new fields are available. To add the fields to the table view:

1. Choose **Analysis** > **Unified Events**.
2. Click the column picker ( ) icon and add these columns:
   - **Authentication Source**
   - **Zero Trust Application**
   - **Zero Trust Application Group**
   - **Zero Trust Application Policy**
3. Click **Apply**.

See the Connection and Security-Related Connection Events in the Secure Firewall Management Center Administration Guide for more information on the connection events.

Zero Trust Dashboard

The Zero Trust dashboard allows you to monitor real-time data from active zero trust sessions on the devices.

The Zero Trust dashboard provides a summary of the top zero trust applications and zero trust users that are managed by the management center. Choose **Overview** > **Dashboards heading** > **Dashboard**, and click the **Zero Trust** tab to access the dashboard.

The dashboard has the following widgets:

- Top Zero Trust Applications
- Top Zero Trust Users

CLI Commands

Log in to the device CLI and use the following commands:

CLI Command	Description
show running-config zero-trust	To view the running configuration for a zero trust configuration.
show zero-trust	To display the run-time zero trust statistics and session information.
show cluster zero-trust	To display the summary of zero trust statistics across nodes in a cluster.
clear zero-trust	To clear zero trust sessions and statistics.
show counters protocol zero_trust	To view the counters that are hit for zero trust flow.

Diagnostics Tool

The diagnostics tool facilitates the troubleshooting process by detecting possible issues with zero trust configurations. The diagnostics can be classified into two types:

- **Application-specific diagnostics** are used to detect issues such as:
  - DNS-related issues
  - Misconfigurations such as socket not open, and issues with classification and NAT rules.
  - Issues with deployment of zero trust policy or SSL rules
  - Issues with source NAT issues and exhaustion of PAT pool
- **General diagnostics** are used to detect issues such as:
  - Strong cipher license not enabled
  - Invalid application certificate
  - SAML-related issues
  - Home agent and cluster bulk sync issues

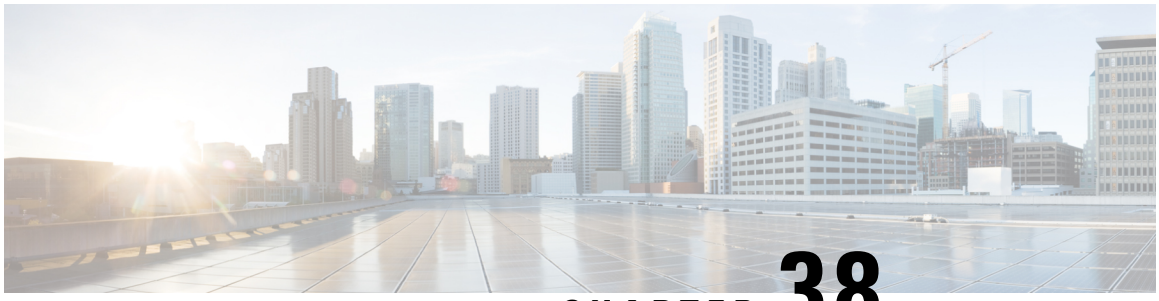
To run the diagnostic tool:

1. Click Diagnostics ( ) next to the zero trust application that you want to troubleshoot. The **Diagnostics** dialog box appears.
2. Choose the device from the **Select Device** drop-down list and click **Run**. A report is generated in the **Reports** tab after the diagnostic process is complete.
3. To view, copy, or download the logs, click the **Logs** tab.

History for zero trust network access

This reference provides the minimum Firewall Management Center and Threat Defense versions needed to support zero trust application policies and monitoring.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Zero trust access enhancements.	7.4.1	7.4.1 with Snort 3	Firewall Management Center now includes the following zero trust access enhancements: • You can configure source NAT for an application. The configured network object or object group translates the incoming request's public network source IP address to a routable IP address inside the application network. • You can troubleshoot the zero trust configuration issues using the diagnostics tool. New/modified screens: **Policies** > **Access Control** > **Zero Trust Application** New/modified CLI commands: **show running-config zero-trust**, **show zero-trust statistics**



Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Clientless zero-trust access.	7.4.0	7.4.0 with Snort 3	Zero Trust Access allows you to authenticate and authorize access to protected web based resources, applications, or data from inside (on-premises) or outside (remote) the network using an external SAML Identity Provider (IdP) policy. The configuration consists of a Zero Trust Application Policy (ZTAP), Application Group, and Applications. New/modified screens: • **Policies** > **Zero Trust Application** • **Analysis** > **Connections** > **Events** • **Overview** > **Dashboard** > **Zero Trust** New/modified CLI commands: • **show running-config zero-trust application** • **show running-config zero-trust application-group** • **show zero-trust sessions** • **show zero-trust statistics** • **show cluster zero-trust statistics** • **clear zero-trust sessions application** • **clear zero-trust sessions user** • **clear zero-trust statistics**

PART VIII

Access Control Policy Basics

- Access Control Policies, on page 1569
- Security Intelligence, on page 1595
- Access Control Rules, on page 1609
- URL Filtering Rules, on page 1651
- Content Restriction, on page 1681
- Intrusion Prevention Overview, on page 1687

CHAPTER 38

Access Control Policies

These topics describe how to work with access control policies:

- Access control policies, on page 1569
- Requirements and prerequisites for access control policies, on page 1574
- Manage access control policies, on page 1575
- History for access control policies, on page 1591

Access control policies

An access control policy is a hierarchical policy that allows you to specify, inspect, and log network traffic. You can use the characteristics of each connection to allow, trust, block, or monitor the connection.

Each managed device can be assigned to one access control policy. The data that the policy's assigned (also known as targeted) devices collect about your network traffic can be used to filter and control that traffic based on:

- simple, easily determined transport and network layer characteristics: source and destination, port, protocol, and so on
- the latest contextual information on the traffic, including characteristics such as reputation, risk, business relevance, application used, or URL visited
- realm, user, user group, or ISE attribute
- custom Security Group Tag (SGT)
- characteristics of encrypted traffic; you can also decrypt this traffic for further analysis
- whether unencrypted or decrypted traffic contains a prohibited file, detected malware, or intrusion attempt
- time and day (on supported devices)

Each type of traffic inspection and control occurs where it makes the most sense for maximum flexibility and performance. For example, reputation-based blocking uses simple source and destination data, so it can block prohibited traffic early in the process. In contrast, detecting and blocking intrusions and exploits is a last-line of defense.

Access control policy components

This list describes the main components of an access control policy.

- Name and description: Each access control policy must have a unique name. A description is optional.
- Inheritance settings: Policy inheritance allows you to create a hierarchy of access control policies. A parent (or base) policy defines and enforces default settings for its descendants. A policy's inheritance settings allow you to select its base policy. You can also lock settings in the current policy to force any descendants to inherit them. Descendant policies can override unlocked settings.
- Policy assignment: Every access control policy identifies which devices use it. Each device can use only one access control policy.
- Rules: Access control rules provide a granular method of handling network traffic. Rules are numbered, starting at 1, including rules inherited from ancestor policies. The system matches traffic to rules from the top down, ascending by rule number.

  Traffic is handled by the first rule for which all conditions match. Conditions can be simple or complex, and often depend on licensing.
- Default action: The default action determines how the system handles and logs traffic that is not handled by any other access control configuration. It can block or trust all traffic without further inspection, or inspect traffic for intrusions and discovery data. Although an access control policy can inherit its default action from an ancestor policy, you cannot enforce this inheritance.
- Security Intelligence: This feature acts as the first line of defense against malicious internet content. It enables blocking of connections based on IP address, URL, and domain name reputation intelligence. To ensure continual access to vital resources, you can override block list entries with custom do not block list entries.
- HTTP responses: When a user's website request is blocked, you can display either a generic response page or a custom page. Alternatively, you can warn users but allow them to proceed to the requested site.
- Logging: Logging settings enable configuration of default syslog destinations for the policy. These settings apply to the policy and all included decryption, prefilter, and intrusion policies unless overridden in individual rules or policies.
- Advanced access control options: Advanced policy settings typically require little modification, and defaults are often suitable. Modifiable options include traffic preprocessing, decryption, identity, and various performance configurations.

Access control policy default actions

The default action is the access control policy configuration that determines how the system handles and logs traffic that is not handled by any other access control configuration. The default action can block or trust all traffic without further inspection, or inspect traffic for intrusions and discovery data.

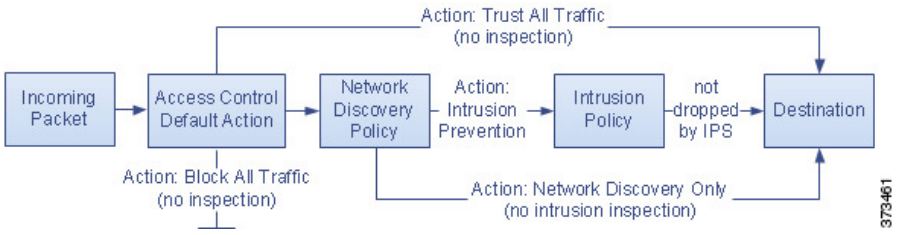
In a simple access control policy, the default action specifies how a device handles all traffic. In a more complex policy, the default action handles traffic that:

- is not fast pathed by the prefilter policy
- is not on a Security Intelligence block list

- is not blocked by the decryption policy (encrypted traffic only)
- matches none of the rules in the policy (except monitor rules, which match and log—but do not handle or inspect—traffic)

Note You cannot perform file or malware inspection on traffic handled by the default action. Logging of connections handled by the default action is initially disabled but can be enabled.

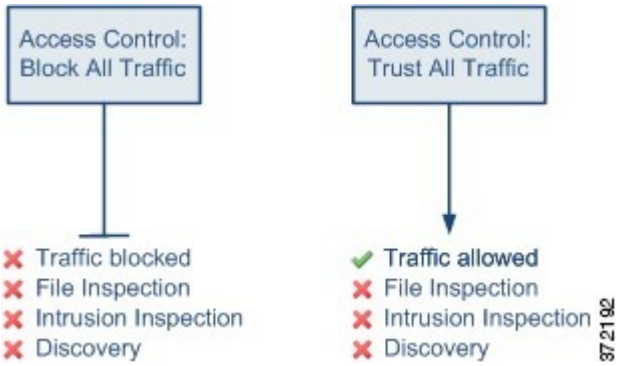
If you are using policy inheritance, the default action for the lowest-level descendant determines how traffic is handled. An access control policy can inherit its default action from the base policy, but this inheritance is not enforced.



This table describes the types of inspection you can perform on traffic handled by each default action.

Table 91: Types of default actions and inspection options

Default action	Effect on traffic	Inspection type and policy
Access Control: Block All Traffic	Block without further inspection.	None.
Access Control: Trust All Traffic	Trust (allow to its final destination without further inspection).	None.
Intrusion Prevention	Allow, as long as it is passed by the intrusion policy you specify.	Intrusion, using the specified intrusion policy and associated variable set. Discovery, using the network discovery policy.
Network Discovery Only	Allow.	Discovery only, using the network discovery policy.
Inherit from base policy	Defined in base policy.	Defined in base policy.



This diagram illustrates the table.

Figure 406: Default action configuration options

This diagram illustrates the **Block All Traffic** and **Trust All Traffic** default actions.

Figure 407: Block all traffic and trust all traffic default actions

This diagram illustrates the **Intrusion Prevention** and **Network Discovery Only** default actions.

Figure 408: Intrusion prevention and network discovery only default actions

Note The purpose of **Network Discovery Only** is to improve performance in a discovery-only deployment. Different configurations can disable discovery if you are only interested in intrusion detection and prevention.

Access control policy inheritance

Access control policy inheritance is a hierarchical policy-based implementation that allows child policies to inherit rules and settings from ancestor or base policies. This structure ensures that mandatory rules defined in parent policies are consistently enforced, while providing the flexibility for child policies to selectively override default configurations.

Access control policy hierarchy structure

You can nest access control policies, where each policy inherits the rules and settings from an ancestor policy. You can enforce this inheritance, or allow lower-level policies to override their ancestors.

Just as you create a domain hierarchy, you can create a corresponding hierarchy of access control policies. A descendant, or child, access control policy inherits rules and settings from its direct parent, or base, policy. That base policy may have its own parent policy from which it inherits rules and settings, and so on.

An access control policy's rules are nested between its parent policy's Mandatory and Default rule sections. This implementation enforces Mandatory rules from ancestor policies, but allows the current policy to write rules that preempt Default rules from ancestor policies.

You can lock these settings to enforce them in all descendant policies:

- Security Intelligence—Connections that are allowed or blocked based on the latest reputation intelligence for IP addresses, URLs, and domain names.
- HTTP response pages—Displaying a custom or system-provided response page when you block a user's website request.
- Advanced settings—Specifying associated subpolicies, network analysis settings, performance settings, and other general options.

When using policy inheritance, the default action for the lowest-level descendant determines final traffic handling. Although an access control policy can inherit its default action from an ancestor policy, you cannot enforce this inheritance.

Policy inheritance and multitenancy

Access control's hierarchical policy-based implementation complements multitenancy.

In a typical multidomain deployment, access control policy hierarchy corresponds to domain structure, and you apply the lowest-level access control policy to managed devices. This implementation allows selective access control enforcement at a higher domain level, while lower-level domain administrators can tailor deployment-specific settings. (You must use roles, not policy inheritance and enforcement alone, to restrict administrators in descendant domains.)

For example, as a Global domain administrator for your organization, you can create an access control policy at the Global level. You can then require that all your devices, which are divided into subdomain by function, use that Global-level policy as a base policy.

When subdomain administrators log into the Secure Firewall Management Center to configure access control, they can deploy the Global-level policy as-is. Or, they can create and deploy a descendant access control policy within the boundaries of the Global-level policy.

Note Although the most useful implementation of access control inheritance and enforcement complements multitenancy, you can create a hierarchy of access control policies within a single domain. You can also assign and deploy access control policies at any level.

Rule and other policy warnings

Policy and rule editors use icons to mark configurations that could adversely affect traffic analysis and flow. Depending on the issue, the system may warn you when you deploy or prevent you from deploying entirely.

Note Move your pointer over an icon to read the warning, error, or informational text.

Table 92: Policy error icons

Icon	Description	Example
Errors ( )	If a rule or configuration has an error, you cannot deploy until you correct the issue, even if you disable any affected rules.	A rule that performs category and reputation-based URL filtering is valid until you assign a device that does not have a URL Filtering license. At that point, an error icon appears next to the rule, and you cannot deploy until you edit or delete the rule, unassign the device, or enable the license.
Warning ( )	You can deploy a policy that displays rule or other warnings. However, misconfigurations marked with warnings have no effect. If you disable a rule with a warning, the warning icon disappears. It reappears if you enable the rule without correcting the underlying issue.	Preempted rules or rules that cannot match traffic due to misconfiguration have no effect. This includes conditions using empty object groups, application filters that match no applications, excluded LDAP users, invalid ports, and so on. However, if a warning icon marks a licensing error or model mismatch, you cannot deploy until you correct the issue.
Information ( )	Information icons convey helpful information about configurations that may affect the flow of traffic. These issues do not prevent you from deploying.	The system might skip matching the first few packets of a connection against some rules, until the system identifies the application or web traffic in that connection. This allows connections to be established so that applications and HTTP requests can be identified.
Rule Conflict ( )	When you enable rule conflict analysis, this icon appears in the rule table for rules that have conflicts.	Conflicts include redundant rules, redundant objects, and shadowed rules. Redundant and shadowed rules do not match traffic because previous rules would already match the criteria. Redundant objects make your rules unnecessarily complex.

Requirements and prerequisites for access control policies

Ensure that your environment meets these requirements before configuring access control policies.

- You must have **Administrator**, **Network Admin**, or **Access Admin** privileges to configure access control policies.
- Custom roles: You can define custom user roles to differentiate between the intrusion configuration in access control policy and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. The existing pre-defined user roles that included the Modify Access Control Policy permission support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions.
  - **Policies** > **Access Control heading** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** allows the selection of intrusion

policy, variable set, and file policy in a rule, the configuration of the advanced options for network analysis and intrusion policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. If a user has this option only, the user can modify no other part of the policy or rule.

- **Modify Remaining Access Control Policy Configuration** controls the ability to edit all other aspects of the policy.

Manage access control policies

Configure and manage access control policies by editing system-provided policies and creating custom access control policies.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

At the top of the page, there are convenient links to some related features: Object management, Intrusion policies, Network Analysis policies, DNS policies, and policy Import/Export.

Step 2 These actions help you to manage your policy:

- Create—Click **New Policy**; see Creating a basic access control policy, on page 1575.
- Edit—Click **Edit** ( ); see Editing an access control policy, on page 1576
- Delete—Click **Delete** ( ). You must remove any device assignments before deleting a policy.
- Copy—Click **Copy** ( ). Device assignments are not retained in the copy.
- Lock or unlock a policy—See Lock an access control policy, on page 1578.

Step 3 These options help you to analyze, monitor, and customize your policies:

- Inheritance—Click **Plus** next to a policy with descendants to expand your view of the policy's hierarchy.
- Report—Click **Report** ( ).. The report is generated as a background process. Go to the message/notifications center and look in the tasks list. When the report is finished, you can download it from the notification.

Creating a basic access control policy

When you create a new access control policy, it contains default actions and settings. After creating the policy, you are immediately placed in an edit session so that you can adjust the policy to suit your requirements.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **New Policy**.

Step 3 Enter a unique **Name** and, optionally, a **Description**.

Step 4 Optionally, choose a base policy.

If an access control policy is enforced on your domain, this step is not optional. You must choose the enforced policy or one of its descendants as the base policy.

If you select a base policy, the base policy defines the default action and you cannot select a new one in this dialog box. Logging for connections handled by the default action depends on the base policy.

Step 5 When you do not select a base policy, specify the initial **Default Action**:

- **Block all traffic** creates a policy with the **Access Control: Block All Traffic** default action.
- **Intrusion Prevention** creates a policy with the **Intrusion Prevention: Balanced Security and Connectivity** default action, associated with the default intrusion variable set.
- **Network Discovery** creates a policy with the **Network Discovery Only** default action.

When you select a default action, logging of connections handled by the default action is initially disabled. You can enable it later when you edit the policy.

Note If you want to trust all traffic by default, or if you chose a base policy and do not want to inherit the default action, you can change the default action later.

Step 6 Optionally, choose the devices to assign to the policy. To narrow the devices that appear, enter a search string.

If you want to deploy this policy immediately, you must perform this step.

Step 7 Click **Save**.

The new policy opens for edit. You can add rules to it and make other changes as needed. See Editing an access control policy, on page 1576.

Editing an access control policy

When you edit an access control policy, you should lock it to ensure that your changes do not get overridden by another person who might edit it simultaneously.

You can only edit access control policies that were created in the current domain. Also, you cannot edit settings that are locked by an ancestor access control policy.

To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Note If you do not lock the policy, consider the following: Only one person should edit a policy at a time, using a single browser window. Although more than one user can edit an access control policy at a time, when one user saves changes, all changes made by the other users are immediately deleted and these users are moved out of edit mode and back to the access control policy listing page. These other users must start again.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control** .

Step 2 Click **Edit** ( ) next to the access control policy you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Edit your access control policy.

Note You can operate on multiple rules at one time by selecting their checkboxes in the left column, then selecting the action you want to perform from the **Select Bulk Rule Actions** drop-down list next to the search box. Bulk editing is available for enabling and disabling, copying, moving, deleting, and editing rules, or viewing hit counts or related events.

You can change the following settings or perform these actions:

- Name and description—Click **Edit** ( ) next to the name, make your changes, and click **Save** .
- Default action and settings—Choose a value from the **Default Action** drop-down list, then click **Cog** ( ) , make your changes to the settings, and click **OK** . For detailed information, see Configure the access control default action, on page 1579 .
- Associated policies—To edit or change policies in the packet flow, click the policy type in the packet flow representation below the policy name. You can select the **Prefilter Rules** , **Decryption** , **Security Intelligence** , and **Identity** policies. When necessary, click **Access Control** to return to the access control rules.
- Policy assignment—To identify the managed devices targeted by this policy, or enforce this policy in a subdomain, click the **Targeted: x devices** link.
- Rules—To manage access control rules, and to inspect and block malicious traffic using intrusion and file policies, click **Add Rule** , or right-click an existing rule and select **Edit** or another appropriate action. The actions are also available from the **More** ( ) button for each rule. See Create and edit access control rules, on page 1631 .
- Layout—Use the **Grid/Table View** icon above the list of rules to change the layout. Grid view provides color-coded objects in an easy-to-see layout. Table view provides a summary list so that you can see more rules at once. You can freely switch views without impacting the rules.

- Columns (table view only)—Click the **Show/Hide Columns** icon above the list of rules to select which information to show in the table. Click **Show/Hide Empty Columns** to quickly add, or remove, all columns that have no information, that is, you are not using those conditions in any rule. Click **Revert to Default** to undo all of your customizations.
- Analyze rule logic—You can select the following options from the **Analyze** menu to examine the logic of your rules:
  - **Manage Rule Hit Counts** —To view statistics on how many connections matched each rule. See View rule hit counts, on page 1586 .
  - **Enable/Disable Rule Conflicts** —Select whether you want to see information on whether rules interfere with each other. You can then view the results using the following commands. See Analyzing rule conflicts and warnings, on page 1588
    - **Show Warnings and Errors** —See whether there are rules with configuration issues that you need to address.
    - **Show Policy Warnings** —See whether there are configuration issues with the policy.
    - **Show Rule Conflicts** —See whether you have redundant or shadowed rules. These conflicts could prevent certain rules from ever being matched by connections, meaning either that you need to fix the match criteria, move the rule, or simply delete the rule.

Step 4 To change additional settings for the policy, select one of these options from the **More** drop-down arrow at the end of the packet flow line.

- **Advanced Settings** —To set preprocessing, decryption, identity, performance, and other advanced options. See Configure advanced settings for the access control policy, on page 2170 .
- **HTTP Responses** —To specify what the user sees in a browser when the system blocks a website request. See Choose HTTP response pages, on page 1671 .
- **Inheritance Settings** —To change the base access control policy for this policy, and to enforce this policy's settings in its descendant policies. See Choose a base access control policy, on page 1581 and Lock settings in descendant access control policies, on page 1581 .
- **Logging** —To set the default logging options for the policy.

Step 5 Click **Save** .

Lock an access control policy

Lock an access control policy to prevent other administrators from editing it, ensuring that your changes will not be invalidated if another administrator edits the policy and saves changes before you save your changes.

Without locking, if multiple administrators edit the policy simultaneously, the first person who saves changes wins, and all other users have their changes erased.

The lock is for the access control policy itself. The lock does not apply to objects used in the policy. For example, another user can edit a network object that is used in a locked access control policy. Your lock remains in place until you explicitly unlock the policy, so you can log out and come back to your edits later.

When locked, other administrators have read-only access to the policy. However, other administrators can assign a locked policy to a managed device.

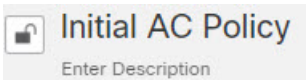
Before you begin

Any user role that has permission to modify the access control policy has permission to lock it, and to unlock a policy that was locked by another user.

However, the ability to unlock a policy that was locked by another administrator is controlled by the following permission: **Policies** > **Access Control heading** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Override Access Control Policy Lock**.

If you are using custom roles, your organization might have limited your unlocking abilities by not assigning this permission. Without this permission, only the administrator who locks a policy can unlock it.

Procedure



Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** ( ) next to the access control policy you want to lock or unlock.

In the access control policy list:

- The **Lock Status** column shows whether a policy is already locked, and if so, who locked it. An empty cell indicates that the policy is not locked.
- If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration. Or, it is locked by another user.

Step 3 Click the lock icon next to the policy name to lock or unlock the policy.

If the policy inherits settings from a parent policy, you must choose one of these options when you click the lock icon.

- **Lock/Unlock this policy**—The locking or unlocking is for this policy only.
- **Lock/Unlock all policies in hierarchy**—This policy and all parent policies are locked or unlocked. If a parent policy is already locked by another administrator, you will see a message and you will not be able to lock that parent policy. When unlocking policies, if you have the Override Access Control Policy Lock permission, all parent policies are unlocked even if they were locked by other users.

Configure the access control default action

Configure the default action for an access control policy when connections do not match specific access control rules.

The default action for an access control policy is applied to any connection that:

- is not fast pathed by the prefilter policy

- is not on a Security Intelligence block list
- is not blocked by the decryption policy (encrypted traffic only)
- matches none of the rules in the policy (except monitor rules, which match and log—but do not handle or inspect—traffic)

Procedure

Step 1 Edit the access control policy whose inheritance settings you want to change; see Editing an access control policy, on page 1576.

Step 2 Select the **Default Action** at the bottom of the rules list.

For detailed information on what each option does, see Access control policy default actions, on page 1570.

Step 3 Click **Cog** () to configure the default action settings.

You can configure the following options. Click **OK** when finished.

- Logging options—Whether to log the connection. You can **Log at beginning of connection**, **Log at end of connection**, or both. If you select block as the default action, you can log at the beginning of the connection only.
- **Send connection events to**—If you select one of the logging options, select whether to send events to any combination of the following:
  - **Firewall Management Center**—Send events to the manager.
  - **Syslog server**—Send events to the default syslog server configured for the policy. You can configure overrides to specify a different severity level or syslog server destination.
- **SNMP trap**—If you enable logging, you can send SNMP traps to an SNMP server. Select an SNMP configuration, or click + to configure a new one.
- **Default action variable set**—If you selected one of the intrusion prevention default actions, select the variable set that should be used with the intrusion policy you selected.

Step 4 Click **Save**.

Manage access control policy inheritance

Inheritance relates to using another policy as a base policy for an access control policy. This allows you to use one policy to define some baseline characteristics that can be applied to multiple policies. To understand how inheritance works, refer to Access control policy inheritance, on page 1572.

Procedure

Step 1 Edit the access control policy whose inheritance settings you want to change; see Editing an access control policy, on page 1576.

Step 2 Manage policy inheritance:

- Change base policy — To change the base access control policy for this policy, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line and proceed as described in Choose a base access control policy, on page 1581.
- Lock settings in descendants — To enforce this policy's settings in its descendant policies, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line and proceed as described in Lock settings in descendant access control policies, on page 1581.
- Inherit settings from base policy — To inherit settings from a base access control policy, proceed as directed in Inherit access control policy settings from the base policy, on page 1582.
- Required in domains — To enforce this policy in a subdomain, click the **Targeted: x devices** link and proceed as described in Enforce an access control policy in a domain, on page 1583.

Choose a base access control policy

Choose a base access control policy to establish policy inheritance, allowing a child policy to inherit rules and settings from its parent while maintaining the ability to modify unlocked configurations.

When you change the base policy for the current access control policy, the system updates the current policy with any locked settings from the new base policy.

Procedure

Step 1 In the access control policy editor, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 2 Choose a policy from the **Select Base Policy** drop-down list.

To remove inheritance, select **None**.

Step 3 Click **OK**.

Step 4 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Lock settings in descendant access control policies

Lock a setting in an access control policy to enforce the setting in all descendant policies.

Descendant policies can override unlocked settings. When you lock settings, the system saves overrides already made in descendant polices so that the overrides can be restored if you unlock settings again.

Procedure

Step 1 In the access control policy editor, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 2 In the Child Policy Inheritance Settings area, check the settings you want to lock.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration.

Step 3 Click **OK** to save the inheritance settings.

Step 4 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Inherit access control policy settings from the base policy

Configure a child access control policy to inherit settings from a base policy or override them with custom configurations.

Child access control policies inherit many settings from their base policy by default. If these settings are unlocked in the base policy, you can override them.

If you later reinherit the settings from the base policy, the Firewall Management Center displays the base policy's settings and dims the controls. However, it saves the overrides you made and restores them if you disable inheritance again.

Procedure

Step 1 In the access control policy editor, click **Security Intelligence**, or select **HTTP Responses**, **Logging**, **Encrypted Visibility Engine**, or **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line

Step 2 Check the **Inherit from (*base policy*)** check box for each setting you want to inherit.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration.

Step 3 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Enforce an access control policy in a domain

Require that every device in a domain use the same base access control policy or one of its descendant policies.

This procedure is relevant in a multi-domain deployment only.

Procedure

Step 1 In the access control policy editor, click the **Targeted: x devices** link.

Step 2 Click **Required on Domains**.

Step 3 Build your domain list:

- Add — Select the domains where you want to enforce the current access control policy, then click **Add** or drag and drop into the list of selected domains.
- Delete — Click **Delete** ( ) next to a leaf domain, or right-click an ancestor domain and choose **Delete Selected**.
- Search — Type a search string in the search field. Click **Clear** ( ) to clear the search.

Step 4 Click **OK** to save the domain enforcement settings.

Step 5 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Assign access control policy to devices

An access control policy specifies the devices that use it. Each device can be assigned to only one access control policy.

Procedure

Step 1 In the access control policy editor, click the **Targeted: x devices** link.

Step 2 Build your target list:

- Add — Select one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**.
- Delete — Click **Delete** ( ) next to a single device, or select multiple devices, right-click, then choose **Delete Selection**.
- Search — Type a search string in the search field. Click **Clear** ( ) to clear the search.

Under **Impacted Devices**, the system lists the devices whose assigned access control policies are children of the current policy. Any change to the current policy affects these devices.

Step 3 Click **OK** to save your assigned device settings.

Step 4 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Logging settings for access control policies

Logging settings for access control policies are configuration option that allow you to configure default syslog destinations for the current access control policy. The settings are applicable to the access control policy and all the included decryption, prefilter, and intrusion policies unless the syslog destination settings are explicitly overridden with custom settings in included rules and policies.

To configure logging settings for an access control policy, select **Logging** from the **More** drop-down arrow at the end of the packet flow line.

You can configure default syslog destinations and syslog alert for the access control policy. The settings are applicable to the access control policy and all the included decryption, prefilter, and intrusion policies unless the syslog destination settings are explicitly overridden with custom settings in included rules and policies.

Logging for connections handled by the default action is initially disabled.

Intrusion settings and file and malware settings are effective only after you have selected an option at the top of the page for sending syslog messages generally.

Default syslog settings

Default syslog settings provide two destination options:

- **Send using specific syslog alert**: Events are sent based on the selected syslog alert as configured using the instructions in *Creating a Syslog alert Response* in the *Cisco Secure Firewall Management Center Administration Guide*. You can select the syslog alert from the list or add one by specifying the name, logging host, port, facility, and severity.

  When using this option, the system sends syslog messages to the server using the Management interface. Ensure there is a route from the Management interface to the syslog server, or messages will not arrive at the server.

- **Use the syslog settings configured in the Threat Defense Platform Settings policy deployed on the device**: Connection or intrusion events are sent with the selected severity to syslog collectors configured in Platform Settings. Using this option, you can unify the syslog configuration by configuring it in platform settings and reusing the settings in access control policy. Severity selected in this section is applied to all connection and intrusion events. The default severity is alert.

Intrusion settings

Intrusion settings include these options:

- **Send syslog messages for intrusion events**: Send intrusion events as syslog messages. The defaults set above are used unless you override them.

- **Show overrides** or **Hide overrides**: If you want to use the default syslog destination and severity, leave these options empty. Otherwise, you can set a different syslog server destination for intrusion events, and change the severity of the events.

File and malware settings

File and malware settings include these options:

- **Send syslog messages for file and malware events**: Send file and malware events as syslog messages. The defaults set above are used unless you override them.
- **Show overrides** or **Hide overrides**: If you want to use the default syslog destination and severity, leave these options empty. Otherwise, you can set a different syslog server destination for file and malware events, and change the severity of the events.

AI defense settings

Associate prefilter, decryption, and identity policies with an access control

Associate subpolicies with an access control policy to create a comprehensive security framework that handles different aspects of network traffic processing.

The easiest way to associate subpolicies to an access control policy is by clicking the policy's link in the packet flow shown at the top of an access control policy. Alternatively, you can use the policy's advanced settings to associate the subpolicy, as described in this topic. The subpolicies that you can associate with access control policy are:

- Prefilter policy—Performs early traffic handling using limited network (layer 4) outer-header criteria.
- Decryption policy—Monitors, decrypts, blocks, or allows application layer protocol traffic encrypted with Secure Socket Layer (SSL) or Transport Layer Security (TLS).
- Identity policy—Performs user identification based on the realm and authentication method associated with the traffic.

Before you begin

Before associating a decryption policy with an access control policy, review the information about TLS server identity discovery in TLS server identity discovery, on page 2173.

Procedure

Step 1 In the access control policy editor, select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 2 Locate the policy settings area for prefilter, decryption, or identity policies.

Step 3 Click **Edit** ( ) in the corresponding policy settings area.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 Choose a policy from the drop-down list.

If you choose a user-created policy, you can click the edit icon that appears to edit the policy.

Step 5 Click **OK**.

Step 6 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

View rule hit counts

Hit count indicates the number of times a policy rule or default action has been matched to a connection. The hit count is incremented only for the first packet of a connection that matches a rule. You can use this information to identify the efficacy of your rules. Hit count information is available only for access control and prefilter rules applied to Firewall Threat Defense devices.

Note

- The count persists through reboots and upgrades.
- Counts are maintained by each unit in an HA pair or cluster separately.
- You will not be able to derive the hit count information from a device when deployment or a task is in progress on the device.
- You can also see rule hit count information in the device CLI using the **show rule hits** command.
- If you have accessed the Hit Count page from the Access Control Policy page, you will not be able to view or edit prefilter rules and vice-versa.
- Hit counts are not available for rules that use the Monitor action.

Before you begin

If you use custom user roles, ensure that the roles include these privileges:

- View Device, to see the hit counts.
- Modify Device, to refresh the hit counts.

Follow these steps to view rule hit counts:

Procedure

Step 1 In the access control policy or prefilter policy editor, click **Analyze** > **Rule Hit Counts** on the top-right of the page.

Step 2 On the Hit Count page, select the device from the **Select a device** drop-down list.

If it is not the first time that you are generating hit counts for this device, the last fetched hit count information appears next to the drop-down box. Also, verify the **Last Deployed** time to confirm recent policy changes.

Step 3 If necessary, click **Refresh** ( ) to obtain current hit count data from the selected device.

In the prefilter policy, you might need to click **Fetch Current Hit Count** to get initial hit count data.

You cannot refresh the hit count while deployment to the device is in progress.

Step 4 View and analyze the data.

You can do these actions:

- Click **Prefilter** or **Access Control** to switch between the hit counts for these policies.
- Search for a specific rule by entering a search string in the **Filter** box.
- Broadly limit the list to **Hit Rules** or **Never Hit Rules** by selecting these options in the **Filter by** field. When viewing hit rules, you can further limit the list by selecting a time range in the **In Last** field (for example, in the last 1 day).
- (When viewed from the access control policy.) Clear the hit counts for one or more rule by selecting the checkbox for the rule, then clicking **Clear Hit Counts**. When confirming the action, choose **Clear and Reload** to refresh the hit count data. You can clear hit counts for up to 500 rules at a time. You cannot undo clearing hit counts.

Note Click the checkbox in the table header to select all rules visible in the list. To select a range of rules, select the first rule's checkbox, then **`Shift+click`** the last rule's checkbox; all rules in between are also selected.

- (When viewed from the access control policy.) You can do these actions with individual rules:
  - Edit the rule by clicking **Edit** from the **More** ( ) menu.
  - Delete the rule from the policy by clicking **Delete** from the **More** ( ) menu.
  - Enable or disable the rule by clicking **Enable Rule** or **Disable Rule** from the **More** ( ) menu.
  - Clear the hit count (reset it to zero) for the rule by clicking **Clear Hit Count** from the **More** ( ) menu. You cannot undo this action.
- (When viewed from the access control policy.) You can do these actions with individual rules:
  - Edit the rule by clicking **Edit** ( ).
  - Delete the rule from the policy by clicking **Delete** ( ).
  - Enable or disable the rule by clicking the **Slider** ( ).
  - Clear the hit count (reset it to zero) for the rule by clicking the **X** for the rule. You cannot undo this action.
- Change the displayed columns by clicking and selecting the columns to show. When viewed from the prefilter policy, use the **Cog** ( ) to select the columns to display.

- (When viewed from the prefilter policy.) Click on a rule name to edit it, or click **View** ( ) in the last column to view the rule details. Clicking on the rule name highlights it in the policy page where you can edit it.
- (When viewed from the prefilter policy.) Clear the hit count information (reset it to zero) for a rule by right-clicking the rule and selecting **Clear Hit Count**. You can select multiple rules by using Ctrl+click. You cannot undo this action.

Step 5 Optionally, you can generate a comma-separated values report of the details on the page by clicking **Generate CSV** on the bottom-left of the page.

Step 6 Click **Close** to return to the policy page.

Analyzing rule conflicts and warnings

View warnings and information about rule conflicts to examine the logic of your access control policy and to identify rules that need changes.

When rules overlap, you can end up with unnecessary rules in the policy, and these rules will never be matched to traffic. The analysis can help you delete unnecessary rules, or identify rules that should be moved or modified so they enforce the desired policy.

Policy warnings and errors point out things that you should understand and perhaps address to ensure that your rules provide the desired services.

Rule conflict analysis identifies these problems:

- Object overlap—An element in a field of a rule is a subset of one or more elements in the same field of the rule. For example, the source field might include a network object for 10.1.1.0/24, and another object for the host 10.1.1.1. Because 10.1.1.1 is within the network covered by 10.1.1.0/24, the object for 10.1.1.1 is redundant and can be deleted, simplifying the rule and saving device memory.
- Redundant rule—Two rules apply the same action to the same type of traffic and removing the base rule would not change the ultimate result. For example, if a rule permitting FTP traffic for a particular network were followed by a rule allowing IP traffic for that same network, and there were no rules in between denying access, then the first rule is redundant and you can delete it.
- Shadowed rule—This is the reverse of a redundant rule. In this case, one rule will match the same traffic as another rule such that the second rule will never be applied to any traffic because it comes later in the access list. If the action for both rules is the same, you can delete the shadowed rule. If the two rules specify different actions for traffic, you might need to move the shadowed rule or edit one of the two rules to implement your desired policy. For example, the base rule might deny IP traffic, and the shadowed rule might permit FTP traffic, for a given source or destination.

Before you begin

When doing the analysis:

- Only the first conflict for a given rule is identified. Once you fix the problem, the rule might be identified as having a conflict with another rule in the table. However, a rule might have multiple warnings or errors.

- Rule conflict analysis considers source/destination security zone, network, VLAN, and service/port match conditions and action only. It does not consider other match criteria, so an apparently redundant rule might not be completely redundant.
- FQDN network objects cannot be analyzed for conflict, because the IP address of an FQDN cannot be known prior to DNS lookup.
- Disabled rules are ignored.
- Time range attributes are ignored. Rules for different time periods might be marked as redundant when they are not actually redundant for the time ranges.
- Icons for warnings and errors, and rule conflicts when you enable the feature, are shown in the rules table. For a reference to the icons, see Rule and other policy warnings, on page 1573.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control** and edit an access control policy.

Step 2 Do one of these to open the rule conflicts and warnings dialog box:

- To view rule conflicts, click the **Analyze** drop-down and click **Enable Rule Conflicts**. When the analysis completes, you see a summary of the conflicts at the top of the page. Then, click **Show Rule Conflicts** from the same menu to see the specific results.

  You must re-enable rule conflict detection each time you open the policy or make a change and save the policy.
- To view rule warnings and errors, click **Analyze** > **Show Rule Warnings and Errors**.

  After you make a change to the policy, you can refresh the results by clicking the reload icon next to the **Analyze** button.
- To view policy warnings, click **Analyze** > **Show Policy Warnings**.
- If you are finished viewing rule conflicts, click **Analyze** > **Disable Rule Conflicts**.

Step 3 In the rule conflicts and warnings dialog box:

- Rule warnings and errors are shown on a separate tab from rule conflicts. There is also a separate tab for policy warnings.
- Each tab contains sub-tabs to let you examine individual types of problems, such as redundant vs. shadowed or warnings vs. errors. You can also search for an item.
- **More** (⋮) next to each rule name provides shortcuts to edit, disable, or delete the rule.

Step 4 Click **Close** when finished.

Search for rules

Use search to help you find rules, especially when you have a large number of them.

When you search for an IP address in the source or destination network (but not as a simple text search), the system returns rules that will match the address. This includes not only exact matches, but also subnet matches. For example, searching for 10.1.1.1 will include rules for 10.1.1.0/24.

Procedure

Step 1 When editing an access control policy, build the search string by clicking in the **Search** box.

- For a simple text string search, type the string. The search returns rules that have that string in any column. You cannot do a string search in conjunction with a tag search, such as combining a string search with a source networks search.
- To search on a specific column, start typing the name of the column until the system prompts you with the full name, such as Source Networks, or select the name from the list of searchable fields. When you select the search tag, you can then enter the search string for that tag. For example, **Source Networks 10.1.1.1**.
- Searches in the port field return exact match only.
- When entering mulitple values, separate the values with commas.
- When building a search string with multiple tags, do not include spaces between the tags.
- When you select a tag, you are prompted with values that appear in those columns. Select the values you want to search for.
- You can quickly filter based on some common features by clicking the filter icon to the left of the search box and selecting to show rules with any combination of the following: Allow, Block, Monitor, Intrusion Policy, Time Range, Conflicts, Warnings, Errors, Disabled rules.
- To see the rules that apply to a specific device or set of devices, click the filter icon and select the devices. Rules apply to a device if they use security zones that contain at least one interface on the device, or if they do not include security zones.

Step 2 With your cursor at the end of the search string in the search box, press Enter.

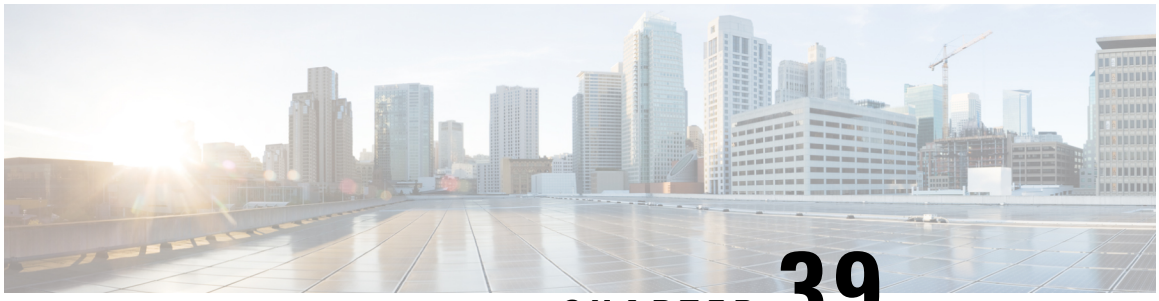
The rules that satisfy the search string are highlighted and non-matching rules are hidden. You can deselect **Show Only Matching Rules** to see the entire table, with the highlighted rules within the table. This lets you see the surrounding rules.

Beside the Show Only Matching Rules checkbox is a summary of the total number of rules in the policy compared to the number that match the search string.

Step 3 After your first search, clicking in the search box prompts you with recent searches and tags. You can quickly repeat a search by selecting it, or build similar searches by selecting previous searches or tags and building on them.

Step 4 To close the search and return to the unfiltered and unhighlighted table, click the **X** at the right of the search box. You can also put your cursor at the end of the search string and press the Esc key.

History for access control policies



This history table provides a comprehensive history of feature changes for access control policies in Cisco Secure Firewall Management Center across releases.

Table 93: Access control policy feature history by release

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Granular permissions for modifying access control policies and rules.	7.4.0	Any	You can define custom user roles to differentiate between the intrusion configuration in access control policies and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. When defining user roles, you can select the **Policies** > **Access Control** > **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** option to allow the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for Network Analysis and Intrusion Policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. You can use the **Modify Remaining Access Control Policy Configuration** to control the ability to edit all other aspects of the policy. The existing pre-defined user roles that included the Modify Access Control Policy permission continue to support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions.
New access control policy user interface and rule conflict analysis.	7.3.0	Any	The access control policy user interface introduced in 7.2 is now the default interface. You can also enable rule conflict analysis to help identify redundant rules and objects, and shadowed rules that cannot be matched due to previous rules in the policy.
Access control policy locking.	7.2.0	Any	You can lock an access control policy to prevent other administrators from editing it. Locking the policy ensures that your changes will not be invalidated if another administrator edits the policy and saves changes before you save your changes. Any user who has permission to modify the access control policy has permission to lock it. We added an icon to lock or unlock a policy next to the policy name while editing the policy. In addition, there is a new permission to allow users to unlock policies locked by other administrators: Override Access Control Policy Lock. This permission is enabled by default in the Administrator, Access Admin, and Network Admin roles.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Rule hit counts persist over reboot.	7.2.0	Any	Rebooting a managed device no longer resets access control rule hit counts to zero. Hit counts are reset only if you actively clear the counters. In addition, counts are maintained by each unit in an HA pair or cluster separately. You can use the **show rule hits** command to see cumulative counters across the HA pair or cluster, or see the counts per node. We modified the device CLI command: **show rule hits**.
Usability improvements for the access control policy.	7.2.0	Any	There is a new user interface available for the access control policy. You can continue to use the legacy user interface, or you can try out the new user interface. The new interface has both a table and a grid view for the rules list, the ability to show or hide columns, enhanced search, infinite scroll, a clearer view of the packet flow related to policies associated with the access control policy, and a simplified add/edit dialog box for creating rules. You can freely switch back and forth between the legacy and new user interfaces while editing an access control policy.
DNS filtering	7.0.0 6.7.0 (experimental)	Any	If URL filtering is enabled and configured, a new option to enhance category and reputation filtering efficacy is enabled by default for each new access control policy. For more information, see DNS filtering, on page 1665 and subtopics. The Advanced tab of access control policy has a new option under General Settings: **Enable reputation enforcement on DNS traffic**.
TLS server identity discovery	6.7.0	Any	Enable access control policies to evaluate URL and application conditions when a client connects to a TLS 1.3-enabled server. TLS server identity discovery enables these conditions to be evaluated without decrypting traffic. Enabling this feature can impact device performance, depending on model. The Advanced tab page of access control policy has new options: • Warning is displayed on the Advanced tab; moving the slider to the right enables TLS server identity discovery. • New option on the Advanced tab page: **TLS Server Identity Discovery**.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
New Security Intelligence categories	—	Any	These categories were introduced at about the time of the 6.6 release, but are not specific to 6.6: • banking_fraud • high_risk • ioc • link_sharing • malicious • newly_seen • spyware

CHAPTER 39

Security Intelligence

The following topics provide an overview of Security Intelligence, including use of lists for blocking and allowing traffic and basic configuration.

- Security intelligence, on page 1595
- License requirements for security intelligence, on page 1596
- Requirements and prerequisites for security intelligence, on page 1596
- Best practices for security intelligence, on page 1596
- Guidelines and limitations for security intelligence, on page 1597
- Security intelligence sources, on page 1598
- Configure security intelligence, on page 1599
- Security intelligence monitoring, on page 1606
- Override security intelligence blocking, on page 1606
- Troubleshooting security intelligence, on page 1607
- History for security intelligence block listing, on page 1608

Security intelligence

Security Intelligence is an early line of defense mechanism that

- uses reputation intelligence to quickly block connections to or from IP addresses, URLs, and domain names
- operates as the first phase of access control, before the system performs more resource-intensive evaluation, and
- improves performance by quickly excluding traffic that does not require inspection through Security Intelligence block listing.

Security intelligence features and limitations

Security Intelligence provides access to regularly updated intelligence feeds from Cisco. Sites representing security threats such as malware, spam, botnets, and phishing appear and disappear faster than you can update and deploy custom configurations.

You can refine Security Intelligence Block listing with Do Not Block lists and monitor-only Block lists. These mechanisms exempt traffic from being blocked by a Block list, but do **not** automatically trust or fastpath

matching traffic. Traffic added to a Do Not Block list or monitored at the Security Intelligence stage is intentionally subject to further analysis with the rest of access control.

Note You cannot use a Block list to block fastpathed traffic. Prefilter evaluation occurs before Security Intelligence filtering. Fastpathed traffic bypasses all further evaluation, including Security Intelligence.

Important You must apply the Network Discovery policy on the device for a successful application of the SI policy.

Best practices for security intelligence

Configure your access control policies to block threats detected by Cisco-provided Security Intelligence feeds. See Configuration example: Security intelligence blocking, on page 1605.

If you want to supplement the Cisco-provided Security Intelligence feeds with custom threat data, or manually block emerging threats:

- For IP addresses, use custom Security Intelligence lists and feeds, or Network objects. To create these, see Security intelligence, on page 2418 and Networks, on page 2386, and their subtopics. To use them for Security Intelligence, see Configure security intelligence, on page 1599. Network objects used in Security Intelligence policy require an IPS license.
- For URLs and domains, use custom Security Intelligence lists and feeds, *not* objects or groups. See details at Manual URL filtering options, on page 1668.
- You can also add entries to a Block list from events. See Global and domain security intelligence lists, on page 2420.

To test new feeds, or for passive deployments, set the action from block to monitor only. See Security intelligence monitoring, on page 1606.

If you need to exclude specific sites or addresses from Security Intelligence blocking, see Override security intelligence blocking, on page 1606.

If your Firepower deployment is integrated with Cisco XDR and you use custom Security Intelligence lists and feeds, be sure to update Security Services Exchange with these lists and feeds. For details, see instructions for configuring auto-promotion of events in the Security Services Exchange online help. For general information about this integration, see *Enable SecureX Integration* in the *Cisco Secure Firewall Management Center Administration Guide*.

System-provided Security Intelligence categories may change over time and without notification; you should plan to check periodically for changes, and modify your policies accordingly.

You should also configure URL filtering, a separate feature with separate licensing requirements, for further protection against malicious sites. See URL Filtering Rules, on page 1651.

To reduce latency and CPU overhead, avoid referencing a single, massive SI feed object across your entire security policy. Instead, utilize customized objects to create smaller, targeted subsets of your intelligence data.

Using URL/Domain feeds instead of IP blocklists can reduce CPU overhead because domain filtering is generally more efficient and less resource-intensive than managing massive IP blocklists.

Excluding trusted IPs by adding known good or essential partner IP addresses to an "Do Not Block" list in Security Intelligence (SI) feeds helps reduce CPU overhead as the firewall or security device bypasses unnecessary scanning and deeper inspection for these IPs.

Guidelines and limitations for security intelligence

Be aware of these limitations when configuring and using Security Intelligence:

- The Security Intelligence configuration that includes detection signatures or malware URLs might lead to false threat alerts when the Firewall Threat Defense troubleshoot files are scanned.
- If a TCP connection attempt is initiated from an IP address that is blocked due to its poor reputation, a TCP reset (RST) packet is sent. This causes the connection to be terminated instantly, preventing the establishment of the TCP session and signalling the rejection to the sender.

Security intelligence sources

Security Intelligence sources are data providers that

- supply regularly updated intelligence feeds for domains, URLs and IP addresses
- enable custom blocking and allow lists for specific sites or addresses, and
- provide global lists for immediate event-based blocking and allowing.

Types of security intelligence sources

Security Intelligence uses these source types:

- **System-provided feeds**: Cisco provides access to regularly updated intelligence feeds for domains, URLs and IP addresses. For more information, see Security intelligence, on page 2418.

  If you see a feed with "TID" in the name, this feed is *not* used by Security Intelligence. Instead, this feed is used by the feature described in Threat Intelligence Director, on page 2121.

- **Third-party feeds**: Optionally, supplement Cisco-provided feeds with third-party reputation feeds, which are dynamic lists that the Secure Firewall Management Center downloads from the internet on a regular basis. See Custom security intelligence feeds, on page 2428.

- **Custom Block lists or feeds (or objects)**: Block specific IP addresses, URLs, or domain names using a manually-created list or feed (for IP addresses, you can also use network objects.)

  For example, if you become aware of malicious sites or addresses that are not yet blocked by a feed, add these sites to a custom Security Intelligence list and add this custom list to the Block list in the Security Intelligence tab of your access control policy, as described in Custom Security Intelligence lists, on page 2430 and Configure security intelligence, on page 1599.

  For IP addresses, you can optionally use network objects rather than lists or feeds for this purpose; for information, see Networks, on page 2386. (For URLs, using lists and feeds is strongly recommended over other methods.)

- **Custom Do Not Block lists or feeds**: Override Security Intelligence blocking for specific sites or addresses. See Override security intelligence blocking, on page 1606.

- **Global Block lists (one each for Network, URL and DNS)**: While reviewing events, you can immediately add an event's IP address, URL, or domain to the applicable Global Block List so that Security Intelligence will handle future traffic from that source. See Global and domain security intelligence lists, on page 2420.

- **Global Do Not Block lists (one each for Network, URL and DNS)**: While reviewing events, you can immediately add an event's IP address, URL, or domain to the applicable Global Do Not Block List if you do not want Security Intelligence to block future traffic from that source. See Global and domain security intelligence lists, on page 2420.

Configure security intelligence

Configure Security Intelligence filtering to automatically block or monitor traffic based on threat intelligence feeds and custom block or allow lists. This provides an additional layer of security by filtering known malicious IP addresses, URLs, and domains before they reach your network resources.

Each access control policy has Security Intelligence options. You can add network objects, URL objects and lists, and Security Intelligence feeds and lists to a Block list or Do Not Block list, and constrain any of these by security zone. You can also associate a DNS policy with your access control policy, and add domain names to a Block or Do Not Block list.

The number of objects in the Do Not Block lists plus the number in the Block lists cannot exceed 125 network objects, or 32767 URL objects and lists.

Before you begin

- Tip: For guidance on minimum configuration recommendations, see also Configuration example: Security intelligence blocking, on page 1605.
- To ensure that ALL options are available to select, add at least one managed device to your management center.
- In passive deployments, or if you want to set Security Intelligence filtering to monitor-only, enable logging; see *Logging Connections with Security Intelligence* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Configure a DNS policy to take Security Intelligence action for domains. For more information, see DNS Policies for Security Intelligence, on page 1993.

Follow these steps to configure Security Intelligence filtering in an access control policy:

Procedure

Step 1 In the access control policy editor, click **Security Intelligence**.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Choose the type of objects to configure.

- Click **Networks** to add network objects (IP addresses).

Note Network objects used in a Security Intelligence policy require a IPS license.

- Click **URLs** to add URL objects.

Step 3 Find the **Available Objects** you want to add to the Block or Do Not Block list.

- Search the available objects by typing in the **Search by name or value** field. Clear the search string by clicking **Reload** ( ) or **Clear** ( ).

- If no existing list or feed meets your needs, click **Add** (+), select **New Network List** or **New URL List**, and proceed as described in Create custom security intelligence feeds, on page 2428 or Upload new custom security intelligence lists to the Secure Firewall Management Center, on page 2431.
- If no existing object meets your needs, click **Add** (+), select **New Network Object** or **New URL Object**, and proceed as described in Create a network object, on page 2388.

Security Intelligence ignores IP address blocks using a `/0` netmask.

Step 4 Choose one or more **Available Objects** to add.

Step 5 (Optional) Choose an **Available Zone** to constrain the selected objects by zone.

You cannot constrain system-provided Security Intelligence lists by zone.

Note The **Any** zone for an SI list applies only to interfaces that are part of a security zone. However, an exception is that if a device does not have any interfaces associated with a security zone, then the **Any** zone will match any interface.

For example, if you have five interfaces on a device and none of them are associated with a security zone, any SI list that is assigned to the **Any** zone will be inspected against traffic on ALL interfaces on the device. If you add one interface to a security zone on that device, it effectively would remove SI inspection on the other four interfaces, where the zone is set to **Any** for an SI list. If you add the other four interfaces to a security zone, they will be evaluated by the SI list attached to the **Any** zone.

Step 6 Click **Add to Do Not Block list** or **Add to Block list**, or click and drag the selected objects to either list.

To remove an object from a Block or Do Not Block list, click **Delete** ( ) To remove multiple objects, choose the objects and right-click to **Delete Selected**.

Step 7 (Optional) Set objects on the Block list to monitor-only by right-clicking the object under **Block List**, then choosing **Monitor-only (do not block)**.

You cannot set system-provided global Security Intelligence lists to monitor only.

Step 8 Choose a DNS policy from the **DNS Policy** drop-down list.

Step 9 Click **Save**.

Security Intelligence filtering is now configured for your access control policy. The system will automatically block or monitor traffic based on the configured Block and Do Not Block lists, providing enhanced protection against known threats.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Related Topics

Security intelligence, on page 2418
Snort restart scenarios, on page 127

Security intelligence options

Use the Security Intelligence tab in the access control policy editor to configure network (IP address) and URL Security Intelligence, and to associate the access control policy with a DNS policy in which you have configured Security Intelligence for domains.

Available objects

Available objects include:

- Security Intelligence categories populated by the system-provided feed.

  For details, see Security intelligence categories, on page 1602.

- System-provided Global Block and Do Not Block lists.

  For descriptions, see Security intelligence sources, on page 1598.

- Security Intelligence lists and feeds that you create under Object > Object Management > Security Intelligence.

  For descriptions, see Security intelligence sources, on page 1598.

- Network and URL objects that are configured on the respective pages under Object > Object Management. These are different from the Security Intelligence objects in the previous bullet.

  For details about network objects, see Networks, on page 2386. (For URLs, use Security Intelligence lists or feeds rather than objects.)

  Note that range and group network object types are not supported in Security Intelligence policy.

Available zones

Except for the system-provided Global lists, you can constrain Security Intelligence filtering by zone.

For example, to improve performance, you might want to target enforcement to specific zones rather than all interfaces. As a more specific example, you can block spam only for a security zone that handles email traffic.

To enforce Security Intelligence filtering for an object on multiple zones, you must add the object to the Block or Do Not Block list separately for each zone.

Note that range and group network object types are not supported in Security Intelligence policy.

DNS policy

In order to match DNS traffic using Security Intelligence, you must select a DNS policy for your Security Intelligence configuration.

Using Block or Do Not Block lists, or monitoring traffic based on a DNS list or feed, also requires that you:

- Configure DNS Security Intelligence lists and feeds. See Security intelligence, on page 2418.
- Create a DNS policy. See Create basic DNS policies, on page 1997 for more information.
- Configure DNS rules that reference your DNS lists or feeds. See Create and edit DNS rules, on page 1999 for more information.
- Because you deploy the DNS policy as part of your access control policy, you must associate both policies. See Requirement: deploy DNS policy configuration changes, on page 2008 for more information.

Do not block list

See Override security intelligence blocking, on page 1606.

To select all objects in the list, right-click an object.

Block list

See Configuration example: Security intelligence blocking, on page 1605 and other topics in this chapter.

For explanations of the visual indicators in the Block list, see Block list icons, on page 1604.

To select all objects in the list, right-click an object.

Logging

Security Intelligence logging, enabled by default, logs all blocked and monitored connections handled by an access control policy's assigned devices. However, the system does not log Do Not Block list matches; logging of connections on the Do Not Block list depends on their eventual disposition. Logging must be enabled for connections on the Block list before you can set objects on that list to monitor-only.

To enable, disable, or view logging settings, right-click an object in the Block list.

Related Topics

Global and domain security intelligence lists, on page 2420
Security intelligence lists and multitenancy, on page 2421

Security intelligence categories

Security Intelligence categories are determined by the system-provided feeds described in Security intelligence, on page 2418.

These categories are used in the following locations:

- The Networks sub-tab on the Security Intelligence tab of an access control policy
- The URLs sub-tab beside the Networks tab on the Security Intelligence tab of an access control policy
- In a DNS policy on the DNS tab in the DNS rule configuration page
- In events generated when traffic matches Block or Monitor configurations in the above locations

Note If your organization is using Secure Firewall Threat Intelligence Director: When viewing events, you may see categories that indicate that the action was taken by TID, such as `TID URL Block`.

Categories are updated by Talos from the cloud, and this list may change independently of Firepower releases.

Table 94:

Security Intelligence Category	Description
Attackers	Active scanners and hosts known for outbound malicious activity

Security Intelligence Category	Description
Banking_fraud	Sites that engage in fraudulent activities that relate to electronic banking
Bogon	Bogon networks and unallocated IP addresses The Security Intelligence Bogon feed is designed to provide threat-specific intelligence. It is not intended to function as a comprehensive filtering list for all bogon traffic. Bogon traffic, including private, multicast, and unallocated address space is generally expected to be filtered by upstream network providers or through standard network security controls. Key aspects of Bogon: • **Active threat indicators**: The feed is populated only when the security intelligence identifies active threat indicators associated with bogon address space. • **Empty feed status**: An empty feed does not indicate a system malfunction or an error. It simply signifies that no active threats have been identified in the monitored bogon space at this time.
Bots	Sites that host binary malware droppers
CnC	Sites that host command-and-control servers for botnets
Cryptomining	Hosts providing remote access to pools and wallets for the purpose of mining cryptocurrency
Dga	Malware algorithms used to generate a large number of domain names acting as rendezvous points with their command-and-control servers
Exploitkit	Software kits designed to identify software vulnerabilities in clients
High_risk	Domains and hostnames that match against the OpenDNS predictive security algorithms from security graph
Ioc	Hosts that have been observed to engage in Indicators of Compromise (IOC)
Link_sharing	Websites that share copyrighted files without permission

Security Intelligence Category	Description
Malicious	Sites exhibiting malicious behavior that do not necessarily fit into another, more granular, threat category
Malware	Sites that host malware binaries or exploit kits
Newly_seen	Domains that have recently been registered, or not yet seen via telemetry. **Attention** Currently, this category does not have any active feed and is reserved for future use.
Open_proxy	Open proxies that allow anonymous web browsing
Open_relay	Open mail relays that are known to be used for spam
Phishing	Sites that host phishing pages
Response	IP addresses and URLs that are actively participating in malicious or suspicious activity
Spam	Mail hosts that are known for sending spam
Spyware	Sites that are known to contain, serve, or support spyware and adware activities
Suspicious	Files that appear to be suspicious and have characteristics that resemble known malware
Tor_exit_node	Hosts known to offer exit node services for the Tor Anonymizer network

Block list icons

The visual indicators may appear in the Block list on the Security Intelligence tab in an access control policy.

Icon or Visual Indicator	Description
Block ( )	The object is set to block.
Monitor ( )	The object is set to monitor-only. See Security intelligence monitoring, on page 1606
An object is displayed in strikethrough text	The same object is also on the Do Not Block list, which overrides the block.

Configuration example: Security intelligence blocking

Configure Security Intelligence blocking to protect your network from known malicious IP addresses, URLs, and domains using regularly updated threat intelligence feeds.

Configure your access control policy to block all threats detectable by the system's regularly updated Security Intelligence feeds.

The number of objects in the Block lists plus the number in the Do Not Block lists cannot exceed 125 network objects, or 32767 URL objects and lists.

Before you begin

- To ensure that all options are available to select, add at least one managed device to your management center.
- Configure a DNS policy to block all Security Intelligence threat categories for domains. For more information, see DNS Policies for Security Intelligence, on page 1993.
- If you have, or will have, custom lists of entities to block, create a Security Intelligence object of each type (URLs, DNS, Networks.) See Security intelligence, on page 2418.

Procedure

Step 1 Click **Policies** > **Access Control heading** > **Access Control**.

Step 2 Create a new access control policy or edit an existing policy.

Step 3 In the access control policy editor, click **Security Intelligence**.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 Click **Networks** to add blocking criteria for IP addresses.

a) Scroll down in the Networks list and select all of the threat categories listed below the Global lists.
b) If applicable, select the security zones for which you want to block these threats.
c) Click **Add to Block List**.
d) If you have created custom lists or feeds with addresses to block, add those to the Block List using the same steps as above.

Step 5 Click **URLs** to add blocking criteria for URLs, and repeat the steps you followed for Networks.

Step 6 Choose a DNS policy from the **DNS Policy** drop-down list; see DNS policies, on page 1993.

Step 7 Click **Save**.

Your access control policy now blocks malicious IP addresses, URLs, and domains based on Security Intelligence threat feeds, providing enhanced protection against known threats.

What to do next

- Enable logging for these connections; see *Logging Connections with Security Intelligence* in the *Cisco Secure Firewall Management Center Administration Guide* .
- Deploy configuration changes; see Deploy configuration changes, on page 135.

- For additional protection, configure URL filtering to block malicious URLs. See URL Filtering Rules, on page 1651.

Security intelligence monitoring

Security Intelligence monitoring is a security feature that

- logs connection events for traffic that would have been blocked by Security Intelligence, but does not block the traffic,
- enables testing of feeds before implementation, and
- optimizes performance in passive deployments.

Use cases for security intelligence monitoring

Monitoring is especially useful for:

- Testing feeds before you implement them.

  Consider a scenario where you want to test a third-party feed before you implement blocking using that feed. When you set the feed to monitor-only, the system allows connections that would have been blocked to be further analyzed by the system, but also logs a record of each of those connections for your evaluation.

- Passive deployments, to optimize performance.

  Managed devices that are deployed passively cannot affect traffic flow; there is no advantage to configuring the system to block traffic. Additionally, because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

Note If configured, Secure Firewall Threat Intelligence Director may impact the action taken (Monitor or Block.) For more information, see Threat Intelligence Director - Firewall Management Center action prioritization , on page 2145.

To configure Security Intelligence monitoring:

After you configure Security Intelligence blocking following the instructions in Configuration example: Security intelligence blocking, on page 1605, right-click each applicable object in the Block list and choose **Monitor-only**. You cannot set system-provided Security Intelligence lists to monitor only.

Override security intelligence blocking

Use Do Not Block lists to exempt specific domains, URLs, or IP addresses from being blocked by Security Intelligence lists or feeds.

You can use Do Not Block lists for various purposes:

- Override the occasional false-positive block in a reputable Security Intelligence feed

- Inspect specific traffic in depth instead of blocking it early based on reputation
- Exempt otherwise-restricted transactions based on zone from Security Intelligence blocking

  For example, you can add an improperly classified URL to a Do Not Block list, but then restrict the Do Not Block list object using a security zone used by those in your organization who need to access those URLs. That way, only those with a business need can access the URLs on the Do Not Block list.

Note Entries on a Do Not Block list are simply exemptions from the block list. Any connection that passes the Security Intelligence policy is subject to the access control rules. Thus, an entry in the Do Not Block list can subsequently be blocked by an access control rule or intrusion policy. Your Do Not Block entries should always be exemptions from your block lists.

Procedure

Step 1 Option 1: Add an IP address, URL, or domain from an event to the Global Do Not Block List. See Global and domain security intelligence lists, on page 2420.

Step 2 Option 2: Use a custom Security Intelligence list or feed.

a) Create the custom Security Intelligence list or feed. See Custom Security Intelligence lists, on page 2430 or Create custom security intelligence feeds, on page 2428.
b) For IP addresses (Networks) and URLs: Edit your access control policy, click the Security Intelligence tab, then click the custom list or feed in the Networks or URLs sub-tab, then click **Add to Do Not Block List**.
c) Save your changes.
d) For domains (DNS): See the "DNS Policy" section in the Security intelligence options, on page 1601 topic.
e) Deploy your changes.

The specified domains, URLs, or IP addresses are now exempted from Security Intelligence blocking and will be subject to access control rules instead.

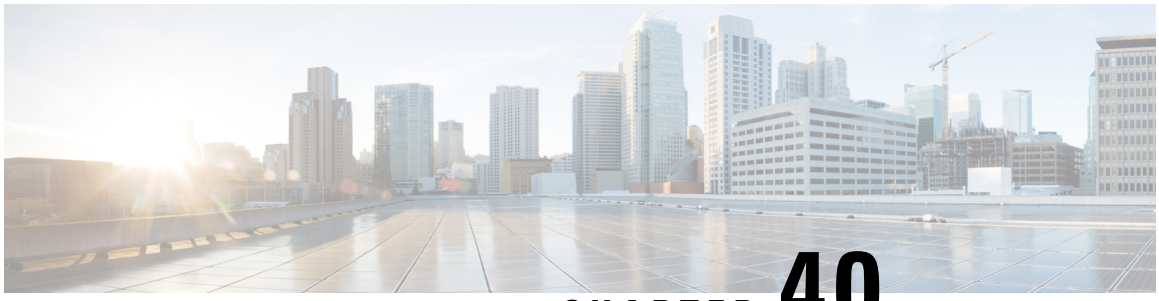
Troubleshooting security intelligence

See the following topics for troubleshooting Security Intelligence.

Security intelligence categories missing from the Available Options List

Security Intelligence categories (such as CnC or Exploitkit) display in the Networks tab under Available Options only after you add at least one managed device to your management center.

You must add a device in order to pull all TALOS feeds that provide the Security Intelligence categories.



If the expected category does not appear in Security Intelligence, verify that it is not a URL filtering category, which uses a different set of categories.

To see URL filtering categories, look at the **URLs** tab in an access control rule.

History for security intelligence block listing

This reference provides a chronological history of changes and updates to Security Intelligence Block Listing features, including terminology changes and new category additions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
New Security Intelligence categories	All	Any	Talos has added the new Security Intelligence categories: • banking_fraud • ioc • high_risk • link_sharing • malicious • newly_seen • spyware You should update your access control and DNS policies to address the new categories, and check periodically for future changes. CHAPTER 40

Access Control Rules

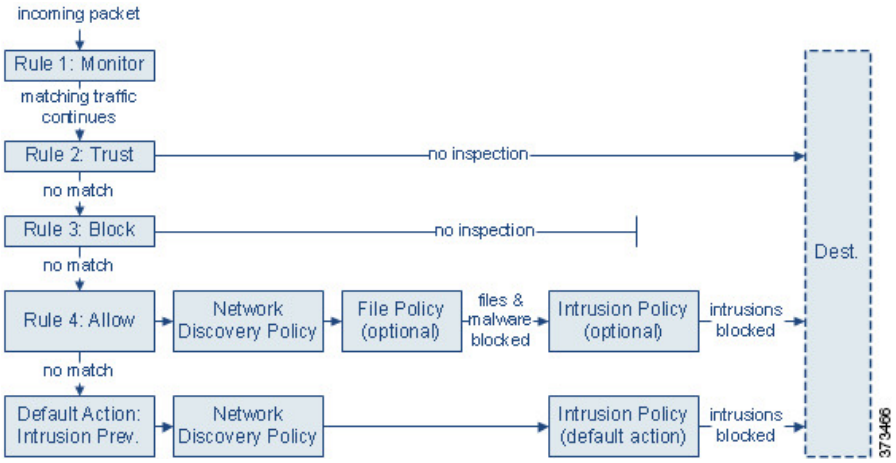
The following topics describe how to configure access control rules.

- Access control rules, on page 1609
- Requirements and prerequisites for access control rules, on page 1620
- Guidelines and limitations for access control rules, on page 1621
- Best practices for application control, on page 1622
- Best practices for access control rules, on page 1625
- Access control rule management, on page 1630
- Examples for access control rules, on page 1645
- History for access control rules, on page 1649

Access control rules

Within an access control policy, access control rules provide a granular method that

- handles network traffic across multiple managed devices within an access control policy
- provides conditions that match traffic in a specified order, and
- determines actions to monitor, trust, block, or allow matching traffic.



Rule evaluation and traffic handling

The system matches traffic to access control rules in the order you specify. In most cases, the system handles network traffic according to the first access control rule where all the rule's conditions match the traffic.

Each rule also has an action, which determines whether you monitor, trust, block, or allow matching traffic. When you allow traffic, you can specify that the system first inspect it with intrusion or file policies to block any exploits, malware, or prohibited files before they reach your assets or exit your network.

Note Security Intelligence filtering, decryption, user identification, and some decoding and preprocessing occur before access control rules evaluate network traffic.

This scenario summarizes the ways that traffic can be evaluated by access control rules in an inline, intrusion prevention deployment.

In this scenario, traffic is evaluated as follows:

- **Rule 1: Monitor** evaluates traffic first. Monitor rules track and log network traffic. The system continues to match traffic against additional rules to determine whether to permit or deny it. (However, see an important exception and caveat at Access control rule monitor action, on page 1614.)
- **Rule 2: Trust** evaluates traffic next. Matching traffic is allowed to pass to its destination without further inspection, though it is still subject to identity requirements and rate limiting. Traffic that does not match continues to the next rule.
- **Rule 3: Block** evaluates traffic third. Matching traffic is blocked without further inspection. Traffic that does not match continues to the final rule.
- **Rule 4: Allow** is the final rule. For this rule, matching traffic is allowed; however, prohibited files, malware, intrusions, and exploits within that traffic are detected and blocked. Remaining non-prohibited, non-malicious traffic is allowed to its destination, though it is still subject to identity requirements and rate limiting. You can configure Allow rules that perform only file inspection, or only intrusion inspection, or neither.
- **Default Action** handles all traffic that does not match any of the rules. In this scenario, the default action performs intrusion prevention before allowing non-malicious traffic to pass. In a different deployment, you might have a default action that trusts or blocks all traffic, without further inspection. (You cannot perform file or malware inspection on traffic handled by the default action.)

Traffic you allow, whether with an access control rule or the default action, is automatically eligible for inspection for host, application, and user data by the network discovery policy. You do not explicitly enable discovery, although you can enhance or disable it. However, allowing traffic does not automatically guarantee discovery data collection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy; additionally, application discovery is limited for encrypted sessions.

Note that access control rules handle encrypted traffic when your decryption configuration allows it to pass, or if you do not configure decryption. However, some access control rule conditions require unencrypted traffic, so encrypted traffic may match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Access control rule management

The rules table of the access control policy editor allows you to add, edit, categorize, search, filter, move, enable, disable, delete, and otherwise manage access control rules in the current policy.

Properly creating and ordering access control rules is a complex task, but one that is essential to building an effective deployment. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations.

Use the search bar to filter the list of access control policy rules. You can deselect the **Show Only Matching Rules** option to see all rules. Matched rules are highlighted.

For each access control rule, the policy editor displays its name, a summary of its conditions, the rule action, and icons that communicate the rule's inspection options or status.

The system provides specific icons to communicate the inspection options or status of each rule:

- **Time Range Option** ( )
- **Intrusion policy** ( )
- **File policy** ( )
- **Logging** ( )
- **Warning** ( )
- **Errors** ( )
- **Rule Conflict** ( )

Disabled rules are dimmed and marked (disabled) after the rule name.

To create or edit a rule, refer to Create and edit access control rules, on page 1631 .

Tip A right-click menu provides shortcuts to many rule management options, including editing, deleting, moving, enabling, and disabling.

Access control rule components

In addition to its unique name, each access control rule has basic components that determine how the system processes and handles network traffic.

State

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

Position

Rules in an access control policy are numbered, starting at 1. If you are using policy inheritance, rule 1 is the first rule in the outermost policy. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.

Rules can also belong to a section and a category, which are organizational only and do not affect rule position. Rule position goes across sections and categories.

Section and category

To help you organize access control rules, every access control policy has two system-provided rule sections, Mandatory and Default. To further organize access control rules, you can create custom rule categories inside the Mandatory and Default sections.

If you are using policy inheritance, the current policy's rules are nested between its parent policy's Mandatory and Default sections.

Conditions

Conditions specify the specific traffic the rule handles. Conditions can be simple or complex; their use often depends on license.

Traffic must meet all of the conditions specified in a rule. For example, if the Application condition specifies HTTP but not HTTPS, the URL category and reputation conditions will not apply to HTTPS traffic.

Applicable time

You can set rules to operate during specified days and times

Action

A rule's action determines how the system handles matching traffic. You can monitor, trust, block, or allow (with or without further inspection) matching traffic. The system does not perform deep inspection on trusted, blocked, or encrypted traffic.

Inspection

Deep inspection options govern how the system inspects and blocks malicious traffic you would otherwise allow. When you allow traffic with a rule, you can specify that the system first inspect it with intrusion or file policies to block any exploits, malware, or prohibited files before they reach your assets or exit your network.

Logging

Logging settings govern records that the system keeps for handled traffic. You can log sessions at connection start, end, or both; log connections to databases, syslog, or SNMP trap servers. You can log connections to the database, as well as to a syslog or an SNMP trap server.

Comments

Each time you save changes to an access control rule, you can add comments.

Access control rule order

Access control rule order is a traffic processing method that

- numbers rules in an access control policy starting at 1
- matches traffic to access control rules in top-down order by ascending rule number, and
- handles network traffic according to the first access control rule where all the rule's conditions match the traffic.

In most cases, except for Monitor rules, the system does not continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule.

To help you organize access control rules, every access control policy has two system-provided rule sections, Mandatory and Default. To further organize, you can create custom rule categories inside the Mandatory or Default sections. After you create a category, you cannot move it, although you can delete it, rename it, and move rules into, out of, within, and around it. The system assigns rule numbers across sections and categories.

If you use policy inheritance, the current policy's rules are nested between its parent policy's Mandatory and Default rule sections. Rule 1 is the first rule in the outermost policy, not the current policy, and the system assigns rule numbers across policies, sections, and categories.

Any predefined user role that allows you to modify access control policies also allows you to move and modify access control rules within and among rules categories. You can, however, create custom roles that restrict users from moving and modifying rules. Any user who is allowed to modify access control policies can add rules to custom categories and modify rules in them without restriction.

Caution Failure to set up your access control rules properly can have unexpected results, including traffic being allowed that should be blocked. In general, application control rules should be lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example.

Access control rules that use *specific* conditions (such as networks and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your access control rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your access control rules. For more information about the OSI model, see this Wikipedia article.

Note Proper access control rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs. For more information, refer to Best practices for ordering rules, on page 1627.

Access control rule actions

An access control rule action is a configuration setting that determines how the system handles and logs matching traffic, with options to monitor, trust, block, or allow traffic with or without further inspection.

Default action behavior

The access control policy's *default action* handles traffic that does not meet the conditions of any access control rule with an action other than Monitor.

Access control rule monitor action

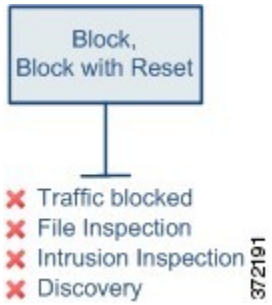
The **Monitor** action is an access control rule action that forces connection logging regardless of how matching traffic is eventually handled. It does not affect traffic flow by permitting or denying traffic immediately, and allows traffic to be matched against additional rules to determine the final action.

When a connection matches a monitor rule, the next non-monitor rule that the connection matches determines traffic handling and any further inspection. If there are no additional matching rules, the Firewall Threat Defense device uses the default action.

There is an exception: If a monitor rule contains layer 7 conditions, such as an application condition, the system allows early packets to pass and the connection to be established (or the SSL handshake to complete), even if a subsequent rule would block the connection. Early packets are not evaluated against subsequent rules, so to prevent uninspected traffic, you can specify an intrusion policy for these packets in the access control policy's advanced settings. For more information, refer to Inspection of packets that pass before traffic is identified. After the system completes its layer 7 identification, it applies the appropriate action to the remaining session traffic.

Access control rule trust action

The **Trust** action is the access control rule action that allows traffic to pass without deep inspection or network discovery, still subjects trusted traffic to identity requirements and rate limiting, and bypasses additional inspection services while maintaining basic security controls.



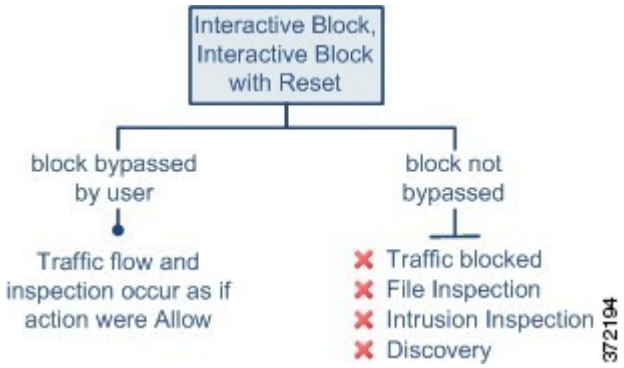
Note

- Some protocols, such as FTP and SIP, use secondary channels, which the system opens through the process of inspection. In some cases, trusted traffic can bypass all inspection, and these secondary channels cannot be opened properly. If you run into this problem, change the trust rule to **Allow**.
- For trust rules with logging options disabled, end-of-flow events are still generated in the system. However, the events are not visible on the event pages.
- Because access control rules are evaluated after other policies, such as decryption, trusting a connection does not necessarily mean it will be fast-pathed with no inspection. For example, if a connection matches both a decryption rule that requires decryption, and a trust access control rule, the connection is decrypted and inspected as needed, prior to being allowed by the trust rule. Trust simply means no additional inspection, such as intrusion inspection, will be applied. If your intention is to allow a connection uninspected, either use the prefilter policy to fast path the connection, or ensure that no other policy applies inspection services to the connection.

Access control rule blocking actions

A block action is an access control rule action that denies network traffic without further inspection and prevents the use of file, intrusion, or network discovery policies for blocked traffic.

Block and **Block with reset** actions immediately stop traffic from entering the network. Block with reset rules reset the connection except for web requests met with an HTTP response page. The HTTP response page is used to notify users when their web request is blocked, but it cannot be displayed if the connection is immediately reset.



For more information, refer to HTTP response pages, on page 1669.

Related Topics

HTTP response pages, on page 1669

Access control rule interactive blocking actions

The **Interactive Block** and **Interactive Block with reset** actions are access control rule actions that give web users a choice to continue to their intended destinations.

If a user bypasses the block, the rule mimics an allow rule. Therefore, you can associate interactive block rules with file and intrusion policies, and matching traffic is also eligible for network discovery.

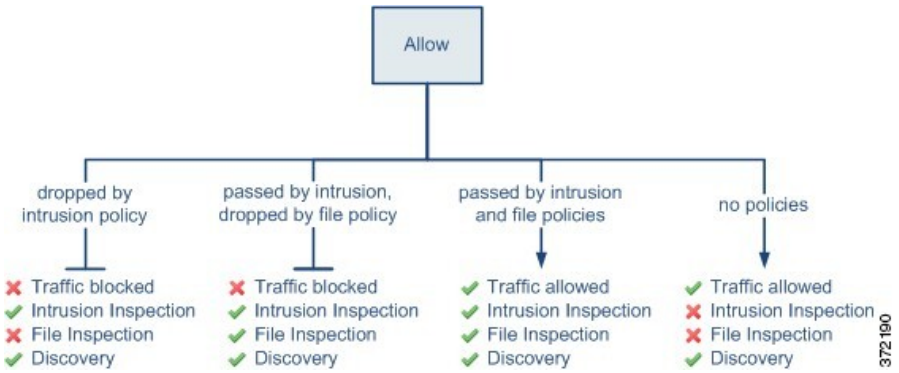
If a user does not (or cannot) bypass the block, the rule mimics a block rule. Matching traffic is denied without further inspection.

Note If you enable interactive blocking, you cannot reset all blocked connections. This is because the response page cannot display if the connection is immediately reset. Use the **Interactive Block with reset** action to (non-interactively) block-with-reset all non-web traffic, while still enabling interactive blocking for web requests.

For more information, refer to HTTP response pages, on page 1669.

Related Topics

Decryption rule blocking actions, on page 1779



Access control rule allow action

An access control rule allow action is a rule action that allows matching traffic to pass. However, traffic is still subject to identity requirements and rate limiting.

Optionally, you can use deep inspection to further inspect and block unencrypted or decrypted traffic before it reaches its destination:

- You can use an intrusion policy to analyze network traffic according to intrusion detection and prevention configurations, and drop offending packets depending on the configuration.
- You can perform file control using a file policy. File control allows you to detect and block your users from uploading (sending) or downloading (receiving) files of specific types over specific application protocols.
- You can perform network-based advanced malware protection (AMP), also using a file policy. malware defense can inspect files for malware, and block detected malware depending on the configuration.

This diagram illustrates the types of inspection performed on traffic that meets the conditions of an Allow rule (or a user-bypassed Interactive Block rule). Notice that file inspection occurs before intrusion inspection; blocked files are not inspected for intrusion-related exploits.

For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with an access control rule. You can, however, configure one without the other. Without a file policy, traffic flow is determined by the intrusion policy; without an intrusion policy, traffic flow is determined by the file policy.

Regardless of whether the traffic is inspected or dropped by an intrusion or file policy, the system can inspect it using network discovery. However, permitting traffic does not guarantee that discovery inspection occurs. The system only performs discovery for connections involving IP addresses explicitly monitored by your network discovery policy. Also, application discovery is limited for encrypted sessions.

Deep inspection using file and intrusion policies

Deep inspection is a security mechanism that uses intrusion and file policies as the last line of defense before traffic is allowed to its destination.

Policy types and capabilities

Deep inspection uses two types of policies to analyze traffic:

- *Intrusion policies* govern the system's intrusion prevention capabilities.
- *File policies* govern the system's file control and malware defense capabilities.

Access control occurs before deep inspection; access control rules and the access control default action determine which traffic is inspected by intrusion and file policies.

By associating an intrusion or file policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect the traffic with an intrusion policy, a file policy, or both.

In an access control policy, you can associate one intrusion policy with each Allow and Interactive Block rule, as well as with the default action. Every unique **pair** of intrusion policy and variable set counts as one policy.

Note By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

To associate intrusion and file policies with an access control rule, see:

- Access Control Rules: Intrusion Policy Selection
- Configure an access control rule to perform malware protection, on page 2024

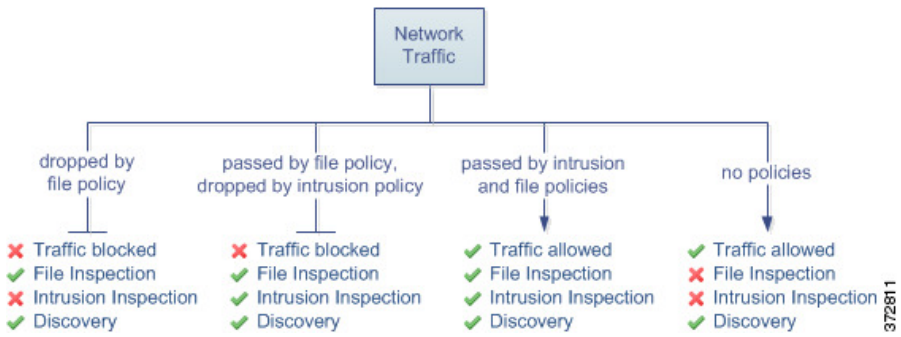
For more information about intrusion policies, refer to Network Analysis and Intrusion Policy Basics.

For more information about file policies, refer to File Policies for Network Malware Protection, on page 2015.

File and intrusion inspection order

File and intrusion inspection order defines the traffic processing sequence that performs file inspection before intrusion inspection for any single connection handled by an access control rule, preventing files blocked by a file policy from being inspected for intrusions while prioritizing simple file blocking by type over malware inspection.

For a connection matching an Allow or Interactive Block rule, the system determines traffic flow based on the following configurations:



- Without a file policy, traffic flow is determined by the intrusion policy.
- Without an intrusion policy, traffic flow is determined by the file policy.
- Without either, allowed traffic is inspected by network discovery only.

