Configure minidump collection on your access point. This lets you capture kernel coredump information for troubleshooting and diagnostics.

Before you begin

- Ensure that no clients are connected to the AP.
- Keep your AP in standalone mode. This prevents it from receiving conflicting payloads from the controller.
- Any configuration pushed from the controller overrides the value you set on your AP.

Procedure

Enable kernel coredump collection on the AP.

Example

```
Device# configure boot minidump enable
```

After you enable kernel coredump collection, the AP stores critical kernel dump data for further analysis.

Configure the minidump from the controller (CLI)

Learn how to configure the Minidump feature from the controller using the CLI, including setting limits and types for kernel core dumps on an AP profile.

Enable and customize collection of kernel core dumps (minidump) for access points to support troubleshooting and diagnostics.

Use this procedure when you need to collect kernel core dumps from access points to assist with root cause analysis of device crashes or unexpected reboots. Configuring the minidump feature allows you to control the number and type of core dumps stored for each AP.

Procedure

1. Enters global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

3. Configure the maximum number of kernel core dumps to be collected on an AP.

   Example

   ```
   Device(config-ap-profile)# core-dump kernel limit limit
   ```

   Valid range is from 0 to 5.

4. Configure the maximum number of directories for AP minidump collection.

   Example

   ```
   Device(config-ap-profile)# core-dump kernel dir-limit dir-limit
   ```

   The valid range is from 15 to 25.

5. Configure the type of kernel core dump to be collected on the AP.

   Example

   ```
   Device(config-ap-profile)# core-dump kernel type mini-dump
   ```

Use the **core-dump kernel type disable** command to disable kernel core dump.

> **Note**
>
> Changing the core dump type from disabled to full-dump or mini-dump or vice versa will cause the APs to reboot.
>
> When you enable the full-dump option, the kernel minidump feature gets deactivated.

6. Return to global configuration mode.

Example

```
Device(config-ap-profile)# end
```

The AP profile is configured to collect kernel minidumps according to the specified limits and type. AP using this profile will store core dumps as configured.

Verify minidump configuration

To view the mini-dump configuration on the controller, use this command:

```
Device# show ap name AP3C57.31C5.99D0 config general  | sec Kernel core dump

Kernel core dump :
  Configured limit                              : 3
  Kernel core dumps collected on AP             : 1
  Kernel core dump type                         : Mini dump
```

To view the mini-dump configuration on the AP, use this command:

```
AP# show boot

--- Boot Variable Table ---
BOOT path-list:      part1
Console Baudrate:    115200
Enable Break:        yes
Manual Boot:         yes
Memory Debug:        no
Crashkernel:         no
Minidump:            yes # Indicates Minidump is enabled.
SCRUB_LIMIT:         40 (default)
Kdump Limit:         5 # Configured limit. (this came from WLC via payload)
Kdump Collected:     0 # Number of times the feature ran after it was enabled.
Debug init:          0
```

Part IX

Cloud Services

Topics:

- Cisco Spaces
- Sensor Connect backup and restore
- AP and Sensor Connect support for full filtering
- Using Cloud Monitoring as a Solution for Network Monitoring
- Wireless Active Testing with ThousandEyes
- Wireless Active Testing SCEP support

112 Cisco Spaces

Topics:

- Cisco Spaces

Cisco Spaces

Introduces Cisco CMX Cloud, covering location analytics features, deployment scenarios, and configuration steps for wireless networks, including integration best practices and supported APIs.

A Cisco Connected Mobile Experience (CMX) deployment is a cloud-based indoor location services platform that

- provides real-time location analytics and engagement capabilities for indoor environments
- enables integration with Cisco wireless controllers through secure protocols such as HTTPS, and
- supports scalable, cloud-delivered access to location-based services.

The Network Mobility Services Protocol (NMSP) cloud-service of the wireless controller communicates with Cisco Spaces using HTTPS as a transport protocol.

Configure Cisco Spaces

Configure Cisco Spaces using commands.

Ensure successful operation of NMSP cloud-services by configuring DNS, importing root CAs, and registering to Cisco Spaces.

To configure, Cisco Spaces, perform these procedures. These steps enable the controller to communicate securely with cloud services and Cisco Spaces.

Before you begin

- *Configure DNS*: To resolve fully qualified domain names used by NMSP cloud-services, configure a *DNS* server using the **ip name-server** *server_address* configuration command as shown in Step 2.
- *Import 3rd party root CAs*: The controller verifies the peer and host based on the certificate sent by the CMX when a connection is established. Root CA certificates are not preinstalled on the controller. Import a set of root CAs trusted by Cisco to the trustpool of the crypto PKI using the **crypto pki trustpool import url** <**url**> configuration command as shown in Step 3.
- Successful registration to Cisco Spaces is required before configuring the **server url** and **server token** parameters to complete setup.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the DNS on the controller to resolve the FQDN names used by the NMSP cloud-services.

   Example

   ```
   Device(config)# ip name-server 10.10.10.205
   ```

3. Import the 3rd party root CA.

Example

```
Device(config)# crypto pki trustpool import url
http://www.cisco.com/security/pki/trs/ios.p7b
```

The controller verifies the peer using the imported certificate.

4. Configure the URL used for cloud services.

Example

```
Device(config)# nmsp cloud-services server url https://cisco.com
```

Use the *no* form of the command to delete the server url from the configuration.

5. Configure the authentication token for the NMSP cloud service.

Example

```
Device(config)# nmsp cloud-services server token test
```

Use the *no* form of the command to delete the server token from the configuration.

6. Optional: Configure HTTP proxy details for the NMSP cloud service.

Example

```
Device(config)# nmsp cloud-services http-proxy 10.0.0.1 port 10
```

Use the *no* form of the command to disable the use of a HTTP proxy.

7. Enable NMSP cloud services.

Example

```
Device(config)# nmsp cloud-services enable
```

Use the *no* form of the command to disable the feature.

Verify Cisco Spaces configuration

Verify Cisco Spaces configuration.

Use the commands to verify the Cisco Spaces configuration.

To view the status of active NMSP connections, use the command:

```
Device# show nmsp status

MSE IP Address   Tx Echo Resp  Rx Echo Req   Tx Data     Rx Data   Transport

------------------------------------------------------------------------------
192.0.2.1        0             0             1           1         TLS
198.51.100.1    0             0            1230        2391      HTTPs
```

To view the NMSP cloud service status, use the command:

```
Device# show nmsp cloud-services summary

CMX Cloud-Services Status
-------------------------
Server:                                 https://yenth8.cmxcisco.com
IP Address:                             198.51.100.1
Cmx Service:                            Enabled
Connectivity:                           https: UP
Service Status:                         Active
Last Request Status:                    HTTP/1.1 200 OK
Heartbeat Status:                       OK
```

To view the NMSP cloud service statistics, use the command:

```
Device# show nmsp cloud-services statistics

CMX Cloud-Services Statistics
-----------------------------
Tx DataFrames:                           3213
Rx DataFrames:                           1606
Tx HeartBeat Req:                       31785
Heartbeat Timeout:                          0
Rx Subscr Req:                           2868
Tx DataBytes:                           10069
Rx DataBytes:                           37752
Tx HeartBeat Fail:                          2
Tx Data Fail:                               0
Tx Conn Fail:                               0
```

To view the mobility services summary, use the command:

```
Device# show nmsp subscription summary

Mobility Services Subscribed:
Index Server IP Services

2 209.165.200.224 RSSI, Statistics, AP Info
```

113 Sensor Connect backup and restore

Topics:

- Sensor Connect backup and restore

This chapter explains Sensor Connect backup and restore.

Sensor Connect backup and restore

Explains how Sensor Connect backup and restore mechanisms safeguard application and configuration data that controller configuration backups alone do not cover.

A Sensor Connect backup and restore is an application recovery mechanism that

- creates a separate backup of the Sensor Connect application database starting from the Sensor Connect 1.2.2 release
- restores the Sensor Connect configuration and operational data that the controller configuration backup does not include, and
- returns a freshly deployed Sensor Connect application to its saved Day-N state.

The Cisco Catalyst 9800 Wireless Controller configuration backup preserves controller settings, such as VLAN and subnet configurations. It does not preserve the Sensor Connect application database, which contains information such as AP and endpoint configurations, application credentials, and controller registration data. To recover a deployment completely, create separate backups of the controller configuration and the Sensor Connect application.

You can use Sensor Connect backup and restore when you replace a controller or redeploy the Sensor Connect application.

During a restore operation, the controller

- stops the running Sensor Connect application
- restores the application database from the backup file
- restarts the application, and
- returns the application to the **Running** state.

Feature history for Sensor Connect backup and restore

This section explains the feature history details of the Sensor Connect backup and restore feature.

- This table provides release and related information for the feature explained in this module.
- This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 107: Feature history for Sensor Connect backup and restore

Feature Name	Release Information	Feature Description
Sensor Connect backup and restore	Cisco IOS XE 26.2.1	Sensor Connect backup and restore is an application recovery mechanism that separately backs up the Sensor Connect application database and restores configuration and operational data not included in the controller configuration backup. It enables a newly deployed Sensor Connect application to return to its saved Day-N state after controller replacement or application redeployment.

Guidelines for Sensor Connect backup and restore

Outlines the essential best practices to follow when backing up or restoring Sensor Connect.

Follow these guidelines when you back up or restore Sensor Connect:

- Create a Sensor Connect application backup in addition to the controller configuration backup.
- For controller replacement, restore the controller configuration and deploy Sensor Connect before you restore the Sensor Connect application backup.
- Ensure that the Sensor Connect application is in the **Running** state before you start a restore operation.
- Allow sufficient time for a backup or restore operation to complete. The operation duration depends on the deployment scale and the resulting backup-file size.

Restrictions for Sensor Connect backup and restore

Outlines the essential restrictions to follow when backing up or restoring Sensor Connect.

Sensor Connect backup and restore has these restrictions:

- Restore is supported only when the destination controller runs the same Sensor Connect application version that was running when you created the backup.
- Cross-platform restore is not supported. Restore the backup only on the same controller platform type on which you created it because controller platforms support different application scales.

Backup the Sensor Connect application

Configure and save a backup artifact of the Sensor Connect application database using HTTP or SFTP methods.

Create a backup artifact of the Sensor Connect application database by downloading the file to your local system through HTTP or storing the file on an SFTP server.

Perform this task from the controller. A successful backup does not stop the Sensor Connect application; the application remains in the **Running** state.

Procedure

1. Log in to the controller and choose **Configuration** > **Services** > **IoT Services**.
2. From the More Actions menu, choose **Backup**.
   The **Backup** panel opens.
3. From the **Transfer Mode** drop-down list, choose a transfer method:
   - **HTTP**: Choose this method to download the generated `.tar.gz` backup file to your local system.
   - **SFTP**: Choose this method and enter the **Server IP Address**, **File Path**, **File Name**, **Server Login Username**, and **Server Login Password** to store the backup on an SFTP server.
4. Click **Backup**.
   The controller displays the backup progress. For **HTTP**, the controller downloads the generated backup file to your local system. For **SFTP**, the controller writes the backup file to the specified server path.

   Ensure `tar.gz` is sucessfully downloaded in your local system or in the specified **SFTP** server path.
5. Confirm that the controller reports a successful backup and displays the last-completed backup timestamp.

The Sensor Connect backup artifact is available at the selected destination, and the application remains in the **Running** state.

Restore the Sensor Connect application

Restore the Sensor Connect application database from a backup file using the controller.

Recover the Sensor Connect application to a previous state by restoring its database from a backup file.

Perform this task after controller configuration is restored and Sensor Connect is redeployed. The restore workflow stops the running application, applies the backup database, and restarts the application.

Before you begin

- Ensure the destination controller is the same platform type as the one used for the backup.
- Deploy the same Sensor Connect application version that was running when you created the backup.
- Verify the Sensor Connect deployment is successful, with the application status as **Running**.
- Make the Sensor Connect `.tar.gz` backup file available on your local system or an SFTP server.

Procedure

1. Log in to the controller and choose **Configuration** > **Services** > **IoT Services**.
2. From the **More Actions** menu, choose **Restore**.
   The Restore panel opens.
3. From the **Transfer Mode** drop-down list, choose a transfer method:
   - **HTTP**: Choose this method and select the Sensor Connect backup file from your local system.
   - **SFTP**: Choose this method and enter the **Server IP Address**, **File Path**, **File Name**, **Server Login Username**, and **Server Login Password**.
4. Click **Restore**.
5. When the controller requests consent to stop the application, confirm that you want to continue.
   The controller stops the application and starts the restore operation.
6. Monitor the operation until the controller reports that the restore is successful and the application returns to the **Running** state.
7. Confirm that the controller displays the last-completed restore timestamp.

The controller restores the Sensor Connect application database and restarts the application in its saved Day-N state.

What to do next

Launch Sensor Connect and verify the restored application state. For more information, refer the Sensor Connect Online Help guide.

Sensor Connect launch and Day-0 configuration

Provides reference information on launching Sensor Connect, Day-0 workflows, restore behaviors, credential use, and help resources.

Sensor Connect offers several key functions during initial setup and launch:

- You must launch Sensor Connect from the controller **IoT Services** page after the application reaches the **Running** state.

- After a restore operation, Sensor Connect opens in its saved Day-N state. Use the old credentials from the restored database to login to the application and verify that the expected AP inventory is present and controller registration is active.
- For fresh deployments without a restored database, Sensor Connect opens the Day-0 workflow. Use your credentials to sign in for the first time, perform credential changes, onboarding, and other application procedures.
- For additional details on sign-in, credential management, onboarding, or other Sensor Connect operations, refer the Sensor Connect Online Help guide.

114 AP and Sensor Connect support for full filtering

Topics:

- AP and Sensor Connect support for full filtering

This topic describes the AP and Sensor Connect support for full filtering details.

AP and Sensor Connect support for full filtering

Explains how Cisco Catalyst access points filter Bluetooth Low Energy (BLE) advertisements before forwarding them to Sensor Connect and Cisco Spaces.

AP and Sensor Connect support for full filtering enables Cisco Catalyst access points to filter Bluetooth Low Energy (BLE) advertisements before forwarding them to Sensor Connect and Cisco Spaces that

- reduces unnecessary BLE advertisement traffic from dense bluetooth environments before forwarding advertisements to upstream applications
- filters BLE advertisements using Bluetooth MAC address type, RSSI threshold, and MAC address prefix criteria, evaluates BLE advertisements using the **Deny List**, **Static Allow List**, **Dynamic Allow List**, and **Limit List** in the configured order, and
- automatically forwards advertisements from onboarded BLE devices through the Dynamic Allow List after the devices are detected by an AP.

Feature history for AP and Sensor Connect support for full filtering

This section explains the feature history details of the AP and Sensor Connect support for full filtering feature.

- This table provides release and related information for the feature explained in this module.
- This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 108: Feature history for AP and Sensor Connect support for full filtering

Feature Name	Release Information	Feature Description
AP and Sensor Connect support for full filtering	Cisco IOS XE 26.2.1	AP and Sensor Connect support for full filtering enables Cisco Catalyst APs to filter Bluetooth Low Energy (BLE) advertisements before forwarding them to Sensor Connect and Cisco Spaces. It reduces unnecessary BLE traffic by applying configurable filtering criteria and ordered deny, allow, and limit lists while automatically forwarding advertisements from onboarded BLE devices.

Guidelines for BLE full filtering

Outlines best practices for configuring and managing BLE full filtering to optimize device detection and security.

Follow these guidelines when using BLE full filtering:

- BLE advertisements are evaluated in these order:
  1. Deny List
  2. Static Allow List
  3. Dynamic Allow List
  4. Limit List for default behavior

- The deny list has the highest precedence and always overrides the static and dynamic allow lists.
- Static deny and static allow lists support up to 64 configured MAC prefix entries.
- The **Dynamic Allow List** is populated automatically with onboarded BLE devices after they are detected by an AP and the advertisement events are enabled for them.
- Devices that do not match the **Deny list**, **Static Allow List**, or **Dynamic Allow List** are processed by the limit list.
- The limit list is the default forwarding behavior and is not configured as an explicit filtering list.
- By default, BLE filtering is disabled.

> **Note**
>
> The **Static Allow List** does not override the deny list. If a BLE advertisement matches both lists, the deny action takes precedence.

Launch Sensor Connect from the Catalyst 9800 controller

Configure BLE full filtering policies using the Sensor Connect application launched from the Catalyst 9800 controller.

Enable BLE full filtering to optimize IoT device communications by configuring appropriate policies with Sensor Connect.

Use the Catalyst 9800 controller to access the Sensor Connect application, which allows you to create and manage BLE full filtering policies for IoT Services.

Procedure

1. Choose **Configuration** > **Services** > **IoT Services**.
2. Click **Launch Sensor Connect**.
3. Configure the required BLE full filtering policy in the **Sensor Connect** application.

> **Note**
>
> For information about configuring BLE filtering policies, refer the Cisco Sensor Connect for IoT Services Online Help.

115 Using Cloud Monitoring as a Solution for Network Monitoring

Topics:

- Cloud monitoring

This chapter explains how to enable and verify Cisco Meraki cloud monitoring for Catalyst 9800 wireless controllers and access points, covering prerequisites, GUI/CLI onboarding, tunnel status, registration verification, and basic troubleshooting.

Cloud monitoring

This topic describes the Cloud Monitoring feature, which enables centralized monitoring of Cisco Catalyst 9800 Wireless Controllers by using the Cisco Meraki Dashboard.

Cloud Monitoring is a network management service that:

- simplifies onboarding without requiring an external onboarding agent
- improves tunnel connectivity by using native Meraki Nextunnel
- aligns operational data models with the Cisco Meraki Dashboard for seamless device authentication and operations

Cloud Monitoring allows network administrators to monitor Cisco Catalyst 9800 Wireless Controllers by using the Cisco Meraki Dashboard.

Feature history for Cloud Monitoring

This table lists release information for the feature described in this section.

This feature is available in all releases after its introduction unless noted otherwise.

Table 109: Feature history

Release	Feature	Feature information
Cisco IOS XE 17.15.1, 17.12.4, and 17.9.5	Cloud Monitoring	Cloud Monitoring is a cloud-native solution that connects devices to the cloud for network monitoring.

Examples of Cloud monitoring

- Automated onboarding requires no external onboarding agent for device registration.
- Native Meraki Nextunnel technology enhances tunnel connectivity.

When to use cloud monitoring

This topic explains when to use Cloud Monitoring and the benefits of using the Cisco Meraki Dashboard for network monitoring without additional on-premises resources.

Cloud Monitoring allows you to monitor your devices from the Cisco Meraki Dashboard without additional on-premises resources.

To monitor your network, you must log in to a specific device or deploy on-premises solutions.

To deploy an on-premises solution, you must set up additional servers and pay ongoing maintenance costs. Supporting on-premises solutions requires significant resources. Offloading these operations to the cloud reduces overhead.

Use Cloud Monitoring to monitor your devices from the Cisco Meraki Dashboard without additional resources.

Cloud monitoring features

This topic explains the features of cloud monitoring, including simplified onboarding, improved tunnel connectivity, operational data alignment, and seamless authentication with the Cisco Meraki dashboard.

This topic explains the features of cloud monitoring, including simplified onboarding, improved tunnel connectivity, operational data alignment, and seamless authentication with the Cisco Meraki dashboard.

- Simplified onboarding without any external onboarding agent.

- Improved tunnel connectivity with native Meraki Nextunnel.
- Aligning pull-based operational data with the current Cisco Meraki dashboard models.
- Seamless authentication from Cisco Meraki dashboard to the device using the cloud console.

Prerequisites for cloud monitoring

Use these guidelines when preparing controllers and user credentials for cloud monitoring with the Cisco Meraki dashboard.

- To enable cloud monitoring for controllers, the controllers must be connected to, registered, and provisioned by the Cisco Meraki dashboard.
- To add a wireless controller to a network, the username and password must have **privilege 15 access** and **enable password** (optional) in the dashboard.
- The wireless controller must have 4 unused consecutive VTY slots.

> **Note**
>
> The VTY lines must be provisioned and secured for only the dashboard to access the controller on these lines.

Enable cloud monitoring (GUI)

Learn how to enable cloud monitoring for Meraki devices using the graphical user interface (GUI) by configuring the required services and applying the changes.

Enable cloud monitoring through the GUI so that you can monitor Meraki devices centrally and have visibility into their registration and connection status.

Procedure

1. Choose **Configuration** > **Services** > **Cloud Services** > **Meraki** .
2. Use the slider to enable **Meraki Connect** .
3. Click **Apply** to automatically refresh and view the registration or Nextunnel connection status.

> **Note**
>
> Click **Refresh** to update the changes.

Cloud monitoring is activated for Meraki devices, and you can view their registration or Nextunnel connection status from the interface.

Enable cloud monitoring (CLI)

Learn how to enable cloud monitoring using CLI commands on your device.

Enable cloud monitoring features so that your device can integrate with cloud-based management tools.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable cloud monitoring.

   Example

   ```
   Device(config)# service meraki connect
   ```

Cloud monitoring is enabled on your device, allowing it to connect to the cloud management service.

Onboard the controller using Cisco Meraki dashboard

This topic explains how to onboard the controller using the Cisco Meraki dashboard for wireless device monitoring.

To monitor wireless devices, claim an eligible wireless controller into your Dashboard inventory.

For more information, see the Catalyst Wireless Onboarding Guide.

Verify cloud monitoring

Use CLI commands to verify the Cloud ID, device registration status, and access point registration for cloud monitoring.

To verify the Cloud ID (Meraki Serial Number) fetched as part of the registration and status of the operation, use this command:

```
Device# show meraki connect
Service meraki connect: enable

Troubleshoot cloud monitoring

This topic explains how to troubleshoot cloud monitoring issues, including common scenarios, reasons for failures, and recommended actions for device and access point registration problems.

This topic provides troubleshooting steps for cloud monitoring, focusing on device and access point registration issues with the Cisco Meraki Dashboard.

Scenario	Reason	Action
Your device cannot register with the Cisco Meraki Dashboard.	You see this error message: **No required SSL certificate was sent**	Check that the required certificate is installed on the device. **Note** Ensure that your device has the hardware SUDI certificates.
Your device cannot register with the Cisco Meraki Dashboard.	You see this error message: **Error message: ip http client source-interface not configured.**	Configure the **http client source interface** by using the **ip http client source-interface <interface name>** command.
If the controller fails to register with the Cisco Meraki Dashboard, it retries nine times.		Disable and then enable **service meraki connect** to reinitiate the registration.
If the access point fails to register with the Cisco Meraki Dashboard, it retries five times.	The **show ap meraki monitoring summary** command displays this status: **AP Registration Has Failed Five Times. Please Reboot the AP.**	Reload the access point to reinitiate the registration.

116 Wireless Active Testing with ThousandEyes

Topics:

- Wireless active testing (WAT)

Wireless active testing (WAT)

This section explains wireless active testing details.

Wireless active testing (WAT) is a solution that

- proactively detects and reports Wi-Fi issues before end-users encounter them
- integrates the Cisco Catalyst 9800 Wireless LAN Controller with ThousandEyes for comprehensive network and application testing, and
- helps troubleshoot Wi-Fi network unpredictability by leveraging APs as WAT devices.

WAT functionality allows you to test wireless network health and application connectivity directly from the edge of your network, with the controller managing the onboarding and configuration of these active test APs to the ThousandEyes platform.

Key aspects of wireless active testing:

- Wireless onboarding test: This part of WAT performs Layer 2 onboarding tests, including 802.11 authentication, association, EAP, key exchange, and DHCP. It reports failures and collects metrics and telemetry for successful onboarding attempts, providing insights into the wireless client experience.
- Synthetic testing with ThousandEyes: This integrates with the ThousandEyes Endpoint Agent, deployed on Catalyst APs, to run synthetic tests over the wireless connection. It checks for success or failure to various web server applications and collects metrics for application performance, offering Layer 3 and above testing capabilities directly from the AP. The controller facilitates the connection and management of these agents with the ThousandEyes platform.

Feature history for wireless active testing with ThousandEyes

This section explains the feature history details of the WAT feature with ThousandEyes.

- This table provides release and related information for the feature explained in this module.
- This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 110: Feature history for wireless active testing (WAT) with ThousandEyes

Feature Name	Release Information	Feature Description
Wireless active testing with ThousandEyes	Cisco IOS XE 17.18.2	Wireless Active Testing (WAT) proactively detects and reports Wi-Fi issues, integrating with the Cisco Catalyst 9800 Wireless LAN Controller and ThousandEyes for comprehensive network and application testing. It leverages APs as WAT devices to troubleshoot Wi-Fi network unpredictability and test network health directly from the edge.

Supported controller and AP platforms

This section explains the supported controller and AP platforms details.

Wireless active testing (WAT) is supported on Cisco Catalyst Wireless LAN Controllers and APs, offering a range of features for network monitoring and assurance by integrating with ThousandEyes.

Supported controller Platforms:

- Cisco CW9800 Series (CW9800L, CW9800M, CW9800H1, CW9800H2).
- Cisco Catalyst 9800 Series (C9800-L, C9800-40, C9800-80).
- Catalyst 9800-CL (virtual controller).

Supported AP Platforms:

- Cisco Wireless 9172H Catalyst AP (Wi-Fi 7 wall-plate model).

Supported security types

This section explains the supported security types details.

WAT supports a variety of security configurations for testing wireless networks, enabling comprehensive assessment of different WLAN setups.

This table includes the supported and non supported WLAN security types.

WLAN types	Supported types	Non supported types
AKM Suites	• 802.1X • PSK • FT-802.1X • FT-PSK • 802.1X-SHA256 • PSK-SHA256 • SAE • FT-SAE • OWE, including OWE Transition Mode	• Suite-B (11) • Suite-B-192 (12) • SAE-EXT-KEY (24) • FT-SAE-EXT-KEY (25)
Ciphers	CCMP-128	• GCMP-128 • CCMP-256 • GCMP-256

WLAN types	Supported types	Non supported types
PHY Mode / Wi-Fi versions	• HE (802.11ax / Wi-Fi 6 + 6E). • VHT (802.11ac / Wi-Fi 5). • HT (802.11n / Wi-Fi 4). • Legacy (802.11abg). **Note** All PHY modes up to Wi-Fi 6E are supported	EHT (802.11be or Wi-Fi 7)
Bands	• 2.4 GHz • 5 GHz • 6 GHz	-

Note

- WPA Support: WPA2 and WPA3 are both supported, including PMF (disabled, optional, required).
- Beacon protection is not supported.
- WAT supports IPv4 for wireless connectivity tests, ThousandEyes agent tests, and HTTP(S) proxy for management traffic.
- Hidden SSIDs are not supported.

Guidelines of wireless active testing

This section explains the guidelines of wireless active testing.

- There is a download server used to obtain the ThousandEyes endpoint agent. There is also a telemetry server, known as the platform server, with which the ThousandEyes endpoint agent communicates. Both servers require internet connectivity, either through an HTTPS proxy or through a direct connection. Ensure that the required IP addresses and URLs are allowlisted to enable access through any firewall. For more information, check Network Connections.
- The Cisco Wireless 9172H Catalyst AP does not broadcast SSIDs when WAT is enabled on the AP. They do not broadcast WLANs and do not serve clients. Use these APs exclusively for monitoring and testing. As a result, all WLANs tagged to the WAT AP in its assigned policy profile are communicated to the TE Platform, allowing selection for SSID test configuration and credentials.
- Because WAT APs require a tag, assign a policy tag based on the location of your AP and tag it as you would for any other AP. If you do not tag at least one of the AP's slots in the RF Tag with a radio profile that has WAT enabled, the AP will not be able to test.

> **Note**
>
> If you use an HTTP(S) proxy with an FQDN, configure a DNS IP address on the AP, either statically or using DHCP. The AP must resolve the proxy FQDN using DNS to connect to the ThousandEyes server.

Configure wireless active testing (GUI)

Use this procedure to configure wireless active testing using the GUI.

Enable and configure wireless active testing (WAT) on your controller and associated APs for integration with ThousandEyes using the GUI.

This task involves setting up global WAT parameters on the controller, configuring AP-specific settings, and enabling WAT on selected APs. It allows APs to act as active test APs, performing wireless and application tests managed by the ThousandEyes platform.

Before you begin

Ensure your controller and APs are running compatible software versions (17.18.2 or later is required).

- You must have a ThousandEyes account and obtain the **ThousandEyes Endpoint Agent Connection String** found in the **Endpoint Experience** section from your ThousandEyes dashboard account settings. This string links your controller and APs to your ThousandEyes organization.

Procedure

1. Choose **Configuration** > **Services** > **Cloud Services**.
2. Click the **Thousand Eyes** tab.
3. The **Wireless Active Testing (WAT) status** toggle is **Enabled** by default.
4. Paste the **ThousandEyes Endpoint Agent Connection String** from the ThousandEyes platform.
5. Click **Apply**.

Configure wireless active testing (CLI)

Use this procedure to configure wireless active testing using commands.

Enable and configure Wireless active testing (WAT) on your controller and associated APs for integration with ThousandEyes using commands.

Before you begin

Ensure your controller and APs are running compatible software versions (17.18.2 or later is required).

- You must have a ThousandEyes account and obtain the **ThousandEyes Endpoint Agent Connection String** found in the **Endpoint Experience** section from your ThousandEyes platform Endpoint Agent settings. This string links your controller and APs to your ThousandEyes organization.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure ThousandEyes endpoint agent connection string.

Example

```
Device(config)# wireless active testing thousand-eyes connection-string STRING
```

This string associates the AP's ThousandEyes agent with your ThousandEyes organization. Use the **no** form of the command to remove the connection string.

> **Note**
>
> Removing the connection string unregisters all WAT APs from the ThousandEyes Platform.

3. Exit the global configuration mode.

Example

```
Device(config)# end
```

Configure HTTP(S) proxy for WAT (GUI)

Use this procedure to configure HTTP(S) proxy for WAT using the GUI.

Follow these steps to configure an HTTP(S) proxy for WAT management traffic to the ThousandEyes server, using GUI.

Before you begin

Unauthenticated HTTP forward proxy is supported.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. Click **Add**.
   The **Add AP Join Profile** page appears.
3. In the **General** tab, enter the **Name** and **Description** for the AP join profile.
4. In the **Management** tab, go to the **HTTP Proxy Configuration** section.
5. Enter the IPV4 or Hostname in the **Client Proxy Server** field.
6. Enter a value in the **Client Proxy Port** field.
7. Click **Apply to Device**.

Configure HTTP(S) proxy for WAT (CLI)

Use this procedure to configure HTTP(S) proxy for WAT using commands.

Follow these steps to configure an HTTP(S) proxy for WAT management traffic to the ThousandEyes server, using commands.

Before you begin

Unauthenticated HTTP forward proxy is supported.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter AP Join Profile configuration mode.

   Example

   ```
   Device(config)# ap profile default-ap-profile
   ```

3. Configure the HTTP(S) proxy.

   Example

   ```
   Device(config-ap-profile)# ip http client proxy hostname URL PORT
   ```

   The valid value range for the port number is 0 to 65535. The **URL** needs to be in the format of `{http|https}://<FQDN or IP>[/<path>]`.

   > **Note**
   >
   > This proxy enables the ThousandEyes Agent IOx package download and manages all subsequent communications between the ThousandEyes Agent and the ThousandEyes platform.

4. Exit AP Join Profile configuration mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

Configure WAT radio selection and tag the RF profile (GUI)

Use this procedure to configure WAT radio selection and tag the RF profile using the GUI.

Follow these steps to configure the radio profile and RF tag to designate AP radios for WAT using the GUI.

This process helps you to identity the APs that you want to become WAT APs.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF/Radio**.
2. Create a new radio profile in the **Radio** tab and then select the profile.
   The **Edit Radio Profile** tab appears.
3. Select **Enabled (Always)** for the **Wireless Active Testing Radio Selection** field's drop-down list.

   The options are **Enabled (Always)** and **Disabled**.
4. Click **Update & Apply to Device**.
5. Choose **Configuration** > **Tags & Profiles** > **Tags**.
6. In the **RF** tab, click the newly created and configured RF profile.
   The **Edit RF Tag** page appears.
7. Tag the profile to **Slot 2** for the **6 GHz Radio Profile** band, to **Slot 1** for the **5 GHz Radio Profile** band and to **Slot 0** for the **2.4 GHz Radio Profile** band.
8. Click **Update & Apply to Device**.

Configure wireless active testing radio selection (CLI)

Use this procedure to configure wireless active testing radio selection using commands.

Follow these steps to configure the radio profile and RF tag to designate AP radios for WAT using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Create or modify a radio profile.

   Example

   ```
   Device(config)# wireless profile radio RADIO_PROFILE_NAME
   ```
3. Enable wireless active testing radio selection within the radio profile.

   Example

   ```
   Device(config-wireless-radio-profile)# active testing radio-selection always
   ```
4. Exit radio profile configuration mode and create or modify an RF tag.

   Example

   ```
   Device(config)# wireless tag rf RF_TAG_NAME
   ```
5. Tag the profile to **Slot 2** for the **6 GHz Radio Profile** band, to **Slot 1** for the **5 GHz Radio Profile** band and to **Slot 0** for the **2.4 GHz Radio Profile** band.

Example

```
Device((config-wireless-rf-tag))# dot11 24ghz slot0 radio-profile
RADIO_PROFILE_NAME
```

```
Device(config-wireless-rf-tag)# dot11 5ghz slot1 radio-profile
RADIO_PROFILE_NAME
```

```
Device(config-wireless-rf-tag)# dot11 6ghz slot2 radio-profile
RADIO_PROFILE_NAME
```

6. Exit RF tag configuration mode.

Example

```
Device(config)# end
```

Enable WAT management for an individual AP (GUI)

Use this procedure to enable WAT management for an individual AP using the GUI.

Follow these steps to enable or disable WAT Management on an individual AP using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. Click the **AP** tab.
3. Go to the **Static** tab for a per AP enablement. Click **Add.**
4. Enter the MAC address in the **AP MAC Address** field.
5. Select the policy-tag, site-tag and RF-tag in the **Policy Tag Name**, **Site Tag Name** and **RF Tag Name** fields as per preference.
6. Click **Apply to Device**.

Enable WAT management for an individual AP (CLI)

Use this procedure to enable WAT management for an individual AP using commands.

Follow these steps to enable or disable WAT management on individual APs using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the Ethernet MAC address of the AP.

Example

```
Device(config)# ap H.H.H
```

3. Map a policy tag to the AP.

   Example

   ```
   Device(config)# policy-tag default-policy-tag
   ```

   Use the **no** form of this command to disable it.

4. Map a RF tag to the AP.

   Example

   ```
   Device(config)# rf-tag wat-rf-tag
   ```

   Use the **no** form of this command to disable it.

5. Map a site tag to the AP.

   Example

   ```
   Device(config)# site-tag wat-site-tag
   ```

   Use the **no** form of this command to disable it.

6. Exit the global configuration mode.

   Example

   ```
   Device(config)# end
   ```

Enable WAT management for multiple APs using location (GUI)

Use this procedure to enable WAT management for multiple APs using location from the GUI.

Follow these steps to enable or disable WAT Management on multiple APs using the location process from the GUI.

Before you begin

For multiple APs, follow these steps of enabling WAT management for multiple APs using location or by using the filter process.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. Click the **AP** tab.
3. Go to the **Location** tab. Click **Add**.
4. Enter a location name and description in the **Location** and **Description** fields.
5. In the **General** tab, select the policy-tag, site-tag and RF-tag in the **Policy Tag Name**, **Site Tag Name** and **RF Tag Name** fields as per preference.

6. Click **Apply to Device**.
7. In the **AP Provisioning** tab, select or add APs in the **Import AP MAC**, **AP MAC Address**, **Available AP list** and **Associated AP list** fields to associate them with the location.
8. Click **Apply to Device**.

Enable WAT management for multiple APs using location (CLI)

Use this procedure to enable WAT management for multiple APs using location from the console.

Follow these steps to enable or disable WAT Management on multiple APs using the location process from the console.

Before you begin

For multiple APs, follow these steps of enabling WAT management for multiple APs using location or by using the filter process.

Procedure

1. Enter the global configuration mode and modify or create AP location configuration.

   Example

   ```
   Device# configure terminal
   ```

   ```
   Device(config)# ap location name wat-location
   ```

2. Add AP to this location.

   Example

   ```
   Device(config-ap-location)# ap-eth-mac H.H.H
   ```

   Use the **no** form of this command to disable it.

3. Configure tags based for this location, configure policy tag for this location and configure rf and site tag for this location.

   Example

   ```
   Device(config-ap-location)# tag policy default-policy-tag
   ```

   ```
   Device(config-ap-location)# tag rf wat-rf-tag
   ```

   ```
   Device(config-ap-location)# tag site wat-site-tag
   ```

   Use the **no** form of this command to disable it.

4. Exit the global configuration mode.

   Example

   ```
   Device(config-ap-location)# end
   ```

Enable WAT management for multiple APs using filter (GUI)

Use this procedure to enable WAT management for multiple APs using filter from the GUI.

Follow these steps to enable or disable WAT Management on multiple APs using the filter process from the GUI.

Before you begin

For multiple APs, follow these steps of enabling WAT management for multiple APs using location or by using the location process.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. Click the **AP** tab.
3. Go to the **Filter** tab for a regex on the AP name and select a WAT AP.
   The **Edit Tags** page appears.
4. Enter the **Rule Name** and the **AP name regex**.

   This results in the tag going to only those selected APs.

5. In the **Active** field, enable the toggle to **Yes**. Click **Update & Apply to Device**.

   Note

   Tags have a priority order. In the **Tag Source** tab, the default setting is static, so the per-AP priority is zero. If no per-AP tag exists, the system checks the location. If the location is not set, it checks for a filter. If there is no filter, the system checks whether the AP has an assigned tag and saves it. To enable this feature, check the **Enable AP Tag Persistency** checkbox. Click **Apply**.

Enable WAT management for multiple APs using filter (CLI)

Use this procedure to enable WAT management for multiple APs using filter from the console.

Follow these steps to enable or disable WAT Management on multiple APs using the filter process from the console.

Before you begin

For multiple APs, follow these steps of enabling WAT management for multiple APs using location or by using the location process.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure ap filter and enter AP filter name.

Example

```
Device(config-ap-filter)# ap filter name wat-aps
```

3. Configure filter based on AP name regular expression match.

   Example

   ```
   Device(config-ap-filter)# ap name-regex WAT-9172H
   ```

   Use the **no** form of this command to disable it.

4. Configure tags based for this filter, configure policy tag for this filter and configure rf and site tag for this filter.

   Example

   ```
   Device(config-ap-filter)# tag policy default-policy-tag
   ```

   ```
   Device(config-ap-filter)# tag rf wat-rf-tag
   ```

   ```
   Device(config-ap-filter)# tag site wat-site-tag
   ```

   Use the **no** form of this command to disable it.

5. Exit the global configuration mode.

   Example

   ```
   Device(config-ap-filter)# end
   ```

Verify wireless active testing

This section provides verifying wireless active testing details.

Use these commands to verify the status of WAT.

- **show run | sec wat-radio-profile**
- **show ap profile name wat-ap-profile detailed**
- **show wireless profile radio detailed wat-radio-profile**
- **show wireless tag rf detailed wat-rf-tag**
- **show wireless active testing configuration**

To verify the WAT radio profile, enter this command from the console:

```
Device# show run | sec wat-radio-profile

wireless profile radio wat-radio-profile
 active testing radio-selection always
Device# show run | sec wat-rf-tag

wireless tag rf wat-rf-tag
```

```
 dot11 24ghz slot0 radio-profile wat-radio-profile
 dot11 5ghz slot1 radio-profile wat-radio-profile
 dot11 6ghz slot2 radio-profile wat-radio-profile
```

To verify the WAT AP profile detailed, enter this command from the console:

```
Device# show ap profile name wat-ap-profile detailed
…
Proxy :
  Hostname                    : http://192.168.1.100
  Port                        : 80
  NO_PROXY list               : Not Configured
  Username                    : Not Configured
…
```

To verify the WAT radio profile detailed, enter this command from the console:

```
Device# show wireless profile radio detailed wat-radio-profile
…
Wireless Active Testing (WAT) Configuration
  WAT Admin State (Radio Selection)              : Enabled (Always)
…
```

To verify the WAT RF tag detailed, enter this command from the console:

```
Device# show wireless tag rf detailed wat-rf-tag

Tag Name                      : wat-rf-tag
Description                   :
---------------------------------------
6ghz RF Policy                : default-rf-profile-6ghz
5ghz RF Policy                : Global Config
2.4ghz RF Policy              : Global Config
2.4ghz slot 0 Radio Profile   : wat-radio-profile
5ghz slot 0 Radio Profile     : default-radio-profile
5ghz slot 1 Radio Profile     : wat-radio-profile
6ghz slot 1 Radio Profile     : default-radio-profile
5ghz slot 2 Radio Profile     : default-radio-profile
6ghz slot 2 Radio Profile     : wat-radio-profile
6ghz slot 3 Radio Profile     : default-radio-profile
AP Beam State                 : Boresight
URWB Profile                  :
```

To verify the WAT wireless active testing configuration, enter this command from the console:

```
Device# show wireless active testing configuration

Wireless Active Testing (WAT) Management - Configuration

117 Wireless Active Testing SCEP support

Topics:

- Wireless Active Testing SCEP support

This chapter explains Wireless Active Testing SCEP support.

Wireless Active Testing SCEP support

Explains how Wireless Active Testing SCEP support provisions, renews, and manages client certificates for EAP-TLS SSIDs, integrating with customer SCEP servers to automate certificate management.

Wireless Active Testing SCEP support is a certificate provisioning capability that

- automatically enrolls client certificates for Wireless Active Testing EAP-TLS SSIDs
- eliminates manual client certificate provisioning by integrating with a customer SCEP server, and
- automatically renews client certificates before they expire.

Key features of Wireless Active Testing SCEP support

Wireless Active Testing SCEP support:

- supports standard RFC 8894 SCEP servers, including Microsoft NDES and EJBCA.
- continues to support PKCS#12 and LSC certificate sources for deployments that do not use SCEP.

Configure the SCEP parameters for the Wireless Active Testing SSID from the ThousandEyes Dashboard. For detailed configuration steps, refer the ThousandEyes Endpoint Experience documentation. After the configuration is pushed, the Wireless Active Testing Manager automatically provisions and manages the client certificate.

Feature history for Wireless Active Testing SCEP support

This section explains the feature history details of the Wireless Active Testing SCEP support feature.

- This table provides release and related information for the feature explained in this module.
- This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 111: Feature history for Wireless Active Testing SCEP support

Feature Name	Release Information	Feature Description
Wireless Active Testing SCEP support	Cisco IOS XE 26.2.1	Wireless Active Testing SCEP support is a certificate-provisioning capability that automatically enrolls and renews client certificates for EAP-TLS SSIDs by integrating with customer SCEP servers, eliminating manual certificate provisioning. It supports RFC 8894-compliant SCEP servers, including Microsoft NDES and EJBCA, while retaining support for PKCS#12 and LSC certificate sources.

SCEP enrollment for Wireless Active Testing

Explains the certificate provisioning process for Wireless Active Testing using SCEP to automate client certificate enrollment and renewal for EAP-TLS SSIDs.

SCEP enrollment for Wireless Active Testing is a certificate provisioning process that

- automatically requests and installs a client certificate from a customer SCEP server for each Wireless Active Testing EAP-TLS SSID
- replaces manual certificate provisioning by using automated certificate enrollment, and
- maintains certificate availability by supporting automatic certificate renewal.

SCEP enrollment process

When you configure SCEP settings for a Wireless Active Testing SSID from the ThousandEyes dashboard, the ThousandEyes agent sends the SCEP configuration to the AP. The Wireless Active Testing Manager creates a trustpoint for the SSID and starts the certificate enrollment process.

During enrollment, the Wireless Active Testing Manager:

- retrieves the CA certificate from the SCEP server.
- validates the configured CA fingerprint, when fingerprint validation is enabled.
- generates the private key and certificate signing request (CSR).
- requests a client certificate from the SCEP server.
- stores the enrolled certificate, private key, and CA certificate in the Wireless Active Testing trustpoint.

After successful enrollment, Wireless Active Testing uses the enrolled client certificate to perform EAP-TLS authentication for the configured SSID. When automatic re-enrollment is enabled, the Wireless Certificate Platform (WCP) renews the certificate before it expires without requiring manual certificate replacement.

Guidelines for Wireless Active Testing SCEP

Outlines recommended actions for configuring and deploying Wireless Active Testing SCEP to ensure reliable certificate enrollment and secure network operation.

Follow these guidelines when deploying Wireless Active Testing SCEP.

- Configure all SCEP parameters from the ThousandEyes dashboard.
- Use AP or controller commands only for verification and troubleshooting.
- Ensure that the AP can reach the SCEP server.
- Synchronize AP time using NTP before certificate enrollment.
- Configure the **Common Name** and **Server URL** correctly before saving the SSID configuration.
- Verify the optional CA fingerprint before enabling fingerprint validation.

- MAC Filtering

MAC Filtering

MAC Filtering details.

You can configure the controller to authorize clients based on the client MAC address by using the MAC filtering feature.

When MAC filtering is enabled, the controller uses the MAC address as the client identity. The authentication server has a database of client MAC addresses that are allowed network access. The controller sends the authentication server a RADIUS-access/request frame with a username and password based on the client MAC address as soon as it gets the association request from the client. If authorization succeeds, the controller sends a successful association response to the client. If authorization fails, the controller rejects the client association.

Clients that were authorized with MAC filtering can be re-authenticated through the WLAN session timeout feature.

MAC Filtering Configuration Guidelines

- MAC filtering authentication occurs at the 802.11 association phase and delays the association response until authentication is done. If you use a RADIUS server for MAC filtering, it is advised to keep a low latency between the controller and the RADIUS server. When latency is too high, the client might timeout while waiting for the association response.
- MAC filtering can be combined with other authentication methods such as 802.1X, Pre-Shared Key or it can be used alone.
- MAC addresses can be spoofed and MAC filtering does not consist in a security measure.
- Many clients can use a private MAC address to connect and change it at every session, therefore making it harder to identify devices through their MAC address.

Note

If wlan-profile-name is configured for a user, guest user authentication is allowed only from that WLAN.

If wlan-profile-name is not configured for a user, guest user authentication is allowed on any WLAN.

The AP fails to join the controller due to an authentication rejection on the RADIUS server. The failure occurs on the Cisco Catalyst 9800 controller, only when the RADIUS server is configured to authenticate the APs with method MAB as endpoints. The reason is that the RADIUS calling-station-id attribute is required for MAB authentication and is not present within the access request packet during the AP join. The workaround is to use a different AP authentication method than MAB as endpoints such as PAP-ASCII using a username and a password.

If you want the client to connect to SSID1, but not to SSID2 using mac-filtering, ensure that you configure **aaa-override** in the policy profile.

In the following example, when a client with MAC address 112233440001 tries to connect to a WLAN, the request is sent to the local RADIUS server, which checks the presence of the client MAC address in its attribute list (FILTER_1 and FILTER_2). If the client MAC address is listed in an attribute list (FILTER_1), the client is allowed to join the WLAN (WLAN_1) that is returned as *ssid attribute* from the RADIUS server. The client is rejected, if the client MAC address is not listed in the attribute list.

Local RADIUS Server Configuration

```
!Configures an attribute list as FILTER_2
aaa attribute list FILTER_2
!Defines an attribute type that is to be added to an attribute list.
attribute type ssid "WLAN_2"
```

```
!Username with the MAC address is added to the filter
username 112233440001 mac aaa attribute list FILTER_2

!
aaa attribute list FILTER_1
attribute type ssid "WLAN_1"
username 112233440001 aaa attribute list FILTER_1
```

Controller Configuration

```
! Sets authorization to the local radius server
aaa authorization network MLIST_MACFILTER local

!A WLAN with the SSID WLAN_2 is created and MAC filtering is set along with
security
parameters.
wlan WLAN_2 2 WLAN_2
mac-filtering MLIST_MACFILTER
no security wpa
no security wpa wpa2 ciphers

!WLAN with the SSID WLAN_1 is created and MAC filtering is set along with
security parameters.
wlan WLAN_1 1 WLAN_1
mac-filtering MLIST_MACFILTER
no security wpa
no security wpa wpa2 ciphers aes
no security wpa akm dot1x
security web-auth
security web-auth authentication-list WEBAUTH

! Policy profile to be associated with the above WLANs
wireless profile policy MAC_FILTER_POLICY
aaa-override
vlan 504
no shutdown
```

Configuring MAC Filtering for Local Authentication (CLI)

Configure MAC Filtering for Local Authentication using commands.

Follow the procedure given below to configure MAB for local authentication.

Before you begin

Configure AAA local authentication.

Configure the username for WLAN configuration (local authentication) using **username** *mac-address* **mac** command.

Note

The mac-address must be in the following format: *abcdabcdabcd*

Procedure

1. **wlan** *profile-name wlan-id*

   Example

   ```
   wlan CR1_SSID_mab-local-default 1 CR1_SSID_mab-local-default
   ```

   Specifies the WLAN name and ID.

2. **mac-filtering default**

   Example

   ```
   Device(config-wlan)# mac-filtering default
   ```

   Sets MAC filtering support for the WLAN.

3. **no security wpa**

   Example

   ```
   Device(config-wlan)# no security wpa
   ```

   Disables WPA secuirty.

4. **no security wpa akm dot1x**

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

   Disables security AKM for dot1x.

5. **no security wpa wpa2**

   Example

   ```
   Device(config-wlan)# no security wpa wpa2
   ```

   Disables WPA2 security.

6. **no security wpa wpa2 ciphers aes**

   Example

   ```
   Device(config-wlan)# no security wpa wpa2 ciphers aes
   ```

Disables WPA2 ciphers for AES.

7. **no shutdown**

Example

```
Device(config-wlan)# no shutdown
```

Enables the WLAN.

Configuring MAC Filtering (GUI)

Configure MAC Filtering using GUI.

Before you begin

Configure AAA external authentication.

Procedure

1. Choose **Configuration** > **Wireless** > **WLANs**.
2. On the **Wireless Networks** page, click the name of the WLAN.
3. In the **Edit WLAN** window, click the **Security** tab.
4. In the **Layer2** tab, check the **MAC Filtering** check box to enable the feature.
5. With MAC Filtering enabled, choose the **Authorization List** from the drop-down list.
6. Save the configuration.

Configuring MAB for External Authentication (CLI)

Configure MAB for External Authentication using commands.

Follow the procedure given below to configure MAB for external authentication.

Before you begin

Configure AAA external authentication.

Procedure

1. **wlan** *wlan-name wlan-id ssid-name*

Example

```
wlan CR1_SSID_mab-ext-radius 3 CR1_SSID_mab-ext-radius
```

Specifies the WLAN name and ID.

2. **mac-filtering** *list-name*

Example

```
Device(config-wlan)# mac-filtering ewlc-radius
```

Sets the MAC filtering parameters. Here, *ewlc-radius* is an example for the *list-name*

3. **no security wpa**

   Example

   ```
   Device(config-wlan)# no security wpa
   ```

   Disables WPA secuirty.

4. **no security wpa akm dot1x**

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

   Disables security AKM for dot1x.

5. **no security wpa wpa2**

   Example

   ```
   Device(config-wlan)# no security wpa wpa2
   ```

   Disables WPA2 security.

6. **mab request format attribute {1 groupsize** *size* **separator** *separator* **[lowercase | uppercase] | 2 {0 | 7 | LINE} LINE** *password* **| 32 vlan access-vlan}**

   Example

   ```
   Device(config)# mab request format attribute 1 groupsize 4 separator
   ```

   Optional. Configures the delimiter while using MAC filtering in a WLAN.

   Here,

   1- Specifies the username format used for MAB requests.

   groupsize *size*- Specifies the number of hex digits per group. The valid values range from 1 to 12.

   separator *separator*- Specifies how to separate groups. The separators are comma, semicolon, and full stop.

   lowercase- Specifies the username in lowercase format.

   uppercase- Specifies the username in uppercase format.

   2- Specifies the global password used for all the MAB requests.

   0- Specifies the unencrypted password.

   7- Specifies the hidden password.

   LINE- Specifies the encrypted or unencrypted password.

   password- LINE password.

   32- Specifies the NAS-Identifier attribute.

vlan- Specifies a VLAN.

access-vlan- Specifies the configured access VLAN.

7. **no security wpa wpa2 ciphers aes**

   Example

   ```
   Device(config-wlan)# no security wpa wpa2 ciphers aes
   ```

   Disables WPA2 ciphers for AES.

8. **no shutdown**

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

   Enables the WLAN.

119 Web-Based Authentication

Topics:

- Local web authentication
- External Web Authentication
- Authenticating sleeping clients
- Sleeping Clients With Multiple Authentication
- Multiple Authentication Combinations with 802.1X and LWA

This chapter describes how to configure web-based authentication on the device. It contains these sections:

Local web authentication

Introduces local web authentication concepts, detailing authentication process, device roles, usage restrictions, customizable web pages, banners, and guidelines. Guides configuration through GUI and CLI, including HTTP/HTTPS requests, parameter maps, WLANs, ACLs, banners, TrustPoint, and provides practical configuration examples.

Local web authentication is a network security mechanism that

- authenticates users through a web browser login page
- enables access control on host systems that do not run IEEE 802.1X supplicants, and
- communicates with authentication, authorization, and accounting (AAA) servers to enforce security policies.

Feature history

Feature Name	Release	Description
Built-in Captive Portal Improvement	Cisco IOS XE 17.1.1	This release introduces support for special characters in the login portal banner title and banner text. The number of characters supported on the banner text has doubled to 400. The **exec-character-bits** command has been introduced.

Presentation options for local web authentication web pages

Local web authentication intercepts HTTP sessions on Layer 2 interfaces, and in some cases, Layer 3 interfaces (with restrictions for some switch models). When users try to access the network, local web authentication displays a login page and verifies user credentials with AAA servers, granting or denying access accordingly.

Local web authentication is categorized by the location where its web pages are hosted.

- **Internal**: Uses HTML pages (login, success, fail, and expire) stored on the controller .
- **Customized**: Uses customized HTML pages (login, success, fail, and expire) downloaded onto the controller for a customized user experience.
- **External**: Uses HTML pages hosted on an external web server.

We recommend that you follow the Cisco guidelines to create a customized web authentication login page. If you use the latest versions of Google Chrome or Mozilla Firefox browsers, ensure that your webauth bundle uses this line in the *login.html* file:

```
<body onload="loadAction();">
```

Web authentication modes

The types of web authentication differ according to the available web authentication pages.

- **Webauth**–The controller displays a page with the user name and password. Users enter valid credentials to gain network access.
- **Consent or web-passthrough**–The controller presents a policy page with the **Accept** and **Deny** buttons. Users simply click **Accept** to access the network – no credentials are required.

- **Webconsent**–This mode combines the features of Webauth and Consent. The controller displays a policy page with Accept or Deny buttons along with user name or password. Users must enter the correct credentials and click **Accept** to access the network.

Additional reference information

- You can view the webauth parameter-map information using the **show running-config** command.
- If you see tracebacks during client authentication, performance and behavior are not affected. Tracebacks may occur if Flexible Forwarding Mode (FFM) replies to Endpoint Profiler Module (EPM) for ACL application after the session is dequeued, usually because a timer expired or the session became **unauthorized**.
- Apply web authentication methods (such as consent, web consent, and webauth) using either a global or named parameter-map under WLAN (for method-type, custom, and redirect). If you do not configure a parameter-map under WLAN, the global parameter-map applies by default.
- You can configure web-based authentication on Layer 2 and layer 3 interfaces.
- When a client reaches the maximum limit of 200 HTTP connections, the system resets TCP connections and excludes your client from the network.

How local web authentication works

Summary

authentication enables secure network access for clients by prompting users to authenticate through a web login page. The process coordinates actions between the user, authentication server, and the network switch. The key components are:

- **User**: Initiates the HTTP session and enters authentication credentials.
- **Network switch**: Intercepts traffic, presents login pages, applies policies, and communicates with the authentication server.
- **Authentication server**: Verifies credentials and provides policy enforcement details.

Workflow

These are the stages of the process.

1. **Session initiation**: The user starts an HTTP session by attempting to access the network.
2. **Traffic interception and login page presentation**: The network switch intercepts the HTTP request and triggers the authorization process. It presents a login page for the user to enter their username and password.
3. **Credential submission and authentication**: After the user submits credentials, the switch forwards them to the authentication server
4. **Authentication outcome:**
   - If authentication succeeds, the switch downloads and activates the access policy assigned to the user from the server, then displays a login success page.
   - If authentication fails, the switch displays a login failure page. After a maximum number of failures, the login expired window appears, and the host is put on a watch list. Once the timeout expires, the user may try again
5. **Server non-response handling**: If the authentication server does not respond, and an AAA fail policy is in place, the switch applies the failure policy to the host and displays a login success page.
6. **Reauthentication triggers**: The switch reauthenticates a client if the host does not respond to an ARP probe (Layer 2) or does not send traffic within an idle timeout (Layer 3)

suppress-feature-id="uabu_2960l_sw"

.

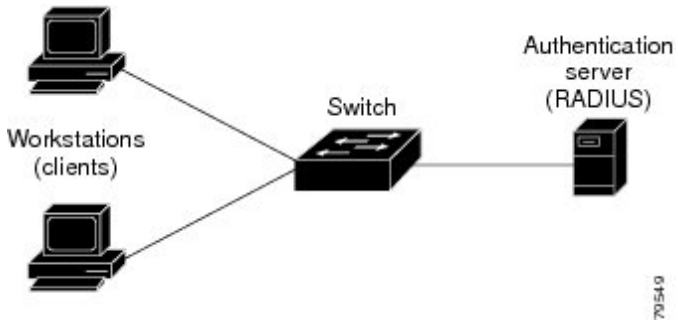
7. **Session timeout enforcement**: The switch applies either the session timeout configured locally or provided by the server. The default local web authentication session timeout on controller is 1800 seconds from Cisco IOS XE 16.1.1 and later. The default session timeout value was infinite seconds, prior to Cisco IOS XE Denali 16.1.1.
8. **Session termination:**
   - If the terminate action is set to RADIUS, the switch sends a nonresponsive host request to the server; the server's response dictates the next action.
   - If the terminate action is set to default, the switch dismantles the session and removes the access policy.

Result

If authentication succeeds and the correct policies are applied, the user gains network access. If authentication fails, failure policies or timeout mechanisms may deny access.

Restrictions

- You cannot configure bypass authentication with the wireless web authentication feature.
- To update the redirect login URL, enable and then disable the WLAN. The redirect login URL specified in the web authentication parameter map changes when an AP rejoins.
- If authentication fails, users receive a failure page and can try to log in again. If the number of allowed attempts is exceeded, users may be excluded and receive a specific reason for the exclusion.
- Use the local web authentication feature to authenticate end users on host systems that do not run the IEEE 802.1x supplicant.



Roles of devices in local web authentication

In a local web authentication scenario, network devices assume specific roles to manage authentication and access to the LAN.

- **Client**: A device, such as a workstation, that requests network access and responds to authentication requests from the switch. The client must have an HTML browser with JavaScript enabled.
- **Authentication server**: A server that validates the identity of the client. The authentication server notifies the switch if the client is allowed or denied access to the LAN and related services.
- **Switch**: A network device that manages physical access to the network based on the authentication status of the client. The switch relays identity information and authorization responses between the client and the authentication server.

These device roles work together to ensure secure access control through local web authentication processes.

Figure 12: Local web authentication device roles

Banner messages for local web authentication

Local web authentication banners provide visual feedback to users during authentication on switches. The banners can display default or customized messages. They may also include branding or additional information on the login and result screens.

Default banner messages

When web authentication is enabled, one of these default messages appears on both the login screen and the authentication result pop-up page:

- Authentication Successful
- Authentication Failed
- Authentication Expired

Commands to configure local web authentication banner

You can configure the local web authentication banner using the new style (Session-aware) CLI mode.

Use the command in the global configuration mode:

```
Device(config)# parameter map type webauth global
Device(config-params-parameter-map)# banner ?
file <file-name>
text <Banner text>
title <Banner title>
```

You can add a custom message, such as a switch, router, or company name, to the banner using the command:

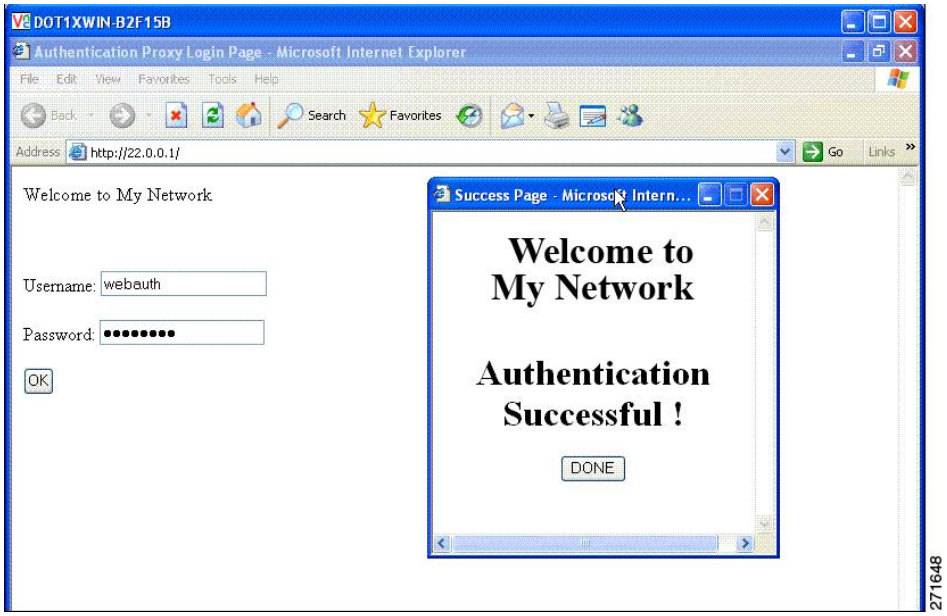
```
Device(config)# parameter map type webauth global
Device(config-params-parameter-map)# banner text <text>
```

You can add a logo or text file to the banner using the command:

```
Device(config)# parameter map type webauth global
Device(config-params-parameter-map)# banner text <filepath>
```

Banner examples

Figure 13: Customized web banner: Authentication Successful



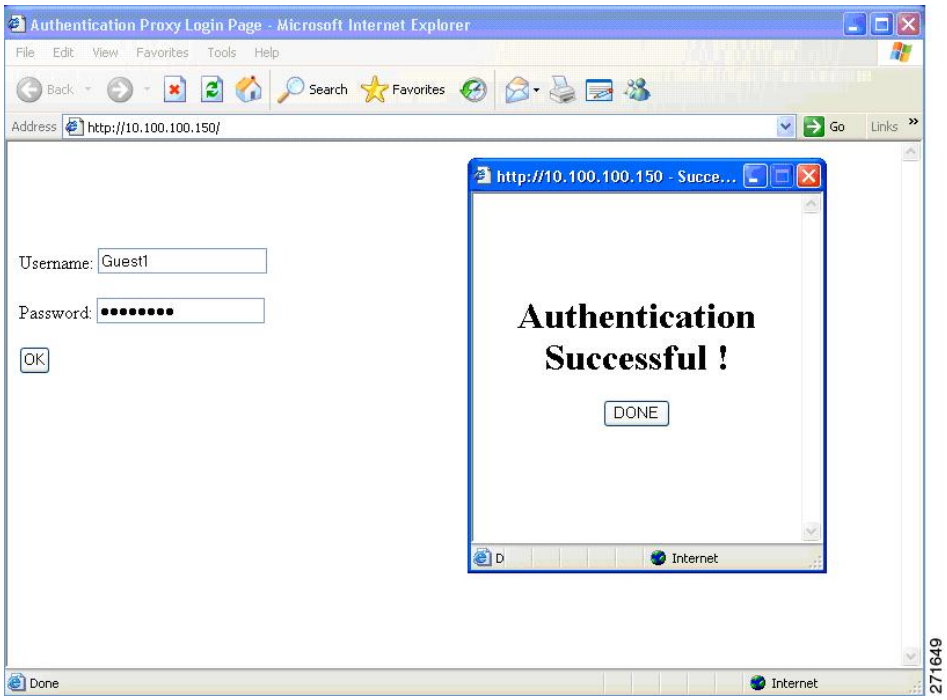


Figure 14: Login screen with no banner

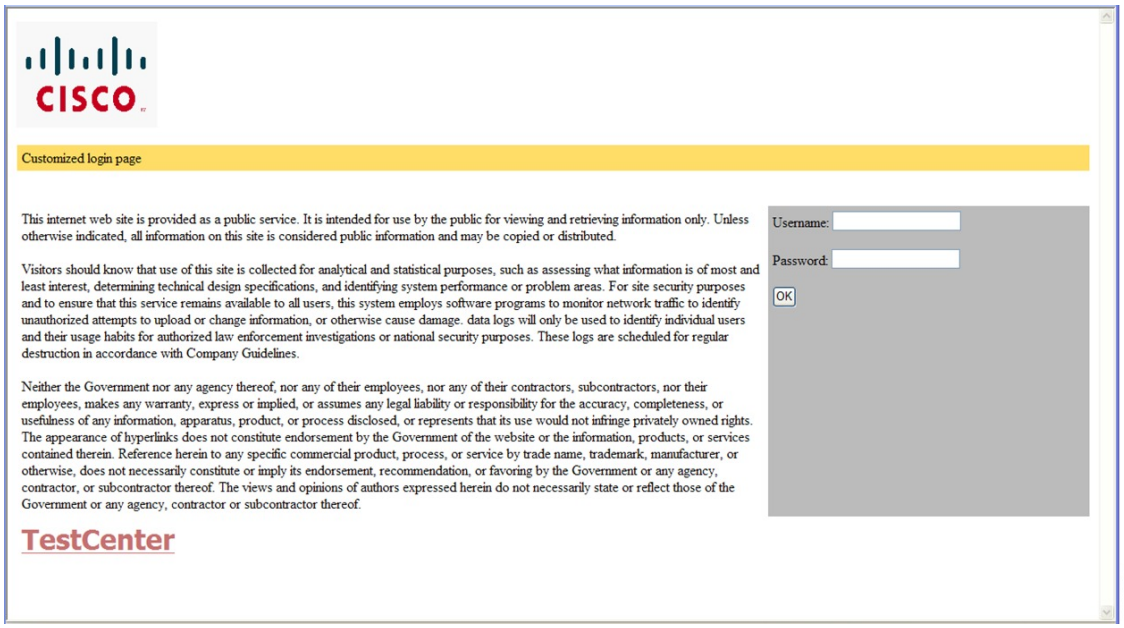
Banner usage and behavior

- The default banners are *Cisco Systems* and *Switch host-name Authentication*. These banners appear on the login page. The *Cisco Systems* banner also appears on the authentication result pop-up page.
- The default banners appear unless custom banners are configured.
- If you do not enable a banner, only username and password dialog boxes appear on the web authentication login screen. You will not see a banner when you log into the switch.

Authentication states in customized local web authentication

During local web authentication, the switch's internal HTTP server hosts four HTML pages that communicate authentication states to the client.

You can replace the default internal HTML pages or specify a URL that redirects users after authentication. This URL replaces the internal Success page.



The four authentication pages and states are:

- Login: Credentials are requested from the client.
- Success: The client has authenticated successfully.
- Fail: Authentication attempt failed.
- Expire: The session expires after excessive failures.

You must configure all four pages. You can specify text or add a logo to each of the four pages.

Banner examples

Figure 15: Customizable Authentication Page

Best practices for customizing web authentication pages

- Add appropriate text to the banner and login pages as needed.
- Always include a valid HTML redirect command in the success page to redirect users to a specific URL after login
- Ensure the URL string is well-formed (for example, "http://www.cisco.com") to avoid browser errors.
- If you configure web pages for HTTP authentication, include the appropriate HTML commands. For example, HTML commands to set the page time out, to set a hidden password, or to confirm that the same page is not submitted twice.
- You can copy the configured web pages to the switch boot flash or the flash.
- The login page can reside on one flash device, while the success and failure pages can be stored on another flash device

- You must configure all four pages.
- All logo files—including image, flash, audio, video, and similar file types—stored in the system directory must use *web_auth_ <filename>* as the file name. System directory examples are flash, disk0, or disk.
- You can copy the configured web pages to the switch boot flash or the flash.

Restrictions for customizing web authentication pages

- The banner page has no effect if it is configured together with a web authentication page.
- When the configured login form is enabled, the CLI command for redirecting users to a specific URL is unavailable. Configure redirection in the web page.
- If you enter the CLI command to redirect users to a specific URL after authentication and then configure web pages, the redirect command does not take effect.
- The configured authentication proxy feature supports both HTTP and SSL.

Guidelines for configuring a redirection URL for Successful Login page

Redirection URL for Successful Login Guidelines

- If you enable the custom authentication proxy web pages feature, you cannot use the redirection URL feature in the CLI. To redirect users after login, configure redirection in the custom login success page.
- If you enable the redirection URL feature, the configured authorization proxy banner is not be used.
- To remove the specification of a redirection URL, use the **no** form of the command.
- If a redirection URL is required after successful authentication, it must begin with a valid protocol prefix (such as http://) followed by the URL. If http:// is omitted, the browser might show a page not found error or similar issue

How to configure local web authentication

-

Configure default local web authentication

Table 112: Default local web authentication configuration

Feature	Default Setting
AAA	Disabled
RADIUS server • IP address • UDP authentication port • Key	• None specified
Default value of inactivity timeout	3600 seconds
Inactivity timeout	Enabled

Configure AAA settings using the wizard

Use the AAA Wizard to streamline the addition of authentication, authorization, and accounting (AAA) servers and settings through a guided interface.

The AAA wizard helps you add the authentication, authorization and accounting details without going into multiple screens.

The AAA Wizard guides you through configuring RADIUS, TACACS+, and LDAP servers, and mapping AAA server groups and methods. If you need to edit details entered with the wizard, use the appropriate configuration screens.

> **Note**
>
> Configure attribute formats as listed in the *Supported authentication and authorization attribute formats* section to ensure successful transactions.

Before you begin

Ensure you have network information and credentials available for the AAA servers to be configured.

Procedure

1. Choose **Configuration > Security** > **AAA**.
2. Click **+ AAA Wizard**.

   The **Add Wizard** window is displayed.
3. Go to the **RADIUS** tab.

   The RADIUS server option is enabled by default. You can switch between **Basic** and **Advanced** options using the radio buttons.

   a) In the **Name** field, enter the name of the RADIUS server.
   b) In the **IPv4 / IPv6 Server Address** field, enter the IPv4 or IPv6 address, or hostname of the server.
   c) Select the **PAC Key** check box to enable Protected Access Credential (PAC) authentication key option.
   d) From the **Key Type** drop-down list, select the authentication key type.
   e) In the **Key** field, enter the authentication key.
   f) In the **Confirm Key** field, re-enter the authentication key.
   g) Click **Advanced** radio button.

      This enables the advanced options.

   h) In the **Auth Port** field, enter the authorization port number.
   i) In the **Acct Port** field, enter the accounting port number.
   j) In the **Server Timeout** field, enter the timeout duration, in seconds.
   k) In the **Retry Count** field, enter the number of retries.
   l) In the **Support for CoA** field, use the toggle button to enable or disable change-of-authorization (CoA).
4. To enter TACACS+ options, check the **TACACS+** check box.

   This enables the TACACS+ options. You can switch between **Basic** and **Advanced** options using the radio buttons.

   a) In the **Name** field, enter the TACACS+ server name.
   b) In the **IPv4 / IPv6 Server Address** field, enter the IPv4 or IPv6 address, or hostname.
   c) In the **Key** field, enter the authentication key.
   d) In the **Confirm Key** field, re-enter the authentication key.
   e) Click **Advanced** radio button.

This enables the advanced options.

f) In the **Port** field, enter the port number to use.
g) In the **Server Timeout** field, enter the timeout duration, in seconds.

5. To enter LDAP options, check the **LDAP** check box.

   This enables the LDAP options. You can switch between **Basic** and **Advanced** options using the radio buttons.

   a) In the **Server Name** field, enter the **LDAP** server name.
   b) In the **IPv4 / IPv6 Server Address** field, enter the IPv4 or IPv6 address, or hostname.
   c) In the **Port Number** field, enter the port number to use.
   d) From the **Simple Bind** drop-down list, select the authentication key type.
   e) In the **User Base DN** field, enter the user base distinguished name.
   f) Click **Advanced** radio button.

      This enables the advanced options.

   g) From the **User Attribute** drop-down list, select the user attribute.
   h) In the **User Object Type** field, enter the details and click the + icon.

      The objects you add appear in the list, and you can use the x mark beside each object to remove it.

   i) In the **Server Timeout** field, enter the timeout duration, in seconds.
   j) Check the **Secure Mode** check box to enable secure mode.

      Selecting the **Secure Mode** option enables the **Trustpoint Name** drop-down list.

   k) From the **Trustpoint Name** drop-down list, select the trustpoint.
   l) Click **Next**.

      This enables the **Server Group Association** screen and RADIUS tab is selected by default.

6. Go to the **RADIUS** tab.
   a) In the **Name** field, enter the name of the RADIUS server group.
   b) From the **MAC-Delimiter** drop-down list, choose the delimiter to be used in the MAC addresses that are sent to the RADIUS servers.
   c) From the **MAC Filtering** drop-down list, choose a value based on which to filter MAC addresses.
   d) To configure dead time for the server group and direct AAA traffic to alternative groups of servers that have different operational characteristics, in the **Dead-Time** field, enter the amount of time, in minutes, after which a server is assumed to be dead.
   e) Choose the servers that you want to include in the server group from the **Available Servers** list and move them to the **Assigned Servers** list.
   f) Click **Next**.

      The **TACACS+** window is displayed, if you have selected **TACACS+** in Server configuration.

7. Use the **TACACS+** window to enter details.
   a) In the **Name** field, enter the name of the TACACS+ server group.
   b) Choose the servers that you want to include in the server group from the **Available Servers** list and move them to the **Assigned Servers** list.
   c) Click **Next**.

      The **LDAP** window is displayed, if you have selected **LDAP** in server configuration.

8. Use the **LDAP** window to enter details.
   a) In the **Name** field, enter the name of the LDAP server group.
   b) Choose the servers that you want to include in the server group from the **Available Servers** list and move them to the **Assigned Servers** list.

9. Click **Next**.

   The **MAP AAA** window is displayed.

   You can use the check boxes to enable the **Authentication**, **Authorization**, and **Accounting** tabs. You cannot deselect all three options. At least one option has to be selected.

10. Use the **Authentication** tab to enter authentication details.
    a) In the **Method List Name** field, enter the name of the method list.
    b) From the **Type** drop-down list, choose the type of accounting you want to perform before allowing access to the network.
    c) From the **Group Type** drop-down list, choose if you want to assign a group of servers as your access server, or if you want to use a local server to authenticate access.

       If you choose local option, **Fallback** to local option is removed.

    d) Check the **Fallback to local** check box to configure a local server to act as a fallback method when servers in the group are unavailable.
    e) From the **Available Server Groups** list, choose the server groups you want to use to authenticate access to your network and click **>** icon to move them to the **Assigned Server Groups** list.
11. Check the **Authorization** check box to configure authorization details.
    a) In the **Method List Name** field, enter the name of the method list.
    b) From the **Type** drop-down list, choose the type of authorization you want to perform before allowing access to the network.
    c) From the **Group Type** drop-down list, choose if you want to assign a group of servers as your access server, or if you want to use a local server to authorize access.

       If you choose local option, **Fallback** to local option is removed.

    d) Check the **Fallback to local** check box to configure a local server to act as a fallback method when servers in the group are unavailable.
    e) From the **Available Server Groups** list, choose the server groups you want to use to authorize access to your network and click **>** icon to move them to the **Assigned Server Groups** list.
12. Check the **Accounting** check box to configure accounting details.
    a) In the **Method List Name** field, enter the name of the method list.
    b) From the **Type** drop-down list, choose the type of accounting you want to perform.
    c) From the **Available Server Groups** list, choose the server groups you want to use to authorize access to your network and click **>** icon to move them to the **Assigned Server Groups** list.
13. Click **Apply to Device**.

The system saves your AAA configuration, associating servers and methods as specified. AAA features are ready for use.

Configure AAA authentication (GUI)

Set up AAA authentication to control network access using the GUI.

Use this task to define and assign authentication methods and server groups for device access.

Before you begin

Confirm that server groups are configured if you plan to use them.

Procedure

---

1. Choose **Configuration** > **Security** > **AAA**.
2. In the **Authentication** section, click **Add**.

3. In the **Quick Setup: AAA Authentication** window that is displayed, enter a name for your method list.
4. Choose the type of authentication you want to perform before allowing access to the network, in the **Type** drop-down list.
5. In the **Group** Type drop-down list, select either a group of servers as your access server or a local server to authenticate access.
6. To configure a local server to act as a fallback method when servers in the group are unavailable, check the **Fallback** to local check box.
7. Choose the server groups you want to use to authenticate access to your network, from the **Available Server Groups** list and click **>** icon to move them to the **Assigned Server Groups** list.
8. Click **Save & Apply to Device**.

The controller is now configured with AAA authentication, and users are authenticated using the chosen methods.

Configure AAA authentication (CLI)

Enable authentication, authorization, and accounting (AAA) on the device to manage login methods and network access.

AAA centralizes user authentication for device access and network services. Select a named method list or the default list, depending on your VTY line configuration.

If no method list is configured under VTY lines, add the default method list to the AAA configuration."

```
line vty 0 4
 authorization commands 15 abc
aaa authorization commands 15 abc group tacacs+
```

If a method-list is not configured under VTY lines, you must add the default method list to the AAA configuration:

```
line vty 0 4
 aaa authorization commands 15 default group tacacs+
```

Note

Use the default list for AAA authorization if you plan to use features such as dACL.

Before you begin

Ensure that the TACACS+ server address and group name are available.

Procedure

---

1. Enable AAA functionality.

   Example

   ```
   Device
   (config)# aaa new-model
   ```

2. Define the list of authentication methods at login using the **aaa authentication login {default** | *named_authentication_list*} **group** *AAA_group_name* command.

Example

```
Device(config)# aaa authentication login default group AAA_group_name
```

named_authentication_list refers to any name that is not greater than 31 characters.

AAA_group_name refers to the server group name. Define the **server_name** at the beginning of the configuration.

3. Create an authorization method list for web-based authorization using the **aaa authorization network {default** | *named_authorization_list*} **group** *AAA_group_name* command.

Example

```
Device(config)# aaa authorization network default group group1
```

4. Specify an AAA server.

Example

```
Device(config)# tacacs server yourserver
```

5. Configure the IP address for the TACACS server.

Example

```
Device(config-server-tacacs)# address ipv4 10.0.1.12
```

6. Specify a AAA server.

Example

```
Device(config)# tacacs-server host 10.1.1.1
```

Configure the HTTP or HTTPS server (GUI)

Set up HTTP and HTTPS access to enable secure web-based management of the device.

HTTP provides basic web access; HTTPS secures connections with SSL encryption. You can configure access ports, authentication, trust points, and session policies to meet your security requirements.

Before you begin

Confirm necessary certificates are available if using HTTPS trust points.

Procedure

---

1. Choose **Administration** > **Management** > **HTTP/HTTPS/Netconf**.
2. In the **HTTP/HTTPS Access Configuration** section, enable HTTP Access and enter the port that will listen for HTTP requests. The default port is 80. Valid values are 80, and ports between 1025 and 65535.

3. Enable **HTTPS Access** on the device and enter the designated port to listen for HTTPS requests. The default port is 1025. Valid values are 443 and ports between 1025 and 65535. Data exchanged over a secure HTTP connection is encrypted before transmission across the Internet. SSL encryption over HTTP enables secure configuration of the switch through a web browser.
4. Choose the **Personal Identity Verification** as enabled or disabled.
5. In the **HTTP Trust Point Configuration** section, enable **Enable Trust Point** to use Certificate Authority servers as trustpoints.
6. From the **Trust Points** drop-down list, choose a trust point.
7. In the **Timeout Policy Configuration** section, enter the HTTP timeout policy in seconds. Enter a value between one to 600 seconds.
8. Enter the number of minutes of inactivity allowed before the session times out. Enter a value between 180 and 1200 seconds.
9. Enter the server life time in seconds. Enter a value between one and 86400 seconds.
10. Enter the maximum number of requests the device can accept. Valid values range from one and 86400 requests.
11. Save the configuration.

The device is configured for HTTP or HTTPS access according to your specified settings.

Configure the HTTP server (CLI)

Enable HTTP or HTTPS server functionality on your device to support local web authentication.

Local web authentication requires the HTTP server to be enabled on the controller.

You can configure both HTTP and HTTPS servers to support device management and user authentication.

Both HTTP and HTTPS servers can be configured to support device management and user authentication.

Note that some browsers, such as the Apple psuedo-browser, do not open if you configure only the **ip http secure-server** command. You should also configure the **ip http server** command.

Procedure

---

1. Enable the HTTP server. The local web authentication feature uses the HTTP server to communicate with the hosts for user authentication.

   Example

   ```
   Device(config)# ip http server
   ```

2. Enable HTTPS.

   Example

   ```
   Device(config)# ip http secure-server
   ```

   You can configure custom authentication proxy web pages or specify a redirection URL for successful login.

> **Note**
>
> To ensure secure authentication when you enter the **ip http secure-server** command, the login page is always in HTTPS (secure HTTP) even if the user sends an HTTP request.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The controller is now configured with the HTTP or HTTPS or both. This enables local web authentication and secure browser access for users.

Allow special characters for serial port

Allow Special Characters for Serial Port using commands.

Configure the serial port to support special characters for advanced device communication.

Use this procedure when the connected device or application must process special characters on the serial console port.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the primary terminal line number.

Example

```
Device(config)# line console 0
```

3. Configure the time to disconnect idle EXEC sessions using the **exec-timeout** *mins sec* command.

Example

```
Device(config-line)# exec-timeout 12 0
```

4. Configure login authentication checking using the **login authentication** *word* **default** command.

Example

```
Device(config-line)# login authentication NO_LOGIN
```

You can configure an authentication list with a name or use the default authentication list

5. Configure the character widths of EXEC command characters using the **exec-character-bit 7 8** command.

Example

```
Device(config-line)# exec-character-bit 8
```

6. Configure the stop bits for the console port using the **stopbits 1 1.5 2** command.

Example

```
Device(config-line)# stopbits 1
```

7. Return to privileged EXEC mode.

Example

```
Device(config-line)# end
```

The serial port is now configured to support special characters according to your settings.

Allow special characters for VTY port

Allow Special Characters for VTY Port using commands.

Enable the use of special (non-standard) characters in the banner text for Virtual Teletype (VTY) ports, which enhances customization options and supports global character sets.

You can allow special (non-standard) characters in the banner text for Virtual Teletype (VTY) ports. This lets you customize banners and support global character sets.

You may want to allow special characters in the banner displayed on the VTY port—for example, to include accented letters, non-English text, or symbols for branding or user communication.

Before you begin

Ensure you have determined the desired banner text and any required special characters.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Create a parameter map and enter parameter-map webauth configuration mode.

Example

```
Device(config)# parameter-map type webauth global
```

3. Create a custom banner using the **banner text** *text* command.

Example

```
Device(config-params-parameter-map)# banner text #Hêllö#
```

You can create a custom banner (of up to 400 characters) by entering *c <banner-text> c*, where *c* is a delimiting character.

If the banner text exceeds 400 characters (400 characters is about 250 words), you see an error message and the configuration is rejected. The parser limits each line to 254 characters (about 150 words), including CLI keywords. If you need more than 254 characters, split the banner text into multiple lines.

The webauth login page displays only the default banner strings, if banner command is not configured.

4. Return to privileged EXEC mode.

Example

```
Device(config-params-parameter-map)# end
```

You can now use special characters in the VTY port banner. When users connect through VTY, they see your custom banner.

HTTP and HTTPS access modes for web authentication

The table describes the various CLI combinations.

You can control HTTP and HTTPS access separately for device management (admin) and web authentication by configuring web authentication using CLI command combinations. The main commands involved are:

- **ip http server** : Enables HTTP access to the device for administration.
- **ip http secure-server** : Enables HTTPS access to the device for administration and is required for HTTPS access to web authentication.
- **webauth-http-enable** (under **parameter-map type webauth global)** : Allows HTTP access for web authentication without enabling HTTP access for administration. This command is not enabled by default.
- **secure-webauth-disable** (under **parameter-map type webauth global**): Disables HTTPS access for web authentication only. This command is not enabled by default.

CLI combinations

The table describes the possible CLI combinations.

Admin (Device Management)		Web Authentication		Required Configurations	
HTTP Access	**HTTPS Access**	**HTTP Access**	**HTTPS Access**	**Admin**	**Web Authentication**

No	Yes	Yes	Yes	`no ip http server`
				`ip http secure-server`
					`no ip http server`
					`ip http secure-server`
					`parameter-map type webauth global`
					`webauth-http-enable`

No	Yes	No	Yes	`no ip http server` `ip http secure-server`	`no ip http server` `ip http secure-server`

No	Yes	Yes	No	`no ip http server`
				`ip http secure-server`
					`no ip http server`
					`ip http secure-server`
					`parameter-map type webauth global`
					`webauth-http-enable`
					`secure-webauth-disable`

No	Yes	No	No	`no ip http server`
				`ip http secure-server`
					`no ip http server`
					`ip http secure-server`
					`parameter-map type webauth global`
					`secure-webauth-disable`

No	No	No	Yes	`no ip http server` `no ip http secure-server`	Not supported
No	No	Yes	No		

Admin (Device Management)		Web Authentication		Required Configurations	
HTTP Access	**HTTPS Access**	**HTTP Access**	**HTTPS Access**	**Admin**	**Web Authentication**

				`no ip http server`
				`no ip http secure-server`
					`no ip http server`
					`no ip http secure-server`
					`parameter-map type webauth global`
					`webauth-http-enable`

Yes	No	Yes	No	`ip http server` `no ip http secure-server`	`ip http server` `no ip http secure-server`

Yes	Yes	Yes	No	`ip http server`
				`ip http secure-server`
					`ip http server`
					`ip http secure-server`
					`parameter-map type webauth global`
					`secure-webauth-disable`

- To enable HTTP access for web authentication without also enabling HTTP administrative access, configure **webauth-http-enable** in **parameter-map type webauth global** mode. Do not use **ip http server** .
- HTTPS access for web authentication always requires **ip http secure-server** .
- To disable HTTPS access for web authentication, use the **secure-webauth-disable** command.
- These combinations allow granular control over how users can access the device for both management and web authentication purposes.

Limitations

These guidelines and limitations help you configure HTTP and HTTPS requests for web authentication.

- Enable HTTPS for device management before you enable HTTPS web authentication
- If **secure-webauth-disable** is configured and the client's initial request is `https://< >`, central web authentication cannot be performed.

Configure HTTP and HTTPS requests for web authentication (CLI)

Configure HTTP and HTTPS server parameters to support secure web authentication.

Perform this configuration when you need to enable or disable HTTP or HTTPS web authentication features on your device.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Set the HTTP server to default.

   Example

   ```
   Device(config)# no ip http server
   ```

4. Enable the HTTP server or the HTTP secure server using the **ip http {server | secure-server}** command.

   Example

   ```
   Device(config)# ip http server
   ```

5. Enable the global parameter map mode.

   Example

   ```
   Device(config)# parameter-map type webauth global
   ```

6. Disable HTTP secure server for web authentication.

   Example

   ```
   Device(config-params-parameter-map)# secure-webauth-disable
   ```

7. Enable HTTP server for web authentication.

   Example

   ```
   Device(config-params-parameter-map)# webauth-http-enable
   ```

The device is configured to send HTTP requests, HTTPS requests, or both to the web authentication module according to your settings.

Create Parameter Maps

Create a parameter map (GUI)

Define criteria-based policies to control device and user access within the local policy framework.

Use this task to create a parameter map by specifying match criteria and associating service templates. This enables dynamic policy application based on device type, user role, and other attributes.

Before you begin

Ensure you have the required policy details and service templates ready.

Procedure

1. Choose **Configuration** > **Security** > **Local Policy**.
2. Click **Add**.
3. Click **Policy Map**.
4. Enter **Policy Map Name**.
5. In the **Match Criteria List** settings, click **Add**.
6. In the **Add Match Criteria** settings, choose the service template from the **Service Template** drop-down list.
7. Choose the filters from **Device Type**, **User Role**, **User Name**, **OUI**, and **MAC Address** drop-down lists.
8. Click **Add Criteria**.
9. Click **Apply to Device**.

The parameter map is created and applied, enabling policy enforcement based on the selected criteria.

Configure local web authentication (GUI)

Enable local web authentication for your network using GUI.

Use this task to set authentication parameters, banner messages, and related settings for web authentication.

Procedure

1. Choose **Configuration** > **Security** > **Web Auth**.
2. On the **Web Auth** page, click **Add**.
3. In the **Create Web Auth Parameter** window that is displayed, enter a name for the parameter map.
4. In the **Maximum HTTP Connections** field, enter the maximum number of HTTP connections that you want to allow.
5. In the **Init-State Timeout** field, enter the timeout duration. The timer expires if the user does not enter valid credentials on the login page
6. Choose the type of Web Auth parameter.
7. Click **Apply to Device**.
8. On the **Web Auth** page, click the name of the parameter map.
9. In the **Edit WebAuth Parameter** window that is displayed, choose the required **Banner Type**.
   - If you choose **Banner Text**, enter the required banner text to be displayed.
   - If you choose **File Name**, specify the path of the file from which the banner text has to be picked up.
10. Enter the virtual IP addresses as required.
11. Set the status of **WebAuth Intercept HTTPS**, **Captive Bypass Portal**, and **Watch List Enable** as required.
12. In the **Watch List Expiry Timeout** field, enter the time in seconds after which the watch list should time out.

13. Set the status for **Disable Success Window**, **Disable Logout Window**, and **Login Auth Bypass for FQDN**, as required.
14. Check the **Sleeping Client Status** check box to enable authentication of sleeping clients. Specify the **Sleeping Client Timeout** in minutes. The valid range is 10 to 43,200 minutes.
15. Click the **Advanced** tab.
16. In the **Redirect for log-in** field, enter the name of the external server to which to send the login request.
17. In the **Redirect On-Success** field, enter the name of the external server to redirect after a successful login.
18. In the **Redirect On-Failure** field, enter the name of the external server to redirect after a login failure.
19. To configure external local web authentication, perform these steps:
    a) Under **Redirect to External Server** in the **Redirect Append for AP MAC Address** field, enter the AP MAC address.
    b) In the **Redirect Append for Client MAC Address** field, enter the client MAC address.
    c) In the **Redirect Append for WLAN SSID** field, enter the WLAN SSID.
    d) In the **Portal IPV4 Address** field, enter the IPv4 address of the portal to send redirects.
    e) In the **Portal IPV6 Address** field, enter the IPv6 address of the portal to send redirects if you are using an IPv6 address.
20. To configure customized local web authentication, perform these steps:
    a) Under **Customized Page**, specify the following pages:
        - **Login Failed Page**
        - **Login Page**
        - **Logout Page**
        - **Login Successful Page**
21. Click **Update & Apply**.

Local web authentication is enabled with your specified settings.

Configure internal local web authentication (CLI)

Set up internal local web authentication on your device using CLI.

Procedure

In the global configuration mode, create a parameter map

Example

```
Device(config)# parameter-map type webauth sample
```

Creates the parameter map.

The name of the parameter map must not exceed 99 characters.

You have configured internal local web authentication.

The device prompts clients to authenticate through the web portal. After authentication, the device grants full network access.

Configure the customized local web authentication (CLI)

Configure custom local web authentication workflow on a Cisco device by specifying custom portal pages using CLI.

Perform this procedure to offer users a personalized login, success, and failure experience during web authentication.

Before you begin

- Ensure you have valid HTML files for login, success, expired, and failure pages uploaded to device storage.
- Configure a virtual IP in the global parameter map to use the customized web authentication bundle.

Procedure

1. Configure the webauth type parameter.

   Example

   ```
   Device(config)# parameter-map type webauth parameter-map-name
   ```

   Configure a virtual IP in the global parameter map so the device uses the customized web authentication bundle.

2. Configures webauth sub-types using the **type** {**authbypass** | **consent** | **webauth** | **webconsent**} command.

   Example

   ```
   Device(config-params-parameter-map)# type webauth
   ```

   The types are **passthru**, **consent**, **webauth**, or **webconsent**.

3. Configure the customized login page using the **custom-page login device** *html-filename* command.

   Example

   ```
   Device(config-params-parameter-map)# custom-page login device
   bootflash:login.html
   ```

4. Configure the customized login expiry page using the **custom-page login expired device** *html-filename* command.

   Example

   ```
   Device(config-params-parameter-map)# custom-page login expired device
   bootflash:loginexpired.html
   ```

5. Configure the customized login success page using the **custom-page success device** *html-filename* command.

   Example

   ```
   Device(config-params-parameter-map)# custom-page success device
   bootflash:loginsuccess.html
   ```

6. Configure the customized login failure page using the **custom-page failure device** *html-filename* command.

Example

```
Device(config-params-parameter-map)# custom-page failure device
bootflash:loginfail.html
```

You have configured the customized local web authentication portal. Users can see the specified custom pages during authentication.

Configure the external local web authentication (CLI)

Configure the External Local Web Authentication using commands.

Enable external local web authentication on your device by configuring the required CLI parameters.

Use this procedure to set up external local web authentication settings, including parameter maps and redirect URLs, using the CLI.

Before you begin

Gather the parameter map name and redirect URLs.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the webauth type parameter.

   Example

   ```
   Device(config)# parameter-map type webauth sample
   ```

3. Configure web authentication subtypes by using the **type** {**authbypass** | **consent** | **webauth** | **webconsent**} command.

   Example

   ```
   Device(config-params-parameter-map)# type webauth
   ```

4. Configure the redirect URL for the login, failure, and success pages using the **redirect** [**for-login** | **on-failure** | **on-success**] *URL* command.

   Example

   ```
   Device(config-params-parameter-map)# redirect for-login
   http://www.cisco.com/login.html
   ```

> **Note**
>
> In the redirect URL, you need to press *Ctrl+v* and type *?* to configure the *?* character.
>
> The *?* character is commonly used in URL when ISE is configured as an external portal.

5. Configure the external portal IPv4 address using the **redirect portal** {**ipv4** | **ipv6**} *ip-address* command.

   Example

   ```
   Device(config-params-parameter-map)# redirect portal ipv4 23.0.0.1
   ```

   When using FQDN, use an IP address associated with the domain. If the domain resolves to more than one IP address, use the FQDN URL instead of an individual IP address.

6. Return to privileged EXEC mode.

   Example

   ```
   Device(config-params-parameter-map)# end
   ```

You have configured external local web authentication. Your device redirects users to the correct portal for authentication events, based on your parameter map and settings.

Configure the web authentication WLANs

Configure the Web Authentication WLANs using commands.

Configure a WLAN with web authentication security using CLI. Map authentication lists and parameter maps using the CLI.

Perform this task to set up a WLAN that uses web authentication, specifying key identifiers and settings through the CLI on your network device.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

Example

```
Device(config)# wlan wlan-name wlan-id SSID-name
```

3. Disable WPA security.

   Example

   ```
   Device(config-wlan)# no security wpa
   ```

4. Enable web authentication for WLAN.

   Example

   ```
   Device(config-wlan)# security web-auth
   ```

5. Enable web authentication for WLAN using the **security web-auth** {**authentication-list** *authentication-list-name* | **parameter-map** *parameter-map-name*} command.

   Example

   ```
   Device(config-wlan)# security web-auth authentication-list webauthlistlocal
   ```

   ```
   Device(config-wlan)# security web-auth parameter-map sample
   ```

   Here is a description of some of the parameters.

   - **authentication-list** *authentication-list-name*: Sets the authentication list for IEEE 802.1x.
   - **parameter-map** *parameter-map-name*: Configures the parameter map.

   > **Note**
   >
   > When **security web-auth** is enabled, you can map the default **authentication-list** and global **parameter-map**. This is applicable for authentication-list and parameter-map that are not explicitly mentioned.

6. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wlan)# end
   ```

The WLAN is configured with web authentication security and the desired authentication and parameter settings.

Configure pre-auth web authentication ACL (GUI)

Configure Pre-Auth Web Authentication ACL using GUI.

Map a pre-authentication access control list (ACL) to a WLAN to control network access for users before authentication.

Use this procedure to enforce security policies by restricting network access to specified resources while users are in the pre-authenticated state on a wireless LAN.

Before you begin

Ensure that you have configured an ACL and a WLAN.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click the name of the WLAN.
3. In the **Edit WLAN** window, click the **Security** tab and then click the **Layer3** tab.
4. Click **Show Advanced Settings**.
5. In the **Preauthenticaion ACL** section, choose the appropriate ACL to map to the WLAN.
6. Click **Update & Apply to Device**.

When you connect to this WLAN, you must adhere to the access restrictions defined by the ACL until authentication is complete.

Configure pre-authentication web authentication ACL (CLI)

Configure Pre-Auth Web Authentication ACL using commands.

Set up a pre-authentication web authentication access control list (ACL) and apply it to a WLAN using CLI commands. This configuration ensures only authorized traffic passes through before web authentication occurs.

Use this task to control the network traffic permitted before clients authenticate on a WLAN. The ACL defines which clients and protocols are permitted through during the web authentication process.

Before you begin

- Gather the required network and client information.
- Determine the ACL rules (permit or deny) and relevant addresses.

Procedure

1. Enters global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create an ACL list using the **access-list** *access-list-number* {**deny** | **permit**} *hostname source-wildcard-bits* command.

Example

```
Device(config)# access-list 2 deny your_host 10.1.1.1 log
```

The *access-list-number* is a decimal number from one to 99, 100 to 199, 300 to 399, 600 to 699, 1300 to 1999, 2000 to 2699, or 2700 to 2799.

Enter **deny** or **permit** to specify whether to deny or permit if the conditions are matched.

The *source* is the source address of the network or host from which the packet is being sent specified as:

- The 32-bit quantity in dotted-decimal format.
- The keyword any as an abbreviation for *source* and *source-wildcard* of 0.0.0.0 255.255.255.255. You do not need to enter a source-wildcard.
- The keyword host as an abbreviation for *source* and *source-wildcard* of source 0.0.0.0.

(Optional) The *source-wildcard* applies wildcard bits to the source.

> **Note**
>
> The AP forwards traffic if it matches any of the ACLs applied in the pre-authentication ACLs. Use bidirectional rules for clients in web authentication pending state and for downstream traffic.

3. Create the WLAN.

Example

```
Device(config)# wlan mywlan 34 mywlan-ssid
```

profile-name is the WLAN name which can contain up to 32 alphanumeric characters.

wlan-id is the wireless LAN identifier. The valid range is from one to 512.

ssid-name is the SSID which can contain 32 alphanumeric characters.

4. Map the ACL to the web auth WLAN.

Example

```
Device(config-wlan)# ip access-group web name
```

access-list-name is the IPv4 ACL name or ID.

5. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The ACL is configured and mapped to the WLAN. Only traffic that matches the permitted criteria passes before web authentication.

Configure the maximum web authentication request retries

Configure the Maximum Web Authentication Request Retries.

Set the maximum number of web authentication request retries to define how many times the system attempts authentication before it stops.

Configure this setting to adjust the tolerance for failed web authentication attempts, which can improve network security and user experience.

Before you begin

Ensure you are in global configuration mode on your device.

Procedure

1. Configure the maximum web authentication request retries.

   Example

   ```
   Device(config)# wireless security web-auth retries  number
   ```

   number is the maximum number of web authentication request retries. The valid range is 0-20.

2. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

You have configured the specified maximum number of web authentication request retries.

Configure a local banner in web authentication page (GUI)

Configure a Local Banner in Web Authentication Page using GUI.

Present a custom banner to users on the web authentication page to meet organizational messaging or compliance requirements.

Use this task to configure a banner that will display on the login page for web authentication sessions.

Before you begin

Procedure

1. Choose **Configuration** > **Security** > **Web Auth**.
2. In the **Webauth Parameter Map** tab, click the parameter map name. The **Edit WebAuth Parameter** window is displayed.
3. In the **General** tab and choose the required Banner Type:
   - If you choose **Banner Text**, enter the required banner text to be displayed.
   - If you choose **File Name**, specify the path of the file from which the banner text has to be picked up.
4. Click **Update & Apply**.

The specified banner displays on the web authentication page as configured.

Configure a local banner in web authentication page (CLI)

Configure a Local Banner in Web Authentication Page using commands.

Present a custom banner to users on the Web Authentication page to meet organizational messaging or compliance requirements.

Use this task to configure a banner that displays on the login page for web authentication sessions.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the web authentication parameters. Enters the parameter map configuration mode.

   Example

   ```
   Device(config)# parameter-map type webauth param-map
   ```

3. Enable the local banner using the **banner** *file* | *banner-text title* command.

   Example

   ```
   Device(config-params-parameter-map)# banner http C My Switch C
   ```

   Create a custom banner by entering *C banner-text C* (where *C* is a delimiting character), or *file* that indicates a file (for example, a logo or text file) that appears in the banner, or *title* that indicates the title of the banner.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-params-parameter-map)# end
   ```

The specified banner displays on the web authentication page as configured.

Configure Type WebAuth, Consent, or both

Configure Type WebAuth, Consent, or Both.

Configure a parameter map to use webauth type, consent, or webconsent login types.

Use this configuration to enable flexible guest access authentication for users on supported devices.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the Webauth type parameter.

   Example

   ```
   Device(config)# parameter-map type webauth webparalocal
   ```

3. Configure webauth type to Consent. You can configure the type as Webauth, Consent, or both (Webconsent).

   Example

   ```
   Device(config-params-parameter-map)# type consent
   ```

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-params-parameter-map)# end
   ```

5. Display the configuration details.

   Example

   ```
   Device(config)#show running-config | section parameter-map type webauth test
   ```

The parameter map is configured to use Webauth, Consent, or Webconsent types as specified and is ready for client authentication.

Configure preauthentication ACL

Configure Preauthentication ACL using commands.

Set up a preauthentication access control list (ACL) to restrict network access prior to client authentication.

Use this task when you need to limit which resources clients can reach before they have authenticated on a WLAN.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN you want to configure.

   Example

   ```
   Device(config)# wlan ramban
   ```

3. Disable the WLAN.

   Example

   ```
   Device(config-wlan)# shutdown
   ```

4. Configure the ACL to apply before authentication.

   Example

   ```
   Device(config-wlan)# ip access-group web preauthrule
   ```

5. Enable the WLAN again.

   Example

   ```
   Device(config)# no shutdown
   ```

6. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wlan)# end
   ```

7. Display the configuration details for the WLAN

   Example

   ```
   Device# show wlan name wlan-name
   ```

The preauthentication ACL is now active on the WLAN, restricting client access prior to authentication.

Configure trustpoint for local web authentication

Configure TrustPoint for Local Web Authentication using commands.

Configure a trustpoint on your controller to support secure local web authentication.

Set up a trustpoint so the controller can present a domain-specific certificate. Client browsers recognize and accept this certificate during redirection to the portal (for example, example.com).

Before you begin

Ensure that a certificate is installed on your controller.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create the parameter map.

   Example

   ```
   Device(config)# parameter-map type webauth global
   ```

3. Configure trustpoint for local web authentication.

   Example

   ```
   Device(config-params-parameter-map)# trustpoint trustpoint-name
   ```

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-params-parameter-map)# end
   ```

During local web authentication, the controller presents the specified domain-specific certificate. Clients' browsers then recognize and accept the portal redirection.

Configuration examples for local web authentication

-

Example: obtain a web authentication certificate

Obtaining Web Authentication Certificate example.

This example shows how to obtain web authentication certificate.

```
DeviceDevice# configure terminal
Device(config)# crypto pki import cert pkcs12
tftp://10.1.0.100/ldapserver-cert.p12 cisco
Device(config)# end
Device# show crypto pki trustpoints cert
 Trustpoint cert:
    Subject Name:
```

```
    e=rkannajr@cisco.com

 security wpa wpa1
 security wpa wpa1 ciphers aes
 security wpa wpa1 ciphers tkip
 security web-auth authentication-list test
 security web-auth parameter-map test
 session-timeout 1800
 no shutdown

Device# show running-config | section parameter-map type webauth test
parameter-map type webauth test
 type webauth
```

Example: choosing a CWA login page from an IPv4 external web server

Choose a Customized Web Authentication Login Page from an IPv4 External Web Server example.

This example shows how to choose a customized web authentication login page from an IPv4 external web server.

```
Device# configure terminal
Device(config)# parameter-map type webauth global
Device(config-params-parameter-map)# virtual-ip ipv4 192.0.2.1.
Device(config-params-parameter-map)# parameter-map type webauth test
Device(config-params-parameter-map)# type webauth
Device(config-params-parameter-map)# redirect for-login
http://9.1.0.100/login.html
Device(config-params-parameter-map)# redirect portal ipv4 9.1.0.100
Device(config-params-parameter-map)# end
Device# show running-config | section parameter-map
parameter-map type webauth global
virtual-ip ipv4 192.0.2.1.
parameter-map type webauth test
type webauth
redirect for-login http://10.1.0.100/login.html
redirect portal ipv4 10.1.0.100
security web-auth parameter-map rasagna-auth-map
security web-auth parameter-map test
```

Example: choose a customized web authentication login page from an IPv6 external web server

Choose a Customized Web Authentication Login Page from an IPv6 External Web Server example.

This example shows how to choose a customized web authentication login page from an IPv6 external web server.

```
Device# configure terminal
Device(config)# parameter-map type webauth global
Device(config-params-parameter-map)# virtual-ip ipv6 2001:DB8::/48
Device(config-params-parameter-map)# parameter-map type webauth test
Device(config-params-parameter-map)# type webauth
Device(config-params-parameter-map)# redirect for-login
http://9:1:1::100/login.html
```

```
Device(config-params-parameter-map)# redirect portal ipv6 9:1:1::100
Device(config-params-parameter-map)# end
Device# show running-config | section parameter-map
parameter-map type webauth global
virtual-ip ipv6 2001:DB8::/48
parameter-map type webauth test
type webauth
redirect for-login http://10:1:1::100/login.html
redirect portal ipv6 10:1:1::100
security web-auth parameter-map rasagna-auth-map
security web-auth parameter-map test
```

Example: assigning login, login failure, and logout pages per WLAN

Assign Login, Login Failure, and Logout Pages per WLAN example.

This example shows how to assign login, login failure and logout pages per WLAN.

```
Device# configure terminal
Device(config)# parameter-map type webauth test
Device(config-params-parameter-map)# custom-page login device
flash:loginsantosh.html
Device(config-params-parameter-map)# custom-page login expired device
flash:loginexpire.html
Device(config-params-parameter-map)# custom-page failure device
flash:loginfail.html
Device(config-params-parameter-map)# custom-page success device
flash:loginsucess.html
Device(config-params-parameter-map)# end
Device# show running-config | section parameter-map type webauth test
 parameter-map type webauth test
 type webauth
 redirect for-login http://10.1.0.100/login.html
 redirect portal ipv4 10.1.0.100
 custom-page login device flash:loginsantosh.html
 custom-page success device flash:loginsucess.html
 custom-page failure device flash:loginfail.html
 custom-page login expired device flash:loginexpire.html
```

Example: configure preauthentication ACL

Configuring Preauthentication ACL example.

This example shows how to configure preauthentication ACL.

```
Device# configure terminal
Device(config)# wlan fff
Device(config-wlan)# shutdown
Device(config-wlan)# ip access-group web preauthrule
Device(config-wlan)# no shutdown
Device(config-wlan)# end
Device# show wlan name fff
```

Example: configure webpassthrough

Configure Webpassthrough example.

This example shows how to configure webpassthrough.

```
Device# configure terminal
Device(config)# parameter-map type webauth webparalocal
Device(config-params-parameter-map)# type consent
Device(config-params-parameter-map)# end
Device# show running-config | section parameter-map type webauth test
 parameter-map type webauth test
 type webauth
 redirect for-login http://10.1.0.100/login.html
 redirect portal ipv4 10.1.0.100
```

Verify web authentication type

Verify Web Authentication Type.

To verify the web authentication type, run the command:

```
Device# show parameter-map type webauth all
Type Name
--------------------------------
Global global
Named webauth
Named ext
Named redirect
Named abc
Named glbal
Named ewa-2
```

```
Device# show parameter-map type webauth global
Parameter Map Name : global
Banner:
Text : CisCo
Type : webauth
Auth-proxy Init State time : 120 sec
Webauth max-http connection : 100
Webauth logout-window : Enabled
Webauth success-window : Enabled

```

External Web Authentication

Explains external web authentication mechanisms for WLAN clients, providing instructions to configure single or multiple WebAuth servers and wired guest EWA using CLI procedures.

Configure EWA with single WebAuth server address and default ports (80/443) (CLI)

The task file describes how to configure External Web Authentication (EWA) with single WebAuth server address and default ports (80/443).

Configure External Web Authentication (EWA) on your device to use a single WebAuth server address with default ports (80 or 443).

Use this procedure to redirect guest WLAN clients to a specific WebAuth portal using default HTTP or HTTPS ports.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Define the authentication method at login.

   Example

   ```
   Device(config)# aaa authentication login WEBAUTH local
   ```

3. Create the parameter map using the **parameter-map type webauth** *parameter-map-name* command.

   Example

   ```
   Device(config)# parameter-map type webauth ISE-Ext-Webauth_IP
   ```

   The *parameter-map-name* must not exceed 99 characters.

4. Configure the webauth type parameter.

   Example

   ```
   Device(config-params-parameter-map)# type webauth
   ```

5. Configure the URL string for redirect during login using the **redirect for-login** *URL-String*command.

   Example

   ```
   Device(config-params-parameter-map)#  redirect for-login
   https://192.168.0.98:443/portal/PortalSetup.action?portal=ad64b062-1098-11e7-8591-005056891b52
   ```

6. Configure the external portal IPv4 address.

   Example

   ```
   Device(config-params-parameter-map)# redirect portal ipv4 192.168.0.98
   ```

7. Return to global configuration mode.

   Example

   ```
   Device(config-params-parameter-map)# exit
   ```

8. Configure a WLAN using the **wlan** *wlan-name wlan-id SSID-name* command.

   Example

   ```
   Device(config)#  wlan EWLC3-GUEST 3 EWLC3-GUEST
   ```

9. Disable adaptive 11r.

   Example

   ```
   Device(config-wlan)# no security ft adaptive
   ```

10. Disable WPA security.

    Example

    ```
    Device(config-wlan)# no security wpa
    ```

11. Disable WPA2 security.

    Example

    ```
    Device(config-wlan)# no security wpa wpa2
    ```

12. Disable WPA2 ciphers for AES.

    Example

    ```
    Device(config-wlan)# no security wpa wpa2 ciphers aes
    ```

13. Disable security AKM for dot1x.

    Example

    ```
    Device(config-wlan)# no security wpa akm dot1x
    ```

14. Enable web authentication for WLAN.

Example

```
Device(config-wlan)# security web-auth
```

15. Enable authentication list for dot1x security using the **security web-auth authentication-list** *authenticate-list-name* command.

Example

```
Device(config-wlan)# security web-auth authentication-list WEBAUTH
```

16. Configure the parameter map using the **security web-auth parameter-map** *parameter-map-name* command.

Example

```
Device(config-wlan)# security web-auth parameter-map ISE-Ext-Webauth_IP
```

> **Note**
>
> If parameter map is not associated with a WLAN, the configuration uses the global parameter map.

17. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

Once enabled for the configured WLAN, web authentication redirects clients to the specified WebAuth portal using default ports.

Configure EWA with multiple web servers and/or ports different than default (80/443)

Configure EWA with Multiple Web Servers and/or Ports Different than Default (80/443) using commands.

Configure an External Web Authentication (EWA) workflow to support multiple web servers and custom port numbers using CLI.

Enable guest access using EWA if there are multiple external web servers or if web authentication must use ports other than the default ports of 80 or 443.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Define an extended IPv4 access list using a name, and enters access-list configuration mode.

Example

```
Device(config)# ip access-list extended preauth_ISE_Ext_WA
```

3. Permit access from any host to the first external web server port number 8443.

Example

```
Device(config)# access-list-number permit tcp any host
external_web_server_ip_address1 eq port-number
```

Example

```
Device(config)# 10 permit tcp any host 192.168.0.98 eq 8443
```

4. Permit access from any host to the second external web server port number 8443.

Example

```
Device(config)# access-list-number permit tcp any host
external_web_server_ip_address2 eq port-number
```

Example

```
Device(config)# 10 permit tcp any host 192.168.0.99 eq 8443
```

5. Permit DNS UDP traffic.

Example

```
Device(config)# access-list-number permit udp any eq domain
```

Example

```
Device(config)# 20 permit udp any any eq domain
```

6. Permit DHCP traffic using the **bootpc**.

Example

```
Device(config)# 30 permit udp any any eq bootpc
```

Example

```
Device(config)# access-list-number permit udp any any eq bootpc
```

7. Permit DHCP traffic using **bootps**.

Example

```
Device(config)# access-list-number permit udp any any eq bootps
```

Example

```
Device(config)# 40 permit udp any any eq bootps
```

8. Permit the access from the first external web server port 8443 to any host.

Example

```
Device(config)# access-list-number permit tcp any host
external_web_server_ip_address1 eq port-number any
```

Example

```
Device(config)# 50 permit tcp host 192.168.0.98 eq 8443 any
```

9. Permit the access from the second external web server port 8443 to any host.

Example

```
Device(config)# access-list-number permit tcp any host
external_web_server_ip_address2 eq port-number any
```

Example

```
Device(config)# 50 permit tcp host 192.168.0.99 eq 8443 any
```

10. Permit DNS TCP traffic.

Example

```
Device(config)# access-list-number permit tcp any eq domain
```

Example

```
Device(config)# 60 permit tcp any any eq domain
```

11. Deny all the other traffic.

Example

```
Device(config)# access-list-number deny ip any any
```

Example

```
Device(config)# 70 deny ip any any
```

12. Create the WLAN using the **wlan** *wlan-name wlan-id ssid* command.

Example

```
Device(config)# wlan wlan-name wlan-id ssid
```

Example

```
Device(config)# wlan EWLC3-GUEST 3 EWLC3-GUEST
```

13. Configure the IPv4 WLAN web ACL

Example

```
Device(config-wlan)# ip access-group web name
```

The variable *name* specifies the user-defined IPv4 ACL name

14. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

This configuration allows EWA with multiple external web servers and ports. It supports DNS or DHCP traffic and blocks unauthorized traffic.

Configure wired guest EWA with multiple web servers, ports different than default (80/443)

Configure Wired Guest EWA with Multiple Web Servers and/or Ports Different than Default (80/443) using commands.

Configure Wired Guest External Web Authentication (EWA) when using multiple web servers or ports other than the default ports of 80 or 443 using CLI.

Wired Guest LAN profiles do not allow manual ACL assignment directly. To support multiple web servers or custom ports, use the bypass ACL in the global parameter map.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Define an extended IPv4 access list using a name, and enter access-list configuration mode.

Example

```
Device(config)# ip access-list extended BYPASS_ACL
```

3. Allow the traffic to switch centrally.

Example

```
Device(config)# 10 deny ip any host 192.168.0.45
```

4. Allow the traffic to switch centrally

Example

```
Device(config)# access-list-number  deny ip any host hostname
```

Example

```
Device(config)# 20 deny ip any host 4.0.0.1
```

5. Creates a parameter map and enter parameter-map webauth configuration mode.

Example

```
Device(config)# parameter-map type webauth global
```

6. Create a WebAuth bypass intercept using the ACL name.

Example

```
Device(config-params-parameter-map)# webauth-bypass-intercept BYPASS_ACL
```

> **Note**
>
> You cannot manually apply an ACL to the wired guest profile to configure external web authentication with multiple IP addresses or different ports. To work around this, use the bypass ACL in the wired guest profile.

7. Return to privileged EXEC mode.

Example

```
Device(config-params-parameter-map)# end
```

The wired guest profile uses the bypass ACL, enabling external web authentication with multiple web servers or custom ports.

Authenticating sleeping clients

Details authentication strategies for sleeping clients on WLANs, covering mobility guidelines, restrictions, and step-by-step procedures for configuration using GUI and CLI interfaces.

A sleeping client is a wireless device that

- has completed web authentication and been granted guest access
- is allowed to enter sleep mode and wake up without reauthenticating through the login page, and
- the controller stores sleeping client information for a configurable duration before requiring reauthentication.

The valid range is 10 minutes to 43200 minutes, with the default being 720 minutes. You can also configure this duration on WebAuth parameter map that is mapped to a WLAN. The sleeping client timer is activated when conditions such as idle timeout, session timeout, WLAN disabling, or AP nonoperational status occur.

> ⚠ **Caution**
>
> If the MAC address of a client in sleep mode is spoofed, a fake device, such as a laptop, can be mistakenly authenticated.

Feature History

Feature Name	Release	Description
Webauth Sleeping Client Support	Cisco IOS XE 17.1.1s	The web authentication sleeping clients feature supports multiple combinations of authentications for a given client, which are configured on the WLAN profile.

Scenarios where sleeping clients do not need reauthentication

- Suppose there are two controller s in a mobility group. A client that is associated with one controller goes to sleep and then wakes up and gets associated with the other controller .
- Suppose there are three controller s in a mobility group. A client that is associated with the second controller that is anchored to the first controller goes to sleep, wakes up, and gets associated with the third controller .
- A client sleeps, wakes up and gets associated with the same or different export foreign controller that is anchored to the export anchor.

Guidelines for mobility scenarios

- This feature is supported on the FlexConnect scenario with local switching and central authentication.
- L2 roaming in the same subnet is supported.
- Anchor sleeping timer is applicable.
- The sleeping client information is shared between multiple auto anchors when a sleeping client moves from one anchor to another.

Restrictions on authenticating sleeping clients

Authenticating Sleeping Clients restrictions.

- If the MAC address of a client in sleep mode is spoofed, a fake device, such as a laptop, can be mistakenly authenticated.
- The sleep client feature works only for WLAN configured with WebAuth security.
- You can configure the sleeping clients only on a per WebAuth parameter-map basis.
- The authentication of sleeping clients feature is supported only on WLANs that have Layer 3 security enabled.
- When Layer 3 security is enabled, the Authentication, Passthrough, and On MAC Filter failure web policies are supported. The Splash Page Web Redirect web policy is not supported.

- The central web authentication of sleeping clients is not supported.
- The authentication of sleeping clients feature is not supported on guest LANs and remote LANs.
- A guest access sleeping client that has a local user policy is not supported. In this case, the WLAN-specific timer is applied.

Configure authentication for sleeping clients (GUI)

Configure Authentication for Sleeping Clients using GUI.

Enable authentication for sleeping clients to ensure devices can maintain secure network access even after entering sleep mode.

Sleeping clients, such as laptops or mobile devices, periodically enter low-power states. You configure authentication to ensure they reconnect securely and seamlessly when they wake.

Procedure

1. Choose **Configuration** > **Security** > **Web Auth**.
2. In the **Webauth Parameter Map** tab, click the parameter map name. The **Edit WebAuth Parameter** window is displayed.
3. Check **Sleeping Client Status** check box.
4. Click **Update & Apply to Device**.

Authentication for sleeping clients is now enabled. Devices entering sleep mode will reconnect securely without manual intervention.

Configure authentication for sleeping clients (CLI)

Configure Authentication for Sleeping Clients using commands.

Configure authentication parameters to manage sleeping wireless clients and control their session persistence on the device.

Sleeping clients are wireless devices that temporarily disconnect due to power-saving or roaming behaviors. Configuring authentication for sleeping clients ensures they are recognized and handled appropriately during these periods.

Procedure

1. Create a parameter map and enters parameter-map webauth configuration mode.

   Example

   ```
   Device(config)# parameter-map type webauth global
   ```

2. Configure the sleeping client timeout to 100 minutes.

   Example

   ```
   Device(config-params-parameter-map)# sleeping-client timeout 100
   ```

   Valid range is between 10 minutes and 43200 minutes.

> **Note**
>
> If you do not use the timeout keyword, the sleeping client is configured with the default timeout value of 720 minutes.

3. Exit parameter-map webauth configuration mode and returns to privileged EXEC mode.

   Example

   ```
   Device# end
   ```

4. Optional: Show the MAC address of the clients and the time remaining in their respective sessions.

   Example

   ```
   Device# show wireless client sleeping-client
   ```

5. Optional: Delete sleeping client entries from the sleeping client cache.
   - **clear wireless client sleeping-client**–Deletes all sleeping client entries from the sleeping client cache.
   - **clear wireless client sleeping-client mac-address** *mac-addr*–Deletes the specific MAC entry from the sleeping client cache.

   Example

   ```
   Device# clear wireless client sleeping-client
   mac-address 00e1.e1e1.0001
   ```

The device displays the global configuration prompt, allowing you to make configuration changes.

Sleeping Clients With Multiple Authentication

Describes multi-authentication for sleeping clients, outlining mobility support, supported authentication combinations, WLAN configuration for Dot1x, MAC bypass, PSK and LWA, and verification procedures.

Mobility support for sleeping clients

Sleeping Clients Mobility Support.

Feature Name	Release	Description
Mobility support for guest and non guest sleeping clients.	Cisco IOS XE 17.1.1s	Mobility support for guest and non guest sleeping clients.

Supported combinations of multiple authentications

Multiple Authentications Supported Combinations.

Multiple authentication feature supports sleeping clients configured in the WLAN profile.

The table outlines the supported combination of multiple authentications.

Table 113: Supported combinations of multiple authentications

Layer 2	Layer 3	Supported
MAB	LWA	Yes
MAB Failure	LWA	Yes
Dot1x	LWA	Yes
PSK	LWA	Yes

Configure WLAN for 802.1X and local web authentication

Configure WLAN for Dot1x and Local Web Authentication using commands.

Configure a WLAN with both 802.1X authentication and local web authentication on a controller using CLI.

Use this procedure when you need to secure a WLAN such that users can authenticate with their credentials (802.1X) or are redirected to a local web authentication portal. This scenario is common in enterprise or campus environments where both secure and user-friendly authentication methods are required.

Before you begin

Enter the global configuration mode.

Procedure

1. Enter WLAN configuration submode.

   Example

   ```
   Device(config)# wlan wlan-test 3 ssid-test
   ```

   - *profile-name*: Profile name of the configured WLAN.
   - *wlan-id*: Wireless LAN identifier. Range is from one to 512.
   - *SSID_Name*: SSID, which can contain up to 32 alphanumeric characters.

2. Enable security authentication list for dot1x security. The configuration is similar for all dot1x security WLANs.

   Example

   ```
   Device(config-wlan)#  security dot1x authentication-list default
   ```

3. Configure web authentication.

Example

```
Device(config-wlan)#  security web-auth
```

4. Enable authentication list for dot1x security.

Example

```
Device(config-wlan)#  security web-auth authentication-list default
```

5. Map the parameter map.

Example

```
Device(config-wlan)# security web-auth parameter-map global
```

> **Note**
>
> If the parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

6. Enable WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The new WLAN is configured with both dot1x and local web authentication enabled. Users connecting to this SSID can authenticate using their credentials or through the local web portal, according to controller policies.

Configure a WLAN for MAC authentication bypass and LWA

Configure a WLAN for MAC Authentication Bypass and Local Web Authentication using commands.

Set up a WLAN so that client devices are authenticated using MAC authentication bypass and provided local web authentication.

Use this task to configure a secure SSID that allows MAC-based device authentication followed by a web portal login, ensuring flexible and layered network access control.

Before you begin

Prepare the list name for MAC filtering and ensure the web authentication parameter map is defined (or note that the global map will be used).

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enter WLAN configuration submode.

Example

```
Device(config)# wlan wlan-test 3 ssid-test
```

- *profile-name*: Profile name of the configured WLAN.
- *wlan-id*: Wireless LAN identifier. Range is from 1 to 512.
- *SSID_Name*: SSID, which can contain up to 32 alphanumeric characters.

3. Set the MAC filtering parameters using the **mac-filtering** *list-name*

Example

```
Device(config-wlan)#  mac-filtering cat-radius
```

4. Disable security AKM for dot1x.

Example

```
Device(config-wlan)#  no security wpa akm dot1x
```

5. Disable the WPA2 cipher.

Example

```
Device(config-wlan)# no security wpa wpa2 ciphers aes
```

aes–Excryption type that specifies WPA/AES support.

6. Map the parameter map.

Example

```
Device(config-wlan)# security web-auth parameter-map global
```

> **Note**
>
> If parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

7. Enable WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The WLAN is configured to use MAC Authentication Bypass with Local Web Authentication.

Configure a WLAN for local web authentication and MAC filtering

Configure a WLAN for Local Web Authentication and MAC Filtering using commands.

Establish a WLAN profile with local web authentication, including MAC address filtering for enhanced security.

Use this task to set up a WLAN on your Cisco device that requires users to authenticate via a local web portal and applies MAC address filtering as an additional security measure.

Before you begin

- Know the desired SSID name, WLAN ID, and profile name.
- Prepare the MAC filter list name.
- Confirm availability of an authentication parameter map (if needed).

Procedure

1. Enters WLAN configuration submode using the **wlan** *profile-name wlan-id SSID_name* command.

   Example

   ```
   Device(config)# wlan wlan-test 3 ssid-test
   ```

   - *profile-name*: Profile name of the configured WLAN.
   - *wlan-id*: Wireless LAN identifier. Range is from one to 512.
   - *SSID_Name*: SSID, which can contain up to 32 alphanumeric characters.

2. Set the MAC filtering parameters.

   Example

   ```
   Device(config-wlan)#  mac-filtering cat-radius
   ```

3. Disable security Authenticated Key Management (AKM) for dot1x.

   Example

   ```
   Device(config-wlan)#  no security wpa akm dot1x
   ```

4. Disable the WPA2 cipher.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2 ciphers aes
   ```

aes: Excryption type that specifies WPA/AES support.

5. Configure the fallback policy with MAC filtering and web authentication.

Example

```
Device(config-wlan)# security web-auth on-macfilter-failure wlan-id
```

6. Map the parameter map.

Example

```
Device(config-wlan)# security web-auth parameter-map global
```

> **Note**
>
> If the parameter map is not associated with a WLAN, the configuration is considered from the global parameter map

7. Enable WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The WLAN is now configured for local web authentication with MAC filtering, ready for users to connect and authenticate through the portal.

Configure a PSK + LWA in a WLAN

Configure a PSK + LWA in a WLAN using commands.

Set up a WLAN with both a preshared key (PSK) and local web authentication (LWA) using CLI commands.

Use this task to enable secure access for clients on a WLAN using both a PSK and web authentication mechanisms.

Before you begin

- Decide the profile name, WLAN ID, and SSID for the new WLAN.
- Create required authentication lists and parameter maps if not already present.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enter the WLAN configuration sub-mode.

Example

```
Device(config)# wlan wlan-name wlan-id SSID-name
```

3. Disables security AKM for dot1x.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

4. Enables web authentication for a WLAN.

   Example

   ```
   Device(config-wlan)# security web-auth
   ```

5. Disable the WPA2 cipher.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2 ciphers aes
   ```

   aes: Excryption type that specifies WPA/AES support.

6. Configure the preshared key on a WLAN.

   Example

   ```
   Device(config-wlan)# security wpa psk set-key ascii 0 1234567
   ```

7. Configure PSK support.

   Example

   ```
   Device(config-wlan)#security wpa akm psk
   ```

8. Enable the authentication list for dot1x security.

   Example

   ```
   Device(config-wlan)# security web-auth authentication-list default
   ```

9. Map the parameter map.

   Example

   ```
   Device(config-wlan)# security web-auth parameter-map global
   ```

> **Note**
>
> If the parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

The WLAN is configured to use both a preshared key and local web authentication for client access.

Configure a sleeping client

Configure a Sleeping Client using commands.

Configure parameters that determine how long a client device remains in "sleeping" state before timing out, using CLI.

Sleeping clients are devices that temporarily disconnect from the network but retain their association for a defined period, allowing smooth reconnection. You may wish to adjust the sleeping client timeout to optimize performance or manage resource use.

Before you begin

Identify the parameter map (by name or use the global map) you wish to modify.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a parameter map and enters *parameter-map-name* configuration mode using the **parameter-map type webauth** {*parameter-map-name* | **global**} command.

   Example

   ```
   Device(config)# parameter-map type webauth MAP-2
   ```

   The specific configuration commands supported for a **global** parameter map defined with the global keyword differ from the commands supported for a named parameter map defined with the *parameter-map-name* argument.

3. Configure the sleeping client timeout, in minutes using the **sleeping client** [**timeout** *time*] command.

   Example

   ```
   Device(config-params-parameter-map)#  sleeping-client timeout 60
   ```

   The available range for the *time* argument is from 10 to 43200.

> **Note**
>
> If you do not use the **timeout** keyword, the sleeping client is configured with the default timeout value of 720 minutes.

The sleeping client timeout is configured for the specified parameter map.

Verify a sleeping client configuration

Verify a Sleeping Client Configuration.

To verify a sleeping client configuration, use the command:

```
Device# show wireless client sleeping-client
Total number of sleeping-client entries: 1

MAC Address                    Remaining time (mm:ss)
------------------------------------------------------------
2477.031b.aa18                 59:56
```

Multiple Authentication Combinations with 802.1X and LWA

Explains multi-authentication integration of 802.1X and Local Web Authentication, outlining information, limitations, CLI configuration procedures, verification steps, and keyref reuse approaches for policy retention.

Multiauthentication combinations with 802.1X authentication and local web authentication

Multiauthentication Combination with 802.1X Authentication and Local Web Authentication details.

A multiauthentication combination is a network access control strategy that

- allows multiple authentication methods (such as 802.1X and web authentication) to be used in sequence
- enables enforcement of security and user consent policies in wireless networks, and
- supports policy merging to maintain consistent access controls throughout device connections.

Expanded Explanation

In a wireless setup, for example, in a university, clients authenticate through 802.1X authentication. Because the 802.1X (dot1X) authentication process is secure and does not require user intervention, the end-users are unaware of the network that their devices are connected to. This could lead to serious concerns if they connect to the university's wireless network and post inappropriate content or access restricted content.

To avoid this situation, web authentication (webauth) and 802.1X authentication are configured in the network. End-user consent is used as a part of webauth to inform users that they are connected to the university's Wi-Fi network.

When the end-users accept the credentials for consent, AAA policies are not applied. The AAA policies that were applied earlier are deleted, resulting in a VLAN change and client disconnection.

A new command is introduced in Cisco IOS XE Dublin 17.11.1 to fix this issue. When you run the **consent activation-mode merge** command, the policy that is applied through consent is merged with the policy applied for 802.1X or MAC

Authentication Bypass (MAB) authentication, thereby allowing clients to access the network. This command is available in parameter-map mode, which is configured with **type consent** command.

Feature History

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.11.1	Multiauthentication Combination of 802.1X and Local Web Authentication	This feature supports the merging of applied policies during multiauthentication of 802.1X or MAC authentication bypass (MAB) and local web authentication (LWA).

Limitations for multi authentication combination of 802.1X and local web authentication

Multi Authentication Combination of 802.1X and Local Web Authentication limitations.

- It is not possible to configure this feature on the controller GUI.
- SNMP is not supported.
- When the **consent activation-mode merge** command is not configured on the webauth parameter map, the default activation mode is Replace. This means that the user profile for consent replaces all the user profile policies that were previously applied.

Enable the multiauthentication combinations of 802.1X authentication and local web authentication (CLI)

Enable the Multiauthentication Combination of 802.1X Authentication and Local Web Authentication using commands.

Configure multiauthentication by combining 802.1X authentication and local web authentication (LWA) on the device using CLI commands.

Use this procedure when you want to allow users to authenticate through both 802.1X and browser-based local web authentication. This is commonly needed for networks supporting multiple authentication types on a single interface.

Before you begin

Ensure that you have working knowledge of multiauthentication concepts, LWA (consent), and AAA override.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the webauth type parameter. Enters the parameter map configuration mode.

   Example

   ```
   Device(config)# parameter-map type webauth parameter-map1
   ```

3. Configure the type as **consent**.

Example

```
Device(config-params-parameter-map)# type consent
```

4. Enable policy activation mode and merges the previous policy using the **[no] consent {activation-mode merge | email}** command.

   Example

   ```
   Device(config-params-parameter-map)# consent activation-mode merge
   ```

   Run the **no** form of this command to disable the feature.

Multiauthentication combining 802.1X authentication and local web authentication is enabled on the device.

Verify multiauthentication combination with 802.1X authentication and local web authentication

Verify Multiauthentication Combination with 802.1X Authentication and Local Web Authentication.

To verify the multiauthentication combination with 802.1X authentication and LWA, run the command:

```
Device# show parameter-map type webauth lwa-consent
Parameter Map Name                : lwa_consent
  Banner Title                    : Consent Title
  Banner Text                     : Please accept the consent
  Type                            : consent
  Auth-proxy Init State time      : 300 sec
  Webauth max-http connection     : 200
  Webauth logout-window           : Enabled
  Webauth success-window          : Enabled
  Consent Email                   : Disabled
  Activation Mode                 : Merge
  Sleeping-Client                 : Disabled
  Webauth login-auth-bypass:
```

Title

Device

120 Central Web Authentication

Topics:

- Central web authentication

Central web authentication

Central Web Authentication details.

A central web authentication is a wireless security mechanism that

- delegates the user login webpage and credential processing to a centralized authentication server such as Cisco ISE
- initiates user redirection and authentication at Layer 2, often in combination with MAC filtering or 802.1X authentication, and
- uses RADIUS server attributes so that network controllers redirect web traffic to the authentication portal. This approach streamlines access and reduces delays.

- **ISE (Identity Services Engine)**: Cisco's centralized network access policy platform that delivers authentication, authorization, accounting, and guest access functionality.
- **ACL (Access control list)**: A set of rules used to control network traffic and enforce security policies, determining which clients can access which network resources.
- **Change of Authorization (CoA)**: A mechanism to reapply or update authorization parameters dynamically without requiring a new login.

> **Note**
>
> Currently, Cisco Identity Services Engine (ISE) supports only one Attribute-Value Pair (AVP) for Access Control Lists (ACLs), either IPv4 or IPv6. This limitation prevents the simultaneous return of both ACLs within the same authentication profile. As a result, dual-stack clients (devices using both IPv4 and IPv6) can operate within a Central Web Authentication (CWA) flow, but only under specific configurations. To avoid issues, it is recommended to configure a default IPv6 ACL with a 'deny all' rule. This ensures that clients do not encounter connectivity problems while the limitation is addressed through a future feature enhancement

Prerequisite

Cisco ISE

Comparison with other authentication methods

Central web authentication (CWA) lets you manage web-based access for wireless clients through a dedicated authentication portal (typically Cisco ISE). Unlike traditional local web authentication, CWA performs core security and redirection at Layer 2, working with authentication mechanisms such as MAC filtering or 802.1X. The RADIUS server sends specific attributes to the controller, which then redirects web traffic for portal-based login. This approach helps streamline authentication, reduce delays, and improve policy enforcement.

There are multiple methods of web authentication used in wireless environments.

- **Local web authentication (LWA)**: Local web authentication (LWA) is Layer 3 security configured on the controller. The authentication page and pre-authentication ACL are configured locally. The controller intercepts HTTP(S) traffic from the client and redirects the client to an internal authentication web page. The controller authenticates credentials locally or through RADIUS or LDAP.
- **External web authentication (EWA)**: Also configured as Layer 3 security on the controller. The controller intercepts HTTP(S) traffic and redirects the client to a login page hosted on an external web server. Credentials are authenticated by the controller locally or through a RADIUS or LDAP server. The pre-authentication ACL is statically configured on the controller.

- **Central web authentication (CWA)**: Typically configured as Layer 2 security, with the redirection URL and pre-authentication ACL residing on Cisco ISE. During Layer 2 authentication, Cisco ISE pushes the redirection attributes to the controller. The controller redirects all web traffic from the client to the Cisco ISE login page. Cisco ISE then validates the credentials entered by the client through HTTPS and authenticates the user.

This table compares different types of authentication methods used in wireless environments.

Table 114: Difference from other authentication types

Method	Layer	Portal	Credential processing	Key attributes
Local web authentication	Layer 3	Controller	Locally or through RADIUS or LDAP	Controller intercepts traffic
External web authentication	Layer 3	External server	Locally or through RADIUS or LDAP	Static ACLs and external portal
Central web authentication	Layer 2	Cisco ISE	Through Cisco ISE (HTTPS)	Cisco ISE

Analogy: concert tickets

Imagine a concert venue with several ways to check tickets and admit guests. You can have ticket booths at every entrance (local authentication), ticket checkers who send guests to a special desk outside (external authentication), or one main VIP booth at the heart of the venue that handles everyone's tickets and access (central authentication). Let's use this concert analogy to understand central web authentication and other methods.

At your concert venue, central web authentication (CWA) is what happens when, instead of letting every entrance or gate have their own ticket booth, you create one exclusive VIP booth—like Cisco ISE—that manages all ticketing for everyone. Instead of waiting until a guest actually tries to enter through a particular door (the way local booth might do), the venue's security starts checking guests' tickets as soon as they enter the red carpet. The VIP booth can give the gatekeepers special instructions: "If you don't recognize someone's ticket, redirect them straight to me!" This means the main ticketing process is handled efficiently and quickly by one central authority.

Let's look at all the ticketing strategies you could use at your concert:

Local Ticket Booth (Local Web Authentication, LWA): Every entrance has its own mini ticket booth and rules. Guards at the door check tickets and can ask guests for their info. Ticket validation is handled locally at each gate, sometimes via a backstage manager or external system.

External Ticket Desk (External Web Authentication, EWA): Instead of ticket checks at the gate, guests are sent to a desk outside the stadium. The desk is run by another company. The security at the entrance gates redirects guests and the validation can still interact with the backstage manager if needed. Rules for who gets through are set upfront.

VIP Central Ticket Booth (Central Web Authentication, CWA): The gates just check basic details (like guest's wristband color), and anyone who isn't recognized is sent straight to the main VIP booth (Cisco ISE) to have their ticket or credentials checked and get access granted for the whole event.

How to configure ISE

Configuring ISE.

To configure ISE, follow these tasks:

1. Create an authorization profile.
2. Create an authentication rule.

3. Create an authorization rule.

Create an authorization profile

Create an Authorization Profile.

Define an authorization profile for central web authentication with required redirect attributes.

Before you begin

Ensure you have the required access and know the ACL name for redirection.

Procedure

1. Click **Policy**, and click **Policy Elements**.
2. Click **Results**.
3. Expand **Authorization**, and click **Authorization Profiles**.
4. Click **Add** to create a new authorization profile for central web authentication.
5. In the **Name** field, enter a name for the profile. For example, CentralWebAuth.
6. Choose **ACCESS_ACCEPT** from the **Access Type** drop-down list.
7. Check the **Web Redirection (CWA, MDM, NSP, CPP)** check box, and choose **Centralized Web Auth** from the drop-down list.
8. In the **ACL** field, enter the name of the ACL that defines the traffic to be redirected. For example, redirect.
9. In the **Value** field, choose the default or customized values.

   This field defines whether the Cisco ISE displays the default or a custom web portal that the Cisco ISE admin created.

10. Click **Save**.

The authorization profile is created and is available for use in your central web authentication policies.

Create an authentication rule

Create an Authentication Rule.

Define an authentication rule to control network access based on specified conditions.

Use authentication rules to specify how users or devices are authenticated in your policy system. This rule determines which authentication methods and identity sources are applied when network access is requested.

Procedure

1. In the **Policy** > **Authentication** page, click **Authentication**.
2. Enter a name for your authentication rule. For example, MAB.
3. In the If condition field, select the plus (+) icon.
4. Choose **Compound condition**, and choose **Wireless_MAB**.
5. Click the arrow next to **and ...** in order to expand the rule further.
6. Click the + icon in the **Identity Source** field, and choose **Internal endpoints**.
7. Choose **Continue** from the **If user not found** drop-down list.

   A device can be authenticated even if its MAC address is not known when you select this option.

8. Click **Save**.

Your new authentication rule is added to the authentication policy.

Create an authorization rule

Create an Authorization Rule.

Define and enforce policies to control access to network resources for users and devices.

Use authorization rules to allow or deny access based on user, device, or authentication attributes in Cisco ISE.

You can configure many rules in the authorization policy, such as the *MAC not known*.

Procedure

1. Click **Policy** > **Authorization**.
2. In the **Rule Name** field, enter a name. For example: *Mac not known*.
3. In the **Conditions** field, click the plus (+) icon.
4. Choose **Compound Conditions**, and choose **Wireless_MAB**.
5. From the settings icon, select **Add Attribute/Value** from the options.
6. In the **Description** field, choose **Network Access** > **AuthenticationStatus** as the attribute from the drop down list.
7. Choose the **Equals** operator.
8. From the right hand field, choose **UnknownUser**.
9. In the **Permissions** field, choose the name of the authorization profile you had created earlier.

   The Cisco ISE continues even though the user (or MAC) is not known.

   Unknown users now see the login page. When they enter their credentials, the Cisco ISE sends another authentication request. To support guest users, configure a rule to check if the user is in the guest group. For instance, if UseridentityGroup Equals Guest is used, all guests are included in this group.

10. In the **Conditions** field, click the plus (+) icon.
11. Choose **Compound Conditions**, and choose to create a new condition.

    Place the new rule so it is evaluated prior to the *MAC not known* rule.

12. From the settings icon, select **Add Attribute/Value** from the options.
13. In the **Description** field, choose **Network Access** > **UseCase** as the attribute from the drop-down list.
14. Choose the **Equals** operator.
15. From the right hand field, choose **GuestFlow**.
16. In the **Permissions** field, click the plus (+) icon to select a result for your rule.

    You can choose **Standard** > **PermitAccess** option or create a custom profile to return the attributes that you like.

    When the user is authorized on the login page, the Cisco ISE triggers a Change of Authorization (COA). This process restarts Layer 2 authentication. If the user is identified as a guest, the user is authorized.

Cisco ISE evaluates user or device access requests against these rules and enforces the appropriate policy. Unknown users see the login page and, if identified as guests, receive guest access upon authentication.

How to configure central web authentication on the controller

Configure Central Web Authentication on the Controller.

To configure central web authentication on the controller, proceed with these tasks.

1. Configure WLAN.
2. Configure policy profile.
3. Configure redirect ACL.
4. Configure AAA for central web authentication.
5. Configure redirect ACL in Flex profile.

Configure WLAN (GUI)

Configure a WLAN using the GUI.

Set up a new WLAN on your wireless controller using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. In the **WLANs** window, click the name of the **WLAN** or click **Add** to create a new one.
   The **Add/Edit WLAN** window is displayed.
3. In the **Add/Edit WLAN** window, click the **General** tab to configure these parameters.
   - In the **Profile Name** field, enter or edit the name of the profile.
   - In the **SSID** field, enter or edit the SSID name.

     The SSID name is alphanumeric and can be up to 32 characters in length.
   - In the **WLAN ID** field, enter or edit the ID number. The valid range is between one and 512.
   - Select the **802.11** radio band from the **Radio Policy** drop-down list.
   - Using the **Broadcast SSID** toggle button, change the status to either **Enabled** or **Disabled**.
   - Using the **Status** toggle button, change the status to either **Enabled** or **Disabled**.
4. Click the **Security** tab, and then select the **Layer 2** tab to configure these parameters:
   - Select **None** from the **Layer 2 Security Mode** drop-down list. This setting disables Layer 2 security.
   - Enter the **Reassociation Timeout** value, in seconds. This value specifies the duration before a fast transition reassociation times out.
   - Check the **Over the DS** check box to enable Fast Transition over a distributed system.
   - Choose **OWE**. Opportunistic Wireless Encryption (OWE) provides data confidentiality with encryption over the air between an AP radio and a wireless client. OWE Transition Mode ensures backwards compatibility.
   - Choose Fast Transition (802.11r), the IEEE standard for fast roaming. This standard allows the initial handshake with a new AP to occur before the client roams to the target AP. This method is known as Fast Transition.
   - Check the check box to enable MAC filtering in the WLAN.
   - Check the **Lobby Admin Access** check box to enable Lobby Admin access.

5. Click **Save & Apply to Device**.

Configure WLAN (CLI)

Set up a new WLAN on your wireless controller using the CLI.

Before you begin

Enable MAC filtering for Layer 2 authentication to download the redirect URL and ACL.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN.

   Example

   ```
   Device(config)# wlan wlan-name wland-id SSID-name
   ```

   - **wlan-name** is the name of the configured WLAN.
   - **wlan-id** is the WLAN identifier. The range is one to 512.
   - **SSID-name** is the SSID name which can have up to 32 alphanumeric characters.

   If you have already created and configured the WLAN, use the **wlan** *wlan-name* command.

3. Enable MAC filtering on a WLAN.

   Example

   ```
   Device(config-wlan)# mac-filtering name
   ```

   If the authentication list is not already configured, the default authentication list is used when configuring MAC filtering.

4. Disable WPA security.

   Example

   ```
   Device(config-wlan)# no security wpa
   ```

5. Enable the WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

6. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The new WLAN is available and active on the controller.

After completing the WLAN configuration, if the changes are not pushed to all the APs, a syslog message appears.

```
2021/01/06 16:20:00.597927186 {wncd_x_R0-4}{1}: [wlanmgr-db] [20583]: UUID:
0, ra: 0, TID: 0
(note): Unable to push WLAN config changes to all APs, cleanup required for
WlanId: 2, profile: wlan1 state: Delete pending
```

If this syslog message appears for more than six minutes, reload the controller

If the controller does not reload and the syslog message continues to appear, collect the archive logs and wncd core file. Then, raise a case by clicking the link: Support Case Manager.

```
Device# config terminal
            Device(config)# wlan wlanProfileName 1 ngwcSSID
            Device(config-wlan)# mac-filtering default
            Device(config-wlan)# no security wpa
            Device(config-wlan)# no shutdown
            Device(config-wlan)# end
```

Configure policy profile (CLI)

Define and activate a policy profile to control WLAN behavior using the CLI.

Use the CLI to set up policy profiles that govern AAA, NAC, and VLAN assignment for wireless clients on Cisco devices. Apply this procedure when building new WLAN policies or adjusting network admission controls.

Before you begin

- Both NAC and AAA override must be configured in the policy profile for proper CWA operation.
- You need a AAA override to apply policies coming from the AAA or ISE servers. When a redirect URL and redirect ACL is received from the ISE server, NAC is used to trigger the Central Web Authentication (CWA).
- The default policy profile is used for APs not associated with a specific policy.
- Clients may experience VLAN assignment during the final RADIUS access-accept following successful authentication.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the WLAN.

Example

```
Device(config)# wlan wlan-name wland-id SSID-name
```

- **wlan-name** is the name of the configured WLAN.
- **wlan-id** is the WLAN identifier. The range is one to 512.
- **SSID-name** is the SSID name which can have up to 32 alphanumeric characters.

If you have already created and configured the WLAN, use the **wlan** *wlan-name* command.

3. Set the policy profile.

Example

```
Device(config)# wireless profile policy default-policy-profile
```

4. Map the VLAN to a policy profile.

Example

```
Device(config-wireless-policy)# vlan vlan-id
```

If vlan-id is not specified, the default native vlan one is applied. The valid range for vlan-id is one to 4096. Management VLAN is applied if no VLAN is configured on the policy profile.

5. Configure AAA override to apply policies coming from the AAA or ISE servers.

Example

```
Device(config-wireless-policy)# aaa-override
```

6. Configure Network Access Control in the policy profile. NAC is used to trigger the Central Web Authentication (CWA).

Example

```
Device(config-wireless-policy)# nac
```

7. Enable the WLAN.

Example

```
Device(config-wireless-policy)# no shutdown
```

8. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The policy profile is configured and active, applying the desired AAA, NAC, and VLAN parameters to WLAN clients.

```
Device# configure terminal
Device(config)# wireless profile policy default-policy-profile
Device(config-wireless-policy)# vlan 41
Device(config-wireless-policy)# aaa-override
Device(config-wireless-policy)# nac
Device(config-wireless-policy)# no shutdown
Device(config-wireless-policy)# end
```

Configure a policy profile (GUI)

Configure a Policy Profile using GUI.

Create and apply a new policy profile using the GUI.

Use this task to define access and traffic management settings by configuring a policy profile in the system's GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. On the **Policy Profile** page, click **Add**.
3. In the **Add Policy Profile** window, in General Tab, enter a name and description for the policy profile.
4. To enable the policy profile, set **Status** as Enabled.
5. Use the slider to enable or disable **Passive Client** and **Encrypted Traffic Analytics** .
6. Optional: In the **CTS Policy** section, choose the appropriate status for the following:
   - Inline Tagging—a transport mechanism using which a embedded wireless controller, controller, or AP understands the source SGT.
   - SGACL Enforcement
7. Specify a default **SGT**. The valid range is from two to 65519.
8. In the **WLAN Switching Policy** section, choose as required:
   - Central Switching
   - Central Authentication
   - Central DHCP
   - Central Association Enable
   - Flex NAT/PAT
9. Click **Save & Apply to Device**.

The new policy profile is created and applied to the device using your configured settings.

Create redirect ACL

Create Redirect ACL using commands.

Create a redirect access control list (ACL). Direct unauthenticated HTTP and HTTPS traffic to the Cisco Identity Service Engine login page. Allow traffic to Cisco ISE and block other traffic

The redirect ACL is a punt ACL that must be predefined on the controller. For FlexConnect local switching, the ACL must be predefined on the AP. The Authentication, authorization, and accounting (AAA) server server returns only the name of the ACL, not its definition.

The redirect ACL defines traffic matching "deny" statements, allowing this traffic to pass through the data plane. Traffic matching "permit" statements is sent to the control plane for further processing, which includes web interception and redirection.

The redirect ACL includes implicit statements that allow DHCP and DNS traffic to all IP addresses, similar to LWA.

It also ends with an implicit deny statement in the security ACL.

Before you begin

Ensure you have the IP address of your Cisco ISE deployment.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create an extended access list.

   Example

   ```
   Device(config)# ip access-list extended redirect
   ```

   If users are not authenticated, HTTP and HTTPS browsing fails because Cisco ISE uses a redirect ACL (named **`redirect`**).

3. Permit traffic to Cisco ISE and block all other traffic.

   Example

   ```
   Device(config)# deny ip any host ISE-IP-address
   ```

4. Permit traffic to Cisco ISE and all other traffic is blocked.

   Example

   ```
   Device(config)# deny ip host ISE-IP-add any
   ```

   > **Note**
   >
   > This ACL is applicable for both local and flex mode.

5. Redirect all HTTP or HTTPS access to the ISE login page. Port number 80 is used for HTTP, and port number 443 is used for HTTPS, configured with the **permit TCP any any eq `web address/port-number`** command.

Example
In case of HTTP:

```
Device(config)# permit TCP any any eq www
```

```
Device(config)# permit TCP any any eq 80
```

Example
In case of HTTPS:

```
Device(config)# permit TCP any any eq 443
```

To allow traffic to Cisco ISE, configure Cisco ISE before the HTTP or HTTPS ACE entry.

6. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

HTTP

```
Device# configure terminal
Device(config)# ip access-list extended redirect
Device(config)# deny ip any host 123.123.134.112
Device(config)# deny ip host 123.123.134.112 any
Device(config)# permit TCP any any eq www
Device(config)# permit TCP any any eq 80
Device(config)# end
```

HTTPS

```
Device# configure terminal
Device(config)# ip access-list extended redirect
Device(config)# deny ip any host 123.123.134.112
Device(config)# deny ip host 123.123.134.112 any
Device(config)# permit TCP any any eq 443

Device(config)# end
```

Configure AAA for CWA

Configure AAA for Central Web Authentication using commands.

Set up AAA to support Central Web Authentication using CLI.

Central Web Authentication requires proper AAA configuration to enable Change of Authorization (CoA) functions using a RADIUS (Remote Authentication Dial-In User Service) server.

Before you begin

Ensure AAA authentication is configured on your device. For more details, see the *Configuring AAA Authentication* documentation.

Before you begin

Procedure

1. Configure the Change of Authorization (CoA) on the controller.

   Example

   ```
   Device(config)# aaa server radius dynamic-author
   ```

2. Specify a RADIUS client and configure the RADIUS key that is shared between the device and the RADIUS client.

   Example

   ```
   Device(config-locsvr-da-radius)# client ISE-IP-add server-key
   radius-shared-secret
   ```

   ISE-IP-add is the IP address of the RADIUS client.

   server-key is the radius client server-key.

   radius-shared-secret can have these values:

   - **0**–Specifies unencrypted key.
   - **6**–Specifies encrypted key.
   - **7**–Specifies HIDDEN key.
   - **Word**–Unencrypted (cleartext) server key.

   When configuring WSMA data in GUI, ensure that the RADIUS shared secret does not exceed 240 characters.

AAA is configured to support Central Web Authentication with dynamic CoA, enabling secure device communication with the RADIUS server.

```
Device# config terminal
Device(config)# aaa server radius dynamic-author
Device(config-locsvr-da-radius)# client 123.123.134.112 server-key 0 SECRET
Device(config-locsvr-da-radius)# end
```

Configure redirect ACL in flex profile (GUI)

Configure Redirect ACL in Flex Profile using GUI.

Set up a redirect ACL within a flex profile so that APs enforce specified access control and web authentication policies.

The redirect ACL definition must be sent to the AP in the FlexConnect profile. The redirect ACL associated with an AP must be configured in the FlexConnect profile that hosts the client. If an AP is not configured with a FlexConnect profile, it is associated with the default FlexConnect profile.

Before you begin

- Identify the FlexConnect profile to be updated or verify if a new Flex profile needs to be created.
- Prepare the ACL details, central web authentication requirements, and any preauthentication URL filters.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Flex**.
2. On the **Flex Profile** page, click the name of the FlexConnect profile or click **Add** to create a new FlexConnect profile.
3. In the **Add/Edit Flex Profile** window that is displayed, click the **Policy ACL** tab.
4. Click **Add** to map an ACL to the FlexConnect profile.
5. Choose the ACL name, enable central web authentication, and specify the preauthentication URL filter.
6. Click **Save**.
7. Click **Update & Apply to Device**.

The AP applies the configured redirect ACL parameters for client traffic as specified in the flex profile.

Configure redirect ACL in flex profile (CLI)

Configure Redirect ACL in Flex Profile using commands.

Set up a redirect ACL within a flex profile so that APs enforce specified access control and web authentication policies.

The redirect ACL definition must be sent to the AP in the FlexConnect profile. The redirect ACL associated with an AP must be configured in the FlexConnect profile that hosts the client. If an AP is not configured with a FlexConnect profile, it is associated with the default FlexConnect profile.

Note

When the ACL is pushed down to the APs, the permission must change from **deny** to **permit** or the other way around. This change does not occur if the ACL contains an object group, causing the ACL not to be fully translated, which may cause the redirection to fail.

Before you begin

- Ensure you have the required ACL policy created on the controller.
- Confirm that AP is operating in FlexConnect mode.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a new flex policy.

   Example

   ```
   Device(config)# wireless profile flex default-flex-profile
   ```

   The default flex profile name is **`default-flex-profile`**.

3. Configure an ACL policy.

   Example

```
Device(config-wireless-flex-profile)# acl-policy
                        acl-policyname
```

4. Configure central web authentication.

   Example

```
Device(config-wireless-flex-profile-acl)# central-webauth
```

5. Return to privileged EXEC mode.

   Example

```
Device(config-wireless-flex-profile-acl)# end
```

The AP in flex profile has the redirect ACL configured. The ACL is now applied and used for client redirection during centralized web authentication.

Troubleshoot CWA

Init-State timer running out

Issue: The client devices are deauthenticated by the controller if users fail to enter their credentials in a limited time interval. The clients are deauthenticated after three times the time configured for the init-state timeout in the controller.

Explanation: This is expected behavior. For central web authentication, the init-state timeout does not apply directly. The reap timer—three times the init-state timeout plus five seconds (3 × init-state timeout + 5)—determines when your device deauthenticates in seconds.

For example, if you have configured the init-state timeout as 10 seconds, then the client devices are deauthenticated if users fail to enter their credentials after 35 seconds; that is (3*10 + 5) = 35 seconds.

For example, if you set the init-state timeout to 10 seconds, your device deuathenticates after 35 seconds if you do not enter your credentials. (This calculation is: 3 × 10 + 5 = 35 seconds.)

121 Private Shared Key

Topics:

- Private preshared keys

Private preshared keys

Introduces Private PSK authentication, detailing system limitations, identity PSK operation, and step-by-step procedures for configuring and applying PSKs on WLANs and policy profiles via GUI and CLI, including verification methods for secure wireless access.

A private preshared key (PSK) is a security protocol for network authentication that

- enables devices to securely connect to wireless local area networks (WLANs),
- assigns unique keys to individual devices or user groups, reducing the risk of unauthorized access, and
- ensures compatibility with systems where advanced authentication methods like 802.1X are unsupported.

Understanding identity PSKs

Identity PSKs are unique PSKs created for individuals or groups of users on the same SSID. They provide the same simplicity of PSK while enabling features such as:

- Stronger security for IoT by supporting devices that do not use 802.1X.
- Easy revocation of access for a specific device or individual without affecting others.
- Scalable management of thousands of keys distributed through the AAA server.

These features make Identiy PSKs ideal for IoT, BYOD, and guest deployments.

Limitations

SSID Preshared Key Special Characters

- Special characters, such as '<' and '>' are supported in SSID Preshared key.
- Avoid using the percentage symbol (%) in a PSK. Some client and access point combinations may interpret the percentage symbol as a special character, which can prevent the client from joining the PSK WLAN. If clients cannot join the WLAN, replace the symbol with another supported ASCII character and retry.

SSID Preshared Key Whitespace Support

PSK supports whitespace in passwords (before or after or in-between) within double quotes only; single quotes for whitespaces are not supported.

How identity PSK authentication works

Identity Pre-Shared Key (IPSK) authentication allows a unique pre-shared key to be assigned to each device or user based on their MAC address, enhancing network security and control. You collaborate with multiple network components to authorize, authenticate, and provision device access.

Summary

The key components involved in the process are:

- Client device: Sends an association request to connect to the access point.
- AP: Broadcasts the SSID and forwards association requests to the controller.
- Embedded Wireless Controller: Constructs RADIUS requests and relays them to the authentication server; manages computation of PSKs and applies received configuration parameters.
- RADIUS (AAA) server: Authenticates client MAC addresses, authorizes access, and returns passphrases or additional parameters as needed.

Workflow

Here are the stages you will follow for Identity PSK authentication:

1. The client device attempts to connect to the wireless network by sending an association request to the SSID broadcast by the access point.
2. The access point forwards the association request to the Embedded Wireless Controller.
3. The controller creates a RADIUS authentication request packet containing the client's MAC address and relays it to the RADIUS (AAA) server.
4. The RADIUS server performs authentication and determines whether the client is authorized.
   - If authorized, the server sends an ACCESS-ACCEPT response; otherwise, it sends an ACCESS-REJECT.
5. If the client is authorized, the RADIUS server includes the AV-pair passphrase (the identity PSK) in the response, as well as optional parameters such as username, VLAN, and Quality of Service (QoS).
6. Upon receiving the response, the controller uses the passphrase to compute the Pairwise Master Key (PMK) and apply any additional attributes for the client's session.
7. If you have multiple devices, the same passphrase can apply to all of them.
8. If a configured PSK is shorter than 15 characters (when Federal Information Processing Standard, FIPS, is enabled), the controller allows the WLAN configuration but displays the following console warning:

> **Note**
>
> AP is allowed to join but corresponding WLAN will not be pushed to the access point.

Result

Your device will either be granted access to the network with its assigned unique PSK and relevant settings, or access will be denied based on the authentication outcome. This information could be better presented in a separate paragraph or subsection to distinctively address the outcome of the process.

Configure a PSK in a WLAN

Configure a PSK in a WLAN using commands.

Set up security for a pre-shared key (PSK) in a WLAN environment using command-line instructions.

Before you begin

- Configure security for a pre-shared key (PSK) in a WLAN.
- If there is no override from the AAA server, the system uses the WLAN value for authentication.
- In Federal Information Processing Standard (FIPS) and common criteria mode, ensure that the PSK WLAN uses at least 15 ASCII characters.

Procedure

1. Configure terminal

Example

```
Device# configure terminal
```

Enters global configuration mode.

2. Configure the WLAN and the SSID

Example

```
Device(config)# wlan test-profile 4 abc
```

Configures the WLAN and SSID.

3. Disable security AKM for 802.11

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

Disables security AKM for 802.11x.

4. Configure the security type PSK

Example

```
Device(config-wlan)# security wpa akm psk
```

Configures the security type PSK.

5. Configure PSK authenticated key management (AKM) shared key

Example

```
Device(config-wlan)# security wpa akm psk set-key asci 0
```

Configures the PSK authenticated key management (AKM) shared key.

> **Note**
>
> You must set the **psk set-key** before configuring AKM PSK.

6. Configure PSK support

Example

```
Device(config-wlan)# security wpa akm psk
```

Configures PSK support.

7. Configure multi-preshared key (MPSK) support

Example

```
Device(config-wlan)# security wpa wpa2 mpsk
```

Configures multi-preshared key (MPSK) support.

> **Note**
>
> Enable AKM PSK to use MPSK.

8. Specify MAC filtering in WLAN

Example

```
Device(config-wlan)# mac-filtering test1
```

Specifies MAC filtering in a WLAN.

The WLAN is configured to use a pre-shared key for client authentication.

Configure a PSK in a WLAN using GUI

Configure a PSK in a WLAN using GUI.

Configure a pre-shared key (PSK) for a WLAN.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. On the **Wireless Networks** page, click **Security** tab.
3. In the **Layer 2** window that is displayed, go to the **WPA Parameters** section.
4. From the **Auth Key Mgmt** drop-down, select the PSK format and type.
5. Enter the Pre-Shared Key in hexadecimal characters.
   - If you selected the PSK format as HEX, the key length must be exactly 64 characters.
   - If you selected the PSK format as ASCII, ensure the key length ranges from 8 to 63 characters.

   After configuring the key, these details are not visible due to security reasons. Even if you click on the eye icon next to the Pre-Shared Key box, the details remain hidden.
6. Click **Save & Apply to Device**.

The PSK is configured and applied to the selected WLAN.

What to do next

Check the WLAN connectivity to ensure successful configuration.

Apply a policy profile to a WLAN (GUI)

Apply a policy profile to a WLAN using GUI.

This task helps you configure WLAN by applying policy profiles for better network management.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. On the **Manage Tags** page, click **Policy** tab.
3. Click **Add** to view the **Add Policy Tag** window.
4. Enter the policy tag name and its description.
5. Click **Add** to map WLAN and policy.
6. Choose the WLAN profile to map with the appropriate policy profile, then click the tick icon.
7. Click **Save & Apply to Device**.

Once the task is completed, you successfully map the WLAN to the chosen policy profile

What to do next

Verify the changes by checking the applied profiles under Wireless Local Area Network (WLAN) settings.

Monitor network performance to confirm the policy effectiveness.

Apply a policy profile to a WLAN using CLI

Apply a policy profile to a WLAN using commands.

The goal of this task is to effectively apply a policy profile to a WLAN using CLI commands, which helps manage network configurations efficiently.

Procedure

1. Enter global configuration mode

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. Configure the default policy profile

   Example

   ```
   Device(config)# wireless profile policy policy-iot
   ```

   Configures the default policy profile.

3. Configure AAA override to apply policies coming from the AAA server

Example

```
Device(config-wireless-policy)# aaa-override
```

Configures AAA override to apply policies coming from the AAA server or ISE, the Cisco Identity Services Engine server.

Once you apply the policy profile, configure the WLAN with the specified policy settings to enable the expected network management and security features.

What to do next

You should verify the applied configuration by checking the WLAN settings to ensure all policies are correctly enforced.

- Confirm connectivity and performance with the new settings.

Verify a private PSK

Verify a private PSK.

To verify the configuration of a WLAN and a client, use the following **show** commands

Verify wireless client configuration

```
Device# show wlan id 2

WLAN Profile Name     : test_ppsk
================================================

122 Multi-Preshared Key

Topics:

- Multi-preshared key
- Procedures

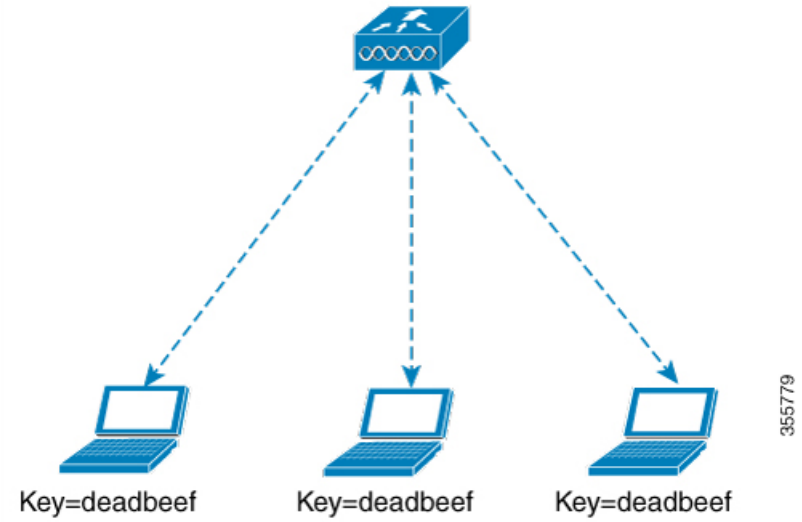
Multi-preshared key

Introduces the core concepts of Multi-Preshared Key, outlining operational details and supported features, and details applicable restrictions impacting deployment and authentication scenarios.

A multi-preshared key (multi-PSK) is a wireless security feature that

- Allows multiple pre-shared keys (PSKs) to be configured for a single SSID
- Enables any configured PSK to grant access to the same wireless network
- Improves network flexibility by supporting concurrent user groups or devices with different credentials.

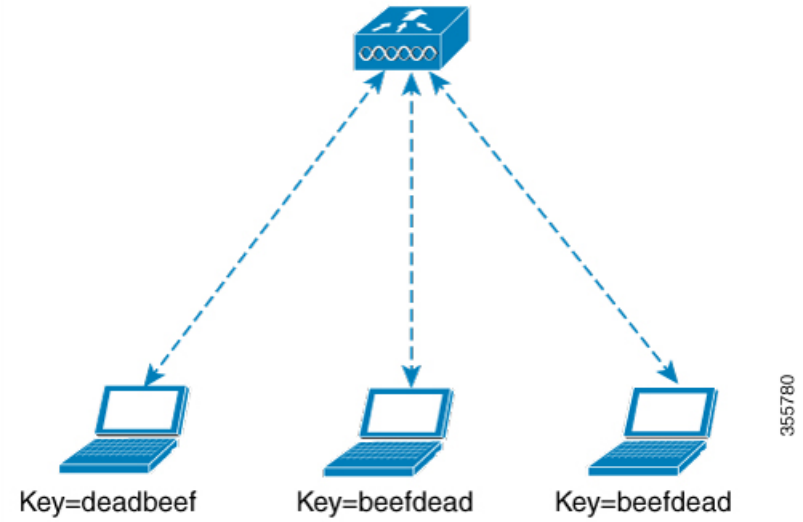
PSK: A pre-shared key is a password or passphrase used to authenticate clients on a wireless network.



Supporting analogy: keycards to the same door

Having multi-PSk keys for a single SSID is like giving different colored keycards to various teams. Each keycard opens the same door, but you can manage which card goes to which team. This approach increases flexibility and security compared to using one generic key.

Comparing traditional PSK with



In a traditional PSK, all the clients joining the network use the same password as shown in the figure.

Figure 16: Traditional PSK

But with multi-PSK, client can use any of the configured pre-shared keys to connect to the network as shown in the figure.

Figure 17: Multi-PSK

In the Multi-PSK example, two passwords—deadbeef and beefdead—are configured for the same SSIDIn this scenario, clients can connect to the network using either of the passwords.

Note

- Each SSID in a Multi-PSK supports five PSKs.
- Multi-PSK is different from iPSK. In iPSK, the PSK password comes from ISE authorization policy, so MAB is required. Multi-PSK uses a pool of passwords locally configured in WLAN, so Identity Service Engine is not used.

Feature	Traditional PSK	Multi-PSK	Identity PSK (iPSK)
Number of PSKs per SSID	One shared key	Multiple keys (up to five)	Unique key per user or per group
Use case flexibility	All users share one credential	Separate keys for groups or devices	Per-user or per-group credentials for high granularity
Example	All staff share same key	Staff, guests, IoT devices have different keys	Each staff member, contractor, or device gets its own key
Key management	Single change affects all users	Changes can target specific groups or devices	Changes can target specific users or devices; policy-driven from ISE
Security granularity	Lowest – one compromise affects all	Better – compromise isolated to that PSK group	Highest – compromise isolated to individual user or device and fully policy-based

Restrictions

Multi-PSK restrictions.

- In central authentication flex mode, the standalone AP allows client join with the highest priority PSK (priority 0 key). New clients that do not use the highest priority PSK are rejected during the standalone mode.
- Multi-PSK does not support local authentication.
- Avoid using the percentage symbol (%) in a PSK. Some client and access point combinations may interpret the percentage symbol as a special character, which can prevent the client from joining the PSK WLAN. If clients cannot join the WLAN, replace the symbol with another supported ASCII character and retry.

Procedures

Guides configuration of Multi-Preshared Key using both GUI and CLI, and provides verification steps to ensure proper deployment and functionality.

Configure a multi-preshared key (GUI)

Configure Multi-Preshared Key using GUI.

Configure a WLAN to use a multi-PSK through the controller's GUI.

Before you begin

Know the required security settings such as Wired Equivalent Privacy (WEP), Wi-Fi Protected Access (WPA), PSK, and so on for your WLAN.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. On the **Wireless Networks** page, click the name of the WLAN.
3. In the **Edit WLAN** window, click the **Security** tab.
4. In the **Layer2** tab, choose the **Layer2 Security Mode** from the options:
   - None: No Layer 2 security
   - 802.1X: WEP 802.1X data encryption type
   - WPA + WPA2: Wi-Fi Protected Access
   - Static WEP: Static WEP encryption parameters
   - Static WEP+802.1X: Both Static WEP and 802.1X parameters

Parameters	Description
802.1X	
WEP Key Size	Choose the key size. The available values are: • None • 40 bits • 104 bits
WPA + WPA2	

Parameters	Description
Protected Management Frame	Possible values are: • Disabled • Optional • Required
WPA Policy	Check the check box to enable WPA policy.
WPA Encryption	Choose the WPA encryption standard. A WPA encryption standard must be specified if you have enabled WPA policy.
WPA2 Policy	Check the check box to enable WPA2 policy.
WPA2 Encryption	Choose the WPA2 encryption standard. A WPA encryption standard must be specified if you have enabled WPA policy.
Auth Key Mgmt	Possible rekeying mechanism options: • 802.1X • FT + 802.1X • PSK: You must specify the PSK format and a preshared key • Cisco Centralized Key Management: You must specify a Cisco Centralized Key Management Timestamp Tolerance value • 802.1X + Cisco Centralized Key Management: You must specify a Cisco Centralized Key Management Timestamp Tolerance value • FT + 802.1X + Cisco Centralized Key Management: You must specify a Cisco Centralized Key Management Timestamp Tolerance value
Static WEP	
Key Size	Possible key size options: • 40 bits • 104 bits
Key Index	Choose a key index from 1 to 4. One unique WEP key index can be applied to each WLAN. As there are only four WEP key indexes, only four WLANs can be configured for static WEP Layer2 encryption.
Key Format	Choose the encryption key format as either ASCII or HEX.
Encryption Key	Enter an encryption key that is 13 characters long.
Static WEP + 802.1X	

Parameters	Description
Key Size	Possible key size options: • 40 bits • 104 bits
Key Index	Choose a key index from 1 to 4. One unique WEP key index can be applied to each WLAN. As there are only four WEP key indexes, only four WLANs can be configured for static WEP Layer2 encryption.
Key Format	Choose the encryption key format as either ASCII or HEX.
Encryption Key	Enter an encryption key that is 13 characters long.
WEP Key Size	Choose from the WEP key sizes: • None • 40 bits • 104 bits

5. Click **Save & Apply to Device**.

The WLAN is updated with the selected multi-PSK security settings.

Configure a multi-preshared key (CLI)

Configure Multi-Preshared Key using commands.

Configure a WLAN to use a multi-PSK through the controller's CLI.

Before you begin

Know the required security settings (WEP, WPA, PSK, and so on.) for your WLAN.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN and SSID.

   Example

   ```
   Device(config)# wlan mywlan 1 SSID_name
   ```

3. Disable security AKM for dot1x.

Example

```
Device(config-wlan)# no security wpa akm
                       dot1x
```

4. Configure PSK.

   Example

   ```
   Device(config-wlan)# security wpa akm psk
   ```

5. Configure multi-PSK.

   Example

   ```
   Device(config-wlan)# security wpa wpa2 mpsk
   ```

6. Configure PSK priority and all its related passwords using the **priority** *priority_value* **set-key** {**ascii** [**0** | **8**] *pre-shared-key* | **hex** [**0** | **8**] *pre-shared-key*} command.

   Example

   ```
   Device(config-mpsk)# priority 0 set-key ascii 0 deadbeef
   ```

   The *priority_value* ranges from 0 to 4.

   > **Note**
   >
   > You need to configure **priority 0** key for multi-PSK.

7. Enable WLAN.

   Example

   ```
   Device(config-mpsk)# no shutdown
   ```

8. Exit WLAN configuration mode and returns to configuration mode.

   Example

   ```
   Device(config-wlan)# exit
   ```

9. Return to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Example

```
Device(config)# end
```

The WLAN is updated with the selected multi-PSK security settings.

Verify multi-PSK configurations

Verify Multi-PSK Configurations.

To verify the configuration of a WLAN and a client, use the following command:

```
Device# show wlan id 8
WLAN Profile Name     : wlan_8
================================================
Identifier                                    : 8

123 Wireless AAA Authentication Survivability Cache

Topics:

- Wireless AAA authentication survivability cache

Wireless AAA authentication survivability cache

Describes the wireless AAA authentication survivability cache feature.

The Wireless AAA authentication survivability cache feature enhances the reliability of wireless client authentication by storing successful authentication results locally on the controller. This cache includes details such as the client's MAC address, user name, hashed password, and Attribute-Value Pairs (AVPs) received from the RADIUS server.

Wireless AAA authentication survivability cache is a mechanism implemented in the controller that:

- provides a fallback methodology in wireless systems for AAA authentication servers,
- implements authentication and policy caching mechanism, and
- leverages the caching capability of the AAA module of System Management Daemon (SMD) in WNCd.

This feature is supported in both local mode and FlexConnect central authentication mode.

Wireless AAA authentication survivability cache as failover mechanism

If the AAA server becomes unreachable, for example, due to a network outage or server failure, the controller uses the cached credentials to authenticate clients. This ensures that the previously authenticated clients are allowed network access, even if the primary authentication source is unavailable.

Use case for wireless AAA authentication survivability cache

Some use cases for the wireless AAA authentication survivability cache feature are:

- Cache can be used when the controller loses connectivity with the AAA server, which may disconnect authenticated clients.
- Cache can be used as the primary source of authentication, with fallback to AAA, to avoid slow authentication time due to WAN latency.

Benefits of using AAA cache for failover

The benefits of using AAA cache for failover are:

- Seamless client access: If the AAA server fails, previously authenticated clients can still access the network without delays or disruptions.
- Reduced dependency on AAA server availability: This mechanism reduces the dependency on the availability of the AAA server for re-authentication, providing business continuity even if there is an issue with the server.
- Improved user experience: Clients do not experience interruptions when reconnecting, as the controller uses the cached authentication information to grant them access immediately.
- Load reduction on AAA server: During network failures or outages, the controller does not need to query the AAA server repeatedly for authentication. This helps reduce the load on the AAA server.
- Failover for high availability: If the primary AAA server temporarily fails, such as during maintenance, the AAA cache maintains client access automatically.

Feature history for wireless AAA authentication survivability cache

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 115: Feature history for wireless AAA authentication survivability cache

Release	Feature Information
Cisco IOS XE 17.18.1	The Wireless AAA authentication survivability cache feature enhances the reliability of wireless client authentication by storing successful authentication results locally on the controller. Cache can be used: • When the controller loses connectivity with the AAA server, which may disconnect authenticated clients. • As the primary source of authentication, with fallback to AAA, to avoid slow authentication time due to WAN latency. This feature is supported in both local mode and FlexConnect central authentication mode.

Configure wireless AAA authentication survivability cache

This section describes the steps to configure wireless AAA authentication survivability cache using CLI commands.

Before you begin

Ensure that the following are met:

- SSID already configured
- A RADIUS server such as Cisco ISE with authentication and authorization policy and profiles are created

Configure a cache profile and apply the cache profile to the AAA server group used for authentication and authorization.

Procedure

1. Enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a profile for the local RADIUS server.

   Example

   ```
   Device# aaa server radius dynamic-author
   ```

   This command creates the profile for local RADIUS server and enters into the local server dynamic author RADIUS configuration.

3. Configure a RADIUS client.

Example

```
Device(config-locsvr-da-radius)# client {A.B.C.D | X:X:X:X::X} server-key {{0
 | 6 | 7}server-key | server-key2}
```

This command specifies the IPv4 or the IPv6 address of the RADIUS client and the RADIUS client server key.

4. Specify the server authorization type.

Example

```
Device(config-locsvr-da-radius)# auth-type {all | any | sessionkey}
```

5. Exit the local server dynamic author configuration mode.

Example

```
Device(config-locsvr-da-radius)# exit
```

Configure RADIUS dynamic-author for CoA

Follow these steps to configure RADIUS dynamic-author for CoA:

Procedure

1. Enter configuration mode.

Example

```
Device# configure terminal
```

2. Configure a profile for the local RADIUS server.

Example

```
Device# aaa server radius dynamic-author
```

This command creates the profile for local RADIUS server and enters into the local server dynamic author RADIUS configuration.

3. Configure a RADIUS client.

Example

```
Device(config-locsvr-da-radius)# client {A.B.C.D | X:X:X:X::X} server-key {{0
 | 6 | 7}server-key | server-key2}
```

This command specifies the IPv4 or the IPv6 address of the RADIUS client and the RADIUS client server key.

4. Specify the server authorization type.

Example

```
Device(config-locsvr-da-radius)# auth-type {all | any | sessionkey}
```

5. Exit the local server dynamic author configuration mode.

   Example

   ```
   Device(config-locsvr-da-radius)# exit
   ```

The RADIUS client is configured.

Example

```
Device# configure terminal
Device# aaa server radius dynamic-author
Device(config-locsvr-da-radius)# client 10.10.10.1 server-key 0 server-key |
server-key2}
Device(config-locsvr-da-radius)# auth-type any
Device(config-locsvr-da-radius)# exit
```

What to do next

Configure the RADIUS server.

Configure RADIUS server

Procedure

1. Enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the RADIUS server.

   Example

   ```
   Device(config)# radius server radius-server-name
   ```

   This command configures the RADIUS server and enters the RADIUS server configuration mode.

3. Configure the RADIUS server address.

   Example

   ```
   Device(config-radius-server)# address ipv4 hostname or A.B.C.D [auth-port |
   alias | acct-port] <0-65534> [acct-port] <0-65534>
   ```

   This command configures the RADIUS server address and the UDP ports for the RADIUS authentication server and accounting server.

   The default port number for the RADIUS accounting server is 1813 and the default port number for the RADIUS authentication server is 1814.

4. Configure the per server encryption key.

Example

```
Device(config-radius-server)# key key
```

The RADIUS server is configured.

Example

```
Device# configure terminal
Device(config)# radius server radius-server-name
Device(config-radius-server)# address ipv4 hostname auth-port 1645 acct-port
1646
Device(config-radius-server)# key key
```

What to do next

Configure the RADIUS server group and cache expiry.

Configure RADIUS server group and cache expiry

Before you begin

> **Note**
>
> Only one AAA server group can be configured for AAA cache feature.

Procedure

1. Enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the RADIUS server group definition.

   Example

   ```
   Device(config)# aaa group server {ldap | radius | tacacs+} server-group-name
   ```

   This command configures the server group name with 32 as the maximum string length. Here, configure the RADIUS server group name.

3. Configure the RADIUS server name.

   Example

   ```
   Device(config-sg-radius)# server {hostmame or A.B.C.D | name} server-name
   ```

4. Configure the cache authorization profile.

Example

```
Device(config-sg-radius)# cache authorization profile cache-auth
```

5. Configure the cache authentication profile.

Example

```
Device(config-sg-radius)# cache authentication profile cache-auth
```

6. Configure the cache expiry.

Example

```
Device(config-sg-radius)# cache expiry 0-2147483647
```

This command configures the cache expiry time in hours. The default is 24 hours. The value 0 stands for never expire.

> **Note**
>
> If the cache entry expires and the AAA server is still unreachable, the client is not authenticated until the server is reachable again.

7. Exit the RADIUS server configuration mode.

Example

```
Device(config-sg-radius)# exit
```

The RADIUS server group and cache profile is configured.

Example

```
Device# configure terminal
Device(config)# aaa group server radius radius-group
Device(config-sg-radius)# server name server-name
Device(config-radius-server)# cache authorization profile cache-auth
Device(config-sg-radius)# cache authentication profile cache-auth
Device(config-sg-radius)# cache expiry 24
Device(config-sg-radius)# exit
```

What to do next

Configure AAA for network access using a cache profile.

Configure AAA cache profile

Procedure

---

1. Enter configuration mode.

Example

```
Device# configure terminal
```

2. Configure the AAA cache profile.

Example

```
Device(config)# aaa cache profile aaa-cache
```

3. Cache all entries.

Example

```
Device(config-profile-map)# all
```

The cache profile is configured.

Example

```
Device# configure terminal
Device(config)# aaa cache profile aaa-cache
Device(config-profile-map)# all
```

What to do next

Configure EAP profile.

Configure EAP profile

Procedure

---

1. Enter configuration mode.

Example

```
Device# configure terminal
```

2. Configure EAP profile.

Example

```
Device(config)# eap profile eap-profile
```

3. Configure EAP-TLS allowed method.

Example

```
Device(config-eap-profile)# method tls
```

4. Configure the default PKI trustpoint.

Example

```
Device(config-eap-profile)# pki-trustpoint pki_trustpoint_name
```

Here, you must specify the name of the PKI trustpoint.

The EAP profile is configured.

Example

```
Device# configure terminal
Device(config)# eap profile eap-profile
Device(config-eap-profile)# method tls
Device(config-eap-profile)# pki-trustpoint default-pki-trustpoint
```

What to do next

Configure WLAN.

Configure WLAN

Procedure

---

1. Enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN profile.

   Example

   ```
   Device(config)# wlan wlan-profile 1-4096 ssid-name
   ```

   This command configures a WLAN profile and enters the WLAN configuration mode.

3. Enable local auth EAP profile.

   Example

   ```
   Device(config-wlan)# local-auth eap-profile
   ```

4. Enable security authentication list for dot1x security.

   Example

   ```
   Device(config-wlan)# security dot1x authentication-list default
   ```

5. Enable security authorization list for dot1x security.

Example

```
Device(config-wlan)# security dot1x authorization-list default
```

6. Enable WLAN.

Example

```
Device(config-wlan)# no shutdown
```

A WLAN profile is configured.

Example

```
Device# configure terminal
Device(config)# wlan wlan-profile 2 ssid-name
Device(config-wlan)# security dot1x authentication-list default
Device(config-wlan)# security dot1x authorization-list default
Device(config-wlan)# no shutdown
```

AAA dead-server detection

This topic explains AAA dead-server detection.

AAA dead-server detection allows you to configure the criteria to be used to mark a RADIUS server as dead. If you have more than one RADIUS server, the following concepts come into picture:

- Deadtime: Defines the time in minutes a server marked as DEAD is held in that state. Once the deadtime expires, the controller marks the server as UP (ALIVE) and notifies the registered clients about the state change. If the server is still unreachable after the state is marked as UP and if the DEAD criteria is met, then server is marked as DEAD again for the deadtime interval.

  For example, `Device(config)# radius-server deadtime 5`.

  > **Note**
  >
  > You can configure deadtime for each server group or on a global level.

- Dead-criteria–To declare a server as DEAD, you need to configure dead-criteria and configure the conditions that determine when a RADIUS server is considered unavailable or dead.

  For example, `Device(config)# radius-server dead-criteria time 5 tries 5`.

Using AAA dead-server detection will result in less deadtime and quicker packet processing.

For more information, see the chapter AAA Dead-Server Detection.

RADIUS configuration for MSCHAPv2

Configure AV-pair attribute on RADIUS

Associate the following Cisco AV-pairs with the authorization profile associated with the client, on the ISE server:

- cisco-av-pair = AS-Username=Cisco

- cisco-av-pair = AS-Credential-Hash=F2E787D376CBF6D6DD3600132E9C215D

> **Note**
>
> Every user must configure the AV-pair attribute on RADIUS.

The Password or AS-Credential-Hash should be in the NT-hash format (https://codebeautify.org/ntlm-hash-generator).

Configure EAP-TLS on ISE

Describes the EAP-TLS configuration on ISE.

1. Generate a CSR and the import certificate into the controller (PCKS 12 or .pkg would be convenient to import as a single file).
2. Configure a PKI trustpoint in the EAP profile as described in .

Verify wireless AAA authentication survivability cache

Verify the wireless AAA authentication survivability using the show commands.

Verify configured cache entries

To verify the configured cache entries, run the **show aaa cache group** command.

> **Note**
>
> This command is extended to show cache entries for the Wireless Network Controller Daemon (WNCD) process.

```
Device# show aaa cache group aaa-cache-grp all
-----------------------------------------------------------
IOSD AAA Auth Cache entries:
Entries in Profile dB aaa-cache-grp for exact match:
No entries found in Profile dB
-----------------------------------------------------------
SMD AAA Auth Cache entries:
Total number of Cache entries is 0
WNCD AAA Auth Cache entries:
MAC ADDR: 0000.AAAA.BBBB
Profile Name: NEWCACHE
User Name: user1
Timeout: 3600
Created Timestamp: 03/12/25 17:11:23 UTC
Server IP Address: 1.1.1.1
MAC ADDR: AAAA.BBBB.CCCC
Profile Name: NEWCACHE
User Name: user2
Timeout: 3600
Created Timestamp: 03/12/25 17:04:59 UTC
Server IP Address: 1.1.1.1
```

```
Total number of Cache entries is 2
------------------------------------------------------------
```

124 Wi-Fi Protected Access 3

Topics:

- Overview of WPA3
- WPA3 Configuration Tasks

Overview of WPA3

Outlines WPA3 fundamentals, describing Simultaneous Authentication of Equals, Opportunistic Wireless Encryption, Hash-to-Element, YANG (RFC model), Transition Disable, and WPA3 SAE iPSK, and explains the core technologies that strengthen Wi-Fi security and user protections.

Simultaneous Authentication of Equals

A simultaneous authentication of equals (SAE) is a protocol used in WPA3 that

- provides stronger password protection from guessing attacks by third parties
- employs discrete logarithm cryptography to perform an efficient exchange that enables mutual authentication using a password, and
- resists offline dictionary attacks.

An offline dictionary attack is where an adversary attempts to determine a network password by trying possible passwords without further network interaction

Feature History

Feature Name	Release	Description
WPA3 – SAE H2E with Identity PSK	Cisco IOS XE 17.9.2	Added support for Identity PSK (iPSK) passphrase for SAE H2E authentication in local mode. iPSK replaces WLAN passphrase during SAE H2E authentication when configured.
Wi-Fi Protected Access 3 Hash-to-Element (H2E) Support for SAE Authentication	Cisco IOS XE 17.7.1	Introduced Hash-to-Element (H2E) support for SAE authentication. WLAN command options added: **h2e**, **hnp**, **both-h2e-hnp** (default).
Wi-Fi Protected Access3	Cisco IOS XE 16.12.1	WPA3 is the latest version of Wi-Fi ProtectedAccess (WPA), which is a suite of protocols and technologies that provide authentication and encryption for Wi-Fi networks.

WPA3 and SAE in Wi-Fi Security

WPA3 is the latest version of Wi-Fi Protected Access (WPA), which is a suite of protocols and technologies that provide authentication and encryption for Wi-Fi networks.

WPA3 leverages SAE to provide stronger protections for users against password guessing attempts by third parties.

- WPA3-Personal protects users through robust password-based authentication, making brute-force dictionary attacks more difficult.
- WPA3-Enterprise provides higher-grade security protocols for sensitive data networks.

When the client connects to the AP, they perform an SAE exchange. If the exchange is successful, both parties create a cryptographically strong key, which is used to derive the session key. The client and AP complete commit and confirm phases. After commitment, the devices transition to confirm states whenever a new session key is generated. This method uses forward secrecy so that if an intruder cracks one key, the other session keys remain secure.

> **Note**
>
> Home SSIDs configured using the OEAP GUI do not support WPA3 security in Cisco IOS-XE 17.6 and 17.7 releases.

Unsupported APs

Cisco APs do not support SAE. If you attempt to connect an AP client to an SAE SSID using these APs, the client will not be able to join after receiving M3 from the AP.

Cisco APs that do not support SAE include:

- Cisco Aironet 1815 Series APs (AP1815W, AP1815T, AP1815I, AP1815M)
- Cisco Aironet 1815T OfficeExtend APs
- Cisco Aironet 1800 Series APs (AP1800I, AP1800S)
- Cisco Aironet 1810 Series APs
- Cisco Aironet 1542 Series Outdoor APs (AP1542D, AP1542I)
- Cisco Aironet 1830 and 1850 Series APs
- Cisco Aironet 1840 Series APs (AP1840I)

> **Note**
>
> For more information on supported APs for SAE, refer to the Feature Matrix for Cisco Wireless Access Points.

Opportunistic Wireless Encryption

Opportunistic Wireless Encryption (OWE) is a wireless security protocol that

- serves as an extension to IEEE 802.11 standards
- provides encryption of the wireless medium without requiring user credentials, and
- enables secure wireless communication between APs and clients, even in networks traditionally considered open.

Expanded explanation

OWE authenticates devices using Diffie-Hellman algorithm-based cryptography to set up wireless encryption. During network access, the client and AP perform a Diffie-Hellman key exchange. This process establishes a unique pairwise secret. The secret is then used with the standard 4-way handshake to secure the session. This method reduces the risks of open wireless networks by encrypting data traffic and increases security for deployments that otherwise use unsecured or pre-shared key(PSK) configurations.

An airport Wi-Fi network that previously offered open access (no password required) can implement OWE to encrypt wireless communications, protecting user data from eavesdropping while still avoiding the need for users to enter a password.

A traditional open wireless network (without OWE) allows any nearby device to connect and intercept wireless transmissions, leaving users vulnerable to data theft.

Hash-to-Element (H2E)

Hash-to-Element (H2E) is a new SAE Password Element method.

An SAE password element method is a cryptographic procedure that

- Derives the secret password element (PWE) in the Simultaneous Authentication of Equals (SAE) protocol
- Transforms a password into a secure intermediary element for authentication, and
- Provides protection against security threats such as group downgrade attacks.

Hash-to-Element is a new SAE Password Element (PWE) calculation method for wireless security protocols.

- **Hash-to-Element (H2E)**: Hash-to-Element is a SAE password element method that derives the PWE directly from a password using a hashing process. When a station (STA) supporting H2E initiates SAE with an AP, it checks if the AP supports H2E. If supported, the AP uses the H2E method to generate the PWE, as indicated by a new Status Code in the SAE Commit message.

PWE derivation steps in H2E

When using the H2E method, PWE derivation consists of two steps:

1. Creation of secret intermediary element (PT): The secret intermediary element (PT) is derived offline from the password when it is initially configured for each supported group.
2. Derivation of the PWE: The PWE is generated in real-time from the stored PT during the SAE exchange, using the negotiated group and the Media Access Control (MAC) addresses of both peers.

Additional reference information

- If a device uses the older Hunting-and-Pecking method, the overall SAE exchange remains unchanged.
- The H2E method protects against man-in-the-middle attacks, including Group Downgrade attacks. During authentication, peers exchange lists of rejected groups as part of PMK derivation. If there is a mismatch, the system terminates authentication to prevent a downgrade attack.
- The 6-GHz band supports only H2E SAE PWE method.
- In a typical SAE exchange on a 6 GHz network, only the H2E method is used for password element generation.
- A station using H2E checks AP support, and if supported, uses H2E for secure and efficient authentication.

YANG (RPC model)

Steps to create an RPC for SAE Password Element mode.

To create an RPC for SAE Password Element (PWE) mode, use this RPC model:

```
<nc:rpc xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0"
message-id="urn:uuid:0a77124f-c563-469d-bd21-cc625a9691cc">
<nc:edit-config>
<nc:target>
<nc:running/>
</nc:target>
<nc:config>
<wlan-cfg-data xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-wlan-cfg">
<wlan-cfg-entries>
<wlan-cfg-entry>
```

```
<profile-name>test</profile-name>
<wlan-id>2</wlan-id>
<sae-pwe-mode>both-h2e-hnp</sae-pwe-mode>
</wlan-cfg-entry>
</wlan-cfg-entries>
</wlan-cfg-data>
</nc:config>
</nc:edit-config>
</nc:rpc>
```

To delete a 6-GHz radio policy and modify the SAE Password Element (PWE) mode, use this RPC model:

```
<nc:rpc xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0"
message-id="urn:uuid:2b8c4be6-492e-4488-b2cf-1f2a1e39fa8c"><nc:edit-config>
<nc:target>
<nc:running/>
</nc:target>
<nc:config>
<wlan-cfg-data xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-wlan-cfg">
<wlan-cfg-entries>
<wlan-cfg-entry>
<profile-name>test</profile-name>
<wlan-id>2</wlan-id>
<wlan-radio-policies>
<wlan-radio-policy nc:operation="delete">
<band>dot11-6-ghz-band</band>
</wlan-radio-policy>
</wlan-radio-policies>
</wlan-cfg-entry>
</wlan-cfg-entries>
</wlan-cfg-data>
</nc:config>
</nc:edit-config>
</nc:rpc>

Note

The **delete** operation performs one action at a time due to the current infra limitation. That is, in YANG module, the **delete** operation on multiple nodes are not supported.

Transition Disable

Disable few transition modes for subsequent connections to the APs network.

A Transition Disable indication is a wireless security feature that

- allows an AP to signal a client device (STA) to disable certain transition modes for future connections
- helps prevent downgrade attacks by restricting less secure connection options, and
- is used to strengthen network security without affecting legacy device connectivity.

Disabling transition modes to enforce WPA3 Security.

A client device (STA) may enable transition modes—such as WPA3-Personal transition mode—by default in its network profile, sometimes allowing fallback to less secure methods like PSK.

The Transition Disable indication lets the AP instruct supported STAs to disable these fallback modes, ensuring only secure connection methods are used when possible.

The Transition Disable indication thus provides protection against downgrade attacks.

> **Note**
>
> An AP that uses Transition Disable indication does not necessarily disable the corresponding transition modes on its own BSS.

The APs in WPA3-Personal network might use the Transition Disable indication to ensure that all STAs supporting WPA3-Personal are protected against the downgrade attack. However, the WPA3-Personal transition mode is enabled on the BSS for the legacy STAs to connect.

WPA3 SAE iPSK

A RADIUS server and Identity PSK that preshares keys for individuals or a group of users in the same SSID.

A WPA3 SAE iPSK is a Wi-Fi authentication method that:

- uses RADIUS server integration to generate unique pre-shared keys for individual users or groups,
- allows more secure and granular authentication in networks where devices do not support 802.1X, and
- limits breach impact so only compromised keys require updating, not all devices on the SSID.
- **SAE (Simultaneous Authentication of Equals)**: A protocol for mutual secure authentication between client and access point.
- **H2E (Hash-to-Element)**: An SAE mode using a password token derived from the authentication passphrase.

iPSK passphrase handling

In networks using WPA3 SAE iPSKs, the WLAN appears like a traditional PSK network from the client's perspective.

From Cisco IOS-XE 17.9.2, the iPSK passphrase is supported for SAE H2E authentication in Local mode. The iPSK passphrase is configured in the client authorization policy in the RADIUS server. The passphrase pushes the policy to the controller during client MAB authentication.

> **Note**
>
> The iPSK passphrase in the RADIUS policy replaces the WLAN profile passphrase when generating the password token.

If only one group's PSK is compromised, that group must update their key; the rest of the WLAN remains secure.

WPA3 Configuration Tasks

Guides configuration of WPA3 features, including SAE in mixed mode, WPA3 Enterprise and OWE via GUI and CLI, WPA3 OWE transition mode, SAE iPSK, SAE H2E, and Transition Disable, and provides verification steps for ensuring proper WPA3 operation and advanced security settings.

Configure SAE (WPA3+WPA2 mixed mode)

Enable secure Wi-Fi connectivity using both WPA3 and WPA2 protocols in a mixed mode for SAE on the device.

Performing this task configures a WLAN to support both legacy WPA2 and newer WPA3 authentication using SAE, enhancing security and compatibility for a range of client devices.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id SSID-name
   ```

   Example

   ```
   Device(config)# wlan WPA3 1 WPA3
   ```

3. Disable security AKM for 802.1X.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

4. Disable fast transition over the data source on the WLAN.

   Example

   ```
   Device(config-wlan)# no security ft over-the-ds
   ```

5. Disable 802.11r fast transition on the WLAN.

   Example

   ```
   Device(config-wlan)# no security ft
   ```

6. Configure WPA2 cipher.

   Example

   ```
   Device(config-wlan)# security wpa wpa2 ciphers aes
   ```

> **Note**
>
> You can check whether cipher is configured using **no security wpa wpa2 ciphers aes**command. If cipher is not reset, configure the cipher.

7. Specify a preshared key.

   Example

   ```
   Device(config-wlan)# security wpa psk set-key ascii value preshared-key
   ```

   Example

   ```
   Device(config-wlan)# security wpa psk set-key ascii 0 Cisco123
   ```

8. Enable WPA3 support.

   Example

   ```
   Device(config-wlan)# security wpa wpa3
   ```

   > **Note**
   >
   > If both WPA2 and WPA3 are supported (SAE and PSK together), it is optional to configure PMF. However, you cannot disable PMF. For WPA3, PMF is mandatory.

9. Enable AKM SAE support.

   Example

   ```
   Device(config-wlan)# security wpa akm sae
   ```

10. Enable AKM PSK support.

    Example

    ```
    Device(config-wlan)# security wpa akm psk
    ```

11. Enable the WLAN.

    Example

    ```
    Device(config-wlan)# no shutdown
    ```

12. Return to the privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The WLAN is configured to support both WPA3 (with SAE) and WPA2 authentication modes for client connectivity.

Configure WPA3 enterprise (GUI)

Enable WPA3 enterprise authentication on your WLAN to secure wireless communications.

Use this task when you need to enable WPA3 enterprise security for a WLAN profile on your wireless controller using the GUI.

Before you begin

Ensure necessary RADIUS or AAA servers and authentication lists are configured.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID** and the **WLAN ID**.
4. Choose **Security** > **Layer2** tab. Choose **WPA2+WPA3** in **Layer 2 Security Mode** drop-down list.
5. Uncheck the **WPA2 Policy** and **802.1x** check boxes. Check the **WPA3 Policy** and **802.1x-SHA256** check boxes.
6. Choose **Security** > **AAA**, and then choose the Authentication List from the **Authentication List** drop-down list.
7. Click **Apply to Device**.

Your newly created WLAN uses WPA3 enterprise security for client authentication.

Configure WPA3 enterprise

Set up a secure wireless LAN (WLAN) that uses WPA3 Enterprise authentication to enhance network security for enterprise environments.

WPA3 Enterprise provides stronger data protection and improved security features compared to earlier WLAN authentication methods. You can enable WPA3 Enterprise on supported APs and controllers with this configuration.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id SSID-name
   ```

3. Disable security AKM for 802.1X.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

4. Disables WPA2 security.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2
   ```

5. Configures 802.1x support.

   Example

   ```
   Device(config-wlan)# security wpa akm dot1x-sha256
   ```

6. Enables WPA3 support.

   Example

   ```
   Device(config-wlan)# security wpa wpa3
   ```

7. Configure security authentication list for dot1x security.

   Example

   ```
   Device(config-wlan)# security dot1x authentication-list list-name
   ```

8. **no shutdown**

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

   Enables the WLAN.

9. **end**

   Example

   ```
   Device(config-wlan)# end
   ```

   Return to the privileged EXEC mode.

> **Note**
>
> C9115 and C9120 access points do not support WLANs configured with WPA3 Enterprise (SUITEB192-1X).

The WPA3 enterprise WLAN is configured and enabled. Devices can now securely connect using WPA3 Enterprise authentication.

Configure WPA3 OWE

Configure the WPA3 OWE using commands.

Enable WPA3 Opportunistic Wireless Encryption (OWE) on a WLAN to provide enhanced security for wireless clients.

Use this task when you need to configure a WLAN with WPA3 OWE mode using CLI.

Before you begin

- Ensure Protected Management Frames (PMF) are configured internally.
- WPA2 ciphers are valid for the cipher configuration.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id SSID-name
   ```

3. Disable fast transition over the data source on the WLAN.

   Example

   ```
   Device(config-wlan)# no security ft over-the-ds
   ```

4. Disable 802.11r fast transition on the WLAN.

   Example

   ```
   Device(config-wlan)# no security ft
   ```

5. Disable security AKM for dot1x.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

6. Disable WPA2 security.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2
   ```

   This action also disables PMF.

7. Enable WPA2 ciphers for AES.

   Example

   ```
   Device(config-wlan)# security wpa wpa2 ciphers aes
   ```

   > **Note**
   >
   > WPA2 and WPA3 use common ciphers.

8. Enable WPA3 support.

   Example

   ```
   Device(config-wlan)# security wpa wpa3
   ```

9. Enable WPA3 OWE support.

   Example

   ```
   Device(config-wlan)# security wpa akm owe
   ```

10. Enable the WLAN to allow client devices to connect.

    Example

    ```
    Device(config-wlan)# no shutdown
    ```

11. Return to the privileged EXEC mode.

    Example

    ```
    Device(config-wlan)# end
    ```

You have enabled WPA3 OWE on your WLAN, enhancing security for your devices when they connect to the SSID.

Configure WPA3 OWE transition mode (GUI)

Configure WPA3 OWE Transition Mode using GUI.

Configure WPA3 OWE Transition Mode using the GUI to enable secure wireless connectivity with Opportunistic Wireless Encryption (OWE) in transition mode.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID** and the **WLAN ID**.
4. Choose **Security** > **Layer2** tab. Choose **WPA2+WPA3** in **Layer 2 Security Mode** drop-down list.
5. Uncheck the **WPA2 Policy**, **802.1x**, **Over the DS**, **FT + 802.1x** and **FT + PSK**check boxes.Check the **WPA3 Policy**, **AES** and **OWE** check boxes.
6. Enter the **Transition Mode WLAN ID**.
7. Click **Apply to Device**.

The WLAN is configured with WPA3 OWE Transition Mode, enabling secure connections for compatible devices.

Configure WPA3 OWE transition mode

Configure a WLAN to support WPA3 OWE transition mode for secure wireless connectivity.

WPA3 Opportunistic Wireless Encryption (OWE) transition mode allows clients to connect using either open or secured (WPA3 OWE) methods during transition deployments.

Policy validation does not take place between the open WLAN and the OWE WLAN. You must configure both WLANs correctly.

Before you begin

Identify the WLAN ID and names for the open and OWE WLANs you will configure.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id SSID-name
   ```

3. Disable security AKM for 802.1X.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

4. Disable fast transition over the data source on the WLAN.

   Example

   ```
   Device(config-wlan)# no security ft over-the-ds
   ```

5. Disable 802.11r fast transition on the WLAN.

   Example

   ```
   Device(config-wlan)# no security ft
   ```

6. Disable WPA2 security. PMF is disabled now.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2
   ```

7. Enable WPA2 ciphers for AES.

   Example

   ```
   Device(config-wlan)# security wpa wpa2 ciphers aes
   ```

8. Enable WPA3 support.

   Example

   ```
   Device(config-wlan)# security wpa wpa3
   ```

9. Enable WPA3 OWE support.

   Example

   ```
   Device(config-wlan)# security wpa akm owe
   ```

10. Configure the open or OWE transition mode WLAN ID.

    Example

    ```
    Device(config-wlan)# security wpa transition-mode-wlan-id wlan-id
    ```

> **Note**
>
> Validation is not performed on the transition mode WLAN. You must configure it correctly by assigning the open WLAN identifier to the OWE WLAN, and the OWE WLAN identifier to the open WLAN configuration.
>
> Assign the OWE WLAN ID as the transition mode WLAN ID in the open WLAN configuration. Similarly, assign the open WLAN ID as the transition mode WLAN ID in the OWE WLAN configuration.

11. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

12. Return to the privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The WLAN is configured in WPA3 OWE transition mode and is ready for client connections using the specified security settings.

Configure WPA3 SAE (GUI)

Set up a wireless LAN (WLAN) that uses WPA3 Simultaneous Authentication of Equals (SAE) security using GUI.

Perform this task to enable enhanced security for your WLAN with WPA3 SAE. Use this configuration to support WPA3 for client authentication and ensure optimal wireless security.

Before you begin

Ensure Protected Management Frames (PMF) are configured internally.

- WPA2 ciphers can be used as associated ciphers.
- Fast Transition Adaptive is not supported for WPA3 SAE.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID** and the **WLAN ID**.
4. Choose **Security** > **Layer2** tab. Choose **WPA2+WPA3** in **Layer 2 Security Mode** drop-down list.
5. Uncheck the **WPAPolicy**, **802.1x**, **Over the DS**, **FT + 802.1x**, and **FT + PSK** checkboxes. Check the **WPA3 Policy**, **AES**, and **PSK** checkboxes. Enter the **Pre-Shared Key**, and choose the PSK Format from the **PSK Format** drop-down list and the PSK Type from the **PSK Type** drop-down list.
6. Click **Apply to Device**.

Your WLAN profile is now configured with WPA3 SAE security, and clients can connect using WPA3 authentication.

Configure WPA3 SAE

Enable WPA3 SAE authentication on a WLAN for enhanced Wi-Fi security.

Use this task to configure WPA3 SAE (Simultaneous Authentication of Equals) on a Cisco device. WPA3 SAE offers stronger security for wireless networks and is required for environments that need improved protection against offline dictionary attacks.

Before you begin

Configure PMF (Protected Management Frames) internally.

- You can use WPA2 ciphers with this configuration.
- Fast Transition Adaptive is not supported for WPA3 SAE.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id SSID-name
   ```

   Example

   ```
   Device(config)# wlan WPA3 1 WPA3
   ```

3. Disable security AKM for dot1x.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

4. Disable fast transition over the data source on the WLAN.

   Example

   ```
   Device(config-wlan)# no security ft over-the-ds
   ```

5. Disable 802.11r fast transition on the WLAN.

   Example

   ```
   Device(config-wlan)# no security ft
   ```

6. Disable WPA2 security. PMF is disabled now.

Example

```
Device(config-wlan)# no security wpa wpa2
```

7. Configure WPA2 cipher.

Example

```
Device(config-wlan)# security wpa wpa2 ciphers aes
```

> **Note**
>
> You can check whether cipher is configured using **no security wpa wpa2 ciphers aes**command. If cipher is not reset, configure the cipher.

8. Specify a preshared key

Example

```
Device(config-wlan)# security wpa psk set-key ascii value preshared-key
```

Example

```
Device(config-wlan)# security wpa psk set-key ascii 0 Cisco123
```

9. Enable WPA3 support.

Example

```
Device(config-wlan)# security wpa wpa3
```

> **Note**
>
> If both WPA2 and WPA3 are supported (SAE and PSK together), it is optional to configure PMF. However, you cannot disable PMF. For WPA3, PMF is mandatory.

10. Enable AKM SAE support.

Example

```
Device(config-wlan)# security wpa akm sae
```

11. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

12. Return to the privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The WLAN is configured using WPA3 SAE authentication, providing enhanced wireless security.

Configure a WPA3 SAE iPSK WLAN profile (CLI)

Configure a WLAN profile with WPA3 SAE individual pre-shared key (iPSK) security on a Cisco device by using CLI.

Use this procedure to set up a WLAN profile with enhanced authentication and security standards (WPA3 SAE iPSK). Only authorized devices can connect using individual preshared keys

Before you begin

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the WLAN.

Example

```
Device(config)# wlanwlan-name wland-id SSID-name
```

- **wlan-name** is the name of the configured WLAN.
- **wlan-id** is the WLAN identifier. The range is one to 512.
- **SSID-name** is the SSID name which can have up to 32 alphanumeric characters.

If you have already created and configured the WLAN, use the **wlan** *wlan-name* command.

3. Set MAC filtering support in WLAN.

Example

```
Device(config-wlan)# mac-filtering mac-filter-name
```

4. Disable adaptive 802.11r.

Example

```
Device(config-wlan)# no security ft adaptive
```

5. Disable WPA2 security.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2
   ```

6. Configures the preshared key in WLAN using the **security wpa psk set-key** [*ascii/hex*] **0** [*key*] command.

   Example

   ```
   Device(config-wlan)# security wpa psk set-key ascii 0 key
   ```

   Note

   WPA preshared keys must contain 8 to 63 ASCII text characters or 64 hexadecimal characters.

7. Disable security AKM for 802.1X.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

8. Enable AKM SAE support.

   Example

   ```
   Device(config-wlan)# security wpa akm sae
   ```

9. Enable AKM SAE PWE support (hash-to-element).

   Example

   ```
   Device(config-wlan)# security wpa akm sae pwe h2e
   ```

   Note

   This step applies to the Hunting and Pecking (HnP) password element method as well.

10. Enable WPA3 support.

Example

```
Device(config-wlan)# security wpa wpa3
```

11. Require clients to negotiate Protected Management Frames (PMF) protection in the WLAN.

Example

```
Device(config-wlan)# security pmf mandatory
```

12. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

Clients can now connect to this WLAN using the specified individual pre-shared keys and WPA3 security protocols after the WPA3 SAE iPSK WLAN profile is configured and enabled.

Configure a policy profile with AAA override and VLAN assignment (CLI)

Create and activate a wireless policy profile using the CLI.

Use this procedure to define a policy profile that controls AAA override, VLAN assignment, and other interface features on a Cisco device.

Before you begin

Verify that necessary VLANs exist on the device.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure policy profile.

Example

```
Device(config)# wireless profile policy policy-profile-name
```

3. Configure AAA override to apply to the policies coming from the AAA or Cisco Identity Services Engine (ISE) server.

Example

```
Device(config-wireless-policy)# aaa-override
```

4. Configure VLAN.

Example

```
Device(config-wireless-policy)# vlan 166
```

5. Enable policy profile.

Example

```
Device(config-wireless-policy)# no shutdown
```

The policy profile is configured and enabled for wireless operations on the device.

Configure a passphrase in a client authorization policy in the RADIUS server(GUI)

Set up a passphrase in a client authorization policy on the RADIUS server to support secure client authentication.

Configure a passphrase in Cisco Identity Services Engine (ISE). To do this, create a client authorization profile and include the required advanced attributes.

Before you begin

Procedure

---

1. Log in to the Cisco Identity Services Engine (ISE).
2. Click **Policy** and then click **Policy Elements**.
3. Click **Results**.
4. Expand **Authorization** and click **Authorization Profiles**.
5. Click **Add** to create a new authorization profile for the URL filter.
6. In the **Name** field, enter a name for the profile, for example, *po-sae-ipsk*.
7. From the **Access Type** drop-down list, choose **ACCESS_ACCEPT**.
8. From the **Termination-Action** drop-down list, choose **RADIUS-Request**.
9. In the **Advanced Attributes Setting** section, from the drop-down list, choose **Cisco:cisco-av-pair**.
10. Enter each value separately. After adding a value, click (+) icon after each of them:
    - `cisco-av-pair = psk-mode=ascii`
    - `cisco-av-pair = psk=123123123`
11. Verify the contents in the **Attributes Details** section and click **Save**.

You created a new client authorization profile in Cisco ISE with a custom passphrase. This enables secure client authentication through RADIUS.

Configure WPA3 SAE H2E (GUI)

Use WPA3 SAE H2E to secure your WLAN through a streamlined GUI-based configuration.

Use this procedure to strengthen Wi-Fi security by configuring WPA3 SAE H2E, which enhances protection against offline dictionary attacks.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID**, and the **WLAN ID**.
4. Choose **Security** > **Layer2** tab. From the **Layer 2 Security Mode** drop-down list, choose **WPA2+WPA3** or **WPA3**.
5. Uncheck the **WPAPolicy**, **802.1x**, **Over the DS**, **FT + 802.1x**, and **FT + PSK** check boxes. Check the **WPA3 Policy**, **AES** and **PSK** check boxes. Enter the **Pre-Shared Key**, and from the **PSK Format** drop-down list, choose the PSK Format, and from the **PSK Type** drop-down list, choose the PSK Type.
6. Check the **SAE** check box.

   Note

   SAE is enabled only if the Fast Transition is disabled.

7. From the **SAE Password Element** drop-down list, choose **Hash to Element Only** to configure the WPA3 SAE H2E.
8. Click **Apply to Device**.

Your WLAN is now secured with WPA3 SAE H2E, based on your configuration.

Configure WPA3 SAE H2E (CLI)

Enable WPA3 SAE Hash-to-Element (H2E) for secure WLAN connectivity.

Use this task to configure WPA3 SAE H2E for a WLAN on a device running Cisco IOS-XE.

Before you begin

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id SSID-name
   ```

   Example

   ```
   Device(config)# wlan WPA3 1 WPA3
   ```

3. Disable security AKM for 802/1X.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

4. Disable fast transition over the data source on the WLAN.

Example

```
Device(config-wlan)# no security ft over-the-ds
```

5. Disable 802.11r fast transition on the WLAN.

Example

```
Device(config-wlan)# no security ft
```

6. Disable WPA2 security. PMF is disabled now.

Example

```
Device(config-wlan)# no security wpa wpa2
```

7. Configure WPA2 cipher.

Example

```
Device(config-wlan)# security wpa wpa2 ciphers aes
```

> **Note**
>
> You can check whether cipher is configured using **no security wpa wpa2 ciphers aes** command. If cipher is not reset, configure the cipher.

8. Specify a preshared key

Example

```
Device(config-wlan)# security wpa psk set-key ascii value preshared-key
```

Example

```
Device(config-wlan)# security wpa psk set-key ascii 0 Cisco123
```

9. Enable WPA3 support.

Example

```
Device(config-wlan)# security wpa wpa3
```

10. Enable AKM SAE support.

Example

```
Device(config-wlan)# security wpa akm sae
```

11. Enable AKM SAE PWE support using the **security wpa akm sae pwe {h2e | hnp | both-h2e-hnp}** command.

Example

```
Device(config-wlan)# security wpa akm sae pwe
```

PWE supports these options:

- h2e: Hash-to-Element only; disables HnP.
- hnp: Hunting and Pecking only; disables H2E.
- Both-h2e-hnp: Both Hash-to-Element and Hunting and Pecking support (Is the default option).

12. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

13. Return to the privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

WPA3 SAE H2E is enabled for the specified WLAN. Wireless clients can now connect securely using WPA3 SAE H2E.