In your access control policy, you can associate multiple Allow and Interactive Block rules with different intrusion and file policies to match inspection profiles to various types of traffic.

Note The system does not perform any kind of inspection on trusted traffic. Although configuring an Allow rule with neither an intrusion nor file policy passes traffic like a Trust rule, Allow rules let you perform discovery on matching traffic.

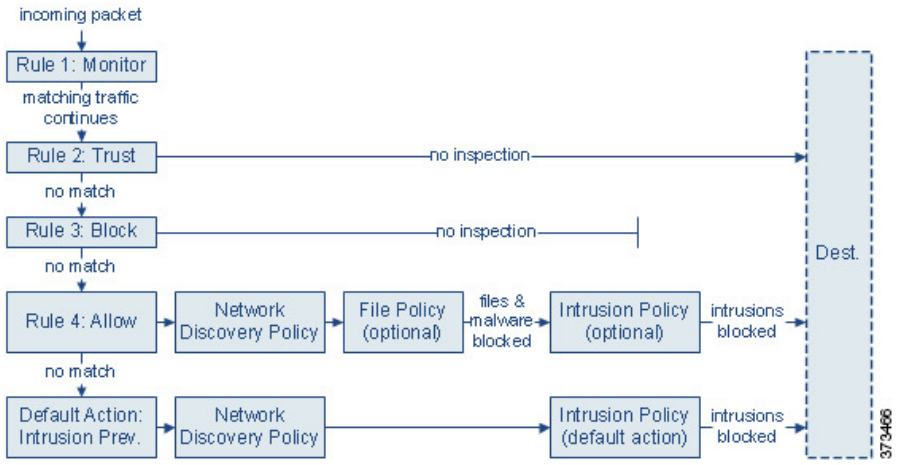
The diagram below illustrates the types of inspection you can perform on traffic that meets the conditions of either an Allow or user-bypassed Interactive Block access control rule. For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with a single access control rule.

Figure 409: Traffic inspection flowchart

For any single connection handled by an access control rule, file inspection occurs before intrusion inspection. That is, the system does not inspect files blocked by a file policy for intrusions. Within file inspection, simple blocking by type takes precedence over malware inspection and blocking.

For example, consider a scenario where you normally want to allow certain network traffic as defined in an access control rule. However, as a precaution, you want to block the download of executable files, examine downloaded PDFs for malware and block any instances you find, and perform intrusion inspection on the traffic.

You create an access control policy with a rule that matches the characteristics of the traffic you want to provisionally allow, and associate it with both an intrusion policy and a file policy. The file policy blocks the download of all executables, and also inspects and blocks PDFs containing malware:



- First, the system blocks the download of all executables, based on simple type matching specified in the file policy. Because they are immediately blocked, these files are subject to neither malware nor intrusion inspection.
- Next, the system performs malware cloud lookups for PDFs downloaded to a host on your network. Any PDFs with a malware disposition are blocked, and are not subject to intrusion inspection.
- Finally, the system uses the intrusion policy associated with the access control rule to inspect any remaining traffic, including files not blocked by the file policy.

Note Until a file is detected and blocked in a session, packets from the session might be subject to intrusion inspection.

How access control traffic handling works with intrusion and file policies

Summary

This diagram shows the flow of traffic in an inline intrusion prevention and malware defense deployment, as governed by an access control policy that contains four different types of access control rules and a default action.

Workflow

In the scenario above, the first three access control rules in the policy—Monitor, Trust, and Block—cannot inspect matching traffic. Monitor rules track and log but do not inspect network traffic, so the system continues to match traffic against additional rules to determine whether to permit or deny it. (However, see an important

exception and caveat at Access control rule monitor action, on page 1614.) Trust and Block rules handle matching traffic without further inspection of any kind, while traffic that does not match continues to the next access control rule.

The fourth and final rule in the policy, an Allow rule, invokes various other policies to inspect and handle matching traffic, in the following order:

1. Discovery: Network Discovery Policy—First, the network discovery policy inspects traffic for discovery data. Discovery is passive analysis and does not affect the flow of traffic. Although you do not explicitly enable discovery, you can enhance or disable it. However, allowing traffic does not automatically guarantee discovery data collection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy.
2. malware defense and File Control: File Policy—After traffic is inspected by discovery, the system can inspect it for prohibited files and malware. malware defense detects and optionally blocks malware in many types of files, including PDFs, Microsoft Office documents, and others. If your organization wants to block not only the transmission of malware files, but all files of a specific type (regardless of whether the files contain malware), file control allows you to monitor network traffic for transmissions of specific file types, then either block or allow the file.
3. Intrusion Prevention: Intrusion Policy—After file inspection, the system can inspect traffic for intrusions and exploits. An intrusion policy examines decoded packets for attacks based on patterns, and can block or alter malicious traffic. Intrusion policies are paired with variable sets, which allow you to use named values to accurately reflect your network environment.
4. Destination—Traffic that passes all the checks described above passes to its destination.

An Interactive Block rule (not shown in the diagram) has the same inspection options as an Allow rule. This is so you can inspect traffic for malicious content when a user bypasses a blocked website by clicking through a warning page.

Traffic that does not match any access control rules in the policy with an action other than Monitor is handled by the default action. In this scenario, the default action is an Intrusion Prevention action, which allows traffic to its final destination as long as it is passed by the intrusion policy you specify. In a different deployment, you might have a default action that trusts or blocks all traffic without further inspection. Note that the system can inspect traffic allowed by the default action for discovery data and intrusions, but not prohibited files or malware. You cannot associate a file policy with the access control default action.

Note Sometimes, when a connection is analyzed by an access control policy, the system must process the first few packets in that connection, allowing them to pass, before it can decide which access control rule (if any) will handle the traffic. However, so these packets do not reach their destination uninspected, you can specify an intrusion policy (in the advanced settings for the access control policy) to inspect these packets and generate intrusion events.

Requirements and prerequisites for access control rules

Ensure that your deployment meets these requirements before you configure access control rules.

Model support

Any

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin
- You can define custom user roles to differentiate between the intrusion configuration in access control policy and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. The existing pre-defined user roles that included the Modify Access Control Policy permission support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions. The granular permissions are:
  - **Policies** > **Access Control heading** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** allows the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for Network Analysis and Intrusion Policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. If a user has this option only, the user can modify no other part of the policy or rule.
  - **Modify Remaining Access Control Policy Configuration** controls the ability to edit all other aspects of the policy.

Guidelines and limitations for access control rules

Consider these limitations when you configure rules in the access control policy:

- There is a limit of 1000 rules that can be shown at a time on the current page. Thus, if you have a very large number of rules, such as 3000 rules within a single category, actions like selecting all rules in a category and deleting them does not delete all of the rules. You might need to select/delete rules again to delete all the rules that you are targeting.
- If you edit an access control rule that is actively in use, the changes do not apply to established connections at deploy-time. The updated rule is used to match against future connections. However, if the system is actively inspecting a connection (for example, with an intrusion policy), it will apply changed matching or action criteria to existing connections.

  For Firewall Threat Defense, you can ensure that your changes apply to all current connections by using the Firewall Threat Defense **clear conn** CLI command to end established connections. Note that you should only do this if it is acceptable to end those connections, on the assumption that the sources for the connections will then attempt to reestablish the connection and thus be matched appropriately against the new rule.

- VLAN tags in access rules only apply to inline sets; they cannot be used in access rules applied to firewall interfaces.
- To use fully-qualified domain name (FQDN) network objects as source or destination criteria, you must also configure DNS for the data interfaces in the platform settings policy. The system does not use the management DNS server setting to do lookups for FQDN objects used in access control rules.

  Note that controlling access by FQDN is a best-effort mechanism. Consider the following points:

  - Whenever possible, use Security Intelligence or URL filtering instead of FQDN rules.
  - Because DNS replies can be spoofed, only use fully trusted DNS servers.
  - Some FQDNs, especially for very popular servers, can have hundreds if not thousands of IP addresses, and these can frequently change. Because the system uses cached DNS lookup results, users might get addresses that are not yet in the cache, and their connections will not match the FQDN rule. Rules that use FQDN network objects function effectively only for names that resolve to fewer than 100 addresses.

    We recommend that you do not create network object rules for an FQDN that resolves to more than 100 addresses, as the likelihood of the address in a connection being one that has been resolved and available in the DNS cache on the device is low. For these cases, use a URL-based rule instead of an FQDN network object rule.
  - For popular FQDNs, different DNS servers can return a different set of IP addresses. Thus, if your users use a different DNS server than the one you configure, FQDN-based access control rules might not apply to all IP addresses for the site that are used by your clients, and you will not get the intended results for your rules.
  - Some FQDN DNS entries have very short time to live (TTL) values. This can result in frequent recompilation of the lookup table, which can impact overall system performance.
  - If more than 8 FQDNs resolve to the same IP address, the system cannot reliably match traffic to the rules for those FQDN. At most 8 FQDNs per IP address can be handled.
- The maximum objects per match criteria per access control rule is 200. For example, you can have up to 200 network objects in a single access control rule.
- Block with reset can be CPU-intensive for rules that drop a high rate of TCP traffic. When the system drops TCP traffic with this action, it also generates TCP reset packets, which can affect device performance during high-volume drops. For access control rules that are expected to drop large amounts of TCP traffic, use **Block** instead of **Block with reset**, unless TCP reset behavior is required.

  If TCP reset behavior is required for denied inbound TCP traffic, you can also evaluate using a regular **Block** rule with the **service resetinbound** command through FlexConfig for the applicable interface.

Best practices for application control

These topics discuss our recommended best practices for controlling applications with access control rules.

Recommendations for application control

Ensure that adaptive profiling is enabled

If adaptive profiling is not enabled (its default state), access control rules cannot perform application control.

Enable application detectors automatically

If no detector is enabled for an application you want to detect, the system automatically enables all system-provided detectors for the application. If none exist, the system enables the most recently modified user-defined detector for the application.

Configure your policy to examine the packets that must pass before an application is identified

The system cannot perform application control before *both* of these conditions occur:

- A monitored connection is established between a client and server
- The system identifies the application in the session

This identification should occur in 3 to 5 packets, or after the server certificate exchange in the SSL handshake if the traffic is encrypted.

If early traffic matches all other criteria but application identification is incomplete, the system allows the packet to pass and the connection to be established (or the SSL handshake to complete). After the system completes its identification, the system applies the appropriate action to the remaining session traffic.

To ensure that your system examines these initial packets, select an intrusion policy in the **Intrusion Policy used before Access Control rule is determined** options in the access control policy advanced settings.

Understand limitations to identifying applications

A server must adhere to the protocol requirements of an application for the system to be able to recognize it. For example, if you have a server that sends a keep-alive packet rather than an ACK when an ACK is expected, that application might not be identified, and the connection will not match the application-based rule. Instead, it will be handled by another matching rule or the default action. This might mean that connections you want to allow can be denied instead. If you run into this problem, and you cannot fix the server to follow the protocol standards, you need to write a non-application-based rule to cover traffic for that server, for example, by matching the IP address and port number.

Create separate rules for URL and application filtering

Create separate rules for URL and application filtering whenever possible, because combining application and URL criteria can lead to unexpected results, especially for encrypted traffic.

Rules that include both application and URL criteria should come after application-only or URL-only rules, unless the application+URL rule is acting as an exception to a more general application-only or URL-only rule.

Place URL rules before application and other rules

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of these criteria:

- They include application conditions.
- The traffic to be inspected is encrypted.

Handling application traffic packets without payloads

When performing access control, the system applies the default policy action to packets that do not have a payload in a connection where an application is identified.

Handling referred application traffic

To handle traffic referred by a web server, such as advertisement traffic, match the referred application rather than the referring application.

Controlling application traffic that uses multiple protocols

Some applications use multiple protocols. To control their traffic, make sure your access control policy covers all relevant options. These applications typically include the application name in each aspect that you can control. Also see Application-specific requirements for filtering, on page 1625.

Controlling evasive application traffic

See Application-specific requirements for filtering, on page 1625.

Best practice for choosing between application matching and port matching

In traditional firewalls, you can match traffic based on OSI layers 3 (protocol) and 4 (transport), such as IP or TCP/80. All traffic on a given port (or a whole protocol) is then either allowed or blocked based on that rule's action.

Application criteria, on the other hand, are OSI layer 7. Different applications can use the same TCP/UDP port. By using application criteria, you can selectively allow or block different applications on the same port without allowing or blocking all applications on that port.

Whether you use port-based or application-based criteria in your rule can impact rule performance. Because TCP/UDP ports are quickly identifiable in packets, the system can match the correct rule on the first packet. With application-layer criteria, it can take 3-5 packets to identify the specific application (if you do not also specify ports).

Consider these best practices:

- If you want to handle all of the traffic on a given TCP/UDP port in the same way for the specified interfaces and networks, use port-based matching. For example, to handle all SSH traffic the same way, select the SSH port (TCP/22) on the Ports tab.
- If you want to narrowly match a specific application that uses the same port as other applications, select the application on the Applications tab. This is how you can handle web applications, which all use TCP/80 or 443, so that you can selectively block or allow certain web applications without blocking or allowing all web applications.
- If you want to control application use by a user group, select the user group on the Users tab and the application on the Application tab. For example, you could block the Gaming applications category for members of the Contractor user group.
- For rules that go from a less secure network (such as the internet) to a more secure network (such as an internal protected network), use the Ports tab whenever possible. For example, you can allow/block ICMP traffic from the internet to an internal network.
- If you do have a mix of port-based and application-based rules, place the port-based rules higher in the rules list, so that connections can be matched to those rules first. Protocol and port can be more quickly identified than applications.

Application-specific requirements for filtering

Office 365 admin portal

If the access policy has logging enabled at the beginning as well as at the end of a connection, the first packet will be detected as Office 365 and the end of connection will be detected as Office 365 Admin Portal. This should not affect blocking.

Skype

To control Skype traffic, choose the **Skype** tag from the **Application Filters** list rather than selecting individual applications. This ensures that the system can detect and control all Skype traffic the same way.

GoToMeeting

In order to fully detect GoToMeeting, your rule must include all of these applications:

- GoToMeeting
- Citrix Online
- Citrix GoToMeeting Platform
- LogMeIn
- STUN

Zoho mail

To control Zoho mail, choose *both* **Zoho** and **Zoho mail** from the Available Application list.

Evasive application detection considerations

For evasive applications such as Bittorrent, Tor, Psiphon, and Ultrasurf, only the highest-confidence scenarios are detected by default. If you need to take action on this traffic (such as block or implement QoS), it may be necessary to configure more aggressive detection with better effectiveness. To do this, contact TAC to review your configurations as these changes may result in false positives.

WeChat

It is not possible to selectively block WeChat Media if you allow WeChat.

RDP file transfer

If allowing the RDP (Remote Desktop Protocol) application does not allow file transfers, ensure that the rule for RDP includes both the TCP and UDP port 3389. RDP file transfer uses UDP.

Best practices for access control rules

Configuring and ordering access control rules properly is essential to protect your network. Consider these best practices to achieve optimal results:

- Always evaluate device compatibility of access control rules before deployment.
- Ensure resources, such as physical memory and processors, can handle expanded rule criteria.

Note Ensure the system evaluates all rules together and creates a set of criteria for devices when you deploy configuration changes. You cannot deploy to a device if these criteria exceed its resources.

General best practice for access control

General best practices

- Use a prefilter policy to provide early blocking for unwanted traffic, and to fastpath traffic that does not benefit from access control inspection. For more information, refer to Best practices for fastpath prefiltering, on page 1978.
- Access control rules are deployed as access control entries (ACE) on the device. To minimize the number of access control entries created per access control rule, and improve overall performance, enable object group search for each device. Object group search is a device setting, not an access control policy setting, so you must edit each device to ensure the feature is enabled. For more information, refer to Configure object group search, on page 798.
- Whenever possible, combine multiple network objects into a single object group. The system automatically creates an object group (during deployment) when you select more than one object (for source or destination separately). Selecting existing groups can avoid object group duplication and reduce the potential impact on CPU usage when there are a large number of duplicate objects.
- Certain features, including URL filtering, application detection, and rate limiting, must allow some packets to pass in order for the system to identify the traffic.
- If you will use syslog or store events externally, avoid special characters in object names such as policy and rule names. Object names should not contain special characters, such as commas, that the receiving application may use as separators.

Licensing and feature support

- Although you can configure the system without licensing your deployment, many features require that you enable the appropriate licenses before you deploy.
- Some features are only available on certain device models. Warning icons and confirmation dialog boxes designate unsupported features.

Deployment considerations

- When you deploy an access control policy, its rules are not applied to existing connections. Traffic on an existing connection is not bound by the new policy that is deployed. In addition, the policy hit count is incremented only for the first packet of a connection that matches a policy. Thus, the traffic on an existing connection that could match a policy is omitted from the hit count. To have the policy rules effectively applied, clear the existing connection sessions, and then deploy the policy.
- For the system to affect traffic, you must deploy relevant configurations to managed devices using routed, switched, or transparent interfaces, or inline interface pairs.
- The system might prevent you from deploying inline configurations to passively deployed devices, including inline devices in tap mode. In other cases, the policy might deploy successfully, but attempts to block or alter traffic can produce unexpected results because passive devices do not enforce traffic

actions. For example, the system might report multiple beginning-of-connection events for a connection that the policy attempts to block.

Best practices for creating, ordering, and implementing access control rules are detailed in Best practices for access control rules, on page 1625 and subtopics.

Best practices for ordering rules

Access control rules are matched top down, first match wins. Thus, to get the results you expect, you must pay careful attention to proper sequencing.

- In general, place top-priority rules that must apply to all traffic near the top of the policy. Always order rules to suit your organization's needs.
- Specific rules should come before general rules, especially when the specific rules are exceptions to general rules. Otherwise, traffic will match the general rule first and never hit the applicable specific rule.
- Rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number) should come as early as possible. Rules based on these criteria do not require inspection to identify matching connections.
- Whenever possible, put specific drop rules near the top of the policy. This ensures the earliest possible decision on undesirable traffic.
- URL filtering, application-based, and geolocation-based rules and others that require inspection should come after rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number), but before rules that specify file and intrusion policies.
- For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:
  - They include application conditions.
  - The traffic to be inspected is encrypted.
- Put URL filtering rules above application rules, and follow application rules with micro-application rules and Common Industrial Protocol (CIP) sub-classification application filtering rules.
- In general, rules with application conditions should be lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example. For more information, see Best practice for choosing between application matching and port matching, on page 1624 and Recommendations for application control, on page 1622.
- Rules that specify file policies and intrusion policies should come at the bottom of the rule order. These rules require resource-intensive deep inspection, and you should eliminate as many threats as possible using less-intensive methods first, for performance reasons, in order to minimize the number of potential threats that require deep inspection.

Application rule order

Place rules with application conditions lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example.

Access control rules that use *specific* conditions (such as networks and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your access control rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your access control rules. For more information about the OSI model, see this Wikipedia article.

For more information, refer to Best practice for choosing between application matching and port matching, on page 1624 and Recommendations for application control, on page 1622.

Rule preemption

Rule preemption is a policy evaluation condition that occurs when a rule will never match traffic because a rule earlier in the evaluation order matches the traffic first. A rule's conditions govern whether it preempts other rules.

Rule preemption scenarios

Any type of rule condition can preempt a subsequent rule. This table shows common preemption scenarios:

Table 95: Rule preemption examples

Rule 1 (preempting)	Rule 2 (preempted)	Rule preemption scenario
Allow Admin users	Block Admin users	The second rule cannot block Admin traffic because the first rule allows it.
Allow Source Network VLAN 22-33	Block Source Network VLAN 27	The VLAN range in the first rule includes the VLAN in the second rule, so the first rule preempts the second. To block VLAN 27, you must move that rule above the one that allows VLAN 22-33.
Allow Source Network 10.4.0.0/16	Allow Source Network 10.4.0.0/16, VLAN 2	The VLAN range in the first rule includes the VLAN in the second rule, so the first rule preempts the second. To block VLAN 27, you must move that rule above the one that allows VLAN 22-33.
Allow Source Network 10.10.10.0/24 to URL www.netflix.com	Allow Source Network 10.10.10.0/24 to URL www.netflix.com	A rule also preempts an identical subsequent rule where all configured conditions are the same.

Best practice for rule actions and rule order

A rule's action determines how the system handles matching traffic. Improve performance by placing rules that do not perform or ensure further traffic handling before the resource-intensive rules that do. Then, the system can divert traffic that it might otherwise have inspected.

The following examples show how you might order rules in various policies, given a set of rules where none is more critical and preemption is not an issue.

If your rules include application conditions, also refer to Best practice for choosing between application matching and port matching, on page 1624.

Optimum order for access control rules

Intrusion, file, and malware inspection requires resources, especially if you use multiple custom intrusion policies and variable sets. Place access control rules that invoke deep inspection last.

1. Monitor—Rules that log matching connections, but take no other action on traffic. (However, see the important exception and caveat at Access control rule monitor action, on page 1614.)
2. Trust, Block, Block with reset—Rules that handle traffic without further inspection.
3. Allow, Interactive Block (no deep inspection)—Rules that do not inspect traffic further, but allow discovery.
4. Allow, Interactive Block (deep inspection)—Rules associated with file or intrusion policies that perform deep inspection for prohibited files, malware, and exploits.

Best practices for simplifying and focusing rules

Follow these best practices to simplify configuration and ensure optimal device performance and rule clarity:

Simplify rule conditions

Minimize individual rule criteria. Use as few elements in rule conditions as possible. For example, use IP address blocks rather than individual IP addresses when defining network conditions.

Avoid redundant conditions

If a single condition is enough to match the traffic you want to handle, do not add more. Redundant conditions can make configuration unnecessarily complex and may negatively impact device performance, especially during cluster or high-availability unit re-join.

For example:

- Use security zones that represent multiple interfaces carefully. If you specify source and destination networks as conditions, and these are enough to match the traffic you are targeting, then specifying a security zone is not required.
- If you want to match a set of internal interfaces to any destination on the Internet (for example), then simply use a source security zone that includes your internal interfaces. No network or destination interface criteria are needed.

Combine elements for organization, not performance

The use of network objects containing many individual IP addresses offers organizational benefits only. It does not improve device performance compared to listing those IP addresses individually.

For recommendations related to application detection, refer to Best practice for choosing between application matching and port matching, on page 1624.

Narrowly constrain resource-intensive rules, especially by interface

As much as possible, use rule conditions to narrowly define the traffic handled by resource-intensive rules. Focused rules are also important because rules with broad conditions can match many different types of traffic, and can preempt later, more specific rules. Examples of resource-intensive rules include:

- TLS/SSL rules that decrypt traffic—Not only the decryption, but further analysis of the decrypted traffic, requires resources. Narrow focus, and where possible, block or choose not to decrypt encrypted traffic.

Certain Firewall Threat Defense models perform TLS/SSL encryption and decryption in hardware, which improves performance significantly. For more information, refer to TLS crypto acceleration, on page 1720.

- Access control rules that invoke deep inspection—Intrusion, file, and malware inspection requires resources, especially if you use multiple custom intrusion policies and variable sets. Make sure you only invoke deep inspection where required.
- If you specify security zones in a rule, the rule is deployed only to devices that have interfaces in the specified zone. So, if you want to focus a rule on only some devices that are assigned to the policy, ensure that you select a security zone that applies to the appropriate subset of devices. This ensures that unnecessary rules are not deployed to a device.

Maximum number of access control rules and intrusion policies

The maximum number of access control rules or intrusion policies that are supported by a device depends on many factors, including policy complexity, physical memory, and the number of processors on the device.

If you exceed the maximum supported by a device, you cannot deploy the access control policy and you must reevaluate.

Guidelines for intrusion policies

Consider these guidelines when configuring intrusion policies:

- In an access control policy, you can associate one intrusion policy with each Allow and Interactive Block rule, as well as with the default action. Every unique **pair** of intrusion policy and variable set counts as one policy.
- You may want to consolidate intrusion policies or variable sets so you can associate a single intrusion policy-variable set pair with multiple access control rules. On some devices you may find you can use only a single variable set for all your intrusion policies, or even a single intrusion policy-variable set pair for the whole device.

Access control rule management

Access control rule management is a security administration process that involves procedures for creating, modifying, and maintaining access control rules.

These topics explain how to manage access control rules.

Add an access control rule category

Categories help organize rules into logical groups so you can understand and manage your policy more easily.

You can divide an access control policy's **Mandatory** and **Default** rule sections into custom categories. After you create a category, you cannot move it, although you can delete it, rename it, and move rules into, out of, within, and around it. The Firewall Management Center assigns rule numbers across sections and categories.

Procedure

Step 1 In the access control policy editor, click **Add Category**.

If your policy already contains rules, you can click a blank area in the row for an existing rule to set the position of the new category before you add it. You can also right-click an existing rule and select **Insert new category**.

Step 2 Enter a **Name**.

Step 3 From the **Insert** drop-down list, choose where you want to add the category:

- To insert a category below all existing categories in a section, choose **into Mandatory** or **into Default**.
- To insert a category above an existing category, choose **above category**, then choose a category.
- To insert a category above or below an access control rule, choose **above rule** or **below rule**, then enter an existing rule number.

Step 4 Click **Apply**.

Step 5 Click **Save** to save the policy.

What to do next

You can now:

- Drag and drop rules into, or out of, the category.
- When creating a rule, select a category it should be part of.
- When editing a rule, reposition the rule to be in the category, or to move it out of the category.

Create and edit access control rules

Use access control rules to apply actions to specific traffic classes. Rules allow you to selectively allow desirable traffic and drop unwanted traffic.

Procedure

Step 1 In the access control policy editor, you have the following options:

- To add a new rule, click **Add Rule**.
- To edit an existing rule, click **Edit** ( ).
- To start with a copy of an existing rule, choose one of the following commands from the **More** ( ) menu.
  - **Copy Rule**, to copy the rule to the clipboard, so you can use the **Paste Above/Below** commands to place it anywhere in the same policy.

- **Copy Rule to Different Policy**, to copy the rule to another access control policy. A dialog box opens so that you can select the policy and chose the rule placement.
- **Clone Rule**, to create the copy immediately below the duplicated rule.

- To edit multiple rules, use the checkboxes to select multiple rules, then select **Edit** or another action from the **Select Action/Bulk Rule Actions** list next to the search box.
- To do inline editing, where you change the configuration of an object in a rule condition, right-click the value and choose **Edit**. You can also use the right-click menu to remove a item, add it to the filter, or copy the text or value.

If **View** ( ) appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.

Step 2 If this is a new rule, enter a **Name**.

Step 3 Configure the rule components.

If you are bulk-editing multiple rules, only a subset of options are available.

Table 96: Access control rule components

Rule component	Configuration description
Position	Specify the rule position (**Insert** for new rules, the **Reposition** icon next to the rule name for existing rules); see Access control rule order, on page 1613.
Action	Choose a rule **Action**; see Access control rule actions, on page 1614.
Logging	Click **Logging** to specify options for connection logging and SNMP traps. See *Best Practices for Connection Logging* in the *Cisco Secure Firewall Management Center Administration Guide* for more information.
Time Range	(Optional.) For Firewall Threat Defense devices, choose the days and times when the rule is applicable. If you do not choose an option, the rule is always active. For details, see Create a time range object, on page 2435.
Enable Rule	Whether the rule is active. Disabled rules are not applied to connections. You can disable rules to temporarily turn them off, for example, during troubleshooting.
Security Protections (Deep inspection)	(Optional.) For Allow and Interactive Block rules, select options for **Intrusion Policy**, **Variable Set**, and **File Policy**. You can apply intrusion and file policies independently; you do not need to configure both.
Conditions	Select the objects you want to add to either source or destination, then click either **Add to Sources** or **Add to Destinations and Applications** to add matching conditions for connections. You can click a tab to restrict the list of available objects, for example, to Networks, Security Zones, Applications, and so forth. However, the sources and destination column always show all selected objects regardless of the tab you are on. See Access control rule conditions, on page 1633 for more information.
Comments	Open the comments list at the bottom of the dialog box, enter your comment, and click **Add Comment/Post** to add a comment.

Step 4 Click **Add** or **Apply** to save the rule.

Step 5 Click **Save** to save the policy.

What to do next

If you will deploy time-based rules, specify the time zone of the device to which the policy is assigned. See Configure a time zone for a device, on page 911.

Deploy configuration changes; see Deploy configuration changes, on page 135.

Related Topics

Best practices for access control rules, on page 1625

Access control rule conditions

Access control rule conditions are traffic matching criteria that define the characteristics of the connections you want to target with each rule. Use the conditions precisely to fine-tune the rule to apply to all, and only, the traffic that should be handled by the rule. The following topics explain the match conditions that you can use.

Security/tunnel zone rule conditions

Security/tunnel zone rule conditions are traffic matching mechanisms that

- use security zones and tunnel zones to select traffic for a rule
- segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices
- allow you to identify tunneled traffic, such as GRE, that should be handled as a tunnel rather than apply access control rules to the encapsulated connections within the tunnel.

You can use security zones to control traffic by its source and destination interfaces. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones for it to match the rule. Just as all interfaces in a security zone must be of the same type (all inline, passive, switched, or routed), all zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

When using tunnel zones, ensure that you have matching rules in the prefilter policy to associate tunneled traffic with the zone. Then, you can select the tunnel zone as a source zone in a rule; tunnel zones cannot be destinations. If you do not have prefilter rules to rezone the tunnels into the tunnel zone, an access control rule for the tunnel will never apply to any connections. You can specify destination security zones to target tunnels that leave the device through specific interfaces.

Security zone considerations

Consider the following when deciding on security zone criteria:

- Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

- Access control rules generate ACL entries (ACEs) in the device configuration to provide early processing and drops whenever possible. If you specify security zones in rules, ACEs are created for each interface in the zone, which can greatly increase the size of the ACL. Excessively large ACLs generated from access control rules can impact system performance.

Network rule conditions

Network rule conditions are the network objects or geographical locations that define the network addresses or locations of the traffic.

Network criteria selection

- To match traffic from an IP address or geographical location, add the criteria to the Sources list.
- To match traffic to an IP address or geographical location, add the criteria to the Destinations list.
- If you add both source and destination network conditions to a rule, matching traffic must originate from one of the specified IP addresses and be destined for one of the destination IP addresses.

When you add this criteria, you select from these tabs:

- **Network**—Select the network objects or groups that define the source or destination IP addresses for the traffic you want to control.

  Whenever possible, combine multiple network objects into a single object group. The system automatically creates an object group (during deployment) when you select more than one object (for source or destination separately). Selecting existing groups can avoid object group duplication and reduce the potential impact on CPU usage when there are a large number of duplicate objects.

  You can use objects that define the address using the fully-qualified domain name (FQDN); the address is determined through a DNS lookup. However, FQDN objects are not supported in these sections in access control policies: original client networks, SGT/ISE attributes, network analysis and intrusion policy, Security Intelligence, threat detection, elephant flow settings.

- **Geolocation**—Select the geographical location to control traffic based on its source or destination country or continent. Selecting a continent selects all countries within the continent. Besides selecting geographical location directly in the rule, you can also select a geolocation object that you created to define the location. Using geographical location, you could easily restrict access to a particular country without needing to know all of the potential IP addresses used there.

Note To ensure that you are using up-to-date geographical location data to filter your traffic, Cisco strongly recommends that you regularly update the geolocation database (GeoDB).

Traffic matching configuration:

- To match traffic from an IP address or geographical location, add the criteria to the Sources list.
- To match traffic to an IP address or geographical location, add the criteria to the Destinations list.
- If you add both source and destination network conditions to a rule, matching traffic must originate from one of the specified IP addresses and be destined for one of the destination IP addresses.

Original client in network conditions (filtering proxied traffic)

For some rules, you can handle proxied traffic based on the originating client. Use a source network condition to specify proxy servers, then add an original client constraint to specify original client IP addresses. The system uses a packet's X-Forwarded-For (XFF), True-Client-IP, or custom-defined HTTP header field to determine original client IP.

Traffic matches the rule if the proxy's IP address matches the rule's source network constraint, and the original client's IP address matches the rule's original client constraint. For example, to allow traffic from a specific original client address, but only if it uses a specific proxy, create three access control rules:

Access Control Rule 1: Blocks proxied traffic from a specific IP address (209.165.201.1)

Source Networks: 209.165.201.1
Original Client Networks: none/any
Action: Block

Access Control Rule 2: Allows proxied traffic from the same IP address, but only if the proxy server for that traffic is one you choose (209.165.200.225 or 209.165.200.238)

Source Networks: 209.165.200.225 and 209.165.200.238
Original Client Networks: 209.165.201.1
Action: Allow

Access Control Rule 3: Blocks proxied traffic from the same IP address if it uses any other proxy server.

Source Networks: any
Original Client Networks: 209.165.201.1
Action: Block

VLAN tag rule conditions

VLAN tags rule conditions are filtering mechanisms that

- control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic
- use the innermost VLAN tag to filter VLAN traffic, with the exception of prefilter policy which uses the outermost VLAN tag, and
- apply only to inline sets and do not match traffic on firewall interfaces.

VLAN tag rule conditions configuration details

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:

- Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
- Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

User rule conditions

A user rule condition is a traffic matching mechanism that

- matches traffic based on whether the user initiating the connection or the group to which they belong
- can be configured for users in Microsoft Active Directory realms only, and
- enables policy enforcement based on user identity and group membership.

Special identities users

In addition to configuring users and groups for configured realms, you can set policies for the special identities users:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.

User rule condition example

Configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

Application rule conditions

Application rule conditions are application awareness and control mechanisms that

- identify and classify applications through IP traffic analysis
- enable control with organized filters
- require one enabled detector for each condition.

Application filters and control benefits

System-provided *application filters* help perform control by organizing applications according to basic characteristics, such as type, risk, business relevance, category, and tags. You can also create reuseable, user-defined filters using combinations of system-provided filters, or custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled, the system automatically enables all available system-provided detectors, or the most recently modified user-defined detector. For more information about application detectors, see Application detectors, on page 2284.

You can utilize both application filters and individually specified applications to ensure complete coverage. Understand the application's requirements to effectively order access control rules.

Application filters help you to quickly configure application control effectively. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

The system characterizes detected applications using several criteria which form effective filters.

Table 97: Application characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email applications are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged `high bandwidth` and `displays ads`.

Configure application conditions and filters

To build an application condition or filter, choose the applications whose traffic you want to control from a list of available applications. It is recommended that you constrain the available applications using filters. You can use filters and individually specified applications in the same condition.

Before you begin

- Adaptive profiling must be enabled (its default state) in the access control policy's advanced settings for access control rules to perform application control.

Follow these steps to configure application conditions and filters:

Procedure

Step 1 In the access policy rule editor, click **Applications**.

Step 2 Find and choose the applications you want to add from the **Available Applications** list.

To constrain the applications displayed in **Available Applications**, choose one or more **Application Filters** or search for individual applications.

Tip Click **Information** ( ) next to an application to display summary information and internet search links. A **lock** icon marks applications that the system can identify only in decrypted traffic.

When you choose filters, singly or in combination, the Available Applications list updates to display only the applications that meet your criteria. You can choose system-provided filters in combination, but not user-defined filters.

- Multiple filters for the same characteristic (risk, business relevance, and so on)—Application traffic must match only one of the filters. For example, if you choose both the medium and high-risk filters, the Available Applications list displays all medium and high-risk applications.
- Filters for different application characteristics—Application traffic must match both filter types. For example, if you choose both the high-risk and low business relevance filters, the Available Applications list displays only applications that meet both criteria.

Step 3 Click **Add Application** or **Add to Rule**, or drag and drop.

Tip Before you add more filters and applications, click **Clear Filters/Selection** to clear your current choices.

Step 4 Save or continue editing the rule or configuration.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 135.

Port, protocol, and ICMP code rule conditions (concept)

A port, protocol, and ICMP code rule condition is a traffic matching criterion that

- matches traffic based on source and destination ports
- supports TCP, UDP, ICMP, and other protocols that do not use ports, and
- controls traffic flow in access control and other policy rules.

Port condition types

Port conditions match traffic based on the source and destination ports. Depending on the rule type, "port" can represent any of these types:

- TCP and UDP—Control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP (6) /22.
- ICMP—Control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—Control traffic using other protocols that do not use ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best practices for port-based rules

Specifying ports is the traditional method used to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Use application filtering criteria when possible; however, note that application filtering is unavailable in prefilter rules.

Use application filtering for FTP and similar applications that open separate channels for control and data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly and could result in blocking desirable connections.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching non-TCP traffic with port conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although configuring port conditions can match non-TCP traffic, restrictions apply:

- Access control rules—For Classic devices, match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, add only network-based conditions: zone, IP address, port, and VLAN tag. The system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For Firewall Threat Defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.

- Decryption rules—These rules support only TCP port conditions.
- IMCP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies, sent in response to ICMP echo requests, are ignored. To match any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

Recommendation: use URL conditions for website access control

Use URL conditions to control the websites that users on your network can access.

For complete information, see URL filtering with category and reputation, on page 1652.

Dynamic attributes rule conditions

Dynamic attributes rule conditions allow you to specify access control rules based on real-time properties such as network objects, device types, locations, and security tags. Dynamic attributes can be used as source criteria and destination criteria in access control rules. These criteria help match traffic more flexibly and accurately.

Dynamic attributes configuration and behavior

You can use these types of dynamic attributes to match connections in DNS rules:

- Dynamic objects (Source or destination): The dynamic attributes connector collects data such as networks and IP addresses from cloud providers for use in access control rules. For more information, refer to About the dynamic attributes connector , on page 2061 .
- SGT objects (Source only): These contain tags defined manually or in Cisco ISE. For more information, refer to Source and destination security group tag (SGT) matching, on page 1912 and Security group tags, on page 2376 .
- Location IP objects (Source only): Defined by Cisco ISE.
- Device type objects (Source only): Defined by Cisco ISE, also referred to as endpoint profile objects.

When you configure dynamic attributes for a DNS rule, objects of the same type within a source or destination list use OR logic, while objects of different types use AND logic. For example, if you select both a security group tag, and a dynamic object that lists IP addresses, the rule matches if traffic with the tag originates from (or is destined to) one of those IP addresses.

When you open the **Dynamic Attributes** tab, all **Dynamic Objects** and **Security Group Tags** appear in the list. To remove objects from the list, deselect the options. To find an object, type in the search box.

Time and Day Rule Conditions

You can specify a continuous time range or a recurring time period.

For example, a rule can apply only during weekday working hours, or every weekend, or during a holiday shutdown period.

Time-based rules are applied based on the local time of the device that processes the traffic.

Time-based rules are supported only on Firewall Threat Defense devices. If you assign a policy with a time-based rule to a different type of device, the time restriction associated with the rule is ignored on that device. You will see warnings in this case.

Enable and disable access control rules

Enable or disable access control rules to control whether they are used to evaluate network traffic.

When you create an access control rule, it is enabled by default. If you disable a rule, the system does not use it to evaluate network traffic and stops generating warnings and errors for that rule. When viewing rules in an access control policy, disabled rules are grayed out but can still be modified. You can also change a rule's status in the rule editor.

Procedure

Step 1 In the access control policy editor, right-click the rule you want to change and choose a rule state.

If **View** ( ) appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.

Step 2 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Copy access control rules from one access control policy to another

You can copy access control rules from one access control policy to another. You can copy the rules either to the **Default** section or the **Mandatory** section of the access control policy.

All the settings of the copied rules, except the comments, are retained in the pasted version

Procedure

Step 1 Do one of the following:

- To copy a single rule, right-click the rule and select **Copy Rule to Different Policy**.
- To copy multiple rules, select their checkboxes, then select **Copy Rules to Different Policy** from the **Select Bulk Action** menu.

Step 2 Select the destination access control policy from the **Access Policy** drop-down list.

Step 3 From the **Place Rules** drop-down list, choose where you want to position the copied rules. You can place them at the bottom of either the Mandatory or Default sections.

Step 4 Click **Copy**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Move access control rules to a prefilter policy

You can move access control rules from an access control policy to the associated non-default prefilter policy.

You must first apply a user-defined prefilter policy to the access control policy. The access control rules cannot be moved to the default prefilter policy because the default prefilter policy cannot have rules.

Before you begin

Note these conditions before you proceed:

- When moving an access control rule to a prefilter policy the layer 7 (L7) parameters, such as application or URL filterin, in the access control rule cannot be moved. The L7 parameters are dropped during the operation.
- The comments in the access control rule configuration are lost after moving the rule. However, a new comment is added in the moved rule mentioning the source access control policy.
- You cannot move access control rules with **Monitor** set as the **Action** parameter.
- The **Action** parameter in the access control rule is changed to a suitable action in the prefilter rule when moved. To know what each action in the access control rule maps to, see this table:

Action in the access control rule	Action in the prefilter rule
Allow	Analyze
Block	Block
Block with reset	Block
Interactive Block	Block
Interactive Block with reset	Block
Trust	Fastpath

- Similarly, based on the action configured in the access control rule, the logging configuration is set to an appropriate setting after the rule is moved, as mentioned in this table.

Action in the access control rule	Enabled logging configurations in the prefilter rule
Allow	None of the check boxes are checked.
Block Block with reset Interactive Block Interactive Block with reset	• Log at Beginning of Connection • Event Viewer • Syslog Server • SNMP Trap

Action in the access control rule	Enabled logging configurations in the prefilter rule
Trust	• Log at Beginning of Connection • Log at End of Connection • Event Viewer • Syslog Server • SNMP Trap

- While moving rules from the source policy, if another user modifies those rules, you will see get a message. You may continue with the process after refreshing the page.

Procedure

Step 1 Do one of the options:

- To move a single rule, right-click the rule and select **Move Rule to Prefilter Policy**.
- To move multiple rules, select their checkboxes, then select **Move Rules to Prefilter Policy** from the **Select Bulk Action** menu.

Step 2 From the **Place Rules** drop-down list, choose where you want to position the moved rules, either **At the bottom** or **At the top**.

Step 3 Click **Move**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Position an access control rule

Position rules correctly within an access control policy to ensure the first match wins behavior produces the intended security outcomes.

You can move an existing rule within an access control policy, or insert new rules in a desired location. When you add or move a rule to a category, the system places it last in the category.

Before you begin

Review rule order guidelines in Best practices for access control rules, on page 1625.

Procedure

Step 1 Do one of these:

- New rule—Insert a new rule by hovering over the line between the existing rules, and clicking **Add Rule**. The location is selected in the **Insert** box in the Add Rule dialog box; you can select a different rule to adjust the location. You can also select **Add Rule Above** or **Add Rule Below** from the right-click menu.
- Existing rules when viewing the rule table—Click and drag the rule to the new position. This action is final, you are not prompted to confirm it.
- Existing rules when viewing the rule table—Right-click a single rule and select **Reposition Rule**. To move multiple rules as a group, select their checkboxes, then select **Reposition Rules** from the **Select Bulk Action** menu. You are prompted for where you want the rule to go.
- Existing rule when editing the rule—Click the **Reposition Rule** icon next to the rule name.

Step 2 When editing or repositioning the rule, choose where you want to move or insert the rule, then click **Move**, **Confirm**, or **Reposition** (depending on what you are doing).

- Choose **into Mandatory** or **into Default**.
- Choose a **into Category**, then choose the category.
- Choose **above rule** or **below rule**, then select the rule.

Step 3 Save the rule if you are editing it.

Step 4 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Add comments to an access control rule

Adding comments to access control rules helps you keep track of the purpose of a rule, and changes made to the rule.

When you create or edit an access control rule, you can add a comment. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the change. You can display a list of all comments for a rule along with the user who added each comment and the date the comment was added.

When you save a rule, all comments made since the last save become read-only.

To search access control rule comments, use the **Search Rules** bar on the rule listing page.

Procedure

Step 1 In the access control rule editor, click **Comments**.

Step 2 Enter your comment and click **Add Comment**. You can edit or delete this comment until you save the rule.

Step 3 Save the rule.

Examples for access control rules

These topics provide examples of access control rules.

How to control access using security zones

Configure security zones and access control rules to inspect incoming traffic for intrusions and malware while allowing unrestricted internet access for internal hosts.

Consider a deployment where you want hosts to have unrestricted access to the internet, but you nevertheless want to protect them by inspecting incoming traffic for intrusions and malware.

First, create two security zones: Internal and External. Then, assign interface pairs on one or more devices to those zones, with one interface in each pair in the Internal zone and one in the External zone. Hosts connected to the network on the Internal side represent your protected assets.

Note You are not required to group all internal (or external) interfaces into a single zone. Choose the grouping that makes sense for your deployment and security policies.

Then, configure an access control rule with a destination zone condition set to Internal. This simple rule matches traffic that leaves the device from any interface in the Internal zone. To inspect matching traffic for intrusions and malware, choose a rule action of **Allow** , then associate the rule with an intrusion and a file policy.

Control application usage

Block web-based applications, particularly anonymizers or proxies, by creating access control rules that identify and restrict traffic based on application attributes

Enterprise networks increasingly rely on web-based delivery platforms and rich media applications, often using the same web protocols. Firewall Threat Defense inspects connections to determine the application, enabling access control rules targeting applications rather than just targeting specific TCP/UDP ports.

Although you can select specific applications to allow or block, you can also write rules based on type, category, tag, risk, or business relevance. For example, you could create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the session is blocked.

Cisco frequently updates and adds additional application detectors via system and vulnerability database (VDB) updates. Thus, a rule blocking high risk applications can automatically apply to new applications without you having to update the rule manually.

In this use case, we will block any application that belongs to the **anonymizer/proxy** category.

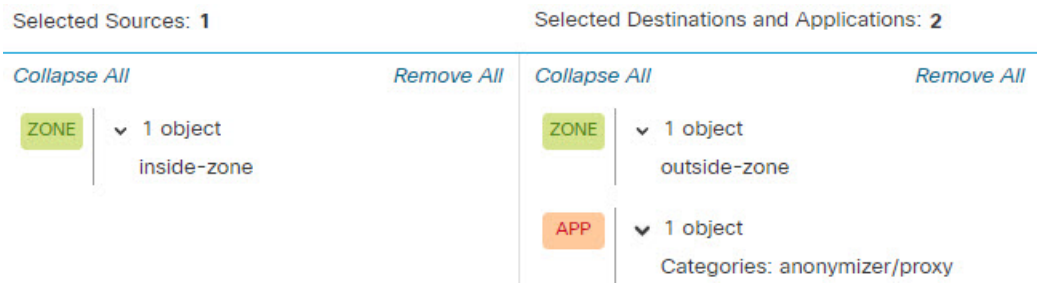
Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control** and edit the access control policy.

Step 2 Click **Add Rule** and configure the rule for application control.

a) Name the rule (for example, Block_Anonymizers).

b) For **Action**, select **Block**.



c) If you have configured security zones and want to restrict traffic from inside to outside, click the **Zones** tab, and choose your inside zone as the source zone, and the outside zone as the destination zone.

d) Click the **Applications** tab, select the applications to match, and click **Add Application**.

As you select criteria, such as category and risk level, the list to the right of the criteria updates to show exactly which applications match the criteria. The rule you are writing applies to these applications.

For purposes of this example, choose **anonymizers/proxy** from the **Categories** list and add it to **Destinations and Applications**. The match criteria should now look similar to the following graphic.

e) Click **Logging** next to the rule action, and enable logging at the start of the connection. You can select a syslog server if you use one.

You must enable logging to get information about any connections blocked by this rule.

Step 3 Move the rule so that it comes after any rules that use protocol and port criteria only, but that would not allow traffic that should be blocked by the application rule.

Matching applications requires Snort inspection. Because Snort inspection is not needed by rules that use protocol and port only, you can improve system performance by grouping these simple rules at the top of the access control policy as much as possible.

Step 4 Deploy the changes.

You can use the application rule hit counts and analysis dashboards to see how this rule is performing and how often users try these applications.

Block threats

You can implement next generation Intrusion Prevention System (IPS) filtering by adding intrusion policies to your access control rules. Intrusion policies analyze network traffic, comparing the traffic contents against known threats. If a connection matches a threat you are monitoring, the system drops the connection, thus preventing the attack.

All other traffic handling occurs before network traffic is examined for intrusions. By associating an intrusion policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect the traffic with an intrusion policy.

You can configure intrusion policies on rules that **allow** traffic only. Inspection is not performed on rules set to **trust** or **block** traffic. In addition, you can configure an intrusion policy as the default action if you do not want to use a simple block.

Security Intelligence policies allow you to preemptively block traffic to or from known bad IP addresses and URLs. This task demonstrates how to add an intrusion policy that allows traffic from the internal 192.168.1.0/24 network to external destinations, assuming block rules exist to eliminate unwanted connections, and adds Security Intelligence to block known threats.

Before you begin

- Apply the IPS license to any managed device that uses this rule.
- Ensure you have created security zones for inside and outside interfaces.
- Create the network object for the inside network.

Procedure

Step 1 Create the access control rule that applies the intrusion policy.

a) Edit the access control policy and add a new rule.

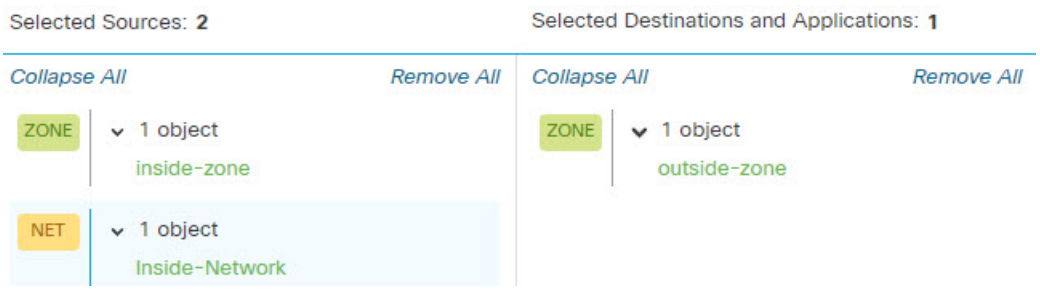
b) Name the rule (for example, Inside_Outside) and set the rule action to **Allow**.

c) Choose **Balanced Security and Connectivity** as the **Intrusion Policy**. You can either accept the default variable set or select your own if you want to customize it.

The **Balanced Security and Connectivity** policy is appropriate for most networks. It provides a good intrusion defense without being overly aggressive, which has the potential of dropping traffic that you might not want to be dropped. If you determine that too much traffic is getting dropped, you can ease up on intrusion inspection by selecting the **Connectivity over Security** policy.

If you need to be aggressive about security, try the **Security over Connectivity** policy. The **Maximum Detection** policy offers even more emphasis on network infrastructure security with the potential for even greater operational impact.

If you create your own custom policy, you can select that one instead.



A discussion of variable sets is beyond the scope of this example. Please read the chapters on intrusion policy for detailed information about variable sets and custom policies.

d) Select the **Zones** tab, and add your inside security zone to the source criteria, and outside zone to the destination criteria.

e) Select the **Networks** tab, and add the network object that defines your inside network to the source criteria.

The match criteria should look similar to the following:

f) Click **Logging** and enable logging at the beginning or end of the connection, or both, as desired.
g) Click **Apply** to save the rule, and then **Save** to save the updated policy.
h) Move the rule to the appropriate location in the access control policy.

Step 2 Configure the Security Intelligence policy to preemptively drop connections with known bad hosts and sites.

By using Security Intelligence to block connections with hosts or sites that are known to be threats, you save your system the time needed to do deep packet inspection to identify threats in each connection. Security Intelligence provides an early block of undesirable traffic, leaving more system time to handle the traffic you really care about.

a) While editing the access control policy, click the **Security Intelligence** link in the packet path.

The link includes two policies: the DNS policy at the top, and the Security Intelligence (Network and URL) at the bottom. In this example, we are configuring the Network and URL lists. By default, these lists already include the global block and do not block lists, but these lists are empty by default until you add items to them.

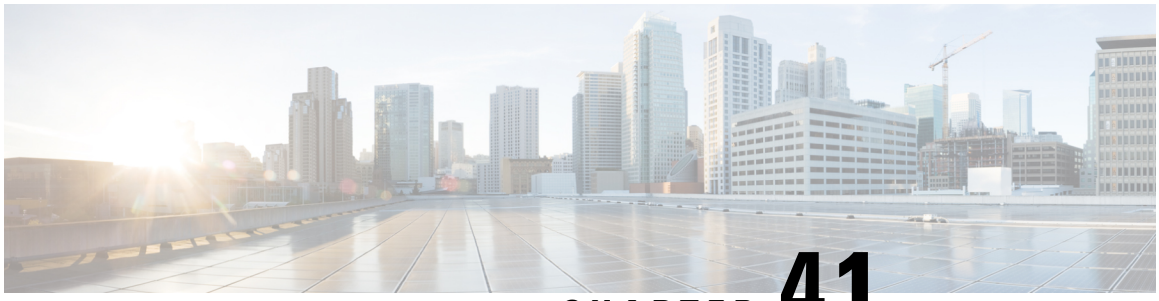
b) With **Networks** selected and the **Any** security zone selected, scroll down in the Networks list until you get to the global feeds, and the first Security Intelligence category (probably Attackers). Click Attackers, then scroll to the end of the categories (probably Tor_exit_node), and Shift+Click to select all of the categories. Click **Add To Block List**.
c) Select the **URL** tab, and **Any** security zone, and use Shift+Click to select URL versions of the same categories. Click **Add To Block List**.
d) Click **Save** to save the policy.
e) As necessary, you can add network and URL objects to the block or do not block lists.

The **Do Not Block** lists are not real "allow" lists. They are exception lists. If an address or URL in the exception list also appears in the blocked list, the connection for the address or URL is allowed to pass on to the access control policy.

This way, you can block a feed, but if you later find that a desirable address or site is being blocked, you can use the exception list to override that block without needing to remove the feed entirely.

Keep in mind that these connections are subsequently evaluated by access control, and if configured, an intrusion policy. Thus, if any connections do contain threats, they can be identified and blocked during intrusion inspection.

Use the events and dashboards to determine what traffic is actually being dropped by the policy, and whether you need to add addresses or URLs to the **Do Not Block** lists.



Step 3 Deploy your changes.

History for access control rules

This history table provides a summary of feature changes by release for the access control policy rules.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Maximum objects per match criteria per access control rule is 200.	7.3	Any	Previously, you could have a maximum of 50 objects per match criteria in a single access control rule. For example, you could have up to 50 network objects in a single access control rule. The limit is now 200 objects per match criteria in a single rule. We updated the access control policy to allow the increased object limit.
Search for access control rule comments	6.7	Any	The **Search Rules** bar now offers the option to search for comments. New/modified pages: Access control rules page, **Search Rules** text entry field. Supported platforms: Firewall Management Center
Copy or move rules between access control and prefilter policies	6.7	Any	You can copy access control rules from one access control policy to another. You can also move access control rules from an access control policy to the associated prefilter policy. New/modified pages: Access control policy page; the right-click menu for the selected rules provides additional options to copy and move. Supported platforms: Firewall Management Center
Bulk edit of certain settings in access control rules	6.6	Any	In the list of rules in a policy, shift-click or control-click to select multiple rules, then right-click and choose an option. Example bulk operations: You can enable or disable the rules, select a rule action, and edit most inspection and logging settings. New/modified pages: Access control rules page. Supported platforms: Firewall Management Center
Enhanced searching on configured rules	6.6	Any	Enhanced searching on configured rules. New/modified pages: Access control rules page. Supported platforms: Firewall Management Center

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Time ranges for rule application	6.6	Any	Ability to specify an absolute or recurring time or time range for a rule to be applied. The rule is applied based on the time zone of the device that processes the traffic. New/modified pages: • A new option on the access control Add Rule page. • A related new option on the **Devices** > **Platform Settings** > **Threat Defense** page to specify time zones for managed devices. Supported platforms: Firewall Threat Defense devices only
View object details from access control rule pages	pre-6.6	Any	To see information about an object in a list of rules or from the rule configuration dialog, right-click the object. New/modified pages: **Policies** > **Access Control** > **Access control**, and **Add Rule** page. Supported platforms: Firewall Management Center

CHAPTER 41

URL Filtering Rules

You can implement URL filtering using access control rules.

- URL filtering, on page 1651
- Best practices for URL filtering, on page 1654
- License requirements for URL filtering, on page 1659
- Requirements and prerequisites for URL filtering, on page 1660
- Configure URL filtering with category and reputation, on page 1660
- Manual URL filtering, on page 1667
- HTTP response pages, on page 1669
- Configure URL filtering health monitors, on page 1673
- Dispute URL category and reputation, on page 1673
- Take action if the URL category set changes, on page 1674
- Troubleshoot URL filtering, on page 1676
- History for URL filtering, on page 1678

URL filtering

URL filtering is a security feature that

- controls the websites that users on your network can access,
- provides category and reputation-based filtering with a URL Filtering license, and
- enables manual specification of individual URLs, groups of URLs, and URL lists with any license.

URL filtering types

Use URL filtering to control website access through these methods:

- Category and reputation-based URL filtering—With a URL Filtering license, you can control access to websites based on the URL's general classification (category) and risk level (reputation). This is the recommended option.
- Manual URL filtering—With any license, you can manually specify individual URLs, groups of URLs, and URL lists and feeds to achieve granular, custom control over web traffic. For more information, see Manual URL filtering, on page 1667.

See also Security Intelligence, on page 1595, a similar but different feature for blocking malicious URLs, domains, and IP addresses.

The URL filtering feature is applicable only when you use a web browser to browse websites via the HTTP/HTTPS protocol. For other applications, you must use an FQDN-based access control rule instead of URL filtering. See Access Control Rules for more information.

URL filtering with category and reputation

URL filtering with category and reputation is a web security mechanism that

- controls access to websites based on the category and reputation of requested URLs,
- uses category classifications to group URLs by type (for example, ebay.com belongs to the Auctions category, and monster.com belongs to the Job Search category),
- assesses reputation levels from Unknown risk (level 0) or Untrusted (level 1) to Trusted (level 5) to determine how likely the URL is to be used for purposes that might be against the security policy for your organization, and
- allows URLs to belong to multiple categories simultaneously.

Reputation is determined by the hostname, e.g. all pages on www.cisco.com are considered to have the same reputation.

Benefits of category and reputation-based URL filtering

URL categories and reputations help you quickly configure URL filtering. For example, you can use access control to block untrusted URLs in the Hacking category. You can also use QoS to limit the rate of traffic from sites in the Streaming Video category. There are also categories for types of threats, such as a Spyware and Adware category.

Using category and reputation data simplifies policy creation and administration. It grants you assurance that the system controls web traffic as expected. Because Cisco continually updates its threat intelligence with new URLs, as well as new categories and risk levels for existing URLs, the system uses up-to-date information to filter requested URLs. Sites that (for example) represent security threats, or serve undesirable content may appear and disappear faster than you can update and deploy new policies.

These examples show how the system can adapt:

- If an access control rule blocks all gaming sites, as new domains are registered and classified as Games, the system can block those sites automatically. Similarly, if a QoS rule rate-limits traffic from all streaming video sites, the system can automatically limit traffic to new streaming video sites.
- If an access control rule blocks all malware sites and a shopping page gets infected with malware, the system can recategorize the URL from Shopping to Malware Sites and block that site.
- If an access control rule blocks untrusted social networking sites and somebody posts a link on their profile page that contains links to malicious payloads, the system can change the reputation of that page from Favorable to Untrusted and block it.

Limitations exist for category-based filtering in decryption policy Do Not Decrypt rules.

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from

its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security.

Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Recommendations for application control, on page 1622.

For more information, refer to Use categories in URL filtering, on page 1658.

URL category and reputation descriptions

This reference lists URL category and reputation level descriptions for security management.

Category descriptions

You can find a description of each URL category at https://www.talosintelligence.com/categories.

Click **Threat Categories** to view those categories.

Reputation level descriptions

Refer to Web reputation levels for information.

URL filtering data from the Cisco cloud

URL filtering data from the Cisco cloud is a threat intelligence dataset that

- allows traffic handling based on a website's general classification, or *category*, and risk level, or *reputation*,
- is automatically enabled when a URL Filtering license is added, and
- provides real-time threat intelligence evaluation for websites not found in local cache or datasets.

URL filtering data evaluation process

By default, when users browse to a URL whose category and reputation are not in a local cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache.

Optionally, you can use a local URL dataset of categories and reputations, which can make web browsing faster. When you enable or re-enable URL filtering, the Firewall Management Center automatically queries Cisco for URL data and pushes the dataset to managed devices. Then, when users browse to an URL, the system checks the local dataset and the cache for category and reputation information before submitting it to the cloud for threat intelligence evaluation. To see your options for using the local dataset, including how to disable individual cloud lookups altogether, see URL filtering options, on page 1662.

Automatic updates of URL data is enabled by default. We strongly recommend that you do not disable these updates.

The set of URL categories may change periodically. When you receive a change notification, review your URL filtering configurations to make sure traffic is handled as expected. For more information, see Take action if the URL category set changes, on page 1674.

Best practices for URL filtering

Filter by category and reputation

Follow the instructions in Configure URL filtering with category and reputation, on page 1660.

Configure your policy to inspect packets that must pass before a URL can be identified

The system cannot filter URLs before:

- A monitored connection is established between a client and server.
- The system identifies the DNS, HTTP or HTTPS application in the session.
- The system identifies the requested domain or URL (for encrypted sessions, from a non-encrypted domain name, the ClientHello message or the server certificate).

This identification should occur within three to five packets, or after the server certificate exchange in the TLS/SSL handshake if the traffic is encrypted.

Important! To ensure that your system examines these initial packets that would otherwise pass, see Inspection of packets that pass before traffic is identified and subtopics.

If early traffic matches all other rule conditions but identification is incomplete, the system allows the packet to pass and the connection to be established (or the TLS/SSL handshake to complete). After the system completes its identification, the system applies the appropriate rule action to the remaining session traffic.

Block threat categories

Be sure that your policies specifically address Threat categories, which identify known malicious sites. Do this in addition to blocking sites with poor reputations.

For example, to protect your network from malicious sites, you must block all Threat categories. Additionally, Talos recommends that you block only sites with Poor category. You can block questionable reputations if you have an aggressive security posture, but this may result in a higher amount of false positives.

For specifics, see **Threat Categories** at the URL in URL category and reputation descriptions, on page 1653.

Position URL rules properly and consider rule order

Position URL rules after all other rules that *must* be hit.

URLs can belong to more than one category. It is possible to want to allow one category of websites and block another—whether explicitly or by relying on the default action. In this case, make sure you create and order URL rules so you get the desired effect, depending on whether the allow or the block should take precedence.

For additional guidelines for rules, see the following topics: Best practices for access control rules, on page 1625.

Handle uncategorized or reputationless URLs appropriately

When you build a URL rule, you first choose the category you want to match. If you explicitly choose **Uncategorized** URLs, you cannot further constrain by reputation.

Uncategorized URLs with Untrusted reputation are handled by the **Malicious Sites** category. If you want to block uncategorized sites with any other reputation level (such as Questionable), you must block all uncategorized sites.

After selecting a category and a reputation level, you can optionally select **Apply to unknown reputation**. For example, you can create a rule that applies to sites with Untrusted, Questionable, and unknown reputations.

You cannot manually assign categories and reputations to URLs, but in access control and QoS policies, you can manually block specific URLs. See Manual URL filtering, on page 1667. See also Dispute URL category and reputation, on page 1673.

URL filtering for encrypted web traffic

When performing URL filtering on encrypted web traffic, the system:

- (If DNS filtering is enabled) Checks to see if the system has previously seen the originating domain or the domain is in the local reputation database, and if so, takes action based on the reputation and category of the domain. Otherwise, the system processes the traffic based on your configurations for encrypted traffic, even if **Retry URL cache miss lookup** is enabled in the access control policy's advanced settings.
- Disregards the encryption protocol; a rule matches both HTTPS and HTTP traffic if the rule has a URL condition but not an application condition that specifies the protocol.
- Does not use URL lists. You must use URL objects and groups instead.
- Matches HTTPS traffic based on the subject common name in the public key certificate used to encrypt the traffic, and also evaluates the reputation of any other URLs presented at any time during the transaction, including the post-decryption HTTP URL.
- Disregards subdomains within the subject common name.
- Does not display an HTTP response page for encrypted connections blocked by access control rules (or any other configuration); see Limitations to HTTP response pages, on page 1669.

URL filtering and TLS server identity discovery considerations

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by RFC 8446, is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate *without* decrypting the entire packet.

Access control policy advanced settings offer an **Early application detection and URL categorization** option for TLS Server Identity Discovery.

We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. An decryption policy is not required because *traffic is not decrypted* in the process of extracting the server certificate.

Note

- TLS server identity discovery *cannot* be used with any of the following:
  - STARTTLS traffic
  - The HTTP CONNECT method
  - Traffic that is already being decrypted by another device on the network
- Because the certificate is decrypted, TLS server identity discovery can reduce performance depending on the hardware platform.
- TLS server identity discovery is not supported in inline tap mode or passive mode deployments.
- Enabling TLS server identity discovery is supported on any Secure Firewall Threat Defense Virtual version deployed in AWS. TLS server identity is incompatible with certain deployment scenarios that involve Gateway Load Balancer (GWLB). Whether the device initiates a server certificate probe depends on its deployment method with GWLB and the traffic direction.
  - Geneve single-arm flow: The probe *is not initiated* for either east–west or north–south traffic. A connection event **PROBE_FLOW_DROP_BYPASS_PROXY** increments every time the device attempts to extract the server certificate.
  - Geneve dual-arm flow: The probe *is initiated only* for north–south traffic.
- TLS Server Identity Discovery also operates on TLS 1.2 sessions.

For more information, see TLS server identity discovery, on page 2173.

HTTP/2 URL extraction limitations

The system can extract HTTP/2 URLs from TLS certificates, but not from a payload.

Use manual URL filtering effectively

- Specify URLs using a custom Security Intelligence list or feed object. Do not use a URL object or directly enter a URL into the rule. For details, see Manual URL filtering options, on page 1668.
- If you manually filter specific URLs using URL objects or by entering URLs directly into the rule, carefully consider other traffic that might be affected. To determine whether network traffic matches a URL condition, the system performs a simple substring match. If the requested URL matches any part of the string, the URLs are considered to match.
- If you use manual URL filtering to create exceptions to other rules, position the specific rule with the exceptions above the general rule that would otherwise apply.

Search query parameters in URLs are not used for matching

The system does not use search query parameters in the URL to match URL conditions. For example, consider a scenario where you block all shopping traffic. In that case, using a web search to search for amazon.com is not blocked, but browsing to amazon.com is.

Maintain default access control policy advanced settings

Unless you have good reason to change them, leave these settings on the Advanced tab of your access control policy at their defaults:

- **General Settings**:
  - **Retry URL cache miss lookup**
  - **Enable reputation enforcement on DNS traffic**

For descriptions of these settings, refer to General settings, on page 2172.

Reduce unnecessary usage of connection table space and NAT table slots

Consider a scenario in which URL filtering is enabled and any traffic that does not conform with the URL filtering rules is blocked. In such a scenario, the threat defence device analyses the initial packets in the traffic flow to extract URL information. After analysis, if the flow does not match any URL filtering rules, the flow is blocked. This means that the packets are dropped by the Threat Defense device. However, the associated connection remains in the connection table. This behaviour results in unnecessary use of connection table space and, if NAT is configured, NAT table slots, which can lead to increased consumption of network resources.

There are different ways to prevent this type of scenario. Since most of the traffic will be TCP, you can use the 'block with reset' option for TCP traffic instead of using 'block'. This approach reduces the usage of connection table space and NAT table slots.

URL filtering in high availability deployments

For guidelines for URL filtering with Firewall Management Centers in high availability, see *URL Filtering and Security Intelligence* in the *Cisco Secure Firewall Management Center Administration Guide* .

Memory limitations for selected device models

Device models with less memory store less URL data locally, and the system may therefore check the cloud more frequently to determine category and reputation for sites that are not in the local database.

Lower-memory devices include

- Firepower 1010
- Firewall Threat Defense Virtual with 8 GB of RAM

HTTPS traffic filtering

HTTPS traffic filtering is a security mechanism that

- determines the requested URL based on information passed during the TLS/SSL handshake using the subject common name in the public key certificate,
- disregards subdomains within the subject common name, requiring manual filtering to use top-level domains only, and
- does not support URL lists, requiring the use of URL objects and groups instead.

HTTPS filtering characteristics

There are several key differences between HTTPS filtering and HTTP filtering:

- Do not include subdomain information when manually filtering HTTPS URLs in access control or QoS policies. For example, use example.com instead of www.example.com.
-

Tip In an decryption policies, you can handle and decrypt traffic to specific URLs by defining a distinguished name decryption policy rule condition. The common name attribute in the subject distinguished name of a certificate contains the site's URL. Decrypting HTTPS traffic allows access control rules to evaluate the decrypted session, which improves URL filtering.

Traffic control by encryption protocol:

The system disregards the encryption protocol (HTTP vs HTTPS) when performing URL filtering in access control or QoS policies. This occurs for both manual and reputation-based URL conditions. In other words, URL filtering treats traffic to these websites identically:

- http://example.com/
- https://example.com/

To configure a rule that matches only HTTP or HTTPS traffic, add an application condition to the rule. For example, you could allow HTTPS access to a site while disallowing HTTP access by constructing two access control rules, each with an application and URL condition.

Application-specific URL filtering rules

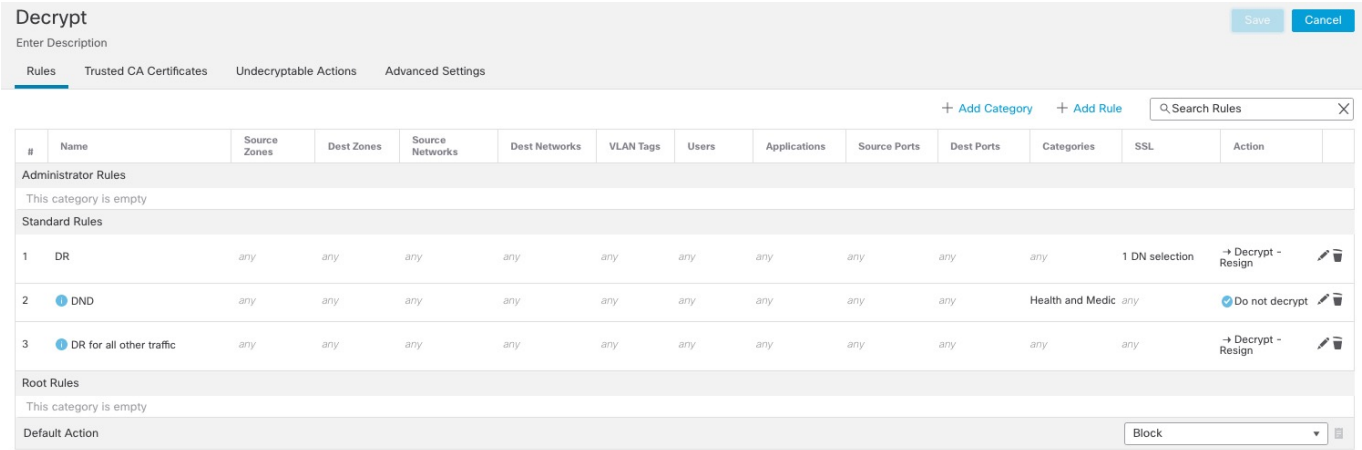
The first rule allows HTTPS traffic to the website:

- Action: Allow
- Application: HTTPS
- URL: example.com

The second rule blocks HTTP access to the same website:

- Action: Block
- Application: HTTP
- URL: example.com

Use categories in URL filtering



Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact

science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the WebMD website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for WebMD and everything else. General information about decryption rules can be found in Guidelines for using TLS/SSL decryption, on page 1746.

Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Recommendations for application control, on page 1622.

QUIC Fingerprinting

Snort can identify client applications in Quick UDP Internet Connections (QUIC sessions) based on EVE analysis. Refer to QUIC fingerprinting in EVE, on page 1806 for more information.

License requirements for URL filtering

This reference provides the license requirements for URL filtering functionality on Cisco Secure Firewall devices, covering both category and reputation filtering as well as manual filtering options.

Threat Defense License

- Category and reputation filtering—URL Filtering
- Manual filtering—No additional license.

Classic License

- Category and reputation filtering—URL Filtering

- Manual filtering—No additional license.

URL filtering licenses for threat defense devices

Refer to *URL Licenses* in the *Licenses* chapter in the Cisco Secure Firewall Management Center Administration Guide.

Requirements and prerequisites for URL filtering

This reference provides the requirements and prerequisites necessary for implementing URL filtering, including model support, supported domains, and required user roles.

Model support

- Network Admin

Configure URL filtering with category and reputation

This task enables URL filtering with category and reputation to protect your network from malicious websites and to control user access to specific website categories.

URL filtering with category and reputation provides comprehensive web security by evaluating websites based on their content categories and reputation scores. This feature helps prevent access to malicious sites while allowing administrators to control access to specific types of content.

Before you begin

- Assign the URL Filtering license to each managed device that will filter URLs.
- Ensure that the Firewall Management Center can communicate with the cloud to obtain URL filtering data. Refer to *Communication Ports and Internet Access* in the *Cisco Secure Firewall Management Center Administration Guide*.

Follow these steps to configure URL filtering with category and reputation:

Procedure

Step 1 Review and understand limitations AND guidelines.

Best practices for URL filtering, on page 1654

Step 2 Enable the URL Filtering feature.

Enable URL filtering using category and reputation, on page 1662

Step 3 Configure rules to filter URLs by category and reputation.

Configure URL conditions, on page 1663

For the best protection against malicious sites, you must block sites by reputation and block URLs in all threat categories.

(Optional) Supplement or selectively override category and reputation-based URL filtering, on page 1668

Step 4 (Optional) Allow users to bypass a website block by clicking through a warning page.

This step is optional.

HTTP response pages, on page 1669

Step 5 Order your rules so that traffic hits the key rules first.

URL rule order, on page 1665

Step 6 (Optional) Modify advanced options related to URL filtering.

This step is optional. Generally, use the defaults unless you have a specific reason to change them.

For information about advanced options, refer to Advanced Settings for Access Control, on page 2169.

- **Maximum URL characters to store in connection events**
- **Allow an Interactive Block to bypass blocking for (seconds)**
- **Retry URL cache miss lookup**
- **Enable reputation enforcement on DNS traffic**

Step 7 Deploy your changes.

Deploy configuration changes, on page 135

Step 8 Ensure that your system receives future URL data updates as expected.

Configure URL filtering health monitors, on page 1673

Step 9 Enable other features to protect your network from malicious sites.

See Security Intelligence, on page 1595.

Enable URL filtering using category and reputation

Enable URL filtering to control and monitor web traffic based on website categories and reputation scores, providing enhanced security for your network.

You must be an Admin user to perform this task.

Before you begin

Complete prerequisites described in Configure URL filtering with category and reputation, on page 1660.

Follow these steps to enable URL filtering using category and reputation:

Procedure

Step 1 Choose **Integration** > **Other Integrations** > **Cloud Services**.

Step 2 Configure URL filtering options, on page 1662.

Step 3 Click **Save**.

URL filtering options

Adding a URL Filtering license automatically enables the URL filtering feature. With this feature, the system handles traffic based on a website's general classification (category) and risk level (reputation).

Although by default the system is configured to submit all URLs to the cloud for threat intelligence evaluation, using a local dataset of category and reputation data can make web browsing faster.When you enable or re-enable URL filtering, the Firewall Management Center automatically queries Cisco for URL data and pushes the dataset to managed devices. This process may take some time.

If you use SSL rules to handle encrypted traffic, also see Decryption Rules guidelines and limitations, on page 1746.

Enable automatic updates

If you **Enable Automatic Updates** (the default), the Firewall Management Center checks the cloud every 30 minutes for updates. If you need strict control over when the system contacts external resources, disable automatic updates and instead create a recurring task using the scheduler. See the *Cisco Secure Firewall Management Center Administration Guide*.

Update now

Click **Update Now** to perform a one-time, on demand URL data update. You cannot start an on demand update if an update is already in progress. Although daily updates tend to be small, if it has been more than five days since your last update, new URL data may take as long as 20 minutes to download, depending on your bandwidth. The update itself may take up to 30 minutes to complete.

URL query source

You can choose how the system assigns a category and reputation to the URLs that your users browse to. You can choose:

- **Local Database Only**: Uses the local dataset only. Use this option if you do not want to submit your uncategorized URLs (category and reputation not in the local dataset) to Cisco, for example, for privacy reasons. However, note that connections to uncategorized URLs do *not* match rules with category or reputation-based URL conditions. You cannot assign categories or reputations to URLs manually.
- **Local Database and Cisco Cloud**: Uses the local dataset when possible, which can make web browsing faster. When users browse to an URL whose category and reputation is not in the local dataset or a cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache.
- **Cisco Cloud Only** (default): Does not use the local dataset. When users browse to an URL whose category and reputation is not in a local cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache. This option guarantees the most up-to-date category and reputation information.

  This option requires Version 7.3 on the device. If you enable this option, devices running earlier versions will use the **Local Database and Cisco Cloud** option.

Cached URLs expire

This setting is not relevant if you chose **Local Database Only** as your URL query source.

Caching category and reputation data makes web browsing faster. By default, cached data for URLs never expires, for fastest performance.

To minimize instances of URLs matching on stale data, you can set cached URLs to expire. For more accurate and current threat data, choose a shorter expiration time. A cached URL refreshes after the first time a user on the network visits it after the specified time passes. The first user does not see the refreshed result, but the next user who visits the URL does.

Configure URL conditions

Configure URL conditions to protect your network by controlling access to sites based on URL category and reputation.

URL conditions allow you to control network access based on website categories and reputations, providing protection against malicious sites and enabling security policy enforcement.

Before you begin

Attention As a prerequisite, ensure that you create at least a Monitor rule at the top of your access control policy, containing Category or Reputation parameters. This is essential to see ANY category or reputation data for ANY URLs that hit the particular access control policy.

If there is no rule in the access control policy with the category or reputation parameters configured, the **Connection Events** page in the management center shows no data for Category or Reputation for ANY URL traffic that hits the access control policy.

Follow these steps to configure URL conditions:

Procedure

Step 1 In the rule editor, click the following for URL conditions:

- Access control or QoS—Click **URLs**.
- SSL—Click **Category**.

Step 2 Find and choose the URL categories that you want to control:

In an access control or QoS rule, click **Category**.

For effective protection from malicious sites, you must block URLs in all Threat categories. Additionally, Talos recommends that you block only sites with Poor category. You can block questionable reputations if you have an aggressive security posture, but this may result in a higher amount of false positives. For a list of Threat categories, see URL category and reputation descriptions, on page 1653.

Be sure to click the arrows at the bottom of the list to see all available categories.

Step 3 (Optional) Constrain URL categories by choosing a **Reputation**.

Note that if you explicitly match **Uncategorized** URLs, you cannot further constrain by reputation. Choosing a reputation level also includes other reputations either more or less severe than the level you choose, depending on the rule action:

- Includes less severe reputations—If the rule allows or trusts web traffic. For example, if you configure an access control rule to allow Favorable (level 4), it also automatically allows Trusted (level 5) sites.
- Includes more severe reputations—If the rule rate limits, decrypts, blocks, or monitors web traffic. For example, if you configure an access control rule to block Questionable sites (level 2), it also blocks Untrusted (level 1) sites.

If you change the rule action, the system automatically changes the reputation levels in URL conditions.

Optionally, select **Apply to unknown reputation**.

Step 4 Click **Add URL** or **Add to Rule**, or drag and drop.

Step 5 (Optional) To choose predefined URL objects, or URL lists and feeds in an access control or QoS rule, click **URL**, select the objects, and add them to the destination.

These objects implement manual URL filtering rather than category-based filtering.

Step 6 Save or continue editing the rule.

URL condition in an access control rule

The following graphic shows the URL condition for an access control rule that blocks all malware sites, all untrusted sites, and all social networking sites with a reputation level of Neutral or worse.

This table summarizes how you build the condition.

Blocked URL	Category	Reputation
Malware sites, regardless of reputation	Malware Sites	ANY
Any untrusted URL (level 1)	ANY	1 - Untrusted
Social networking sites with a reputation level of Neutral or worse (levels 1 through 3)	Social Network	3 - Neutral

Rules with URL conditions

This table lists rules that support URL conditions, and the types of filtering that each rule type supports.

Rule Type	Supports Category and Reputation Filtering?	Supports Manual Filtering?
Access control	Yes	Yes
Decryption policy	Yes	No. Use distinguished name conditions instead.
QoS	Yes	Yes

To use URL filtering in a decryption policy that has **Do Not Decrypt** rule conditions, refer to Use categories in URL filtering, on page 1658.

URL rule order

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:

- They include application conditions.
- The traffic to be inspected is encrypted.
- If you configure exceptions to a rule, place the exception above the other rule.

DNS filtering

DNS filtering is a URL filtering feature that

- evaluates domain category and reputation early in URL transactions, when the browser looks up the domain name to get the IP address,
- can often determine category and reputation of encrypted traffic without decryption, and
- is enabled by default through the **Enable reputation enforcement on DNS traffic** option on the **Advanced** tab of each new access control policy.

DNS filtering behavior

DNS filtering slightly modifies URL filtering behavior and is applicable only when URL filtering is enabled and configured.

If DNS filtering cannot determine the URL of encrypted traffic, that traffic is processed using your configurations for encrypted traffic.

Enable DNS filtering to identify URLs during domain lookup

DNS filtering allows you to identify and block URLs based on category and reputation during domain lookup, providing an additional layer of security by preventing access to malicious or unwanted domains before connections are established.

DNS filtering is enabled by default in new access control policies. However, additional configurations may be required in order for this setting to take effect.

Before you begin

- URL filtering using category and reputation must be licensed, enabled, and configured.

  DNS filtering does not use these settings in the URLs tab: URL groups, URL objects, URL lists and feeds, and URLs entered into the "Enter URL" text box.
- Refer to limitations at DNS filtering behavior for block actions, on page 1667.

Procedure

Step 1 In your access control policy's advanced settings, select **Enable reputation enforcement on DNS traffic**.

Step 2 In the same policy, for each access control rule that has URL category and reputation blocking configured:

- Application conditions—If the application condition is anything other than **any** (or empty), add **DNS** to that list. Other DNS-related options are not relevant for this purpose.
- Port condition—If the port/protocol condition is anything other than **any** (or empty), add **DNS_over_TCP** and **DNS_over_UDP**.

Step 3 Save your changes.

What to do next

If you are done making changes, Deploy configuration changes, on page 135.

DNS filtering behavior for block actions

Traffic that matches rules having action **Block with reset**, **Interactive Block**, or **Interactive Block with reset** will be treated as if the rule action were **Block**.

End users trying to access a blocked URL will experience this as an unexplained inability to connect to their page. The connection will spin and then time out.

DNS filtering and events

DNS filtering and events is a logging mechanism that

- generates connection events using specific fields such as DNS Query, URL Category, URL Reputation, and Destination Port,
- populates the DNS Query field with the domain name while leaving the URL field blank for DNS filtering matches, and
- sets the Destination Port to 53.

Event generation behavior

DNS filtering generates events based on the access control rule action:

- When the access control rule action is **Allow** or **Trust**, two connection events will be generated for the same traffic, one for DNS filtering (with the **DNS Query** field populated) and one for URL filtering (with the **URL** field populated).
- The first time the system encounters a particular URL, two events appear for that single session: one event showing uncategorized or reputationless for the DNS Query, and one event showing the actual category and reputation for the URL, which the system retrieves during the DNS Query and applies to the session while processing using standard URL filtering.

Manual URL filtering

Manual URL filtering is a URL filtering capability that

- supplements or selectively overrides category and reputation-based URL filtering by manually filtering individual URLs, groups of URLs, or URL lists and feeds in access control and QoS rules, and
- enables URL filtering without requiring a special license when manually permitting or blocking URLs through Allow or Block rules within an access control policy.

Manual URL filtering implementation examples

Examples:

- You might use access control to block a category of websites that are not appropriate for your organization. However, if the category contains a website that is appropriate, and to which you want to provide access, you can create a manual Allow rule for that site and place it before the Block rule for the category.
- If you prefer not to use category-based URL filtering, you can manually permit or block a URL or a group of URLs by creating an Allow or Block rule within an access control policy. You can perform this type of URL filtering without a special license.

Manual URL filtering is not supported in SSL rules. Use distinguished name conditions instead.

Caution Depending on how you implement manual URL filtering, URL matching may not be what you intend. Refer to Manual URL filtering options, on page 1668.

Manual URL filtering options

There are several ways to specify URLs for manual URL filtering.

Option	Description
(Best practice) Use custom Security Intelligence URL list or feed objects.	This is the recommended method for manual URL filtering. You can create a new list or feed, or choose an existing one in an access control or QoS rule. For more information, see Custom security intelligence lists and feeds, on page 2425 and subtopics.
Use URL objects, individually or as groups. URL objects are described at URLs, on page 2437. Or Enter URLs directly into the access control rule. (The **Enter URL** option on the rule page in the web interface.)	If you do not include a path (that is, there are no slash (/) characters in the URL), the match is based on the server's hostname only. If you include one or more / character, the entire URL string is used for a substring match. Then, a URL is considered a match if any of these are true: • The string is at the beginning of the URL. • The string follows a dot. • The string contains a dot in the beginning. • The string follows the :// characters. For example, ign.com matches ign.com or www.ign.com, but not versign.com. **Note** We recommend that you do not use manual URL filtering to block or allow individual web pages or parts of sites (that is, URL strings with / characters), as servers can be reorganized and pages moved to new paths. The **Enter URL** option does not support wildcards.

Supplement or selectively override category and reputation-based URL filtering

This task allows you to use Security Intelligence URL lists and feeds to supplement or create exceptions to your category and reputation-based URL filtering rules in access control or QoS policies.

In access control or QoS rules, you can use Security Intelligence URL lists and feeds to supplement, or to specify exceptions to, your category and reputation-based URL filtering rules.

Important! If the list or feed you are configuring in this procedure contains exceptions to category- or reputation-based rules, put this rule above those rules in the rule order.

In SSL rules, use distinguished name conditions to configure parallel behavior.

Before you begin

- Configure URL filtering using category and reputation. Refer to Configure URL conditions, on page 1663.
- Understand important best practices for manual URL filtering. Refer to Best practices for URL filtering, on page 1654 and Manual URL filtering options, on page 1668.
- Configure one or more Security Intelligence objects (lists or feeds) containing the URLs that you want to use for manual filtering. Refer to Custom security intelligence lists and feeds, on page 2425.

Follow these steps to supplement or selectively override category and reputation-based URL filtering:

Procedure

Step 1 Navigate to the access control or QoS policy in which you will define the rule.

Step 2 Create or edit the rule in which you will add the new condition:

- If you are supplementing a category- or reputation-based URL filtering rule, edit the existing rule.
- If you are overriding or creating exceptions to a category- or reputation-based URL filtering rule, create a new rule.

Step 3 Select the list or feed you created as the destination URL criteria.

Step 4 Save the rule.