Configure WPA3 WLAN for Transition Disable

Configure WPA3 WLAN for Transition Disable using commands.

Enable the transition-disable feature for a WPA3 Wi-Fi network. This improves wireless security and prevents fallback to less secure protocols.

Use this task to ensure clients connect only with WPA3 security. The configuration prevents fallback to WPA2 in transition mode.

Before you begin

Make sure the **security wpa wpa3** command is enabled on your device, as transition disable is available only when WPA3 is enabled.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enter the WLAN configuration sub-mode.

Example

```
Device(config)# wlan wlan-name wlan-id SSID-name
```

3. Enable Transition Disable support.

Example

```
Device(config-wlan)# transition-disable
```

4. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

After completing these steps, clients can connect to your WPA3 WLAN only using WPA3 security.

Configure anti-clogging and SAE retransmission (GUI)

Set up Anti-Clogging and SAE retransmission parameters for a WLAN profile using the graphical user interface.

Perform this task to enable stronger wireless security features. This task also optimizes retransmission settings for your SSID.

Before you begin

Gather necessary values for Profile Name, SSID, WLAN ID, anti-clogging threshold, maximum retries, and retransmit timeout.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID** and the **WLAN ID**.
4. Enable or disable **Status** and **Broadcast SSID** toggle buttons.
5. From the **Radio Policy** drop-down list, choose a policy.
6. Choose **Security** > **Layer2** tab. Check the **SAE** check box.
7. Enter the **Anti Clogging Threshold**, **Max Retries** and **Retransmit Timeout**.
8. Click **Apply to Device**.

Anti-clogging and SAE retransmission settings are applied to the selected WLAN profile. Devices connecting to this SSID will now use the updated security and retransmission settings.

Configure anti-clogging and SAE retransmission (CLI)

Configure anti-clogging thresholds and SAE retransmission settings on a WLAN using CLI commands.

Anti-clogging and Secure Authentication of Equals (SAE) retransmission settings help prevent authentication floods and improve handshake reliability for your WLAN. Perform these steps after you configure the basic SAE WLAN settings.

Before you begin

Complete the SAE WLAN configuration

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id SSID-name
   ```

3. Disable the WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

4. Enable simultaneous authentication of equals as a security protocol.

   Example

   ```
   Device(config-wlan)# security wpa akm sae
   ```

5. Configure threshold on the number of open sessions to trigger the anti-clogging procedure for new sessions.

   Example

   ```
   Device(config-wlan)# security wpa akm sae anti-clogging-threshold 2000
   ```

6. Configure the maximum number of retransmissions.

   Example

   ```
   Device(config-wlan)# security wpa akm sae max-retries retry-limit
   ```

7. Configure SAE message retransmission timeout value.

Example

```
Device(config-wlan)# security wpa akm sae retransmit-timeout
retransmit-timeout-limit
```

8. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

9. Return to the privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

Anti-clogging and SAE retransmission settings are applied to the WLAN.

Verify WPA3 SAE and OWE

Verify WPA3 SAE and OWE.

To view the system level statistics for the client that has undergone successful SAE authentication, SAE authentication failures, SAE ongoing sessions, SAE commit and confirm message exchanges, use this show command:

```
Device# show wireless stats client detail

        Total Number of Clients : 0

        client global statistics:

------------------------------------------------------------------------------

        Total association requests received             : 0
        Total association attempts                      : 0
        Total FT/LocalAuth requests                     : 0
        Total association failures                      : 0
        Total association response accepts              : 0
        Total association response rejects              : 0
        Total association response errors               : 0
        Total association failures due to blacklist     : 0
        Total association drops due to multicast mac    : 0
        Total association drops due to throttling       : 0
        Total association drops due to unknown bssid    : 0
        Total association drops due to parse failure    : 0
        Total association drops due to other reasons    : 0
        Total association requests wired clients        : 0
        Total association drops wired clients           : 0
        Total association success wired clients         : 0
        Total peer association requests wired clients   : 0
        Total peer association drops wired clients      : 0
        Total peer association success wired clients    : 0
        Total 11r ft authentication requests received   : 0
        Total 11r ft authentication response success    : 0
        Total 11r ft authentication response failure    : 0
        Total 11r ft action requests received           : 0
```

```
        Total 11r ft action response success             : 0
        Total 11r ft action response failure             : 0
        Total AID allocation failures                    : 0
        Total AID free failures                          : 0
        Total roam attempts                              : 0
        Total CCKM roam attempts                       : 0
        Total 11r roam attempts                        : 0
        Total 11i fast roam attempts                   : 0
        Total 11i slow roam attempts                   : 0
        Total other roam type attempts                 : 0
        Total roam failures in dot11                     : 0

        Total WPA3 SAE attempts                          : 0
        Total WPA3 SAE successful authentications        : 0
        Total WPA3 SAE authentication failures           : 0
        Total incomplete protocol failures             : 0
        Total WPA3 SAE commit messages received          : 0
        Total WPA3 SAE commit messages rejected          : 0
        Total unsupported group rejections             : 0
        Total WPA3 SAE commit messages sent              : 0
        Total WPA3 SAE confirm messages received         : 0
        Total WPA3 SAE confirm messages rejected         : 0
        Total WPA3 SAE confirm messgae field mismatch  : 0
        Total WPA3 SAE confirm message invalid length  : 0
        Total WPA3 SAE confirm messages sent             : 0
        Total WPA3 SAE Open Sessions                     : 0
        Total SAE Message drops due to throttling        : 0

        Total Flexconnect local-auth roam attempts       : 0
        Total AP 11i fast roam attempts                : 0
        Total 11i slow roam attempts                   : 0

        Total client state starts                        : 0
        Total client state associated                    : 0
        Total client state l2auth success                : 0
        Total client state l2auth failures               : 0
        Total blacklisted clients on dot1xauth failure   : 0
        Total client state mab attempts                  : 0
        Total client state mab failed                    : 0
        Total client state ip learn attempts             : 0
        Total client state ip learn failed               : 0
        Total client state l3 auth attempts              : 0
        Total client state l3 auth failed                : 0
        Total client state session push attempts         : 0
        Total client state session push failed           : 0
        Total client state run                           : 0
        Total client deleted                             : 0
```

To view the WLAN summary details, use this command.

```
Device# show wlan summary

        Number of WLANs: 3

        ID   Profile Name                    SSID
  Status Security

--------------------------------------------------------------------------------------------------
```

```
      1    wlan-demo                          ssid-demo
 DOWN   [WPA3][SAE][AES]

      3    CR1_SSID_mab-ext-radius            CR1_SSID_mab-ext-radius
 DOWN   [WPA2][802.1x][AES]

      109  guest-wlan1                        docssid
 DOWN   [WPA2][802.1x][AES],[Web Auth]
```

To view the WLAN properties (WPA2 and WPA3 mode) based on the WLAN ID, use this command.

```
Device# show wlan id 1

        WLAN Profile Name     : wlan-demo

125 WPA3 Security Enhancements for Access Points

Topics:

- WPA3 security enhancements for APs

About WPA3 security enhancements for APs.

WPA3 security enhancements for APs

Introduces WPA3 security enhancements for access points and outlines key guidelines and limitations to consider when deploying WPA3 features in wireless environments.

WPA3 security enhancements for access points are wireless security features that

- introduce advanced encryption methods such as GCMP-256 and SuiteB-192-1X AKM
- strengthen authentication and data protection with features like SAE-EXT-KEY support and AP beacon protection, and
- allow multiple cipher suites to be configured per WLAN, providing greater flexibility and security for wireless networks.

Cipher suites are sets of encryption and integrity algorithms designed to protect radio communication on your wireless LANs. You must use a cipher suite when using Wi-Fi Protected Access (WPA), WPA2, WPA3, or Cisco Centralized Key Management (CCKM). Wired Equivalent Privacy, or WEP, is a form of wireless authentication used for associating to 802.11 wireless networks.

Feature Name	Release	Description
Wi-Fi 7 WPA3 Security Constraints	Cisco IOS XE 17.15.2	In this release, the Wi-Fi 7 standard dictates these security constraints, which are applicable for Wi-Fi 7-compliant APs. The security standards listed are beaconed as Wi-Fi 7 clients, which is a deviation from the actual security constraint. • Open authentication as Wi-Fi 7 is not permitted to associate. • WPA1 as Wi-Fi 7 is not permitted to associate. • WPA2 as Wi-Fi 7 is not permitted to associate. • WPA3 is permitted with certain restrictions. Restrictions to permit WPA3. • SAE (24/25) is permitted with GCMP-256. • SAE (8/9) is permitted. This is a deviation from the actual security constraint. • WPA2 PSK/802.1X with PMF is permitted. This is a deviation from the actual security constraint. • 802.1X-SHA256 with PMF is permitted. • Suite-B-192 with PMF is permitted.

Feature Name	Release	Description
Decoupled GCMP-256 and Suite-B-192-1X AKM Configuration	Cisco IOS XE 17.15.1	There is a strong dependency between the GCMP-256 cipher and the Suite-B-192-1X AKM. Until Cisco IOS XE 17.14.1, configuring the GCMP-256 cipher automatically enabled the Suite-B-192-1X AKM because it could not be enabled separately using commands. In the Cisco IOS XE 17.15.1 release, this dependency is removed through new configuration options, allowing the GCMP-256 cipher to be used with other supported AKMs. Suite-B-192-1X AKM is useful for enterprise networks, including federal government and health care deployments that require the highest level of security. Until Cisco IOS XE 17.14.1, Suite-B-192-1X AKM was tied to GCMP-256 and was implicitly enabled when GCMP-256 was configured at the WLAN level. From Cisco IOS XE 17.15.1 onward, a new AKM configuration allows Suite-B-192-1X AKM to be enabled separately, and GCMP-256 cipher configuration applies only to the cipher.

Feature Name	Release	Description
Wi-Fi Protected Access (WPA3) Security Enhancements for Access Points	Cisco IOS XE 17.15.1	From Cisco IOS XE 17.15.1 onwards, OWE association is supported on both CCMP-128 and GCMP-256 ciphers. If you configure both ciphers, a client will select its desired cipher suite while connecting in the association request. The security enhancements developed in Cisco IOS XE 17.15.1 for APs are: • GCMP-256 Cipher and Secure Agile Exchange (SAE) Autonomous Key Management (AKM) • SAE-EXT Key Support • AP Beacon Protection • Multiple Cipher Support Per WLAN • Opportunistic Wireless Encryption (OWE) Support with GCMP-256 Cipher The configuration commands introduced are: • **security wpa akm sae ext-key** • **security wpa akm ft sae ext-key** • **security wpa akm suiteb-192** • **security wpa akm suiteb** • **security wpa wpa2 ciphers** • **security wpa wpa3 beacon-protection**
Opportunistic Wireless Encryption (OWE) Support with GCMP-256 Cipher	Cisco IOS XE 17.14.1	Until Cisco IOS XE 17.14.1, OWE was supported with the CCMP-128 cipher.

Benefits of using GCMP-Based ciphers

- Provides secure communication and data transmission.
- Provides confidentiality and integrity protection.
- Provides parallel processing and fast encryption.

Wireless Encryption Methods for Data Protection

Encryption protects data by making it unreadable to unauthorized users.

These are the encryption protocols are used in wireless authentication.

- **Temporal Key Integrity Protocol (TKIP)**: TKIP is the encryption method used by WPA and supports legacy WLAN equipment. TKIP addresses the original flaws associated with the 802.11 WEP encryption method. It makes use of WEP but encrypts the Layer 2 payload using TKIP and carries out a message integrity check (MIC) in encrypted packets to ensure that messages have not been altered.
- **Advanced Encryption Standard (AES)**: AES uses Counter Cipher Mode with Block Chaining Message Authentication Code Protocol (CCMP), which allows destination hosts to recognize if the encrypted and non-encrypted bits have been altered.

  Attention

  AES is a preferred method because of its strong encryption.

  CCMP is the standard encryption protocol for use with Wi-Fi Protected Access 2 (WPA2) and is much more secure than the WEP protocol, and TKIP of WPA.
- **Galois or Counter Mode Protocol (GCMP):** GCMP is more secure and efficient than CCMP.

Note

Choose the appropriate note type from the attributes.

Supported platforms

- Cisco Catalyst 9800-CL Wireless Controller for Cloud
- Cisco Catalyst 9800-L Wireless Controller
- Cisco Catalyst 9800-40 Wireless Controller
- Cisco Catalyst 9800-80 Wireless Controller
- Cisco Catalyst 9300 Series Switches
- Cisco Embedded Wireless Controller on Catalyst Access Points

Supported APs

- Cisco Aironet 2800 Series Access Points
- Cisco Aironet 3800 Series Access Points
- Cisco Aironet 4800 Series Access Points
- Cisco Catalyst 9117 Series Access Points
- Cisco Catalyst 9124AX Series Access Points
- Cisco Catalyst 9130AX Series Access Points
- Cisco Catalyst 9136 Series Access Points
- Cisco Catalyst 9162 Series Access Points
- Cisco Catalyst 9164 Series Access Points

- Cisco Catalyst 9166 Series Access Points
- Cisco Aironet 1560 Series Outdoor Access Points

Restrictions

This section lists the guidelines and limitations for AP WPA3 security enhancements.

- WPA3 is not supported on Cisco Wave 1 APs.
- GCMP-256 is not supported on Cisco Catalyst 9105, 9110, 9115, 9120 APs and 802.11ac Wave2 QCA APs such as 1852.
- Beacon Protection is only supported on QCA-based APs, such as 9130 , 9136, 9162, 9164, and 9166.

Wi-Fi 7 WPA3 security constraints

In the Cisco IOS XE 17.15.2 release, the Wi-Fi 7 standard dictates these security constraints, which are applicable for Wi-Fi 7 compliant APs:

The security standards described here are advertised as Wi-Fi 7 clients. This is a deviation from the actual security constraint.

- Open authentication as Wi-Fi 7 is not permitted to associate.
- WPA1 as Wi-Fi 7 is not permitted to associate.
- WPA2 as Wi-Fi 7 is not permitted to associate.
- WPA3 is permitted with certain restrictions:
  - SAE 24 or 25 is permitted with GCMP-256.
  - SAE 8 or 9 is permitted. (This is a deviation from the actual security constraint.)
  - WPA2 PSK or 802.1x with PMF is permitted. (This is a deviation from the actual security constraint.)
  - 802.1x-SHA256 with PMF is permitted.
  - Suite-B-192 with PMF is permitted.

GCMP-256 Cipher and SuiteB-192-1X AKM

Explains support for GCMP-256 cipher and SuiteB-192-1X AKM, providing procedures for configuring SuiteB-192-1X AKM using both GUI and CLI interfaces.

A GCMP-256 cipher and SuiteB-192-1X AKM are Wi-Fi security mechanisms that

- provide strong encryption and authentication for wireless communications
- help meet high-security requirements for environments such as government and healthcare, and
- support flexible configuration in recent Cisco IOS XE releases.

Decoupled GCMP-256 and Suite-B-192-1X AKM configuration

There is a strong dependency between the GCMP-256 cipher with Suite-B-192-1X AKM. Therefore, until Cisco IOS XE 17.14.1, if you configure the GCMP-256 cipher, the Suite-B-192-1X AKM automatically gets enabled, as Suite-B-192-1X Authentication and Key Management (AKM) cannot be enabled separately using commands.

In the Cisco IOS XE 17.15.1 release, certain commands eliminate the dependency between Suite-B-192-1X AKM and the GCMP-256 cipher. CMP-256 cipher can be configured with other supported AKMs.

GCMP-256 cipher and Suite-B-192-1X AKM were previously strongly dependent features.

- Until Cisco IOS XE 17.14.1, enabling GCMP-256 cipher also enabled Suite-B-192-1X AKM, and Suite-B-192-1X AKM could not be enabled separately.
- From Cisco IOS XE 17.15.1 onwards, the dependency is removed and each can be configured independently.

Configure SuiteB-192-1X AKM (GUI)

Enable SuiteB-192-1X Authentication and Key Management (AKM) for a WLAN using the required cipher combinations.

Use this procedure to configure secure authentication and encryption for WLANs, ensuring compliance with SuiteB-192-1X standards.

Before you begin

Confirm the device supports SuiteB-192-1X AKM and required cipher options.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.

   The **Add WLAN** window is displayed.
3. In the **General** tab, enter the **Profile Name**, **SSID**, and the **WLAN ID**.
4. Choose **Security** > **Layer2**, select one of these options:
   - **WPA + WPA2**
   - **WPA2 + WPA3**
   - **WPA3**

   The **Auth Key Mgmt (AKM)** section displays the AKMs supported by the cipher you select in the **WPA2/WPA3 Encryption** section. Valid cipher and AKM combinations are displayed in the **Auth Key Mgmt (AKM)** section.

   For example, to enable SuiteB-192-1x AKM,
   - The valid security encryption and AKM combination for **WPA + WPA2** and **WPA2 + WPA3** is **CCMP256** and/or **GCMP256** cipher + **SuiteB-192-1X** AKM.

     Note

     CCMP256 cipher is not valid without the GCMP256 cipher for SuiteB-192-1X AKM.

   - The valid security encryption and AKM combination for **WPA3** is **GCMP256** cipher + **SUITEB-192-1X** or **OWE** or **SAE-EXT-KEY** or **FT + SAE-EXT-KEY** AKM.

     Note

     At least one AKM should be enabled. To enable SuiteB-192-1X, check the SUITEB 192-1X check box.

5. In the **WPA2 Encryption** section, check the **GCMP256** check box.

   Valid cipher and AKM combinations are displayed in the **Auth Key Mgmt (AKM)** section.

6. In the **Fast Transition** section, in the **Status** drop-down list, select **Disabled**.

> **Note**
>
> Disable **Fast Transition** when Suite-B cipher (GCMP256, CCMP256, GCMP128) is configured.

7. In the **Auth Key Mgmt (AKM)** section, check the **SUITEB192-1X** check box.
8. Click **Apply to Device**.

The WLAN is now configured with SuiteB-192-1X AKM and the required ciphers, enabling secure authentication and encryption.

Configure SuiteB-192-1X AKM (CLI)

Enable SuiteB-192-1X Authentication and Key Management (AKM) for a WLAN using the required cipher combinations.

Use this procedure to configure secure authentication and encryption for WLANs, ensuring compliance with SuiteB-192-1X standards.

Before you begin

Confirm the device supports SuiteB-192-1X AKM and required cipher options.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the WLAN profile and SSID. Enter the WLAN configuration mode.

Example

```
Device(config)# wlan wlan-profile-name wlan-id ssid-name
```

3. Disable adaptive 802.11r.

Example

```
Device(config-wlan)# no security ft adaptive
```

4. Disable security AKM for 802.1X.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

5. Configure the SuiteB-192-1X support.

Example

```
Device(config-wlan)# security wpa akm suiteb-192
```

6. Configure the GCMP256 support using the **security wpa wpa2 ciphers {aes | ccmp256 | gcmp128 | gcmp256}** command.

Example

```
Device(config-wlan)# security wpa wpa2 ciphers gcmp256
```

The WLAN is now configured with SuiteB-192-1X AKM and the required ciphers, enabling secure authentication and encryption.

SAE-EXT-KEY support

Describes SAE-EXT-KEY and FT-SAE-EXT-KEY AKM capabilities, offering step-by-step instructions for configuring them through GUI and CLI, and explains how to verify SAE-EXT-KEY AKM support.

The Cisco IOS XE 17.15.1 release introduces new SAE AKMs: SAE-EXT-KEY (24) and FT-SAE-EXT-KEY (25).

- Devices can connect using the new SAE AKMs (24 and 25) and negotiate encryption with GCMP-256, CCMP-128, or both ciphers.

> **Note**
>
> Ensure that the WPA3 policy is enabled for the new AKMs to be displayed.

Configure SAE-EXT-KEY AKMs (GUI)

Set up SAE-EXT-KEY Authentication and Key Management (AKM) on a WLAN to enhance wireless security with advanced password-based authentication protocols.

Use this task when configuring a Wi-Fi network profile requiring the SAE-EXT-KEY or Fast Transition (FT) + SAE-EXT-KEY AKMs for WPA2 or WPA3-enabled WLANs. These settings enable secure password management and provide robust wireless security.

Before you begin

- Ensure that the WLAN controller supports SAE-EXT-KEY and FT + SAE-EXT-KEY AKMs.
- Verify that WPA3 security policies are enabled.
- Gather values for anti-clogging threshold, maximum retries, retransmit timeout, and the required pre-shared key (PSK).

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.

   The **Add WLAN** window is displayed.

3. In the **General** tab, enter the **Profile Name**, **SSID**, and the **WLAN ID**.
4. Choose **Security** > **Layer2** and select one of these options:
   - **WPA2 + WPA3**
   - **WPA3**

   The **Auth Key Mgmt (AKM)** section will be populated with the possible AKMs that are supported by the cipher that is selected in the **WPA2/WPA3 Encryption** section. Valid AKMs are displayed in the **Auth Key Mgmt (AKM)** section.

   > **Note**
   >
   > Ensure that the WPA3 policy is enabled for the new AKMs to be displayed.

5. In the **WPA2/WPA3 Encryption** section, check the **GCMP256** check box, or the **AES(CCMP128)** check box, or a combination of both these check boxes.

   > **Note**
   >
   > The AES(CCMP128) cipher check box is selected by default.

   The AKMs are displayed in the **Auth Key Mgmt (AKM)** section.

6. In the **Auth Key Mgmt (AKM)** section, check either the **SAE-EXT-KEY** check box or the **FT + SAE-EXT-KEY** check box, or select both the AKMs.

   Complete these steps:

   a) Enter the **Anti Clogging Threshold** value. Valid range is 0 to 3000; default value is 1500.
   b) Enter the number of allowed **Max Retries**. Valid range is 1 to 10; default value is five.
   c) Enter the **Retransmit Timeout** value in seconds. Valid range is 1 to 10000; default value is 400.
   d) From the drop-down lists, select the **PSK Format** and the **PSK Type**.
   e) Enter the **Pre-Shared Key**.
   f) From the **SAE Password Element** drop-down list, select one of these methods to generate the SAE password element:
      - **Both H2E and HnP**: The password element is generated from both Hash-to Element (H2E) and Hunting and Pecking methods (HnP). This is the default option.
      - **Hash to Element only**: In this method, the secret password element used in the SAE protocol is generated from a password. H2E is based on a noniterative algorithm that is more computationally efficient and provides robust resistance to side-channel attacks. If selected, HnP is disabled.
      - **Hunting and Pecking only**: This method uses the iterative looping algorithm to generate the password element. As this method is prone to attacks, we recommend that you use the other two methods. If you select the Hunting and Pecking only option, H2E is disabled.

> **Note**
>
> SAE-EXT-KEY and FT + SAE-EXT-KEY requires the password element mode to be **Both H2E and HnP** or **Hash to Element only**.

If you select an option with WPA2, configure MPSK by completing these steps:

a. In the **MPSK Configuration** section, check the **Enable MPSK** check box.

b. In the **Auth Key Mgmt** section, choose the **PSK Format** (default is ASCII), PSK Type (default is unencrypted), and enter the **Pre-Shared Key**.

c. In the **MPSK Configuration** section, click **Add**.

Ensure that there are no warnings or error messages in the **Auth Key Mgmt** section, related to encryption and cipher combination.

d. Click **Apply**, and then click **Apply to Device**.

7. Click **Apply to Device**.

The WLAN is now configured with enhanced SAE-EXT-KEY authentication key management, providing robust, standards-based password security for WPA2 or WPA3 wireless networks.

Configure SAE-EXT-KEY AKMs (GUI)

Set up SAE-EXT-KEY Authentication and Key Management (AKM) on a WLAN to enhance wireless security with advanced password-based authentication protocols.

Use this task when configuring a Wi-Fi network profile requiring the SAE-EXT-KEY or Fast Transition (FT) + SAE-EXT-KEY AKMs for WPA2 or WPA3-enabled WLANs. These settings enable secure password management and provide robust wireless security.

Before you begin

- Ensure that the WLAN controller supports SAE-EXT-KEY and FT + SAE-EXT-KEY AKMs.
- Verify that WPA3 security policies are enabled.
- Gather values for anti-clogging threshold, maximum retries, retransmit timeout, and the required pre-shared key (PSK).

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the WLAN profile and SSID. Enter the WLAN configuration mode.

Example

```
Device(config)# wlan wlan-profile-name wlan-id ssid-name
```

3. Disable adaptive 802.11r.

   Example

   ```
   Device(config-wlan)# no security ft adaptive
   ```

4. Configure the pre-shared key (PSK) either in the ASCII format or the HEX format. with the **security wpa psk set-key {ascii | hex} {0 | 8}** *pre-shared-key* command.

   Example

   ```
   Device(config-wlan)# security wpa psk set-key ascii 0 123456789
   ```

5. Disable security Auth Key Management (AKM) for 802.1X.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

6. Configure the SAE-EXT-KEY AKM support.

   Example

   ```
   Device(config-wlan)# security wpa akm sae ext-key
   ```

7. Configure WPA3 support.

   Example

   ```
   Device(config-wlan)# security wpa wpa3
   ```

8. Configure WPA2 and GCMP-256 cipher support.

   Example

   ```
   Device(config-wlan)# security wpa wpa2 ciphers gcmp256
   ```

The WLAN is now configured with enhanced SAE-EXT-KEY authentication key management, providing robust, standards-based password security for WPA2 or WPA3 wireless networks.

Configure FT-SAE-EXT-KEY AKMs (CLI)

Enable FT-SAE-EXT-KEY Authentication and Key Management (AKM) for a WLAN profile on your device using CLI.

Use this task when you want to support fast transition (FT) and SAE AKM with extended keys for secure wireless authentication.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN profile and SSID. Enter the WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan-profile-name wlan-id ssid-name
   ```

3. Configure fast transition

   Example

   ```
   Device(config-wlan)# security ft adaptive
   ```

4. Configure the pre-shared key (PSK) either in the ASCII format or the HEX format using the **security wpa psk set-key {ascii | hex} {0 | 8}** *pre-shared-key* command.

   Example

   ```
   Device(config-wlan)# security wpa psk set-key ascii 0 123456789
   ```

5. Disable security Auth Key Management (AKM) for 802.1X.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

6. Configure the FT-SAE-EXT-KEY AKM support.

   Example

   ```
   Device(config-wlan)# security wpa akm ft sae ext-key
   ```

7. Configure WPA3 support.

   Example

   ```
   Device(config-wlan)# security wpa wpa3
   ```

8. Configure WPA2 and GCMP-256 cipher support.

   Example

   ```
   Device(config-wlan)# security wpa wpa2 ciphers gcmp256
   ```

The WLAN profile is configured to use FT-SAE-EXT-KEY AKM for secure, fast wireless transitions supporting WPA3 and WPA2 or GCMP-256.

Verify the SAE-EXT-KEY AKM support

Describes the verification of the SAE-EXT-KEY AKM Support

Summary of SAE-EXT-KEY AKMs

To view the summary of the SAE-EXT-KEY AKMs, use this command:

```
Device# show wlan summary
Number of WLANs: 5

ID   Profile Name                      SSID                              Status

Cipher and AKMs based on client MAC address

To view the details of the cipher and AKMs based on the client MAC address, use this command:

```
Device# show wireless client mac-address 3089.4aXX.f0XX detail
Client MAC Address : 3089.4aXX.f0XX
.
.
.
Policy Type : WPA3
Encryption Cipher : GCMP-256
Authentication Key Management : SAE-EXT-KEY
.
.
.
Client MAC Address : 3089.4aXX.f0XX
.
.
.
Policy Type : WPA3
Encryption Cipher : GCMP-256
Authentication Key Management : FT-SAE-EXT-KEY
.
.
.
```

AKM support statistics report

To view the AKM support statistics report, use this command:

```
Device# show wireless stats client detail
Total WPA3 SAE attempts                          :71
Total WPA3 SAE successful authentications        : 9
  Total SAE-EXT-KEY successful authentications   : 3
Total WPA3 SAE authentication failures           : 22
  Total incomplete protocol failures             : 0
Total WPA3 SAE commit messages received          : 126
Total WPA3 SAE commit messages rejected                                  : 58
  Total unsupported group rejections                                     : 0
  Total PWE method mismatch for SAE Hash to Element commit received      : 0
  Total PWE method mismatch for SAE Hunting And Pecking commit received : 0
Total WPA3 SAE commit messages sent              : 175
Total WPA3 SAE confirm messages received         : 13
Total WPA3 SAE confirm messages rejected         : 4
  Total WPA3 SAE message confirm field mismatch  : 4
  Total WPA3 SAE confirm message invalid length  : 0
Total WPA3 SAE confirm messages sent             : 13
Total WPA3 SAE Open Sessions                     : 0
Total SAE Message drops due to throttling        : 0
Total WPA3 SAE Hash to Element commit received   : 111
Total WPA3 SAE Hunting and Pecking commit received : 15
```

AP beacon protection

Outlines AP beacon protection features, guiding users through configuration using GUI and CLI, and presents verification steps to confirm beacon protection status.

An AP beacon protection is a WLAN security feature that

- prevents attackers from modifying AP beacons and their capabilities
- uses a Beacon Integrity Key to generate a Message Integrity Code (MIC) in AP beacons, and
- enables clients to validate beacon authenticity and reject APs sent by attackers.

Expanded explanation

AP beacon protection works by transmitting a Beacon Integrity Key during the WPA2 or WPA3 four-way handshake. Genuine APs use this key to produce a MIC in their beacon frames. Clients verify the MIC to ensure beacons are authentic. The system rejects any beacon that fails validation.

A client device receives a beacon from an AP and checks the MIC. If the MIC is valid, the client associates with the AP; if not, the client ignores the beacon, preventing rogue AP attack

Configure AP beacon protection (GUI)

You can perform this task to enable AP beacon protection on your WLAN using the CLI and WPA3 security.

Before you begin

- Ensure that you are configuring a WLAN profile that supports WPA3 AKM (for example, SAE, FT-SAE, OWE, DOT1X-SHA256, and so on).
- Replace the sample AKMs with the specific WPA3 AKM you want to use.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.

   The **Add WLAN** window is displayed.
3. In the **General** tab, enter the **Profile Name**, **SSID**, and the **WLAN ID**.
4. Choose **Security** > **Layer 2**, select either the **WPA2 + WPA3** option or the **WPA3** option.

   The **Beacon Protection** check box appears in the WPA parameters section when you enable the WPA3 policy.
5. Check the **Beacon Protection** check box.

   Note

   Protected Management Frame (PMF) is required for Beacon Protection to be enabled.
6. Click **Apply to Device**.

You have enabled AP beacon protection on your WLAN. This provides enhanced protection against beacon frame attacks when WPA3 is used.

What to do next

=

Configure AP beacon protection (CLI)

You can perform this task to enable AP beacon protection on your WLAN using the CLI and WPA3 security.

Before you begin

- Ensure that you are configuring a WLAN profile that supports WPA3 AKM (for example, SAE, FT-SAE, OWE, DOT1X-SHA256, and so on).
- Replace the sample AKMs with the specific WPA3 AKM you want to use.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN profile and SSID. Enter the WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan-profile-name wlan-id ssid-name
   ```

3. Disable adaptive 802.11r.

   Example

   ```
   Device(config-wlan)# no security ft adaptive
   ```

4. Configure the pre-shared key (PSK) either in the ASCII format or the HEX format using the **security wpa psk set-key {ascii | hex} {0 | 8}** *pre-shared-key* command.

   Example

   ```
   Device(config-wlan)# security wpa psk set-key ascii 0 123456789
   ```

5. Disable security Authentication and Key Management (AKM) for 802.1X.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

6. Configure SAE support.

   Example

   ```
   Device(config-wlan)# security wpa akm sae
   ```

7. Configure WPA3 support.

Example

```
Device(config-wlan)# security wpa wpa3
```

8. Configure AP beacon protection.

Example

```
Device(config-wlan)# security wpa wpa3 beacon-protection
```

9. Disable WPA2 security.

Example

```
Device(config-wlan)# no security wpa wpa2
```

10. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

You have enabled AP beacon protection on your WLAN. This provides enhanced protection against beacon frame attacks when WPA3 is used.

Verify AP beacon protection

Describes the show command to verify AP beacon protection

To view the AP beacon protection details, use this command:

```
Device# show wlan name wl-sae
WLAN Profile Name     : wl-sae
================================================
Identifier                                       : 7
Description                                      :
Network Name (SSID)                              : wl-sae
<...>
Security
    Security-2.4GHz/5GHz
        <...>
        Beacon Protection                        : Enabled
    Security-6GHz
        <...>
        Beacon Protection                        : Enabled
<...>
```

Multiple cipher support per WLAN

Details configuring multiple ciphers per WLAN, providing instructions for setup via GUI and CLI to enhance flexibility and security in wireless network deployments.

Multiple cipher support per WLAN is a WLAN security feature that

- allows multiple encryption ciphers to operate on a single WLAN,

- enables compatibility with various Authentication and Key Management (AKM)options, and
- supports broader device interoperability by accommodating mixed device requirements.

Mapping of cipher suites

Until Cisco IOS XE 17.14.1, only a single cipher was allowed in a WLAN, limiting the supported AKMs combinations. Only CCMP-128 cipher was used with multiple AKMs, while GCMP-128 was tightly coupled with the Suite-B-1x AKM and CCMP-256 or GCMP-256 were tightly coupled with the Suite-B-192-1x AKM.

With Cisco IOS XE 17.15.1 and later, support for multiple AKMs and cipher combinations on a single WLAN is introduced. One WLAN can now serve devices requiring different ciphers, such as GCMP-256 and CCMP-128.

The configured cipher suite(s) for a WLAN is mapped to the Pairwise Cipher Suite, Group Cipher Suite, and Management Cipher Suite broadcasted in the Beacons or Probe Responses.

Table 116: Mapping of cipher suites

Configured Cipher Suite	Pairwise Cipher Suite	Group Cipher Suite	Management Cipher Suite
CCMP-128 only	CCMP-128	CCMP-128	BIP-CMAC-128
GCMP-256 only	GCMP-256	GCMP-256 management	BIP-GMAC-256
CCMP-128 + GCMP-256	CCMP-128 or GCMP-256 (client chooses)	CCMP-128	BIP-CMAC-128

Configure multiple ciphers (GUI)

Enable support for multiple security ciphers on a WLAN using CLI commands.

Use these steps to configure a wireless LAN for multiple WPA2 ciphers, allowing enhanced security and compatibility for connecting devices.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.

   The **Add WLAN** window is displayed.
3. In the **General** tab, enter the **Profile Name**, **SSID**, and the **WLAN ID**.
4. Choose **Security** > **Layer2**, select one of the following options:
   - **WPA + WPA2**
   - **WPA2 + WPA3**
   - **WPA3**

   The **AES(CCMP128)** cipher is selected by default.

   The **Auth Key Mgmt (AKM)** section will be populated with the possible AKMs that are supported by the cipher that is selected in the **WPA2/WPA3 Encryption** section. Valid cipher and AKM combinations are displayed in the **Auth Key Mgmt (AKM)** section.
5. In the **WPA2/WPA3 Encryption** check the **GCMP256** check box, or the **AES(CCMP128)** check box, or a combination of both these check boxes, to display the AKMs in the same WLAN.

6. In the **Auth Key Mgmt (AKM)** section, check the AKM check boxes to enable the required AKMs. At least one AKM should be enabled.
7. Click **Apply to Device**.

Multiple WPA2 ciphers are now configured for the WLAN. This enhances network security and allows flexibility for supported clients.

Configure multiple ciphers (CLI)

Enable support for multiple security ciphers on a WLAN using CLI commands.

Use these steps to configure a wireless LAN for multiple WPA2 ciphers, allowing enhanced security and compatibility for connecting devices.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN profile and SSID. Enter the WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan-profile-name wlan-id ssid-name
   ```

3. Disable adaptive 802.11r.

   Example

   ```
   Device(config-wlan)# no security ft adaptive
   ```

4. Configure the pre-shared key (PSK) either in the ASCII format or the HEX format using the **security wpa psk set-key {ascii | hex} {0 | 8}** *pre-shared-key* command.

   Example

   ```
   Device(config-wlan)# security wpa psk set-key ascii 0 123456789
   ```

5. Disable security AKM for 802.1X.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

6. Configure SAE support.

   Example

   ```
   Device(config-wlan)# security wpa akm sae
   ```

7. Configure SAE-EXT-KEY AKM support.

   Example

   ```
   Device(config-wlan)# security wpa akm sae ext-key
   ```

8. Configure WPA3 support.

   Example

   ```
   Device(config-wlan)# security wpa wpa3
   ```

9. Configure WPA2 cipher support. In this example, CCMP-128 cipher is configured using the **security wpa wpa2 ciphers {aes | ccmp256 | gcmp128 | gcmp256}** command.

   Example

   ```
   Device(config-wlan)# security wpa wpa2 ciphers aes
   ```

10. Configure another WPA2 cipher (multiple cipher support). In this example, GCMP-256 cipher is configured using the **security wpa wpa2 ciphers {aes | ccmp256 | gcmp128 | gcmp256}** command.

    Example

    ```
    Device(config-wlan)# security wpa wpa2 ciphers gcmp256
    ```

Multiple WPA2 ciphers are now configured for the WLAN. This enhances network security and allows flexibility for supported clients.

OWE support with GCMP-256 cipher

Explains OWE support leveraging the GCMP-256 cipher, including procedures for configuring Opportunistic Wireless Encryption AKM through GUI and CLI for improved wireless security.

In Cisco IOS XE 17.14.1 and earlier, OWE is supported only with the CCMP-128 cipher. Starting with Cisco IOS XE 17.15.1, you can configure OWE with both CCMP-128 and GCMP-256. When you configure both, the client selects the cipher suite during association.

Configure OWE AKM (GUI)

Enable Opportunistic Wireless Encryption (OWE) for a WLAN to enhance wireless security by allowing encrypted connections without requiring pre-shared keys.

Use OWE to provide secure, open wireless access using the WLAN configuration interface, leveraging WPA3 security and modern encryption standards for wireless networks.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.

   The **Add WLAN** window is displayed.

3. In the **General** tab, enter the **Profile Name**, **SSID**, and the **WLAN ID**.
4. Choose **Security** > **Layer 2** and click the **WPA3** option.
5. In the **WPA2/WPA3 Encryption** section, check the **GCMP256** check box, or the **AES(CCMP128)** check box, or a combination of both these check boxes. The **AES(CCMP128)** check box is selected by default.
6. In the **Fast Transition** section, from the **Status** drop-down list, select **Disabled**
7. In the **Auth Key Mgmt (AKM)** section, check the **OWE** check box.

   The **Transition Mode WLAN ID** field is displayed.
8. Enter the **Transition Mode WLAN ID**. The transition-mode WLAN ID ranges are the same as the WLAN ID ranges, that is, the valid range is between 0 and 4096.
9. Click **Apply to Device**.

OWE is enabled for the selected WLAN, allowing clients to connect securely without the need for a shared password.

Configure OWE AKM (CLI)

Describes the steps to configure the OWE AKM.

Enable Opportunistic Wireless Encryption (OWE), Authentication and Key Management (AKM), for a Wireless Local Area Network (WLAN) using the CLI.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Configure the WLAN profile and SSID. Enters the WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan-profile-name wlan-id ssid-name
   ```
3. Disable adaptive 802.11r.

   Example

   ```
   Device(config-wlan)# no security ft adaptive
   ```
4. Configure the OWE AKM.

   Example

   ```
   Device(config-wlan)# security wpa akm owe
   ```

The WLAN profile is now configured to use Opportunistic Wireless Encryption AKM.

126 IP Source Guard

Topics:

- IP source guard

This chapter explains how to enable the feature on specific WLANs using GUI or commands, detailing IP/MAC binding behavior, configuration steps, and effects on forwarding to prevent IP address spoofing.

IP source guard

Explains how IP source guard features secure wireless networks by preventing unauthorized packets based on IP/MAC bindings.

A set of IP source guard features are Layer 2 security mechanisms that

- prevent the controller from forwarding packets with source IP addresses unknown to the wireless controller
- require explicit configuration per WLAN and are not enabled by default, and
- maintain an IP/MAC binding table to track and authorize valid wireless clients.

It supports both IPv4 and IPv6 wireless clients. The IPSG feature prevents the wireless controller from forwarding packets with unknown source IP addresses. This security feature is disabled by default. You must configure it explicitly for each WLAN. When you enable this feature, all wireless clients on the WLAN inherit the security setting.

Using the IP/MAC binding table, the wireless controller keeps track of IP and MAC address binding information for all wireless clients. The wireless controller collects binding information as part of the IP learning process. When this feature is enabled on a WLAN, the wireless controller forwards incoming packets from wireless clients only if a matching binding table entry exists for the source IP and MAC address combination. If the entry does not exist, the controller drops the packets.

Configure IP source guard (GUI)

Use this procedure to configure IP source guard using the GUI.

Enable IP source guard to prevent IP address spoofing on the selected WLAN using the GUI.

Before you begin

Ensure you have administrative access to the GUI. Confirm that the WLAN exists and is configured.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click on the WLAN.
3. In the **Advanced** tab, check the **IP Source Guard** checkbox.
4. Click **Update & Apply to Device**.

Configure IP source guard (CLI)

Use this procedure to configure IP source guard using commands.

Use this procedure to configure IP source guard on a WLAN using commands to protect against spoofed IP addresses.

Enabling IP source guard increases network security by ensuring that only valid IP sources are allowed on the WLAN.

Before you begin

Ensure you have administrator access to the device CLI. Have the WLAN name and ID information available.

Procedure

1. Specify the WLAN name and ID to use.

Example

```
Device(config)# wlan profile-name wlan-id ssid
```

> **Note**
>
> If a WLAN is not already configured, this step creates the WLAN.

2. Disable the WLAN.

   Example

   ```
   Device(config-wlan)# shutdown
   ```

3. Enable the IP source guard feature.

   Example

   ```
   Device(config-wlan)# ip verify source mac-check
   ```

4. Enable the WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

---

127 Traffic Filtering on AP by Source IP ACL

Topics:

- Traffic filtering on AP by source IP ACL

Traffic filtering on AP by source IP ACL

Traffic filtering on access points by source IP ACL enables administrators to control network access by allowing or blocking incoming data packets based on their source IP address. This feature applies access control rules, managed by the controller, directly to the AP and supports both FlexConnect and Local modes for enhanced network security.

This feature enables APs to filter incoming data packets based on their source IP address. This is achieved when the controller pushes Access Control List (ACL) rules to the AP.

Its primary purpose is to:

- act as the listening device filtering incoming packets based on source IP addresses, while the controller manages and pushes the relevant ACL rules to the AP.
- enhance the security of AP services by allowing administrators to restrict access to trusted sources or block known malicious entities, regardless of whether the AP is operating in flex-connect mode or local mode.

This feature is supported in both FlexConnect mode and Local mode.

Feature History for Traffic Filtering on AP by Source IP ACL

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 117: Feature history for traffic filtering on AP by source IP ACL

Release	Feature Information
Cisco IOS XE 17.18.1	This feature enables APs to filter incoming data packets based on their source IP address. This is achieved when the controller pushes Access Control List (ACL) rules to the AP. This feature is supported in both FlexConnect mode and Local mode.

Configure AP management ACL on controller

Describes the CLI steps to define and configure ACL on the controller.

Follow these steps to define the AP management ACL rules, configure ACL on the controller, attach the site tag to the AP profile, and map the site tag to the AP.

> **Note**
>
> - The default action for AP MGMT ACL is allow. Therefore, there is no need to add **allow all** at the end of the ACL.
> - Ensure not to block the UDP source ports 5246/5247, or else the AP will lose CAPWAP registering, immediately after TLV is pushed to the AP. The only way to recovery it is to clear the configuration on the controller and factory reset the AP.

Define AP management ACL rules

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Define an extended IP access-list.

   Example

   ```
   Device(config)# ip access-list extended deny-host-ssh
   ```

   ```
   Device(config)# ipv6 access-list deny-host-ssh-v6
   ```

3. Define rules to deny SSH connection from IPv4 and IPv6 source addresses.

   Example

   ```
   Device(config-ext-nacl)# 10 deny tcp host 100.100.202.1 any eq 22
   Device(config-ext-nacl)# 11 deny tcp host 100.100.202.2 any eq 22
   ```

   ```
   Device(config-ipv6-acl)# sequence 10 deny tcp host 2001:1202:DED::1 any eq
   22
   ```

Rules are defined for AP management ACL.

Example

```
Device# configure terminal
Device(config)# ip access-list extended deny-host-ssh
Device(config-ext-nacl)# 10 deny tcp host 100.100.202.1 any eq 22
Device(config-ext-nacl)# 11 deny tcp host 100.100.202.2 any eq 22
Device(config)# ipv6 access-list deny-host-ssh-v6
Device(config-ipv6-acl)# sequence 10 deny tcp host 2001:1202:DED::1 any eq 22
```

Configure AP management ACL on the controller

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the AP profile.

   Example

   ```
   Device(config)# ap profile flex-ap-profile
   ```

3. Configure the AP management access list.

   Example

   ```
   Device(config-ap-profile)# access-list {access-list-v4 | access-list-v6}
   access-list-name
   ```

4. Exit sub-mode.

   Example

   ```
   Device(config-ap-profile)# exit
   ```

AP management ACL is configured on the controller.

Example

```
Device# configure terminal
Device(config)# ap profile flex-ap-profile
Device(config-ap-profile)# access-list access-list-v4 deny-host-ssh
Device(config-ap-profile)# access-list access-list-v6 deny-host-ssh-v6
Device(config-ap-profile)# exit
```

What to do next

Attach the site tag to the AP profile and then map the site tag to the AP. For example:

```
Device(config)# wireless tag site flex-site-tag
Device(config-site-tag)# description "flex site tag"
Device(config-site-tag)# ap-profile flex-ap-profile
Device(config-site-tag)# no local-site

Device(config)# ap 48XX.d5XX.e3XX
Device(config-ap-tag)# site-tag flex-site-tag
```

Verify mapped ACLs

Describes the show commands to verify the mapped ACLs.

Verify mapped ACL details

To verify the detailed AP profile configuration with mapped ACLs, on the controller, run the **show ap profile name** *ap-profile-name* **detailed** command:

```
Device# show ap profile name flex-ap-profile etailed
AP Profile Name                : flex-ap-profile
Description                    :
Country code                   : Not configured
Stats Timer                    : 180
Link Latency                   : DISABLED
Data Encryption                : DISABLED
LED State                      : ENABLED
…

Static path MTU                   : 0
AP Management IPv4 ACL               : deny-host-ssh
AP Management IPv6 ACL               : deny-host-ssh-v6
```

Verify AP management ACL on AP

To verify the IPv4 AP management ACL on the AP, run the **show ip access-lists**command.

```
Cisco-AP# show ip access-lists
AP MGMT ACLs:
Extended IP access list deny-host-ssh
   1 deny tcp 100.100.202.1 0.0.0.0 range 0 65535 any eq 22
   2 deny tcp 100.100.202.2 0.0.0.0 range 0 65535 any eq 22
```

To verify IPv6 AP management ACL on the AP, run the **show ipv6 access-list** command.

```
Cisco-AP# show ipv6 access-list
AP MGMT ACLs:
Extended IPv6 access list deny-host-ssh-v6
    1 deny tcp host 2001:1202:ded::1 range 0 65535 any eq 22
```

Verify AP host firewall ACL drop count

To verify the statistics of the ACL drop count on the AP, run the **show datapath gateway 1213 statistics** command.

```
Cisco-AP# show datapath gateway l2l3 statistics
error stats:
Eth-Errs IP-Errs Drops MAC-filters Drop-by-ACL
       0       0     0           0           0

```

128 802.11w

Topics:

- Protected management frames with 802.11w
- Configure 802.11w

Protected management frames with 802.11w

Introduces protected management frames in 802.11w, explains IGTK and BIP integrity protocols, details SA teardown protection and associated procedures, and summarizes prerequisites and restrictions for deploying 802.11w.

A protected management frame is a wireless security feature that

- uses the 802.11w protocol to safeguard management frames
- prevents spoofing and forgery of authentication, de-authentication, association, and disassociation frames, and
- enhances the overall security of Wi-Fi networks by protecting key network management actions from attack.

While data frames can be encrypted, management frames were traditionally sent in the clear, making them vulnerable to interception and forgery. The 802.11w standard addresses this vulnerability by requiring cryptographic protection for certain management frames between client and access point.

An attacker attempting to disconnect a legitimate client by sending forged disassociation frames will fail on networks supporting protected management frames, as only cryptographically validated frames are accepted.

Types of management frames protected by 802.11w

The 802.11w protocol protects certain management frames by using the Protected Management Frames (PMF) service. These frames are classified as robust management frames and include:

- Disassociation frames
- De-authentication frames
- Robust Action frames

Robust Action frames protected by 802.11w include:

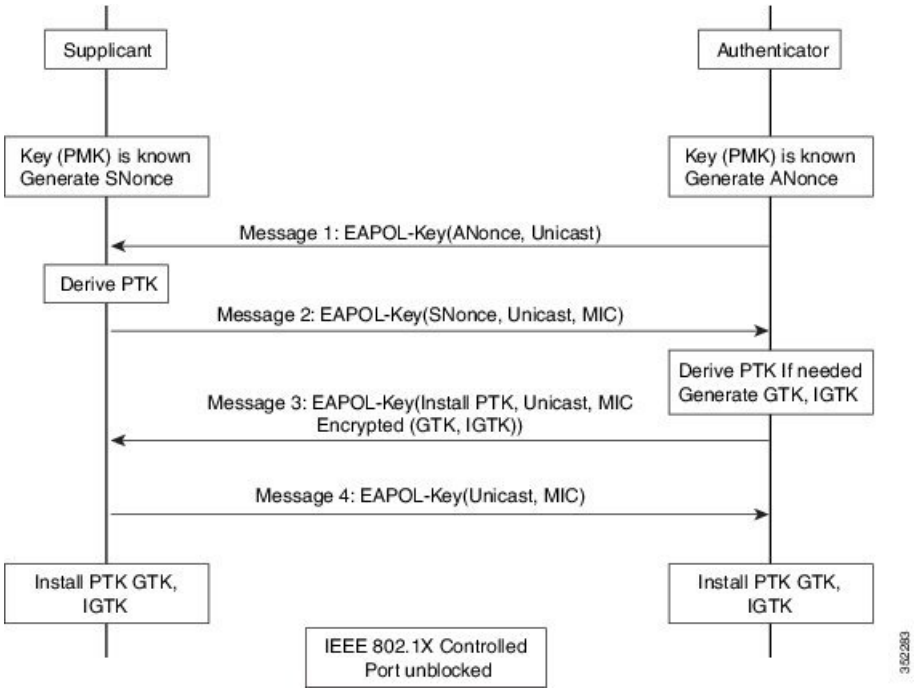
- Spectrum Management
- Quality of Service (QoS)
- Direct Link Setup (DLS)
- Block acknowledgement
- Radio Measurement
- Fast Basic Service Set (BSS) Transition
- Security Association (SA) Query
- Protected Dual of Public Action
- Vendor-specific Protected

Frames not included in this list are not protected by 802.11w.

Protections offered by 802.11w

When 802.11w is implemented, these protections are provided:

- **Client protection:** The AP adds cryptographic protection to de-authentication and dissociation frames, preventing spoofing in DOS attacks.
- **Infrastructure protection**: Security Association (SA) teardown protection is implemented using Association Comeback Time and SA-Query procedures to prevent spoofed association requests from disconnecting connected clients.



Integrity Group Temporal Key (IGTK)

The Integrity Group Temporal Key (IGTK) is a cryptographic key introduced in 802.11w to protect broadcast and multicast robust management frames.

An integrity group temporal key (IGTK) is a wireless security mechanism that

- protects broadcast and multicast robust management frames.
- uses random values assigned by the authenticator station (such as a wireless LAN controller), and
- secures MAC management protocol data units (MMPDUs) in 802.11w networks.

Figure 18: IGTK exchange in four-way handshake

802.11w introduced IGTKs to enhance the security of management frames in wireless networks.

How IGTK is used in 802.11w management frame protection

When you enable management frame protection, the AP encrypts the group temporal key (GTK) and IGTK values in an Extensible Authentication Protocol over LAN-Key (EAPoL-Key) frame. The AP includes this frame in the third message of the four-way handshake.

- IGTK is exchanged during the four-way handshake process.
- If the AP changes the GTK later, it sends the new GTK and the new IGTK to your client device using the Group Key Handshake

Imagine a wireless network as a secured meeting room, with announcements broadcast to everyone inside. The IGTK acts like a special group password that lets only authorized members hear these important messages. The authenticator (such as a wireless LAN controller) is like the meeting organizer, who gives each member a random, unique password at the door. When the password changes for added security, the organizer discreetly shares the new password with all members so that only legitimate participants can continue to hear future group announcements.

Broadcast or multicast integrity protocol (BIP)

Broadcast/Multicast Integrity Protocol (BIP) is defined by 802.11w to provide data integrity and replay protection for broadcast and multicast robust management frames.

A broadcast or multicast integrity protocol (BIP) is a wireless security mechanism that

- ensures data integrity of broadcast and multicast robust management frames
- provides replay protection for these frames after you establish an Integrity Group Temporal Key Security Association (IGTKSA), and
- adds a message integrity code (MIC) calculated using the shared IGTK key.

SA teardown protection

SA teardown protection is a wireless network security mechanism that prevents unauthorized disconnections by verifying t2he authenticity of association requests.

SA teardown protection is a wireless network security mechanism that

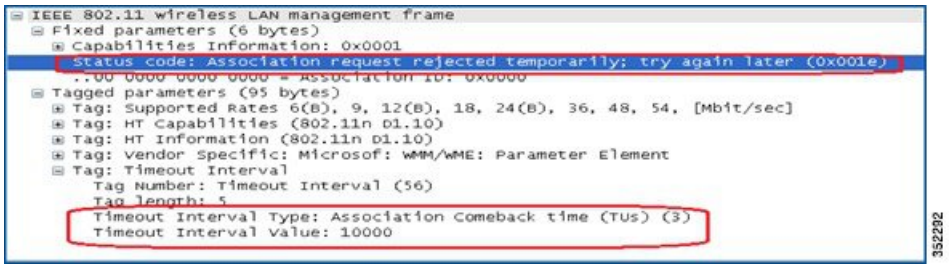
- prevents spoofed or replay attacks from disconnecting already associated clients
- uses Association Comeback Time and an SA-Query procedure to verify the authenticity of association requests, and
- ensures the AP only accepts new associations after the original security association is proven invalid.

How association comeback time and SA query procedures work

The Association Comeback Time and SA Query procedures prevent replay attacks from tearing down active wireless client sessions.

This process describes how Association Comeback Time and SA Query procedures protect wireless client sessions from replay-based association teardown attacks."

Summary



The key components involved in the process are:

- AP: implements security association (SA) teardown protection and manages association requests."
- Client device: Maintains a security association and sends and receives association and SA Query frames.
- SA Teardown Protection Mechanism: Provides the logic for handling replay and spoofed association attempts.

In this process, the AP and client device exchange association and SA Query frames. This exchange validates security associations and prevents unauthorized session teardown.

Workflow

Figure 19: Association Reject with Comeback Time

These stages describe how the Association Comeback Time and SA Query procedures operate to protect client sessions:

1. When an AP receives an Association Request from a client with an existing valid security association (SA) negotiated with 802.11w, the AP rejects the request with status code 30 (“Association request rejected temporarily; try again later”) and sends an Association Comeback Time.
2. The AP does not modify the existing association during the comeback interval.
3. If no ongoing SA Query session with the client exists, the AP sends SA Query requests repeatedly until it receives a valid SA Query response or the comeback time expires.
4. Receiving a matching SA Query response or a valid protected frame indicates a valid SA. The AP may then allow a new association attempt without more SA Query cycles.

Result

This process ensures that spoofed requests cannot disconnect valid clients, protecting against replay-based association teardown attacks.

Prerequisites for 802.11w

802.11w prerequisites.

- To configure 802.11w feature for optional and mandatory, you must have WPA and AKM configured.

> **Note**
>
> The RNS (Robust Secure Network) IE must be enabled with an AES Cipher.

Restrictions for 802.11w

Learn about restrictions for using 802.11w.

- You cannot use 802.11w with open WLANs, Wired Equivalent Privacy (WEP)-encrypted WLANs, or Temporal Key Integrity Protocol (TKIP)-encrypted WLANs.
- You can use 802.11w with Protected Management Frames (PMF) for non-Apple clients. For Apple iOS version 11 and earlier, request a fix from Apple to resolve association issues
- When clients do not use 802.11w PMF, the controller ignores disassociation frames or deauthentication frames they send. If a client uses PMF, its entry is deleted immediately when the controller receives such a frame. This process helps prevent denial-of-service attacks by malicious devices, since frames without PMF are not secure.

Configure 802.11w

Provides instructions for configuring, disabling, and monitoring 802.11w, including step-by-step procedures for GUI-based and other configurations to ensure effective implementation and management of 802.11w features.

Configure 802.11w (GUI)

Configure 802.11w using GUI.

To protect management traffic against spoofing and replay attacks, configure 802.11w settings after enabling WPA and AKM.

Enable protected management frames (PMF) on a WLAN to strengthen security for management communications.

Before you begin

Ensure WPA and AKM are configured on the target WLAN.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add** to create WLANs.

   The **Add WLAN** page is displayed.
3. In the **Security** > **Layer2** tab, navigate to the **Protected Management Frame** section.
4. Choose **PMF** as *Disabled*, *Optional*, or *Required*. By default, the PMF is *disabled*.

   If you choose **PMF** as *Optional* or *Required*, you can view these fields:

   - **Association Comeback Timer**–Enter a value between 1 and 10 seconds to configure 802.11w association comeback time.
   - **SA Query Time**–Enter a value between 100 to 500 milliseconds. This is required for clients to negotiate 802.11w PMF protection on a WLAN.
5. Click **Save & Apply to Device**.

802.11w PMF is enabled with the parameters you selected. This strengthens the security of management frames on the WLAN.

Configure 802.11w (CLI)

Configure 802.11w using commands.

Configuring 802.11w improves security for management frames on wireless LANs.

Enable 802.11w Protected Management Frames (PMF) on a WLAN using CLI commands.

Before you begin

- Configure WPA.
- Configure AKM (Authentication and Key Management) on the WLAN.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Configure a WLAN and enters configuration mode.

   Example

   ```
   Device(config)# wlan profile-name wlan-id ssid
   ```
3. Configure 802.1x support using the **security wpa akm dot1x-sha256** command.

Example

```
Device(config-wlan)#security wpa akm dot1x-sha256
```

4. Configure the 802.11w association comeback time.

Example

```
Device(config-wlan)# security pmf association-comeback comeback-interval
```

Example

```
Device(config-wlan)# security pmf association-comeback 10
```

5. Require clients to negotiate 802.11w PMF protection on a WLAN.

Example

```
Device(config-wlan)# security pmf mandatory
```

6. Configure time interval identified in milliseconds before which the SA query response is expected.

Example

```
Device(config-wlan)# security pmf saquery-retry-time timeout
```

Example

```
Device(config-wlan)# security pmf saquery-retry-time 100
```

If the device does not get a response, another SQ query is tried.

802.11w Protected Management Frames are enabled and mandatory on the specified WLAN, providing improved protection of management frames.

Disable 802.11w

Disable 802.11w using commands.

Disabling 802.11w may be necessary for compatibility with legacy or non-compliant devices.

Prevent wireless clients from using 802.11w Protected Management Frames on a specified WLAN.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a WLAN and enters configuration mode.

Example

```
Device(config)# wlan profile-name wlan-id ssid
```

3. Disable 802.1x support using the **no security wpa akm dot1x-sha256** command.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x-sha256
   ```

4. Configure the 802.11w association comeback time.

   Example

   ```
   Device(config-wlan)# security pmf association-comeback comeback-interval
   ```

   ```
   Device(config-wlan)# security pmf association-comeback 10
   ```

5. Disable client negotiation of 802.11w PMF protection on a WLAN.

   Example

   ```
   Device(config-wlan)# no security pmf mandatory
   ```

6. Disable SQ query retry.

   Example

   ```
   Device(config-wlan)# no security pmf saquery-retry-time 100
   ```

802.11w PMF protection is disabled for the specified WLAN.

Monitor 802.11w

Monitor 802.11w using commands.

Use these commands to monitor 802.11w.

Procedure

---

1. Display the WLAN parameters on the WLAN.

   The PMF parameters are displayed.

   ```
   Device# show wlan name wlan-name
                           . . . .
                           . . . .
                           Auth Key Management
                           802.1x                                  : Disabled
                           PSK                                     : Disabled
                           CCKM                                    : Disabled
   ```

```
                        FT dot1x                                : Disabled
                        FT PSK                                  : Disabled
                        FT SAE                                  : Disabled
                        Dot1x-SHA256                            : Enabled
                        PSK-SHA256                              : Disabled
                        SAE                                     : Disabled
                        OWE                                     : Disabled
                        SUITEB-1X                               : Disabled
                        SUITEB192-1X                            : Disabled
                        CCKM TSF Tolerance                             : 1000
                       FT Support                                    : Adaptive

                        FT Reassociation Timeout                : 20
                        FT Over-The-DS mode                     : Enabled
                       PMF Support                                  : Required

                        PMF Association Comeback Timeout        : 1
                        PMF SA Query Time                       : 500
                        . . . .
                        . . . .
```

2. Display the summary of the 802.11w authentication key management configuration on a client.

```
Device# show wireless client mac-address mac-address detail
                        . . . .
                        . . . .
                        Policy Manager State: Run
                        NPU Fast Fast Notified : No
                        Last Policy Manager State : IP Learn Complete
                        Client Entry Create Time : 497 seconds
                        Policy Type : WPA2
                        Encryption Cipher : CCMP (AES)
                        Authentication Key Management : 802.1x-SHA256
                        Encrypted Traffic Analytics : No
                        Management Frame Protection : No
                        Protected Management Frame - 802.11w : Yes
                        EAP Type : LEAP
                        VLAN : 39

                        Access VLAN : 39
                        Anchor VLAN : 0
                        WFD capable : No
                        Manged WFD capable : No
                        . . . .
                        . . . .
```

129 Management Frame Protection

Topics:

- Information About Management Frame Protection

Information About Management Frame Protection

Management Frame Protection details.

By default, 802.11 management frames are unauthenticated and hence not protected against spoofing. Infrastructure management frame protection (MFP) and 802.11w protected management frames (PMF) provide protection against such attacks.

Infrastructure MFP

Infrastructure MFP protects management frames by detecting adversaries that are invoking denial-of-service attacks, flooding the network with associations and probes, interjecting as rogue APs, and affecting network performance by attacking the QoS and radio measurement frames. Infrastructure MFP is a global setting that provides a quick and effective means to detect and report phishing incidents.

Specifically, infrastructure MFP protects 802.11 session management functions by adding message integrity check information elements (MIC IEs) to the management frames emitted by APs (and not those emitted by clients), which are then validated by other APs in the network. Infrastructure MFP is passive, can detect and report intrusions but has no means to stop them.

Infrastructure MFP consists of three main components:

- **Management frame protection**: The AP protects the management frames it transmits by adding a MIC IE to each frame. Any attempt to copy, alter, or replay the frame invalidates the MIC, causing any receiving AP configured to detect MFP frames to report the discrepancy. MFP is supported for use with Cisco Aironet lightweight APs.
- **Management frame validation**: In infrastructure MFP, the AP validates every management frame that it receives from other APs in the network. It ensures that the MIC IE is present (when the originator is configured to transmit MFP frames) and matches the content of the management frame. If it receives any frame that does not contain a valid MIC IE from a BSSID belonging to an AP that is configured to transmit MFP frames, it reports the discrepancy to the network management system. In order for the timestamps to operate properly, all controllers must be Network Time Protocol (NTP) synchronized.
- **Event reporting**: The AP notifies the controller when it detects an anomaly, and the controller aggregates the received anomaly events and can report the results through SNMP traps to the network management system.

Infrastructure MFP is disabled by default, and you can enable it globally. When you upgrade from a previous software release, infrastructure MFP is disabled globally if you have enabled AP authentication because the two features are mutually exclusive. When you enable infrastructure MFP globally, signature generation (adding MICs to outbound frames) can be disabled for selected WLANs, and validation can be disabled for selected APs.

> **Note**
>
> CCXv5 client MFP is no longer supported. Client MFP is enabled as optional by default on WLANs that are configured for WPA2. However, client MFP is not supported on Wave 2 APs or 802.11ax Wi-Fi6 APs, and there exist no clients that support CCXv5.

Supported Access Point Models

Cisco MFP is supported on the following AP models:

- Cisco Aironet 2802, 3802, and 4802 series access points
- Cisco Aironet 2800, 3800, 4800, and 1560 series access points

Unsupported Access Point Models

Cisco MFP is not supported on the following AP models:

- Cisco Aironet 1800 series access points
- Cisco 802.11ax access points
- All Cisco IOS access points

Restrictions for Management Frame Protection

Management Frame Protection restrictions.

- Lightweight access points support infrastructure MFP in local and monitor modes and in FlexConnect mode when the access point is connected to a controller.
- Client MFP is supported for use only with CCXv5 clients using WPA2 with TKIP or AES-CCMP.
- Client MFP is not supported on Cisco Wave 1 APs and Cisco Wave 2 APs.
- 802.11ax access points do not support MFP.
- Non-CCXv5 clients may associate to a WLAN, if client MFP is disabled or optional.
- Error reports generated on a FlexConnect access point in standalone mode cannot be forwarded to the controller and are dropped.
- Keys are generated using random number generator but you can improve the keys by changing to SHA.
- MFP key for each BSSID is not supported.

Configure Management Frame Protection (CLI)

Configure management frame protection using command-line interface (CLI) commands.

Configure Management Frame Protection (MFP) on a device using the command-line interface (CLI).

Before you begin

Use these steps to configure management frame protection.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure management frame protection.

   Example

   ```
   Device(config)# wireless wps mfp
   ```

3. Configure AP impersonation detection or set the MFP key refresh interval in hours.

Example

```
Device(config)# wireless wps mfp ap-impersonation
```

```
Device(config)# wireless wps mfp key-refresh-interval
```

key-refresh-interval: Set sthe MFP key refresh interval in hours.

The valid range is one to 24 hours. The default value is 24 hours.

4. Save the configuration, exit configuration mode, and return to privileged **EXEC** mode.

Example

```
Device(config)# end
```

The device protects wireless management traffic according to the configured settings.

Verifying Management Frame Protection Settings

Verify Management Frame Protection Settings.

To verify if the Management Frame Protection (MFP) feature is enabled or not, use the following command:

```
Device# show wireless wps summary
Client Exclusion Policy
  Excessive 802.11-association failures   : unknown
  Excessive 802.11-authentication failures: unknown
  Excessive 802.1x-authentication         : unknown
  IP-theft                                : unknown
  Excessive Web authentication failure    : unknown
  Failed Qos Policy                       : unknown

Management Frame Protection
  Global Infrastructure MFP state : Enabled
  AP Impersonation detection      : Disabled
  Key refresh interval            : 15
```

To view the MFP details, use the following command:

```
Device# show wireless wps mfp summary
Management Frame Protection
  Global Infrastructure MFP state : Enabled
  AP Impersonation detection      : Disabled
  Key refresh interval            : 15
```

To view the MFP statistics details, use the following command:

```
Device# show wireless wps mfp statistics
BSSID          Radio DetectorAP                          LastSourceAddr Error
        Count     FrameTypes

aabb.ccdd.eeff a     AP3800                              aabb.ccdd.eeff Invalid
MIC     10        Beacon, Probe Response
                                                                        Invalid
MIC     20        Beacon, Probe Response
```

To verify if access points support MFP validation and protection, use the following command:

```
Device# show wireless wps mfp ap summary
AP Name                          Radio MAC               Validation
   Protection
-------------------------------------------------------------------------------

- How to configure ACLs
- Configuration examples for ACLs
- Monitor IPv4 ACLs

Network security with ACLs

Explains how access control lists (ACLs) are used to secure network traffic on a switch.

This chapter describes how to configure network security on the switch by using access control lists (ACLs), which in commands and tables are also referred to as access lists.

ACL overview

This section explains ACL overview.

An access control list (ACL) is a network security mechanism that

- defines permit and deny conditions for network packets
- filters inbound and outbound traffic as it traverses network devices, and
- enforces access and segmentation policies by controlling which packets are forwarded or dropped.

When a packet is received on an interface, the switch compares the fields in the packet against any applied ACLs to verify that the packet has the required permissions to be forwarded, based on the criteria specified in the access lists. The controller checks each packet against the conditions you set in the access list, one at a time. The controller accepts or rejects the packets based on the first matching condition. Arrange your access list conditions carefully because the controller stops checking once it finds a match. If you do not set any restrictions, the controller forwards the packet. If you set restrictions and none are matched, the controller drops the packet. The controller can use ACLs on all packets it forwards . There is an implicit "deny any host" rule.

Configure access list

Configure access lists on the controller to provide basic security for your network. If you do not configure ACLs, the switch might allow all packets onto every part of your network.

Control access and traffic types

You can use ACLs to control which hosts access various parts of your network and to decide which types of traffic are forwarded or blocked at router interfaces. For example, you can allow email traffic but block Telnet traffic.

Access control entries

This section explains access control entry details.

An access control entry (ACE) is a rule component that

- specifies a *permit* or *deny* action for network packets
- defines conditions such as source or destination IP, protocol, or port that packets must meet to match the rule, and
- determines packet handling within an ordered ACL.

The meaning of *permit* or *deny* depends on the context in which the ACL is used.

> **Note**
>
> The maximum number of ACEs that can be applied under an access policy (ACL) for central switching is 256 ACEs. For Flex Mode Local Switching, the maximum is 64 ACEs.

ACL supported types

This section provides ACL supported type details.

The switch supports IP ACLs and Ethernet (MAC) ACLs:

- IP ACLs filter IPv4 traffic, including TCP, user datagram protocol (UDP), internet group management protocol (IGMP), and internet control message protocol (ICMP).
- Ethernet ACLs filter non-IP traffic.

This switch also supports quality of service (QoS) classification ACLs.

Supported ACLs

This section provides supported ACLs details.

The controller supports three types of ACLs to filter traffic:

- Port ACL: Port ACLs control access to traffic entering a Layer 2 interface. You can apply port ACLs to a Layer 2 interface in both directions for each access list type: IPv4 and MAC.
- Router ACL: Router ACLs control access to routed traffic between VLANs. They are applied to Layer 3 interfaces in a specific direction (inbound or outbound).
- FQDN ACL: FQDN ACLs are encoded along with IPv6 ACLs and sent to the AP. FQDN ACLs are always custom ACLs. The AP performs DNS snooping and sends the IPv4 and IPv6 addresses to the controller.

> **Note**
>
> On switches running the LAN base feature set, router ACLs are supported only on SVIs. VLAN maps are not supported.

ACL precedence

This section provides ACL precedence details.

When VLAN maps, port ACLs, and router ACLs are configured on the same switch, the filtering precedence for ingress traffic is greatest for port ACL, followed by VLAN map, and then router ACL. For egress traffic, router ACLs have the highest filtering precedence, followed by VLAN maps, and then port ACLs. These examples describe simple use cases:

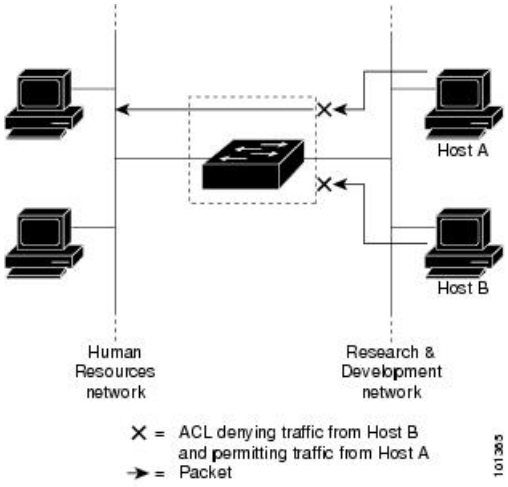
- When both an input port ACL and a VLAN map are applied, incoming packets received on ports with a port ACL are filtered by the port ACL. Other packets are filtered by the VLAN map.
- When an input router ACL and an input port ACL exist in a switch virtual interface (SVI), incoming packets received on ports with a port ACL are filtered by the port ACL. Incoming routed IP packets are filtered by the router ACL. Other packets are not filtered.

- When an output router ACL and an input port ACL exist in an SVI, incoming packets received on ports with a port ACL are filtered by the port ACL. Outgoing routed IP packets are filtered by the router ACL. Other packets are not filtered.
- When a VLAN map, an input router ACL, and an input port ACL exist in an SVI, incoming packets received on ports with a port ACL are filtered only by the port ACL. Incoming routed IP packets received on other ports are filtered by both the VLAN map and the router ACL. Other packets are filtered only by the VLAN map.
- When a VLAN map, an output router ACL, and an input port ACL exist in an SVI, incoming packets received on ports with a port ACL are filtered only by the port ACL. Outgoing routed IP packets are filtered by both the VLAN map and the router ACL. Other packets are filtered only by the VLAN map.

Port ACLs

This section explains port ACL details.

A port ACL is an access control mechanism that



- applies to Layer 2 physical or EtherChannel interfaces on a switch
- supports the use of both IP and MAC-based access lists to filter traffic, and
- controls traffic in the inbound and outbound directions on the respective interface.

These access lists are supported:

- Standard IP access lists that use source addresses.
- Extended IP access lists that use source and destination addresses and may include protocol type information.
- MAC extended access list that use source and destination MAC addresses and may include protocol type information.

The switch examines ACLs on an interface and permits or denies packet forwarding based on how the packet matches the entries in the ACL. In this way, ACLs control access to a network or to part of a network.

Figure 20: Using ACLs to Control Traffic in a Network

This is an example of using port ACLs to control access to a network when all workstations are in the same VLAN. When you apply ACLs at the Layer 2 input, they allow Host A to access the Human Resources network while preventing Host B from accessing it. Port ACLs can only be applied to Layer 2 interfaces in the inbound direction.

When you apply a port ACL to a trunk port, the ACL filters traffic on all VLANs present on the trunk port. When you apply a port ACL to a port with a voice VLAN, it filters traffic on both data and voice VLANs.

With port ACLs, you can filter IP traffic by using IP access lists and non-IP traffic by using MAC addresses. You can filter both IP and non-IP traffic on the same Layer 2 interface by applying both an IP access list and a MAC access list to the interface.

Note

You can apply only one IP access list and one MAC access list to a Layer 2 interface. If an IP access list or MAC access list is already configured on a Layer 2 interface and you apply a new IP access list or MAC access list to the interface, the new ACL replaces the previously configured one.

Router ACLs

This section explains router ACL details.

A router ACL is a network security mechanism that

- can be applied to Layer 3 interfaces (such as SVIs, physical interfaces, and EtherChannels)
- filters traffic based on defined rules in specific directions (inbound or outbound), and
- supports both standard and extended IP matching criteria.

You can apply one router ACL in each direction on an interface.

The switch supports these access lists for IPv4 traffic:

- Standard IP access lists use source addresses for matching operations.
- Extended IP access lists use source and destination addresses and optional protocol type information for matching operations.

As with port ACLs, the switch examines ACLs associated with features configured on each interface. When packets enter the switch on an interface, ACLs associated with all inbound features configured on that interface are examined. After routing, and prior to forwarding to the next hop, the switch examines all ACLs associated with outbound features configured on the egress interface.

ACLs permit or deny packet forwarding based on how the packet matches the entries in the ACL. They can be used to control access to a network or to part of a network.

ACEs and fragmented and unfragmented traffic

This section explains ACEs, fragmented and unfragmented traffic details.

A fragmented or unfragmented packet is a type of network traffic that

- may be divided into multiple fragments as it traverses a network
- only includes Layer 4 information in the first fragment (such as TCP/UDP port, ICMP type/code), and
- requires specific ACE matching behavior depending on the presence or absence of Layer 4 information in its fragments.

IP packets can be fragmented as they cross the network. The first fragment, which contains the beginning of the packet, includes Layer 4 information such as TCP or UDP port numbers, or ICMP type and code. All other fragments lack Layer 4 information.

Some access control entries (ACEs) do not check Layer 4 information, so they can be applied to all packet fragments. ACEs that test Layer 4 information cannot be applied to most fragments in a fragmented IP packet. If a fragment contains no Layer 4 information and the ACE tests Layer 4 information, matching rules are modified.

- Permit ACEs that check Layer 3 information in the fragment, including protocol type such as TCP or UDP, match the fragment regardless of missing Layer 4 details.

  Note

  For TCP ACEs with Layer 4 options, fragmented packets are dropped in accordance with RFC 1858.

- Deny ACEs that check Layer 4 information match a fragment only if the fragment contains Layer 4 information.

ACEs and fragmented and unfragmented traffic examples

This topic provides ACEs, fragmented and unfragmented traffic examples.

Consider access list 102, configured with these commands, applied to three fragmented packets:

```
Device(config)# access-list 102 permit tcp any host 10.1.1.1 eq smtp
Device(config)# access-list 102 deny tcp any host 10.1.1.2 eq telnet
Device(config)# access-list 102 permit tcp any host 10.1.1.2
Device(config)# access-list 102 deny tcp any any
```

Note

In the first and second ACEs, the *eq* keyword after the destination address checks if the TCP destination port matches the well-known port numbers for Simple Mail Transfer Protocol (SMTP) or Telnet.

- Packet A is a TCP packet from host 10.2.2.2, port 65000, sent to host 10.1.1.1 on the SMTP port. If the packet is fragmented, the first fragment matches the first ACE (a permit) because all Layer 4 information is included. The remaining fragments also match the first ACE, even if they do not include the SMTP port information, because the first ACE checks only Layer 3 information when applied to fragments. In this example, the fragment is a TCP packet sent to 10.1.1.1.
- Packet B is sent from host 10.2.2.2, port 65001, to host 10.1.1.2 on the Telnet port. If the packet is fragmented, the first fragment matches the second ACE (a deny) because it includes all Layer 3 and Layer 4 information. The remaining fragments in the packet do not match the second ACE because they are missing Layer 4 information. Instead, they match the third ACE (a permit).

  Because the first fragment was denied, host 10.1.1.2 cannot reassemble a complete packet. As a result, packet B cannot be reassembled on host 10.1.1.2. Permitted fragments still use network bandwidth and resources on host 10.1.1.2 during the attempted reassembly.
- Packet C is sent from host 10.2.2.2, port 65001, to host 10.1.1.3 on the FTP port. This packet is fragmented. If this packet is fragmented, the first fragment matches the fourth ACE (a deny). All other fragments also match the fourth ACE because it does not check Layer 4 information. Layer 3 information in each fragment shows they are sent to host 10.1.1.3, while previous permit ACEs check different hosts.

Standard and extended IPv4 ACLs

This section describes standard and extended IPv4 ACLs details.

An IPv4 access control list (ACL) is a packet-filtering feature that

- sequentially compares packets against a set of permit or deny conditions
- determines packet acceptance or rejection based on the first match, and
- enforces traffic control policies on network interfaces.

The switch stops testing after the first match. The order of the conditions is critical. If no conditions match, the switch denies the packet.

The software supports two types of ACLs for IPv4:

- Standard IP access lists use source addresses for matching operations.
- Extended IP access lists use source and destination addresses for matching operations and can include protocol-type information for more granular control.

Note

Only extended ACLs are supported; standard ACLs are not supported.

IPv4 ACL switch unsupported features

This section provides IPv4 ACL switch unsupported feature details.

Configuring IPv4 ACLs on this switch is similar to configuring IPv4 ACLs on other Cisco switches and routers.

The switch does not support the following ACL-related features:

- Non-IP protocol ACLs or bridge-group ACLs.
- IP accounting.
- Inbound and outbound rate limiting (except with QoS ACLs).
- Reflexive ACLs, URL redirect ACLs and dynamic ACLs are not supported. (except for some specialized dynamic ACLs used by the switch clustering feature).
- ACL logging for port ACLs and VLAN maps.

Access list numbers

This section provides access list number details.

The ACL number determines the type of access list you create.

Table 118: Access List Numbers

This lists the access-list number and corresponding access list type and shows whether or not they are supported in the switch. The switch supports IPv4 standard and extended access lists, numbers 1 to 199 and 1300 to 2699.

Access List Number	Type	Supported
1–99	IP standard access list	Yes
100–199	IP extended access list	Yes
200–299	Protocol type-code access list	No
300–399	DECnet access list	No

Access List Number	Type	Supported
400–499	XNS standard access list	No
500–599	XNS extended access list	No
600–699	AppleTalk access list	No
700–799	48-bit MAC address access list	No
800–899	IPX standard access list	No
900–999	IPX extended access list	No
1000–1099	IPX SAP access list	No
1100–1199	Extended 48-bit MAC address access list	No
1200–1299	IPX summary address access list	No
1300–1999	IP standard access list (expanded range)	Yes
2000–2699	IP extended access list (expanded range)	Yes

In addition to numbered standard and extended ACLs, you can create standard and extended named IP ACLs with the supported numbers. For example, you can name standard IP ACLs with numbers from 1 to 99, and extended IP ACLs with numbers from 100 to 199. With named ACLs, you can delete individual entries, but with numbered lists, you cannot.

Numbered standard IPv4 ACLs

This section provides numbered standard IPv4 ACL details.

When you create an ACL, an implicit deny statement is automatically present at the end. Any packet that does not match an earlier entry in the ACL is denied by this statement. For standard access lists, if you omit the mask in an IP host address ACL entry, the switch assumes a mask of 0.0.0.0.

- The switch rewrites standard access lists to move host match entries and entries with a don't care mask of 0.0.0.0 to the top of the list. Entries with non-zero don't care masks are placed below them. As a result, the ACEs may appear in a different order in show command output and in the configuration file than the order in which you entered them.
- After you create a numbered standard IPv4 ACL, you can apply it to VLANs, feature-id terminal lines (virtual teletype (VTY) lines), or interfaces.

Numbered extended IPv4 ACLs

This section explains numbered extended IPv4 ACLs.

A numbered extended IPv4 ACL is an access control mechanism that

- matches IPv4 traffic using both source and destination addresses
- optionally uses protocol type information for greater refinement, and
- requires that Access Control Entries (ACEs) be appended to the list since reordering or selective removal is unsupported.

When you are creating ACEs in numbered extended access lists, remember that after you create the ACL, any additions are placed at the end of the list.

The switch does not support dynamic or reflexive access lists. It also does not support filtering based on the type of service (ToS) minimize-monetary-cost bit.

Some protocols also have specific parameters and keywords that apply to that protocol.

You can define an extended TCP, UDP, ICMP, IGMP, or other IP ACL. The switch also supports these IP protocols:

- Authentication Header Protocol (**ahp**)
- Encapsulation Security Payload (**esp**)
- Enhanced Interior Gateway Routing Protocol (**eigrp**)
- generic routing encapsulation (**gre**)
- Internet Control Message Protocol (**icmp**) and Open Shortest Path First routing (**ospf**)
- Internet Group Management Protocol (**igmp**) and Payload Compression Protocol (**pcp**)
- any Interior Protocol (**ip**) and Protocol-Independent Multicast (**pim**)
- IP in IP tunneling (**ipinip**) and Transmission Control Protocol (**tcp**)
- KA9Q NOS-compatible IP over IP tunneling (**nos**) and User Datagram Protocol (**udp**)

Named IPv4 ACLs

This section provides named IPv4 ACL details.

You can identify IPv4 ACLs with an alphanumeric string (a name) rather than a number. You can use named ACLs to configure more IPv4 access lists in a router than if you were to use numbered access lists. If you identify your access list with a name rather than a number, the mode and command syntax are slightly different. However, at times, not all commands that use IP access lists accept a named access list.

Consider these guidelines before configuring named ACLs:

- Numbered ACLs are also available.
- A standard ACL and an extended ACL cannot have the same name.
- VLAN ACLs or VLAN maps are not supported.
- You can use standard or extended ACLs whether named or numbered, in VLAN maps.
- With IPv4 QoS ACLs, if you enter the class-map { match-all | match-any} class-map-name global configuration command, you can enter these match commands:

  1. **match access-group** *acl-name*

     > **Note**
     >
     > The ACL must be an extended named ACL.

  2. **match input-interface** *interface-id-list*
  3. **match ip dscp** *dscp-list*
  4. **match ip precedence** *ip-precedence-list*

Note

You cannot enter the **match access-group** *acl-index* command.

ACL logging

This topic explains ACL logging details.

ACL logging is a router logging feature that

- generates informational messages about packets permitted or denied by a standard IP access control list (ACL)
- records each message with details such as the action taken, the source IP address, and the access list number, and
- supports logging only for router ACLs (RACLs), not for ACLs used with Unicast Reverse Path Forwarding (uRPF).

The controller software can provide logging messages about packets permitted or denied by a standard IP access list. The level of messages logged to the console is controlled by the **logging console** commands, which control the syslog messages.

Note

Because routing is done in hardware and logging is done in software, if a large number of packets match a *permit* or *deny* ACE containing a **log** keyword, the software might not be able to match the hardware processing rate, and not all packets will be logged.

The first packet that triggers the ACL generates a logging message immediately. Subsequent packets are collected over 5-minute intervals before they are logged. The logging message includes the access list number, an indication of whether the packet was permitted or denied, the source IP address, and the number of packets from that source permitted or denied during the prior 5-minute interval.

Note

The logging facility might drop some message packets if there are too many to handle, or if more than one logging message must be processed in a second. This behavior prevents the router from crashing due to too many logging packets. Therefore, do not use the logging facility as a billing tool or as an accurate source for the number of matches to an access list.

Hardware and software treatment of IP ACLs

This section provides hardware and software treatment details of IP ACLs.

ACL processing is performed in hardware. If the hardware reaches its capacity to store ACL configurations, all packets on that interface are dropped.

The ACL scale for controllers is as follows:

- Cisco Catalyst 9800-40 wireless controller, Cisco Catalyst 9800-L wireless controller, Cisco Catalyst 9800-CL wireless controller (small and medium) support 128 ACLs with 128 access list entries (ACEs).
- Cisco Catalyst 9800-80 wireless controller and Cisco Catalyst 9800-CL wireless controller (large) support 256 ACLs and 256 ACEs.
- FlexConnect and Fabric mode APs support 96 ACLs.

Note

If an ACL configuration cannot be implemented in the hardware due to an out-of-resource condition on the controller, then only the traffic in that VLAN arriving on that controller is affected. Software forwarding of packets might adversely impact the performance of the switch or switch stack, depending on the number of CPU cycles that this consumes.

For router ACLs, other factors can cause packets to be sent to the CPU:

- Using the log keyword
- Generating ICMP unreachable messages

When traffic flows are both logged and forwarded, forwarding is done by hardware, but logging must be done by software. Because of the difference in packet handling capacity between hardware and software, if the sum of all flows being logged (both permitted flows and denied flows) is of great enough bandwidth, not all of the packets that are forwarded can be logged.

If a router ACL configuration cannot be applied in hardware, packets that arrive in a VLAN and must be routed are processed in software. However, packets are bridged in hardware. If ACLs cause large numbers of packets to be sent to the CPU, the switch performance can be negatively affected.

When you enter the show ip access-lists privileged EXEC command, the match count displayed does not account for packets that are access controlled in hardware. Use the show access-lists hardware counters and show platform acl counters hardware privileged EXEC commands to obtain basic hardware ACL statistics for switched and routed packets.

Router ACLs operate in this way:

- The hardware controls permit and deny actions of standard and extended ACLs (input and output) for security access control.
- If log has not been specified, and if ip unreachables is disabled, the hardware drops flows that match a deny statement in a security ACL. The flows matching a permit statement are switched in hardware.
- Adding the log keyword to an ACE in a router ACL causes a copy of the packet to be sent to the CPU for logging only. If the ACE is a permit statement, the packet is switched and routed in hardware.

IPv4 ACL interface considerations

This section provides IPv4 ACL interface consideration details.

When you apply the ip access-group interface configuration command to a Layer 3 interface (an SVI, a Layer 3 EtherChannel, or a routed port), the interface must have been configured with an IP address. Layer 3 access groups filter packets that are routed and packets that are received by Layer 3 processes on the CPU. They do not affect packets bridged within a VLAN.

- For inbound ACLs, after receiving a packet, the controller checks the packet against the ACL. If the ACL permits the packet, the controller continues to process the packet. If the ACL rejects the packet, the controller discards the packet.

- For outbound ACLs, after receiving and routing a packet to a controlled interface, the controller checks the packet against the ACL. If the ACL permits the packet, the controller sends the packet. If the ACL rejects the packet, the controller discards the packet.

If an undefined ACL has nothing listed in it, it is an empty access list.

By default, the input interface sends ICMP Unreachable messages whenever a packet is discarded, regardless of whether the packet was discarded because of an ACL on the input interface or because of an ACL on the output interface. ICMP Unreachables are normally limited to no more than one every half second per input interface. You can change this by using the ip icmp rate-limit unreachable global configuration command.

Restrictions for configuring IPv4 access control lists

This topic describes the restrictions for configuring IPv4 access control list restrictions.

General Network Security

These are restrictions for configuring network security with ACLs:

- A standard ACL and an extended ACL cannot have the same name.
- **AppleTalk** appears in the command-line help strings but is not supported as a matching condition for the **deny** and **permit** MAC access-list configuration mode commands.
- DNS traffic is permitted by default for clients that are awaiting web authentication, regardless of ACL entries.

IPv4 ACL Network Interfaces

These restrictions apply to IPv4 ACLs to network interfaces:

- When controlling access to an interface, you can use a named or numbered ACL.
- You do not have to enable routing to apply ACLs to Layer 2 interfaces.

MAC ACLs on a Layer 2 Interface

After you create a MAC ACL, you can apply it to a Layer 2 interface to filter non-IP traffic coming in that interface. When you apply the MAC ACL, consider these guidelines:

- You can apply no more than one IP access list and one MAC access list to the same Layer 2 interface. The IP access list filters only IP packets, and the MAC access list filters non-IP packets.
- A Layer 2 interface can have only one MAC access list. If you apply a MAC access list to a Layer 2 interface that has a MAC ACL configured, the new ACL replaces the previously configured one.

> **Note**
>
> The **mac access-group** interface configuration command is only valid when applied to a physical Layer 2 interface. You cannot use the command on EtherChannel port channels.

IP Access List Entry Sequence Numbering

- This feature does not support dynamic, reflexive, or firewall access lists.

How to configure ACLs

Configure ACLs.

Configure IPv4 ACLs (GUI)

Use this procedure to configure IPv4 ACLs using the GUI.

Define and apply IPv4 ACL rules for traffic management and security.

Procedure

1. Choose **Configuration** > **Security** > **ACL**.
2. Click **Add**.
3. In the **Add ACL Setup** dialog box, enter the details for these parameters.
   - ACL Name: Enter the name for the ACL.
   - ACL Type: IPv4 Standard.
   - Sequence: Enter the sequence number.
   - Action: Select ***Permit*** or ***Deny*** the packet flow from the drop-down list.
   - Source Type: Choose ***any***, ***Host*** or ***Network*** from which the packet is sent.
   - Log: Enable or disable logging.
4. Click **Add**.
5. Add the rest of the rules and click **Apply to Device**.

Configure IPv4 ACLs

Use this procedure to configure IPv4 ACLs.

Follow the procedure given below to use IP ACLs on the switch:

Procedure

1. Create an ACL by specifying an access list number or name and the access conditions.
2. Apply the ACL to interfaces or terminal lines. .

Create a numbered standard ACL (GUI)

Use this procedure to create a numbered standard ACL using the GUI.

Define and apply a numbered standard ACL using the device's web interface using GUI.

Procedure

1. Choose **Configuration** > **Security** > **ACL**.

2. On the **ACL** page, click **Add**.
3. In the **Add ACL Setup** window, enter the details for these parameters.
   - ACL Name: Enter the name for the ACL.
   - ACL Type: IPv4 Standard.
   - Sequence: Enter the sequence number.
   - Action: Select **Permit** or **Deny** access from the drop-down list.
   - Source Type: Choose **any** , **Host** or **Network**.
   - Log: Enable or disable logging, this is limited to ACLs associated to Layer 3 interface only.
4. Click **Add**.
5. Click **Save & Apply to Device**.

Create a numbered standard ACL (CLI)

Use this procedure to create a numbered standard ACL using commands.

Follow the procedure given below to create a numbered standard ACL using commands:

Procedure

1. Enable the privileged EXEC mode and enter your password if prompted.

   Example

   ```
   Device# enable
   ```

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Define a standard IPv4 access list by using a source address and wildcard.

   Example

   ```
   Device(config)# access-list 2 {deny | permit} source source-wildcard your_host
   ```

   The *access-list-number* is a decimal number from 1 to 99 or 1300 to 1999.

   Enter **deny** or **permit** to specify whether to deny or permit access if conditions are matched.

   The *source* is the source address of the network or host from which the packet is being sent. Specify the source as:

   - The 32-bit quantity in dotted-decimal format.
   - The keyword **any** abbreviates for *source* and *source-wildcard* as 0.0.0.0 255.255.255.255. You do not need to enter a source-wildcard.
   - The keyword **host** abbreviates source and *source-wildcard* as *source* 0.0.0.0.

The *source-wildcard* applies wildcard bits to the source address.

> **Note**
>
> Logging is supported only on ACLs attached to Layer 3 interfaces.

4. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

5. Verify your entries.

Example

```
Device# show running-config
```

6. Optional: Save your entries in the configuration file.

Example

```
Device# copy running-config startup-config
```

Create a numbered extended ACL (GUI)

Use this procedure to create a numbered extended ACL using the GUI.

Set up a numbered extended ACL to control network traffic based on source, destination, and protocol using the GUI.

Procedure

1. Choose **Configuration** > **Security** > **ACL**.
2. On the **ACL** page, click **Add**.
3. In the **Add ACL Setup** window, enter the details for these parameters.
   - ACL Name: Enter the name for the ACL.
   - ACL Type: IPv4 Extended.
   - Sequence: Enter the sequence number.
   - Action: Select **Permit** or **Deny** the packet flow from the drop-down list.
   - Source Type: Choose **any** , **Host** or **Network** from which the packet is sent.
   - Destination Type: Choose **any** , **Host** or **Network** to which the packet is sent.
   - Protocol: Select a protocol from the drop-down list.
   - Log: Enable or disable logging.

- DSCP: Enter to match packets with the DSCP value.

4. Click **Add**.
5. Click **Save & Apply to Device**.

Create a numbered extended ACL (CLI)

Use this procedure to create a numbered extended ACL using commands.

Follow the procedure given below to create a numbered extended ACL using commands:

Procedure

1. Enters global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Defines an extended IPv4 access list and the access conditions.

   Example

   ```
   Device# access-list 101 {deny | permit} ip host 10.1.1.2 any [precedence 0]
   [tos 0] [fragments] log [log-input | smartlog] [time-range time-range-name]
   [dscp dscp]
   ```

   The *access-list-number* is a decimal number from 100 to 199 or 2000 to 2699.

   Enter **deny** or **permit** to specify whether to deny or permit the packet if conditions are matched.

   For *protocol* , enter the name or number of an P protocol: **ahp**, **eigrp**, **esp**, **gre**, **icmp**, **igmp**, **igrp**, **ip**, **ipinip**, **nos**, **ospf**, **pcp**, **pim**, **tcp**, or **udp**, or an integer in the range 0 to 255 representing an IP protocol number. To match any Internet protocol (including ICMP, TCP, and UDP), use the keyword **ip**.

   > **Note**
   >
   > This step includes options for most IP protocols. For additional specific parameters for TCP, UDP, ICMP, and IGMP, see the following steps.

   The *source* is the number of the network or host from which the packet is sent.

   The *source-wildcard* applies wildcard bits to the source.

   The *destination* is the network or host number to which the packet is sent.

   The *destination-wildcard* applies wildcard bits to the destination.

   Source, source-wildcard, destination, and destination-wildcard can be specified as:

   - The 32-bit quantity in dotted-decimal format.
   - The keyword **any** for 0.0.0.0 255.255.255.255 (any host).
   - The keyword **host** for a single host 0.0.0.0.

The other keywords are optional and have these meanings:

- **precedence**: Enter to match packets with a precedence level specified as a number from 0 to 7 or by name: ***routine*** (0), ***priority*** (1), ***immediate*** (2), ***flash*** (3), ***flash-override*** (4), ***critical*** (5), ***internet*** (6), ***network*** (7).
- **fragments**: Enter to check non-initial fragments.
- **tos**: Enter to match by type of service level, specified by a number from 0 to 15 or a name: ***normal*** (0), ***max-reliability*** (2), ***max-throughput*** (4), ***min-delay*** (8).
- **time-range**: Specify the time-range name.
- **dscp**: Enter to match packets with the DSCP value specified by a number from 0 to 63, or use the question mark (?) to see a list of available values.

> **Note**
>
> Your controller must support the ability to:
>
> - Mark DCSP
> - Mark UP
> - Map DSCP and UP
>
> For more information on DSCP-to-UP Mapping , see:
>
> https://tools.ietf.org/html/draft-ietf-tsvwg-ieee-802-11-01

> **Note**
>
> If you enter a **dscp** value, you cannot enter **tos** or **precedence**. You can enter both a **tos** and a **precedence** value with no **dscp**.

3. Define an extended TCP access list and the access conditions.

Example

```
Device(config)# access-list 101 {deny | permit} tcp source source-wildcard
[operator-port] destination destination-wildcard 500 [established] [precedence
 0] [tos 0] [fragments] log [log-input | smartlog] [time-range time-range-name]
 [dscp dscp] [flag]
```

The parameters are the same as those described for an extended IPv4 ACL, with these exceptions:

Enter an *operator* and *port* to compare source (if positioned after *source source-wildcard*) or destination (if positioned after *destination destination-wildcard*) port. Possible operators include **eq** (equal), **gt** (greater than), **lt** (less than), **neq** (not equal), and **range** (inclusive range). Operators require a port number (range requires two port numbers separated by a space).

Enter the *port* number as a decimal number (from 0 to 65535) or the name of a TCP port. Use only TCP port numbers or names when filtering TCP.

The other optional keywords have these meanings:

- *flag*: Enter one of these flags to match by the specified TCP header bits: **ack** (acknowledge), **fin** (finish), **psh** (push), **rst** (reset), **syn** (synchronize), or **urg** (urgent).

4. Define an extended UDP access list and the access conditions.

Example

```
Device(config)# access-list 101 {deny | permit} udp source source-wildcard
[operator port] destination destination-wildcard 100 precedence 0] [tos 0]
[fragments] log [log-input | smartlog] [time-range time-range-name] [dscp
dscp
```

The UDP parameters are the same as those described for TCP except that the [operator [port]] port number or name must be a UDP port number or name, and the **flag** not valid for UDP.

5. Define an extended ICMP access list and the access conditions.

Example

```
Device(config)# access-list 101 {deny | permit} icmp source source-wildcard
destination destination-wildcard [ icmp-type | [[ icmp-type icmp-code ] | [
icmp-message ]] precedence 0] [tos 0] [fragments] log [log-input | smartlog]
 [time-range time-range-name] [dscp dscp]
```

The ICMP parameters are the same as those described for most IP protocols in an extended IPv4 ACL, with the addition of the ICMP message type and code parameters. These optional keywords have these meanings:

- *icmp-type*: Enter to filter by ICMP message type, a number from 0 to 255.
- *icmp-code*: Enter to filter ICMP packets that are filtered by the ICMP message code type, a number from 0 to 255.
- *icmp-message*: Enter to filter ICMP packets by the ICMP message type name or the ICMP message type and code name.

6. Optional: Define an extended IGMP access list and the access conditions.

Example

```
Device(config)# access-list 101 {deny | permit} igmp source source-wildcard
destination destination-wildcard [ igmp-type ] precedence 0] [tos 0]
[fragments] log [log-input | smartlog] [time-range time-range-name] [dscp
dscp]
```

The IGMP parameters are the same as those described for most IP protocols in an extended IPv4 ACL, with this optional parameter.

igmp-type: To match IGMP message type, enter a number from 0 to 15, or enter the message name: **dvmrp**, **host-query**, **host-report**, **pim**, or **trace**.

7. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

8. Optional: Save your entries in the configuration file.

Example

```
Device# copy running-config startup-config
```

Create named standard ACLs (GUI)

Use this procedure to create named standard ACLs using the GUI.

Use this procedure to set up and apply ACLs for network security management within the device's GUI.

Procedure

1. Click **Configuration** > **Security** > **ACL**.
2. Click **Add** to create a new ACL setup.
3. In the **Add ACL Setup** window, enter these parameters:
   - ACL Name: Enter the name for the ACL.
   - ACL Type: IPv4 Standard.
   - Sequence: The valid range is between 1 and 99 or 1300 and 1999.
   - Action: Select **Permit** or **Deny** access from the drop-down list.
   - Source Type: Choose **any**, **Host** or **Network**.
   - Log: Enable or disable logging, this is limited to ACLs associated to Layer 3 interface only.
4. Click **Add** to add the rule.
5. Click **Save & Apply to Device**.

Create named standard ACLs (CLI)

Use this procedure to create named standard ACLs using commands.

Define and apply named standard ACLs to permit or deny traffic from specified IPv4 source addresses using commands.

Procedure

1. Enter the privileged EXEC mode.

Example

```
Device# enable
```

2. Enter the global configuration mode.

Example

```
Device# configure terminal
```

3. Define a standard IPv4 access list using a name, and enter the access-list configuration mode.

   Example

   ```
   Device(config)# ip access-list standard 20
   ```

   The name can be a number from 1 to 99.

4. Specify one or more conditions denied or permitted to decide if the packet is forwarded or dropped in access-list configuration mode. Use one of the these:

   - **deny** { *source* [*source-wildcard*] | **host** *source* | **any** } [**log**]
   - **permit** { *source* [*source-wildcard*] | **host** *source* | **any** } [**log**]

   Example

   ```
   Device(config-std-nacl)# deny 192.168.0.0 0.0.255.255 255.255.0.0 0.0.255.255
   ```

   or

   ```
   Device(config-std-nacl)# permit 10.108.0.0 0.0.0.0 255.255.255.0 0.0.0.0
   ```

   - **host** *source*: A source and source wildcard of *source* 0.0.0.0.
   - **any**: A source and source wildcard of 0.0.0.0 255.255.255.255.

5. Returns to privileged EXEC mode.

   Example

   ```
   Device(config-std-nacl)# end
   ```

6. Verify your entries.

   Example

   ```
   Device# show running-config
   ```

7. Optional: Save your entries in the configuration file.

   Example

   ```
   Device# copy running-config startup-config
   ```

Create extended named ACLs (GUI)

Use this procedure to create extended named ACLs using the GUI.

Follow these steps to filter traffic based on granular criteria, such as source/destination, protocol, or DSCP using the GUI.

Procedure

1. Choose **Configuration** > **Security** > **ACL**.
2. Click **Add**.
3. In the **Add ACL Setup** window, enter these parameters.
   - ACL Name: Enter the name for the ACL.
   - ACL Type: IPv4 Extended.
   - Sequence: Enter the sequence number.
   - Action: Select *Permit* or *Deny* the packet flow from the drop-down list.
   - Source Type: Choose *any*, *Host* or *Network* from which the packet is sent.
   - Destination Type: Choose *any*, *Host* or *Network* to which the packet is sent.
   - Protocol: Select a protocol from the drop-down list.
   - Log: Enable or disable logging.
   - DSCP: Enter to match packets with the DSCP value.
4. Click **Add**.
5. Add the rest of the rules and click **Apply to Device**.

Create extended named ACLs (CLI)

Use this procedure to create extended named ACLs using commands.

Use this procedure to create extended named access control lists (ACLs) using CLI commands.

Procedure

1. Enable the privileged EXEC mode and enter your password if prompted.

   Example

   ```
   Device# enable
   ```

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Define an extended IPv4 access list using a name, and enter the access-list configuration mode.

   Example

   ```
   Device(config)# ip access-list extended 150
   ```

   The name can be a number from 100 to 199.

4. Specify the conditions allowed or denied in access-list configuration mode { **deny** | **permit** } *protocol* { *source* [*source-wildcard*] | **host** *source* | **any** } { *destination* [*destination-wildcard*] | host *destination* | **any** } [**precedence** *precedence*] [**tos***tos*] [**log**] [**time-range** *time-range-name*]

   Example

   ```
   Device(config-ext-nacl)# permit 0 any any
   ```

   Use the **log** keyword to get access list logging messages, including violations.

   - **host** *source*: A source and source wildcard of *source* 0.0.0.0.
   - **host** *destintation*: A destination and destination wildcard of *destination* 0.0.0.0.
   - **any**: A source and source wildcard or destination and destination wildcard of 0.0.0.0 255.255.255.255.

5. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-ext-nacl)# end
   ```

6. Verifiy your entries.

   Example

   ```
   Device# show running-config
   ```

7. Optional: Save your entries in the configuration file.

   Example

   ```
   Device# copy running-config startup-config
   ```

When you create extended ACLs, an implicit deny statement is added by default at the end of the ACL. If no match occurs before reaching the end, all traffic is denied. For standard ACLs, omitting the mask from an IP host address access list specification causes the system to use 0.0.0.0 as the mask.

New entries are always placed at the end of the ACL after you create it. You cannot add ACL entries at specific positions within an ACL. However, you can remove entries from a named ACL using the **no permit** and **no deny** access-list configuration mode commands.

Being able to selectively remove lines from a named ACL is one reason you might use named ACLs instead of numbered ACLs.

What to do next

After you create a named ACL, apply it to interfaces or to VLANs .

Apply an IPv4 ACL to an interface (GUI)

Use this procedure to apply an IPv4 ACL to an interface using GUI.

Use this procedure when you need to restrict or permit traffic through a device interface based on IPv4 ACL rules using the GUI.

Procedure

1. Choose **Configuration** > **Security** > **ACL**.
2. Click **Associating Interfaces**.
3. Choose the interface from the **Available Interfaces** list to view its ACL details on the right-hand side. You can change the ACL details, if required.
4. Click **Save & Apply to Device**.

Apply an IPv4 ACL to an interface (CLI)

Use to procedure to apply an IPv4 ACL to an interface using commands.

Restrict or permit packets on an interface by associating an ACL using commands.

This section describes how to apply IPv4 ACLs to network interfaces.

Beginning in privileged EXEC mode, follow the procedure given below to control access to an interface:

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Identify a specific interface for configuration, and enter the interface configuration mode.

   Example

   ```
   Device(config)#
   ```

   The interface is a layer 2 interface (port ACL) , or a layer 3 interface (router ACL).

3. Control access to the specified interface.

   Example

   ```
   Device(config-if)# ip access-group {access-list-number 2 | name} {in | out}
   ```

4. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-if)# end
   ```

5. Display the access list configuration.

   Example

   ```
   Device# show running-config
   ```

6. Optional: Save your entries in the configuration file.

Example

```
Device# copy running-config startup-config
```

Apply ACL to policy profile (GUI)

Use this procedure to apply ACL to policy profile using the GUI.

Use this procedure to apply an ACL to a policy profile using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. On the **Policy Profile** page, click **Add**.
3. In the **Add Policy Profile** window, click **Access Policies** tab.
4. In the **WLAN ACL** area, select the IPv4 ACL from the **IPv4 ACL** drop-down list.
5. Click **Apply to Device**.

Apply ACL to policy profile (CLI)

Use this procedure to apply ACL to policy profile using commands.

Use these steps to attach a preconfigured IPv4 ACL to a specific WLAN policy profile using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a WLAN policy profile and enter the wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy profile-policy
```

3. Configure an IPv4 ACL.

Example

```
Device(config-wireless-policy)# ipv4 acl test-acl
```

4. Return to the privileged EXEC mode.

Example

```
Device(config-wireless-policy)# end
```

Alternatively, you can also press *Ctrl-Z* to exit global configuration mode.

Configuration examples for ACLs

Demonstrates practical ACL implementations through configuration examples, including commented entries, applying ACLs to policy profiles, small network scenarios, numbered, extended, and named ACLs, time-based rules, and logging configurations.

Examples: including comments in ACLs

This section provides details about including comments in ACLs examples.

You can use the **remark** keyword to include comments (remarks) about entries in any IP standard or extended ACL. The remarks make the ACL easier for you to understand and scan. Each remark line is limited to 100 characters.

The remark can go before or after a permit or deny statement. Place remarks consistently to clarify which permit or deny statement each remark describes. If remarks are placed both before and after permit or deny statements, it may be unclear which remark applies to which statement.

To include a comment for IP numbered standard or extended ACLs, use the **access-list** *access-list number* **remark** *remark* global configuration command. To remove the remark, use the **no** form of this command.

In this example, the workstation that belongs to Jones is allowed access, and the workstation that belongs to Smith is not allowed access:

```
Device(config)# access-list 1 remark Permit only Jones workstation through
Device(config)# access-list 1 permit 171.69.2.88
Device(config)# access-list 1 remark Do not allow Smith through
Device(config)# access-list 1 deny 171.69.3.13
```

For an entry in a named IP ACL, use the **remark** access-list configuration command. To remove the remark, use the **no** form of this command.

In this example, the Jones subnet is not allowed to use outbound Telnet:

```
Device(config)# ip access-list extended telnetting
Device(config-ext-nacl)# remark Do not allow Jones subnet to telnet out
Device(config-ext-nacl)# deny tcp host 171.69.2.88 any eq telnet
```

Examples: apply an IPv4 ACL to a policy profile in a wireless environment

This section provides details about applying an IPv4 ACL to a policy profile in a wireless environment examples.

This example shows how to apply an IPv4 ACL to a policy profile in a wireless environment.

> **Note**
>
> All IPv4 ACLs must be associated to a policy profile.

This example uses extended ACLs to permit TCP traffic.

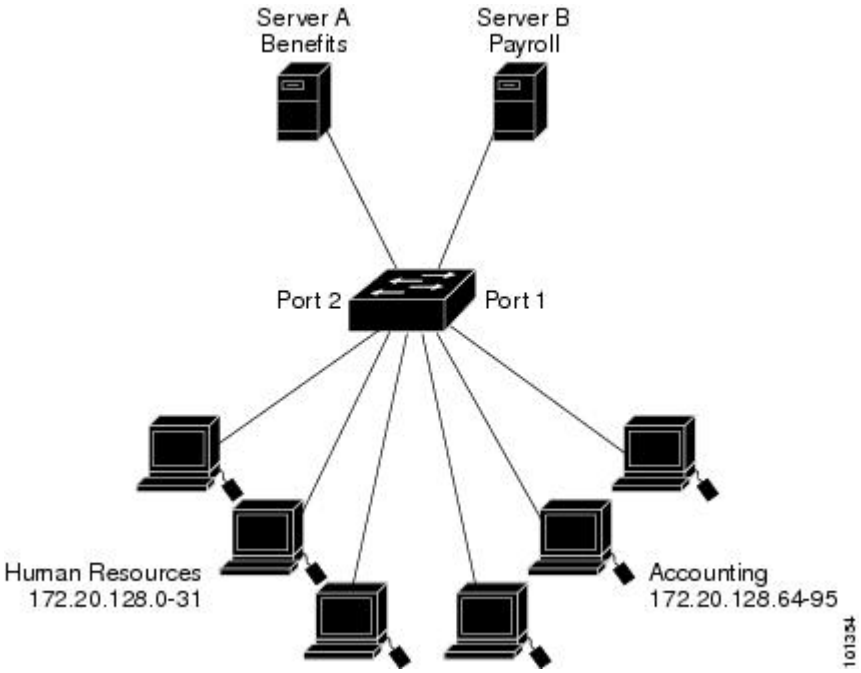
1. Creating an IPv4 ACL.

```
Device(config)# ip access-list extended <acl-name>
Device(config-ext-nacl)# 10 permit ip any 10.193.48.224 0.0.0.31
Device(config-ext-nacl)# 20 permit ip any any
```

2. Applying the IPv4 ACL to a policy profile.

```
Device(config)# wireless profile policy <policy-profile-name>
Device(config-wireless-policy)# shutdown
Device(config-wireless-policy)# ipv4 acl <acl-name>
Device(config-wireless-policy)# no shutdown
```

IPv4 ACL Configuration Examples



IPv4 ACL Configuration examples.

This section provides examples of configuring and applying IPv4 ACLs. For detailed information about compiling ACLs, see the *Cisco IOS Security Configuration Guide, Release 12.4* and to the Configuring IP Services" section in the "IP Addressing and Services" chapter of the *Cisco IOS IP Configuration Guide, Release 12.4*.

ACLs in a small networked office

This section provides ACLs in a small networked office details.

Figure 21: Using Router ACLs to Control Traffic

The diagram illustrates a small networked office. Routed Port 2 connects to Server A, which hosts benefits and other information accessible to all employees. Routed Port 1 connects to Server B, which contains confidential payroll data. All users can access Server A. Server B is restricted to authorized users.

Use router ACLs to do this in one of two ways:

- Create a standard ACL to filter traffic coming to the server from Port 1.
- Create an extended ACL to filter traffic coming from the server into Port 1.

Examples: ACLs in a small networked office

This section provides details about ACLs in a small networked office examples.

This example uses a standard ACL to filter traffic coming into Server B from a port. The ACL permits traffic only from accounting's source addresses 172.20.128.64 to 172.20.128.95. The ACL is applied to traffic that comes out of routed Port 1 from the specified source address.

```
Device(config)# access-list 6 permit 172.20.128.64 0.0.0.31
Device(config)# end
Device# how access-lists

Standard IP access list 6
10 permit 172.20.128.64, wildcard bits 0.0.0.31
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip access-group 6 out
```

This example uses an extended ACL to filter traffic from Server B into a port. It permits traffic from any source address (in this case Server B) only to accounting destination addresses in the range 172.20.128.64 to 172.20.128.95. The ACL is applied to traffic going into routed Port 1, permitting it to go only to the specified destination addresses. With extended ACLs, enter the protocol (IP) before specifying source and destination information.

```
Device(config)# access-list 106 permit ip any 172.20.128.64 0.0.0.31
Device(config)# end
Device# show access-lists
```

```
Extended IP access list 106
10 permit ip any 172.20.128.64 0.0.0.31
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip access-group 106 in
```

Example: numbered ACLs

This section provides details about numbered ACLs examples.

In this example, network 10.0.0.0 is a Class A network. Its second octet specifies a subnet, and its subnet mask is 255.255.0.0. The third and fourth octets in a 10.0.0.0 network address specify a particular host. Using access list 2, the switch accepts one address on subnet 48 and rejects all other addresses on that subnet. The last line of the list shows that the switch accepts addresses on all other subnets of network 10.0.0.0. The ACL is applied to packets entering a port.

```
Device(config)# access-list 2 permit 10.48.0.3
Device(config)# access-list 2 deny 10.48.0.0 0.0.255.255
Device(config)# access-list 2 permit 10.0.0.0 0.255.255.255
Device(config)#

Device(config-if)# ip access-group 2 in
```

Examples: extended ACLs

This section provides details about extended ACLs examples.

In this example, the first line permits any incoming TCP connections with destination ports greater than 1023. The second line permits incoming TCP connections to the Simple Mail Transfer Protocol (SMTP) port of host 128.88.1.2. The third line permits incoming ICMP messages for error feedback.

```
Device(config)# access-list 102 permit tcp any 128.88.0.0 0.0.255.255 gt 1023
Device(config)# access-list 102 permit tcp any host 128.88.1.2 eq 25
Device(config)# access-list 102 permit icmp any any
Device(config)#

Device(config-if)# ip access-group 102 in
```

In this example, suppose that you have a network connected to the Internet, and you want any host on the network to be able to form TCP connections to any host on the Internet. However, you do not want IP hosts to be able to form TCP connections to hosts on your network, except to the mail (SMTP) port of a dedicated mail host.

SMTP uses TCP port 25 on one end of the connection and a random port number on the other end. The same port numbers are used throughout the life of the connection. Mail packets coming in from the Internet have a destination port of 25. Because the secure system of the network always accepts mail connections on port 25, incoming are separately controlled.

```
Device(config)# access-list 102 permit tcp any 128.88.0.0 0.0.255.255 eq 23
Device(config)# access-list 102 permit tcp any 128.88.0.0 0.0.255.255 eq 25
Device(config)#

Device(config-if)# ip access-group 102 in
```

Examples: named ACLs

This section provides details about named ACLs examples.

Creating named standard and extended ACLs

This example creates a standard ACL named *internet_filter* and an extended ACL named *marketing_group*. The *internet_filter* ACL allows all traffic from the source address 1.2.3.4.

```
Device(config)# ip access-list standard Internet_filter
Device(config-ext-nacl)# permit 1.2.3.4
Device(config-ext-nacl)# exit
```

The *marketing_group* ACL allows any TCP Telnet traffic to the destination address and wildcard 171.69.0.0 0.0.255.255 and denies any other TCP traffic. It permits ICMP traffic, denies UDP traffic from any source to the destination address range 171.69.0.0 through 179.69.255.255 with a destination port less than 1024, denies any other IP traffic, and provides a log of the result.

```
Device(config)# ip access-list extended marketing_group
Device(config-ext-nacl)# permit tcp any 171.69.0.0 0.0.255.255 eq telnet
Device(config-ext-nacl)# deny tcp any any
Device(config-ext-nacl)# permit icmp any any
Device(config-ext-nacl)# deny udp any 171.69.0.0 0.0.255.255 lt 1024
Device(config-ext-nacl)# deny ip any any log
Device(config-ext-nacl)# exit
```

The *Internet_filter* ACL is applied to outgoing traffic and the *marketing_group* ACL is applied to incoming traffic on a Layer 3 port.

```
Device(config)# interface gigabitethernet3/0/1

Device
Device(config-if)# ip address 2.0.5.1 255.255.255.0
Device(config-if)# ip access-group Internet_filter out
Device(config-if)# ip access-group marketing_group in
```

Deleting individual ACEs from named ACLs

This example shows how you can delete individual ACEs from the named access list *border-list*:

```
Device(config)# ip access-list extended border-list
Device(config-ext-nacl)# no permit ip host 10.1.1.3 any
```

Monitor IPv4 ACLs

Explains monitoring techniques for IPv4 ACLs, offering methods to observe ACL activity, assess effectiveness, and troubleshoot operations to maintain robust network security.

You can monitor IPv4 ACLs by displaying the ACLs configured on the switch and those applied to interfaces and VLANs .

Table 119: Commands for Displaying Access Lists and Access Groups

When you use the **ip access-group** interface configuration command to apply ACLs to a Layer 2 or 3 interface, you can display the access groups on the interface. You can also display the MAC ACLs applied to a Layer 2 interface. You can use the privileged EXEC commands as described in this table to display this information.

Command	Purpose
show access-lists [*number* | *name*]	Displays the contents of one or all current IP and MAC address access lists or a specific access list (numbered or named).
show ip access-lists [*number* | *name*]	Displays the contents of all current IP access lists or a specific IP access list (numbered or named).
show ip interface *interface-id*	Displays detailed configuration and status of an interface. If IP is enabled on the interface and ACLs have been applied by using the **ip access-group** interface configuration command, the access groups are included in the display.
show running-config [**interface** *interface-id*]	Displays the contents of the configuration file for the switch or the specified interface, including all configured MAC and IP access lists and which access groups are applied to an interface.

131 Downloadable ACL

Topics:

- Downloadable ACLs

Outlines the Downloadable ACL feature, covering its functionality, history, scale considerations, configuration steps in ISE and controllers, guidelines, and verification procedures for centralized ACL management using Cisco ISE.

Downloadable ACLs

Introduces the Downloadable ACL feature, detailing its capabilities, feature history, scale considerations, configuration in Cisco ISE and controllers, guidelines and restrictions, explicit authorization server setup, and methods for verifying dACL configuration.

A downloadable ACL is a type of access control list that

- restricts network access to users or devices based on predefined criteria
- is specified as a list of Access Control Entries (ACEs), and
- can be maintained centrally in Cisco ISE and downloaded to controllers.

Supporting reference information

You can easily maintain and update ACLs in Cisco ISE.

Each ACE has a matching condition based on packet header fields:

- IP addresses
- ports
- protocols
- combination of IP addresses, ports, and protocols
- Result (permit or deny)

ACLs are applied to each controller on a per-wireless-client basis.

Typically, you can configure ACLs in a controller itself. However, you can also configure ACLs on a connected Cisco ISE server and download them to the controller when a wireless client connects.

These ACLs are referred to as downloadable ACLs, per-user Dynamic ACLs, or dACLs.

You can easily maintain downloadable ACLs because they define or update ACLs in Cisco ISE and can be downloaded to all applicable controllers.

(In Cisco IOS-XE 17.8 and earlier releases, you must configure the name in Cisco ISE and define the ACL individually on each controller.)

Feature history for downloadable ACL

Downloadable ACL feature history.

This table provides release and related information about the feature explained in this section. This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.10.1	Downloadable ACL	The Downloadable ACL (dACL) feature defines and updates access control lists (ACLs) in one place (Cisco ISE) and allows ACL download to all the applicable controllers. In Cisco IOS-XE 17.8 and earlier releases, you had to configure the name in Cisco ISE and define the ACL individually in each of the controllers. The dACL feature is supported only in a centralized controller with Local mode APs. **Note** The dACL feature is not supported in RLAN environments.

Scale considerations for downloadable ACL

Downloadable ACL scale considerations.

This table provides the ACL scale numbers for controllers.

ACL Scale for Controllers

- Cisco Catalyst 9800-40 Wireless Controller (small or medium): Supports 128 ACLs with 128 ACEs.
- Cisco Catalyst 9800-80 Wireless Controller (large): Supports 256 ACLs and 256 ACEs.

Controllers	ACL Scale
Cisco Catalyst 9800-40 Wireless Controller (small or medium)	Supports 128 ACLs with 128 ACEs.
Cisco Catalyst 9800-80 Wireless Controller (large)	Supports 256 ACLs and 256 ACEs.

Restrictions for downloadable ACL

Outlines downloadable ACL guidelines and restrictions.

Restrictions on dACL usage

These restrictions apply to downloadable ACLs (dACL):

- dACL does not support FlexConnect local switching.
- You can use IPv6 dACLs only in Cisco ISE 3.0 or later.
- You can use the dACL feature only in a centralized controller that uses Local mode Access Points.

> **Note**
>
> The dACL feature is not supported in RLAN environments.

Configuring dACL name and definition in Cisco ISE

Configure dACL Name and Definition in Cisco ISE.

Before you configuring a dACL in a controller, you must configure the dACL name and definition in Cisco ISE. For more information, refer to Configure Per-User Dynamic Access Control Lists in ISE.

The RADIUS authorization response for a client assigned downloadable ACL includes the Cisco AV pair *ACS:CiscoSecure-Defined-ACL* with a value in this format: `#ACSACL#-IP-<ACL_NAME>-<ACL_HASH>`. For example, a dACL named *ACL_USER1* may be returned as `#ACSACL#-IP-ACL_USER1-65e89aab`. Use the ACL name and hash generated for that dACL by Cisco ISE. The example hash is provided only as a sample.

Configure dACL in a controller (CLI)

Configure dACL in a controller using commands.

Before you begin

Ensure you have configured the RADIUS server and the **aaa-override** command in the policy profile. For more information, see **Configuring AAA for Local Authentication (CLI)**.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the wireless profile policy.

   Example

   ```
   Device(config)# wireless profile policy policy-profile-name
   ```

3. Configure AAA override to apply policies coming from the Cisco ISE servers.

   Example

   ```
   Device(config-wireless-policy)# aaa-override
   ```

4. Enable the profile policy.

Example

```
Device(config-wireless-policy)# no shutdown
```

Configure explicit authorization server list (CLI)

Configure explicit authorization server list using commands.

Deploy an explicit authorization server list for network authorization.

This configuration is used to set up RADIUS servers for network authorization in a Cisco device.

Before you begin

Ensure you have the necessary RADIUS server details and access to the device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the RADIUS server name.

   Example

   ```
   Device(config)# radius server server-name
   ```

3. Specify the RADIUS server parameters.

   Example

   ```
   Device(config-radius-server)# address ipv4 ip-address
   ```

4. Specify the authorization and encryption key used between the device and the RADIUS server.

   Example

   ```
   Device(config-radius-server)# pac key key
   ```

5. Return to the configuration mode.

   Example

   ```
   Device(config-radius-server)# exit
   ```

6. Create a RADIUS server-group identification.

Example

```
Device(config)# aaa group server radius server-group-name
```

server-group-name refers to the server group name. The valid range is from 1 to 32 alphanumeric characters.

7. Create an authorization method list for web-based authorization.

Example

```
Device(config)# aaa authorization network authorization-list group
server-group-name
```

You must use the already created authorization method list.

8. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The explicit authorization server list is now configured and ready for use.

Verify dACL configuration

Verifies dACL configuration.

To verify the dACL, use this command:

```
Device# show wireless client mac-address <client_mac> detail
                Local Policies:
                Service Template : wlan_svc_named-policy-profile_1_local
(priority 254)
                VLAN             : 16
                Absolute-Timer   : 1800
                Server Policies:
                ACS ACL          : xACSACLx-IP-tftpv4_2-62de6299
                ACS ACL          : xACSACLx-IPV6-tftpv6_2-62de8087
                Resultant Policies:
                ACS ACL          : xACSACLx-IP-tftpv4_2-62de6299
                ACS ACL          : xACSACLx-IPV6-tftpv6_2-62de8087
                VLAN Name        : VLAN0016
                VLAN             : 16
                Absolute-Timer   : 1800
```

To verify dACLs, use this commands:

```
Device# show ip access-lists xACSACLx-IP-tftpv4_2-62de6299
                Extended IP access list xACSACLx-IP-tftpv4_2-62de6299
                1 deny ip any host 9.8.29.13
                2 permit ip any any (58 matches)
```

```
Device# show ipv6 access-list xACSACLx-IPV6-tftpv6_2-62de8087
                IPv6 access list xACSACLx-IPV6-tftpv6_2-62de8087
                deny ipv6 any host 2001:9:8:29:3AAD:A27A:973A:97CC sequence 1
```

```
                permit ipv6 any any (2 matches) sequence 2
```

To view all the downloaded dACLs, use this command:

```
Device# show ip access-lists
```

132 DNS-Based Access Control Lists

Topics:

- DNS-based access control lists
- URL filters
- Configure ISE for central web authentication
- FlexConnect client IPv6 support with WebAuth pre and post ACL

This chapter explains how to configure and apply DNS-based security features and IPv6 web authentication to manage wireless client traffic. It provides procedures for URL filtering and dynamic IP learning to protect network resources across local and FlexConnect deployment modes.

DNS-based access control lists

Explains how DNS-based access control lists (ACLs) enable wireless network administrators to manage client access to network resources based on DNS domain names.

A DNS-based access control list is a wireless network security feature that

- allows administrators to permit or deny wireless client access to resources based on DNS domain names
- dynamically learns allowed or denied IP addresses through DNS snooping on access points, and
- enables pre-authentication and post-authentication URL filtering for enhanced client security.

DNS-based ACLs are used for wireless client devices. You can set pre-authentication ACLs on the Cisco Catalyst 9800 Series Wireless Controller to determine which data requests are allowed or blocked.

To enable DNS-based ACLs on the controller, configure the allowed or denied URLs for the ACLs. The URLs need to be pre-configured on the ACL.

During the registration phase, DNS-based ACLs allow the client to connect to the configured URLs. The controller is configured with the ACL name provided by the AAA server. If the AAA server returns the ACL name, the controller applies the ACL to the client for web redirection.

During client authentication, the AAA server returns the pre-authentication ACL (url-redirect-acl), which is the attribute name assigned to the ACL by the AAA server. The AP performs DNS snooping for each client until registration is complete and the client reaches the SUPPLICANT PROVISIONING state. When the controller receives the ACL configured with URLs, it sends a CAPWAP payload to the access point to enable DNS snooping for those URLs.

After URL snooping is enabled, the access point learns the IP address of the resolved domain name from the DNS response. If the domain name matches the configured URL, the access point parses the DNS response for the IP address and sends the IP address to the controller as a CAPWAP payload. The controller adds the IP address to the allowed list, which enables the client to access the configured URLs.

URL filtering allows access to the IP address for DNS ports 80 or 443.

During pre-authentication or post-authentication, the DNS ACL is applied to the client in the AP. If the client roams from one AP to another AP, tthe DNS-learned IP addresses from the previous access point remain valid on the new AP.

Note

Standard URL filtering is used for local mode, whereas enhanced URL filtering is used for FlexConnect local switching.

Note

Attach the URL filter to a policy profile for local mode. In FlexConnect mode, attach the URL filter to the flex profile; attaching it to a policy profile is not required.

Use the **urlfilter enhanced-list** command only with FlexConnect local switching mode. Do not configure **enhanced-list** in policy profiles for local mode or Flex central switching, as this may cause client connection issues.

Note

DNS-based URLs require an active DNS query from the client. For URL filtering to work, configure DNS settings correctly.

Note

The URL filter takes precedence over punt or redirect ACLs, as well as custom or static pre-authentication ACLs.

Restrictions on DNS-based access control lists

This section provides the restrictions of DNS-based access control list restrictions.

Restrictions for DNS-based ACLs

- In local modes, both Pre-authentication and Post-authentication filters are supported. In Flex (Fabric) mode, only the Pre-authentication filter is supported. ACL override pushed from ISE is not supported.
- FlexConnect Local Switching with External Web authentication, using URL filtering, is not supported until Cisco IOS XE Gibraltar 16.12.x.
- Fully qualified domain name (FQDN) ACLs and DNS-based ACLs are not supported on Cisco Wave 1 Access Points.
- The URL filter considers only the first 20 URLs, though you can add more. It uses regular regex patterns and permits wildcard characters only at the beginning or at the end of an URL. URL ACLs are defined and added to the FlexConnect policy profile, which is then associated with a WLAN. URL ACL creation follows a mechanism similar to local mode URL ACLs.
- In FlexConnect mode, the URL domain ACL works only when it is connected to a FlexConnect policy profile. The ACL can be attached to a WLAN by associating the policy profile with either the WLAN or local policies. However, you can override it using 'url-redirect-acl'. When the Cisco AV pair is received from ISE, the required policy for a client is pushed as part of the ADD MOBILE message.

- When an AP joins or when an existing URL ACL is modified and applied to a FlexConnect profile, the ACL definition, along with the mapped URL filter list, is pushed to the AP. The AP stores the URL ACL definition with the mapped ACL name and snoops DNS packets to learn the first IP address for each URL in the ACL. When the AP learns the IP addresses, it updates the controller of the URL and IP bindings. The controller records this information in the client database for future use.
- When a client roams to another AP during the pre-authentication state, the learned IP addresses are pushed to a new AP. Otherwise, these learned IP addresses are purged when a client enters the post-authentication state or when the TTL for the learned IP address expires.
- The **urlfilter enhanced-list** command is intended only for use with FlexConnect local switching mode. Do not configure **enhanced-list** in policy profiles for local mode or FlexConnect central switching, as this may cause client connection issues.

Restrictions on Wildcard Support in URLs

- The generic wildcard URL, such as ***.*** is not allowed.
- Wildcards between the domain names, such as ***a.cisco.com**, **a.cisco*.com**, **a.b.c.test*.apply.play** are not allowed.
- Multiple wildcards, such as **test.*.cisco.*.com** are not allowed in a URL.
- The wildcard ***.cisco.com** is allowed in the URL.
- The wildcard with a suffix such as **wpr.cisco.*** is a valid configuration.
- A maximum of 16 wildcard-based URLs must be configured for a given ACL.

Define ACLs

This section provides defining ACL details.

Extended ACLs are similar to standard ACLs, but they identify traffic more precisely.

- These commands allow you to define ACLs by name or by identification number.

```
Device(config)#ip access-list extended ?
<100-199> Extended IP access-list number
<2000-2699> Extended IP access-list number (expanded range)
WORD Access-list name
```

- This is the structure of a CLI ACL statement:

```
<sequence number> [permit/deny] <protocol> <address or any> eq <port number>
 <subnet> <wildcard>
```

- For example:

```
1 permit tcp any eq www 192.168.1.0 0.0.0.255
```

The sequence number specifies where to insert the Access Control List Entry (ACE) in the order of ACEs within the ACL. You can define your statements using sequence numbers such as 10, 20, 30, 40, and so on.

The controller GUI allows you to write a complete ACL by going to the Configuration > Security > ACL page. You can view a list of protocols to choose from and make changes to an existing ACL.

Methods for applying ACLs

This section provides methods for applying ACLs.

These are the ways to apply ACLs:

Security ACL: A security ACL defines the types of traffic to allow through the device and the types to block or drop. A security ACL can be applied in various scenarios:

- On SVI interfaces: The ACL is evaluated only against traffic routed through the interface.

```
Device(config)# interface Vlan<number>
```

```
Device(config-if)# ip access-group myACL in/out
```

- On a physical interface of the controller: The ACL is evaluated against all traffic passing through the interface. This method also restricts traffic on the controller management plane, along with SVI interface application.

```
Device(config)#interface GigabitEthernet1
```

```
Device(config-if)#ip access-group myACL in/out
```

In the wireless policy profile or WLAN. You can configure an ACL to apply to wireless client traffic in cases of central or local traffic switching. These ACLs are supported only in the inbound direction.

On the AP during FlexConnect local switching. The ACL is configured and applied from the policy profile on the controller. The ACL must be downloaded to the AP through the FlexConnect profile before it can be applied. Fabric mode APs in Software Defined Access also use Flex ACLs, even though these APs are not operating in FlexConnect mode.

A punt ACL or redirect ACL specifies which traffic is sent to the CPU for further processing instead of normal handling by the dataplane. For example, the Central Web Authentication (CWA) redirect ACL determines which traffic is intercepted and redirected to the web login portal. The ACL does not define traffic to drop or allow. It follows normal processing or forwarding rules and identifies what is sent to the CPU for interception.

A redirect ACL includes an implicit deny statement at the end. This security access list entry drops any traffic not explicitly allowed or sent to the CPU.

Configure ISE for central web authentication (GUI)

Use this procedure to configure ISE for central web authentication using GUI.

Perform these steps to configure ISE for Central Web Authentication using the GUI.

Procedure

1. Login to the Cisco Identity Services Engine (ISE). Click **Policy** and then click **Policy Elements**. Click **Results**.
2. Expand **Authorization** and click **Authorization Profiles**.
3. Click **Add** to create a new authorization profile for URL filter.
4. Enter a name for the profile in the **Name** field. For example, CentralWebauth.
5. Select **ACCESS_ACCEPT** option from the **Access Type** drop-down list. Alternatively, in the **Common Tasks** section, check **Web Redirection**.
6. Select the **Centralized Web Auth** option from the drop-down list. Specify the ACL and select the ACL value from the drop-down list.
7. In the **Advanced Attributes Setting** section, select **Cisco:cisco-av-pair** from the drop-down list.

> **Note**
>
> Multiple ACL can be applied on the controller based on priority. In L2 Auth + webauth multi-auth scenario, if the ISE returns ACL during L2 Auth then ISE ACL takes precedence over the default webauth redirect ACL. This leads to traffic running in webauth pending state, if ISE ACL has permit rule. To avoid this scenario, you need to set the precedence for L2 Auth ISE returned ACL. The default webauth redirect ACL priority is 100. To avoid traffic issue, you need to configure the redirect ACL priority above 100 for ACL returned by ISE.

8. Enter these one by one and click (+) icon after each of them:
   - url-redirect-acl=<sample_name>
   - url-redirect=<sample_redirect_URL>

     For example,

```
Cisco:cisco-av-pair = priv-lvl=15
Cisco:cisco-av-pair = url-redirect-acl=ACL-REDIRECT2
Cisco:cisco-av-pair = url-redirect=
https://9.10.8.247:port/portal/gateway?
sessionId=SessionIdValue&portal=0ce17ad0-6d90-11e5-978e-005056bf2f0a&daysToExpiry=value&action=cwa
```

9. Verify contents in the **Attributes Details** section and click **Save**.

View DNS-based access control lists

This section provides viewing DNS-based access control list details.

To view details of a specified wireless URL filter, use this command:

```
Device# show wireless urlfilter details <urllist_flex_preauth>
```

To view the summary of all wireless URL filters, use this command:

```
Device# show wireless urlfilter summary
```

To view the URL filter applied to the client in the resultant policy section, use this command:

```
Device# show wireless client mac-address <MAC_addr> detail
```

Configuration examples for DNS-based access control lists

This section provides DNS-based access control lists configuration examples.

FlexConnect Mode

Example: Defining URL Filter List

This example shows how to define URL list in FlexConnect mode:

```
Device# configure terminal
Device(config)# urlfilter enhanced-list urllist_flex_pre
```

```
Device(config-urlfilter-params)# url www.dns.com preference 1 action permit
Device(config-urlfilter-params)# end
```

Example: Applying URL Filter List to Flex Profile

This example shows how to apply an URL list to the FlexConnect profile in FlexConnect mode:

```
Device# configure terminal
Device(config)# wireless profile flex default-flex-profile
Device(config-wireless-flex-profile)# acl-policy acl_name
Device(config-wireless-flex-profile-acl)# urlfilter list urllist_flex_preauth
Device(config-wireless-flex-profile-acl)# end
```

Local Mode

Example: Defining Preauth URL Filter List

This example shows how to define URL filter list (pre-authentication):

```
Device# configure terminal
Device(config)# urlfilter list urllist_local_preauth
Device(config-urlfilter-params)# action permit
Device(config-urlfilter-params)# redirect-server-ipv4 9.1.0.101
Device(config-urlfilter-params)# redirect-server-ipv6 2001:300:8::82
Device(config-urlfilter-params)# url url1.dns.com
Device(config-urlfilter-params)# end
```

Example: Defining Postauth URL Filter List

This example shows how to define URL filter list (post-authentication):

```
Device# configure terminal
Device(config)# urlfilter list urllist_local_postauth
Device(config-urlfilter-params)# action permit
Device(config-urlfilter-params)# filter-type post-authentication
Device(config-urlfilter-params)# redirect-server-ipv4 9.1.0.101
Device(config-urlfilter-params)# redirect-server-ipv6 2001:300:8::82
Device(config-urlfilter-params)# url url1.dns.com
Device(config-urlfilter-params)# end
```

Example: Applying URL Filter List to Policy Profile

This example shows how to apply an URL list to the policy profile in local mode:

```
Device# configure terminal
Device(config)# wireless profile policy default-policy-profile
Device(config-wireless-policy)# urlfilter list pre-auth-filter
urllist_local_preauth
Device(config-wireless-policy)# urlfilter list post-auth-filter
urllist_local_postauth
Device(config-wireless-policy)# end
```

Verify DNS snoop agent (DSA)

This section provides how to verify DNS snoop agent (DSA) details.

To view details of the DNS snooping agent client, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
client
```

To view details of the DSA enabled interface, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
client enabled-intf
```

To view the pattern list in uCode memory, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
client hw-pattern-list
```

To view the OpenDNS string for the pattern list, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
client hw-pattern-list odns_string
```

To view the FQDN filter for the pattern list, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
client hw-pattern-list fqdn-filter <fqdn_filter_ID>
```

Note

The valid range of *fqdn_filter_ID* is from 1 to 16.

To view details of the DSA client, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
client info
```

To view the pattern list in CPP client, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
client pattern-list
```

To view the OpenDNS string for the pattern list, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
client pattern-list odns_string
```

To view the FQDN filter for the pattern list, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
client pattern-list fqdn-filter <fqdn_filter_ID>
```

> **Note**
>
> The valid range of *fqdn_filter_ID* is from 1 to 16.

To view details of the DSA datapath, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
datapath
```

To view details of the DSA IP cache table, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
datapath ip-cache
```

To view details of the DSA address entry, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
datapath ip-cache address {ipv4 <IPv4_addr> | ipv6 <IPv6_addr>}
```

To view details of all the DSA IP cache address, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
datapath ip-cache all
```

To view details of the DSA IP cache pattern, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
datapath ip-cache pattern <pattern>
```

To view details of the DSA datapath memory, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
datapath memory
```

To view the DSA regular expression table, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
datapath regexp-table
```

To view the DSA statistics, use this command:

```
Device# show platform hardware chassis active qfp feature dns-snoop-agent
datapath stats
```

URL filters

Explains how URL filters control wireless network web access, the types available, and their interaction with ACLs.

A URL filter is a wireless network access control feature that

- restricts access to websites based on specified URLs
- can operate before or after client authentication, and

- is applied together with an IP-based ACL for granular access control.

There are the two types of URL filters:

- Standard: Standard URL filters can be applied before client authentication (pre-auth) or after a successful client authentication (post-auth). Pre-auth filters are extremely useful for external web authentication because they allow access to the external login page and some internal websites before authentication takes place. After authentication, filters can block specific websites or allow only selected websites, while all other websites are blocked by default. After authentication, this type of URL filtering can be handled more flexibly by using Cisco DNS Layer Security (formerly called Umbrella). The standard URL filters apply the same action (permit or deny) for the whole list of URLs. It is either all permit or all deny. Standard URL filters work only on local mode APs.
- Enhanced: Enhanced URL filters allow you to specify a different action (deny or permit) for each URL in the list and include per-URL hit counters. Enhanced URL filters work only on FlexConnect mode APs.

In both types of URL filters, you can use a wildcard sub-domain such as `*.cisco.com`. URL filters are standalone features but are always applied together with an IP-based ACL. A maximum of 20 URLs are supported in a given URL filter. Because one URL can resolve to multiple IP addresses, each client can track up to 40 resolved IP addresses. URL filters track only DNS records. The controller or APs do not track the resolved IP address if the DNS response uses a CNAME alias record.

> **Note**
>
> If you have a POST-type URL filter and an ACL applied to a policy profile, the ACL blocks traffic to the URL if it does not include permit statements for the URLs. This issue can occur when the URL filter is POST with a permit statement but the ACL does not include a permit statement for the URLs. We recommend creating permit statements within the ACL for the IP addresses of the URLs rather than relying on the POST URL filter.

FlexConnect mode

Explains how to configure a URL filter list for the FlexConnect profile.

Define URL filter list (CLI)

Use this procedure to define URL filter list using commands.

Define a custom list of permitted or blocked URLs for use with FlexConnect local switching mode using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the URL filter enhanced list.

   Example

   ```
   Device(config)# urlfilter enhanced-list urllist_flex_preauth
   ```

> **Note**
>
> Use the **urlfilter enhanced-list** command only with FlexConnect local switching mode. Do not configure **enhanced-list** in policy profiles for local mode or FlexConnect central switching. This action may cause client connection issues.

Here, *list-name* refers to the URL filter list name. The list name must not exceed 32 alphanumeric characters.

3. Configure the action: permit (allowed list) or deny (blocked list).

Example

```
Device(config-urlfilter-enhanced-params)# url url-name preference [0-65535]
action {deny | permit}
```

4. Return to privileged EXEC mode.

Example

```
Device(config-urlfilter-params)# end
```

Apply URL filter list to FlexConnect profile (CLI)

Use this procedure to apply URL filter list to FlexConnect profile using commands.

Use this procedure to enforce web access policies on FlexConnect APs through defined URL filter lists using commands.

Procedure

---

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Create a new flex policy.

Example

```
Device(config)# wireless profile flex default-flex-profile
```

3. Configure ACL policy.

Example

```
Device(config-wireless-flex-profile)# acl-policy acl_name
```

4. Apply the URL list to the Flex profile.

Example

```
Device(config-wireless-flex-profile-acl)# urlfilter list urllist_flex_preauth
```

5. Return to privileged EXEC mode.

Example

```
Device(config-wireless-flex-profile-acl)# end
```

Local mode

Explains how to configure a URL filter list for the Local profile.

Define URL filter list (CLI)

Use this procedure to define URL filter list using commands.

Configure a URL filter list to control access to specific web resources by creating an allowed or blocked list, setting redirect servers, and applying actions for post-authentication filtering using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the URL filter list.

Example

```
Device(config)# urlfilter list urllist_local_preauth
```

Here, *list-name* refers to the URL filter list name. The list name must not exceed 32 alphanumeric characters.

3. Configure the action: permit (allowed list) or deny (blocked list).

Example

```
Device(config-urlfilter-params)# action permit
```

4. Configure the URL list as post-authentication filter.

Example

```
Device(config-urlfilter-params)# filter-type post-authentication
```

> **Note**
>
> This step is applicable while configuring post-authentication URL filter only.

5. Configure the IPv4 redirect server for the URL list.

   Example

   ```
   Device(config-urlfilter-params)# redirect-server-ipv4 192.0.2.1
   ```

   Here, *IPv4-address* refers to the IPv4 address.

6. Configure the IPv6 redirect server for the URL list.

   Example

   ```
   Device(config-urlfilter-params)# redirect-server-ipv6 2001:DB8::82
   ```

   Here, *IPv6-address* refers to the IPv6 address.

7. Configure an URL.

   Example

   ```
   Device(config-urlfilter-params)# url url1.dns.com
   ```

   Here, *url* refers to the name of the URL.

8. Return to privileged EXEC mode.

   Example

   ```
   Device(config-urlfilter-params)# end
   ```

Apply URL filter list to policy profile (GUI)

Use this procedure to apply URL filter list to policy profile using GUI.

Assign URL filters to a policy profile to manage and restrict user web access using the GUI.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click on the **Policy Name**.
3. Go to **Access Policies** tab.
4. In the **URL Filters** section, select the filters from the **Pre Auth** and **Post Auth** drop-down lists.
5. Click **Update & Apply to Device**.

Apply URL filter list to policy profile (CLI)

Use this procedure to apply URL filter list to policy profile using commands.

Restrict or permit user access to network resources by applying specific URL filter lists to a designated policy profile using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure wireless policy profile.

   Example

   ```
   Device(config)# wireless profile policy default-policy-profile
   ```

   Here, *profile-policy* refers to the name of the WLAN policy profile.

3. Apply the URL list to the policy profile.

   Example

   ```
   Device(config-wireless-policy)# urlfilter list pre-auth-filter
   urllist_local_preauth
   ```

   ```
   Device(config-wireless-policy)# urlfilter list post-auth-filter
   urllist_local_postauth
   ```

   Here, *name* refers to the name of the pre-authentication or post-authentication URL filter list configured earlier.

   > **Note**
   >
   > When a client joins, the policy's configured URL filter applies to the client.

4. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

Configure ISE for central web authentication

Explains how to configure ISE for central web authentication.

Create authorization profiles (GUI)

Use this procedure to create authorization profiles.

Define authorization profiles that control network access through URL filters using the GUI.

Procedure

1. Login to the Cisco Identity Services Engine (ISE). Click **Policy**, and click **Policy Elements**.
2. Click **Results**.
3. Expand **Authorization**, and click **Authorization Profiles**.
4. Click **Add** to create a new authorization profile for URL filter.
5. In the Name field, enter a name for the profile. For example, *CentralWebauth*.
6. Select **ACCESS_ACCEPT** from the access type drop-down list.
7. In the Advanced Attributes Setting section, select **Cisco:cisco-av-pair** from the drop-down list.
8. Enter these parameters one by one and click (+) icon after each of them:
   - url-filter-preauth=<preauth_filter_name>
   - url-filter-postauth=<postauth_filter_name>

   For example,

```
Cisco:cisco-av-pair = url-filter-preauth=urllist_pre_cwa
Cisco:cisco-av-pair = url-filter-postauth=urllist_post_cwa
```

9. Verify contents in the attributes details section and click **Save**.

Map authorization profiles to authentication rule (GUI)

Use this procedure to map authorization profiles to authentication rule.

Define rules that determine how authentication requests are processed by mapping authorization profiles to authentication criteria in the Policy interface using the GUI.

Procedure

1. In the **Policy** > **Authentication** page, click **Authentication**.
2. Enter a name for your authentication rule.

   For example, *MAB*.
3. In the **If condition** field, select the plus (+) icon.
4. Choose **Compound condition** , and choose **WLC_Web_Authentication**.
5. Click the arrow located next to **and ...** in order to expand the rule further.
6. Click the + icon in the Identity Source field, and choose **Internal endpoints**.
7. Select **Continue** from the 'If user not found' drop-down list.

   This option allows a device to be authenticated even if its MAC address is not known.

8. Click **Save**.

Map authorization profiles to authorization rule (GUI)

Use this procedure to map authorization profiles to authorization rule.

Map an authorization profile to an authorization rule to control network access permissions based on selected identity and condition attributes using the GUI.

Procedure

1. Click **Policy** > **Authorization**. In the Rule Name field, enter a name.

   For example, *CWA Post Auth*.
2. In the Conditions field, select the plus (+) icon.
3. Select the **Identity Groups** area to view from the drop-down list. Choose **User Identity Groups** > **user_group**.
4. Click the plus (+) sign located next to **and ...** in order to expand the rule further.
5. In the Conditions field, select the plus (+) icon. Choose **Compound Conditions**, and choose to create a new condition.
6. From the settings icon, select **Add Attribute/Value** from the options.
7. In the Description field, select **Network Access** > **UseCase** as the attribute from the drop-down list. Choose the **Equals** operator.
8. From the right-hand field, choose **GuestFlow**.
9. In the Permissions field, select the plus (+) icon to select a result for your rule.

   You can choose **Standard** > **PermitAccess** option or create a custom profile to return the attributes that you like.

FlexConnect client IPv6 support with WebAuth pre and post ACL

Explains how to configure FlexConnect client IPv6 support with WebAuth pre and post ACL.

FlexConnect client IPv6 support with WebAuth pre and post ACL

This section explains FlexConnect client IPv6 support with WebAuth pre and post ACL details.

A WebAuth IPv6 ACL is an access control mechanism that

- enables an access point to enforce web authentication policies for IPv6 client traffic
- uses IOS IPv6 ACL definitions that are pushed to the AP in response to join events or policy changes, and
- differentiates pre-authentication and post-authentication access by assigning default or custom ACLs.

A change in the ACL policies of the FlexConnect profile can include adding a new ACL, deleting an ACL, or modifying an existing ACL.

ACL definitions are pushed to AP when any of these events occur:

- AP join.
- New ACL mapping in a new FlexConnect profile.
- Configuring IPv6 ACL definition in FlexConnect profile.

Default Local Web Authentication ACLs

The pre-defined default LWA IPv6 ACL is pushed to AP and assigned to the data plane.

Default External Web Authentication ACL

The default EWA ACLs are derived from the redirect portal address configured in the parameter map.

The types of default EWA ACLs include:

- Security ACL which is pushed and assigned to the AP.
- Intercept ACL which is pushed and assigned to the data plane.

FQDN ACL

- FQDN ACL is encoded along with IPv6 ACL and sent to AP.
- FQDN ACL is always a custom ACL.

These applies to FlexConnect and Local mode:

- If you are migrating from AireOS, you would explicitly need to execute these commands:

```
redirect append ap-mac tag ap_mac
```

```
redirect append wlan-ssid tag wlan
```

```
redirect append client-mac tag client_mac
```

- If the login page has any resource that needs to be fetched from the server, you will need to include those resource URLs in URL filtering.
- If you are trying to access an IPv6 URL and you have an IPv4 web server, the controller redirects the client to an internal page. Domain redirection is not supported in this context. It is recommended to have a dual-stack web server and configure virtual IPv6 address in the global parameter map.

Enable pre-authentication ACL for LWA and EWA (GUI)

Use this procedure to enable pre-authentication ACL for LWA and EWA using GUI.

Allow or restrict traffic before authentication on specified WLANs using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID** and the **WLAN ID**.
4. Choose **Security** > **Layer2** tab. Uncheck the **WPAPolicy**, **AES** and **802.1x** check boxes.
5. Choose **Security** > **Layer3** tab. Select the Web Auth Parameter Map from the **Web Auth Parameter Map** drop-down list and authentication list from the **Authentication List** drop-down list.
6. Click **Show Advanced Settings** and under the **Preauthenticated ACL** settings, and select the IPv6 ACL from the **IPv6** drop-down list.
7. Choose **Security** > **AAA** tab. Select the authentication list from the **Authentication List** drop-down list.

8. Click **Apply to Device**.

Enable pre-authentication ACL for LWA and EWA (CLI)

Use this procedure to enable pre-authentication ACL for LWA and EWA using commands.

Configure pre-authentication access control for WLAN client web authentication scenarios using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-demo 1 ssid-demo
   ```

   - *wlan-name*: Enter the profile name. The range is from 1 to 32 alphanumeric characters.
   - *wlan-id*: Enter the WLAN ID. The range is from 1 to 512.
   - *SSID-name*: Enter the Service Set Identifier (SSID) for this WLAN. If the SSID is not specified, the WLAN profile name is set as the SSID.

   > **Note**
   >
   > If you have already configured WLAN, enter **wlan wlan-name** command.

3. Create a pre-authentication ACL for web authentication and disable the WPA security.

   Example

   ```
   Device(config-wlan)# ipv6 traffic-filter web preauth_v6_acl
   ```

   ```
   Device(config-wlan)# no security wpa
   ```

4. Disable WPA2 ciphers for AES.

   Example

   ```
   Device(config-wlan)#no security wpa wpa2 ciphers aes
   ```

5. Disable security AKM for dot1x.

Example

```
Device(config-wlan)#no security wpa akm dot1x
```

6. Configure web authentication.

Example

```
Device(config-wlan)# security web-auth
```

7. Enable authentication list for WLAN.

Example

```
Device(config-wlan)# security web-auth authentication-list wcm_dot1x
```

8. Map the parameter map.

Example

```
Device(config-wlan)# security web-auth parameter-map param-custom-webconsent
```

9. Shutdown the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

Enable post-authentication ACL for LWA and EWA (GUI)

Use this procedure to enable post-authentication ACL for LWA and EWA using GUI.

Enable post-authentication access control for LWA and EWA WLANs to enforce security policies after successful user authentication using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**. The **Profile Name** is the profile name of the policy profile.
4. Enter the **SSID** and the **WLAN ID**.
5. Click **Apply to Device**.

Enable post-authentication ACL for LWA and EWA (CLI)

Use this procedure to enable post-authentication ACL for LWA and EWA using commands.

Configure security policies that restrict client access after authentication using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create policy profile for the WLAN.

   Example

   ```
   Device(config)# wireless profile policy test1
   ```

   The *profile-name* is the profile name of the policy profile.

3. Create a named WLAN ACL.

   Example

   ```
   Device(config-wireless-policy)# ipv6 acl testacl
   ```

4. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

   Alternatively, you can also press ***Ctrl-Z*** to exit global configuration mode.

Enable DNS ACL for LWA and EWA (GUI)

Use this procedure to enable DNS ACL for LWA and EWA (GUI).

Enable DNS-based access control for LWA and EWA WLANs by configuring the required settings using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**. The **Profile Name** is the profile name of the policy profile.
4. Enter the **SSID** and the **WLAN ID**.
5. Click **Apply to Device**.

Enable DNS ACL for LWA and EWA (CLI)

Use this procedure to enable DNS ACL for LWA and EWA using commands.

Enable DNS ACLs to control DNS access for WLAN policy profiles that use LWA or EWA using commands.

> **Note**
>
> Post-authentication DNS ACL is not supported.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create policy profile for the WLAN.

   Example

   ```
   Device(config)# wireless profile policy test1
   ```

   The *profile-name* is the profile name of the policy profile.

3. Return to the privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press ***Ctrl-Z*** to exit global configuration mode.

Verify FlexConnect client IPv6 support with WebAuth pre and post ACL

This section provides verifying FlexConnect client IPv6 support with WebAuth pre and post ACL details.

To verify the client state after L2 authentication, use this command:

```
Device# show wireless client summary
Number of Local Clients: 1

MAC Address    AP Name                          WLAN  State            Protocol
 Method     Role
-------------------------------------------------------------------------------------------
1491.82b8.f8c1 AP4001.7A03.544C                  4      Webauth Pending   11n(5)
   None       Local
Number of Excluded Clients: 0
```

To verify the IP state, discovery, and MAC, use this command:

```
Device# show wireless dev da ip
IP                                          STATE       DISCOVERY   MAC
-------------------------------------------------------------------------------
15.30.0.4                                   Reachable   ARP
1491.82b8.f8c1
```

```
2001:15:30:0:d1d7:ecf3:7940:af60            Reachable   IPv6 Packet
1491.82b8.f8c1
fe80::595e:7c29:d7c:3c84                    Reachable   IPv6 Packet
1491.82b8.f8c1
```

133 Allowed List of Specific URLs

Topics:

- Allowed lists of specific URLs

Allowed lists of specific URLs

Introduces the concept of an allowed list for specific URLs and provides instructions for adding URLs to the list, addresses issues with portals resolving to multiple IP addresses, and explains verification procedures for URL allowed-listing.

An allowed list of specific URLs is a wireless controller feature that

- lets you add URLs to a list on the controller or access point so designated sites remain accessible
- enables web authentication use cases such as captive portals and walled gardens, and
- allows users to reach permitted sites before authenticating, even without full internet access.

Additional reference information

You do not need to authenticate to access URLs in the allowed list. If you try to reach a site not in the allowed list, you are redirected to the login page.

Accessing a support site

If "support.example.com" is added to the allowed list, users can access this site for help or information prior to logging into the network.

Add URL to allowed list

Learn how to add a URL to the allowed list.

To configure a URL filter that allows specific URLs while blocking others.

This procedure is used in network environments where URL filtering is necessary to control access to web resources.

Before you begin

Ensure you have administrative access to the device and that URL filtering is supported.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the URL filter profile.

   Example

   ```
   Device(config)# urlfilter list url-allowedlist-nbn
   ```

3. Set the action for the URL filter list.

   Example

   ```
   Device(config-urlfilter-params)# action permit
   ```

   Configures the list as an allowed list, and the **deny** command configures the list as a blocked list.

4. Configure the IP address of the redirect servers to which user requests will be redirected in case of denied requests.

Example

```
Device(config-urlfilter-params)# redirect-server-ipv4 X.X.X.X
```

5. Configure the URL to be allowed.

Example

```
Device(config-urlfilter-params)# url www.cisco.com
```

Note

redirect-server-ipv4 and **redirect-server-ipv6** is applicable only in the local mode, specifically in post-authentication. For any further tracking or displaying any warning messages, the denied user request is redirected to the configured server.

But the **redirect-server-ipv4** and **redirect-server-ipv6** configurations do not apply to pre-authentication scenario as you will be redirected to the controller for the redirect login URL for any denied access.

You can associate the allowed URL with the ACL policy in flex profile.

Associating the allowed URL with the ACL policy in flex profile:

```
Device(config)# wireless profile flex default-flex-profile
            Device(config-wireless-flex-profile)# acl-policy user_v4_acl
            Device(config-wireless-flex-profile-acl)# urlfilter list
url_allowedlist_nbn
            Device(config-wireless-flex-profile-acl)# exit
            Device(config-wireless-flex-profile)# description "default flex
profile"
```

```
Device(config)# urlfilter enhanced-list urllist_pre_cwa
                Device(config-urlfilter-enhanced-params)# url url1.dns.com
preference 1 action permit
                Device(config-urlfilter-enhanced-params)# url url2.dns.com
preference 2 action deny
                Device(config-urlfilter-enhanced-params)# url url3.dns.com
preference 3 action permit
```

```
Device(config)# wlan wlan5 5 wlan5
                    Device(config-wlan)#ip access-group web user_v4_acl
                    Device(config-wlan)#no security wpa
                    Device(config-wlan)#no security wpa
                    Device(config-wlan)#no security wpa wpa2 ciphers aes
                    Device(config-wlan)#no security wpa akm dot1x
                    Device(config-wlan)#security web-auth
                    Device(config-wlan)#security web-auth authentication-list
 default
                  Device(config-wlan)#security web-auth parameter-map global

                    Device(config-wlan)#no shutdown
```

Portal resolving to multiple IP addresses

This section lists the network controller behavior and configuration steps required when a portal resolves to multiple IP addresses.

You can use two IP addresses with the controller. However, the Web Auth Parameter Map allows pre-authentication to only one IP address. If an external portal, such as Cisco Spaces, resolves to multiple IP addresses or other HTTP resources require pre-authentication, you need a URL filter. The URL filter dynamically permits traffic to the configured URLs by snooping DNS requests and adding each resolved IP address to the intercept (redirect) and security (pre-auth) ACLs. This process enables you to access clients when necessary.

Additional information

- For FlexConnect deployments with local switching, apply the URL filter to the client at the AP for DNS snooping to work properly.
- Configuring the Web Auth Parameter Map automatically creates the following ACLs:
  - Redirect or intercept ACL (WA-v4-int): handles URL redirection.
  - Security ACL (WA-sec-): permits pre-auth access for HTTP or HTTPS, DNS, DHCP, and other required services.

Configuration steps for URL filter in FlexConnect profile

If you miss this step, the AP cannot dynamically add IP addresses. Clients may fail to redirect to the portal page when they request a secondary portal IP address.

> **Note**
>
> Tip: Use visuals, diagrams, or tables as needed to clarify configuration mapping, ACL lists, or traffic flow.

Associating the allowed URL with the ACL policy in a Flex profile

```
                Device(config)# wireless profile flex default-flex-profile
                Device(config-wireless-flex-profile)# acl-policy WA-v4-<ip>
(security ACL)
                Device(config-wireless-flex-profile-acl)# urlfilter list
url_allowedlist_nbn
                Device(config-wireless-flex-profile-acl)# exit
                Device(config-wireless-flex-profile)# description "default
flex profile"
```

Verify URLs on the allowed list

Verify URLs on the Allowed List.

```
Device# show wireless urlfilter summary
Black-list    - DENY
White-list    - PERMIT
Filter-Type   - Specific to Local Mode

URL-List                          ID  Filter-Type  Action   Redirect-ipv4
Redirect-ipv6
```

```
_____________________________________________________________________________________
url-whitelist                    1    PRE-AUTH     PERMIT   192.0.2.1

Device#

Device# show wireless urlfilter details url-whitelist

134 Cisco Umbrella WLAN

Topics:

- Cisco Umbrella WLAN

This chapter explains how to register and configure an embedded wireless controller with the cloud DNS-security service, covering certificate import, parameter-map setup, DNS encryption, UDP timeouts, policy application, and verification commands to enforce DNS-layer protection.

Cisco Umbrella WLAN

Introduces Cisco Umbrella WLAN, detailing core integration concepts, the process for registering the Embedded Wireless Controller to a Cisco Umbrella account, and explaining DNS enforcement restrictions for Umbrella WLAN deployments.

A Cisco Umbrella WLAN is a cloud-based security solution for wireless networks that

- provides DNS-level protection by detecting and blocking both known and emergent threats
- enables granular policy configuration per user group, network, device, and IP address, and
- offers real-time security dashboards and scheduled reporting.

Additional features and policy configuration

- Allows policy configuration at a single point for each user group and supports local policy, AP group, and WLAN priority order.
- Publishes visual, real-time activity dashboards with aggregated reports.
- Supports up to 60 content categories and lets administrators add custom allowed and blocked list entries.
- Enables scheduled email reporting.
- Supports custom Umbrella profiles (one global, up to 15 custom profiles).
- Flexconnect mode allows DNS handling within the AP, supporting multiple profiles in Flex mode.
- Provides communication over IPv6, though device registration occurs only through IPv4.

Policy priority order

When you configure multiple policies in Cisco Umbrella WLAN, you enforce them in order of priority:

1. **Local policy** – This is the most specific policy and is applied first. Local policies override any broader group or network rules for individual devices or users.
2. **AP group policy** – If no local policy exists, the rules defined for the AP group are applied next.
3. **WLAN policy** – If there are no local or AP group policies, the general policy for the entire wireless network (WLAN) is applied.

To summarize, the most specific rules take priority over broader ones. If a local rule exists, it is enforced first. If not, the system checks for an AP group rule. If neither exists, the general WLAN policy is used.

Register Controller to Cisco Umbrella account

This process explains how Controller are registered with Cisco Umbrella accounts, including the required components, step-by-step stages, and considerations for DNS query handling and profile application.

This section describes the process followed to register the Controller to the Cisco Umbrella account. Here are the prerequisites:

- Have an account with Cisco Umbrella.
- Have an API token from Cisco Umbrella.

Summary

Registering Controller to Cisco Umbrella accounts enables centralized DNS security management and policy enforcement for wireless devices. This integration requires account access, API tokens, and specific parameter mappings.

The key components involved in the process are:

- embedded wireless controllercontroller: Wireless network devices that will be registered with Cisco Umbrella for DNS query management.
- **Cisco Umbrella account**: The cloud-based platform providing DNS security services and device identity management.
- **API token**: A credential generated from Cisco Umbrella and used for authenticating and mapping devices during registration.
- **Umbrella parameter map**: Controller-side configuration map that links API tokens to device profiles.
- **DHCP servers and DNS servers**: Network services facilitating IP assignment and DNS query redirection for WLAN clients.

This process involves obtaining an API token, applying it to the controller, and verifying device registration in Cisco Umbrella.

Workflow

These stages describe the registration of the Controller to Cisco Umbrella Account.

1. **Obtain prerequisites:** Ensure you have a Cisco Umbrella account and generate an API token from the Umbrella dashboard.
2. **Configure umbrella parameter map on the controller:** Create an Umbrella parameter map on the controller embedded wireless controller, assigning the API token.
3. **Register the device:** Register the controller to the Cisco Umbrella server using the configured parameter map. Cisco Umbrella responds with a device ID, mapped in a one-to-one relationship with the parameter map name.
4. **Verify device registration:** In the Cisco Umbrella dashboard, confirm that the controller embedded wireless controller appears under Device Name with its identity information.
5. **Apply the API token configuration:** Register the Cisco Umbrella API token on the network through controller configuration.
6. **Redirect DNS queries:** Once registration and parameter mapping are complete, DNS queries from WLAN clients not matching local RegEx domain settings are redirected to the Umbrella DNS resolver, with encryption applied based on DNScrypt options in the parameter map.
7. **Apply profiles and handle mobility:** Apply wireless Cisco Umbrella profiles to WLAN or AP groups if device registration is successful. For Layer 3 mobility, always apply Cisco Umbrella on the anchor controller.
8. **Distribute Umbrella server IPs through DHCP:** When two DNS servers are configured under DHCP, two Cisco Umbrella server IPs are sent to clients using DHCP option 6; only one IP is sent if a single DNS server is configured.

Result

Controller are successfully registered with Cisco Umbrella accounts. Wireless entities can be managed with Umbrella profiles, and DNS queries are securely redirected according to policy. Device identity, profile application, and DNS traffic handling are centrally managed.

For more information on the Cisco Umbrella configurations, see the Integration for ISR 4K and ISR 1100 – Security Configuration Guide.

Restrictions for Umbrella WLAN

Cisco Umbrella WLAN relies on DNS traffic for protection enforcement; certain scenarios may bypass these safeguards.

- Wireless Cisco Umbrella profiles can be applied only to WLAN or AP groups after successful device registration.

- In Layer 3 mobility environments, Cisco Umbrella must be enabled on the anchor Controller Embedded wireless controllers.
- DHCP configuration determines how many Cisco Umbrella DNS server IPs are distributed to clients.

DNS dependency restrictions

Cisco Umbrella WLAN protections are only effective when client devices perform DNS queries through the network. If DNS is bypassed, Umbrella protection does not apply.

- If an application or host connects directly using an IP address, bypassing DNS resolution, Umbrella WLAN protections are not enforced.

These restrictions apply to all deployments of Cisco Umbrella WLAN where DNS traffic is required for policy enforcement.

Umbrella WLAN leverages DNS queries to monitor and enforce security policies. Direct IP or proxy-based connections circumvent DNS-based protections.

Clients that bypass DNS, or use web proxies that resolve server addresses without DNS queries, may not be protected by Umbrella WLAN security policies.

Ensure all client devices perform DNS queries through the WLAN and avoid proxy configurations that bypass DNS to maintain optimal Umbrella protection.

Configure Cisco Umbrella WLAN

Guides Cisco Umbrella WLAN configuration, providing step-by-step instructions for importing CA certificates, creating local domain RegEx parameter maps, configuring Umbrella parameters and GUI settings, enabling or disabling DNScrypt, adjusting UDP session timeouts, establishing Flex Profiles and Policy Profiles (CLI and GUI), and verifying configuration.

To configure Cisco Umbrella on the Controller, you need to meet these prerequisites:

- Obtain the API token from the Cisco Umbrella dashboard.
- You must have the root certificate to establish an HTTPS connection with the Cisco Umbrella registration server: api.opendns.com. Import the root certificate from digicert.com to the Controller using the command **crypto pki trustpool import terminal** .

Import CA certificate to the trust pool

Learn how to import a CA certificate to the trust pool.

Before you begin

Ensure you have the root certificate and an established HTTPS connection with the Cisco Umbrella registration server.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Perform either of these steps:

- Import the root certificate directly from the Cisco website. The Trustpool bundle contains the root certificate of *digicert.com* together with other CA certificates.

```
Device(config)# crypto pki trustpool import url
http://www.cisco.com/security/pki/trs/ios.p7b
```

- Import the root certificate by executing the **import terminal** command.

```
Device(config)# crypto pki trustpool import terminal
```

- Import the root certificate by pasting the CA certificate from the digicert.com. Enter the PEM-formatted CA certificate from these location. See the Related Information section to download the CA certificate.

```

Create a local domain RegEx parameter map

Learn how to create a Local Domain RegEx Parameter Map using commands.

To create a regex parameter map for matching specific domain patterns.

This procedure is used in network configurations where domain name filtering is required based on regex patterns.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a regex parameter map.

   Example

   ```
   Device(config)# parameter-map type regex parameter-map-name
   ```

3. Configure the regex pattern to match.

   Example

   ```
   Device(config-profile)# pattern regex-pattern
   ```

   Example

   ```
   Device(config-profile)# pattern www.google.com
   ```

   Note

   These patterns are supported:

   - Begins with `.*`. For example: **`.*facebook.com`**
   - Begins with `.*` and ends with `*`. For example: **`.*google*`**
   - Ends with `*`. For example: **`www.facebook*`**
   - No special character. For example: **`www.facebook.com`**

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-profile)# end
   ```

The local domain RegEx parameter map is created and configured successfully.

Configure parameter map name in WLAN (GUI)

Use this procedure to configure the parameter map name in a WLAN using the graphical user interface (GUI) to apply security and access policies for wireless clients..

Assign a parameter map to a WLAN, enabling custom policy enforcement for DNS traffic and access restrictions.

This procedure ensures that your WLAN profile enforces the intended policies for DNS and wireless client access using Cisco Umbrella integration.

Before you begin

Confirm that required parameter maps are defined

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy** .
2. Click on the Policy Profile Name. The **Edit Policy Profile** window is displayed.
3. Choose the **Advanced** tab.
4. In the **Umbrella** settings, from the **Umbrella Parameter Map** drop-down list, choose the parameter map.
5. Enable or disable **Flex DHCP Option for DNS** and **DNS Traffic Redirect** toggle buttons.
6. Click Update & Apply to Device.

The WLAN profile is updated with the selected parameter map, and the associated DNS and access policies are enforced for connected wireless clients.

Configure the Umbrella parameter map

Configure the Umbrella Parameter Map using commands.

To configure the Umbrella Parameter Map for network security and management.

This configuration is used to manage and secure network traffic through the Umbrella service, which provides DNS-layer security.

Before you begin

Ensure you have the necessary permissions and access to the device for configuration.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create an Umbrella global or customized parameter map.

   Example

   ```
   Device(config)# parameter-map type umbrella global parameter-map-name
   ```

Example

```
Device(config)# parameter-map type umbrella custom_pmap
```

Creates an umbrella global or customized parameter map.

3. Configure an Umbrella token.

Example

```
Device(config-profile)# token token-value
```

Example

```
Device(config-profile)# token 5XXXXXXXXCXXXXXXXAXXXXXXXFXXXXCXXXXXXXX
```

4. Configure local domain RegEx parameter maps.

Example

```
Device(config-profile)# local-domain regex-parameter-map-name
```

Example

```
Device(config-profile)# local-domain dns_wl
```

Configures local domain RegEx parameter map.

5. Configure the Anycast address.

Example

```
Device(config-profile)# resolver IPv6 10:1:1:1::10
```

The default address is applied when there is no specific address configured.

6. Return to privileged EXEC mode.

Example

```
Device(config-profile)# end
```

The Umbrella parameter map is now configured and ready for use in managing network security.

Enable or disable DNScrypt (GUI)

Learn how to enable or disable DNScrypt encryption for DNS packets using the graphical user interface (GUI). This procedure helps manage DNS security and filtering settings on your device

Use this task when you need to control whether DNS queries are encrypted, or to specify exceptions and update your Umbrella settings.

Configure DNScrypt to enhance or relax DNS traffic encryption as needed to adapt your organization's security requirements.

Before you begin

- Obtain the registration token from Cisco Umbrella.
- Determine domains to whitelist if needed.

Procedure

1. Choose **Configuration** > **Security** > **Threat Defence** > **Umbrella**.
2. Enter the **Registration Token** received from Umbrella. Alternatively, you can click on **Click here to get your Token** to get the token from Umbrella.
3. Enter the **Whitelist Domains** that you want to exclude from filtering.
4. Check or uncheck the **Enable DNS Packets Encryption** check box to encrypt or decrypt the DNS packets.
5. Click **Apply**.

The DNScrypt setting is updated. DNS packets is now be encrypted or unencrypted based on your selection, and any specified domains will be excluded from filtering.

Enable or disable DNScrypt

Learn how to enable or disable DNScrypt using commands.

To configure DNScrypt settings for enhanced DNS security.

This procedure is used to enable or disable DNScrypt, which provides encryption for DNS queries, enhancing privacy and security.

Before you begin

Ensure you have access to the device's global configuration mode.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create an umbrella global parameter map.

   Example

   ```
   Device(config)# parameter-map type umbrella global
   ```

3. Enable DNScrypt

   Example

   ```
   Device(config-profile)# no dnscrypt
   ```

   By default, the DNScrypt option is enabled.

> **Note**
>
> Cisco Umbrella DNScrypt is not supported when DNS-encrypted responses are sent in the data-DTLS encrypted tunnel (either mobility tunnel or AP CAPWAP tunnel).

4. Optional: Return to privileged EXEC mode.

Example

```
Device(config-profile)# end
```

The DNScrypt settings have been successfully configured.

Configure timeout for UDP sessions

Learn how to configure the timeout for UDP sessions using commands.

To set a timeout value for UDP sessions to manage session persistence and resource allocation.

This configuration is useful in environments where UDP sessions need to be managed effectively to prevent resource exhaustion.

Before you begin

Ensure you have access to the device and the necessary privileges to enter global configuration mode.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Create an umbrella global parameter map.

Example

```
Device(config)# parameter-map type umbrella global
```

3. Configure timeout value for UDP sessions.

Example

```
Device(config-profile)# udp-timeout timeout_value
```

The *timeout_value* ranges from 1 to 30 seconds.

> **Note**
>
> The **public-key** and **resolver** parameter-map options are automatically populated with the default values. So, you need not change them.

4. Optional: Return to privileged EXEC mode.

Example

```
Device(config-profile)# end
```

The UDP session timeout is configured successfully, allowing for better management of UDP resources.

Configure parameter Map Name in WLAN (GUI)

Configure Parameter Map Name in WLAN using GUI.

Set the parameter map name on a WLAN to apply specific security and policy settings.

Use this task when you need to assign or modify a parameter map for a WLAN on your wireless network device, ensuring the correct DNS and security parameters are active.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click on the Policy Profile Name. The **Edit Policy Profile** window is displayed.
3. Choose the **Advanced** tab.
4. In the **Umbrella** settings, from the **Umbrella Parameter Map** drop-down list, choose the parameter map.
5. Enable or disable **Flex DHCP Option for DNS** and **DNS Traffic Redirect** toggle buttons.
6. Click **Update & Apply to Device**.

The selected parameter map and options are applied to the WLAN Policy Profile. DNS and Umbrella security settings will operate based on the parameter map configuration.

Configure parameter map name in WLAN

Configure Parameter Map Name in WLAN using commands.

Configure a parameter map name to enable Cisco Umbrella OpenDNS integration on a WLAN.

This procedure is used when secure DNS filtering and policy enforcement are required on WLANs. The parameter map defines the Umbrella integration settings for the profile.

Before you begin

Ensure that the WLAN profile has been created and the network device is running the appropriate software version for Umbrella OpenDNS support.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. Create a policy profile for the WLAN.

   Example

   ```
   Device(config)# wireless profile policy policy-profile-name
   ```

   The *default-policy-profile* is the profile name of the policy profile.

3. Configure the Umbrella parameter map in the policy profile.

   Example

   ```
   Device(config-wireless-policy)# umbrella-param-map umbrella-name
   ```

   Configures the Cisco Umbrella OpenDNS feature for the WLAN using the specified parameter map.

   The *global* parameter map contains policy and key settings for Umbrella integration.

4. Exit wireless policy configuration and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

   Alternatively, you can press Ctrl-Z.

The Umbrella parameter map name is now configured for the WLAN. DNS protection policies will be applied to wireless clients associating with this profile.

Configure the Umbrella Flex profile (CLI)

Configure the Umbrella Flex Profile using commands.

To configure the Umbrella Flex Profile for enhanced network management.

This procedure is used in environments where Umbrella services are integrated with wireless profiles to provide security and policy management.

Before you begin

Ensure you have the necessary permissions to configure the wireless profiles and Umbrella settings.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Create a new flex policy and enter flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex flex-profile-name
   ```

   The *flex-profile-name* is the flex profile name.

3. Configure the Umbrella flex feature.

   Example

   ```
   Device(config-wireless-flex-profile)# umbrella-profile umbrella-profile-name
   ```

   Use the **no** form of this command to negate the command or to set the command to its default.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

   Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The Umbrella Flex Profile is now configured and ready for use in the network.

Configure the Umbrella Flex profile (GUI)

Use this task to configure the Umbrella Flex Profile through the graphical user interface to apply your desired parameter map settings to devices.

Configure Umbrella Flex Profile settings using the GUI.

Perform this task to set up or modify Umbrella Flex Profiles, applying the appropriate parameter maps to target devices.

Procedure

---

1. Choose **Configuration > Tags & Profiles > Flex** .
2. Click a **Flex Profile Name** . The **Edit Flex Profile** dialog box appears.
3. Under the **Umbrella** tab, click the **Add** button.
4. Select a name for the parameter map from the **Parameter Map Name** drop-down list and click **Save** .
5. Click the **Update & Apply to Device** button. The configuration changes are successfully applied.

The Umbrella Flex Profile is configured and the changes are successfully applied to your devices.

Configure Umbrella Flex parameters (CLI)

Configure Umbrella Flex Parameters using commands.

To configure Umbrella Flex parameters for WLAN policy profiles.

This procedure is used in environments where Umbrella services are integrated with WLAN policy profiles to manage DNS traffic effectively.

Before you begin

Ensure you have access to the device and the necessary permissions to configure WLAN policy profiles.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile and enter the wireless policy profile configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-policy-name
   ```

   The *profile-policy-name* is the WLAN policy profile name.

3. Configure the Umbrella DHCP option for DNS.

   Example

   ```
   Device(config-wireless-policy-profile)# [no] flex umbrella dhcp-dns-option
   ```

   By default, the option is enabled.

4. Configure the DNS traffic redirection mode to Umbrella.

   Example

   ```
   Device(config-wireless-policy-profile)# [no] flex umbrella mode {force |
   ignore}
   ```

   You can either forcefully redirect the traffic or choose to ignore the redirected traffic to Umbrella. The default mode is **ignore**.

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

   Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The Umbrella Flex parameters are now configured for the WLAN policy profile.

Configure the Umbrella Flex policy profile (GUI)

CUse this task to configure an Umbrella Flex Policy Profile through the graphical user interface (GUI) to establish DNS redirection and related network policies for managed devices.

Define and deploy DNS redirection and other policy settings using Cisco Umbrella for your organization's network devices.

Perform this task whenever you want to enforce or update DNS-related policies and parameters for network devices using the GUI

Procedure

1. Choose **Configuration > Tags & Profiles > Policy** .
2. Click the **Add** button. The **Add Policy Profile** dialog box appears.
3. In the **Advanced** tab, and under the **Umbrella** section, complete the following:
   a) Select the parameter map from the **Umbrella Parameter Map** drop-down list. Click the **Clear** hyperlink to clear the selection.
   b) Click the field adjacent to **Flex DHCP Option for DNS** to **Disable** the option. By default it is **Enabled** .
   c) Click the field adjacent to **DNS Traffic Redirect** to set the option to **Force** . By default it is set to **Ignore** .
4. Click the **Apply to Device** button.

The specified Umbrella Flex Policy Profile is created and applied, enforcing your DNS and policy settings for selected devices.

Verify the Cisco Umbrella configuration

Verify the Cisco Umbrella Configuration.

To view the Umbrella configuration details, use the command:

```
Device# show umbrella config
Umbrella Configuration
=======================
Token: 5XXXXXXABXXXXXFXXXXXXXXXXDXXXXXXXXXXXXABXX
API-KEY: NONE
OrganizationID: xxxxxxx
Local Domain Regex parameter-map name: dns_bypass
DNSCrypt: Not enabled
Public-key: NONE
UDP Timeout: 5 seconds
Resolver address:
1. 10.1.1.1
2. 5.5.5.5
3. XXXX:120:50::50
4. XXXX:120:30::30
```

To view the device registration details, use the command:

```
Device# show umbrella deviceid
Device registration details
Param-Map Name                  Status          Device-id
global                          200 SUCCESS     010aa4eXXXXXXX8d
vj-1                            200 SUCCESS     01XXXXXXXf4541e1
GUEST                           200 SUCCESS     010a4f6XXXXXXX42
EMP                             200 SUCCESS     0XXXXXXXXd106ecd
```

To view the detailed description for the Umbrella device ID, use the command:

```
Device# show umbrella deviceid detailed
Device registration details
```

```
 1.global
      Tag               : global
      Device-id         : 010aa4eXXXXXXX8d
      Description       : Device Id recieved successfully
      WAN interface     : None
 2.vj-1
      Tag               : vj-1
      Device-id         : 01XXXXXXXf4541e1
      Description       : Device Id recieved successfully
      WAN interface     : None
```

To view the Umbrella DNSCrypt details, use the command:

```
Device# show umbrella dnscrypt
DNSCrypt: Enabled
   Public-key:
B111:XXXX:XXXX:XXXX:3E2B:XXXX:XXXX:XXXE:XXX3:3XXX:DXXX:XXXX:BXXX:XXXB:XXXX:FXXX

135 RADIUS Server Load Balancing

Topics:

- RADIUS server load balancing

Introduces RADIUS server load balancing concepts and explains how to distribute authentication requests across multiple servers for improved performance and redundancy.

RADIUS server load balancing

Explains RADIUS server load balancing, its prerequisites and restrictions, and provides instructions for enabling load balancing on named RADIUS server groups.

RADIUS server load balancing is a transaction distribution mechanism that

- distributes batches of AAA transactions across multiple RADIUS servers in a server group
- assigns each batch to the server with the lowest number of outstanding transactions in its queue, and
- ensures active utilization of all servers rather than using standby configuration.

Load balancing operation

By default, if two RADIUS servers are configured in a server group, only one is used. The other server acts as standby, if the primary server is declared as dead, the secondary server receives all the load.

If you need both servers to perform transactions actively, you need to enable Load Balancing.

> **Note**
>
> By default, load balancing is not enabled on the RADIUS server group.

If you enable load balancing in a RADIUS server group with two or more RADIUS servers, the Server A and Server B receives a AAA transaction. The transaction queues are checked in Server A and Server B. The server with less number of outstanding transactions are assigned the next batch of AAA transaction.

The process of assigning a batch of transactions is as follows:

1. The first transaction is received for a new batch.
2. All server transaction queues are checked.
3. The server with the lowest number of outstanding transactions is identified.
4. The identified server is assigned the next batch of transactions.

The batch size is a user-configured parameter. Changes in the batch size may impact CPU load and network throughput. As batch size increases, CPU load decreases, and network throughput increases. However, if a large batch size is used, all available server resources may not be fully utilized. As batch size decreases, CPU load increases and network throughput decreases.

> **Note**
>
> There is no set number for large or small batch sizes. A batch with more than 50 transactions is considered large and a batch with fewer than 25 transactions is considered small.

> **Note**
>
> If a server group contains ten or more servers, we recommend that you set a high batch size to reduce CPU load.

You can configure load balancing either per-named RADIUS server group or for the global RADIUS server group. The load balancing server group must be referred to as "radius" in the authentication, authorization, and accounting (AAA) method lists. All public servers that are part of the RADIUS server group are then load balanced.

You can configure authentication and accounting to use the same RADIUS server or different servers. In some cases, the same server can be used for preauthentication, authentication, or accounting transactions for a session. The preferred server, which is an internal setting and is set as the default, informs AAA to use the same server for the start and stop record for a session regardless of the server cost. When using the preferred server setting, ensure that the server that is used for the initial transaction (for example, authentication), the preferred server, is part of any other server group that is used for a subsequent transaction (for example, accounting).

The preferred server is not used if one of the following criteria is true:

- The **load-balance method least-outstanding ignore-preferred-server** command is used.
- The preferred server is dead.
- The preferred server is in quarantine.
- The want server flag has been set, overriding the preferred server setting.

The want server flag, an internal setting, is used when the same server must be used for all stages of a multistage transaction regardless of the server cost. If the want server is not available, the transaction fails.

You can use the **load-balance method least-outstanding ignore-preferred-server** command if you have either of the following configurations:

- Dedicated authentication server and a separate dedicated accounting server
- Network where you can track all call record statistics and call record details, including start and stop records and records that are stored on separate servers
- The **least outstanding** load-balancing method in RADIUS is only recommended while doing 802.1X without accounting.

If you have a configuration where authentication servers are a superset of accounting servers, the preferred server is not used.

Note

If a third-party RADIUS load balancer is used and RADIUS packets are routed based on the NAS source port, it is recommended to move to any other rule based on the following Attribute-Value Pairs (AVPs):

- If the load balancer uses NAS source port in the Access-Request to load balance, rules may not work as expected as the source port in NAS might change during transaction.
- If the load balancer compares AVPs between Access-Challenge and Access-Request to route packets, you will need to use the AVP value of t-State.
- If the load balancer compares AVPs in Access-Request from NAS, you will need to use one or a combination of the following AVPs:
  - t-State value
  - Calling-Station-ID and NAS IP or Identifier

Prerequisites for RADIUS server load balancing

Lists the prerequisites for RADIUS Server Load Balancing.

This reference lists the prerequisites you must meet before configuring RADIUS Server Load Balancing.

- Configure Authentication, Authorization, and Accounting (AAA) on the RADIUS server.
- Configure AAA RADIUS server groups.
- Configure RADIUS for functions such as authentication, accounting, or static route download.

RADIUS server load balancing restrictions

Learn about RADIUS Server Load Balancing restrictions that affect your implementation.

Use this reference to understand RADIUS Server Load Balancing restrictions and limitations before implementing this feature.

- Incoming RADIUS requests, such as Packet of Disconnect (POD) requests are not supported.
- Load balancing is not supported on proxy RADIUS servers and private server groups.
- Central Web Authentication (CWA) does not support load balancing. CWA and CoA are linked to accounting. With load balancing enabled, the system may send accounting data to a different server than the one processing the CoA request.
- RADIUS Load Balancing does not support client stickiness during the same session. Do not use it for authentication mechanisms like CWA or CoA. It may impact server clusters when client session ownership changes across servers.
- The **Least-outstanding** load-balancing method is not recommended for RADIUS in CWA or NAC scenarios that require CoA and multiple RADIUS transactions. When implementing 802.1X with accounting, this method may lead to inconsistencies, as the system does not send all accounting packets to the same server, potentially impacting the ISE.

Enable load balancing for a named RADIUS server group (CLI)

Learn how to enable load balancing for a named Remote Authentication Dial-In User Service (RADIUS) server group to distribute authentication and accounting requests across multiple servers.

Enable load balancing to distribute authentication and accounting requests across multiple RADIUS servers in a named server group for improved performance and reliability.

Load balancing for RADIUS server groups helps distribute the authentication load across multiple servers, reducing the risk of server overload and improving response times. This configuration is particularly useful in high-traffic environments where multiple RADIUS servers are available.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter server group configuration mode.

   Example

   ```
   Device(config)# aaa group server radius group-name
   ```

   Example

   ```
   Device(config)# aaa group server radius rad-sg
   ```

3. Configure the IP address of the RADIUS server for the group server.

   Example

   ```
   Device(config-sg-radius)# server ip-address auth-port port-number acct-port
   port-number
   ```

   Example

   ```
   Device(config-sg-radius)# server 192.0.2.238 auth-port 2095 acct-port 2096
   ```

4. Enable the least-outstanding load balancing for a named server group.

   Example

   ```
   Device(config-sg-radius)# load-balance method least-outstanding batch-size
   number
   ```

   Example

   ```
   Device(config-sg-radius)# load-balance method least-outstanding batch-size
   30
   ```

5. Exit server group configuration mode and enter privileged EXEC mode.

Example

```
Device(config-sg)# end
```

Load balancing is now enabled for the named RADIUS server group, allowing authentication and accounting requests to be distributed across multiple RADIUS servers based on the least-outstanding method.

136 AAA Dead-Server Detection

Topics:

- AAA dead-server detection

AAA dead-server detection

Introduces AAA dead-server detection concepts, covering an overview of the feature along with prerequisites and operational restrictions for deploying dead-server detection in network environments.

A dead-server detection feature is an AAA capability that

- allows configuration of criteria for marking RADIUS servers as dead
- uses tunable deadtime and dead-criteria values to determine server status, and
- provides faster failover and packet processing by quickly detecting and isolating non-responding servers.

You can configure the deadtime (in minutes) per server group or globally. This defines how long a server marked as DEAD remains in that state.

Deadtime—The period (in minutes) that a server, once marked as DEAD, remains in that state before being re-evaluated. This value can be set per server group or globally.

Dead-criteria—The specific conditions, such as timeout intervals or number of missed responses, that must be met before a server is considered DEAD. To declare a server as DEAD, you need to configure **dead-criteria** and configure the conditions that determine when a RADIUS server is considered unavailable or dead.

Criteria for marking a RADIUS server as dead

AAA dead-server detection uses two main criteria for marking a RADIUS server as unavailable: the minimum time since the last valid response, and the number of consecutive timeouts. When both criteria are met, the server is marked as dead and remains in that state for the configured dead time. After dead time expires, the controller re-evaluates the server's state and updates clients accordingly.

This approach ensures that only unresponsive servers are marked as dead. It minimizes authentication delays and prevents unnecessary switches between dead and alive status due to slow responses.

For configuration details and packet handling rules, see the definitions above.

Additional reference information

- Both time and tries criteria must be met for a server to be marked as dead.
- The detection process helps avoid unnecessary state changes between dead and alive for temporarily slow servers.
- Both authentication and accounting packets are counted when applying the dead-criteria.

Example of AAA dead-server detection

If a controller has multiple RADIUS servers and one stops responding for the configured dead time and number of consecutive timeouts, it is marked as dead. Requests are then redirected to working servers, improving reliability.

Counter-example: Without AAA dead-server detection

Without AAA dead-server detection, a controller may continually attempt to communicate with a non-responsive RADIUS server, increasing authentication delays and denying access to users.

Prerequisites for AAA dead-server detection

AAA Dead-Server Detection prerequisites.

- You must have access to a RADIUS server.
- You must be familiar with configuring a RADIUS server.

- You must be familiar with configuring Authentication, Authorization, and Accounting (AAA).
- Before a server can be marked as dead, yo configure **radius-server dead-criteria time** *time-in-seconds* **tries** *number-of-tries* to mark the server as DOWN.

  Also, you must configure the **radius-server deadtime** *time-in-mins* to retain the server in DEAD status.

Restrictions for AAA dead-server detection

AAA Dead-Server Detection restrictions.

Original transmissions are not counted in the number of consecutive timeouts that must occur on the controller before the server is marked as dead--only the number of retransmissions are counted.

Configure AAA dead-server detection (CLI)

Provides instructions for configuring AAA dead-server detection using CLI, including steps to set up, manage, and verify dead-server detection to ensure effective monitoring and recovery of unresponsive AAA servers.

Enable detection of dead RADIUS servers to maintain network reliability.

This configuration is essential in environments using RADIUS servers for authentication. It ensures you can effectively manage server availability.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable the AAA access control model.

   Example

   ```
   Device(config)# aaa new-model
   ```

3. Define how long, in minutes, a server marked as DEAD will remain in that state.

   Example

   ```
   Device(config)# radius-server deadtime time-in-mins
   ```

   Example

   ```
   Device(config)# radius-server deadtime 5
   ```

   When the deadtime expires, the controller marks the server as UP (ALIVE) and notifies registered clients about the state change.

   time-in-mins – Valid values range from 1 to 1440 minutes. Default value is zero. To return to the default value, use the **no radius-server deadtime** command.

   The **radius-server deadtime** command can be configured globally or per AAA group server level.

You can use the **show aaa dead-criteria** or **show aaa servers** command to check for dead-server detection. If the default value is zero, deadtime is not configured.

4. Declare a server as DEAD and configure the conditions that determine when a RADIUS server is considered unavailable or dead.

   Example

   ```
   Device(config)# radius-server dead-criteria [time time-in-seconds] [tries number-of-tries]
   ```

   Example

   ```
   Device(config)# radius-server dead-criteria time 5 tries 4
   ```

   time-in-seconds : Time in seconds during which no response is received from the RADIUS server to consider it as dead. Valid values range from 1 to 120 seconds.

   > **Note**
   >
   > The total time to declare the server as dead depends on the configured time in seconds, retries, and pending transactions.
   >
   > The calculated resulting time may range from ten to sixty seconds based on these criteria.

   number-of-tries : Number of transmits to RADIUS server without responses before marking the server as dead. Valid values range from 1 to 100.

5. Exit configuration mode and enter privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

You have now configured the AAA Dead-Server Detection, allowing you to manage RADIUS server availability effectively.

Verify AAA dead-server detection

This section lists the commands to verify AAA dead-server detection, configuration, and status across devices.

This topic describes how to verify AAA Dead-Server Detection using various show commands.

To verify dead-criteria, use this command:

```
Device# show run | s dead-criteria
radius-server dead-criteria time 20 tries 20
```

To verify the dead-criteria details, use this command:

```
Device# sh aaa dead-criteria radius <server>
sh aaa dead-criteria radius 192.0.2.55
RADIUS Server Dead Criteria:
```

```
Server Details:
Address : 192.0.2.55
Auth Port : 1645
Acct Port : 1646
Server Group : radius
Dead Criteria Details:
Configured Retransmits : 3
Configured Timeout : 5
Estimated Outstanding Access Transactions: 2
Estimated Outstanding Accounting Transactions: 0
Dead Detect Time : 30s
Computed Retransmit Tries: 6
Statistics Gathered Since Last Successful Transaction
Max Computed Outstanding Transactions: 3
Max Computed Dead Detect Time: 90s
Max Computed Retransmits : 18
```

To verify the state of servers, number of requests being processed, and so on, use the command:

```
Device# show aaa servers | s WNCD
Platform State from WNCD (1) : current UP
Platform State from WNCD (2) : current UP
Platform State from WNCD (3) : current UP
Platform State from WNCD (4) : current UP
Platform State from WNCD (5) : current UP, duration 773s, previous duration
0s
Platform Dead: total time 0s, count 0
Quarantined: No
```

137 ISE Simplification and Enhancements

Topics:

- Security utilities configuration options
- Captive bypassing
- DHCP option 55 and 77 parameters
- Captive portals

This chapter provides step-by-step configurations to simplify RADIUS/AAA setup, enable captive portal and bypass behaviors, configure DHCP options for ISE profiling, and tune EAP timeouts to enforce secure wireless authentication.

Security utilities configuration options

Introduces security configuration utilities and provides instructions for configuring multiple RADIUS servers with procedures to verify AAA and RADIUS server configurations.

You can set up the RADIUS server using this simplified method:

wireless-default radius server *ip* **key** *secret*

- Configures AAA authorization for network services, including authentication for web authentication and Dot1x.
- Enables local authentication with default authorization.
- Applies the default redirect ACL for Central Web Authentication (CWA).
- Creates a global parameter map with a virtual IP and enables captive bypass portal.
- Configures all default AAA settings required when configuring a RADIUS server.
- Sets method-list configuration and enables RADIUS accounting by default.
- Disables RADIUS aggressive failovers by default and sets the RADIUS request timeout to five seconds.
- Implements a default access control list (ACL) for CWA URL redirect.

```
aaa new-model
                aaa authentication webauth default group radius
                aaa authentication dot1x default group radius
                aaa authorization network default group radius
                aaa accounting identity default start-stop group radius
                !
                aaa server radius dynamic-author
                client <IP> server-key cisco123
                !
                radius server RAD_SRV_DEF_<IP>
                description Configured by wireless-default
                address ipv4 <IP> auth-port 1812 acct-port 1813
                key <key>
                !
                aaa local authentication default authorization default
                aaa session-id common
                !
                ip access-list extended CISCO-CWA-URL-REDIRECT-ACL-DEFAULT
                remark " CWA ACL to be referenced from ISE "
                deny udp any any eq domain
                deny tcp any any eq domain
                deny udp any eq bootps any
                deny udp any any eq bootpc
                deny udp any eq bootpc any
                deny ip any host <IP>
                permit tcp any any eq www
                !
                parameter-map type webauth global
                captive-bypass-portal
                virtual-ip ipv4 192.0.2.1
                virtual-ip ipv6 2001:DB8::1
                !
                wireless profile policy default-policy-profile
                aaa-override
                local-http-profiling
                local-dhcp-profiling
```

```
                accounting
```

Key benefits

- Simplifies deployment of RADIUS server configuration for wireless controllers.
- Eliminates the need for step-by-step manual configuration across multiple CLI commands.
- Ensures consistent and secure default settings for AAA and authentication services.

Configure multiple RADIUS servers

Learn how to configure multiple radius servers using commands.

To configure multiple RADIUS servers for authentication in a network.

Before you begin

Ensure you have the necessary IP addresses and shared secrets for the RADIUS servers.

Procedure

1. Enter global configuration mode

   Example

   ```
   Device# configure terminal
   ```

2. Configure a RADIUS server

   Example

   ```
   Device(config)# wireless-default radius server ip key secret
   ```

   Example

   ```
   Device(config)# wireless-default radius server 192.2.58.90 key cisco123
   ```

   You can configure up to ten RADIUS servers.

3. Return to privileged EXEC mode

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Multiple RADIUS servers are now configured and ready for use in the network.

Verify AAA and Radius server configurations

Verify AAA and Radius Server Configurations.

To view details of AAA server, use these command:

```
Device# show run aaa
!
aaa new-model
aaa authentication webauth default group radius
aaa authentication dot1x default group radius
aaa authorization network default group radius
aaa accounting Identity default start-stop group radius
!
aaa server radius dynamic-author
 client 192.0.2.10 server-key cisco123
!
radius server RAD_SRV_DEF_192.0.2.10
 description Configured by wireless-default
 address ipv4 192.0.2.10 auth-port 1812 acct-port 1813
 key cisco123
!
aaa local authentication default authorization default
aaa session-id common
!
!
ip access-list extended CISCO-CWA-URL-REDIRECT-ACL-DEFAULT
remark " CWA ACL to be referenced from ISE "
deny udp any any eq domain
deny tcp any any eq domain
deny udp any eq bootps any
deny udp any any eq bootpc
deny udp any eq bootpc any
deny ip any host 192.0.2.10
permit tcp any any eq www
!
parameter-map type webauth global
  captive-bypass-portal
  virtual-ip ipv4 192.0.2.1
  virtual-ip ipv6 2001:DB8::1
!
wireless profile policy default-policy-profile
   aaa-override
   local-http-profiling
   local-dhcp-profiling
   accounting
```

Note

The **show run aaa** output may change when new commands are added to this utility.

Captive bypassing

Configuring Captive Bypassing for WLAN in LWA and CWA (GUI), Configuring Captive Bypassing for WLAN in LWA and CWA

A captive bypass is a network behavior that

- enables client devices to automatically determine Internet connectivity and initiate authentication flows,
- may enable users to bypass captive portal splash pages through protocols such as WISPr.

- involves interaction between devices (such as Apple iOS) and Controllers, affecting web redirection and authentication.

Additional reference information

WISPr is a draft protocol that enables users to roam between different wireless service providers. Devices like Apple iOS use HTTP WISPr requests to check if they are connected to the Internet.

When direct Internet connectivity is not detected, these mechanisms prompt the device to open a web browser so the user can enter credentials for Internet access. Authentication occurs in the background whenever the device connects to a new SSID.

When an Apple iOS device connects, it sends a WISPr request to the Controller, which checks the user agent details and then triggers an HTTP request with web authentication interception. After verifying the iOS version and browser details, the Controller allows the client device to bypass captive portal settings and access the Internet.

This HTTP request triggers web authentication interception on the Controller just as any other page requests do. This leads to the standard web authentication process. If web authentication uses splash page features (such as a URL from a configured RADIUS server), the splash page might not appear for the user because WISPr requests occur at short intervals. Once a query reaches the server, web redirection or splash page display running in the background is cancelled, and the device processes the page request, which may prevent the splash page from being displayed as intended.

Example

For instance, Apple introduced an iOS feature that detects captive portals by sending a web request upon connecting to a wireless network. On iOS 6 and earlier, the request is sent to http://www.apple.com/library/test/success.html. On iOS 7 and later, multiple possible URLs are used. If a response is received, Internet access is assumed and no further interaction occurs. If no response is received, Internet access is assumed to be blocked and the device's Captive Network Assistant (CNA) auto-launches a pseudo-browser to prompt for portal login. The CNA may not function properly if it is redirected to an ISE captive portal. The Controller can suppress the pop-up of the pseudo-browser. Network administrators can configure the Controller to bypass WISPr detection. In this configuration, web authentication interception only occurs when a user intentionally requests a web page, ensuring the splash page is loaded in the user's browser context and not triggered by background connectivity probes.

Analogy: Sneaking into an amusement park

Captive bypassing is like someone sneaking into an amusement park through a side door, instead of showing their ticket at the main entrance. Some devices use automated checks to find shortcuts and access the internet without going through the intended login page, just as clever visitors might bypass security by finding an easier way in. Network controls are needed to make sure everyone enters through the main gate and checks in properly.

Configure captive bypassing for WLAN in LWA and CWA (GUI)

Use this task to enable captive bypass on a WLAN for local web authentication (LWA) or central web authentication (CWA) using the GUI.

Enable client devices to bypass captive portal authentication on the selected WLAN.

Before you begin

Use this task when you need certain clients to connect without passing through the captive portal, typically for pre-authorized devices.

Ensure you have administrative access to the device and the parameter map is appropriately configured.

Procedure

1. Choose **Configuration** > **Security** > **Web Auth** .
2. In the **Webauth Parameter Map** tab, click the parameter map name. The **Edit WebAuth Parameter** window is displayed.

3. Select **Captive Bypass Portal** check box.
4. Click **Update & Apply to Device** .

The selected WLAN now allows captive bypass in accordance with your configuration.

Configure captive bypassing for WLAN in LWA and CWA

Use this procedure to configure captive bypassing for WLAN in LWA and CWA using commands.

Enable captive bypassing for WLAN to allow users to bypass the captive portal.

This configuration is applicable in environments where users need to access the network without going through a captive portal.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create the parameter map.

   Example

   ```
   Device(config)# parameter-map type webauth parameter-map-name
   ```

   The *parameter-map-name* must not exceed 99 characters.

3. Configure captive bypassing.

   Example

   ```
   Device(config)# captive-bypass-portal
   ```

4. Specify the WLAN name and ID.

   Example

   ```
   Device(config)# wlan profile-name wlan-id ssid-name
   ```

   - *profile-name* is the WLAN name which can contain 32 alphanumeric characters.
   - *wlan-id* is the wireless LAN identifier. The valid range is from 1 to 512.
   - *ssid-name* is the SSID which can contain 32 alphanumeric characters.

5. Enable the web authentication for the WLAN.

   Example

   ```
   Device(config-wlan)# security web-auth
   ```

6. Map the parameter map.

   Example

   ```
   Device(config-wlan)# security web-auth parameter-map parameter-map-name
   ```

   If the parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

7. Optional: Return to privileged EXEC mode.

   Example

   ```
   Device(config-wlan)# end
   ```

   Alternatively, you can also press *Ctrl-Z* to exit global configuration mode.

The WLAN is now configured with captive bypassing enabled, allowing users to bypass the captive portal.

DHCP option 55 and 77 parameters

Describes DHCP options 55 and 77 functionality and provides configuration procedures for sending these options to ISE, including EAP request timeout settings via GUI and CLI.

The DHCP sensors use these DHCP options on the ISE for both native and remote device profiling:

- Option 12: Hostname
- Option 6: Class Identifier

These options must also be sent to ISE for accurate profiling:

- Option 55: Parameter Request List
- Option 77: User Class

Configure the DHCP options 55 and 77 to ISE using the GUI

Use this task to configure DHCP options 55 and 77 for integration with Cisco Identity Services Engine (ISE) using the graphical interface.

Ensure DHCP options 55 and 77 are sent to ISE to enable device profiling and policy enforcement

These options allow ISE to collect device-specific DHCP information for accurate profiling on wireless networks.

Before you begin

Confirm that your network devices are compatible with ISE profiling features.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. On the **Policy Profile** page, click **Add** to view the **Add Policy Profile** window.
3. Click **Access Policies** tab, choose the **RADIUS Profiling** and **DHCP TLV Caching** check boxes to configure radius profiling and DHCP TLV Caching on a WLAN.

4. Click **Save & Apply to Device**

---

he network device now sends DHCP options 55 and 77 to ISE, enabling accurate device profiling and network access policy enforcement.

Configure the device to send DHCP options 55 and 77 to ISE (CLI)

Use this procedure to configure your device using CLI commands to send DHCP options 55 and 77 to Cisco Identity Services Engine (ISE) for effective client profiling.

Enable the device to send specific DHCP options to ISE for improved client profiling.

This configuration is essential for environments where client profiling is necessary for network access control and monitoring.

Before you begin

Ensure that the device is running a compatible version of the software that supports DHCP options 55 and 77.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enters the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-policy
   ```

   The *profile-policy* is the name of the WLAN policy profile being configured.

3. Configure DHCP TLV caching on a WLAN.

   Example

   ```
   Device(config-wireless-policy)# dhcp-tlv-caching
   ```

   Enables caching of DHCP TLV information for better profiling.

4. Configure client radius profiling on a WLAN.

   Example

   ```
   Device(config-wireless-policy)# radius-profiling
   ```

   Enables RADIUS profiling to enhance client identification.

5. Optional: Return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

Alternatively, you can also press *Ctrl-Z* to exit global configuration mode.

The device is configured to include DHCP options 55 and 77 in client profiling information sent to Cisco ISE.

Configure the EAP request timeout using the GUI

Configure EAP Request Timeout using GUI.

Use the steps to configure the EAP request timeout through the GUI:

Procedure

---

1. Choose **Configuration** > **Security** > **Advanced EAP**.
2. In the **EAP-Identity-Request Timeout** field, specify the amount of time (in seconds) in which the device attempts to send an EAP identity request to wireless clients using local EAP.
3. In the **EAP-Identity-Request Max Retries** field, specify the maximum number of times that the device attempts to retransmit the EAP identity request to wireless clients using local EAP.
4. Set **EAP Max-Login Ignore Identity Response** to **Enabled** state to limit the number of clients that can be connected to the device with the same username. You can log in up to eight times from different clients (PDA, laptop, IP phone, and so on) on the same device. The default state is **Disabled**.
5. In the **EAP-Request Timeout** field, specify the amount of time (in seconds) in which the device attempts to send an EAP request to wireless clients using local EAP.
6. In the **EAP-Request Max Retries** field, specify the maximum number of times that the device attempts to retransmit the EAP request to wireless clients using local EAP.
7. In the **EAPOL-Key Timeout** field, specify the amount of time (in seconds) in which the device attempts to send an EAP key over the LAN to wireless clients using local EAP.
8. In the **EAPOL-Key Max Retries** field, specify the maximum number of times that the device attempts to send an EAP key over the LAN to wireless clients using local EAP.
9. In the **EAP-Broadcast Key Interval** field, specify the time interval between rotations of the broadcast encryption key used for clients and click **Apply**.

> **Note**
>
> After configuring the EAP-Broadcast key interval to a new time period, you must shut down or restart the WLAN for the changes to take effect. Once the WLAN is shut down or restarted, the M5 and M6 packets are exchanged when the configured timer value expires.

Configure EAP request timeout

Use this procedure to configure EAP request timeout using commands.

Set the timeout for EAP requests to manage client exclusion effectively.

This configuration is useful in environments where EAP authentication is used, and it is necessary to handle clients that do not respond in a timely manner.

Before you begin

Ensure you have access to the device and are in the appropriate configuration mode.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable exclusion on timeout and no response.

   Example

   ```
   Device(config)# wireless wps client-exclusion dot1x-timeout
   ```

   By default, this feature is enabled. To disable, append a *no* at the beginning of the command.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press *Ctrl-Z* to exit global configuration mode.

The EAP request timeout is now configured, allowing for better management of client exclusions.

Configure the EAP request timeout in wireless security

Use this procedure to configure EAP request timeout in wireless security using commands.

Set the EAP request timeout to ensure timely authentication in wireless security.

This configuration is essential in environments where EAP is used for authentication, as it affects the responsiveness of the authentication process.

Before you begin

Ensure you have access to the device and are in privileged EXEC mode.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. Configure the EAP request retransmission timeout value in seconds.

   Example

   ```
   Device(config)# wireless security dot1x request timeout timeout
   ```

Configures the EAP request retransmission timeout value in seconds.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The EAP request timeout is now configured, which will help in managing the authentication process in wireless security.

Captive portals

Outlines captive portal implementation concepts and provides comprehensive configuration procedures through GUI and CLI, with verification commands to confirm portal functionality.

A captive portal is a network authentication mechanism that

- intercepts and redirects user web requests to a designated login or acceptance page,
- allows administrators to enforce authentication or policy acceptance before granting network access, and
- supports configuration of multiple web authentication URLs based on access point (AP), WLAN, or global scope.

Order of precedence

Captive portal configurations let you define different web authentication URLs—including external URLs—for the same SSID, based on the specific access point or WLAN. By default, the system uses a global URL for user authentication, but administrators may override this at the WLAN or AP level to customize user experience.

Order of precedence

1. AP-level configuration (highest priority)
2. WLAN-level configuration
3. Global configuration (default)

Restrictions

- This feature is supported on standalone controllers only.
- Export-Anchor configurations are not supported.

Configure captive portal (GUI)

Configure Captive Portal using GUI.

Configure a secure WLAN that uses captive portal authentication for guest or user access.

Configure a captive portal when you require user authentication on your Wi-Fi network for guests or employees.

Before you begin

Confirm the web authentication parameter map and necessary authentication lists are already created.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID**, and the **WLAN ID**.
4. In the **Security** > **Layer2** tab, uncheck the **WPA Policy**, **AES** and **802.1x** check boxes.
5. In the **Security** > **Layer3** tab, choose the parameter map from the **Web Auth Parameter Map** drop-down list and authentication list from the **Authentication List** drop-down list.
6. In the **Security** > **AAA** tab, choose the Authentication list from the **Authentication List** drop-down list.
7. Click **Apply to Device**.
8. Choose **Configuration** > **Security** > **Web Auth**.
9. Choose a **Web Auth Parameter Map**.
10. In the **General** tab, enter the **Maximum HTTP connections**, **Init-State Timeout(secs)** and choose **webauth** from the **Type** drop-down list.
11. In the **Advanced** tab, under the **Redirect to external server** settings, enter the **Redirect for log-in** server.
12. Click **Update & Apply**.

The captive portal WLAN is available, and users associating with this SSID will be redirected for authentication as defined in the parameter map.

Configure captive portal

Use this procedure to configure captive portal using commands.

Set up a captive portal to manage user access to the network.

The captive portal is used to authenticate users before granting them access to the network, typically in public Wi-Fi environments.

Before you begin

Ensure that the WLAN is properly configured and that you have the necessary access rights.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. Configure the WLAN profile.

   Example

   ```
   Device(config)# wlan profile-name
   ```

   Enables or disables all WLANs and creates the WLAN identifier. The *profile-name* and the SSID network name should be up to 32 alphanumeric characters.

3. Configure the WLAN web ACL.

Example

```
Device(config-wlan)# ip access-group web IPv4-ACL-Name
```

WLAN needs to be disabled before performing this operation.

4. Disable WPA security.

Example

```
Device(config-wlan)# no security wpa
```

5. Disable security AKM for dot1x.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

Disables security AKM for dot1x.

6. Disable WPA2 ciphers for AES.

Example

```
Device(config-wlan)# no security wpa wpa2 ciphers aes
```

Disables WPA2 ciphers for AES.

7. Enable web authentication for WLAN.

Example

```
Device(config-wlan)# security web-auth authentication-list
authentication-list-name
```

```
Device(config-wlan)# security web-auth parameter-map parameter-map-name
```

Enables web authentication for WLAN. Here,

- **authentication-list**

  authentication-list-name : Sets the authentication list for IEEE 802.1x.

- **authorization-list**

  authorization-list-name : Sets the override-authorization list for IEEE 802.1x.

- **on-macfilter-failure** : Enables Web authentication on MAC filter failure.

- **parameter-map**

  parameter-map-name : Configures the parameter map.

> **Note**
>
> When **security web-auth** is enabled, you get to map the default **authentication-list** and global **parameter-map** . This is applicable for authentication-list and parameter-map that are not explicitly mentioned.

8. Optional: Enable the WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

9. Exit from the WLAN configuration.

   Example

   ```
   Device(config-wlan)# exit
   ```

10. Create a parameter map and enter parameter-map webauth configuration mode.

    Example

    ```
    Device(config)# parameter-map type webauth parameter-map-name
    ```

    Creates a parameter map and enters parameter-map webauth configuration mode.

11. Configure the webauth type parameter.

    Example

    ```
    Device(config-params-parameter-map)# type webauth parameter-map-name
    ```

12. Configure the WEBAUTH timeout in seconds.

    Example

    ```
    Device(config-params-parameter-map)# timeout init-state sec <timeout-seconds>
    ```

    Valid range for the time in sec parameter is 60 seconds to 3932100 seconds.

13. Configure the URL string for redirect during login.

    Example

    ```
    Device(config-params-parameter-map)# redirect for-login <URL-String>
    ```

    Example

    ```
    Device(config-params-parameter-map)# redirect for-login
    https://172.16.100.157/portal/login.html
    ```

    Configures the URL string for redirect during login.

14. Exit the parameters configuration.

Example

```
Device(config-params-parameter-map)# exit
```

15. Configure policy tag and enter policy tag configuration mode.

Example

```
Device(config)# wireless tag policy policy-tag-name
```

16. Attach a policy profile to a WLAN profile.

Example

```
Device(config-policy-tag)# wlan wlan-profile-name policy policy-profile-name
```

17. Save the configuration and exit configuration mode.

Example

```
Device(config-policy-tag)# end
```

The captive portal is now configured and ready to manage user access to the network.

Example: Captive portal configuration

Captive Portal Configuration example.