HTTP response pages

An HTTP response page is a web page that displays when the system blocks web requests using either access control rules or the access control policy default action.

HTTP response page types

The response page displayed depends on how you block the session:

- **Block Response Page**: Overrides the default browser or server page that explains that the connection was denied.
- **Interactive Block Response Page**: Warns users, but also allows them to click a button (or refresh the page) to load the originally requested site. Users may have to refresh after bypassing the response page to load page elements that did not load.

If you do not choose a response page, the system blocks sessions without interaction or explanation.

Limitations to HTTP response pages

The system displays a response page only for unencrypted or decrypted HTTP/HTTPS connections blocked (or interactively blocked) either by access control rules or by the access control policy default action. The system does not display a response page for connections that are blocked by any other policy or mechanism.

The system cannot display a response page if the connection is reset (RST packet sent). If you enable response pages, the system prioritizes that configuration. Even if you choose **Block with reset** or **Interactive Block with reset** as the rule action, the system displays the response page and does not reset matching web connections. To ensure that blocked web connections are reset, you must disable response pages.

- Note that all non-web traffic that matches the rule *is* blocked with reset.

The system does not display a response page for encrypted connections that are blocked by access control rules (or any other configuration). Access control rules evaluate encrypted connections if you did not configure an SSL policy, or your SSL policy passes encrypted traffic.

-
- However, the system does display a response page for connections that are decrypted by the SSL policy, then blocked (or interactively blocked) either by access control rules or by the access control policy default action. In these cases, the system encrypts the response page and sends it at the end of the reencrypted SSL stream.

The system does not display a response page when web traffic is blocked because of a promoted access control rule (an early-placed blocking rule with only simple network conditions).

If a URL is entered without specifying "http" or "https", and the browser initiates the connection on port 80, and the user clicks through a response page, and the connection is subsequently redirected to port 443, the user will not see a second interactive response page because the response to this URL is already cached.

The system does not display a response page when web traffic is blocked before the system identifies the requested URL. Refer to Best practices for URL filtering, on page 1654.

The system does not display a response page if the block URL access control rule is configured after the allow application rule.

Requirements and prerequisites for HTTP response pages

Model support

Any

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin

Describe the necessary conditions, user roles, and supported domains required for setting up HTTP response pages.

Choose HTTP response pages

HTTP response pages provide feedback to users when their sessions are blocked by access control policies, allowing for better user experience and network transparency.

Reliable display of HTTP response pages depends on your network configuration, traffic loads, and size of the page. Smaller pages are more likely to display successfully.

Procedure

Step 1 In the access control policy editor, select **HTTP Responses** from the **More** drop-down arrow at the end of the packet flow line.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Choose the **Block Response Page** and **Interactive Block Response Page**:

- System-provided—Displays a generic response. Click **View** ( ) to view the code for this page.
- Custom—Create a custom response page. A pop-up window appears, prepopulated with system-provided code that you can replace or modify by clicking **Edit** ( ). A counter shows how many characters you have used.
- None—Disables the response page and blocks sessions without interaction or explanation. To quickly disable interactive blocking for the whole access control policy, choose this option.

Step 3 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Interactive blocking with HTTP response pages

Interactive blocking with HTTP response pages is a security mechanism that

- allows users to load an originally requested site after reading a warning page,
- provides user control over whether to proceed with potentially blocked traffic, and
- enables temporary bypass with configurable duration settings.

Configuration behavior and bypass settings

When you configure interactive blocking, users may have to refresh after bypassing the response page to load page elements that did not load.

Tip To quickly disable interactive blocking for the whole access control policy, display neither the system provided page nor a custom page. The system then blocks all connections without interaction.

If a user does not bypass an interactive block, matching traffic is denied without further inspection. If a user bypasses an interactive block, the access control rule allows the traffic, although the traffic may still be subject to deep inspection and blocking.

By default, a user bypass is in effect for 10 minutes (600 seconds) without displaying the warning page on subsequent visits. You can set the duration to as long as a year, or you can force the user to bypass the block every time. This limit applies to every Interactive Block rule in the policy. You cannot set the limit per rule.

Logging options for interactively blocked traffic are identical to those in allowed traffic. If a user does not bypass the interactive block, the system can log only beginning-of-connection events. When the system initially warns the user, it marks any logged beginning-of-connection event with the `Interactive Block` or `Interactive Block with reset` action. If the user bypasses the block, additional connection events logged for the session have an action of `Allow`.

Configure interactive blocking

Interactive blocking allows users to bypass URL filtering rules while maintaining security controls and logging capabilities.

This procedure describes how to allow users to bypass URL filtering rules.

Procedure

Step 1 As part of access control, configure an access control rule that matches web traffic; see Create and edit access control rules, on page 1631:

- Action—Set the rule action to **Interactive Block** or **Interactive Block with reset**; see Access control rule interactive blocking actions, on page 1615.
- Conditions—Use URL conditions to specify the web traffic to interactively block.
- Logging—Assume users will bypass the block and choose logging options accordingly; see *Logging for Allowed Connections* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Inspection—Assume users will bypass the block and choose deep inspection options accordingly; see Access control policies, on page 1569.

Step 2 (Optional) (Optional) In the access control policy **HTTP Responses**, choose a custom interactive-block HTTP response page; see Choose HTTP response pages, on page 1671.

Step 3 (Optional) (Optional) In the access control policy **Advanced** settings, change the user bypass timeout; see Set the user bypass timeout for a blocked website, on page 1673.

After a user bypasses a block, the system allows the user to browse to that page without warning until the timeout period elapses.

Step 4 Save the access control policy.

Step 5 Deploy configuration changes; see Deploy configuration changes, on page 135.

Set the user bypass timeout for a blocked website

Set the duration that users can browse after bypassing a URL filtering block before having to bypass the block again.

This procedure explains how to set the time allowed for browsing after the user bypasses a URL filtering block. When the timeout expires, the user must bypass the block again.

Procedure

Step 1 Click **Policies** > **Access Control heading** > **Access Control** and edit the policy.

Step 2 Select **Advanced Settings** from the **More** drop-down menu at the end of the packet flow line.

Step 3 Click **Edit** ( ) next to General Settings.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 In the **Allow an Interactive Block to bypass blocking for (seconds)** field, enter the number of seconds that must elapse before the user bypass expires.

Setting this value to 0 means the interactive block response is displayed once and the user bypass never expires.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure URL filtering health monitors

The following health policies alert if the system has problems obtaining or updating URL category and reputation data.

- URL Filtering Monitor
- Threat Data Updates on Device

To ensure that these are configured the way you want them, refer to *Health Modules* and *Configuring Health Monitoring* in the *Cisco Secure Firewall Management Center Administration Guide*.

Dispute URL category and reputation

This task allows you to challenge URL categorizations or reputation scores when you disagree with the assignments made by Talos Intelligence.

If you disagree with a category or reputation assigned by Talos, you can submit a request for re-evaluation.

Before you begin

You will need your Cisco account credentials.

Procedure

Step 1 In the Firewall Management Center web interface, do one of the following:

Location of dispute option	Path to dispute option
Cloud Services configuration page	a. Navigate to the **Integration** > **Other Integrations** > **Cloud Services** page. b. Select **Dispute URL categories and reputations**.
Manual URL Lookup page	a. Navigate to the manual URL Lookup page: **Analysis** > **Advanced** > **URL**. b. Look up the URL in question. c. To see **Dispute** at the end of the table row, hover over the relevant entry in the list of results, then click **Dispute**.
URL Connection Event	a. Navigate to any page under the **Analysis** > **Connections** > **Events** menu that has a table that includes URLs. b. Right-click an item in the **URL Category** or **URL Reputation** column (show hidden columns if needed) and select an option.

The Talos web site opens in a separate browser window.

Step 2 Sign in to the Talos site with your Cisco credentials.

Step 3 Review the information and follow the instructions on the Talos page.

Step 4 On the Talos site, review how submitted disputes are handled. Check what response you can expect, if any.

The dispute process is independent of Secure Firewall products.

Take action if the URL category set changes

URL filtering categories may occasionally change to accommodate new web trends and evolving usage patterns. Taking action when these changes occur ensures that your policies continue to function properly and can be deployed successfully.

The set of URL Filtering categories may occasionally change, in order to accommodate new web trends and evolving usage patterns.

These changes affect both policies and events.

Shortly before URL category changes are scheduled to occur, and after they occur, you will see alerts in the list of rules in any access control, SSL, and QoS policy that is affected by the changes, and on URL or Category in rules that you edit.

You should take action when you see these alerts.

Note Updates to the URL category set as described in this topic are distinct from the changes that simply add new URLs to existing categories or re-classify misclassified URLs. This topic does not apply to category changes for individual URLs.

Procedure

Step 1 If you see an alert beside a rule in an access control policy, hover over the alert to see details.

Step 2 If the alert mentions changes to URL categories, edit the rule to see further details.

Step 3 Hover over the URL or Category in the rule dialog to see general information about the type of changes.

Step 4 If you see an alert beside a category, click the alert to view details.

Step 5 If you see a "More information" link in the description of a change, click it to view information about the category on the Talos web site.

Alternatively, see a list and descriptions of all categories at the link in URL category and reputation descriptions, on page 1653.

Step 6 Depending on the type of change, take appropriate action:

Type of Category Change	What The System Will Do	What You Should Do
Existing category will soon be deprecated	Nothing yet. You have a few weeks to change affected rules. If you do not take action in that time, the system eventually will not be able to redeploy the policy.	Remove this category from all rules that include it. If there is a similar new category, consider using that category instead.
New category is added	By default, the system does not use newly added categories.	Consider creating new rules for the new category.
Existing category is deleted	The category will appear in the rule in strikethrough text (that is, with a line through the category name.)	You must delete the obsolete category from the rule before you can deploy the policy.

Step 7 Check your SSL rules (Category) for these changes and take action as needed.

Step 8 Check your QoS rules (URL) for these changes and take action as needed.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 135.

URL category and reputation changes

URL category and reputation changes are system modifications that

- affect how events are categorized and labeled in the system,
- result in different handling of events processed before and after the changes, and
- impact the display of URL reputation information in event viewers.

Effects on event processing

URL category and reputation changes affect events differently based on when they were processed:

- When URL categories change, events that the system processed before the category change will be associated with their original category names and will be labeled with **Legacy**. Events that the system processed after the category change will be associated with the new categories.

  Older, legacy events will age out of the system over time.
- If a URL does not have a reputation at the time it was processed, the URL Reputation column in the event viewer will be empty.

Troubleshoot URL filtering

This reference provides troubleshooting information for common URL filtering issues including missing categories, uninspected packets, registration failures, lookup errors, and performance problems.

Expected URL category is missing from the categories list

The URL filtering feature uses a different set of categories than the Security Intelligence feature. The category that you expect to see may be a Security Intelligence category. To see those categories, look at the **URLs** tab on the **Security Intelligence** tab in an access control policy.

Initial packets are passing uninspected

Refer to Inspection of packets that pass before traffic is identified and subtopics.

See also DNS filtering, on page 1665.

Health alert: "URL filtering registration failure"

Verify that the Firewall Management Center and any proxies can connect to the Cisco cloud. Refer to *Communication Ports and Internet Access* in the *Cisco Secure Firewall Management Center Administration Guide*.

How can I find the category and reputation of a particular URL?

Do a manual lookup. Refer to *Finding URL Category and Reputation* in the *Cisco Secure Firewall Management Center Administration Guide*.

Error when attempting a manual lookup: "cloud lookup failure for <URL>"

Make sure the feature is properly enabled. Refer to the prerequisites in *Finding URL Category and Reputation* in the *Cisco Secure Firewall Management Center Administration Guide*.

URL appears to be incorrectly handled based on its URL category and reputation

Problem: The system does not handle the URL correctly based on its URL category and reputation.

Solutions:

- Verify that the URL category and reputation associated with the URL are what you think they are. See *Finding URL Category and Reputation* in the *Cisco Secure Firewall Management Center Administration Guide*.
- These issues may be addressed by settings described in URL filtering options, on page 1662, accessible using Enable URL filtering using category and reputation, on page 1662.
  - The URL cache may hold stale information. See information about the **Cached URLs Expire** setting in URL filtering options, on page 1662.
  - The local data set may not be updated with current information from the cloud. See information about the **Enable Automatic Updates** setting in URL filtering options, on page 1662.
  - The system may be configured to *not* check the cloud for current data. See information about the **Query Cisco cloud for unknown URLs** setting in URL filtering options, on page 1662.
- Your access control policy may be configured to pass traffic to the URL without checking the cloud. See information about the **Retry URL cache miss lookup** setting in General settings, on page 2172.
- See also Best practices for URL filtering, on page 1654.
- If the URL is processed using an SSL rule, see Decryption Rules guidelines and limitations, on page 1746 and Best practice for Decryption policy rule order
- Verify that the URL is being handled using the access control rule that you think it is being handled by, and that the rule does what you think it does. Consider rule order.
- Verify that the local URL category and reputation database on the Firewall Management Center is successfully being updated from the cloud and that managed devices are successfully being updated from the Firewall Management Center.

  Status of these processes are reported in the Health Monitor, in the **URL Filtering Monitor** module and the **Threat Data Updates on Devices** module. For details, see *Health* in the *Cisco Secure Firewall Management Center Administration Guide*.

If you want to immediately update the local URL category and reputation database, go to **Integration** > **Other Integrations** > **Cloud Services**, then click **Update Now** in the **URL Filtering** area. For more information, see URL filtering options, on page 1662.

A URL category or reputation is not correct

For access control or QoS rules: Use manual filtering, paying careful attention to rule order. See Manual URL filtering, on page 1667 and Configure URL conditions, on page 1663.

For SSL rules: Manual filtering is not supported. Instead, use distinguished name conditions.

See also Dispute URL category and reputation, on page 1673.

Web pages are slow to load

There is a tradeoff between security and performance. Some options:

- Consider modifying the **Cached URLs Expire** setting. Choose **Integration** > **Other Integrations** > **Cloud Services**. For information, see URL filtering options, on page 1662.
- Consider deselecting the **Retry URL cache miss lookup** setting in General settings, on page 2172.

Events do not include URL category and reputation

- Make sure you have included applicable URL rules in an access control policy, the rules are active, and the policies have been deployed to the relevant devices.
- URL category and reputation do not appear in an event if the connection is processed before it matches a URL rule.
- The rule that handles the connection must be configured for URL category and reputation.
- Even if you have configured URL categories in the Categories tab in an SSL rule, you must also configure the URLs tab in a rule in your access control policy.

DNS filtering is not working

Make sure you have completed all prerequisites and steps in Enable DNS filtering to identify URLs during domain lookup, on page 1666.

An end user tries to access a blocked URL and the page just spins and times out

When DNS Filtering is enabled and end users access a URL that is blocked, the page will spin but not load. End users are not notified that the page is blocked. This is currently a limitation when DNS filtering is enabled.

Refer to DNS filtering behavior for block actions, on page 1667.

Events include URL category and reputation but URL field is blank

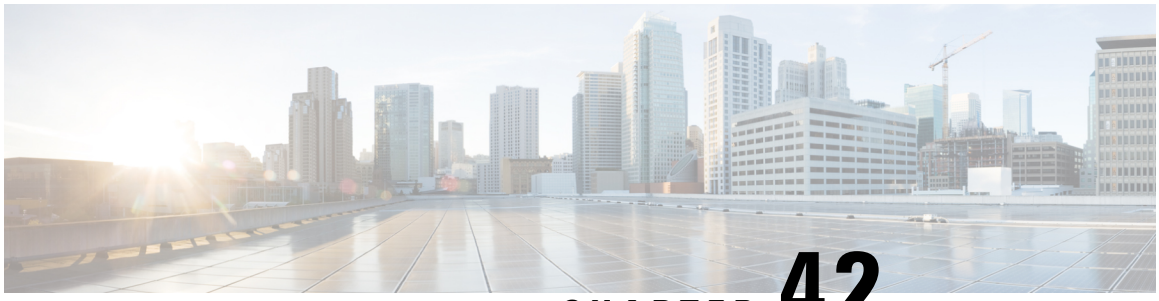
If the DNS Query field is populated and the URL field is empty, this is expected when the DNS filtering feature is enabled.

Refer to DNS filtering and events, on page 1667.

Multiple events are generated for a single transaction

A single web transaction sometimes generates two connection events, one for DNS filtering and one for URL filtering. This is expected when DNS filtering is enabled and:

- the access control rule action for the traffic is Allow or Trust.
- the system encounters a URL for the first time.



Refer to DNS filtering and events, on page 1667.

History for URL filtering

This reference provides a chronological history of URL filtering features, including release versions, supported platforms, and implementation details for each enhancement or change.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
New URL category	New in release 7.0, applies to all releases	Any	New URL category: Private IP address For details, see Talosintelligence.com
DNS filtering	7.0 6.7 (Beta)	Any	A new option in the advanced settings for each access control policy allows earlier filtering of web traffic by category and reputation. By default, this feature is enabled on new installations.
Ability to specify handling for sites with unknown reputation	6.7	Any	You can now specify handling for URLs with unknown reputation. Modified screens: URL rules in access control policies and QoS policies, and category rules in SSL policies, include a new checkbox for this purpose below the reputation selection area.
New and changed URL categories New names for reputation levels	6.5	6.5	These changes apply to URL rules in access control and QoS policies and to Category rules in SSL policies: The set of URL categories has changed. There are now two pages of categories from which to select when you create a URL rule. The name associated with each reputation level has changed. For descriptions of the new categories and reputation names, see URL category and reputation descriptions, on page 1653. For complete details specific to upgrades, see also the Release Notes and upgrade instructions for version 6.5. If there are future category set changes, your rules will display icons to alert you. Modified screens: URL rules in access control policies, SSL policies, and QoS policies; event data related to URL categories.
Minor change to Classic device licensing	6.5	Any	For devices that use Classic licenses, URL filtering will not be enabled until the device is registered to the Firewall Management Center and a URL Filtering license is assigned to the device. Supported platforms: NGIPSv and ASA with FirePOWER Services devices.
Addresses for retrieving URL data from the Cisco cloud have changed	6.5	Any	Refer to *Communication Ports and Internet Access* in the *Cisco Secure Firewall Management Center Administration Guide*.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Opportunity to dispute an assigned URL category	6.5	Any	If you disagree with the category that the system assigns to a URL, you can submit a request to change the category. New and modified screens: • New menu option when right-clicking a URL category or reputation in tables of connection events under the **Analysis** menu. • New button on the URL Lookups page (**Analysis** > **Advanced** > **URL**). (Hover your pointer over the URL to display the button.) • New option on the **System** > **Integration** > **Cloud Services** page
The **Cisco CSI** tab is renamed to **Cloud Services**	6.4	Any	Modified screens and navigation: **System** > **Integration** > **Cisco CSI** is now **System** > **Integration** > **Cloud Services**
New option: Cached URLs Expire	6.3	Any	Use this new control to balance performance with freshness of URL category and reputation data in order to minimize instances of URLs matching on stale data. Modified screens: **System** > **Integration** > **Cisco CSI**.
Changed menu path	6.3	Any	The path to the manual URL Lookup page has changed from **Analysis** > **Lookup** > **URL** to **Analysis** > **Advanced** > **URL**.

CHAPTER 42

Content Restriction

The following topics describe how to configure access control policies to use content restriction features:

- About content restriction, on page 1681
- Requirements and prerequisites for content restriction, on page 1682
- Guidelines and limitations for content restriction, on page 1683
- Using access control rules to enforce content restriction, on page 1683
- Use a DNS sinkhole to enforce content restriction, on page 1684

About content restriction

Major search engines and content delivery services provide features that allow you to restrict search results and website content. For example, schools use content restriction features to comply with the Children's Internet Protection Act (CIPA).

When implemented by search engines and content delivery services, you can enforce content restriction features only for individual browsers or users. The system allows you to extend these features to your entire network.

The system allows you to enforce:

- *Safe Search*—Supported in many major search engines, this service filters out explicit and adult-oriented content that business, government, and education environments classify as objectionable. The system does not restrict a user's ability to access the home pages for supported search engines.

You can use two methods to configure the system to enforce these features:

Method: Access Control Rules
: Content restriction features communicate the restricted status of a search or content query via an element in the request URI, an associated cookie, or a custom HTTP header element. You can configure access control rules to modify these elements as the system processes traffic.

Method: DNS Sinkhole
: For Google searches, you can configure the system to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes filters for Safe Search.

The table below describes the differences between these enforcement methods.

Table 98: Comparison of content restriction methods

Attribute	Method: Access Control Rules	Method: DNS Sinkhole
Supported devices	Any	Secure Firewall Threat Defense only
Search engines supported	Any tagged `safesearch supported` in the **Applications** tab of the rule editor	Google only
YouTube Restricted Mode supported	Yes	Yes
SSL policy required	Yes	No
Hosts must be using IPv4	No	Yes
Connection event logging	Yes	Yes

When determining which method to use, consider the following limitations:

- The access control rules method requires an SSL policy, which impacts performance.
- The Google SafeSearch VIP supports IPv4 traffic only. If you configure a DNS sinkhole to manage Google searches, any hosts on the affected network must be using IPv4.

The system logs different values for the **Reason** field in connection events, depending on the method:

- Access Control Rules—`Content Restriction`
- DNS Sinkhole—`DNS Block`

Requirements and prerequisites for content restriction

Model support

Any, or as indicated in the procedure.

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin

Guidelines and limitations for content restriction

- Safe search is supported by Snort 2 only.
- YouTube and Google do not support the YouTubeEDU feature that was implemented in access control rules. Please remove any access control rules that configure YouTubeEDU as they are not truly functional. You can also remove associated decryption rules.

Using access control rules to enforce content restriction

The following procedure explains how to configure access control rules to restrict content."

Note When safe search is enabled in an access control rule, inline normalization is enabled automatically.

Procedure

Step 1 Create a decryption policy.

Step 2 Add rules for handling Safe Search traffic:

- Choose **Decrypt - Resign** as the **Action** for the rules.
- In **Applications**, add selections to the **Selected Applications and Filters** list:
  - Safe Search—Add the `Category: search engine` filter.

Step 3 Set rule positions for the rules you added. Click and drag, or use the right-click menu to cut and paste.

Step 4 Create or edit an access control policy, and associate the decryption policy with the access control policy.

For more information, see Associate prefilter, decryption, and identity policies with an access control, on page 1585.

Step 5 In the access control policy, add rules for handling Safe Search traffic:

- Choose **Allow** as the **Action** for the rules.
- In **Applications**, click the icon for **Safe search** ( ) and set related options.
  - Safe search options for access control rules, on page 1684
- In **Applications**, refine application selections in the **Selected Applications and Filters** list.

  In most cases, enabling Safe Search populates the **Selected Applications and Filters** list with the appropriate values. The system does not automatically populate the list if a Safe Search application is already present in the list when you enable the feature. If applications do not populate as expected, manually add them as follows:

- Safe Search—Add the `Category: search engine` filter.

For more information, see Configure application conditions and filters, on page 1638.

Step 6 Set rule positions for the access control rules you added. Click and drag, or use the right-click menu to cut and paste.

Step 7 Configure the HTTP response page that the system displays when it blocks restricted content; see Choose HTTP response pages, on page 1671.

Step 8 Deploy configuration changes; see Deploy configuration changes, on page 135.

Safe search options for access control rules

The system supports Safe Search filtering for specific search engines only. For a list of supported search engines, see applications tagged `safesearch supported` in the **Applications** tab of the access control rule editor. For a list of unsupported search engines, see applications tagged `safesearch unsupported`.

When enabling Safe Search for an access control rule, set the following parameters:

Enable Safe Search
Enables Safe Search filtering for traffic that matches this rule.

Unsupported Search Traffic
Specifies the action you want the system to take when it processes traffic from unsupported search engines. If you choose **Block** or **Block with Reset**, you must also configure the HTTP response page that the system displays when it blocks restricted content; see Choose HTTP response pages, on page 1671.

Use a DNS sinkhole to enforce content restriction

This task configures a DNS sinkhole to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes content filters on Google and YouTube search results.

Typically, a DNS sinkhole directs traffic away from a particular target. This procedure describes how to configure a DNS sinkhole to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes content filters on Google and YouTube search results.

Because Google SafeSearch uses a single IPv4 address for the VIP, hosts must use IPv4 addressing.

Caution If your network includes proxy servers, this content restriction method is not effective unless you position your Firewall Threat Defense devices between the proxy servers and the Internet.

This procedure enforces content restriction for Google searches only. It does not apply to any other search engine.

Before you begin

This procedure applies to Firewall Threat Defense only, and requires the IPS license.

Follow these steps to use a DNS sinkhole to enforce content restriction:

Procedure

Step 1 Obtain a list of supported Google domains via the following URL: https://www.google.com/supported_domains.

Step 2 Create a custom DNS list on your local computer, and add the following entries:

- To enforce Google SafeSearch, add an entry for each supported Google domain.
- To enforce YouTube Restricted Mode, add a "youtube.com" entry.

The custom DNS list must be in text file (.txt) format. Each line of the text file must specify an individual domain name, stripped of any leading periods. For example, the supported domain ".google.com" must appear as "google.com".

Step 3 Upload the custom DNS list to the Firewall Management Center; see Upload new custom security intelligence lists to the Secure Firewall Management Center, on page 2431.

Step 4 Determine the IPv4 address for the Google SafeSearch VIP. For example, run **nslookup** on forcesafesearch.google.com.

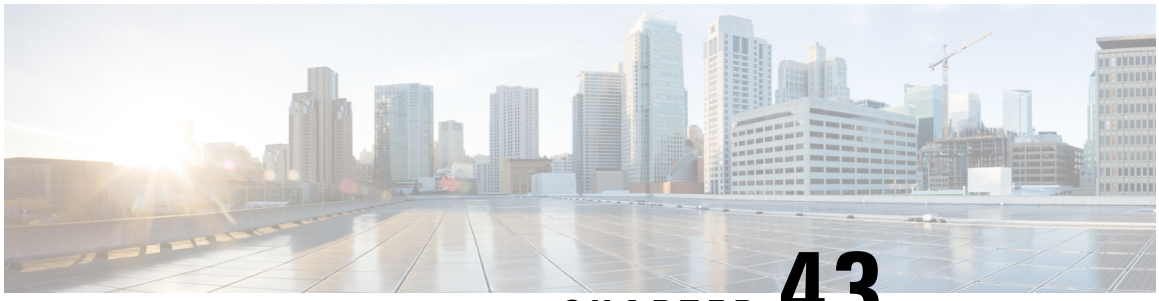
Step 5 Create a sinkhole object for the SafeSearch VIP; see Create a sinkhole object, on page 2432.

Use the following values for this object:

- IPv4 Address—Enter the SafeSearch VIP address.
- IPv6 Address—Enter the IPv6 loopback address (**::1**).
- Log Connections to Sinkhole—Click Log Connections.
- Type—Choose **None**.

Step 6 Create a basic DNS policy; see Create basic DNS policies, on page 1997.

Step 7 Add a DNS rule for the sinkhole; see Create and edit DNS rules, on page 1999.



For this rule:

- Check the **Enabled** check box.
- Choose **Sinkhole** from the **Action** drop-down list.
- Choose the sinkhole object you created from the **Sinkhole** drop-down list.
- Add the custom DNS list you created to the **Selected Items** list on **DNS**.
- (Optional) Choose a network in **Networks** to limit content restriction to specific users. For example, if you want to limit content restriction to student users, assign students to a different subnet than faculty, and specify that subnet in this rule.

Step 8 Associate the DNS policy with an access control policy; see Associate prefilter, decryption, and identity policies with an access control, on page 1585.

Step 9 Deploy configuration changes; see Deploy configuration changes, on page 135.

The DNS sinkhole is configured to enforce content restriction by redirecting traffic to the Google SafeSearch VIP, which filters Google and YouTube search results.

CHAPTER 43

Intrusion Prevention Overview

This chapter provides an overview of the Snort 2 inspection engine, and the network analysis and intrusion policies. It also provides an insight into system-provided and custom network analysis and intrusion policies. In most cases, the system-provided policies are all you need. For advanced users with specific needs, you can create custom rules. To configure custom Snort 2 rules, see *Custom Snort 2 Intrusion Policies for Access Control*.

Note .

To configure custom Snort 3 rules, see *Custom Snort 3 Intrusion Policies for Access Control*.

- Network Analysis and Intrusion Policy Basics, on page 1687
- How Policies Examine Traffic For Intrusions, on page 1689
- System-Provided and Custom Network Analysis and Intrusion Policies, on page 1694
- License Requirements for Network Analysis and Intrusion Policies, on page 1700
- Requirements and Prerequisites for Network Analysis and Intrusion Policies, on page 1700
- Guidelines and Limitations for Network Analysis and Intrusion Policies, on page 1700
- The Navigation Panel: Network Analysis and Intrusion Policies, on page 1701
- Conflicts and Changes: Network Analysis and Intrusion Policies, on page 1702

Network Analysis and Intrusion Policy Basics

Network analysis and intrusion policies work together as part of the system's intrusion detection and prevention feature.

- The term *intrusion detection* generally refers to the process of passively monitoring and analyzing network traffic for potential intrusions and storing attack data for security analysis. This is sometimes referred to as "IDS."
- The term *intrusion prevention* includes the concept of intrusion detection, but adds the ability to block or alter malicious traffic as it travels across your network. This is sometimes referred to as "IPS."

Note

- You must configure Network Analysis Policy (NAP) in **Prevention** mode if you are using Snort 3 and SSL decryption or TLS Server Identity. The SSL functionality does not work when Snort 3 NAP is in detection mode.
- We strongly recommend that your intrusion policy (IPS) and network analysis policy (NAP) have the same settings. If IPS is in detection mode, set the NAP in detection mode, and conversely as well.

In an intrusion prevention deployment, when the system examines packets:

- A **network analysis policy** governs how traffic is *decoded* and *preprocessed* so it can be further evaluated, especially for anomalous traffic that might signal an intrusion attempt.
- An **intrusion policy** uses *intrusion and preprocessor rules* (sometimes referred to collectively as *intrusion rules*) to examine the decoded packets for attacks based on patterns. Intrusion policies are paired with *variable sets*, which allow you to use named values to accurately reflect your network environment.

Both network analysis and intrusion policies are invoked by a parent access control policy, but at different times. As the system analyzes traffic, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (additional preprocessing and intrusion rules) phase. Together, network analysis and intrusion policies provide broad and deep packet inspection. They can help you detect, alert on, and protect against network traffic that could threaten the availability, integrity, and confidentiality of hosts and their data.

The system is delivered with several similarly named network analysis and intrusion policies (for example, Balanced Security and Connectivity) that complement and work with each other. By using system-provided policies, you can take advantage of the experience of the Talos Intelligence Group. For these policies, Talos sets intrusion and preprocessor rule states, as well as provides the initial configurations for preprocessors and other advanced settings.

You can also create custom network analysis and intrusion policies. You can tune settings in custom policies to inspect traffic in the way that matters most to you so that you can improve both the performance of your managed devices and your ability to respond effectively to the events they generate.

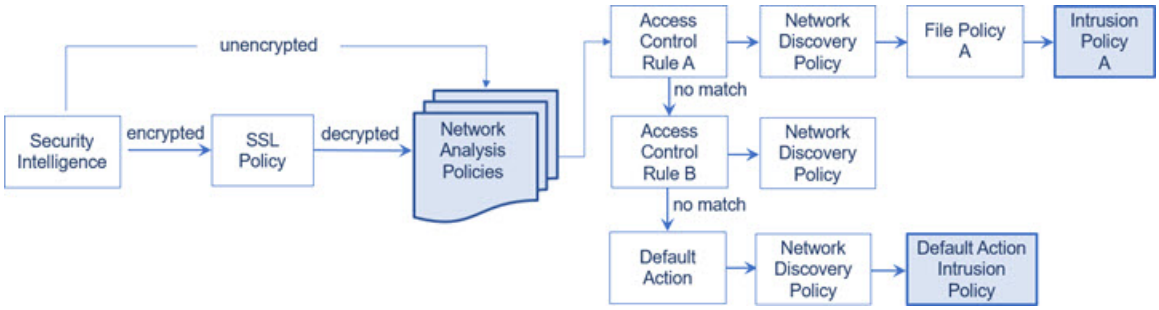
You create, edit, save, and manage network analysis and intrusion policies using similar policy editors in the web interface. When you are editing either type of policy, a navigation panel appears on the left side of the web interface; the right side displays various configuration pages.

Attention

Detection mode deprecation: From management center Version 7.4.0, for a network analysis policy (NAP), the **Detection** inspection mode is deprecated and will be removed in an upcoming release.

The **Detection** mode was intended to be used as a test mode so that you can enable inspections and see how they behave in your network before setting it to drop traffic, that is, to show traffic that would be dropped.

This behavior is improved where all inspector drops are controlled by the rule state, and you can set each one to generate events. This is done to test them before configuring the rule state to drop traffic. As we now have granular control over traffic drops in Snort 3, the **Detection** mode only adds more complexity to the product and is not needed, so the detection mode is deprecated.



If you change a NAP in **Detection** mode to **Prevention**, the NAP that processes the traffic of intrusion events and have the result "will be dropped" will now be "dropped" and the corresponding traffic will drop the traffic from these events. This is applicable for rules whose GIDs are not 1 or 3. GIDs 1 and 3 are text/compiled rules (typically provided by Talos or from your custom/imported rules) and all other GIDs are inspections for anomalies. These are more uncommon rules to trigger in a network. Changing to **Prevention** mode is unlikely to have any impact on the traffic. You need to just disable the intrusion rule that is applicable for the dropped traffic and set it to just generate or disable.

We recommend you choose **Prevention** as the inspection mode, but if you choose **Prevention**, you cannot revert to **Detection** mode.

How Policies Examine Traffic For Intrusions

When the system analyzes traffic as part of your access control deployment, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (intrusion rules and advanced settings) phase.

The following diagram shows, in a simplified fashion, the order of traffic analysis in an inline, intrusion prevention and malware defense deployment. It illustrates how the access control policy invokes other policies to examine traffic, and in which order those policies are invoked. The network analysis and intrusion policy selection phases are highlighted.

In an inline deployment (that is, where relevant configurations are deployed to devices using routed, switched, or transparent interfaces, or inline interface pairs), the system can block traffic without further inspection at almost any step in the illustrated process. Security Intelligence, the SSL policy, network analysis policies, file policies, and intrusion policies can all either drop or modify traffic. Only the network discovery policy, which passively inspects packets, cannot affect the flow of traffic.

Similarly, at each step of the process, a packet could cause the system to generate an event. Intrusion and preprocessor events (sometimes referred to collectively as *intrusion events*) are indications that a packet or its contents may represent a security risk.

Tip The diagram does not reflect that access control rules handle encrypted traffic when your SSL inspection configuration allows it to pass, or if you do not configure SSL inspection. By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Note that for a single connection, although the system selects a network analysis policy before an access control rule as shown in the diagram, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does **not** affect how you configure preprocessing in custom network analysis policies.

Decoding, Normalizing, and Preprocessing: Network Analysis Policies

Without decoding and preprocessing, the system could not appropriately evaluate traffic for intrusions because protocol differences would make pattern matching impossible. Network analysis policies govern these traffic-handling tasks:

- **after** traffic is filtered by Security Intelligence
- **after** encrypted traffic is decrypted by an optional SSL policy
- **before** traffic can be inspected by file or intrusion policies

A network analysis policy governs packet processing in phases. First the system decodes packets through the first three TCP/IP layers, then continues with normalizing, preprocessing, and detecting protocol anomalies:

- The packet decoder converts packet headers and payloads into a format that can be easily used by the preprocessors and later, intrusion rules. Each layer of the TCP/IP stack is decoded in turn, beginning with the data link layer and continuing through the network and transport layers. The packet decoder also detects various anomalous behaviors in packet headers.
- In inline deployments, the inline normalization preprocessor reformats (normalizes) traffic to minimize the chances of attackers evading detection. It prepares packets for examination by other preprocessors and intrusion rules, and helps ensure that the packets the system processes are the same as the packets received by the hosts on your network.

Note In a passive deployment, Cisco recommends that you enable adaptive profile updates at the access control policy level, instead of inline normalization at the network analysis level.

- Various network and transport layers preprocessors detect attacks that exploit IP fragmentation, perform checksum validation, and perform TCP and UDP session preprocessing.

  Note that some advanced transport and network preprocessor settings apply globally to all traffic handled by the target devices of an access control policy. You configure these in the access control policy rather than in a network analysis policy.

- Various application-layer protocol decoders normalize specific types of packet data into formats that the intrusion rules engine can analyze. Normalizing application-layer protocol encodings allows the system to effectively apply the same content-related intrusion rules to packets whose data is represented differently, and to obtain meaningful results.
- The Modbus, DNP3, CIP, and s7commplus SCADA preprocessors detect traffic anomalies and provide data to intrusion rules. Supervisory Control and Data Acquisition (SCADA) protocols monitor, control, and acquire data from industrial, infrastructure, and facility processes such as manufacturing, production, water treatment, electric power distribution, airport and shipping systems, and so on.
- Several preprocessors allow you to detect specific threats, such as Back Orifice, portscans, SYN floods and other rate-based attacks.

  Note that you configure the sensitive data preprocessor, which detects sensitive data such as credit card numbers and Social Security numbers in ASCII text, in intrusion policies.

In a newly created access control policy, one default network analysis policy governs preprocessing for *all* traffic for *all* intrusion policies invoked by the same parent access control policy. Initially, the system uses the Balanced Security and Connectivity network analysis policy as the default, but you can change it to another system-provided or custom network analysis policy. In a more complex deployment, advanced users can tailor traffic preprocessing options to specific security zones, networks, and VLANs by assigning different custom network analysis policies to preprocess matching traffic.

Note For an access control policy with rule action as **Trust** and a prefilter rule with action as **Fastpath** with logging options disabled, you will observe that the end-of-flow events are still generated in the system. The events are not visible on the management center event pages.

Access Control Rules: Intrusion Policy Selection

After initial preprocessing, access control rules (when present) evaluate traffic. In most cases, the first access control rule that a packet matches is the rule that handles that traffic; you can monitor, trust, block, or allow matching traffic.

When you allow traffic with an access control rule, the system can inspect the traffic for discovery data, malware, prohibited files, and intrusions, in that order. Traffic not matching any access control rule is handled by the access control policy's default action, which can also inspect for discovery data and intrusions.

Note All packets, **regardless** of which network analysis policy preprocesses them, are matched to configured access control rules—and thus are potentially subject to inspection by intrusion policies—in top-down order.

The diagram in How Policies Examine Traffic For Intrusions, on page 1689 shows the flow of traffic through a device in an inline, intrusion prevention and malware defense deployment, as follows:

- Access Control Rule A allows matching traffic to proceed. The traffic is then inspected for discovery data by the network discovery policy, for prohibited files and malware by File Policy A, and then for intrusions by Intrusion Policy A.
- Access Control Rule B also allows matching traffic. However, in this scenario, the traffic is not inspected for intrusions (or files or malware), so there are no intrusion or file policies associated with the rule. Note

that by default, traffic that you allow to proceed is inspected by the network discovery policy; you do not need to configure this.

- In this scenario, the access control policy's default action allows matching traffic. The traffic is then inspected by the network discovery policy, and then by an intrusion policy. You can (but do not have to) use a different intrusion policy when you associate intrusion policies with access control rules or the default action.

The example in the diagram does not include any blocking or trusting rules because the system does not inspect blocked or trusted traffic.

Intrusion Inspection: Intrusion Policies, Rules, and Variable Sets

You can use intrusion prevention as the system's last line of defense before traffic is allowed to proceed to its destination. Intrusion policies govern how the system inspects traffic for security violations and, in inline deployments, can block or alter malicious traffic. The main function of intrusion policies is to manage which intrusion and preprocessor rules are enabled and how they are configured.

Intrusion and Preprocessor Rules

An intrusion rule is a specified set of keywords and arguments that detects attempts to exploit vulnerabilities on your network; the system uses an intrusion rule to analyze network traffic to check if it matches the criteria in the rule. The system compares packets against the conditions specified in each rule and, if the packet data matches all the conditions specified in a rule, the rule triggers.

The system includes the following types of rules created by Talos Intelligence Group:

- *shared object intrusion rules*, which are compiled and cannot be modified (except for rule header information such as source and destination ports and IP addresses)
- *standard text intrusion rules*, which can be saved and modified as new custom instances of the rule.
- *preprocessor rules*, which are rules associated with preprocessors and packet decoder detection options in the network analysis policy. You cannot copy or edit preprocessor rules. Most preprocessor rules are disabled by default; you must enable them to use preprocessors to generate events and, in an inline deployment, drop offending packets.

When the system processes packets according to an intrusion policy, first a rule optimizer classifies all activated rules in subsets based on criteria such as: transport layer, application protocol, direction to or from the protected network, and so on. Then, the intrusion rules engine selects the appropriate rule subsets to apply to each packet. Finally, a multi-rule search engine performs three different types of searches to determine if the traffic matches the rule:

- The protocol field search looks for matches in particular fields in an application protocol.
- The generic content search looks for ASCII or binary byte matches in the packet payload.
- The packet anomaly search looks for packet headers and payloads that, rather than containing specific content, violate well-established protocols.

In a custom intrusion policy, you can tune detection by enabling and disabling rules, as well as by writing and adding your own standard text rules. You can also use Cisco recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.

Variable Sets

Whenever the system uses an intrusion policy to evaluate traffic, it uses an associated *variable set*. Most variables in a set represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions and dynamic rule states.

The system provides a single default variable set, which is comprised of predefined default variables. Most system-provided shared object rules and standard text rules use these predefined default variables to define networks and port numbers. For example, the majority of the rules use the variable `$HOME_NET` to specify the protected network and the variable `$EXTERNAL_NET` to specify the unprotected (or outside) network. In addition, specialized rules often use other predefined variables. For example, rules that detect exploits against web servers use the `$HTTP_SERVERS` and `$HTTP_PORTS` variables.

Tip Even if you use system-provided intrusion policies, Cisco **strongly** recommends that you modify key default variables in the default set. When you use variables that accurately reflect your network environment, processing is optimized and the system can monitor relevant systems for suspicious activity. Advanced users can create and use custom variable sets for pairing with one or more custom intrusion policies.

Intrusion Event Generation

When the system identifies a possible intrusion, it generates an *intrusion or preprocessor event* (sometimes collectively called *intrusion events*). Managed devices transmit their events to the Firewall Management Center, where you can view the aggregated data and gain a greater understanding of the attacks against your network assets. In an inline deployment, managed devices can also drop or replace packets that you know to be harmful.

Each intrusion event in the database includes an event header and contains information about the event name and classification; the source and destination IP addresses; ports; the process that generated the event; and the date and time of the event, as well as contextual information about the source of the attack and its target. For packet-based events, the system also logs a copy of the decoded packet header and payload for the packet or packets that triggered the event.

The packet decoder, the preprocessors, and the intrusion rules engine can all cause the system to generate an event. For example:

- If the packet decoder (configured in the network analysis policy) receives an IP packet that is less than 20 bytes, which is the size of an IP datagram without any options or payload, the decoder interprets this as anomalous traffic. If, later, the accompanying decoder rule in the intrusion policy that examines the packet is enabled, the system generates a preprocessor event.
- If the IP defragmentation preprocessor encounters a series of overlapping IP fragments, the preprocessor interprets this as a possible attack and, when the accompanying preprocessor rule is enabled, the system generates a preprocessor event.
- Within the intrusion rules engine, most standard text rules and shared object rules are written so that they generate intrusion events when triggered by packets.

As the database accumulates intrusion events, you can begin your analysis of potential attacks. The system provides you with the tools you need to review intrusion events and evaluate whether they are important in the context of your network environment and your security policies.

System-Provided and Custom Network Analysis and Intrusion Policies

Creating a new access control policy is one of the first steps in managing traffic flow using the system. By default, a newly created access control policy invokes system-provided network analysis and intrusion policies to examine traffic.

The following diagram shows how a newly created access control policy in an inline, intrusion-prevention deployment initially handles traffic. The preprocessing and intrusion prevention phases are highlighted.

Figure 410: New Access Control Policy: Intrusion Prevention

Note how:

- A default network analysis policy governs the preprocessing of *all* traffic handled by the access control policy. Initially, the system-provided *Balanced Security and Connectivity network analysis policy* is the default.
- The default action of the access control policy allows all non-malicious traffic, as determined by the system-provided *Balanced Security and Connectivity intrusion policy*. Because the default action allows traffic to pass, the discovery feature can examine it for host, application, and user data before the intrusion policy can examine and potentially block malicious traffic.
- The policy uses default Security Intelligence options (global Block and Do Not Block lists only), does not decrypt encrypted traffic with an SSL policy, and does not perform special handling and inspection of network traffic using access control rules.

A simple step you can take to tune your intrusion prevention deployment is to use a different set of system-provided network analysis and intrusion policies as your defaults. Cisco delivers several pairs of these policies with the system.

Or, you can tailor your intrusion prevention deployment by creating and using custom policies. You may find that the preprocessor options, intrusion rule, and other advanced settings configured in those policies do not address the security needs of your network. By tuning your network analysis and intrusion policies you can configure, at a very granular level, how the system processes and inspects the traffic on your network for intrusions.

System-Provided Network Analysis and Intrusion Policies

Cisco delivers several pairs of network analysis and intrusion policies with the system. By using system-provided network analysis and intrusion policies, you can take advantage of the experience of the Talos Intelligence Group. For these policies, Talos provides intrusion and preprocessor rule states as well as initial configurations for preprocessors and other advanced settings.

No system-provided policy covers every network profile, traffic mix, or defensive posture. Each covers common cases and network setups that provide a starting point for a well-tuned defensive policy. Although you can use system-provided policies as-is, Cisco strongly recommends that you use them as the base for custom policies that you tune to suit your network.

Tip Even if you use system-provided network analysis and intrusion policies, you should configure the system's intrusion variables to accurately reflect your network environment. At a minimum, modify key default variables in the default set.

As new vulnerabilities become known, Talos releases intrusion rule updates (also known as *Snort Rule Updates*). These rule updates can modify any system-provided network analysis or intrusion policy, and can provide new and updated intrusion rules and preprocessor rules, modified states for existing rules, and modified default policy settings. Rule updates may also delete rules from system-provided policies and provide new rule categories, as well as modify the default variable set.

If a rule update affects your deployment, the web interface marks affected intrusion and network analysis policies as out of date, as well as their parent access control policies. You must re-deploy an updated policy for its changes to take effect.

For your convenience, you can configure rule updates to automatically re-deploy affected intrusion policies, either alone or in combination with affected access control policies. This allows you to easily and automatically keep your deployment up-to-date to protect against recently discovered exploits and intrusions.

To ensure up-to-date preprocessing settings, you **must** re-deploy access control policies, which also deploys any associated SSL, network analysis, and file policies that are different from those currently running, and can also can update default values for advanced preprocessing and performance options.

Cisco delivers the following network analysis and intrusion policies with the system:

Balanced Security and Connectivity network analysis and intrusion policies

These policies are built for both speed and detection. Used together, they serve as a good starting point for most organizations and deployment types. The system uses the Balanced Security and Connectivity policies and settings as defaults in most cases.

Connectivity Over Security network analysis and intrusion policies

These policies are built for organizations where connectivity (being able to get to all resources) takes precedence over network infrastructure security. The intrusion policy enables far fewer rules than those enabled in the Security over Connectivity policy. Only the most critical rules that block traffic are enabled.

Security Over Connectivity network analysis and intrusion policies

These policies are built for organizations where network infrastructure security takes precedence over user convenience. The intrusion policy enables numerous network anomaly intrusion rules that could alert on or drop legitimate traffic.

Maximum Detection network analysis and intrusion policies

These policies are built for organizations where network infrastructure security is given even more emphasis than is given by the Security Over Connectivity policies, with the potential for even greater operational impact. For example, the intrusion policy enables rules in a large number of threat categories including malware, exploit kit, old and common vulnerabilities, and known in-the-wild exploits.

No Rules Active intrusion policy

In the No Rules Active intrusion policy, all intrusion rules, and all advanced settings except intrusion rule thresholds, are disabled. This policy provides a starting point if you want to create your own intrusion policy instead of basing it on the enabled rules in one of the other system-provided policies.

Note Depending on the system-provided base policy that is selected, the settings of the policy vary. To view the policy settings, click the **Edit** icon next to the policy and then click the **Manage Base Policy** link.

Benefits of Custom Network Analysis and Intrusion Policies

You may find that the preprocessor options, intrusion rules, and other advanced settings configured in the system-provided network analysis and intrusion policies do not fully address the security needs of your organization.

Building custom policies can improve the performance of the system in your environment and can provide a focused view of the malicious traffic and policy violations occurring on your network. By creating and tuning custom policies you can configure, at a very granular level, how the system processes and inspects the traffic on your network for intrusions.

All custom policies have a base policy, also called a base layer, which defines the default settings for all configurations in the policy. A layer is a building block that you can use to efficiently manage multiple network analysis or intrusion policies.

In most cases, you base custom policies on system-provided policies, but you can use another custom policy. However, all custom policies have a system-provided policy as the eventual base in a policy chain. Because rule updates can modify system-provided policies, importing a rule update may affect you even if you are using a custom policy as your base. If a rule update affects your deployment, the web interface marks affected policies as out of date.

Benefits of Custom Network Analysis Policies

By default, one network analysis policy preprocessors all unencrypted traffic handled by the access control policy. That means that all packets are decoded and preprocessed according to the same settings, regardless of the intrusion policy (and therefore intrusion rule set) that later examines them.

Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default. A simple way to tune preprocessing is to create and use a custom network analysis policy as the default.

Tuning options available vary by preprocessor, but some of the ways you can tune preprocessors and decoders include:

- You can disable preprocessors that do not apply to the traffic you are monitoring. For example, the HTTP Inspect preprocessor normalizes HTTP traffic. If you are confident that your network does not include any web servers using Microsoft Internet Information Services (IIS), you can disable the preprocessor option that looks for IIS-specific traffic and thereby reduce system processing overhead.

Note If you disable a preprocessor in a custom network analysis policy, but the system needs to use that preprocessor to later evaluate packets against an enabled intrusion or preprocessor rule, the system automatically enables and uses the preprocessor although the preprocessor remains disabled in the network analysis policy web interface.

- Specify ports, where appropriate, to focus the activity of certain preprocessors. For example, you can identify additional ports to monitor for DNS server responses or encrypted SSL sessions, or ports on which you decode telnet, HTTP, and RPC traffic.

For advanced users with complex deployments, you can create multiple network analysis policies, each tailored to preprocess traffic differently. Then, you can configure the system to use those policies to govern the preprocessing of traffic using different security zones, networks, or VLANs.

Note Tailoring preprocessing using custom network analysis policies—especially multiple network analysis policies—is an advanced task. Because preprocessing and intrusion inspection are so closely related, you **must** be careful to allow the network analysis and intrusion policies examining a single packet to complement each other.

Benefits of Custom Intrusion Policies

In a newly created access control policy initially configured to perform intrusion prevention, the default action allows all traffic, but first inspects it with the system-provided Balanced Security and Connectivity intrusion policy. Unless you add access control rules or change the default action, all traffic is inspected by that intrusion policy.

To customize your intrusion prevention deployment, you can create multiple intrusion policies, each tailored to inspect traffic differently. Then, configure an access control policy with rules that specify which policy inspects which traffic. Access control rules can be simple or complex, matching and inspecting traffic using multiple criteria including security zone, network or geographical location, VLAN, port, application, requested URL, or user.

The main function of intrusion policies is to manage which intrusion and preprocessor rules are enabled and how they are configured, as follows:

- Within each intrusion policy, you should verify that all rules applicable to your environment are enabled, and improve performance by disabling rules that are not applicable to your environment. In an inline deployment, you can specify which rules should drop or modify malicious packets.
- Cisco recommendations allow you to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.
- You can modify existing rules and write new standard text rules as needed to catch new exploits or to enforce your security policies.

Other customizations you might make to an intrusion policy include:

- The sensitive data preprocessor detects sensitive data such as credit card numbers and Social Security numbers in ASCII text. Note that other preprocessors that detect specific threats (back orifice attacks, several portscan types, and rate-based attacks that attempt to overwhelm your network with excessive traffic) are configured in network analysis policies.
- Global thresholds cause the system to generate events based on how many times traffic matching an intrusion rule originates from or is targeted to a specific address or address range within a specified time period. This helps prevent the system from being overwhelmed with a large number of events.
- Suppressing intrusion event notifications and setting thresholds for individual rules or entire intrusion policies can also can prevent the system from being overwhelmed with a large number of events.

- In addition to the various views of intrusion events within the web interface, you can enable logging to syslog facilities or send event data to an SNMP trap server. Per policy, you can specify intrusion event notification limits, set up intrusion event notification to external logging facilities, and configure external responses to intrusion events. Note that in addition to these per-policy alerting configurations, you can globally enable or disable email alerting on intrusion events for each rule or rule group. Your email alert settings are used regardless of which intrusion policy processes a packet.

Limitations of custom policies

Configuration coordination requirements

You **must** be careful that your configuration allows the network analysis and intrusion policies processing and examining a single packet to complement each other because preprocessing and intrusion inspection are so closely related.

- If you disable a preprocessor in a custom network analysis policy but the system needs to evaluate preprocessed packets against an enabled intrusion or preprocessor rule, the system automatically enables and uses the preprocessor although it remains disabled in the network analysis policy web interface.
- All packets, **regardless** of which network analysis policy preprocessed them, are subsequently matched to access control rules—and thus to potential inspection by intrusion policies—in their own process. Preprocessing a packet with a particular network analysis policy does **not** guarantee that the packet will be examined with any particular intrusion policy.

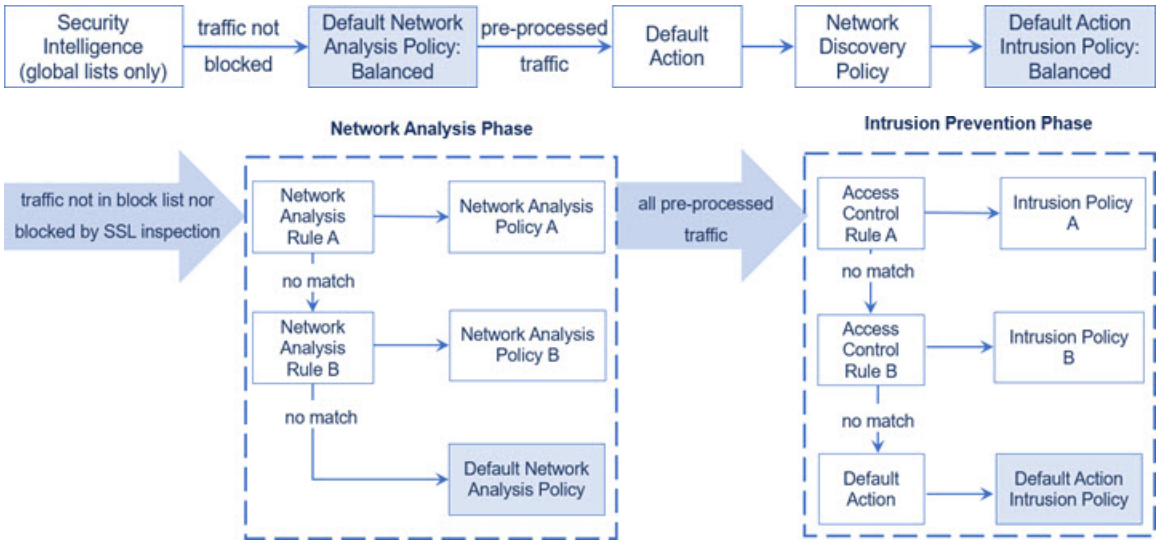
Performance optimization requirements

To get the performance benefits of disabling a preprocessor, you **must** make sure that none of your intrusion policies have enabled rules that require that preprocessor.

Access control policy configuration requirements

You **must** carefully configure your access control policy so it invokes the correct network analysis and intrusion policies to evaluate a particular packet.

- Each packet's handling is governed by a network analysis policy and intrusion policy pair, but the system does **not** coordinate the pair for you.
- Tailoring preprocessing using network analysis rules and custom policies is an **advanced** task due to the complexity of ensuring proper coordination between network analysis and access control rules.



By default, the system uses one network analysis policy to preprocess all traffic handled by managed devices using a single access control policy. The system matches packets to any configured network analysis rules in top-down order by rule number. Traffic that does not match any network analysis rule is preprocessed by the default network analysis policy.

A default network analysis policy governs the preprocessing of *all* traffic handled by the access control policy. Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default.

For advanced users with complex deployments, you can tailor preprocessing to specific security zones, networks, and VLANs by assigning custom network analysis policies to preprocess matching traffic. To accomplish this, you add custom *network analysis rules* to your access control policy. Each rule has an associated network analysis policy that governs the preprocessing of traffic that matches the rule.

Tip You configure network analysis rules as an advanced setting in an access control policy. Unlike other types of rules in the system, network analysis rules invoke—rather than being contained by—network analysis policies.

Figure 411: New access control policy: intrusion prevention

In this scenario, an access control policy is configured with two network analysis rules and a default network analysis policy:

- Network Analysis Rule A preprocessors matching traffic with Network Analysis Policy A. Later, you want this traffic to be inspected by Intrusion Policy A.
- Network Analysis Rule B preprocessors matching traffic with Network Analysis Policy B. Later, you want this traffic to be inspected by Intrusion Policy B.
- All remaining traffic is preprocessed with the default network analysis policy. Later, you want this traffic to be inspected by the intrusion policy associated with the access control policy's default action.

After the system preprocessors traffic, it can examine the traffic for intrusions. The diagram shows an access control policy with two access control rules and a default action:

- Access Control Rule A allows matching traffic. The traffic is then inspected by Intrusion Policy A.
- Access Control Rule B allows matching traffic. The traffic is then inspected by Intrusion Policy B.
- The access control policy's default action allows matching traffic. The traffic is then inspected by the default action's intrusion policy.

Note that for a single connection, although the system selects a network analysis policy before an access control rule, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does **not** affect how you configure preprocessing in custom network analysis policies.

Guidelines and Limitations for Network Analysis and Intrusion Policies

- A high percentage of traffic with small packets causes Snort performance to decrease. This behaviour is observed even when all the preprocessors are disabled.
- When you attempt to deploy a configuration change on a threat defense device with low memory, snort deployment is also triggered. This results in high consumption of RSS memory. Snort memory usage is also impacted if you deploy large configurations on the device, such as multiple IPS policies containing a large number of snort IPS rules, network objects, and access-control lists. You can mitigate such memory issues by optimizing the configuration. For best practices on how to configure access control rules to optimize the configuration, see Best Practices for Access Control Rules.
- If you increase the memory of a Threat Defense Virtual instance, you must redeploy the configuration for Snort 3 to utilize the additional memory.

Note The Snort 3 memory allocation is not automatically adjusted when you increase the memory of the Threat Defense Virtual instance. You must redeploy the configuration to regenerate relevant configuration files, such as `memory_allocation.lua`, which apply the updated resource limits to Snort 3.

- If an SIP stream is followed by RTP streams from the same connection, Snort inspects the initial SIP communication that is sent for connection establishment and allows SIP traffic. The RTP streams that follow the SIP communication are also trusted by default and bypass the configured rules. To prevent such scenarios, trusting the parent SIP connection or adding the parent SIP connection to a prefilter rule ensures that only the SIP stream bypasses Snort inspection and allows the subsequent RTP streams to be evaluated separately against the corresponding rules.
- If several Snort rules with the same action match a packet in the Management Center, an event is logged for each rule. However, if the matching rules have different actions, only the rule with the highest priority action generates an event. The action priority from highest to lowest is: pass, reset, block, drop, alert, log.
- When intrusion packet events are forwarded via syslog or the eStreamer fully-qualified event feed, the packet data field may be truncated due to limitations in the buffer size available for syslog generation and the eStreamer. In such scenarios, the packet length will not match the actual packet data that is sent.

The Navigation Panel: Network Analysis and Intrusion Policies

Network analysis and intrusion policies use similar web interfaces to edit and save changes to their configurations.

A navigation panel appears on the left side of the web interface when you are editing either type of policy. The following graphic shows the navigation panel for the network analysis policy (left) and the intrusion policy (right).

A dividing line separates the navigation panel into links to policy settings you can configure with (below) or without (above) direct interaction with policy layers. To navigate to any settings page, click its name in the navigation panel. Dark shading of an item in the navigation panel highlights your current settings page. For

example, in the illustration above the Policy Information page would be displayed to the right of the navigation panel.

Policy Information

The Policy Information page provides configuration options for commonly used settings. As shown in the illustration for the network analysis policy panel above, a **Policy Change icon** appears next to **Policy Information** in the navigation panel when the policy contains unsaved changes. The icon disappears when you save your changes.

Rules (intrusion policy only)

The Rules page in an intrusion policy allows you to configure rule states and other settings for shared object rules, standard text rules, and preprocessor rules.

Cisco Recommendations (intrusion policy only)

The Cisco Recommendations page in an intrusion policy allows you to associate the operating systems, servers, and client application protocols detected on your network with intrusion rules specifically written to protect those assets. This allows you to tailor your intrusion policy to the specific needs of your monitored network.

Settings (network analysis policy) and Advanced Settings (intrusion policy)

The Settings page in a network analysis policy allows you to enable or disable preprocessors and access preprocessor configuration pages. Expanding the **Settings** link displays sublinks to individual configuration pages for all enabled preprocessors in the policy.

The Advanced Settings page in an intrusion policy allows you to enable or disable advanced settings and access configuration pages for those advanced settings. Expanding the **Advanced Settings** link displays sublinks to individual configuration pages for all enabled advanced settings in the policy.

Policy Layers

The Policy Layers page displays a summary of the layers that comprise your network analysis or intrusion policy. Expanding the Policy Layers link displays sublinks to summary pages for the layers in your policy. Expanding each layer sublink displays further sublinks to the configuration pages for all rules, preprocessors, or advanced settings that are enabled in the layer.

Conflicts and Changes: Network Analysis and Intrusion Policies

When you edit a network analysis or intrusion policy, a **Policy Change icon** appears next to **Policy Information** in the navigation panel to indicate that the policy contains unsaved changes. You must save (or *commit*) your changes before the system recognizes them.

Note After you save, you must deploy the network analysis or intrusion policy for your changes to take effect. If you deploy a policy without saving, the system uses the most recently saved configuration.

Resolving Editing Conflicts

The Network Analysis Policy page (**Policies** > **Access Control heading** > **Access Control**, and then click **Network Analysis Policy** or **Policies** > **Access Control heading** > **Intrusion**, and then click **Network Analysis Policies**) and Intrusion Policy page (**Policies** > **Access Control heading** > **Intrusion**) display whether each policy has unsaved changes, as well as information about who is currently editing the policy. Cisco recommends that only one person edit a policy at a time. If you are performing simultaneous editing, the consequences are as follows:

- If you are editing a network analysis or intrusion policy at the same time another user is editing the same policy, and the other user saves their changes to the policy, you are warned when you commit the policy that you will overwrite the other user's changes.
- If you are editing the same network analysis or intrusion policy via multiple web interface instances as the same user, and you save your changes for one instance, you cannot save your changes for the other instance.

Resolving Configuration Dependencies

To perform their particular analysis, many preprocessors and intrusion rules require that traffic first be decoded or preprocessed in a certain way, or have other dependencies. When you save a network analysis or intrusion policy, the system either automatically enables required settings, or warns you that disabled settings will have no effect on traffic, as follows:

- You cannot save an intrusion policy if you added an SNMP rule alert but did not configure SNMP alerting. You must either configure SNMP alerting or disable the rule alert, then save again.
- You cannot save an intrusion policy if it includes enabled sensitive data rules but you have not enabled the sensitive data preprocessor. You must either allow the system to enable the preprocessor and save the policy, or disable the rules and save again.
- If you disable a required preprocessor in a network analysis policy, you can still save the policy. However, the system automatically uses the disabled preprocessor with its current settings, even though the preprocessor remains disabled in the web interface.
- If you disable inline mode in a network analysis policy but enable the Inline Normalization preprocessor, you can still save the policy. However, the system warns you that normalization settings will be ignored. Disabling inline mode also causes the system to ignore other settings that allow preprocessors to modify or block traffic, including checksum verification and rate-based attack prevention.

Committing, Discarding, and Caching Policy Changes

While editing a network analysis or intrusion policy, if you exit the policy editor without saving your changes, the system caches those changes. Your changes are cached even when you log out of the system or experience a system crash. The system cache can store unsaved changes for one network analysis and one intrusion policy per user; you must commit or discard your changes before editing another policy of the same type. The system discards the cached changes when you edit another policy without saving your changes to the first policy, or when you import an intrusion rule update.

You can commit or discard policy changes on the Policy Information page of either the network analysis or intrusion policy editor.

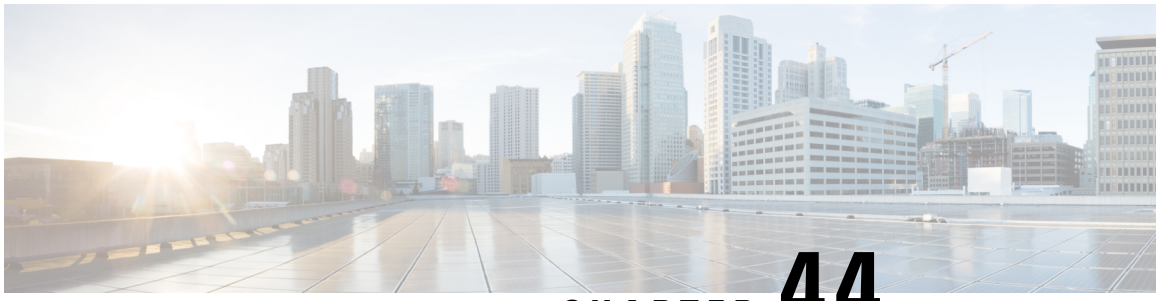
In the Secure Firewall Management Center configuration, you can control:

- whether you are prompted (or required) to comment on your network analysis or intrusion policy changes when you commit them
- whether changes and comments are recorded in the audit log

Exiting a Network Analysis or Intrusion Policy

Procedure

If you want to exit the network analysis or intrusion policy advanced editor, you have the following choices:



- Cache — To exit the policy and cache changes, choose any menu or other path to another page. On exiting, click **Leave page** when prompted, or click **Stay on page** to remain in the advanced editor.
- Discard — To discard unsaved changes, click **Discard Changes** on the Policy Information page, then click **OK**.
- Save — To save changes to the policy, click **Commit Changes** on the Policy Information page. If prompted, enter a comment, and then click **OK**.

Decryption Policies and Encrypted Visibility for Access Control

- Traffic Decryption Overview, on page 1707
- Decryption Policies, on page 1727
- Decryption Rules, on page 1745
- Decryption rules and Policy Example, on page 1793
- Encrypted Visibility Engine, on page 1803

CHAPTER 44

Traffic Decryption Overview

These topics provide an overview of Transport Layer Security/Secure Sockets Layer (TLS/SSL) inspection, discuss the prerequisites for TLS/SSL inspection configuration, and detail deployment scenarios.

Note Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, see a resource such as SSL vs. TLS - What's the Difference?

- Traffic decryption, on page 1707
- How TLS/SSL handshakes work, on page 1708
- Decryption rule and policy basics, on page 1713
- TLS crypto acceleration, on page 1720
- History for decryption policy , on page 1723

Traffic decryption

Traffic decryption enables deep inspection of traffic for analysis.

Traffic handling options

Most traffic on the internet is encrypted and in most cases, you might choose not to decrypt it. You can glean some information from encrypted traffic and you can also block it from your network if desired.

Your choices are:

- Decrypt the traffic and subject it to the full array of deep inspection:
  - Advanced Malware Protection
  - Security intelligence
  - Threat Intelligence Director
  - Application detectors

    - URL and category filtering

- Leave the traffic encrypted and set up your access control and decryption policy to look for and potentially block:
    - Old protocol versions (such as Secure Sockets Layer)
    - Unsecure cipher suites
    - Applications with high risk and low business relevance
    - Untrusted issuer Distinguished Names

Access control policy integration

An access control policy is the main configuration that invokes subpolicies and other configurations, including a decryption policy. If you associate a decryption policy with access control, the system uses that decryption policy to handle encrypted sessions before it evaluates the sessions with access control rules. If you do not configure TLS/SSL inspection, or your devices do not support it, access control rules handle all encrypted traffic.

Access control rules also handle encrypted traffic when your TLS/SSL inspection configuration allows the traffic to pass. However, some access control rule conditions require unencrypted traffic, so encrypted traffic might match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improves performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Note As long as your managed devices have Snort 3 enabled, the system supports decrypting TLS 1.3 traffic. You can enable TLS 1.3 decryption in an decryption policy's advanced options; for more information, see Decryption policy advanced options, on page 1742.

Notes

Decryption rules require processing overhead that can impact performance. Before you decide to decrypt traffic, see Best practice for deciding when to decrypt traffic, on page 1714.

The system does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign** or **Decrypt - Known Key** decryption rule actions.

If you set the value of TCP maximum segment size (MSS) using FlexConfig, the observed MSS could be less than your setting. For more information, see TCP MSS, on page 714.

How TLS/SSL handshakes work

In this documentation, the term *TLS/SSL handshake* represents the two-way handshake that initiates encrypted sessions in both the SSL protocol and its successor protocol, TLS.

In an inline deployment, the system processes the TLS/SSL handshake, potentially modifying the ClientHello message and acting as a TCP proxy server for the session.

The figure shows an inline deployment.

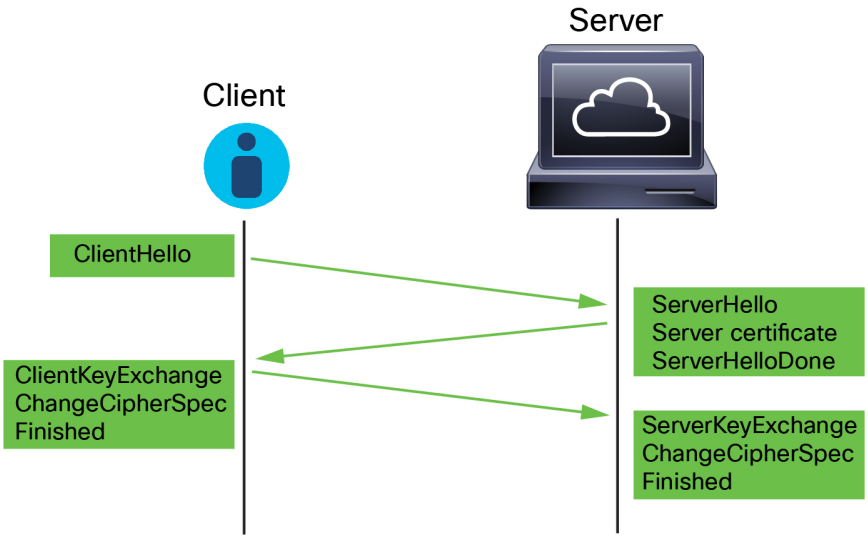
Summary

The key components involved in the TLS/SSL handshake process are:

- Client: Initiates the encrypted session by sending a ClientHello message specifying multiple supported values for each encryption attribute
- Server: Responds with a ServerHello message specifying a single supported value for each encryption attribute, determining the encryption method for the secure session
- Managed device: Monitors TCP sessions for encrypted session initiation attempts and can act as a TCP proxy server
- Handshake messages: Specialized packets that communicate encryption attributes between client and server

Workflow

These stages describe how TLS/SSL handshakes establish encrypted sessions:



1. The client establishes a TCP connection with the server after successfully completing the TCP three-way handshake.
2. The managed device monitors the TCP session for any attempt to initiate an encrypted session.
3. The client and server exchange specialized handshake messages to establish an encrypted session.
   - ClientHello—The client specifies multiple supported values for each encryption attribute.
   - ServerHello—The server specifies a single supported value for each encryption attribute, and the ServerHello response determines which encryption method the system uses during the secure session.
4. After the TLS/SSL handshake completes, the managed device caches encrypted session data and server certificate data.

   This caching allows session resumption without requiring the full handshake and enables faster handshake processing in subsequent sessions that use the same certificate.

ClientHello message handling

The client sends the ClientHello message to the server, which acts as the packet destination, when a secure connection can be established. The client uses this message to initiate the TLS/SSL handshake to respond to a ServerHello message from the destination server.

The following figure shows an example. Also see RFC 8446, sec. 4 . You can also consult a resource such as What Happens in a TLS Handshake? at cloudflare.com.

ClientHello message process

The process consists of these steps:

1. ClientHello initiates the process.

   The ClientHello message contains the Server Name Indication (SNI), which has the server's fully qualified domain name.

2. After a managed device processes a ClientHello message and transmits it to the destination server, the server determines whether it supports the decryption attributes the client specified in the message. If it does not support those attributes, the server sends a handshake failure alert to the client. If it supports those attributes, the server sends the ServerHello message. If the agreed-upon key exchange method uses certificates for authentication, the server certificate message immediately follows the ServerHello message.

   The server certificate contains the Subject Alternative Name (SAN), which can have fully qualified domain names and IP addresses. For more information about the SAN, see Distinguished names, on page 2364.

3. When the managed device receives these messages, it attempts to match them with decryption rules configured on the system. These messages contain information that was absent from either the ClientHello message or the session data cache. Specifically, the system can potentially match these messages on decryption rules' Distinguished Names, Certificate Status, Cipher Suites, and Versions conditions.

The entire process is encrypted.

Data exchange

If you configure TLS/SSL decryption, when a managed device receives a ClientHello message, the system attempts to match the message to decryption rules that have the **Decrypt - Resign** , or **Decrypt - Known Key** action. The match relies on data from the ClientHello message and from cached server certificate data. The table lists the possible types of data available for matching conditions.

Table 99: Data Availability for Decryption rule Conditions

Decryption rule Condition	Data Present In
Zones	ClientHello
Networks	ClientHello
VLAN Tags	ClientHello
Ports	ClientHello
Users	ClientHello
Applications	ClientHello (Server Name Indicator extension)
Categories	ClientHello (Server Name Indicator extension)
Certificate	Server certificate (potentially cached)
Distinguished Names	Server certificate (potentially cached)
Certificate Status	Server certificate (potentially cached)
Cipher Suites	ServerHello
Versions	ServerHello

Important Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with **Decrypt - Resign** or **Decrypt - Known Key** rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

ClientHello message modifications

If the ClientHello message matches a **Decrypt - Resign** , or **Decrypt - Known Key** rule, the system modifies the ClientHello message.

- (TLS 1.2 only; TLS 1.3 does not support compression.) Compression methods—Strips the `compression_methods` element, which specifies the compression methods the client supports. The system cannot decrypt compressed sessions.
- Cipher suites—Strips cipher suites from the `cipher_suites` element if the system does not support them. If the system does not support any of the specified cipher suites, the system transmits the original, unmodified element. This modification reduces the Unknown Cipher Suite and Unsupported Cipher Suite types of undecryptable traffic.
- Session identifiers—Strips any value from the `Session Identifier` element and the SessionTicket extension (RFC 5077, sec 3.2) that does not match cached session data. If a ClientHello value matches cached data, an interrupted session can resume without the client and server performing the full TLS/SSL handshake. This modification improves the likelihood of session resumption and reduces the Session Not Cached incidents of undecryptable traffic..

- Elliptic curves—Strips elliptic curves from the Supported Elliptic Curves extension if the system does not support them. If the system does not support any of the specified elliptic curves, the managed device removes the extension and strips any related cipher suites from the `cipher_suites` element.
- ALPN extensions—Strips any value from the Application-Layer Protocol Negotiation (ALPN) extension that is unsupported in the system (for example, the HTTP/2 protocol).
- Other Extensions—Strips the Next Protocol Negotiation (NPN) and TLS Channel IDs extensions.

  Decryption rules with a **Decrypt - Resign** , or **Decrypt - Known Key** action now natively support the Extended Master Secret (EMS) extension during ClientHello negotiation, enabling more secure communications. The EMS extension is defined by RFC 7627 .

After the system modifies the ClientHello message, it determines whether the message passes access control evaluation (which can include deep inspection). If the message passes, the system transmits it to the destination server.

If the ClientHello message does *not* match a **Decrypt - Resign** , or **Decrypt - Known Key** rule, the system does not modify the message. It then determines whether the message passes access control evaluation (which can include deep inspection). If the message passes inspection, the system transmits it to the destination server.

ClientHello is *not* modified if traffic matches a **Monitor** rule condition.

Man-in-the-middle

Direct communication between the client and server is not possible during the TLS/SSL handshake. After the message is modified, the Message Authentication Codes (MACs) computed by the client and server no longer match. For all subsequent handshake messages (and for the encrypted session once established), the managed device acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. Each session contains distinct cryptographic session details.

Note The cipher suites that the system can decrypt are frequently updated and do not correspond directly to the cipher suites you can use in decryption rule conditions. For the current list of decryptable cipher suites, contact Cisco TAC .

How ServerHello and server certificate messages work

Summary

The key components involved in ServerHello and server certificate message handling are:

- Managed device: Processes ServerHello and server certificate messages and performs rule matching
- decryption rules: Define actions to take when messages match specific criteria
- Server certificate data: Certificate information used for matching against internal certificate objects
- TLS/SSL handshake: The secure connection establishment process
- Certificate authority (CA): Used for re-signing certificates in decrypt-resign actions

Workflow

These stages describe how ServerHello and server certificate message handling works:

1. The managed device receives ServerHello and server certificate messages and checks for rule matches.

   If the messages do not match any decryption rules, the managed device performs the Decryption policy default actions, on page 1739.

2. When messages match a rule that belongs to a decryption policy associated with an access control policy, the managed device performs actions based on the rule configuration.

   - **Monitor**: The TLS/SSL handshake continues to completion. The managed device tracks and logs traffic but does not decrypt it.
   - **Block or Block with Reset**: The managed device blocks the TLS/SSL session and, if configured, resets the TCP connection.
   - **Do Not Decrypt**: The TLS/SSL handshake continues to completion. The managed device does not decrypt the application data exchanged during the TLS/SSL session.

3. For decrypt actions with known key or resign methods, the managed device performs certificate matching and processing.

   - **Decrypt - Known Key**: The managed device attempts to match the server certificate data to an Internal Certificate object previously imported into the Secure Firewall Management Center. Because you cannot generate an Internal Certificate object, and you must possess its private key, we assume you own the server on which you're using known key decryption.
   - **Decrypt - Resign**: The managed device processes the server certificate message and re-signs the server certificate with the previously imported or generated certificate authority (CA). The TLS/SSL handshake continues to completion. The managed device then uses the uploaded private key to decrypt and re-encrypt the application data exchanged during the TLS/SSL session.

   If the certificate matches a known certificate, the TLS/SSL handshake continues to completion. The managed device uses the uploaded private key to decrypt and re-encrypt the application data exchanged during the TLS/SSL session.

   If the server changes its certificate between the initial connection with the client and subsequent connections, you must import the new server certificate in the Secure Firewall Management Center for future connections to be decrypted.

Note The system does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign** or **Decrypt - Known Key** decryption rule actions.

Decryption rule and policy basics

This section discusses information you should keep in mind when creating your Decryption rules and policies.

Key information for decryption policy creation

Consider this information when creating your decryption policies and rules.

Note Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, refer to a resource such as SSL vs. TLS - What's the Difference?

Guidelines for traffic decryption

Traffic that is encrypted when it passes through the system can be allowed or blocked, but it *cannot* be subjected to deep inspection or the full range of policy enforcement (such as intrusion prevention).

All encrypted connections are sent through the decryption policy to determine if they should be decrypted or blocked.

You can also configure decryption rules to block encrypted traffic of types you know you do not want on your network, such as traffic that uses the nonsecure SSL protocol or traffic with an expired or invalid certificate.

If unblocked, whether or not decrypted, traffic goes through the access control policy for a final allow or block decision.

Only *decrypted* traffic takes advantage of the system's threat defense and policy enforcement features, including:

- Advanced Malware Protection
- Security intelligence
- Threat Intelligence Director
- Application detectors
- URL and category filtering

Keep in mind that decrypting and then re-encrypting traffic adds a processing load on the device, which can reduce overall system performance.

Encrypted traffic can be allowed or blocked by policy; encrypted traffic *cannot* be inspected.

Decrypted traffic is subject to threat defense and policy enforcement; decrypted traffic can be allowed or blocked by policy.

Detects encrypted application traffic using StartTLS (SMTPS, POPS, FTPS, TelnetS, IMAPS). Also identifies certain encrypted applications based on Server Name Indication in the TLS ClientHello message or subject distinguished name from the server certificate.

Best practice for deciding when to decrypt traffic

When not to decrypt traffic

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information
- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as *TLS/SSL pinning*) must remain encrypted to prevent breaking the connection

(Snort 3.) Decryption policy is *not* bypassed for any connections that match access control rules with actions of Trust, Block, or Block with Reset, unless the traffic is prefiltered. The encrypted traffic is first evaluated by decryption policy and then proceeds to the access control policy, where a final allow or block decision is made.

Encrypted traffic can be allowed or blocked on any decryption rule condition, including, but not limited to:

- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)
- URL category and reputation
- Port
- User group

Decryption rules provide a **Do Not Decrypt** action for traffic you do not want to decrypt; for more information, see Decryption rule Do Not Decrypt action, on page 1778.

Note The related information links at the end of this topic explain how some aspects of rule evaluation work. Conditions such as URL and application filtering have limitations with respect to encrypted traffic. Make sure you understand those limitations.

For more information about using URL filtering in **Do Not Decrypt** rules, see Decryption rule Do Not Decrypt action, on page 1778.

When to decrypt traffic

All encrypted traffic must be decrypted to take advantage of the system's threat protection and policy enforcement features. If your managed device has sufficient memory and processing power to decrypt traffic, you should decrypt traffic that is not prohibited by law or regulation.

If you must decide what traffic to decrypt, base your decision on the risk of allowing the traffic on your network. The system provides a flexible framework for classifying traffic using rule conditions, which include URL reputation, cipher suite, protocol, and many other factors.

Decrypt and re-sign (outgoing traffic)

Decrypt and re-sign of traffic enables the system to act as a man in the middle, intercepting, decrypting, and (if the traffic is allowed to pass) inspecting and re-encrypting traffic. It is used with outgoing traffic where the destination server is outside your protected network and requires the client to trust the firewall's certificate to complete the connection.

How decrypt and re-sign works

The Firewall Threat Defense device negotiates with the client using an internal Certificate Authority (CA) object specified in the rule and builds a TLS/SSL tunnel between the client and the Firewall Threat Defense device. At the same time, the device connects to the destination web site and creates a TLS/SSL tunnel between the server and the Firewall Threat Defense device.

Thus, the client sees the CA certificate configured for the decryption rule instead of the certificate from the destination server. The client must trust the firewall's certificate to complete the connection. The Firewall Threat Defense device then performs decryption/re-encryption in both directions for traffic between the client and the destination server.

Prerequisite

To use the **Decrypt - Resign** rule action, you must create an internal CA object using a CA file and paired private key file. You can generate a CA and private key in the system if you don't already have them.

Note The system does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign** or **Decrypt - Known Key** decryption rule actions.

Known key decryption for incoming traffic

The **Decrypt - Known Key** decryption rule action uses a server's private key to decrypt traffic. The **Decrypt - Known Key** rule action is used with incoming traffic, where the destination server is inside your protected network.

The main purpose of decrypting with a known key is to protect your servers from external attacks.

Prerequisites and requirements

To use the **Decrypt - Known Key** rule action, you must create an internal certificate object using the server's certificate file and paired private key file.

Note The system does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign** or **Decrypt - Known Key** decryption rule actions.

Other decryption rule actions

These topics discuss other decryption rule actions.

Decryption rule components

Each decryption rule has the following components.

State

A rule can have either of two states: enabled or disabled. By default, rules are enabled. If you disable a rule, the system does not use it to evaluate network traffic, and stops generating warnings and errors for that rule.

Position

Rules in a decryption policy are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number.

Conditions

Conditions specify the specific traffic the rule handles. Conditions can match traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate subject or issuer, certificate status, cipher suite, or encryption protocol version. The use of conditions can depend on target device licenses.

Action

A rule's action determines how the system handles matching traffic. You can monitor, allow, block, or decrypt encrypted matching traffic. Decrypted traffic is subject to further inspection. Note that the system does *not* inspect blocked encrypted traffic.

Logging

A rule's logging settings govern the records the system keeps of the traffic it handles. You can keep a record of traffic that matches a rule. You can log a connection when the system blocks an encrypted session or allows it to pass without decryption, according to the settings in an decryption policy. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. You can log connections to the Secure Firewall Management Center database, as well as to the system log (syslog) or to an SNMP trap server.

For more information about logging, see Best Practices for Connection Logging in the *Cisco Secure Firewall Management Center Administration Guide*.

Tip Properly creating and ordering decryption rules is a complex task. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. To help ensure that the system handles traffic as you expect, the decryption policy interface has a robust warning and error feedback system for rules.

Categories

For information about using decryption rule categories (such as Applications, Category, and Cert Status), see Decryption Rule conditions, on page 1758.

Decryption Rule order evaluation

Decryption Rule order evaluation determines the sequence in which the system evaluates decryption rules in a policy.

Rule evaluation process

When you create a decryption rule in a decryption policy , you specify its position using the **Insert** list in the rule editor. Decryption rules in an a decryption policy are numbered, starting at 1. The system matches traffic to decryption rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic flow), the system does *not* continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.

Rules that use *specific* conditions (such as network and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules.

Note Proper decryption rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.

Best practices for access control rules, on page 1625

Multi-rule example

This reference example demonstrates how the firewall handles traffic using a decryption policy that contains multiple rules.

The following scenario summarizes the ways that decryption rules handle traffic in an inline deployment.

In this scenario, traffic is evaluated as follows:

- **Undecryptable Traffic Action** evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.
- **Decryption rule 1: Monitor** evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.
- **Decryption rule 2: Do Not Decrypt** evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.

- **Decryption rule 3: Block** evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.
- **Decryption rule 4: Decrypt - Known Key** evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule continues to the next rule.
- **Decryption rule 5: Decrypt - Resign** is the final rule. If traffic matches, the system re-signs the server certificate with an uploaded CA certificate and decrypts traffic. The decrypted traffic is then evaluated against access control rules, which treat decrypted and unencrypted traffic the same. This additional inspection allows the system to block traffic. All remaining traffic is re-encrypted before being sent to its destination. Traffic that does not match the decryption rule rule continues to the next rule.
- **Decryption policy Default Action** handles all traffic that does not match any of the decryption rules. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

TLS crypto acceleration

TLS crypto acceleration accelerates the following:

- TLS/SSL encryption and decryption
- VPN, including TLS/SSL and IPsec

Supported hardware and acceleration details

The following hardware models support TLS crypto acceleration:

- Secure Firewall 3100
- Secure Firewall 4200
- Firepower 2100
- Firepower 4100/9300

  For information about TLS crypto acceleration support on Firepower 4100/9300 Firewall Threat Defense container instances, see the *FXOS Configuration Guide*.