The example shows how you can have APs at different locations, broadcasting the same SSID but redirecting clients to different redirect portals:

Configuring multiple parameter maps pointing to different redirect portal:

```
parameter-map type webauth parMap1
type webauth
timeout init-state sec 21600
redirect for-login
https://172.16.12.3:8080/portal/PortalSetup.action?portal=cfdbce00-2ce2-11e8-b83c-005056a06b27
redirect portal ipv4 172.16.12.3
!
!
parameter-map type webauth parMap11
type webauth
timeout init-state sec 21600
redirect for-login
https://172.16.12.4:8443/portal/PortalSetup.action?portal=094e7270-3808-11e8-9797-02421e4cae0c
redirect portal ipv4 172.16.12.4
!
```

Associating these parameter maps to different WLANs:

```
wlan edc1 1 edc
ip access-group web CPWebauth
```

```
no security wpa
no security wpa akm dot1x
no security wpa wpa2 ciphers aes
security web-auth
security web-auth authentication-list cp-webauth
security web-auth parameter-map parMap11
no shutdown
wlan edc2 2 edc
ip access-group web CPWebauth
no security wpa
no security wpa akm dot1x
no security wpa wpa2 ciphers aes
security web-auth
security web-auth authentication-list cp-webauth
security web-auth parameter-map parMap1
no shutdown
```

Note

All WLANs have identical SSIDs.

Associating WLANs to different policy tags:

```
wireless tag policy policy_tag_edc1
wlan edc1 policy policy_profile_flex
wireless tag policy policy_tag_edc2
wlan edc2 policy policy_profile_flex
```

Assigning these policy tags to the desired APs:

```
ap E4AA.5D13.14DC
policy-tag policy_tag_edc1
site-tag site_tag_flex
ap E4AA.5D2C.3CAC
policy-tag policy_tag_edc2
site-tag site_tag_flex
```

138 RADIUS DTLS

Topics:

- RADIUS DTLS

RADIUS protocol provides centralized security for users attempting to gain management access to a network.

RADIUS DTLS

Describes RADIUS DTLS as a client or server protocol that provides centralized security for users attempting to gain management access to a network.

RADIUS DTLS is a client or server protocol that

- provides centralized security for users attempting to gain management access to a network
- delivers a complete Authentication, Authorization, and Accounting (AAA) solution, and
- uses RADIUS-over-DTLS (UDP) for secure communication.

RADIUS DTLS components and configuration

The Remote Authentication Dial-In User Service (RADIUS) is a widely deployed authentication and authorization protocol.

RADIUS DTLS includes these components:

- **RADIUS DTLS Port**: Used for authentication and accounting with default DTLS server port 2083
- **Shared Secret**: Uses RADIUS/DTLS as the shared secret when DTLS is enabled for a specific server
- **PAC Handling**: Downloads PAC from ISE for CTS communication and encrypts CTS attributes with the PAC key
- **Session Management**: Depends on DTLS server responses and closes sessions for ideal timeout or invalid responses
- **Load Balancing**: Supports multiple DTLS servers and load balancing methods

You can change the RADIUS DTLS port number using **DTLS port** *port_number*. For more information, see the Configuring RADIUS DTLS Port Number section.

RADSEC consists of two types: RADIUS-over-TLS (using TCP) and RADIUS-over-DTLS (using UDP). Cisco IOS-XE support RADIUS-over-DTLS (UDP) but does not support RADIUS-over-TLS (TCP), as outlined in RFC 7360.

RADIUS DTLS timeout and retry configuration includes these parameters:

- **Connection Timeout**: Default connection timeout is 5 seconds
- **Connection Retries**: Default connection retries is 5
- **Idle Timeout**: Default idle timeout is 60 seconds

After the encrypted RADIUS packet is sent, you need to start the retransmission timer. If you do not get a response before the retransmission timer expires, the packet is re-encrypted and re-transmitted. You can continue for number of times as per the **DTLS retries** configuration or till the default value. Once the number of tries exceeds the limit, the server becomes unavailable and responses are sent back to the AAA clients.

As the RADIUS DTLS is UDP based, you need to retry the connection after a specific timeout interval for a specific number of retries. After all retries are exhausted, the DTLS connection performs these actions:

- Is marked as unsuccessful.
- Looks up for the next available server for processing the RADIUS requests.

When the idle timer expires and no transactions exists since the last idle timeout, the DTLS session remains closed. After you establish the DTLS session, you can start the idle timer. If you start the idle timer for 30 seconds and one of the RADIUS DTLS packet is sent, then after 30 seconds, the idle timer expires and checks for number of RADIUS DTLS transactions. If the idle timer value exceeds zero, the idle timer resets the transaction counter and restarts the timer.

You can configure RADIUS servers with and without DTLS. It is recommended to create AAA server groups with DTLS enabled servers and non-DTLS servers. However, you will not find any such restriction while configuring AAA server groups.

Suppose you choose a DTLS server, the DTLS server establishes connection and RADIUS request packet is sent to the DTLS server. If the DTLS server does not respond after all RADIUS retries, it would fall over to the next configured server in the same server group. If the next server is a DTLS server, the processing of the RADIUS request packet continues with the next server. If the next server is a non-DTLS server, the processing of RADIUS request packet does not happen in that server group. Then the server group failover occurs and the same sequence continues with the next server group, if the next server group is available.

Note

You need to use either only DTLS or non-DTLS servers in a server group.

Requirement: Port RADIUS DTLS support to BINOS platforms

Outlines the prerequisite for porting RADIUS DTLS support from IOS to BINOS platforms where AAA servers run.

Support for IOS and BINOS AAA

Port RADIUS DTLS support to BINOS after completing implementation in IOS, since the AAA server runs on both IOS and BINOS platforms.

Configure RADIUS DTLS server (CLI)

Configure RADIUS DTLS server on a wireless controller.

Enable secure RADIUS communication using DTLS encryption on a wireless controller.

DTLS (Datagram Transport Layer Security) provides secure communication for RADIUS authentication in wireless networks. This configuration is used to protect RADIUS traffic between the wireless controller and RADIUS server.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Specify the RADIUS server name.

   Example

   ```
   Device(config)# radius server server-name
   ```

Example

```
Device(config)# radius server R1
```

4. Configure DTLS parameters.

Example

```
Device(config-radius-server)# dtls
```

5. Return to privileged EXEC mode.

Example

```
Device(config-radius-server)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The RADIUS server is now configured with DTLS security, enabling encrypted communication for authentication requests.

Configure RADIUS DTLS connection timeout

Configure RADIUS DTLS connection timeout on a wireless controller.

Set the timeout value for DTLS connections to RADIUS servers to ensure proper connection management and security.

DTLS (Datagram Transport Layer Security) connection timeout configuration is necessary when using encrypted communication between the wireless controller and RADIUS servers. This setting determines how long the controller waits before timing out a DTLS connection attempt.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device# enable
```

2. Enter global configuration mode.

Example

```
Device# configure terminal
```

3. Specify the RADIUS server name.

Example

```
Device(config)# radius server server-name
```

Example

```
Device(config)# radius server R1
```

4. Configure RADIUS DTLS connection timeout.

Example

```
Device(config-radius-server)# dtls connectiontimeout timeout-value
```

Example

```
Device(config-radius-server)# dtls connectiontimeout 1
```

The *timeout-value* refers to the DTLS connection timeout value. The valid range is from 1 to 65535.

5. Return to privileged EXEC mode.

Example

```
Device(config-radius-server)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The RADIUS DTLS connection timeout is now configured with the specified timeout value for the designated RADIUS server.

Configure RADIUS DTLS idle timeout

Configure RADIUS DTLS idle timeout on a wireless controller.

Set up RADIUS DTLS idle timeout to control the duration before idle DTLS connections are terminated.

RADIUS DTLS idle timeout configuration is necessary to manage connection resources and ensure proper cleanup of inactive DTLS sessions between the wireless controller and RADIUS server.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device# enable
```

2. Enter global configuration mode.

Example

```
Device# configure terminal
```

3. Specify the RADIUS server name.

Example

```
Device(config)# radius server server-name
```

Example

```
Device(config)# radius server R1
```

4. Configure RADIUS DTLS idle timeout.

Example

```
Device(config-radius-server)# dtls idletimeout idle-timeout-value
```

Example

```
Device(config-radius-server)# dtls idletimeout 2
```

The DTLS idle timeout value valid range is from 1 to 65535.

5. Return to privileged EXEC mode.

Example

```
Device(config-radius-server)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The RADIUS DTLS idle timeout is configured and will terminate idle DTLS connections after the specified timeout period.

Configure source interface for RADIUS DTLS server

Configure source interface for RADIUS on a wireless controller.

Configure the source interface for RADIUS DTLS server to establish secure communication between the wireless controller and RADIUS server.

When configuring RADIUS authentication with DTLS encryption, you need to specify the source interface that the wireless controller will use to communicate with the RADIUS server. This ensures proper routing and security for authentication traffic.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device# enable
```

2. Enter global configuration mode.

Example

```
Device# configure terminal
```

3. Specify the RADIUS server name.

Example

```
Device(config)# radius server server-name
```

Example

```
Device(config)# radius server R1
```

4. Configure source interface for RADIUS DTLS server.

Example

```
Device(config-radius-server)# dtls ip radius source-interface Ethernet-Internal
 interface-number
```

Example

```
Device(config-radius-server)# dtls ip radius source-interface Ethernet-Internal
 0
```

The *interface-number* refers to the Ethernet-Internal interface number. The default value is 0.

5. Return to privileged EXEC mode.

Example

```
Device(config-radius-server)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The source interface for RADIUS DTLS server is now configured, enabling secure RADIUS communication through the specified Ethernet-Internal interface.

Configure RADIUS DTLS port number (CLI)

Configure RADIUS DTLS port number on a wireless controller.

Configure the RADIUS DTLS port number to establish secure RADIUS communication using DTLS protocol.

RADIUS DTLS provides secure authentication and accounting communication between the wireless controller and RADIUS server. Configure the DTLS port when you need to specify a custom port number for DTLS communication.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device# enable
```

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Specify the RADIUS server name.

   Example

   ```
   Device(config)# radius server server-name
   ```

   Example

   ```
   Device(config)# radius server R1
   ```

4. Configure RADIUS DTLS port number.

   Example

   ```
   Device(config-radius-server)# dtls port port-number
   ```

   Example

   ```
   Device(config-radius-server)# dtls port 2
   ```

   The *port-number* refers to the DTLS port number.

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-radius-server)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The RADIUS DTLS port number is configured and the controller can now use the specified port for secure DTLS communication with the RADIUS server.

Configure RADIUS DTLS connection retries (CLI)

Configure RADIUS DTLS connection retries on a wireless controller.

Set the number of RADIUS DTLS connection retry attempts to ensure reliable authentication server connectivity.

RADIUS DTLS connection retries help maintain authentication service availability when network conditions cause connection failures. Configure this setting when you need to control how many times the wireless controller attempts to reconnect to the RADIUS server before giving up.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Specify the RADIUS server name.

   Example

   ```
   Device(config)# radius server server-name
   ```

   Example

   ```
   Device(config)# radius server R1
   ```

4. Configure RADIUS connection retries.

   Example

   ```
   Device(config-radius-server)# dtls retries retry-number
   ```

   Example

   ```
   Device(config-radius-server)# dtls retries 3
   ```

   The *retry-number* refers to the DTLS connection retries. The valid range is from 1 to 65535.

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-radius-server)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The RADIUS DTLS connection retry count is configured and the wireless controller will attempt the specified number of reconnections before failing over or giving up.

Configure RADIUS DTLS trustpoint (CLI)

Configure RADIUS DTLS trustpoint on a wireless controller.

Establish secure DTLS communication between the wireless controller and RADIUS server by configuring appropriate trustpoints for authentication.

RADIUS DTLS trustpoints provide secure communication channels for RADIUS authentication traffic. Configure both client and server trustpoints to ensure proper certificate validation during DTLS handshakes.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Specify the RADIUS server name.

   Example

   ```
   Device(config)# radius server server-name
   ```

   Example

   ```
   Device(config)# radius server R1
   ```

4. Configure trustpoint for client and server.

   Example

   ```
   Device(config-radius-server)# dtls trustpoint client client-trustpoint-name
   dtls
   ```

   Example

   ```
   Device(config-radius-server)# dtls trustpoint server server-trustpoint-name
   dtls
   ```

   Example

   ```
   Device(config-radius-server)# dtls trustpoint client client1 dtls
   ```

   Example

   ```
   Device(config-radius-server)# dtls trustpoint server server1 dtls
   ```

5. Return to privileged EXEC mode.

Example

```
Device(config-radius-server)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The RADIUS DTLS trustpoints are now configured, enabling secure DTLS communication between the wireless controller and RADIUS server for authentication traffic.

Configure RADIUS DTLS match-server-identity

Configure RADIUS DTLS trustpoint on a wireless controller.

This task configures RADIUS DTLS match-server-identity parameters to establish secure authentication between the wireless controller and RADIUS server.

RADIUS DTLS (Datagram Transport Layer Security) provides encrypted communication for RADIUS authentication. The match-server-identity feature validates the RADIUS server's certificate against its hostname or IP address to ensure secure connections.

Procedure

---

1. Configure the RADSEC certification validation parameters.

   Example

   ```
   dtls match-server-identity hostname <name>
   ```

2. Configure the RADSEC certification validation parameters.

   Example

   ```
   dtls match-server-identity ip-address <IPv4 or IPv6>
   ```

The RADIUS DTLS match-server-identity parameters are configured, enabling secure certificate validation for RADSEC communication.

Configure DTLS Dynamic Author (CLI)

Configure DTLS Dynamic Author on a wireless controller.

Enable DTLS support for RADIUS dynamic authorization (RFC 3576) on the wireless controller.

DTLS Dynamic Author provides secure communication for RADIUS Change of Authorization (CoA) and disconnect messages. This configuration is needed when implementing dynamic policy changes and session management in wireless networks.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device# enable
```

2. Enter global configuration mode.

Example

```
Device# configure terminal
```

3. Configure local server profile for RFC 3576 support.

Example

```
Device(config)# aaa server radius dynamic-author
```

4. Configure DTLS source parameters.

Example

```
Device(config-locsvr-da-radius)# dtls
```

5. Return to privileged EXEC mode.

Example

```
Device(config-locsvr-da-radius)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

DTLS Dynamic Author is now configured on the wireless controller, enabling secure RADIUS dynamic authorization communications.

Enable DTLS for client (CLI)

Enable DTLS for client on a wireless controller.

Enable DTLS encryption for client communications to secure RADIUS dynamic authorization messages.

DTLS (Datagram Transport Layer Security) provides encryption for UDP-based communications between the wireless controller and RADIUS clients. This configuration enhances security for RFC 3576 dynamic authorization operations.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device# enable
```

2. Enter global configuration mode.

Example

```
Device# configure terminal
```

3. Configure local server profile for RFC 3576 support.

Example

```
Device(config)# aaa server radius dynamic-author
```

4. Enable DTLS for the client.

Example

```
Device(config-locsvr-da-radius)# client IP-address dtls
```

Example

```
Device(config-locsvr-da-radius)# client 10.104.49.14 dtls
```

5. Return to privileged EXEC mode.

Example

```
Device(config-locsvr-da-radius)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

DTLS is now enabled for the specified client, providing encrypted communication for RADIUS dynamic authorization messages.

Configure client trustpoint for DTLS (CLI)

Configure client trustpoint for DTLS on a wireless controller.

Establish secure DTLS communication between the wireless controller and RADIUS dynamic authorization clients.

Client trustpoint configuration for DTLS is required when implementing secure communication for RFC 3576 dynamic authorization services on wireless controllers.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device# enable
```

2. Enter global configuration mode.

Example

```
Device# configure terminal
```

3. Configure local server profile for RFC 3576 support.

Example

```
Device(config)# aaa server radius dynamic-author
```

4. Configure client trustpoint for DTLS.

Example

```
Device(config-locsvr-da-radius)# client IP-address dtls client-tp
client-tp-name
```

Example

```
Device(config-locsvr-da-radius)# client 10.104.49.14 dtls client-tp
client_tp_name
```

5. Return to privileged EXEC mode.

Example

```
Device(config-locsvr-da-radius)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The client trustpoint for DTLS is now configured, enabling secure communication between the wireless controller and the specified RADIUS dynamic authorization client.

Configure DTLS idle timeout (CLI)

Configure DTLS idle timeout on a wireless controller.

Set the DTLS idle timeout interval to control when inactive DTLS connections are terminated.

DTLS idle timeout configuration is necessary to manage inactive DTLS connections and optimize resource utilization on wireless controllers.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device# enable
```

2. Enter global configuration mode.

Example

```
Device# configure terminal
```

3. Configure local server profile for RFC 3576 support.

Example

```
Device(config)# aaa server radius dynamic-author
```

4. Configure DTLS idle time.

Example

```
Device(config-locsvr-da-radius)# client IP_addr dtls idletimeout
timeout-interval  {client-tp client_tp_name | server-tp server_tp_name}client
IP-address dtls idletimeout timeout-interval client-tp client-tp-name
```

Example

```
Device(config-locsvr-da-radius)# client 10.104.49.14 dtls idletimeout 62
client-tp dtls_ise
```

The *timeout-interval* refers to the idle timeout interval. The valid range is from 60 to 600.

5. Return to privileged EXEC mode.

Example

```
Device(config-locsvr-da-radius)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The DTLS idle timeout is now configured and will terminate inactive DTLS connections after the specified timeout interval.

Configure server trustpoint for DTLS (CLI)

Configure server trustpoint for DTLS on a wireless controller.

Enable secure DTLS communication between the wireless controller and RADIUS clients by configuring a server trustpoint.

Server trustpoints are required when implementing DTLS (Datagram Transport Layer Security) for RFC 3576 Change of Authorization (CoA) messages between RADIUS clients and the wireless controller. This ensures encrypted and authenticated communication.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device# enable
```

2. Enter global configuration mode.

Example

```
Device# configure terminal
```

3. Configure local server profile for RFC 3576 support.

Example

```
Device(config)# aaa server radius dynamic-author
```

4. Configure server trust point for the DTLS client.

Example

```
Device(config-locsvr-da-radius)# client IP-address dtls server-tp
server-trustpoint-name
```

Example

```
Device(config-locsvr-da-radius)# client 10.104.49.14 dtls server-tp dtls_client
```

5. Return to privileged EXEC mode.

Example

```
Device(config-locsvr-da-radius)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The server trustpoint for DTLS is now configured, enabling secure communication between the wireless controller and the specified RADIUS client for Change of Authorization messages.

Verify RADIUS DTLS server configuration

Provides command to view information about the DTLS enabled servers.

To view information about the DTLS enabled servers, use this command:

```
Device# show aaa servers
DTLS: Packet count since last idletimeout 1,
Send handshake count 3,
Handshake Success 1,
Total Packets Transmitted 1,
Total Packets Received 1,
Total Connection Resets 2,
Connection Reset due to idle timeout 0,
Connection Reset due to No Response 2,
Connection Reset due to Malformed packet 0,
```

Clear RADIUS DTLS specific statistics

Clear DTLS server statistics to reset monitoring counters.

Clear RADIUS DTLS specific statistics to reset monitoring counters and start fresh data collection.

Use this task when you need to reset DTLS server statistics for monitoring purposes or troubleshooting.

Procedure

Clear the RADIUS DTLS specific statistics.

Example

```
Device# clear aaa counters servers radius {<server-id> | all}
```

Note

Here, *server-ID* refers to the server ID displayed by **show aaa servers**. The valid range is from 0 to 2147483647.

The RADIUS DTLS specific statistics are cleared and reset to zero.

139 Policy Enforcement and Usage Monitoring

Topics:

- Policy enforcement and usage monitoring

Outlines policy enforcement and usage monitoring concepts, guides through configuration using the command-line interface, and provides methods for verifying policy application and effectiveness.

Policy enforcement and usage monitoring

Explains how policy enforcement and usage monitoring provide dynamic QoS policy application and real-time data rate control for 802.11 clients.

A policy enforcement and usage monitoring system is a network management mechanism that

- applies dynamic QoS policies and enforces upstream and downstream TCP or UDP data rate limits on 802.11 clients
- monitors each client's data usage without disrupting ongoing sessions, and
- supports multiple wireless authentication methods such as 802.1X, PSK, and web authentication.

APs send client statistics to the controller periodically. This includes bandwidth consumption. The AAA server receives Accounting-Interim messages at configured intervals to accumulate consumption data for each client. When a client exceeds the configured data threshold, the AAA server sends a Change-of-Authorization (CoA) message to the controller. This process ensures continuous client connectivity. It maintains session persistence during policy changes.

> **Note**
>
> Only FlexConnect local switching mode is supported.

Configure policy enforcement and enable CoA (CLI)

Use this procedure to configure policy enforcement and enable change-of-authorization using command.

Configure network device policy enforcement and enable dynamic reauthorization for RADIUS clients.

This task is required when implementing RADIUS-based policy control on supported network devices and enabling Change-of-Authorization capabilities for dynamic policy updates.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a local server RADIUS profile in the controller.

   Example

   ```
   Device(config)# aaa server radius dynamic-author
   ```

3. Configure a server key for a RADIUS client.

   Example

   ```
   Device(config-locsvr-da-radius)# client client-ip-addr server-key key
   ```

4. Optional: Display the AAA CoA packet statistics.

Example

```
Device# show aaa command handler
```

The device is now configured to enforce policy and support change-of-authorization for RADIUS clients. You can verify configuration or monitor status as needed.

Example: Configure policy enforcement and usage monitoring

This section lists a sample configuration for applying policy enforcement and usage monitoring on a wireless network group.

Policy enforcement and usage monitoring is applied on a group where a class-map is created for quality of service (QoS) policies. This is done using Change of Authorization (CoA).

Here is a sample configuration for policy enforcement and usage monitoring:

```
aaa new-model
  radius server radius_free
  address ipv4 10.0.0.1 auth-port 1812 acct-port 1813
  key cisco123
  exit

aaa new-model
  aaa server radius dynamic-author
  client 10.0.0.1 server-key cisco123
aaa new-model
  aaa group server radius rad_eap
  server name radius_free
  exit
aaa new-model
  dot1x system-auth-control
  aaa authentication dot1x eap_methods group rad_eap
  dot1x system-auth-control
class-map client_dscp_clsmapout
match dscp af13
exit
class-map client_dscp_clsmapin
match dscp af13
exit
policy-map qos_new
  class client_dscp_clsmapout
  police 512000 conform-action transmit exceed-action drop
  policy-map qos_nbn
  class client_dscp_clsmapin
  police 16000000 conform-action transmit exceed-action drop
wlan test1 3 test2
  broadcast-ssid
  security wpa wpa2 ciphers aes

Verify policy usage and enforcement

This section lists CLI commands to view detailed information about policy usage and enforcement.

To view the detailed information about the policies applied to a specific client, use this command:

```
Device# show wireless client mac-address mac-address detail
```

To view client-level mobility statistics, use this command:

```
Device# show wireless client mac-address mac-address mobility statistics
```

To view client-level roaming history for an active client in a sub-domain, use this command:

```
Device# show wireless client mac-address mac-address mobility history
```

To view detailed parameters of a given profile policy, use this command:

```
Device# show wireless profile policy detailed policy-name
```

140 Local Extensible Authentication Protocol

Topics:

- Local EAP

Local EAP

Explains how Local Extensible Authentication Protocol (EAP) enables the controller to act as an authentication server.

Local EAP is a controller feature that

- makes the controller act as both authenticator and authentication server
- allows 802.1x authentication on WPA Enterprise wireless clients without the use of any RADIUS server, and
- refers to the EAP authentication server activity and not necessarily tied to the user credentials validation that can be delegated to an external LDAP database.

Feature scenarios

Local EAP is designed to allow administrators to use Enterprise-grade 802.1x authentication for a limited number of users in situations and branches where an external dedicated RADIUS server may not be available. It can also work as an emergency backup in case the RADIUS server is not available.

You can implement Local EAP either with users local to the controller or use an external LDAP database to store the user credentials.

Restrictions for local EAP

Outlines the limitations and requirements when using local EAP profile on a wireless controller.

Consider these restrictions when implementing local EAP on wireless controllers.

- It is not possible to configure AAA attributes, such as per-user ACL or per-user session timeout using local EAP.
- Local EAP only allows user database either locally on the controller or on an external LDAP database.
- Local EAP supports TLS 1.2 as of 17.1 and later software release.
- Local EAP uses the trustpoint of your choice on the controller. You will either need to install a publicly trusted certificate on the controller or import it on the clients for the EAP session to be trusted by the client.
- Local EAP supports *EAP-FAST*, *EAP-TLS*, and *PEAP* as EAP authentication methods.

> **Note**
>
> *PEAP-mschapv2* does not work when using certain external LDAP databases that only support clear text passwords.

- When FIPS mode is enabled on the controller, the password for local EAP users must be configured with an encryption higher than type six, otherwise the users fail to authenticate. To ensure successful authentication, configure the password using the command **algorithm-type sha256 secret <password>**.

Configure local EAP profile (CLI)

Configure local EAP profile using commands.

Create and configure a local EAP profile to support authentication methods for wireless clients.

EAP profiles define authentication methods and security parameters for wireless network access. This configuration establishes a local EAP profile with PEAP method and PKI trustpoint for secure client authentication.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create an EAP profile.

   Example

   ```
   Device(config)# eap profile profile-name
   ```

   Example

   ```
   Device(config)# eap profile mylocapeap
   ```

3. Configure the PEAP method on the profile.

   Example

   ```
   Device(config-eap-profile)# method peap
   ```

4. Configure the PKI trustpoint on the profile.

   Example

   ```
   Device(config-eap-profile)# pki-trustpoint trustpoint-name
   ```

   Example

   ```
   Device(config-eap-profile)# pki-trustpoint admincert
   ```

The local EAP profile is configured with PEAP authentication method and associated PKI trustpoint, ready for use in wireless network authentication.

Configure local EAP profile (GUI)

Configure local EAP profile using GUI.

Configure a local EAP profile to enable secure authentication for wireless clients using various EAP methods.

Use this procedure to create a local EAP profile through the graphical user interface when you need to provide secure wireless authentication capabilities.

Procedure

1. Choose **Configuration** > **Security** > **Local EAP**.
2. Click **Add**.
3. In the **Create Local EAP Profiles** page, enter a profile name.

> **Note**
>
> It is not advised to use LEAP EAP method due to its weak security. You can use any of these EAP methods to configure a trustpoint:
>
> - EAP-FAST
> - EAP-TLS
> - PEAP
>
> Clients do not trust the default controller certificate, so you need to deactivate the server certificate validation on the client side or install a certificate trustpoint on the controller.

4. Click **Apply to Device**.

The local EAP profile is successfully created and applied to the device, enabling secure authentication for wireless clients.

Configure AAA authentication (GUI)

Configure AAA authentication using the GUI interface.

This task enables you to set up authentication, authorization, and accounting (AAA) authentication methods using the graphical user interface to control network access and security.

AAA authentication is a security framework that controls access to network resources. You can configure different authentication methods such as local authentication or external authentication servers to validate user credentials before granting network access.

Procedure

---

1. Choose **Configuration** > **Security** > **AAA**, and navigate to the **AAA Method List** > **Authentication** tabs.
2. Click **Add**.
3. Choose **dot1x** as the **Type** and **local** as the **Group Type**.
4. Click **Apply to Device**.

The AAA authentication method is configured and applied to the device. The system will now use the specified authentication method (dot1x with local group type) to validate user access requests.

Configure AAA authorization method (GUI)

Configure AAA authorization method using GUI.

Configure AAA authorization methods to control access permissions for network and credential-download operations.

AAA authorization methods define how the system determines what actions authenticated users are permitted to perform. This configuration is essential for maintaining network security and access control.

Procedure

---

1. Navigate to **Authorization** sub-tab.

2. Create a new method for **credential-download** type and point it to local.

> **Note**
>
> Perform the same for **network** authorization type.

AAA authorization methods are configured for both credential-download and network authorization types, pointing to local authentication.

Configure AAA authorization method (CLI)

Configure AAA authorization method using commands.

Configure AAA authorization method to establish authentication and authorization policies for network access control using CLI commands.

Use this procedure when you need to set up AAA authorization method through the command line interface to control network access and credential management.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a AAA authentication model.

   Example

   ```
   Device(config)# aaa new-model
   ```

3. Configure the default local RADIUS server.

   Example

   ```
   Device(config)# aaa authentication dot1x default local
   ```

4. Configure default database to download credentials from local server.

   Example

   ```
   Device(config)# aaa authorization credential-download default local
   ```

5. Configure the local authentication method list.

Example

```
Device(config)# aaa local authentication default authorization default
```

6. Configure authorization for network services.

Example

```
Device(config)# aaa authorization network default local
```

AAA authorization method is configured with local authentication and authorization for dot1x, credential download, and network services.

Configure local advanced methods (GUI)

Configure local advanced methods using GUI.

Configure local advanced authentication and authorization methods to control access to network resources using the graphical user interface.

Local advanced methods provide enhanced security controls for authentication and authorization in AAA configurations. Use this procedure when you need to set default local authentication and authorization methods through the GUI.

Procedure

---

1. In the **Configuration** > **Security** > **AAA** window, perform the following:
   a. Navigate to **AAA Advanced** tab.
   b. From the **Local Authentication** drop-down list, choose a default local authentication.
   c. From the **Local Authorization** drop-down list, choose a default local authorization.
2. Click **Apply**.

The local advanced authentication and authorization methods are configured and applied to the AAA settings.

Configure WLAN (GUI)

Configure WLAN using GUI.

Configure a WLAN profile to enable wireless network access for clients.

WLAN configuration allows you to define wireless network parameters including SSID, radio policy, and authentication settings.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. In the **WLANs** window, click the name of the **WLAN** or click **Add** to create a new one.
3. In the **Add/Edit WLAN** window that is displayed, click the **General** tab to configure the following parameters.
   - In the **Profile Name** field, enter or edit the name of the profile.

- In the **SSID** field, enter or edit the SSID name.

  The SSID name can be alphanumeric, and up to 32 characters in length.
- In the **WLAN ID** field, enter or edit the ID number. The valid range is between 1 and 512.
- From the **Radio Policy** drop-down list, choose the **802.11** radio band.
- Using the **Broadcast SSID** toggle button, change the status to either **Enabled** or **Disabled**.
- Using the **Status** toggle button, change the status to either **Enabled** or **Disabled**.

4. In the **AAA** tab, you can configure the following:
   a. Choose an authentication list from the drop-down.
   b. Check the **Local EAP Authentication** check box to enable local EAP authentication on the WLAN. Also, choose the required **EAP Profile Name** from the drop-down list.
5. Click **Save & Apply to Device**.

The WLAN is configured and applied to the device. The wireless network is now available for client connections with the specified settings.

Configure WLAN (CLI)

Configure WLAN using commands.

Configure a WLAN using CLI commands to establish wireless network connectivity with dot1x security authentication.

Use this procedure when you need to set up a wireless LAN with security authentication through the command line interface.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id ssid-name
   ```

   ```
   Device(config)# wlan localpeapssid 1 localpeapssid
   ```

   wlan-name: Is the name of the configured WLAN.

   wlan-id: Is the wireless LAN identifier. The range is 1 to 512.

   ssid-name: Is the SSID name which can contain 32 alphanumeric characters.

> **Note**
>
> If you have already configured this command, enter **wlan** *wlan-name* command.

3. Enable security authentication list for dot1x security. The configuration is similar for all dot1x security WLANs.

   Example

   ```
   Device(config-wlan)# security dot1x authentication-list auth-list-name
   ```

   ```
   Device(config-wlan)# security dot1x authentication-list default
   ```

4. Set EAP Profile on an WLAN.

   Example

   ```
   Device(config-wlan)# local-auth profile-name
   ```

   ```
   Device(config-wlan)# local-auth mylocaleap
   ```

   profile name: Is the EAP profile on an WLAN.

The WLAN is configured with dot1x security authentication and the specified EAP profile.

Create a user account (CLI)

Configure a user account using commands.

This task creates a new user account with specified parameters including username, password, creation time, description, and user type.

Use this procedure when you need to create a user account through the command-line interface. This method allows you to specify detailed account parameters during the creation process.

Before you begin

Follow these steps to create a user account using CLI commands:

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a user account.

Example

```
Device(config)# user-name user-name
```

```
Device(config)# user-name 1xuser
```

3. Set the creation time of the user account.

   Example

   ```
   Device(config)# creation-time time
   ```

   ```
   Device(config)# creation-time 1572730075
   ```

4. Add a user-defined description to the new user account.

   Example

   ```
   Device(config)# description user-name
   ```

   ```
   Device(config)# description 1xuser
   ```

5. Create a password for the user account.

   Example

   ```
   Device(config)# password 0 password
   ```

   ```
   Device(config)# password 0 Cisco123
   ```

6. Specify the type of user account.

   Example

   ```
   Device(config)# type network-user description user-name
   ```

   ```
   Device(config)# type network-user description 1xuser
   ```

The user account is created with the specified username, password, creation time, description, and user type. The account is now available for use on the device.

Attach a policy profile to a WLAN interface (GUI)

Configure policy profile attachment to a WLAN interface using GUI.

This task allows you to attach a policy profile to a WLAN interface to control network access and security policies for wireless connections.

Policy profiles define access control rules and security settings for WLAN interfaces. Attaching a policy profile to a WLAN interface ensures that wireless clients connecting through that interface are subject to the defined policies.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. On the **Manage Tags** page, click **Policy** tab.
3. Click **Add** to view the **Add Policy Tag** window.
4. Enter a name and description for the policy tag.
5. Click **Add** to map the WLAN and policy.
6. Choose the WLAN profile to map with the appropriate policy profile, and click the tick icon.
7. Click **Save & Apply to Device**.

The policy profile is attached to the WLAN interface. The configuration is saved and applied to the device, ensuring that the policy rules are enforced for clients connecting through the specified WLAN interface.

Deploy policy tag to access points (GUI)

Configure policy tag deployment to access points using the GUI interface.

Deploy policy tags to access points to apply specific wireless policies and configurations to designated access points in your network.

Use this procedure when you need to assign policy tags to access points through the graphical user interface. Policy tags allow you to apply consistent configurations across multiple access points.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. On the **All Access Points** page, click the access point you want to configure.

   Make sure that the tags assigned are the ones you configured.
3. Click **Apply**.

The policy tag is successfully deployed to the selected access point, and the wireless policies associated with the tag are applied to that access point.

141 Local EAP Ciphersuite

Topics:

- Local EAP Ciphersuite

Outlines the Local Extensible Authentication Protocol ciphersuite feature, explaining how to configure and manage supported ciphersuites on the controller for secure local authentication and enhanced compatibility.

Local EAP Ciphersuite

This topic explains the Local EAP ciphersuite feature, which controls the list of ciphersuites that the controller, acting as an SSL server, supports for local authentication. It describes the default behavior and the ability to configure supported ciphersuites.

A local EAP ciphersuite is a security protocol configuration that

- determines which encryption algorithms the controller supports during EAP transactions
- allows customization of enabled or disabled ciphersuites for improved security and compatibility, and
- is manageable by administrators from Cisco IOS XE Cupertino 17.7.1 Release onwards.

Feature history

Feature Name	Release	Description
Ciphersuite Selection for Local EAP Authentication	Cisco IOS XE 17.1.1s	This feature provides the controller with a knob to control the list of ciphersuites used in local EAP authentication Prior to Cisco IOS XE Cupertino 17.7.1 Release, the controller acts as an SSL server supporting a hardcoded list of ciphersuites for each EAP application.

Supported and configurable ciphersuites for Local EAP

The controller, acting as an SSL server, negotiates ciphersuites with the client during the SSL handshake. The client sends a prioritized list of supported ciphersuites, and the server selects one that is mutually acceptable.

The table lists the hardcoded ciphersuites and their descriptions:

Table 120: Hardcoded List of Ciphersuites

Ciphersuites	Description
aes128-sha	Encryption Type tls_rsa_with_aes_128_cbc_sha.
aes256-sha	Encryption Type tls_rsa_with_aes_256_cbc_sha.
dhe-rsa-aes-gcm-sha2	Encryption Type tls_dhe_rsa_with_aes_128_gcm_sha256 and tls_dhe_rsa_with_aes_256_gcm_sha384(TLS1.2 and above).
dhe-rsa-aes-sha2	Encryption Type tls_dhe_rsa_with_aes_128_cbc_sha256 and tls_dhe_rsa_with_aes_256_cbc_sha256 (TLS 1.2 and above).
dhe-rsa-aes128-sha	Encryption Type tls_dhe_rsa_with_aes_128_cbc_sha.
dhe-rsa-aes256-sha	Encryption Type tls_dhe_rsa_with_aes_256_cbc_sha.
ecdhe-ecdsa-aes-gcm-sha2	Encryption Type tls_ecdhe_ecdsa_with_aes_128_gcm_sha256 and tls_ecdhe_ecdsa_with_aes_256_gcm_sha384(TLS1.2 and above).

Ciphersuites	Description
ecdhe-ecdsa-aes-sha	Encryption Type tls_ecdhe_ecdsa_with_aes_128_cbc_sha and tls_ecdhe_ecdsa_with_aes_256_cbc_sha.
ecdhe-ecdsa-aes-sha2	Encryption Type tls_ecdhe_ecdsa_with_aes_128_cbc_sha256 and tls_ecdhe_ecdsa_with_aes_256_cbc_sha384(TLS1.2 and above).
ecdhe-rsa-aes-gcm-sha2	Encryption Type tls_ecdhe_rsa_with_aes_128_gcm_sha256 and tls_ecdhe_rsa_with_aes_256_gcm_sha384(TLS1.2 and above).
ecdhe-rsa-aes-sha	Encryption Type tls_ecdhe_rsa_with_aes_128_cbc_sha and tls_ecdhe_rsa_with_aes_256_cbc_sha.
ecdhe-rsa-aes-sha2	Encryption Type tls_ecdhe_rsa_with_aes_128_cbc_sha256 and tls_ecdhe_rsa_with_aes_256_cbc_sha384(TLS1.2 and above).

Note

By default, all the ciphersuites are supported. Using the Local EAP ciphersuite feature, you can enable or disable the ciphersuites based on your requirement.

Restrictions for Local EAP Ciphersuite

Adhere to these restrictions when configuring local EAP Ciphersuite on a wireless controller.

- SNMP is not supported.
- Ciphersuites are specific to 802.1X.

Configure Local EAP Ciphersuite (CLI)

Use this procedure to configure local EAP ciphersuite using commands.

Configure Local Extensible Authentication Protocol (EAP) ciphersuite for secure authentication.

This configuration is used in environments where EAP authentication is required for network access.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Enter global configuration mode.

Example

```
Device# configure terminal
```

3. Create an EAP profile.

Example

```
Device(config)# eap profile name
```

Example

```
Device(config)# eap profile local_EAP_TLSv1
```

4. Select a ciphersuite.

Example

```
Device(config-eap-profile)# ciphersuite cipher-suite
```

Using this command, you will be able to configure only one ciphersuite. To configure more than one ciphersuite, you need to issue this command with various ciphersuites.

By default, all ciphersuites are supported if you issue the **no ciphersuite** command.

> **Note**
>
> To remove the ciphersuites, remove the ciphersuites one by one or all at once.

5. Return to privileged EXEC mode.

Example

```
Device(config-eap-profile)# end
```

Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The local EAP ciphersuite is now configured for secure authentication.

142 Authentication and Authorization Between Multiple RADIUS Servers

Topics:

- Authentication and authorization between multiple RADIUS servers
- Configure web authentication for WLAN with split authentication and authorization servers
- RADIUS Message-Authenticator support for non-EAP requests

This chapter explains how to configure and verify split RADIUS authentication and authorization on Cisco Catalyst 9800 controllers, including GUI and CLI steps for server groups, AAA lists, 802.1X, and web authentication.

Authentication and authorization between multiple RADIUS servers

Explains how authentication and authorization roles are managed across single and multiple RADIUS servers in wireless controller configurations.

A RADIUS authentication and authorization role is a function within a RADIUS-based wireless controller configuration that:

- allows authentication and authorization duties to be carried out by a single RADIUS server or split between different servers
- enables the controller to relay authentication attributes to a separate authorization server, and
- in a split configuration, requires both servers to return ACCESS-ACCEPT for a client session to be established.

Cisco Catalyst 9800 Series Wireless Controller use a request and response transaction with a single RADIUS server that combines both authentication and authorization.

A RADIUS server can assume the role of either an authentication server, authorization server, or both. In cases where there are separate RADIUS servers for authentication and authorization, the Session Aware Networking (SANet) component on the controller allows authentication on one server and authorization on another when a client joins controller .

Authentication can be performed using Cisco ISE, Cisco Catalyst Center, Free RADIUS, or any third-party RADIUS Server. After the authentication server successfully authenticates a user, the controller relays attributes received from the authentication server to another RADIUS server designated as the authorization server.

The authorization server then performs these:

- Processes received attributes with the other policies or rules defined on the server.
- Derives attributes as part of the authorization response and returns them to the controller .

> **Note**
>
> The Authentication/Authorization list created through Cisco Catalyst Center provisioning supports a maximum of 100 entries. Entries beyond 100 can be created, but they do not function.

Configure explicit authentication and authorization server list (GUI)

Use this procedure to configure explicit authentication and authorization server list using GUI.

Set up and customize authentication and authorization server lists to control network access and user verification methods using the GUI.

Designate specific authentication and authorization servers, such as RADIUS, TACACS+, or LDAP, to handle AAA (Authentication, Authorization, and Accounting) operations on your device.

Procedure

1. Choose **Configuration** > **Security** > **AAA**. On the **Authentication Authorization and Accounting** page, click the **Servers/Groups** tab. Click the type of AAA server you want to configure from these options:
   - RADIUS
   - TACACS+
   - LDAP

   In this procedure, the RADIUS server configuration is described.

2. With the **RADIUS** option selected, click **Add** and enter a name for the RADIUS server and the IPv4 or IPV6 address of the server.
3. Enter the authentication and encryption key to be used between the device and the key string RADIUS daemon running on the RADIUS server. You can choose to use either a PAC key or a non-PAC key.
4. Enter the server timeout value; the valid range is 1 to 1000 seconds. Enter a retry count; the valid range is 0 to 100.
5. Leave the **Support for CoA** field in **Enabled** state and click **Save & Apply to Device**.
6. On the **Authentication Authorization and Accounting** page, with **RADIUS** option selected, click the **Server Groups** tab. In the **Create AAA RADIUS Server Group** window that is displayed, enter a name for the RADIUS server group.
7. From the **MAC-Delimiter** drop-down list, select the delimiter to be used in the MAC addresses that are sent to the RADIUS servers. From the **MAC Filtering** drop-down list, select a value based on which to filter MAC addresses.
8. To configure dead time for the server group and direct AAA traffic to alternative groups of servers that have different operational characteristics, in the **Dead-Time** field, enter the amount of time, in minutes, after which a server is assumed to be dead.
9. Choose the servers that you want to include in the server group from the **Available Servers** list and move them to the **Assigned Servers** list. Click **Save & Apply to Device**.

Configure explicit authentication server list (GUI)

Use this procedure to configure explicit authentication server list using the GUI.

Set up and manage RADIUS authentication servers and server groups to control authentication and accounting within your network environment using the GUI.

Use this task when you need to explicitly designate which RADIUS servers and groups are available for authentication in your AAA configuration, using the device's graphical interface.

Procedure

1. Choose **Configuration** > **Security** > **AAA** > **Servers/Groups**.
2. Choose **RADIUS** > **Servers** tab.
3. Click **Add** to add a new server or click an existing server.
4. Enter the **Name**, the **Server Address**, **Key**, **Confirm Key**, **Auth Port** and **Acct Port**. Check the **PAC Key** checkbox and enter the **PAC key** and **Confirm PAC Key**.
5. Click **Apply to Device**.
6. Choose **RADIUS** > **Server Groups** and click **Add** to add a new server group or click an existing server group.
7. Enter the **Name** of the server group and choose the servers that you want to include in the server group, from the **Available Servers** list and move them to the **Assigned Servers** list.
8. Click **Apply to Device**.

Configure explicit authentication server list (CLI)

Use this procedure to configure explicit authentication server list using commands.

Set up an authentication server list by explicitly defining RADIUS server parameters using commands.

Use this procedure on Cisco devices when you require explicit configuration of authentication server parameters for AAA.

Procedure

1. Enable the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Specify the RADIUS server name.

   Example

   ```
   Device(config)# radius server server name
   ```

4. Specify the RADIUS server parameters.

   Example

   ```
   Device(config-radius-server)# address ipv4 192.0.2.56 auth-port 1812 acct-port
    1813
   ```

5. Specify the authentication and encryption key used between the device and the key string RADIUS daemon running on the RADIUS server.

   Example

   ```
   Device(config-radius-server)# pac key key
   ```

6. Return to the configuration mode.

   Example

   ```
   Device(config-radius-server)# exit
   ```

7. Create a radius server-group identification.

   Example

   ```
   Device(config)# aaa group server radius server-group
   ```

   server-group refers to the server group name. The valid range is from 1 to 32 alphanumeric characters.

   If the IP address of the RADIUS server is not added to the routes defined for the controller, the default route is used. We recommend that you define a specific route to source the traffic from the defined SVI in the AAA server group.

8. Configure the server name.

Example

```
Device(config)# server name server-name
```

9. Return to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Example

```
Device(config)# end
```

For more information, see *Configuring AAA for External Authentication*.

Configure explicit authorization server list (GUI)

Use this procedure to configure explicit authorization server list using the GUI.

Set up and organize RADIUS authorization servers and groups for secure network authentication and accounting using the GUI.

Configuring an explicit authorization server list ensures that devices can authenticate users and account activity through specified RADIUS servers. This centralized management helps enforce access policies and simplifies administration.

Procedure

1. Choose **Configuration** > **Security** > **AAA** > **Servers/Groups**.
2. Choose **RADIUS** > **Servers** tab.
3. Click **Add** to add a new server or click an existing server.
4. Enter the **Name**, the **Server Address**, **Key**, **Confirm Key**, **Auth Port** and **Acct Port.** Check the **PAC Key** checkbox and enter the **PAC key** and **Confirm PAC Key**.
5. Click **Apply to Device**.
6. Choose **RADIUS** > **Server Groups** and click **Add** to add a new server group or click an existing server group.
7. Enter the **Name** of the server group and choose the servers that you want to include in the server group, from the **Available Servers** list and move them to the **Assigned Servers** list.
8. Click **Apply to Device**.

Configure explicit authorization server list (CLI)

Use this procedure to configure explicit authorization server list using commands.

You must direct AAA validation access requests to a specific server. Otherwise, the wireless controller selects any available AAA server from the configured pool to validate access requests. Because the controller cannot target a specific server for validation, you may face inefficiencies and potential security vulnerabilities.

To address this, an authorization method list is created to allow administrators to explicitly direct the controller to use a specific AAA server or the local database for validation. This configuration ensures a streamlined and secure validation process by eliminating randomness in server selection.

Benefits of this approach are:

- **Improved Control**: You can explicitly define which AAA server handles validation requests and ensure precise control over server selection.
- **Flexibility**: You can configure either an external AAA server or a local database based on the network's requirements.

- **Enhanced Security**: By specifying the AAA server, you can ensure that only trusted servers are used for validation, reducing the risk of unauthorized access.

Follow these steps to configure an explicit authorization server list using commands:

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Set up the security framework by enabling AAA features for authentication, authorization, and accounting.

   Example

   ```
   Device# aaa new-model
   ```

4. Configure a RADIUS server to enable centralized authentication, authorization, and accounting for secure and scalable network access control.
   a) Specify the RADIUS server name.
   b) Specify the RADIUS server parameters.
   c) Specify the authorization and encryption key used between the device and the RADIUS daemon running on the RADIUS server by key string encryption.

   Example

   ```
   Device(config)# radius server server-name
   ```

   ```
   Device(config)# address ipv4 address auth-port auth_port_number acct-port
   acct_port_number
   ```

   ```
   Device(config)# pac key key
   ```

   ```
   Device(config)# end
   ```

5. Configure the RADIUS group.
   a) Create a radius server-group identification.

> **Note**
>
> **server-group** refers to the server group name. The valid range is from one to 32 alphanumeric characters.

Example

```
Device(config)# aaa group server radius server-name
Device(config-sg-radius)# server name server-name
Device(config-sg-radius)# exit
```

6. Define a network-level authorization policy for access control using the previously specified server group.

   Example

   ```
   Device(config)# aaa authorization network rogued group group-name
   ```

7. Create an attribute list to apply custom authentication or authorization attributes.
   a) Create an attribute list to specify policies for rogue AP detection and control and enter the attribute list configuration mode.
   b) Identify the device with a specific rogue state for network policies.
   c) Identify the device with a specific rogue class for network policies.

   Example

   ```
   Device(config)# aaa attribute list aaa-attribute-list-name
   Device(config-attr-list)# attribute type rogue-ap-state {alert | contain |
   threat }
   Device(config-attr-list)# attribute type rogue-ap-class {unclassified |
   malicious | friendly }
   Device(config-attr-list)# exit
   ```

8. Define a client with a specific MAC address as a *username* and associate it with the previously defined AAA attribute list. This allows for controlled access or applies policy decisions for that specific client.

   Important

   For rogue validation, the *username* must be a MAC address in the semicolon format.

   Example

   Define a client with a specific MAC address (00:00:00:00:00:00) as a *username* and associate it with an AAA attribute list named **rogue-attributes**. This allows for the use of specific AAA (authentication, authorization, and accounting) attributes to be applied to this MAC address, typically to control access or apply policy decisions for that client.

   ```
   Device(config)# username 00:00:00:00:00:00 mac aaa attribute list
   aaa-attribute-list-name
   ```

9. Display the AAA running configuration for review.

Example

```
Device(config)# show running-config | include aaa
```

Setting up these configurations ensure that only authorized clients can access the network, and any suspicious activity is flagged and handled appropriately.

Configure authentication and authorization list for 802.1X security (GUI)

Use this procedure to configure authentication and authorization list for 802.1X security using the GUI.

Set up 802.1X security by specifying authentication and authorization lists through the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name** , the **SSID** , and the **WLAN ID**.
4. In the **Security** > **AAA** tab, select an authentication list from the **Authentication List** drop-down list.
5. Click **Apply to Device**.

Configure authentication and authorization list for 802.1X security (CLI)

Use this procedure to configure authentication and authorization list for 802.1X security using commands.

Configure 802.1X authentication and authorization on a WLAN using commands.

Use this procedure when you need to enforce 802.1X security for a specific wireless network on your device.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id ssid name
   ```

- *wlan-name* : is the name of the configured WLAN.
- *wlan-id* : is the wireless LAN identifier. The valid range is from 1 to 512.
- *SSID-name* : is the SSID name which can contain 32 alphanumeric characters.

> **Note**
>
> If you have already configured this command, enter **wlan** *wlan-name* command.

4. Enable authentication list for 802.1x security.

   Example

   ```
   Device(config-wlan)# security dot1x authentication-list authenticate-list-name
   ```

5. Specify authorization list for 802.1x security.

   Example

   ```
   Device(config-wlan)# security dot1x authorization-list authorize-list-name
   ```

   For more information on the Cisco Catalyst Center, see the Cisco Catalyst Center documentation.

6. Return to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

   Example

   ```
   Device(config-wlan)# end
   ```

Configure web authentication for WLAN with split authentication and authorization servers

This section explains how to configure web authentication for WLAN with split authentication and authorization servers on a wireless controller.

Configure authentication and authorization list for web authentication (GUI)

Use this procedure to configure authentication and authorization list for web authentication using GUI.

Configure authentication and authorization lists to secure web authentication on WLANs using the GUI.

This task ensures only authorized users can access the WLAN, and that access policies are applied during web authentication by assigning the correct authentication and authorization lists.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.

2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID**, and the **WLAN ID**.
4. In the **Security** > **Layer2** tab, uncheck the **WPAPolicy**, **AES** and **802.1x** check boxes.
5. Check the **MAC Filtering** check box to enable the feature. With MAC Filtering enabled, select the authorization list from the **Authorization List** drop-down list.
6. In the **Security** > **AAA** tab, select the authentication list from the **Authentication List** drop-down list.
7. Click **Apply to Device**.

Configure authentication and authorization list for web authentication (CLI)

Use this procedure to configure authentication and authorization list for web authentication using commands.

Enable web-based authentication and authorization for users connecting to a specified WLAN using commands.

Web authentication allows users to be authenticated through a web browser before gaining access to network resources.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id ssid-name
   ```

   - *wlan-name* : is the name of the configured WLAN.
   - *wlan-id* : is the wireless LAN identifier.
   - *SSID-name* : is the SSID name which can contain 32 alphanumeric characters.

   Note

   If you have already configured this command, enter **wlan** *wlan-name* command.

4. Disable WPA security.

Example

```
Device(config-wlan)# no security wpa
```

5. Disable security AKM for 802.1x.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

6. Disable WPA2 security.

Example

```
Device(config-wlan)# no security wpa wpa2
```

7. Enable authentication or authorization list for 802.1x security.

Example

```
Device(config-wlan)# security web-auth { authentication-list
authenticate-list-name | authorization-list authorize-list-name }
```

> **Note**
>
> When the WPA security, AKM for 802.1x, and WPA2 security settings are not disabled, the system displays the error:
>
> *% switch-1:dbm:wireless:web-auth cannot be enabled. Invalid WPA/WPA2 settings.*

8. Return to the privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Example

```
Device(config-wlan)# end
```

Verify split authentication and authorization configuration

This section explains how to verify split authentication and authorization configuration on a wireless controller.

To view the WLAN details, use this command:

```
Device# show run wlan

wlan wlan-foo 2 foo-ssid
security dot1x authentication-list authc-server-group
security dot1x authorization-list authz-server-group
wlan wlan-bar 3 bar-ssid
security web-auth authentication-list authc-server-group
security web-auth authorization-list authz-server-group
```

To view the AAA authentication and server details, use this command:

```
Device# show run aaa

!
aaa authentication dot1x default group radius
username cisco privilege 15 password 0 cisco
!
!
radius server free-radius-authc-server
 address ipv4 9.2.62.56 auth-port 1812 acct-port 1813
 key cisco
!
radius server cisco-catalyst-center-authz-server
 address ipv4 9.4.62.32 auth-port 1812 acct-port 1813
 pac key cisco
!
!
aaa new-model
aaa session-id common
!
```

To view the authentication and authorization list for 802.1X security, use this command:

```
Device# show wlan name wlan-foo | sec 802.1x

802.1x authentication list name               : authc-server-group
802.1x authorization list name                : authz-server-group
            802.1x                            : Enabled
```

To view the authentication and authorization list for web authentication, use this command:

```
Device# show wlan name wlan-bar | sec Webauth

Webauth On-mac-filter Failure             : Disabled
Webauth Authentication List Name          : authc-server-group
Webauth Authorization List Name           : authz-server-group
Webauth Parameter Map                     : Disabled
```

Configuration examples

This section provides sample configurations for authentication with a third-party RADIUS server.

Configure Cisco Catalyst 9800 Series Wireless Controller for authentication with a third-party RADIUS server: example

This example shows how to configure Cisco Catalyst 9800 Series Wireless Controller for authentication with a third-party RADIUS server:

```
Device(config)# radius server free-radius-authc-server

Device(config-radius-server)# address ipv4 9.2.62.56 auth-port 1812 acct-port
 1813

Device(config-radius-server)# key cisco

Device(config-radius-server)# exit

Device(config)# aaa group server radius authc-server-group

Device(config)# server name free-radius-authc-server

Device(config)# end
```

Configure Cisco Catalyst 9800 Series Wireless Controller for authorization with Cisco ISE or Cisco Catalyst Center: example

This example shows how to configure Cisco Catalyst 9800 Series Wireless Controller for authorization with Cisco ISE or Cisco Catalyst Center:

```
Device(config)# radius server cisco-catalyst-center-authz-server

Device (config-radius-server)# address ipv4 9.4.62.32 auth-port 1812 acct-port
 1813

Device (config-radius-server)# pac key cisco

Device (config-radius-server)# exit

Device(config)# aaa group server radius authz-server-group

Device(config)# server name cisco-catalyst-center-authz-server

Device(config)# end
```

RADIUS Message-Authenticator support for non-EAP requests

Introduces RADIUS Message-Authenticator support for non-EAP requests, explains sending and validating Message-Authenticator in request and response packets, outlines related configuration commands, and highlights protection against the Blast-RADIUS vulnerability (CVE-2024-3596).

A RADIUS Message-Authenticator configuration is a RADIUS server-group setting that:

- sends Message-Authenticator in every RADIUS request packet

- validates Message-Authenticator in every RADIUS response packet, and
- supports non-EAP RADIUS requests, including web authentication and management authentication.

Cisco IOS XE Release 17.18 provides the `send-ma` and `validate-ma` commands in RADIUS server-group configuration mode. Use these commands to configure Message-Authenticator handling for a RADIUS server group. The configuration helps protect against the Blast-RADIUS vulnerability (CVE-2024-3596).

Configure RADIUS Message-Authenticator support for non-EAP requests (CLI)

Provides instructions for configuring a RADIUS server group to send and validate Message-Authenticator attributes in every non-EAP request and response using CLI, supporting authentication methods such as web and management authentication.

Configure a RADIUS server group to send Message-Authenticator in every request and validate Message-Authenticator in every response.

Use this task when the RADIUS server supports Message-Authenticator responses for non-EAP authentication methods, such as web authentication and management authentication.

Before you begin

- Ensure that a RADIUS server group is available.
- Confirm that the RADIUS server supports Message-Authenticator responses for non-EAP authentication methods.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the RADIUS server group name and server group configuration.

   Example

   ```
   Device(config)# aaa group server radius radius-group-name
   ```

3. Send Message-Authenticator in every request packet.

   Example

   ```
   Device(config-sg-radius)# send-ma
   ```

4. Validate Message-Authenticator in every response packet.

   Example

   ```
   Device(config-sg-radius)# validate-ma
   ```

The device sends Message-Authenticator in every RADIUS request, including non-EAP requests, and validates Message-Authenticator in every RADIUS response for the configured RADIUS server group.

143 CUI Information in RADIUS Accounting

Topics:

- CUI information in RADIUS accounting request

Outlines the use and configuration of Chargeable User Identity information in RADIUS accounting requests, including authentication prerequisites, supported modes, and verification procedures for wireless controllers.

CUI information in RADIUS accounting request

This topic explains how Chargeable User Identity (CUI) is used as a unique identifier for clients in RADIUS accounting requests, and how it is processed and transmitted between the controller and AAA server.

Chargeable User Identity (CUI) is a unique identifier for a client visiting a network that

- is distinct from the outer identity or device used for login
- serves as an obscured version of a username, and
- can be used as an alternative for a client's username during authentication.

Feature History

Feature Name	Release	Description
Chargeable UserIdentity in RADIUS Accounting	Cisco IOS XE 17.9.1	Chargeable User Identity (CUI) is a unique identifier for a client visiting a network. This attribute can be used as an alternative for the client's username as part of the authentication process. The **access-session wireless cui-enable** command is introduced.

Processing of CUI in RADIUS accounting requests

To handle RADIUS attribute 89 processing, attach a null value of CUI to an access request sent to a AAA server.

Use the **access-session wireless cui-enable** command. A CUI-capable AAA server sends the CUI string to the controller as part of an access-accept message.

The controller then sends this received CUI attribute in accounting packets and other access-request packets, if any.

Prerequisites and restrictions

Use these guidelines when configuring AAA override. Understand the supported authentication protocols and controller modes to ensure proper operation.

Ensure that AAA override is enabled.

Restrictions

Adhere to these restrictions when configuring AAA override:

- Only 802.1x network authentication protocol is supported.
- Inter-Release Controller Mobility (IRCM) is not supported.
- FlexConnect local authentication is not supported. Only local mode and FlexConnect central authentication mode is supported.

Add CUI information in a RADIUS accounting request

Use this procedure to add CUI information in a RADIUS accounting request to enhance the data sent to the AAA server.

Enhance RADIUS accounting requests by including CUI information for better tracking and management.

This configuration is useful in environments where detailed user session information is required for auditing and reporting purposes.

Before you begin

Ensure that the RADIUS server is properly configured to handle CUI attributes.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Add CUI attribute in authentication and accounting messages sent to the AAA server.

   Example

   ```
   Device(config)# access-session wireless cui-enable
   ```

The CUI information is now included in RADIUS accounting requests, allowing for enhanced tracking and management of user sessions.

Verify CUI information in a RADIUS accounting request

Verify CUI information in a RADIUS accounting request on a wireless controller.

To view the CUI attribute in an accounting request on aAAA server, use this command:

```
Device# show wireless client mac-address aaa.bbb.ccc.ddd detail
.
.
.
Session Manager:
  Point of Attachment : capwap_90000005
  IIF ID              : 0x90000005
  Authorized          : TRUE
  Session timeout     : 1800
  Common Session ID: 8A45400A0000000CE0527C5F
  Acct Session ID  : 0x00000003
  Last Tried Aaa Server Details:
        Server IP : 10.64.69.141
  Auth Method Status List
        Method : Dot1x
                 SM State         : AUTHENTICATED
                 SM Bend State    : IDLE
  Local Policies:
        Service Template : wlan_svc_default-policy-profile_local (priority
254)
                 VLAN             : 59
                 Absolute-Timer   : 1800
  Server Policies:
                 CUI              : 13e158006855c2ff718cc84487653f5a6ea55def
  Resultant Policies:
                 CUI              : 13e158006855c2ff718cc84487653f5a6ea55def
                 VLAN Name        : VLAN0059
```

```
                VLAN              : 59
                Absolute-Timer    : 1800
```

144 Secure LDAP

Topics:

- Lightweight Directory Access Protocol (LDAP)

Lightweight Directory Access Protocol (LDAP)

Explains how Lightweight Directory Access Protocols (LDAPs) function as client-server protocols for directory information management and their use in secure authentication and authorization.

A Lightweight Directory Access Protocol (LDAP) is a client-server protocol that

- allows clients to access and manage directory information stored on servers
- supports user authentication and authorization using operations such as bind and search, and
- operates over TCP/IP on port 389, optionally using Transport Layer Security (TLS) for secure communications.

Transport Layer Security (TLS)

Transport Layer Security (TLS) is an application-level protocol that enables secure data transactions by providing privacy, authentication, and data integrity. TLS relies on certificates, public keys, and private keys to prove the identity of clients.

Certificate Authorities (CAs) issue the certificates.

Each certificate includes these:

- The name of the authority that issued it.
- The name of the entity to which the certificate was issued.
- The public key of the entity.
- The timestamps indicating the expiration date of the certificate.

TLS support for LDAP is described in RFC 2830, which is an extension to the LDAP protocol.

LDAP Operations

Bind

The bind operation authenticates a user to the server and starts a connection with the LDAP server. LDAP is a connection-oriented protocol. The client specifies the protocol version and authentication information.

LDAP supports these binds:

- Authenticated bind: An authenticated bind is performed when a root Distinguished Name (DN) and password are available.
- Anonymous bind: An anonymous bind is performed when no root DN and password are provided.

In LDAP deployments, the search operation is commonly performed before the bind operation. If a password attribute is returned as part of the search operation, the LDAP client can verify the password locally, eliminating the need for an extra bind operation. If the password attribute is not returned, the bind operation can occur later. Another advantage of performing the search operation first is that the LDAP client can use the DN received in the search result as the user DN, instead of constructing it by prefixing the username (cn attribute) with the base DN. All entries stored in an LDAP server have a unique DN.

The DN consists of two parts:

- Relative Distinguished Name (RDN)
- Location in the LDAP server where the record resides.

Most of the entries that you store in an LDAP server will have a name, and the name is frequently stored in the Common Name (cn) attribute. Because every object has a name, most objects stored in an LDAP server use their cn value as the basis for their RDN.

Search

A search operation is used to search the LDAP server. The client specifies the starting point (base DN) of the search, the search scope (either the object, its children, or the subtree rooted at the object), and a search filter.

For authorization requests, the search operation is performed without a bind operation. The LDAP server must be configured with sufficient privileges for the search operation to succeed. These privileges are established during the bind operation.

An LDAP search operation can return multiple entries for a specific user. When this occurs, the LDAP client returns an error code to AAA. To prevent these errors, configure search filters to match only a single entry.

Compare

The compare operation replaces a bind request for authentication and helps maintain the initial bind parameters for the connection.

LDAP Dynamic Attribute Mapping

The Lightweight Directory Access Protocol (LDAP) is a powerful and flexible protocol for communication with AAA servers. LDAP attribute maps provide a method to cross-reference attributes retrieved from a server with Cisco attributes supported by security appliances.

When a user authenticates to a security appliance, the appliance authenticates the server and uses LDAP to retrieve the user's record. The record consists of LDAP attributes associated with fields displayed on the server's user interface. Each attribute retrieved includes a value entered by the administrator responsible for updating user records.

SLDAP prerequisite

This section explains the prerequisites for configuring SLDAP on a wireless controller.

This section lists the prerequisite for setting up SLDAP on a wireless controller and describes when to configure certificates.

- If you are using a Transport Layer Security (TLS) secure connection, you must configure X.509 certificates.

SLDAP restrictions

This section explains the restrictions for configuring SLDAP on a wireless controller.

- LDAP referrals are not supported.
- The LDAP server’s unsolicited messages or notifications are not handled.
- LDAP authentication is not supported for interactive terminal sessions.

Configure SLDAP (CLI)

Use this procedure to configure SLDAP on a wireless controller.

Set up Secure LDAP (SLDAP) for authentication and directory queries on the wireless controller using commands.

Before you begin

Ensure you have administrator access to the controller. Gather LDAP server details (IP address, base DN, credentials).

Procedure

1. Enable privileged EXEC mode.

Example

```
Device# enable
```

Enter your password if prompted.

2. Enter the global configuration mode.

Example

```
Device# configure terminal
```

3. Define a Lightweight Directory Access Protocol (LDAP) server and enter the LDAP server configuration mode.

Example

```
Device(config)# ldap server server-name
```

4. Specify the LDAP server IP address using IPv4.

Example

```
Device(config-ldap-server)# ipv4 ipv4-address
```

5. Specify the number of seconds the Cisco Catalyst 9800 Series Wireless Controller or the embedded wireless controller waits for a reply to a LDAP request before retransmitting the request.

Example

```
Device(config-ldap-server)# timeout retransmit seconds
```

6. Specify a shared secret text string used between the Cisco Catalyst 9800 Series Wireless Controller or the embedded wireless controller and a LDAP server.

Example

```
Device(config-ldap-server)# bind authenticate root-dn
CN=ldapipv6user,CN=Users,DC=ca,DC=ssh2,DC=com password Cisco12345
```

Use the **0** line option to configure an unencrypted shared secret.

Use the **7** line option to configure an encrypted shared secret.

7. Specify the base Distinguished Name (DN) of the search.

Example

```
Device(config-ldap-server)# base-dn string CN=Users,DC=ca,DC=ssh2,DC=com
```

8. Configure LDAP to initiate the TLS connection and specify the secure mode.

Example

```
Device(config-ldap-server)# mode secure no- negotiation
```

9. Return to the privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Example

```
Device(config-ldap-server)# end
```

Configure a AAA server group (GUI)

Use this procedure to configure a AAA server group using a GUI.

Configure a AAA server group using the GUI for RADIUS, TACACS+, or LDAP server hosts using the GUI.

Configuring a device to use AAA server groups helps you group existing server hosts, select a subset of those hosts, and assign them for a particular service. A server group is used with a global server-host list. The server group lists the IP addresses of the selected server hosts.

You can create these server groups:

Before you begin

Procedure

1. RADIUS
   a) Choose **Services** > **Security** > **AAA** > **Server Groups** > **RADIUS**.
   b) Click the **Add** button. The **Create AAA Radius Server Group** dialog box appears.
   c) Enter a name for the RADIUS server group in the **Name** field.
   d) Select a desired delimiter from the **MAC-Delimiter** drop-down list. The available options are colon, hyphen, and single-hyphen.
   e) Select a desired filter from the **MAC-Filtering** drop-down list. The available options are mac and Key.
   f) Enter a value in the **Dead-Time (mins)** field to make a server non-operational. You must specify a value between 1 and 1440.
   g) Choose any of the available servers from the **Available Servers** list and move them to the **Assigned Servers** list by clicking the **>** button.
   h) Click the **Save & Apply to Device** button.

2. TACACS+
   a) Choose **Services** > **Security** > **AAA** > **Server Groups** > **TACACS+**.
   b) Click the **Add** button. The **Create AAA Tacacs Server Group** dialog box appears.
   c) Enter a name for the TACACS server group in the **Name** field.
   d) Choose any of the available servers from the **Available Servers** list and move them to the **Assigned Servers** list by clicking the **>** button.
   e) Click the **Save & Apply to Device** button.

3. LDAP
   a) Choose **Services** > **Security** > **AAA** > **Server Groups** > **LDAP**.
   b) Click the **Add** button. The **Create AAA Ldap Server Group** dialog box appears.
   c) Enter a name for the LDAP server group in the **Name** field.
   d) Choose any of the available servers from the **Available Servers** list and move them to the **Assigned Servers** list by clicking the **>** button.
   e) Click the **Save & Apply to Device** button.

Configure a AAA server group (CLI)

Use this procedure to configure a AAA server group using commands.

Establish a AAA server group for centralized authentication, authorization, and accounting using commands.

AAA server groups allow you to centrally manage user access and policy enforcement with protocols such as LDAP, RADIUS, or TACACS+.

Procedure

1. Enable the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Enable AAA.

   Example

   ```
   Device(config)# aaa new-model
   ```

4. Define the AAA server group with a group name and enter the LDAP server group configuration mode.

   Example

   ```
   Device(config)# aaa group server ldap group-name
   ```

   All members of a group are of the same type: RADIUS, LDAP, or TACACS+.

5. Associate a particular LDAP server with the defined server group.

   Example

   ```
   Device(config-ldap-sg)# server server-name
   ```

   Each security server is identified by its IP address and UDP port number.

6. Exit the LDAP server group configuration mode.

   Example

   ```
   Device(config-ldap-sg)# exit
   ```

Configure search and bind operations for authentication requests (CLI)

Use this procedure to configure search and bind operations for an authentication request on a wireless controller.

Enable LDAP-based authentication by defining how the controller searches and binds user credentials during authentication requests using commands.

Configuring search and bind operations determines whether the LDAP server first binds the user and then performs a search, or compares credentials without binding. This affects how authentication requests are processed on the controller.

Procedure

1. Enable the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Enable AAA.

   Example

   ```
   Device(config)# aaa new-model
   ```

4. Define a Lightweight Directory Access Protocol (LDAP) server and enter the LDAP server configuration mode.

   Example

   ```
   Device(config)# ldap server server-name
   ```

5. Configure the sequence of search and bind operations for an authentication request.

   Example

   ```
   Device(config-ldap-server)# authentication bind-first
   ```

6. Replace the bind request with the compare request for authentication.

   Example

   ```
   Device(config-ldap-server)# authentication compare
   ```

7. Exit the LDAP server group configuration mode.

Example

```
Device(config-ldap-server)# exit
```

Configure a dynamic attribute map on a SLDAP server (CLI)

Use this procedure to configure a dynamic attribute map on a SLDAP server on a wireless controller.

Configure dynamic LDAP attribute maps to ensure seamless interoperability between user-defined attribute names and Cisco attribute requirements on a wireless controller using commands.

You must create LDAP attribute maps that map your existing user-defined attribute names and values to Cisco attribute names and values that are compatible with the security appliance. You can then bind these attribute maps to LDAP servers or remove them as required.

> **Note**
>
> To use the attribute mapping features correctly, make sure you understand Cisco LDAP and user-defined attribute names and values.

Before you begin

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Configure a dynamic LDAP attribute map and enter the attribute-map configuration mode.

   Example

   ```
   Device(config)# ldap attribute-map map-name
   ```

4. Define an attribute map.

   Example

   ```
   Device(config-attr-map)# map type ldap-attr-type aaa-attr-type
   ```

5. Exit the attribute-map configuration mode.

Example

```
Device(config-attr-map)# exit
```

Verify the SLDAP configuration

This section provides the show commands to verify the secure LDAP configuration.

To view details about the default LDAP attribute mapping, use this command:

```
Device# show ldap attributes
```

To view the LDAP server state information and various other counters for the server, use this command:

```
Device# show ldap server
```

145 Network Access Server Identifier

Topics:

- Network Access Server Identifier (NAS-ID)

Network Access Server Identifier (NAS-ID)

Explains the Network Access Server Identifier (NAS-ID) and how it is used to inform the RADIUS server of a RADIUS access request, enabling it to select a policy for that request.

A network access server identifier (NAS-ID) is a RADIUS attribute that

- identifies the source device, WLAN profile, VLAN interface, or AP group initiating a RADIUS access request
- enables the RADIUS server to apply appropriate authentication and policy selection, and
- supports customized policy enforcement based on user groups or device types.

The NAS-ID is sent to the RADIUS server by the controller through an authentication request to classify users to different groups. This enables the RADIUS server to send a customized authentication response.

Starting with Cisco IOS XE Cupertino 17.7.1, a new string named custom-string (custom string) is available.

> **Note**
>
> The acct-session-id is sent with the RADIUS access request only if accounting is enabled on the policy profile.

If you configure a NAS-ID for an AP group, it overrides the NAS-ID that is configured for a WLAN profile or the VLAN interface. Similarly, if you configure a NAS-ID for a WLAN profile, it overrides the NAS-ID that is configured for the VLAN interface.

These options can be configured for a NAS ID:

- sys-name (System Name)
- sys-ip (System IP Address) and sys-mac (System MAC Address)
- ap-ip (AP's IP address) and ap-name (AP's Name)
- ap-mac (AP's MAC Address)
- ap-eth-mac (AP's Ethernet MAC Address)
- ap-policy-tag (AP's policy tag name)
- ap-site-tag (AP's site tag name)
- ssid (SSID Name) and ap-location (AP's Location)
- custom-string (custom string)

Create a NAS ID policy (GUI)

Use this procedure to create a NAS ID policy using GUI.

Configure a NAS ID policy that defines how network access server identifiers are applied within your wireless AAA policy using the GUI.

Creating a NAS ID policy ensures correct identification and handling of wireless authentication requests. This is typically performed when setting up or modifying wireless AAA policies.

Procedure

1. Choose **Configuration** > **Security** > **Wireless AAA Policy**.
2. On the **Wireless AAA Policy** page, click the name of the **Policy** or click **Add** to create a new one.
3. In the **Add/Edit Wireless AAA Policy** window that is displayed, enter the name of the policy in the **Policy Name** field.
4. Select from one of the NAS ID options from the **Option 1** drop-down list.
5. Select from one of the NAS ID options from the **Option 2** drop-down list.
6. Select from one of the NAS ID options from the **Option 3** drop-down list.
7. Save the configuration.

Create a NAS ID policy (CLI)

Use this procedure to create a NAS ID policy on a wireless controller.

Create and configure a NAS ID policy for wireless RADIUS authentication and accounting using commands.

Follow the procedure given below to create NAS ID policy:

Before you begin

- A NAS ID can combine up to a maximum of three options.
- The maximum length of the NAS ID attribute is 253. Before adding a new attribute, the system checks the attribute buffer. If there is not enough space, the system ignores the new attribute.
- By default, a wireless aaa policy (default-aaa-policy) is created with the default configuration (sys-name). You can update this policy with various NAS ID options. However, the default-aaa-policy cannot be deleted.
- If you do not configure a NAS ID, the system uses the default sys-name as the NAS ID for all wireless-specific RADIUS packets (authentication and accounting) from the controller .
- Starting with Cisco IOS XE Cupertino 17.7.1, you can configure a custom NAS ID string using combinations of option1, option2, and option3 (**nas-id option3custom-string***custom-string*) for RADIUS packets.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a new AAA policy.

   Example

   ```
   Device(config)# wireless aaa policy policy-name
   ```

3. Configure NAS ID for option1.

Example

```
Device(config-aaa-policy)# nas-id option1 sys-name
```

4. Configure NAS ID for option2.

Example

```
Device(config-aaa-policy)# nas-id option2 sys-ip
```

5. Configure NAS ID for option3.

Example

```
Device(config-aaa-policy)# nas-id option3 sys-mac
```

Attach a policy to a tag (GUI)

Use this procedure to attach a policy to a tag using GUI.

Map a policy to a tag for consistent network device configuration using the GUI.

Attach a predefined policy to a tag to apply specific settings or profiles across selected devices.

Before you begin

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click **Add** and enter a name for the new policy, for example, test1, in the **General** tab.
3. Click the **Advanced** tab, and under **AAA Policy**, from the **Policy Name** drop-down list, select the policy name that you had created in the **General** tab.
4. Click **Apply to Device**.
5. Choose **Configuration** > **Tags & Profiles** > **Tags** > **Policy**.
6. Click **Add** to view the **Add Policy Tag** window.
7. Enter a name and description for the policy tag.
8. Click **Add** to map WLAN profile and policy profile.
9. Choose the **WLAN Profile** to map with the appropriate **Policy Profile**, and click the tick icon. Click **Save & Apply to Device**.

Attach a policy to a tag (CLI)

Use this procedure to attach a policy to a tag using commands.

Configure and attach a NAS ID policy to a wireless policy tag using commands.

Follow the procedure given below to attach a NAS ID policy to a tag:

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN policy profile.

   Example

   ```
   Device(config)# wireless profile policy policy-name
   ```

3. Configure a AAA policy profile.

   Example

   ```
   Device(config-wireless-policy)# aaa-policy aaa-policy-name
   ```

4. Return to the global configuration mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

5. Configure a wireless policy tag.

   Example

   ```
   Device(config)# wireless tag policy policy-tag
   ```

6. Map a WLAN profile to a policy profile.

   Example

   ```
   Device(config)# wlan wlan1 policy policy-name
   ```

   Note

   You can also use the **ap-tag** option to configure a NAS ID for an AP group. This NAS ID overrides the NAS ID configured for a WLAN profile or VLAN interface.

Verify the NAS ID configuration

This section provides the show commands to verify NAS ID configuration.

Use this **show** command to verify the NAS ID configuration:

```
Device# show wireless profile policy detailed test1

Policy Profile Name           : test1
Description                   :
Status                        : ENABLED
VLAN                          : 1
Client count                  : 0

:
:
AAA Policy Params
  AAA Override                : DISABLED
  NAC                         : DISABLED
  AAA Policy name             : test
```

146 Locally Significant Certificates

Topics:

- Locally significant certificates
- Provisioning locally significant certificates
- AP certificate renewal (LSC)
- MIC and LSC APs joining the controller
- LSC fallback APs
- Configuring controller self-signed certificate for wireless AP join

Outlines the concepts, provisioning workflows, renewal processes, controller integration, fallback mechanisms, and configuration procedures for Locally Significant Certificates (LSC) in wireless deployments, guiding users through AP certificate management, controller settings, and related operational tasks.

Locally significant certificates

Explains how to configure a wireless controller and LAP to use the locally significant certificate (LSC).

A locally significant certificate (LSC) is a PKI certificate that

- provides mutual authentication between Cisco Catalyst 9800 Series Wireless Controller and Lightweight Access Points (LAPs)
- generates certificates directly on APs and controllers, and
- enables organizations to use their own PKI for better security control and Certificate Authority (CA) management.

LSC provisioning and communication process

You need to provision the new LSC certificate on the controller and then the Lightweight Access Point (LAP) from the CA Server.

The LAP communicates with the controller using the CAPWAP protocol. Any request to sign the certificate and issue the CA certificates for LAP and controller itself must be initiated from the controller. The LAP does not communicate directly with the CA server. The CA server details must be configured on the controller and must be accessible.

The controller makes use of the Simple Certificate Enrollment Protocol (SCEP) to forward certReqs generated on the devices to the CA and makes use of SCEP again to get the signed certificates from the CA.

The SCEP is a certificate management protocol that the PKI clients and CA servers use to support certificate enrollment and revocation. It is widely used in Cisco and supported by many CA servers. In SCEP, HTTP is used as the transport protocol for the PKI messages. The primary goal of SCEP is the secure issuance of certificates to network devices. SCEP is capable of many operations, but for our release, SCEP is utilized for the following operations:

- CA and Router Advertisement (RA) Public Key Distribution
- Certificate Enrollment

Certificate provisioning in controllers

Explains the provisioning of new LSC certificates (CA and device) on the controller.

Certificate provisioning in controllers is a security process that you use to:

- Install new Locally Significant Certificate (LSC) certificates (both Certificate Authority (CA) certificates and device certificates) on the controller
- Use Simple Certificate Enrollment Protocol (SCEP) to receive Certificate Authority (CA) certificates from the CA server during initial setup when the controller has no certificates, and
- Push the same Certificate Authority (CA) certificates to Access Points (APs) when you provision the Access Points (APs) with Locally Significant Certificates (LSCs).

RSA keypair recommendations

These recommendations apply when configuring PKI certificates with RSA keypairs:

Note

We recommend that you use a new RSA keypair name for the newly configured PKI certificate. If you want to reuse an existing RSA keypair name (that is associated with an old certificate) for a new PKI certificate, do either of the following:

- Do not regenerate a new RSA keypair with an existing RSA keypair name. Instead, reuse the existing RSA keypair name. All certificates associated with the existing RSA keypair become invalid when you regenerate a new RSA keypair with an existing name.
- Remove the old PKI certificate configurations before reusing the existing RSA keypair name for the new PKI certificate.

How device certificate enrollment works

Learn how to enroll device certificates through CA-signed certificate requests using PKCS#10 and SCEP protocols.

When your Lightweight Access Point (LAP) and controller request Certificate Authority (CA)-signed certificates, they send the certRequest as a PKCS#10 message. The Certificate Authority (CA) receives a PKCS#10 certRequest. The Certificate Authority (CA) requires additional information to authenticate the identity of the requester and verify that the request is unaltered.

Summary

The key components involved in the device certificate enrollment process are:

- Lightweight Access Point (LAP) and controller: request Certificate Authority (CA)-signed certificates by sending PKCS#10 messages. These messages contain Subject Name, Public Key, and other attributes.
- Certificate Authority (CA): transforms the certRequest into an X.509 certificate after authentication and verification
- PKCS#10 certRequest: contains digitally signed certificate request information including Subject Name and Public Key
- Simple Certificate Enrollment Protocol (SCEP) client: provides functionality to wrap PKCS#10 in PKCS#7 Signed Data message type

Workflow

Your device certificate enrollment process works through these stages:

1. The Lightweight Access Point (LAP) and controller create a PKCS#10 certificate request containing the Subject Name, Public Key, and other attributes to be included in the X.509 certificate, and digitally sign it with the Private Key of the requester.
2. The PKCS#10 is wrapped in a PKCS#7 Signed Data message type as part of the Simple Certificate Enrollment Protocol (SCEP) client functionality, and the PKCSReq message is sent to the controller.
3. The Certificate Authority (CA) receives the PKCS#10 certRequest and authenticates the identity of the requester and verifies that the request is unaltered.
4. The Certificate Authority (CA) transforms the certRequest into an X.509 certificate.

Result

Upon successful enrollment operation, both the Certificate Authority (CA) and device certificates are available on the controller.

How certificate provisioning works on lightweight APs

Describes how lightweight APs provision new certificates through CAPWAP mode using controller-assisted certificate requests and automated installation processes.

Certificate provisioning enables lightweight APs (LAPs) to obtain new signed X.509 certificates while operating in CAPWAP mode. This process ensures secure communications between APs and controllers using updated security credentials.

Summary

The key components involved in certificate provisioning on lightweight APs are:

- Lightweight Access Point (LAP): Initiates certificate requests and receives new certificates while in CAPWAP mode
- Controller: Acts as a CA proxy to help obtain signed certificates from the Certificate Authority for the LAP
- Certificate Authority (CA): Signs and validates certificate requests to issue new X.509 certificates
- LWAPP payloads: Transport mechanism for certificate requests and responses between LAP and controller

Workflow

These stages describe how certificate provisioning works on lightweight APs:

1. The LAP sends a certificate request to the controller to obtain a new signed X.509 certificate.

   The controller acts as a CA proxy and helps obtain the certificate request signed by the CA for the LAP.
2. The certificate requests and certificate responses are transmitted between the LAP and controller using LWAPP payloads.
3. Both the LSC CA and LAP device certificates are installed in the LAP, and the system reboots automatically.
4. When the system comes up after reboot, the AP sends the LSC device certificate to the controller as part of the JOIN Request because it is configured to use LSCs.

   As part of the JOIN Response, the controller sends the new device certificate and validates the inbound LAP certificate with the new CA root certificate.

What's next

To configure, authorize, and manage certificate enrollment with the existing PKI infrastructure for controller and AP, you need to use the LSC provisioning functionality.

Restrictions for locally significant certificates

Lists restrictions for locally significant certificates.

- The locally significant certificate (LSC) workflow differs in FIPS and WLANCC mode. Your Certificate Authority (CA) server must support Enrollment over Secure Transport (EST) protocol. Your CA server must also issue EC certificates in FIPS and WLANCC mode.
- The Elliptic Curve Digital Signature Algorithm (ECDSA) cipher works only if both your AP and controller have EC certificates provisioned with LSC.
- EC certificates (LSC-EC) can be provisioned only if CA server supports EST (and not SCEP).
- You must configure FIPS and CC security modes to provision EC certificates.
- Correct all AP misconfigurations before you enable LSC. You can view the count for misconfigured APs in the output of this **show** command:

```
Device# show wireless summary
Priming controller         : DISABLED
```

```
Max APs supported          : 3000
Max clients supported      : 32000
Access Point Summary
                       Total    Up    Down
-----------------------------------------
802.11 2.4GHz              2     2       0
802.11 5GHz                5     2       3
802.11 6GHz                1     1       0
802.11 dual-band           2     0       2
802.11 dual-band(5/6GHz)   0     0       0
802.11 rx-dual-band        0     0       0
Client Serving(2.4GHz)     3     1       2
Client Serving(5GHz)       4     1       3
Client Serving(6GHz)       1     1       0
Monitor(Dual band)         0     0       0
Monitor(2.4GHz)            1     1       0
Monitor(5GHz)              1     1       0
Monitor(6GHz)              0     0       0
Sniffer(Dual band)         0     0       0
Sniffer(2.4GHz)            0     0       0
Sniffer(5GHz)              0     0       0
Sniffer(6GHz)              0     0       0
Misconfigured APs          1 (For more info use 'show ap tag summary')
```

For more information about misconfigured APs, run the **wireless config validate** command. To view reported errors, run the **show wireless config validation status** command.

Provisioning locally significant certificates

Details the configuration, provisioning, management, and verification of locally significant certificates (LSCs), including RSA key and PKI trustpoint setup, certificate enrollment, AP LSC provisioning, trustpool management, and secure wireless network authentication using both GUI and CLI procedures.

Configure RSA key for PKI trustpoint

Configure RSA key for PKI trustpoint on a wireless controller.

Generate RSA cryptographic keys for PKI trustpoint authentication and secure communications.

RSA keys are essential components of PKI infrastructure, providing the cryptographic foundation for certificate-based authentication and encryption on wireless controllers.

Before you begin

Ensure the device is in a stable operational state and has sufficient processing resources for key generation.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Generate RSA key for PKI trustpoint.

Example

```
Device(config)# crypto key generate rsa exportable general-keys modulus
key-size label RSA-key-label
```

Example

```
Device(config)# crypto key generate rsa exportable
general-keys modulus 2048 label lsc-tp
```

exportable is an optional keyword. You may or may not want to configure an exportable-key. If selected, you can export the key out of the box, if required.

- *key-size*: Size of the key modulus. The valid range is from 2048 to 4096.
- *RSA-key-label*: RSA key pair label.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The RSA key is successfully generated and labeled for use with PKI trustpoint configurations.

Configure PKI trustpoint parameters

Configure RSA key for PKI trustpoint.

Configure a PKI trustpoint with RSA key parameters for certificate enrollment and authentication.

PKI trustpoints define the relationship between the device and a Certificate Authority (CA), enabling secure certificate-based authentication and encryption.

Before you begin

Ensure the CA server is accessible and configured to accept certificate requests.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Create a new trustpoint for an external CA server.

Example

```
Device(config)# crypto pki trustpoint trustpoint-name
```

Example

```
Device(config)# crypto pki trustpoint microsoft-ca
```

The *trustpoint-name* refers to the trustpoint name.

3. Specify the URL of the CA on which your router should send certificate requests.

Example

```
Device(ca-trustpoint)# enrollment url HTTP-URL
```

Example

```
Device(ca-trustpoint)# enrollment url http://CA_server/certsrv/mscep/mscep.dll
```

HTTP-URL: URL of the file system where your router should send certificate requests. An IPv6 address can be added in the URL enclosed in brackets. For example: http://[2001:DB8:1:1::1]:80. For more enrollment method options, see the enrollment url (ca-trustpoint) command page.

4. Create subject name parameters for the trustpoint.

Example

```
Device(ca-trustpoint)# subject-name subject-name
```

Example

```
Device(ca-trustpoint)# subject-name C=IN, ST=KA, L=Bengaluru, O=Cisco,
CN=eagle-eye/emailAddress=support@abc.com
```

5. Map RSA key with that of the trustpoint.

Example

```
Device(ca-trustpoint)# rsakeypair RSA-key key-size
```

Example

```
Device(ca-trustpoint)# rsakeypair ewlc-tp1
```

- *RSA-key*: RSA key pair label.
- *key-size*: Signature key length. Range is from 360 to 4096.

6. Configure revocation checking method.

Example

```
Device(ca-trustpoint)# revocation {crl | none | ocsp}
```

Example

```
Device(ca-trustpoint)# revocation none
```

7. Return to privileged EXEC mode.

Example

```
Device(ca-trustpoint)# end
```

The PKI trustpoint is now configured with the specified parameters and ready for certificate enrollment operations.

Authenticate and enroll a Public Key Infrastructure (PKI) trustpoint (GUI)

Use this procedure to authenticate and enroll a Public Key Infrastructure (PKI) trustpoint through the device's graphical user interface.

Use this procedure to add and authenticate a Public Key Infrastructure (PKI) trustpoint to enable certificate-based security for your device.

Before you begin

Obtain the enrollment URL and certificate authority information from your network administrator.

Procedure

---

1. Choose **Configuration** > **Security** > **Public Key Infrastructure (PKI) Management**.
2. In the **Public Key Infrastructure (PKI) Management** window, click the **Trustpoints** tab.
3. In the **Add Trustpoint** dialog box, provide this information:
   a) In the **Label** field, enter the RSA key label.
   b) In the **Enrollment URL** field, enter the enrollment URL.
   c) Check the **Authenticate** check box to authenticate the Public Certificate from the enrollment URL.
   d) In the **Subject Name** section, enter the **Country Code**, **State**, **Location**, **Organization**, **Domain Name**, and **Email Address**.
   e) Check the **Key Generated** check box to view the available RSA keypairs. Choose an option from the **Available RSA Keypairs** drop-down list.
   f) Check the **Enroll Trustpoint** check box.
   g) In the **Password** field, enter the password.
   h) In the **Re-Enter Password** field, confirm the password.
   i) Click **Apply to Device**.

   The new trustpoint is added to the trustpoint name list.

The new trustpoint is now listed in the trustpoint name list and is ready for use.

What to do next

After enrolling the trustpoint, configure it for use with your security policies or certificate-based authentication features.

Authenticate and enroll the PKI trustpoint with CA server (CLI)

Configure authentication and enrollment of a PKI trustpoint with CA server using commands.

Establish secure communication between the device and Certificate Authority by authenticating and enrolling a PKI trustpoint.

PKI trustpoints enable secure certificate-based authentication. The authentication process fetches the CA certificate, while enrollment generates and submits a certificate request to obtain a client certificate.

Before you begin

Ensure the PKI trustpoint is configured and the CA server is accessible.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Fetch the CA certificate.

   Example

   ```
   Device(config)# crypto pki authenticate trustpoint-name
   ```

   Example

   ```
   Device(config)# crypto pki authenticate microsoft-ca
   ```

3. Accept the CA certificate.

   Example

   ```
   Device(config)# % Do you accept this certificate? [yes/no]:
   yes Trustpoint CA certificate accepted.
   ```

4. Enroll the client certificate.

   Example

   ```
   Device(config)# crypto pki enroll trustpoint-name
   ```

   Example

   ```
   Device(config)# crypto pki enroll microsoft-ca
   %
   % Start certificate enrollment ..
   % Create a challenge password. You will need to verbally
   provide this password to the CA Administrator in order to
   revoke your certificate. For security reasons your password
   will not be saved in the configuration.
   Please make a note of it.
   ```

5. Enter a challenge password to the CA server.

Example

```
Device(config)# password
```

Example

```
Device(config)# abcd123
```

6. Re-enter the challenge password to the CA server.

Example

```
Device(config)# password
```

Example

```
Device(config)# abcd123
```

7. Include the router serial number in the subject name.

Example

```
Device(config)# % Include the router serial number
in the subject name? [yes/no]: yes
```

8. Exclude IP address from the subject name.

Example

```
Device(config)# % Include an IP address
in the subject name? [no]: no
```

9. Request certificate from CA.

Example

```
Device(config)#
Request certificate from CA? [yes/no]: yes
% Certificate request sent to Certificate Authority
% The 'show crypto pki certificate verbose
client' command will show the fingerprint.
```

10. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The PKI trustpoint is authenticated and enrolled with the CA server, enabling secure certificate-based communication.

Configure AP join attempts with LSC certificate

Learn how to configure AP join attempts with LSC certificate using the GUI.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. In the **All Access Points** window, click the LSC Provision name.
3. From the **Status** drop-down list, choose a status to enable LSC.
4. From the **Trustpoint Name** drop-down list, choose the trustpoint.
5. In the **Number of Join Attempts** field, enter the number of retry attempts that will be permitted.
6. Click **Apply**.

Configure AP join attempts with LSC certificate (CLI)

Configure AP join attempts with LSC certificate using commands.

Configure the maximum number of AP join failure attempts with a newly provisioned LSC certificate to ensure proper fallback to MIC when needed.

When APs attempt to join with LSC certificates and exceed the configured failure limit, they automatically fall back to using their Manufacturer Installed Certificate (MIC) for authentication.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the maximum number of AP join failure attempts with the newly provisioned LSC certificate.

   Example

   ```
   Device(config)# ap lsc-provision join-attempt number-of-attempts
   ```

   Example

   ```
   Device(config)# ap lsc-provision join-attempt 10
   ```

   When the number of AP joins exceed the specified limit, AP joins back with the Manufacturer Installed Certificate (MIC).

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The AP join attempt limit with LSC certificate is now configured. APs will fall back to MIC authentication after exceeding the specified number of failed join attempts.

Configure subject-name parameters in LSC certificate

Configure subject-name parameters in LSC certificate.

Configure the subject-name parameters that will be included in LSC certificates generated by access points.

Subject-name parameters define the identity information included in Local Significant Certificate (LSC) requests generated by access points. These parameters include geographical and organizational details that identify the certificate holder.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the attributes to be included in the subject-name parameter of the certificate request generated by an AP.

   Example

   ```
   Device(config)# ap lsc-provision subject-name-parameter
   country country-str state state-str city city-str domain domain-str org
   org-str email-address email-addr-str
   ```

   Example

   ```
   Device(config)# ap lsc-provision subject-name-parameter
   country India state Karnataka city Bangalore domain domain1 org
   Right email-address adc@gfe.com
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The subject-name parameters are now configured for LSC certificate generation on access points.

Configure key size for LSC certificate

Configure key size for LSC certificate.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Specify the size of keys to be generated for the LSC on AP.

Example

```
Device(config)# ap lsc-provision key-size key-size
```

Example

```
Device(config)# ap lsc-provision key-size 2048
```

Valid key size options are 2048, 3072, or 4096 bits.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configure trustpoint for LSC provisioning on an AP

Configure trustpoint for LSC provisioning on an access point.

Establish a trustpoint for Local Significant Certificate (LSC) provisioning to enable secure communication between access points and the controller.

LSC provisioning allows access points to obtain certificates from a designated trustpoint, enhancing network security through certificate-based authentication.

Before you begin

Ensure the trustpoint is properly configured and accessible on the network.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Specify the trustpoint with which the LSC is provisioned to an AP.

Example

```
Device(config)# ap lsc-provision trustpoint tp-name
```

Example

```
Device(config)# ap lsc-provision trustpoint microsoft-ca
```

The *tp-name* is the trustpoint name.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The trustpoint for LSC provisioning is now configured and ready to provision certificates to access points.

Configure an AP LSC provision list (GUI)

Configure an AP LSC provision list using GUI.

Procedure

---

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. In the **All Access Points** window, click the corresponding LSC Provision name.
3. From the **Status** drop-down list, choose a status to enable LSC.
4. From the **Trustpoint Name** drop-down list, choose a trustpoint.
5. In the **Number of Join Attempts** field, enter the number of retry attempts that are allowed.
6. From the **Key Size** drop-down list, choose a key.
7. In the **Edit AP Join Profile** window, click the **CAPWAP** tab.
8. In the **Add APs to LSC Provision List** section, click **Select File** to upload the CSV file that contains AP details.
9. Click **Upload File**.
10. In the **AP MAC Address** field, enter the AP MAC address. and add them. (The APs added to the provision list are displayed in the **APs in provision List** .)
11. In the **Subject Name Parameters** section, enter the following details:
    - **Country**
    - **State**
    - **City**
    - **Organization**
    - **Department**
    - **Email Address**
12. Click **Apply**.

Configure an AP LSC provision list (CLI)

Configure an AP LSC provision list using commands.

Add access points to the LSC provision list for certificate-based authentication.

The LSC provision list allows you to specify which access points can use locally significant certificates for authentication with the wireless controller.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Add the AP to the LSC provision list.

   Example

   ```
   Device(config)# ap lsc-provision mac-address mac-address
   ```

   Example

   ```
   Device(config)# ap lsc-provision
   mac-address 001b.3400.02f0
   ```

   Note

   You can provision a list of APs using the **ap lsc-provision provision-list** command.

   (Or)

   You can provision all the APs using the **ap lsc-provision** command.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The AP is now added to the LSC provision list and can use locally significant certificates for authentication.

Configure LSC provisioning for all the APs (GUI)

Configure LSC provisioning for all the APs using GUI.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. In the **Access Points** window, expand the **LSC Provision** section.
3. Set **Status** to **Enabled** state.

> **Note**
>
> If you set **Status** to **Provision List**, LSC provisioning will be configured only for APs that are a part of the provision list.

4. From the **Trustpoint Name** drop-down list, choose the appropriate trustpoint for all APs.
5. In the **Number of Join Attempts** field, enter the number of retry attempts that the APs can make to join the controller.
6. From the **Key Size** drop-down list, choose the appropriate key size of the certificate:
   - **2048**
   - **3072**
   - **4096**
7. In the **Add APs to LSC Provision List** section, click **Select File** to upload the CSV file that contains the AP details.
8. Click **Upload File**.
9. In the **AP MAC Address** field, enter the AP MAC address. (The APs that are added to the provision list are displayed in the **APs in Provision List** section.)
10. In the **Subject Name Parameters** section, enter the following details:
    a. **Country**
    b. **State**
    c. **City**
    d. **Organization**
    e. **Department**
    f. **Email Address**
11. Click **Apply**.

Configure LSC provisioning for all APs (CLI)

Configure LSC provisioning for all APs using commands.

Enable LSC (Local Significant Certificate) provisioning across all access points to enhance security through automatic certificate management.

LSC provisioning allows access points to automatically obtain and manage security certificates, reducing manual certificate deployment overhead while maintaining secure wireless communications.

Before you begin

Ensure you have administrative access to the wireless controller and that all APs are properly registered with the controller.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enable LSC provisioning for all APs.

   Example

   ```
   Device(config)# ap lsc-provision
   ```

   By default, LSC provisioning is disabled for all APs.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

LSC provisioning is now enabled for all access points, allowing them to automatically obtain and manage security certificates.

Configure LSC provisioning for the APs in the provision list

Configure LSC provisioning for access points in provision list.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable LSC provisioning for a set of APs configured in the provision list.

   Example

   ```
   Device(config)# ap lsc-provision provision-list
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Import a CA certificate to the trustpool (GUI)

Configure CA certificate import to the trustpool using GUI.

PKI Trustpool Management is used to store a list of trusted certificates (either downloaded or built in) used by the different services on the controller. This is also used to authenticate a multilevel CA certificate. The built in CA certificate bundle in the PKI trustpool receives automatic updates from Cisco if they are not current, are corrupt, or if certain certificates need to be updated.

Perform this task to manually update the CA certificates in the PKI trustpool.

> **Note**
>
> If your LSC has been issued by an intermediate CA, you must import the complete chain of CA certificates into the trustpool. Otherwise, you will not be able to provision the APs without the complete chain being present on the controller. The import step is not required if the certificate has been issued by a root CA.

Follow these steps to import a CA certificate to the trustpool using GUI:

Procedure

1. Choose **Configuration** > **Security** > **PKI Management**.
2. In the **PKI Management** window, click the **Trustpool** tab.
3. Click **Import**.
4. In the **CA Certificate** field, copy and paste the CA certificate. Link together the multiple CA certificates in **.pem** format.
5. Click **Apply to Device**.

Import a CA certificate to the trustpool

Configure a CA certificate import to the trustpool using commands.

Import a CA certificate to establish trust relationships for secure communications.

The trustpool stores CA certificates that the device uses to validate certificates presented by other entities during secure communications.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Import the root certificate to the trustpool.

   Example

   ```
   Device(config)# crypto pki trust pool import terminal
   % Enter PEM-formatted CA certificate.
   % End with a blank line or "quit" on a line by itself.
   -----BEGIN CERTIFICATE-----
   -----END CERTIFICATE-----
   ```

```
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
Aug 23 02:47:33.450: %PKI-6-TRUSTPOOL_DOWNLOAD_SUCCESS:
Trustpool Download is successful
```

You need to paste the CA certificate from the **digicert.com**.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The CA certificate is successfully imported to the trustpool and can be used for certificate validation.

Clean the CA certificates imported in trustpool (GUI)

Configure the system to remove CA certificates imported in trustpool using GUI.

Procedure

---

1. Choose **Configuration** > **Security** > **PKI Management**.
2. In the **PKI Management** window, click the **Trustpool** tab.
3. Click **Clean**.

> **Note**
>
> This erases the downloaded CA certificate bundles. However, it does not erase the built-in CA certificate bundles.

4. Click **Yes**.

Clean CA certificates imported in trustpool (CLI)

Clean the CA certificates imported in Trustpool using commands.

You cannot delete a specific CA certificate from the trustpool. However, you can clear all the CA certificates that are imported to the Trustpool.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Erase the downloaded CA certificate bundles.

   Example

   ```
   Device(config)# crypto pki trustpool clean
   ```

   This command does not erase the built-in CA certificate bundles.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Create a new trustpoint dedicated to a single CA certificate

Configure a new trustpoint dedicated to a single CA certificate.

Establish a trustpoint that is specifically configured for a single Certificate Authority (CA) certificate to enable secure PKI operations.

A trustpoint represents a Certificate Authority (CA) or identity certificate that is used for PKI operations. Creating a dedicated trustpoint for a single CA certificate helps organize and manage different certificate authorities in the network.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a trustpoint.

   Example

   ```
   Device(config)# crypto pki trustpoint tp-name
   ```

   Example

   ```
   Device(config)# crypto pki trustpoint tp_name
   ```

3. Create an enrollment terminal for the trustpoint.

   Example

   ```
   Device(ca-trustpoint)# enrollment terminal
   ```

4. Exit from the trustpoint configuration.

Example

```
Device(ca-trustpoint)# exit
```

5. Authenticate the trustpoint.

Example

```
Device(config)# crypto pki authenticate tp-name
```

Example

```
Device(config)# crypto pki authenticate tp_name
<<< PASTE CA-CERT in PEM format followed by quit >>>
```

The trustpoint is now created and authenticated with the CA certificate, ready for PKI operations.

Verify LSC configuration

Provides commands to verify LSC configuration details.=""?>

Use show commands to verify Local Security Certificate (LSC) configuration. View wireless management trustpoint details and Local Security Certificate (LSC) provision-related configuration for your access points.

To view the wireless management trustpoint details, use this command:

```
Device# show wireless management trustpoint

Trustpoint  Name : microsoft-ca
Certificate Info : Available
Certificate Type : LSC
Certificate Hash : 9e5623adba5307facf778e6ea2f5082877ea4beb
 Private key Info : Available
```

To view the Local Security Certificate (LSC) provision-related configuration details for an AP, use this command:

```
Device# show ap lsc-provision summary

AP LSC-provisioning : Disabled
Trustpoint used for LSC-provisioning : lsc-root-tp
Certificate chain status : Available
Number of certs on chain : 2
Certificate hash : 7f9d05183deecac4e5a79db65d538245685e8e30
LSC Revert Count in AP reboots : 1

AP LSC Parameters :
Country : IN
State : KA
City : BLR
Orgn : ABC
Dept : ABC
Email : support@abc.com
Key Size : 2048
EC Key Size : 384 bit

AP LSC-provision List :
```

```
Total number of APs in provision list: 2

Mac Addresses :
--------------
1880.90f5.1540
2c5a.0f70.84dc
```

Configure management trustpoint to LSC

Configure management trustpoint to LSC using GUI.

Procedure

1. Choose **Administration** > **Management** > **HTTP/HTTPS**.
2. In the **HTTP Trust Point Configuration** section, set **Enable Trust Point** to the **Enabled** state.
3. From the **Trust Points** drop-down list, choose the appropriate trustpoint.
4. Save the configuration.

Configure management trustpoint to LSC (CLI)

Configure management trustpoint to LSC using commands.

Configure management trustpoint to enable Local Significant Certificate (LSC) authentication for access points.

After LSC provisioning, the APs will automatically reboot and join at the LSC mode after bootup. Similarly, if you remove the AP LSC provisioning, the APs reboot and join at non-LSC mode.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the management trustpoint to LSC.

   Example

   ```
   Device(config)# wireless management trustpoint trustpoint-name
   ```

   Example

   ```
   Device(config)# wireless management trustpoint microsoft-ca
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The management trustpoint is now configured for LSC authentication, and access points will join using LSC mode after rebooting.

AP certificate renewal (LSC)

Explains AP certificate renewal with LSC, describing benefits, prerequisites, restrictions, and procedures for configuring automatic and forced renewal through GUI and CLI, including verification steps.

AP certificate renewal (LSC)

Describes the conceptual information about AP certificate renewal (LSC).

AP certificate renewal (LSC) is a feature that

- allows the renewal of Locally Significant Certificates (LSCs) for Access Points before their expiration
- ensures that the APs can continue to provide seamless services by renewing their certificates in a timely manner
- enables the controller to orchestrate this process to minimize service disruption. The process focuses on automatic renewal mechanisms that do not require manual intervention.

LSC provisioning and renewal methods

From Cisco IOS XE 26.2.1, supported access points can provision and renew LSC through either controller-based proxy enrollment or Cisco Catalyst Center secure AP onboarding. These certificates are crucial for your Access Points because they authenticate network communications. This renewal process is essential. Without a valid certificate, Access Points may lose network connectivity and affect network services.

The controller uses these methods to renew certificates:

- **Gradual Succession**: A method where Access Points are renewed one at a time, which is suitable when the number of Access Points that are due for renewal is under a certain threshold.
- **Staggered Rollover**: Access Points are renewed in a staggered fashion, minimizing the impact on radio coverage when the number of Access Points is larger.
- **One-Shot Renewal**: All affected Access Points are renewed simultaneously, which can be disruptive and should be used as a last resort.

Benefits of AP certificate renewal (LSC)

Lists the benefits of Access Point certificate renewal using Locally Significant Certificate (LSC).

- **Automated Renewal Process**: Reduces the need for manual certificate updates, ensuring continuous service.
- **Seamless Network Operations**: Minimizes network downtime by renewing certificates before they expire.
- **Enhanced Security**: Maintains a high level of security by ensuring that all Access Points have valid certificates.
- **Scalable Management**: Supports staggered AP renewal to reduce impact on network operations.

Requirements for AP certificate renewal (LSC)

Lists the requirements for access point certificate renewal using locally significant certificates.

Configure the controller and access points to use locally significant certificates before you proceed with certificate renewal.

- Provision or renew the locally significant certificates through either the controller-based proxy-enrollment workflow or the Cisco Catalyst Center secure AP onboarding workflow.
- Define the maintenance windows if scheduling is required for renewal.

Restrictions for AP certificate renewal (LSC)

This document describes the restrictions for access point certificate renewal (Local Significant Certificate).

These restrictions for access point certificate renewal (Local Significant Certificate) are:

- Only one Local Significant Certificate is supported per access point.
- Enable either staggered or one-shot renewal, not both.
- Local Significant Certificate renewal applies to Cisco Wave 2 access points and newer models; older access points do not support this feature.
- The staggered algorithm does not apply to access points in bridge mode. All Local Significant Certificate renewals for bridge mode access points occur at the same time.

Configure AP certificate auto-renewal (LSC) (GUI)

Learn how to configure AP certificate auto-renewal (LSC) to automatically renew access point locally significant certificates according to a defined schedule.

Follow these steps to configure AP certificate auto-renewal (LSC):

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points** > **LSC Provision**.
2. In the **LSC Renewal** section, check the **LSC Auto-Renewal** check box and follow these steps:
   a. Enter a value for due time. The valid range is 5 to 60.
   b. From the **Renewal Schedule** drop-down list, select an existing calendar profile schedule or click the icon to create a new calendar profile. For more information about creating a calendar profile, see the **Configuring a Calendar Profile (GUI)** and **Configuring a Calendar Profile (CLI)**.
   c. Use the slider to enable **Syslog** messages for the LSC renewal updates.
   d. From the **Renewal Mode** drop-down list, choose either *One Shot* or *Staggered*.
      - If you choose One Shot, all impacted AP LSCs renew in a single iteration.
      - If you choose Staggered, the system staggers the LSC renewal configuration for the APs and follow these steps:
        - Enter a value for the iteration expiry to set the expiry time for each iteration.
        - From the **AP LSC Renewal per Iteration** drop-down list, choose one of the following options to configure the percentage of APs to be renewed per iteration: 5%, 15%, or 25%.

          You can also see 1% and serial.
        - Enable the **Client Steering** slider to move clients attached to APs undergoing renewal to other APs.
        - Enable the **Client Deauthentication** slider to deauthenticate clients associated with the AP before it starts upgrading.

- From the **Accounting Percentage** drop-down list, select the percentage of APs that should join the controller after each iteration to consider the renewal successful.
- Use the slider to configure **Accounting Action**. If you select **Terminate**, the renewal stops if the configured percentage of APs does not join the controller. If you select **Ignore**, the renewal continues regardless.

3. Click **Apply**.

Configure AP certificate renewal (LSC) (CLI)

Use this procedure to configure AP certificate renewal (LSC) via CLI.

Follow these steps to configure AP certificate renewal (LSC) in the controller:

Procedure

1. Enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure LSC provisioning on an AP.

   Example

   ```
   Device(config)# ap lsc-provision
   ```

3. Configure AP certificate renewal.

   Example

   ```
   Device(config)# ap lsc-provision renew
   ```

4. Renew AP LSCs automatically within the specified number of days.

   Example

   ```
   Device(config)# ap lsc-provision renew due-time number-of-days
   ```

   The valid range is from 5 to 60 days, with a default value of 30 days.

5. Renew all AP LSCs in a single iteration.

   Example

   ```
   Device(config)# ap lsc-provision renew one-shot
   ```

> **Note**
>
> The one-shot AP LSC renewal feature is disabled by default.

6. Renew AP LSCs automatically in a staggered manner.

   Example

   ```
   Device(config)# ap lsc-provision renew staggered timeout
   iteration-timeout-in-mins
   ```

   Staggered AP LSC renewal is enabled by default.

   > **Note**
   >
   > You cannot use one-shot and staggered renewal methods at the same time.
   >
   > *iteration-timeout-in-mins*: The valid range is from 5 to 60 minutes.

7. Configure time schedule for auto-renewal within a maintenance window.

   Example

   ```
   Device(config)# ap lsc-provision renew scheduler calendar-profile
   ```

   No scheduler is enabled by default.

   When no scheduler is applied, the device auto-renews AP LSCs at 24-hour intervals and is triggered daily at 12:00 AM local time.

   > **Note**
   >
   > You must configure the calendar-profile definition beforehand. For more information, see **Configuring a Calendar Profile (CLI)**.

You have successfully configured AP certificate renewal (LSC).

Configure forced renewal of AP certificate (LSC) for individual or multiple APs (GUI)

Configure forced renewal of AP certificate (LSC) for individual or multiple APs using the GUI interface.

Follow these steps to configure forced renewal of AP certificate (LSC) for individual or multiple APs via GUI:

Procedure

1. Choose **Configuration** > **Wireless** > **Bulk AP Provisioning**.
2. On the **Select Parameters** page, check the **Renew LSC** check box to renew the LSC for all selected APs.
3. Click **Next**.

Configure forced renewal of AP Certificate (LSC) based on site tag (GUI)

Configure the forced renewal of Access Point (AP) Certificate (LSC) based on site tag through the graphical user interface.

Before you begin

Follow these steps to configure force renewal of AP certificate (LSC) based on site tag:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. In the **Site** tab, check the check box for the required site tag.
3. Click **Renew LSC** and follow these steps:
   a. Enter the due time in days. The value must be between 1 and 60.
   b. Click **Apply to Device**.

Configure forced renewal of AP Certificate (LSC) based on site tag (CLI)

Use this procedure to configure forced renewal of AP certificate (LSC) based on site tag using the CLI.

Follow these steps to configure the forced renewal of an AP certificate (LSC) based on a site tag using the CLI:

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Renew a specific site-tag AP that is set to expire within the specified time.

   Example

   ```
   Device# ap lsc renew due-time number-of-days site-tag site-tag-name
   ```

   number-of-days: The valid range is from 1 to 60 days.

The configuration of the forced renewal of an AP Certificate (LSC) based on a site tag is complete.

Configure forced renewal of all APs (GUI)

Configure forced renewal of Local Significant Certificates (LSC) for all access points using the graphical user interface.

Follow these steps to configure forced renewal of all APs (GUI):

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. From the **Select an Action** drop-down list, choose **Renew LSC**.

   The **Renew LSC** pop-up window is displayed.
3. Enter a due time value in minutes between 5 and 60.
4. Click **Apply to Device**.

Verify AP certificate renewal (LSC)

This section shows you how to verify AP Certificate Renewal (Local Significant Certificate) using show commands.

Lists the various show commands and their outputs during the verification of the AP Certificate Renewal (LSC).

Verify LSC configuration

To verify LSC provision-related configuration details for an AP, use this command:

```
Device# show ap lsc-provision info
AP name     Ethernet MAC     Radio MAC      LSC authentication  LSC workflow
   Cert expiry   Last renew attempt  Last renew failure
=============================================================================================================
AP-abc      1111.2222.3333  aaaa.bbbb.ccc0  Port-802.1x         PNP Onboarding
  <time-stamp>  <time-stamp>/NA     reason-code
AP-123      1234.5678.9012  dddd.eeee.fff0  DTLS                SCEP proxy
   <time-stamp>  <time-stamp>/NA     reason-code
AP-xyz      1010.1010.1010  abcd.efab.cde0  DTLS, Port-802.1x   SCEP proxy
   <time-stamp>  <time-stamp>/NA     reason-code
                                                                     0.0.0.0
                       372           64                AGL          Enabled
```

Verify staggered LSC renewal upgrade configuration

To verify progress and status of staggered LSC renewal upgrade, use this command:

```
Device# show ap upgrade
Status: In progress
From version:
To version: Unknown

Started at: 10/23/2025 08:16:01 IST
Configured percentage: 15
Percentage complete: 0
Expected time of completion: 10/23/2025 08:24:01 IST

Client steering: Enabled
Client de-authentication: Enabled
Accounting percentage: 90%
```

```
Iteration expiry time: 15 minutes

MIC and LSC APs joining the controller

Explains the authorization policy, configuration workflows, and verification steps for enabling MIC and LSC APs to securely join the controller, highlights behavioral changes, and outlines recommendations and limitations for policy deployment.

Support for MIC and LSC APs joining the controller

Explains the authorization policy that allows MIC APs to join the LSC-deployed controller, enabling LSC and MIC APs to coexist.

Support for MIC and LSC access points joining the controller is an authorization policy feature that

- allows MIC APs to join LSC-deployed controllers without requiring LSC provisioning
- enables LSC and MIC APs to coexist on the same controller simultaneously, and
- eliminates the need to provision LSC on MIC APs before moving them to LSC-deployed controllers.

Authorization policy behavior changes

The authorization policy behavior differs between software releases:

- **Cisco IOS XE Bengaluru 17.4.1 and earlier**: If your APs have default certificates (Manufacturing Installed Certificates [MIC] or Secure Unique Device Identifier [SUDI]), they cannot join an LSC-deployed controller, where the management certificate of the controller is an LSC. To resolve this issue, provision LSC on your APs. Use the provisioning controller before you move them to the LSC-deployed controller.
- **Cisco IOS XE Bengaluru 17.5.1 onwards**: The new authorization policy configuration allows MIC APs to join the LSC-deployed controller, so that LSC APs and MIC APs can coexist on the controller.

Recommendations and limitations

Outlines recommendations and limitations for MIC and LSC Access Points joining the controller.

When you configure the CA server with manual enrollment to accept certificate signing request (CSR), the controller monitors for the CA server response. If the CA server does not respond for 10 minutes, the fallback mode activates.

- Cisco Wave 2 APs regenerate CSR, and a fresh CSR is sent to the CA server.
- Cisco IOS APs restart, and then Cisco IOS APs send a fresh CSR, which is in turn sent to the CA server.

The locally significant certificate (LSC) feature on the controller does not work with password challenge authentication. Therefore, for LSC to work, you must disable password challenge on the CA server.

If you are using Microsoft CA, use Windows Server 2012 or later as the CA server.

MIC and LSC access point authentication

Describes the configuration workflow for MIC and LSC access points joining the controller.

Summary

The Manufacturer Installed Certificate (MIC) and Local Significant Certificate (LSC) access point authentication configuration involves these stages:

- Controller: Manages authentication policies and trustpoint configuration for secure access point connections
- Access points: Require certificate-based authentication to join the controller
- LSC trustpoint: Provides local significant certificate authentication mechanism
- AP certificate policy: Defines authentication requirements and allowed access point lists

Workflow

The key components involved in the MIC and LSC access point authentication configuration are:

1. The network administrator configures the LSC trustpoint on the LSC deployed controller using CLI.

   Configure LSC on the controller (CLI) on page 1767

2. The network administrator enables the AP certificate policy on access points using CLI.

   Enable the AP certificate policy on the APs (CLI) on page 1767

3. The network administrator configures the AP policy certificate using the GUI interface.

Configure the AP policy certificate (GUI) on page 1769

4. The network administrator configures the allowed list of APs to join the controller using CLI.

Configure the allowed list of APs to join the controller (CLI) on page 1769

Result

Access points are properly authenticated and authorized to join the controller with secure certificate-based authentication enabled.

Configure LSC on the controller (CLI)

Configure LSC on the controller using commands.

The server certificate used by the controller for CAPWAP-DTLS (Control and Provisioning of Wireless Access Points - Datagram Transport Layer Security) is based on the following configuration.

Before you begin

- Ensure that you enable LSC by setting the appropriate trustpoints for the following wireless management services:
  - AP join process: CAPWAP DTLS server certificate
  - Mobility connections: Mobility DTLS certificate
  - NMSP (Network Mobility Services Protocol) and CMX (Connected Mobile Experiences) connections: NMSP TLS certificate

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the LSC trustpoint in the LSC-deployed controller.

Example

```
Device(config)# wireless management trustpoint trustpoint-name
```

Enable the AP certificate policy on the APs (CLI)

Configure the AP certificate policy on the APs using commands.

Enable AP certificate policy during CAPWAP-DTLS handshake to allow MIC APs to join the controller.

- If the management trustpoint is a locally significant certificate (LSC), by default, manufacturing installed certificate (MIC) APs fail to join the controller. This configuration acts as an enable or disable configuration knob that allows MIC APs to join the controller.
- This configuration is a controller authorization to allow APs to join MIC at the time of Datagram Transport Layer Security (DTLS) handshake.

To prevent manufacturing installed certificate (MIC) expiry failures, ensure that you configure a policy, as shown here:

- Create a certificate map and add the rules:

```
configure terminal
crypto pki certificate map map1 1
issuer-name co Cisco Manufacturing CA
```

> **Note**
>
> You can add multiple rules and filters under the same map. The rule mentioned in the example above specifies that any certificate whose issuer-name contains *Cisco Manufacturing CA* (case insensitive) is selected under this map.

- Use the certificate map under the trustpool policy:

```
configure terminal
crypto pki trustpool policy
match certificate map1 allow expired-certificate
```

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the trustpoint name for the controller certificate chain.

   Example

   ```
   Device(config)# ap auth-list ap-cert-policy allow-mic-ap trustpoint
   trustpoint-name
   ```

   > **Note**
   >
   > The allow-mic-ap trustpoint command is required only for the virtual controller (Cisco Catalyst 9800-CL Wireless Controller for Cloud). In all the other appliance controller platforms, the default certificate is selected. This default certificate is manufacturer-installed SUDI.

3. Enable the AP certificate policy during CAPWAP-DTLS handshake.

   Example

   ```
   Device(config)# ap auth-list ap-cert-policy allow-mic-ap
   ```

4. Enable the AP certificate policy as MIC.

Example

```
Device(config)# ap auth-list ap-cert-policy mac-address H.H.H policy-type mic
```

Example

```
Device(config)# ap auth-list ap-cert-policy mac-address 1111.1111.1111
policy-type mic
```

The AP certificate policy is now enabled and configured for MIC APs to join the controller during CAPWAP-DTLS handshake.

Configure the AP policy certificate (GUI)

Configure the AP policy certificate using GUI.

Procedure

1. Choose **Configuration > Wireless > Access Points**
2. In the **All Access Points** window, click **AP Certificate Policy**.
3. In the **AP Policy Certificate** window, complete the following actions:
   a) Click the **Authorize APs joining with MIC** toggle button to enable AP authorization.
   b) From the **Trustpoint Name** drop-down list, choose the required trustpoint.
   c) Click **Add MAC or Serial Number** to add a MAC address or a serial number manually or through a .csv file. The **Add MAC or Serial Number** window is displayed.
   d) Click the **AP Authlist Type** and enter the MAC address or the serial number. Upload the .csv file or enter the MAC address in the list box.
   The newly added MAC address and serial numbers are displayed under **List of MAC Address and Serial Numbers**.
   e) Click **Apply**.

   The AP certificate policy is added to the **AP Inventory** window.

> **Note**
>
> To add a new AP with MIC, perform Step 1 to Step 3 described in Configuring the AP Policy Certificate (GUI) section. To add a new AP with LSC, perform the procedure described in the Configuring AP LSC Provision List (GUI) and Step 1 to Step 3 in the Configuring the AP Policy Certificate (GUI) section.

Configure the allowed list of APs to join the controller (CLI)

Configure the allowed list of APs to join the controller using commands.

Create an allowed list of access points that can join the controller based on MAC address or serial number authentication.

The allowed list of APs can either be populated based on the Ethernet MAC address or based on the serial number of the APs.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the AP certificate policy based on the Ethernet MAC address or based on the assembly serial number of the AP.

   Example

   ```
   Device(config)# ap auth-list ap-cert-policy mac-address AP-Ethernet-MAC-address
    policy-type mic
   ```

   Example

   ```
   Device(config)# ap auth-list ap-cert-policy serial-number AP-serial-number
   policy-type mic
   ```

   Example

   ```
   Device(config)# ap auth-list ap-cert-policy mac-address 00b0.e192.0d98
   policy-type mic
   ```

The AP certificate policy is configured and the specified access points are added to the allowed list for joining the controller.

Verifying the configuration status

Provides commands to verify the configuration status of AP certificate policy authorization.

To verify if the APs have been authorized by the AP certificate policy, use this command:

```
Device# show ap auth-list ap-cert-policy
Authorize APs joining with MIC : ENABLED
MIC AP policy trustpoint
Name : CISCO_IDEVID_SUDI
Certificate status : Available
Certificate Type : MIC
Certificate Hash : xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
```

To verify the AP certificate policy on the MAC address and the serial number of the AP, use these commands:

```
Device# show ap auth-list ap-cert-policy mac-address
MAC address      AP cert policy
---------------------------------
1111.2222.3333   MIC
```

```
Device# show ap auth-list ap-cert-policy serial-number
Serial number    AP cert policy
```

```
--------------------------------
F1234567890      MIC
```

Note

If you set an invalid trustpoint (not SSC), the **allow-mic-ap policy** does not enable. If you set an invalid trustpoint, this error displays on the console:

```
Device(config)# ap auth-list ap-cert-policy allow-mic-ap trustpoint lsc-root-tp
Dec 18 07:38:29.944: %CERT_MGR_ERRMSG-3-CERT_MGR_GENERAL_ERR: Chassis 1 R0/0:
 wncd: General error: MIC AP Policy trustpoint: 'lsc-root-tp' cert-chain type
 is LSC, It must be either MIC or vWLC-SSC
```

LSC fallback APs

Explains LSC fallback mechanisms for CAPWAP authentication, provides methods to identify APs in fallback state, guides troubleshooting and syslog analysis, and details recovery commands to restore normal LSC functionality.

LSC fallback APs

Explains the state when the AP falls back to its default certificate (MIC) for CAPWAP after maximum number of failures.

LSC fallback is a state that

- occurs when an AP configured with LSC for CAPWAP fails to establish DTLS connection after reaching the maximum number of retry attempts
- causes the AP to revert to its default certificate (MIC) for CAPWAP authentication, and
- provides a backup authentication method when LSC-based CAPWAP connection attempts fail.

LSC fallback process

When you configure an AP with LSC for CAPWAP but it fails to establish a DTLS connection, the AP reboots. The AP then retries for a certain number of times. For information on how to configure an AP with LSC, see Configure AP join attempts with LSC certificate (CLI) on page 1747.

The AP falls back to its default certificate (MIC) for CAPWAP after maximum number of failures. The AP fallback state is referred to as the LSC fallback.

Note

MIC is also known as SUDI certificate.

Troubleshoot LSC fallback state

Configure troubleshooting procedures to identify and resolve LSC fallback APs using show wireless summary.=""?>

This task enables you to identify access points in LSC fallback state and understand the recovery process when APs fail to establish proper LSC connections with the controller.

When an AP in LSC fallback state joins the controller, it generates specific syslog messages and is held in a misconfigured state. The AP does not broadcast WLAN or SSID configurations in this state, which permits the admin to examine the reason for previous failures and recover APs.

Before you begin

Procedure

1. Identify the syslog message generated when an AP in LSC fallback state joins the controller.

   Example

   ```
   Jun 15 23:24:14.836: %APMGR_TRACE_MESSAGE-3-WLC_GEN_ERR: Chassis 1 R0/0: wncd:
    Error
   in AP: 'AP2c5a.0f70.84dc' with address 70db.9888.cc20 is joined with MIC,
   while configuration
   requires LSC. No WLANs will be pushed.
   ```

   The controller allows such an AP to be joined with MIC (when AP certificate policy allows it) and AP is held in misconfigured state.

   > **Note**
   >
   > The AP does not broadcast WLAN or SSID configurations in such state. This permits the admin to examine the reason for previous failures and recover APs.

2. Use **show wireless summary** to identify LSC fallback APs.

   Example

   ```
   Device# show wireless summary
   …
   Access Point Summary
   …
   DTLS LSC fallback APs     20 (No WLANs will be pushed to these APs)
   …
   For more information on DTLS LSC fallback APs,
       execute 'wireless config validate' and look for reported errors in
       'show wireless config validation status' CLI output.

   Use 'show ap config general | inc AP Name | LSC fallback' to list DTLS LSC
   fallback APs.
   Examine LSC fallback reasons / DTLS handshake failures with LSC then
       issue 'ap lsc dtls-fallback clear-certificate / clear-flag' to recover
   APs
   ```

You have successfully identified LSC fallback APs and understand the commands available for further investigation and recovery.

Recover from LSC fallback

Configure recovery steps to restore LSC functionality after DTLS fallback occurs.

Recover APs from LSC fallback state and restore normal LSC functionality for CAPWAP DTLS connections.

When LSC fallback occurs, APs may require recovery actions to restore normal operation. Recovery options depend on whether you want to retain the LSC certificate or clear it completely.

Procedure

Choose one of the following recovery methods based on your requirements:

- To clear the LSC fallback flag and retain the LSC certificate, use the **ap lsc dtls-fallback clear-flag** command to instruct the AP to reload.

  Note

  The AP reuses the LSC for CAPWAP DTLS connection post the reload.

- To clear the LSC certificate completely, use the **ap lsc dtls-fallback clear-certificate** command to clear LSC and instruct the AP to reload.

  Note

  The AP uses MIC for CAPWAP-DTLS post the reload. If LSC is used for Dot1x port authentication then further recovery is needed on switch port for AP authentication.

Note

- The **ap lsc dtls-fallback clear-flag** command is sufficient to retain LSC on AP. Both **ap lsc dtls-fallback clear-flag** and **ap lsc dtls-fallback clear-certificate** commands are not required at the same time.
- APs must be in connected state when issuing the recovery command. You will need to reissue the command, if any **LSC fallback** AP joins afterwards.

The access point reloads and recovers from the LSC fallback state according to the selected recovery method.

Configuring controller self-signed certificate for wireless AP join

Outlines the process of configuring and managing controller self-signed certificates to enable wireless AP join, covering use cases, prerequisites, setup steps, PKI server and trustpoint configuration, verification, and server management.

Use cases for controller self-signed certificate for wireless AP join

Lists the scenarios in which controller self-signed certificates are required for wireless AP join, including platform limitations and compatibility issues with certain APs.

You need controller self-signed certificates in specific circumstances to enable wireless APs to join the controller successfully.

Controller self-signed certificate use cases

These situations require controller self-signed certificates:

- The Cisco Catalyst 9800-CL platform is not equipped with manufacturer-installed SUDI certificates. Configure self-signed certificates on these controllers.
- Some APs running earlier software and using a Manufacturer Installed Certificate (MIC) issued by a SHA1 Cisco Trusted CA cannot join controllers with SHA2 SUDI certificates. During the CAPWAP join process, these APs display a bad certificate error and fail the DTLS handshake.

  Workaround: To support AP upgrades, configure a self-signed certificate for the controller as a workaround for the second use case. After updating all APs, delete the self-signed certificates. Then, revert to the SUDI certificate.

  > **Note**
  >
  > This workaround does not apply to Embedded Wireless Controllers running on Catalyst 9000 series switches. It is only valid for hardware appliance controllers such as Cisco Catalyst 9800-40, 9800-80, and 9800-L.

- The command **wireless management certificate ssc auth-token** is required for ensuring resilient operation of Cisco Catalyst 9800-CL controllers. It is mandatory to configure an explicit authentication token on all 9800-CL devices within the network. Additionally, this command is required when migrating from an AireOS controller to a Cisco Catalyst 9800-CL controller to facilitate secure AP join, as the 9800-CL uses a self-signed certificate instead of a MIC used by AireOS controllers.

Prerequisites for controller self-signed certificate for wireless AP join

Follow these guidelines to prepare the controller for self-signed certificate configuration. This enables wireless AP join. Meet all prerequisites before setup.

- Ensure that the VLAN interface is up and that the IP address is reachable.
- Ensure that the **ip http server** is enabled. For more information, see Enabling HTTP Server .
- Set the **clock calendar-valid** command appropriately. For more information, see *Configure clock calendar.*
- Check whether the PKI CA server is configured. If it is, delete the existing CA server configuration.

> **Note**
>
> The **show crypto pki server** command output should not display anything.

Configure clock calendar (CLI)

Configure clock calendar using commands to ensure accurate timekeeping on the device.

Set the clock calendar to ensure accurate timekeeping on the device.

This configuration is necessary for time-sensitive operations and logging on the device.

Before you begin

Access to the device with appropriate privileges to enter global configuration mode.

Follow these steps to configure clock calendar:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable clock calendar.

   Example

   ```
   Device(config)# clock calendar-valid
   ```

3. Exit configuration mode.

   Example

   ```
   Device(config)# exit
   ```

The clock calendar is now configured and operational on the device.

Enable HTTP server using CLI

Configure the HTTP server to enable web-based management of the device using commands.

Enable the HTTP server to allow web-based management of the device.

This configuration is applicable for devices that require HTTP access for management purposes.

Before you begin

Ensure you have administrative access to the device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable the HTTP server on your IP or IPv6 system.

   Example

   ```
   Device(config)# ip http server
   ```

   Enables the HTTP server on your IP or IPv6 system, including a Cisco web browser user interface. By default, the HTTP server uses the standard port 80.

3. Enable the secure HTTP server on your IP or IPv6 system.

   Example

   ```
   Device(config)# ip http secure-server
   ```

   Enables the secure HTTP server on your IP or IPv6 system, providing encrypted access to the web interface.

4. Exit configuration mode.

   Example

   ```
   Device(config)# exit
   ```

The HTTP server is now enabled, allowing web-based management of the device.

Configure CA server (CLI)

Configure a CA server using commands to manage certificates for devices in the network.

Deploy a CA server to manage certificates for devices in the network.

This configuration is essential for environments that require secure communication through certificates.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Generate RSA keys for the CA server.

Example

```
Device(config)# crypto key generate rsa general-keys modulus size_of_key_module
 label keypair_name
```

Configures a certificate for the controller.

When you generate RSA keys, you are prompted to enter a modulus length. A longer modulus length might be more secure, but it takes longer to generate and to use.

> **Note**
>
> The recommended key-pair name is *WLC_CA* and key modulus is *2048* bits.

3. Enable the IOS certificate server.

Example

```
Device(config)# crypto pki server certificate_server_name
```

Enables IOS certificate server.

> **Note**
>
> The *certificate_server_name* must be the same name as the *keypair_name*.

4. Configure the issuer name for the CA certificate.

Example

```
Device(cs-server)# issuer-name O=Cisco Virtual Wireless LAN Controller,
CN=CA-vWLC
```

Configures X.509 distinguished name for the issuer CA certificate.

> **Note**
>
> You need to configure the same *issuer-name* as suggested for AP join.

5. Grant certificate requests automatically.

Example

```
Device(cs-server)# grant auto
```

Grants certificate requests automatically.

6. Optional: Specify the hash function for the signature used in the granted certificates.

   Example

   ```
   Device(cs-server)# hash sha256
   ```

   Specifies the hash function for the signature used in the granted certificates.

7. Optional: Specify the lifetime in days of a CA certificate.

   Example

   ```
   Device(cs-server)# lifetime ca-certificate time-interval
   ```

   Specifies the lifetime in days of a CA certificate.

8. Optional: Specify the lifetime in days of a granted certificate.

   Example

   ```
   Device(cs-server)# lifetime certificate time-interval
   ```

   Specifies the lifetime in days of a granted certificate.

9. Set the CA key and CA certificate archive format and password.

   Example

   ```
   Device(cs-server)# database archive pkcs12 password 0 cisco123
   ```

   Sets the CA key and CA certificate archive format and password to encrypt the file.

10. Enable the certificate server.

    Example

    ```
    Device(cs-server)# no shutdown
    ```

    Enables the certificate server.

    > **Note**
    >
    > Issue this command only after you have completely configured your certificate server.

11. Return to privileged EXEC mode.

    Example

    ```
    Device(cs-server)# end
    ```

    Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The CA server is now configured and ready to manage certificates for devices in the network.

Configure trustpoint (CLI)

Configure a trustpoint to enable secure communication with a Certificate Authority (CA) using commands.

Configure a trustpoint to enable secure communication with a Certificate Authority (CA).

This configuration is necessary for devices that require secure communications and certificate management.

Before you begin

Ensure you have access to the device and the necessary permissions to configure trustpoints.

Follow these steps to configure trustpoint using CLI commands:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Generate RSA keys for the trustpoint.

   Example

   ```
   Device(config)# crypto key generate rsa exportable general-keys modulus
   size-of-the-key-modulus label label
   ```

   When you generate RSA keys, you are prompted to enter a modulus length. A longer modulus length might be more secure, but it takes longer to generate and to use.

3. Create a new trustpoint for an external CA server.

   Example

   ```
   Device(config)# crypto pki trustpoint trustpoint_name
   ```

   Here, *trustpoint_name* refers to the trustpoint name.

   > **Note**
   >
   > Ensure that same names are used for key-pair (*label*) and *trustpoint_name*.

4. Map RSA key with that of the trustpoint.

   Example

   ```
   Device(ca-trustpoint)# rsakeypair RSA_key
   ```

   Maps RSA key with that of the trustpoint.

- RSA_key–Refers to the RSA key pair label.
- key_size–Refers to the signature key length. The value ranges from 360 to 4096.

5. Create subject name parameters for the trustpoint.

   Example

   ```
   Device(ca-trustpoint)# subject-name subject_name
   ```

   Specifies the subject name for the trustpoint.

6. Check revocation.

   Example

   ```
   Device(ca-trustpoint)# revocation-check none
   ```

   Specifies whether to check for certificate revocation.

7. Specify the hash algorithm.

   Example

   ```
   Device(ca-trustpoint)# hash sha256
   ```

   Specifies the hash algorithm to be used.

8. Specify the serial number.

   Example

   ```
   Device(ca-trustpoint)# serial-number
   ```

   Specifies the serial number for the trustpoint.

9. Optional: Set certificate key-usage purpose.

   Example

   ```
   Device(ca-trustpoint)# eku request server-auth client-auth
   ```

   Sets the extended key usage for the certificate.

10. Enable password for the trustpoint.

    Example

    ```
    Device(ca-trustpoint)# password 0 password
    ```

11. Enroll the URL for the CA server.

    Example

    ```
    Device(ca-trustpoint)# enrollment url url
    ```

Replace the dummy IP with management VLAN interface IP of the controller where CA server is configured.

12. Exit the configuration mode.

Example

```
Device(ca-trustpoint)# end
```

The trustpoint is now configured and ready for use with the CA server.

Authenticate and enroll the PKI trustpoint with CA server

Configure the PKI trustpoint to authenticate and enroll with the Certification Authority (CA) server using commands.

Authenticate and enroll the PKI trustpoint to establish a secure connection with the Certification Authority (CA) server.

This procedure is used in environments where a PKI trustpoint needs to be authenticated and enrolled with a Certification Authority (CA) server for certificate management.

Before you begin

Ensure that the Certification Authority (CA) server is reachable and the trustpoint is properly configured.

Follow these steps to authenticate and enroll the PKI trustpoint with CA server:

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Authenticate the PKI trustpoint with the CA server.

Example

```
Device(config)# crypto pki authenticate trustpoint-name
Certificate has the following attributes:
Fingerprint MD5: 64C5FC9A C581D827 C25FC3CF 1A7F42AC
Fingerprint SHA1: 6FAFF812 7C552783
6A8FB566 52D95849 CC2FC050
% Do you accept this certificate? [yes/no]: yes
Trustpoint CA certificate accepted.
```

Fetches the CA certificate.

3. Enroll the PKI trustpoint for a client certificate.

Example

```
Device(config)# crypto pki enroll trustpoint-name
Enter following answers for UI interaction:
% Include an IP address in the subject name? [no]: no
Request certificate from CA? [yes/no]: yes
```

4. Exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

   Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The PKI trustpoint is now authenticated and enrolled with the Certification Authority (CA) server, allowing for secure certificate management.

Tag wireless management trustpoint name

Configure a wireless management trustpoint name for identification and management purposes using commands.

Tag a wireless management trustpoint name for identification and management purposes.

This configuration is used in environments where wireless management trustpoints need to be clearly identified for management and security.

Before you begin

Ensure you have the necessary privileges to enter global configuration mode.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Tag the wireless management trustpoint name.

   Example

   ```
   Device(config)# wireless management trustpoint trustpoint-name
   ```

3. Exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

   Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The wireless management trustpoint name is successfully tagged and can be used for management purposes.

Disable PKI server

Configure the PKI server to be disabled and prevent it from issuing certificates using commands.

Disable the PKI server to prevent it from issuing certificates.

This procedure is used in scenarios where the PKI server is no longer needed or must be temporarily disabled.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a new server for an external CA server.

   Example

   ```
   Device(config)# crypto pki server certificate-server-name
   ```

   The *certificate-server-name* refers to the server name.

   > **Note**
   >
   > Here, server_name refers to the server name.

3. Disable the certificate server.

   Example

   ```
   Device(cs-server)# shutdown
   ```

   Update purpose string to \

4. Return to privileged EXEC mode.

   Example

   ```
   Device(cs-server)# end
   ```

   Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The PKI server is now disabled and will not issue certificates.

Verify controller certificates for wireless AP join

Lists commands to verify controller certificates for wireless AP join.

Use these commands to verify controller certificates for wireless access point (AP) join.

To view the CA server details, use the command:

```
Device# show crypto pki server
Certificate Server WLC_CA:
```

```
Status: enabled
State: enabled
Server's configuration is locked (enter "shut" to unlock it)
Issuer name: O=Cisco Virtual Wireless LAN Controller, CN=CA-vWLC
CA cert fingerprint: 79A3DBD5 59A7E384 73ABD152 C133F4E2
Granting mode is: auto
Last certificate issued serial number (hex): 1
CA certificate expiration timer: 12:04:00 UTC Mar 8 2029
CRL NextUpdate timer: 18:04:00 UTC Mar 11 2019
Current primary storage dir: nvram:
Database Level: Minimum - no cert data written to storage
```

To view the trustpoint details, use this command:

```
Device# show crypto pki trustpoint ewlc-tp1 status
Trustpoint ewlc-tp1:
...
State:
Keys generated ..... Yes (General Purpose, exportable)
Issuing CA authenticated ..... Yes
Certificate request(s) ..... Yes
```

To view the wireless management trustpoint details, use this command:

```
Device# do show wireless management trustpoint
Trustpoint Name : ewlc-tp1
Certificate Info : Available
Certificate Type : SSC
Certificate Hash : 4a5d777c5b2071c17faef376febc08398702184e
Private key Info : Available
FIPS suitability : Not Applicable
```

To view the Hypertext Transfer Protocol (HTTP) server status, use this command:

```
Device# show ip http server status | include server status
HTTP server status: Enabled
HTTP secure server status: Enabled
```

147 Public Key Infrastructure Management

Topics:

- About PKI management (GUI)
- Configuration Tasks

About PKI management (GUI)

Introduces Public Key Infrastructure concepts and GUI-based management, highlighting restrictions such as CSR generation hanging indefinitely and providing foundational information for secure certificate administration.

A public key infrastructure (PKI) management is a network application tool that

- enables graphical configuration of PKI components using GUI.
- provides tabs for configuring and monitoring trustpoints, certificate authorities, keys, and certificates,
- allows administrators to generate, enroll, and manage cryptographic credentials for secure communications, and

Feature history

Feature Name	Release	Description
Enhanced Certificate Management Through GUI	Cisco IOS XE 17.3.1	The PKI Management page now includes tabs for Trustpoints, CA Server, Key Pair Generation, and Certificate Management operations.

Tabs for PKI management in GUI

- **Trustpoints tab:** Add, create, or enroll a new trustpoint, view the current trustpoints and their usage.
- **CA Server tab**: Enable or disable Certificate Authority (CA) server functionality. This is required for generating a self-signed certificate (SSC).
- **Key Pair Generation tab**: Generate key pairs.
- **Certificate Management tab**: Generate and manage certificates, and perform all certificate-related operations.

Restriction: CSR generation on the GUI may hang indefinitely

The controller's GUI-based certificate management feature relies on Embedded Event Manager (EEM) scripts. If TACACS command authorization is enabled, the user is authenticated on the GUI but the controller does not pass the user details to the EEM environment. As a result, the user is not authorized, and the user cannot enter the configuration mode using the EEM scripts.

The restriction applies if you have this command-authorization configuration:

```
aaa authorization commands 1 MethodName group GroupName local if-authenticated
aaa authorization commands 15 MethodName group GroupName local if-authenticated
ip http authentication aaa command-authorization 1 MethodName
ip http authentication aaa command-authorization 15 MethodName
```

To resolve this issue, enter this command before you generate the Certificate Signing Request (CSR) using the GUI. For proper authorization, configure the desired username.

```
event manager session cli username <username>
```

After you issue the CSR using the GUI, remove this configuration.

The restriction does not affect CSR generation through the CLI.

Configuration Tasks

Details GUI-driven configuration tasks for PKI, including trustpoint authentication and enrollment, AP self-signed certificate generation, CA server addition, RSA or EC key setup, and certificate management, covering CSR generation and PKCS12 import procedures.

Authenticate and enroll a Public Key Infrastructure (PKI) trustpoint (GUI)

Use this procedure to authenticate and enroll a Public Key Infrastructure (PKI) trustpoint through the device's graphical user interface.

Use this procedure to add and authenticate a Public Key Infrastructure (PKI) trustpoint to enable certificate-based security for your device.

Before you begin

Obtain the enrollment URL and certificate authority information from your network administrator.

Procedure

1. Choose **Configuration** > **Security** > **Public Key Infrastructure (PKI) Management**.
2. In the **Public Key Infrastructure (PKI) Management** window, click the **Trustpoints** tab.
3. In the **Add Trustpoint** dialog box, provide this information:
   a) In the **Label** field, enter the RSA key label.
   b) In the **Enrollment URL** field, enter the enrollment URL.
   c) Check the **Authenticate** check box to authenticate the Public Certificate from the enrollment URL.
   d) In the **Subject Name** section, enter the **Country Code**, **State**, **Location**, **Organization**, **Domain Name**, and **Email Address**.
   e) Check the **Key Generated** check box to view the available RSA keypairs. Choose an option from the **Available RSA Keypairs** drop-down list.
   f) Check the **Enroll Trustpoint** check box.
   g) In the **Password** field, enter the password.
   h) In the **Re-Enter Password** field, confirm the password.
   i) Click **Apply to Device**.

   The new trustpoint is added to the trustpoint name list.

The new trustpoint is now listed in the trustpoint name list and is ready for use.

What to do next

After enrolling the trustpoint, configure it for use with your security policies or certificate-based authentication features.

Generate an AP self-signed certificate (GUI)

Generate an AP self-signed certificate using GUI.

Create a self-signed certificate (SSC) for APs on a virtual controller using the graphical interface.

Use this procedure only for virtual controllers.

- Cisco Catalyst 9800-CL Wireless Controller for Cloud
- Cisco Catalyst 9800-40 Wireless Controller
- Cisco Catalyst 9800-80 Wireless Controller

- Cisco Catalyst 9800-L Wireless Controller (Copper uplink)
- Cisco Catalyst 9800-L Wireless Controller (Fiber uplink)

Procedure

1. Choose **Configuration** > **Security** > **PKI Management**.
2. In the **AP SSC Trustpoint** area, click **Generate** to generate an AP SSC trustpoint.
3. From the **RSA Key-Size** drop-down list, choose a key size.
4. From the **Signature Algorithm** drop-down list, choose an option.
5. From the **Password Type** drop-down list, choose a password type.
6. In the **Password** field, enter a password. The valid range is between 8 and 32 characters.
7. Click **Apply to Device**.

The controller creates and applies a new self-signed certificate for the AP.

Add the CA server (GUI)

Add the certificate authority server using GUI.

Register a new certificate authority (CA) server in the system using the graphical user interface.

Perform this task when you need to establish a new certificate authority for PKI management.

Procedure

1. Choose **Configuration** > **Security** > **PKI Management**.
2. In the **PKI Management** window, click the **CA Server** tab.
3. In the **CA Server** section, click the **Shutdown Status** to enable the status. If you choose the shutdown status as **Enabled**, enter and confirm the password.
4. If you choose the shutdown status as **Disabled**, you must enter the **Country Code**, **State**, **Location**, **Organization**, **Domain Name**, and **Email Address**.
5. Click **Apply** to add the CA server.
6. Click **Remove CA Server** to delete the CA server.

The certificate authority server is added and configured as specified.

Add an RSA or EC Key for PKI trustpoint (GUI)

Add an RSA or EC key for PKI trustpoint using GUI.

To enable certificate-based authentication, add an RSA or EC key to a PKI trustpoint.

Procedure

1. Choose **Configuration > Security** > **PKI Management**.
2. In the **PKI Management** window, click the **Key Pair Generation** tab.
3. In the **Key Pair Generation** section, click **Add**.
4. In the dialog box that is displayed, provide this information:

> **Note**
>
> To allow Japanese characters in **Key Name** field, ensure that the line vty configuration includes "exec-character-bits 8".

a)

> **Note**
>
> To allow Japanese characters in **Key Name** field, ensure that the line vty configuration includes "exec-character-bits 8".

In the **Key Name** field, enter the key name.

b) In the **Key Type** options, select either **RSA Key** or **EC Key**.
c) In the **Modulus Size** field, enter the modulus value for the RSA key or the EC key. The default modulus size for the RSA key is 4096 and the default value for the EC key is 521.
d) Check the **Key Exportable** check box to export the key. By default, this is checked.
e) Click **Generate**.

A new RSA or EC key is created for the PKI trustpoint and is ready for use in certificate operations.

Add and manage certificates

Add and manage certificates.

To add and manage certificates, use one of these methods.

Generate and import a certificate signing request (CSR)

Add and manage certificates.

Secure the system by adding and managing device certificates.

Perform this task when onboarding a new device, renewing expiring certificates, or updating trust relationships.

Before you begin

- When configuring a password for the .pfx file, avoid using these ASCII characters: "*, ^, (), [], \, ", and +". Using these ASCII characters results in a configuration error and prevents the certificate from being imported to the controller.
- Ensure you have the required certificate files and CA information.

Before you begin

You can add and manage certificates using either of the following methods:

Procedure

---

1. Choose **Configuration** > **Security** > **PKI Management** > **Add Certificate**.
2. Click **Generate Certificate Signing Request**.
   a) In the **Certificate Name** field, enter the certificate name.

b) From the **Key Name** drop-down list, choose an RSA key pair. (Click the plus (+) icon under the **Key Pair Generation** tab to create new RSA key pairs.).
c) Enter values in the **Country Code**, **Location**, **Organization**, **State**, **Organizational Unit**, and the **Domain Name** fields.
d) Click **Generate**.
The generated Certificate Signing Request (CSR) is displayed on the right. Click **Copy** to copy and save a local copy. Click **Save to Device** to save the generated CSR to the /bootflash/csr directory.

> **Note**
>
> If an IP address is used on the Domain Name field the controller creates the CSR without a Subject Alternative Name (SAN), since the IP address is not supported as an attribute in the SAN field of the CSR when the CSR is generated from the controller.

3. Click **Authenticate Root CA**.
   a) From the **Trustpoint** drop-down list, choose the trustpoint label generated in Step 2, or any other trustpoint label that you want to authenticate.
   b) In the **Root CA Certificate (.pem)** field, copy and paste the certificate that you have received from the CA.

   > **Note**
   >
   > Ensure that you copy and paste the PEM Base64 certificate of the issuing CA of the device certificate.

   c) Click **Authenticate**.
4. Click **Import Device Certificate**.
   a) From the **Trustpoint** drop-down list, choose the trustpoint label that was generated in Step 2, or any other trustpoint label that you want to authenticate.
   b) In the **Signed Certificate (.pem)** field, copy and paste the signed certificate that you received, from your CA.
   c) Click **Import**.

This completes the device certificate import process and the certificate can now be assigned to features.

Import a PKCS12 certificate

Import a PKCS12 certificate into the system to enable secure authentication and encryption for network communications.

Use this task when you need to install a PKCS12 certificate file for system, server, or application authentication.

The certificate can be located on any of these sources: FTP, SFTP, TFTP, SCP, or Desktop (HTTPS).

Before you begin

Obtain the PKCS12 certificate file and its password.

Procedure

---

1. Click **Import PKCS12 Certificate**.
2. From the **Transport Type** drop-down list, choose either **FTP**, **SFTP**, **TFTP**, **SCP**, or **Desktop (HTTPS)**.

Transport Type	Action
For FTP, SFTP, and SCP	enter values in the **Server IP Address (IPv4/IPv6)**, **Username**, **Password**, **Certificate File Path**, **Certificate Destination File Name**, and **Certificate Password** fields.
For TFTP	enter values in the **Server IP Address (IPv4/IPv6)**, **Certificate File Path**, **Certificate Destination File Name**, and **Certificate Password** fields.
For Desktop (HTTPS)	enter values in the **Source File Path** and **Certificate Password** fields.

3. Click **Import**.

The system imports the PKCS12 certificate. You see a confirmation message when the process completes successfully.

148 Controller Self-Signed Certificate for Wireless AP Join

Topics:

- Controller self-signed certificates for wireless AP Join

Explains how to configure and manage controller self-signed certificates to enable secure wireless access point authentication and join processes.

Controller self-signed certificates for wireless AP Join

This topic explains controller self-signed certificates, which are digital certificates generated by a wireless controller to enable secure CAPWAP communication and facilitate access point (AP) onboarding when manufacturer-installed certificates are unavailable or incompatible.

A controller self-signed certificate is a digital certificate generated and issued by a wireless controller itself that

- enables secure CAPWAP communication for access point (AP) join processes
- is used when manufacturer installed SUDI certificates are unavailable or incompatible, and
- helps ensure connectivity and secure onboarding of APs under specific scenarios.

Self-signed certificates allow Cisco Catalyst controllers to fulfill certificate requirements for AP joining and management, especially when manufacturer-installed or third-party certificates are missing or cannot be validated.

Use cases for controller self-signed certificate for wireless AP join

Lists the scenarios in which controller self-signed certificates are required for wireless AP join, including platform limitations and compatibility issues with certain APs.

You need controller self-signed certificates in specific circumstances to enable wireless APs to join the controller successfully.

Controller self-signed certificate use cases

These situations require controller self-signed certificates:

- The Cisco Catalyst 9800-CL platform is not equipped with manufacturer-installed SUDI certificates. Configure self-signed certificates on these controllers.
- Some APs running earlier software and using a Manufacturer Installed Certificate (MIC) issued by a SHA1 Cisco Trusted CA cannot join controllers with SHA2 SUDI certificates. During the CAPWAP join process, these APs display a bad certificate error and fail the DTLS handshake.

  Workaround: To support AP upgrades, configure a self-signed certificate for the controller as a workaround for the second use case. After updating all APs, delete the self-signed certificates. Then, revert to the SUDI certificate.

  > **Note**
  >
  > This workaround does not apply to Embedded Wireless Controllers running on Catalyst 9000 series switches. It is only valid for hardware appliance controllers such as Cisco Catalyst 9800-40, 9800-80, and 9800-L.

- The command **wireless management certificate ssc auth-token** is required for ensuring resilient operation of Cisco Catalyst 9800-CL controllers. It is mandatory to configure an explicit authentication token on all 9800-CL devices within the network. Additionally, this command is required when migrating from an AireOS controller to a Cisco Catalyst 9800-CL controller to facilitate secure AP join, as the 9800-CL uses a self-signed certificate instead of a MIC used by AireOS controllers.

Requirement: Use minimum RSA key size for DTLS connections

Use these guidelines when configuring DTLS connections for AP and mobility: always use certificates with an RSA key size of at least 2048 bits to ensure successful connections after a reload.

Always ensure certificates used for DTLS connections (for AP and mobility) have an RSA key size of at least 2048 bits. Using a smaller key size will cause AP and mobility connections to fail after a reload.

This principle applies to all DTLS connections involving access points (AP) and mobility features that require device certificates.

Using a minimum RSA key size of 2048 bits ensures compliance with security best practices and prevents connection failures due to insufficient key strength.

DTLS connections for AP and mobility will remain operational after a reload when certificates meet the minimum RSA key size requirement.

To verify the device certificate key size, use this command:

```
show crypto pki certificate verbose tp-name
```

Replace *tp-name* with your trustpoint name.

Prerequisites for controller self-signed certificate for wireless AP join

Follow these guidelines to prepare the controller for self-signed certificate configuration. This enables wireless AP join. Meet all prerequisites before setup.

- Ensure that the VLAN interface is up and that the IP address is reachable.
- Ensure that the **ip http server** is enabled. For more information, see Enabling HTTP Server .
- Set the **clock calendar-valid** command appropriately. For more information, see *Configure clock calendar.*
- Check whether the PKI CA server is configured. If it is, delete the existing CA server configuration.

> **Note**
>
> The **show crypto pki server** command output should not display anything.

Configure clock calendar (CLI)

Configure clock calendar using commands to ensure accurate timekeeping on the device.

Set the clock calendar to ensure accurate timekeeping on the device.

This configuration is necessary for time-sensitive operations and logging on the device.

Before you begin

Access to the device with appropriate privileges to enter global configuration mode.

Follow these steps to configure clock calendar:

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enable clock calendar.

   Example

   ```
   Device(config)# clock calendar-valid
   ```

3. Exit configuration mode.

   Example

   ```
   Device(config)# exit
   ```

The clock calendar is now configured and operational on the device.

Enable HTTP server using CLI

Configure the HTTP server to enable web-based management of the device using commands.

Enable the HTTP server to allow web-based management of the device.

This configuration is applicable for devices that require HTTP access for management purposes.

Before you begin

Ensure you have administrative access to the device.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable the HTTP server on your IP or IPv6 system.

   Example

   ```
   Device(config)# ip http server
   ```

   Enables the HTTP server on your IP or IPv6 system, including a Cisco web browser user interface. By default, the HTTP server uses the standard port 80.

3. Enable the secure HTTP server on your IP or IPv6 system.

   Example

   ```
   Device(config)# ip http secure-server
   ```

   Enables the secure HTTP server on your IP or IPv6 system, providing encrypted access to the web interface.

4. Exit configuration mode.

Example

```
Device(config)# exit
```

The HTTP server is now enabled, allowing web-based management of the device.

Configure CA server (CLI)

Configure a CA server using commands to manage certificates for devices in the network.

Deploy a CA server to manage certificates for devices in the network.

This configuration is essential for environments that require secure communication through certificates.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Generate RSA keys for the CA server.

   Example

   ```
   Device(config)# crypto key generate rsa general-keys modulus size_of_key_module
    label keypair_name
   ```

   Configures a certificate for the controller.

   When you generate RSA keys, you are prompted to enter a modulus length. A longer modulus length might be more secure, but it takes longer to generate and to use.

   > **Note**
   >
   > The recommended key-pair name is *WLC_CA* and key modulus is *2048* bits.

3. Enable the IOS certificate server.

   Example

   ```
   Device(config)# crypto pki server certificate_server_name
   ```

   Enables IOS certificate server.

> **Note**
>
> The *certificate_server_name* must be the same name as the *keypair_name*.

4. Configure the issuer name for the CA certificate.

   Example

   ```
   Device(cs-server)# issuer-name O=Cisco Virtual Wireless LAN Controller,
   CN=CA-vWLC
   ```

   Configures X.509 distinguished name for the issuer CA certificate.

   > **Note**
   >
   > You need to configure the same *issuer-name* as suggested for AP join.

5. Grant certificate requests automatically.

   Example

   ```
   Device(cs-server)# grant auto
   ```

   Grants certificate requests automatically.

6. Optional: Specify the hash function for the signature used in the granted certificates.

   Example

   ```
   Device(cs-server)# hash sha256
   ```

   Specifies the hash function for the signature used in the granted certificates.

7. Optional: Specify the lifetime in days of a CA certificate.

   Example

   ```
   Device(cs-server)# lifetime ca-certificate time-interval
   ```

   Specifies the lifetime in days of a CA certificate.

8. Optional: Specify the lifetime in days of a granted certificate.

   Example

   ```
   Device(cs-server)# lifetime certificate time-interval
   ```

   Specifies the lifetime in days of a granted certificate.

9. Set the CA key and CA certificate archive format and password.

Example

```
Device(cs-server)# database archive pkcs12 password 0 cisco123
```

Sets the CA key and CA certificate archive format and password to encrypt the file.

10. Enable the certificate server.

Example

```
Device(cs-server)# no shutdown
```

Enables the certificate server.

> **Note**
>
> Issue this command only after you have completely configured your certificate server.

11. Return to privileged EXEC mode.

Example

```
Device(cs-server)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The CA server is now configured and ready to manage certificates for devices in the network.

Configure trustpoint (CLI)

Configure a trustpoint to enable secure communication with a Certificate Authority (CA) using commands.

Configure a trustpoint to enable secure communication with a Certificate Authority (CA).

This configuration is necessary for devices that require secure communications and certificate management.

Before you begin

Ensure you have access to the device and the necessary permissions to configure trustpoints.

Follow these steps to configure trustpoint using CLI commands:

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Generate RSA keys for the trustpoint.

   Example

   ```
   Device(config)# crypto key generate rsa exportable general-keys modulus
   size-of-the-key-modulus label label
   ```

   When you generate RSA keys, you are prompted to enter a modulus length. A longer modulus length might be more secure, but it takes longer to generate and to use.

3. Create a new trustpoint for an external CA server.

   Example

   ```
   Device(config)# crypto pki trustpoint trustpoint_name
   ```

   Here, *trustpoint_name* refers to the trustpoint name.

   > **Note**
   >
   > Ensure that same names are used for key-pair (*label*) and *trustpoint_name*.

4. Map RSA key with that of the trustpoint.

   Example

   ```
   Device(ca-trustpoint)# rsakeypair RSA_key
   ```

   Maps RSA key with that of the trustpoint.

   - RSA_key–Refers to the RSA key pair label.
   - key_size–Refers to the signature key length. The value ranges from 360 to 4096.

5. Create subject name parameters for the trustpoint.

   Example

   ```
   Device(ca-trustpoint)# subject-name subject_name
   ```

   Specifies the subject name for the trustpoint.

6. Check revocation.

   Example

   ```
   Device(ca-trustpoint)# revocation-check none
   ```

   Specifies whether to check for certificate revocation.

7. Specify the hash algorithm.

Example

```
Device(ca-trustpoint)# hash sha256
```

Specifies the hash algorithm to be used.

8. Specify the serial number.

Example

```
Device(ca-trustpoint)# serial-number
```

Specifies the serial number for the trustpoint.

9. Optional: Set certificate key-usage purpose.

Example

```
Device(ca-trustpoint)# eku request server-auth client-auth
```

Sets the extended key usage for the certificate.

10. Enable password for the trustpoint.

Example

```
Device(ca-trustpoint)# password 0 password
```

11. Enroll the URL for the CA server.

Example

```
Device(ca-trustpoint)# enrollment url url
```

Replace the dummy IP with management VLAN interface IP of the controller where CA server is configured.

12. Exit the configuration mode.

Example

```
Device(ca-trustpoint)# end
```

The trustpoint is now configured and ready for use with the CA server.

Authenticate and enroll the PKI trustpoint with CA server

Configure the PKI trustpoint to authenticate and enroll with the Certification Authority (CA) server using commands.

Authenticate and enroll the PKI trustpoint to establish a secure connection with the Certification Authority (CA) server.

This procedure is used in environments where a PKI trustpoint needs to be authenticated and enrolled with a Certification Authority (CA) server for certificate management.

Before you begin

Ensure that the Certification Authority (CA) server is reachable and the trustpoint is properly configured.

Follow these steps to authenticate and enroll the PKI trustpoint with CA server:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Authenticate the PKI trustpoint with the CA server.

   Example

   ```
   Device(config)# crypto pki authenticate trustpoint-name
   Certificate has the following attributes:
   Fingerprint MD5: 64C5FC9A C581D827 C25FC3CF 1A7F42AC
   Fingerprint SHA1: 6FAFF812 7C552783
   6A8FB566 52D95849 CC2FC050
   % Do you accept this certificate? [yes/no]: yes
   Trustpoint CA certificate accepted.
   ```

   Fetches the CA certificate.

3. Enroll the PKI trustpoint for a client certificate.

   Example

   ```
   Device(config)# crypto pki enroll trustpoint-name
   Enter following answers for UI interaction:
   % Include an IP address in the subject name? [no]: no
   Request certificate from CA? [yes/no]: yes
   ```

4. Exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

   Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The PKI trustpoint is now authenticated and enrolled with the Certification Authority (CA) server, allowing for secure certificate management.

Tag wireless management trustpoint name

Configure a wireless management trustpoint name for identification and management purposes using commands.

Tag a wireless management trustpoint name for identification and management purposes.

This configuration is used in environments where wireless management trustpoints need to be clearly identified for management and security.

Before you begin

Ensure you have the necessary privileges to enter global configuration mode.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Tag the wireless management trustpoint name.

   Example

   ```
   Device(config)# wireless management trustpoint trustpoint-name
   ```

3. Exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

   Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The wireless management trustpoint name is successfully tagged and can be used for management purposes.

Disable PKI server

Configure the PKI server to be disabled and prevent it from issuing certificates using commands.

Disable the PKI server to prevent it from issuing certificates.

This procedure is used in scenarios where the PKI server is no longer needed or must be temporarily disabled.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a new server for an external CA server.

   Example

   ```
   Device(config)# crypto pki server certificate-server-name
   ```

   The *certificate-server-name* refers to the server name.

> **Note**
>
> Here, server_name refers to the server name.

3. Disable the certificate server.

   Example

   ```
   Device(cs-server)# shutdown
   ```

   Update purpose string to \

4. Return to privileged EXEC mode.

   Example

   ```
   Device(cs-server)# end
   ```

   Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The PKI server is now disabled and will not issue certificates.

Verify controller certificates for wireless AP join

Lists commands to verify controller certificates for wireless AP join.

Use these commands to verify controller certificates for wireless access point (AP) join.

To view the CA server details, use the command:

```
Device# show crypto pki server
Certificate Server WLC_CA:
Status: enabled
State: enabled
Server's configuration is locked (enter "shut" to unlock it)
Issuer name: O=Cisco Virtual Wireless LAN Controller, CN=CA-vWLC
CA cert fingerprint: 79A3DBD5 59A7E384 73ABD152 C133F4E2
Granting mode is: auto
Last certificate issued serial number (hex): 1
CA certificate expiration timer: 12:04:00 UTC Mar 8 2029
CRL NextUpdate timer: 18:04:00 UTC Mar 11 2019
Current primary storage dir: nvram:

149 Managing Rogue Devices

Topics:

- Rogue devices and detection
- Wireless Service Assurance (WSA) rogue events
- Rogue AP scale modes per class
- Rogue PMF containment

This chapter explains configuring and operating rogue device detection and containment on Cisco wireless controllers—covering RLDP, management frame protection, AP authentication, off-channel PMF, WSA event reporting, and scale quotas/priorities.

Rogue devices and detection

Introduces rogue device concepts, covering detection techniques, containment strategies, integration with Cisco Prime Infrastructure, MFP-based and off-channel PMF containment, AP impersonation detection, security level configuration, management frame protection, policy configuration, and provides verification procedures for comprehensive rogue threat management.

A rogue device is any unauthorized network device.

A rogue device can:

- disrupt wireless LAN operations by hijacking legitimate clients,
- facilitate attacks such as plaintext, denial-of-service, and man-in-the-middle attacks on wireless networks, and
- pose serious security risks by allowing unauthorized access, interception, and breaches inside the corporate firewall.

Risks and impact on network security

Rogue access points are a common form of rogue devices. Hackers can use rogue access points to capture sensitive information such as usernames and passwords. By transmitting a series of Clear to Send (CTS) frames, a rogue access point can mimic a legitimate access point. This action instructs a specific client to transmit while forcing other clients to wait, which prevents legitimate clients from accessing network resources.

Ban rogue access points from the air space to protect users and maintain network integrity.

Because rogue access points are inexpensive and available, staff may connect unauthorized access points to existing LANs. This can create ad hoc wireless networks without approval from IT departments.

These rogue access points can create serious security risks because they may connect inside the corporate firewall. If security settings are disabled on these devices, unauthorized users can intercept network traffic and hijack client sessions. When wireless users connect to rogue access points within the enterprise network, the risk of a security breach increases.

Rogue client status change

The controller marks the rogue client as a threat if a wireless client in the RUN state has the same MAC address.

Restrictions on rogue detection

- Rogue containment is not supported on DFS channels.

Rogue AP containment and attack signatures

Use this concept to understand how rogue AP containment operates and the types of attack signatures relevant for wireless security, including mechanisms introduced in release 17.7.1.

A rogue AP containment and attack signature is a set of wireless network security mechanisms that

- detect and contain unauthorized rogue wireless APs,
- use automated or manual methods to select the best access point for containment actions, and
- define specific attack signatures, including behaviors of rogue AP impersonators and new threats based on beacon frames.

Containment operation

A rogue access point is moved to a contained state either automatically or manually. The controller selects the best available access point (AP) for containment and pushes the containment information to it. Each AP stores its list of containments per radio.

For auto-containment, you can configure the controller to use only APs in monitor mode. Containment operations occur through two primary methods:

- The container AP periodically reviews its containment list and sends unicast containment frames. For rogue AP containment, these are sent only if a rogue client is associated.
- When the system detects contained rogue activity, the AP immediately transmits containment frames.

Individual rogue containment involves sending a sequence of unicast disassociation and deauthentication frames.

Attack signature examples

These signatures help identify sophisticated attack methods targeting wireless networks and support more effective containment and remediation strategies.

- **Beacon DS Attack** –When managed and rogue APs use the same BSSID, the rogue APs are termed as impersonators. An attacker can add the Direct-Sequence parameter set information element with any channel number. If the added channel number is different from the channel number used by the managed AP, the attack is termed as Beacon DS Attack.
- **Beacon Wrong Channel** –When managed and rogue APs use the same BSSID, the rogue APs are termed as AP impersonators. If an AP impersonator uses a channel number that is different from the one used by the managed AP with the same BSSID, the attack is termed as Beacon Wrong Channel. In such a case, the Direct-Sequence Information Element might not even be present in the Beacon frame.

Cisco Prime Infrastructure interaction and rogue detection

Cisco Prime Infrastructure uses rule-based classification and interacts with the controller to detect and manage rogue access points based on configured classification rules and rogue states.

A rogue access point classification rule is a network security mechanism that

- applies predefined criteria to evaluate and categorize access points detected on the network,
- determines the current state of each detected access point (such as Friendly, Malicious, Internal, or External), and
- defines when and how the controller communicates rogue events to Cisco Prime Infrastructure.

How Cisco Prime Infrastructure interacts with the controller for rogue detection

Cisco Prime Infrastructure interacts with controllers to detect and manage rogue access points according to the classification rules set on the controllers. The rule-based classification enables Cisco Prime Infrastructure to receive detailed trap notifications when rogue access point events occur. Key interactions and behaviors include:

- The controller uses its configured classification rules to determine the state of each rogue access point.
- When certain rogue access point events occur (such as state changes or rogue entry removal), the controller sends traps (notifications) to Cisco Prime Infrastructure.
- Trap notifications depend on both the rogue state and the event type, including these cases:
  - If an unknown access point moves to the Friendly state for the first time and the rogue state is Alert, a trap is sent.
  - No trap is sent if the rogue state is Internal or External.

  - If a rogue entry is removed after timeout, the controller sends a trap for entries classified as Malicious (Alert, Threat) or Unclassified (Alert).
  - The controller does not remove rogue entries with the following states: Contained, Contained Pending, Internal, and External.

- When a new, unknown access point is detected and moves to the Friendly state under Alert, Cisco Prime Infrastructure receives a notification.
- If a rogue entry with a Malicious or Unclassified (Alert) state is removed after a timeout, a trap is generated and sent to Cisco Prime Infrastructure.
- Rogue entries in Contained, Contained Pending, Internal, and External states are retained by the controller and not removed automatically, so no removal trap is sent for them.

Rogue containment (Protected Management Frames (PMF) enabled)

Information about rogue containment.

Starting with Cisco IOS XE 17.3.1, the system does not contain rogue devices enabled with 802.11w Protected Management Frames (PMF). Instead, the system marks the rogue device as *Contained Pending*, and raises a Web Security Appliance (WSA) alarm for the *Contained Pending* event. Skipping device containment prevents unnecessary use of AP resources.

Run the **show wireless wps rogue ap detailed** command to verify device containment when PMF is enabled on a rogue device.

> **Note**
>
> This feature is supported only on Wave 2 APs.

Off-channel PMF rogue containment

This content describes the conceptual information about off-channel PMF rogue containment.

A off-channel PMF rogue containment is a wireless security technique that

- detects rogue access points using off-channel or non-serving radios
- enables access points to report rogue APs to a central controller, and
- allows continuous monitoring and containment of rogue APs without disrupting client service on the primary radio.

The containment process involves three steps:

1. An AP detects a rogue AP and reports its details to the controller.
2. The controller sends a containment request specifying the off-channel PMF containment type.
3. The AP validates the request and contains the rogue AP using designated off-channel radios.

The **pmf-offchannel** command is introduced in the AP profile of the controller to enable off-channel PMF rogue containment.

If a rogue AP is detected operating on a frequency not currently used by client devices, the Cisco AP can use its off-channel radio to monitor and contain that rogue AP, minimizing interruption to legitimate wireless clients.

Standard rogue containment only uses the serving radio, which can interfere with client service. Off-channel PMF rogue containment specifically avoids disruption by using non-serving or dedicated radios.

Limitations for off-channel PMF rogue containment

Describes the limitations of off-channel PMF rogue containment.

The limitations for off-channel PMF rogue containment are:

- You can only contain rogue clients that are not in power-saving mode.
- You cannot contain rogue clients on Dynamic Frequency Selection (DFS), or 5 gigahertz (GHz).
- You cannot contain rogue clients on the 6 gigahertz (GHz) band.
- After you contain rogue clients, they might re-associate with the rogue Service Set Identifier (SSID).
- Containment depends on client behavior and may not work if future changes are made to client wireless drivers.

AP impersonation detection

Access Point (AP) impersonation is a wireless security attack where an attacker mimics a legitimate access point to intercept and manipulate communication between devices and the network.

An AP impersonation is a wireless security attack that

- allows a rogue device to masquerade as a legitimate AP
- enables attackers to intercept and manipulate wireless communication between client devices and the network, and
- threatens the confidentiality, integrity, and security of wireless network traffic.

Detection methods

The various methods to detect AP impersonation are:

- You can detect AP impersonation if a managed AP reports itself as Rogue. This method is always enabled and does not require configuration.
- AP impersonation detection uses Management Frame Protection (MFP).
- AP impersonation detection uses AP authentication.

Management Frame Protection (MFP)-based detection

Infrastructure MFP protects 802.11 session management by adding Message Integrity Check (MIC) elements to management frames sent by APs (not clients). Other APs in the network then validate these management frames.

- If infrastructure MFP is enabled, managed APs check whether the MIC elements are present and valid.
- If either condition is not met, the managed AP sends rogue AP reports with an updated AP authentication failure counter field.

AP authentication-based detection

When you enable AP authentication, the controller creates an AP domain secret and shares it with all APs in the same network. This process enables APs to authenticate each other.

- An AP authentication information element is attached to beacon and probe response frames.
- If the AP authentication information element has an incorrect signature, an off timestamp, or the information element is missing, the AP that detects the condition increments the **AP authentication failure count** field.

- An impersonation alarm is raised after the **AP authentication failure count** field exceeds its threshold.
- The rogue AP is classified as **Malicious** with the state **Threat**.

Run the **show wireless wps rogue ap detail** command to see when AP impersonation is detected as a result of authentication errors.

Configuration notes

- Run the **CCX Aironet-IESupport** command in all WLAN procedures to prevent the BSSID from being detected as a rogue.
- For AP impersonation detection, Network Time Protocol (NTP) must be enabled under the AP profile. CAPWAP-based time is not sufficient.

Rogue detection security level

The rogue detection security level configuration allows you to set rogue detection parameters for different deployment needs.

A rogue detection security level is a configuration preset that

- determines the sensitivity and scope of rogue wireless device detection
- restricts or allows configuration of specific detection parameters, and
- provides predefined or customizable options for different deployment needs.

- Rogue detection: identifies unauthorized or unknown wireless devices in a network environment.
- Security level: specifies a preset combination of parameters for rogue detection.

The system provides four rogue detection security levels.

- Critical: Provides basic rogue detection for highly sensitive deployments. Fixed configuration parameters ensure maximum security and consistency.
- High: Provides basic rogue detection suitable for medium-scale environments. Several parameters are fixed to balance protection and operational simplicity.
- Low: Provides basic rogue detection suitable for small-scale deployments. Fixed parameters provide easy management.
- Custom: The default security level. You can fully configure all rogue detection parameters to suit any environment.

> **Note**
>
> To modify all parameters, select the Custom security level. The critical, high, and low levels have fixed settings.

Table 121: Rogue Detection: Predefined Levels

Parameter	Critical	High	Low
Cleanup Timer	3600 seconds (1 hour)	1200 seconds (20 minutes)	240 seconds (4 minutes)
AAA Validate Clients	Disabled	Disabled	Disabled
AAA Validate AP	Disabled	Disabled	Disabled

Parameter	Critical	High	Low
Adhoc Reporting	Enabled	Enabled	Enabled
Monitor Mode Report Interval	10 seconds (0:10)	30 seconds (0:30)	60 seconds (1:00)
Minimum RSSI	-128 dBm	-80 dBm	-80 dBm
Transient Interval	600 seconds (10 minutes)	300 seconds (5 minutes)	120 seconds (2 minutes)
Auto Contain **This feature works only on Monitor Mode APs.**	Disabled	Disabled	Disabled
Auto Contain Level	1	1	1
Auto Contain Same SSID	Disabled	Disabled	Disabled
Auto Contain Valid Clients on Rogue AP	Disabled	Disabled	Disabled
Auto Contain Adhoc	Disabled	Disabled	Disabled
Containment Auto Rate	Enabled	Enabled	Enabled
Validate Clients with Cisco Connected Mobile Experiences (CMX)	Enabled	Enabled	Enabled
Containment FlexConnect	Enabled	Enabled	Enabled

You can configure all these parameters in the Custom security level.

- A hospital implements the Critical security level to maintain rigorous control over rogue detection with fixed settings.
- A small business chooses the Low security level for straightforward rogue detection with minimal configuration.
- An enterprise IT team uses the Custom security level to tailor all rogue detection parameters to their unique requirements.

Set rogue detection security level (CLI)

Set the rogue detection security level.

Set the wireless rogue detection security level for your network deployment.

Before you begin

Use these steps to set the rogue detection security level.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the rogue detection security level to custom.

Example

```
Device(config)# wireless wps rogue security-level custom
```

3. Configure the rogue detection security level for small-scale deployments.

Example

```
Device(config)# wireless wps rogue security-level low
```

4. Configure the rogue detection security level for medium-scale deployments.

Example

```
Device(config)# wireless wps rogue security-level high
```

5. Configure the rogue detection security level for highly sensitive deployments.

Example

```
Device(config)# wireless wps rogue security-level critical
```

The device applies the selected rogue detection security level to enhance wireless intrusion protection for your deployment.

Configuring rogue detection (GUI)

Configure rogue detection using the GUI.

Enable rogue access point detection and set parameters in the GUI.

Use rogue detection to identify and manage unauthorized or suspicious APs in your network. Complete this task when you establish or update your wireless security policies.

Before you begin

Use these steps to configure rogue detection using the GUI:

Procedure

---

1. Choose Configuration, then Tags and Profiles, then AP Join.
2. Click the **AP Join Profile Name** to edit the access point (AP) join profile properties.
3. In the **Edit AP Join Profile** window, click the **Rogue AP** tab.
4. Check the **Rogue Detection** check box to enable rogue detection.
5. In the **Rogue Detection Minimum RSSI** field, enter the RSSI value.
6. In the **Rogue Detection Transient Interval** field, enter the interval in seconds (minutes).
7. In the **Rogue Detection Report Interval** field, enter the report interval value in seconds (minutes).

8. In the **Rogue Detection Client Number Threshold** field, enter the threshold for rogue client detection.
9. Check the **Auto Containment on FlexConnect Standalone** check box to enable auto containment.
10. Click **Update and Apply to Device**.

The rogue-detection feature is activated with your configured parameters. This helps you identify and contain unauthorized access points (APs) in the network.

Configure rogue detection (CLI)

Configure rogue detection using CLI commands.

You enable and customize rogue detection on Cisco wireless access points using specific CLI commands.

Use these commands to detect and contain unauthorized access points (APs) and improve wireless network security.

Before you begin

Use these steps to configure rogue detection.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set the minimum RSSI value for APs to detect rogues and create entries in the system.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

   ```
   Device(config)# rogue detection rssi in dBm
   ```

   You can enter an RSSI value from -128 to -70 dBm. The default is -128 dBm.

   Note

   You can use this feature with any AP mode.

   Many rogues have weak RSSI values and do not provide useful information for rogue analysis. Specify a minimum RSSI value to filter these rogues.

3. Choose a rogue containment option.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

   ```
   Device(config)# rogue detection containment flex-rate
   ```

The **auto-rate** option contains rogues automatically. The **flex-rate** option contains standalone FlexConnect APs.

4. Turn on rogue detection for all APs.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

   ```
   Device(config)# rogue detection enable
   ```

5. Set the interval for rogue reports on monitor mode APs.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

   ```
   Device(config)# rogue detection report-interval time in seconds
   ```

   The valid range for the reporting interval is 10 to 300 seconds.

   If the controller detects thousands of rogue APs, the PUBD (Public Utility Bulletin Daemon) process may cause sustained high CPU usage. Increase the Rogue Detection Report Interval to a value higher than the default of 10 to resolve this issue.

Rogue detection is active using your specified parameters on the AP profile. This improves security by monitoring and containing unauthorized devices.

Configure RSSI deviation notification threshold for rogue APs (CLI)

Configure the RSSI deviation notification threshold for rogue APs using CLI commands.

Set the signal strength deviation threshold to trigger notifications for rogue access points on your network.

Before you begin

Use these steps to configure the RSSI deviation notification threshold for rogue APs.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the RSSI deviation notification threshold for rogue APs.

   Example

   ```
   Device(config)# wireless wps rogue ap notify-rssi-deviation
   ```

3. Return the system to privileged EXEC mode.

Example

```
Device(config)# end
```

You can press Ctrl and Z to exit global configuration mode.

The system notifies you when a rogue APs RSSI deviation exceeds the set threshold.

Configure management frame protection (GUI)

Configure management frame protection using the GUI.

Enable and configure management frame protection (MFP) to secure wireless network communications against attacks such as rogue AP impersonation.

Before you begin

Use these steps to configure management frame protection.

Procedure

---

1. Choose **Configuration**, then **Security**, then **Wireless Protection Policies**.
2. In the **Rogue Policy** tab, under the **MFP Configuration** section, check the **Global MFP State** check box to enable the global MFP state.
3. Check the **AP Impersonation Detection** check box to enable AP impersonation detection.
4. In the **MFP Key Refresh Interval** field, specify the refresh interval in hours.
5. Click **Apply**.

Management frame protection is enabled and configured, providing enhanced security for wireless management frames.

Configure Management Frame Protection (CLI)

Configure management frame protection using command-line interface (CLI) commands.

Configure Management Frame Protection (MFP) on a device using the command-line interface (CLI).

Before you begin

Use these steps to configure management frame protection.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure management frame protection.

   Example

   ```
   Device(config)# wireless wps mfp
   ```

3. Configure AP impersonation detection or set the MFP key refresh interval in hours.

   Example

   ```
   Device(config)# wireless wps mfp ap-impersonation
   ```

   ```
   Device(config)# wireless wps mfp key-refresh-interval
   ```

   key-refresh-interval: Set sthe MFP key refresh interval in hours.

   The valid range is one to 24 hours. The default value is 24 hours.

4. Save the configuration, exit configuration mode, and return to privileged **EXEC** mode.

   Example

   ```
   Device(config)# end
   ```

The device protects wireless management traffic according to the configured settings.

Enable AP authentication

Enable access point authentication on a wireless controller.

Set up AP authentication on a wireless controller. This enhances network security by authenticating APs and by configuring threshold values for authentication failures.

Before you begin

Use these steps to enable AP authentication.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the wireless Wi-Fi Protected Setup (WPS) AP authentication.

   Example

   ```
   Device(config)# wireless wps ap-authentication
   ```

3. Configure AP neighbor authentication and set the threshold for AP authentication failures.

   Example

   ```
   Device(config)# wireless wps ap-authentication threshold threshold
   ```

4. Configure a WLAN.

Example

```
Device(config)# wlan wlan-namewlan-idSSID-name
```

5. Enable support for Aironet information elements on this Wireless Local Area Network (WLAN).

Example

```
Device(config-wlan)# ccx aironet-iesupport
```

6. Return to privileged EXEC mode.

Example

```
Device# end
```

AP authentication is enabled on the wireless controller. Authentication thresholds and Aironet IE support are configured for the specified WLAN.

Configure off-channel PMF rogue containment (GUI)

This task explains how to enable off-channel PMF rogue containment using the GUI.

This task enables off-channel Protected Management Frame (PMF) rogue containment on an AP policy profile.

Before you begin

Perform the steps in this section to configure off-channel PMF rogue containment.

Procedure

---

1. Choose **Configuration**, then **Tags & Profiles**, then **AP Join**.
2. Click **Add**.

   The window labeled **Add AP Join Profile** appears.
3. In the **Add AP Join Profile** window, click the **General** tab and enter the profile name.
4. Click the **Security** tab.
5. Under the **Rogues** section, check the **Rogue Containment PMF-Offchannel** check box.
6. Click **Apply to Device**.

Off-channel PMF rogue containment is enabled on the AP policy profile.

Configure off-channel PMF rogue containment (CLI)

This topic explains how to configure off-channel PMF containment using the CLI.

Set up off-channel Protected Management Frame (PMF) rogue AP containment on APs using CLI commands.

Before you begin

Use these steps to configure off-channel PMF rogue containment on APs.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter a profile name to create an AP profile.

   Example

   ```
   Device(config)# ap profile ap-pmf-off-channel
   ```

3. Enable PMF-denial for rogue AP containment.

   Example

   ```
   Device(config-ap-profile)# rogue detection containment pmf-denial
   ```

   Note

   The **pmf-deauth** feature is enabled by default when **pmf-denial** is enabled. If you do not want **pmf-deauth** , then you must disable it explicitly.

4. Enable PMF-denial type off-channel PMF rogue AP containment.

   Example

   ```
   Device(config-pmf-denial)# pmf-offchannel
   ```

Off-channel PMF containment for rogue APs is enabled on the configured AP profile.

Verify management frame protection

Verify management frame protection on a wireless controller.

To verify if the Management Frame Protection (MFP) feature is enabled or not, use this command:

```
Device# show wireless wps summary
Client Exclusion Policy
  Excessive 802.11-association failures   : unknown
  Excessive 802.11-authentication failures: unknown
  Excessive 802.1x-authentication         : unknown
  IP-theft                                : unknown
  Excessive Web authentication failure    : unknown
  Failed Qos Policy                       : unknown

Management Frame Protection
  Global Infrastructure MFP state : Enabled
```

```
  AP Impersonation detection      : Disabled
  Key refresh interval            : 15
```

To view the MFP details, use this command:

```
Device# show wireless wps mfp summary
Management Frame Protection
  Global Infrastructure MFP state : Enabled
  AP Impersonation detection      : Disabled
  Key refresh interval            : 15
```

Verify rogue events

Show command to verify rogue events.

To verify the rogue event history, run the **show wireless wps rogue ap detailed** command:

```
Device# show wireless wps rogue ap detailed
Rogue Event history

Timestamp                   #Times   Class/State Event                Ctx
                  RC

Verify rogue detection

Command to verify rogue detection on the device.

This section describes the new command for rogue detection.

These commands can be used to verify rogue detection on the device.

Table 122: Verifying Adhoc rogues information

Command	Purpose
show wireless wps rogue adhoc detailed *mac_address*	Displays the detailed information for an Adhoc rogue.
show wireless wps rogue adhoc summary	Displays a list of all Adhoc rogues.

Table 123: Verifying rogue AP information

Command	Purpose
show wireless wps rogue ap clients *mac_address*	Displays the list of all rogue clients associated with a rogue.
show wireless wps rogue ap custom summary	Displays the custom rogue AP information.
show wireless wps rogue ap detailed *mac_address*	Displays the detailed information for a rogue AP.
show wireless wps rogue ap friendly summary	Displays the friendly rogue AP information.
show wireless wps rogue ap list *mac_address*	Displays the list of rogue APs detected by a given AP.
show wireless wps rogue ap malicious summary	Displays the malicious rogue AP information.
show wireless wps rogue ap summary	Displays a list of all Rogue APs.
show wireless wps rogue ap unclassified summary	Displays the unclassified rogue AP information.

Table 124: Verifying Rogue Auto-Containment Information

Command	Purpose
show wireless wps rogue auto-contain	Displays the rogue auto-containment information.

Table 125: Verifying Classification Rule Information

Command	Purpose
show wireless wps rogue rule detailed *rule_name*	Displays the detailed information for a classification rule.
show wireless wps rogue rule summary	Displays the list of all rogue rules.

Table 126: Verifying Rogue Statistics

Command	Purpose
show wireless wps rogue stats	Displays the rogue statistics.

Table 127: Verifying Rogue Client Information

Command	Purpose
show wireless wps rogue client detailed *mac_address*	Displays detailed information for a Rogue client.
show wireless wps rogue client summary	Displays a list of all the Rogue clients.

Table 128: Verifying Rogue Ignore List

Command	Purpose
show wireless wps rogue ignore-list	Displays the rogue ignore list.

Verify off-channel PMF rogue containment

Describes the various show commands and their outputs during the verification of the off-channel PMF containment.

Verify rogue containment summary

To verify rogue containment summary, use this command:

```
Device# show wireless wps rogue containment summary
Rogue Containment activities for each managed AP

AP: 6XXX.b4XX.2aXX  Slot: 1
  Active Containments   : 3
   Containment Mode     : OFFCHAN_PMF
   Rogue AP MAC         : 68XX.b4XX.2aXX
   Containment Channels : 40
                                                0.0.0.0
   372           64               AGL          Enabled
```

Verify rogue statistics

To display rogue statistics, use this command:

```
Device# show wireless wps rogue stats
 Stats
  Alert                         : 256
  Internal                      : 0
  External                      : 0
  Contained                     : 1
  Containment-pending           : 0
  Threat                        : 0
  Pending                       : 0
Rogue Clients
  Total/Max Scale               : 20/16000
  Contained                     : 0
  Containment-pending           : 0
.
.
.
                     0.0.0.0                          372           64
        AGL          Enabled
```

Examples: rogue detection onfiguration

Example for rogue detection configuration.

This example shows how to configure the minimum RSSI that a detected rogue AP needs to be at, to have an entry created in the device:

```
Device# configure terminal
Device(config)# ap profile profile1
```

```
Device(config)# rogue detection min-rssi -100
Device(config)# end
Device# show wireless wps rogue client summary/show wireless wps rogue ap
summary
```

This example shows how to configure the classification interval:

```
Device# configure terminal
Device(config)# ap profile profile1
Device(config)# rogue detection min-transient-time 500
Device(config)# end
Device# show wireless wps rogue client summary/show wireless wps rogue ap
summary
```

Configure rogue policies (GUI)

You can configure rogue policies using the GUI.

Use this task to define and customize rogue wireless protection policies. These policies help the system detect and respond to unauthorized wireless activity.

Before you begin

Perform the steps in this section to configure rogue policies.

Procedure

1. Choose **Configuration**, then **Security**, then **Wireless Protection Policies**.
2. In the **Rogue Policies** tab, select the security level from the **Rogue Detection Security Level** drop-down.
3. In the **Expiration timeout for Rogue APs** field, enter the timeout value in seconds.
4. Select the **Validate Rogue Clients against AAA** check box to validate rogue clients using the AAA server.
5. Select the **Validate Rogue APs against AAA** check box to validate rogue access points using the AAA server.
6. In the **Rogue Polling Interval** field, enter the interval in seconds at which the system polls the AAA server for rogue information.
7. Select the **Detect and Report Adhoc Networks** check box to enable detection of rogue ad hoc networks.
8. In the **Rogue Detection Client Number Threshold** field, enter the number of clients at which the system generates an SNMP trap.
9. In the **Auto Contain** section, enter these details.
10. Select the containment level from the **Auto Containment Level** drop-down.
11. Select the **Auto Containment only for Monitor Mode APs** check box to limit automatic containment to monitor-mode APs.
12. Select the **Using our SSID** check box to limit automatic containment to rogue APs that use an SSID that is configured on the controller.
13. Select the **Adhoc Rogue AP** check box to enable automatic containment for ad hoc rogue APs.
14. Click **Apply**.

The system updates rogue policies to enhance detection and containment of unauthorized wireless threats according to your configuration.

Configure rogue policies (CLI)

Use this procedure to configure rogue policies using commands.

Establish rogue policies to enhance network security by managing rogue access points and clients.

This configuration is essential in environments where rogue devices may pose a security threat to the network.

Before you begin

Ensure you have access to the device's global configuration mode.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. Configure the rogue detection security level.

   Example

   ```
   Device(config)# wireless wps rogue security-level security-level
   ```

   You can set the *security-level* to be **critical** for highly sensitive deployments, **custom** for customizable security level, **high** for medium-scale deployments, and **low** for small-scale deployments.

3. Configure the expiration time for rogue entries.

   Example

   ```
   Device(config)# wireless wps rogue ap timeout timout-in-seconds
   ```

   Valid range for the time in seconds is 240 seconds to 3600 seconds.

4. Configure the use of AAA or local database to detect valid MAC addresses.

   Example

   ```
   Device(config)# wireless wps rogue client aaa
   ```

   Configures the use of AAA or local database to detect valid MAC addresses.

5. Configure the use of MSE to detect valid MAC addresses.

   Example

   ```
   Device(config)# wireless wps rogue client mse
   ```

   Configures the use of MSE to detect valid MAC addresses.

6. Configure the minimum RSSI notification threshold for rogue clients.

Example

```
Device(config)# wireless wps rogue client notify-min-rssi RSSI-threshold
```

Valid range for the RSSI threshold in dB is -128 dB to -70 dB.

7. Configure the RSSI deviation notification threshold for rogue clients.

Example

```
Device(config)# wireless wps rogue client notify-min-deviation
RSSI-threshold-value
```

Valid range for the RSSI threshold in dB is 0 dB to 10 dB.

8. Configure the use of AAA or local database to classify rogue AP based on rogue AP MAC addresses.

Example

```
Device(config)# wireless wps rogue ap aaa
```

Configures the use of AAA or local database to classify rogue AP based on rogue AP MAC addresses.

9. Configure rogue AP AAA validation interval.

Example

```
Device(config)# wireless wps rogue ap aaa polling-interval
AP-AAA-interval-value
```

The valid range for the AP AAA interval in seconds is 60 seconds to 86400 seconds.

10. Enable detecting and reporting adhoc rogue (IBSS).

Example

```
Device(config)# wireless wps rogue adhoc
```

Enables detecting and reporting adhoc rogue (IBSS).

11. Configure the rogue client per a rogue AP SNMP trap threshold.

Example

```
Device(config)# wireless wps rogue client client-threshold threshold-value
```

The valid range for the threshold is 0 to 256.

12. Configure the init timer for rogue APs.

Example

```
Device(config)# wireless wps rogue ap init-timer timer-value
```

The default timer value is set to 180 seconds.

> **Note**
>
> When a rogue AP is detected, an init timer is started and the rules are applied when this timer expires. This allows for rogue AP information to stabilize before applying any rules. However, you can change the value of this timer using this command. For instance, the init timer can be set to 0, if the rules need to be applied as soon as a new rogue AP is detected.

The rogue policies are now configured, enhancing the network's security against rogue devices.

Wireless Service Assurance (WSA) rogue events

Explains wireless service assurance rogue events, including event monitoring and configuration steps, to enhance visibility and proactive management of rogue devices in the wireless network.

Wireless Service Assurance (WSA) rogue events are telemetry notifications that replicate the information of corresponding SNMP traps. Support is available in Release 16.12.x, where x denotes a release version.

- You receive details such as the MAC address of the rogue AP.
- You receive information about the managed AP and the radio that detected the rogue AP with the strongest RSSI.
- You receive event-specific data, such as SSID; channel for potential honeypot events; and MAC address of the impersonating AP for impersonation events.

WSA Rogue Events: Details and Support

For all exported events, these details are provided to the wireless service assurance (WSA) infrastructure:

- MAC address of the rogue AP
- Details of the managed AP and the radio that detected the rogue AP with the strongest RSSI
- Event-specific data such as SSID; channel for potential honeypot events; and MAC address of the impersonating AP for impersonation events.

You can scale the WSA rogue events feature up to four times the maximum number of supported access points (APs). You can also scale it to one-half of the maximum number of supported clients.

The WSA rogue events feature is supported on Cisco Catalyst Center and other third-party infrastructure.

Wireless service assurance rogue events

Configure wireless service assurance rogue events.

Configure your wireless device to send service assurance rogue event data to the event queue.

Before you begin

To configure wireless service assurance for rogue events, complete these steps.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enable wireless service assurance.

   Example

   ```
   Device# network-assurance enable
   ```

3. Enable wireless service assurance for rogue devices.

   Example

   ```
   Device# wireless wps rogue network-assurance enable
   ```

   This ensures that the wireless service assurance (WSA) rogue events are sent to the event queue.

Your device sends wireless service assurance rogue events to the event queue for enhanced monitoring.

Monitor wireless service assurance rogue events

View wireless service assurance (WSA) rogue event statistics and details.

Before you begin

Use these steps to monitor wireless service assurance rogue events.

Procedure

---

1. **show wireless wps rogue stats**

   Example

   ```
   Device# show wireless wps rogue stats
              WSA Events
              Total WSA Events Triggered          : 9
              ROGUE_POTENTIAL_HONEYPOT_DETECTED   : 2
              ROGUE_POTENTIAL_HONEYPOT_CLEARED    : 3
              ROGUE_AP_IMPERSONATION_DETECTED     : 4
              Total WSA Events Enqueued           : 6
              ROGUE_POTENTIAL_HONEYPOT_DETECTED   : 1
              ROGUE_POTENTIAL_HONEYPOT_CLEARED    : 2
              ROGUE_AP_IMPERSONATION_DETECTED     : 3
   ```

   In this example, nine events occurred, but only six events were enqueued. Three events occurred before you enabled the WSA rogue feature.

2. **show wireless wps rogue stats internal**

   show wireless wps rogue ap detailed *rogue-ap-mac-addr*

   These commands display information about WSA events in the event history.

You can track WSA rogue event activity, investigate event history, and verify system responsiveness to rogue threats.

Rogue AP scale modes per class

Describes rogue AP scale modes, feature history, advantages and disadvantages of various role-scale modes, configuration procedures, and verification steps to optimize rogue AP management and scaling across different deployment classes.

A rogue AP scale mode is a database management mechanism that

- decides if the system adds or discards a newly detected rogue AP when the database reaches its capacity
- lets you set quotas or priorities by rogue AP classification to use available space efficiently, and
- allows you to customize storage management based on classification needs and resources.

Types of rogue AP scale modes

These modes determine whether the system adds a rogue AP to the database when it reaches maximum scale:

- **Quota**: Quotas apply to each classification as a percentage of the maximum scale. If a classification has a quota of X percent, that portion of the rogue AP database is reserved for the classification. If all memory for that classification is used, the system drops any new rogue APs in that classification.
- **Priority**: Priorities apply to different classifications. If you do not set quotas, the system uses priority mode by default. The system uses these priorities:
  - malicious: highest
  - custom: high
  - unclassified: medium
  - friendly: low

  The system enforces priorities only when the maximum database scale is reached. If you classify a new rogue AP and the database is full, the system adds it only if there are lower-priority rogue APs that are present. If this happens, the system deletes the newest rogue AP entry of the lowest priority. If there are no lower-priority rogue APs, the system drops the new AP.
- **Hybrid**: Hybrid mode combines quotas and priorities. When space is available, rogue APs of lower priority use any unused quota reserved for higher-priority rogue APs.

Rogue AP scale mode logic after reaching maximum scale

After the rogue AP database reaches maximum scale, the system applies this logic when it classifies a new rogue AP:

- If the number of stored rogue APs in the new rogue AP's class is below its quota, store the new rogue AP and delete the newest rogue AP of the lowest-priority classification that exceeds its quota.
- If a lower-priority classification exceeds its quota, the system deletes the newest rogue AP in that classification and stores the new rogue AP.
- If neither condition applies, the system drops the new rogue AP.

Note

- Configure quotas and priorities carefully to balance security requirements with database limitations.
- If you do not configure quotas, the system uses priority mode.

Suppose the database has reached maximum scale and a new rogue AP classified as malicious is detected. If the malicious quota allows storage, the system stores the new rogue AP and removes the newest rogue AP from the lowest-priority classification that exceeds its quota. If no such rogue AP exists, the system drops the new rogue AP.

Feature history for rogue full scale quotas and priorities

Feature history for rogue full scale quotas and priorities.

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 129: Feature History for Rogue Full Scale Quotas and Priorities

Release	Feature	Feature information
Cisco IOS XE 17.9.1	Rogue full scale quotas and priorities	The rogue full scale quotas and priorities feature helps you to improve the scalability, performance, manageability, and serviceability of rogue Access Points (APs).

Advantages and disadvantages of role-scale modes

This section lists information for choosing the appropriate role-scale mode, along with their main benefits and drawbacks.

Mode	Advantages	Disadvantages
Quota	Simple to use and understand.	• Memory is not used efficiently. • New rogue APs for a class that is already in its maximum quota are dropped. While the memory reserved for another class that does not have any rogue APs, stays empty. For example, this could lead to dropping malicious rogue APs, while there is still memory available.
Priority	• Simple to use and understand. • Utilizes the available memory. • Stores the important rogue APs.	Some of the lower-priority rogue AP classes might not be represented in the rogue database, if higher-priority rogue APs utilize all the available memory.

Mode	Advantages	Disadvantages
Hybrid	Utilizes the available memory, while providing quotas so that all the classes are represented in the database.	Difficult for users to understand the exact behavior.

Configure rogue AP scale (CLI)

Configure rogue AP scale using commands.

Set scale quotas, priorities, and hybrid modes for rogue AP types (malicious, custom, unclassified, friendly) using CLI commands.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure rogue scale quota for malicious, custom, unclassified, and friendly rogue APs.

   Example

   ```
   Device(config)# wireless wps rogue scale quota
   malicious percentage-malicious-rogue-AP custom percentage-custom-rogue-AP
   unclassified percentage-unclassified-rogue-AP friendly
   percentage-friendly-rogue-AP
   ```

   The default value for quota is 0. The sum of all the quotas must be less than or equal to 100 percent.

   If the sum of all the configured quotas is equal to 0, then priority mode is used. If the sum of all the quotas is not equal to 0, then quota mode is used. If hybrid mode is configured, hybrid mode is used no matter what the quota configuration is. Hybrid mode with all the quotas equal to 0, is identical to the priority mode.

   > **Note**
   >
   > Hybrid mode is enabled after the maximum scale is reached. All the rogue APs are stored before the maximum scale is reached.

3. Configure rogue scale priority for malicious, custom, unclassified, and friendly rogue APs.

   Example

   ```
   Device(config)# wireless wps rogue scale priority malicious highest custom
   high unclassified medium friendly low
   ```

Example

```
[no] wireless wps rogue scale priority malicious { high | highest | low | medium } custom { high | highest | low | medium } unclassified { high | highest | low | medium } friendly { high | highest | low | medium }
```

The default value for malicious is **highest** , the default value for custom is **high** , the default value for unclassified is **medium** , and the default value for friendly is **low** .

4. Configure rogue scale hybrid mode.

Example

```
Device(config)# wireless wps rogue scale mode hybrid
```

Unused quota reserved for higher-priority rogue APs are used by rogue APs of lower priority when space is available.

Rogue AP classification uses configured quotas, priorities, or hybrid mode to efficiently manage detected rogue APs according to defined organizational policies.

Verify rogue scale details

Command to verify rogue scale details.

To verify the rogue scale details, run this command:

```
Device# show wireless wps rogue stats
  Total Post Init/Max            : 0/4000
  Total/Max                      : 0/4200
  Init                           : 0
Classification
  Friendly                       : 0/0/0 (Total/Init/Quota[%])
  Malicious                      : 0/0/0 (Total/Init/Quota[%])
  Custom                         : 0/0/0 (Total/Init/Quota[%])
  Unclassified                   : 0/0/0 (Total/Init/Quota[%])
  Unknown                        : 0/0 (Total/Init)
Configured Quotas by Classification
  Custom         : <% of max scale>
  Friendly       : <% of max scale>
  Malicious      : <% of max scale>
  Unclassified   : <% of max scale>
Configured Priorities by Classification
  Custom          :  2 (High)
  Friendly        :  4 (Low)
  Malicious       :  1 (Highest)
  Unclassified    :  3 (Medium)

Configured Rogue Scale Mode: [Priority|Quota|Hybrid]
```

To view the rogue ad hoc summary, run this command:

```
Device# show wireless wps rogue adhoc summary
Detect and report Ad-Hoc Networks : Enabled
Auto-Contain Ad-Hoc Networks      : Disabled
Total Number of Rogue Ad-Hoc      : 0
Friendly Ad-Hoc Rogues            : 0
Malicious Ad-Hoc Rogues           : 0
Custom Ad-Hoc Rogues              : 0
```

```
Unclassified Ad-Hoc Rogues        : 0
Unknown Ad-Hoc Rogues             : 0
Client MAC Address   Adhoc BSSID        Classification  State        # APs
Last Heard
-------------------------------------------------------------------------------------------
```

Rogue PMF containment

Provides an overview of rogue Protected Management Frame (PMF) concepts, configuration tasks, and verification references for wireless security management.

Rogue PMF containment is a wireless security feature that

- uses 802.11w Protected Management Frames (PMF) to contain rogue APs and clients
- operates on centrally switched WLANs when the radio channel of the detecting AP matches the rogue AP's channel, and
- activates only when certain mode and channel conditions are met to secure the network against unauthorized devices.

Feature history

Table 130: Feature history table for rogue PMF containment

Feature name	Release information	Feature description
Rogue PMF containment	Cisco IOS XE 17.12.1	Starting with Cisco IOS XE Dublin 17.12.1, the controller contains a rogue AP with 802.11w Protected Management Frame (PMF) on centrally switched wireless LANs. Containment occurs if the client-serving radio channel of a rogue-detecting AP matches the channel of the corresponding rogue AP.

Operational scenarios

PMF containment occurs in these scenarios:

- You can use PMF containment only in the local mode.
- You can perform PMF containment only for rogue clients that have not joined a rogue AP.
- You can use PMF containment only if a rogue-detecting AP shares the same primary channel with a rogue client.
- You cannot use PMF containment on DFS channels, even if a DFS channel serves as the client-serving channel.
- PMF containment works only if at least one WLAN operates on the serving radio.

For information about APs that support the Rogue PMF Containment feature, see Cisco AP Feature Matrix.

Enable rogue PMF containment

Enable Rogue PMF Containment using commands.

Enable PMF containment to protect your wireless network from rogue APs.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile
   ```

3. Enable PMF-denial rogue AP containment.

   Example

   ```
   Device(config-ap-profile)# rogue detection containment pmf-denial
   ```

4. Enable PMF-denial type deauthentication rogue AP containment.

   Example

   ```
   Device(config-pmf-denial)# pmf-deauth
   ```

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

Rogue AP PMF containment is enabled for the specified AP profile.