TLS crypto acceleration is *not* supported on any virtual appliances or on any hardware except for the preceding.

Note For more information about TLS crypto acceleration and the 4100/9300, see the *FXOS Configuration Guide*.

Features *not* supported by TLS crypto acceleration include:

- Managed devices where Firewall Threat Defense container instance is enabled.

- If the inspection engine is configured to preserve connections and the inspection engine fails unexpectedly, TLS/SSL traffic is dropped until the engine restarts.

  This behavior is controlled by the **configure snort preserve-connection {enable | disable}** command.

TLS crypto acceleration guidelines and limitations

HTTP-only performance

Using TLS crypto acceleration on a managed device that is not decrypting traffic can affect performance.

Federal information processing standards (FIPS)

If TLS crypto acceleration and Federal Information Processing Standards (FIPS) are both enabled, connections with the following options fail:

- RSA keys less than 2048 bytes in size
- Rivest cipher 4 (RC4)
- Single Data Encryption Standard (single DES)
- Merkle–Damgard 5 (MD5)
- SSL v3

FIPS is enabled when you configure the Firewall Management Center and managed devices to operate in a security certifications compliance mode. To allow connections when operating in those modes, you can configure web browsers to accept more secure options.

For more information:

- Ciphers supported by FIPS: Configure SSL settings, on page 885.
- Security certifications compliance modes.
- Common Criteria.

TLS heartbeat

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

When a managed device with TLS crypto acceleration enabled encounters a packet that uses the TLS heartbeat extension, the managed device takes the action specified by the setting for **Decryption Errors** in the decryption policy's **Undecryptable Actions**:

- Block
- Block with reset

For more information, see Default handling options for undecryptable traffic, on page 1739.

To determine whether applications are using TLS heartbeat, see Troubleshoot TLS heartbeat, on page 1784.

You can configure a **Max Heartbeat Length** in a Network Analysis Policy (NAP) to determine how to handle TLS heartbeats. For more information, refer to *The SSL Preprocessor* section in the "Custom Snort 2 Intrusion Policies for Access Control" document.

TLS/SSL oversubscription

TLS/SSL oversubscription is a state where a managed device is overloaded with TLS/SSL traffic. Any managed device can experience TLS/SSL oversubscription but only managed devices that support TLS crypto acceleration provide a configurable way to handle it.

When a managed device with TLS crypto acceleration enabled is oversubscribed, any packet received by the managed device is acted on according to the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions**:

- Inherit default action
- Do not decrypt
- Block
- Block with reset

If the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions** is **Do Not decrypt** and the associated access control policy is configured to inspect the traffic, inspection occurs; decryption does *not* occur.

If a significant amount of oversubscription is occurring, you have these options:

- Upgrade your managed devices to increase TLS/SSL processing capacity.
- Change your decryption policies to add **Do Not Decrypt** rules for traffic that is not a high priority to decrypt.

Keep these guidelines in mind if your managed device has TLS crypto acceleration enabled.

View the status of TLS crypto acceleration

This task allows you to determine if TLS crypto acceleration is enabled on your managed devices.

Perform this task in the Firewall Management Center to check the TLS crypto acceleration status for your managed devices.

Procedure

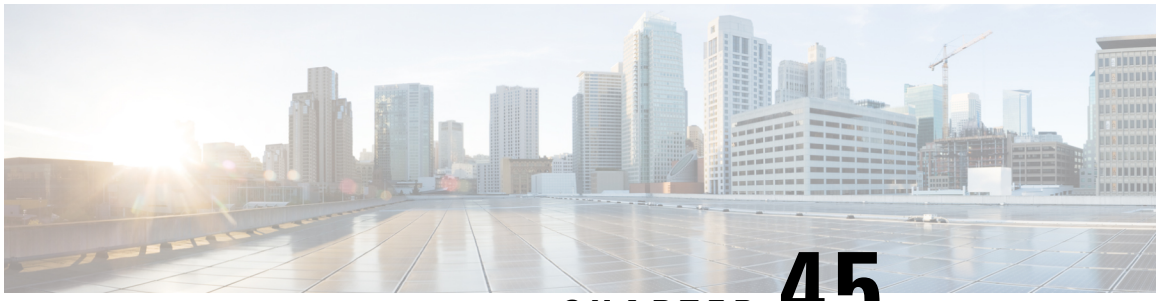
Step 1 Log in to the Firewall Management Center.

Step 2 Click **Devices** > **Device Management**.

Step 3 Click **Edit** ( ) to edit a managed device.

Step 4 Click **Device** page.

TLS crypto acceleration status is displayed in the General section.



History for decryption policy

Provides a chronological overview of decryption policy features, including version support and configuration changes.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Decryption policy.	7.3.0	7.3.0	Feature renamed to *decryption policy* to better reflect what it does. We now enable you to configure a decryption policy with one or more **Decrypt - Resign** or **Decrypt - Known Key** rules at the same time. New/modified screens: • **Policies** > **Access Control heading** > **Decryption** (create new decryption policy) • The Create Decryption Policy dialog box now has two tab pages: **Outbound Connections** and **Inbound Connections** . • **Policies** > **Access Control heading** > **Decryption** (edit a decryption rule) **Advanced Settings** has new options discussed in TLS 1.3 decryption best practices, on page 1743 . • **Policies** > **Access Control Heading** > **Access Control** (edit an access control policy), click the word **Decryption** to associate a decryption policy with an access control policy.
TLS 1.3 decryption.	7.2.0	7.2.0	You can now enable TLS 1.3 decryption in an SSL policy's advanced actions. TLS 1.3 decryption requires the managed device run Snort 3. Other options are available as well; for more information, see TLS 1.3 decryption best practices, on page 1743 . New/modified screens: **SSL Policy** > **Advanced Settings**
SSL policy advanced settings.	7.2.0	7.1.0	SSL policy advanced settings New/modified screens: **SSL Policy** > **Advanced Settings**
Ability to specify handling of URLs having unknown reputation.	6.7.0	6.7.0	For details, see URL filtering with category and reputation, on page 1652 .
ClientHello modification for **Decrypt - Known** key rules.	6.7.0	6.7.0	For details, see ClientHello message handling, on page 1709 .

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Ability to extract the certificate in TLS 1.3 traffic to enable traffic to match URL and application criteria in access control rules.	6.7.0	6.7.0	New/modified screens: **Policies** > **Access Control** > **(edit an access control policy)** > **Advanced** link. For details, see Decryption policy advanced options, on page 1742 .
Changes to category and reputation-based URL Filtering.	6.7.0	6.5.0	For details, see URL filtering with category and reputation, on page 1652 .
TLS crypto acceleration cannot be disabled.	6.4.0	6.4.0	TLS crypto acceleration is enabled on all supported devices. On a managed device with native interfaces, TLS crypto acceleration cannot be disabled. Removed commands: • **system support ssl-hw-accel enable** • **system support ssl-hw-accel disable** • **system support ssl-hw-status**
Support for TLS crypto acceleration on one container instance on a Firepower 4100/9300 module/security engine.	6.4.0	6.4.0	You can now enable TLS crypto acceleration for one container instance on a module/security engine. New/modified commands: • **config hwCrypto enable** • **show crypto accelerator status**
TLS/SSL hardware acceleration is now referred to as TLS crypto acceleration .	6.4.0	6.4.0	The name change reflects that TLS/SSL encryption and decryption acceleration is supported on more devices. New/modified screens: **Devices** > **Device Management** > **Edit** > **Device** > **General** > **TLS Crypto Acceleration**
Extended Master Secret extension supported (see RFC 7627).	6.3.0.1	6.3.0.1	The TLS Extended Master Secret extension is supported for SSL policies; specifically, policies with a rule action of **Decrypt - Resign** or **Decrypt - Known Key** .
Extended Master Secret extension not supported.	6.3.0	6.3.0	The extension is stripped during ClientHello modification for **Decrypt - Resign** rules.
TLS/SSL hardware acceleration enabled by default.	6.3.0	6.3.0	TLS/SSL hardware acceleration is enabled by default on all supported devices but can be disabled if desired.
Extended Master Secret extension supported (see RFC 7627).	6.2.3.9	6.2.3.9	The TLS Extended Master Secret extension is supported for SSL policies; specifically, policies with a rule action of **Decrypt - Resign** or **Decrypt - Known Key** .

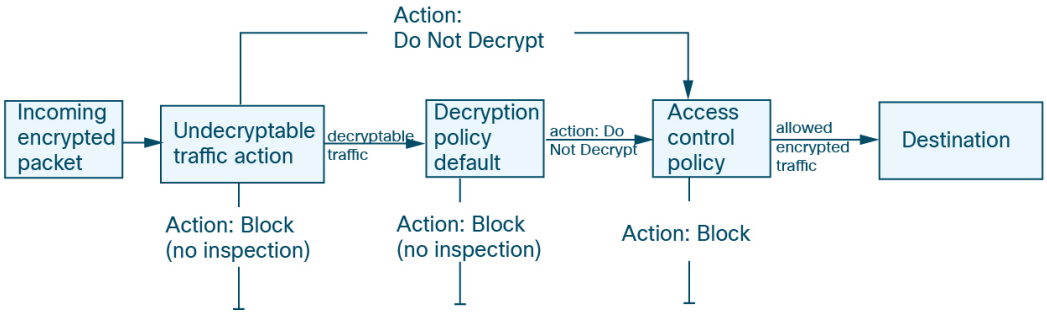
Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Aggressive TLS 1.3 downgrade.	6.2.3.7	6.2.3.7	Using the **system support ssl-client-hello-enabled aggressive_tls13_downgrade {true|false}** CLI command, you can determine the behavior for downgrading TLS 1.3 traffic to TLS 1.2.
TLS/SSL hardware acceleration introduced.	6.2.3	6.2.3	Certain managed device models perform TLS/SSL encryption and decryption in hardware, improving performance. By default, the feature is enabled. Affected screen: To view the status of TLS/SSL hardware acceleration , **Devices** > **Device Management** > **Device** , General page.
Category and reputation conditions supported.	6.2.2	6.2.2	Access control rules or SSL rules with category/reputation conditions.
SafeSearch supported.	6.1.0	6.1.0	The system displays an HTTP response page for connections decrypted by the SSL policy, then blocked (or interactively blocked) either by access control rules or by the access control policy default action. SafeSearch filters objectionable content and stops people from searching adult sites.
TLS/SSL policy.	6.0.0	6.0.0	Feature introduced.

CHAPTER 45

Decryption Policies

The following topics provide an overview of decryption policy creation, configuration, management, and logging.

- About Decryption Policies, on page 1727
- Requirements and Prerequisites for Decryption Policies, on page 1728
- Create a decryption policy , on page 1728
- Decryption policy default actions, on page 1739
- Default handling options for undecryptable traffic, on page 1739
- Decryption policy advanced options, on page 1742



About Decryption Policies

A decryption policy determines how the system handles encrypted traffic on your network. You can configure one or more decryption policies, associate a decryption policy with an access control policy, then deploy the access control policy to a managed device. When the device detects a TCP handshake, the access control policy first handles and inspects the traffic. If it subsequently identifies a TLS/SSL-encrypted session over the TCP connection, the decryption policy takes over, handling and decrypting the encrypted traffic.

You can create multiple rules at the same time, including rules for decrypting incoming traffic (**Decrypt - Known Key** rule action) and outgoing traffic (**Decrypt - Resign** rule action). To create a rule with a **Do Not Decrypt** or other rule action (such as **Block** or **Monitor**), create an empty decryption policy and add the rule afterward.

Do Not Decrypt policy example

Following is an example decryption policy with a **Do Not Decrypt** rule action:

The simplest decryption policy, as shown in the following diagram, directs the device where it is deployed to handle encrypted traffic with a single default action. You can set the default action to block decryptable traffic without further inspection, or to inspect undecrypted decryptable traffic with access control. The system can then either allow or block the encrypted traffic. If the device detects undecryptable traffic, it either blocks the traffic without further inspection or does not decrypt it, inspecting it with access control.

Requirements and Prerequisites for Decryption Policies

Create a decryption policy

A decryption policy is a rule-based security policy that controls how encrypted network traffic is handled.

Create decryption policy to protect outbound and inbound network connections through various rule actions.

You can create any of these types of decryption policies:

- *Outbound protection* policy with rules that protect outbound connections. The destination server is outside your protected network. This type of rule has a **Decrypt - Resign** rule action.

  Refer to Create a decryption policy with outbound connection protection, on page 1728 for guidance on creating a decryption rule with outbound connection.

- *Inbound protection* policy with a rule that protects inbound connections; that is, the destination server is inside your protected network. This type of rule has a **Decrypt - Known Key** rule action.

  Refer to Create a decryption policy with inbound connection protection, on page 1730 or guidance on creating a decryption rule with inbound connection.

- Other actions (including **Do Not Decrypt**, **Block**, and **Block with Reset**).

  See Create a decryption policy with other rule actions, on page 1737

Create a decryption policy with outbound connection protection

This task creates a decryption policy that protects outbound connections by intercepting and decrypting SSL/TLS traffic between internal clients and external servers, then re-encrypting the traffic with an internal CA certificate.

This task discusses how to create a decryption policy with a rule that protects outbound connections; that is, the destination server is outside your protected network. This type of rule has a **Decrypt - Resign** rule action.

When you create a decryption policy, you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules and multiple **Decrypt - Resign** rules.

Before you begin

You can optionally must upload or generate an internal CA certificate for your managed device before you can create a decryption policy that protects outbound connections. You can do this in any of the following ways:

- Create an internal CA certificate object by going to **Objects** > **Object Management** > **PKI** > **Internal CAs** and referring to PKI objects, on page 2389.
- At the time you create this decryption policy.

Follow these steps to create a decryption policy with outbound connection protection:

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Create Decryption Policy**.

Step 4 Give the policy a unique **Name** and, optionally, a **Description**.

The following characters are not supported in decryption policy names:

- Leading period
- `#,?,{,},=,$,<,>`

Step 5 Click the **Outbound Connections** tab.

Step 6 From the **Internal CA** list, upload or choose certificates for the rules.

For more information about internal certificates, see Generate an internal CA for outbound protection, on page 1735 and Upload an internal CA for outbound protection, on page 1736.

a) (Optional.) Choose networks and ports.

For more information:

- Network rule conditions, on page 1321
- Best practice: use application-based rules over port-based rules, on page 1323

What to do next

- Add rule conditions: Decryption Rule conditions, on page 1758
- Add a default policy action: Decryption policy default actions, on page 1739
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the *Cisco Secure Firewall Management Center Administration Guide* .

- Set advanced policy properties: Decryption policy advanced options, on page 1742.
- Associate the decryption policy with an access control policy as described in Associate prefilter, decryption, and identity policies with an access control, on page 1585.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Create a decryption policy with inbound connection protection

This task creates a decryption policy that protects inbound connections using either a **Decrypt - Known Key** rule action.

This task discusses how to create a decryption policy with a rule that protects inbound connections; that is, the destination server is inside your protected network. This type of rule has a **Decrypt - Known Key** rule action.

When you create a decryption policy, you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules and multiple **Decrypt - Resign** rules.

Before you begin

You must upload an internal certificate for your internal server before you can create a decryption policy that protects inbound connections. You can do this in any of the following ways:

- Create an internal certificate object by going to **Objects** > **Object Management** > **PKI** > **Internal Certs** and referring to PKI objects, on page 2389.
- At the time you create this decryption policy.

Follow these steps to create a decryption policy with inbound connection protection:

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Create Decryption Policy**.

Step 4 Perform these steps:

a) Give the policy a unique **Name** and, optionally, a **Description**.

The following characters are not supported in decryption policy names:

- Leading period
- `#,;,{,},=,$,<,>`

b) From the **Internal Certificates** list, upload or choose certificates for the rules.

For more information about internal CA certificates, see Internal certificate authority objects, on page 2390.

c) (Optional.) Choose networks and ports.

For more information:

- Network rule conditions, on page 1321
- Best practice: use application-based rules over port-based rules, on page 1323

d) Click **Next**.

Step 5 Continue with Configure Decryption policy exclusions, on page 1731.

Step 6 Click **Save**.

What to do next

- Add rule conditions: Decryption Rule conditions, on page 1758
- Add a default policy action: Decryption policy default actions, on page 1739
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Set advanced policy properties: Decryption policy advanced options, on page 1742.
- Associate the decryption policy with an access control policy as described in Associate prefilter, decryption, and identity policies with an access control, on page 1585.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Configure Decryption policy exclusions

This task helps you create exclusions in your decryption policy to prevent decryption of traffic that should remain encrypted for compliance, security, or functional reasons.

This task discusses how to exclude certain types of traffic from decryption. We create **Do Not Decrypt** rules in your decryption policy for this purpose. The rules are initially enabled only for an outbound decryption policy (a policy that uses the **Decrypt - Resign** policy action).

Before you begin

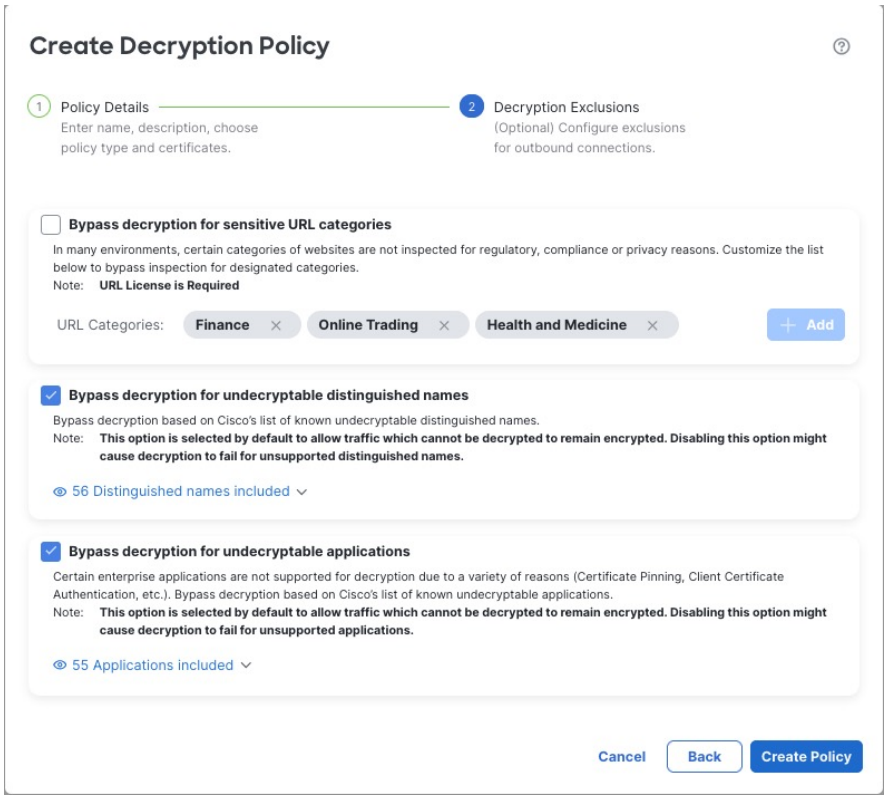
You must upload an internal CA certificate for your managed device before you can create a decryption policy that protects outbound connections. You can do this in any of the following ways:

- Create an internal CA certificate object by going to **Objects** > **Object Management** > **PKI** > **Internal CAs** and referring to PKI objects, on page 2389.
- At the time you create this decryption policy.

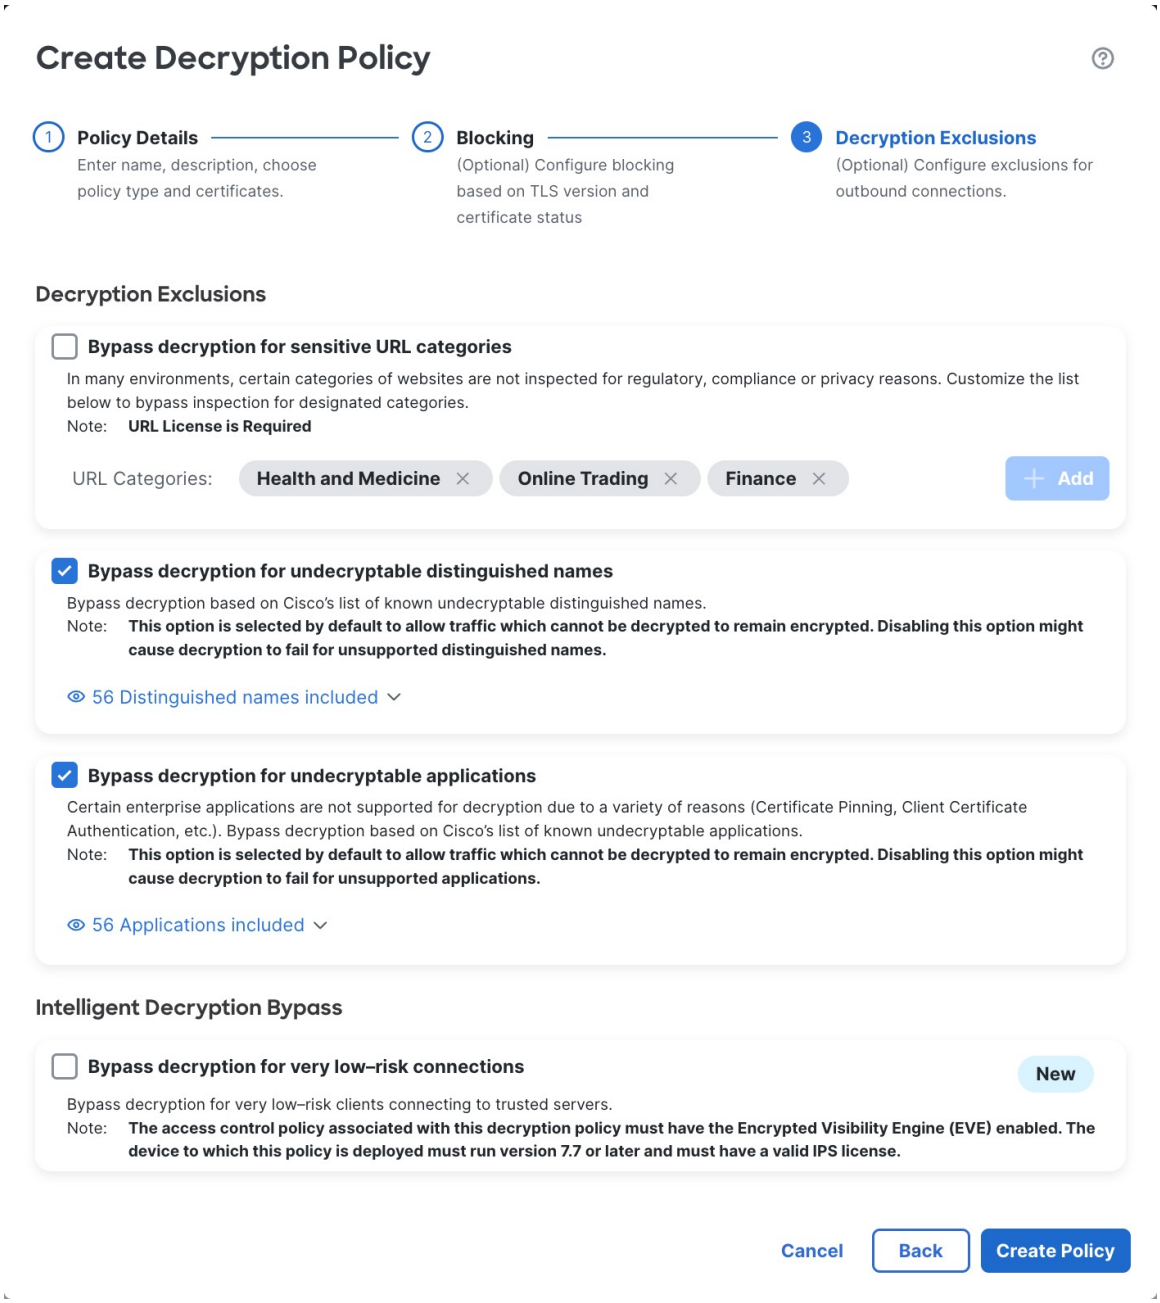
Follow these steps to configure decryption policy exclusions:

Procedure

Step 1 Complete the tasks discussed in:



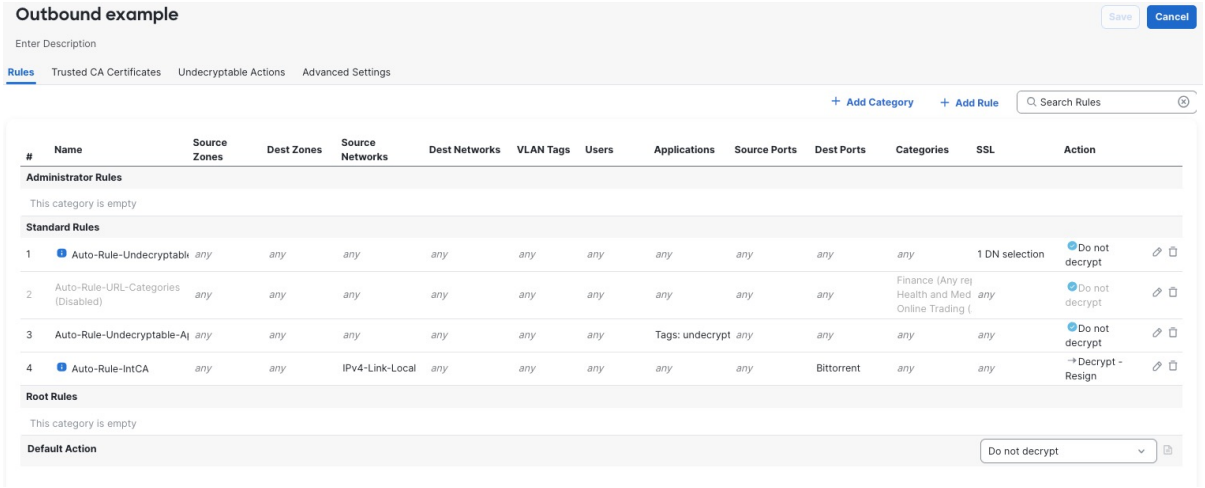
- Create a decryption policy with outbound connection protection, on page 1728
- For more information, see Create a decryption policy with inbound connection protection, on page 1730



Step 2 Select the appropriate exclusion options based on your security requirements.

The exclusions page provides the following options. All options are *enabled* for an outbound protection policy (**Decrypt - Resign** rule action) and *disabled* for all other decryption policy actions.

Item	Description
Bypass decryption for sensitive URL categories	Check the box to not decrypt traffic from the indicated categories. Depending on the laws in your area, decryption certain traffic, such as finance or health-related, might be prohibited. Consult an authority in your area for more information. Click **Add** to add more categories. Click **Delete** (✕) to remove categories.
Bypass decryption for undecryptable distinguished names	Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with *certificate pinning*, which is discussed in TLS/SSL certificate pinning guidelines, on page 1752. The list of undecryptable distinguished names is maintained by Cisco.
Bypass decryption for undecryptable applications	Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with *certificate pinning*, which is discussed in TLS/SSL certificate pinning guidelines, on page 1752. Undecryptable applications are updated automatically in the Vulnerability Database (VDB). You can find a list of all applications on the Secure Firewall Application Detectors page; the **undecryptable** tag identifies applications Cisco determines are undecryptable. The list of undecryptable applications is maintained by Cisco.



This figure shows default options.

Create Decryption Policy
1 Policy Details
Enter name, description, choose policy type and certificates.
2 Decryption Exclusions
(Optional) Configure exclusions for outbound connections.
Bypass decryption for sensitive URL categories
In many environments, certain categories of websites are not inspected for regulatory, compliance or privacy reasons. Customize the list below to bypass inspection for designated categories.
Note: URL License is Required
URL Categories:
Finance
Online Trading
Health and Medicine
Add
Bypass decryption for undecryptable distinguished names
Bypass decryption based on Cisco's list of known undecryptable distinguished names.
Note: This option is selected by default to allow traffic which cannot be decrypted to remain encrypted. Disabling this option might cause decryption to fail for unsupported distinguished names.
56 Distinguished names included
Bypass decryption for undecryptable applications
Certain enterprise applications are not supported for decryption due to a variety of reasons (Certificate Pinning, Client Certificate Authentication, etc.). Bypass decryption based on Cisco's list of known undecryptable applications.
Note: This option is selected by default to allow traffic which cannot be decrypted to remain encrypted. Disabling this option might cause decryption to fail for unsupported applications.
55 Applications included
Cancel
Back
Create Policy

Step 3 Click **Create Policy**.

This figure shows a sample outbound protection policy.

In the preceding example, the **Do Not Decrypt** rules corresponding to your choices for rule exclusions are automatically added before the **Decrypt - Resign** rule. The rule for sensitive URL categories is disabled because, by default, that exclusion is disabled. Had you selected the **Bypass decryption for sensitive URL categories** check box, the rule would have been enabled.

What to do next

- Add rule conditions: Decryption Rule conditions, on page 1758
- Add a default policy action: Decryption policy default actions, on page 1739
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the *Cisco Secure Firewall Management Center Administration Guide* .
- Set advanced policy properties: Decryption policy advanced options, on page 1742.
- Associate the decryption policy with an access control policy as described in Associate prefilter, decryption, and identity policies with an access control, on page 1585.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Generate an internal CA for outbound protection

This task allows you to generate an internal certificate authority object to protect outbound connections when creating a decryption rule.

This task discusses how you can optionally generate an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects** > **Object Management** as discussed in Upload a signed certificate issued in response to a CSR, on page 2394.

Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in Internal certificate authority objects, on page 2390.

Procedure

Step 1 From the **Internal CA** list, click **Create New** > **Generate CA**.

Step 2 Give the internal CA a **Name** and provide a two-letter **Country Name**.

Step 3 Click **Self-Signed** or **CSR**.

For more information about these options, see Internal certificate authority objects, on page 2390.

Step 4 Enter the requested information in the provided fields.

Step 5 Click **Save**.

Step 6 If you chose **CSR**, after the signing request has been completed, click **Install Certificate** as follows:

a) Repeat the preceding steps in this procedure.

b) Edit the CA from the **Internal CA** list as follows.

c) Click **Install Certificate**.

d) Follow the prompts on your screen to complete the task.

Step 7 Continue creating the policy as discussed in Create a decryption policy with outbound connection protection, on page 1728.

Upload an internal CA for outbound protection

Upload an internal certificate authority to create a decryption rule that protects outbound connections.

This task discusses how you can optionally upload an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects** > **Object Management** as discussed in Upload a signed certificate issued in response to a CSR, on page 2394.

Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in Internal certificate authority objects, on page 2390.

Follow these steps to upload an internal CA for outbound protection:

Procedure

Step 1 From the **Internal CA** list, click **Create New** > **Upload CA**.

Step 2 Give the internal CA a **Name**.

Step 3 Paste or browse to locate the certificate and its private key in the provided fields.

Step 4 If the CA has a password, select the **Encrypted** check box and enter the password in the adjacent field.

Step 5 Continue creating the policy as discussed in Create a decryption policy with outbound connection protection, on page 1728.

Upload an internal certificate for inbound protection

This task helps you manage certificate objects and configure decryption for secure access control by uploading an internal certificate for inbound protection.

This task discusses how to upload an internal certificate when you create a decryption rule that protects inbound connections. You can also upload the internal certificate using **Objects** > **Object Management** as discussed in Import a CA certificate and private key, on page 2391.

Before you begin

Make sure you have an internal certificate in one of the formats discussed in Internal certificate authority objects, on page 2390.

Follow these steps to upload an internal certificate for inbound protection:

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Create Decryption Policy**.

Step 4 Enter a name for the policy in the **Name** field and an optional description in the **Description** field.

Step 5 Click the **Inbound Connections** tab.

Step 6 From the **Internal Certificates** list, click **Add** (+).

Step 7 If an internal certificate object exists, click its name. Otherwise, click **Upload**.

a) Enter the required information.

See Add internal certificate objects, on page 2400.

Continue creating the decryption policy as discussed in Create a decryption policy with inbound connection protection, on page 1730.

Create a decryption policy with other rule actions

Create and manage decryption policies in the Secure Firewall Management Center to control encrypted traffic actions, such as **Do Not Decrypt**, **Block**, **Block With Reset**, or **Monitor**.

To create a decryption rule with a **Do Not Decrypt**, **Block**, **Block With Reset**, or **Monitor** rule action, create a decryption policy and edit the policy to add the rule.

When you create a decryption policy , you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules, and multiple **Decrypt - Resign** rules.

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Perform these actions:

a) Give the policy a unique **Name** and, optionally, a **Description**.

The following characters are not supported in decryption policy names:

- Leading period
- `#,;,{,},=,$,<,>`

b) Wait for the policy to be created.

Step 4 Click **Edit** ( ) next to the decryption policy name.

Step 5 Click **Add Rule**.

a) Give the rule a **Name**.

b) From the **Action** list, click a rule action and see one of the sections for more information:

- Decryption rule Do Not Decrypt action, on page 1778
- Decryption rule blocking actions, on page 1779
- Decryption rule monitor action, on page 1777

Step 6 Click **Save**.

What to do next

- Add rule conditions: Decryption Rule conditions, on page 1758
- Add a default policy action: Decryption policy default actions, on page 1739
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the *Cisco Secure Firewall Management Center Administration Guide* .
- Set advanced policy properties: Decryption policy advanced options, on page 1742.
- Associate the decryption policy with an access control policy as described in Associate prefilter, decryption, and identity policies with an access control, on page 1585.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Decryption policy default actions

The default action for a decryption policy determines how the system handles decryptable encrypted traffic that does not match any non-monitor rule in the policy. When you deploy a decryption policy without a decryption rules, the default action determines how all decryptable traffic on your network is handled. Note that the system does not perform any kind of inspection on encrypted traffic that the default action blocks.

To set the policy default action:

1. Log in to the Secure Firewall Management Center if you haven't already done so.
2. Click **Policies** > **Access Control heading** > **Decryption**.
3. Click **Edit** ( ) next to the name of the decryption policy.
4. In the Default Action row, click one of the actions from the list.

Table 100: Decryption policy Default Actions

Default Action	Effect on Encrypted Traffic
Block	Block the TLS/SSL session without further inspection.
Block with reset	Block the TLS/SSL session without further inspection and reset the TCP connection. Choose this option if traffic uses a connectionless protocol like UDP. In that case, the connectionless protocol tries to reestablish the connection until it is reset. This action also displays a connection reset error in the browser so the users are informed that the connection is blocked.
Do not decrypt	Inspect the encrypted traffic with access control.

Default handling options for undecryptable traffic

This reference provides information about identifying and managing undecryptable TLS/SSL traffic types in decryption policies. It covers handling handshake errors, unsupported cipher suites, compressed sessions, and session caching issues, along with user-facing actions for blocking or allowing such encrypted connections.

Table 101: Undecryptable traffic types

Type	Description	Default Action	Available Action
Compressed Session	The TLS/SSL session applies a data compression method.	Inherit default action	Do not decrypt Block Block with reset Inherit default action

Type	Description	Default Action	Available Action
SSLv2 Session	The session is encrypted with SSL version 2. Note that traffic is decryptable if the ClientHello message is SSL 2.0, and the remainder of the transmitted traffic is SSL 3.0.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Unknown Cipher Suite	The system does not recognize the cipher suite.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Unsupported Cipher Suite	The system does not support decryption based on the detected cipher suite.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Session not cached	The TLS/SSL session has session reuse enabled, the client and server reestablished the session with the session identifier, and the system did not cache that session identifier.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Handshake Errors	An error occurred during TLS/SSL handshake negotiation.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Decryption Errors	An error occurred during traffic decryption.	Block	Block Block with Reset

When you first create a decryption policy, logging connections that are handled by the default action is disabled by default. Because the logging settings for the default action also apply to undecryptable traffic handling, logging connections handled by the undecryptable traffic actions is disabled by default.

Note that if your browser uses certificate pinning to verify a server certificate, you cannot decrypt this traffic by re-signing the server certificate. For more information, see Decryption Rules guidelines and limitations, on page 1746.

If a decryption policy is associated with an access control policy that uses TCP state bypass, matching traffic is acted on based on the policy's configured **Undecryptable Actions** for **Handshake Errors**.

For example, if a decryption policy's **Handshake Errors** is set to **Block**, traffic matching the rule is blocked and the connection event's action is reported as a handshake error.

For more information about TCP state bypass, see:

- Configure TCP state bypass, on page 2200
- Bypass TCP state checks for asymmetrical routing (TCP state bypass), on page 2198

Related Topics

Set default handling for undecryptable traffic, on page 1741

Set default handling for undecryptable traffic

Set undecryptable traffic actions to handle certain types of encrypted traffic the system cannot decrypt or inspect, ensuring proper network security enforcement for encrypted connections.

You can set undecryptable traffic actions at the decryption policy level to handle certain types of encrypted traffic the system cannot decrypt or inspect. When you deploy adecryption policy that contains no decryption rules, the undecryptable traffic actions determine how all undecryptable encrypted traffic on your network is handled.

Depending on the type of undecryptable traffic, you can choose to:

- Block the connection.
- Block the connection, then reset it. This option is preferrable for connectionless protocols like UDP, which keep trying to connect until the connection is blocked.
- Inspect the encrypted traffic with access control.
- Inherit the default action from the decryption policy.

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** (✎) next to the name of the decryption policy.

Step 4 In the decryption policy editor, click **Undecryptable Actions**.

Step 5 For each field, choose either the decryption policy's default action or another action you want to take on the type of undecryptable traffic. See Default handling options for undecryptable traffic, on page 1739 and Decryption policy default actions, on page 1739 for more information.

Step 6 Click **Save** to save the policy.

What to do next

- Configure default logging for connections handled by the undecryptable traffic actions; see *Logging Connections with a Policy Default Action* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Decryption policy advanced options

A decryption policy 's **Advanced Settings** page contains global settings. These settings apply to all managed devices that are configured for Snort 3.

A decryption policy advanced settings are all ignored on any managed device that runs:

- A version earlier than 7.1
- Snort 2

Block flows requesting ESNI

Encrypted Server Name Indication (ESNI (link to draft proposal)) is a way for a client to tell a TLS 1.3 server what the client is requesting. Because the SNI is encrypted, the system cannot identify the server. You can choose to block these connections.

Disable HTTP/3 advertisement

This option strips HTTP/3 (RFC 9114) from the ClientHello in TCP connections. HTTP/3 is part of the QUIC transport protocol, not the TCP transport protocol. Blocking clients from advertising HTTP/3 provides protection against attacks and evasion attempts potentially burried within QUIC connections.

Propagate untrusted server certificates to clients

This setting applies only to traffic matching a **Decrypt - Resign** rule action.

Enable this option when the server certificate is untrusted. The managed device substitutes its certificate authority (CA) for the server certificate. An *untrusted* server certificate is one that is not listed as a trusted CA in the Secure Firewall Management Center. (**Objects** > **Object Management** > **PKI** > **Trusted CAs**).

Enable TLS 1.3 decryption

Whether to apply decryption rules to TLS 1.3 connections. If you do not enable this option, the decryption rules apply to TLS 1.2 or lower traffic only. See TLS 1.3 decryption best practices, on page 1743.

Enable adaptive TLS server identity probe

Automatically enabled when TLS 1.3 decryption is enabled. A *probe* is a partial TLS connection with the server, the purpose of which is to obtain the server certificate and cache it. (If the certificate is already cached, the probe is never established.)

If TLS 1.3 Server Identity Discovery is disabled on the access control policy with which the decryption policy is associated, we attempt to use the Server Name Indication (SNI), which is not as reliable.

The adaptive TLS server identity PROBE occurs on any of these conditions as opposed to on every connection as in earlier releases:

- Certificate Issuer—Matched when the value of **Issuer DNs** in a decryption rule's DN rule condition is matched.

  For more information, see Conditions for distinguished name rules in decryption policies, on page 1765.

- Certificate Status—Matched when any of the **Cert Status** conditions are matched in a decryption rule.

For more information, see Certificate Status Decryption rule conditions, on page 1771.

- Internal/External Certificate—Internal certificates can be matched by the certificate used in **Decrypt - Known Key** rule actions; external certificates can be matched in **Certificates** rule conditions.

  For more information, see Known key decryption for incoming traffic, on page 1716 and Certificate rule conditions, on page 1765.

- Application ID—Can be matched by **Applications** rule conditions in either an access control policy or a decryption policy.

  For more information, see Application rule conditions, on page 1322.

- URL Category—Can be matched by **URLs** rule conditions in an access control policy.

  For more information, see Recommendation: use URL conditions for website access control , on page 1324.

Note **Enable adaptive TLS server discovery mode** is not supported on any Secure Firewall Threat Defense Virtual deployed to AWS. If you have any such managed devices managed by the Secure Firewall Management Center, the connection event **PROBE_FLOW_DROP_BYPASS_PROXY** increments every time the device attempts to extract the server certificate.

TLS 1.3 decryption best practices

Both the decryption policy and the access control policy have advanced options that affect how traffic is handled, whether the traffic is being decrypted or not.

The advanced options are:

- Decryption policy:
  - TLS 1.3 decryption
  - TLS adaptive server identity probe
- Access control policy: TLS 1.3 Server Identity Discovery

  The access control policy setting takes precedence over the decryption policy setting.

Use the following table to decide which option to enable:

TLS adaptive server identity probe setting (decryption policy)	TLS 1.3 Server Identity Discovery setting (access control policy)	Result	Recommended when
Enabled	Disabled	Adaptive probe sent if decryption policy contains *any* rule conditions specified in Decryption policy advanced options, on page 1742 *and* if the server certificate is not cached.	• You're not using application or URL conditions in access control rules • You're decrypting traffic
Enabled	Enabled	Probe is always sent if the server certificate is not cached.	Use only if your access control rules have URL or application conditions
Disabled	Enabled	Probe is always sent if the server certificate is not cached.	Not recommended.
Disabled	Disabled	Probe is never sent.	Very limited usefulness; use only if not decrypting traffic and not using application or URL conditions in the access control rule

Note A cached TLS server's certificate is available to all Snort instances on a particular Firewall Threat Defense. The cache can be cleared with a CLI command and is automatically cleared when the device is rebooted.

For more information, see the discussion of TLS server identity discovery on secure.cisco.com.

CHAPTER 46

Decryption Rules

The following topics provide an overview of creating, configuring, managing, and troubleshooting decryption rules:

Note Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, refer to a resource such as SSL vs. TLS - What's the Difference?

- Decryption Rule overview, on page 1745
- Requirements and prerequisites for Decryption Rules, on page 1745
- Decryption Rules guidelines and limitations, on page 1746
- Decryption Rule traffic handling, on page 1754
- Decryption Rule conditions, on page 1758
- Decryption Rule actions, on page 1777
- Monitor TLS/SSL hardware acceleration, on page 1780

- Troubleshoot using crypto archives, on page 1790

Decryption Rule overview

Decryption rules provide a granular method of handling encrypted traffic across multiple managed devices, whether blocking the traffic without further inspection, not decrypting the traffic and inspecting it with access control, or decrypting the traffic for access control analysis.

Requirements and prerequisites for Decryption Rules

This reference provides the domain support and user role requirements necessary for Decryption Rules.

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin

Decryption Rules guidelines and limitations

Keep these points in mind when setting up your decryption rule. Properly configuring decryption rule is a complex task, but one that is essential to building an effective deployment that handles encrypted traffic. Many factors influence how you configure rules, including certain application behavior that you cannot control.

In addition, rules can preempt each other, require additional licenses, or contain invalid configurations. Thoughtfully configured rules can also reduce the resources required to process network traffic. Creating overly complex rules and ordering rules the wrong way can adversely affect performance.

For detailed information, see Best practices for access control rules, on page 1625.

For guidelines related specifically to TLS crypto acceleration, see TLS crypto acceleration, on page 1720.

Guidelines for using TLS/SSL decryption

General guideline

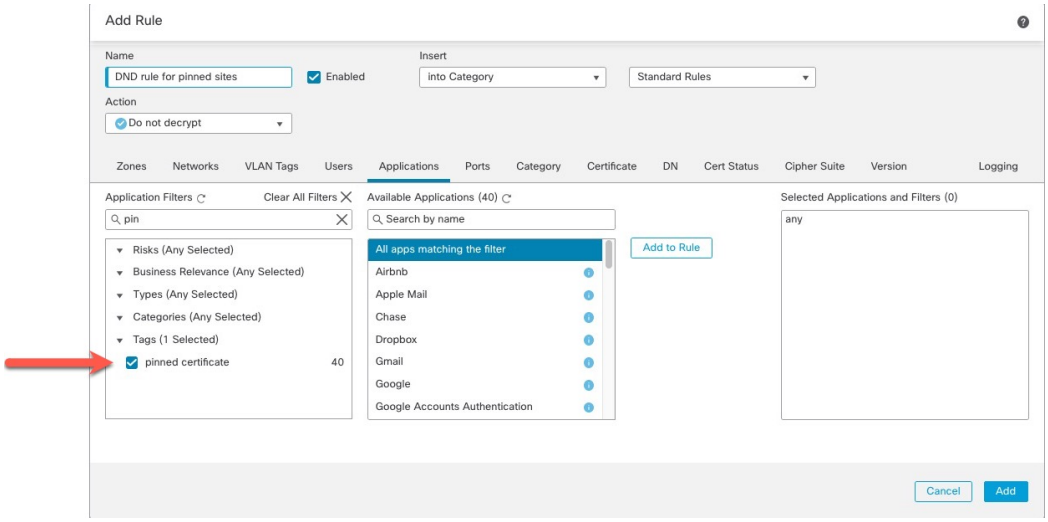
Decryption Rules require processing overhead that can impact performance. Determine which traffic must be decrypted and subjected to deep inspection before you set up any policies or rules.

- You cannot decrypt traffic on a device that uses passive interface.

- You cannot decrypt traffic on a device that uses inline tap interface.
- You cannot decrypt traffic on a device that uses TCP state bypass (only if the interfaces are in routed mode).

Guidelines for undecryptable traffic

We can determine that certain traffic is not decryptable either because the website itself is not decryptable or because the website uses TLS/SSL pinning, which effectively prevents users from accessing a decrypted site without errors in their browser.



For more information about certificate pinning, see TLS/SSL pinning, on page 1784.

We maintain the list of these sites as follows:

- A Distinguished Name (DN) group named **Cisco-Undecryptable-Sites**
- The **pinned certificate** or **undecryptable** application filter

If you are decrypting traffic and you do not want users to see errors in their browsers when going to these sites, we recommend you set up a **Do Not Decrypt** rule toward the bottom of your decryption rules.

An example of setting up a **pinned certificate** application filter follows.

Decryption Rules unsupported features

This reference provides guidance for handling RC4, DES, and TLS 1.3 limitations in the Cisco Firepower System, including configuration requirements for decryption policies when dealing with unsupported cipher suites and interface types.

RC4 cipher not unsupported

The Rivest Cipher 4 (also referred to as *RC4* or *ARC4* cipher is known to have vulnerabilities and is considered unsecure.

decryption policies identify the RC4 cipher suite as unsupported; you should configure the **Unsupported Cipher Suite** action in the decryption policies policy's **Undecryptable Actions** page to match your organization's requirements. For more information, see Default handling options for undecryptable traffic, on page 1739.

Passive, inline tap mode, and SPAN interfaces not supported

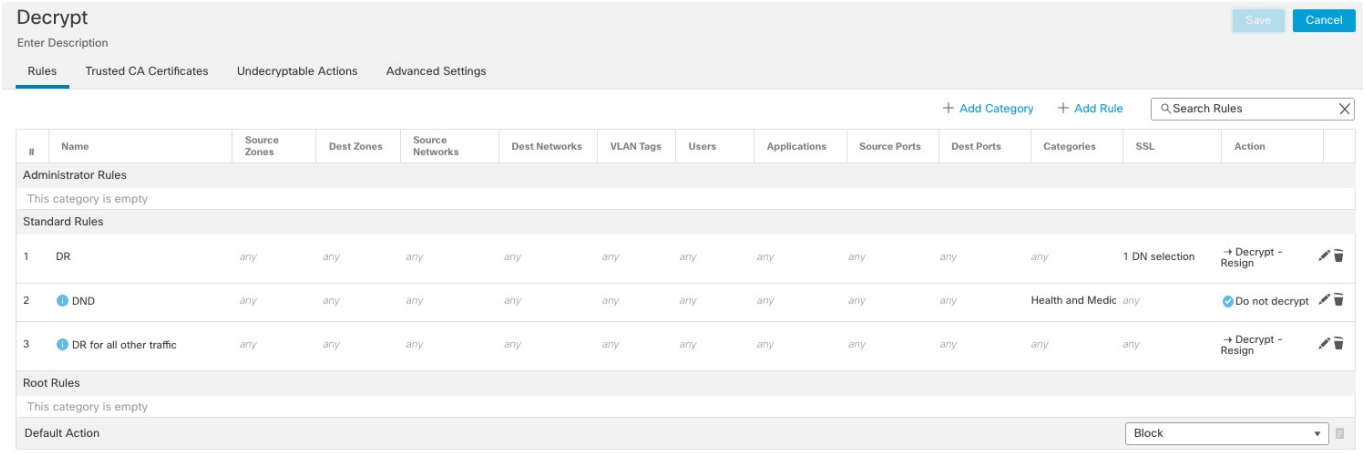
TLS/SSL traffic cannot be decrypted on passive, inline tap mode, or SPAN interfaces.

Guidelines for TLS/SSL Do Not Decrypt configuration

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information
- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as *TLS/SSL pinning*) must remain encrypted to prevent breaking the connection

Encrypted traffic can be allowed or blocked on any decryption rule condition, including, but not limited to:



- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)
- URL category and reputation
- Port
- User group

Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is not based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the WebMD website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for WebMD and everything else. General information about decryption rules can be found in Guidelines for using TLS/SSL decryption, on page 1746.

Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Recommendations for application control, on page 1622.

TLS/SSL Decrypt - Resign guidelines

You can associate one internal Certificate Authority (CA) certificate and private key with the **Decrypt - Resign** action. If traffic matches this rule, the system re-signs the server certificate with the CA certificate, then acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. Each session contains different cryptographic session details, and allows the system to decrypt and reencrypt traffic.

- Use the **Decrypt - Resign** rule action for decrypting *outgoing* traffic, as opposed to incoming traffic for which we recommend the **Decrypt - Known Key** rule action.

  For more information about **Decrypt - Known Key**, see TLS/SSL Decrypt - Known Key Guidelines, on page 1751.

- Always check the **Replace Key Only** check box when you set up a **Decrypt - Resign** rule action.

  When a user browses to a web site that uses a *self-signed* certificate, the user sees a security warning in the web browser and is aware that they are communicating with an unsecure site.

  When a user browses to a web site that uses a trusted certificate, the user does not see a security warning.

Certificate algorithm compatibility

If you configure a rule with the **Decrypt - Resign** action, the rule matches traffic based on the referenced internal CA certificate's signature algorithm type, in addition to any configured rule conditions. Because you associate one CA certificate with a **Decrypt - Resign** action, you cannot create a decryption rule that decrypts multiple types of outgoing traffic encrypted with different signature algorithms. In addition, any external certificate objects and cipher suites you add to the rule must match the associated CA certificate encryption algorithm type.

- For example, outgoing traffic encrypted with an elliptic curve (EC) algorithm matches a **Decrypt - Resign** rule only if the action references an EC-based CA certificate; you must add EC-based external certificates and cipher suites to the rule to create certificate and cipher suite rule conditions.
- Similarly, a **Decrypt - Resign** rule that references an RSA-based CA certificate matches only outgoing traffic encrypted with an RSA algorithm; outgoing traffic encrypted with an EC algorithm does not match the rule, even if all other configured rule conditions match.

Guidelines and limitations

Anonymous cipher suite unsupported:

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

- **Do not use Version or Cipher Suite rule conditions**:

Important *Never* use either **Cipher Suite** or **Version** rule conditions in a rule with a **Decrypt - Resign** or **Decrypt - Known Key** rule action. The use of these conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

- Decrypt - Resign rule action and a Certificate Signing Request: To use a **Decrypt - Resign** rule action, you should create a Certificate Signing Request (CSR) and have it signed by a trusted certificate authority. (You can use the FMC to create a CSR: **Objects** > **Object Management** > **PKI** > **Internal Certs**.)

  To be used in a **Decrypt - Resign** rule, your certificate authority (CA) must have at least one of these extensions

  - **CA: TRUE**

    For more information, see the discussion of Basic Constraints in RFC3280, section 4.2.1.10.

  - **KeyUsage=CertSign**

    For more information see RFC 5280, section 4.2.1.3.

  To verify your CSR or CA has at least one of the preceding extensions, you can use the **openssl** command as discussed in a reference such as the openssl documentation.

  This is necessary because for **Decrypt - Resign** inspection to work, the certificate that used in the decryption policy generates certificates on-the-fly and signs them so as to act as man-in-the middle and proxy all TLS/SSL connections.

- **Certificate pinning**: If the customer's browser uses certificate pinning to verify a server certificate, you cannot decrypt this traffic by re-signing the server certificate. To allow this traffic, configure a decryption rule with the **Do Not Decrypt** action to match the server certificate common name or distinguished name.
- **Non-matching cipher suite**: This error is displayed if you attempt to save a decryption rule with a cipher suite that does not match the certificate. To resolve the issue, see Verify TLS/SSL cipher suites, on page 1789.

```
Traffic cannot match this rule; none of your selected cipher suites contain a
signature algorithm that the resigning CA's signature algorithm
```

- **Untrusted Certificate Authority**: If the client does not trust the Certificate Authority (CA) used to re-sign the server certificate, it warns the user that the certificate should not be trusted. To prevent this, import the CA certificate into the client trusted CA store. Alternatively, if your organization has a private PKI, you can issue an intermediate CA certificate signed by the root CA which is automatically trusted by all clients in the organization, then upload that CA certificate to the device.
- **HTTP proxy limitation**: The system cannot decrypt traffic if an HTTP proxy is positioned between a client and your managed device, and the client and server establish a tunneled TLS/SSL connection using the CONNECT HTTP method. The **Handshake Errors** undecryptable action determines how the system handles this traffic.
- **Upload signed CA**: If you create an internal CA object and choose to generate a certificate signing request (CSR), you cannot use this CA for a **Decrypt - Resign** action until you upload the signed certificate to the object.
- **Mismatched signature algorithm**: If you configure a rule with the **Decrypt - Resign** action, and mismatch signature algorithm type for one or more external certificate objects or cipher suites, the policy editor displays an **Information** ( ) next to the rule. If you mismatch signature algorithm type for all external certificate objects, or all cipher suites, the policy displays a warning icon **Warning** ( ) next to the rule, and you cannot deploy the access control policy associated with the decryption policy.

TLS/SSL Decrypt - Known Key Guidelines

When you configure the **Decrypt - Known Key** action, you can associate one or more server certificates and paired private keys with the action. If traffic matches the rule, and the certificate used to encrypt the traffic matches the certificate associated with the action, the system uses the appropriate private key to obtain the session encryption and decryption keys. Because you must have access to the private key, this action is best suited to decrypt traffic incoming to servers your organization controls.

Also note the following:

Anonymous cipher suite unsupported

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

Cannot match on Distinguished Name or Certificate

You cannot match on **Distinguished Name** or **Certificate** rule conditions when creating a decryption rule with a **Decrypt - Known Key** action. The assumption is that if this rule matches traffic, the certificate, subject DN, and issuer DN already match the certificate associated with the rule.

Do not use Version or Cipher Suite rule conditions

Important *Never* use either **Cipher Suite** or **Version** rule conditions in a rule with a **Decrypt - Resign** or **Decrypt - Known Key** rule action. The use of these conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

Elliptic Curve Digital Signature Algorithm (*ECDSA*) certificate results in blocked traffic
(TLS 1.3 decryption enabled only.) If you use an ECDSA certificate with a **Decrypt - Known Key** rule action, matching traffic will be blocked. To avoid this, use a certificate with another type of certificate.

TLS/SSL block guidelines

If your decryption rule is associated with an access control policy that has a rule with an action of either **Interactive Block** or **Interactive Block with reset**, the system displays a customizable response page.

If you enabled logging in your rule, two connection events are displayed (in **Analysis** > **Unified Events**): One event for the interactive block and another event to indicate whether or not the user chose to continue to the site or not.

Related Topics

HTTP response pages, on page 1669

TLS/SSL certificate pinning guidelines

Some applications use a technique referred to as *TLS/SSL pinning* or *certificate pinning*, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a decryption rule with a **Decrypt - Resign** action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

Because TLS/SSL pinning is used to avoid man-in-the-middle attacks, there is no way to prevent or work around it. We recommend adding a **Do Not Decrypt** rule before the **Decrypt - Resign** rule so pinning traffic is excluded from being decrypted.

- Create a **Do Not Decrypt** for those applications rule ordered before **Decrypt - Resign** rules.
- Instruct users to access the applications using a web browser.

For more information about rule ordering, see Best practice for Decryption policy rule order.

To determine whether applications are using TLS/SSL pinning, see Troubleshoot TLS/SSL pinning, on page 1785.

TLS/SSL heartbeat guidelines

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

You can configure a **Max Heartbeat Length** in a Network Analysis Policy (NAP) to determine how to handle TLS heartbeats. For more information, refer to *The SSL Preprocessor* section in the "Custom Snort 2 Intrusion Policies for Access Control" document.

For more information, refer to TLS heartbeat, on page 1783.

TLS/SSL anonymous cipher suite limitation

Anonymous cipher suites impact decryption rules.

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

You can add an anonymous cipher suite to the **Cipher Suite** condition in a decryption rule, but the system automatically strips anonymous cipher suites during ClientHello processing. For the system to use the rule, you must also configure your decryption rules in an order that prevents ClientHello processing. For more information, refer to Best practice for Decryption policy rule order

TLS/SSL normalizer guidelines

If you enable the **Normalize Excess Payload** option in the inline normalization preprocessor, when the preprocessor normalizes decrypted traffic, it might drop a packet and replace it with a trimmed packet. This does not end the TLS/SSL session. If the traffic is allowed, the trimmed packet is encrypted as part of the TLS/SSL session.

Other Decryption Rule guidelines

Consider users and groups configuration when creating decryption rules. If you add a group or user to a rule, then change your realm settings to exclude that group or user, the rule has no effect. (The same applies to disabling the realm.) For more information about realms, see Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.

Consider all relevant categories when configuring decryption rules. If your decryption policy has a **Decrypt - Resign** action but web sites are not being decrypted, check **Category** page on rules associated with that policy.

In some cases, a web site redirects to another site for authentication or other purposes and the redirected site might have a different URL categorization than the site you're trying to decrypt. For example, `gmail.com` (**Web based email** category) redirects to `accounts.gmail.com` (**Internet Portals** category) for authentication. Be sure to include all relevant categories in the SSL rule.

Note In order to fully process traffic based on URL category, you must also configure URL filtering. See the URL Filtering Rules, on page 1651 chapter.

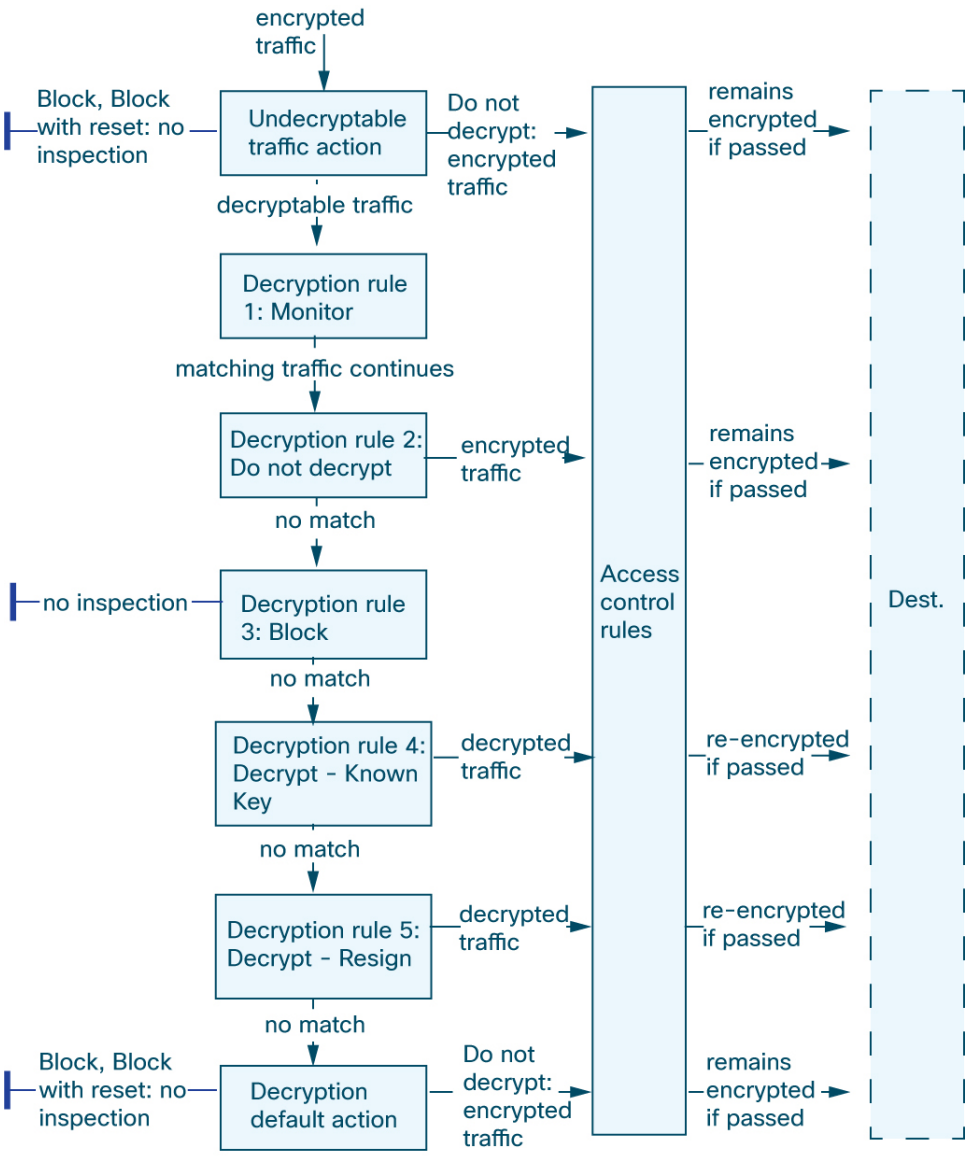
Consider configuring cloud query settings for URLs not in the local database. If you create a **Decrypt - Resign** rule and users browse to a web site whose category and reputation are not in the local database, data might

not be decrypted. Some web sites are not categorized in the local database and, if not, data from those web sites is not decrypted by default.

You can control this behavior with the **Query Cisco cloud for unknown URLs** setting in **Integration** > **Other Integrations** > **Cloud Services**

Decryption Rule traffic handling

Decryption Rule traffic handling is a security mechanism that matches traffic to decryption rules in a specified order to determine appropriate actions.



Traffic matching and processing behavior

The system matches traffic to decryption rules in the order you specify. In most cases, the system handles encrypted traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does inspect encrypted and undecryptable traffic with access control. However, some access control rule conditions require unencrypted traffic, so encrypted traffic may match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads.

Traffic handling process

This scenario summarizes the ways that Decryption Rule handle traffic in an inline deployment.

In this scenario, traffic is evaluated as follows:

- Undecryptable Traffic Action evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.
- Rule 1: Monitor evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.
- Rule 2: Do Not Decrypt evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.

- Rule 3: Block evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.
- Rule 4: Decrypt - Known Key evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule continues to the next rule.
- Rule 5: Decrypt - Resign is the final rule. If traffic matches, the system re-signs the server certificate with an uploaded CA certificate and decrypts traffic. The decrypted traffic is then evaluated against access control rules, which treat decrypted and unencrypted traffic the same. This additional inspection allows the system to block traffic. All remaining traffic is re-encrypted before being sent to its destination. Traffic that does not match the decryption rule rule continues to the next rule.
- Default Action handles all traffic that does not match any of the decryption rule. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

Encrypted traffic inspection configuration

You must create reusable public key infrastructure (PKI) objects to control encrypted traffic based on encrypted session characteristics and decrypt encrypted traffic. You can add this information on the fly when uploading trusted certificate authority (CA) certificates to the a decryption policy and creating decryption rule, creating the associated object in the process. However, configuring these objects ahead of time reduces the chance of improper object creation.

Decrypting encrypted traffic with certificates and paired keys

The system can decrypt incoming encrypted traffic if you configure an internal certificate object by uploading the server certificate and private key used to encrypt the session. If you reference that object in a decryption policy rule with an action of **Decrypt - Known Key** and traffic matches that rule, the system uses the uploaded private key to decrypt the session.

The system can also decrypt outgoing traffic if you configure an internal CA object by uploading a CA certificate and private key. If you reference that object in a decryption rule with an action of **Decrypt - Resign** and traffic matches that rule, the system re-signs the server certificate passed to the client browser, then acts as a man-in-the-middle to decrypt the session. You can optionally replace the self-signed certificate key only and not the entire certificate, in which case users see a self-signed certificate key notice in the browser.

Controlling traffic based on encrypted session characteristics

The system can control encrypted traffic based on the cipher suite or server certificate used to negotiate the session. You can configure one of several different reusable objects and reference the object in a decryption rule condition to match traffic. This table describes the different types of reusable objects you can configure:

If you configure...	You can control encrypted traffic based on whether...
A cipher suite list containing one or more cipher suites	The cipher suite used to negotiate the encrypted session matches a cipher suite in the cipher suite list

If you configure...	You can control encrypted traffic based on whether...
A trusted CA object by uploading a CA certificate your organization trusts	The trusted CA trusts the server certificate used to encrypt the session, whether: • The CA issued the certificate directly • The CA issued a certificate to an intermediate CA that issued the server certificate
An external certificate object by uploading a server certificate	The server certificate used to encrypt the session matches the uploaded server certificate
A distinguished name object containing a certificate subject or issuer distinguished name	The subject or issuer common name, country, organization, or organizational unit on the certificate used to encrypt the session matches the configured distinguished name

PKI objects, on page 2389

Decryption Rule order evaluation

Decryption Rule order evaluation determines the sequence in which the system evaluates decryption rules in a policy.

Rule evaluation process

When you create a decryption rule in a decryption policy , you specify its position using the **Insert** list in the rule editor. Decryption rules in an a decryption policy are numbered, starting at 1. The system matches traffic to decryption rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic flow), the system does *not* continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.

Rules that use *specific* conditions (such as network and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules.

Note Proper decryption rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.

Related Topics

Best practices for access control rules, on page 1625

Decryption Rule conditions

A decryption rule condition identifies the type of encrypted traffic the rule handles. Conditions can be simple or complex, and you can specify more than one condition type per rule. Only if traffic meets all the conditions in a rule does the rule apply to the traffic.

Condition evaluation and rule actions

If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion. For example, a rule with a certificate condition but no version condition evaluates traffic based on the server certificate used to negotiate the session, regardless of the session SSL or TLS version.

Every decryption policy has an associated action that determines handling and logging for matching encrypted traffic:

- Handling: Most importantly, the rule action governs whether the system will monitor, trust, block, or decrypt encrypted traffic that matches the rule's conditions.
- Logging: The rule action determines when and how you can log details about matching encrypted traffic.

Your TLS/SSL inspection configuration handles, inspects, and logs decrypted traffic:

- The decryption policy's undecryptable actions handle traffic that the system cannot decrypt.
- The policy's default action handles traffic that does not meet the condition of any non-Monitor decryption rule.

You can log a connection event when the system blocks or trusts an encrypted session. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. Connection logs for encrypted sessions contain details, such as the certificate used to encrypt that session. You can log only end-of-connection events.

- For blocked connections (Block, Block with reset), the system immediately ends the sessions and generates an event.
- For Do Not Decrypt connections, the system generates an event when the session ends.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Security zone rule conditions

A security zone rule condition is a network traffic control mechanism that

- segments your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices,
- controls or decrypts traffic by its source and destination security zones, and
- requires all interfaces in a zone to be of the same type (all inline, passive, switched, or routed).

Zone condition traffic matching

If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

All zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

Security zone conditions in multidomain environments

In a multidomain deployment, a zone created in an ancestor domain can contain interfaces that reside on devices in different domains. When you configure a zone condition in an descendant domain, your configurations apply to only the interfaces you can see.

Network rule conditions

A network condition is a traffic matching criterion that

- controls or decrypts traffic based on source and destination IP addresses using inner packet headers,
- enables administrators to specify exact IP addresses or blocks for granular policy enforcement, and
- can be built using predefined network objects or by manually entering IP addresses or address blocks.

Network rule condition restrictions

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

VLAN tag rule conditions

VLAN tags rule conditions are filtering mechanisms that

- control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic
- use the innermost VLAN tag to filter VLAN traffic, with the exception of prefilter policy which uses the outermost VLAN tag, and
- apply only to inline sets and do not match traffic on firewall interfaces.

VLAN tag rule conditions configuration details

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

User rule conditions

A user rule condition is a traffic matching mechanism that

- matches traffic based on whether the user initiating the connection or the group to which they belong
- can be configured for users in Microsoft Active Directory realms only, and
- enables policy enforcement based on user identity and group membership.

Special identities users

In addition to configuring users and groups for configured realms, you can set policies for the special identities users:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.

User rule condition example

Configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

Application rule conditions

Application rule conditions are application awareness and control mechanisms that

- identify and classify applications through IP traffic analysis
- enable control with organized filters
- require one enabled detector for each condition.

Application filters and control benefits

System-provided *application filters* help perform control by organizing applications according to basic characteristics, such as type, risk, business relevance, category, and tags. You can also create reuseable, user-defined filters using combinations of system-provided filters, or custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled, the system automatically enables all available system-provided detectors, or the most recently modified user-defined detector. For more information about application detectors, see Application detectors, on page 2284.

You can utilize both application filters and individually specified applications to ensure complete coverage. Understand the application's requirements to effectively order access control rules.

Application filters help you to quickly configure application control effectively. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

The system characterizes detected applications using several criteria which form effective filters.

Table 102: Application characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email applications are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.

Characteristic	Description	Example
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged `high bandwidth` and `displays ads`.

Best practice: use application-based rules over port-based rules

Use application filtering criteria instead of port filtering to target traffic. Applications can be configured to use unique ports to bypass access control blocks.

Port conditions allow you to control traffic by its source and destination ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

The traditional method targets applications by using port specifications, but applications can manipulate unique ports to bypass these controls

Application filtering is recommended for applications to avoid blocking legitimate applications, like Firewall Threat Defense, that dynamically open separate channels for control and data flow. Port-based access control rules could block such applications, impacting desirable operations.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP).

- For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).
- If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

Category rule conditions

Category rule conditions are policy elements that

- enable control of web access based on Cisco Talos intelligence
- support policy creation through URL filtering without relying on company vertical, intent, or declared security, and
- can be included in decryption policies to manage encrypted traffic.

Additional information

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from

its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security.

For more information, see URL filtering, on page 1651.

If you are using category rule conditions in decryption policies in a rule with the **Do Not Decrypt** rule action, see Decryption rule Do Not Decrypt action, on page 1778.

Server certificate-based rule conditions

Server certificate-based rule conditions are decryption rules configurations that

- handle and decrypt encrypted traffic based on server certificate characteristics
- inspect traffic using certificate attributes, status, cipher suites, and session versions, and
- enhance secure traffic management and visibility through certificate validation criteria.

Server certificate attribute conditions

You can configure decryption rules based on these server certificate attributes:

- **Distinguished name conditions**: Allow you to handle and inspect encrypted traffic based on the CA that issued a server certificate, or the certificate holder. Based on the issuer distinguished name, you can handle traffic based on the CA that issued a site's server certificate.
- **Certificate conditions**: In decryption rules allow you to handle and inspect encrypted traffic based on the server certificate used to encrypt that traffic. You can configure a condition with one or more certificates; traffic matches the rule if the certificate matches any of the condition's certificates.
- **Certificate status conditions**: In decryption rules allow you to handle and inspect encrypted traffic based on the status of the server certificate used to encrypt the traffic, including whether a certificate is valid, revoked, expired, not yet valid, self-signed, signed by a trusted CA, whether the Certificate Revocation List (CRL) is valid; whether the Server Name Indication (SNI) in the certificate matches the server in the request.
- **Cipher suite conditions**: In decryption rules allow you to handle and inspect encrypted traffic based on the cipher suite used to negotiate the encrypted session.
- **Session conditions**: In decryption rules allow you to inspect encrypted traffic based on the SSL or TLS version used to encrypt the traffic.

To detect multiple cipher suites in a rule, the certificate issuer, or the certificate holder, you can create reusable cipher suite list and distinguished name objects and add them to your rule. To detect the server certificate and certain certificate statuses, you must create external certificate and external CA objects for the rule.

Certificate rule conditions

When you build a certificate-based decryption rule condition, you can upload a server certificate and save it as an external certificate *object* The certificate object is reusable and associates a name with a server certificate. Alternately, you can configure certificate conditions with existing external certificate objects and object groups.

You can search the **Available Certificates** field in the rule condition based for external certificate objects and object groups based on these certificate distinguished name characteristics:

- Subject or issuer common name (CN), or if the URL is contained in the certificate's Subject Alternative Name (SAN)

  The URL the user enters in the browser matches the Common Name (CN)

- Subject or issuer organization (O)
- Subject or issuer organizational unit (OU)

You can choose to match against multiple certificates in a single certificate rule condition. If the certificate used to encrypt the traffic matches any of the uploaded certificates, the encrypted traffic matches the rule.

You can add a maximum of 50 external certificate objects and external certificate object groups to the **Selected Certificates** in a single certificate condition.

Note these items:

- You cannot configure a certificate condition if you also select the **Decrypt - Known Key** action. That action requires you to select a server certificate to decrypt traffic. Therefore, the certificate already matches the traffic.
- If you configure a certificate condition with an external certificate object, any cipher suites you add to a cipher suite condition or internal CA objects you associate with the **Decrypt - Resign** action, must match the external certificate's signature algorithm type. For example, if your rule's certificate condition references an EC-based server certificate, any cipher suites you add or CA certificates you associate with the **Decrypt - Resign** action, must also be EC-based. If you mismatch signature algorithm types in this case, the policy editor displays a warning next to the rule.
- When the system first detects an encrypted session to a new server, it does not have certificate data for ClientHello processing. As a result, the first session may not be decrypted. After the initial session, the managed device caches data from the server Certificate message. For subsequent connections from the same client, the system can match the ClientHello message conclusively to rules with certificate conditions and process the message to maximize decryption potential.

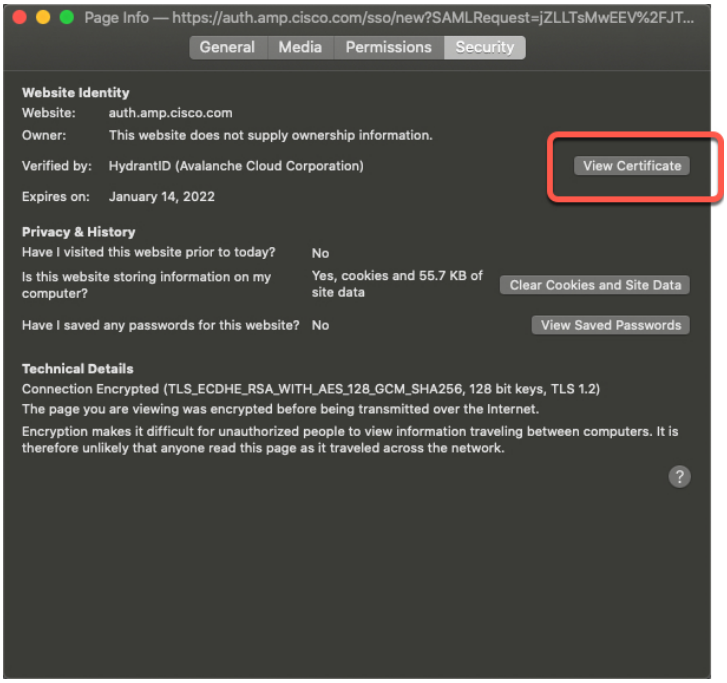
Conditions for distinguished name rules in decryption policies

Learn to use distinguished name conditions in a decryption rule. If you're not sure, you can find a certificate's Subject Alternative Name (SAN) and Common Name using a web browser. You can then you can add those values to a decryption rule as distinguished name conditions.

For detailed information about SANs, see RFC 5280, section 4.2.1.6.

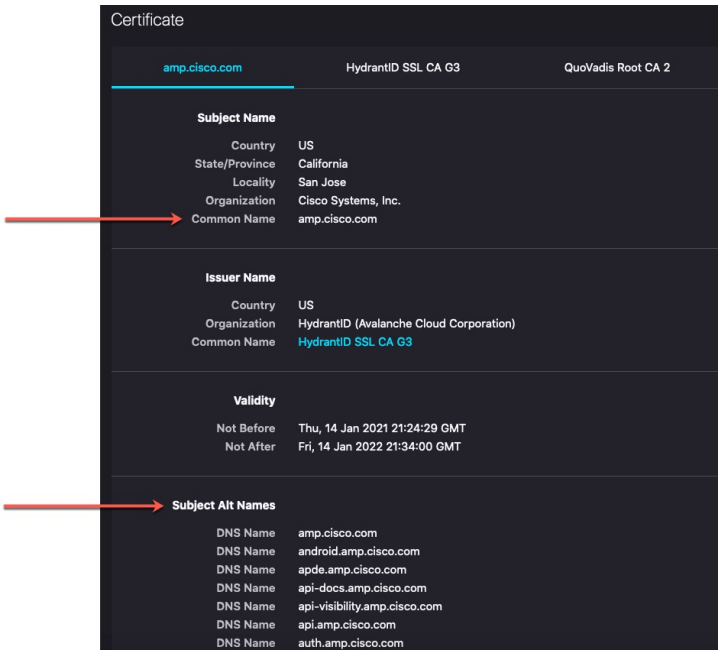
Overview

Distinguished name (DN) conditions allow you to specify certificate field values in decryption rules. This helps control which encrypted traffic is decrypted or excluded from decryption based on the certificate's Common Name (CN) and Subject Alternative Name (SAN)



Identifying Certificate Values

Use these steps to find a certificate's Common Name. These steps also work to find the Common Name and SANs for a self-signed certificate.



These instructions use Firefox as an example, but other browsers work similarly. The following procedure uses `amp.cisco.com` as an example.

1. Browse to `amp.cisco.com` in Firefox.
2. In the browser's location bar, to the left of the URL, click .
3. Click **Connection secure** > **More Information**.

   (For a non-secure or self-signed certificate, click **Connection not secure** > **More Information**.)
4. On the Page Info dialog box, click **View Certificate**.

5. The next page shows certificate details.

Note the following:

- `CN=auth.amp.cisco.com`, if used as a DN rule condition, would match ONLY that host name (that is, SNI). The SNI `amp.cisco.com` would NOT match.
- Wildcards can be used in DNs to match multiple domains.

  For example, to match `auth.amp.cisco.com`, use `CN=*.amp.cisco.com`. To match `auth.us.amp.cisco.com`, use `CN=*.*.amp.cisco.com`.

  A DN like `CN=*.example.com` matches `www.example.com` but NOT `example.com`. To match both SNIs, use two DNs in the rule condition.
- Avoid overly broad wildcards like `CN=*.google.com` matches a very large number of SANs. Instead of `CN=*.google.com`, use a DN object like `CN=*.youtube.com` as the DN object so it matches names like `www.youtube.com`.

  You can also use variations of the SNI that match SANs like `CN=*.youtube.com`, `CN=youtu.be`, `CN=*.yt.be`, and so on.
- A self-signed certificate should work the same way. You can confirm it's a self-signed certificate by the fact the issuer DN is the same as the subject DN.

Example: DN rule matching

Suppose you want to prevent decryption for traffic going to `amp.cisco.com` or YouTube. Configure DN rule conditions such as:

These DN conditions would match URLs like:

- www.amp.cisco.com
- auth.amp.cisco.com
- auth.us.amp.cisco.com
- www.youtube.com
- kids.youtube.com
- www.yt.be

These DN conditions would not match any of the URLs listed, so the traffic would not match the Do Not Decrypt rule. However, it might match another decryption rules in the same decryption policy .

- amp.cisco.com
- youtube.com

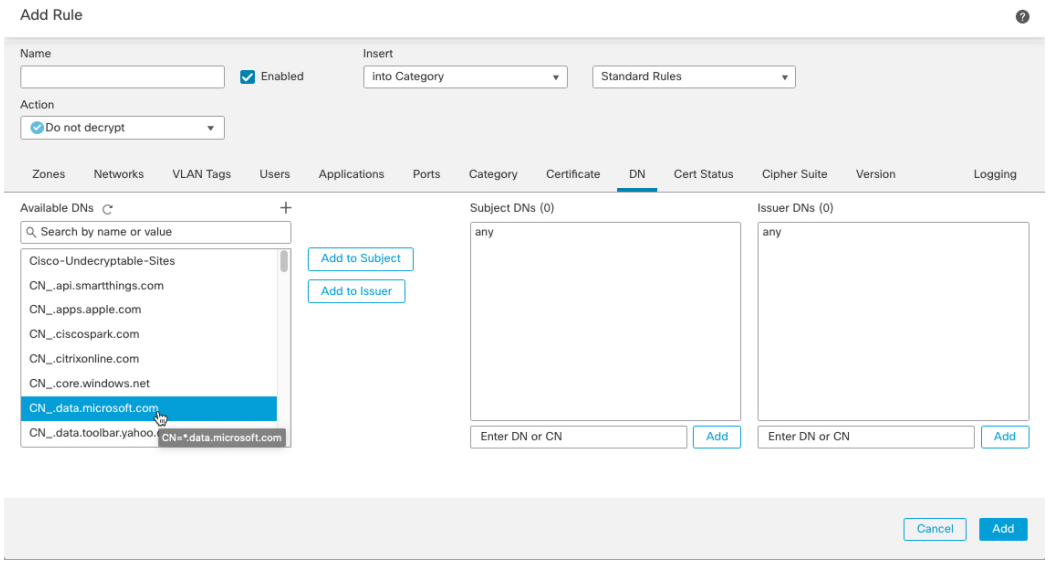
- yt.be

To match any of the preceding host names, add more CNs to the rule (for example, adding `CN=yt.be` would match that URL.)

System behavior: SNI and SANs usage

The host name in the client request is called the Server Name Indication (SNI). During the TLS handshake, the client specifies which hostname they want to connect to (for example, `auth.amp.cisco.com`) using the SNI extension. The server then selects the corresponding private key and certificate chain that are required to establish the connection while hosting all certificates on a single IP address.

If the SNI matches the CN or a SAN in the certificate, the SNI is used for DN rule matching.



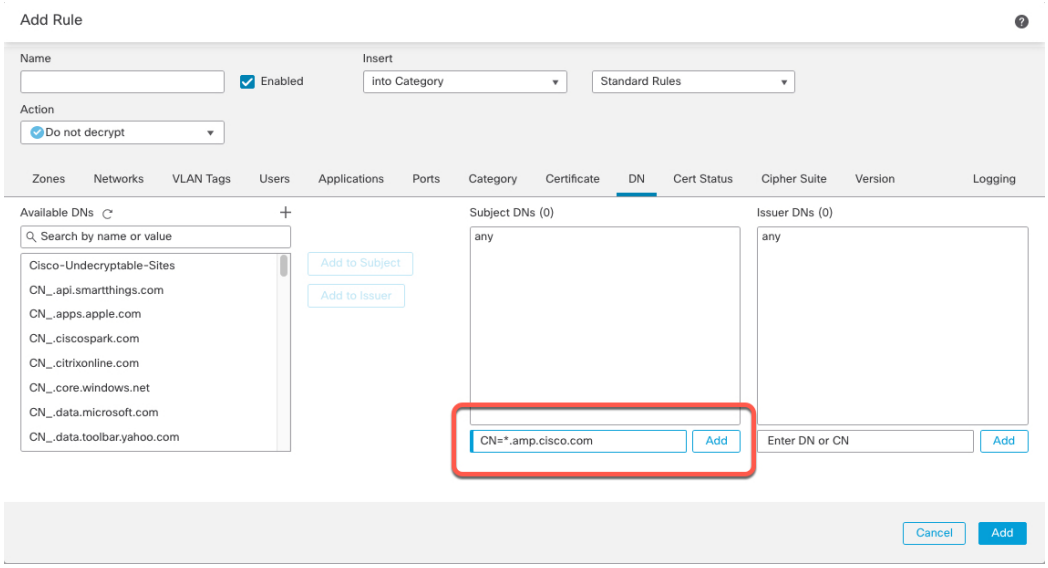
If there is no SNI, or the SNI does not match the certificate, the CN is used for DN rule matching.

Add a DN rule condition

After you identify the CN you want to match,, edit the decryption rule by using an existing DN, creating a new DN object, or adding the DN directly.

- Use an existing DN.

  Click the name of a DN and then click either **Add to Subject** or **Add to Issuer**. (**Add to Subject** is much more common.) To view the value of a DN object, hover the mouse pointer over it.)



- Create a new DN object.

  Click **Add** (+) to the right of Available DNs. The DN object must consist of a name and a value.

- Add the DN directly.

  Enter the DN in the field at the bottom of the **Subject DNs** field or the **Issuer DNs** field. (**Subject DNs** is more common.) After you enter the DN, click **Add**.

Trust external certificate authorities

Trust CAs by adding root and intermediate CA certificates to your decryption policy, then use these trusted CAs to verify server certificates used to encrypt traffic.

If a trusted CA certificate contains an uploaded certificate revocation list (CRL), you can also verify whether a trusted CA revoked the encryption certificate.

Tip Upload all certificates in a root CA's chain of trust to the list of trusted CA certificates, including the root CA certificate and all intermediate CA certificates. Otherwise, it is more difficult to detect trusted certificates issued by intermediate CAs. Also, if you configure certificate status conditions to trust traffic based on the root issuer CA, all traffic within a trusted CA's chain of trust can be allowed without decryption, rather than unnecessarily decrypting it.

For more information, see Trusted CA objects, on page 2396.

Note When you create a decryption policy, the policy's **Trusted CA Certificate** tab page is populated with several trusted CA certificates, including the **Cisco-Trusted-Authorities** group, which is added to the **Select Trusted CAs** list.

Procedure

Step 1 Log in to the Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** ( ) next to the decryption policy to edit.

Step 4 Click **Add Rule** to add a new decryption rule or click **Edit** ( ) to edit an existing rule.

Step 5 Click the **Certificates** tab.

Step 6 Find the trusted CAs you want to add from the **Available Certificates**, as follows:

- To add a trusted CA object on the fly, which you can then add to the condition, click **Add** ( ) above the **Available Certificates** list.
- To search for trusted CA objects and groups to add, click the **Search by name or value** prompt above the **Available Certificates** list, then enter either the name of the object, or a value in the object. The list updates as you type to display matching objects.

Step 7 To select an object, click it. To select all objects, right-click and then **Select All**.

Step 8 Click **Add to Rule**.

Tip You can also drag and drop selected objects.

Step 9 Add or continue editing the rule.

The trusted CA certificates are configured in your decryption policy and can be used to verify server certificates for secure traffic inspection.

What to do next

- Add a certificate status decryption rule condition to your SSL rule.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Certificate Status Decryption rule conditions

For each certificate status decryption rule you configure, you can match traffic against the presence or absence of a given status. You can select several statuses in one rule condition. If the certificate matches any of the selected statuses, the rule matches the traffic.

You can choose to match against the presence or absence of multiple certificate statuses in a single certificate status rule condition. The certificate needs to match only one of the criteria to match the rule.

You should consider, when setting this parameter, whether you're configuring a decrypt rule or a block rule. Typically, you should click **Yes** for a block rule and **No** for a decrypt rule. Examples:

- If you're configuring a **Decrypt - Resign** rule, the default behavior is to decrypt traffic with an expired certificate. To change that behavior, click **No** for **Expired** so traffic with an expired certificate is not decrypted and resigned.
- If you're configuring a **Block** rule, the default behavior is to allow traffic with an expired certificate. To change that behavior click **Yes** for **Expired** so traffic with an expired certificate is blocked.

This table describes how the system evaluates encrypted traffic based on the status of the encrypting server's certificate.

Table 103: Certificate status rule condition criteria

Status Check	Status Set to Yes	Status Set to No
Revoked	The policy trusts the CA that issued the server certificate, and the CA certificate uploaded to the policy contains a CRL that revokes the server certificate.	The policy trusts the CA that issued the ser certificate, and the CA certificate uploaded policy does not contain a CRL that revoke certificate.
Self-signed	The detected server certificate contains the same subject and issuer distinguished name.	The detected server certificate contains dif subject and issuer distinguished names.
Valid	All of these are true: • The policy trusts the CA that issued the certificate. • The signature is valid. • The issuer is valid. • None of the policy's trusted CAs revoked the certificate. • The current date is between the certificate Valid From and Valid To date.	At least one of these is true: • The policy does not trust the CA that certificate. • The signature is invalid. • The issuer is invalid. • A trusted CA in the policy revoked th certificate. • The current date is before the certifica From date. • The current date is after the certificate date.
Invalid signature	The certificate's signature cannot be properly validated against the certificate's content.	The certificate's signature is properly validat the certificate's content.
Invalid issuer	The issuer CA certificate is not stored in the policy's list of trusted CA certificates.	The issuer CA certificate is stored in the po of trusted CA certificates.
Expired	The current date is after the certificate Valid To date.	The current date is before or on the certific To date.
Not yet valid	The current date is before the certificate Valid From date.	The current date is after or on the certificat From date.

Status Check	Status Set to Yes	Status Set to No
Invalid certificate	The certificate is not valid. At least one of these is true: • Invalid or inconsistent certificate extension; that is, a certificate extension had an invalid value (for example, an incorrect encoding) or some value inconsistent with other extensions. • The certificate cannot be used for the specified purpose. • The Basic Constraints path length parameter has been exceeded. For more information, see RFC 5280, section 4.2.1.9. • The certificate's value for Not Before or Not After is invalid. These dates can be encoded as UTCTime or GeneralizedTime For more information, see RFC 5280 section 4.1.2.5. • The format of the name constraint is not recognized; for example, an email address format of a form not mentioned in RFC 5280, section 4.2.1.10. This could be caused by an improper extension or some new feature not currently supported. An unsupported name constraint type was encountered. OpenSSL currently supports only directory name, DNS name, email, and URI types. • The root certificate authority is not trusted for the specified purpose. • The root certificate authority rejects the specified purpose.	The certificate is valid. All of these are • Valid certificate extension. • The certificate can be used for the purpose. • Valid Basic Constraints path lengt • Valid values for Not Before and N • Valid name constraint. • The root certificate is trusted for t purpose. • The root certificate accepts the spec

Status Check	Status Set to Yes	Status Set to No
Invalid CRL	The Certificate Revocation List (CRL) digital signature is not valid. At least one of these is true: • The value of the CRL's Next Update or Last Update field is invalid. • The CRL is not yet valid. • The CRL has expired. • An error occurred when attempting to verify the CRL path. This error occurs only if extended CRL checking is enabled. • CRL could not be found. • The only CRLs that could be found did not match the scope of the certificate.	The CRL is valid. All of these are true: • Next Update and Last Update fields a • The CRL's date is valid. • The path is valid. • The CRL was found. • The CRL matches the certificate's sco
Server mismatch	The server name does not match the server's Server Name Indication (SNI) name, which could indicate an attempt to spoof the server name.	The server name matches the SNI name of to which the client is requesting access.

Note that even though a certificate might match more than one status, the rule causes an action to be taken on the traffic only once.

Checking whether a CA issued or revoked a certificate requires uploading root and intermediate CA certificates and associated CRLs as objects. You then add these trusted CA objects to an decryption policy's list of trusted CA certificates.

Cipher suite rule conditions

The system provides predefined cipher suites you can add to a cipher suite rule condition for Block or Block WITH Reset rule actions. You can also add cipher suite list objects containing multiple cipher suites.

Important Cipher suite rule conditions should be used only to *block* traffic, they should not be used to *decrypt* traffic.

Note You cannot add new cipher suites. You can neither modify nor delete predefined cipher suites.

You can add a maximum of 50 cipher suites and cipher suite lists to the **Selected Cipher Suites** in a single cipher suite condition. The system supports adding these cipher suites to a cipher suite condition:

- SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA
- SSL_RSA_FIPS_WITH_DES_CBC_SHA
- TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA

- TLS_DHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_DHE_RSA_WITH_CAMELLIA_128_CBC_SHA
- TLS_DHE_RSA_WITH_CAMELLIA_128_CBC_SHA256
- TLS_DHE_RSA_WITH_CAMELLIA_256_CBC_SHA
- TLS_DHE_RSA_WITH_CAMELLIA_256_CBC_SHA256
- TLS_DHE_RSA_WITH_DES_CBC_SHA
- TLS_DH_Anon_WITH_AES_128_GCM_SHA256
- TLS_DH_Anon_WITH_AES_256_GCM_SHA384
- TLS_DH_Anon_WITH_CAMELLIA_128_CBC_SHA
- TLS_DH_anon_WITH_CAMELLIA_128_CBC_SHA256
- TLS_DH_Anon_WITH_CAMELLIA_256_CBC_SHA
- TLS_DH_anon_WITH_CAMELLIA_256_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_3DES_EDE_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_ECDSA_WITH_NULL_SHA
- TLS_ECDHE_ECDSA_WITH_RC4_128_SHA
- TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384

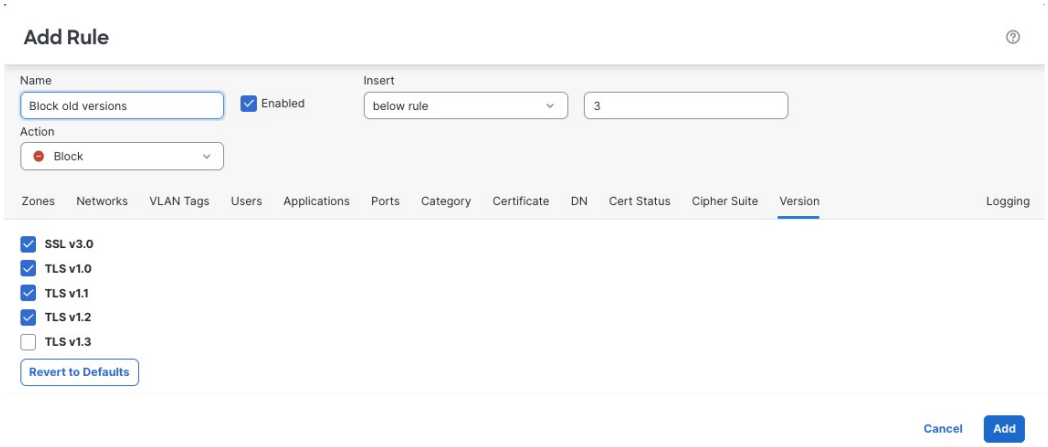
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_NULL_SHA
- TLS_ECDHE_RSA_WITH_RC4_128_SHA
- TLS_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA256
- TLS_RSA_WITH_AES_128_GCM_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_RSA_WITH_AES_256_GCM_SHA384
- TLS_RSA_WITH_CAMELLIA_128_CBC_SHA
- TLS_RSA_WITH_CAMELLIA_128_CBC_SHA256
- TLS_RSA_WITH_CAMELLIA_256_CBC_SHA
- TLS_RSA_WITH_CAMELLIA_256_CBC_SHA256
- TLS_RSA_WITH_DES_CBC_SHA
- TLS_RSA_WITH_NULL_MD5
- TLS_RSA_WITH_NULL_SHA
- TLS_RSA_WITH_RC4_128_MD5
- TLS_RSA_WITH_RC4_128_SHA

Note these considerations:

- If you add cipher suites not supported for your deployment, you cannot deploy your configuration. For example, passive deployments do not support decrypting traffic with the any of the ephemeral Diffie-Hellman (DHE) or ephemeral elliptic curve Diffie-Hellman (ECDHE) cipher suites. Creating a rule with these cipher suites prevents you from deploying your access control policy.
- You can add an anonymous cipher suite to the **Cipher Suite** condition in decryption policy. To use the rule, you must also configure your settings in an order that prevents ClientHello processing. For more information, refer to Best practice for Decryption policy rule order.
- When you specify a cipher suite as a rule condition, the rule matches the negotiated cipher suite in the ServerHello message, not the entire list from the ClientHello message. During ClientHello processing, the managed device removes unsupported cipher suites from the ClientHello message. If all specified cipher suites are removed, the system retains the original list. If the system keeps unsupported cipher suites, it cannot decrypt the session during subsequent evaluation.

Encryption protocol version rule conditions

You can choose to match against traffic encrypted with SSL version 3.0, or TLS version 1.0, 1.1, or 1.2. By default, all protocol versions are selected when you create a rule; if you select multiple versions, encrypted traffic that matches any of the selected versions matches the rule. You must select at least one protocol version when saving the rule condition.



You can use SSL 3.0 in a Do Not Decrypt, Block, or Block with Reset rule action.

You *cannot* select SSL v2.0 in a version rule condition; the system does not support decrypting traffic encrypted with SSL version 2.0. You can configure an undecryptable action to allow or block this traffic without further inspection. For more information, see Set default handling for undecryptable traffic, on page 1741.

Important Protocol version rule conditions should be used *only* to *block* traffic, they should not be used to *decrypt* traffic.

For example, to block all SSL v3.0, TLS v1.0, TLS v1.1, and TLS v1.2 traffic, set the options as follows:

Figure 412: Block all SSL v3.0, TLS v1.0, TLS v1.1, and TLS 1.2 traffic

Decryption Rule actions

Decryption Rule actions are operational functions that define how the system processes SSL/TLS traffic based on configured decryption rules.

Available actions

The system provides various actions for decryption rule.

Decryption rule monitor action

The **Monitor** action is not designed to permit or deny traffic. Rather, its primary purpose is to force connection logging, regardless of how matching traffic is eventually handled. The ClientHello message is not modified if traffic matches a **Monitor** rule condition.

Monitor action traffic handling

Traffic that matches a **Monitor** rule is processed in this sequence:

1. Traffic matches the Monitor rule condition and connection logging is forced.
2. Traffic is then matched against additional rules, if present, to determine whether to trust, block, or decrypt it.
3. The first non-Monitor rule matched determines traffic flow and any further inspection.
4. If there are no additional matching rules, the system uses the default action.

The system automatically logs end-of connection events for monitored traffic to the Secure Firewall Management Center database, regardless of the logging configuration of the rule or default action that later handles the connection.

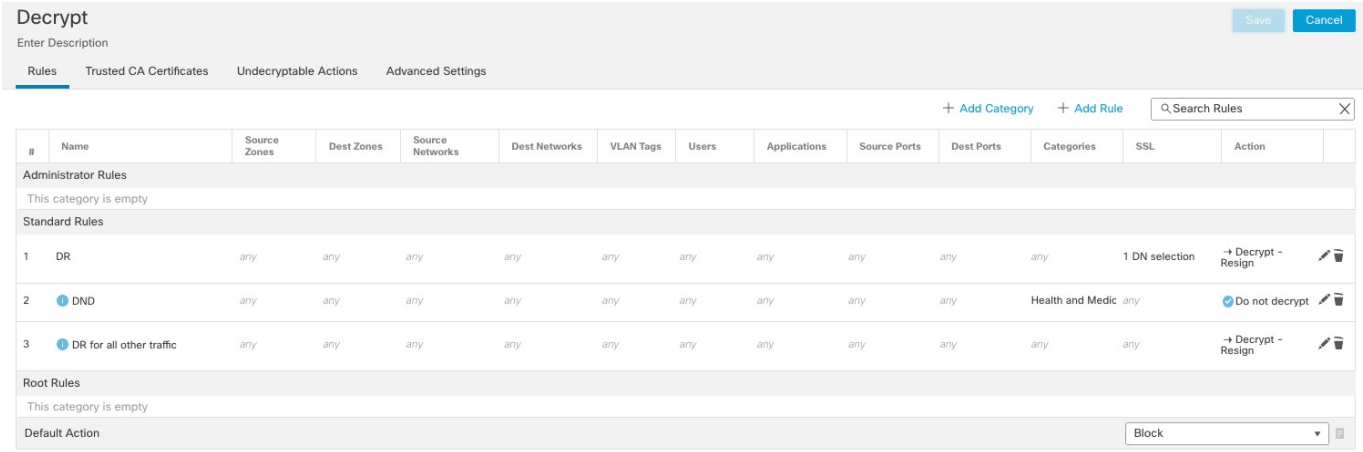
Decryption rule Do Not Decrypt action

The Do Not Decrypt action passes encrypted traffic for evaluation by the access control policy's rules and default action. Because some access control rule conditions require unencrypted traffic, this traffic might match fewer rules. The system cannot perform deep inspection on encrypted traffic, such as intrusion or file inspection.

Typical use cases for do not decrypt rules

Typical reasons for a **Do Not Decrypt** rule action include:

- When decrypting TLS/SSL traffic is prohibited by law.
- Sites you know you can trust.
- Sites you can disrupt by inspecting traffic (such as Windows Update).
- To view the values of TLS/SSL fields using connection events. (You do not need to decrypt traffic to view connection event fields.) For more information, see *Requirements for Populating Connection Event Fields* in the *Cisco Secure Firewall Management Center Administration Guide*.



For more information, see Default handling options for undecryptable traffic, on page 1739

Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the WebMD website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for WebMD and everything else. General information about decryption rules can be found in Guidelines for using TLS/SSL decryption, on page 1746.

Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Recommendations for application control, on page 1622.

Decryption rule blocking actions

Decryption rule blocking actions provide different termination methods to control connection handling.

Available blocking actions

The system provides these decryption rule actions for traffic you do not want to pass through the system:

- **Block**: Terminates the connection, resulting in an error in the client browser. The error message does not indicate the site was blocked due to policy. Instead, errors might indicate that there are no common encryption algorithms. It is not obvious from this message that you blocked the connection on purpose.
- **Block with reset**: Terminates and resets the connection, resulting in an error in the client browser. The error indicates the connection was reset but does not indicate why.

Tip You cannot use the **Block** or **Block with reset** action in a passive or inline (tap mode) deployment because the device does not directly inspect the traffic. If you create a rule with the **Block** or **Block with reset** action that contains passive or inline (tap mode) interfaces within a security zone condition, the policy editor displays a warning (⚠) next to the rule.

Decryption rule decrypt actions

Decrypt - Known Key, and **Decrypt - Resign** are rule actions that decrypt encrypted traffic. The system inspects decrypted traffic with access control. Access control rules handle decrypted and unencrypted traffic

identically — you can inspect it for discovery data as well as detect and block intrusions, prohibited files, and malware. The system reencrypts allowed traffic before passing it to its destination.

Certificate authority recommendations

We recommend you use a certificate from a trusted Certificate Authority (CA) to decrypt traffic. This prevents **Invalid Issuer** from being displayed in the SSL Certificate Status column in connection events.

For more information about adding trusted objects, see Trusted certificate authority objects, on page 2395.

Monitor TLS/SSL hardware acceleration

TLS/SSL hardware acceleration monitoring is a set of topics that discuss how to monitor the status of TLS/SSL hardware acceleration.

Informational counters

Monitor TLS/SSL hardware acceleration performance and interpret KEY counter values, such as PRIV_KEY_RECV and SECU_PARAM_RECV, to assess system load and connection activity using the **show counters** command.

If a system under load is working well, you should see large counts for the following counters. Because there are two sides to the tracker process per connection, you can see these counters increase by two per connection. The PRIV_KEY_RECV and SECU_PARAM_RECV counters are the most important, and are highlighted. The CONTEXT_CREATED and CONTEXT_DESTROYED counters relate to the allocation of cryptographic chip memory.

```
> show counters
Protocol     Counter                          Value   Context
SSLENC       CONTEXT_CREATED                 258225   Summary
SSLENC       CONTEXT_DESTROYED               258225   Summary
TLS_TRK      OPEN_SERVER_SESSION             258225   Summary

TCP_PRX      CLIENT_CLEAN_UP                 258222   Summary
```

Alert counters

Alert counters identify potential issues based on standardized alert types.

These counters are based on the TLS 1.2 specification. FATAL or BAD alerts could indicate issues. However, ALERT_RX_CLOSE_NOTIFY is normal.

For details, see RFC 5246 section 7.2.

```
TLS_TRK      ALERT_RX_CNT                       311   Summary
TLS_TRK      ALERT_TX_CNT                         2   Summary
TLS_TRK      ALERT_TX_IN_HANDSHAKE_CNT            2   Summary
TLS_TRK      ALERT_RX_IN_HANDSHAKE_CNT            2   Summary
TLS_TRK      ALERT_RX_WARNING_ALERT             308   Summary
TLS_TRK      ALERT_RX_FATAL_ALERT                 3   Summary
TLS_TRK      ALERT_TX_FATAL_ALERT                 2   Summary
TLS_TRK      ALERT_RX_CLOSE_NOTIFY              308   Summary
TLS_TRK      ALERT_RX_BAD_RECORD_MAC              2   Summary
TLS_TRK      ALERT_TX_BAD_RECORD_MAC              2   Summary
TLS_TRK      ALERT_RX_BAD_CERTIFICATE             1   Summary
```

Error counters

Error counters help you interpret system performance data to identify potential issues and optimize performance using the show counters command.

Fatal counters

Monitor and interpret TLS/SSL hardware acceleration fatal counters to identify serious errors, assess system health, and troubleshoot persistent crypto acceleration issues on Cisco devices. Reset or review counters for proactive system maintenance and support.

Fatal counters indicate serious errors. These counters should be at or near 0 on a healthy system. This is an example list of the fatal counters.

```
> show counters
Protocol     Counter                         Value   Context
CRYPTO       RING_FULL                           1   Summary
CRYPTO       ACCELERATOR_CORE_TIMEOUT            1   Summary
CRYPTO       ACCELERATOR_RESET                   1   Summary
CRYPTO       RSA_PRIVATE_DECRYPT_FAILED          1   Summary
```

The RING_FULL counter is not a fatal counter, but indicates how often the system overloaded the cryptographic chip. The ACCELERATOR_RESET counter is the number of times the TLS crypto acceleration process failed unexpectedly, which also causes the failure of pending operations, which are the numbers you see in ACCELERATOR_CORE_TIMEOUT and RSA_PRIVATE_DECRYPT_FAILED.

If you have persistent problems, disable TLS crypto acceleration (or **config hwCrypto disable**) and work with Cisco TAC to resolve the issues.

Note You can do additional troubleshooting using the **show snort tls-offload** and **debug snort tls-offload** commands. Use the **clear snort tls-offload** command to reset the counters displayed in the **show snort tls-offload** command to zero.

Troubleshoot Decryption Rules

This topic discusses how to troubleshoot decryption rules.

TLS/SSL oversubscription

TLS/SSL oversubscription is a state where a managed device is overloaded with TLS/SSL traffic. Any managed device can experience TLS/SSL oversubscription but only managed devices that support TLS crypto acceleration provide a configurable way to handle it.

TLS/SSL oversubscription details

When a managed device with TLS crypto acceleration enabled is oversubscribed, any packet received by the managed device is acted on according to the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions**:

- Inherit default action
- Do not decrypt
- Block
- Block with reset

If the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions** is **Do Not decrypt** and the associated access control policy is configured to inspect the traffic, inspection occurs; decryption does *not* occur.

Troubleshoot TLS/SSL oversubscription

Monitor and troubleshoot TLS/SSL oversubscription by configuring decryption policies, enabling logging, and adding SSL Flow Flags to connection event views in Firewall Management Center.

If your managed device has TLS crypto acceleration enabled, you can view connection events to determine whether or not the devices are experiencing SSL oversubscription. You must add at least the **SSL Flow Flags** event to the table view of connection events.

Before you begin

- Configure a decryption policy with a setting for **Handshake Errors** on **Undecryptable Actions** page.

  For more information, see Set default handling for undecryptable traffic, on page 1741.

- Enable logging for your SSL rules as discussed in the section on logging decryptable connections in decryption rules in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Follow these steps to troubleshoot TLS/SSL oversubscription:

Procedure

Step 1 If you haven't done so already, log in to the Firewall Management Center.

Step 2 Click **Analysis** > **Connections** > **Events**.

Step 3 Click **Table View of Connection Events**.

Step 4 Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

Step 5 Click **Apply**.
TLS/SSL oversubscription is indicated by the values of `ERROR_EVENT_TRIGGERED` and `OVER_SUBSCRIBED` in the **SSL Flow Flags** column.

Step 6 If TLS/SSL oversubscription is occurring, log in to the managed device and enter any of the following commands:

Command	Result
show counters	If the value of **TCP_PRX BYPASS_NOT_ENOUGH_MEM** is large, consider upgrading your device to one with a larger capacity for SSL traffic or use **Do NOT Decrypt** rules for lower priority encrypted traffic.
show snort TLS-offload	If the value of **BYPASS_NOT_ENOUGH_MEM** is large, consider upgrading your device to one with a larger capacity for SSL traffic or use **Do NOT Decrypt** rules for lower priority encrypted traffic.

TLS heartbeat

A TLS heartbeat extension enables applications to confirm active TLS or DTLS connections.

TLS heartbeat handling

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

When a managed device with TLS crypto acceleration enabled encounters a packet that uses the TLS heartbeat extension, the managed device takes the action specified by the setting for **Decryption Errors** in the decryption policy's **Undecryptable Actions**:

- Block
- Block with reset

Related Topics

Troubleshoot TLS heartbeat, on page 1784

Troubleshoot TLS heartbeat

This task helps you identify TLS heartbeat activity in your network to determine if applications are using the TLS heartbeat extension.

If your managed device has TLS crypto acceleration enabled, you can view connection events to determine whether or not the devices are seeing traffic with the TLS heartbeat extension. You must add at least the **SSL Flow Messages** event to the table view of connection events.

TLS heartbeat is indicated by the value of `HEARTBEAT` in the **SSL Flow Messages** column in the table view of connection events.

Before you begin

To determine if applications in your network use TLS heartbeat, first perform these tasks:

- Configure an decryption policy with a setting for **Decryption Errors** on **Undecryptable Actions** page.

  For more information, refer to Set default handling for undecryptable traffic, on page 1741.

- Enable logging for your SSL rules as discussed in Secure Firewall Management Center and Threat Defense Management Network Administration.

Follow these steps to troubleshoot TLS heartbeat:

Procedure

Step 1 If you haven't done so already, log in to the Firewall Management Center.

Step 2 Click **Analysis** > **Connections** > **Events**.

Step 3 Click **Table View of Connection Events**.

Step 4 Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

Step 5 Click **Apply**.
TLS heartbeat is indicated by the value of `HEARTBEAT` in the **SSL Flow Messages** column.

Step 6 If applications in your network use TLS heartbeat, refer to Decryption Rules guidelines and limitations, on page 1746.

TLS/SSL pinning

TLS/SSL pinning is a security mechanism that

- validates server certificates against a predetermined set of trusted certificates or keys
- prevents man-in-the-middle attacks by rejecting connections to servers with unexpected certificates, and
- requires applications to maintain a local store of trusted certificate information for validation.

TLS/SSL pinning implementation details

Some applications use a technique referred to as *TLS/SSL pinning* or *certificate pinning*, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a decryption rule with a **Decrypt - Resign** action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

To confirm that TLS/SSL pinning is occurring, attempt to log in to a mobile application like Facebook. If a network connection error is displayed, log in using a web browser. (For example, you *cannot* log in to a Facebook mobile application but *can* log in to Facebook using Safari or Chrome.) You can use Firepower Management Center connection events as further proof of TLS/SSL pinning

Note TLS/SSL pinning is not limited to mobile applications.

If applications in your network use SSL pinning, see TLS/SSL certificate pinning guidelines, on page 1752.

Related Topics

Troubleshoot TLS/SSL pinning, on page 1785

Troubleshoot TLS/SSL pinning

This task helps you identify and confirm whether applications in your network are using TLS/SSL pinning by analyzing SSL connection events and flow DATA.

You can view connection events to determine whether or not the devices are experiencing TLS/SSL pinning. You must add at least the **SSL Flow Flags** and **SSL Flow Messages** columns to the table view of connection events.

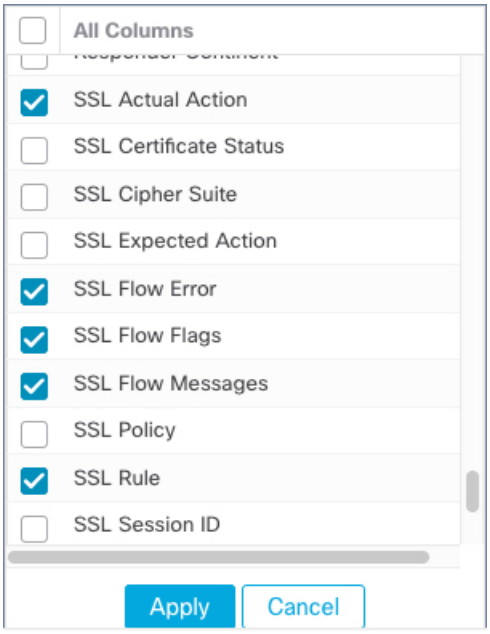
Before you begin

- Enable logging for your decryption rules as discussed in the section on logging decryptable connections in decryption rules in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.
- Log in to a mobile application like Facebook. If a network connection error displays, log in to Facebook using Chrome or Safari. If you *can* log in using a web browser but not the native application, TLS/SSL pinning is likely occurring.

Follow these steps to troubleshoot TLS/SSL pinning:

Procedure

Step 1 If you haven't DONE so already, log in to the Firewall Management Center.



Step 2 Click **Analysis** > **Connections** > **Events**.

Step 3 Click **Table View of Connection Events**.

Step 4 Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.

The columns are added in the order discussed in the section on connection and security intelligence event fields in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Step 5 Click **Apply**.

Step 6 Analyze the SSL flow DATA to identify SSL pinning behavior.

Step 7 If you determine that applications in your network use SSL pinning, see Decryption Rules guidelines and limitations, on page 1746.

What to do next

You can use TLS/SSL connection events to confirm TLS/SSL pinning is occurring by looking for any of the following:

- Applications that send an SSL ALERT Message as soon as the CLIENT receives the SERVER_HELLO, SERVER_CERTIFICATE, SERVER_HELLO_DONE message from the SERVER, followed by a TCP Reset, exhibit the following symptoms. (The ALERT, `Unknown CA (48)`, can be viewed using a packet capture.)
  - The SSL Flow Flags column displays `ALERT_SEEN` but *not* `APP_DATA_C2S` or `APP_DATA_S2C`.

- If your managed device has SSL hardware acceleration enabled, the SSL Flow Messages column typically displays: `CLIENT_ALERT`, `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`.
- If your managed device doesn't support SSL hardware acceleration or if the feature is disabled, the SSL Flow Messages column typically displays: `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`.
- `Success` is displayed in the SSL Flow Error column.

- Applications that send no alerts but instead send TCP Reset after the SSL handshake is FINISHED exhibit the following symptoms:
  - The SSL Flow Flags column does *not* display `ALERT_SEEN`, `APP_DATA_C2S`, or `APP_DATA_S2C`.
  - If your managed device has SSL hardware acceleration enabled, the SSL Flow Messages column typically displays: `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`, `CLIENT_KEY_EXCHANGE`, `CLIENT_CHANGE_CIPHER_SPEC`, `CLIENT_FINISHED`, `SERVER_CHANGE_CIPHER_SPEC`, `SERVER_FINISHED`.
  - If your managed device doesn't support SSL hardware acceleration or if the feature is disabled, the SSL Flow Messages column typically displays: `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`, `CLIENT_KEY_EXCHANGE`, `CLIENT_CHANGE_CIPHER_SPEC`, `CLIENT_FINISHED`,`SERVER_CHANGE_CIPHER_SPEC`, `SERVER_FINISHED`.
  - `Success` is displayed in the SSL Flow Error column.

Related Topics

Troubleshoot unknown or bad certificates or certificate authorities, on page 1787

Troubleshoot unknown or bad certificates or certificate authorities

Enable logging for TLS/SSL decryption rules to monitor connection events and identify certificate-related issues. This helps you diagnose problems with certificate authorities, bad certificates, or unknown certificates in your TLS/SSL connections.

You can view connection events to determine whether or not the devices are experiencing unknown certificate authorities, bad certificates, or unknown certificates. This procedure can also be used if a TLS/SSL certificate has been pinned. You must add at least the **SSL Flow Flags** and **SSL Flow Messages** columns to the table view of connection events.

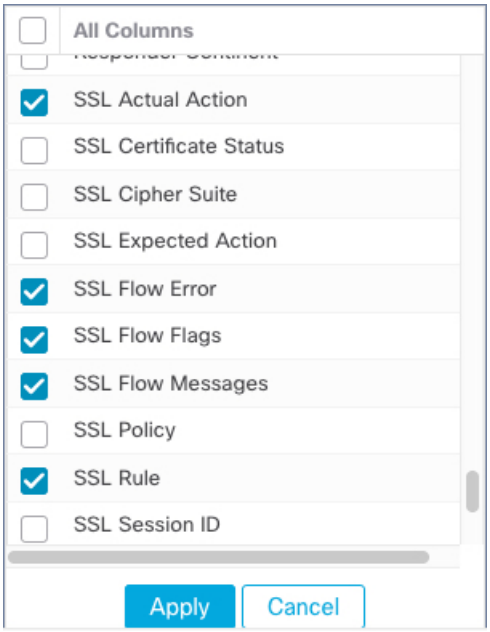
Before you begin

- Set up a decryption rule.
- Enable logging for your decryption rules as discussed in the section on logging decryptable connections in decryption rules in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Follow these steps to troubleshoot unknown or bad certificates or certificate authorities:

Procedure

Step 1 If you haven't done so already, log in to the Firewall Management Center.



Step 2 Click **Analysis** > **Connections** > **Events**.

Step 3 Click **Table View of Connection Events**.

Step 4 Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.

The columns are added in the order discussed in the section on connection and security intelligence event fields in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Step 5 Click **Apply**.

Step 6 Review the SSL flow flags to determine if a certificate or certificate authority is bad or missing.

SSL flow flag	Meaning
CLIENT_ALERT_SEEN_UNKNOWN_CA	Indicates a valid certificate chain or partial chain was received by an SSL client application, but the certificate was not accepted because the CA certificate could not be located or could not be matched with a known, trusted CA. This message always indicates an unrecoverable error.
CLIENT_ALERT_SEEN_BAD_CERTIFICATE	A certificate was corrupt, contained signatures that did not verify correctly, or had other problems.
CLIENT_ALERT_SEEN_CERTIFICATE_UNKNOWN	Some other (unspecified) issue arose in processing the certificate, rendering it unacceptable.

Verify TLS/SSL cipher suites

This task helps you resolve cipher suite incompatibility errors that occur when saving a decryption rule that has cipher suite conditions. The error indicates that one or more of the cipher suites you chose for the decryption rule condition are incompatible with the certificate used in the decryption rule.

This topic discusses actions you must take if you see the following error when saving a decryption rule that has cipher suite conditions:

```
Traffic cannot match this rule; none of your selected cipher suites contain a signature
algorithm that matches the resigning CA's signature algorithm
```

Before you begin

To resolve the issue, you must have access to the certificate you're using.

Note The tasks in this topic assume knowledge of how TLS/SSL encryption works.

Follow these steps to verify TLS/SSL cipher suites:

Procedure

Step 1 When you attempt to save a decryption rule rule with either **Decrypt - Resign** or **Decrypt - Known Key** with specified cipher suites, the following error is displayed:

Example:

```
Traffic cannot match this rule; none of your selected cipher suites contain a
signature algorithm that the resigning CA's signature algorithm
```

Step 2 Locate the certificate you're using to decrypt traffic and, if necessary, copy the certificate to a system that can run openssl commands.

Step 3 Run the following command to display the signature algorithm used by the certificate:

Example:

openssl x509 -in *CertificateName* **-text -noout**

The first few lines of output are displayed similar to the following:

```
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number: 4105 (0x1009)
    Signature Algorithm: ecdsa-with-SHA256
```

Step 4 The **Signature algorithm** tells you the following:

- The cryptographic function used (in the preceding example, **ECDSA** means Elliptic Curve Digital Signature Algorithm).
- The hash function used to create a digest of the encrypted message (in the preceding example, **SHA256**).

Step 5 Search a resource such as *OpenSSL at University of Utah* for cipher suites that match those values. The cipher suite must be in RFC format.
You can also search a variety of other sites, such as Server Side TLS at the Mozilla wiki or Appendix C of RFC 5246. Cipher Suites in TLS/SSL (Schannel SSP) in Microsoft documentation has a detailed explanation of cipher suites.

Step 6 If necessary, translate the OpenSSL name to an RFC name that the Firepower Management System uses. See the RFC mapping list on the on the `https://testssl.sh` site.

Step 7 The previous example, **ECDSA-with-SHA256**, can be found in the Modern Compatibility List on the Mozilla wiki.

Choose only cipher suites that have **ECDSA** and **SHA-256** in the name. These cipher suites follow:

```
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES128-SHA256
```

Find the corresponding RFC cipher suite on RFC mapping list. These cipher suites follow:

```
TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
```

Step 8 Add the preceding cipher suites to your decryption rule.

Troubleshoot using crypto archives

Crypto issues are difficult to triage. Crypto archives help you to troubleshoot these issues. A crypto archive contains crypto session information about the crypto request, peer information, the component that sent the crypto request, and the timed-out crypto session information.

About crypto archives

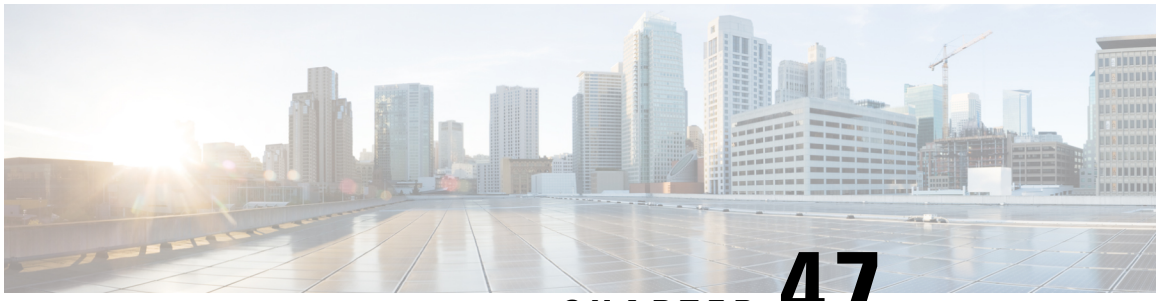
Threat defense does not save keys and initialization vectors (IVs) for the session. For SSL and IPsec, you can also view these information:

- For SSL: Session SSL version, source, destination IP addresses, and ports.
- For IPsec: IPsec security association information.

A ring can hold 2000 crypto command entries. Threat defense pushes the crypto command in one of the rings and pulls out the result after completing the crypto request. Crypto archive files now have the timed-out crypto request's ring and entry index. The ring and its entry index help in troubleshooting problematic crypto commands.

The crypto archive has two formats: a text file and a binary file. You can use the **debug menu ctm 103** command to decode the binary file. The crypto archive files are available at disk0:/crypto_archive.

For example:



```
FTD# debug menu ctm 103 crypto_eng0_arch_4.bin
[Nitrox V Archive Header v1.0 Info]

```

In this example, the highlighted information shows the timeout ring, the crash time (timeout entry), and SSL session information.

Supported devices for crypto archives

These devices with Nitrox V crypto accelerator support crypto archives:

- Cisco Firepower 3105, 3110, 3120, 3130, 3140
- Cisco Firepower 4112, 4115, 4125, 4145
- Cisco Firepower 9300 SM-40, SM-48 and SM-56
- Cisco Secure Firewall 4200

CHAPTER 47

Decryption rules and Policy Example

This chapter builds on concepts discussed in this guide to provide a specific example of an SSL policy with decryption rules that follow our best practices and recommendations. You should be able to apply this example to your situation, adapting it to the needs of your organization.

In short:

- For trusted traffic (such as transferring a large compressed server backup), bypass inspection entirely, using prefiltering and flow offload.
- Put *first* any decryption rules that can be evaluated quickly, such as those that apply to specific IP addresses.
- Put *last* any decryption rules that require processing, **Decrypt - Resign**, and rules that block unsecure protocol versions and cipher suites.

- Decryption rule Examples, on page 1793
- , on page 1793
- : Decrypt Specific Test Traffic, on page 1794
- Decryption rules: Block or Monitor Certificates and Protocol Versions, on page 1794
- Associate the Decryption policy with an Access Control Policy and Advanced Settings, on page 1798
- Traffic to Prefilter, on page 1800
- Decryption rule Settings, on page 1801

Decryption rule Examples

This section provides an example of decryption rule that illustrate our best practices.

See one of the following sections for more information.

The first decryption rule in the example does not decrypt traffic that goes to an internal network (defined as **intranet**). **Do Not Decrypt** rule actions are matched during ClientHello so they are processed very fast.

Note If you have traffic going from internal DNS servers to internal DNS resolvers (such as Cisco Umbrella Virtual Appliances), you can add **Do Not Decrypt** rules for them as well. You can even add those to prefiltering policies if the internal DNS servers do their own logging.

However, we strongly recommend you *do not* use **Do Not Decrypt** rules or prefiltering for DNS traffic that goes to the internet, such as internet root servers (for example, Microsoft internal DNS resolvers built into Active Directory). In those cases, you should fully inspect the traffic or even consider blocking it.

Rule detail:

: Decrypt Specific Test Traffic

The next rule is *optional* in the example; use it to decrypt and monitor limited types of traffic before determining whether or not to allow it on your network.

Rule detail:

Decryption rules: Block or Monitor Certificates and Protocol Versions

The last decryption rules, because they are the most specific and require the most processing, are rules that either monitor or block bad certificates and unsecure protocol versions.

Rule details:

Example: Decryption rule to Monitor or Block Certificate Status

The last decryption rules, because they are the most specific and require the most processing, are rules that either monitor or block bad certificates and unsecure protocol versions. The example in this section shows how to monitor or block traffic by certificate status.

Important Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with **Decrypt - Resign** or **Decrypt - Known Key** rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** ( ) next to your decryption policy.

Step 4 Click **Edit** ( ) next to a decryption rule.

Step 5 Click **Add Rule**.

Step 6 n the Add Rule dialog box, in the **Name** field, enter a name for the rule.

Step 7 Click **Cert Status**.

Step 8 For each certificate status, you have the following options:

- Click **Yes** to match against the *presence* of that certificate status.
- Click **No** to match against the *absence* of that certificate status.
- Click **Any** to skip the condition when matching the rule. In other words, choosing **Any** means the rule matches whether the certificate status is present or absent.

Step 9 From the **Action** list, click either **Monitor** to only monitor and log traffic that matches the rule or click **Block** or **Block with Reset** to block the traffic and optionally reset the connection.

Step 10 To save changes to the rule, at the bottom of the page, click **Add**.

Step 11 To save changes to the policy, at the top of the page, click **Save**.

Example

The organization trusts the Verified Authority certificate authority. The organization does not trust the Spammer Authority certificate authority. The system administrator uploads the Verified Authority certificate and an intermediate CA certificate issued by Verified Authority to the system. Because Verified Authority revoked a certificate it previously issued, the system administrator uploads the CRL that Verified Authority provided.

The following figure shows a certificate status rule condition checking for valid certificates, those issued by a Verified Authority, are not on the CRL, and still within the Valid From and Valid To date. Because of the configuration, traffic encrypted with these certificates is not decrypted and inspected with access control.

The following figure shows a certificate status rule condition checking for the absence of a status. In this case, because of the configuration, it matches against traffic encrypted with a certificate that has not expired.

In the following example, traffic would match this rule condition if the incoming traffic is using a certificate that has an invalid issuer, is self-signed, expired, and it is an invalid certificate.

The following graphic illustrates a certificate status rule condition that matches if the SNI of the request matches the server name or if the CRL is not valid.

Example: Decryption rule to Monitor or Block Protocol Versions

This example shows how to block TLS and SSL protocols on your network that are no longer considered secure, such as TLS 1.0, TLS 1.1, and SSLv3. It's included to give you a little more detail about how protocol version rules work.

You should exclude nonsecure protocols from your network because they are all exploitable. In this example:

- You can block some protocols using **Version** page on the decryption rule.

- Because the system considers SSLv2 as undecryptable, you can block it using the **Undecryptable Actions** on the decryption policy.
- Similarly, because compressed TLS/SSL is not supported, you should block it as well.

Important Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with **Decrypt - Resign** or **Decrypt - Known Key** rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

Procedure

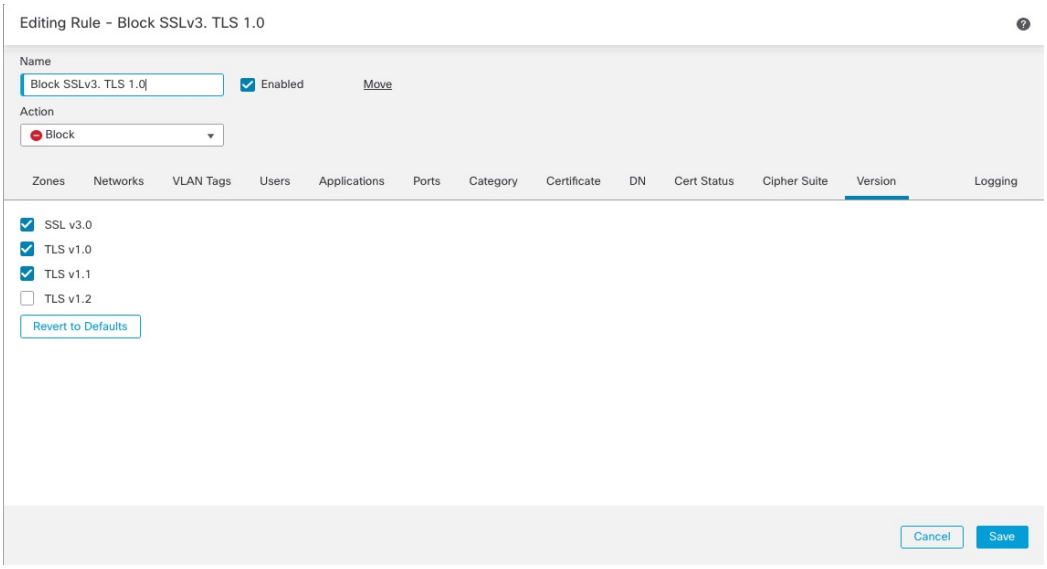
Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** (✎) next to your decryption policy.

Step 4 Click **Edit** (✎) next to a decryption rule.

Step 5 Click **Add Rule**.



Step 6 In the Add Rule dialog box, in the **Name** field, enter a name for the rule.

Step 7 From the **Action** list, click **Block** or **Block with reset**.

Step 8 Click **Version** page.

Step 9 Check the check boxes for protocols that are no longer secure, such as **SSL v3.0**, **TLS 1.0**, and **TLS 1.1**. Clear the check boxes for any protocols that are still considered secure.

The following figure shows an example.

Step 10 Choose other rule conditions as needed.

Step 11 Click **Add**.

Optional Example: Manual Decryption rule to Monitor or Block Certificate Distinguished Name

This rule is included to give you an idea about how to monitor or block traffic based on the server certificate's distinguishedname. It's included to give you a little more detail.

The distinguished name can consist of country code, common name, organization, and organizational unit, but typically consists of a common name only. For example, the common name in the certificate for `https://www.cisco.com` is `cisco.com`. (However, it's not always this simple; Conditions for distinguished name rules in decryption policies, on page 1765 shows how to find common names.)

The host name portion of the URL in the client request is the Server Name Indication (SNI). The client specifies which hostname they want to connect to (for example, `auth.amp.cisco.com`) using the SNI extension in the TLS handshake. The server then selects the corresponding private key and certificate chain that are required to establish the connection while hosting all certificates on a single IP address.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** ( ) next to your decryption policy.

Step 4 Click **Edit** ( ) next to a decryption rule.

Step 5 Click **Add Rule**.

Step 6 In the Add Rule dialog box, in the **Name** field, enter a name for the rule.

Step 7 From the **Action** list, click **Block** or **Block with reset**.

Step 8 Click **DN**.

Step 9 Find the distinguished names you want to add from the **Available DNs**, as follows:

- To add a distinguished name object on the fly, which you can then add to the condition, click **Add** ( ) above the **Available DNs** list.
- To search for distinguished name objects and groups to add, click the **Search by name or value** prompt above the **Available DNs** list, then type either the name of the object, or a value in the object. The list updates as you type to display matching objects.

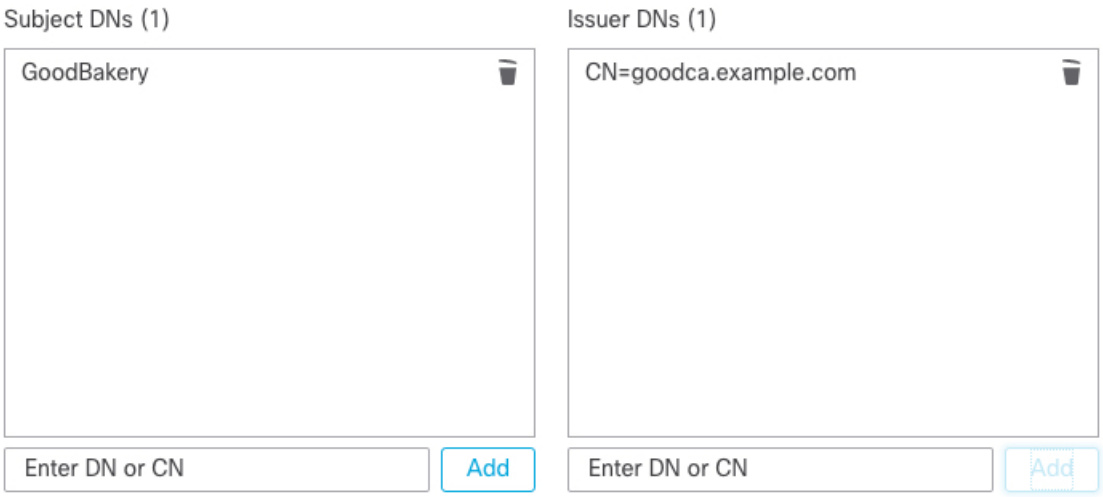
Step 10 To select an object, click it. To select all objects, right-click and then **Select All**.

Step 11 Click **Add to Subject** or **Add to Issuer**.

Tip You can also drag and drop selected objects.

Step 12 Add any literal common names or distinguished names that you want to specify manually. Click the **Enter DN or CN** prompt below the **Subject DNs** or **Issuer DNs** list; then type a common name or distinguished name and click **Add**.

Although you can add a CN or DN to either list, it's more common to add them to the **Subject DNs** list.



Step 13 Add or continue editing the rule.

Step 14 When you're done, to save changes to the rule, click **Add** at the bottom of the page.

Step 15 To save changes to the policy, click **Save** at the top of the page.

Example

The following figure shows a distinguished name rule condition searching for certificates issued to goodbakery.example.com or issued by goodca.example.com. Traffic encrypted with these certificates is allowed, subject to access control.

Associate the Decryption policy with an Access Control Policy and Advanced Settings

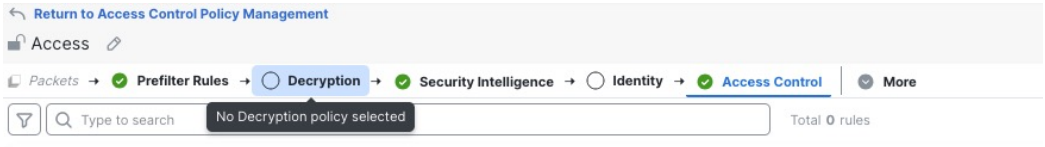
This task discusses how to associate the decryption policy with an access control policy and setting recommended advanced settings for the access control policy.

For your decryption policy to be used by the system, you *must* associate it with an access control policy.

Before you begin

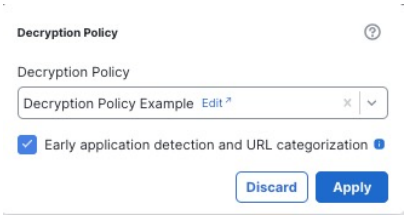
Create the sample decryption policy as discussed in this guide.

For more information about decryption policy advanced options, see Decryption policy advanced options, on page 1742.



Procedure

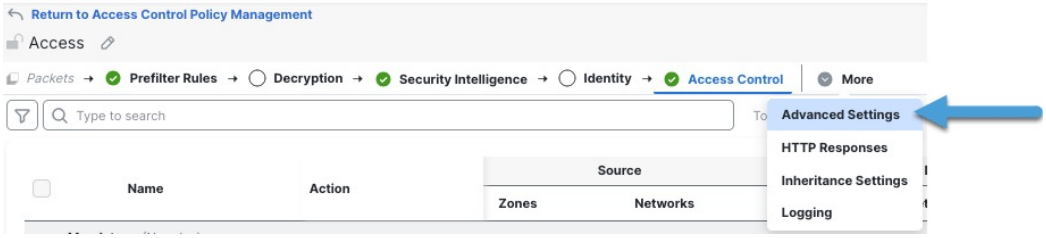
Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.



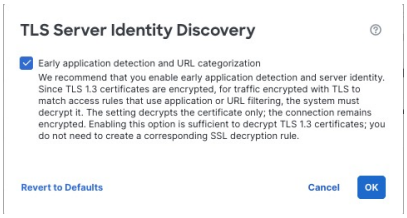
Step 2 Click **Policies** > **Access Control heading** > **Access Control**.

Step 3 Either create a new access control policy or click **Edit** (✎) to edit an existing one.

Step 4 Click the word Decryption as the following figure shows.



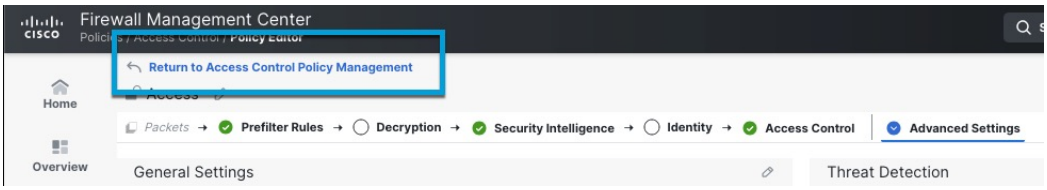
Step 5 From the list, click the name of your decryption policy and also check **Early application detection and URL categorization** as the following figure shows.



Step 6 Click **Apply**.

Step 7 Click **More** > **Advanced Settings** as the following figure shows.

Step 8 Click **Edit** (✎) next to **TLS Server Identity Discovery**.



Step 9 Select the check box as the following figure shows.

Step 10 Click **OK**.

Step 11 At the top of the page, click **Save**.

Step 12 At the top of the page, click **Return to Access Control Policy Management**, as the following figure shows

Step 13 Click **Edit** ( ) to edit the access control rule.

Step 14 At the bottom of the page, next to the default action, click (Default Logging and Inspection).

Step 15 Check **Log at beginning of connection** and any other options you choose.

For more information, see Logging settings for access control policies, on page 1584Logging Settings for Access Control Policies in the *Cisco Secure Firewall Management Center Device Configuration Guide*.

Step 16 Click **Apply**.

Step 17 At the top of the page, click **Save**.

What to do next

- Add rule conditions: Decryption Rule conditions, on page 1758.
- Add a default policy action: Decryption policy default actions, on page 1739.
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the *Cisco Secure Firewall Management Center Administration Guide* .
- Set advanced policy properties: Decryption policy advanced options, on page 1742.
- Associate the decryption policy with an access control policy as described in Associate prefilter, decryption, and identity policies with an access control, on page 1585.
- Deploy configuration changes; see Deploy configuration changes, on page 135.

Traffic to Prefilter

Prefiltering is the first phase of access control, before the system performs more resource-intensive evaluation. Prefiltering is simple, fast, and early compared to subsequent evaluation, which uses inner headers and has more robust inspection capabilities.

Based on your security needs and traffic profile, you should consider prefiltering and therefore excluding from any policy and inspection the following:

- Common intraoffice applications such as Microsoft Outlook 365
- Elephant flows, such as server backups

Decryption rule Settings

How to configure recommended best practice settings for your decryption rules.

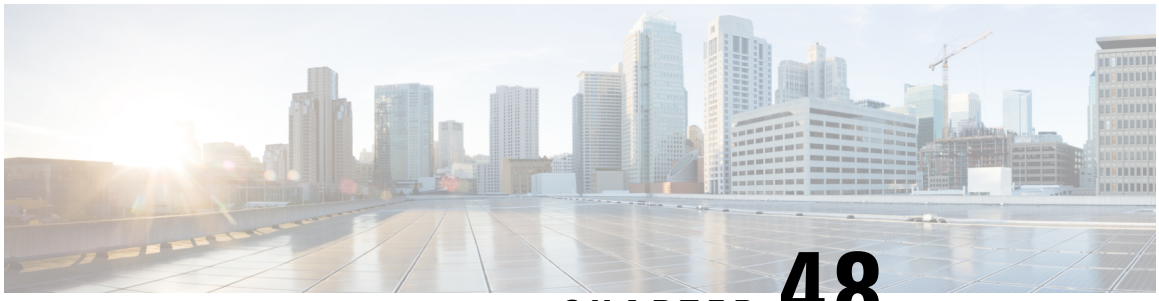
Decryption rules: Enable logging for every rule except those with a **Do Not Decrypt** rule action. (It's up to you; if you want to see information about traffic that isn't decrypted, enable logging for those rules also.)

Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** ( ) next to your decryption policy.



Step 4 Click **Edit** ( ) next to a decryption rule.

Step 5 Click the **Logging** tab.

Step 6 Click **Log at End of Connection**.

Step 7 Click **Save**.

Step 8 Click **Save** at the top of the page.

CHAPTER 48

Encrypted Visibility Engine

Encrypted Visibility Engine (EVE) is used to identify client applications and processes utilizing Transport Layer Security (TLS) encryption. It enables visibility and allows administrators to take actions and enforce policy within their environments. The EVE technology can also be used to identify and stop malware.

- Encrypted Visibility Engine, on page 1803
- How EVE works, on page 1804
- Indications of compromise events, on page 1805
- QUIC fingerprinting in EVE, on page 1806
- Configure EVE, on page 1806
- Configure EVE Exception Rules, on page 1809
- Use case - Block Traffic Based on the EVE Threat Confidence Score, on page 1810

Encrypted Visibility Engine

The encrypted visibility engine (EVE) is used to provide more visibility into the encrypted sessions without the need to decrypt them. These insights into encrypted sessions are obtained by Cisco's open-source library that is packaged in Cisco's vulnerability database (VDB). The library fingerprints and analyzes incoming encrypted sessions and matches it against a set of known fingerprints. This database of known fingerprints is also available in the Cisco VDB.

Key capabilities

Important features of Encrypted Visibility Engine (EVE) include the following:

- Access control policy actions on traffic using information derived from EVE
- Vulnerability Database (VDB) integration with Cisco Secure Firewall for assigning applications to EVE-detected processes with high confidence values
- Custom application detector creation for mapping EVE-detected processes to user-defined applications and overriding built-in process confidence values
- Detection of the operating system type and version of clients that create Client Hello packets in encrypted traffic
- Quick UDP Internet Connections (QUIC) traffic fingerprinting and analysis with server name display in the URL field of the **Connection Events** page

For custom application detector configuration, see the **Configuring Custom Application Detectors** and **Specifying EVE Process Assignments** sections in the **Application Detection** chapter of the Cisco Secure Firewall Management Center Device Configuration Guide.

Note The encrypted visibility engine feature is supported only on Firewall Management Center-managed devices running Snort 3. This feature is not supported on Snort 2 devices and Firewall Device Manager-managed devices.

Attention To use EVE on Firewall Management Center, you must have a valid IPS license on your device. In the absence of a IPS license, the policy displays a warning and deployment is not allowed.

Note

- EVE can detect the operating system type and version of SSL sessions. Normal usage of the operating system, such as running applications and package management software, can trigger OS detection. To view client OS detection, in addition to enabling the EVE toggle button, you must enable **Hosts** under **Policies** > **Network Discovery**. To view a list of possible operating systems on the host IP address, click **Analysis** > **Hosts heading** > **Network Map**, and then choose the required host.
- After enabling EVE for your access control policy, ensure that you have turned on logging for the access control rules within that policy to display the expected results on the EVE dashboard whenever any specific rule conditions are met. For more information on how to turn on logging, see Create and Edit Access Control Rules.
- EVE will not provide visibility or insights for encapsulated traffic.

How EVE works

Encrypted Visibility Engine (EVE) provides the ability to identify and control applications without enabling TLS decryption. By using fingerprints of known malicious processes, EVE technology can also be used to identify and block encrypted malicious traffic without outbound decryption.

Summary

The key components involved in how EVE works are:

- Client Hello inspection: EVE examines the initial TLS handshake packet to create client fingerprints
- Fingerprint database: Contains over 5,000 identified client processes mapped to applications
- Machine learning technology: Processes over one billion TLS fingerprints and over 10,000 malware samples daily
- Cisco Vulnerability Database (VDB): Delivers updated fingerprints to customers

Workflow

These stages describe how EVE identifies and processes client applications:

1. EVE inspects the Client Hello portion of the TLS handshake to identify client processes. The Client Hello is the initial data packet that is sent to the server. This gives a good indication of the client process on the host.
2. The system combines the fingerprint with other data such as destination IP address to provide the basis for EVE's application identification. By identifying specific application fingerprints during the TLS session establishment, the system can identify the client process and take appropriate action, such as allowing or blocking it.
3. If EVE does not recognize a fingerprint, it identifies the client application and estimates the threat score of the first flow using the destination details, such as IP address, port, and server name. At this point, the status of the fingerprints are randomized and the status can be viewed in the debug logs. For subsequent flows with the same fingerprint, EVE skips reanalysis and marks the fingerprint status as unlabeled. If you intend to block traffic based on EVE's Low or Very Low score thresholds, the initial flow is blocked. Future flows are allowed once the application's fingerprint is cached.
4. Through machine learning (ML) technology, Cisco processes over one billion TLS fingerprints and over 10000 malware samples daily to create and update EVE fingerprints. These updates are then delivered to customers using Cisco Vulnerability Database (VDB) package.

Indications of compromise events

An Indication of Compromise (IoC) event is a security detection mechanism that

- identifies connection events with a very high malware confidence level, as reported by EVE,
- triggers for encrypted sessions generated from a host using a malicious client, and
- provides information such as the IP address, MAC address, operating system information of the malicious host, and timestamp of the suspicious activity.

A session with an Encrypted Visibility Threat Confidence score of 'Very High' as seen in connection events generates an IoC event. You must enable **Hosts** from **Policies** > **Network Discovery**. In the Firewall Management Center, view the IoC event existence from here:

- **Analysis** > **Hosts heading** > **Indications of Compromise**, and then **Analysis** > **Indications of Compromise**.
- **Analysis** > **Hosts heading** > **Network Map** > Choose the host that must be checked.

  You can view the process information of the session that generated the IoC on the **Connection Events** page. Click **Analysis** > **Connections** > **Events** to access the **Connection Events** page. Note that you must manually select the Encrypted Visibility fields and IoC field from the **Table View of Connection Events** tab.
- Click **Analysis** > **Unified Events** and choose the Encrypted Visibility fields and IoC field from the column picker option.

QUIC fingerprinting in EVE

QUIC fingerprinting in EVE is a Snort identification mechanism that

- detects applications over QUIC without enabling decryption,
- identifies malware without enabling decryption, and
- detects service applications for access control rule assignment based on the service detected over the QUIC protocol.

Configure EVE

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** ( ) next to the access control policy you want to edit.

Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 Click **Edit** ( ) next to **Encrypted Visibility Engine**.

Step 5 On the **Encrypted Visibility Engine** page, enable the **Encrypted Visibility Engine (EVE)** toggle button.

Step 6 **Use EVE for Application Detection**—This toggle button is enabled by default, which means that EVE is allowed to assign client applications to processes.

EVE's fingerprint information is added in the **Encrypted Visibility Fingerprint** column header of the connection events or unified events. For further analysis of the EVE data collected, you can right-click the fingerprint information to open a dropdown menu. In the menu, click **View Encrypted Visibility Engine Process Analysis** to go to the Secure Firewall Application Detectors site and view details, such as the fingerprint, VDB version, and so on. Different rows with the same fingerprint string and potential process names associated with them and their prevalence are displayed. Prevalence indicates the frequency of a process associated with a particular fingerprint in the data collection system. You can choose the process names and click **Submit Request** to give feedback about any discrepancy in EVE's process detection. For example, you can submit requests if the process name that is detected does not match with the traffic that is being sent or if the process name is not detected at all for a particular fingerprint.

Access to view additional details on the Secure Firewall Application Detectors page is currently not available to users with non-Cisco email addresses.

If you disable the **Use EVE for Application Detection** toggle button:

- AppID-identified clients are assigned to processes and you can see the EVE process and score, but there is no mapping of EVE-detected processes to applications and no action is taken. You can see the details of the events under **Connection Events** or **Unified Events**. To see the difference in connection events (with and without application assignment), see the **Client Application** column header.
- The **Encrypted Visibility Fingerprint** field in the connection events or unified events is empty.

Step 7 Enable the **Block Malware Processes Based on Threat Confidence Level** toggle button to block malicious client processes with the prefix *malware_* based on EVE's threat confidence level.

The default block threshold is 99 percent, which means:

- If EVE detects the traffic to be malware with 99 percent confidence or more, the traffic is blocked.
- If EVE detects the traffic to be malware with less than 99 percent confidence, EVE takes no action.

Note If EVE has blocked the traffic, the **Reason** column header on the **Connection Events** page displays **Encrypted Visiblity Block**.

Step 8 Use the slider to adjust the threshold for blocking based on EVE's threat confidence, which ranges from **Very Low** to **Very High**.

Step 9 For further granular control, enable the **Advanced Mode** toggle button. Now, you can assign a specific EVE Threat Confidence Level for blocking traffic. The default block threshold is 99 percent.

Caution We recommend that you do not set a threshold below 50 percent to ensure optimal performance.

Step 10 Click **OK**.

Step 11 Click **Save**.

What to do next

Deploy configuration changes.

View Encrypted Visibility Engine events

This task allows you to access and view connection events generated by the Encrypted Visibility Engine (EVE) in the Firewall Management Center.

After enabling the **Encrypted Visibility Engine** and deploying your access control policy, you can start sending live traffic through your system. You can view the logged connection events in the **Unified Events** page.

Perform this procedure to access the connection events in the Firewall Management Center.

Procedure

Step 1 Click **Analysis** > **Unified Events**.

Additionally, you can use the **Security-Related Connection Events** page (**Analysis** > **Connections** > **Security-Related Events**) to view the connections that are blocked by Encrypted Visibility Engine, as well as malicious connections with medium, high, and very high threat confidence levels.

The Encrypted Visibility Engine can identify the client process that initiated a connection and the operating system in the client, and indicate if the process contains malware or not.

Step 2 In the **Unified Events** page, explicitly enable these columns that are added for the Encrypted Visibility Engine:

- **Encrypted Visibility Fingerprint**
- **Encrypted Visibility Process Name**
- **Encrypted Visibility Process Confidence Score**
- **Encrypted Visibility Threat Confidence**
- **Encrypted Visibility Threat Confidence Score**
- **Detection Type**

For information about these fields, refer to Connection and Security-Related Connection Event Fields in the *Cisco Secure Firewall Management Center Administration Guide*.

Note On the **Connection Events** page, if processes are assigned applications, the **Detection Type** column displays **Encrypted Visibility Engine**, indicating that the client application was identified by the Encrypted Visibility Engine. Without application assignments to process names, the **Detection Type** column displays **AppID**, indicating that the engine that identified the client application was AppID.

View EVE dashboard

You can use the EVE dashboard to monitor encrypted visibility data, view threat confidence levels, and analyze process identification results across your network.

Before you begin

- In an access control policy, the **Encrypted Visibility Engine (EVE)** must be enabled under **Advanced Settings**.

Follow these steps to view the EVE dashboards:

Procedure

Step 1 Go to **Overview** > **Dashboards heading** > **Dashboard**.

Step 2 In the **Summary Dashboard** window, click the **switch dashboard** link and choose **Application Statistics** from the dropdown box.

Step 3 Choose the **Encrypted Visibility Engine** tab to view the following two dashboards:

- **Top Encrypted Visibility Engine Discovered Processes**—Displays top client processes used in your network and the connection count. Click the process name in the table to view the **Connection Events** page, filtered by the process name.

- **Connections by Encrypted Visibility Engine Threat Confidence**—Displays connections by the confidence levels (Very High, Very Low, and so on). Click the Threat confidence level in the table to view the **Connection Events** page, filtered by the confidence level.

Configure EVE Exception Rules

You can create an encrypted visibility engine (EVE) exception rule to ensure the continuity of trusted connections and services by bypassing the EVE's block action. You can add attributes such as process names and destination IP address to the exception rule. For example, you may want to bypass EVE's block verdict for trusted networks. All the connections in the bypassed networks are exempted from EVE's block verdict based on the threat confidence level.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** ( ) next to the access control policy you want to edit.

Step 3 From the **More** drop-down arrow at the end of the packet flow line, choose **Advanced Settings**.

Step 4 Next to **Encrypted Visibility Engine (EVE)**, click **Edit** ( ).

Step 5 On the **Encrypted Visibility Engine** page, click the **Encrypted Visibility Engine (EVE)** toggle button to enable EVE.

Step 6 Enable the **Block Traffic Based on EVE Score** toggle button to block traffic based on EVE's threat confidence level.

Step 7 Click **Add Exception Rule** and add one or more of the following attributes.

a) Under the **Process Name** tab, enter an EVE-identified process name, and click **Add to Process** on the right side of the window.

You can add multiple process names to the same exception rule. EVE exception list based on process names works only with EVE-identified process names, which are case- and space-sensitive.

b) Under the **Network Objects** tab, perform one of the following:

- Choose one or more IP addresses from the list and add to the **Selected Networks** list.
- Under **Selected Networks**, manually enter the IP address and click the **+** icon to add it to the list of selected networks.

c) (Optional) In the **Comment** field available on all the tabs, you can enter a reason for adding the required attributes to the EVE exception rule.

Step 8 Click **Save** to save the EVE exception rule.

Step 9 Save and deploy the access control policy on the devices.

Note When a connection matches an exception rule, it bypasses the EVE's block verdict. You can view EVE's action in the **Connection Events** or **Unified Events** page. The **Reason** column header displays **EVE Exempted** for identification of such EVE-bypassed traffic.

Add exception rule from unified events

Add exception rules for connections that are blocked by EVE using the information in the Unified Events page.

Use the **Unified Events** page to add exception rules for connections that are blocked by EVE.

Before you begin

Exception list is supported only from threat defense version 7.6.0 or later.

Follow these steps to add exception rules for connections that are blocked by EVE:

Procedure

Step 1 Click **Analysis** > **Unified Events**.

Step 2 In the **Reason** column with **Encrypted Visibility Block** as the reason, click the **Ellipsis**(⋮) icon inside the cell.

Step 3 Choose **Add EVE Exception Rule** from the drop-down list.

Step 4 In the **Encrypted Visibility Engine** window that is displayed, the rule is automatically added to the bottom of the exception list. You can review and make changes to the added rule before saving and deploying the configuration.

Use case - Block Traffic Based on the EVE Threat Confidence Score

About Encrypted Visibility Engine

You can use the Encrypted Visibility Engine (EVE) to identify client applications and processes using Transport Layer Security (TLS) encryption. EVE provides more visibility into the encrypted sessions without decryption. Based on EVE's findings, administrators can enforce policy actions on the traffic within their environments. You can also use the EVE to identify and stop malware.

Benefits

Administrators can leverage and adjust EVE's threat score to block malicious encrypted traffic. If the probability that the incoming traffic is malicious, then based on the threat score, you can configure EVE to block the connection.

Sample Business Scenario

A large corporate network uses Snort 3 as its primary intrusion detection and prevention system. In a rapidly evolving threat landscape, adoption of robust network security measures is necessary and important. The security team uses EVE to enhance encrypted traffic inspection without the need to implement full man-in-the-middle (MITM) decryption. The EVE technology uses fingerprints of known malicious processes to identify and stop malware. Network administrators must have the flexibility to configure EVE's block traffic thresholds to block potentially malicious connections, which are based on their configured block thresholds.

Prerequisites

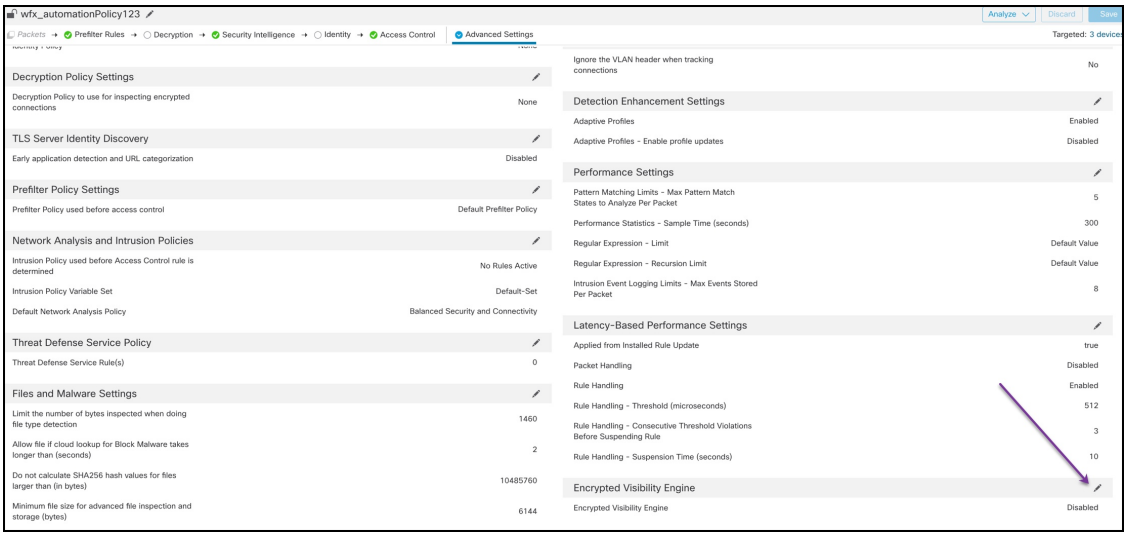
- You must be running management center 7.4.0 or later, and the managed threat defense must also be 7.4.0 or later.
- Ensure that you have a valid Intrusion Prevention System (IPS) license and Snort 3 is the detection engine.

High-Level Workflow

1. EVE analyzes the incoming traffic and gives a verdict on the probability of incoming traffic being malware or not.
2. If EVE detects incoming traffic to be malware with a certain level of confidence, you can configure EVE to block that traffic.
3. The packets are first checked for malware probability or threat score, and the threat score is compared with the block threshold that you have set.
4. If the threat score is higher than the configured threshold, EVE blocks the traffic.
5. If the threat score is lesser than the configured threshold, EVE takes no action.

Configure Block Thresholds in EVE

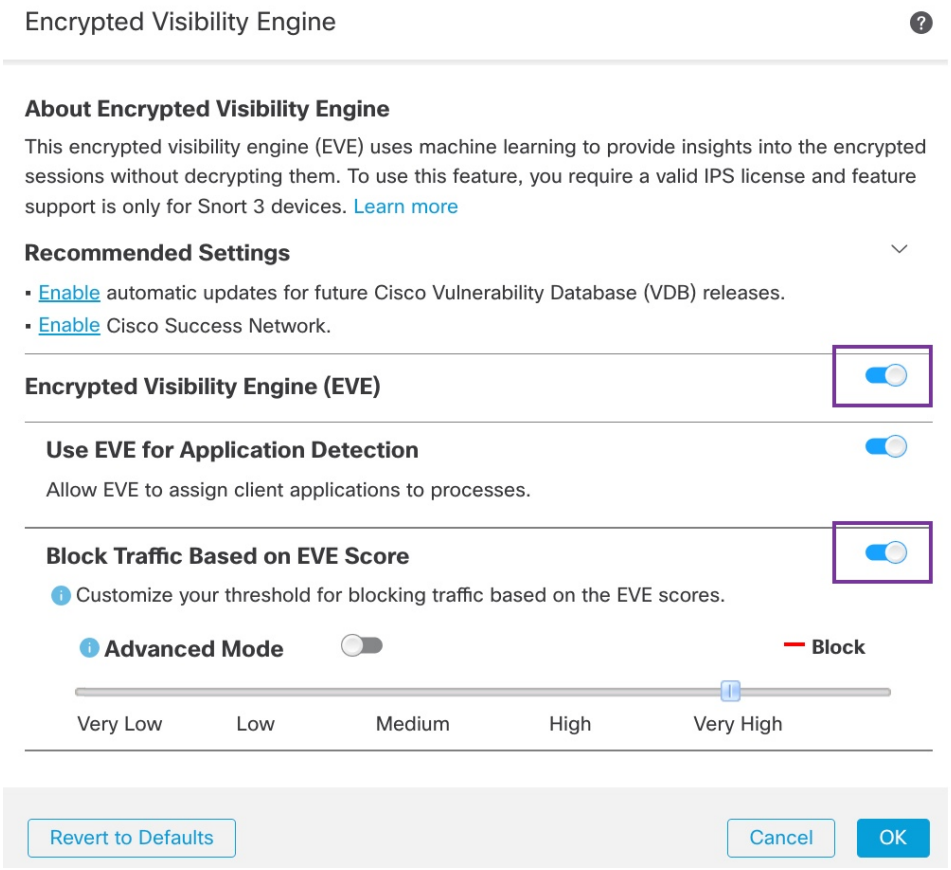
This procedure shows how to block potentially malicious traffic, based on the EVE threat confidence score of 90 percent or higher.



Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

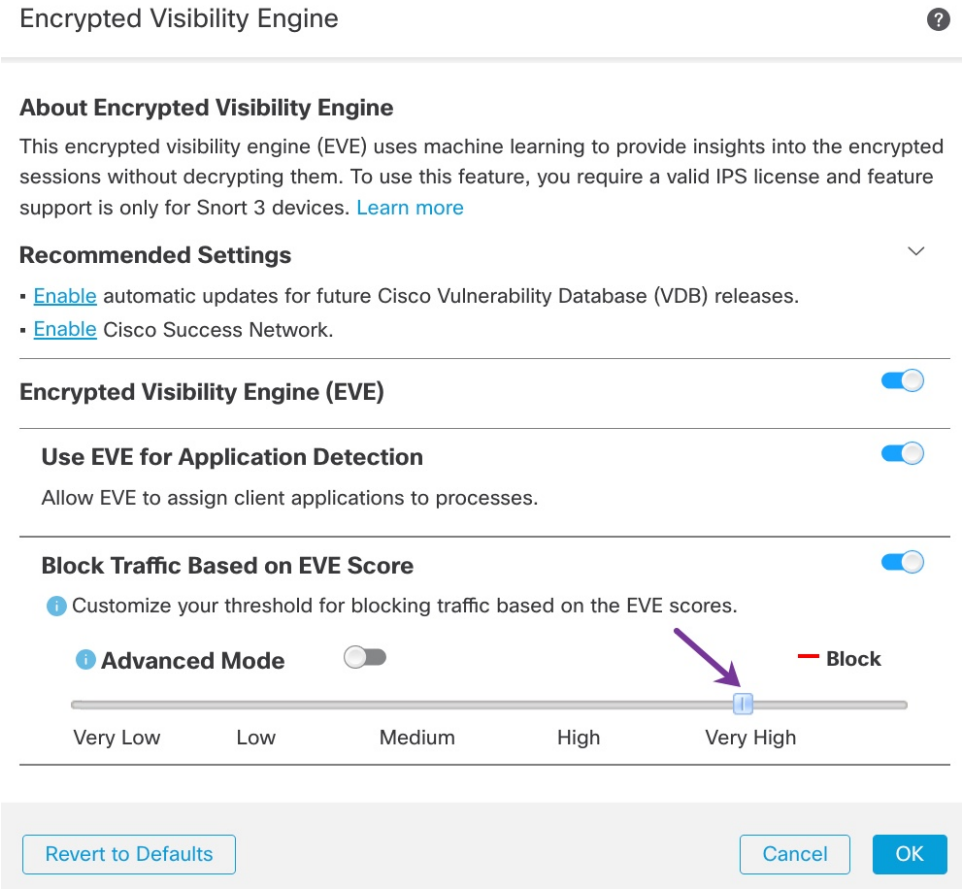
Step 2 Click **Edit** (✎) next to the access control policy you want to edit.



Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 Click **Edit** (✎) next to **Encrypted Visibility Engine**.

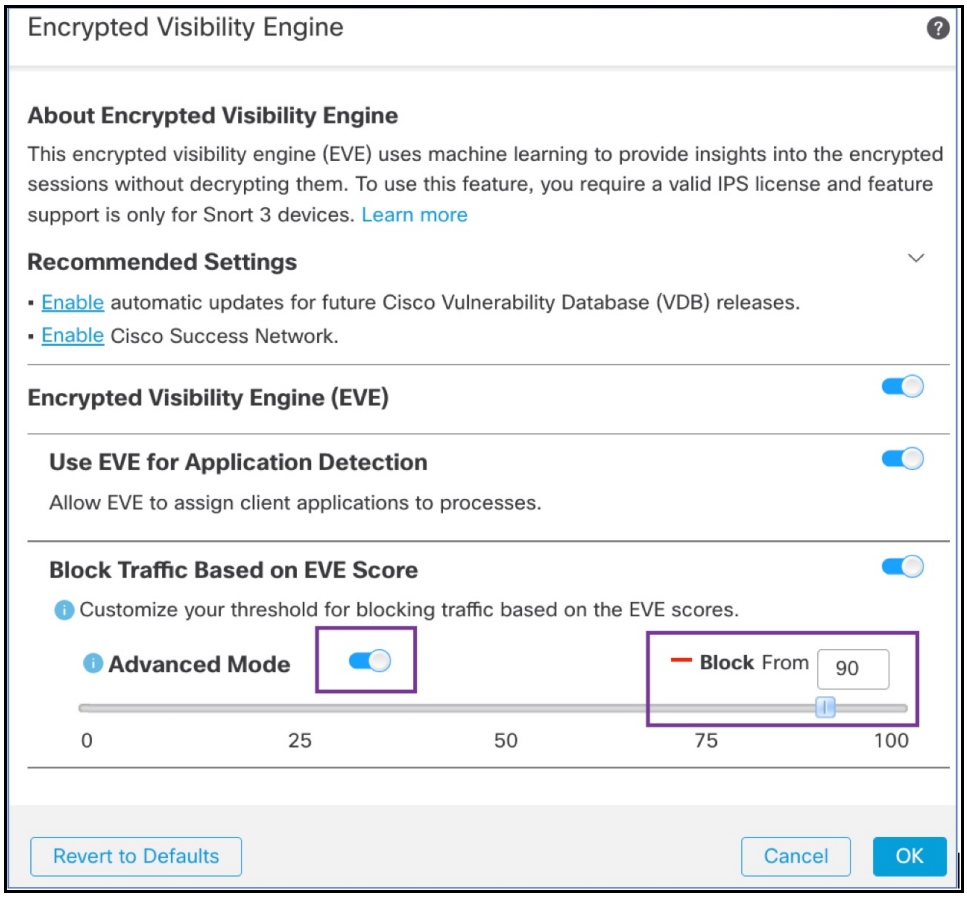
Step 5 In the **Encrypted Visibility Engine** page, enable the **Encrypted Visibility Engine (EVE)** toggle button.



Step 6 Enable the **Block Traffic Based on EVE Score** toggle button. Any incoming traffic that is a potential threat is blocked by default.

Note By default, the threshold at which malware is blocked is 99 percent, which means:

- If EVE detects the traffic to be malware with 99 percent confidence or higher, EVE blocks the traffic.
- If EVE detects the traffic to be malware with less than 99 percent confidence, EVE takes no action.



Step 7 Use the slider to adjust the threshold for blocking based on EVE threat confidence. This ranges from **Very Low** to **Very High**. In this example, the slider is set to **Very High**.

Step 8 For further granular control, enable the **Advanced Mode** toggle button. Now, you can assign a specific EVE Threat Confidence Score for blocking traffic. The default threshold is 99 percent.

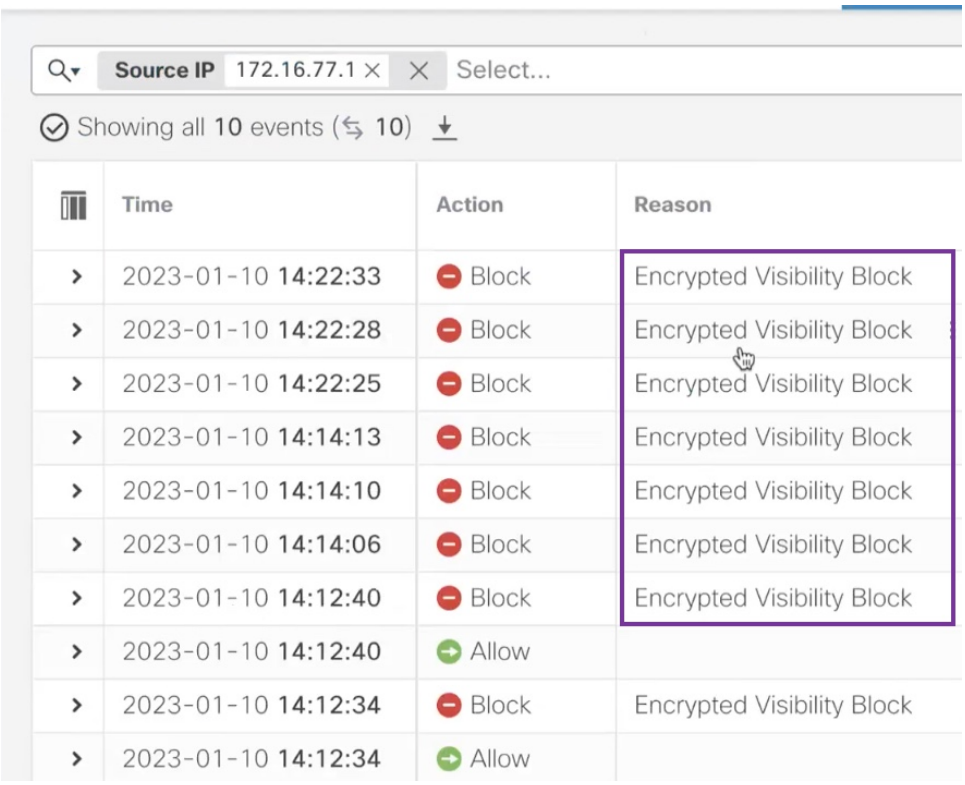
Step 9 In this example, change the block threshold to **90** percent.

Attention As a best practice, we recommend that you do not set the block threshold to below 50 percent to ensure optimum performance.

Step 10 Click **OK**.

Step 11 Click **Save**.

What to do next



Deploy configuration changes.

View EVE Events

Procedure

Step 1 To verify the block action, choose **Analysis** > **Connections** > **Events**. You can also view the events from the **Unified Events** viewer.

Step 2 If you have configured EVE to block traffic, the **Reason** field shows **Encrypted Visibility Block**.

Step 3 The following is an example of the **Encrypted Visibility Process Name** as **test_malware**, **Encrypted Visibility Threat Confidence** as **Very High**, and **Encrypted Visibility Threat Confidence Score** as **90** percent.

PART X

Identity Policies for Access Control

- Identity Overview, on page 1819
- Realms, on page 1835
- Identity Source: Captive Portal, on page 1887
- Identity Source: ISE/ISE-PIC, on page 1911
- Identity Source: Remote Access VPN, on page 1931
- Identity source: TS agent, on page 1937
- Identity Policies, on page 1941

CHAPTER 49

Identity Overview

The following topics discuss user identity:

- User identity, on page 1819
- Host and user limits, on page 1830
- Recommendation: identity realm limit, on page 1833
- User limits for microsoft azure active directory realms, on page 1833

User identity

User identity information can help you to identify the source of policy breaches, attacks, or network vulnerabilities, and trace them to specific users.

User identity information can help you determine:

- Who owns the host targeted by an intrusion event that has a Vulnerable (level 1: red) impact level.
- Who initiated an internal attack or portscan.
- Who is attempting unauthorized access to a specified host.
- Who is consuming an unreasonable amount of bandwidth.
- Who has not applied critical operating system updates.
- Who is using instant messaging software or peer-to-peer file-sharing applications in violation of company policy.
- Who is associated with each indication of compromise on your network.

Armed with this information, you can use other features of the system to mitigate risk, perform access control, and take action to protect others from disruption. These capabilities also significantly improve audit controls and enhance regulatory compliance.

After you configure user identity sources to gather user data, you can perform user awareness and user control.

For more information about identity sources, see About user identity sources, on page 1820.

Identity terminology

Identity terminology is a set of concepts that

- identifies users on networks using identity sources
- enables user awareness from authoritative and non-authoritative sources, and
- manages user access using identity policies.

Key identity terminology

This topic discusses common terminology for user identity and user control.