```
Device# configure terminal
Device(config)# ap profile pmf-ap-profile
Device(config-ap-profile)# rogue detection containment pmf-denial
Device(config-pmf-denial)# pmf-deauth
Device(config-ap-profile)# end
```

Verify PMF containment

Verify PMF Containment using commands.

To verify PMF containment and the relevant statistics, use these commands.

To view the summary of containment details for all AP radios, use this command

```
Device# show wireless wps rogue containment summary

Rogue Containment activities for each managed AP

AP: 687d.b45f.2ae0  Slot: 1
```

```
  Active Containments   : 3
   Containment Mode     : DEAUTH_PMF
   Rogue AP MAC         : 687d.b45f.2a2d
   Containment Channels : 40
```

To verify the rogue statistics, use this command:

```
Device# show wireless wps rogue stats
.
.
.
 States
  Alert                          : 256
  Internal                       : 0
  External                       : 0
  Contained                      : 1
  Containment-pending            : 0

  Pending                        : 0
Rogue Clients
  Total/Max Scale                : 20/16000
  Contained                      : 0
  Containment-pending            : 0
.
.
.
```

150 Classifying Rogue Access Points

Topics:

- Rogue AP classifications

Explains how unauthorized wireless access points are detected, classified, and contained using controller rules or manual actions.

Rogue AP classifications

Outlines how the controller classifies, organizes, and manages rogue APs using configurable rules, describes classification types and rogue states, explains rule and manual transitions, and provides examples of classification mapping and allowable state changes.

A rogue AP classification is a wireless security mechanism that

- enables administrators to group rogue APs as Friendly, Malicious, Custom, , or Unclassified,
- uses configurable rules to automate the categorization and state assignment of unauthorized APs, and
- allows both automatic and manual reclassification of rogues based on network security requirements.

Additional reference information

- By default, no classification rules are active, so all unknown access points are assigned the Unclassified state. Administrators must enable classification rules to begin organizing rogue access points.
- When rules are enabled, all rogue access points in the Alert state are reclassified automatically based on the latest conditions and rule configurations.
- Changing or adding a rule triggers reclassification of all applicable rogue access points that are in the Alert state.
- You can manually move any rogue or ad hoc rogue access point to Unclassified and state, which represents the default state. Manually moved rogues are subject to rule-based reclassification.
- Rule-based classification does not apply to ad hoc rogues and rogue clients.
- You can configure up to 64 rogue classification rules per controller .
-

How the controller classifies rogue access points

When the controller software receives a rogue report from one of its managed access points, it follows this process:

- If the unknown access point is listed in the friendly MAC address list, the controller classifies it as Friendly.
- If it is not on the friendly MAC list, the controller applies the configured rogue classification rules.
-
- Rule-based classification is not applied to rogue access points that were manually classified.
- If a rogue matches the criteria in a classification rule, the controller assigns the classification type specified in that rule.
- If a rogue does not match any configured rules, it remains Unclassified.
- If a rogue access point is detected on the same wired network, the controller marks its state as Threat and classifies it as Malicious automatically (regardless of rules). You can manually contain such rogues, changing their state to Contained. If the rogue becomes unavailable, the controller moves it to the Alert state until you manually contain it.
- Administrators can always manually change the classification type and state of an access point as needed.
- Before classification, rogue access points are marked Pending.

Examples: Classification mapping

Rule-Based Classification Type	Rogue State
Custom	• Alert–No action is taken other than notifying the management station. The management station in the controller manages the controller and wired networks. • Contained–The unknown AP is contained. If none of the managed APs are available for containment, the rogue is in Contained Pending state.
Delete	Deletes the rogue AP.
Friendly	• Internal–If the unknown AP poses no threat to WLAN security, you can manually configure it as Friendly, Internal. An example of this would be the APs in your lab network. • External–If the unknown AP is outside the network and poses no threat to WLAN security, you can manually configure it as Friendly, External. An example of this would be the AP in your neighboring coffee shop. • Alert– No action is taken other than notifying the management station. The management station manages the controller and wired networks.
Malicious	• Alert– No action is taken other than notifying the management station. The management station manages the controller and wired networks. • Threat–The unknown AP is found to be on the network and poses a threat to WLAN security. • Contained–The unknown AP is contained. If none of the managed APs are available for containment, the rogue is in Contained Pending state.
Unclassified	• Alert– No action is taken other than notifying the management station. The management station manages the controller and wired networks. • Contained–The unknown AP is contained. If none of the managed APs are available for containment, the rogue is in contained pending state.

As mentioned earlier, the controller can automatically change the classification type and rogue state of an unknown AP based on user-defined rules. Alternatively, you can manually move the unknown AP to a different classification type and rogue state.

Allowable classification type and rogue state transitions

Assigning rogue APs classifications is like sorting emails automatically into spam or inbox based on filters (rules), while still allowing the user to manually move an email to a different folder when needed.

Rogue containment methods

Use this concept to understand the different methods for containing rogue access points, including how auto-containment applies to monitor mode APs and the priorities of various containment options.

A rogue containment method is a wireless security approach that

- detects unauthorized access points in the network environment,
- applies different containment strategies including manual, rule-based, and auto-containment, and
- prioritizes and restricts the actions of access points based on containment configuration and AP operating mode.

Containment methods and priorities

- **Manual rogue containment (Priority 1):** Administrators manually designate which rogue APs to contain, offering the highest control and flexibility. Containment levels can range from 1 to 4 APs participating.
- **Rule-based rogue containment (Priority 2):** The controller automatically contains rogue APs based on predefined rules, always using 1 AP for containment.
- **Auto-containment (Priority 3):** The controller automatically contains rogue APs, but only when specific options (such as "Using our SSID", "A valid client on the Rogue AP", or "Ad-hoc Rogue AP") are enabled.

Auto-containment for monitor mode APs

- When you enable 'Auto Containment only for Monitor Mode APs', only monitor mode APs perform auto-containment. Local or FlexConnect mode APs do not.
- This option applies only to auto-containment. It does not affect your manual or rule-based methods.
- Other AP modes (local or FlexConnect) still enforce rogue containment actions outside the scope of this auto-containment setting.

Containment prioritization and exceptions

- Manual containment always takes highest priority, followed by rule-based, with auto-containment last.
- If a rogue AP matches both manual or rule-based configurations, auto-containment does not occur for that AP.

Example

An ad-hoc rogue AP detected with a valid client connected triggers auto-containment by monitor mode APs only if the corresponding option is enabled. If manual containment is also configured for this rogue AP, manual containment takes precedence and disables auto-containment for that case.

Guidelines and restrictions for classifying Rogue APs

This section lists guidelines and restrictions for classifying rogue access points.

Classifying Custom type rogues is tied to rogue rules. Therefore, it is not possible to manually classify a rogue as Custom. Custom class change can occur only when rogue rules are used.

Some SNMP traps are sent for containment by rule and every 30 minutes for rogue classification change.

Rogue rules are applied on every incoming new rogue report in the controller in the order of their priority.

After a rogue satisfies a rule and is classified, it does not move down the priority list for the same report.

Previously classified rogue gets re-classified on every new rogue report with the following restrictions:

- Rogues which are classified as friendly by rule and whose state is set to ALERT, go through re-classification on receiving the new rogue report.
- If a rogue is classified as friendly by the administrator manually, then the state is INTERNAL and it does not get re-classified on successive rogue reports.
- If rogue is classified as malicious, irrespective of the state it does not get re-classified on subsequent rogue reports.

The rogue classification rules are re-evaluated at every report received by the managed access points. Hence, a rogue access point can move from one state to another, if a different rule matches the last report.

If a rogue AP is classified as friendly or ignored, all rogue clients associated with it are not tracked.

Until the controller discovers all the APs through neighbor reports from APs, the rogue APs are kept in unconfigured state for three minutes after they are detected. After 3 minutes, the rogue policy is applied on the rogue APs and the APs are moved to unclassified, friendly, malicious, or custom class. Rogue APs kept in unconfigured state means that no rogue policy has yet been applied on them.

When a rogue BSSID is submitted for a containment on Cisco Catalyst 9800 Series Wireless Controller, if the controller has enough resources, it will contain. The APs that detect the particular contained rogue AP starts broadcasting the DEAUTH packets.

Wireless client connected to the contained rogue BSSID will disconnect once DEAUTH packets are received. However, when the client assumes being in a connected state, repeatedly tries to reconnect and the wireless client's user browsing experience would be badly affected.

Also, in a high RF environment like that of a stadium, though DEAUTH packets are broadcasted, client does not receive all of them because of RF disturbance. In this scenario, the client may not be fully disconnected but will be affected badly.

The rouge AP manual classification limit has been enhanced from 625 to 10,000 configurations at a time. The rouge client manual classification limit has been enhanced from 625 to 10,000 configurations at a time.

How to classify rogue APs

-

Classify a rogue AP manually (GUI)

Use this procedure to classify a detected rogue access point (AP) as either authorized or unauthorized using the GUI.

Set the correct classification for rogue access points to maintain wireless network security and compliance.

Use this task after the system detects unclassified APs and you need to determine their status.

Procedure

1. Choose **Monitoring > Wireless** > **Rogues**.
2. In the **Unclassified** tab, select an AP to view the detail in the lower pane.
3. Use the **Class Type** drop-down to set the status.
4. Click **Apply**.

The AP is reclassified and removed from the unclassified list; its status is updated accordingly.

Classify rogue APs and clients manually (CLI)

Use this procedure to classify rogue access points (AP) manually using commands.

Classify rogue access points and clients to enhance network security.

This procedure is used in environments where rogue access points and clients need to be identified and managed to prevent unauthorized access to the network.

Before you begin

Ensure you have the necessary permissions to configure the device.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Detect and report the ad hoc rogue.

   Example

   ```
   Device(config)# wireless wps rogue adhoc alert mac-addr
   ```

   Enter one of these options after you enter the **adhoc** keyword:

   - **alert**–Sets the ad hoc rogue access point to alert mode. If you choose this option, enter the MAC address for the *mac-addr* parameter.
   - **auto-contain**–Sets the automatically containing ad hoc rogue to auto-contain mode.
   - **contain**–Sets the containing ad hoc rogue access point to contain mode. If you choose this option, enter the MAC address for the *mac-addr* parameter and containment level for the *containment-level* parameter. The valid range for *containment-level* is from 1 to 4.
   - **external**–Sets the ad hoc rogue access point as **external**. If you choose this option, enter the MAC address for the *mac-addr* parameter.
   - **internal**–Sets the ad hoc rogue access point as **internal**. If you choose this option, enter the MAC address for the *mac-addr* parameter.

3. Configure the rogue APs.

   Example

   ```
   Device(config)# wireless wps rogue ap malicious mac-addr state contain
   containment-level
   ```

   Example

   ```
   Device(config)# wireless wps rogue ap malicious 74a0.2f45.c520 state contain
    3
   ```

   Enter one of the following options after the **ap** keyword:

   - **friendly**–Configures the friendly rogue access points. If you choose this option, enter the MAC address for the *mac-addr* parameter. After that enter the **state** keyword followed by either of these options: **internal** or **external**.
   - **malicious**–Configures the malicious rogue access points. If you choose this option, enter the MAC address for the *mac-addr* parameter. After that enter the **state** keyword followed by either of these options: **alert** or **contain**.
   - **alert**–Sets the malicious rogue access point to **alert** mode.
   - **contain**–Sets the malicious rogue access point to **contain** mode. If you choose this option, enter the containment level for the *containment-level* parameter. The valid range is from 1 to 4.

4. Configure the rogue clients.

   Example

   ```
   Device(config)# wireless wps rogue client contain mac-addr containment-level
   ```

Example

```
Device(config)# wireless wps rogue client contain 74a0.2f45.c520 2
```

Enter the following option after you enter the **client** keyword:

contain–Contains the rogue client. After you choose this option, enter the MAC address for the *mac-addr* parameter and the containment level for *containment-level* parameter. The valid range for *containment-level* is from 1 to 4.

5. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Configure rogue classification rules (GUI)

Configure rogue classification rules using GUI.

Procedure

---

1. Choose **Configuration** > **Security** > **Wireless Protection Policies**.
2. In the **Wireless Protection Policies** page, choose **Rogue AP Rules** tab.
3. On the **Rogue AP Rules** page, click the name of the **Rule** or click **Add** to create a new one.
4. In the **Add/Edit Rogue AP Rule** window that is displayed, enter the name of the rule in the **Rule Name** field.
5. Choose the rule type from the following **Rule Type** drop-down list options:
   - Friendly
   - Malicious
   - Unclassified
   - Custom

Configure rogue classification rules (CLI)

Use this procedure to configure rogue classification rules using commands.

Establish rules for classifying rogue access points to enhance network security.

This configuration is used in environments where rogue access points need to be identified and classified to prevent unauthorized access.

Before you begin

Ensure you have the necessary permissions to configure rogue classification rules on the device.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Create or enable a rule and set its priority.

Example

```
Device(config)# wireless wps rogue rule rule-name priority priority
```

When creating a rule, you must enter the priority for the rule.

> **Note**
>
> After creating a rule, you can edit the rule and change the priority only for the rogue rules that are disabled. You cannot change the priority for the rogue rules that are enabled. While editing, changing the priority for a rogue rule is optional.

3. Classify a rule.

Example

```
Device(config)# wireless wps rogue rule rule_3 priority 3
```

```
Device(config-rule)# classify friendly state {alert | external | internal}
```

Specifies the classification that needs to be applied to the rogue access points matching this rule.

- **friendly**–Configures the friendly rogue access points. After that enter the **state** keyword followed by either of these options: **alert**, **internal**, or **external**. If you select an **internal** option, it indicates that you trust a foreign access point. If you select an **external** option, it indicates that you acknowledge the presence of a rogue access point.
- **malicious**–Configures the malicious rogue access points. After that enter the state keyword followed by either of these options: alert or contained.
- **alert**–Sets the malicious rogue access point to alert mode.
- **contained**–Sets the malicious rogue access point to contained mode.

4. Add conditions to a rule.

Example

```
Device(config)# wireless wps rogue rule rule_3 priority 3
```

```
Device(config-rule)# condition {client-count condition_value | duration
duration_value | encryption | infrastructure | rssi | ssid ssid_name |
wildcard-ssid}
```

Adds the following conditions to a rule, which the rogue access point must meet:

- **client-count**–Requires that a minimum number of clients be associated to the rogue access point. For example, if the number of clients associated to the rogue access point is greater than or equal to the configured value, the

access point could be classified as Malicious. If you choose this option, enter the minimum number of clients to be associated to the rogue access point for the *value* parameter. The valid range is from 1 to 10 (inclusive), and the default value is 0.

- **duration**—Requires that the rogue access point be detected for a minimum period of time. If you choose this option, enter a value for the minimum detection period for the *duration_value* parameter. The valid range is from 0 to 3600 seconds (inclusive), and the default value is 0 seconds.
- **encryption**—Requires that the advertised WLAN does not have encryption enabled. You can choose **any** for any type of encryption, **off** for no encryption, **wpa1** for WPA encryption, **wpa2** for WPA2 encryption, **wpa3-owe** for WPA3 OWE encryption, or **wpa3-sae** for WPA3 SAE encryption.
- **infrastructure**—Requires the SSID to be known to the controller.
- **rssi**—Requires the rogue access point to be detected with a minimum RSSI value. If the classification is Friendly, the condition requires the rogue access point to be detected with a maximum RSSI value. The valid range is from -95 to -50 dBm (inclusive).
- **ssid**—Requires the rogue access point to have a specific SSID. You could specify up to 25 different SSIDs. You should specify an SSID that is not managed by the controller. If you choose this option, enter the SSID for the *ssid_name* parameter. The SSID is added to the configured SSID list you just created.
- **wildcard-ssid**—Allows you to specify an expression that could match an SSID string. You can specify up to 25 of these SSIDs.

5. Specify matching conditions for the rule.

Example

```
Device(config)# wireless wps rogue rule rule_3 priority 3
```

```
Device(config-rule)# match {all | any}
```

Specifies whether a detected rogue access point must meet all or any of the conditions specified by the rule for the rule to be matched and the rogue access point to adopt the classification type of the rule.

6. Set a command to its default.

Example

```
Device(config-rule)# default
```

7. Exit the sub-mode.

Example

```
Device(config)# wireless wps rogue rule rule_3 priority 3
```

```
Device(config-rule)# exit
```

```
Device(config)#
```

8. Disable a particular rogue rule.

Example

```
Device(config)# wireless wps rogue rule rule_3 priority 3
```

```
Device(config-rule)# shutdown
```

Disables a particular rogue rule. In this example, the rule *rule_3* is disabled.

9. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

10. Enter global configuration mode.

Example

```
Device# configure terminal
```

11. Disable all the rogue rules.

Example

```
Device(config)# wireless wps rogue rule shutdown
```

12. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

You have now configured the rogue classification rules, enabling effective management of rogue access points in the network..

Monitor rogue classification rules

This section provides CLI command examples for classifying rogue access points using different rules and conditions.

You can monitor the rogue classification rules using these commands.

Table 131: Commands for monitoring rogue classification rules

Command	Purpose
show wireless wps rogue rule detailed	Displays detailed information of a classification rule.
show wireless wps rogue rule summary	Displays a summary of the classification rules.

Examples: classifying rogue AP

This section provides CLI command examples for classifying rogue access points using different rules and conditions.

This example shows how to classify a rogue AP with MAC address 00:11:22:33:44:55 as malicious and mark it for being contained by 2 managed APs:

```
Device# configure terminal
Device(config)# wireless wps rogue ap malicious 0011.2233.4455 state contain
2
```

This example shows how to create a rule that can categorize a rogue AP that is using SSID **my-friendly-ssid**, and it is seen for at least for 1000 seconds as friendly internal:

```
Device# configure terminal
Device(config)# wireless wps rogue rule ap1 priority 1
Device(config-rule)# condition ssid my-friendly-ssid
Device(config-rule)# condition duration 1000
Device(config-rule)# match all
Device(config-rule)# classify friendly state internal
Device(config-rule)# no shutdown
```

This example shows how to apply a condition that a rogue access point must meet:

```
Device# configure terminal
Device(config)# wireless wps rogue rule ap1 priority 1
Device(config-rule)# condition client-count 5
Device(config-rule)# condition duration 1000
Device(config-rule)# no shutdown
Device(config-rule)# end
```

This example shows a condition to classify rogue devices with the controller SSIDs as malicious:

```
Device# configure terminal
Device(config)# wireless wps rogue rule ap1 priority 1
Device(config-rule)#  classify malicious state alert
Device(config-rule)#  condition duration 30
Device(config-rule)#  condition infrastructure ssid
Device(config-rule)#  match all
Device(config-rule)#  no shutdown
Device(config-rule)# end
```

151 Advanced WIPS

Topics:

- Advanced WIPS

This chapter explains how to enable, configure, and verify Cisco Advanced WIPS on supported controllers and APs, manage signatures and forensic capture, and view and analyze real-time and historical WIPS alarms via GUI and CLI.

Advanced WIPS

Outlines Advanced WIPS features, covering solution components, supported modes and platforms, signature definitions, guidelines and restrictions, enabling methods through GUI and CLI, syslog support and thresholds, alarm monitoring, and verification procedures for secure wireless environments.

A Cisco Advanced Wireless Intrusion Prevention System (aWIPS) is a wireless security system that

- uses advanced techniques for wireless threat detection and performance management
- enables the AP to detect threats and generate alarms, and
- combines network traffic analysis, topology information, signatures, and anomaly detection for comprehensive wireless threat prevention.

Feature history for advanced WIPS

This table provides release and related information for the features explained in this module. These features are available on all releases subsequent to the one they were introduced in, unless noted otherwise.

Table 132: Feature history for advanced WIPS

Release	Feature name	Feature information
Cisco IOS XE 17.5.1	Advanced WIPS Signatures	Up to 15 additional signatures are supported.
Cisco IOS XE 17.6.1	Syslog Support for Advanced WIPs	From 17.6.1 release onwards: • Two additional signatures are supported. • Syslog support has been added to the controller for advanced WIPS.

Advanced WIPS signatures and definitions

This section lists advanced WIPS (Wireless Intrusion Prevention System) signatures and their definitions, including alarms introduced in Cisco IOS XE Bengaluru 17.5.1 and later, as well as alarms introduced in prior releases.

The table lists alarms introduced starting with Cisco IOS XE Bengaluru Release 17.5.1.

Table 133: Advanced WIPS signatures and definitions (Cisco IOS XE Bengaluru 17.5.1 and later)

Advanced WIPS signature	Definition
RTS Virtual Carrier Sense Attack	This alarm extends the RTS flood alarm introduced in Cisco IOS XE Bengaluru 17.4.x. The alarm triggers when an RTS frame with a large duration value is detected. An attacker can use these frames to exhaust airtime and disrupt wireless client services.
CTS Virtual Carrier Sense Attack	This alarm extends the CTS flood alarm introduced in Cisco IOS XE Bengaluru 17.4.x. The alarm triggers when a CTS frame with a large duration value is detected. An attacker can use these frames to exhaust airtime and disrupt wireless client services.

Advanced WIPS signature	Definition
Deauthentication Flood by Pair	This alarm provides enhanced threat context by tracking both the source (attacker) and the destination (victim) involved in the attack.
Fuzzed Beacon	A fuzzed beacon occurs when an attacker introduces invalid, unexpected, or random data into a beacon frame and replays the modified frames over the air. This can cause unexpected behavior on the destination device, such as driver crashes, operating system crashes, and stack-based overflows, and may allow execution of arbitrary code.
Fuzzed Probe Request	A fuzzed probe request occurs when an attacker introduces invalid, unexpected, or random data into a probe request and replays the modified frames over the air.
Fuzzed Probe Response	A fuzzed probe response occurs when an attacker introduces invalid, unexpected, or random data into a probe response and replays the modified frames over the air.
PS Poll Flood by Signature	A PS poll flood occurs when an attacker spoofs the MAC address of a wireless client and sends a large number of PS poll frames. The access point sends buffered data frames to the client, which may cause the client to miss data frames while operating in power-save mode.
EAPOL Start Flood by Signature	An Extensible Authentication Protocol over LAN (EAPOL) start flood occurs when an attacker floods an access point with EAPOL start frames to exhaust its internal resources.
Reassociation Request Flood by Destination	A reassociation request flood occurs when a device floods an access point with a large number of spoofed client reassociation requests to exhaust its resources, particularly the client association table. When the table overflows, legitimate clients cannot associate, resulting in a denial-of-service (DoS) attack.
Beacon Flood by Signature	A beacon flood occurs when stations receive a large number of beacons generated with different MAC addresses and SSIDs. This flood prevents clients from detecting beacons sent by corporate access points and can result in a denial-of-service (DoS) attack.
Probe Response Flood by Destination	A probe response flood occurs when a device floods clients with a large number of spoofed probe responses. This prevents clients from detecting valid probe responses sent by corporate access points.
Block Acknowledgement Flood by Signature	A block acknowledgement flood occurs when an attacker sends an invalid Add Block Acknowledgement (ADDBA) frame to an access point while spoofing a valid client MAC address. The access point then ignores valid traffic from the client until traffic outside the invalid frame range is received.

Advanced WIPS signature	Definition
AirDrop Session	An AirDrop session uses Apple AirDrop to establish a peer-to-peer link for file sharing. This activity can introduce security risks by allowing unauthorized peer-to-peer networks to appear in the WLAN environment.
Malformed Association Request	A malformed association request occurs when an attacker sends a malformed request to an access point to exploit software defects, potentially resulting in a denial-of-service (DoS) attack.
Authentication Failure Flood by Signature	An authentication failure flood occurs when a device floods an access point with invalid authentication requests spoofed from a valid client, which can cause client disconnections.
Invalid MAC OUI by Signature	An invalid MAC OUI event occurs when a spoofed MAC address that does not contain a valid organizationally unique identifier (OUI) is used.
Malformed Authentication	Malformed authentication occurs when an attacker sends malformed authentication frames that may expose vulnerabilities in certain wireless drivers.

The table lists alarms introduced prior to Cisco IOS XE Bengaluru Release 17.5.1.

Table 134: Advanced WIPS signatures (prior to Cisco IOS XE Bengaluru 17.5.1)

Advanced WIPS signature
Authentication Flood Alarm
Association Flood Alarm
Broadcast Probe Flood Alarm
Disassociation Flood Alarm
Broadcast Disassociation Flood Alarm
Deauthentication Flood Alarm
Broadcast Deauthentication Flood Alarm
EAPOL Logoff Flood Alarm
CTS Flood Alarm
RTS Flood Alarm

Guidelines and Restrictions

Guidelines and restrictions for aWIPS profile and supported access points.

- In the aWIPS profile, Cisco Aironet 1850 Series Access Points, Cisco Catalyst 9117 Series Access Points, and Cisco Catalyst 9130AX Series Access Points can detect EAPOL logoff attack and raise alarms accordingly, only on off-channel. They can not detect EAPOL logoff attack and raise alarms on on-channel.

- From Cisco IOS XE 17.12.6 onwards, aWIPS profile download is supported when Cisco Catalyst Center is configured using the fully qualified domain name (FQDN). It strictly requires an IP name-server and a valid DNS record, as it bypasses local IP host entries.

Enable advanced WIPS

From Cisco IOS XE Release 17.5.1 onward, aWIPS security has higher priority than Hyperlocation/Fastlocate.

These are the possible scenarios.

All Catalyst APs that support Fastlocate can operate with aWIPS regardless of AP mode or configuration.

When both aWIPS and Hyperlocation are enabled on Cisco Aironet 4800 APs in any mode except Monitor mode, only aWIPS is available.

Table 135: Feature availability for Cisco Aironet 4800 AP (All Modes)

Hyperlocation/Fastlocate	Advanced WIPS	Cisco Aironet 4800 AP Mode	Cisco Aironet 4800 AP effective feature
Enable	Enable	Any Non-Monitor	aWIPS [2]
Enable	Disable	Any Non-Monitor	Hyperlocation/Fastlocate
Disable	Disable	Any Non-Monitor	Hyperlocation/Fastlocate and aWIPS are disabled.
Disable	Enable	Any Non-Monitor	aWIPS
Enable	Enable	Monitor	aWIPS and Hyperlocation [3]
Disable	Enable	Monitor	aWIPS [4]
Enable	Disable	Monitor	Hyperlocation/Fastlocate
Disable	Disable	Monitor	Hyperlocation/Fastlocate and aWIPS are disabled.

Syslog messages for advanced WIPS

This feature adds syslog support to the controller for Advanced WIPS.

A syslog message for advanced WIPS is a controller notification mechanism that

- logs alarms sent from APs
- applies throttling to prevent redundant messages during configured intervals, and
- omits client-specific information from logs to protect privacy.

Sample syslog message format

A typical syslog message for advanced WIPS includes key elements such as:

[2] In modes other than the Monitor mode, if both aWIPS and Hyperlocation/Fastlocate are enabled, only aWIPS is available.
[3] In Monitor mode, if both aWIPS and Hyperlocation/Fastlocate are enabled, both aWIPS and Hyperlocation/Fastlocate are available.
[4] To monitor the status of aWIPS and Hyperlocation/Fastlocate simultaneously on AP, use the **show capwap client rcb** command.

- AP name
- AP Ethernet MAC address
- AP Radio MAC address
- Alarm description (signature ID)

```
Nov 18 20:45:23.746: %APMGR_AWIPS_SYSLOG-6-APMGR_AWIPS_MESSAGE: Chassis 1 R0/0:
 wncd: AWIPS alarm:(AP00B0.E19A.5720) 00b0.e19a.5720 Radio MAC 00b0.e19b.c300
 detected Probe Response Flood by Destination (10019)
```

Additional notes

- When an AP sends an alarm to the controller, the controller raises the corresponding syslog message.
- Throttling ensures that if the same signature is detected from the same AP within a set interval (e.g., 1 minute), only one syslog message is generated for that period, regardless of the number of occurrences.
  - For example, 100 occurrences of the same signature from an AP within a minute will result in only one syslog message for that interval.
- Syslog messages generated for advanced WIPS do not display any client device information or context.

Advanced WIPS solution components and capabilities

Advanced WIPS solution components and capabilities.

The aWIPS solution comprises these components and capabilities.

Solution components

The aWIPS solution comprises these components

- Cisco Catalyst 9800 Series Wireless Controller
- Cisco Aironet Wave 2 APs
- Cisco Catalyst Center

Because aWIPS functionality is integrated into Cisco Catalyst Center, aWIPS can configure WIPS policies, monitor alarms, and report threats.

Capabilities

aWIPS supports these capabilities

- Static signatures

  Beginning with Cisco IOS XE version 17.4.1, Cisco Catalyst Center can change threshold values and push new signature files to the AP.
- Enable or disable signature forensic capture from Cisco Catalyst Center.
- Standalone signature detection only
- Only alarms are supported.
- GUI support
- CLI to view alarms

- The static signature file is packaged with the controller and AP image.
- Export alarms to Cisco Catalyst Center through WSA channel

> **Note**
>
> aWIPS alarm details such as the AP MAC address, alarm ID, alarm string, and signature ID are displayed on the Cisco Catalyst 9800 series wireless controller GUI.

Supported modes and platforms

Controllers supporting advanced WIPS.

aWIPS is supported on these controllers:

- Cisco Catalyst 9800 Series Wireless Controllers
- Cisco Embedded Wireless Controller on Catalyst Access Points

> **Note**
>
> aWIPS is not supported on Cisco IOS APs.

Enable advanced WIPS (GUI)

Enable advanced WIPs using GUI.

Enable advanced WIPS features on your access points for improved network security.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. Click **Add**. The **Add AP Join Profile** window is displayed.
3. In the **Add AP Join Profile** window, click the **Security** tab.
4. Under the **aWIPS** section, check the **aWIPS Enable** check box.
5. Click **Apply to Device**. You return to the **General** tab.
6. Click the **Security** tab.
7. Under the **aWIPS** section, check the **Forensic Enable** check box.
8. Click **Apply to Device**.

Advanced WIPS and forensic features are enabled for the selected AP profile.

Enable advanced WIPS (CLI)

Enable advanced WIPS.

Enable advanced WIPS to enhance network security and ensure proper priority over location services.

To enable aWIPS from the controller and ensure that aWIPS has higher priority than Hyperlocation/Fastlocate , perform these steps:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the default AP profile.

   Example

   ```
   Device(config)# ap profile ap-profile-name
   ```

3. Enable aWIPS.

   Example

   ```
   Device(config-ap-profile)# awips
   ```

   Note

   aWIPS is disabled by default on the controller.

4. Enable forensics for aWIPS alarms.

   Example

   ```
   Device(conf-ap-profile)# awips forensic
   ```

5. Enable Hyperlocation/Fastlocate on all the supported APs that are associated with this AP profile.

   Example

   ```
   Device(config-ap-profile)# hyperlocation
   ```

6. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

The controller is now configured with advanced WIPS and forensics, and prioritizes aWIPS above Hyperlocation/Fastlocate features on AP.

Configure syslog threshold for advanced WIPS (CLI)

Configure syslog threshold for advanced WIPS using command.

Set the syslog throttle interval for advanced WIPS, so you can manage syslog message frequency and reduce unnecessary log volume.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the syslog threshold for aWIPS.

   Example

   ```
   Device(config)# awips-syslog throttle period syslog-throttle-interval
   ```

   syslog-throttle-interval : Enter the syslog throttle interval, in seconds. The range is from 30 to 600.

   > **Note**
   >
   > The default throttling interval is 60 seconds.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The syslog throttle interval for advanced WIPS is configured. Syslog messages for WIPS events will now be generated according to the specified interval.

View advanced WIPS alarms (GUI)

View advanced WIPS alarms using GUI.

Identify and analyze current and historical WIPS alarms.

Procedure

1. Navigate to **Monitoring** > **Security** > **Advanced Wireless Intrusion Prevention System (aWIPS)** .
2. To view the details of the alarms in the last five minutes (0.08 hours), click the **Current Alarms** tab.
3. To view the alarm count for longer periods such as hourly or daily (24 hours), click the **Historical Statistics** tab.
4. Sort or filter the alarms based on these parameters:

- **AP Radio MAC address**
- **Alarm ID**
- **Time Stamp**
- **Signature ID**
- **Alarm Description**
- **Alarm Message Index**

Advanced WIPS alarms appear according to the selected criteria. You receive real-time and historical data for security monitoring and analysis.

Verify advanced WIPS

Command to verify advanced WIPS.

To view the aWIPS status, use the **show awips status** *radio_mac* command:

```
Device# show awips status 0xx7.8xx8.2xx0

AP Radio MAC  AWIPS Status  Forensic Capture Status   Alarm Message Count
------------------------------------------------------------------------------
0xx7.8xx8.2xx0      ENABLED       CONFIG_NOT_ENABLED  14691
```

The various aWIPS status indicators are:

- `ENABLED`: aWIPS enabled.
- `NOT_SUPPORTED`: The AP does not support AWIPS.
- `CONFIG_NOT ENABLED`: aWIPS is not enabled on the AP.

To view details of specific alarm signatures, use the **show awips alarm signature** *signature_id* command:

```
Device# show awips alarm signature 10001

AP Radio MAC    AlarmID   Timestamp          SignatureID    Alarm Description
     Message Index
_____________________________________________________________________________
0xx7.8xx8.2f80   1714    11/02/2020 13:02:19   10001      Authentication Flood
     3966
```

To view alarm message statistics, use the **show awips alarm statistics** command:

```
Device# show awips alarm statistics
```

To view a list of alarms since the last clear, use the **show awips alarm ap** *ap_mac* **detailed** command:

```
Device# show awips alarm ap 0xx7.8xx8.2f80 detailed
AP Radio MAC    AlarmID     Timestamp              SignatureID   Alarm
Description

152 Cisco TrustSec

Topics:

- Cisco TrustSec
- Security Group Access Control List (SGACL)
- Cisco TrustSec - ISE communication over IPv6
- TrustSec IP-SGT High Availability binding

Cisco TrustSec

Outlines Cisco TrustSec architecture, including user and device identity, scalable access controls, data confidentiality, and enforcement using Cisco ISE and SGACLs. Highlights SGACL and SGT inline tagging features, supported platforms, HA policy for FlexConnect, and commands for managing environment data.

A Cisco TrustSec solution is a network security architecture that

- strongly identifies users, hosts, and network devices within the network
- provides topology-independent and scalable access controls by classifying data traffic based on user or device roles, and
- ensures data confidentiality and integrity by establishing trust among authenticated peers and encrypting network links.

The key component of Cisco TrustSec is the Cisco Identity Services Engine (ISE). Cisco ISE can provision switches with TrustSec Identities and Security Group ACLs (SGACLs). SGACLs may be configured manually on the switch.

Note

Before changing CTS server to a new one, manually clear the CTS environment data using the **clear cts environment-data** command. Running the **show cts environment-data** command will return updated data.

Feature History

Feature Name	Release	Description
TrustSec IP-to-SGT High Availability binding	Cisco IOS XE 26.2.1	The feature synchronizes supported IP-to-SGT bindings between the active and standby devices, preserves binding information during a Stateful Switchover (SSO), and helps maintain consistent Security Group Access Control List (SGACL) enforcement after the switchover.
Trustsec policy HA support for FlexConnect mode APs	Cisco IOS XE 17.18.2	The feature ensures that CTS SGACL enforcement remains available and consistent during HA events such as Stateful Switchover (SSO) between wireless controllers. This provides uninterrupted security policy enforcement on Flex mode APs even during controller failover or redundancy events.
TrustSec support for Cisco Catalyst IW6300 Heavy Duty Series and 6300 Series Embedded Services APs	Cisco IOS XE 17.8.1	Enable and configure Cisco TrustSec Security Group ACL (SGACL) in FlexConnect and Flex+Bridge mode. SGACL enforcement on the controller is available for local and Bridge mode. Inline tagging and SXP are supported only in FlexConnect.

Feature Name	Release	Description
Support for SGT Inline Tagging Over Port-Channel Uplink	Cisco IOS XE 17.3.5a	SGT inline tagging over port-channel uplink is supported for Cisco Catalyst 9800-L, 9800-40, and 9800-80 Wireless Controllers. If you downgrade to releases that do not support SGT inline tagging over port-channel, the port-channel may be suspended.

Cisco TrustSec features

This section explains the Cisco TrustSec features.

This table lists the TrustSec features that will be implemented on TrustSec-enabled Cisco switches. Future releases will support more switches and provide additional TrustSec features.

Cisco TrustSec Feature	Description
802.1AE Tagging (MACsec)	Protocol for IEEE 802.1AE-based wire-rate hop-to-hop Layer 2 encryption. On MACsec-capable devices, your network traffic is encrypted when leaving one device, decrypted when entering the next device, while staying unencrypted inside the devices. This feature is only available between TrustSec hardware-capable devices.
Endpoint Admission Control (EAC)	EAC authenticates each device or user connecting to the TrustSec domain. This usually happens at the access level switch. If authentication and authorization are successful, your device or user session receives a Security Group Tag. You can use 802.1X, MAC Authentication Bypass (MAB), or Web Authentication Proxy (WebAuth) with EAC.
Network Device Admission Control (NDAC)	With NDAC, each network device in your TrustSec domain verifies the credentials and trustworthiness of peer devices. NDAC uses an authentication framework based on IEEE 802.1X port-based authentication and EAP-FAST as its EAP method. Successful authentication and authorization in NDAC process results in Security Association Protocol negotiation for IEEE 802.1AE encryption.
Security Group Access Control List (SGACL)	Security Group Access Control List (SGACL): An SGACL links a Security Group Tag with a policy that your devices enforce on SGT-tagged traffic leaving the TrustSec domain.
Security Association Protocol (SAP)	After NDAC authentication, the Security Association Protocol (SAP) automatically negotiates keys and the cipher suite for subsequent MACSec link encryption between TrustSec peers. SAP is defined in IEEE 802.11i.

Cisco TrustSec Feature	Description
Security Group Tag (SGT)	An SGT is a 16-bit label indicating the security classification of a source in the TrustSec domain. It is appended to an Ethernet frame or an IP packet.
SGT Exchange Protocol (SXP)	Security Group Tag Exchange Protocol (SXP). With SXP, devices that are not TrustSec-hardware-capable can receive SGT attributes for authenticated users and devices from the Cisco Identity Services Engine (ISE) or the Cisco Secure Access Control System (ACS). The devices can then forward a sourceIP-to-SGT binding to a TrustSec-hardware-capable device will tag the source traffic for SGACL enforcement.

When both ends of a link support 802.1AE MACsec, SAP negotiation occurs. An EAPOL-key exchange occurs between the supplicant and the authenticator to negotiate a cipher suite, exchange security parameters, and manage keys. Successful completion of these tasks results in the establishment of a security association (SA).

Depending on your software version, licensing, and link hardware support, SAP negotiation can use one of these modes of operation:

- Galois Counter Mode (GCM): authentication and encryption
- GCM authentication (GMAC): GCM authentication, no encryption
- No Encapsulation: no encapsulation (clear text)
- Null: encapsulation, no authentication or encryption

Configure a device SGT manually (CLI)

Use this procedure to manually configure a device STG using commands.

Configure a device Security Group Tag (SGT) using commands when the authentication server is unavailable.

When the authentication server is accessible, it assigns an SGT to your device for packets originating from your device. If the authentication server is not available, configure an SGT manually. The server-assigned SGT is always used instead of your manual configuration if both are present.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-policy
   ```

3. Specify the Security Group Tag (SGT) number.

Example

```
Device(config-wireless-policy)# cts sgt sgt-value
```

The valid values are from 0 to 65,535.

4. Return to the global configuration mode.

Example

```
Device(config-wireless-policy)# exit
```

Configure ISE for TrustSec (CLI)

Use this procedure to configure ISE for TrustSec.

Set up ISE to enable secure network access using TrustSec policies using commands.

This task involves configuring a device to communicate with an ISE server as a RADIUS server and integrating TrustSec authorization.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Specify the RADIUS server name.

Example

```
Device(config)# radius server server-name
```

3. Specify the primary RADIUS server parameters.

Example

```
Device(config-radius-server)# address ipv6 ip-address
```

4. Specify the authentication and encryption key used between the Device and the key string RADIUS daemon running on the RADIUS server.

Example

```
Device(config-radius-server)# pac key key
```

5. Return to the configuration mode.

Example

```
Device(config-radius-server)# exit
```

6. Create a radius server-group identification.

Example

```
Device(config)# aaa group server radius server-group
```

> **Note**
>
> *server-group* refers to the server group name. The valid range is from 1 to 32 alphanumeric characters.

7. Create a CTS authorization list.

Example

```
Device(config)# cts authorization list mlist-name
```

8. Create an authorization method list for web-based authorization.

Example

```
Device(config)# aaa authorization network mlist-name group group-name
```

> **Note**
>
> Ensure that the ISE IP address configured on your controller is the same as the IP address configured on ISE (**Work Center** > **TrustSec** > **Components** > **Trustsec AAA Servers**).

> **Note**
>
> If the ISE version is 002.005(000.239), 002.004(000.357), 002.003(000.298), 002.002(000.470), 002.001(000.474), 002.000(001.130), or 002.000(000.306), use the **access-session tls-version 1.0** command to download PAC from ISE. For other ISE versions, the above command is not required.

Verify Cisco TrustSec configuration

This section explains the commands to verify Cisco TrustSec configuration.

To display the wireless CTS SGACL configuration summary, use this command:

```
Device# show wireless cts summary

Local Mode CTS Configuration

Policy Profile Name               SGACL Enforcement     Inline-Tagging
Default-Sgt
-------------------------------------------------------------------------------------
xyz-policy                        DISABLED              ENABLED          0

wireless-policy1                  DISABLED              DISABLED         0

w-policy-profile1                 DISABLED              DISABLED         0

default-policy-profile            DISABLED              DISABLED         0

Flex Mode CTS Configuration

Flex Profile Name                 SGACL Enforcement     Inline-Tagging
-----------------------------------------------------------------------
xyz-flex                          DISABLED              ENABLED
demo-flex                         DISABLED              DISABLED
flex-demo                         DISABLED              DISABLED
xyz-flex-profile                  DISABLED              DISABLED
default-flex-profile              DISABLED              DISABLED
```

To display CTS-specific configuration status for various wireless profiles, use this command:

```
Device# show cts wireless profile policy xyz-policy

Policy Profile Name           : xyz-policy
CTS
  Role-based enforcement         : ENABLED
  Inline-tagging                 : ENABLED
   Default SGT   : 100

Policy Profile Name            : foo2
CTS
  Role-based enforcement         : DISABLED
  Inline-tagging                 : ENABLED
  Default SGT           : NOT-DEFINED

Policy Profile Name                    : foo3
CTS
  Role-based enforcement         : DISABLED
  Inline-tagging                 : DISABLED
  Default SGT    : 65001
```

To display CTS configuration for a given wireless profile, use this command:

```
Device# show wireless profile policy detailed xyz-policy

Policy Profile Name           : xyz-policy
Description                   :
Status                        : DISABLED
VLAN                          : 1
Client count                  : 0
```

```
Passive Client                  : DISABLED
ET-Analytics                    : DISABLED
StaticIP Mobility               : DISABLED
!
.
.
.WGB Policy Params
  Broadcast Tagging             : DISABLED
  Client VLAN                   : DISABLED
Mobility Anchor List
  IP Address                                  Priority
CTS
  Role-based enforcement          : ENABLED
  Inline-tagging                  : ENABLED
  Default SGT                    : NOT-DEFINED
```

Security Group Access Control List (SGACL)

Explains how security group access control lists (SGACLs) enforce role-based, topology-independent access control in Cisco TrustSec deployments.

A security group access control list (SGACL) is a network security policy mechanism that

- enforces access control between groups of users, devices, and resources based on their assigned security group
- simplifies policy management by using unique security group tags (SGTs) to dynamically control permissions, and
- reduces administrative overhead by decoupling access policies from the network topology or addressing.

Security groups are defined by the administrator in Cisco Identity Services Engine (ISE). As new users and devices are added to the Cisco TrustSec domain, the authentication server assigns these new entities to the appropriate security groups. Cisco TrustSec assigns each security group a unique 16-bit number that is globally scoped within a Cisco TrustSec domain. The number of security groups on a wireless device is limited by the number of authenticated network entities. You do not need to configure the security group numbers manually.

After a device is authenticated, Cisco TrustSec tags each packet originating from that device with an SGT containing the device's security group number. The packet carries this SGT everywhere in the network, in the Cisco TrustSec header.

As the SGT contains the security group of the source, the tag can be referred to as the source SGT (S-SGT). The destination device is also assigned to a security group (destination SG) that can be referred to as the destination SGT (D-SGT), even though the Cisco TrustSec packet does not contain the security group number of the destination device.

You can control the operations that users can perform based on the security group assignments of users and destination resources, using the Security Group Access Control Lists (SGACLs). Policy enforcement in a Cisco TrustSec domain is represented by a permission matrix, with the source security group numbers on one axis and the destination security group numbers on the other axis. Each cell in the matrix body contains an ordered list of SGACLs, which specify the permissions that must be applied to packets originating from the source security group and destined for the destination security group. When a wireless client is authenticated, the controller downloads all the SGACLs in the matrix cells.

When a wireless client connects to the network, the client pushes all the ACLs to the controller .

Cisco TrustSec achieves role-based topology-independent access control in a network by assigning users and devices in the network to security groups and applying access control between the security groups. The SGACLs define access control policies based on the device identities. The security policy remains unchanged if the roles and permissions stay the same, even when the network topology changes. Assigning a user to an appropriate security group immediately grants the user permissions for that group when the user is added to the wireless group.

Role-based permissions reduce ACL size and simplify their maintenance. With Cisco TrustSec, the number of Access Control Entities (ACEs) that are configured is determined by the number of permissions specified, resulting in a much smaller number of ACEs.

For a list of Cisco APs that support SGACL, see the release notes.: https://www.cisco.com/c/en/us/support/wireless/catalyst-9800-series-wireless-controllers/products-release-notes-list.html

> **Note**
>
> Clients receive zero SGT value and DHCP clients receive an Automatic Private IP Addressing (APIPA) address when TrustSec policy “unknown to unknown” is denied in TrustSec matrix.
>
> Clients receive correct SGT values and DHCP clients receive an IP address when TrustSec policy “unknown to unknown” is permitted in TrustSec matrix.

Supported SGACL

The scenarios supported for SGACLs on the Cisco Catalyst 9800 Series Wireless Controller are:

- Wireless-to-wireless (within Enterprise network):
  - In FlexConnect mode with local switching, the egress AP enforces SGACL when a packet moves from a source wireless network to a destination wireless network.
  - In FlexConnect mode with central switching, SGACL enforcement is performed on the egress AP. To achieve this, the controller exports IP address to security group tag (IP-SGT) binding over SGT Exchange Protocol (SXP).
- Wired-to-wireless (DC-to-Enterprise network): Enforcement occurs when a packet reaches the destination AP.
- Wireless-to-wired (Enterprise network-to-DC): Enforcement occurs on the uplink switch when a packet reaches the ingress of the wired network.

Guidelines and restrictions of SGACL

This section explains the guidelines and restrictions of SGACL.

These are the guidelines and restrictions of Security Group Access Control List (SGACL).

- SGACL enforcement is carried out on the controller for local mode.
- CTS SGACL high availability is available on Flex mode. This provides uninterrupted security policy enforcement on Flex mode APs even during controller failover or redundancy events.
- SGACL enforcement is carried out on an AP for flex-mode APs performing local switching.
- SGACL enforcement for wireless clients is carried out either on the upstream switch or on the border gateway in a Branch-to-DC scenario.
- SGACL enforcement is not supported for non-IP or IP broadcast or multicast traffic.
- Per-WLAN SGT assignment is not supported. Static SGACL configuration on an AP is not supported.
- SGACL enforcement is not carried out for control-plane traffic between an AP and the wireless controller (for upstream or from upstream traffic).
- Non-static SGACL configurations are supported only for dynamic SGACL policies received from ISE.
- In case of Allow List model, you need to explicitly allow DHCP protocol for the client devices to get the DHCP IP address and then request the controller for SGACL policies.

Enable SGACL on the AP (GUI)

Use this procedure to enable SGACL on the APs using GUI.

Use the GUI to apply SGACL enforcement to APs as part of your security configuration workflow.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Flex**.
2. Click **Add**.
3. In the **General** tab, check the **Inline Tagging** and **SGACL Enforcement** check boxes and select the CTS profile name from the **CTS Profile Name** drop-down list.
4. Click **Apply to Device**.

Enable SGACL on the AP (CLI)

Use this procedure to enable SGACL on the APs using commands.

Enable role-based access control on APs for enhanced network security using commands.

> **Note**
>
> Use the **no** form of the commands given below to disable the configuration. For example, **cts role-based enforcement** disables role-based access control enforcement for APs.

Before you begin

- Security Group Access Control List (SGACL) on an AP is enabled only when the wireless controller is in FlexConnect mode.
- Configure the **cts manual** command on the uplink port to send or receive a tagged packet.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an RF profile and enter the RF profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex flex-profile
   ```

3. Enable role-based access control enforcement for the AP.

Example

```
Device(config-wireless-flex-profile)# cts role-based enforcement
```

4. Enable inline tagging on the AP.

   Example

   ```
   Device(config-wireless-flex-profile)# cts inline-tagging
   ```

5. Enable the CTS profile name and return to the global configuration mode.

   Example

   ```
   Device(config-wireless-flex-profile)# cts profile profile-name
   ```

   ```
   Device(config-wireless-flex-profile)# exit
   ```

6. Configure a site tag and enter the site tag configuration mode.

   Example

   ```
   Device(config)# wireless tag site site-name
   ```

7. Configure a FlexConnect profile and return to the global configuration mode.

   Example

   ```
   Device(config-site-tag)# flex-profile flex-profile-name
   ```

   ```
   Device(config-site-tag)# exit
   ```

8. Configure an AP and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap mac-address
   ```

9. Map a site tag to an AP.

   Example

   ```
   Device(config-ap-tag)# site-tag site-tag-name
   ```

What to do next
show cts ap sgt-info *ap-name* command to verify the SGACL configuration on the AP.

Policy enforcement

Policy enforcement for Cisco TrustSec access control.

A policy enforcement mechanism is a network security control that

- applies access control policies to network traffic using predefined rules
- uses attributes such as Security Group Tags (SGTs) to dynamically determine permitted actions, and
- enables context-based enforcement at key points within the network infrastructure.

Cisco TrustSec access control is implemented using ingress tagging and egress enforcement. At the ingress point to the Cisco TrustSec domain, the traffic from the source is tagged with an SGT containing the security group number of the source entity. The SGT is propagated across the domain with the traffic. At the egress point of the Cisco TrustSec domain, an egress device uses the security group of the destination entity (D-SGT) to determine the access policy to apply from the SGACL policy matrix.

> **Note**
>
> A Cisco AP must be in Listener mode or Both (Listener and Speaker) mode to enforce traffic because Listener mode maintains the complete set of IP-SGT bindings. After you enable enforcement on an AP, the corresponding policies are downloaded and pushed to the AP.

SGACL policies for guest wireless clients

This topic explains the SGACL policies for guest wireless clients.

A SGACL policy is an access control mechanism that

- defines the network permissions for wireless guest clients
- is enforced on the anchor controller in guest mobility scenarios, and
- uses integration with Cisco ISE for policy download and enforcement.

When a client joins the wireless network (WLAN), its session is managed by the Cisco Catalyst 9800 Series Wireless LAN Controller that the AP is connected to is the foreign controller. Auto-Anchor Mobility allows a specific WLAN (for example, Guest WLAN) to be anchored to a particular controller, regardless of the client's entry point into the network. Auto-Anchor Mobility is a wireless guest service in which all guest traffic tunnels back to the DMZ controller, regardless of the client's association point on the network.

In case of Auto-Anchor mobility, these apply to Cisco TrustSec support:

- Classification: Occurs during authentication and hence on Foreign for Layer 2 security WLANs and on Anchor for Layer 3 security cases.
- Propagation: Always occurs at the Anchor controller where the client traffic enters the wired network.
- Enforcement: SGACL download and enforcement occur on the Anchor controller; the Anchor controller must have connectivity to Cisco Identity Services Engine (ISE) and be registered as a Network Access Server (NAS). Enforcement is not supported on the Foreign controller even if the enforcement CLI is configured there.

This feature is supported in local mode and in FlexConnect Central Switching of the controller. FlexConnect mode with local switching and Fabric mode are not supported in guest scenarios because traffic does not pass through the controller.

Roaming of a guest client occurs only at the Guest Foreign controller, and the Guest Anchor remains fixed. The two types of supported roaming are inter-controller roaming and intra-controller roaming. Roaming during WebAuth pending is a special case that is also supported for Central Web Authentication (CWA) and Local Web Authentication (LWA).

Enable SGACL policy enforcement globally (CLI)

Enable SGACL policy enforcement globally using commands.

Enforce Cisco TrustSec SGACL policies on all routed interfaces to provide unified access control for both IPv4 and IPv6 traffic using commands.

You must enable SGACL policy enforcement globally on Cisco Catalyst 9800 Series Wireless Controller. The same configuration commands that are used for enforcement of IPv4 traffic apply for IPv6 traffic as well.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable Cisco TrustSec SGACL policy enforcement on routed interfaces.

   Example

   ```
   Device(config)# cts role-based enforcement
   ```

Enable SGACL policy enforcement per interface (CLI)

Use this procedure enable SGACL policy enforcement per interface using commands.

Enforce access control policies on selected network interfaces for enhanced security using SGACLs using commands.

After enabling the SGACL policy enforcement globally, enable Cisco TrustSec-on the uplink interfaces.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify interface on which to enable or disable SGACL enforcement.

   Example

   ```
   Device(config)# interface gigabitethernet interface number
   ```

3. Enable Cisco TrustSec SGACL policy enforcement on routed interfaces.

   Example

   ```
   Device(config-if)# cts role-based enforcement
   ```

4. Verify that SGACL enforcement is enabled.

Example

```
Device(config-if)# do show cts interface
```

Inline tagging

This section explains Inline tagging as a transport mechanism using which a controller or AP understands the source SGT.

An inline tag is a transport mechanism that

- carries the source SGT in packet headers as wireless traffic moves through the network
- enables enforcement of Security Group Access Control Lists (SGACLs) by controllers, and
- supports both centrally and locally switched wireless deployments.

There are two types of transport mechanisms: central switching and local switching.

- For central switching, the controller performs inline tagging of all packets sourced from wireless clients associated with the controller by tagging these packets with the Cisco Meta Data (CMD) tag. For packets inbound from the distribution system, inline tagging also requires the controller to strip the CMD header from the packet to identify the S-SGT tag. Afterward, the controller forwards the packet, which includes the S-SGT, for SGACL enforcement.
- To transmit locally switched traffic, an AP performs inline tagging for packets that are associated with the AP and sourced from clients. To receive traffic, the AP handles both locally and centrally switched packets, uses the S-SGT tag, and applies the SGACL policy.

When wireless Cisco TrustSec is enabled on the controller , enabling and configuring SXP to exchange tags with the switches is optional. Both wireless Cisco TrustSec and SXP modes are supported; however, there is no use case for enabling both wireless Cisco TrustSec (on an AP) and SXP concurrently.

Consideration and restriction for inline tagging over port-channel

- Configure the **cts manual** command on port-channel and its member interfaces to send or receive a tagged packet.
- If you downgrade to Cisco IOS XE releases that do not support inline tagging over port-channel, the port-channel may be suspended.

> **Note**
>
> Inline tagging over port-channel is supported in Cisco IOS XE 17.3.5 17.6.3 17.8.1 releases.

Configure SGACL, inline tagging, and SGT in local mode (GUI)

Use this procedure to configure SGACL, inline tagging, and SGT in local mode using GUI.

Configure SGACL enforcement, inline tagging, and default SGT values in local mode through the GUI.

Enable Security Group Access Control Lists (SGACL), inline tagging, and assign default Security Group Tags (SGT) on a policy profile operating in local mode.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click the Policy Profile Name. The **Edit Policy Profile** is displayed.
3. Choose **General** tab.
4. In the **CTS Policy** settings, check or uncheck the **Inline Tagging** and **SGACL Enforcement** check boxes, and enter the **Default SGT** value.
5. Click **Update & Apply to Device**.

Configure SGACL, inline tagging, and SGT in local mode (CLI)

Use this procedure to configure SGACL, inline tagging, and SGT in local mode using commands.

Use this procedure to configure Secure Group Access Control Lists (SGACL), inline tagging, and Security Group Tag (SGT) enforcement in local mode on a controller using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a policy profile for the WLAN.

   Example

   ```
   Device(config)# wireless profile policy profile-name
   ```

3. Enable CTS inline tagging.

   Example

   ```
   Device(config-wireless-policy)# cts inline-tagging
   ```

   Note

   Configure the **cts manual** on the physical interface. If the **cts manual** is configured on the physical interface and **cts inline-tagging** is not enabled, packets remain tagged at egress in the controller.

4. Enable CTS SGACL enforcement.

   Example

   ```
   Device(config-wireless-policy)# cts role-based enforcement
   ```

5. Optional: Set the default Security Group Tag (SGT).

Example

```
Device(config-wireless-policy)# cts sgt sgt-value
```

Note

SGT is required for a user session only when the client uses open authentication, and not the ISE server.

SGACL and environment data download over REST

Cisco TrustSec leverages a REST-based transport protocol for improved policy provisioning and environment data download from Cisco Identity Services Engine (ISE). This protocol offers enhanced security, reliability, and speed compared to traditional RADIUS methods for delivering Security Group Access Control List (SGACL) policies and environment data.

Cisco TrustSec uses the REST-based transport protocol that

- ensures more secure communication for provisioning Security Group Access Control List (SGACL) policies and environment data compared to older RADIUS protocols
- provides faster and more reliable policy and data downloads across the network,
- simplifies integration between Cisco TrustSec and ISE, supporting efficient delivery and enforcement of security group policies.

Both REST API-based and RADIUS-based protocols for downloading Cisco TrustSec data are supported. Only one protocol can be active on a device at a time. You can change the protocol to RADIUS by configuring the **cts authorization list** command.

Note

Cisco TrustSec Change of Authorization (CoA) will still use RADIUS as the protocol.

Cisco TrustSec SGACL and environment data are synchronized from the active device to the standby device, after the policy is installed. However, REST API connections or sessions are not synchronized during a switchover.

Prerequisites for SGACL and environment data download over REST

Learn the requirements that must be met to ensure successful SGACL and environment data downloads over REST.

To ensure proper operation of SGACL and environment data downloads over REST, observe these requirements:

- Cisco Identity Services Engine (ISE) must use version 2.7 or later.
- Cisco TrustSec-enabled devices must use Cisco IOS XE 26.1.1 or later releases.
- Update the network device configuration on Cisco ISE to allow REST API calls from a network device IP address (NAS-IP). The network device uses the device ID and password specified in the Cisco ISE configuration as its username and password when making REST API calls to Cisco ISE.

Restrictions for SGACL and environment data download over REST

Outlines the requirements you must follow when configuring SGACL and environment data downloads using the REST interface.

To ensure proper operation of SGACL and environment data downloads over REST, observe these requirements:

- Cisco TrustSec Change of Authorization (CoA) uses RADIUS as the protocol.
- Only port 9063 is supported as the ERS server port.
- Server statistics are not persistent after a refresh of the environment data.
- Only one Fully Qualified Domain Name (FQDN) per server is supported.

Cisco TrustSec environment data

Environment data comprises of operational data that supplement Cisco TrustSec functions. The environment data request from a device to Cisco ISE consists of:

- Device name: Specifies the name of the device.
- Device capability: Specifies additional data.

The environment data response from Cisco ISE to a device consists of:

- Device security group tag (SGT): Derived from Cisco ISE based on the device name.
- Server list: Displays the list of Cisco TrustSec servers specified in Cisco ISE.
- SG-Name Table: Displays the mapping between SGT and the device name. SGT is displayed in numerals and the device name in text format.
- Refresh time: Indicates the time when the environment data will be refreshed.

Note

- As part of Cisco TrustSec environment data refresh, the last received servers are deleted and newly received servers are added to the server list. As a result of the refresh, the server list statistics restarts from zero, and the server status is set to *Inactive* and the IP address state is set to *Reachable*. The device then updates the server statistics and status based on the subsequent policy request and response.
- Starting with Cisco IOS XE Bengaluru 17.4.1, you can configure automated tester to be VRF aware. You can use the **vrf** keyword with the **automate-tester** command to enable automate-tester for a non-default VRF.

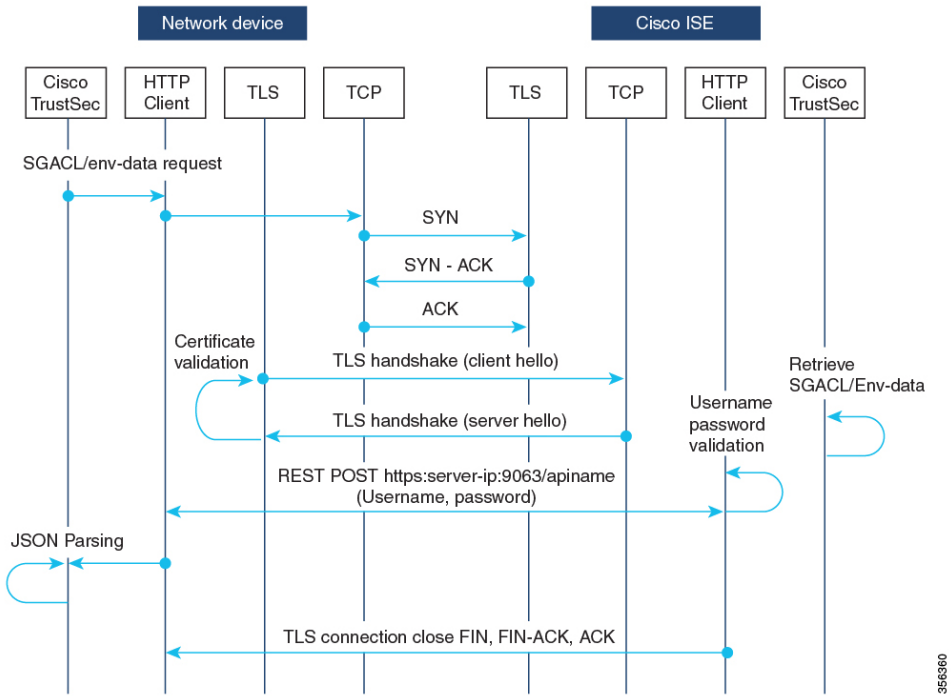
  For VRF aware automate-tester to work, you have to configure **global config ipv4/ipv6 source interface** interface-name **vrf** vrf-name command.

Message flow between a network device and a server

Learn how REST API communication is established and managed between a network device and a Cisco ISE server.

Summary

This process outlines how secure REST API communication is managed between a network device and a Cisco Identity Services Engine (ISE) server using TLS and authentication steps.



The key components involved in the process are:

- Cisco ISE server: Hosts the REST API service and handles incoming requests over secure connections.
- Network device: Initiates REST API calls to request SGACL and environment data from the server.
- TLS connection: Ensures encrypted, authenticated communication between the device and the server.

The server terminates the connection through a TCP-FIN message after all REST requests are processed.

Workflow

Figure 22: Figure 1. Message flow between a network device and a server

1. Cisco ISE REST API service runs on a secure socket using TLS 1.2 on port 9063. This service handles network device requests for SGACL and environment data.
2. The device uses a make-or-break approach to the TLS connection establishment, and there is no persistent TLS connection between the device and Cisco ISE. The server terminates the connection through a TCP FIN message after all REST requests are processed. For new REST API calls a new connection must be established with the server.
3. The REST API call from the device to Cisco ISE starts with a TCP connection establishment. Cisco ISE must be configured with device IP address to allow ingress connections from the device. If you send a TCP connection request from a source IP address not configured on Cisco ISE, Cisco ISE drops the request and creates an audit log.
4. Username and password–Every REST API call must include username and password authentication while requesting access to a resource uniform resource identifier (URI). The authentication helps the server to determine if the caller should be given access to the resource or to deny the request.
5. "To establish a secure TLS connection with Cisco ISE, you must install its server certificate signature or PEM as the trustpoint on the device. Use the **crypto pki trustpoint** command for this step. Export and install only the fingerprint or signature of the server certificate on the device under a trustpoint. You do not need to import the server certificate's private key.
6. After establishing the TLS connection, the HTTP client on the device initiates a REST call to Cisco ISE on the specified resource.

Result

The process allows devices to securely communicate and exchange environment or policy data with Cisco ISE servers by using authenticated and encrypted REST API sessions.

Policy server selection criteria

Learn how Cisco TrustSec devices select among multiple configured HTTP policy servers, detailing the criteria and algorithms used for server selection.

To explain the criteria and methods used by Cisco TrustSec devices to select a policy server from multiple configured HTTP servers, ensuring efficient communication with Cisco ISE and optimized load distribution.

You can configure multiple HTTP policy servers on your Cisco TrustSec device. After a server is selected, the device uses that server to interact with Cisco ISE until the server is inactive.

There are two types of server selection:

- In-order selection: This is the default behavior, where servers are picked in the order in which they are configured (from the public server list) or downloaded (from the private server list). After the device selects a server, it continues using that server until it becomes inactive. Then, the device selects the next server in the list.

  When environment data is successfully downloaded, and a server-list is available, these servers are added to the private server list.

- Random server selection: When multiple HTTP policy servers are configured on a device, a single Cisco ISE instance may get overloaded if the device always selects the first configured server. To avoid this situation, each device will randomly select a server. The device generates a random number, and based on this number, selects a server. For different devices to generate random numbers, the unique board ID and the Cisco TrustSec process ID of the device is used to initialize the random number generator.

  After the device selects a server, it sends all future requests to this server until it becomes inactive. When a server becomes inactive, the device uses the random server selection logic to pick the next available server. The device does not include inactive servers when selecting a new server. The device numbers servers starting at zero.

  Selected Server = (Generated Random Number) % (Total Number of Active Servers).

To change the server selection logic to random, use the **cts policy-server order random** command.

Server and IP address selection process

Learn how devices select servers and IP addresses using prioritized lists and selection algorithms in Cisco IOS XE.

Summary

The server and IP address selection process determines how a device chooses which server and IP address to use for connecting to Cisco ISE. This process provides failover, supports IPv4 and IPv6, and prioritizes server lists to ensure reliable connectivity.

Workflow

The order of server selection is the private server list, which is received as part of server list download, followed by the public server list, which contains the configured servers. The device selects a server at random or in order, depending on whether you enable the **cts policy-server order random** command.

In Cisco IOS XE 17.2.1 and later releases, each server can have multiple IP addresses (both IPv4 and IPv6). The device selects IPv4 addresses first (IPv6 addresses second), and lastly FQDN.

Here is how the device selects a server and IP address:

- When a device boots up for the first time, a server from the public (configured) list is selected.
- If the **cts environment-data enable** command is configured, the device uses the public server to download the private server-list from Cisco ISE.
- After selecting a server and IP address, the device connects to Cisco ISE using that combination.

- After the server and IP address are selected, the device connects to Cisco ISE using the server and IP address combination. This server will interact with Cisco ISE until it fails to get a response.
- If the device does not receive a response from the current active server in the private list, it switches to the next server. When the server is selected for the first time, the device searches for the first reachable IP or IPv6 address.
- After selecting a server and IP address, the device uses this combination until the device goes down.
- If none of the servers in the private list are reachable, the device attempts to connect to the servers in the public list. The server switching logic and IP selection are the same for private and public list.
- The server change happens only when the server list is refreshed.
- If all servers in both the private and public server list are dead, the device restarts the server and IP address selection logic from the start of the private list.
- When a specific server and IP address combination fails, the device waits for 60 seconds before it attempts a new combination.

Result

The device reliably connects to Cisco ISE by selecting available servers and IP addresses to maximize resilience and compatibility.

Server liveliness check

This topic explains how Cisco ISE checks server availability and how it responds during server selection

Summarize the methods and criteria Cisco ISE uses to assess and respond to server availability in the server selection process.

Cisco ISE determines whether a server is alive after receiving an environment-data or SGACL request. Cisco ISE does not run a liveliness detection phase on the server after it is configured or downloaded as part of a server list. By default, Cisco ISE considers all types of servers to be alive.

When a request is sent to Cisco ISE, if the server is not reachable or the response is lost, the server is marked as dead. The server selection logic will choose the same server and the next IP address (if multiple addresses are configured) to send the next set of Cisco ISE requests. If the device receives an overloaded response (HTTP 429) from Cisco ISE, the logic will select the next server in the list.

A server can be marked as dead because of any of these reasons that include:

- The configured IP address is not reachable.
- Incorrect port number.
- The Cisco ISE instance with the IP address is down.
- The interface towards Cisco ISE is down.
- A Transport Layer Security (TLS) handshake failure.
- An HTTP response timeout.
- An incorrectly configured domain name (if a domain name is used).

If you configure both a static IP address and a domain name for a server, Cisco ISE uses the static IP address first. If there is no response to the static IP address, the device tries with the domain name. If no response is received from both the static IP address and the domain name, the server is marked as dead.

When all servers in the private list are marked as dead, the device uses the public list. If all remaining servers are also marked as dead, the recovery mechanism starts. The device waits for the next Cisco TrustSec request, such as a policy refresh, environment data download, or a similar action. Then it marks all servers as alive to retry the download. If there is no new Cisco TrustSec request, the servers remain in the dead state.

Configure Cisco TrustSec username and password

Configure a Cisco TrustSec username and password on your device to enable REST API-based authentication with Cisco ISE.

Set up a username and password for Cisco TrustSec on your device. This enables REST API-based policy communication with Cisco Identity Services Engine (ISE) for secure network access enforcement.

Before you begin

Configure the username and password in Cisco ISE as the REST API access credentials, before configuring it on the device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Cisco TrustSec policy server and enter policy-server configuration mode.

   Example

   ```
   Device(config)# cts policy-server name ISE-server
   ```

3. Exit policy-server configuration mode and return to global configuration mode.

   Example

   ```
   Device(config-policy-server)# exit
   ```

4. Configure a username and password.

   Example

   ```
   Device(config)# cts policy-server username username password {0 | 6 |7 |
   password} {password}
   ```

   Note

   This username and password must be created on Cisco ISE as the REST API access credentials before configuring it on the device.

5. Optional: Exit global configuration mode and return to privileged EXEC mode.

Example

```
Device(config)# end
```

The device is now configured to use the specified username and password to communicate with Cisco ISE through REST API for TrustSec operations.

```
Device# configure terminal
Device(config)# cts policy-server name ISE-server
Device(config-policy-server)# exit
Device(config)# cts policy-server username admin password 6 password1
Device(config)# end
```

Download certificate from ISE

Learn how to configure and download the server certificate from Cisco Identity Services Engine (ISE) for secure TLS communications.

Obtain the TLS-based server certificate from ISE to enable secure authentication with external services.

This task is typically performed when you need to export a self-signed server certificate from ISE for use in network authentication protocols or to integrate with other secure services.

Procedure

---

1. Log in to the Identity Services Engine GUI with your administrative user credentials.
2. Choose **Administration** > **Certificates**. The **System Certificates** page is displayed.
3. From the list of certificates, select **Default self-signed server certificate** for TLS-based authentication. The **Used By** column lists the certificate's purpose.
4. Click **Export**.
   The **Export Certificate 'Default self-signed server certificate'** page is displayed.
5. Click the **Export** button in the dialog box.
   The certificate file is downloaded and saved to your local machine.

The system successfully downloads the TLS-based server certificate from ISE. You can now use it in secure authentication workflows.

Configure certificate enrollment

Learn to configure certificate enrollment on your device to establish trust with a Certificate Authority (CA). These steps ensure your device can authenticate and obtain digital certificates required for secure communications.

Use this task to enroll your device with a Certificate Authority, which is necessary for implementing secure certificate-based authentication and encrypted communications within your network.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Define the trustpoint and a name, and enter CA trustpoint configuration mode.

   Example

   ```
   Device(config)# crypto pki trustpoint name
   ```

3. Enroll the CA certificate through the terminal. The certificate is imported through the terminal.

   Example

   ```
   Device(ca-trustpoint)# enrollment terminal
   ```

4. Exit CA trustpoint configuration mode and return to global configuration mode.

   Example

   ```
   Device(ca-trustpoint)# exit
   ```

5. Retrieve the Certificate Authority (CA) certificate and authenticate it. Check the certificate fingerprint if prompted.

   Example

   ```
   Device(config)# crypto pki authenticate name
   ```

   You will receive a message to enter the base 64 encoded certificate. Open the certificate that you had downloaded in your local folder, copy the contents and paste it at the prompt.

   The certificate fingerprints are displayed. Accept the certificate when prompted.

   The trustpoint CA certificate is accepted and successfully imported.

   > **Note**
   >
   > This command is optional if the CA certificate is already loaded into the configuration.

6. Optional: Exit global configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

After completing these steps, your device will have established a trust relationship with the Certificate Authority and be ready to request and use digital certificates for secure operations.

```
Device# configure terminal
Device(config)# crypto pki trustpoint ca-trustpoint
Device(ca-trustpoint)# enrollment terminal
Device(ca-trustpoint)# exit
Device(config)# crypto pki authenticate ca-trustpoint
<Cut and paste the downloaded CA certificate>
Device(config)# end
```

What to do next

Associate the trustpoint with the policy server.

Configure CTS policy server and parameters

Learn how to configure a Cisco TrustSec (CTS) policy server and specify its settings to enable secure policy enforcement within your network.

Define the parameters and set up a Cisco TrustSec policy server to enable secure policy enforcement within your network for certificate enrollment, communication, and security.

Before you begin

- Configure certificate enrollment policy.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Cisco TrustSec policy server and enter policy-server configuration mode.

   Example

   ```
   Device(config)# cts policy-server name ISE-server
   ```

3. Configure the domain name address, IPv4 address, or IPv6 address of the policy server.

   Example

   ```
   Device(config-policy-server)# address {domain-name name| ipv4
   policy-server-address | ipv6 policy-server-address}
   ```

   IPv6 addresses are supported starting with Cisco IOS XE 26.1.1.

4. Configure the Transport Layer Security (TLS) certificate trustpoint.

   Example

   ```
   Device(config-policy-server)# tls server-trustpoint trustpoint-name
   ```

5. Optional: Configure the response timeout in seconds.

   Example

   ```
   Device(config-policy-server)# timeout seconds
   ```

   The range is from 1 to 60 seconds. The default is 5 seconds.

6. Optional: Configure the maximum number of retries from the server.

Example

```
Device(config-policy-server)# retransmit number-of-retries
```

The range is from 0 to 5. The default is 4.

7. Optional: Specify the policy server port number.

Example

```
Device(config-policy-server)# port port-number
```

The range is from 1025 to 65535.

> **Note**
>
> The ERS server port number must be 9063. You cannot change this port number.

8. Optional: Set the content type so the system sources SGACL and environment data from Cisco ISE.

Example

```
Device(config-policy-server)# content-type json
```

9. Optional: Exit policy-server configuration mode and return to privileged EXEC mode.

Example

```
Device(config-policy-server)# end
```

The CTS policy server uses specified parameters, enabling secure communication and policy enforcement for your network devices.

```
Device# configure terminal
Device(config)# cts policy-server name ISE-server
Device(config-policy-server)# address ipv6 2001.DB8::1
Device(config-policy-server)# tls server-trustpoint tls15
Device(config-policy-server)# timeout 15
Device(config-policy-server)# retransmit 4
Device(config-policy-server)# port 9063
Device(config-policy-server)# content-type json
Device(config-policy-server)# end
```

Download environment data

This feature enables the device to retrieve and apply environment-specific configuration data from Cisco ISE. This data is required for secure network access and policy enforcement.

This task allows you to configure your device to download environment data from Cisco ISE. Obtaining this information ensures that policies are applied accurately, and it enables seamless integration with your network access devices.

Before you begin

The source interface to use for HTTP connections must be specified in the **ip http client source-interface** command.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the policy server device ID to send environment data requests to Cisco ISE.

   Example

   ```
   Device(config)# cts policy-server device-id device-id
   ```

   Use the same device-ID that you used to add the network access device (NAD) in Cisco ISE.

3. Enable environment data downloads from Cisco ISE.

   Example

   ```
   Device(config)# cts environment-data enable
   ```

   > **Note**
   >
   > The **cts environment-data enable** command and the **cts authorization list** command are mutually exclusive. These commands cannot be configured together.

4. Optional: Exit global configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

Your device is now configured to download environment data from Cisco ISE. This step keeps policy and access-control configuration synchronized with the central ISE server.

```
Device# configure terminal
Device(config)# cts policy-server device-id server1
Device(config)# cts environment-data enable
Device(config)# end
```

Debug the SGACL and environment data over REST configuration

This reference lists debug commands used to troubleshoot SGACL and environment data configurations over REST, including command syntax and functional descriptions.

This reference provides a list of debug commands to assist in troubleshooting SGACL and environment data configurations over REST.

Use these **debug** commands for debugging the configuration.

- **debug cts policy-server http**

  Enables HTTP client debugging.

- **debug cts policy-server json**

  Enables JSON client debugging.

Verify the SGACL and environment data download over REST

This reference section presents command outputs and error descriptions used to verify SGACL and environment data downloads through REST.

To provide reference information for commands used to verify SGACL and environment data downloads over REST. You will find instructions for viewing policy server details, interpreting server statistics, understanding error codes, and displaying environment data server lists.

To display information about the specified policy server, use this command:

```
Device# show cts policy-server details name ise_server_1
Server Name   : ise_server_1
Server Status : Active
  IPv4 Address     : 10.64.69.84
  IPv6 Address     : 2001:DB::2
  Trustpoint       : ISE84
  Port-num         : 9063
  Retransmit count : 3
  Timeout          : 15
  App Content type : JSON
```

To display statistics information about active policy servers, use this command:

If you use the command without the **active**, the statistics of all servers will be listed.

```
Device# show cts policy-server statistics active
Server Name  : ise_server_1
Server State : ALIVE
  Number of Request sent        : 7
  Number of Request sent fail   : 0
  Number of Response received   : 4
  Number of Response recv fail  : 3
    HTTP 200 OK                 : 4
    HTTP 400 BadReq             : 0
    HTTP 401 UnAuthorized Req   : 0
    HTTP 403 Req Forbidden      : 0
    HTTP 404 NotFound           : 0
    HTTP 408 ReqTimeout         : 0
    HTTP 415 UnSupported Media  : 0
    HTTP 500 ServerErr          : 0
    HTTP 501 Req NoSupport      : 0
    HTTP 503 Service Unavailable: 0
    TCP or TLS handshake error  : 3
    HTTP Other Error            : 0
```

Table 136: List of errors displayed in the show command and their descriptions

Errors	Description
HTTP 200 OK	Indicates that the client's request to the server has been processed.

Errors	Description
HTTP 400 BadReq	Indicates that the server cannot process the request due to a problem on the client's end.
HTTP 401 UnAuthorized Req	Indicates that the request has not been completed because it lacks valid authentication credentials for the requested resource.
HTTP 403 Req Forbidden	Indicates that the server understood the request but refuses to authorize it. This is often due to insufficient permissions or, less commonly, server misconfiguration.
HTTP 404 NotFound	Indicates that the web server cannot find the requested resource.
HTTP 408 ReqTimeout	Indicates that the server did not receive a complete request from the client within the time that the server was prepared to wait.
HTTP 415 UnSupported Media	Indicates that the server refuses to accept the request because the payload format is in a format not supported by the server for the target resource.
HTTP 500 ServerErr	Indicates that the server encountered an unexpected condition preventing it from fulfilling a request.
HTTP 501 Req NoSupport	Indicates that the server cannot fulfill the request because it does not support the required functionality.
HTTP 503 Service Unavailable	Indicates a temporary server failure, often due to overloading, maintenance, or misconfigured application pools.
TCP or TLS handshake error	Occurs when a client and server fail to establish a secure, encrypted connection.

To view the list of servers that are downloaded as part of the environment data, use this command.

These servers are included in the private server list.

This output shows the HTTP based download information:

```
Device# show cts server-list
HTTP Server-list:
  Server Name      : cts_private_server_0
  Server State     : ALIVE
  IPv4 Address     : 10.64.69.151
  IPv6 Address     : 2001:DB8:8086:6502::
  IPv6 Address     : 2001:db8::2
  IPv6 Address     : 2001:db8::402:99
  IPv6 Address     : 2001:DB8:4::802:16
  Domain-name      : ise-267.cisco.com
  Trustpoint       : cts_trustpoint_0

  Server Name      : cts_private_server_1
  Server State     : ALIVE
  IPv4 Address     : 10.10.10.3
  IPv4 Address     : 10.10.10.2
```

```
IPv6 Address     : 2001:DB8::20
IPv6 Address     : 2001:DB8::21
Domain-name      : www.ise.cisco.com
Trustpoint       : cts_trustpoint_1
```

Cisco TrustSec - ISE communication over IPv6

Outlines Cisco TrustSec's IPv6 capabilities, including policy-centric security management, RADIUS-based ISE communication, enforcement of security and identity policies, SGACL provisioning, and IPv6 address support to enable secure, scalable network modernization.

IPv6 transition for Cisco TrustSec

Cisco TrustSec is a security framework that

- implements business security needs through policy-centric management,
- provides integrated security features such as segmentation, identity management, access control, and data protection,
- facilitates communication between network devices and policy servers using the RADIUS protocol over IPv6.

This framework allows organizations to enforce security policies effectively across their networks, adapting to the growing demand for IPv6 addressing.

The transition to IPv6 for Cisco TrustSec involves:

- Supporting IPv6 addresses for end-user policy enforcement and identity management.
- Enabling communication with the Identity Services Engine (ISE) for provisioning Security Group ACL (SGACL) policies over IPv6.
- Maintaining a list of IPv6 addresses and load balancing them during policy download.

This transition is essential for organizations looking to modernize their network security infrastructure and ensure compatibility with future technologies.

Limitations of IPv4

The limitations of IPv4 addressing include:

- **Limited address space**: Due to its 32-bit addressing system, IPv4 is limited to approximately 4.3 billion unique addresses, which is insufficient for the increasing number of internet-connected devices.
- **Dependency on NAT**: It requires Network Address Translation (NAT) to extend the address space, which complicates network design and can hinder connectivity.
- **Lack of native support**: It lacks native support for modern features such as end-to-end encryption and mobility.
- **Routing inefficiencies**: It creates inefficiencies in routing tables, leading to increased processing overhead for routers.

Configure ISE for TrustSec (CLI)

Use this procedure to configure ISE for TrustSec.

Set up ISE to enable secure network access using TrustSec policies using commands.

This task involves configuring a device to communicate with an ISE server as a RADIUS server and integrating TrustSec authorization.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the RADIUS server name.

   Example

   ```
   Device(config)# radius server server-name
   ```

3. Specify the primary RADIUS server parameters.

   Example

   ```
   Device(config-radius-server)# address ipv6 ip-address
   ```

4. Specify the authentication and encryption key used between the Device and the key string RADIUS daemon running on the RADIUS server.

   Example

   ```
   Device(config-radius-server)# pac key key
   ```

5. Return to the configuration mode.

   Example

   ```
   Device(config-radius-server)# exit
   ```

6. Create a radius server-group identification.

   Example

   ```
   Device(config)# aaa group server radius server-group
   ```

   Note

   server-group refers to the server group name. The valid range is from 1 to 32 alphanumeric characters.

7. Create a CTS authorization list.

   Example

   ```
   Device(config)# cts authorization list mlist-name
   ```

8. Create an authorization method list for web-based authorization.

Example

```
Device(config)# aaa authorization network mlist-name group group-name
```

Note

Ensure that the ISE IP address configured on your controller is the same as the IP address configured on ISE (**Work Center** > **TrustSec** > **Components** > **Trustsec AAA Servers**).

Note

If the ISE version is 002.005(000.239), 002.004(000.357), 002.003(000.298), 002.002(000.470), 002.001(000.474), 002.000(001.130), or 002.000(000.306), use the **access-session tls-version 1.0** command to download PAC from ISE. For other ISE versions, the above command is not required.

Configure TrustSec SXP with IPv6 (GUI)

Use this task to configure TrustSec to support IPv6 communication for enhanced security policy management.

Enable IPv6 communication for Cisco TrustSec to enhance security policy management.

Use this task to configure RADIUS server settings to support IPv6 addresses for TrustSec operations.

Before you begin

- Ensure that your network devices are capable of supporting IPv6.
- Verify that the Identity Services Engine (ISE) is configured to accept IPv6 connections.

Procedure

1. Choose **Configuration** > **Security** > **Trustsec**.
2. On the Trustsec page, click the **SXP** tab. The **Peer Connections** section is displayed.
3. In the **SXP Parameters** section, enable the **SXP Status**.
4. Specify the **Default Source IPv6** address and the default password.
5. In the **Peer Connections** section, click **Add**.
6. On the **Add Peer Connection** page, configure these parameters:
   a) From the **Mode of Local Device** drop-down list, select either **listener**, **speaker**, or **both**.
   b) From the **IP Type** drop-down list select **IPv6**.
   c) Enter the **Peer IP** and the **Source IP** addresses.
   d) Enter the **Password**.
   e) Click **Apply to Device**.

7. Click **Apply**.

IPv6 is now enabled for TrustSec operations and RADIUS communications.

Configure TrustSec SXP with IPv6

Use this task to configure TrustSec to support IPv6 communication for enhanced security policy management.

Enable IPv6 communication for Cisco TrustSec to enhance security policy management.

Use this task to configure RADIUS server settings to support IPv6 addresses for TrustSec operations.

Before you begin

- Ensure that your network devices are capable of supporting IPv6.
- Verify that the Identity Services Engine (ISE) is configured to accept IPv6 connections.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure CTS SXP with IPv6 address.

   Example

   ```
   Device(config)# cts sxp default source-ipv6 <X:X:X:X::X source ipv6 address>
   ```

3. Complete these steps to configure the CTS SXP connection parameters.
   a) Configure CTS SXP connection peer IP address. You can configure either IPv4 or IPv6 IP address of the peer.
   b) Set the password option. You can choose a default password, or use a configured key-chain for authentication, or opt for no password.
   c) Set the connection role as either local or peer and then set an SXP mode.
   d) Specify the VRF. If the SXP connection should be in a specific VRF, include the VRF name.

   Example

   ```
   Device(config)# cts sxp connection peer {A.B.C.D | X:X:X:X::X}
                                              password {default | key-chain
    | none}
                                              mode {local | peer} {both |
   listener hold-time | speaker hold-time}
                                              vrf <vrf-name>
   ```

   ```
   Device(config)# cts sxp connection peer 2001:db8::1 password default mode
    local both vrf mgmt-vrf
   ```

4. Configure CTS SXP node ID.

Example

```
Device(config)# cts sxp node-id {interface | ipv4 | ipv6}
```

> **Note**
>
> The node ID is a 32-bit value. When enabling SXP over IPv6, a node ID must be explicitly configured; an IPv6 address cannot be used as the node ID.

5. Configure CTS SXP export-import VRF group.

Example

```
Device(config)# cts sxp export-import-group <group-name>
```

6. Configure CTS SXP export-import VRF group.

Example

```
Device(config)# cts sxp export-import-group <group-name>
```

TrustSec SXP is successfully configured to support IPv6 communication, enabling enhanced security policy management and seamless connectivity between devices using IPv6 addresses.

Verify Cisco TrustSec PAC over IPv6 RADIUS

To verify Cisco TrustSec PAC over IPv6 RADIUS, use these **show** commands:

To view the A-ID and PAC information for PACs in the key store, use this command:

```
Device# show cts pacs
AID: 60DABBF8AD435A7B63900EE07E68D2FD
PAC-Info:
  PAC-type = Cisco Trustsec
  AID: 60DABBF8AD435A7B63900EE07E68D2FD
  I-ID: ha_senth_cat9k
  A-ID-Info: Identity Services Engine
  Credential Lifetime: 16:17:20 UTC Mon Feb 24 2025
PAC-Opaque:
[redacted]
Refresh timer is set for 12w4d
```

To view the queue for provisioning requests, use this command:

```
Device# show ctw provisioning queue
Server: 20XX:420:54XX:4::400:11, Type: Radius, Provisioned: YES
AID: 3ec5d7e02bde9fd04c453918a5e2d3b4
```

To view the Cisco TrustSec environment data, use this command:

```
Device# show cts environment-data
CTS Environment Data
```

```

TrustSec IP-SGT High Availability binding

Introduces TrustSec IP-to-SGT High Availability binding, highlighting how it synchronizes IP-to-SGT bindings between active and standby devices, preserves bindings during SSO, and ensures consistent SGACL enforcement for uninterrupted policy application during failover events.

TrustSec IP-to-SGT binding High Availability is a redundancy capability that

- synchronizes supported IP-to-SGT bindings between the active and standby devices
- preserves binding information during a Stateful Switchover (SSO), and
- helps maintain consistent Security Group Access Control List (SGACL) enforcement after the switchover.

An IP-to-SGT binding associates an IP address with a Security Group Tag (SGT). TrustSec uses this association to classify traffic and apply the appropriate security policy.

Without binding synchronization, a new active device may need to re-establish connections and relearn bindings after a switchover. Policy enforcement can be delayed while this process occurs. High-availability support makes the required binding information available on the standby device before it assumes the active role.

The list of source-bindings supported for binding synchronization in Cisco TrustSec are:

- Local source: IP-SGT binding received through authentication of hosts, learned through Endpoint Policy Manager (EPM) and device tracking.
- SXP source: IP-SGT binding received through Security Group Tag Exchange Protocol (SXP) peers.
- VLAN source: IP-SGT binding received through VLAN-to-SGT mapping.
- L3IF binding: Binding received through Layer 3 Logical Interface (L3IF) learning.

Verify TrustSec IP-SGT High Availability binding support

As part of the system's synchronization functionality, active bindings are automatically propagated to and displayed on the standby unit to ensure High Availability and consistent policy enforcement across the cluster.

To view all the mappings of IP address to Security Group Tag, use this command:

```
Device# show cts role-based sgt-map all
Active IPv4-SGT Bindings Information

153 SGT Inline Tagging and SXPv4

Topics:

- SGT inline tagging on AP and SXPv4

Introduces Security Group Tags and Security Exchange Protocol version 4 as foundational components of Cisco TrustSec architecture for network segmentation and policy enforcement.

SGT inline tagging on AP and SXPv4

Introduces SGT and SXPv4 concepts, and guides users through creating SXP profiles, configuring SGT inline tagging on APs, establishing SXP connections using GUI and CLI, and verifying successful SGT push to APs.

SGT inline tagging on AP and SXPv4 is a set of Cisco TrustSec enhancements that

- enables secure propagation of scalable group tag (SGT) information across network devices using the SXP protocol
- introduces loop detection in SXP version 4 to prevent stale binding in the network, and
- supports embedding SGTs in clear-text Ethernet packets with inline tagging.

When a wireless client is authenticated by Cisco Identity Services Engine (ISE), the IP-SGT binding is generated on the controller and pushed to the access point along with other client details.

Additional information

Cisco TrustSec (CTS) builds secure networks by establishing domains of trusted network devices. CTS uses SGTs and the SXP protocol to securely exchange group information and enhance network segmentation.

For details on SGT inline tagging on the AP and SXP version 4, see the Cisco TrustSec Configuration Guide.

Create an SXP profile

Create an SXP profile.

Configuring an SXP profile is essential for enabling Cisco TrustSec features in a wireless environment.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a wireless CTS profile and enter cts-sxp profile configuration mode.

   Example

   ```
   Device(config)# wireless cts-sxp profile profile-name
   ```

   The *profile-name* is the name of the SXP profile being created.

3. Enable SXP for Cisco TrustSec.

   Example

   ```
   Device(config-cts-sxp-profile)# cts sxp enable
   ```

The SXP profile is now created and SXP is enabled for Cisco TrustSec.

Configure SGT inline tagging on APs

Use this procedure to configure SGT inline tagging on access points (APs).

Enable SGT inline tagging on APs to support dynamic SGT allocation through ISE authentication.

Follow the procedure given below to configure SGT inline tagging on APs.

Before you begin

Ensure that the SGTs pushed to the AP for inline tagging will only be from dynamic SGT allocation through ISE authentication. It is not supported for static bindings configured on the controller . SGTs will be pushed to an AP only when it is operating in flex mode. To know the list of Cisco APs that support SGT inline tagging, see the release notes: https://www.cisco.com/c/en/us/support/wireless/catalyst-9800-series-wireless-controllers/products-release-notes-list.html.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

   Enters the global configuration mode.

2. Configure a wireless flex profile and enter the wireless flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex flex-profile
   ```

   The *flex-profile* is the name of the wireless flex profile being configured.

3. Enable inline-tagging on the AP.

   Example

   ```
   Device(config-wireless-flex-profile)# cts inline-tagging
   ```

   Enables inline-tagging on the AP.

SGT inline tagging is now configured on the access points, allowing for dynamic SGT allocation.

Configure an SXP connection (GUI)

Learn how to configure an SXP connection using the graphical user interface (GUI) by following step-by-step instructions for global, peer, and AP profile settings.

Configure an SXP (Security Group Tag Exchange Protocol) connection using the graphical user interface (GUI) to enable secure policy exchange between network devices.

Procedure

1. In the **Global** section, select the **SXP Enabled** check box to enable SXP.
2. Enter an IP address in the **Default Source IP** field.

3. Enter a value in the **Reconciliation Period (sec)** field.
4. Enter a value in the **Retry Period (sec)** field.
5. Select the **Set New Default Password** check box. Selecting this check box displays the **Password Type** and **Enter Password** fields.
6. Choose any one of the available types from the **Password Type** drop-down list.
7. Enter a value in the **Enter Password** field.
8. Click the **Apply** button.
9. In the **Peer** section, click the **Add** button.
10. Enter an IP address in the **Peer IP** field.
11. Enter an IP address in the **Source IP** field.
12. Choose any one of the available types from the **Password** drop-down list.
13. Choose any one of the available types from the **Mode of Local Device** drop-down list.
14. Click the **Save & Apply to Device** button.
15. In the **AP** tab, click the **Add** button. The **Add SXP AP** dialog box appears.
16. Enter a name for the profile in the **Profile Name** field.
17. Set the **Status** field to **Enabled** to enable AP.
18. Enter a value in the **Default Password** field.
19. Enter a value (in seconds) for the **CTS Speaker Seconds, CTS Recon Period, CTS Retry Period, CTS Listener Maximum** , and **CTS Listener Minimum**
20. In the **CTS SXP Profile Connections** section, click **Add** .
21. Enter an IP address in the **Peer IP** field.
22. Choose any one of the modes from the **Connection Mode** drop-down list. The available modes are **Both** , **Listener** , and **Speaker** .
23. From the **Password Type** drop-down list, choose either **None** or **Default** .
24. Click the **Add** button.
25. Click the **Save & Apply to Device** button.

You have a fully configured SXP connection, including global settings, peer devices, and AP (Access Point) profiles, ready for secure operation in your network.

Configure an SXP connection

Use this procedure to configure an SXP connection using commands.

Follow the procedure given below to configure an SXP connection:

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. Enable CTS SXP support.

Example

```
Device(config)# cts sxp enable
```

Enables CTS SXP support.

3. Configure the CTS-SXP peer address connection.

Example

```
Device(config)# cts sxp connection peer ipv4-address password password-value
 mode mode-value speaker
```

Configures the CTS-SXP peer address connection.

> **Note**
>
> The password need not be *none* always and the mode can either be Speaker or Listener, or Both.

What to do next

Use the following command to verify the configuration:

```
Device# show running-config | inc sxp
```

Verify SGT push to APs

Verifies SGT push to AP.

When a wireless client is connected and authenticated by ISE, the IP-SGT binding is generated on the controller . This can be verified using these commands:

```
Device# show cts role-based sgt-map all

Active IPv4-SGT Bindings Information

IP Address              SGT     Source
============================================
1.1.1.1                 100     CLI

IP-SGT Active Bindings Summary
============================================
Total number of CLI      bindings = 1
Total number of active   bindings = 1
```

Use this command to verify the SXP connections status:

```
Device# show cts sxp connections

 SXP              : Enabled
 Highest Version Supported: 4
```

```
 Default Password : Not Set
 Default Source IP: Not Set
Connection retry open period: 120 secs
Reconcile period: 120 secs
Retry open timer is running
Peer-Sequence traverse limit for export: Not Set
Peer-Sequence traverse limit for import: Not Set
----------------------------------------------
Peer IP          : 198.51.100.1
Source IP        : 198.51.100.2
Conn status      : On
Conn version     : 4
Conn capability  : IPv4-IPv6-Subnet
Conn hold time   : 120 seconds
Local mode       : SXP Listener
Connection inst# : 1
TCP conn fd      : 1
TCP conn password: none
Hold timer is running
Duration since last state change: 0:00:00:06 (dd:hr:mm:sec)

Total num of SXP Connections = 1
```

Use this command to see the bindings learnt over SXP connection:

```
Device# show cts role-based sgt-map all

Active IPv4-SGT Bindings Information

154 Ciphersuites for CAPWAP-DTLS

Topics:

- Default ciphersuites supported for CAPWAP-DTLS

Default ciphersuites supported for CAPWAP-DTLS

Lists the default ciphersuites used for CAPWAP-DTLS, AP priorities, platform exclusions, and configuration guidance.

Starting with Cisco IOS XE Bengaluru 17.5.1, the Elliptic Curve Diffie-Hellman Ephemeral (ECDHE) or Galois Counter Mode (GCM) ciphersuite with perfect forward secrecy (PFS) is included in the default list, together with the existing AES128-SHA ciphersuite. All Cisco AP models, except Cisco IOS APs, prioritize the PFS ciphersuite for CAPWAP-DTLS under the default configuration.

> **Note**
>
> If link encryption is enabled for secure data channel traffic, the COS AP (DTLS client) prioritizes DHE-RSA-AES128-SHA over the ECDHE or GCM ciphersuite.

- The preference order of the ciphersuites during the DTLS handshake is important. You can set the priority order when configuring cipher suites using this feature.
- When explicit ciphersuites are not configured, the default ciphersuites listed in the table apply.

Table 137: Default Ciphersuites

Security Mode	Ciphersuite
FIPS and non-FIPS	·TLS_RSA_WITH_AES_128_CBC_SHA · TLS_DHE_RSA_WITH_AES_128_CBC_SHA · TLS_DHE_RSA_WITH_AES_256_CBC_SHA · TLS_DHE_RSA_WITH_AES_256_CBC_SHA256 · TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 · TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 · TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
WLANCC	·TLS_DHE_RSA_WITH_AES_128_CBC_SHA · TLS_DHE_RSA_WITH_AES_256_CBC_SHA · TLS_DHE_RSA_WITH_AES_256_CBC_SHA256 · TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 · TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 · TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256

This feature is supported on all variants of Cisco Catalyst 9800 Series Wireless Controllers and APs, except for Cisco Industrial Wireless 3702 AP.

Refer to the release notes for a list of supported controllers and APs for each release: https://www.cisco.com/c/en/us/support/wireless/catalyst-9800-series-wireless-controllers/products-release-notes-list.html.

Configure multiple ciphersuites (CLI)

Use this procedure to configure multiple ciphersuites using commands.

Configure the allowed ciphersuites for AP DTLS on the controller using commands.

Note

- If a controller is loaded with a startup configuration using a ciphersuite selection configuration that predates Cisco IOS XE Bengaluru 17.5.1, it is automatically converted to the latest ciphersuite selection version.
- Changing the ciphersuite configuration causes APs to disconnect and reconnect.
- If you downgrade to a Cisco IOS XE Bengaluru version earlier than 17.5.1, the ciphersuite configurations are lost.
- When downgrading to a version below 17.12.1 in FIPS mode or WLANCC mode, verify that the ECDHE-RSA-AES128-GCM-SHA256 cipher suite is selected for AP DTLS. By default, it is selected. Otherwise, the downgrade causes connectivity issues for all Cisco Wave 2 APs.
- This can be verified by using the **show wireless certification config** command.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set priority for a particular cipher suite.

   Example

   ```
   Device(config)# ap dtls-ciphersuite priority-num ciphersuite
   ```

   Use zero to set the highest priority.

   Note

   Any configuration change will automatically disconnect all currently connected APs.

3. Return to the privileged EXEC mode.

   Example

   ```
   Device(config)# exit
   ```

Set server preference (CLI)

Use this procedure to set server preference using commands.

Configure whether the server dictates ciphersuite priority order during a DTLS handshake for AP join profiles using commands.

The ciphersuite configuration enforces the priority order during the DTLS handshake. To give equal priority to all configured ciphersuites, use the **no ciphersuite server-preference** command in the corresponding AP join profile. By default, server preference is enabled.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

3. Set the cipher suite server preference.

   Example

   ```
   Device(config-ap-profile)# [no] ciphersuite server-preference
   ```

   Use the **no** form of this command to disable server preference. By default, server preference is enabled.

4. Return to global configuration mode.

   Example

   ```
   Device(config)# exit
   ```

Verify operational ciphersuites and priority

This topic describes the verifying operational ciphersuites and priority command.

To view the operational ciphersuites and their priority, use this command:

```
Device# show wireless certification config

WLANCC                          : Not Configured
AP DTLS Version                 : DTLS v1.0 - v1.2

AP DTLS Cipher Suite List:

  Priority                Ciphersuite
------------------------------------------------------------------------------

   0                      AES128-SHA
   1                      DHE-RSA-AES256-SHA256
```

155 Configure Secure Shell

Topics:

- SSH

Introduces Secure Shell protocol fundamentals, configuration options, and security considerations for establishing encrypted remote connections to network devices.

> **Note**
>
> Starting with, Secure Shell Version 1 (SSHv1) is deprecated.

SSH

Explains Secure Shell (SSH), a network security protocol that establishes encrypted and authenticated connections between remote devices, protecting data confidentiality and integrity during communication.

A secure shell (SSH) protocol is a network security mechanism that

- establishes encrypted and authenticated connections between remote devices. and
- protects data confidentiality and integrity during communication.
- supports multiple version standards, including SSHv1 and SSHv2.

How SSH sorks and security benefits

Secure Shell (SSH) protocols offer a secure alternative to older remote access methods, such as Telnet, by encrypting data exchanged between a client and a server. Authentication further ensures that only authorized users can access devices. SSH increases security for network administrators by preventing eavesdropping and protecting credentials.

- Connecting securely to a router or switch for remote configuration.
- Transferring files securely between devices using SCP, which operates over SSH.

SSH and device access

Explains how Secure Shell (SSH) provides a secure, remote connection to a device, offering enhanced security over Telnet by using strong encryption and supporting both IPv4 and IPv6 environments.

A Secure Shell (SSH) protocol is a network access method that

- uses strong encryption and authentication to secure remote connections
- offers enhanced security over Telnet by encrypting session and authentication data, and
- supports both IPv4 and IPv6 environments for flexible device access.

Additional information

SSH is a secure protocol for remote device access, supporting both IPv4 and IPv6, and provides strong encryption for authenticated sessions.

SSH servers and integrated clients

The Secure Shell (SSH) Integrated Client feature is an application that runs over the SSH protocol to provide device authentication and encryption.

A SSH integrated client is a feature that - runs over the SSH protocol to provide device authentication - enables secure, encrypted connections to other devices, and - supports various user authentication methods.

Supported versions and functionalities

The SSH client enables a Cisco device to make a secure, encrypted connection to another Cisco device or to any other device running the SSH server.

This connection provides functionality similar to that of an outbound Telnet connection except that the connection is encrypted.

With authentication and encryption, the SSH client allows for secure communication over an unsecured network.

The SSH server and SSH integrated client are applications that run on the switch.

The switch supports an SSHv1 or an SSHv2 server.

The switch supports an SSHv1 client.

> **Note**
>
> The SSH client functionality is available only when the SSH server is enabled.

User authentication is performed like that in the Telnet session to the device. SSH also supports the following user authentication methods:

- TACACS+
- RADIUS
- Local authentication and authorization

SSH configuration guidelines

Provides guidelines for configuring the switch as an SSH server or SSH client.

General SSH configuration guidelines

Follow these guidelines when configuring the switch as an SSH server or SSH client:

- An RSA key pair generated by a SSHv1 server can be used by an SSHv2 server, and the reverse.
- If the SSH server is running on an active switch and the active switch fails, the new active switch uses the RSA key pair generated by the previous active switch.
- If you get CLI error messages after entering the **crypto key generate rsa** global configuration command, an RSA key pair has not been generated. Reconfigure the hostname and domain, and then enter the **crypto key generate rsa** command.
- When generating the RSA key pair, the message No host name specified might appear. If it does, you must configure a hostname by using the **hostname** global configuration command.
- When generating the RSA key pair, the message No domain specified might appear. If it does, you must configure an IP domain name by using the **ip domain-name** global configuration command.
- When configuring the local authentication and authorization authentication method, make sure that AAA is disabled on the console.

SCP

Provides an overview of Secure Copy Protocol (SCP).

A Secure Copy Protocol is a method for securely transferring files that

- provides a secure and authenticated method for copying switch configurations or switch image files
- relies on Secure Shell (SSH) for secure transport, and
- requires correct configuration of SSH, authentication, and authorization on the switch.

Supporting reference information

For SSH to work, the switch needs an RSA public or private key pair. This is the same with SCP, which relies on SSH for its secure transport.

Because SSH also relies on AAA authentication, and SCP relies further on AAA authorization, correct configuration is necessary.

- Before enabling SCP, you must correctly configure SSH, authentication, and authorization on the switch.
- Because SCP relies on SSH for its secure transport, the router must have a Rivest, Shamir, and Adelman (RSA) key pair.

> **Note**
>
> When using SCP, you cannot enter the password into the copy command. You must enter the password when prompted.

Secure copy protocol

The Secure Copy Protocol (SCP) feature provides a secure and authenticated method for copying device configurations or switch image files.

A Secure Copy Protocol is a network protocol that

- provides a secure and authenticated method for copying files
- relies on SSH for security, and
- requires authentication, authorization, and accounting (AAA) authorization.

Additional information on SCP

The behavior of SCP is similar to that of remote copy (rcp), which comes from the Berkeley r-tools suite.

To configure the SCP, you should understand the SCP concepts.

SFTP support

Provides Secure File Transfer Protocol (SFTP) support.

SFTP client support is introduced from Cisco IOS XE Gibraltar 16.10.1 release onwards. SFTP client is enabled by default and no separate configuration required. The SFTP procedures can be invoked using the **copy** command, which is similar to that of **scp** and **tftp** commands. A typical file download procedure using **sftp** command can be carried out as shown below:

copy sftp://*user* **:***password* **@***server-ip***/***file-name* **flash0://** *file-name*

For more details on the **copy** command, see the following URL:
https://www.cisco.com/c/m/en_us/techdoc/dc/reference/cli/nxos/commands/fund/copy.html

Prerequisites for configuring SSH

Outlines prerequisites for configuring secure shell.

- For SSH to work, the switch needs an Rivest, Shamir, and Adleman (RSA) public/private key pair. This is the same with Secure Copy Protocol (SCP), which relies on SSH for its secure transport.
- Before enabling SCP, you must correctly configure SSH, authentication, and authorization on the switch.
- Because SCP relies on SSH for its secure transport, the router must have an Rivest, Shamir, and Adelman (RSA) key pair.
- SCP relies on SSH for security.

- SCP requires that authentication, authorization, and accounting (AAA) authorization be configured so the router can determine whether the user has the correct privilege level.
- A user must have appropriate authorization to use SCP.
- A user who has appropriate authorization can use SCP to copy any file in the Cisco IOS File System (IFS) to and from a switch by using the **copy** command. An authorized administrator can also do this from a workstation.
- The Secure Shell (SSH) server requires an IPsec (Data Encryption Standard [DES] or 3DES) encryption software image; the SSH client requires an IPsec (DES or 3DES) encryption software image.
- Configure a hostname and host domain for your device by using the **hostname** and **ip domain-name** commands in global configuration mode.

Restrictions for configuring SSH

Restrictions for configuring secure shell.

These are restrictions for configuring the device for secure shell.

- From Cisco IOS XE Dublin 17.10.x, Key Exchange and MAC algorithms like diffie-hellman-group14-sha1, hmac-sha1, hmac-sha2-256, and hmac-sha2-512 are not supported by default and it may impact some SSH clients that only support these algorithms. However, you can add them manually if required. For information on manually adding these algorithms, see the https://www.cisco.com/c/en/us/td/docs/routers/ios/config/17-x/sec-vpn/b-security-vpn/m_sec-secure-shell-algorithm-ccc.html.
- The switch supports Rivest, Shamir, and Adelman (RSA) authentication.
- SSH supports only the execution-shell application.
- The SSH server and the SSH client are supported only on Data Encryption Standard (DES) (56-bit) and 3DES (168-bit) data encryption software. In DES software images, DES is the only encryption algorithm available. In 3DES software images, both DES and 3DES encryption algorithms are available.
- The device supports the Advanced Encryption Standard (AES) encryption algorithm with a 128-bit key, 192-bit key, or 256-bit key. However, symmetric cipher AES to encrypt the keys is not supported.
- When using SCP, you cannot enter the password into the **copy** command. You must enter the password when prompted.
- The login banner is not supported in Secure Shell Version 1. It is supported in Secure Shell Version 2.
- The -l keyword and userid :{number} {ip-address} delimiter and arguments are mandatory when configuring the alternative method of Reverse SSH for console access.
- To authenticate clients with FreeRADIUS over RADSEC, you should generate an RSA key longer than 1024 bit. Use the **crypto key generate rsa general-keys exportable label** *label-name* command to achieve this.

Set up the device to run SSH

Use this procedure to set up the device to run SSH.

Enable SSH on the device for secure remote access.

Follow the procedure given below to set up your device to run SSH:

Before you begin

Configure user authentication for local or remote access.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the hostname and IP domain name for your device.

   Example

   ```
   Device(config)# hostname your_hostname
   ```

   Note

   Follow this procedure only if you are configuring the device as an SSH server.

3. Configure a host domain for your device.

   Example

   ```
   Device(config)# ip domain name your_domain
   ```

4. Enable the SSH server and generate an RSA key pair.

   Example

   ```
   Device(config)# crypto key generate rsa
   ```

   Generating an RSA key pair for the device automatically enables SSH.

   We recommend that a minimum modulus size of 1024 bits.

   When you generate RSA keys, you are prompted to enter a modulus length. A longer modulus length might be more secure, but it takes longer to generate and to use.

   Note

   Follow this procedure only if you are configuring the device as an SSH server.

5. Exit configuration mode.

   Example

   ```
   Device(config)# end
   ```

The device is now set up to run SSH, allowing secure remote access.

Configure the SSH server

Learn how to configure the SSH server to allow secure remote access to the device.

Set up the SSH server to allow secure remote access to the device.

Follow the procedure given below to configure the SSH server:

> **Note**
>
> This procedure is only required if you are configuring the device as an SSH server.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Optional: Configure the device to run SSH Version 2.

   Example

   ```
   Device(config)# ip ssh version 2
   ```

   If you do not enter this command or do not specify a keyword, the SSH server selects the latest SSH version supported by the SSH client.

3. Specify the SSH window size.

   Example

   ```
   Device(config)# ip ssh window-size
   window-size-value
   ```

   The recommended window size is 32K or less. The default window size is 8912.

   Selecting **window-size** greater than 32K might have some impact on the CPU, unless:

   - The network bandwidth is good.
   - Client can accommodate this size.
   - No latency in network.

> **Note**
>
> This CLI is recommended only for SCP operations and can be disabled once the copy is done.

4. Configure the SSH control parameters.

   Example

   ```
   Device(config)# ip ssh timeout
   seconds
   authentication-retries
   number
   ```

   Specify the time-out value in seconds; the default is 120 seconds. The range is 0 to 120 seconds. This parameter applies to the SSH negotiation phase.

   By default, up to five simultaneous, encrypted SSH connections for multiple CLI-based sessions over the network are available (session 0 to session 4).

5. Optional: Use one or both of the following:

   - **line vty** *line_number ending_line_number*
   - **transport input ssh**

   Example

   ```
   Device(config)# line vty
   line-number
   ending-line-number
   ```

   or

   ```
   Device(config-line)# transport input ssh
   ```

   Enters line configuration mode to configure the virtual terminal line settings. For *line-number* and *ending-line-number* , specify a pair of lines. The range is 0 to 15.

   Specifies that the device prevent non-SSH Telnet connections. This limits the router to only SSH connections.

6. Return to privileged EXEC mode.

   Example

   ```
   Device(config-line)# end
   ```

   Returns to privileged EXEC mode.

The SSH server is now configured and ready for secure remote access.

Monitor the SSH configuration and status

Provides commands for displaying the SSH server configuration and status.

This table displays the SSH server configuration and status.

Command	Purpose
show ip ssh	Shows the version and configuration information for the SSH server.
show ssh	Shows the status of the SSH server.

156 MACsec support on APs

Topics:

- MACsec support on AP
- Auto MACsec for wireless APs

Introduces MACsec support on APs, describing key terminology, supported AP models, MACsec modes, supported ciphers, and restrictions. Details step-by-step configuration and verification procedures for enabling MACsec with PSK and 802.1X authentication across controllers, APs, and switches.

MACsec support on AP

MACsec support on AP is a security feature that encrypts and protects the integrity of data transmitted between devices using the IEEE 802.1X standard.

MACsec protection is a network security feature that

- uses the IEEE 802.1AE standard to apply hop-by-hop link encryption between the AP and the access switch
- secures data confidentiality and integrity to defend against attacks such as denial of service, intrusion, eavesdropping, and man-in-the-middle, and
- supports both pre-shared key (PSK) and IEEE 802.1X authentication methods.

Feature History

Feature Name	Release	Description
MACsec support on APs	Cisco IOS XE 26.1.1	With this release, MACsec support is introduced on APs to provide Layer 2 hop-by-hop encryption and integrity protection for data transmitted between the AP and the connected switch. This feature leverages the IEEE 802.1AE standard and ensures robust security against eavesdropping and man-in-the-middle attacks without impacting AP performance. These commands are introduced: • **key chain** *chain name* **macsec** • **ap profile** *name* **macsec** • **show ap macsec summary** • **show macsec** • **debug macsec**
Failover mechanism	Cisco IOS XE 26.1.2	This release introduces automatic MACsec failover for AP wired uplinks. If an AP cannot detect a valid MACsec peer, it falls back after a timeout to maintain controller connectivity. On APs with multiple uplinks, fallback occurs only when MACsec fails on all applicable links; if any uplink establishes MACsec successfully, the AP continues secure operation on that link.

Feature Name	Release	Description
MACsec replay protection window support	Cisco IOS XE 26.1.2	With this release, a configurable replay protection window has been added to securely accommodate out-of-order packet delivery. The setting defines how many sequence numbers may arrive out of order before packets are identified as potential replay attacks and dropped.

Expanded explanation

This feature uses MACsec (IEEE 802.1AE) to secure the link between the AP and the access switch. It employs hop-by-hop link encryption to mitigate attacks such as denial of service, intrusion, eavesdropping, and man-in-the-middle attacks.

Common MACsec terminology

This section lists the key MACSec security and key management terms used in this release, along with their definitions.

- **MKA**: or MACsec Key Agreement is the protocol that creates, distributes, and manages the encryption keys used by MACsec. It is defined in **IEEE 802.1X-2010** and works on top of EAPOL (Extensible Authentication Protocol over LAN).
- **MSK**: or Master Session Key is generated during EAP exchange. Supplicant and authentication server use the MSK to generate the CAK.
- **CAK**: or Connectivity Association Key is derived from MSK. CAK is a long-lived master key used to generate all other keys used for MACsec.
- **CKN**: or Connectivity Association Key Name identifies the CAK.
- **SAK**: or Secure Association Key is derived from the CAK and is the key used by supplicant and switch to encrypt traffic for a given session.
- **KS**: or Key Server is responsible for selecting and advertising a cipher suite. KS is responsible for generating the Secure Association Key (SAK) from the Connectivity Association Key (CAK).
- **Key server priority**: is a value used by MKA (MACsec Key Agreement) to determine which device becomes the Key Server in a MACsec session.
- **Key chain**: is a configuration structure used to store and manage cryptographic keys, mainly for protocols that require authentication or key exchange. For MACsec, the key chain holds the CAK (Connectivity Association Key) and CKN (Connectivity Key Name) used by MKA (MACsec Key Agreement).

Supported AP

Find the list of supported Cisco Catalyst access point models that support MACsec across Wi-Fi 7, Wi-Fi 6E, and Wi-Fi 6 generations. This helps you identify compatible hardware for different wireless standards, including CW917x and CX91xx series devices. Use this information to select appropriate APs for your network deployment.

You can find a list of supported APs in the Feature Matrix for Cisco Wireless Access Points.

MACsec modes, authentication options, and supported ciphers

Lists the MACsec authentication modes supported, including PSK and IEEE 802.1X with its available EAP methods.

Here are the modes supported by MACsec.

- Pre-Shared Key (PSK)
- IEEE 802.1X
  - Extensible Authentication Protocol - Transport Layer Security (EAP-TLS)
  - Extensible Authentication Protocol - Flexible Authentication through Secure Tunneling (EAP-FAST)

Here are the ciphers supported by MACsec.

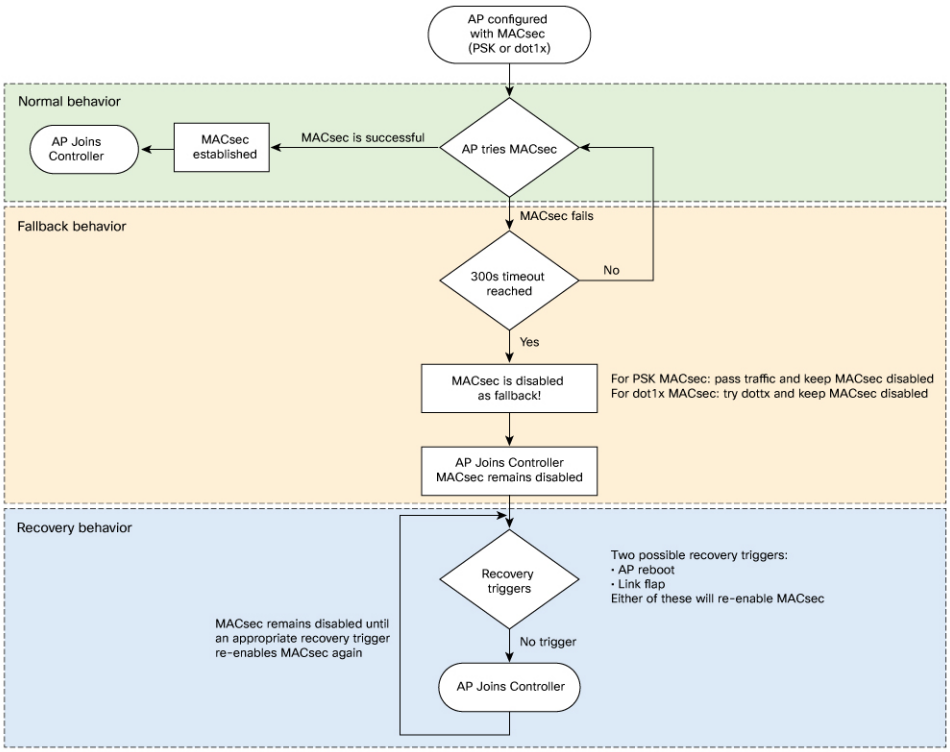
- AES-128-GCM
- AES-256-GCM

Restrictions

Lists the configuration restrictions for MACsec.

The AP cannot act as a key server (KS).

MACsec failover mechanism



Describes how an access point (AP) manages retry attempts and timeout periods when attempting a connection.

Summary

When MACsec is enabled, the AP checks its wired uplinks for a valid MACsec peer. If MACsec cannot be established on any applicable uplink within the timeout period, the AP reports the failure to the controller and falls back to maintain connectivity. If at least one uplink establishes MACsec, the AP continues secure operation on that link. After fallback, MACsec restart remains blocked until recovery is triggered by an AP reboot, or by a controller rejoin followed by a wired-port link flap.

Workflow

Figure 23: MACsec failure mechanism

1. The AP starts with MACsec configured using **PSK** or **802.1X**.
2. The AP attempts to establish MACsec on all applicable wired uplinks.
3. If MACsec succeeds:
   - MACsec is enabled.
   - The AP joins the controller securely.
4. If MACsec fails:
   - The AP continues retrying.
   - The process checks whether the **300-second timeout** has expired.
5. If the timeout has not expired, the AP retries MACsec.
6. When the timeout expires, the AP enters fallback mode:
   - PSK MACsec: The AP passes traffic with MACsec disabled.
   - 802.1X MACsec: The AP attempts 802.1X authentication while keeping MACsec disabled.
7. The AP joins the controller with MACsec remaining disabled.
8. MACsec stays disabled until one of these recovery triggers occurs:
   - AP reboot
   - Wired-link flap
9. After a recovery trigger, the AP enables MACsec processing and attempts to establish the session again.

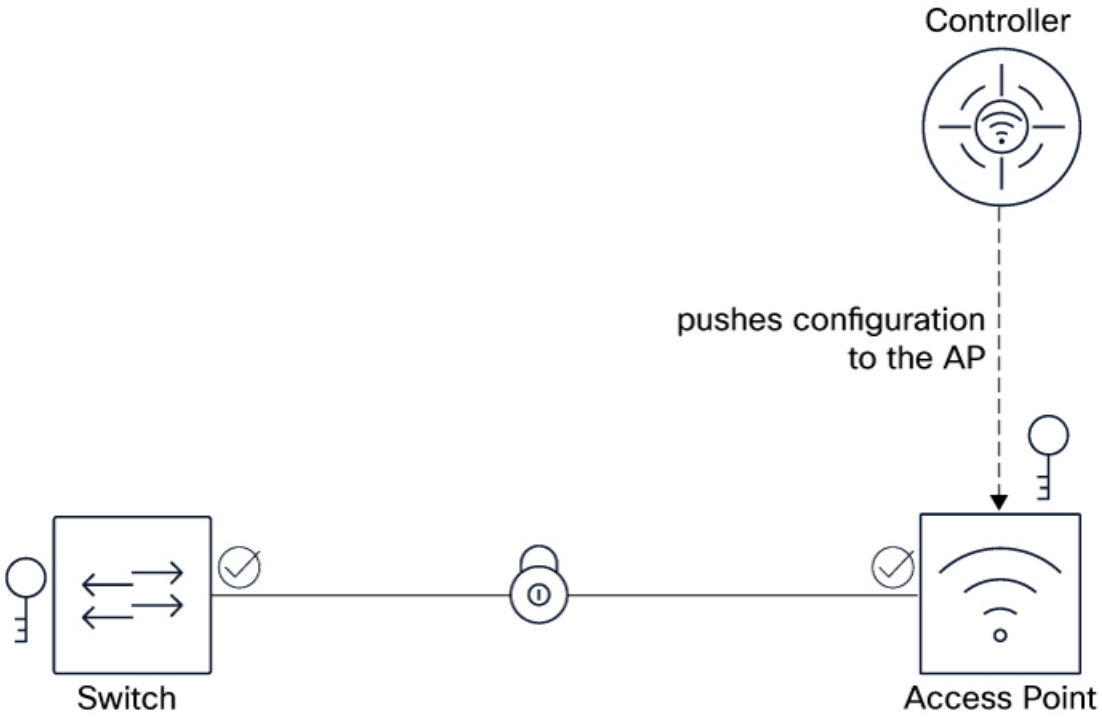
Result

The AP remains connected when MACsec establishment fails by falling back after 300 seconds. MACsec stays disabled until an AP reboot or link flap triggers recovery. Wireless service during fallback depends on the AP Join Profile configuration.

Configuring MACsec with PSK

This process describes configuring MACsec using pre-shared key (PSK) mode to enable secure encryption between a switch and an access point (AP), including required steps, configuration elements, and verification commands.

MACsec can be deployed in PSK mode. This process requires that you configure the same password on both network endpoints. The Connectivity Association Key (CAK), which serves as the PSK, and the Connectivity Association Key Name (CKN) must match on both sides.



Summary

The key components involved in the process are:

- **Controller:** For key chain creation and AP join profile configuration.
- **Switch**: For key chain setup, MKA policy configuration, and interface settings.
- **AP**: Joins the network under controller management and uses the shared keys for secure communication.

Workflow

Figure 24: MACsec PSK flow diagram

The process involves these stages:

1. *Configure MACsec PSK on the controller*: On the controller, add a new key chain and configure it with a key. The key string (PSK or CAK) is a hex string that matches with the switch.

   In this PSK scenario, the CAK (same as PSK) and the CKN must be manually entered.

2. *Configure MACsec PSK on the AP join profile*: On the controller, configure an AP join profile, enable MACsec, and select the previously created key chain.

3. *Configure MACsec PSK on the switch*: Create a key chain, configure the MKA policy, and configure the desired interface.

4. *Verify MACsec configuration:* Use various show commands on the controller, AP, and the switch.

Result

After completing these steps, MACsec PSK is successfully enabled between the AP and the switch. You now have encrypted and authenticated communication across the network.

Configure MACsec PSK on controller (GUI)

Enable MACSec to secure data transmission between the access point and the connected switch.

Enable MACsec to secure data transmission between the AP and the connected switch. This ensures network traffic between the AP and switch is encrypted, enhancing security.

MACsec must be configured on both the AP and the switch to ensure proper encryption and security.

Before you begin

Ensure that the AP is connected to a switch that supports MACsec.

Procedure

1. Choose **Configuration** > **Security** > **MACsec**.

2. Select the new MACsec key chain.
3. In the **Add Key Chain** window that is displayed, configure the key chain.
   a) Add a **Key Identifier**. This is a unique identifier for the key used in the MACsec protocol. Enter a hexadecimal value with an even number of digits. This is the **Connectivity Association Key name** (CKN) and must match on both sides.
   b) Select a **Crypto Algorithm** to protect the control-plane communications.

      You can choose either AES-128-CMAC or AES-256-CMAC .

      > **Note**
      >
      > Data-plane encryption is set by the Key server, which is the switch.

   c) Select a **Key String Type**.
      - Clear Text: Stores and transmits the key string in an unencrypted, readable format.
      - Hidden: Masks the key string from clear display, though it may still be retrievable.
      - Encrypted: Stores and transmits the key string in encrypted form for maximum security.

   d) Enter the **Key String**. This must be a hexadecimal string with 32 digits for AES-128, 64 digits for AES-256. This is the **Pre-Shared Key** (PSK), which is equivalent to the **Connectivity Association Key** (CAK). This key must match on both network endpoints.
   e) Add a **Key Name**. This is the key chain name.
4. Click **Save**. Click **Apply to Device**.
5. Choose **Configuration > Tags & Profiles** > **AP Join**.
6. Click **Add** to create a new AP Join profile.
7. In the **Add AP Join Profile** window, click the **AP** tab.
8. Perform these steps:
   a) Enable or disable MACsec on the AP wired interface.

      By default, MACsec is disabled.

      When enabled, communication between the AP and the connected switch is secured using MACsec encryption.

   b) Select a **Pre-Shared Key Chain**.

      Choose the key chain configured earlier in the **Add Key Chain** window.

      This key chain is used to configure the Pre-Shared Key (PSK) Chain for MACsec authentication and to derive the Secure Association Key (SAK).

      If IEEE 802.1X is enabled, it takes priority over the PSK configuration.
9. Save the configuration and apply the changes.

MACsec is successfully enabled on the AP. This secures the data transmission with the connected switch.

What to do next

Monitor the MACsec status and performance to ensure proper operation.

Configure MACsec PSK on controller(CLI)

Learn how to configure MACsec security on a wireless LAN controller by creating a MACsec key chain, specifying encryption parameters, and enabling MACsec on an AP's wired interface using the CLI.

To configure MACsec and an AP join profile on the controller to enable secure, encrypted communication on AP wired interfaces.

This task creates a MACsec key chain, defines encryption parameters, and applies MACsec settings within an AP join profile. This ensures that data in transit between APs and the wired infrastructure is protected.

Procedure

1. Enter the global configuration mode.