- **User awareness**: Identifying users on your network using *identity sources* (such as, TS Agent, or Cisco ISE). User awareness enables you to identify users from both *authoritative* (such as Active Directory) and *non-authoritative* (application-based) sources. To use Active Directory as an identity source, you must configure a realm and directory. For more information, see About user identity sources, on page 1820.
- **User control**: Configuring an *identity policy* that you associate with an *access control policy*. (The identity policy is then referred to as an access control *subpolicy*.) The identity policy specifies the identity source and, optionally, users and groups belonging to that source. By associating the identity policy with an access control policy, you determine whether to monitor, trust, block, or allow users or user activity in traffic on your network. For more information, see Access Control Policies, on page 1569.
- **Authoritative identity source**: a trusted server that validates user logins (for example, Active Directory). You can use the data obtained from authoritative logins to perform user awareness and user control. Authoritative user logins are obtained from passive and active authentications:
  - *Passive authentications* occur when a user authenticates through an external repository. ISE/ISE-PIC, the TS Agent, Microsoft Active Directory, and Microsoft Azure Active Directory are passive authentication user repositories supported by the system.
  - *Active authentications* occur when a user authenticates through preconfigured managed devices. Captive portal is another name for active authentication. Active authentication generally uses the same user repositories as passive authentication (the exceptions being ISE/ISE-PIC, and TS Agent, which are passive only).
- **Non-authoritative identity source**: an unknown or untrusted server that validates the user login. Traffic-based detection is the only non-authoritative identity source supported by the system. You can use the data obtained from non-authoritative logins to perform user awareness.

About user identity sources

Learn how to select and configure user identity sources for the firewall to enable user awareness and access control policies. This overview covers supported identity sources, authentication types, and key considerations for optimizing user identity management.

The table provides a brief overview of the user identity sources supported by the system. Each identity source provides a store of users for user awareness. These users can then be controlled with identity and access control policies.

User Identity Source	Server Requirements	Login Type	Authentication Type	User Control	For more, see...
Captive portal	OpenLDAP Microsoft Active Directory	Authoritative	Active	Yes	Captive portal identity source, on page 1887
Passive authentication	OpenLDAP Microsoft Active Directory	Non-authoritative	Active	Yes	Create an LDAP realm or an Active Directory realm and realm directory, on page 1860
Passive authentication with the TS Agent	Microsoft Windows Terminal Server	Authoritative	Passive	Yes	Terminal services agent identity source, on page 1937
Remote Access VPN	OpenLDAP or Microsoft Active Directory	Authoritative	Active	Yes	Remote access VPN identity sources, on page 1931
	RADIUS	Authoritative	Active	No, awareness only	
ISE/ISE-PIC	Microsoft Active Directory	Authoritative	Passive	Yes	The ISE/ISE-PIC identity source, on page 1911
Traffic-based detection (Configured in the network discovery policy.)	—	Non-authoritative	—	No, awareness only	Traffic-based detection identity sources, on page 2314

Consider the information when selecting identity sources to deploy:

- You must use traffic-based detection for non-LDAP user logins.
- You must use traffic-based detection or captive portal to record failed login or authentication activity. A failed login or authentication attempt does not add a new user to the list of users in the database.
- The captive portal identity source requires a managed device with a routed interface. You *cannot* use an inline (also referred to as tap mode) interface with captive portal.

Data from those identity sources is stored in the Secure Firewall Management Center's users database and the user activity database. You can configure Secure Firewall Management Center-server user downloads to automatically and regularly download new user data to your databases.

After you configure identity rules using the desired identity source, you must associate each rule with an access control policy and deploy the policy to managed devices for the policy to have any effect. For more information about access control policies and deployment, see Associate prefilter, decryption, and identity policies with an access control, on page 1585.

For general information about user identity, see User identity, on page 1819.

Best practices for user identity

General recommendations for identity policy setup

Review the following recommendations before you set up identity policies.

- Know user limits
- Health monitor
- Use latest version of ISE/ISE-PIC, two types of remediation
- User agent support drops in 6.7
- Captive portal requires routed interface, several individual tasks

Microsoft active directory and LDAP

Create one realm per LDAP server or Active Directory domain. The system supports Active Directory, LDAP, and other user repositories for user awareness and control. The association between an Active Directory or LDAP repository and the Secure Firewall Management Center is referred to as a *realm*. For details about which versions are supported, see Supported servers for realms, on page 1841.

- The only user identity source supported by LDAP is captive portal. To use other identity sources (with the exception of ISE/ISE-PIC), you must use Active Directory.
- For Active Directory only: Create one *directory* per domain controller. For details, see Create an LDAP realm or an Active Directory realm and realm directory, on page 1860
- Users and groups in trust relationships between two domains are supported provided you add all Active Directory domains and domain controllers as realms and directories, respectively. For more information, see Realms and trusted domains, on page 1837.

Passive Identity Agent identity source
pxGrid Cloud Identity Source
Proxy sequence
Health monitor

The Secure Firewall Management Center health monitor provides valuable information about the status of various Secure Firewall Management Center functions, including user/realm mismatches, Snort memory usage, and ISE connection status.

- For more information about health modules, see *Health Modules* in the *Cisco Secure Firewall Management Center Administration Guide*.
- To set up policies to monitor health modules, see *Creating Health Policies* in the *Cisco Secure Firewall Management Center Administration Guide*.

Device-specific user limits

Every physical or virtual Firewall Management Center device has limits to the number of users that can be downloaded. When the user limit is reached, the Firewall Management Center can run out of memory and can function unreliably as a result.

- User limits are discussed in User limits for microsoft active directory, on page 1831.

- If you use the ISE/ISE-PIC identity source, you can optionally limit the subnets the Firewall Management Center monitors to reduce memory usage using identity mapping filters as discussed in Create an identity policy, on page 1943.

Use the latest version of ISE/ISE-PIC

If you expect to use the ISE/ISE-PIC identity source, we strongly recommend you always use the latest version to make sure you get the latest features and bug fixes.

- pxGrid 2.0 (which is used by version 2.6 patch 6 or later; or 2.7 patch 2 or later) also changes the remediation used by ISE/ISE-PIC from Endpoint Protection Service (EPS) to Adaptive Network Control (ANC). If you upgrade ISE/ISE-PIC, you must migrate your mediation policies from EPS to ANC.
- More information about using ISE/ISE-PIC can be found in Best practices for ISE/ISE-PIC integration, on page 1914.
- To set up the ISE/ISE-PIC identity source, see ISE/ISE-PIC configurations for user control , on page 1916.

Captive portal information

Captive portal is the only identity source that supports LDAP in addition to Active Directory. The captive portal identity source is triggered when a user tries to access network resources using the managed device in AWS, using either an IP address or host name. Captive portal gets user information from LDAP or Active Directory using the proxy sequence and sends user information to Secure Firewall Management Center.

- For more information about the captive portal identity source, see Captive portal identity source, on page 1887.

TS agent information

The TS Agent user identity source is required to identify user sessions on a Windows Terminal Server. The TS Agent software must be installed on the Terminal Server machine as discussed in the *Cisco Terminal Services (TS) Agent Guide*. In addition, you must synchronize the time on your TS Agent server with the time on the Secure Firewall Management Center.

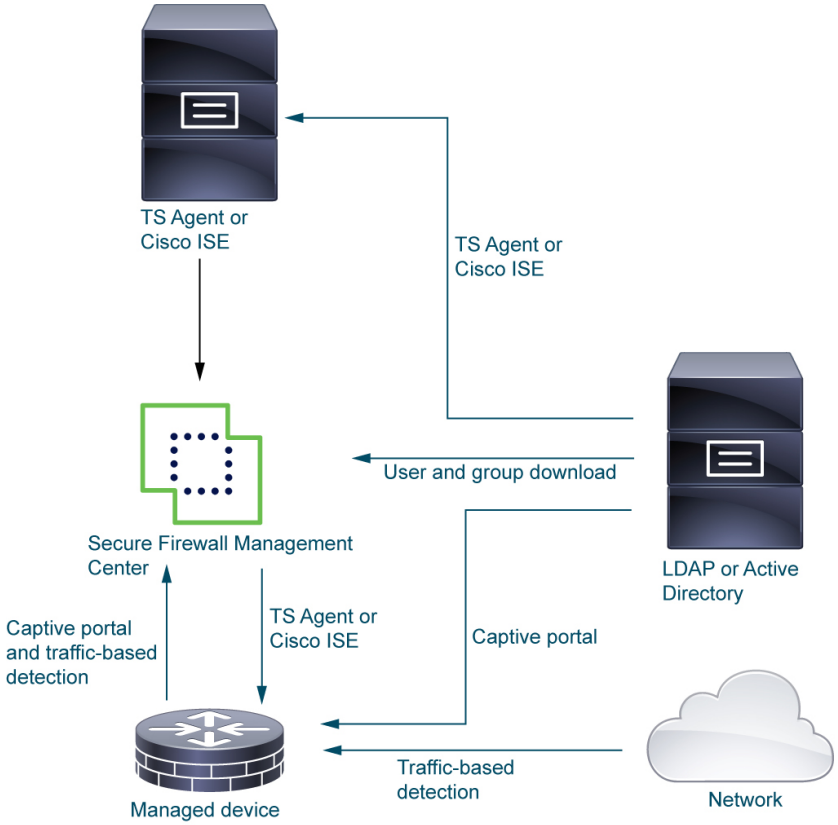
- TS Agent data is visible in the Users, User Activity, and Connection Event tables and can be used for user awareness and user control.
- For more information, see Best practices for TS agent configuration, on page 1938.

Associate the identity policy with an access control policy

After you configure your realm, directory, and user identity source, you must set up identity rules in an identity policy. To make the policy effective, you must associate the identity policy with an access control policy.

- For more information about creating an identity policy, see Create an identity policy, on page 1943.
- For more information about creating identity rules, see Create an identity rule, on page 1952.
- To associate an identity policy with an access control policy, see Associate prefilter, decryption, and identity policies with an access control, on page 1585.

Identity deployments



The Secure Firewall Management Center uses various identity sources, such as TS Agent, ISE/ISE-PIC, pxGrid Cloud, passive identity agent, and captive portal, to collect and manage user and group data for access control and user awareness.

User data collection and storage

When the system detects user data from a user login, from any identity source, the user from the login is checked against the list of users in the Secure Firewall Management Center user database. If the login user matches an existing user, the data from the login is assigned to the user. Logins that do not match existing users cause a new user to be created, unless the login is in SMTP traffic. Non-matching logins in SMTP traffic are discarded.

The group to which the user belongs is associated with the user as soon as the user is seen by the Secure Firewall Management Center.

This diagram illustrates how the system collects and stores user data:

Here are examples of identity deployments.

In the preceding figure, Secure Firewall Management Center and one managed device are deployed to AWS and the other devices are located on premises. These devices can be either physical or virtual; they just need to be able to communicate with each other.

LDAP or Active Directory are required only for TS Agent and captive portal, as the following paragraphs explain.

For more information about setting up a system like this, see Set up an identity policy, on page 1825.

ISE/ISE-PIC identity source

When you deploy the ISE/ISE-PIC identity source, the ISE/ISE-PIC server sends users, groups, and subscriptions to the Secure Firewall Management Center.

You can optionally have an LDAP server in an ISE/ISE-PIC deployment but because it's optional, it isn't shown in this figure.

For more information about ISE/ISE-PIC, see The ISE/ISE-PIC identity source, on page 1911.

TS Agent identity source

The Terminal Services (TS) Agent software runs on a Microsoft Server and sends Secure Firewall Management Center user information based on the port range the users log in to the server with. TS Agent gets user identity information from LDAP or Active Directory and sends it to Secure Firewall Management Center.

For more information about the TS Agent identity source, see Terminal services agent identity source, on page 1937.

Captive portal

Captive portal is the only identity source that supports LDAP in addition to Active Directory. The captive portal identity source is triggered when a user tries to access network resources using the managed device in AWS—using either an IP address or host name. Captive portal gets user information from LDAP or Active Directory using the proxy sequence and sends user information to Secure Firewall Management Center.

For more information about the captive portal identity source, see Captive portal identity source, on page 1887.

Set up an identity policy

Set up an identity policy to control user access and filter network traffic using various user identity sources such as TS Agent, ISE/ISE-PIC, captive portal.

An identity policy is not required if all these conditions are true:

- You use the ISE or ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies.

This topic provides a high-level overview of setting up an identity policy using any available user identity source: TS Agent, ISE/ISE-PIC, captive portal.

Procedure

	Command or Action	Purpose
Step 1	(Optional.) Create a realm and directory, one realm for every domain in the forest that contain users you want to use in user control. Also	Creating a realm, realm directory is optional if any of these are true:

	Command or Action	Purpose
	create one directory for every domain controller. Only users and groups that have corresponding Firewall Management Center realms and directories can be used in identity policies.	• You use SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions. • You are using an identity policy only to filter network traffic. The *realm* is a trusted user and group store, typically a Microsoft Active Directory repository. The Firewall Management Center downloads users and groups at intervals you specify. You can include or exclude users and groups from being downloaded. See Create an LDAP realm or an Active Directory realm and realm directory, on page 1860. For details about the options to create a realm, see Realm fields, on page 1844. A *directory* is an Active Directory domain controller that organizes information about a computer network's users and network shares. An Active Directory controller provides Directory Services for the realm. Active Directory distributes user and group objects across multiple domain controllers, which are peers that propagate local changes between each other by the use of Directory Services. For more information, see the Active Directory technical specification glossary on MSDN. You can specify more than one directory for a realm, in which case each domain controller is queried in the order listed on the realm's **Directory** tab page to match user and group credentials for user control. **Note** Configuring a realm or realm se not user, group, realm, Endpoint
Step 2	Synchronize users and groups from the realm.	To be able to control users and groups, you must synchronize them with the Firewall Management Center. You can synchronize them with users and groups whenever you want or you can configure the system to synchronize them at a specified interval. When you synchronize users and groups, you can specify exceptions; for example, you can exclude the Engineering group from all user

	Command or Action	Purpose
		control for that realm, or you can exclude the user `joe.smith` from user controls that apply to the Engineering group. See Synchronize users and groups, on page 1865
Step 3	(Optional.) Create a realm sequence.	A realm sequence is an ordered list of realms that, when used in an identity policy, causes the system to search the realms in the specified order to find users to match the rule. See Create a realm sequence, on page 1867.
Step 4	Create a method to retrieve user and group data (the *identity source*).	Set up an identity source with its unique configuration to be able to control users and groups using data stored in the realm. Identity sources include TS Agent, captive portal, or Remote VPN. See one of these: • Configure the captive portal for user control, on page 1891 • Configure Remote Access VPN for AD-authenticated users, on page 1932
Step 5	Create an identity policy.	An identity policy contains one or more identity rules, optionally organized in categories. See Create an identity policy, on page 1943. **Note** Configuring a realm or realm not user, group, realm, Endp only to filter network traffic.
Step 6	Create one or more identity rules.	Identity rules enable you to specify a number of matching criteria, including the type of authentication, network zones, networks or geolocation, realms, realm sequences, and so on. See Create an identity rule, on page 1952.
Step 7	Associate your identity policy with an access control policy.	An access control policy filters and optionally inspects traffic. An identity policy must be associated with an access control policy to have any effect. See Associate prefilter, decryption, and identity policies with an access control, on page 1585.

What to do next

1. Deploy the access control policy to at least one managed device.

To use your policy to control user activity, the policy must be deployed to the managed devices to which clients connect. See Deploy configuration changes, on page 135.

2. Monitor user activity.

   View a list of active sessions collected by user identity sources or a list of user information collected by user identity sources. See *Using Workflows* in the *Cisco Secure Firewall Management Center Administration Guide* .

User activity database

The user activity database on the Secure Firewall Management Center is a logging system that contains records of user activity on your network detected or reported by all of your configured identity sources.

User activity logging events

The system logs events in these circumstances:

- When it detects individual logins or logoffs.
- When it detects a new user.
- When a system administrator manually delete a user.
- When the system detects a user that is not in the database, but cannot add the user because you have reached your user limit.
- When you resolve an indication of compromise associated with a user, or enable or disable indication of compromise rules for a user.

Note If the TS Agent monitors the same users as another passive authentication identity source (such as the ISE/ISE-PIC), the Firewall Management Center prioritizes the TS Agent data. If the TS Agent and another passive source report identical activity from the same IP address, only the TS Agent data is logged to the Firewall Management Center.

You can view user activity detected by the system using the Secure Firewall Management Center. (**Analysis** > **Users heading** > **User Activity**.)

Users database

A users database on the Secure Firewall Management Center is a system component that

- contains a record for each user detected or reported by all configured identity sources
- stores data obtained from authoritative sources for user control, and
- prioritizes user data based on identity source type when user limits are reached.

User database management and limitations

For more information about the supported non-authoritative and authoritative identity sources, refer to About user identity sources, on page 1820.

The total number of users the Secure Firewall Management Center can store depends on the Secure Firewall Management Center model, as described in User limits for microsoft active directory, on page 1831. After the user limit is reached, the system prioritizes previously-undetected user data based on its identity source, as described in this list:

- Non-authoritative identity source: If the new user is from a non-authoritative identity source, the system does not add the user to the database. To allow new users to be added, you must delete users manually or with a database purge.
- Authoritative identity source: If the new user is from an authoritative identity source, the system deletes the non-authoritative user who has remained inactive for the longest period and adds the new user to the database.

If an identity source is configured to exclude specific user names, user activity data for those user names are not reported to the Secure Firewall Management Center. These excluded user names remain in the database, but are not associated with IP addresses. For more information about the type of data stored by the system, refer to *User Data* in the *Cisco Secure Firewall Management Center Administration Guide*.

If you have Firewall Management Center high availability configured and the primary fails, no logins reported by a captive portal, ISE/ISE-PIC, TS Agent, or Remote Access VPN device can be identified during failover downtime, even if the users were previously seen and downloaded to the Firewall Management Center. The unidentified users are logged as Unknown users on the Firewall Management Center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.

Note If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the Firewall Management Center prioritizes the TS Agent data. If the TS Agent and another passive source report identical activity from the same IP address, only the TS Agent data is logged to the Firewall Management Center.

When the system detects a new user session, the user session data remains in the users database until one of these conditions occurs:

- A user on the Firewall Management Center manually deletes the user session.
- An identity source reports the logoff of that user session.
- A realm ends the user session as specified by the realm's **User Session Timeout: Authenticated Users**, **User Session Timeout: Failed Authentication Users**, or **User Session Timeout: Guest Users** setting.

Note In deployments that use multitenancy with Firewall Management Center domains, passive identity sessions apply to all managed Firewall Threat Defense devices, regardless of domain.

Host and user limits

Host and user limits are deployment restrictions that determine how many individual hosts you can monitor with your deployment, as well as how many users you can monitor and use to perform user control.

Host limits

The system adds a host to the network map when it detects activity associated with an IP address in your monitored network (as defined in your network discovery policy). The number of hosts a Secure Firewall Management Center can monitor, and therefore store in the network map, depends on its model.

Table 104: Host Limits by Secure Firewall Management Center Model

Firewall Management Center Model	Hosts
MC1600	50,000
MC1700	50,000
MC2600	150,000
MC2700	150,000
MC4600	600,000
MC4700	600,000
virtual	50,000

You cannot view contextual data for hosts not in the network map. However, you can perform access control. For example, you can perform application control on traffic to and from a host not in the network map, even though you cannot use a compliance allow list to monitor the host's network compliance.

Note The system counts MAC-only hosts separately from hosts identified by both IP addresses and MAC addresses. All IP addresses associated with a host are counted together as one host.

Reaching the host limit and deleting hosts

The network discovery policy controls what happens when you detect a new host after reaching the host limit. You can drop the new host, or replace the host that has been inactive for the longest time. You can also set the period after which the system removes a host from the network map due to inactivity. Although you can manually delete a host, an entire subnet, or all of your hosts from the network map, if the system detects activity associated with a deleted host, it re-adds the host.

User limits for microsoft active directory

User limits impact monitoring and login capacity in Secure Firewall Management Center and Secure Firewall Threat Defense models for Microsoft Active Directory realms. These limits include maximum downloaded users and concurrent session limits. User prioritization, session management, and troubleshooting information help manage user database constraints.

About user limits

Your Firewall Management Center model determines how many individual users you can monitor. The user is added to the Firewall Management Center user database when:

- The user is downloaded from a realm.
- A captive portal or RA-VPN user logs in.
- A user is detected from any identity source (for example, TS Agent).

Only authoritative users are available for user control with access control policies.

Note the following:

- The maximum number of *downloaded* users depends on your Firewall Management Center model.
- The maximum number of *concurrent* user sessions (that is, logins) depends on your managed device model. A single user can have multiple sessions from different unique IP addresses.

Note The system downloads all user sessions to all Firewall Threat Defense devices. If you have devices with different user concurrent user session limits, the Firewall Threat Defense with the smallest limit reports health warnings when its memory reaches the configured limit. (For example, if your Firewall Management Center manages a Firepower 2110 and a 4125, the 2110 reports health warnings when the number of concurrent user sessions approaches its maximum of 64,000.)

User limits for microsoft active directory

Table 105: Maximum Concurrent User Login Limits by Firewall Threat Defense

Firewall Threat Defense Model	Maximum Concurrent User Logins per Realm
Firewall Threat Defense Virtual 5, 10, 20, 30, 50 (any supported hypervisor)	64,000
Firepower 1010, 1120, 1140, 1150 Firepower 2110, 2120, 2130 Secure Firewall 3105, 3110, 3120	64,000

Firewall Threat Defense Model	Maximum Concurrent User Logins per Realm
Firepower 2140 Secure Firewall 3130, 3140 Firepower 4112, 4115, 4125	150,000
Firepower 4145 Firepower 9300	300,000
Secure Firewall 4215	300,000
Secure Firewall 4225, 4245, 4250	315,000

User limits are applied per Microsoft Active Directory realm. That is, if you attempt to download more than the maximum users in a *single* realm, the download stops after that many users and a health alert is displayed. If, however, you attempt to download more than the maximum number of users spread across *different* realms, the download succeeds (unless any one realm has more than 150,000 users, in which case the download fails for that realm).

Table 106: Maximum Downloaded Users by Firewall Management Center Model

Firewall Management Center Model	Maximum Downloaded Users
FMC 1600	50,000
FMC 1700	50,000
FMC 2600	150,000
FMC 2700	150,000
FMC 2800	150,000
FMC 4600	600,000
FMC 4700	600,000
Firewall Management Center Virtual (any supported hypervisor)	50,000
Firewall Management Center Virtual 300 (any supported hypervisor)	150,000

When the system detects a new, previously-undetected user after the limit has been reached, it prioritizes user data based on their identity source:

- If the new user is from a non-authoritative source, the system does not add the non-authoritative user to the database. To allow new users to be added, you must delete users manually or purge the database.
- If the new user is from an authoritative identity source, the system deletes the non-authoritative user who has remained inactive for the longest period and adds the new authoritative user to the database.

  If there are only authoritative users, the system deletes the authoritative user who has remained inactive for the longest period of time and adds the new user to the database.

Troubleshooting information can be found in Troubleshoot user control, on page 1962.

Tip Note that if you are using traffic-based detection, you can restrict user logging by protocol to help minimize username clutter and preserve space in the database. For example, you could prevent the system from adding users discovered in AIM, POP3, and IMAP traffic because you know it is traffic from specific contractors or visitors you do not want to monitor.

Recommendation: identity realm limit

We limit you to a maximum of 25 realms regardless of Firewall Threat Defense model; the same limit applies to the Cloud-Delivered Firewall Management Center.

The number of *users* you can download to a system is limited according to the information provided in:

User limits for microsoft active directory, on page 1831

User limits for microsoft azure active directory realms

This reference provides user limit information for Microsoft Azure Active Directory realms, showing how different device models handle user monitoring and login capacity.

Microsoft azure active directory user limits

About user limits

Your Firewall Management Center model determines how many individual users you can monitor.

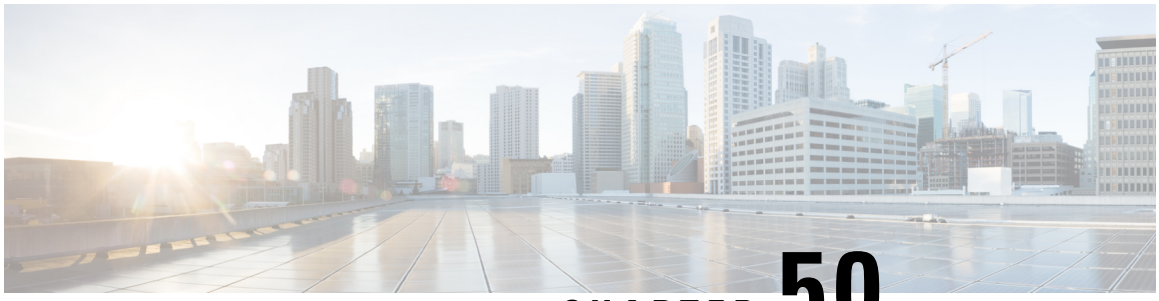
Note the following:

- The maximum number of *downloaded* users depends on your Firewall Management Center model.
- The maximum number of *concurrent* user sessions (that is, logins) depends on your managed device model. A single user can have multiple sessions from different unique IP addresses.

Note The system downloads all user sessions to all Firewall Threat Defense devices. If you have devices with different user concurrent user session limits, the Firewall Threat Defense with the smallest limit reports health warnings when its memory reaches the configured limit. (For example, if your Firewall Management Center manages a Firepower 2110 and a 4125, the 2110 reports health warnings when the number of concurrent user sessions approaches its maximum of 64,000.)

Refer to these tables.

Table 107: Maximum Downloaded Users by Firewall Management Center Model[1]



Firewall Management Center Model	Number of Dynamic Attributes Connector Connectors	Maximum Downloaded Users
FMC1600, FMC1700	10	50,000
FMC2600, FMC2700	20	150,000
FMC4600, FMC4700	30	600,000
Firewall Management Center Virtual (any supported hypervisor)	10	50,000
Firewall Management Center Virtual 300 (any supported hypervisor)	20	150,000

[1]—Firewall Management Center models are subject to end of life and end of sale. For more information, see End-Of-Life and End-Of-Sale Notices.

Table 108: Maximum Concurrent User Login Limits by Firewall Threat Defense

Firewall Threat Defense Model	Maximum Concurrent User Logins
Firewall Threat Defense Virtual 5, 10, 20, 30, 50 (any supported hypervisor)	50,000
Firepower 1010, 1120, 1140, 1150 Firepower 2110, 2120, 2130 Secure Firewall 3110, 3120, 3130, 3140	50,000
Firepower 2140 Secure Firewall 3130, 3140	150,000
Firepower 4140, 4145, 4150 Firepower 9300 Secure Firewall 4215	225,000
Secure Firewall 4225, 4245	300,000

Note The Secure Firewall 200 series can download a *cumulative total* of 10,000 user IPs, SXP/SGT mappings, endpoint profiles, and dynamic objects. After a total of 10,000 have been downloaded, the Secure Firewall 200 stops downloading any objects until some previously downloaded objects have been removed. (For example, if users log out, the memory is free for other objects.)

CHAPTER 50

Realms

The following topics describe realms and identity policies:

- Realms and realm sequences, on page 1835
- License requirements for realms, on page 1843
- Requirements and prerequisites for realms, on page 1843
- Prerequisites for kerberos authentication, on page 1843
- Realm fields, on page 1844
- Realm directory and synchronize fields, on page 1848
- Create a Microsoft Azure AD Realm, on page 1850
- Create an LDAP realm or an Active Directory realm and realm directory, on page 1860
- Create a realm sequence, on page 1867
- Cross-domain trust setups with Firewall Management Center, on page 1868
- Manage a realm, on page 1876
- Compare realms, on page 1877
- Troubleshoot realms and user downloads, on page 1877
- History for realms, on page 1885

Realms and realm sequences

Realms are connections between the Secure Firewall Management Center and the user accounts on the servers you monitor that

- specify the connection settings and authentication filter settings for the server,
- specify the users and user groups whose activity you want to monitor, and
- query the user repository for user metadata on authoritative users, as well as some non-authoritative users: POP3 and IMAP users detected by traffic-based detection and users detected by traffic-based detection, a TS Agent, or ISE/ISE-PIC.

(Microsoft AD realm only.) A *realm sequence* is an ordered list of two or more Active Directory realms to use in identity policy. When you associate a realm sequence with an identity rule, the system searches the Active Directory domains in order from first to last as specified in the realm sequence.

Realm configuration requirements

You can add multiple domain controllers as directories in a realm, but they must share the same basic realm information. The directories in a realm must be exclusively LDAP or exclusively Active Directory (AD) servers. After you enable a realm, your saved changes take effect next time the Secure Firewall Management Center queries the server.

To perform user awareness, you must configure a realm for any of the supported server types. The system uses these connections to query the servers for data associated with POP3 and IMAP users, and to collect data about LDAP users discovered through traffic-based detection.

The system uses the email addresses in POP3 and IMAP logins to correlate with LDAP users on an Active Directory, Microsoft Azure Active Directory, or OpenLDAP. For example, if a managed device detects a POP3 login for a user with the same email address as an LDAP user, the system associates the LDAP user's metadata with that user.

To perform user control, you can configure any of these:

- A realm or realm sequence for an Active Directory, Microsoft Azure Active Directory, server, or for ISE/ISE-PIC

Note Configuring a Microsoft AD realm or realm sequence is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions; or if you use your identity policy only to filter network traffic.

Realm sequence is not available for Microsoft Azure AD realms.

- A realm or realm sequence for a Microsoft AD server for the TS Agent.
- For captive portal, an LDAP realm.

  A realm sequence is not supported for LDAP.

You can nest Microsoft AD groups and the Firewall Management Center downloads those groups and the users they contain. You can optionally restrict which groups and users get downloaded as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.

User synchronization

You can configure a realm or realm sequence to establish a connection between the Firewall Management Center and an LDAP or Microsoft AD server to retrieve user and user group metadata for certain detected users:

- LDAP and Microsoft AD users authenticated by captive portal or reported by ISE/ISE-PIC. This metadata can be used for user awareness and user control.
- POP3 and IMAP user logins detected by traffic-based detection, if those users have the same email address as an LDAP or AD user. This metadata can be used for user awareness.

The Firewall Management Center obtains this information and metadata about each user:

- LDAP user name
- First and last names

- Email address
- Department
- Telephone number

Important To reduce latency between the Firewall Management Center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the Firewall Management Center.

For example, if your Firewall Management Center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

User activity data

User activity data is stored in the user activity database and user identity data is stored in the users database. The maximum number of users you can store and use in access control depends on your Firewall Management Center model. When choosing which users and groups to include, make sure the total number of users is less than your model limit. If your access control parameters are too broad, the Firewall Management Center obtains information on as many users as it can and reports the number of users it failed to retrieve in the Tasks tab page of the Message Center.

To optionally limit the subnets on which a managed device watches for user awareness data, you can use the **configure identity-subnet-filter** command as discussed in the *Cisco Secure Firewall Threat Defense Command Reference*.

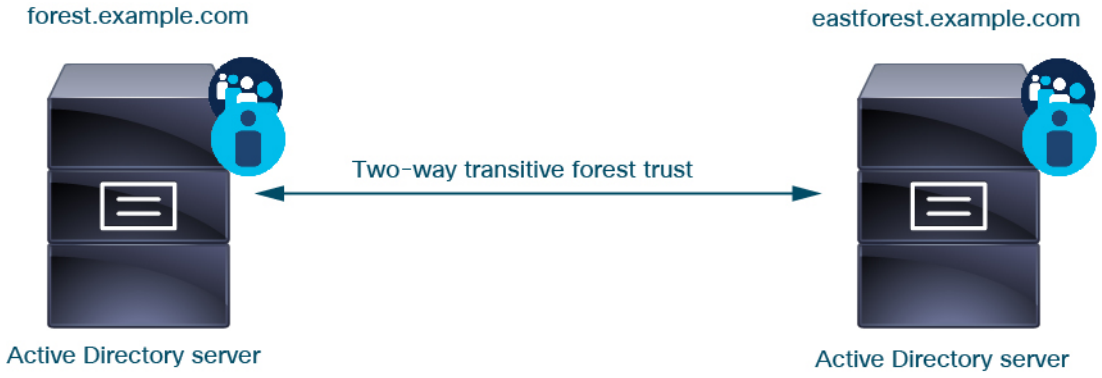
Note If you remove a user that has been detected by the system from your user repository, the Firewall Management Center does *not* remove that user from its users database; you must manually delete it. However, your LDAP changes *are* reflected in access control rules when the Firewall Management Center next updates its list of authoritative users.

Realms and trusted domains

When you configure a Microsoft Active Directory (AD) *realm* in the Firewall Management Center, it is associated with a Microsoft Active Directory or LDAP *domain*.

Microsoft active directory forests and trust relationships

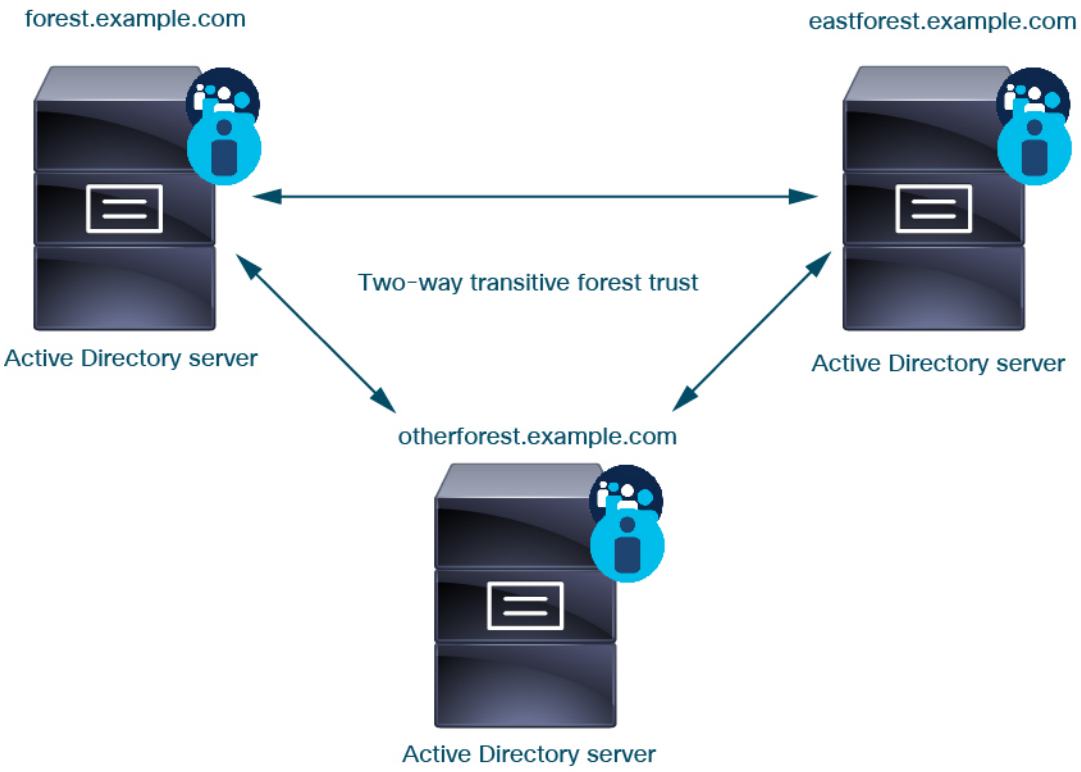
A grouping of Microsoft Active Directory (AD) domains that trust each other is commonly referred to as a *forest*. This trust relationship can enable domains to access each other's resources in different ways. For example, a user account defined in domain A can be marked as a member of a group defined in domain B.



Note Trusted domains apply to Microsoft Active Directory domains only. They do *not* apply to either Microsoft Azure Active Directory or LDAP domains.

The system supports AD forests that are configured in a trust relationship. There are several types of trust relationships; this guide discusses two-way, transitive forest trust relationships. This simple example shows two forests: **forest.example.com** and **eastforest.example.com**. Users and groups in each forest can be authenticated by AD in the other forest, provided you configure the forests that way.

If you set up the system with one realm for each domain and one directory for each domain controller, the system can discover up to 100,000 foreign security principals (users and groups). If these foreign security principals match a user downloaded in another realm, then they can be used in access control policy.



You need not configure a realm for any domain that has no users you wish to use in access control policies.

Figure 413: Two-forest configuration with two-way transitive trust

To continue the example, suppose you have three AD forests (one of which could be a subdomain or an independent forest), all set up as two-way transitive forest relationships, all users and groups are available in all three forests as well as in the system. (As in the preceding example, all three AD domains must be set up as realms and all domain controllers must be configured as directories in those realms.)

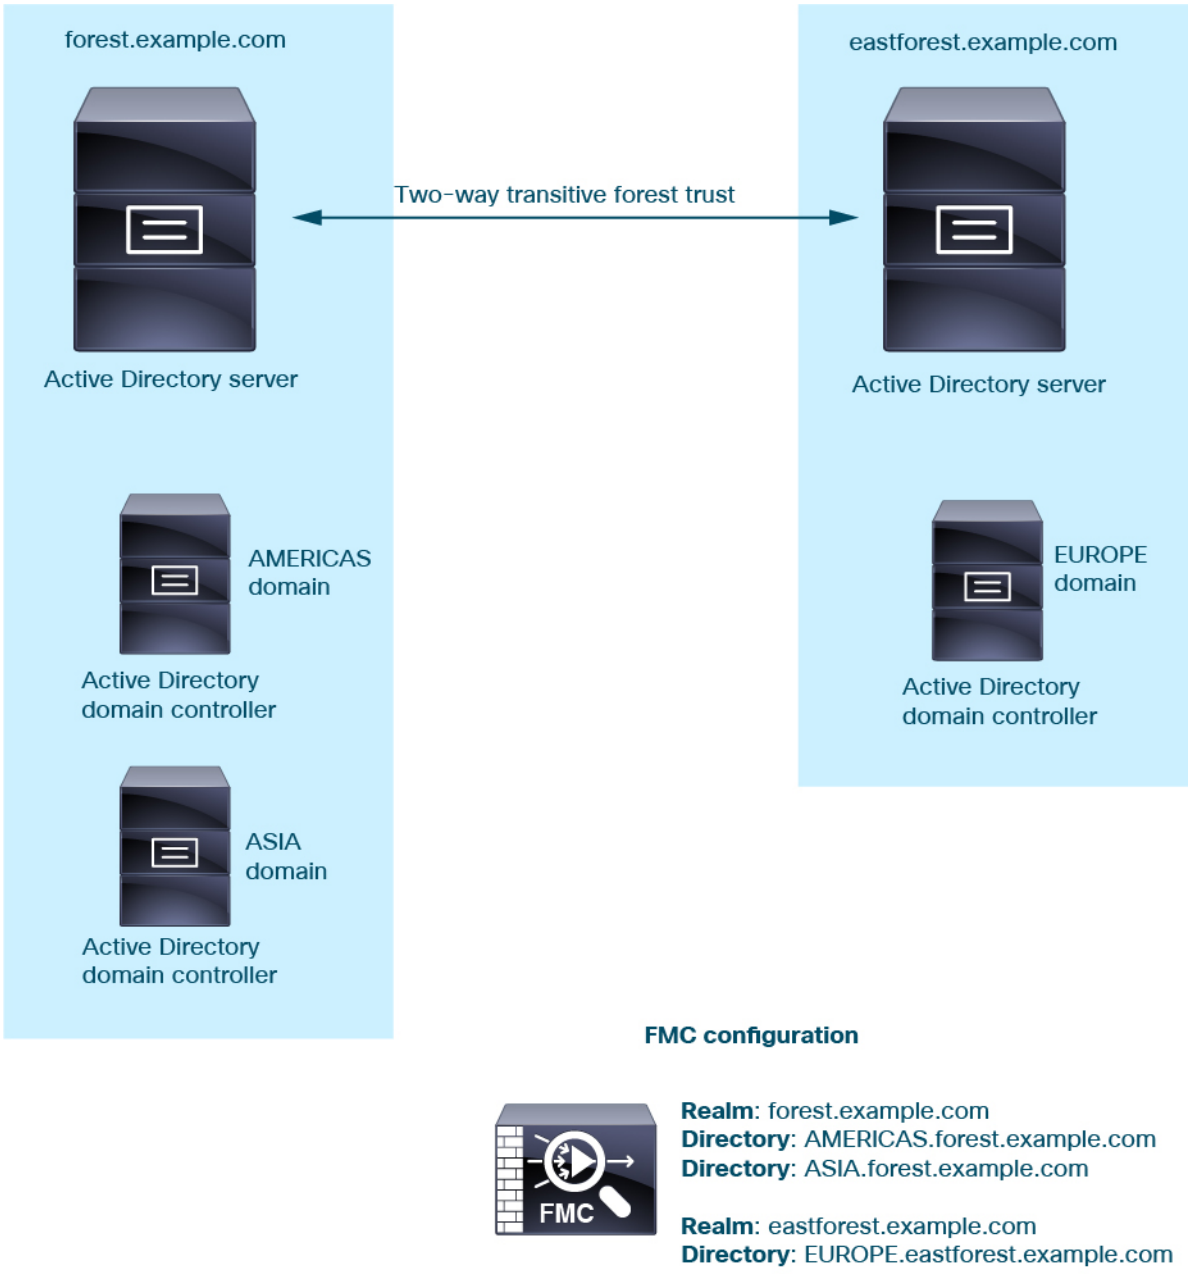


Figure 414: Three-forest configuration with two-way transitive trust

Finally, you can set up the Firewall Management Center to be able to enforce identity policies on users and groups in a two-forest system with two-way transitive forest trust. Suppose each forest has at least one domain controller, each of which authenticates different users and groups. For the Firewall Management Center to be able to enforce identity policies on those users and groups, you must set up each domain containing relevant users as Firewall Management Center realm and each domain controller as Firewall Management Center directory in the respective realm.

Failure to properly configure the Firewall Management Center prevents some of the users and groups from being able to be used in policies. You will see warnings when you try to synchronize users and groups in that case.

Figure 415: Multi-domain forest configuration

Using the preceding example, set up the Firewall Management Center as follows:

- Realm for any domain in **forest.example.com** that contains users you want to control with access control policies
  - Directory in the realm for **AMERICAS.forest.example.com**
  - Directory in the realm for **ASIA.forest.example.com**

- Realm for any domain in **eastforest.example.com** that contains users you want to control with access control policies
  - Directory in the realm for **EUROPE.eastforest.example.com**

Note The Firewall Management Center uses the AD field **msDS-PrincipalName** to resolve references to find user and group names in each domain controller. **msDS-PrincipalName** returns a NetBIOS name.

Supported servers for realms

You can configure realms to connect to the following types of servers, providing they have TCP/IP access from the Firewall Management Center:

Server Type	Supported for ISE/ISE-PIC data retrieval?	Supported for TS Agent data retrieval?	Supported for captive portal data retrieval?
Microsoft Active Directory on Windows Server 2012, 2016, and 2019	Yes	Yes	Yes
Microsoft Azure AD	Yes	No	No
OpenLDAP on Linux	No	No	Yes

An Active Directory Global Catalog server is *not supported* as a realm directory. For more information about the Global Catalog Server, refer to Global Catalog on learn.microsoft.com.

Note If the TS Agent is installed on a Microsoft Active Directory Windows Server shared with another passive authentication identity source (ISE/ISE-PIC), the Firewall Management Center prioritizes the TS Agent data. If the TS Agent and a passive identity source report activity by the same IP address, only the TS Agent data is logged to the Firewall Management Center.

Note the following about your server group configurations:

- To perform user control on user groups or on users in groups, you must configure user groups on the LDAP or Active Directory server.
- Group names cannot start with `S-` because it is used internally by LDAP.

  Neither group names nor organizational unit names can contain special characters like asterisk (*), equals (=), or backslash (\); otherwise, users in those groups or organizational units are not downloaded and are not available for identity policies.

- To configure an Active Directory realm that includes or excludes users who are members of a sub-group on your server, note that Microsoft recommends that Active Directory has no more than 5000 users per group in Windows Server 2012. For more information, see Active Directory Maximum Limits—Scalability on MSDN.

  If necessary, you can modify your Active Directory server configuration to increase this default limit and accommodate more users.

- To uniquely identify the users reported by a server in your Remote Desktop Services environment, you must configure the Cisco Terminal Services (TS) Agent. When installed and configured, the TS Agent assigns unique ports to individual users so the system can uniquely identify those users. (Microsoft changed the name *Terminal Services* to *Remote Desktop Services*.)

  For more information about the TS Agent, see the *Cisco Terminal Services (TS) Agent Guide*.

Supported server object class and attribute names

Map user metadata attributes from your LDAP servers to the correct firewall fields to ensure user information is accurately retrieved and populated in the firewall.

The servers in your realms *must* use the attribute names listed in the following table for the Secure Firewall Management Center to retrieve user metadata from the servers. If the attribute names are incorrect on your server, the Secure Firewall Management Center cannot populate its database with the information in that attribute.

Table 109: Map of attribute names to Secure Firewall Management Center fields

Metadata	Firewall Management Center Attribute	LDAP ObjectClass	Active Directory Attribute	OpenLDAP Attribute
LDAP user name	Username	• user • inetOrgPerson	samaccountname	cn uid
first name	First Name		givenname	givenname
last name	Last Name		sn	sn
email address	Email		mail userprincipalname (if mail has no value)	mail
department	Department		department distinguishedname (if department has no value)	ou
telephone number	Phone		telephonenumber	telephonenumber

Note The LDAP ObjectClass for groups is `group`, `groupOfNames`, (`group-of-names` for Active Directory) or `groupOfUniqueNames`.

For more information about ObjectClasses and attributes, see these references:

- Microsoft Active Directory:
  - ObjectClasses: All Classes on MSDN
  - Attributes: All Attributes on MSDN
- OpenLDAP: RFC 4512

License requirements for realms

This topic outlines the specific license requirements necessary to enable and manage realms.

Threat Defense License

Any

Classic License

Control

Requirements and prerequisites for realms

Model support

Any.

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin

Prerequisites for kerberos authentication

If you're using Kerberos to authentication captive portal users, keep the following in mind.

Hostname character limit

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

DNS response character limit

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.

Realm fields

Configure a realm to manage user authentication, directory access, and session timeouts for Active Directory, LDAP, or LOCAL user repositories in the Secure Firewall Management Center. Learn how to set realm type, credentials, supported characters, and session duration for identity policies and RA-VPN configurations.

Realm configuration fields

These settings apply to all Active Directory servers or domain controllers (also referred to as *directories*) in a realm.

Name

A unique name for the realm.

- To use the realm in identity policies, the system supports alphanumeric and special characters.
- To use the realm in RA VPN configurations, the system supports alphanumeric, hyphen (-), underscore (_), and plus (+) characters.

Description

(Optional.) Enter a description of the realm.

Type

The type of realm, **AD** for Microsoft Active Directory, **LDAP** for other supported LDAP repositories, or **LOCAL**. For a list of supported LDAP repositories, see Supported servers for realms, on page 1841. You can authenticate captive portal users with an LDAP repository; all others require Active Directory.

Note Only captive portal supports an LDAP realm.

The realm type **LOCAL** is used for configuring LOCAL user settings. The LOCAL realm is used in remote access user authentication.

Add the following LOCAL User Information for the LOCAL realm:

- **Username**—Name of the LOCAL user.
- **Password**—LOCAL user password.
- **Confirm Password**—Confirm the LOCAL user password.

Note **Click Add another LOCAL user** to add more users to the LOCAL realm.

You can add more users after creating the realm and update password for the LOCAL users. You can also create multiple LOCAL realms but cannot disable them.

AD Primary Domain

For Microsoft Active Directory realms only. Domain for the Active Directory server where users should be authenticated.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

AD Join Username and AD Join Password
(Available on the **Realm Configuration** tab page when you edit a realm.)

For Microsoft Active Directory realms intended for Kerberos captive portal active authentication, the distinguished username and password of any Active Directory user with appropriate rights to create a Domain Computer account in the Active Directory domain.

Keep the following in mind:

- DNS must be able to resolve the domain name to an Active Directory domain controller's IP address.
- The user you specify must be able to join computers to the Active Directory domain.
- The user name must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).

If you choose **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) as the **Authentication Protocol** in an identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

Note The SHA-1 hash algorithm is not secure for storing passwords on your Active Directory server and should not be used. For more information, consult a reference such as Migrating your Certification Authority Hashing Algorithm from SHA1 to SHA2 on Microsoft TechNet or Password Storage Cheat Sheet on the Open Web Application Security Project website.

We recommend SHA-256 for communicating with Active Directory.

Group Attribute
(Available on the **Realm Configuration** tab page.)

These group attributes are available for Microsoft Active Directory or LDAP realms.

- Member: A user attribute that indicates the groups to which a user belongs. Each user entry contains a Member attribute that lists the groups the user is part of, rather than each group listing its members.
- Unique Member: A group attribute that lists the distinguished names (DNs) of the members of the group.

Directory Username and Directory Password

The distinguished username and password for a user with appropriate access to the user information you want to retrieve.

Note the following:

- For OpenLDAP, the user's access privileges are determined by the `<level>` parameter discussed in section 8 of the OpenLDAP specification. The user's `<level>` should be `auth` or better.
- The user name must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).

Note The SHA-1 hash algorithm is not secure for storing passwords on your Active Directory server and should not be used. For more information, consult a reference such as Migrating your Certification Authority Hashing Algorithm from SHA1 to SHA2 on Microsoft TechNet or Password Storage Cheat Sheet on the Open Web Application Security Project website.

We recommend SHA-256 for communicating with Active Directory.

Base DN

(Optional.)The directory tree on the server where the Secure Firewall Management Center should begin searching for user data. If you don't specify a **Base DN**, the system retrieves the top-level DN provided you can connect to the server.

Typically, the base distinguished name (DN) has a basic structure indicating the company domain name and operational unit. For example, the Security organization of the Example company might have a base DN of **`ou=security,dc=example,dc=com`**.

Group DN

(Optional.)The directory tree on the server where the Secure Firewall Management Center should search for users with the group attribute. A list of supported group attributes is shown in Supported server object class and attribute names, on page 1842. If you don't specify a **Group DN**, the system retrieves the top-level DN provided you can connect to the server.

Note The following is the list of characters the system *supports* in users, groups, DNS in your directory server. Using any characters other than these could result in the system failing to download users and groups.

Entity	Supported characters
User name	**a-z A-Z 0-9 ! # $ % ^ & ( ) _ - { } ' . ~ `**
Group name	**a-z A-Z 0-9 ! # $ % ^ & ( ) _ - { } ' . ~ `**
Base DN and Group DN	**a-z A-Z 0-9 ! @ $ % ^ & * ( ) _ - . ~ `**

A space is not supported anywhere in a user name, including at the end.

These fields are available when you edit an existing realm.

User Session Timeout

(Available on the **Realm Configuration** tab page when you edit a realm.)

Enter the number of minutes before user sessions time out. The default is 1440 (24 hours) after the user's login event. After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Secure Firewall Management Center as Unknown (except for **Failed Captive Portal Users**).

In addition, if you set up ISE/ISE-PIC without a realm and the timeout is exceeded, a workaround is required. For more information, contact Cisco TAC.

You can set timeout values for the following:

- **User Agent and ISE/ISE-PIC Users**: Timeout for users tracked by the user agent or by ISE/ISE-PIC, which are types of passive authentication.

  The timeout value you specify does *not* apply to pxGrid SXP session topic subscriptions (for example, destination SGT mappings). Instead, session topic mappings are preserved as long as there is no delete or update message for a given mapping from ISE.

  For more information about ISE/ISE-PIC, see The ISE/ISE-PIC identity source, on page 1911.

- **Terminal Services Agent Users**: Timeout for users tracked by the TS Agent, which is a type of passive authentication. For more information, see Terminal services agent identity source, on page 1937.

- **Captive Portal Users**: Timeout for users who successfully log in using the captive portal, which is a type of active authentication. For more information, see Captive portal identity source, on page 1887.

- **Failed Captive Portal Users**: Timeout for users who do not successfully log in using the captive portal. You can configure the **Maximum login attempts** before the user is seen by the Secure Firewall Management Center as Failed Auth User. A Failed Auth User can optionally be granted access to the network using access control policy and, if so, this timeout value applies to those users.

  For more information about failed captive portal logins, see Captive portal fields, on page 1903.

- **Guest Captive Portal Users**: Timeout for users who log in to the captive portal as a guest user. For more information, see Captive portal identity source, on page 1887.

Realm directory and synchronize fields

Configure Active Directory realm directory and user synchronization fields to enable secure authentication, user data lookup, and group management in the Secure Firewall Management Center. Learn how to specify server, encryption, domain, and group settings for optimized user awareness and access control.

Realm directory fields

These settings apply to individual servers (such as Active Directory domain controllers) in a realm.

Hostname / IP Address

Fully qualified host name of the Active Directory domain controller machine. To find the fully qualified name, see Find the active directory server's name, on page 1863.

If you're using Kerberos for authenticating captive portal, also make sure you understand these considerations:

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.

Port

The server's port.

Encryption

(Strongly recommended.) The encryption method to use:

- **`STARTTLS`**—encrypted LDAP connection
- **`LDAPS`**—encrypted LDAP connection
- **`None`**—unencrypted LDAP connection (unsecured traffic)

To communicate securely with an Active Directory server, see Connect securely to Active Directory or LDAP, on page 1862.

CA Certificate

The TLS/SSL certificate to use for authentication to the server. You must configure **`STARTTLS`** or **`LDAPS`** as the **Encryption** type to use a TLS/SSL certificate.

If you are using a certificate to authenticate, the name of the server in the certificate must match the server **Hostname / IP Address**. For example, if you use 10.10.10.250 as the IP address but **`computer1.example.com`** in the certificate, the connection fails.

Interface used to connect to Directory server

Required only for RA VPN authentication so the Secure Firewall Threat Defense can connect securely to your Active Directory server. This interface is not used for downloading users and groups, however.

You can choose only a routed interface group. For more information, see Interfaces, on page 2383.

Click one of these options:

- **Resolve via route lookup**: Use routing to connect to the Active Directory server.
- **Choose an interface**: Choose a specific managed device interface group to connect to the Active Directory server.

User synchronize fields

AD Primary Domain

For Microsoft Active Directory realms only. Domain for the Active Directory server where users should be authenticated.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

Enter query to look for users and groups

Base DN:

(Optional.) The directory tree on the server where the Firewall Management Center should begin searching for user data.

Typically, the base distinguished name (DN) has a basic structure indicating the company domain name and operational unit. For example, the Security organization of the Example company might have a base DN of `ou=security,dc=example,dc=com`.

Group DN:

(Optional.) The directory tree on the server where the Firewall Management Center should search for users with the group attribute. A list of supported group attributes is shown in Supported server object class and attribute names, on page 1842.

Note Neither the group name nor the organizational unit name can contain special characters like asterisk (*), equals (=), backslash (\) because users in those groups are not downloaded and cannot be used in identity policies.

Load Groups

Enables you to download users and groups for user awareness and user control.

Available Groups, Add to Include, Add to Exclude

Limits the groups that can be used in policy.

- Groups that are displayed in the **Available Groups** field are available for policy unless you move groups to the **Included Groups and Users** or **Excluded Groups and Users** field.
- If you move groups to the **Included Groups and Users** field, only those groups and users they contain are downloaded and user data is available for user awareness and user control.
- If you move groups to the **Excluded Groups and Users** field, all groups and users they contain *except* these are downloaded and available for user awareness and user control.
- To include users from groups that are not included, enter the user name in the field below **User Inclusion** and click **Add**.
- To exclude users from groups that are not excluded, enter the user name in the field below **User Exclusion** and click **Add**.

Note The users that are downloaded to the Firewall Management Center is calculated using the formula **R = I - (E+e) + i**, where

- R is list of downloaded users
- I is included groups
- E is excluded groups
- e is excluded users
- i is included users

Synchronize Now
Click to synchronize groups and users with AD.

Begin automatic synchronization at
Enter the time and time interval at which to download users and groups from AD.

Create a Microsoft Azure AD Realm

You can use a Microsoft Azure Active Directory (AD) realm with Cisco ISE to authenticate users and get user sessions for user control. We get groups from Azure AD and logged-in user session data from Cisco ISE.

Authentication options

You have two authentication options:

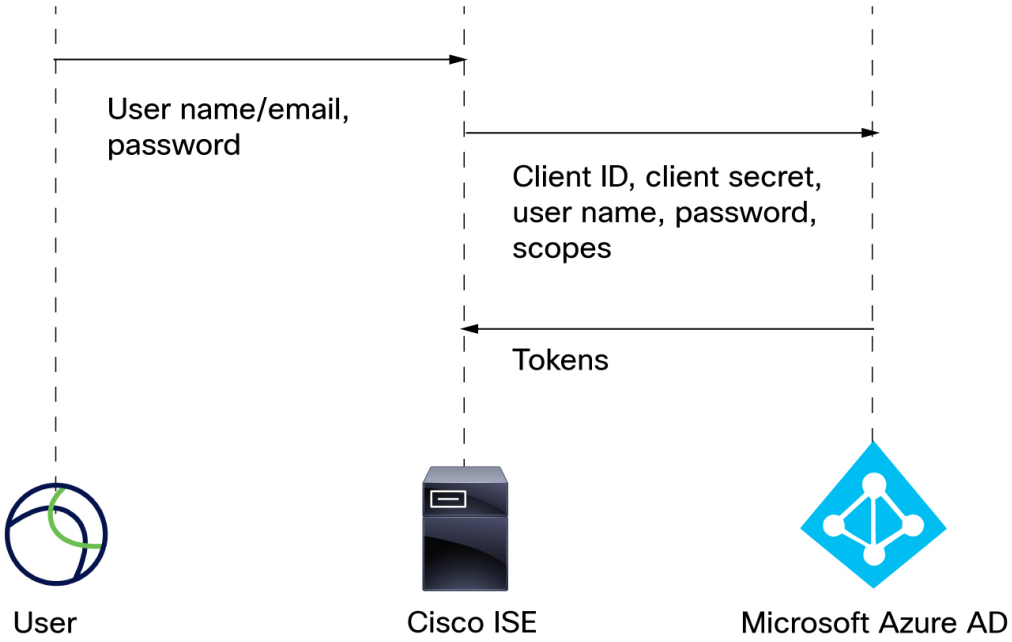
- Resource owned password credentials (ROPC): Enables users to log in with a client like AnyConnect using a user name and password. ISE sends user sessions to the Secure Firewall Management Center. For more information, see How Entra ID and Cisco ISE authentication with resource owned password credentials works, on page 1851.

  Additional resource: Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com.

- Extensible Authentication Protocol (EAP) Chaining with Tunnel-based Extensible Authentication Protocol (TEAP) and Transport Layer Security (TLS), abbreviated EAP/TEAP-TLS: TEAP is a tunnel-based EAP

method that establishes a secure tunnel and executes other EAP methods under the protection of that secured tunnel. ISE is used to validate user credentials and to send user sessions to the Secure Firewall Management Center. For more information, see How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS, on page 1852.

Note Before deploying policies related to a Microsoft Azure AD realm, see User limits for microsoft azure active directory realms, on page 1833.



How Entra ID and Cisco ISE authentication with resource owned password credentials works

Summary

The key components involved in the Entra ID authentication with resource owned password credentials process are:

- User: Logs in with credentials using a VPN client
- Cisco Secure Client: VPN client that sends user credentials
- Entra ID (formerly Azure AD): Validates credentials and issues tokens
- Cisco ISE: Receives tokens and manages user sessions
- Secure Firewall Management Center: Receives user sessions from ISE

Workflow

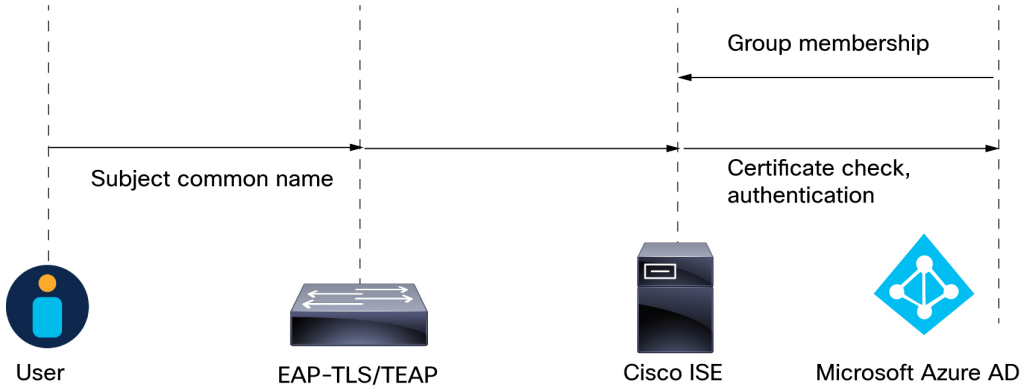
These stages describe how Entra ID and Cisco ISE authentication with resource owned password credentials works:

1. The user logs in with a user name (or email address) and password using a VPN client like Cisco Secure Client.
2. The client ID, client secret, user name, password, and scopes are sent to Entra ID.
3. Tokens are sent from Entra ID to Cisco ISE, which sends user sessions to the Secure Firewall Management Center.

   For details about configuring Cisco ISE, see Configure ISE 3.0 REST ID with Azure Active Directory.

   Additional resource: Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com.

How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS



Tunnel Extensible Authentication Protocol (TEAP), defined by RFC7170, can be used with ISE and the Secure Firewall Management Center for secure authentication.

Summary

The key components involved in this authentication process are:

- User device: Provides certificate through EAP-TLS or TEAP protocol
- ISE: Validates certificate and performs user lookup through Azure Graph API
- Entra ID: Provides user attributes and group information for authorization

Workflow

These stages describe how the authentication process works and are based on Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory:

1. The user's certificate is sent to ISE through EAP-TLS or TEAP with EAP-TLS as the inner method.
2. ISE evaluates the user's certificate (validity period, trusted certificate authority, certificate revocation list, and so on).

3. ISE takes the certificate subject name (CN) and performs a look-up to the Azure Graph API to fetch the user's groups and other attributes. This is referred to by Azure as User Principal name (UPN).
4. ISE authorization policies are evaluated against the user's attributes returned from Azure.

Create a Microsoft Azure AD realm

Create and configure a (now called *Entra ID*) realm for passive authentication use with the Secure Firewall Management Center.

This configuration enables passive authentication between Microsoft Entra ID and your firewall system through proper realm setup and access control policy integration.

Procedure

Step 1 Enable the Dynamic Attributes Connector.

The Dynamic Attributes Connector is required to use a realm. You can do it first or you can enable it when you create the realm. For more information, see Enable the dynamic attributes connector, on page 2063.

Step 2 Configure Microsoft Entra ID.

Several configuration tasks are required, including setting up an event hub, giving your application permission to the Microsoft Graph API, and enabling the audit log.

See Configure Microsoft Entra ID, on page 1854.

Step 3 Configure Cisco ISE.

The way you configure ISE depends on how users authenticate with your system. For more information, see Configure Cisco ISE for Microsoft Azure AD, on page 1855.

Step 4 Create a Cisco ISE identity source.

The identity source enables ISE to communicate with the Secure Firewall Management Center.

Step 5 Get the information required to configure your Microsoft Azure AD realm.

This information includes client and tenant IDs, client secret, and other information store in Microsoft Entra ID.

Step 6 Configure and verify your realm.

Test the realm's configuration before you start to use it in access control policies.

Step 7 Create access control policies and rules using your Microsoft Azure AD (SAML) realm.

Unlike other types of realms, you do not need to create an identity policy or associate the identity policy with an access control policy.

See Creating a basic access control policy, on page 1575 and Create and edit access control rules, on page 1631.

What to do next

See How Entra ID and Cisco ISE authentication with resource owned password credentials works, on page 1851.

Configure Microsoft Entra ID

Configure Microsoft Entra ID to enable passive authentication and user group synchronization with the Secure Firewall Management Center.

This task provides basic information about how to set up a Microsoft Entra ID (formerly called *Microsoft Azure Active Directory (AD)*) as a realm you can use with the Secure Firewall Management Center. We expect you to already be familiar with Entra ID; if not, consult documentation or a support resource before you get started.

Procedure

Step 1 Grant your Entra ID application the Microsoft Graph permissions.

Grant your Entra ID application the following permissions to Microsoft Graph as discussed in Authorization and the Microsoft Graph Security API on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the Secure Firewall Management Center to download users and groups from Entra ID the first time.

Required information from this step for setting up the Entra ID realm in the Secure Firewall Management Center:

- Name of the app you registered
- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

Step 2 Set up an event hub.

Set up the event hub as discussed in Quickstart: Create an event hub using Azure portal on the Microsoft site. The Secure Firewall Management Center uses the event hub audit log to download periodic updates to users and groups.

More information: Features and terminology in Azure Event Hubs.

Important You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

Required information from this step for setting up the Entra ID realm in the Secure Firewall Management Center:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

Step 3 Enable the audit log.

Enable the audit log as discussed in Tutorial: Stream Azure Active Directory logs to an Azure event hub on the Microsoft site.

Step 4 Configure Cisco ISE for Entra ID.

To send user session information to the Secure Firewall Management Center, configure Cisco ISE for Entra ID as discussed in Configure ISE 3.0 REST ID with Azure Active Directory.

What to do next

See Configure Cisco ISE for Microsoft Azure AD, on page 1855.

Configure Cisco ISE for Microsoft Azure AD

In a Microsoft Azure AD (now called *Entra ID*) realm, it's the responsibility of ISE to send user sessions (login, logout) to the Secure Firewall Management Center. This topic discusses how to set up ISE for use with an Azure AD realm.

Resource owned password credentials authentication

To use ISE with Microsoft Azure ADMicrosoft Azure AD implemented through Representational State Transfer (REST) Identity (ID) service with the help of Resource Owner Password Credentials (ROPC), see Configure ISE 3.0 REST ID with Azure Active Directory.

TEAP/EAP-TLS

To use ISE with authorization policies based on Azure AD group membership and other user attributes with EAP-TLS or TEAP as the authentication protocols, see Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory.

What to do next

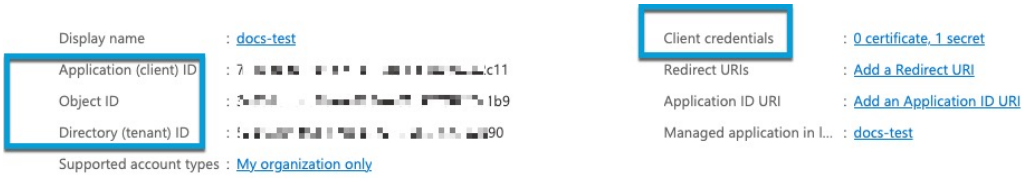
Get required information For Your Microsoft Azure AD realm, on page 1855

Get required information For Your Microsoft Azure AD realm

This task enables you to collect the necessary credentials and configuration information from Microsoft Entra ID (formerly Azure AD) and Event Hubs to establish a SAML authentication realm in your Secure Firewall Management Center.

This task explains how to get the information required to set up a Microsoft Azure AD (now called *Entra ID*) realm in the Secure Firewall Management Center. You might have already obtained this information when you set up Microsoft Entra ID as discussed in Configure Microsoft Entra ID, on page 1854.

Procedure



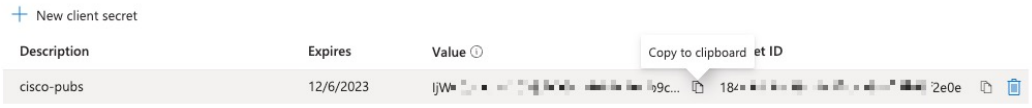
Step 1 Log in to https://portal.azure.com/ as a user with at least the Product Designer role.

Step 2 At the top of the page, click **Microsoft Entra ID**.

Step 3 In the left column, click **App Registrations**.

a) If necessary, filter the list of displayed apps to show the one you want to use.

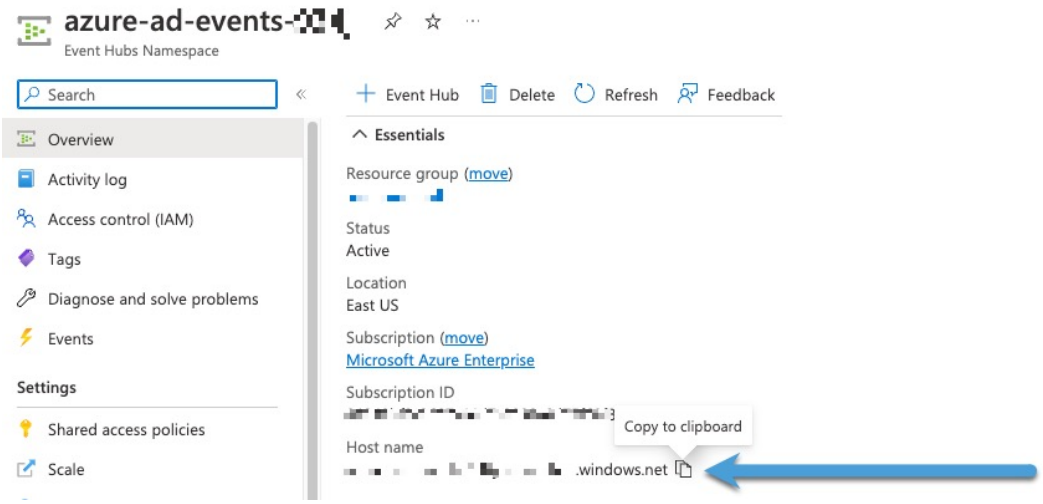
b) Click the name of your app.



c) Click **Copy** ( ) next to the following values on this page and paste those values to a text file.

- **Application (Client) ID**
- **Directory (tenant) ID**

d) Click **Client Credentials**.

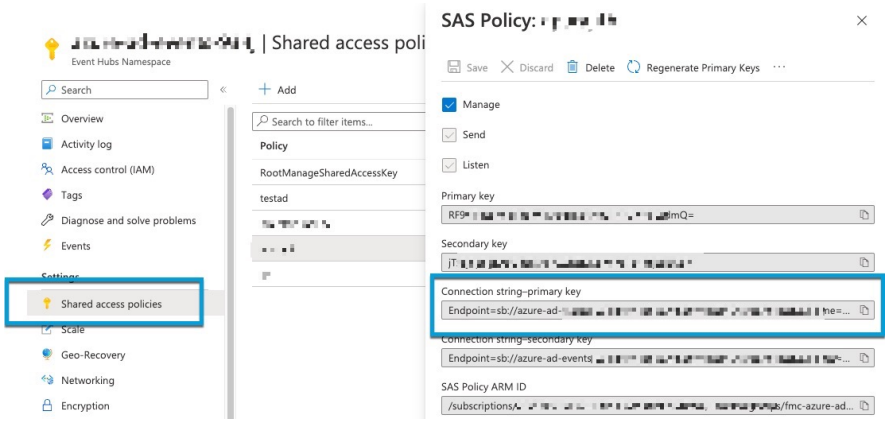


e) Unless you already know the client secret *value* (as opposed to the client *secret ID*), you must create a new client secret as follows:

1. Click **New Client Secret**.
2. Enter the required information in the provided fields.
3. Click **Add**.
4. Click **Copy** ( ) next to Value as the following figure shows.

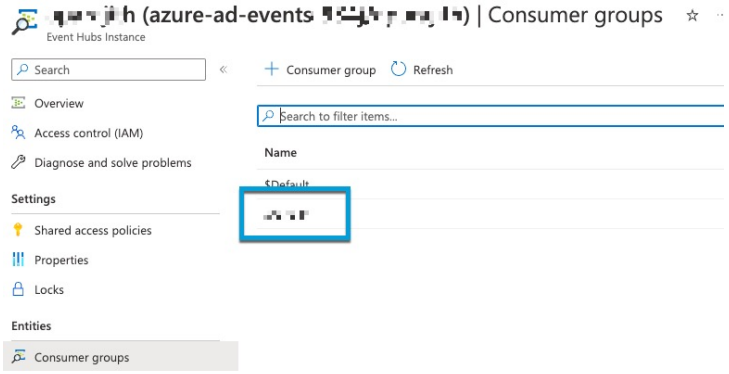
Step 4 From https://portal.azure.com/, click **Event Hubs** > **(name of an event hub)**.

a) In the right pane, click **Copy** ( ) next to the value of **Host name** and paste the value to the clipboard. This is your event hub host name.



b) Write down or copy to a text file the name of the event hub (same as the **Event Hubs Namespace** at the top of the page).

c) In the left pane, under Settings, click **Shared access policies**.



d) Click the name of a policy.

e) Click **Copy** ( ) next to **Connection string-primary key**.

Step 5 Click **Overview** > **Entities** > **Event Hubs** > **(name of an event hub)** > **Entities** > **Consumer Groups**.

Write down this value or copy it to the clipboard. This is your consumer group name.

Step 6 In the left pane, click **Overview**.

Step 7 Click **Copy** ( ) next to **Namespace**.

This is your event hubs topic name.

Create an Azure AD realm

This task creates a *realm* (a connection between the Firewall Management Center and a Microsoft Azure AD realm) to enable user and identity control through access control policies.

Note To perform user and identity control with an Azure AD realm, you need only an access control policy with an associated Azure AD realm. You do not need to create an identity policy.

Before you begin

Complete all of the following tasks:

- Configure ISE as discussed in Configure Cisco ISE for Microsoft Azure AD, on page 1855
- Create an ISE identity source as discussed in ISE/ISE-PIC configuration, on page 1919
- Enable the Dynamic Attributes Connector as discussed in Enable the dynamic attributes connector, on page 2063 .
- Get values required for the Azure AD realm as discussed in Get required information For Your Microsoft Azure AD realm, on page 1855.
- Configure Azure AD as discussed in Configure Microsoft Entra ID, on page 1854

Follow these steps to create an Azure AD realm:

Procedure

Step 1 Log in to Secure Firewall Management Center .

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 To create a new realm, click **Add Realm** > **Azure AD**.

Step 4 Enter the required information.

Item	Description
Name	
(Optional.) **Description**	
Client ID	Enter the information you found as discussed in Get required information For Your Microsoft Azure AD realm, on page 1855.
Client Secret	
Tenant ID	
Event Hubs Host Name	
Event Hub Name	
Event Hub Connection String	
(Optional.) **Excluded User Groups**	Enter one or more groups from which to *not* download users for identity control. Users in these groups will not be available for use in access control policies. Enter one group name per line followed by a line break. Group names are case-sensitive.

Step 5 Enter the values you found as discussed in Get required information For Your Microsoft Azure AD realm, on page 1855.

Step 6 Click **Test**.

Step 7 Fix any errors that are displayed in the test.

Step 8 Click **Save**.

What to do next

Create an access control policy and rule as discussed in Creating a basic access control policy, on page 1575.

Note Before deploying policies related to a Microsoft Azure AD realm, see User limits for microsoft azure active directory realms, on page 1833.

Azure AD user session timeout

Set the Entra ID user session timeout for ISE or ISE-PIC to define how long users stay authenticated, ensuring network access control after timeout via the User Session Timeout page when editing an Entra ID realm.

The Azure AD user session timeout for ISE/ISE-PIC is available on the **User Session Timeout** page when you edit an Azure AD realm.

The default value 1440 minutes (24 hours). After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Firewall Management Center as Unknown (except for **Failed Captive Portal Users**).

Create an LDAP realm or an Active Directory realm and realm directory

Before you begin

If you're using Kerberos authentication for captive portal, see the following section before you begin: Prerequisites for kerberos authentication, on page 1843 .

Note Microsoft Azure Active Directory is not supported for captive portal.

Important To reduce latency between the Firewall Management Center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the Firewall Management Center.

For example, if your Firewall Management Center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

If you're setting up ISE/ISE-PIC without a realm, be aware there is a user session timeout that affects how users are seen by the Firewall Management Center.

The following procedure enables you to create a *realm* (a connection between the Firewall Management Center and an Active Directory realm) and a *directory* (a connection between the Firewall Management Center and an LDAP server or an Active Directory domain controller).

(Recommended.) To connect securely from the Firewall Management Center to your Active Directory server, first perform the following tasks:

- Export the active directory server's root certificate, on page 1863
- Find the active directory server's name, on page 1863

Microsoft has announced that Active Directory servers will start enforcing LDAP binding and LDAP signing in 2020. Microsoft is making these a requirement because when using default settings, an elevation of privilege vulnerability exists in Microsoft Windows that could allow a man-in-the-middle attacker to successfully forward an authentication request to a Windows LDAP server. For more information, refer to 2020 LDAP channel binding and LDAP signing requirement for Windows on the Microsoft support site.

For more information about realm and directory configuration fields, see Realm fields, on page 1844 and Realm directory and synchronize fields, on page 1848 .

A step-by-step example of setting up a realm with cross-domain trust is shown in Cross-domain trust setups with Firewall Management Center, on page 1868 .

An Active Directory Global Catalog server is *not supported* as a realm directory. For more information about the Global Catalog Server, refer to Global Catalog on learn.microsoft.com.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

Procedure

Step 1 Log in to the Secure Firewall Management Center. Click **Integration** > **Other Integrations** > **Realms** > **Realms**

Step 2 To create a new realm, choose from **Add Realm** drop-down list.

Step 3 To perform other tasks (such as enable, disable, or delete a realm), see Manage a realm, on page 1876 .

Step 4 Enter realm information as discussed in Realm fields, on page 1844 .

Step 5 In the Directory Server Configuration section, enter directory information as discussed in Realm directory and synchronize fields, on page 1848 .

Step 6 (Optional.) To configure another domain for this realm, click **Add another directory** .

Step 7 Click **Configure Groups and Users** .

Information	Description
AD Primary Domain	Domain for the Active Directory server where users should be authenticated. For additional information, see Realm fields, on page 1844 . You must create the realm with the original domain name of the domain and not any alternative user principal name (UPN) suffixes of the domain. Otherwise, users and groups fail to download and identity policies will not be enforced. For example, if the original domain is `domain.example.com` and the alternative UPN name is`domain2.mydomain.com`, you must configure the realm to use `domain.example.com`. For more information about configuring an alternative UPN suffix, see a resource like Configuring Alternate Login ID on learn.microsoft.com.
Base DN	The directory tree on the server where the Firewall Management Center should begin searching for user data.
Group DN	The directory tree on the server where the Firewall Management Center should begin searching for group data.

Information	Description
Load Groups	Click to load groups from the Active Directory server. If no groups are displayed, enter or edit information in the **AD Primary Domain** , **Base DN** , and **Group DN** fields and click **Load Groups** . For more information about those fields, see Realm fields, on page 1844 .
Available Groups section	Limit the groups to use in policy by moving them to either the **Included Groups and Users** or **Excluded Groups and Users** list. Moving one group to the **Included Groups and Users** list, for example, allows that group only to be used in policy but excludes all other groups. Groups in the **Excluded Groups and Users** and the users they contain are excluded from user awareness and control. All other groups and users *are* available. For more information, see Realm directory and synchronize fields, on page 1848 .

Configure the Realm

Before you begin

You must have created a new realm and its groups and users, as described in the prior procedure.

Procedure

Step 1 Click the **Realm Configuration** tab.

Step 2 Enter **Group Attribute** , and (if you use Kerberos authentication for captive portal) enter **AD Join Username** and **AD Join Password** . For more information, see Realm directory and synchronize fields, on page 1848 .

Step 3 If you use Kerberos authentication, click **Test** . If the test fails, wait a short time and try again.

Step 4 Enter user session timeout values, in minutes, for **ISE/ISE-PIC Users** , **Terminal Server Agent Users** , **Captive Portal Users** , **Failed Captive Portal Users** , and **Guest Captive Portal Users** .

Step 5 When you're finished configuring the realm, click **Save** .

Connect securely to Active Directory or LDAP

To create a secure connection between an Active Directory or LDAP server and the Secure Firewall Management Center (which we strongly recommend), you must perform all of the following tasks:

- Export the server's *root* certificate.
- Import the root certificate into the Secure Firewall Management Center as a trusted CA certificate (**Objects** > **Object Management** > **PKI** > **Trusted CAs**).
- Find the server's fully qualified name.

- Create the realm directory.

Related Topics

Create an LDAP realm or an Active Directory realm and realm directory, on page 1860

Find the active directory server's name

Find the fully qualified server name in Microsoft Active Directory that you need to configure a realm directory.

To configure a realm directory in the Firewall Management Center, you must know the fully qualified server name, which you can find as discussed in the procedure that follows.

These tasks apply to Microsoft Active Directory only. If you use LDAP, consult an appropriate reference for the procedure.

Before you begin

You must log in to the Active Directory server as a user with sufficient privileges to view the computer's name.

Follow these steps to find the Active Directory server's name:

Procedure

Step 1 Log in to the Active Directory server.

Step 2 Click **Start**.

Step 3 Right-click **This PC**.

Step 4 Click **Properties**.

Step 5 Click **Advanced System Settings**.

Step 6 Click the **Computer Name** tab.

Step 7 Note the value of **Full computer name**.
You must enter this exact name when you configure the realm directory in the Firewall Management Center.

What to do next

Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.

Related Topics

Export the active directory server's root certificate, on page 1863

Export the active directory server's root certificate

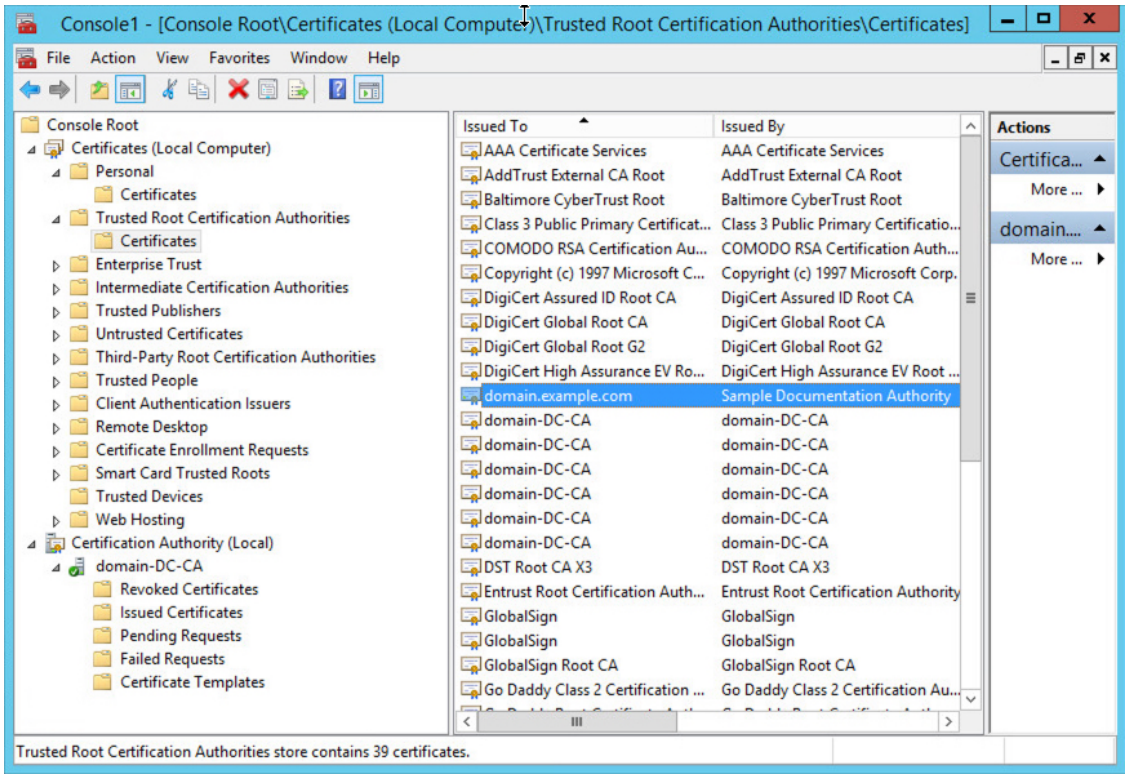
Export the Active Directory server's root certificate to enable secure connection to the Firewall Management Center for obtaining user identity information and authentication purposes.

The task that follows discusses how to export the Active Directory server's root certificate, which is required to connect securely to the Firewall Management Center to obtain user identity information.

These tasks apply to Microsoft Active Directory only. If you use LDAP, consult an appropriate reference for the procedure.

Before you begin

You must know the name of your Active Directory server's root certificate. The root certificate might have the same name as the domain or the certificate might have a different name. The procedure that follows shows one way you can find the name; there could be other ways, however.



Follow these steps to export the Active Directory server's root certificate:

Procedure

Step 1 Find the name of the Active Directory Server's root certificate using the Microsoft Management Console.

This is one way to find the name of the Active Directory Server's root certificate; consult Microsoft documentation for more information:

a) Log in to the Active Directory server as a user with privileges to run the Microsoft Management Console.
b) Click **Start** and enter **mmc**.
c) Click **File** > **Add/Remove Snap-in**
d) From the Available Snap-ins list in the left pane, click **Certificates (local)**.
e) Click **Add**.
f) At the Certificates snap-in dialog box, click **Computer Account** and click **Next**.
g) At the Select Computer dialog box, click **Local Computer** and click **Finish**.
h) *Windows Server 2012 only*. Repeat the preceding steps to add the Certification Authority snap-in.
i) Click **Console Root** > **Trusted Certification Authorities** > **Certificates**.
The server's trusted certificates are displayed in the right pane. The following figure is only an example for Windows Server 2012; yours will probably look different.

Step 2 Export the certificate using the **certutil** command.

This is only one way to export the certificate. It is a convenient way to export the certificate, especially if you can run a web browser and connect to the Firewall Management Center from the Active Directory server.

a) Click **Start** and enter **cmd**.
b) Enter the command **certutil -CA.cert** *certificate-name*.
The server's certificate is displayed on the screen.
c) Copy the entire certificate to the clipboard, starting with **-----BEGIN CERTIFICATE-----** and ending with **-----END CERTIFICATE-----** (including those strings).

What to do next

Import the Active Directory server's certificate into the Firewall Management Center as a trusted CA certificate as discussed in Add a trusted CA object, on page 2396.

Related Topics

Find the active directory server's name, on page 1863

Synchronize users and groups

This task synchronizes users and groups from Active Directory domains to enable their use in identity policies.

Synchronizing users and groups means the Firewall Management Center queries the realms and directories you configured for groups and users in those groups. All users the Firewall Management Center finds can be used in identity policies.

If issues are found, you most likely need to add a realm that contains users and groups the Firewall Management Center cannot load. For details, see Realms and trusted domains, on page 1837.

Before you begin

Create a Secure Firewall Management Center *realm* for each Active Directory domain and a Firewall Management Center *directory* for each Active Director domain controller in each forest. See Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.

Note Synchronizing users and groups is not necessary for Microsoft Azure AD realms.

You must create a realm only for domains that have users you want to use in user control.

You can nest Microsoft AD groups and the Firewall Management Center downloads those groups and the users they contain. You can optionally restrict which groups and users get downloaded as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.

You must create the realm with the original domain name of the domain and not any alternative user principal name (UPN) suffixes of the domain. Otherwise, users and groups fail to download and identity policies will not be enforced. For example, if the original domain is `domain.example.com` and the alternative UPN name is`domain2.mydomain.com`, you must configure the realm to use `domain.example.com`. For more information about configuring an alternative UPN suffix, see a resource like Configuring Alternate Login ID on learn.microsoft.com.

Follow these steps to synchronize users and groups:

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 Next to each realm, click **Download** ( ).

Step 4 To see the results, click the **Sync Results** tab.
The Realms column indicates whether or not there were issues synchronizing users and groups in Active Directory forests. Look for the following indicators next to each realm.

Indicator in Realms column	Meaning
(nothing)	All users and groups synchronized without error. No action is necessary.

Indicator in Realms column	Meaning
Yellow Triangle ( )	There were issues synchronizing users and groups. Make sure you added a realm for each Active Directory domain and a directory for each Active Directory domain controller. For more details, see Troubleshoot cross-domain trust, on page 1882.

Create a realm sequence

Creating a realm sequence provides an ordered list of realms the system searches when it applies identity policy, allowing you to specify the priority order for user authentication across multiple Active Directory servers.

The following procedure enables you to create a realm sequence, which is an ordered list of realms the system searches when it applies identity policy. You add a realm sequence to an identity rule exactly the same way as you add a realm; the difference is that the system searches all the realms in the order specified in the realm sequence when applying an identity policy.

Before you begin

You must create and enable at least two realms, each corresponding to a connection with an Active Directory server. You cannot create realm sequences for LDAP realms.

Create a realm as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.

Follow these steps to create a realm sequence:

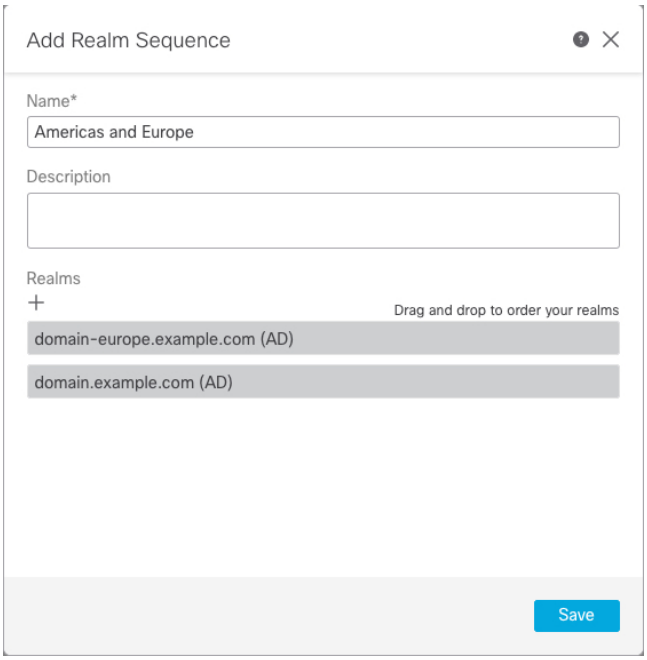
Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so and click **Integration** > **Other Integrations** > **Realms** > **Realm Sequences**.

Step 2 Under the **Realm Sequences** tab, click **Add Sequence**.

Step 3 In the **Name** field, enter a name to identify the realm sequence.

Step 4 (Optional.) In the **Description** field, enter a description for the realm sequence.



Step 5 Under Realms, click **Add** ( ).

Step 6 Click the name of each realm to add to the sequence.

To narrow your search, enter all or part of a realm name in **Filter** field.

Click **OK**.

Step 7 In the Add Realm Sequence dialog box, drag and drop the realms in the order in which you want the system to search for them.
The following figure shows an example of a realm sequence consisting of two realms. The **domain-europe.example.com** realm will be searched for users before the **domain.example.com** realm.

Step 8 Click **Save**.

What to do next

See Create an identity policy, on page 1943.

Cross-domain trust setups with Firewall Management Center

A cross-domain trust setup allows discovery and use of users and groups from multiple domains in access control policies.

This is an introduction to several topics that walk you through configuring the Firewall Management Center with two realms having cross-domain trust.

Example setup configuration

This step-by-step example involves two forests: **forest.example.com** and **eastforest.example.com**. The forests are configured so that certain users and groups in each forest can be authenticated by Microsoft AD in the other forest.

Note This topic applies to Microsoft AD realms only. It does *not* apply to Microsoft Azure AD realms.

The example setup uses this configuration:

Using this example, you would set up the Firewall Management Center with these components:

- Realm and directory for any domain in **forest.example.com** that contains users you want to control with access control policy
- Realm and directory for any domain in **eastforest.example.com** that contains users you want to control with access control policy

Each realm in the example has one domain controller, which is configured in the Firewall Management Center as a directory. The directories in this example are configured as follows:

- **forest.example.com**
  - Base distinguished name (DN) for users: **ou=UsersWest,dc=forest,dc=example,dc=com**
  - Base DN for groups: **ou=EngineringWest,dc=forest,dc=example,dc=com**
- **eastforest.example.com**
  - Base DN for users: **ou=EastUsers,dc=eastforest,dc=example,dc=com**
  - Base DN for groups: **ou=EastEngineering,dc=eastforest,dc=example,dc=com**

Configure Secure Firewall Management Center for cross-domain-trust step 1: Configure realms and directories, on page 1869

Configure Secure Firewall Management Center for cross-domain-trust step 1: Configure realms and directories

This task configures the Firewall Management Center to recognize Active Directory servers in a cross-domain trust relationship, enabling the discovery and use of users and groups from multiple domains in access control policies.

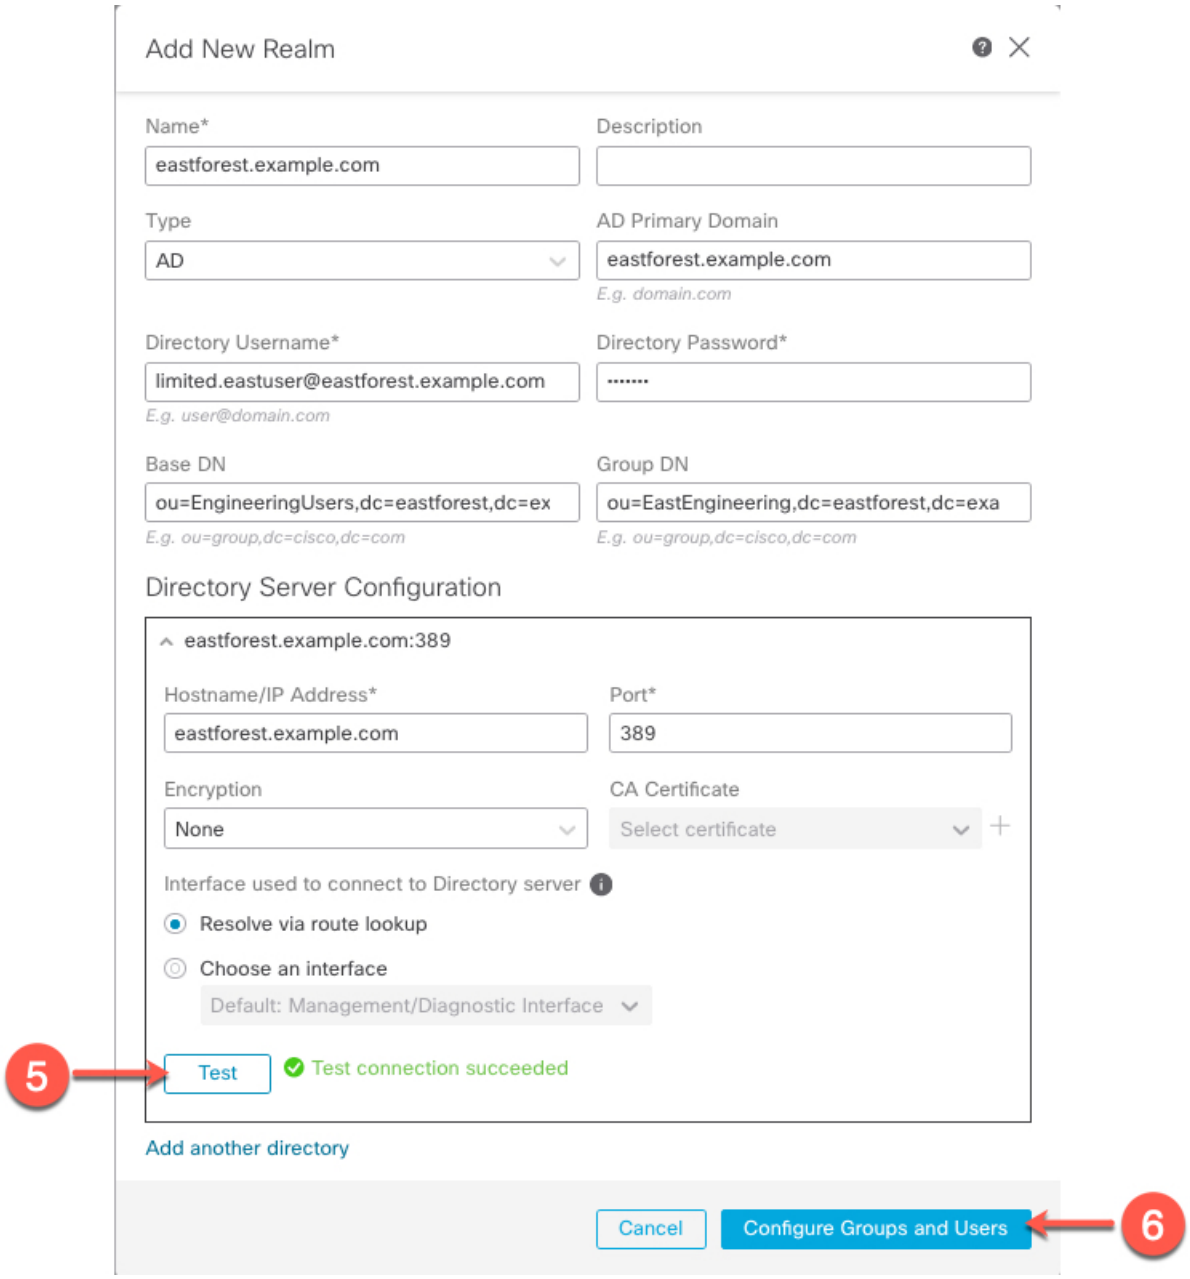
This is the first task in a step-by-step procedure that explains how to configure the Firewall Management Center to recognize Active Directory servers configured in a cross-domain trust relationship, which is an increasingly common configuration for enterprise organizations. For an overview of this sample configuration, see Cross-domain trust setups with Firewall Management Center, on page 1868.

If you set up the system with one realm for each domain and one directory for each domain controller, the system can discover up to 100,000 foreign security principals (users and groups). If these foreign security principals match a user downloaded in another realm, then they can be used in access control policy.

Before you begin

You must configure Microsoft Active Directory servers in a cross-domain trust relationship; see Realms and trusted domains, on page 1837 for more information.

If you authenticate users with LDAP or Microsoft Azure AD, you *cannot* use this procedure.



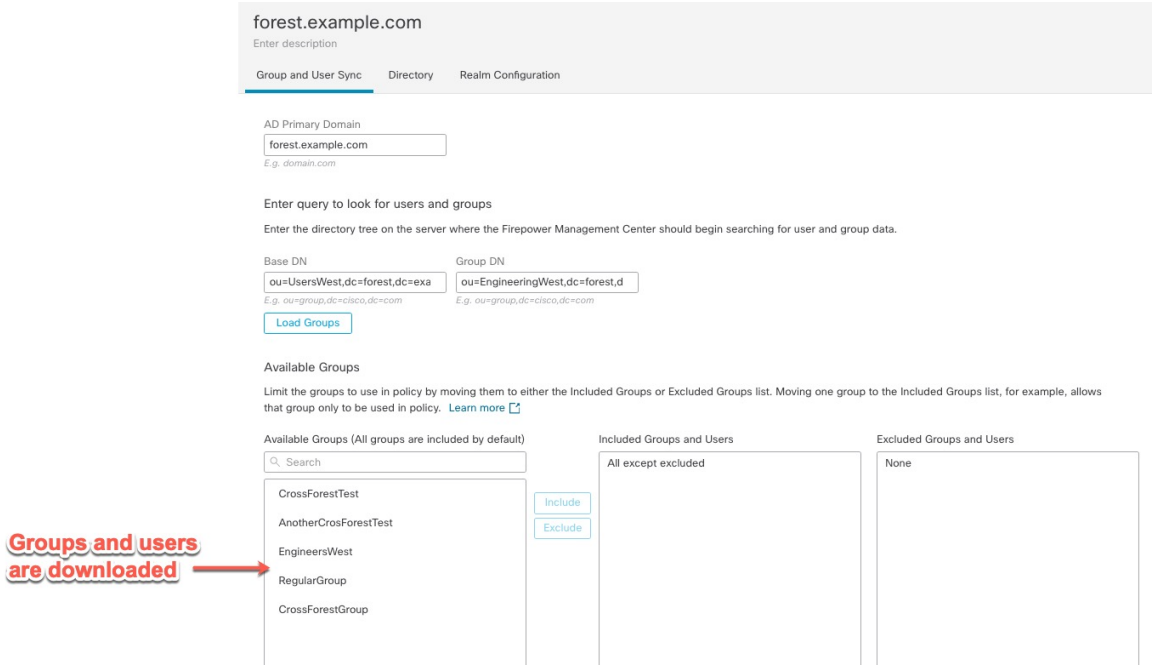
Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 Click **Add Realm** > **Active Directory/LDAP**.

Step 4 Enter the following information to configure **forest.example.com**.



Note The **Directory Username** can be any user in the Active Directory domain; no special permissions are required.

The **Interface used to connect to Directory server** can be any interface that can connect to the Active Directory server.

Step 5 Click **Test** and make sure the test succeeds before you continue.

Step 6 Click **Configure Groups and Users**.

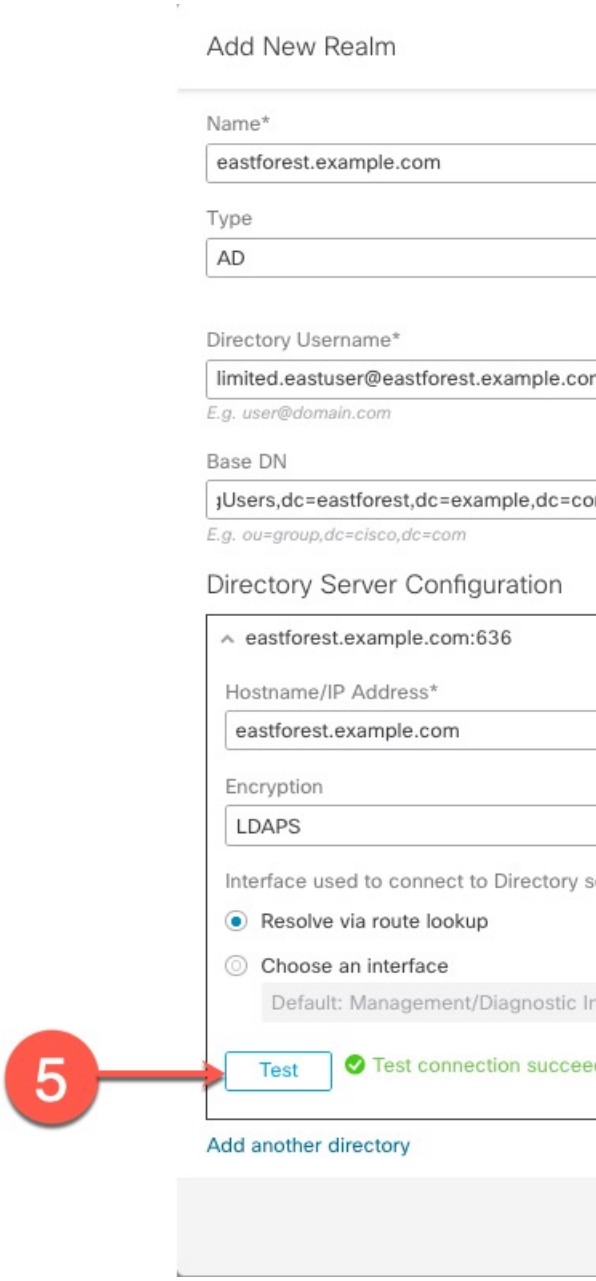
Step 7 Verify your configuration was successful by checking that the next page is displayed similar to the following.

Note If groups and users were not downloaded, verify the values in the **Base DN** and **Groups DN** fields and click **Load Groups**.

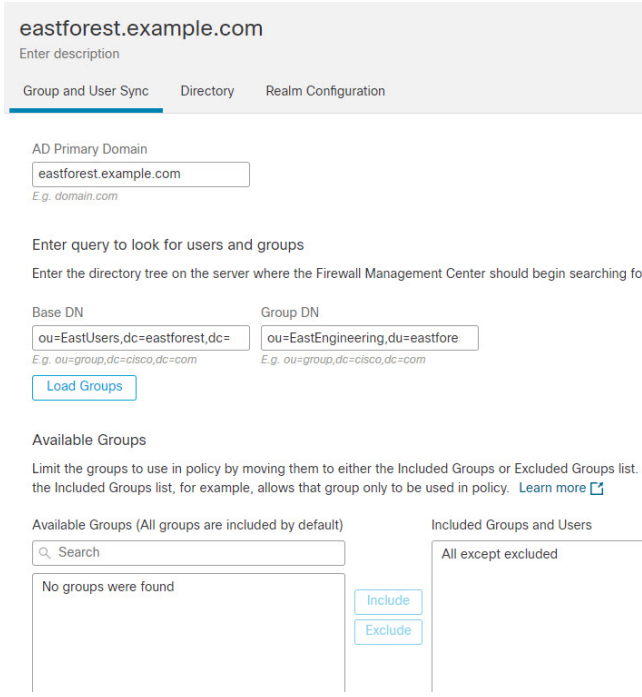
There are other optional configurations available on this page; for more information about them, see Realm fields, on page 1844 and Realm directory and synchronize fields, on page 1848.

Step 8 If you made changes on this page or tab pages, click **Save**.

Create another realm



Before you begin



Complete the configuration of your first realm as in the prior task.

Follow these steps to create another realm.

Procedure

	Command or Action	Purpose
Step 1	Click **Integration** > **Other Integrations** > **Realms** > **Realms**.	
Step 2	Click **Add Realm**.	

	Command or Action	Purpose
Step 3	Enter the following information to configure **eastforest.example.com**.	
Step 4	Click **Test** and make sure the test succeeds before you continue.	
Step 5	Click **Configure Groups and Users**.	

	Command or Action	Purpose
Step 6	Verify your configuration was successful by checking that the next page is displayed similar to the following.	

You have successfully configured two realms (**forest.example.com** and **eastforest.example.com**) with their respective directories.

Configure the Secure Firewall Management Center for cross-domain trust Step 2: Synchronize users and groups

This task allows you to download users and groups from Active Directory servers with cross-domain trust relationships to synchronize identity data in the Secure Firewall Management Center and resolve download issues by verifying directory setup and device communication.

After you configure two or more Active Directory servers that have a cross-domain trust relationship, you must download users and groups. That process exposes possible issues with the Active Directory configuration (for example, groups or users downloaded for one Active Directory domain but not the other).

Before you begin

Make sure you have performed the tasks discussed in Configure Secure Firewall Management Center for cross-domain-trust step 1: Configure realms and directories, on page 1869.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 At the end of the row of any realm in the cross-domain trust, click **Download Now**( ), then click **Yes**.

Step 4 Click **Check Mark** ( ) (Notifications) > **Tasks**.

If groups and users fail to download, try again. If subsequent attempts fail, review your realm and directory setup as discussed in Realm fields, on page 1844 and Realm directory and synchronize fields, on page 1848.

Step 5 Click **Integration** > **Other Integrations** > **Realms** > **Sync Results**.

Related Topics

Configure the Secure Firewall Management Center for cross-domain trust step 3: Resolve issues, on page 1875

Configure the Secure Firewall Management Center for cross-domain trust step 3: Resolve issues

This task enables you to make sure users and groups are downloaded without errors during cross-domain trust setup.

The final step in setting up cross-domain trust in the Firewall Management Center is to make sure users and groups are downloaded without errors. A typical reason why users and groups do not download properly is that the realms to which they belong have not been downloaded to the Firewall Management Center.

This topic discusses how to diagnose that a group referred in one forest to cannot be downloaded because the realm is not configured to find the group in the domain controller hierarchy.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

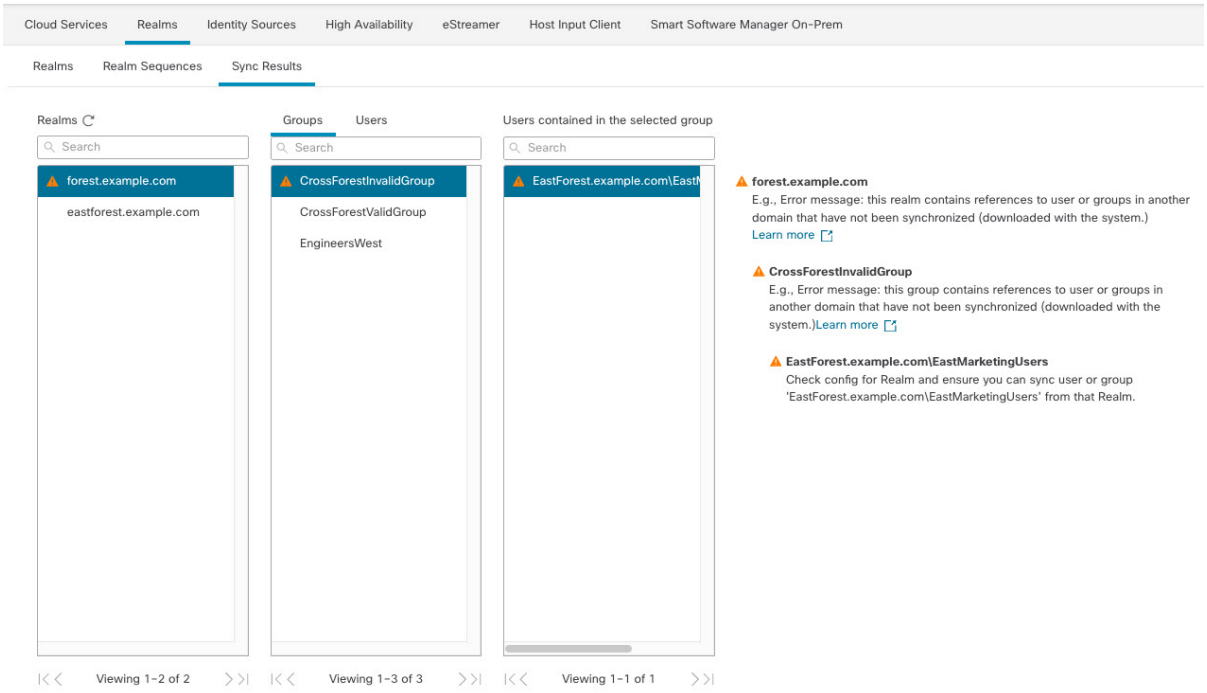
Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

In the Realms column, if **Yellow Triangle** ( ) is displayed next to the name of a realm, you have issues that must be resolved. If not, your results are configured properly and you can quit.

Step 3 Download users and groups again from the realms that display issues.

a) Click the **Realms** tab.

b) Click (Download Now), then click **Yes**.



Step 4 Click the **Sync Results** tab page.

If the **Yellow Triangle** ( ) is displayed in the Realms column, click **Yellow Triangle** ( ) next to the realm that has issues.

Step 5 In the middle column, click either **Groups** or **Users** to find more information.

Step 6 In the Groups or Users tab page, click **Yellow Triangle** ( ) to display more information.

The right column should display enough information you can isolate the source of the issue.

In the preceding example, **forest.example.com** includes a cross-domain group **CrossForestInvalidGroup** that contains another group **EastMarketingUsers** that was not downloaded by the Firewall Management Center. If, after synchronizing the **eastforest.example.com** realm again, the error does not resolve, it likely means that the Active Directory domain controller does not include **EastMarketingUsers**.

To resolve this issue, you can:

- Remove the **EastMarketingUsers** from **CrossForestInvalidGroup**, synchronize the **forest.example.com** realm again, and recheck.
- Remove the **ou=EastEngineering** value from the **Group DN** of the **eastforest.example.com** realm, which causes the Firewall Management Center to retrieve groups from the highest level in the Active Directory hierarchy, synchronize **eastforest.example.com**, and recheck.

Manage a realm

This task enables you to perform various maintenance operations on realms to manage authentication and user access control.

This section discusses how to perform various maintenance tasks for a realm using controls on the Realms page:

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so. Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 2 To delete a realm, click **Delete** ( ).

Step 3 To edit a realm, click **Edit** ( ) next to the realm and make changes as described in Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.

Step 4 To enable a realm, slide **State** to the right; to disable a realm, slide it to the left.

Step 5 To download users and user groups, click **Download** ( ).

Step 6 To copy a realm, click **Copy** ( ).

Step 7 To compare realms, see Compare realms, on page 1877.

Compare realms

Use this task to compare identity realms in the Secure Firewall Management Center to review differences between selected realms, generate comparison reports, and analyze changes to support identity integration management.

You must be an Admin, Access Admin, Network Admin, or Security Approver to perform this task.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so. Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 2 Click **Compare Realms**.

Step 3 Choose **Compare Realm** from the **Compare Against** list.

Step 4 Choose the realms you want to compare from the **Realm A** and **Realm B** lists.

Step 5 Click **OK**.

Step 6 To navigate individually through changes, click **Previous** or **Next** above the title bar.

Step 7 (Optional.) Click **Comparison Report** to generate the realm comparison report.

Step 8 (Optional.) Click **New Comparison** to generate a new realm comparison view.

Troubleshoot realms and user downloads

If you notice unexpected server connection behavior, consider tuning your realm configuration, device settings, or server settings. For other related troubleshooting information, see:

- Troubleshoot Cisco ISE/ISE-PIC or Cisco TrustSec issues, on page 1927
- Troubleshoot the TS agent identity source, on page 1938
- Troubleshoot the captive portal identity source, on page 1906
- Troubleshooting guidelines for remote access VPN identity source, on page 1934
- Troubleshoot user control, on page 1962

Realms and groups reported but not downloaded

The Secure Firewall Management Center's health monitor informs you of user or realm mismatches, which are defined as:

- User mismatch: A user is reported to the Secure Firewall Management Center without being downloaded.

  A typical reason for a user mismatch is that the user belongs to a group you have excluded from being downloaded to the Secure Firewall Management Center. Review the information discussed in *Cisco Secure Firewall Management Center Device Configuration Guide*.

- Realm mismatch: A user logs into a domain that corresponds to a realm not known to the Firewall Management Center.

For example, if you defined a realm that corresponds to a domain named **domain.example.com** in the Firewall Management Center but a login is reported from a domain named **another-domain.example.com**, this is a *realm mismatch*. Users in this domain are identified by the Firewall Management Center as Unknown.

You set the mismatch threshold as a percentage, above which a health warning is triggered. Examples:

- If you use the default mismatch threshold of 50%, and there are two mismatched realms in eight incoming sessions, the mismatch percentage is 25% and no warning is triggered.
- If you set the mismatch threshold to 30% and there are three mismatched realms in five incoming sessions, the mismatch percentage is 60% and a warning is triggered.

Unknown users that do not match identity rules have no policies applied to them. (Although you can set up identity rules for Unknown users, we recommend keeping the number of rules to a minimum by identifying users and realms correctly.)

For more information, see Detect realm or user mismatches, on page 1881.

Users are not downloaded

Possible causes include:

- If you have the realm **Type** configured incorrectly, users and groups cannot be downloaded because of a mismatch between the attribute the system expects and what the repository provides. For example, if you configure **Type** as **LDAP** for a Microsoft Active Directory realm, the system expects the `uid` attribute, which is set to `none` on Active Directory. (Active Directory repositories use `sAMAccountName` for the user ID.)

  Solution: Set the realm **Type** field appropriately: **AD** for Microsoft Active Directory or **LDAP** for another supported LDAP repository.

- Users in Active Directory groups that have special characters in the group or organizational unit name might not be available for identity policy rules. For example, if a group or organizational unit name

contains the characters asterisk (*), equals (=), or backslash (\), users in those groups are not downloaded and can't be used for identity policies.

Solution: Remove special characters from the group or organizational unit name.

Important To reduce latency between the Firewall Management Center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the Firewall Management Center.

For example, if your Firewall Management Center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

Not all users in a realm are downloaded

Possible causes include:

- If you attempt to download more than the maximum number of users in any one realm, the download stops at the maximum number of users and a health alert is displayed. User download limits are set per Secure Firewall Management Center model. For more information, see User limits for microsoft active directory, on page 1831.
- Every user must be a member of a group. Users that are members of no groups do not get downloaded.

Access control policy doesn't match group membership

This solution applies to an AD domain that is in a trust relationship with other AD domains. In this discussion, *external domain* means a domain other than the one to which the user logs in.

If a user belongs to a group defined in a trusted external domain, the Secure Firewall Management Center doesn't track membership in the external domain. For example, consider this scenario:

- Domain controllers 1 and 2 trust each other
- Group A is defined on domain controller 2
- User `mparvinder` in controller 1 is a member of Group A

Even though user `mparvinder` is in Group A, the Secure Firewall Management Center access control policy rules specifying membership Group A don't match.

Solution: Create a similar group in domain controller 1 that contains has all domain 1 accounts that belong to group A. Change the access control policy rule to match any member of Group A or Group B.

Access control policy doesn't match child domain membership

If a user belongs to a domain that is child of parent domain, Firepower doesn't track the parent/child relationships between domains. For example, consider this scenario:

- Domain `child.parent.com` is child of domain `parent.com`
- User `mparvinder` is defined in `child.parent.com`

Even though user `mparvinder` is in a child domain, the Firepower access control policy matching the `parent.com` don't match `mparvinder` in the `child.parent.com` domain.

Solution: Change the access control policy rule to match membership in either `parent.com` or `child.parent.com`.

Realm or realm directory test fails

The **Test** button on the directory page sends an LDAP query to the hostname or IP address you entered. If it fails, check these items:

- The **Hostname** you entered resolves to the IP address of an LDAP server or Active Directory domain controller.
- The **IP Address** you entered is valid.

The **Test AD Join** button on the realm configuration page verifies these items:

- DNS resolves the **AD Primary Domain** to an LDAP server or Active Directory domain controller's IP address.
- The **AD Join Username** and **AD Join Password** are correct.

  AD Join Username must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).
- The user has sufficient privileges to create a computer in the domain and join the Secure Firewall Management Center to the domain as a Domain Computer.

User timeouts are occurring at unexpected times

If you notice the system performing user timeouts at unexpected intervals, confirm that the time on your ISE/ISE-PIC server is synchronized with the time on the Secure Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

If you notice the system performing user timeouts at unexpected intervals, confirm that the time on your ISE/ISE-PIC, or TS Agent server is synchronized with the time on the Secure Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

User data for previously-unseen ISE/ISE-PIC users is not displaying in the web interface

After the system detects activity from an ISE/ISE-PIC or TS Agent user whose data is not yet in the database, the system retrieves information about them from the server. In some cases, the system requires additional time to successfully retrieve this information from Microsoft Windows servers. Until the data retrieval succeeds, activity seen by the ISE/ISE-PIC, or TS Agent user is *not* displayed in the web interface.

Note that this can also prevent the system from handling the user's traffic using access control rules.

User data in events is unexpected

If you notice user or user activity events contain unexpected IP addresses, check your realms. The system does not support configuring multiple realms with the same **AD Primary Domain** value.

Users originating from terminal server logins are not uniquely identified by the system

If your deployment includes a terminal server and you have a realm configured for one or more servers connected to the terminal server, you must deploy the Cisco Terminal Services (TS) Agent to accurately report user logins in terminal server environments. When installed and configured, the TS Agent assigns unique ports to individual users so the system can uniquely identify those users in the web interface.

For more information about the TS Agent, see the *Cisco Terminal Services (TS) Agent Guide*.

Detect realm or user mismatches

Detection of realm or user mismatches helps ensure accurate user identification and proper policy application in the Cisco Secure Firewall Management Center.

This section discusses how to detect realm or user *mismatches*, which are defined as:

- User mismatch: A user is reported to the Secure Firewall Management Center without being downloaded.

  A typical reason for a user mismatch is that the user belongs to a group you have excluded from being downloaded to the Secure Firewall Management Center. Review the information discussed in *Cisco Secure Firewall Management Center Device Configuration Guide*.

- Realm mismatch: A user logs into a domain that corresponds to a realm not known to the Firewall Management Center.

For additional details, see Troubleshoot realms and user downloads, on page 1877.

Unknown users that do not match identity rules have no policies applied to them. (Although you can set up identity rules for Unknown users, we recommend keeping the number of rules to a minimum by identifying users and realms correctly.)

Procedure

Step 1 Enable detection of realm or user mismatches:

a. Log in to the Firewall Management Center if you have not already done so.

b. Click **System** (⚙) > **Health** > **Policy**.

c. Create a new health policy or edit an existing one.

d. On the Editing Policy page, set a **Policy Runtime Interval**.

This is the frequency at which all health monitor tasks run.

e. In the left pane, click **Realm**.

f. Enter the following information:

- **Enabled**: Click **On**
- **Warning Users match threshold %**: The percentage of either realm mismatches or user mismatches that triggers a warning in the Health Monitor. For more information, see Troubleshoot realms and user downloads, on page 1877.

g. At the bottom of the page, click **Save Policy & Exit**.

h. Apply the health policy to managed devices as discussed in *Applying Health Policies* in the *Cisco Secure Firewall Management Center Administration Guide*.

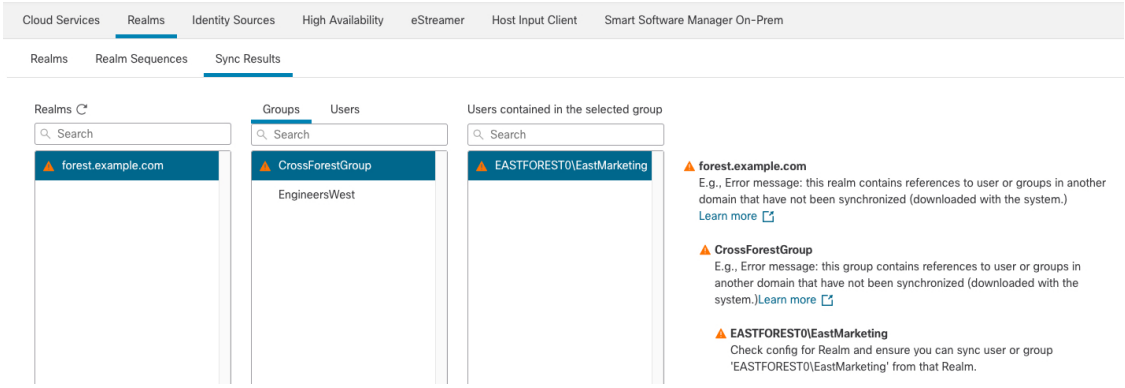
Step 2 View user and realm mismatches in any of the following ways:

- If the warning threshold is exceeded, click **Warning** > **Health** in the top navigation of the Firewall Management Center. This opens the Health Monitor.
- Click **System** (⚙) > **Health** > **Monitor**.

Step 3 On the Health Monitor page, in the Display column, expand **Realm: Domain** or **Realm: User** to view details about the mismatch.

Troubleshoot cross-domain trust

Troubleshoot user and group synchronization issues in the Secure Firewall Management Center configuration for cross-domain trust. This reference provides information on typical issues, error interpretation, and resolution steps for Active Directory forest synchronization problems.



Typical issues

Typical issues with troubleshooting the Secure Firewall Management Center configuration for cross-domain trust include these items:

- Not adding realms or directories for all forests that have shared groups.
- Configure a realm to exclude users from being downloaded and those users are referenced in a group in a different realm.
- Certain temporary issues.

Understand the issues

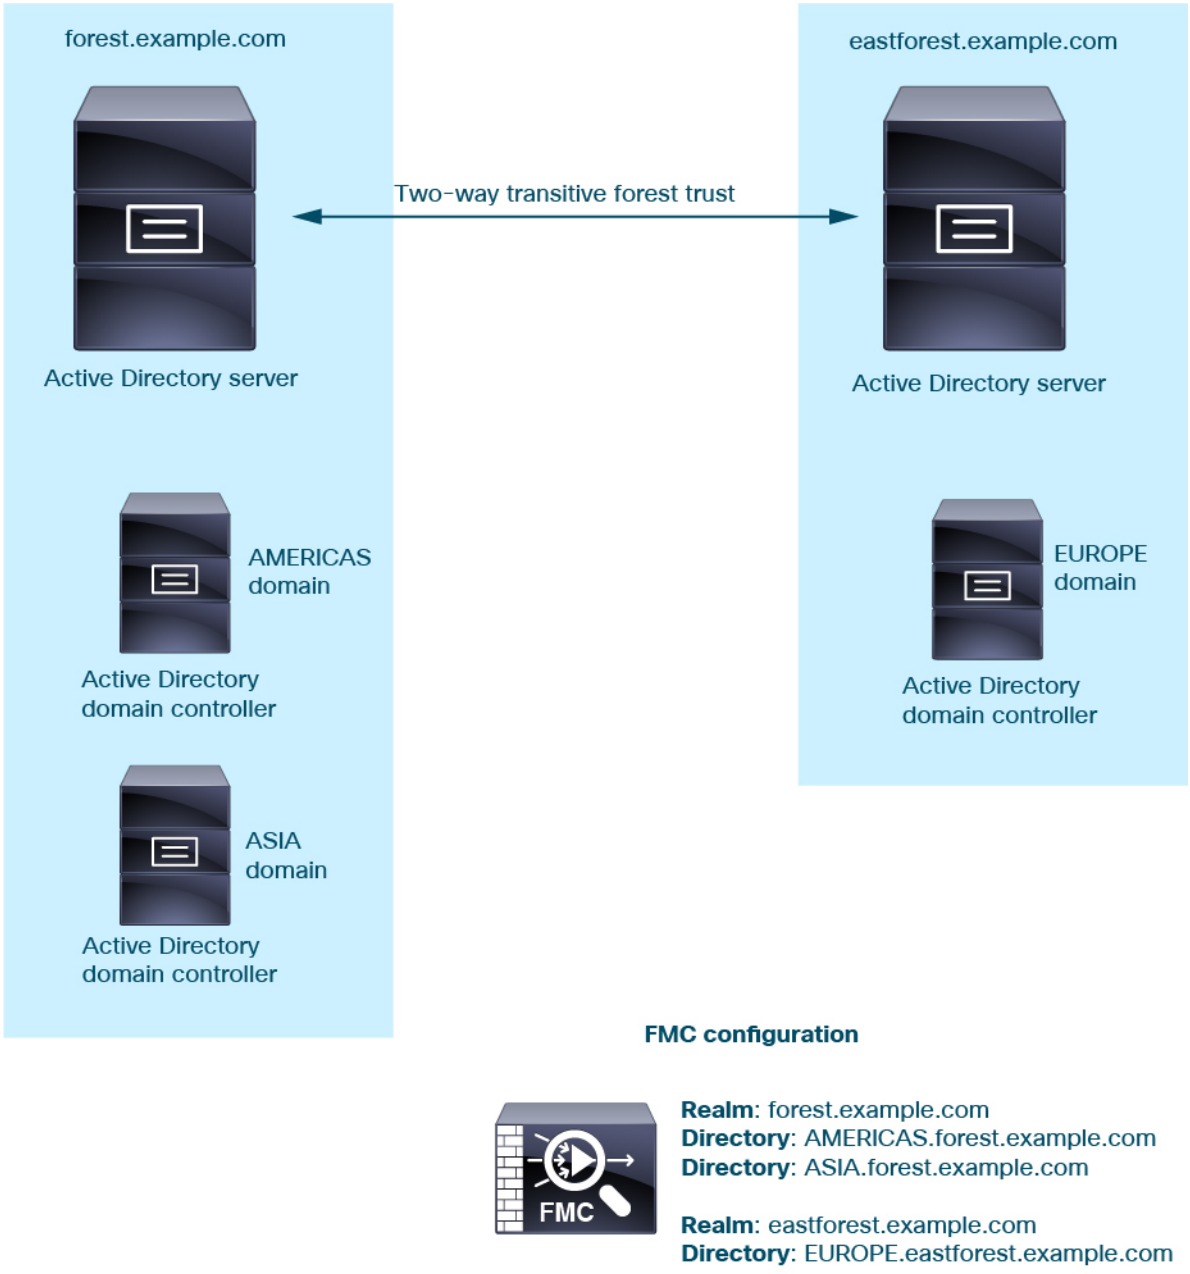
If there are issues with the Firewall Management Center being able to synchronize users and groups with your Active Directory forests, the Sync Results tab page is displayed similar to this.

This table explains how to interpret the information.

Column	Meaning
Realms	Displays all realms configured in the system. Click **Refresh** ( ) to update the list of realms. **Yellow Triangle** ( ) is displayed to indicate issues in the realm. Nothing is displayed next to a realm if all users and groups synchronized successfully.
Groups	Click **Groups** to display all groups in the realm. As with realms, **Yellow Triangle** ( ) is displayed to indicate issues. Click **Yellow Triangle** ( ) to see more detail about the issue.
Users	Click **Users** to display all users, sorted by group.
Users contained in the selected group	Displays all users in the group you selected in the Groups column. Clicking **Yellow Triangle** ( ) displays more information to the right of the table.
Groups that contain selected user	Displays all groups the selected user belongs to. Clicking **Yellow Triangle** ( ) displays more information to the right of the table.
Error detail information (displayed to the right of the table).	The system displays the NetBIOS forest name and group name it could not synchronize. Typical reasons the system cannot synchronize these users and groups follow: • **Problem**: The forest containing the groups and users do not have corresponding realms configured in the Firewall Management Center. **Solution**: Add a realm for the forest that contains the group as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 1860. • **Problem**: You excluded groups from being downloaded to the Firewall Management Center. **Solution**: Click the **Realms** tab page, click **Edit** ( ), then move the indicated group or user from the **Excluded Groups and Users** list.

Try downloading users and groups again

If there is a possibility the issues are temporary, download users and groups for all realms.

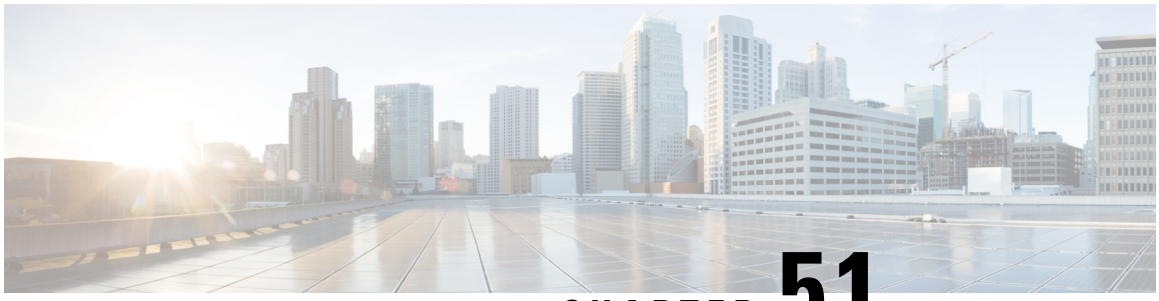


1. If you haven't done so already, log in to the Firewall Management Center.
2. Click **Integration** > **Other Integrations** > **Realms** > **Realms**.
3. Click **Download** ( ).
4. Click the **Sync Results** tab page.
5. If no indicator is displayed for entries in the Realms column, the issues have been resolved.

Add a realm for all forests

Make sure you configured:

- Firewall Management Center realm for each forest that has users you want to use in identity policies.
- Firewall Management Center directory for each domain controller in that forest with users you want to use in identity polices.



This figure shows an example.

History for realms

This reference provides the version history and implementation details for realm-related features across different versions of the Cisco security platform.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Microsoft Azure Active Directory (AD) realms.	7.4.0	7.4.0	You can use a Microsoft Azure Active Directory (AD) realm with ISE to authenticate users and get user sessions for user control. New/modified screens: **System** > **Integration** > **Realms** > **Add Realm** > **Azure AD**
Proxy sequences.	7.2.0	7.2.0	Similar to a realm sequence, a proxy sequence is one or more managed devices that can communicate with Security Cloud Control in the event Security Cloud Control cannot communicate with the LDAP or Active Directory server. New/modified screens: **Integration** > **Other Integrations** > **Realms** > **Proxy Sequence**
Cross-domain trust for Active Directory domains.	7.2.0	7.0.0	A grouping of Microsoft Active Directory (AD) domains that trust each other is commonly referred to as a *forest*. This trust relationship can enable domains to access each other's resources in different ways. For example, a user account defined in domain A can be marked as a member of a group defined in domain B. The Firewall Management Center can get users from Active Directory forests for identity rules.
Realm sequences.	7.2.0	6.7.0	A *realm sequence* is an ordered list of two or more realms to which to apply identity rules. When you associate a realm sequence with an identity policy, the Firepower System searches the Active Directory domains in order from first to last as specified in the realm sequence. New/modified screens: **Integration** > **Other Integrations** > **Realms** > **Realm SequencesSystem** > **Integration** > **Realms** > **Realm Sequences**
Realms for user control.	7.2.0	Any	A realm is a connection between the Firewall Management Center either an Active Directory or LDAP user repository.

CHAPTER 51

Identity Source: Captive Portal

- Captive portal identity source, on page 1887
- License requirements for captive portal, on page 1888
- Requirements and prerequisites for captive portal, on page 1888
- Best practices for captive portal guidelines and limitations, on page 1889
- Configure the captive portal for user control, on page 1891
- Troubleshoot the captive portal identity source, on page 1906
- History for captive portal, on page 1907

Captive portal identity source

A captive portal identity source is an active authentication method that

- presents a login page to users and authenticates HTTP and HTTPS traffic to enable secure access to network resources
- requires authentication to access the internet or to access restricted internal resources
- differs from passive authentication by presenting users with a login page on the managed device rather than querying the authentication realm.

You typically use captive portal to require authentication to access the internet or to access restricted internal resources; you can optionally configure guest access to resources. After the system authenticates captive portal users, it handles their user traffic according to access control rules. Captive portal performs authentication on HTTP and HTTPS traffic only.

Captive portal authentication details

Captive portal is one of the authoritative identity sources supported by the system. Active authentication differs from passive authentication in that the user is presented with a login page by the managed device, whereas passive authentication queries the authentication realm (for example, Microsoft AD) to authenticate the user.

After the system authenticates captive portal users, it handles their user traffic according to access control rules. Captive portal performs authentication on HTTP and HTTPS traffic only. You can optionally configure guest access to resources.

Note HTTPS traffic must be decrypted before captive portal can perform authentication.

Captive portal also records failed authentication attempts. A failed attempt does not add a new user to the list of users in the database. The user activity type for failed authentication activity reported by captive portal is **Failed Auth User**.

The authentication data gained from captive portal can be used for user awareness and user control.

Hostname redirect

A hostname redirect uses the managed device's fully-qualified domain name (FQDN) instead of an IP address for authentication redirections.

(Snort 3 only) An active authentication identity rule redirects to the captive portal port using its configured interface. Because the redirect is typically done to an IP address, the user gets an untrusted certificate error. As this behavior is similar to a man-in-the-middle attack, users might be reluctant to accept the untrusted certificate.

To avoid this problem, you can configure the captive portal to use the managed device's fully-qualified domain name (FQDN). With a properly configured certificate, users will not get an untrusted certificate error, and the authentication will be more seamless and appear to be more secure.

License requirements for captive portal

This reference provides the license requirements for captive portal functionality.

- Network Admin

Best practices for captive portal guidelines and limitations

Captive portal and policies

You configure captive portal in your identity policy and invoke active authentication in your identity rules. Identity policies are associated with access control policies and access control policies define access to resources in the network. For example, you might exclude users in the US-West/Finance group to access Engineering servers or you can prohibit users from accessing nonsecure applications on the network.

You configure some captive portal identity policy settings on the identity policy's **Active Authentication** tab page and configure the rest in the identity rule associated with the access control policy.

An active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected. In each case the system transparently enables or disables TLS/SSL decryption, which restarts the Snort process.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

When the captive portal authenticates users that match an identity rule, any user in a Microsoft Active Directory or LDAP group that has not been downloaded is identified as Unknown. To avoid users being identified as Unknown, configure the realm or realm sequence to download users in all groups you expect to authenticate with captive portal. Unknown users are handled according to the associated access control policy; if the access control policy is configured to block Unknown users, these users are blocked.

To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

Microsoft Azure AD SAML realm configuration

To use a Microsoft Azure AD (SAML) realm as a captive portal, see Create a Microsoft Azure AD (SAML) realm for active authentication (captive portal).

Routed interface requirements

Ensure that captive portal active authentication is performed only by a device with a routed interface configured. If you are configuring an identity rule for captive portal and your captive portal device contains inline and routed interfaces, you must configure interface rule conditions in the access control policy to target only the routed interfaces on the device.

If the identity policy associated with your access control policy contains one or more captive portal identity rules and you deploy the policy on the Secure Firewall Management Center that manages one or more devices with routed interfaces configured, the policy deployment succeeds and the routed interfaces perform active authentication.

For more information about synchronizing users and groups, see Synchronize users and groups, on page 1865.

Required certificates and certificate authorities

Before you can use the captive portal for user control and awareness, you must have all of the following:

- To authenticate with Microsoft AD, export the server's root certificate and import it into the Secure Firewall Management Center as a trusted CA certificate.
- An internal certificate object for authenticating with the managed device to which the identity policy is deployed.
- An internal certificate authority for the required decryption rule.

Captive portal requirements and limitations

Note the requirements and limitations when configuring captive portal:

- Captive portal does not support HTTP/3 QUIC connections.
- The system supports up to 20 captive portal logins per second.
- A failed login attempt is counted toward the maximum login attempts only if it occurs within five minutes of the previous failed attempt. The five minute limit is not configurable.

  Connection events show the number of maximum login attempts. To view connection events, click **Analysis** > **Unified Events**.

  If more than five minutes elapse between failed logins, the user is redirected to captive portal for authentication and will not be designated a failed login user or a guest user, and will not be reported to the Secure Firewall Management Center.
- Captive portal does not negotiate TLS v1.0 connections. Only TLS v1.1, v1.2, and TLS 1.3 connections are supported.
- To securely log a user out of captive portal and prevent the user from logging in again, an administrator can close their session: **Analysis** > **Users heading** > **Active Sessions**. If the user closes their browser, the browser does not reauthenticate automatically.
- If a realm is created for a parent domain and the managed device detects a login to a child of that parent domain, the user's subsequent logout is not detected by the managed device.
- To limit the amount of non-HTTP or HTTPS traffic that is allowed through the managed device, you should enter typical HTTP and HTTPS ports in the identity policy's **Ports** tab page.
- Your access control rule must allow traffic destined for the IP address and port of the device you plan to use for captive portal.
- To perform captive portal active authentication on HTTPS traffic, you must use a decryption policy to decrypt the traffic from the users you want to authenticate. You cannot decrypt the traffic in the connection between a captive portal user's web browser and the captive portal daemon on the managed device; this connection is used to authenticate the captive portal user.
- The managed device changes a previously unseen user from **`Pending`** to **`Unknown`** when it determines that the incoming request does not use the HTTP or HTTPS protocol. As soon as the managed device changes a user from **`Pending`** to another state, access control, Quality of Service, and decryption policies can be applied to that traffic. If your other policies don't permit non-HTTP or HTTPS traffic, configuring ports on the captive portal identity policy can prevent undesired traffic from being allowed through the managed device.

Kerberos prerequisites

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.

Configure the captive portal for user control

Configure captive portal active authentication to enable user authentication through the portal by setting up the necessary components and associating them with access control policies.

To use the captive portal for active authentication, you must set up an LDAP realm; or a Microsoft AD realm or realm sequence; Microsoft Azure AD (SAML) realm; access control policy; an identity policy; a decryption policy; and associate the identity and decryption policies with the same access control policy. Finally, you must deploy the policies to managed devices. This topic provides a high-level summary of those tasks.

Note Microsoft Azure Active Directory is not supported for captive portal.

Before you begin

Perform these tasks first:

- Confirm that your Secure Firewall Management Center manages one or more devices with a *routed* interface configured.
- To use encrypted authentication with the captive portal, either create a PKI object for the authenticating managed device or have your certificate data and key available on the machine from which you're accessing the Secure Firewall Management Center. To create a PKI object, see PKI objects, on page 2389.

Follow these steps to configure the captive portal for user control:

Procedure

Step 1 Create and enable an LDAP realm; or a Microsoft AD realm and optionally realm sequence as discussed in these topics:

- Create an LDAP realm or an Active Directory realm and realm directory, on page 1860
- Synchronize users and groups, on page 1865

To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

For more information, see Synchronize users and groups, on page 1865.

Step 2 Get required certificates and certificate authorities.

You must have all of these:

- To authenticate with Microsoft AD, export the server's root certificate and import it into the Secure Firewall Management Center as a trusted CA certificate.
- An internal certificate object for authenticating with the managed device to which the identity policy is deployed.
- An internal certificate authority for the required decryption rule.

Step 3 Create a network object with an associated trusted certificate authority.

See Create a network object, on page 1892.

Step 4 Create identity policy with an active authentication rule.

The identity policy enables selected users in your realm access resources after authenticating with the captive portal.

For more information, see Create an identity policy and active authentication rule, on page 1894.

Step 5 Configure an access control rule for the captive portal that allows traffic on the captive portal port (by default, TCP 885).

You can choose any available TCP port for the captive portal to use. Whatever your choice, you must create a rule that allows traffic on that port.

For more information, see Create a TCP port access control rule, on page 1896.

Step 6 Add another access control rule to allow users in the selected realm or realm sequence to access resources using the captive portal.

For more information, see Create a user access control rule, on page 1898.

Step 7 Configure a decryption policy with a **Decrypt - Resign** rule for the **Unknown** user so captive portal users can access web pages using the HTTPS protocol.

The captive portal can authenticate users only if the HTTPS traffic is decrypted before the traffic is sent to the captive portal. The captive portal itself is seen by the system as the **Unknown** user.

Create a decryption policy with an outbound rule, on page 1899

Step 8 Associate the identity and decryption policies with the access control policy from step 3.

This final step enables the system to authenticate users with the captive portal.

For more information, see Associate Identity and decryption policies with the access control policy, on page 1903.

What to do next

See Create a network object, on page 1892.

Create a network object

Create a network object to enable access using a fully qualified domain name for captive portal authentication.

This task discusses how to start configuring the captive portal as an identity source.

Before you begin

(Snort 3 only.) Create a fully-qualified host name (FQDN) using your DNS server and upload the Firewall Threat Defense's internal certificate to the Firewall Management Center. You can consult a resource such as this one if you've never done it before. Specify the IP address of a routed interface on one of the devices managed by your Firewall Management Center.

For more information about the network object, see Redirect to host name network rule conditions, on page 1946.

Procedure

Step 1 If you haven't already done so, log in to your Firewall Management Center and click **Objects** > **Object Management**..

Step 2 Expand **PKI**.

Step 3 Click **Internal Certs**.

Step 4 Click **Add Internal Cert**.

a) In the **Name** field, enter a name to identify the internal cert (for example, **`MyCaptivePortal`**).

b) In the **Certificate Data** field, either paste the certificate or use the **Browse** button to locate it.

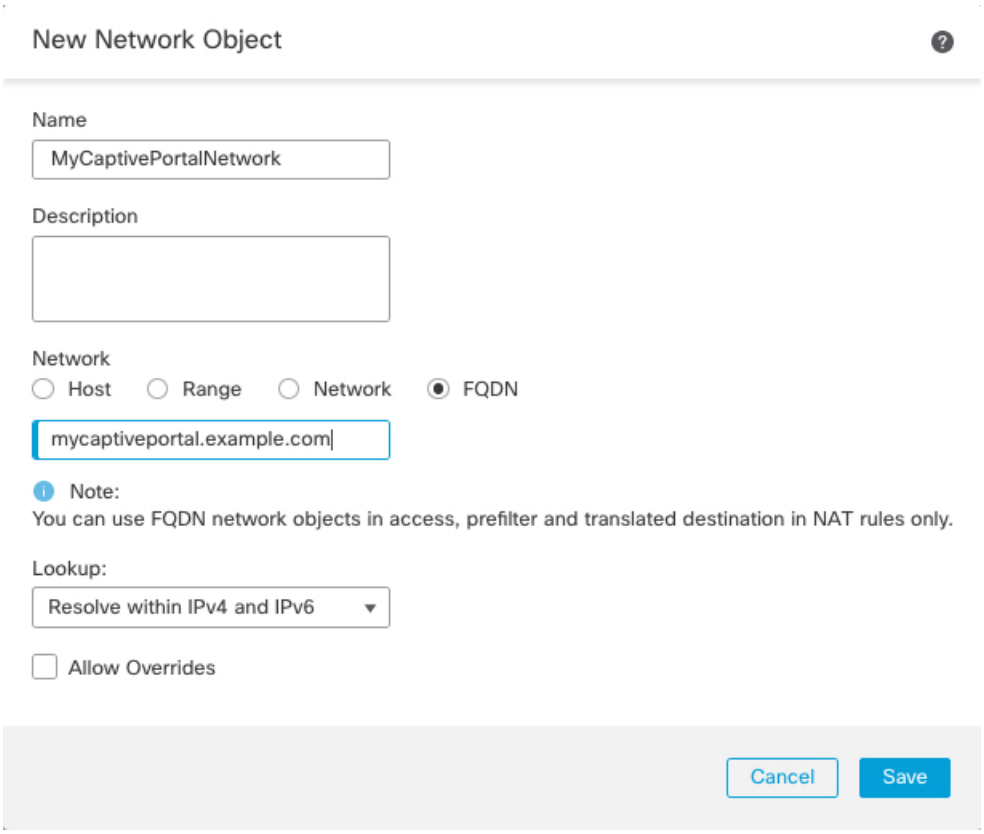
The certificate Common Name must exactly match the FDQN with which you want captive portal users to authenticate.

c) In the **Key** field, either paste the certificate's private key or use the **Browse** button to locate it.

d) If the certificate is encrypted, select the **Encrypted** check box and enter the password in the adjacent field.

e) Click **Save**.

Step 5 Click **Network**.



Step 6 Click **Add Network** > **Add Object**.

a) In the **Name** field, enter a name to identify the object (for example, **`MyCaptivePortalNetwork`**).

b) Click **FDQN** and, in the field, enter the name of the captive portal's FDQN.

c) Click an option for **Lookup**.

The following figure shows an example.

d) Click **Save**.

What to do next

Create an identity policy and active authentication rule, on page 1894.

Create an identity policy and active authentication rule

This procedure enables captive portal to perform active authentication for users in your domains using the Secure Firewall Management Center.

This multi-part procedure shows how to set up the captive portal using the default TCP port 885 and using a Secure Firewall Management Center server certificate for both the captive portal and for TLS/SSL decryption. Each part of this example explains one task required to enable the captive portal to perform active authentication.

If you follow all the steps in this procedure, you can configure captive portal to work for users in your domains. You can optionally perform additional tasks, which are discussed in each part of the procedure.

For an overview of the entire procedure, see Configure the captive portal for user control, on page 1891.

Procedure

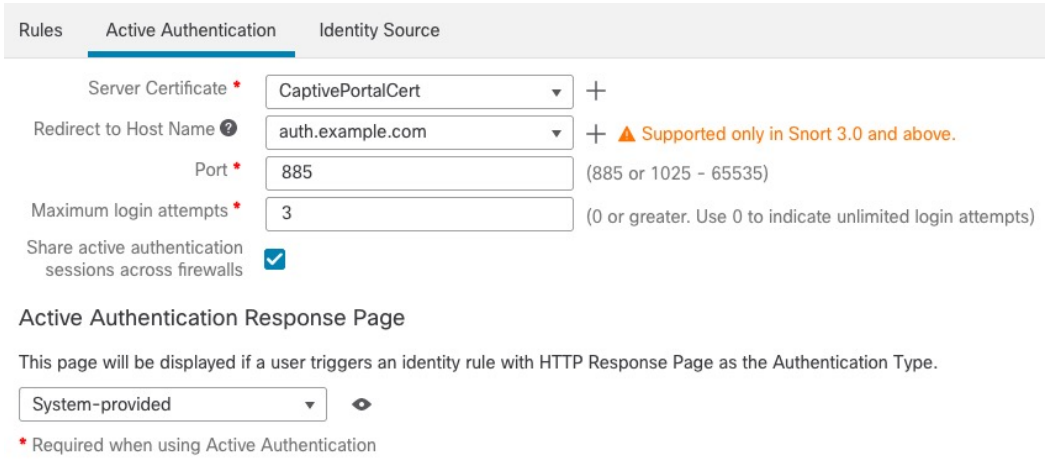
Step 1 In the Firewall Management Center, click **Policies** > **Access Control heading** > **Identity** and create or edit an identity policy.

Step 2 (Optional.) Click **Add Category** to add a category for the captive portal identity rules and enter a **Name** for the category.

Step 3 Click the **Active Authentication** tab.

a) Choose the appropriate *root* **Server Certificate** from the list or click **Add** (+) to add a certificate.

For more information, see Connect securely to Active Directory or LDAP, on page 1862.



Note Captive portal does *not* support the use of Digital Signature Algorithm (DSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) certificates.

b) From the **Redirect to Host Name** field, click the network object you previously created or click **Add** (+).

c) Enter **885** in the **Port** field and specify the **Maximum login attempts**.

d) Uncheck **Share active authentication across firewalls** to enable the Firewall Management Center to require users to reauthenticate every time they access your network using a different managed device than the last time.
For more information about this option, see Captive portal fields, on page 1903.

e) (Optional.) Choose an **Active Authentication Response Page** as described in Captive portal fields, on page 1903.

f) (If you upgraded to version 7.4.1 from an earlier version only and you authenticate users with a realm sequence.) Click **Edit** (✎) and see Update a custom authentication form, on page 1896.

Step 4 Click **Save**.

Step 5 Click the **Rules** tab.

Step 6 Click **Add Rule** to add a new captive portal identity policy rule, or click **Edit** (✎) to edit an existing rule.

In the **Add Rule** page,

a) Enter a **Name** for the rule.
b) From the **Action** list, choose **Active Authentication**.
c) Click **Realm & Settings**.
d) From the **Realms** list, choose a realm or realm sequence to use for user authentication
e) (Optional.) Check **Identify as Guest if authentication cannot identify user**. For more information, see Captive portal fields, on page 1903.
f) Choose an **Authentication Protocol** from the list.

   You *cannot* authenticate users with a realm sequence if you choose **NTLM**, **Kerberos**, or **HTTP Negotiate** authentication protocols. Choose **HTTP Basic** or **HTTP Response Page** instead.

g) (Optional.) To exempt specific application traffic from captive portal, see Exclude applications from captive portal, on page 1905.
h) Add conditions to the rule (port, network, and so on) as discussed in Identity rule conditions, on page 1945.
i) Click **Add**.

Step 7 At the top of the page, click **Save**.

What to do next

Continue with Create a TCP port access control rule, on page 1896.

Update a custom authentication form

Allow users to see a list of domains when they authenticate with captive portal by adding a custom realm selection to your authentication form.

After you upgrade to version 7.4.1 (or later) from an earlier release, you must update custom authentication forms for users to see available domains during authentication. This task is always required if you use the HTTP Response Page authentication type; if users authenticate with a realm using another authentication type, this task is optional.

Procedure

Step 1 On the **Active Authentication** tab page of your identity rule, click **Edit** ( ).

Step 2 Enter the following code in the part of the form that requires the user to log in:

Example:

```
<select name="realm" id="realm"></select>
```

Users can now view and select from available domains during captive portal authentication.

Create a TCP port access control rule

Create an access control rule that allows the captive portal to communicate with clients using TCP port 885, enabling secure user authentication.

This part of the procedure shows how to create an access control rule that allows the captive portal to communicate with clients using TCP port 885, which is the captive portal's default port. You can choose another port if you wish, but the port must match the one you chose in Create an identity policy and active authentication rule, on page 1894.

Before you begin

For an overview of the entire captive portal configuration, see Configure the captive portal for user control, on page 1891.

Follow these steps to create a TCP port access control rule:

Procedure

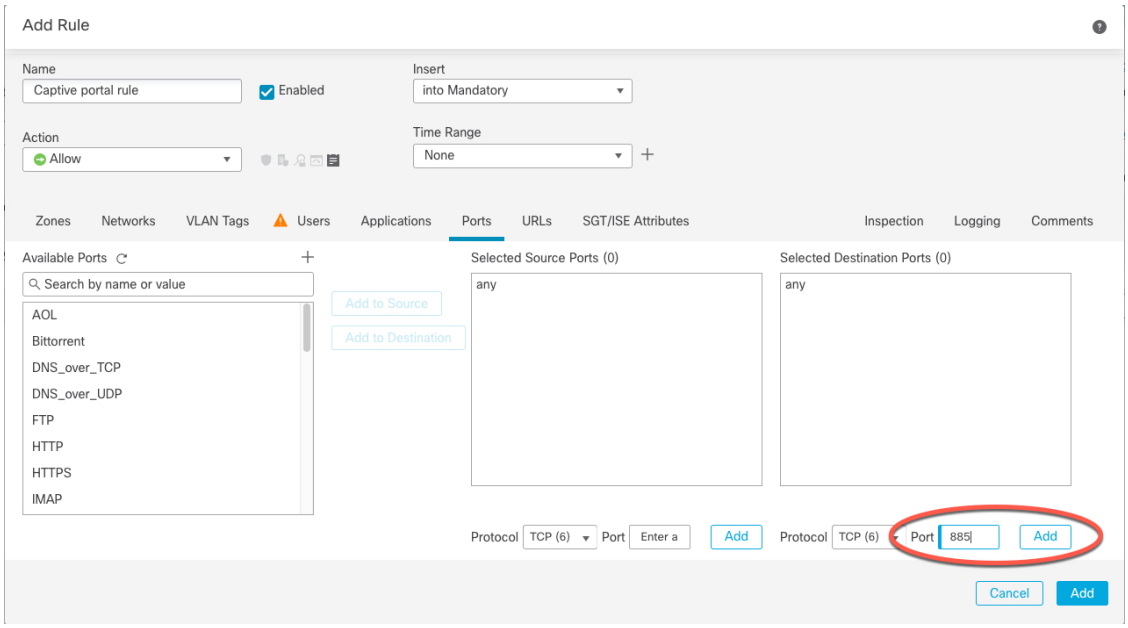
Step 1 Log in to the Firewall Management Center if you have not already done so.

If you haven't done so already, create a certificate for the captive portal as discussed in PKI objects, on page 2389.

Step 2 Click **Policies** > **Access Control heading** > **Access Control** and create or edit an access control policy.

Step 3 Click **Add Rule**.

Step 4 Enter a **Name** for the rule.



Step 5 Choose **Allow** from the **Action** list.

Step 6 Click **Ports**.

Step 7 From the **Protocol** list under the **Selected Destination Ports** field, choose **TCP**.

Step 8 In the **Port** field, enter **885** and click **Add** next to the **Port** field.

The following figure shows an example.

Step 9 Click **Add** at the bottom of the page.

What to do next

Continue with Create a user access control rule, on page 1898.

Create a user access control rule

Configure an access control rule to allow users in a specified realm to authenticate using captive portal, then adjust rule order in the policy editor to optimize traffic handling and resource use.

This part of the procedure discusses how to add an access control rule that enables users in a realm to authenticate using captive portal.

Before you begin

For an overview of the entire captive portal configuration, see Configure the captive portal for user control, on page 1891.

Procedure

Step 1 In the rule editor, click **Add Rule**.

Step 2 Enter a **Name** for the rule.

Step 3 Choose **Allow** from the **Action** list.

Step 4 Click **Users**.

Step 5 In the **Available Realms** list, click the realms to allow.

If no realms display, click **Refresh** ( ).

Step 6 In the **Available Users** list, choose the users to add to the rule and click **Add to Rule**.

Step 7 (Optional.) Add conditions to the access control policy as discussed in Identity rule conditions, on page 1945.

Step 8 Click **Add**.

Step 9 On the access control rule page, click **Save**.

In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption

What to do next

Create a decryption policy with an outbound rule, on page 1899

Create a decryption policy with an outbound rule

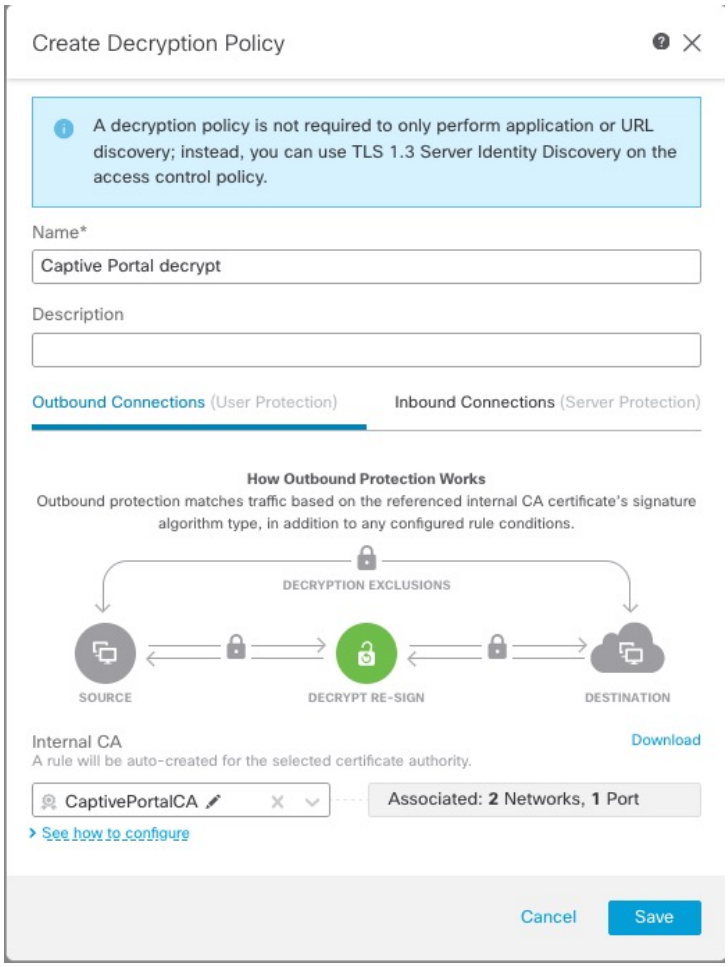
Create a decryption policy to decrypt and resign outbound traffic before captive portal authentication in the Secure Firewall Management Center.

This part of the procedure discusses how to create a decryption policy to decrypt and resign traffic before the traffic reaches the captive portal. The captive portal can authenticate traffic only after it has been decrypted.

Before you begin

You must have an internal certificate authority (CA) for your outbound server; in other words, the managed device that decrypts the traffic for captive portal users to authenticate. This certificate must be different from the *internal certificate* you use to authenticate the captive portal with the managed device.

Procedure



Step 1 Log in to the Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **New Policy**.

Step 4 Give the policy a unique **Name** and, optionally, a **Description**.

Step 5 Click the **Outbound Connections** tab.

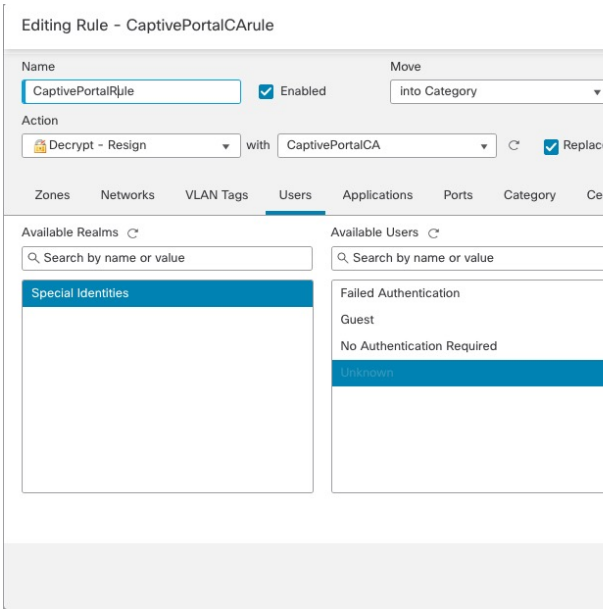
Step 6 Upload or choose certificates for the rules.

The system creates one rule per combination of CA and networks/ports.

Step 7 (Optional.) Choose networks and ports.

For more information:

- Decryption Rule conditions, on page 1758
- Network rule conditions, on page 1321
- Best practice: use application-based rules over port-based rules, on page 1323



Step 8 Click **Save**.

What to do next

Configure the decryption rule.

Configure a decryption rule

Procedure

	Command or Action	Purpose
Step 1	Click **Edit** ( ) next to the decryption policy you just created.	
Step 2	Click **Edit** ( ) next to the decryption rule for captive portal.	
Step 3	Click **Users**.	
Step 4	Above the **Available Realms** list, click **Refresh** ( ).	
Step 5	In the **Available Realms** list, click **Special Identities**.	
Step 6	In the **Available Users** list, click **Unknown**.	
Step 7	Click **Add to Rule**.	The following figure shows an example. 
Step 8	(Optional.) Set other options as discussed in Decryption Rule conditions, on page 1758.	
Step 9	Click **Add**.	

Create A decryption policy with a Decrypt-Resign rule

Create a decryption policy to decrypt and resign traffic before the traffic reaches the captive portal.

This part of the procedure discusses how to create a decryption policy to decrypt and resign traffic before the traffic reaches the captive portal. The captive portal can authenticate traffic only after it has been decrypted.

Before you begin

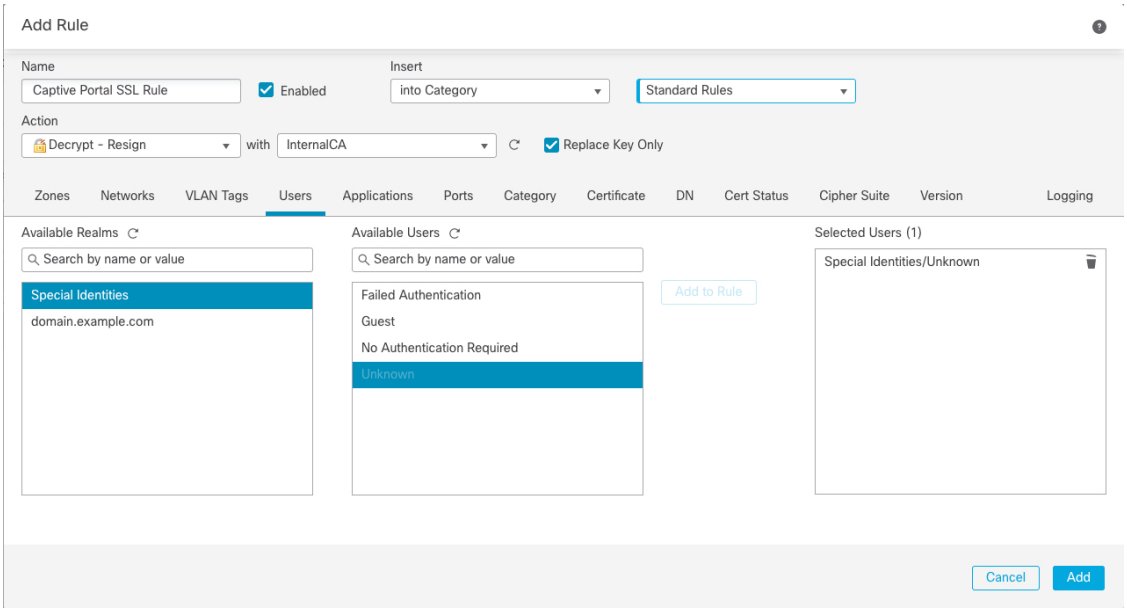
For an overview of the entire captive portal configuration, see Configure the captive portal for user control, on page 1891.

Follow these steps to create A decryption policy with a Decrypt-Resign rule:

Procedure

Step 1 If you haven't done so already, log in to the Firewall Management Center and create a certificate object to decrypt TLS/SSL traffic as discussed in PKI objects, on page 2389.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.



Step 3 Click **New Policy**.

Step 4 Enter a **Name** and choose a **Default Action** for the policy. Default actions are discussed in Decryption policy default actions, on page 1739.

Step 5 Click **Save**.

Step 6 Click **Add Rule**.

a) Enter a **Name** for the rule.
b) From the **Action** list, choose **Decrypt - Resign**.
c) From the **with** list, choose your PKI object.
d) Under the **Users** tab, refresh the **Available Realms**list by clicking **Refresh** ( ).
e) In the **Available Realms** list, click **Special Identities**.
f) In the **Available Users** list, click **Unknown**.
g) Click **Add to Rule**.
The following figure shows an example.

Step 7 (Optional.) Set other options as discussed in Decryption Rule conditions, on page 1758.

Step 8 Click **Add**.

Step 9 At the top of the page, click **Save**.

What to do next

Associate the identity and decryption policies with the access control policy from step 3.

This final step enables the system to authenticate users with the captive portal.

For more information, see Associate Identity and decryption policies with the access control policy, on page 1903.

Associate Identity and decryption policies with the access control policy

Associate the identity policy and TLS/SSL **Decrypt - Resign** rule with your access control policy to enable captive portal authentication.

This part of the procedure discusses how to associate the identity policy and TLS/SSL **Decrypt - Resign** rule with the access control policy you created earlier. After this, users can authenticate using the captive portal.

For an overview of the entire captive portal configuration, see Configure the captive portal for user control, on page 1891.

Procedure

Step 1 Click **Policies** > **Access Control heading** > **Access Control** and edit the access control policy you created as discussed in Create a TCP port access control rule, on page 1896. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Either create a new access control policy or edit an existing policy.

Step 3 At the top of the page, click the word **Identity**.

Step 4 From the list, choose the name of your identity policy and, at the top of the page, click **Save**.

Step 5 Repeat the preceding steps to associate your captive portal decryption policy with the access control policy.

Step 6 If you haven't done so already, target the policy at managed devices as discussed in Assign access control policy to devices, on page 1583.

What to do next

- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 135.
- Monitor user activity as discussed in *Using Workflows* in the *Cisco Secure Firewall Management Center Administration Guide*.

Captive portal fields

Use these fields to configure captive portal on the **Active Authentication** tab page of your identity policy. See also Identity rule fields, on page 1953 and Exclude applications from captive portal, on page 1905.

Server Certificate

An internal certificate presented by the captive portal daemon.

Note Captive portal does *not* support the use of Digital Signature Algorithm (DSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) certificates.

Port

The port number to use for the captive portal connection. You must set up your access control rule with a TCP port to use for the captive portal, then associate the identity policy with that access control policy. For more information, see Create a TCP port access control rule, on page 1896.

Maximum login attempts

The maximum allowed number of failed login attempts before the system denies a user's login request.

Share active authentication sessions across firewalls

Determines whether or not users are required to authenticate when their authentication session is sent to a different managed device than one they previously connected to. If your organization requires users to authenticate every time they change locations or sites, you should *disable* this option.

- (Default, which continues previous behavior.) Check the box to allow users to authenticate with any managed device associated with the active authentication identity rule.
- Uncheck the box to require the user to authenticate with a different managed device, even if they have already authenticated with another managed device to which the active authentication rule is deployed. Use this option if your organization requires authentication per location or site and a managed device is deployed per site.

Managed devices are either clustered or are in a high availability pair act as if they are the same device; in particular,

- Managed devices in the same cluster or high availability pair: Saves the user session to maintain consistency across the pair. On failover, the secondary has the current user session data.
- Managed devices in a different cluster or high availability pair: User session data is not shared with and therefore not stored on these devices.

Active Authentication Response Page

The system-provided or custom HTTP response page you want to display to captive portal users. After you select an **Active Authentication Response Page** in your identity policy active authentication settings, you also must configure one or more identity rules with **`HTTP Response Page`** as the **Authentication Protocol**.

The system-provided HTTP response page includes **Username** and **Password** fields, a list of realms if you chose to authenticate with a realm sequence, as well as a **Login as guest** button to allow users to access the network as guests. To display a single login method, configure a custom HTTP response page.

An example of what users see when logging in with a response page is shown in Create a sample identity policy with an active authentication rule, on page 1956.

Choose these options:

- To use a generic response, click **System-provided**. You can click **View** ( ) to view the HTML code for this page.
- To create a custom response, click **Custom**. A window with system-provided code is displayed that you can replace or modify. When you are done, save your changes. You can edit a custom page by clicking **Edit** ( ).

Exclude applications from captive portal

This task allows you to exempt specific applications from captive portal active authentication, enabling their traffic to pass through the identity policy without requiring authentication.

You can select applications (identified by their HTTP `User-Agent` strings) and exempt them from captive portal active authentication. This allows traffic from the selected applications to pass through the identity policy without authenticating.

Note Only applications with the **`User-Agent Exclusion` Tag** are displayed in this list.

Before you begin

Follow these steps to exclude applications from captive portal authentication:

Procedure

Step 1 If you haven't done so already, log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Edit the identity policy that contains the captive portal rule.

Step 4 On **Realm & Settings** tab page, expand **HTTP User Agent Exclusions**.

- In the first column, select the check box next to each item to filter applications, then one or more applications, and click **Add to Rule**.

  Check boxes are ANDed together.
- To narrow the filters that are displayed, type a search string in the **Search by name** field; this is especially useful for categories and tags. To clear the search, click **Clear** ( ).
- To refresh the filters list and clear any selected filters, click **Reload** ( ).

Note The list displays 100 applications at a time.

Step 5 Choose the applications that you want to add to the filter from the **Available Applications** list:

- To narrow the individual applications that appear, enter a search string in the **Search by name** field. To clear the search, click **Clear** ( ).

- Use paging at the bottom of the list to browse the list of individual available applications.
- To refresh the applications list and clear any selected applications, click **Reload** ( ).

Step 6 Add the selected applications to exclude from external authentication. You can click and drag, or you can click **Add to Rule**. The result is the combination of the application filters you selected.

What to do next

- Continue configuring the identity rule as described in Create an identity rule, on page 1952.

Troubleshoot the captive portal identity source

For other related troubleshooting information, see Troubleshoot realms and user downloads, on page 1877 and Troubleshoot user control, on page 1962.

If you experience issues with captive portal, check these items:

- The time on your captive portal managed device must be synchronized with the time on the Firewall Management Center.
- If you have DNS resolution configured and you create an identity rule to perform **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) captive portal, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN must match the hostname you provided when configuring DNS.

  For more information, see Hostname redirect, on page 1888.
- If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

  DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.
- If the device you want to use for captive portal contains both inline and routed interfaces, you must configure a zone condition in your captive portal identity rules to target only the routed interfaces on the captive portal device.
- If the captive portal is configured correctly but the redirect to an IP address or fully-qualified domain name (FQDN) fails, disable endpoint security software. This type of software can interfere with the redirection.
- The ERR_CONNECTION_TIMED_OUT error during active authentication occurs when the redirect URL fails to resolve to the managed device's IP address. This error could prevent the client from receiving a user authentication prompt after redirection, cause client traffic on port 885 to be missing from managed device packet captures, or lead to other connection issues. To mitigate connection issues, ensure that the redirect URL resolves to the managed device's IP address on the client's ingress path, where active portal

authentication is configured. Verify the configuration by using the `system support captive-portal-debug` command.

- To securely log a user out of captive portal and prevent the user from logging in again, an administrator can close their session: **Analysis** > **Users heading** > **Active Sessions**. If the user closes their browser, the browser does not reauthenticate automatically.
- If you select **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) as the **Authentication Type** in an identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

  If you select **`HTTP Basic`** as the **Authentication Type** in an identity rule, users on your network might not notice their sessions time out. Most web browsers cache the credentials from **`HTTP Basic`** logins and use the credentials to seamlessly begin a new session after an old session times out.
- If the connection between your Firewall Management Center and a managed device fails, no captive portal logins reported by the device can be identified during the downtime, unless the users were previously seen and downloaded to the Firewall Management Center. The unidentified users are logged as Unknown users on the Firewall Management Center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.

  When the captive portal authenticates users that match an identity rule, any user in a Microsoft Active Directory or LDAP group that has not been downloaded is identified as Unknown. To avoid users being identified as Unknown, configure the realm or realm sequence to download users in all groups you expect to authenticate with captive portal. Unknown users are handled according to the associated access control policy; if the access control policy is configured to block Unknown users, these users are blocked.

  To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

  For more information, see Synchronize users and groups, on page 1865.

History for captive portal

This reference provides the development history and version information for the captive portal feature across different software releases.

Feature	Minimum Firewall Management CenterFirewall Management Center	Minimum Firewall Threat Defense	Details
Authentication using a realm or realm sequence.	7.4.1	7.4.1	You can configure active authentication for either an LDAP realm; or a Microsoft Active Directory realm or a realm sequence. In addition, you can configure a passive authentication rule to fall back to active authentication using either a realm or a realm sequence. You can optionally share sessions between managed devices that share the same identity policy in access control rules. In addition, you have the option to require users to authenticate again when they access the system using a different managed device than they accessed previously. Microsoft Azure Active Directory cannot be used with captive portal. New/modified screens: • **Policies** > **Identity** > **(edit policy)** > **Active Authentication** > **Share active authentication sessions across firewalls** • **Identity policy** > **(edit)** > **Add Rule** > **Passive Authentication** > **Realms & Settings** > **Use active authentication if passive or VPN identity cannot be established** • **Identity policy** > **(edit)** > **Add Rule** > **Active Authentication** > **Realms & Settings** > **Use active authentication if passive or VPN identity cannot be established**
Share active authentication sessions across firewalls.	7.4.1	7.4.1	Determines whether or not users are required to authenticate when their authentication session is sent to a different managed device than one they previously connected to. If your organization requires users to authenticate every time they change locations or sites, you should *disable* this option. • (Default.) Enable to allow users to authenticate with any managed device associated with the active authentication identity rule. • Disable to require the user to authenticate with a different managed device, even if they have already authenticated with another managed device to which the active authentication rule is deployed. New/modified screens: **Policies** > **Identity** > **(edit policy)** > **Active Authentication** > **Share active authentication sessions across firewalls**
Hostname redirect.	7.1.0	7.1.0 with Snort 3	You can use a network object that contains the fully-qualified host name (FQDN) of the interface that captive portal can use for active authentication requests.
Guest login.	6.1.0	6.1.0	Users can log in as guest using captive portal.

Feature	Minimum Firewall Management CenterFirewall Management Center	Minimum Firewall Threat Defense	Details
Captive portal.	6.0.0	6.0.0	Feature introduced. You can use the captive portal to require users to enter their credentials when prompted in a browser window. The mapping also allows policies to be based on a user or group of users.

CHAPTER 52

Identity Source: ISE/ISE-PIC

The following topics discuss how to perform user awareness and user control with ISE/ISE-PIC:

- The ISE/ISE-PIC identity source, on page 1911
- License requirements for ISE/ISE-PIC, on page 1913
- Requirements and prerequisites for ISE/ISE-PIC, on page 1913
- Best practices for ISE/ISE-PIC integration, on page 1914
- ISE/ISE-PIC configurations for user control , on page 1916
- ISE/ISE-PIC configuration, on page 1919
- Configure ISE for user control, on page 1924
- Troubleshoot Cisco ISE/ISE-PIC or Cisco TrustSec issues, on page 1927
- History for ISE/ISE-PIC, on page 1929

The ISE/ISE-PIC identity source

The ISE/ISE-PIC identity source is an authoritative identity source that

- provides user awareness data for users who authenticate using Active Directory (AD), LDAP, RADIUS, or RSA
- enables passive authentication and user control on Active Directory users
- integrates with the system to manage network access and classify traffic in a Cisco TrustSec environment, and
- supports security group tags (SGT) for access control.

ISE/ISE-PIC integration capabilities

You can integrate your Cisco Identity Services Engine (ISE) or ISE Passive Identity Connector (ISE-PIC) deployment with the system to use ISE/ISE-PIC for passive authentication.

In addition to user awareness and control, if you use ISE Cisco ISE to define and use security group tags (SGT) for classifying traffic in a Cisco TrustSec network, you can write access control rules that use SGT as both source and destination matching criteria. This enables you to block or allow access based on security group membership rather than IP addresses or network objects. Also see Best practices for ISE/ISE-PIC integration, on page 1914.

ISE/ISE-PIC does not report failed login attempts or the activity of ISE Guest Services users.

Note The system does not parse IEEE 802.1x machine authentication but it *does* parse 802.1x user authentication. If you are using 802.1x with ISE, you must include user authentication. 802.1x machine authentication will not provide a user identity to the Firewall Management Center that can be used in policy.

For more information on Cisco ISE/ISE-PIC, see the Identity Services Engine Passive Identity Connector administrator guides or the Identity Services Engine administrator guides.

Note We strongly recommend you use the latest version of ISE/ISE-PIC to get the latest feature set and the most number of issue fixes.

Source and destination security group tag (SGT) matching

If you use Cisco ISE to define and use security group tags (SGT) for classifying traffic in a Cisco TrustSec network, you can write access control rules that use SGT as both source and destination matching criteria. This enables you to block or allow access based on security group membership rather than IP addresses or network objects.

Benefits and implementation details

Matching on SGT tags provides these benefits:

- The Firewall Management Center can subscribe to Security Group Tag eXchange Protocol (SXP) mappings from ISE.

  ISE uses SXP to propagate the IP-to-SGT mapping database to managed devices. When you configure Firewall Management Center to use an ISE server, you enable the option to listen to the SXP topic from ISE. This causes the Firewall Management Center to learn about the security group tags and mappings directly from ISE. The Firewall Management Center then publishes SGTs and mappings to managed devices.

  The SXP Topic receives security group tags based on static and dynamic mappings learned through the SXP protocol between ISE and other SXP compliant devices (like switches).

  You can create security group tags in ISE and assign host or network IP addresses to each tag. You can also assign SGTs to user accounts, and the SGT is assigned to the user's traffic. If the switches and routers in the network are configured to do so, these tags then get assigned to packets as they enter the network controlled by ISE, the Cisco TrustSec cloud.

  SXP is *not* supported by ISE-PIC.

- The Firewall Management Center and managed devices can learn about SGT mappings without deploying additional policy. (In other words, you can view connection events for SGT mappings without deploying an access control policy.)
- Supports Cisco TrustSec, which enables you to segment your network to protect critical business assets.
- When a managed device evaluates SGT as a traffic matching criteria for a rule, it uses this priority:

  1. The source SGT tag defined in the packet, if any.

For the SGT tag to be in the packet, the switches and routers in the network must be configured to add them. See the ISE documentation for information on how to implement this method.

For the SGT tag to be in the packet, the switches and routers in the network must be configured to add them. See the ISE documentation for information on how to implement this method.

2. The SGT assigned to the user session, as downloaded from the ISE session directory. The SGT can be matched to source or destination.
3. The SGT-to-IP address mapping downloaded using SXP. If the IP address is in the range for an SGT, then the traffic matches the rule that uses the SGT. The SGT can be matched to source or destination.

SGT matching examples

- In ISE, create an SGT tag named Guest Users and associate it with the 192.0.2.0/24 network.

  For example, you could use Guest Users as a source SGT condition in your access control rule and restrict access to certain URLs, web site categories, or networks from anyone who accesses your network.

- In ISE, create an SGT tag named Restricted Networks and associate it with the 198.51.100.0/8 network.

  For example, you could use Restricted Networks as a destination SGT rule condition and block access from Guest Users and other networks that have users who are not authorized to access the network.

License requirements for ISE/ISE-PIC

This reference provides license requirements for ISE and ISE-PIC systems.

- Network Admin

Best practices for ISE/ISE-PIC integration

ISE/ISE-PIC version and configuration compatibility

Ensure your ISE/ISE-PIC version and configuration supports proper integration with the Secure Firewall Management Center.

- Use the latest version of ISE/ISE-PIC to get the latest feature set.
- Synchronize the time on the ISE/ISE-PIC server and the Secure Firewall Management Center. Otherwise, the system might perform user timeouts at unexpected intervals.
- Configure and enable a realm for the ISE server assuming the pxGrid persona to implement user control using ISE or ISE-PIC data as described in Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.
- Ensure each Secure Firewall Management Center host name that connects to an ISE server is unique; otherwise, the connection to one of the Secure Firewall Management Centers will be dropped.
- If you use ISE 3.4 Patch 4 or later as an identity source for Secure Firewall Management Center in a hybrid deployment, where authorization can use either Microsoft Entra ID (Azure) or on-prem Active Directory, ensure that your ISE authorization policy rule order evaluates on-premises Active Directory external identity source rules before any Entra ID-based authorization rules. This guideline applies to hybrid deployments in which remote access VPN users can authenticate with Microsoft Entra ID, and Secure Firewall Management Center uses the on-premises Microsoft Active Directory realm for user identity and user-based access control.

For the specific versions of ISE/ISE-PIC that are compatible with this version of the system, see the Cisco Firepower Compatibility Guide.

If you configure ISE/ISE-PIC to monitor a large number of user groups, the system might drop user mappings based on groups due to managed device memory limitations. As a result, rules with realm or user conditions might not perform as expected.

For any device running version 6.7 or later, you can optionally use the **configure identity-subnet-filter** command to limit the subnets that the managed device monitors. For more information, see the *Cisco Secure Firewall Threat Defense Command Reference*.

Alternatively, you can configure a network object and apply that object as an Identity Mapping Filter in the identity policy. See Create an identity policy, on page 1943.

IPv6 support

Verify IPv6 compatibility between ISE/ISE-PIC and your managed devices.

- Compatible versions of ISE/ISE-PIC version 2.x include support for IPv6-enabled endpoints.
- Version 3.0 (patch 2) and later of ISE/ISE-PIC enables IPv6 communication between ISE/ISE-PIC and the Firewall Management Center.

Client approval in ISE

Manually approve clients in ISE before the connection between the ISE server and the Firewall Management Center succeeds. Typically, there are two clients: one for the connection test and another for ISE agent.

You can also enable **Automatically approve new accounts** in ISE as discussed in the chapter on Managing users and external identity sources in the *Cisco Identity Services Engine Administrator Guide*.

Unreachable session management

If a user session in ISE/ISE-PIC is reported as unreachable, the system prunes that session so another user with the same IP cannot match the unreachable user's identity rules.

You can control this behavior in ISE/ISE-PIC by going to **Providers** > **Endpoint Probes** and clicking one of these options:

- **Enabled** to cause ISE/ISE-PIC to monitor endpoint connections and therefore to cause the Secure Firewall Management Center prune a session from an unreachable user.
- **Disabled** to cause ISE/ISE-PIC to ignore endpoint connections.

Security group tags (SGT) implementation

A Security Group Tag (SGT) specifies the privileges of a traffic source within a trusted network. Cisco ISE and Cisco TrustSec use a feature called Security Group Access (SGA) to apply SGT attributes to packets as they enter the network. These SGTs correspond to a user's assigned security group within ISE or TrustSec. If you configure ISE as an identity source, the Firepower System can use these SGTs to filter traffic.

Security Group Tags can be used both as source and destination matching criteria in access control rules.

Note

- To implement user control using only the ISE SGT attribute tag, you do not need to configure a realm for the ISE server. ISE SGT attribute conditions can be configured in policies with or without an associated identity policy.
- In some rules, custom SGT conditions can match traffic tagged with SGT attributes that were *not* assigned by ISE. This is not considered user control, and works only if you are not using ISE/ISE-PIC as an identity source.

To match destination SGT tags in addition to source SGT tags, verify these requirements:

Required ISE version: 2.6 patch 6 or later, 2.7 patch 2 or later

Router support: Any Cisco router that supports SGT inline tagging over Ethernet. For more information, consult a reference such as the Cisco Group Based Policy Platform and Capability Matrix Release

Limitations:

- Quality of Service (QoS) policy uses source SGT matching only; it does *not* use destination SGT matching
- RA-VPN does not receive SGT mappings directly through RADIUS

ISE and high availability

When the primary ISE/ISE-PIC server fails, understand the impact on operations.

As a result of the integration with pxGrid v2, the Secure Firewall Management Center round-robins between both configured ISE hosts until one accepts the connection.

If the connection is lost, the Secure Firewall Management Center resumes round-robin attempts to the connected hosts.

Endpoint location (or location IP)

An Endpoint Location attribute is the IP address of the network device that used ISE to authenticate the user, as identified by ISE.

You must configure and deploy an identity policy to control traffic based on **Endpoint Location (Location IP)**.

ISE attributes

Configuring an ISE connection populates the Secure Firewall Management Center database with ISE attribute data. You can use ISE attributes for user awareness and user control. This is not supported with ISE-PIC.

Endpoint profile (or device type)

An Endpoint Profile attribute is the user's endpoint device type, as identified by ISE.

You must configure and deploy an identity policy to control traffic based on **Endpoint Profile (Device Type)**.

ISE/ISE-PIC configurations for user control

An ISE/ISE-PIC configuration uses realms, identity policies, and access control policies to control user access to network resources.

Configuration options

You can use ISE/ISE-PIC in any of these configurations:

- With a realm, identity policy, and associated access control policy: Use a realm to control *user* access to network resources in policy. You can still use ISE/ISE-PIC Security Group Tags (SGT) metadata in your policies.
- With an access control policy only. No realm or identity policy are necessary: Use this method to control network access using SGT metadata alone.

Configure ISE/ISE-PIC without a realm

Configure ISE to allow or block access to the network using SGT tags for enhanced network security and access control.

This topic provides a high-level overview of tasks you must complete to configure ISE to be able to allow or block access to the network using SGT tags.

Procedure

Step 1 SGT matching: Enable SXP on ISE.

This enables the Secure Firewall Management Center to receive updates from ISE when SGT metadata changes.

Step 2 Export system certificates from ISE/ISE-PIC.

The certificates are required to connect securely between the ISE/ISE-PIC pxGrid, monitoring (MNT) servers and the Secure Firewall Management Center. See Export certificates from the ISE/ISE-PIC server for use in the Secure Firewall Management Center, on page 1921

Step 3 Import the certificates in the Secure Firewall Management Center.

The certificates must be imported as follows:

- pxGrid client certificate: internal certificate with key (**Objects** > **Object Management** > **PKI** > **Internal Certs**)
- pxGrid server certificate: trusted CA (**Objects** > **Object Management** > **PKI** > **Trusted CAs**)
- MNT certificate: trusted CA

Step 4 Create the ISE/ISE-PIC identity source.

The ISE/ISE-PIC identity source enables you to control user activity using Security Group Tags (SGT) provided by ISE/ISE-PIC.

Step 5 Create an access control rule.

The access control rule specifies an action to take (for example, allow or block) if traffic matches the rule criteria. You can use source and destination SGT metadata as matching criteria in the access control rule. See Access control rules, on page 1609.

Step 6 Deploy the access control policy to managed devices.

Before your policy can take effect, it must be deployed to managed devices. See Deploy configuration changes, on page 135.

What to do next

Export certificates from the ISE/ISE-PIC server for use in the Secure Firewall Management Center, on page 1921

Configure ISE/ISE-PIC for user control using a realm

This task enables you to configure ISE/ISE-PIC for user control and to allow or block user or group access to the network. Users and groups can be stored in any server listed in Supported servers for realms, on page 1841.

This topic provides a high-level overview of tasks you must complete to configure ISE/ISE-PIC for user control and to be able to allow or block user or group access to the network.

Procedure

Step 1 Enable SXP on ISE for destination SGT only.

This enables the Secure Firewall Management Center to receive updates from ISE when SGT metadata changes.

Step 2 Export system certificates from ISE/ISE-PIC.

The certificates are required to connect securely between the ISE/ISE-PIC pxGrid, monitoring (MNT) servers and the Secure Firewall Management Center. See the following:

- pxGrid server and MNT server certificate: Export certificates from the ISE/ISE-PIC server for use in the Secure Firewall Management Center, on page 1921
- pxGrid client certificate: Generate a self-signed certificate, on page 1923

Step 3 Import the certificates in the Secure Firewall Management Center.

The certificates must be imported as follows:

- pxGrid client certificate: internal certificate with key (**Objects** > **Object Management** > **PKI** > **Internal Certs**)
- pxGrid server certificate: trusted CA (**Objects** > **Object Management** > **PKI** > **Trusted CAs**)
- MNT certificate: trusted CA

Step 4 Create a realm.

You must create a realm only to control access to the network by the users and groups you choose.

See Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.

a) Download users and groups, and enable the realm.

Downloading users and groups enables you to use them in access control rules. See Synchronize users and groups, on page 1865.

Step 5 Create the ISE/ISE-PIC identity source.

The ISE/ISE-PIC identity source enables you to control user activity using Security Group Tags (SGT) provided by ISE/ISE-PIC.

Step 6 Create an identity policy.

An identity policy is a container for one or more identity rules. See Create an identity policy, on page 1943.

a) Create an identity rule.

An identity rule specifies how a realm is used to control access to the network by users and groups. See Create an identity rule, on page 1952.

Step 7 Associate the identity policy with an access control policy.

This enables the access control policy to use users and groups in the realm.

a) Create an access control rule.

The access control rule specifies an action to take (for example, allow or block) if traffic matches the rule criteria. You can use source and destination SGT metadata as matching criteria in the access control rule. See Access control rules, on page 1609.

Step 8 Deploy the access control policy to managed devices.

Before your policy can take effect, it must be deployed to managed devices. See Deploy configuration changes, on page 135.

What to do next

Export certificates from the ISE/ISE-PIC server for use in the Secure Firewall Management Center, on page 1921

ISE/ISE-PIC configuration

This section explains how to configure the ISE/ISE-PIC server for use with identity policies in the Firewall Management Center, including:

- export certificates from the ISE/ISE-PIC server to authenticate with the Firewall Management Center
- publish SXP topics so the Firewall Management Center can be updated with Security Group Tags (SGT) on the ISE server.

Configure security groups and SXP publishing in ISE

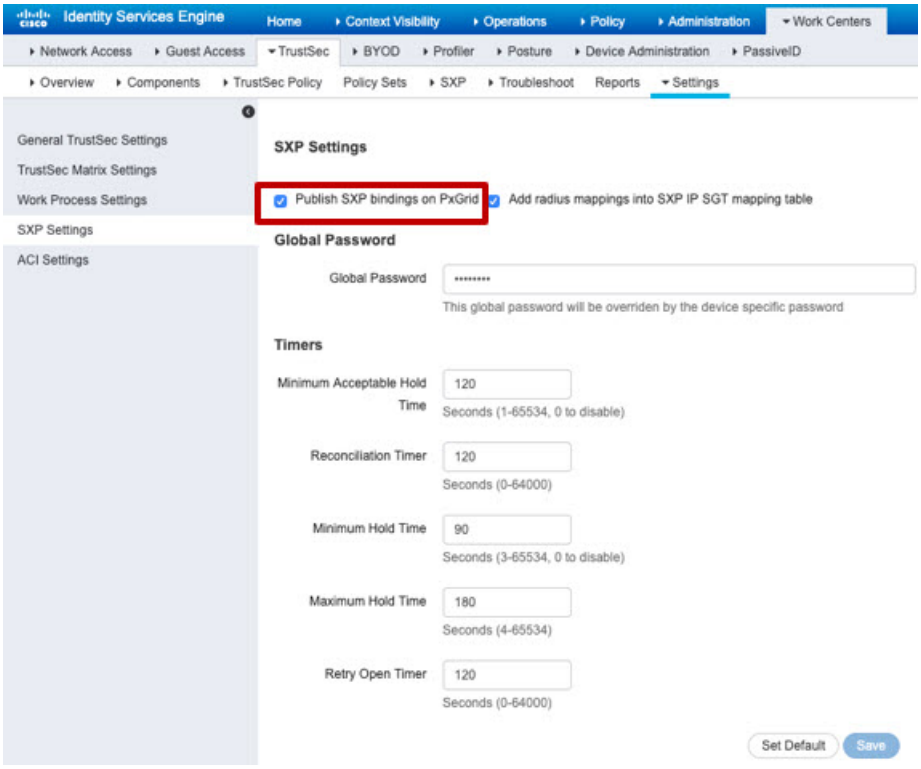
This task enables static SGT-to-IP address mappings for Secure Firewall Threat Defense devices, allowing TrustSec policies and access control based on source and destination security group tags (SGT).

There is a lot of configuration that you must do in Cisco Identity Services Engine (ISE) to create the TrustSec policy and security group tags (SGT). Please look at the ISE documentation for more complete information on implementing TrustSec.

The following procedure picks out the highlights of the core settings you must configure in ISE for the Firewall Threat Defense device to be able to download and apply static SGT-to-IP address mappings, which can then be used for source and destination SGT matching in access control rules. See the ISE documentation for detailed information.

The figures in this procedure are based on ISE 2.4. The exact paths to these features might change in subsequent releases, but the concepts and requirements will be the same. Although ISE 2.4 or later is recommended, and preferably 2.6 or later, the configuration should work starting with ISE 2.2 patch 1.

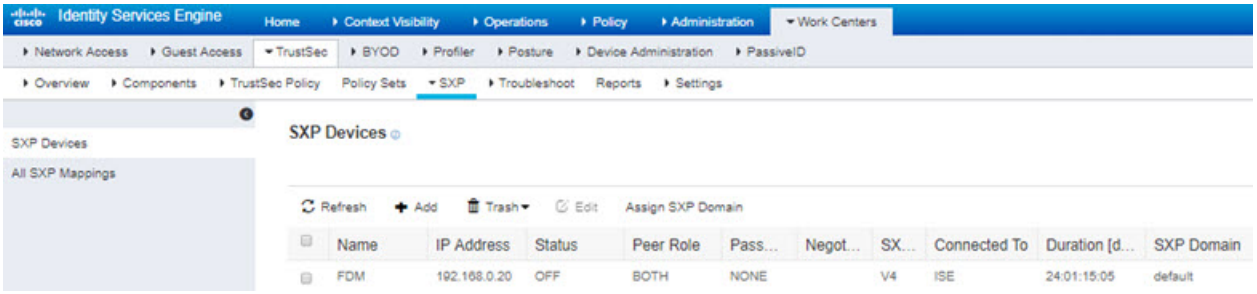
Before you begin



You must have the ISE Plus license to publish SGT-to-IP address static mappings and to get user session-to-SGT mappings so that the Firewall Threat Defense device can receive them.

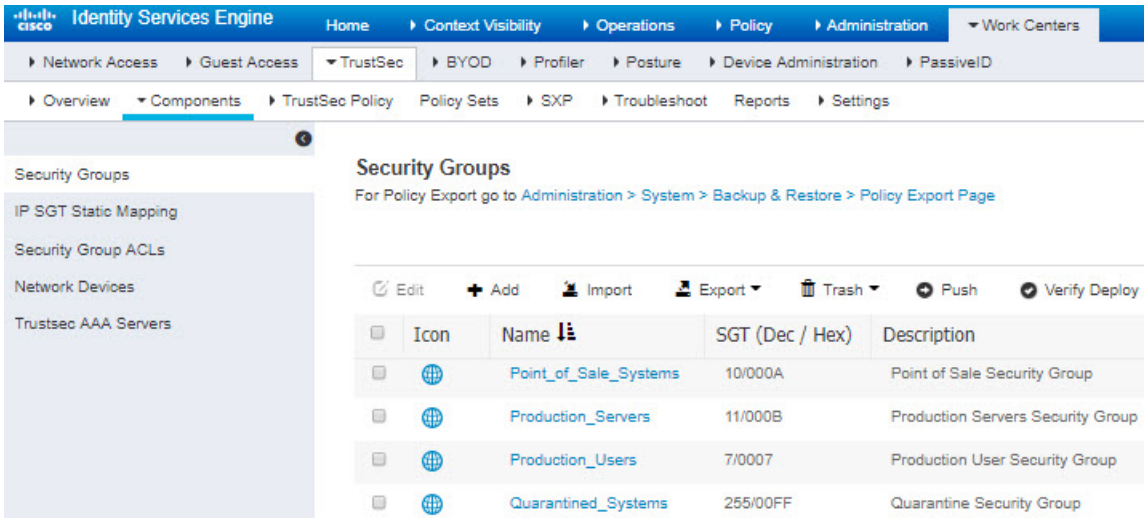
Procedure

Step 1 Choose **Work Centers** > **TrustSec** > **Settings** > **SXP Settings**, and select the **Publish SXP Bindings on PxGrid** option.



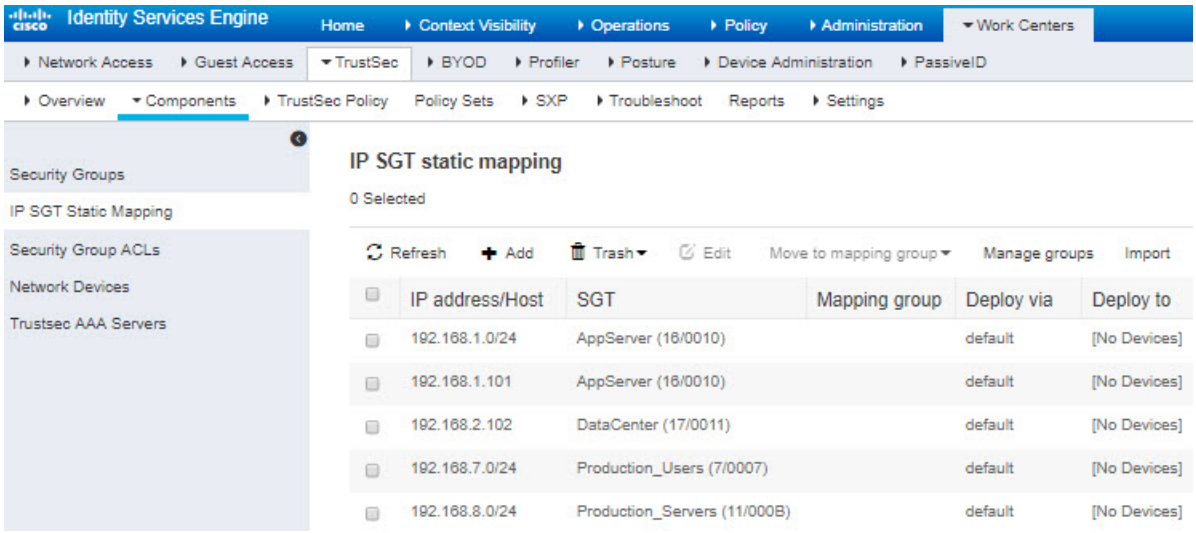
This option makes ISE send the SGT mappings out using SXP. You must select this option for the Firewall Threat Defense device to "hear" anything from listing to the SXP topic. This option must be selected for the

Firewall Threat Defense device to get static SGT-to-IP address mapping information. It is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.



Step 2 Choose **Work Centers** > **TrustSec** > **SXP** > **SXP Devices**, and add a device.

This does not have to be a real device, you can even use the management IP address of the Firewall Threat Defense device. The table simply needs at least one device to induce ISE to publish the static SGT-to-IP address mappings. This step is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.



Step 3 Choose **Work Centers** > **TrustSec** > **Components** > **Security Groups** and verify there are security group tags defined. Create new ones as necessary.

Step 4 Choose **Work Centers** > **TrustSec** > **Components** > **IP SGT Static Mapping** and map host and network IP addresses to the security group tags.

This step is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.

You have configured ISE with the necessary security groups, SXP publishing settings, and static SGT-to-IP mappings required for Secure Firewall Threat Defense devices to receive and apply TrustSec policies.

Export certificates from the ISE/ISE-PIC server for use in the Secure Firewall Management Center

Certificate exported from Identity Services Engine (ISE) / Identity Services Engine - Passive Identity Connector (ISE-PIC) servers enables secure authentication between the Firewall Management Center and ISE systems.

You might need to export one, or as many as three, certificates, depending on how your ISE system is set up:

- One certificate for the pxGrid server
- One certificate for the monitoring (MNT) server
- One certificate, including the private key, for the pxGrid client (that is, the Firewall Management Center)

  Unlike the first two certificates, this is a self-signed certificate.

These certificates are then imported into the Firewall Management Center:

- pxGrid client certificate: internal certificate with key (**Objects** > **Object Management** > **PKI** > **Internal Certs**)
- pxGrid server certificate: trusted CA (**Objects** > **Object Management** > **PKI** > **Trusted CAs**)
- MNT certificate: trusted CA

Export a system certificate

Export a system certificate or a certificate with its associated private key for backup or transfer to another system.

You can export a system certificate or a certificate and its associated private key. If you export a certificate and its private key for backup purposes, you can reimport them later if needed.

Before you begin

To perform the following task, you must be a Super Admin or System Admin.

Procedure

Step 1 In the Cisco ISE GUI, click the **Menu** icon (☰) and choose **Administration** > **System** > **Certificates** > **System Certificates**.

Step 2 Check the check box next to the certificate that you want to export and click **Export**.

Step 3 Choose whether to export only the certificate, or the certificate and its associated private key.

Tip We do not recommend exporting the private key that is associated with a certificate because its value may be exposed. If you must export a private key (for example, when you export a wildcard system certificate to be imported into the other Cisco ISE nodes for inter-node communication), specify an encryption password for the private key. You must specify this password while importing this certificate into another Cisco ISE node to decrypt the private key.

Step 4 Enter the password if you have chosen to export the private key. The password should be at least eight characters long.

Step 5 Click **Export** to save the certificate to the file system that is running your client browser.

If you export only the certificate, the certificate is stored in the PEM format. If you export both the certificate and private key, the certificate is exported as a .zip file that contains the certificate in the PEM format and the encrypted private key file.

Generate a self-signed certificate

Generate a self-signed certificate to add a new local certificate for internal testing and evaluation purposes in Cisco ISE.

Add a new local certificate by generating a self-signed certificate. Cisco recommends that you only employ self-signed certificates for your internal testing and evaluation needs. If you plan to deploy Cisco ISE in a production environment, use CA-signed certificates whenever possible to ensure more uniform acceptance around a production network.

Note If you use a self-signed certificate and you want to change the hostname of your Cisco ISE node, log in to the administration portal of the Cisco ISE node, delete the self-signed certificate that has the old hostname, and generate a new self-signed certificate. Otherwise, Cisco ISE continues to use the self-signed certificate with the old hostname.

Before you begin

To perform this task, you must be a Super Admin or System Admin.

Follow these steps to generate a self-signed certificate:

Procedure

Step 1 In the Cisco ISE GUI, click the **Menu** icon (☰) and choose **Administration** > **System** > **Certificates** > **System Certificates**.

To generate a self-signed certificate from a secondary node, choose **Administration** > **System** > **Server Certificate**.

Step 2 In the ISE-PIC GUI, click the **Menu** icon (☰) and choose **Certificates** > **System Certificates**.

Step 3 Click **Generate Self Signed Certificate** and enter the details in the window displayed.

Step 4 Check the check boxes in the **Usage** area based on the service for which you want to use this certificate.

Step 5 Click **Submit** to generate the certificate.

To restart the secondary nodes, from the CLI, enter these commands in this order:

a) **application stop ISE**
b) **application start ISE**

Import ISE/ISE-PIC certificates

Import certificates and keys from your ISE or ISE-PIC server to the firewall to enable secure pxGrid and MNT integration for cloud-delivered firewall management.

This procedure is optional.

- pxGrid client certificate: internal certificate with key (**Objects** > **Object Management** > **PKI** > **Internal Certs**)
- pxGrid server certificate: trusted CA (**Objects** > **Object Management** > **PKI** > **Trusted CAs**)
- MNT certificate: trusted CA

Before you begin

Export certificates from the ISE/ISE-PIC server as discussed in Export a system certificate, on page 1922. The certificates and key must be present on the machine from which you log in to the Secure Firewall Management Center.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Objects** > **Object Management** > **PKI** > **Internal Certs**.

Step 3 Click **Add Internal Cert**.

Step 4 Follow the prompts on your screen to import the certificate and private key.

Step 5 Click **Trusted CAs**.

Step 6 Click **Add Trusted CA**.

Step 7 Follow the prompts on your screen to import the pxGrid server certificate.

Step 8 Repeat the preceding steps, if necessary, to import the MNT server's trusted CA.

Configure ISE for user control

Configure ISE/ISE-PIC identity source to enable user session retrieval from Microsoft Active Directory or LDAP servers for identity-based access control.

The following procedure discusses how to configure the ISE/ISE-PIC identity source. You must be in the global domain to perform this task.

Before you begin

- To get user sessions from a Microsoft Active Directory Server or supported LDAP server, configure and enable a realm for the Cisco ISE server, assuming the pxGrid persona, as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.
- To get all mappings that are defined in Cisco ISE, including SGT-to-IP address mappings published through SXP, use the procedure that follows. As an alternative, you have the following options:

- To use the SGT information in the packets only, and not use mappings downloaded from Cisco ISE, skip the steps discussed in Create and edit access control rules, on page 1631. Note that in this case, you can use SGT tags as a source condition only; these tags will never match destination criteria.
- To use SGT in packets and user-to-IP-address/SGT mappings only, do not subscribe to the SXP topic in the Cisco ISE identity source, and do not configure ISE to publish SXP mappings. You can use this information for both source and destination matching conditions.

- Export certificates from the ISE/ISE-PIC server and optionally import them into the Secure Firewall Management Center as discussed in Export certificates from the ISE/ISE-PIC server for use in the Secure Firewall Management Center, on page 1921.
- To publish SXP topics so the Secure Firewall Management Center can be updated with Security Group Tags (SGT) on the ISE server, see ISE/ISE-PIC configuration, on page 1919.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Integration** > **Other Integrations** > **Identity Sources**.

Step 3 Click **Identity Services Engine** for the **Service Type** to enable the ISE connection.

Note To disable the connection, click **None**.

Step 4 Enter a **Primary Host Name/IP Address** and, optionally, a **Secondary Host Name/IP Address**.

Step 5 Click the appropriate certificate authorities from the **pxGrid Server CA** and **MNT Server CA** lists, and the appropriate certificate from the **pxGrid Client Certificate** list. You can also click **Add** (+) to add a certificate.

Note The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.

Step 6 (Optional.) Enter an **ISE Network Filter** using CIDR block notation.

Step 7 In the Subscribe To section, check the following:

- **Session Directory Topic** to receive ISE user session information from the ISE server.
- **SXP Topic** to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.

Step 8 To test the connection, click **Test**.

If the test fails, click **Additional Logs** for more information about the connection failure.

Note If you set up load balancing with ISE, the node that responds to the test should be the currently active node. For more information, see Cisco pxGrid Node.

What to do next

- Specify users to control and other options using an identity policy as described in Create an identity policy, on page 1943.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.
- Use Security Group Tags (SGT) from Cisco ISE as dynamic attributes in access control policies.
- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 135.
- Monitor user activity as discussed in *Using Workflows* in the *Cisco Secure Firewall Management Center Administration Guide*.

ISE/ISE-PIC configuration fields

The fields in this reference are used to configure a connection to ISE/ISE-PIC.

Connection and certificate configuration fields for ISE/ISE-PIC integration:

- **Primary and Secondary Host Name/IP Address**: The hostname or IP address for the primary and, optionally, the secondary pxGrid ISE servers. The ports used by the host names you specify must be reachable by both ISE and the Secure Firewall Management Center.
- **pxGrid Server CA**: The trusted certificate authority for the pxGrid framework. If your deployment includes a primary and a secondary pxGrid node, the certificates for both nodes must be signed by the same certificate authority.
- **MNT Server CA**: The trusted certificate authority for the ISE certificate when performing bulk downloads. If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.
- pxGrid Client Certificate: The internal certificate and key that the Secure Firewall Management Center must provide to /ISE-PIC to connect to /ISE-PIC or to perform bulk downloads.

Note The **pxGrid Client Certificate** must include the clientAuth extended key usage value, or it must not include any extended key usage values.

Data filtering, subscription, and proxy configuration fields:

- **ISE Network Filter**: An optional filter you can set to restrict the data that ISE reports to the Secure Firewall Management Center. If you provide a network filter, ISE reports data from the networks within that filter. You can specify a filter in these ways:
  - Leave the field blank to specify **`any`**.
  - Enter a single IPv4 address block using CIDR notation.
  - Enter a list of IPv4 address blocks using CIDR notation, separated by commas.
- **Subscribe to**: **Session Directory Topic**: Check this box to subscribe to user session information from the ISE server. Includes SGT and endpoint metadata. **SXP Topic**: Check this box to subscribe to SXP mappings from the ISE server.

Note This version of the system does not support filtering using IPv6 addresses, regardless of your ISE version.

Troubleshoot Cisco ISE/ISE-PIC or Cisco TrustSec issues

This reference helps you troubleshoot issues with Cisco TrustSec, ISE, or ISE-PIC integration to ensure Security Group Tag propagation, user mapping, and certificate requirements are correctly configured for Cloud-Delivered Firewall Management Center and Secure Firewall Management Center deployments.

Troubleshoot Cisco TrustSec issues

A device interface can be configured to propagate Security Group Tags (SGTs) either from ISE/ISE-PIC or from a Cisco device on the network (referred to as Cisco TrustSec.) On the device management page (**Devices** > **Device Management**), the **Propagate Security Group Tag** check box for an interface is disabled by default. If you want the interface to propagate TrustSec data, check the box.

Troubleshoot ISE/ISE-PIC issues

For other related troubleshooting information, see Troubleshoot realms and user downloads, on page 1877 and Troubleshoot user control, on page 1962.

If you experience issues with the ISE or ISE-PIC connection, check these items:

- The pxGrid Identity Mapping feature in ISE must be enabled before you can successfully integrate ISE with the system.
- When the primary server fails, you must manually promote the secondary to primary; there is no automatic failover.
- Before a connection between the ISE server and the Firewall Management Center succeeds, you must manually approve the clients in ISE. (Typically, there are two clients: one for the connection test and another for ISE agent.)

  You can also enable **Automatically approve new accounts** in ISE as discussed in the chapter on Managing users and external identity sources in the Identity Services Engine administrator guides.
- The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.

- The time on your ISE server must be synchronized with the time on the Secure Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.
- If your deployment includes a primary and a secondary pxGrid node,
  - The certificates for both nodes must be signed by the same certificate authority.
  - The ports used by the host name must be reachable by both the ISE server and by the Secure Firewall Management Center.
- If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.

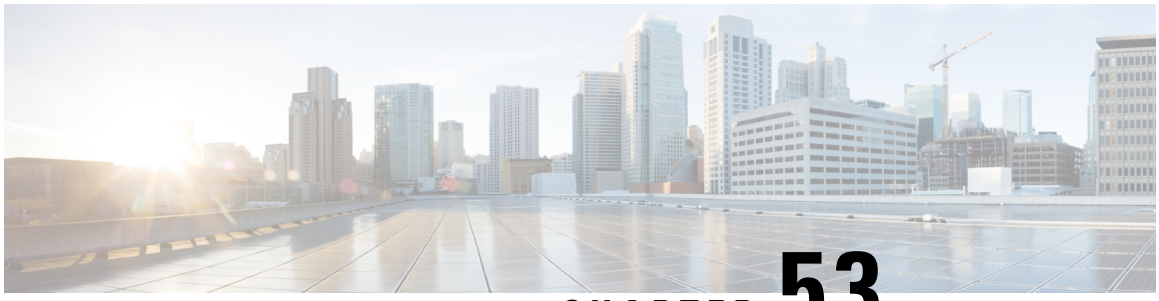
To exclude subnets from receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE, use the **configure identity-subnet-filter** {**add** | **remove**} command. You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.

If you experience issues with user data reported by ISE or ISE-PIC, note these items:

- After the system detects activity from an ISE user whose data is not yet in the database, the system retrieves information about them from the server. Activity seen by the ISE user is *not* handled by access control rules, and is *not* displayed in the web interface until the system successfully retrieves information about them in a user download.
- You cannot perform user control on ISE users who were authenticated by an LDAP, RADIUS, or RSA domain controller.
- The Secure Firewall Management Center does not receive user data for ISE Guest Services users.
- If ISE monitors the same users as TS Agent, the Secure Firewall Management Center prioritizes the TS Agent data. If the TS Agent and ISE report identical activity from the same IP address, only the TS Agent data is logged to the Secure Firewall Management Center.
- Your ISE version and configuration impact how you can use ISE in the system. For more information, see The ISE/ISE-PIC identity source, on page 1911.
- If you have Secure Firewall Management Center high availability configured and the primary fails, see the section on ISE and high availability in Best practices for ISE/ISE-PIC integration, on page 1914.
- ISE-PIC does not provide ISE attribute data.
- ISE-PIC cannot perform ISE ANC remediations.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, refer to RFC 959.

If you experience issues with supported functionality, see The ISE/ISE-PIC identity source, on page 1911 for more information about version compatibility.

ISE/ISE-PIC user timeout



If you're setting up ISE/ISE-PIC without a realm, be aware there is a user session timeout that affects how users are seen by the Firewall Management Center.

History for ISE/ISE-PIC

This reference provides the historical development of ISE and ISE-PIC integration features across different software versions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
pxGrid 2.0 is the default for supported ISE/ISE-PIC versions	6.7.0	6.7.0	Note: • Supported ISE/ISE-PIC versions: 2.6 patch 6 or later, 2.7 patch 2 or later • Adaptive Network Control (ANC) policies replace Endpoint Protection Service (EPS) remediations. If you have EPS policies configured in the Firewall Management Center, you must migrate them to use ANC.
Optionally exclude subnets from receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE. You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.	6.7.0	6.7.0	New command: **configure identity-subnet-filter** {**add** | **remove**}
Destination Security Group Tag matching (SGT)	6.5.0	6.5.0	Feature introduced. Enables you to use ISE SGT tags for both source and destination matching criteria in access control rules. SGT tags are tag-to-host/network mappings obtained by ISE. New/modified screens: • New options to configure Destination SGT matching: **System** > **Integration** > **Identity Sources** > **ISE/ISE-PIC** • **Session Directory Topic**: Subscribe to ISE user session information. • **SXP Topic**: Subscribe to SGT tag updates on the ISE server. • New and renamed columns in **Analysis** > **Connections** > **Events** • Renamed: Security Groups Tags renamed to Source SGT • New: Destination SGT
Integration with ISE-PIC	6.2.1	6.2.1	You can now use data from ISE-PIC.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
SGT tags for user control.	6.2.1	6.2.0	You no longer need to create a realm or identity policy to perform user control based on ISE Security Group Tag (SGT) data.
Integration with ISE.	6.0	6.0	Feature introduced. By subscribing to Cisco's Platform Exchange Grid (PxGrid), the Firepower Management Center can download additional user data, device type data, device location data, and Security Group Tags (SGTs) —a method used by ISE to provide network access control).

CHAPTER 53

Identity Source: Remote Access VPN

The following topics discuss how to perform user awareness and user control with Remote Access VPN:

- Remote access VPN identity sources, on page 1931
- Configure Remote Access VPN for AD-authenticated users, on page 1932
- Hybrid Entra ID and on-premises AD deployments, on page 1933
- Troubleshooting guidelines for remote access VPN identity source, on page 1934
- History for RA VPN, on page 1935

Remote access VPN identity sources

A remote access VPN identity source authenticates a user before establishing secure remote connection to the network. It requires the user to provide credentials through a client to verify the identity.

Identity source configuration

Secure Client is the only client supported on endpoint devices for remote VPN connectivity to Firewall Threat Defense devices.

When you set up a secure VPN gateway as discussed in Configure a remote access VPN policy, you can set up an identity policy for those users and associate the identity policy with an access control policy, provided your users are in an Active Directory repository.

Note If you use remote access VPN with User Identity and RADIUS as the identity source, you must configure the realm (**Objects** > **Object Management** > **AAA Server** > **RADIUS Server Group**).

The login information provided by a remote user is validated by an LDAP or AD realm or a RADIUS server group. These entities are integrated with the Secure Firewall Threat Defense secure gateway.

Note If users authenticate with remote access VPN using Active Directory as the authentication source, users must log in using their username; the format domain\username or username@domain fails. (Active Directory refers to this username as the logon name or sometimes as sAMAccountName.) For more information, see User Naming Attributes on MSDN.

If you use RADIUS to authenticate, users can log in with any of the preceding formats.

Once authenticated through a VPN connection, the remote user takes on a VPN identity. This VPN identity is used by identity policies on the Secure Firewall Threat Defense secure gateway to recognize and filter network traffic belonging to that remote user.

Identity policies are associated with access control policies, which determine who has access to network resources. It is in this way that a remote user blocked or allowed to access your network resources.

Related Topics

Secure Connections Overview, on page 1329
Remote access VPN
VPN basics, on page 1330
Configure a remote access VPN policy

Configure Remote Access VPN for AD-authenticated users

Configure remote access VPN for Active Directory-authenticated users. Manage VPN connections and apply identity-based policies to control user access and traffic filtering.

Remote access VPN user control allows you to implement identity-based policies that manage and monitor VPN user connections, providing enhanced security and access control for your network environment.

Before you begin

- Create a realm as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.
- To use authentication, authorization, and auditing (AAA), set up a RADIUS server group as discussed in Add a RADIUS server group, on page 2346.

Follow these steps to configure RA VPN for user control:

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Devices** > **VPN** > **Remote Access**.

Step 3 See Configure a remote access VPN policy.

Step 4 Specify users to control and other options using an identity policy as described in Create an identity policy, on page 1943.

Step 5 Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.

Step 6 Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 135.

What to do next

Monitor VPN user traffic as discussed in Monitor remote access VPNs.

Hybrid Entra ID and on-premises AD deployments

The hybrid Entra ID and on-premises AD deployment model enables secure, flexible authentication and authorization for remote access users, provided the correct policy order and rule configuration are maintained.

In a hybrid deployment, remote access VPN users can authenticate with Microsoft Entra ID (formerly Azure AD). Cisco ISE authorizes the session and Firewall Management Center uses an on-premises Microsoft Active Directory realm for user identity and user-based access control. In this deployment model:

- Remote access VPN (RA VPN) is configured on Firewall Threat Defense
- Microsoft Entra ID or Azure is used as the SAML identity provider for VPN authentication
- Cisco ISE is used for session authorization
- Cisco ISE authorization policies may include both Microsoft Entra ID/Azure and on-premises AD rules or conditions
- Firewall Management Center uses the on-premises AD domain as the realm for user identity and user enforcement

Best practice: ISE authorization policy order for hybrid deployments

Beginning with Cisco ISE Release 3.4 Patch 4, when ISE evaluates an Entra ID identity source during authorization, it associates Entra ID attributes with the session. If Firewall Management Center uses an on-premises AD realm, the presence of Entra ID attributes may prevent correct user-to-IP mapping for RA VPN sessions. Identity-based access control rules that depend on user or group identity might not match as expected.

To prevent this issue:

Place ISE authorization rules that use the on-premises AD external identity source before rules that evaluate Entra ID or Azure conditions for the same users. This ensures that the session attributes published to FMC through pxGrid align with the configured on-premises AD realm.

After configuring the authorization policy order, verify that new RA VPN sessions create user mappings in Firewall Management Center and that user-based or group-based access control rules match as expected.

Note This behavior applies to Cisco ISE Release 3.4 Patch 4 and later. If user mappings stopped appearing after an ISE upgrade, review the ISE authorization policy order as described in this section.

Troubleshooting guidelines for remote access VPN identity source

For other related troubleshooting information, see Troubleshoot realms and user downloads, on page 1877 and Troubleshoot user control, on page 1962.

If you experience issues with Remote Access VPN, check the connection between your Firewall Management Center and a managed device. If the connection fails, all Remote Access VPN logins reported by the device cannot be identified during the downtime, unless the users were previously seen and downloaded to the Firewall Management Center.

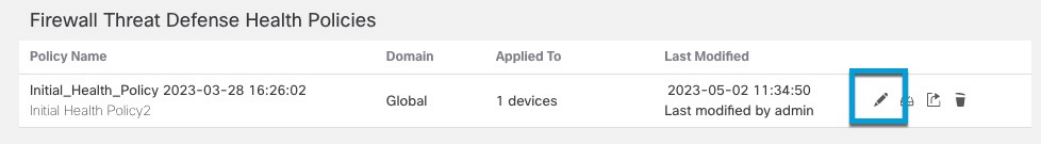
The unidentified users are logged as Unknown users on the Firewall Management Center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.

The host name of the managed device must be less than 15 characters for Kerberos authentication to succeed.

Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 95

Not Observing Correct Settings for VPN Statistics

This task ensures that managed devices receive the correct health policy settings after modifying VPN statistics configurations.



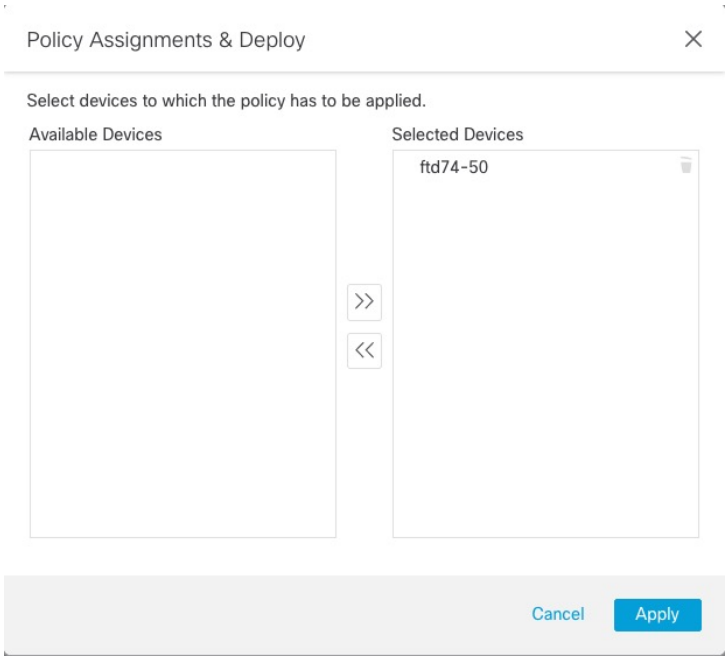
This task discusses steps you must take after either enabling or disabling the **VPN Statistics** setting in a health policy. Failure to perform this task means managed devices have a health policy with incorrect settings.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **System** (⚙) > **Health** > **Policy**.

Step 3 Under Firewall Threat Defense Health Policies, click **Edit** (✎) next to a policy to edit.



Step 4 On the **Health Modules** tab page, scroll down to locate **VPN Statistics**.

Step 5 Verify the VPN statistics setting is correct or change it if necessary.

Step 6 If you changed the setting, click **Save**, then click **Cancel** to return to the health policy.

Step 7 Under Firewall Threat Defense Health Policies, click **Deploy health policy** (🚀) to apply the policy.

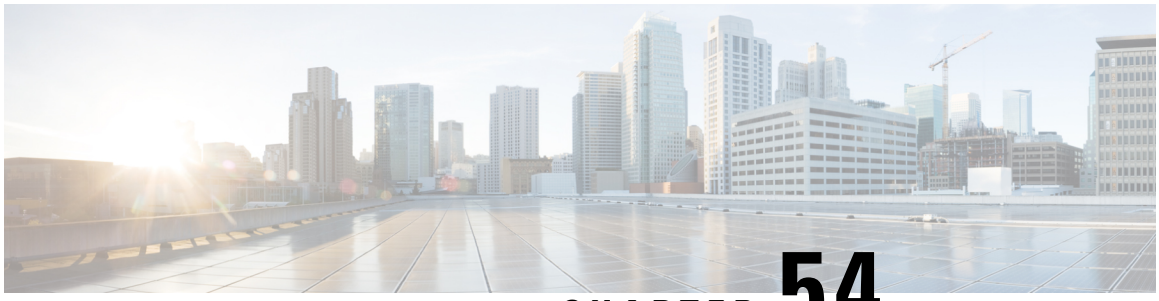
Step 8 In the **Policy Assignments & Deploy** dialog box, move the devices to which to deploy the health policy to the **Selected Devices** field.

Step 9 Click **Apply**.
A message is displayed when the health policy is deployed.

Step 10 After the health policy has finished deploying, click **Policies** > **Access Control heading** > **Access Control** to edit an access control policy.

Step 11 Click **Edit** (✎) next to a policy to edit.

Step 12 Make a minor change to the policy, such as changing its name.



Step 13 Save the access control policy.

Step 14 Deploy configuration changes; see Deploy configuration changes, on page 135..

History for RA VPN

This reference provides the version history and introduction details for Remote Access VPN (RA VPN) feature support across Firewall Management Center and Firewall Threat Defense versions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Remote Access VPN	6.2.1	Any	Feature introduced. RA VPN allows individual users to connect to a private business network from a remote location using a laptop or desktop computer connected to the internet, or an Android or Apple iOS mobile device. Remote users transfer data securely and confidentially using encryption techniques crucial for data being transferred over shared mediums and the Internet.

CHAPTER 54

Identity source: TS agent

To use the TS Agent as an identity source for user awareness and user control, install and configure the TS Agent software as discussed in the Terminal Services (TS) Agent guides.

What to do next:

- Specify users to control and other options using an identity policy as described in Create an identity policy, on page 1943.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.
- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 135.
- Monitor user activity as discussed in *Using Workflows* in the *Cisco Secure Firewall Management Center Administration Guide* .

- Terminal services agent identity source, on page 1937
- Best practices for TS agent configuration, on page 1938
- Identity source: TS agent, on page 1938
- Troubleshoot the TS agent identity source, on page 1938
- History for TS agent, on page 1939

Terminal services agent identity source

The TS Agent is a passive authentication method and one of the authoritative identity sources supported by the system. A Windows Terminal Server performs the authentication, and the TS Agent reports it to a standalone or high availability .

TS agent functionality

When installed on Windows Terminal Servers, the TS Agent assigns a unique port range to individual users as they log in or log out of a monitored network. The Secure Firewall Management Center uses the unique port to identify individual users in the system. You can use one TS Agent to monitor user activity on one Windows Terminal Server and send encrypted data to a Secure Firewall Management Center.

The TS Agent does not report failed login attempts. The data gained from the TS Agent can be used for user awareness and user control.

Best practices for TS agent configuration

Configure the TS Agent on a Windows Terminal Server to monitor user activity and identity realms. The TS Agent enables user awareness in the Secure Firewall Management Center.

- Install and configure the TS Agent on a Windows Terminal Server.
- Configure one or more identity realms targeting the users your server is monitoring.

TS Agent data is visible in the Users, User Activity, and Connection Event tables and can be used for user awareness and user control. For detailed information about the multi-step TS Agent installation and configuration and a complete discussion of the server and system requirements, see the Terminal Services (TS) Agent guides.

Note If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the Secure Firewall Management Center prioritizes the TS Agent data. If the TS Agent and another passive identity source report activity by the same IP address, only the TS Agent data is logged to the Secure Firewall Management Center.

Identity source: TS agent

To use the TS Agent as an identity source for user awareness and user control, install and configure the TS Agent software as discussed in the Terminal Services (TS) Agent guides.

What to do next:

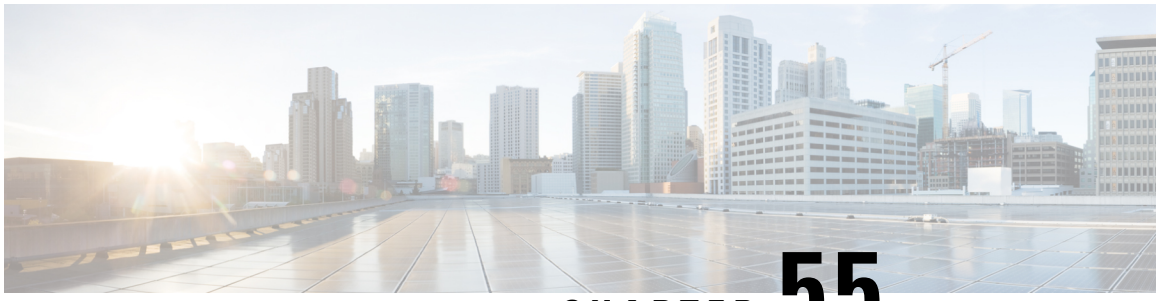
- Specify users to control and other options using an identity policy as described in Create an identity policy, on page 1943.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.
- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 135.
- Monitor user activity as discussed in *Using Workflows* in the *Cisco Secure Firewall Management Center Administration Guide* .

Troubleshoot the TS agent identity source

This reference provides troubleshooting guidance for TS Agent integration issues with the Secure Firewall Management Center. It addresses synchronization requirements, user data prioritization, and activity logging for overlapping passive identity sources.

For other related troubleshooting information, see Troubleshoot realms and user downloads, on page 1877 and Troubleshoot user control, on page 1962.

If you experience issues with the TS Agent integration, check:



- You must synchronize the time on your TS Agent server with the time on the Secure Firewall Management Center.
- If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the Secure Firewall Management Center prioritizes the TS Agent data. If the TS Agent and a passive identity source report activity by the same IP address, only the TS Agent data is logged to the Secure Firewall Management Center.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, refer to RFC 959.

For more troubleshooting information, see the Terminal Services (TS) Agent guides.

History for TS agent

This reference provides the historical development timeline and version information for the TS Agent feature, including compatibility details and feature introductions across different Firepower Management Center and Threat Defense versions.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
TS Agent for user control.	7.2.0	6.2.0	Feature introduced. Firepower now provides the ability to better identify individual users in shared environments, such as Citrix's Virtual Desktop Infrastructure (VDI), to accurately enforce user-based policy rules on the firewall. Users are identified by ports used. The TS Agent software is updated independently of the Firepower Management Center. For more information, see: • *Cisco Terminal Services (TS) Agent Guide* available on cisco.com • Cisco Firepower Compatibility Guide

CHAPTER 55

Identity Policies

The following topics discuss how to create and manage identity rules and identity policies:

- Identity policies, on page 1941
- License requirements for identity policies, on page 1942
- Requirements and prerequisites for identity policies, on page 1942
- Create an identity policy, on page 1943
- Identity rule conditions, on page 1945
- Create an identity rule, on page 1952
- Sample identity policies and rules, on page 1954
- Manage an identity policy, on page 1961
- Manage an identity rule, on page 1961
- Troubleshoot user control, on page 1962

Identity policies

Identity policies contain identity rules. Identity rules associate sets of traffic with a realm and an authentication method: passive authentication, active authentication, or no authentication.

Configuration requirements

With the exception noted below, you must configure realms and authentication methods you plan to use before you can invoke them in your identity rules:

- You configure realms outside of your identity policy, at **Integration** > **Other Integrations** > **Realms** > **Realms**. For more information, see Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.
- You configure ISE/ISE-PIC, a passive authentication identity source, at **Integration** > **Other Integrations** > **Identity Sources**.
- You configure the TS Agent, a passive authentication identity source, outside the system. For more information, see the *Cisco Terminal Services (TS) Agent Guide*.
- You configure captive portal, an active authentication identity source, within the identity policy. For more information, see Configure the captive portal for user control, on page 1891.
- You configure Remote Access VPN, an active authentication identity source, in Remote Access VPN policies. For more information, see Configure AAA settings for a remote access VPN policy.

After you add multiple identity rules to a single identity policy, order the rules. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles the traffic.

You can also filter traffic by network object, which limits the network each device monitors in the event your devices are at or near their memory limits.

After you configure one or more identity policies, you must associate one identity policy with your access control policy. When traffic on your network matches the conditions in your identity rule, the system associates the traffic with the specified realm and authenticates the users in the traffic using the specified identity source.

If you do not configure an identity policy, the system does not perform user authentication.

Exception to creating an identity policy

An identity policy is not required if all these conditions are true:

- You use the ISE/ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies.

Create an identity policy

Create an identity policy to control user and group access in a realm for access control policies.

This task discusses how to create an identity policy.

Before you begin

An identity policy is required to use users and groups in a realm in access control policies. Create and enable one or more realms as described in Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.

(Optional.) If a particular managed device monitors a large number of user groups, the system might drop user mappings based on groups due to managed device memory limitations. As a result, rules with realm or user conditions might not perform as expected. Provided the devices run version 6.7 or later, you can configure the identity rule to monitor traffic by one network or network group object only. To create a network object, see Create a network object, on page 2388.

An identity policy is not required if all these conditions are true:

- You use the ISE/ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity** and click **New Policy**.

Step 3 Enter a **Name** and, optionally, a **Description**.

Step 4 Click **Save**.

Step 5 To add a rule to the policy, click **Add Rule** as described in Create an identity rule, on page 1952.

Step 6 To create a rule category, click **Add Category**.

Step 7 To configure captive portal active authentication, click **Active Authentication** and see Create an identity policy and active authentication rule, on page 1894.

Step 8 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 9 Click **Save** to save the identity policy.

What to do next

- Add rules to your identity policy that specify which users to match and other options; see Create an identity rule, on page 1952.
- Associate the identity policy with an access control policy to allow or block selected users from accessing specified resources; see Associate prefilter, decryption, and identity policies with an access control, on page 1585.
- (Not required for Microsoft Azure AD realms.) Deploy configuration changes to managed devices; see Deploy configuration changes, on page 135.

If you encounter issues, see Troubleshoot user control, on page 1962.

Related Topics

Create an identity policy and active authentication rule, on page 1894
Captive portal fields, on page 1903
Troubleshoot user control, on page 1962
Create an identity mapping filter, on page 1944

Create an identity mapping filter

An identity mapping filter can be used to limit the networks to which an identity rule applies. For example, if your Firewall Management Center manages FTDs that have a limited amount of memory, you can limit the networks they monitor.

You must create separate identity mapping filters for IPv4 and IPv6 addresses.

You can also optionally exclude subnets from the following:

- Receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE.

You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.

Before you begin

Perform the following tasks:

1. Create a realm, which is required for an identity policy. See Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.
2. Create an identity policy. See Create an identity policy, on page 1943.
3. Create a network object or network group object as discussed in Create a network object, on page 2388. The network object or group you create should define the network you want managed devices to monitor in identity policies.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Click **Edit** ( ).

Step 4 Click the **Identity Source** tab.

Step 5 From the **Identity Mapping Filter** list, choose the name of a network object to use as a filter .

To create a new network object, see Create a network object, on page 2388.

Note To restrict traffic to IPv6 addresses, you must add at least one address, network, or group to the filter.

Step 6 Click **Save**.

Step 7 (Not required for Microsoft Azure AD realms.) Deploy configuration changes to managed devices; see Deploy configuration changes, on page 135.

What to do next

(Not required for Microsoft Azure AD realms.) Associate the identity policy with an access control policy as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.

To check or change ISE identity mapping filters (also referred to as *subnet filters*), use these commands:

```
show identity-subnet-filter
configure identity-subnet-filter { add | remove } subnet
```

Identity rule conditions

Identity rule conditions enable you to fine-tune your identity policy to target specific users and networks you want to control. See one of the following topics for more information.

Related Topics

Security zone rule conditions, on page 1759

VLAN tag rule conditions, on page 1635
Best practice: use application-based rules over port-based rules, on page 1323
Realm & settings rule conditions, on page 1949

Security zone rule conditions

A security zone rule condition is a network traffic control mechanism that

- segments your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices,
- controls or decrypts traffic by its source and destination security zones, and
- requires all interfaces in a zone to be of the same type (all inline, passive, switched, or routed).

Zone condition traffic matching

If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

All zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

Security zone conditions in multidomain environments

In a multidomain deployment, a zone created in an ancestor domain can contain interfaces that reside on devices in different domains. When you configure a zone condition in an descendant domain, your configurations apply to only the interfaces you can see.

Network rule conditions

A network condition is a traffic matching criterion that

- controls or decrypts traffic based on source and destination IP addresses using inner packet headers,
- enables administrators to specify exact IP addresses or blocks for granular policy enforcement, and
- can be built using predefined network objects or by manually entering IP addresses or address blocks.

Network rule condition restrictions

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

Redirect to host name network rule conditions

(Snort 3.0 only)—You can use a network object that contains the fully-qualified host name (FQDN) of the interface that captive portal can use for active authentication requests.

The FQDN must resolve to the IP address of one of the interfaces on a managed device. By using an FQDN, you can assign a certificate for active authentication that the client will recognize, thus avoiding the untrusted certificate warning users get when being redirected to a managed device's IP address.

Certificate and redirection behavior

The certificate can specify one FQDN, a wildcard FQDN, or multiple FQDNs in the Subject Alternate Names (SAN) in the certificate.

If an identity rule requires active authentication for a user, but you do not specify a redirect FQDN, the user is redirected to the captive portal port on the managed device interface to which they are connected.

If you do not supply a Redirect to Host Name FQDN, the HTTP Basic, HTTP Response Page, and NTLM authentication methods redirect the user to the captive portal using the IP address of the interface. However, for HTTP Negotiate, the user is redirected using the fully-qualified DNS name *firewall-hostname.directory-server-domain-name*. If you use HTTP Negotiate without a Redirect to Host Name FQDN, update your DNS server to map this name to the IP addresses of all inside interfaces that require active authentication. If you do not update the DNS server, the redirection does not complete and users cannot authenticate.

We recommend that you always provide a Redirect to Host Name FQDN to ensure consistent behavior regardless of authentication method.

VLAN tag rule conditions

VLAN tags rule conditions are filtering mechanisms that

- control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic
- use the innermost VLAN tag to filter VLAN traffic, with the exception of prefilter policy which uses the outermost VLAN tag, and
- apply only to inline sets and do not match traffic on firewall interfaces.

VLAN tag rule conditions configuration details

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

Best practice: use application-based rules over port-based rules

Use application filtering criteria instead of port filtering to target traffic. Applications can be configured to use unique ports to bypass access control blocks.

Port conditions allow you to control traffic by its source and destination ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

The traditional method targets applications by using port specifications, but applications can manipulate unique ports to bypass these controls

Application filtering is recommended for applications to avoid blocking legitimate applications, like Firewall Threat Defense, that dynamically open separate channels for control and data flow. Port-based access control rules could block such applications, impacting desirable operations.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP).

- For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).
- If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

Port, protocol, and ICMP code rule conditions (concept)

A port, protocol, and ICMP code rule condition is a traffic matching criterion that

- matches traffic based on source and destination ports
- supports TCP, UDP, ICMP, and other protocols that do not use ports, and
- controls traffic flow in access control and other policy rules.

Port condition types

Port conditions match traffic based on the source and destination ports. Depending on the rule type, "port" can represent any of these types:

- TCP and UDP—Control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP (6) /22.
- ICMP—Control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.

- Protocol—Control traffic using other protocols that do not use ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best practices for port-based rules

Specifying ports is the traditional method used to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Use application filtering criteria when possible; however, note that application filtering is unavailable in prefilter rules.

Use application filtering for FTP and similar applications that open separate channels for control and data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly and could result in blocking desirable connections.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching non-TCP traffic with port conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although configuring port conditions can match non-TCP traffic, restrictions apply:

- Access control rules—For Classic devices, match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, add only network-based conditions: zone, IP address, port, and VLAN tag. The system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For Firewall Threat Defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support only TCP port conditions.
- IMCP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies, sent in response to ICMP echo requests, are ignored. To match any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

Realm & settings rule conditions

The **Realm & Settings** tab page enables you to choose a realm or realm sequence to which to apply the identity rule. If you are using captive portal, you have additional options.

Authentication realm

From the **Realm** list, click a realm or realm sequence.

The realm or realm sequence containing the users you want to perform the specified **Action** on. You must fully configure a realm or realm sequence before selecting it as the realm in an identity rule.

Note If remote access VPN is enabled and your deployment is using a RADIUS server group for VPN authentication, make sure you specify the realm associated with this RADIUS server group.

Active authentication only: other options

If you either choose **Active Authentication** as the authentication type or if you check the box, **Use active authentication if passive or VPN identity cannot be established**, you have these options.

Use active authentication if passive or VPN identity cannot be established

(Passive authentication rule only.) Selecting this option authenticates users using captive portal active authentication if a passive or a VPN authentication fails to identify them. You must configure an Active Authentication rule in your identity policy in order to select this option. (That is, users must authenticate using the captive portal.)

If you disable this option, users that do not have a VPN identity or that passive authentication cannot identify are identified as Unknown.

Also see the discussion of the **Authentication Realm** list later in this topic,

Identify as Special Identities/Guest if authentication cannot identify user

Selecting this option allows users who fail captive portal active authentication the specified number of times to access your network as a guest. These users appear in the Firewall Management Center identified by their username (if their username exists on the AD or LDAP server) or by **Guest** (if their user name is unknown). Their realm is the realm specified in the identity rule. (By default, the number of failed logins is 3.)

This field is displayed only if you configure **Active Authentication** (that is, captive portal authentication) as the rule **Action**.

Authentication Protocol

The method to use to perform captive portal active authentication. An example of what users see when logging in with a response page is shown in Create a sample identity policy with an active authentication rule, on page 1956.

The selections vary depending on the type of realm, LDAP or AD:

- Choose **HTTP Basic** if you want to authenticate users using an unencrypted HTTP Basic Authentication (BA) connection. Users log in to the network using their browser's default authentication pop-up window.

  Most web browsers cache the credentials from **HTTP Basic** logins and use the credentials to seamlessly begin a new session after an old session times out.

- Choose **NTLM** to authenticate users using a NT LAN Manager (NTLM) connection. This selection is available only when you select an AD realm. If transparent authentication is configured in a user's browser, the user is automatically logged in. If transparent authentication is not configured, users log in to the network using their browser's default authentication pop-up window.

- Choose **Kerberos** to authenticate users using a Kerberos connection. This selection is available only when you select an AD realm for a server with secure LDAP (LDAPS) enabled. If transparent authentication is configured in a user's browser, the user is automatically logged in. If transparent

authentication is not configured, users log in to the network using their browser's default authentication pop-up window.

Note The **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

Note If you are creating an identity rule to perform Kerberos captive portal and you have DNS resolution configured, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN must match the host name you provided when configuring DNS.

For Firewall Threat Defense devices, the FQDN must resolve to the IP address of the routed interface used for captive portal.

- Choose **HTTP Negotiate** to allow the captive portal server to choose between HTTP Basic, Kerberos, or NTLM for the authentication connection. This type is available only when you select an AD realm.

Note The **Realm** you choose must be configured with an **AD Join Username** and **AD Join Password** for **HTTP Negotiate** to choose Kerberos captive portal active authentication.

Note If you are creating an identity rule to perform **HTTP Negotiate** captive portal and you have DNS resolution configured, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN of the device you are using for captive portal must match the hostname you provided when configuring DNS.

- Choose **HTTP Response Page** to enable users to choose a realm to log in to.

  You can optionally customize the response page; for example, to conform to company style standards.

Active Authentication Realm

(Passive authentication rule only.) If you clicked **Use active authentication if passive or VPN identity cannot be established**, you must click the name of a realm or realm sequence. The availability of a realm or realm sequence is determined by your choice for Authentication Protocol as follows:

- **HTTP Basic** or **HTTP Response Page** authentication protocol: You can choose either a realm or a realm sequence.
- **NTLM**, **Kerberos**, or **HTTP Negotiate** authentication protocol: You can choose a realm only. You *cannot* choose a realm sequence.

Create an identity rule

Identity rules enable you to control user authentication and traffic handling by specifying which identity realm should authenticate users for specific network criteria.

For details about configuration options for identity rules, see Identity rule fields, on page 1953.

Before you begin

You must create and enable a realm or realm sequence.

- Create a Microsoft Active Directory realm and realm directory as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 1860.
- (Microsoft AD realm only.) Download users and groups and enable the realm as discussed in Synchronize users and groups, on page 1865.
- (Optional.) Create a realm sequence as discussed in Create a realm sequence, on page 1867.
- Rules are evaluated top-down. For a connection that matches the specified network criteria of a given rule, the user is evaluated against the identity realm specified in the rule. If the user is not part of that realm, they will be marked as unknown, and no further rules in the identity policy will be evaluated. Thus, if you have more than one realm that needs to be evaluated, be sure to use realm sequences instead of a single realm.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Click **Edit** ( ) next to the identity policy to which to add the identity rule.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Click **Add Rule**.

a) Enter a **Name**.

b) If the Specified rule is applicable, check the check box of **Enabled**.

c)

d) To add the rule to an existing category, indicate where you want to **Insert** the rule. To add a new category, click **Add Category**.
e) Choose a rule **Action** from the list.
f) If you're configuring captive portal, see Configure the captive portal for user control, on page 1891.
g) (Optional) To add conditions to the identity rule, see Identity rule conditions, on page 1945.
h) Click **Add**.

Step 5 In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 135.

Identity rule fields

Configure identity rules to specify authentication actions for users, including Passive Authentication, Active Authentication, or No Authentication. Learn how VPN identity preference affects authentication and rule processing in remote access scenarios.

Use these fields to configure identity rules.

Enabled

Enabling this option enables the identity rule in the identity policy. Unselecting this option disables the identity rule.

Action

Specify the type of authentication you want to perform on the users in the specified realm: **Passive Authentication** (default), **Active Authentication**, or **No Authentication**. You must fully configure the authentication method, or *identity source*, before selecting it as the action in an identity rule.

Additionally, if VPN is enabled (configured on at least one managed device), remote access VPN sessions are actively authenticated by VPN. Other sessions use the rule action. This means that, if VPN is enabled, VPN identity determination is performed first for all sessions regardless of the selected action. If a VPN identity is found on the specified realm, this is the identity source used. No additional captive portal active authentication is done, even if selected.

If the VPN identity source is not found, the process continues according to the specified action. You cannot restrict the identity policy to VPN authentication only because if the VPN identity is not found, the rule is applied according to the selected action.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include an SSL policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 129.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

For information about which passive and active authentication methods are supported in your version of the system, see About user identity sources, on page 1820.

Sample identity policies and rules

These sections provide examples of configuring an identity policy with either a passive authentication rule or an active authentication rule. In addition, because you can authenticate users with active authentication using either realms or realm sequences, separate examples are provided.

Authentication types

Active authentication means the user authenticates using the captive portal; the user enters network credentials before being allowed to access allowed resources. (RA-VPN is another type of active authentication but it cannot be used together with captive portal authentication. For more information, see Remote access VPN identity sources, on page 1931.)

Passive authentication covers all other types. Passive authentication includes using Microsoft Active Directory realms, Microsoft Azure Active Directory realms, Cisco Identity Services Engine, and others.

These examples use these assumptions:

- Microsoft Active Directory (AD) realm named forest.example.com with two child domains configured in a trust relationship:
  - US-West
  - US-East
- A realm sequence named US that includes both realms
- Passive authentication rule that authenticates users with a realm sequence
- Two active authentication rules:
  - One rule that authenticates users with a realm and uses the NTLM authentication protocol
  - One rule that authenticates users with a realm sequence and uses the HTTP Response Page authentication protocol
- Each sample identity rule is associated with a different identity policy

When you configure a Passive Authentication identity rule, you can choose to authenticate users either with LDAP, a Microsoft Active Directory realm, or a Microsoft AD realm sequence. You can use a realm to authenticate with any authentication type; realm sequence restricts the authentication types you can use. For an example, see Create an identity policy with a passive authentication rule, on page 1955.

When you configure an Active Authentication identity rule, you can choose to authenticate users either with LDAP, a Microsoft Active Directory realm, or a Microsoft AD realm sequence. You can use a realm to authenticate with any authentication type; realm sequence restricts the authentication types you can use.

You can also authenticate users with a Microsoft Active Directory realm sequence except for these authentication types:

- NTLM
- Kerberos
- HTTP Negotiate

For an example, see Create a sample identity policy with an active authentication rule, on page 1956.

Create an identity policy with a passive authentication rule

Create an identity policy that authenticates users using passive authentication with realm sequences for user identification.

This task discusses how to create an identity policy with a passive authentication rule that authenticates users using the US realm sequence. If a user is not found in the first realm in the sequence, the system searches the other realms in the sequence in the order listed in the realm sequence. If a user is still not found in the realm or realm sequence, the user is identified as Unknown.

You can optionally authenticate a user with the captive portal (that is, active authentication) if the user is not found in any realm in the sequence. For more information, see Best practices for captive portal guidelines and limitations, on page 1889.

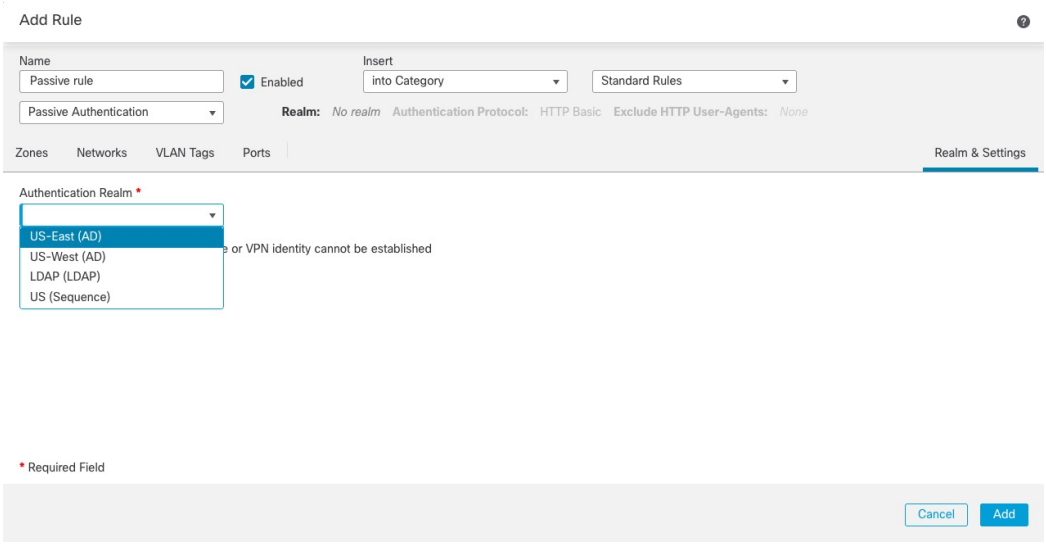
Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Click **New Policy**.

a) Enter a **Name** for the policy and an optional **Description**.
b) Click **Save**.



Step 4 Click **Add Rule**.

a) Enter a **Name** for the rule.
b) From the list, click **Passive Authentication**.

Step 5 Click the **Realms & Settings** tab page.

a) From the list, click the name of a realm or realm sequence.

The following figure shows an example.

- If you choose a realm (such as **US-East** in the example), the system searches that realm for users to match the rule. If a user is not found, the user is identified as Unknown.
- If you choose a realm sequence (**US (Sequence)** in the example), users are searched in every realm in the sequence in the order specified in the sequence. If the user is not found, the user is identified as Unknown.
- You can also choose an LDAP realm.
- For additional ways to authenticate the user, check **Use active authentication if passive or VPN identity cannot be established**. For more information, see Best practices for captive portal guidelines and limitations, on page 1889.

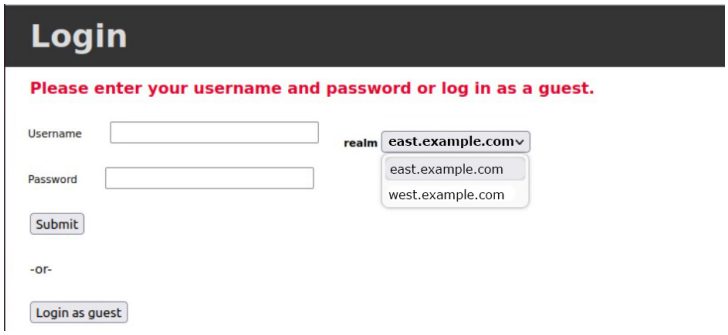
Step 6 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 7 Set identity rule conditions as discussed in Identity rule conditions, on page 1945.

Step 8 Associate the identity rule with an access control rule as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.

Step 9 Deploy configuration changes to managed devices; see Deploy configuration changes, on page 135.

Create a sample identity policy with an active authentication rule



This task shows you how to configure an identity policy with an Active Authentication rule where authentication is performed using either a realm or a realm sequence. This enables secure network access management through customizable captive portal settings.

The associated tasks show an examples of configuring an identity policy with an **Active Authentication** rule where authentication is performed using either a realm or a realm sequence.

The differences follow:

- *Realm* enables you to use any supported authentication type (currently, **HTTP Basic**, **NTLM**, **Kerberos**, **HTTP Negotiate**, or **HTTP Response Page**).
- *Realm sequence* limits you to only the **HTTP Basic** or **HTTP Response Page** authentication types.

  Users who authenticate with a realm sequence and the HTTP Response Page authentication type see the following by default:

  The user can authenticate in any of the following ways:

  - If a list of realms in the realm sequence is displayed (as shown), the user must enter their user name and password in the provided fields and click the name of their realm from the list.
  - If realms are not displayed in a list, the user can enter their credentials in `username@domain` format.

  Users who authenticate with a realm and the HTTP Basic authentication page see the following:

  The user must enter their user name in `username@domain` format.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Click **New Policy**.

a) Enter a **Name** for the policy and an optional **Description**.

b) Click **Save**.

Step 4 Click the **Active Authentication** tab.

Enter the following information:

- **Server Certificate**: From the list, click an internal certificate object to use for secure connection to the Firewall Threat Defense device, or click **Add** (+) to add one.
- **Redirect to Host Name**: (Optional.) From the list, click a network object to which to redirect captive portal requests. If you omit this value, requests redirect to the IP address of the managed device. You can click **Add** (+) to create a new network object. For more information, see Redirect to host name network rule conditions, on page 1946.

  Managed devices must have Snort 3 enabled to use this option.
- **Port**: Enter a port for the captive portal to use. This port must be unique for the captive portal and must match an access control rule you set up as discussed in Create a TCP port access control rule, on page 1896. (Default is 885.)
- **Maximum login attempts**: Enter the maximum number of login attempts before login fails. (Default is 3.)
- **Share active authentication sessions across firewalls**: Uncheck to enable the Firewall Management Center to force users to reauthenticate every time they access your network using a different managed device than the last time.

  For more information about this option, see Captive portal fields, on page 1903.
- **Active Authentication Response Page**: Choose a system-provided or custom login page for captive portal users. For more information about your options, see Captive portal fields, on page 1903.

Step 5 Click **Save** to save your changes to the identity policy.

Step 6 Click the **Rules** tab.

Step 7 Click **Add Rule**.

a) Enter a **Name** for the rule.
b) From the list, click **Active Authentication**.

Step 8 Click the **Realms & Settings** tab page. Then configure an active authentication method for the users.

What to do next

Continue with one of the following sections:

- Active authentication using a realm, on page 1958
- Active authentication using a realm sequence, on page 1959

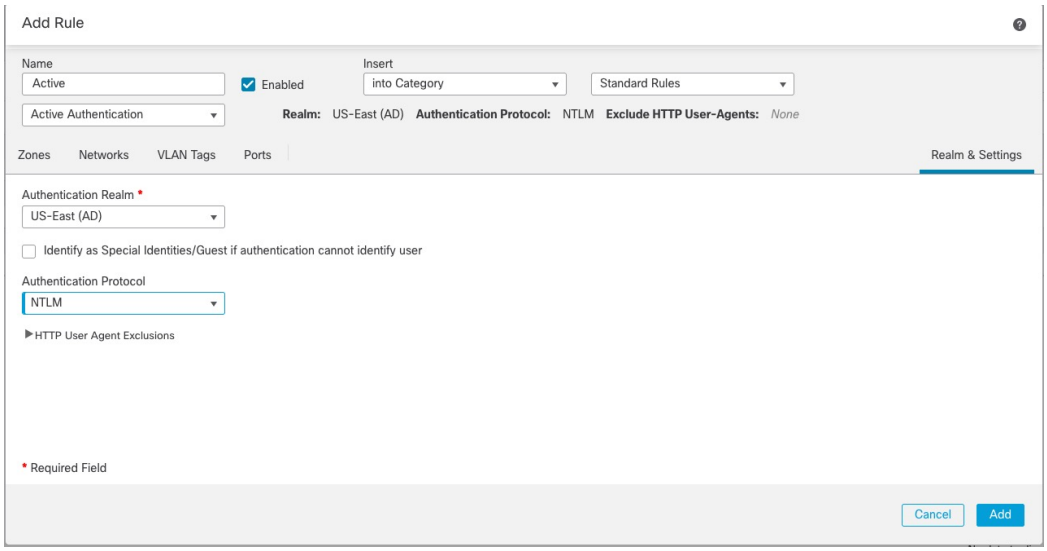
Active authentication using a realm

This task authenticates captive portal users with a realm and any available authentication protocol (currently, **HTTP Basic**, **NTLM**, **Kerberos**, **HTTP Negotiate**, or **HTTP Response Page**).

Active authentication using a realm provides secure user verification for captive portal access by integrating with your organization's authentication infrastructure.

Before you begin

Complete the task discussed in Create a sample identity policy with an active authentication rule, on page 1956.



Procedure

Step 1 Continue from Create a sample identity policy with an active authentication rule, on page 1956.

Step 2 On the **Realms & Settings** tab page, click **US-East**.

Step 3 From the **Authentication Protocol** list, click **NTLM**.

The following figure shows an example.

If you choose a realm (such as in the example), the system searches that realm for users to match the rule. If a user is not found, the user is identified as Unknown.

Step 4 Click **Add**.

Step 5 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 6 Set identity rule conditions as discussed in Identity rule conditions, on page 1945.

Step 7 Associate the identity rule with an access control rule as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.

Step 8 Deploy configuration changes to managed devices; see Deploy configuration changes, on page 135.

Active authentication using a realm sequence

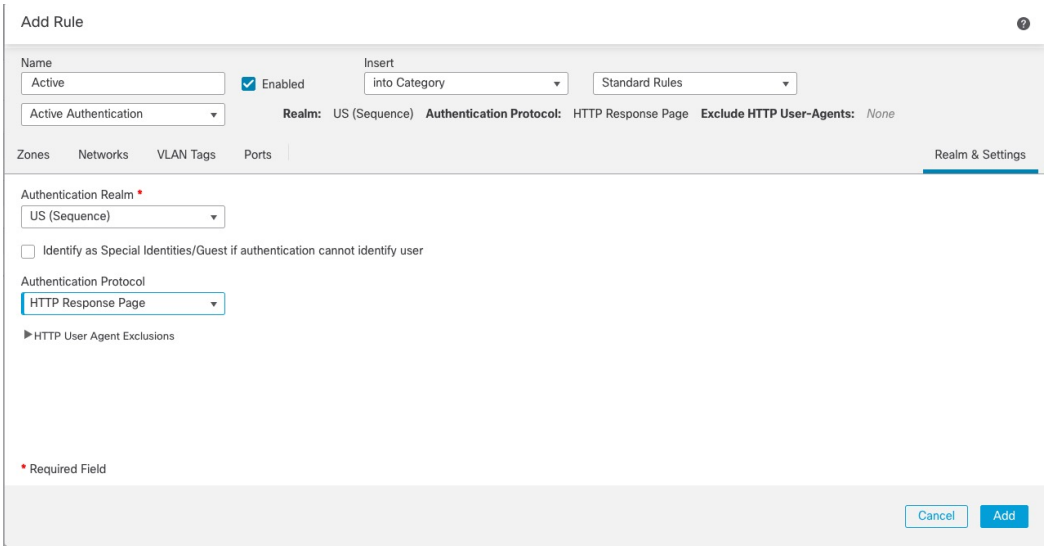
This task enables authentication of captive portal users using a realm sequence, allowing you to control access through HTTP Basic or HTTP Response Page protocols. It helps you select realms, set identity rule conditions, and associate them with access control rules to filter network traffic and manage user identification.

This task discusses how to authenticate captive portal users with a realm sequence, which restricts you to the **HTTP Basic** or **HTTP Response Page** authentication protocols.

Before you begin

Complete the task discussed in Create a sample identity policy with an active authentication rule, on page 1956.

Procedure



Step 1 Continue from Create a sample identity policy with an active authentication rule, on page 1956.

Step 2 On the **Realms & Settings** tab page, click the name of a realm from the list.

Step 3 From the list, click **US-East**.

Step 4 From the **Protocol** list, click **HTTP Response Page**.

The following figure shows an example.

If you choose a realm sequence (such as in the example), the system searches realms in the sequence in the order specified in the realm sequence. The first realm in the sequence can be referred to as the *default* realm; it's the realm that is used if the user does not change it. If a user is not found, the user is identified as Unknown.

(Only if you upgraded to version 7.4.1 from an earlier version.) Edit the HTTP response page so it shows the list of realms in the sequence as discussed in Update a custom authentication form, on page 1896.

Step 5 Click **Add**.

Step 6 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 7 Set identity rule conditions as discussed in Identity rule conditions, on page 1945.

Step 8 Associate the identity rule with an access control rule as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 1585.

Step 9 Deploy configuration changes to managed devices; see Deploy configuration changes, on page 135.

Manage an identity policy

This task allows you to manage identity policies by performing various administrative actions including editing, deleting, copying, generating reports, and organizing policies into categories for optimized security policy administration.

Identity policies control access to network resources based on user identity. Managing these policies effectively ensures proper security enforcement and administrative organization within the Secure Firewall Management Center.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 To delete a policy, click **Delete** ( ). If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 To edit a policy, click **Edit** ( ) next to the policy and make changes as described in Create an identity policy, on page 1943. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 5 To copy a policy, click **Copy** ( ).

Step 6 To generate a report for the policy, click **Report** ( ) as described in Generate current policy reports, on page 153.

Step 7 To compare policies, see Compare policies, on page 152.

Step 8 To create a folder in which to organize policies, click **Add Category**.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 135.

Manage an identity rule

This task allows you to edit, delete, or organize identity rules in access control policies to manage user access and security within the Secure Firewall Management Center.

Use this procedure to modify existing identity rules, remove unnecessary rules, or organize rules using categories to maintain effective security policies.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Click **Edit** ( ) next to the policy you want to edit. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 To edit an identity rule, click **Edit** ( ) and make changes as described in Create an identity policy, on page 1943.