```
Device(config)# configuration terminal
```

2. Create a MACsec key chain.

```
Device(config)# key chain chain-name macsec
```

The device enters the keychain MACsec configuration mode.

3. Configure the MACsec key parameters.

```
Device(config-keychain-macsec)# key Hex String
```

The device enters the keychain MACsec key configuration mode.

4. Configure the MACsec cryptographic authentication algorithm.

```
Device(config-keychain-macsec-key)# cryptographic-algorithm algorithm
```

Values are AES-128-CMAC or AES-256-CMAC .The default value is AES-128-CMAC.

5. Configure the MACsec key string.

```
Device(config-keychain-macsec-key)# key-string key_string
```

6. Exit the keychain MACsec key configuration mode.

```
Device(config-keychain-macsec-key)# exit
```

7. Exit the keychain MACsec configuration mode.

```
Device(config-keychain-macsec)# exit
```

MACsec is enabled on the controller

```
Device(config)#key chain MACsecKeyChain macsec
Device(config-keychain-macsec)#key ABCDEF
Device(config-keychain-macsec-key)# cryptographic-algorithm aes-128-cmac
Device(config-keychain-macsec-key)# key-string ABCDEF0123456789ABCDEF0123456789
Device(config-keychain-macsec)# exit
Device(config-keychain)# exit
```

What to do next
Apply the key to the AP's wired interfaces.

Apply MACsec PSK on AP(CLI)

Enable MACsec on an AP’s wired interface using the CLI.

The task aims to apply a pre-shared key (PSK) on an AP using the controller CLI and enable MACsec encryption on the AP’s wired interface. This enhances security by encrypting communication over the wired Ethernet links between the controller and the AP.

Procedure

1. Enter the global configuration mode.

```
Device(config)# configuration terminal
```

2. Enter the AP profile configuration mode.

```
Device(config)# ap profile <name>
```

3. Apply the MACsec PSK configured earlier.

```
Device(config-ap-profile)# macsec psk-chain Pre-shared-key-name
```

4. Exit the global configuration mode.

MACsec is enabled on the AP wired interfaces, providing encrypted communication over the wired Ethernet links.

Verify MACsec configuration on controller (CLI)

Learn how to verify MACsec encryption on the controller to ensure secure packet transmission.

To verify that MACsec is correctly configured on the controller, ensuring that the AP profile is properly set, MACsec is enabled with the correct key chain and cipher suite, and that secure sessions are established and transmitting encrypted and validated packets.

Verify the AP profile and ensure that MACsec is enabled and the correct key chain is applied.

```
Device# show ap profile name <ap-profile-name> detailed
AP Profile Name                :<ap-profile-name>
[…]
Macsec :
  Enabled                       : True
  Auth Method                   : PSK
  PSK chain name                : MACsecKeyChain
  Replay protection window size: 0
```

Verify the MACsec summary.

```
Device# show ap macsec summary
AP Name                             AP Mac                              Capable
   Port 0          Port 1
-------------------------------------------------------------------------------------

SUCCESS         UNKNOWN
```

Verify MACsec configuration on AP

Learn how to verify the macsec configuration and operational status on an Access Point to ensure secure communication.

Verify and troubleshoot MACsec configuration and operational status on an AP.

Ensure secure communication by confirming MACsec encryption is enabled, the correct cipher suite and key chain are in use, and the AP authentication and physical layer status are properly functioning.

Check the MACsec status.

> **Note**
>
> The output of this command varies according to the AP model.

```
Device# show macsec status

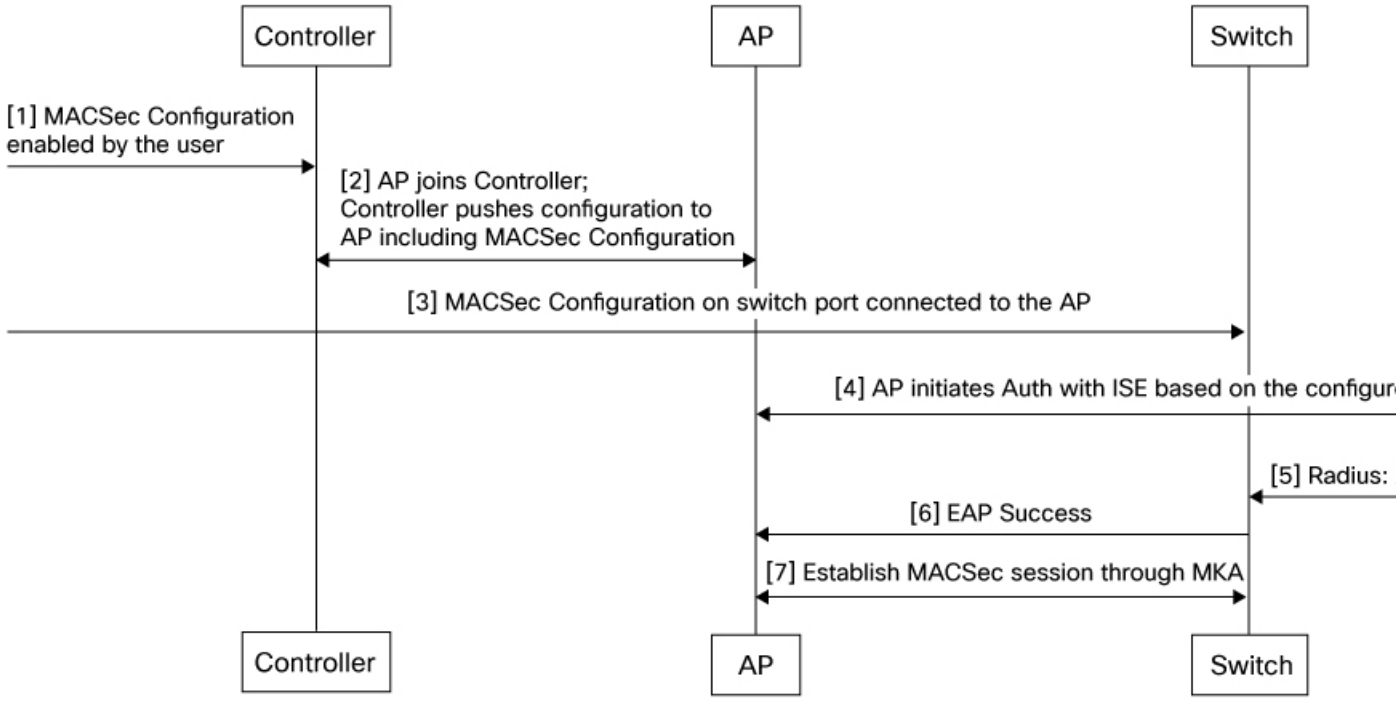
Configuring MACsec with IEEE 802.1X



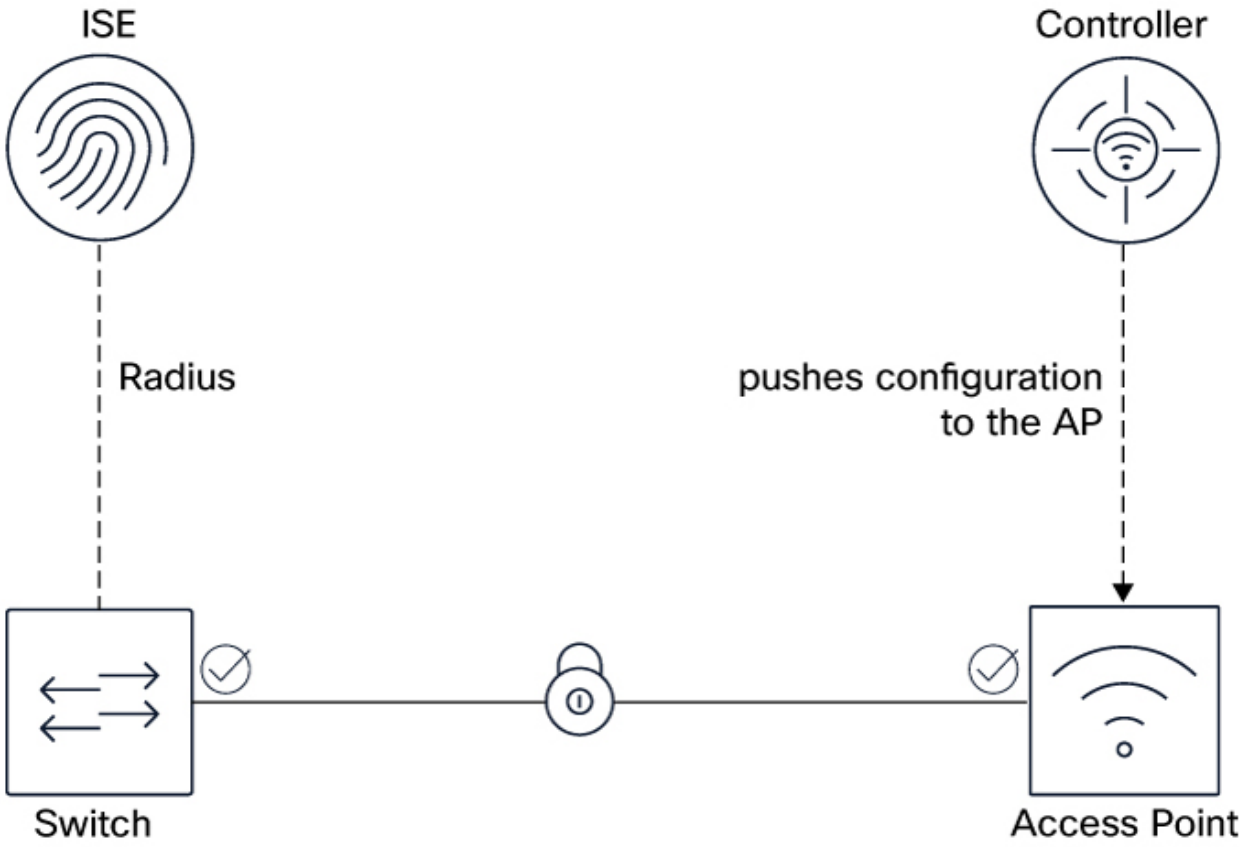
Learn how to configure MACsec with IEEE 802.1X authentication on controllers, APs, and switches for encrypted and authenticated network access.

MACsec can also be configured with IEEE 802.1X. Only two IEEE 802.1X flavors are supported. Here are the basic differences:

Table 138: EAP Types

EAP Type	Client Certificate	Server Certificate	Username
EAP-TLS	Yes	Yes	No
EAP-FAST	No	No	Yes

Figure 25: MACsec IEEE 802.1X flow chart



Summary

The key components involved in the process are:

- **Controller:** For IEEE 802.1X confguration, key chain creation, and AP Join Profile configuration.
- **Switch**: For IEEE 802.1X confguration, MKA policy configuration, and interface settings.
- **RADIUS Server**: For authentication.
- **AP**: Joins the network under the controller management and after authenticating with 802.1X establishes secure communication using MACsec.

Workflow

Figure 26: Understanding MACsec IEEE 802.1X

Ensure you have a working IEEE 802.1X setup before attempting MACsec.

The process involves these stages in this recommended order:

1. Configure IEEE 802.1X on the switch, AP, controller, and RADIUS server.
2. Configure MACsec on th AP using the controller.
3. Configure MACsec on the switch.
4. Verify MACsec configuration: Use various show commands on the controller, AP, and the switch.

What's next

For more details, see:

- Configure 802.1X Supplicant for Access Points with 9800 Controller
- Configure 802.1X on APs for PEAP or EAP-TLS with LSC

- EAP-FAST Authentication with Wireless LAN Controllers and Identity Services Engine

Configure MACsec IEEE 802.1X on controller (GUI)

Enable MACsec to secure data transmission between the access point and the connected switch.

IEEE 802.1X provides robust, centralized authentication for devices connecting to your network, ensuring that only authorized users and devices can access network resources. Unlike PSK, which relies on a shared password, IEEE 802.1X leverages individual credentials and a RADIUS server for enhanced security and better management.

IEEE 802.1X provides strong Layer 2 security by authenticating devices and encrypting all traffic between the APs and its uplink switch, ensuring secure and protected data transmission.

Procedure

1. Choose **Configuration > Tags & Profiles** > **AP Join**.
2. Click **Add**.
3. In the **Add AP Join Profile** window, click the **AP** tab.
4. In the **AP MACsec Configuration** section, configure these values:
   a) Click **MACSec** to enable or disable MACsec on the AP wired interface.

      MACsec is disabled by default.

   b) Leave the **Pre-Shared Key Chain** field empty.

      A pre-shared key chain is not required for this configuration.
5. Click **Save**. Click **Apply to Device**.

What to do next

Configure MACsec on the switch. For example, refer to MACsec with encryption on Catalyst 9300

Verify MACsec configuration on controller (CLI)

Learn how to verify MACsec encryption on the controller to ensure secure packet transmission.

To verify that MACsec is correctly configure on the controller, ensuring that the AP profile is properly set, MACsec is enabled with the correct key chain and cipher suite, and that secure sessions are established and transmitting encrypted and validated packets.

Verify MACsec configuration and operational status

This task involves confirming the MACsec configuration status on the controller, validating the AP profile, checking MACsec session summaries, verifying the status on the AP, and ensuring that the MKA session on the switch is secured with the correct key chain and cipher suite. It includes reviewing MACsec statistics and session security to confirm encrypted and validated packet transmission.

Verify the AP profile and ensure that MACsec is enabled and the correct key chain is applied.

```
Device# show ap profile name <ap-profile-name> detailed
 […]
Macsec :
  Enabled                       : True
  Replay protection window size: 0
```

Verify the MACsec summary.

```
Device# show ap macsec summary
AP Name                          AP Mac                          Capable
   Port 0          Port 1
-------------------------------------------------------------------------------
AP11AA.22BB.33CC                 99ff.88ee.77dd                  Yes
SUCCESS        UNKNOWN
```

Verify MACsec configuration on AP

Learn how to verify the macsec configuration and operational status on an Access Point to ensure secure communication.

Verify and troubleshoot MACsec configuration and operational status on an AP.

Ensure secure communication by confirming MACsec encryption is enabled, the correct cipher suite and key chain are in use, and the AP authentication and physical layer status are properly functioning.

Verify MACsec status.

> **Note**
>
> The output of this command varies according to the AP model.

Auto MACsec for wireless APs

Introduces Auto MACsec for wireless APs, detailing peer detection via LLDP, 802.1X authentication, encrypted link establishment, default settings, onboarding processes, compatibility requirements, and instructions for disabling the feature in AP join profiles.

Auto MACsec is a link-security capability that

- detects a compatible peer through LLDP
- authenticates the AP through 802.1X using a hardware-backed identity, and
- establishes hop-by-hop MACsec protection before the AP joins the wireless controller.

Auto MACsec reduces the manual configuration required to protect the wired uplink between a wireless AP and its directly connected access switch. The encrypted link helps protect traffic on the last network hop from interception and man-in-the-middle attacks.

Auto MACsec peer detection functionality is supported on Wi-Fi 7 APs equipped with MACsec-capable physical layer (PHY) interfaces.

> **Note**
>
> Cisco IOS XE 26.2 uses LLDP for Auto MACsec peer detection.

During initial Auto MACsec onboarding, the access point can use its hardware SUDI when no locally significant certificate (LSC) or other port-authentication configuration is available.

This feature supports Day 0 APs and APs that do not have an 802.1X username or MACsec preshared key (PSK) configured.

Auto MACsec is enabled by default. If an AP does not have an 802.1X username or MACsec PSK configuration, it automatically attempts to establish an Auto MACsec connection.

You can disable Auto MACsec in the AP join profile. If the AP currently uses an Auto MACsec connection, disabling the feature immediately interrupts the connection and causes the AP to rejoin. If the AP cannot recover, verify the switch configuration and remove the corresponding Auto MACsec configuration from the switch.

If an AP has an 802.1X username or MACsec PSK configured, it uses that configuration instead of Auto MACsec, even when Auto MACsec is enabled.

Benefits of auto MACsec

Outlines how auto MACsec improves network security and simplifies deployment through automated discovery, authentication, and configuration.

Automatic MACsec provides these benefits:

- Encrypts traffic between a supported access point and access switch.
- Mitigates packet snooping and man-in-the-middle attacks on the last network hop.
- Discovers Auto MACsec-capable access points automatically through LLDP.
- Applies the required switch access-session configuration automatically.
- Uses HW SUDI to authenticate a new access point without requiring a previously provisioned access-point identity.
- Reduces manual MACsec configuration on individual access-point-facing ports.
- Supports access-port deployments and customized trunk-port deployments.
- Rediscovers and resecures validated access-point links after a switch reload.

Enable auto MACsec (GUI)

Configure an access point join profile to enable automatic MACsec link encryption and secure communication between AP and connected switch.

Enable auto MACsec to ensure secure wired communication between access points and their connected switches using MACsec encryption.

Auto MACsec simplifies the process of enabling secure link encryption for access points. By following these instructions, you configure an AP join profile to automatically enable MACsec, protecting data on the wired interface and preventing replay attacks.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. Click **Add** to create an AP join profile or edit the AP Join Profile assigned to your AP.
3. In the AP join profile page, click the **AP** tab.
4. In the **General** tab, under the **AP MACsec Configuration** section, complete these steps:
   a) **MACsec**: Enable or disable MACsec on the AP wired interface. By default, MACsec is disabled. When enabled, communication between the AP and the connected switch is secured using MACsec encryption.
   b) **Replay Protection Window Size**: Enter a value to configure the security parameter that defines how many sequence numbers (packets) can arrive out of order and still be accepted before the device starts treating them as replay attacks and drops them. The range is from 0 to 4294967295.
   c) **Pre-Shared Key Chain**: Select a **Pre-Shared Key Chain**. Choose the key chain configured earlier in the **Add Key Chain** window.
   d) **Auto MACsec**: Indicates whether automatic MACsec link encryption is enabled on the AP. By default, **Auto MACsec** is enabled.
5. Click **Update & Apply to Device**.

Auto MACsec is successfully enabled on the access point, securing wired communication with the connected switch using MACsec encryption.

Enable auto MACsec in AP join profile (CLI)

Configure auto MACsec on an AP wired interface within an AP join profile using command-line interface (CLI) commands.

Secure AP wired interfaces by enabling automatic MACsec within the AP join profile.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device (config)# ap profile profile-name
   ```

3. Enable auto MACsec on the AP wired interface.

   Example

   ```
   Device (config-ap-profile)# [no] auto secure macsec
   ```

   Use the **no** form of this command to disable the feature.

The AP join profile is configured to automatically enable MACsec encryption on the wired interface of access points, enhancing network security.

Verify auto MACsec

Lists the commands for verifying auto MACsec operation and provides key criteria for assessment.

Provide clear criteria and methods for verifying the proper operation and security status of auto MACsec on network devices, helping users assess whether auto MACsec is correctly configured and functioning.

To view the MACsec configuration summary for all APs, use this command:

```
Device# show ap macsec summary
Capability Codes:
(M) MACSec, (A) Auto-MACSec

AP Name                          AP Mac                          Capability
  Auto        Port 0          Port 1
-------------------------------------------------------------------------------
AP6849.926F.A870         10a8.29f3.d9a0                              M
  Disabled   NA                NA
AP780F.819F.2140          2c65.8db6.e0e0                             M,A
   Disabled   SUCCESS       UNKNOWN
APF01D.2DB7.4138         84f1.476e.0b40                              -
   Disabled    NA                NA
```

To view the common information for a particular Cisco AP, use this command:

```
Device# show ap name Cisco-AP config general
Macsec Capability                                : Capable
  Auto MACsec                                    : Disabled
  Port 0
    Macsec Status                                : SUCCESS
    Macsec Ciphersuite                           : GCM_AES_128
  Port 1
    Macsec Status                                : UNKNOWN
    Macsec Ciphersuite                           : GCM_AES_128
```

Recovery for Auto MACsec

Outlines the recovery procedure for Auto MACsec configuration mismatches, guiding you through verification of switch and AP settings, identification of handshake failures, temporary disabling of MACsec, restoring connectivity, and re-enabling MACsec to ensure successful AP controller joins.

Summary

The recovery process for Auto MACsec addresses issues where an Access Point (AP) fails to join a controller or obtain an IP address due to Auto-MACsec configuration mismatches. The process involves verifying switch and AP configurations, identifying handshake or MACsec failures, temporarily disabling Auto-MACsec on the switch interface to allow the AP to reboot and connect without MACsec security, and then restoring the MACsec configuration after confirming connectivity and controller settings.

Workflow

1. Verify switch-side configuration: Run these commands on the switch to check interface status and MACsec sessions.
   - `show interface <interface_id> status`
   - `show macsec interface <interface_id>`
   - `show run interface <interface_id>`
   - `show derived-config interface <interface_id>`
2. Verify AP-side status: On the Access Point, check MACsec and authentication status.
   - `show macsec status`
   - `show ap authentication status details`
3. Look for EAP handshake failures or MACsec failures in the outputs.
4. Trigger recovery mode: Temporarily disable Auto MACsec on the switch interface by executing:

   ```
   shutdown
   no access-session interface-template sticky
   access-session inherit disable interface-template-sticky
   no auto detect macsec
   no shutdown
   ```

   This allows the AP to reboot, obtain an IP address, and join the Wireless LAN Controller without MACsec security.
5. Restore connectivity: Verify controller management settings with `show ip http secure-server status` command.

   Ensure secure access policies are not blocking discovery.
6. Reapply MACsec configuration:

- Confirm the configuration template and MKA parameters are correct on the switch.
- Re-enable Auto MACsec on the switch port.

Result

This workflow ensures recovery from Auto-MACsec configuration mismatches by temporarily disabling MACsec to restore network connectivity and then re-enabling it after verification.

157 FIPS

Topics:

- Federal Information Processing Standard (FIPS)
- Common criteria
- TLS signature algorithm enhancements for NDcPP v3.0e
- HTTPS server security considerations with NDcPP 4.0

This chapter explains enabling and verifying federal cryptographic compliance mode on controllers, including self-test behavior, restrictions (SSH, TrustSec, PAC keys), HA setup with matching authorization keys, CLI commands, and troubleshooting notes.

Federal Information Processing Standard (FIPS)

Introduces FIPS, outlining its guidelines and restrictions, providing instructions for self-tests and configuration, explaining FIPS operation in HA setups, and describing procedures for monitoring and verifying FIPS compliance.

A Federal Information Processing Standard (FIPS) is a security standard that

- defines requirements for cryptographic modules intended to secure sensitive but unclassified (SBU) information
- is mandated for use by U.S. government agencies and adopted by many regulated industries such as finance and healthcare, and
- establishes assurance levels to validate the strength and reliability of cryptographic implementations.

Sensitive but unclassified (SBU) information: Data that, while not classified for national security, still requires protection due to its sensitive nature and potential impact if disclosed.

Additional reference information
Federal Information Processing Standard (FIPS) 140-2 is a well-known FIPS standard specifying security requirements for cryptographic modules protecting SBU information. These cryptographic modules are produced by the private sector for use in government and regulated environments.

With FIPS in the enabled state, some passwords and pre-shared keys must have the following minimum lengths:

- For Software-Defined Access Wireless, between the controller and map server, a pre-shared key (such as the LISP authentication key) used for authenticating TCP messages must be at least 14 characters long.
- The ISAKMP key (for example, the Crypto ISAKMP key) must also be at least 14 characters long.

Guidelines and restrictions for FIPS

Guidelines and restrictions for FIPS.

- Controller switches use a legacy key to support legacy APs. In FIPS mode, the crypto engine identifies the key as weak and displays this error message: **% Error in generating keys: could not generate test signature.** Ignore error messages during controller startup in FIPS mode.
- When you enable FIPS, SSH clients that use SHA1 cannot access the controller.
- When you configure a WLAN, set the PSK to at least 15 characters. Otherwise, APs cannot join the controller after you change tags.
- You need to use FIPS-compliant SSH clients to access the controller.
- You cannot use TrustSec in FIPS mode.
- You cannot configure PAC keys in FIPS mode.
- The console of APs get disabled when the controller is operating in FIPS mode.
- The weak or legacy cipher like SHA1 is not supported in FIPS mode.
- APs would not reload immediately, if you change the FIPS status.
- We recommend a minimum RSA key size of 2048 bits under RADSEC when operating in FIPS mode. Otherwise, the RADSEC fails.

FIPS self-tests

This concept explains FIPS self-tests, which are mechanisms performed by cryptographic modules to confirm integrity and operational soundness during startup and throughout device operation by running power-up and conditional checks as required by FIPS 140-2 standards.

A FIPS self-test is a cryptographic module validation mechanism that

- verifies functionality and integrity during device power-up
- performs conditional checks whenever security functions are invoked, and
- ensures FIPS 140-2 compliance by enforcing automated self-testing procedures.

Power-up self-tests

Power-up self-tests run automatically after the device powers up. A device enters FIPS mode only after all self-tests are successfully completed. If any self-test fails, the device logs a system message and transitions into an error state. If the power-up self-test fails, the device also fails to boot.

The module uses a known-answer test (KAT), in which a cryptographic algorithm runs on data for which the correct output is already known, and then the calculated output is compared to this expected value. If the calculated output does not equal the known answer, the known-answer test fails.

Power-up self-tests include:

- Software integrity: Validates the integrity of module software as it loads.
- Algorithm tests: Verifies correct operation of cryptographic algorithms using KATs.

Conditional self-tests

Conditional self-tests are performed each time an applicable security function or operation is accessed, unlike power-up self-tests that run only at startup.

The device uses a cryptographic algorithm known-answer test (KAT) on each FIPS 140-2-approved function, which includes encryption, decryption, authentication, and random number generation. The algorithm is applied to a set of data with a known correct output, and the calculated output is compared to this known value. If the calculated output is different, the KAT fails.

Conditional self-tests run automatically whenever their associated security function or operation is invoked. They include the following:

- Pair-wise consistency test: Runs when a public or private key-pair is generated to confirm the correct relationship.
- Continuous random number generator test: Runs each time a random number is generated to check the quality of randomness.
- Bypass: Evaluates bypass operations if performed.
- Software load: Validates integrity when new software is loaded.

Examples

- When a device boots, it performs power-up self-tests to confirm its cryptographic algorithms work as intended before entering FIPS mode.
- Whenever the device generates a new cryptographic key pair, a pair-wise consistency test is executed.
- If a random number is generated, the system runs a continuous random number generator test, verifying the output for compliance.

Configure FIPS (CLI)

Use this procedure to enable or disable FIPS mode on both active and standby controllers to comply with federal standards.

Enable or disable FIPS mode on controllers for compliance and security.

Ensure that both the active and standby controllers have the same FIPS authorization key.

> **Note**
>
> Changing the FIPS status removes AES-encrypted password configurations from the controller. After enabling or disabling FIPS mode and rebooting the controller, reconfigure all affected password-based settings, including the AP management credentials.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device
   # configure terminal
   ```

2. Enable FIPS mode.

   Example

   ```
   Device
   (config)#
   fips authorization-key key
   ```

   The key length must be 32 hexadecimal characters.

   > **Note**
   >
   > When FIPS is enabled, you may need to trigger more than one factory reset using the reset button.

   To disable FIPS mode on the device, use the **no** form of this command.

3. Return to privileged EXEC mode.

   Example

   ```
   Device
   ```

```
(config)#
end
```

Enable or disable FIPS mode. Reboot the controller to apply changes. After the controller reboots, access points also reboot once they rejoin.

What to do next

Reboot the controller each time you enable or disable FIPS mode.

How FIPS configuration works in high availability setups

This process describes how to configure both active and standby controllers with the same FIPS authorization key independently before forming a high availability (HA) pair. This prevents synchronization issues and reload loops.

Set up a high availability (HA) pair in FIPS mode by configuring both controllers with the same FIPS authorization key before forming the HA pair.

If you configure the key after forming the HA pair, it will not sync to the standby. This may cause reload loops when you reboot.

- Break the HA pair if you configured the FIPS key after pairing.
- Configure the same FIPS authorization key on both members independently.
- Form the HA pair again.

Summary

In this process, you configure FIPS in an HA setup by setting the same FIPS authorization key on both members before forming the HA pair.

- You must perform the configuration steps on both controllers.
- Configure and pair both controllers (member1 and member2) in HA mode.

Matching FIPS authorization keys on both controllers in the HA pair prevent synchronization issues and reload loops.

Workflow

These stages describe the steps to configure FIPS in an HA setup.

1. Turn off both members of the stack.
2. Power on only member1 and wait for the controller to start. Log in from the console when prompted.
3. Log in to member1 with valid credentials and use the following commands to verify FIPS status and configuration:
   - Use the **show fips status** command
   - Use the **show fips authorization-key** command
   - Use the **show romvar** command
   - Use the **show chassis** command

> **Note**
>
> Keep the configured FIPS authorization key available.

4. Configure the FIPS key on member1 if you have not already configured it.
   - conf t
   - fips authorization-key <thirty-two hexadecimal characters>
5. Save your changes and power off member1.
6. Power on only member2 and wait for the controller to start. Log in from the console when prompted.
7. Log in to member2 with valid credentials and use the following commands to verify FIPS status and configuration:
   - Use the **show fips status** command
   - Use the **show fips authorization-key** command
   - Use the **show romvar** command
   - Use the **show chassis** command

> **Note**
>
> Keep the configured FIPS authorization key available.

8. Configure the FIPS key on member2 if you have not already configured it.

> **Note**
>
> The key value must be the same on both members of the stack.

   - conf t
   - fips authorization-key <thirty-two hexadecimal characters>
9. Save your changes and power off member2.
10. Power on both members together and wait for the stack to form.
11. Monitor the system for any crash or unexpected reload events.

> **Note**
>
> The members are not expected to reload because of FIPS issues.

Result

Both controllers in the HA pair operate in synchronized FIPS mode. Correct configuration prevents synchronization issues and reload loops caused by mismatched or improperly applied FIPS authorization keys.

Verify FIPS configuration

Verify FIPS configuration.

You can verify FIPS configuration using these commands:

Use this **show** command to display the installed authorization key:

```
Device# show fips authorization-key
FIPS: Stored key (16) : 12345678901234567890123456789012
```

Use this **show** command to display the status of FIPS on the device:

```
Device# show fips status
Chassis is running in fips mode
```

Common criteria

Details Common Criteria, offering configuration procedures, verification steps, and guidelines for operating in CC mode to achieve and maintain relevant security certification requirements.

A Common Criteria certificate is a security assurance certification that

- provides independent verification that IT products meet specified security requirements,
- twenty-four countries worldwide officially recognize this certification,
- and this scheme uses defined protection profiles for requirements, tests, and evaluation methodologies.

Common Criteria protection profiles and further information

Common Criteria (CC) is a global testing standard. It verifies whether a device provides the security functionalities claimed by product developers. The standard establishes requirements, tests, and an evaluation methodology to ensure that IT products comply with recognized security standards.

The Target of Evaluation (ToE) is the product or system under evaluation. It must conform to protection profiles under the Common Criteria scheme. The applicable protection profiles are:

- Collaborative Protection Profile for Network Devices (NDcPP) version 2 dated 2017-05-05,
- Wireless Local Area Network (WLAN) Access Systems Extended Package version 1 dated 2015-05-29.

The CC certificate's recognition by twenty-four countries ensures that vendors can demonstrate compliance with internationally accepted security requirements.

For more information about CC, refer to the Cisco Common Criteria documentation.

Configure the common criteria (CLI)

Use this procedure to enable common criteria mode on a controller, including configuring DTLS cipher suites and versions required for regulatory compliance.

Enable common criteria mode for enhanced security compliance on your wireless controller.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the common criteria mode for the controller.

   Example

   ```
   Device(config)# wireless wlancc
   ```

   > **Note**
   >
   > Reboot the controller after enabling the common criteria mode.

3. Configure the cipher suite supported by DTLS.

   Example

   ```
   Device(config)# ap dtls-cipher ciphersuite
   ```

   > **Note**
   >
   > Reboot the controller to activate the selected cipher suite.

4. Configure DTLS version 1.0 or 1.2.

   Example

   ```
   Device(config)# ap dtls-version dtls_1_0 dtls_1_2
   ```

> **Note**
>
> Save the configuration and reload the controller for the changes to take effect.

5. Exit the configuration mode and enter the privileged EXEC mode.

Example

```
Device(config)# end
```

The controller operates in common criteria mode with the chosen DTLS cipher suite and protocol version. The changes take effect after you reboot the controller.

Verify CC configuration

Verify CC configuration.

Use the this **show** command to display the wireless certification configurations:

```
Device# show wireless certification config
Wireless Certification Configurations

WLANCC                                    : Configured
AP DTLS Cipher Suite                      : DHE-RSA-AES128-SHA
                                            DHE-RSA-AES256-SHA
                                            DHE-RSA-AES256-SHA256
                                            ECDHE-ECDSA-AES128-GCM-SHA256
                                            ECDHE-ECDSA-AES256-GCM-SHA384
AP DTLS Version                           : DTLS v1.2
```

Check points for CC mode operation

Check points for CC mode operation.

This topic describes the key check points and considerations for CC mode operation on Cisco Catalyst 9800 Series Wireless Controllers.

Check points for CC mode operation

You need to be aware of these for CC mode operation:

Table 139: Check points for CC mode operation

Features	Description
Link encryption	Data link encryption is not supported for C91xx wireless mobility express platform.
Link encryption	For non-C91xx wireless mobility express platfoms - Enabling Data link encryption (using ECDHE keypair) would make AP flap continually.

Features	Description
LDAP	Secure LDAP does not support strong ciphers and is not part of CC certification.
Mobility	Mobility between Cisco Catalyst 9800 Series Wireless controllers is possible with LSC as wireless management trustpoint (having RSA based keys).
Mobility	Mobility between AireOS WLC and Cisco Catalyst 9800 Series Wireless controllers is supported (using SUDI and MIC certificates for wireless management trustpoint).
Mobility	Mobility between AireOS WLC and Cisco Catalyst 9800 Series Wireless controllers is not supported (if using LSC certficates for wireless management trustpoint).
CC mode	The **show wireless certification config** command displays the configured values for WLANCC, or AP-dtls-ciphersuite, or AP-dtls-version, and needs reload after re-configuring these parameters.
CC mode	The AES128-SHA option is not supported for AP-dtls-ciphersuite when Cisco Catalyst 9800 Series Wireless Controller is operating in CC mode.
CC mode	The AES128-SHA option is supported for AP-dtls-ciphersuite when Cisco Catalyst 9800 Series Wireless Controller is operating in FIPS mode.
CC mode	If you want your Cisco Catalyst 9800 Series Wireless Controller to operate in CC mode (you need to enable both FIPS mode and CC mode).
LSC	To secure communication between Cisco Catalyst 9800 Series Wireless Controller and LSC server, you need to deploy ESTCA as LSC server (which uses TLS to secure related communication).
LSC	Cisco Catalyst 9800 Series Wireless Controllers do not support HTTPS to secure its communication with the LSC server.
LSC	During LSC provisioning, APs generate EC based keys only when related Cisco Catalyst 9800 Series Wireless Controller is operating in CC mode.
LSC	During LSC provisioning, APs generate RSA based keys when related Cisco Catalyst 9800 Series Wireless Controller is operating in FIPS mode.
LSC	During LSC provisioning, APs generate RSA based keys when related Cisco Catalyst 9800 Series Wireless Controlle is operating in non-FIPS or non-CC mode.

Features	Description
Password Obfuscation	You can use the following commands for password obfuscation: • **key config-key password-encrypt** • **service password-encryption** • **password encryption aes** • **passwd key obfuscate**
CC mode	APs reload immediately, if you change the **wlancc** status.
FIPS mode	APs do not reload immediately, if you change the FIPS status.
Cisco 1562 AP	To assist Cisco 1562 APs join the Cisco Catalyst 9800 Series wireless controller, you need to have the ethernet MAC of the AP in the username list.
AP serial number authorization	Serial number authorization is possible only when Cisco Catalyst 9800 Series wireless controller is in FIPS and CC mode, and with LSC based trustpoints/certficates only (not with SUDI trustpoint).
Display	FIPS suitability displays **Suitable only** if the controller is in CC mode and LSC certificate is compatible. Both wireless management and Certs CN should match the hostname of the controller and length of RSA Key (> 2048) (or) EC keys being used.
RADSEC	RSA key size must contain a minimum of 2048 bits (of certificate under RADSEC) when operating in FIPS or CC mode, else RADSEC fails.

TLS signature algorithm enhancements for NDcPP v3.0e

Outlines TLS signature algorithm enhancements for NDcPP v3.0e, including compliance in FIPS CC mode, removal of outdated algorithms and ciphersuites, and strengthened protection against vulnerabilities for both TLS clients and servers.

The TLS signature algorithm enhancements in FIPS Common Criteria (CC) mode is a security posture that

- ensures compliance with the NDcPP v3.0e standard
- removes outdated and less secure signature algorithms and ciphersuites, and
- protects against known vulnerabilities.

Feature history

Table 140: Feature history for TLS signature algorithm enhancements for NDcPP v3.0e

Feature Name	Release Information	Feature Description
TLS signature algorithm enhancements for NDcPP v3.0e	Cisco IOS XE 17.18.2	This feature ensures that Cisco products operating in FIPS Common Criteria (CC) mode are fully compliant with the NDcPP v3.0e security standard. It achieves this by: • Removing outdated and unapproved algorithms • Eliminating weaker algorithms thereby ensuring robust cryptographic protection for sensitive communications. • Enabling both TLS clients (listing supported signature algorithms in the Client Hello message) and TLS/DTLS servers (listing signature algorithms in the Certificate Request message) to operate within the strict requirements of NDcPP v3.0e.

Common criteria certifications using NDcPP v3.0e mandate that TLS Signature Algorithms that are outdated or unapproved are removed from being offered in TLS 1.2 and TLS 1.3, DTLS 1.2. For TLS clients, the signature algorithms are listed in the **Client Hello** message whereas for TLS/DTLS server, the signature algorithms are listed in the **Certificate Request** message.

As security standards evolve and threats become more sophisticated, it is crucial to update and remove outdated and less secure signature algorithms and ciphersuites. This enhancement prevents potential non-compliance and security risks, ensuring robust and compliant network operations. This requirement is vital for maintaining secure communications in environments adhering to the NDcPP v3.0e standard.

Signature algorithms and ciphersuites in TLS and DTLS applications

Allowed signature algorithms

In FIPS Common Criteria mode, you can use the following signature algorithms with TLS and DTLS:

- ecdsa_secp256r1_sha256 (0x0403)
- ecdsa_secp384r1_sha384 (0x0503)
- ecdsa_secp521r1_sha512 (0x0603)
- rsa_pss_pss_sha256 (0x0809)
- rsa_pss_pss_sha384 (0x080a)
- rsa_pss_pss_sha512 (0x080b)
- rsa_pss_rsae_sha256 (0x0804)
- rsa_pss_rsae_sha384 (0x0805)

- rsa_pss_rsae_sha512 (0x0806)
- rsa_pkcs1_sha256 (0x0401)
- rsa_pkcs1_sha384 (0x0501)
- rsa_pkcs1_sha512 (0x0601)

> **Note**
>
> No signature algorithms other than those listed are allowed in CC mode.

These sections provide a brief description of the allowed and deprecated signature algorithms and ciphersuites for EST TLS client, RadSec, Syslog, and HTTP Secure (TLS) Server in IOS-XE under FIPS Common Criteria mode:

EST TLS client

Allowed signature algorithms: The EST TLS client offers only allowed signature Algorithms in CC mode, where the IOS-XE device has a TLS client connection to an EST capable CA-server.

Ciphersuites: This is the list of plain RSA ciphers supported from the HTTP side. As part of FIPS Common Criteria mode these ciphersuites are not offered from default client 'Hello' message.

- AES128-SHA
- AES256-SHA
- AES128-SHA256
- AES256-SHA256
- AES128-GCM-SHA256
- AES256-GCM-SHA384

> **Note**
>
> - Because the changes are in HTTP client infrastructure, all HTTP client applications in FIPS Common Criteria mode are affected.
> - If the peer supports a wide range of ciphersuites, applications are not affected.
> - If the peer supports only the listed ciphers, the TLS handshake fails in FIPS+CC mode.

RadSec

For RadSec TLS and DTLS, these are the ciphers that are supported and deprecated with FIPS common criteria mode.

Supported cipher list when FIPS + CC mode is enabled:

- **DTLS (IOS and BINOS)**
  - ECDHE-ECDSA-AES128-GCM-SHA256 and ECDHE-ECDSA-AES256-GCM-SHA384
  - ECDHE-ECDSA-AES128-SHA256 and ECDHE-ECDSA-AES256-SHA384

- ECDHE-RSA-AES128-GCM-SHA256 and ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-RSA-AES128-SHA256 and ECDHE-RSA-AES256-SHA384

- **TLS (BINOS)**
  - ECDHE-ECDSA-AES128-GCM-SHA256 and ECDHE-ECDSA-AES256-GCM-SHA384
  - ECDHE-RSA-AES128-GCM-SHA256 and ECDHE-RSA-AES256-GCM-SHA384

- **TLS (IOS)**
  - ECDHE-ECDSA-AES128-GCM-SHA256
  - ECDHE-RSA-AES128-GCM-SHA256

Deprecated Cipher list when FIPS + CC mode is enabled:

- **DTLS (IOS and BINOS)**:
  - AES128-SHA256
  - AES256-SHA256

- **TLS (BINOS)**:
  - RC4-MD5
  - NULL-SHA
  - AES128-SHA

- **TLS (IOS)**:
  - AES128-SHA

> **Note**
>
> - When FIPS mode is not enabled, the current existing set of ciphers is supported, which is a combination of both strong and weak ciphers.
> - RadSec TLS connections allow only TLS signature algorithms listed in the 'Allowed signature algorithms' section.

Syslog

These are the list of ciphersuites from the Syslog component that are deprecated for FIPS Common Criteria mode.

- AES128-SHA
- AES256-SHA
- AES128-SHA256
- AES256-SHA256
- AES128-GCM-SHA256
- AES256-GCM-SHA384

> **Note**
>
> These ciphersuites are excluded in the Syslog default ciphersuite and can be configured through commands.

HTTP secure (TLS) server

Signature algorithm:

When client authentication is enabled on the IOS-XE device, the HTTP secure (TLS) server includes the list of signature algorithms in the Certificate Request Message.

Ciphersuites:

The HTTP side supports these plain RSA ciphers. In FIPS Common Criteria mode, these ciphersuites are not included in the default client 'Hello'.

- AES128-SHA
- AES256-SHA
- AES128-SHA256
- AES256-SHA256
- AES128-GCM-SHA256
- AES256-GCM-SHA384

Configure syslog TLS profile ciphersuites (CLI)

Configure syslog TLS profile ciphersuites (CLI)

To specify the allowed ciphersuites for secure Syslog communication in FIPS Common Criteria mode.

In FIPS Common Criteria mode, certain weaker ciphersuites are deprecated and removed from the default list for Syslog. You can view the available ciphersuites and configure them.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Access the TLS profile for syslog. Replace `tls-profile-name` with your profile name.

   Example

   ```
   Device(config)# logging tls-profile tls-profile-name
   ```

3. Select and configure a ciphersuite.

Example

```
Device(config-tls-profile)# ciphersuite ecdhe-rsa-aes-cbc-sha2
```

You can view the ciphersuites by running the `Device(config-tls-profile)# ciphersuite ?` command.

The syslog TLS profile is configured with the specified ciphersuite.

Configure HTTP secure ciphersuites

To explicitly configure secure ciphersuites for HTTP client and server communications.

This feature ensures that HTTP client and server communications adhere to enhanced security standards by allowing explicit configuration of secure ciphersuites. There is no change in default ciphersuite behavior for HTTP client and server.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure secure ciphersuites for the HTTP server. You can specify one or more ciphersuites.

   Example

   ```
   Device(config)# ip http secure-ciphersuite ciphersuites
   ```

3. Configure secure ciphersuites for the HTTP client.

   Example

   ```
   Device(config)# ip http client secure-ciphersuite ciphersuites
   ```

HTTP client and server communications use the explicitly configured secure ciphersuites.

Verify Syslog TLS profile

To verify the configured Syslog TLS profile, use this command.

```
Device# show running-config | section logging tls-profile syslog_1
logging tls-profile syslog_1
ciphersuite ecdhe-ecdsa-aes-gcm-sha2
```

Verify HTTP client and server applications

To verify the configured HTTP secure ciphersuites for the server, use this command.

```
Device# show running-config | include ip http secure-ciphersuite
ip http secure-ciphersuite ecdhe-ecdsa-aes-gcm-sha2 tls13-aes256-gcm-sha384
```

To verify the configured HTTP secure ciphersuites for the client, use this command.

```
Device# show running-config | include ip http client secure-ciphersuite
ip http client secure-ciphersuite ecdhe-rsa-aes-gcm-sha2 tls13-aes128-gcm-sha256
```

To verify the configured HTTP secure server status information, use this command.

```
Device# show ip http server secure status
HTTP secure server status: Enabled
HTTP secure server port: 443
HTTP secure server ciphersuite:  dhe-aes-cbc-sha2 dhe-aes-gcm-sha2
       ecdhe-rsa-aes-cbc-sha2 ecdhe-rsa-aes-gcm-sha2 ecdhe-ecdsa-aes-gcm-sha2

        tls13-aes128-gcm-sha256 tls13-aes256-gcm-sha384
HTTP secure server TLS version:  TLSv1.2
HTTP secure server client authentication: Disabled
HTTP secure server PIV authentication: Disabled
HTTP secure server PIV authorization only: Disabled
HTTP secure server trustpoint: TP-self-signed-745339156
HTTP secure server peer validation trustpoint:
HTTP secure server ECDHE curve: secp256r1
HTTP secure server active session modules: ALL
```

To verify the configured HTTP secure client status information, use this command.

```
Device# show ip http client secure status
HTTP secure client ciphersuite:  dhe-aes-cbc-sha2 dhe-aes-gcm-sha2
       ecdhe-rsa-aes-cbc-sha2 ecdhe-rsa-aes-gcm-sha2 ecdhe-ecdsa-aes-gcm-sha2

        tls13-aes128-gcm-sha256 tls13-aes256-gcm-sha384
HTTP secure client TLS version:  TLSv1.3 TLSv1.2
HTTP secure client trustpoint:
```

HTTPS server security considerations with NDcPP 4.0

Outlines HTTPS server security configurations that enforce advanced cryptographic protocols, ensure NDcPP v4.0 compliance, and allow administrators to restrict access to modern TLS versions and secure cipher suites for enhanced data protection.

HTTPS server security configurations are security standards for the Cisco web-based management interface that

- enforce advanced cryptographic protocols for client-server communication
- align with NDcPP v4.0 certification requirements for enhanced data protection, and
- allow administrators to restrict usage to modern TLS versions and secure cipher suites.

These configurations replace legacy default settings by mandating the use of secure elliptic curves and high-strength encryption algorithms, thereby reducing the attack surface of the web management interface.

Feature history

Table 141: Feature history for HTTPS server security considerations with NDcPP 4.0

Feature Name	Release Information	Feature Description
HTTPS server security considerations with NDcPP 4.0	Cisco IOS XE 26.2.1	This feature hardens the Cisco web-based management interface by enforcing advanced cryptographic protocols for client-server communication, ensuring alignment with NDcPP v4.0 certification requirements for robust data protection while providing administrators with granular control to restrict interface access to modern TLS versions and secure cipher suites.

Best practices for HTTPS server security

Ensure that you maintain a secure management interface using these guidelines:

- Enforce TLS 1.3: Configure the HTTPS server to exclusively use TLS 1.3 to ensure the highest level of connection security.
- Maintain updated curves: Use the secp384r1 curve for ECDHE key exchange to align your device with current industry security standards
- Validate configurations: Verify your security policy settings immediately after any changes by executing the `show ip http server secure status` command to confirm that the active settings are correctly applied.

Configure HTTP server security settings (CLI)

Provides instructions for configuring HTTP server security settings, including specifying TLS versions, setting cipher suites, configuring elliptic curve parameters, and verifying security status to secure device web access.

Configure network device HTTP server security to ensure management access is encrypted and resilient to modern security threats.

Perform this task when securing web-based device access, or after a security audit recommends updating transport security standards.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the allowed TLS version.

   Example

   ```
   Device(config)# ip http tls-version TLSv1.3
   ```

3. Set the secure cipher suite.

   Example

   ```
   Device(config)# ip http secure-ciphersuite tls13-aes256-gcm-sha384
   ```

4. Configure the default elliptic curve for key exchange.

   Example

   ```
   Device(config)# ip http secure-ecdhe-curve secp384r1
   ```

5. Verify the current security status.

   Example

   ```
   Device# show ip http server secure status
   ```

Device web management interfaces now enforce strong encryption and current best-practice TLS configuration.

Configure HTTP client security settings (CLI)

Provides instructions for configuring HTTP client security settings, including specifying TLS versions, setting cipher suites, and verifying security status to secure device web access.

Configure network device HTTP client security to ensure management access is encrypted and resilient to modern security threats.

Perform this task when securing web-based device access, or after a security audit recommends updating transport security standards.

Procedure

---

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the allowed TLS version.

   Example

   ```
   Device(config)# ip http client tls-version TLSv1.3
   ```

3. Set the secure cipher suite.

   Example

   ```
   Device(config)# ip http client secure-ciphersuite tls13-aes256-gcm-sha384
   ```

4. Verify the current security status.

Example

```
Device# show ip http client secure status
```

Device web management interfaces now enforce strong encryption and current best-practice TLS configuration.

158 Internet Protocol Security

Topics:

- Internet Protocol Security (IPsec)

Guides users through configuring Internet Protocol Security protocols and settings to establish secure network communications and protect data transmission.

Internet Protocol Security (IPsec)

Introduces IPSec fundamentals covering IKEv1 and IKEv2 transform sets, configuration procedures for both protocol versions, X.509 certificate implementation, session interruption handling, and traffic verification methods with practical configuration examples.

Internet Protocol Security (IPsec) ia framework of open standards that

- ensures confidentiality by encrypting data packets before transmission
- guarantees data integrity by authenticating packets, and
- provides data origin authentication to verify the source

IPsec includes an anti-replay feature that helps you detect and reject replayed packets.

An IPsec tunnel is a secure communication channel connecting two IPsec peers. It encrypts selected network traffic, uses security associations (SAs) to determine protocols, algorithms, and keying material for traffic protection, and applies access lists and crypto map sets to define which packets are encrypted and routed through the tunnel.

A security association (SA) is an agreement between two IPsec peers that defines the security protocols and algorithms to apply to protected packets, specifies the keying material used, and operates unidirectionally for each protocol.

Key Features of IPsec

IPsec provides the following security features:

- Confidentiality: IPsec encrypts packets to protect sensitive information during transmission.
- A framework of open standards, IPsec verifies the source of the packets, enhancing security.
- Anti-replay: The IPsec receiver can detect and reject replayed packets.

The controller supports IPsec configuration, securing syslog traffic and enabling a robust network-wide security policy.

If an you wants to encrypt all traffic between two sites, you can:

- Create access lists specifying relevant IP address ranges
- Apply those access lists to a crypto map set, and
- Bind the crypto map set to the device interface facing the remote site.

All matching packets is encrypted and transmitted through the IPsec tunnel.

Think of access lists as the guest list at a secure building.

Crypto maps are the guard's special instructions for who receives extra screening.

Transform sets are the security checks both guard and guest agree on.

Only guests who pass the right checks get inside; others are turned away.

IKEv1 transform sets

This concept explains how IKEv1 transform sets define a combination of security protocols and algorithms used to protect data flows in IPsec VPNs.

An IKEv1 transform set is a cryptographic configuration set that

- specifies a combination of security protocols and algorithms
- enables peers to negotiate security parameters for IPsec Security Associations (SAs), and

- is assigned to specific data flows through crypto map entries.

Transform set behavior during IPsec SA negotiation

During IPsec SA negotiation:

- Both peers search for a transform set that matches on each side.
- If a matching transform set is found, it is applied to the relevant protected traffic as part of the IPsec SA.

Additional reference information

- Administrators can define multiple transform sets and assign one or more to crypto map entries.
- The transform set associated with a crypto map entry determines the security protocols and algorithms used to protect specified data flows.
- Changing a transform set during operation does not affect existing SAs.
  - The new configuration applies only to future SA negotiations.
  - To apply changes immediately, you can clear all or part of the SA database using the **clear crypto sa** command.

Example

The configuration snippet shows how to configure an IPsec IKEv1 transform set using AES-CBC-128 for payload encryption. To use AES-CBC-256, specify **encryption aes 256**.

```
Device # conf t
Device (config)#crypto isakmp policy 1
Device (config-isakmp)# hash sha
Device (config-isakmp)# encryption aes
```

Configure IPsec using IKEv1

Use this procedure to configure IPSec using Internet Key Exchange version 1.

Follow the procedure given below to configure IPsec IKEv1 to use AES-CBC-128 for payload encryption.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. Define an Internet Key Exchange (IKE) policy and assign a priority to the policy.

   Example

   ```
   Device(config)# crypto isakmp policy priority
   ```

- *priority*: Uniquely identifies the IKE policy and assigns a priority to the policy. Valid values: 1 to 10,000; 1 is the highest priority.

3. Specify the hash algorithm.

   Example

   ```
   Device(config-isakmp)# hash sha
   ```

   Specifies the hash algorithm.

4. Configure IPsec IKEv1 to use AES-CBC-128 for payload encryption.

   Example

   ```
   Device(config-isakmp)# encryption aes
   ```

   AES-CBC-256 can be selected with 'encryption aes 256'.

   > **Note**
   >
   > The authorized administrator must ensure that the keysize for this setting is greater than or equal to the keysize selected for ESP in section IPsec Transforms and Lifetimes. If AES 128 is selected here, then the highest keysize that can be selected on the device for ESP is AES 128 (either CBC or GCM).
   >
   > Both confidentiality and integrity are configured with the **hash sha** and **encryption aes** commands respectively. As a result, confidentiality-only mode is disabled.

5. Configure IPsec to use the specified preshared keys as the authentication method.

   Example

   ```
   Device(config-isakmp)# authentication pre-share
   ```

   Preshared keys require that you separately configure these preshared keys.

6. Exit config-isakmp configuration mode.

   Example

   ```
   Device(config-isakmp)# exit
   ```

   Exits config-isakmp configuration mode.

7. Configure a preshared authentication key.

   Example

   ```
   Device(config)# crypto isakmp key keystring address peer-address
   ```

> **Note**
>
> To ensure a secure configuration, we recommend that you enter the pre-shared keys with at least 22 characters in length and can be composed of any combination of upper and lower case letters, numbers, and special characters (that include: "!", "@", "#", "$", "%", "^", "&", "*", "(", and ")").
>
> The device supports pre-shared keys up to 127 characters in length. While longer keys increase the difficulty of brute-force attacks, longer keys increase processing time.

8. Specify the Diffie-Hellman (DH) group identifier as 2048-bit DH group 14 and selects DH Group 14 (2048-bit MODP) for IKE.

   Example

   ```
   Device(config-isakmp)# group 14
   ```

   However, 19 (256-bit Random ECP), 24 (2048-bit MODP with 256-bit POS), 20 (384-bit Random ECP), 15 (3072 bit MODP), and 16 (4096-bit MODP) are also allowed and supported.

9. Specify the lifetime of the IKE SA.

   Example

   ```
   Device(config-isakmp)# lifetime seconds
   ```

   The default time value for Phase 1 SAs is 24 hours (86400 seconds), but this setting can be changed using the command above with different values.

   - *seconds*: Time, in seconds, before each SA expires. Valid values: 60 to 86,400; default value: 86,400.

   > **Note**
   >
   > The shorter the lifetime (up to a point), the more secure your IKE negotiations will be. However, with longer lifetimes, future IPsec SAs can be set up more quickly.

10. Ensure all IKEv1 Phase 1 exchanges will be handled in the default main mode.

    Example

    ```
    Device(config-isakmp)# crypto isakmp aggressive-mode disable
    ```

11. Exit config-isakmp configuration mode.

    Example

    ```
    Device(config-isakmp)# exit
    ```

IKEv2 transform sets

This concept explains how IKEv2 transform sets define the parameters used in the negotiation of IKEv2 Security Associations during the IKE_SA_INIT exchange.

An IKEv2 transform set is a security proposal that

- consists of a set of cryptographic transforms (encryption, integrity, and Diffie-Hellman group) used during IKEv2 negotiation,
- is required for a valid IKEv2 Security Association (SA), and
- enables the devices to negotiate compatible security parameters during the IKE_SA_INIT phase.

Expanded explanation

If you do not attach a user-configured IKEv2 proposal to an IKEv2 policy, the system uses the default proposal for negotiation.

Example

This configuration snippet demonstrates how to define and apply an IKEv2 transform set and related parameters:

```
device # conf t
device(config)#crypto ikev2 proposal sample
device(config-ikev2-proposal)# integrity sha1
device (config-ikev2-proposal)# encryption aes-cbc-128
device(config-ikev2-proposal)# group 14
device(config-ikev2-proposal)# exit
device(config)# crypto ikev2 keyring keyring-1
device (config-ikev2-keyring)# peer peer1
device (config-ikev2-keyring-peer)# address 192.0.2.4 255.255.255.0
device (config-ikev2-keyring-peer)# pre-shared-key cisco123!cisco123!CISC
device (config-ikev2-keyring-peer)# exit
device(config)#crypto ikev2 keyring keyring-1
device (config-ikev2-keyring)# peer peer1
device (config-ikev2-keyring-peer)# address 192.0.2.4 255.255.255.0
device (config-ikev2-keyring-peer)# pre-shared-key cisco123!cisco123!CISC
device (config-ikev2-keyring-peer)# exit
device(config)#crypto logging ikev2
```

Configure IPsec using IKEv2

Use this procedure to configure IPSec using Internet Key Exchange version 2.

Follow the procedure given below to configure the IPsec with IKEv2:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Define an IKEv2 proposal name.

Example

```
Device(config)# crypto ikev2 proposal name
```

3. Define the integrity algorithm for the IKEv2 proposal.

Example

```
Device(config-ikev2-proposal)# integrity sha1
```

4. Configure IPsec IKEv2 to use AES-CBC-128 for payload encryption.

Example

```
Device(config-ikev2-proposal)# encryption aes-cbc-128
```

AES-CBC-256 can be selected with encryption aes-cbc-256. AES-GCM-128 and AES-GCM-256 can also be selected similarly.

> **Note**
>
> The authorized administrator must ensure that the keysize for this setting is greater than or equal to the keysize selected for ESP in section IPsec Transforms and Lifetimes. If AES 128 is selected here, then the highest keysize that can be selected on the device for ESP is AES 128 (either CBC or GCM).
>
> Both confidentiality and integrity are configured with the **hash sha** and **encryption aes** commands respectively. As a result, confidentiality-only mode is disabled.

5. Selects DH Group 14 (2048-bit MODP) for IKE.

Example

```
Device(config-ikev2-proposal)# group 14
```

However, 19 (256-bit Random ECP), 24 (2048-bit MODP with 256-bit POS), 20 (384-bit Random ECP), 15 (3072 bit MODP), and 16 (4096-bit MODP) are also allowed and supported.

6. Exit IKEv2 proposal configuration mode.

Example

```
Device(config-ikev2-proposal)# exit
```

7. Define an IKEv2 keyring.

Example

```
Device(config)# crypto ikev2 keyring keyring-name
```

8. Define the peer or peer group.

Example

```
Device(config-ikev2-keyring)# peer peer-name
```

9. Specify an IPv4 or IPv6 address or range for the peer.

Example

```
Device(config-ikev2-keyring)# address 192.0.2.4 255.255.255.0
```

> **Note**
>
> This IP address is the IKE endpoint address and is independent of the identity address.

10. Specify the preshared key for the peer.

Example

```
Device(config-ikev2-keyring)# pre-shared-key cisco123!cisco123!CISC
```

You can enter the local or remote keyword to specify an asymmetric preshared key. By default, the preshared key is symmetric.

> **Note**
>
> To ensure a secure configuration, we recommend that you enter the pre-shared keys with at least 22 characters in length and can be composed of any combination of upper and lower case letters, numbers, and special characters (that include: “!”, “@”, “#”, “$”, “%”, “^”, “&”, “*”, “(“, and “)”).
>
> The device supports pre-shared keys up to 127 characters in length. While longer keys increase the difficulty of brute-force attacks, longer keys increase processing time.
>
> HEX keys generated off system can also be input for IKEv2 using the **pre-shared-key hex** *[hex key]* command instead of the pre-shared-key command above:. For example: pre-shared-key hex 0x6A6B6C. This configures IPsec to use pre-shared keys.

11. Exit IKEv2 keyring peer configuration mode.

Example

```
Device(config-ikev2-keyring)# exit
```

12. Enable IKEv2 syslog messages.

Example

```
Device(config)# crypto logging ikev2
```

> **Note**
>
> The configuration above is not a complete IKE v2 configuration, and that additional settings will be needed.

IPsec transforms and lifetimes

This section lists configuration commands, available algorithms, and default values for IPsec transforms and security association (SA) lifetimes for IPsec ESP encryption and integrity.

Regardless of the IKE version, the device must be configured with appropriate IPsec ESP transforms (encryption and integrity algorithms) and SA lifetimes. The tables and commands below show how to set these parameters.

This configuration sets IPsec ESP to use HMAC-SHA-1 and AES-CBC-128. To change this to any of the other allowed algorithms, replace **esp-aes 128** in the command

IPsec transform command example

To configure an IPsec ESP transform set with AES-CBC-128 and HMAC-SHA-1:

```
device(config)# crypto ipsec transform-set example esp-aes 128 esp-sha-hmac
```

This command sets ESP to use HMAC-SHA-1 for integrity and AES-CBC-128 for encryption.

Supported Encryption Algorithms

The table lists supported encryption algorithms and their commands:

Encryption Algorithm	Command
AES-CBC-256	esp-aes 256
AES-GCM-128	esp-gcm 128
AES-GCM-256	esp-gcm 256

> **Note**
>
> The key size for the algorithm in the transform set must not exceed the key size selected for IKE encryption. For example, if AES-CBC-128 is selected for IKE, then only AES-CBC-128 or AES-GCM-128 may be selected here.

Configuring IPsec modes

Set the operational mode for IPsec using one of these commands:

```
device(config-crypto)# mode tunnel
```

- Requests and accepts only tunnel mode for IPsec. Tunnel is the default mode.

```
device(config-crypto)# mode transport
```

- Configures transport mode for IPsec.

Configuring SA lifetimes

By time (seconds):

The default lifetime for Phase 2 SAs is 3600 seconds (1 hour). To change it (for example to 8 hours or 28800 seconds) use this command:

```
device(config)# crypto ipsec security-association lifetime seconds 28800
```

By data volume (kilobytes):

Default is 2560 KB (minimum configurable). The maximum is 4 GB. For example, to set a 100 MB (100000 KB) limit use this command:

```
device(config)# crypto ipsec security-association lifetime kilobytes 100000
```

Additional notes

- No configuration is needed for default values; configure only for custom values to meet policy or compliance.
- Always ensure that your IPsec transforms and lifetimes are compatible between your IPsec peers to prevent negotiation failures.

Use of X.509 with IKE version

Use this procedure to configure X.509 certificate-based authentication for IKEv1 on the Cisco Catalyst 9800 Series Wireless Controller.

Enable X.509v3 certificate authentication for secure IKEv1 negotiation.

The controller supports RSA and ECDSA based certificates. Once X.509v3 keys are installed on the device, they can be set for use with IKEv1 with the commands:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Define an Internet Key Exchange (IKE) policy and assign a priority to the policy.

   Example

   ```
   Device(config)# crypto isakmp policy policy-name
   ```

3. Use RSA based certificates for IKEv1 authentication.

   Example

   ```
   Device(config-isakmp)# authentication rsa-sig
   ```

4. Use ECDSA based certificates for IKEv1 authentication.

Example

```
Device(config-isakmp)# authentication ecdsa-sig
```

The X.509 certificates are now configured for use with IKEv1.

IPsec session interruption and recovery

This section describes the behavior of IPsec sessions when an unexpected interruption occurs and explains the automatic recovery process when the peer reconnects..

If an IPsec session with a peer is unexpectedly interrupted, the connection will be broken. In this scenario, no administrative interaction is required. The IPsec session will be reestablished (a new SA set up) once the peer is back online.

Example: Configure IPsec using ISAKMP

This section provides a sample configuration for IPsec using ISAKMP.

This example displays the IPSec **isakmp** configuration.

The sample outputs display the IPSec **isakmp** configuration:

```
crypto isakmp policy 1
                 encr aes 256
                 hash sha256
                 authentication pre-share
                 group 14
                 lifetime 28800
                crypto isakmp key 0 Cisco!123 address 192.0.2.4
                crypto isakmp peer address 192.0.2.4
                crypto ipsec transform-set aes-gcm-256 esp-gcm 256
                 mode tunnel
                crypto map IPSEC_ewlc_to_syslog 1 ipsec-isakmp
                 set peer 192.0.2.4
                 set transform-set aes-gcm-256
                 match address acl_ewlc_to_syslog
                interface Vlan15
                 crypto map IPSEC_ewlc_to_syslog
                end
```

Verify IPSec traffic

This section lists sample commands and their outputs to help you verify the status of IPSec tunnels and Internet Key Exchange Version 2 (IKEv2) traffic on a device.

This example shows how to verify the IPSec traffic configuration in isakmp configuration:

```
Device# show crypto map
Crypto Map IPv4 "IPSEC_ewlc_to_syslog" 1 ipsec-isakmp
        Peer = 192.0.2.4
        Extended IP access list acl_ewlc_to_syslog
            access-list acl_ewlc_to_syslog permit ip host 192.0.2.2 host
192.0.2.4
        Current peer: 192.0.2.4
        Security association lifetime: 4608000 kilobytes/3600 seconds
        Responder-Only (Y/N): N
        PFS (Y/N): N
```

```
        Mixed-mode : Disabled
        Transform sets={
                aes-gcm-256:  { esp-gcm 256  } ,
        }
        Interfaces using crypto map IPSEC_ewlc_to_syslog:
                Vlan15
```

```
Device# show crypto isakmp sa
IPv4 Crypto ISAKMP SA
dst             src             state          conn-id status
192.0.2.5       192.0.2.4       QM_IDLE           1011 ACTIVE

IPv6 Crypto ISAKMP SA
```

```
Device# show crypto ipsec sa

Example: Configure IPsec using IKEv2

This section provides a sample configuration for IPSec using Internet Key Exchange Version 2 (IKEv2).

The sample outputs display the IPsec **IKEv2** configuration:

```
topology : [192.0.2.6]DUT — (infra) — PEER[192.0.2.9]

159 Transport Layer Security Tunnel Support

Topics:

- Transport layer security tunnels
- Configure a transport layer security tunnel
- Transport layer security tunnel verification

Transport layer security tunnels

Explains how Transport Layer Security (TLS) tunnel support enables the controller to reach a public cloud automatically and securely manage wireless solutions.

A transport layer security tunnel is a secure communication protocol that

- enables the controller to reach a public cloud automatically
- encrypts all data sent over the TCP connection, and
- ensures reliable and secure communication between the controller and Digital Network Architecture (DNA) on Cloud.

Cisco plug and play solution

Supported controllers

The Cisco Catalyst 9800 Series Wireless Controller requires direct access to a public cloud to implement the teleworker solution using Cisco OfficeExtend Access Points (OEAPs). With the introduction of Transport Layer Security (TLS) tunnel support from Cisco IOS XE Amsterdam 17.3.2 onwards, the controller can now reach a public cloud automatically. This helps Cisco Catalyst Center on Cloud to establish TLS communication channels with the controller to monitor and manage wireless solutions.

The TLS connection ensures that the configuration and telemetry are reliably and securely communicated between the controller and the Digital Network Architecture (DNA) on Cloud. The TLS tunnel encrypts all the data that is sent over the TCP connection. The TLS tunnel provides a more secure protocol across the internet. After the controller discovery, the Cisco Catalyst Center on Cloud uses Cisco DNA Assurance and Automation features to manage the controller centrally.

The Cisco Plug and Play solution is a converged solution that provides a highly secure, scalable, seamless, and unified zero-touch deployment experience.

Plug-n-Play Agent

The Cisco Plug and Play (PnP) agent is an embedded software component that is present in all the Cisco network devices that support simplified deployment architecture. The PnP agent understands and interacts only with a PnP server. The PnP agent, using DHCP, DNS, or other such methods, tries to acquire the IP address of the PnP server with which it wants to communicate. After a server is found and a connection is established, the agent communicates with the PnP server to perform deployment-related activities.

For more information on Cisco Plug and Play, see the Cisco Plug and Play Feature Guide.

The Transport Layer Security Tunnel (TLS) over PnP feature is supported on the following controllers:

- Cisco Catalyst 9800-80 Wireless Controller
- Cisco Catalyst 9800-40 Wireless Controller
- Cisco Catalyst 9800-L Wireless Controller

Configure a transport layer security tunnel

Configure a transport layer security tunnel to enable secure communication between devices.

Establish a secure TLS tunnel to protect data exchanged between network devices.

Use this procedure when you need to secure traffic between devices using a TLS tunnel, typically in environments requiring encrypted communication for compliance or security reasons.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a crypto TLS tunnel channel.

   Example

   ```
   Device(config)# crypto tls-tunnel TLS-tunnel-name
   ```

   Example

   ```
   Device(config)# crypto tls-tunnel cloud-primary
   ```

3. Specify the server IPv4 address, IPv6 address, or URL name and the port number.

   Example

   ```
   Device(config-crypto-tls-tunnel)# server ipv4 server-ipv4-address port
   port-number
   ```

   Example

   ```
   Device(config-crypto-tls-tunnel)# server ipv4 172.31.255.255 port 4043
   ```

   The server can be specified as an IPv4 address, IPv6 address, or URL. The port number must be in the range 1025-65535.

4. Specify the overlay interface and interface number.

   Example

   ```
   Device(config-crypto-tls-tunnel)# overlay interface interface-name
   ```

   Example

   ```
   Device(config-crypto-tls-tunnel)# overlay interface Loopback0
   ```

   An overlay interface is a logical, multiaccess, multicast-capable interface. It encapsulates Layer 2 frames in IP unicast or multicast headers.

5. Specify the LAN interface type, number, and the priority rank.

   Example

   ```
   Device(config-crypto-tls-tunnel)# local-interface interface-name priority
   priority-rank
   ```

Example

```
Device(config-crypto-tls-tunnel)# local-interface vlan 1 priority 1
```

Currently, the tunnel supports only one WAN interface with priority 1 and does not support the list of WAN interfaces with multiple priorities.

6. Specify a preshared key and password options.

Example

```
Device(config-crypto-tls-tunnel)# psk id identity key psk-key
```

Example

```
Device(config-crypto-tls-tunnel)# psk id test key
```

7. Specify the trustpoints for use with the RSA signature authentication method.

Example

```
Device(config-crypto-tls-tunnel)# pki trustpoint trustpoint-label
sign-or-verify
```

Example

```
Device(config-crypto-tls-tunnel)# pki trustpoint tsp1 sign
```

Use the certificate from the trustpoint for signing or verifying. If the **sign** or **verify** keyword is not specified, the trustpoint is used for both signing and verification. Authentication can be done using either pre-shared key (PSK) or PKI (certificate based).

8. Optional: Enable common criteria mode (FIPS mode).

Example

```
Device(config-crypto-tls-tunnel)# cc-mode
```

Indicates a common criteria mode, which is a Federal Information Processing Standards (FIPS) mode.

9. Enable the TLS tunnel.

Example

```
Device(config-crypto-tls-tunnel)# no shutdown
```

10. Return to privileged EXEC mode.

Example

```
Device(config-crypto-tls-tunnel)# end
```

The TLS tunnel is now configured and enabled, providing secure encrypted communication between devices.

Transport layer security tunnel verification

Provides steps and commands to verify a transport layer security (TLS) tunnel, including client summary, session details, statistics, and session summary information.

This reference describes how to verify a transport layer security (TLS) tunnel by using various show commands to display client summary, session details, statistics, and session summary information.

The TLS client support includes BinOS processes using Linux Tun/Tap Interface. To verify the TLS client summary details, use the following command:

```
Device# show platform software tlsc client summary
TLS Client - Config Summary

Name         ID     Gateway    Port   Auth     Trustpoint  DPD Time    Rekey
Time  Retry Time
-------------------------------------------------------------------------------------
fqdn         0                 8443   PSK      N/A            60          300
         20
```

To verify the TLS client session detail, session statistics, tunnel statistics, and DNS counters, use the following command:

```
Device# show platform software client detail <tls-name>

Session Name     : fqdn
FQDN resolved IP : 10.255.255.255
ID               : 0

160 Configuring RFC 5580 Location Attributes

Topics:

- RFC 5580 location attributes

This chapter shows how to enable and manage civic and geo profiles, operator names, AP/NAS associations, out-of-band delivery, and verification commands on Cisco controllers to send location data in RADIUS exchanges.

RFC 5580 location attributes

Introduces RFC 5580 related location attributes, covering the location-capable attribute, configuration restrictions, delivery of location information using out-of-band agreements, methods for defining civic and geo profiles, operator name setup, associating location attributes with user and NAS locations, and verification steps for attribute deployment.

An RFC 5580 location attribute is a RADIUS protocol attribute that

- conveys location related information for authentication and accounting exchanges,
- supports both user and NAS locations using Civic profiles and Geo profiles, and
- enables services such as location-aware authorization, billing, and enhanced user privacy.

Feature history for RFC 5580 location attributes

This table lists the release and related information for this feature.

This feature is available in all subsequent releases unless stated otherwise.

Table 142: Feature history for RFC 5580 location attributes

Release	Feature	Feature information
Cisco IOS XE 17.9.1	Support for RFC 5580 location attributes in the controller	This feature uses RFC 5580 location attributes to convey location related information for authentication and accounting exchanges. The controller supports these RFC 5580-related attributes: • Location-Information • Location-Data CIVIC Profile: Country • Location-Data CIVIC Profile: CAtype 1 (state) • Location-Data CIVIC Profile: CAtype 3 (city) • Location-Data CIVIC Profile: CAtype 23 (venue name) • Location-Data CIVIC Profile: CAtype 24 (zip code) • Location-Data GEO Profile (longitude, latitude, and altitude) • Operator Name

Various operators use RFC 5580 location attributes in wireless networks deployed in public places such as shopping malls, airports, hotels, and coffee shops.

To enable location-aware authorization, billing, or services, the network may require the user location.

You must protect the location information against unauthorized access and distribution.

- **User location** specifies a user-specific location, typically configured at the access point.
- **NAS location** refers to the common host location for all users connected to a specific network access server, configurable in AAA (Authentication, Authorization, and Accounting).

Each location can have two profiles: a Civic profile and a Geo profile.

- **Civic Profile** describes a location using civic attributes such as country, state, city, area, and postal code.
- **Geo Profile** describes a location using geographic attributes such as latitude, longitude, and altitude.

Location Attributes and Profiles

If a user has both user location and NAS location, you can configure each location using Civic profiles and Geo profiles.

You can configure these locations:

- Civic user location
- Civic NAS location
- Geo user location
- Geo NAS location

Each location information, for example, the civic user location, is sent using the attributes that include:

- Location-Information
- Location-Data

The controller supports these RFC 5580-related attributes:

- Location-Information
- Location-Data CIVIC Profile: Country
- Location-Data CIVIC Profile: CAtype 1 (state)
- Location-Data CIVIC Profile: CAtype 3 (city)
- Location-Data CIVIC Profile: CAtype 23 (venue name)
- Location-Data CIVIC Profile: CAtype 24 (zip code)
- Location-Data GEO Profile (longitude, latitude, and altitude)
- Operator Name

You can configure four locations and one operator name for each user.

The Out-of-Band Agreement delivery method (Flow one) mentioned in RFC 5580 is supported for transferring location information if the feature is enabled and location information is configured.

Location-capable attribute

Information about the location-capable attribute.

A location-capable attribute is a Remote Authentication Dial-In User Service (RADIUS) attribute that

- signals to a RADIUS server that a device is capable of providing location information,
- is included in network access authentication or authorization requests for wireless clients, and
- enables support for location-based services as specified in RFC 5580.

Additional reference information

Cisco IOS XE 17.11.1 supports the location-capable attribute defined by RFC 5580. You can enable this attribute by using the following command: **radius-server attribute wireless location delivery out-of-band include-location-capable** .

According to RFC 5580, the attribute is typically sent in Flow two, which refers to location delivery based on the Initial Request. This configuration also enables sending the attribute in Flow one, which refers to an out of band agreement.

The location-capable attribute appears in RADIUS requests for wireless clients. The server may use this data to provide or restrict network access based on device location capability.

Restriction for configuring RFC 5580 location attributes

Restriction for configuring RFC 5580 location attributes.

This feature is supported only for 802.11ax users.

Configure location delivery based on out-of-band agreement (CLI)

Configure location delivery based on out-of-band agreement using commands.

Configure RFC 5580 out-of-band location delivery on network devices through CLI.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure RFC 5580 Out-of-Band location support.

   Example

   ```
   Device(config)# radius-server attribute wireless location delivery out-of-band
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The device is configured to support out-of-band location delivery as per RFC 5580.

Configure the location-capable attribute (CLI)

Configure location-capable attribute using commands.

Enable and include the location-capable attribute in RADIUS access requests for wireless location delivery features according to RFC 5580.

Before you begin

Use the **radius-server attribute wireless location delivery out-of-band** command to enable the feature globally.

You can use the **radius-server attribute wireless location delivery out-of-band include-location-capable** command to include the location-capable attribute along with other location attributes.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure RFC 5580 out-of-band location attributes along with enabling the location-capable attribute to be part of the access request.

   Example

   ```
   Device(config)# radius-server attribute wireless location delivery out-of-band
    include-location-capable
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The device includes the location-capable attribute in RADIUS access requests, enabling the server to support advanced wireless location tracking and services.

Configure a civic profile (CLI)

Use commands to configure the civic profile.

Configure civic profiles to specify user location information for Remote Authentication Dial-In User Service (RADIUS) requests and network services.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the civic profile for the user location.

   Example

   ```
   Device(config)# location civic-location identifier civic_identifier
   ```

   Here, *civic_identifier* refers to the civic location identifier string. The identifier can be up to 215 characters long. You can allocate up to 250 bytes for civic address attributes. Of these, Cisco reserves 50 bytes for internal information, leaving 200 bytes available for user-configured civic location information.

> **Note**
>
> You can configure these types of civic attributes and add them to RADIUS requests:
>
> - Country,
> - City,
> - State,
> - ZIP code, and
> - Name

3. Set the country ID.

   Example

   ```
   Device(config-civic)# country country_ID
   ```

   > **Note**
   >
   > Only two-letter ISO 3166 country codes are accepted.

4. Set the city name.

   Example

   ```
   Device(config-civic)# city city_name
   ```

5. Set the state name.

   Example

   ```
   Device(config-civic)# state state_name
   ```

6. Set the ZIP code.

   Example

   ```
   Device(config-civic)# postal-code postal_code
   ```

7. Set the residence name.

   Example

   ```
   Device(config-civic)# name residence_name
   ```

8. Return to privileged EXEC mode.

   Example

   ```
   Device(config-civic)# end
   ```

The civic profile is configured, and the device now uses the specified location details in RADIUS requests.

Configure a geo profile (CLI)

Use CLI commands to set location parameters—identifier, latitude, longitude, altitude, and resolution—for your network device.

Set precise geographic information—identifier, latitude, longitude, altitude, and resolution—for the user's location on your device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a geo profile for the user location.

   Example

   ```
   Device(config)# location geo-location identifier geo_identifier
   ```

   Here, the geographic location identifier string is referenced. It can contain up to 215 characters.

3. Set latitude information.

   Example

   ```
   Device(config-geo)# latitude latitude_in_degrees resolution resolution_value
   ```

   Optional parameters appear in square brackets.

   If you do not specify a resolution, the system uses a default value of 10 meters (32.8 feet).

4. Set longitude information.

   Example

   ```
   Device(config-geo)# longitude longitude_in_degrees resolution resolution_value
   ```

   Optional parameters appear in square brackets.

   If you do not specify a resolution, the system uses a default value of 10 meters (32.8 feet).

5. Configure altitude for the geographic location.

Example

```
Device(config-geo)# altitude altitude_value feet resolution resolution_value
 floor meters resolution resolution_value
```

Example

```
Device(config-geo)# altitude 10 meters (32.8 feet) resolution 10
```

Optional parameters appear in square brackets.

- *altitude_value* : refers to the altitude, in feet, floors, or meters.
- *resolution_value* : refers to the resolution, in feet or meters.

> **Note**
>
> Altitude and altitude resolution values must use the same unit.

6. Specify a resolution for both latitude and longitude.

Example

```
Device(config-geo)# resolution resolution_value
```

7. Return to privileged EXEC mode.

Example

```
Device(config-geo)# end
```

The geo profile is now configured on your device. It is associated with the identifier, latitude, longitude, altitude, and resolution you specified.

Configure an operator name (CLI)

Use commands to configure the operator name.

Establish a unique operator-name identifier for your device user or Network Access Server (NAS) location so you can reference it for administrative or tracking purposes.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure an operator name for the user's location.

   Example

   ```
   Device(config)# location operator identifier identifier_name
   ```

   In this context, *identifier_name* supports strings with a maximum length of 215 characters (215 bytes).

3. Configure the operator name for the location.

   Example

   ```
   Device(config-operator)# name operator-name
   ```

   In this context, *operator-name* supports strings with a maximum length of 248 characters (248 bytes).

4. Configure the namespace for the location where the operator name applies.

   Example

   ```
   Device(config-operator)# namespace-id E212 ICC REALM TADIG
   ```

   You can use these namespace options.

   - **E212** refers to the Mobile Country Code (MCC) and Mobile Network Code (MNC).
   - **ICC** refers to the International Telecommunication Union Carrier Codes (ICC).
   - **REALM** refers to any registered domain name.
   - **TADIG** refers to the Transferred Account Data Interchange Group (TADIG) code.

   Note

   - If you have not configured any namespace, **REALM** is used as the default.
   - You can associate the operator name with both NAS-Location and USER-Location. If you configure an operator name at both locations, the operator name you configure in USER-Location takes precedence.

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-operator)# end
   ```

The operator name is now configured for the location you specified. The device uses this operator name to identify the appropriate context.

Associate a location attribute with a user location (CLI)

Use this procedure to associate civic, geographic, and operator location attributes with a user location for access points using CLI commands.

Assign location metadata to user-defined locations for APs for improved location-based services.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a location name for an AP.

   Example

   ```
   Device(config)# ap location name location_name
   ```

3. Add the AP to the location.

   Example

   ```
   Device(config-ap-location)# ap-eth-mac AP_Ethernet_MAC
   ```

   Here, *AP_Ethernet_MAC* refers to the AP Ethernet MAC address.

4. Associate the civic location attribute with the user location.

   Example

   ```
   Device(config-ap-location)# location civic-location-id identifier_name
   ```

5. Associate the geographic location attribute with the user location.

   Example

   ```
   Device(config-ap-location)# location geo-location-id identifier_name
   ```

6. Associate the operator location attribute with the user location.

   Example

   ```
   Device(config-ap-location)# location operator-id identifier_name
   ```

7. Return to privileged EXEC mode.

Example

```
Device(config-ap-location)# end
```

The selected AP has its civic, geographic, and operator attributes associated with the specified user location.

Associate the NAS location with location attributes (CLI)

Use this procedure to associate location attributes (civic, geographic, operator) with the NAS location using CLI commands.

Apply location attributes to a NAS device for wireless location tracking and compliance.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Associate the civic location attribute with the NAS location.

   Example

   ```
   Device(config)# radius-server attribute wireless location civic-location-id
   identifier_name
   ```

   Here, *identifier_name* supports strings up to 215 characters in length.

3. Associate the geographic location attribute with the NAS location.

   Example

   ```
   Device(config)# radius-server attribute wireless location geo-location-id
   identifier_name
   ```

   Here, *identifier_name* supports strings up to 215 characters in length. Enter a valid or existing identifier name.

4. Associate the operator location attribute with the NAS location.

   Example

   ```
   Device(config)# radius-server attribute wireless location operator-id
   identifier_name
   ```

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The specified location attributes are now associated with the NAS location.

Verify RFC 5580 location attribute configuration

Verify RFC 5580 location attribute configuration.

To verify the location attributes associated with a given location, use this command:

```
Device# show ap location details AAA_location
Location Name.....................: AAA_location
Location description..............:
Policy tag........................: default-policy-tag
Site tag..........................: default-site-tag
RF tag............................: default-rf-tag
AAA Location Status ..............: Enabled
Civic Location Identifier : NAS_C_1
Geo Location Identifier   : NAS_G_1
Operator Name Identifier  : NAS_O_1

Configured list of APs
38ed.18ca.5a20
```

To verify the Cisco AP location, use this command:

```
Device# show ap name AP38ED.18CA.5A20 config general
Cisco AP Name   : AP38ED.18CA.5A20
================================================

Cisco AP Identifier                              : 38ed.18cb.cf00
Country Code                                     : Multiple Countries :
Regulatory Domain Allowed by Country           : 802.11bg:   802.11a:   802.11
 6GHz:
AP Country Code                                  : US  -
AP Regulatory Domain
  802.11bg                                       : -A
  802.11a                                        : -A
MAC Address                                      : 38ed.18ca.5a20
IP Address Configuration                         : Static IP assigned
IP Address                                       : 192.0.2.254
IP Netmask                                       : 255.255.255.0
Gateway IP Address                               : 9.4.172.1
Fallback IP Address Being Used                   :
Domain                                           :
Name Server                                      :
CAPWAP Path MTU                                  : 1485
Capwap Active Window Size                        : 1
Telnet State                                     : Disabled
CPU Type                                        :  ARMv7 Processor rev 0 (v7l)
Memory Type                                      : DDR3
Memory Size                                      : 995328 KB
SSH State                                        : Disabled
Cisco AP Location                                : AAA_location
-
-
-
```

To verify the location attributes associated with a given MAC address, use this command:

```
Device# show wireless client mac 0080.5222.545c detail

Client MAC Address : 0080.5222.545c
```

```
Client MAC Type : Universally Administered Address
Client DUID: NA
Client IPv4 Address :
AP MAC Address : 38ed.18cb.cf00
AP Name: AP38ED.18CA.5A20
AP slot : 1
Client State : Associated
Policy Profile : default-policy-profile
Flex Profile : N/A
…
Civic Location Identifier : NAS_C_1
Geo Location Identifier   : NAS_G_1
Operator Name Identifier  : NAS_O_1
```

Note

You will be able to view this output only if the RFC 5580 feature is enabled.

To verify the Civic location details, use this command:

```
Device# show location civic-location identifier TEST1
Civic location information
--------------------------
Identifier              : TEST1
Name                    : home
City                    : Morges
State                   : Vaud
Postal code             : 1110
Country                 : CH
```

To verify the Geo location details, use this command:

```
Device# show location geo-location identifier TEST4
Geo location information
------------------------
Identifier  : TEST4
Latitude    : 46.5112700
Longitude   : 6.4985400
Altitude    : 380 meters          Resolution : 10
Resolution  : 100
```

To verify the Operator location details, use this command:

```
Device# show location operator-location identifier myoperator
Operator location information
-----------------------
Operator Identifier     : myoperator
Operator Name           : myoperator
Operator Namespace      : REALM
-----------------------
```

161 IP MAC Binding

Topics:

- IP MAC binding

Explains the IP-MAC binding feature and provides guidance on configuring and managing MAC address to IP address associations for network security.

IP MAC binding

Explains the IP MAC address binding configuration that enables wireless device tracking features, such as theft detection, proxy, DHCP relay, gleaning, and suppression.

IP MAC binding is a wireless configuration feature that

- enables wireless device tracking features such as theft detection, proxy, DHCP relay, gleaning, and suppression
- tracks wireless clients' IPv4 addresses by binding them to their MAC addresses, and
- is enabled by default in the policy profile.

No IP MAC binding

No IP MAC binding disables all the wireless device tracking features for wireless clients' IPv4 address.

> **Note**
>
> It is not normally necessary to disable IP MAC binding, except for the following scenarios:
>
> - When you have a single wireless station with multiple IP addresses.
> - When you intentionally have duplicate IP addresses across clients.
> - When you are using ARP-spoofing Network Access Control (NAC) devices.

> **Note**
>
> The IP MAC address binding is enabled by default in the policy profile.

> **Note**
>
> IP MAC binding is required for DHCP Option 82 to work in some situations.

Use cases for no IP MAC binding

Lists use cases for no IP MAC binding.

The following are the use cases for No IP MAC binding:

- Disabling IP Learning in FlexConnect Mode
- Disabling Device Tracking to Support NAC Devices
- Disabling IP Learning in FlexConnect Mode

Disable IP MAC binding (CLI)

Configure wireless policy settings to disable IP MAC binding using command line interface.

Disable IP MAC binding on a wireless policy profile to remove the restriction that binds client IP addresses to their MAC addresses.

IP MAC binding prevents clients from using IP addresses that are not associated with their MAC addresses. Disabling this feature allows more flexible IP address assignment for wireless clients.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the wireless profile policy.

   Example

   ```
   Device(config)# wireless profile policy profile-policy-name
   ```

   Example

   ```
   Device(config)# wireless profile policy test-profile-policy
   ```

3. Disable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

   Disabling policy profile results in associated AP and client to rejoin.

4. Disable IP MAC binding.

   Example

   ```
   Device(config-wireless-policy)# no ip mac-binding
   ```

5. Enable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

6. Return to privileged EXEC mode.

Example

```
Device(config-wireless-policy)# exit
```

IP MAC binding is disabled on the wireless policy profile, allowing clients to use IP addresses without MAC address restrictions.

Verify IP MAC binding

Verify IP MAC binding status to confirm whether it is enabled or disabled.

Procedure

Use the following command to verify if IP MAC binding is disabled or enabled:

Example

```
Device# show run | b wireless profile policy test-profile-policy
wireless profile policy test-profile-policy
 no ip mac-binding
 vlan VLAN0169
```

162 Disabling IP Learning in FlexConnect Mode

Topics:

- Disabling IP learning in FlexConnect mode

Guides you through the process of disabling Internet Protocol learning functionality when operating network devices in FlexConnect mode.

Disabling IP learning in FlexConnect mode

Explains how disabling IP learning in FlexConnect mode prevents IP theft errors and client exclusion by avoiding device tracking for clients with overlapping IP addresses.

A disabling IP learning in FlexConnect mode feature is a WLAN configuration option that

- prevents device tracking for clients in FlexConnect local switching scenarios
- avoids IP theft errors by ensuring no device tracking is done for clients, and
- supports overlapping IP address allocation across different sites.

IP address handling in FlexConnect local switching

In FlexConnect local switching scenarios, clients from the same sites may share the same address range, which can result in multiple clients being allocated or registered with the same IP address. The controller receives IP address information from the AP, and if more than one client attempts to use the same IP address, the controller discards the last device trying to register an already-used address as an IP theft event, potentially resulting in client exclusion.

The **no ip mac-binding** command ensures that no device tracking is done for clients, thus preventing the IP theft error.

Note

- This feature is applicable only for IPv4 addresses.
- Configuring **ip overlap** in FlexConnect Profile assists overlapping IP address support for clients across different sites in FlexConnect local switching.

Restrictions for disabling IP learning in FlexConnect mode

Outlines restrictions for disabling IP learning in FlexConnect mode.

- The **wireless client ip deauthenticate** command works by referring to the IP table binding entries directly. It does not work for client whose IPs are not learnt.
- Overlapping IP addresses within a single site tag and across different site tags require different settings. Furthermore, if a single site tag contains overlapping IP addresses, L3 web authentication is necessary. However, L3 web authentication relies on IP addresses, and ensuring the uniqueness of IP addresses cannot be guaranteed, making this combination incorrect.
- When IP Source Guard (IPSG) is enabled and multiple binding information is sent with the same IP and preference level (such as DHCP, ARP, and so on) to CPP, the CPP starts to ignore the later bindings after the first binding creation. Hence, you should not configure IPSG and disable IP MAC binding together. If IPSG and **no ip mac-binding** are configured together then IPSG does not work.

Disable IP learning in FlexConnect mode

Configure IP learning in FlexConnect mode using CLI commands.

Configure the wireless policy profile to disable IP learning in FlexConnect mode for improved client management.

Disabling IP learning in FlexConnect mode prevents the controller from learning client IP addresses through MAC binding, which can be useful in certain deployment scenarios where IP-MAC binding is not required or causes issues.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the wireless profile policy.

   Example

   ```
   Device(config)# wireless profile policy profile-policy-name
   ```

   Example

   ```
   Device(config)# wireless profile policy test-profile-policy
   ```

3. Disable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

   Disabling the policy profile results in associated AP and client rejoining.

4. Disable IP learning in FlexConnect mode.

   Example

   ```
   Device(config-wireless-policy)# no ip mac-binding
   ```

5. Enable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

6. Exit wireless policy configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

IP learning is disabled in FlexConnect mode, and the wireless policy profile is active.

MAC entry verification from database

Provides instructions to verify MAC entries from the database using the appropriate command.

This reference explains how to verify MAC address details from the database using the relevant CLI command.

To verify the MAC details from database, use the following command:

```
Device# show wireless device-tracking database mac
MAC VLAN IF-HDL IP
-----------------------------------------------------------------------------------------------
6c96.cff2.889a 64 0x90000008 9.9.64.175
```

163 Disabling Device Tracking to Support NAC Devices

Topics:

- Disabling device tracking to support NAC devices

Outlines the considerations and procedures for disabling device tracking to ensure compatibility with Network Access Control devices.

Disabling device tracking to support NAC devices

Explains how disabling device tracking helps control the flow of traffic between wireless clients using a network access control (NAC) device.

A device tracking disablement is a network configuration feature that

- controls the flow of traffic between wireless clients using a network access control (NAC) device
- blocks direct traffic between wireless clients through ARP spoofing, and
- disables wireless client device tracking to support NAC devices.

Command usage for disabling device tracking

Use the **no ip mac-binding** command to enable ARP spoofing from the NAC. This command also disables wireless client device tracking.

> **Note**
>
> You can use this feature only with IPv4 addresses.

Feature history for disable device tracking support for NAC devices

Provides the feature history for disable device tracking support for NAC devices.

This reference provides the release and related information for the feature that disables device tracking to support NAC devices.

Table 143: Feature history for disabling device-tracking to support NAC devices

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.8.1	Disabling Device Tracking to Support NAC Devices	This feature helps to control the flow of traffic between wireless clients using network access control (NAC) device.

Restrictions for disabling device tracking to support NAC devices

Outlines restrictions for disabling device tracking to support NAC devices, including command limitations and unsupported Layer 3 policies. Review these constraints before configuration changes.

Restrictions for disabling device tracking to support NAC devices

- The **wireless client ip deauthenticate** command refers directly to the IP table binding entries. The command does not work if the client's IP address is not learned.
- Layer 3 web authentication and other L3 policies are not supported.
- When IP Source Guard (IPSG) is enabled and multiple binding information with the same address and preference level (such as DHCP or ARP) is sent to Cisco Packet Processor (CPP), the CPP ignores later bindings after creating the first binding. Do not configure IPSG and **no ip mac-binding** together. If you configure IPSG and **no ip mac-binding** together, IPSG does not work.

Disable device tracking for wireless clients (CLI)

Configure the system to disable device tracking for wireless clients using the CLI.

Disable device tracking for wireless clients to prevent the system from monitoring their IP and MAC address bindings.

Device tracking is used to monitor and bind IP and MAC addresses of wireless clients for security and management. Disabling this feature may be required in environments where such tracking is not needed or interferes with network operations.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the wireless profile policy.

   Example

   ```
   Device(config)# wireless profile policy profile-policy-name
   ```

   Example

   ```
   Device(config)# wireless profile policy test-profile-policy
   ```

3. Disable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

   Disabling the policy profile results in associated AP and client to rejoin.

4. Disable the IP-MAC address binding.

   Example

   ```
   Device(config-wireless-policy)# no ip mac-binding
   ```

5. Enable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

6. Exit wireless policy configuration mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

7. Configure a VLAN and enter VLAN configuration mode.

   Example

   ```
   Device(config)# vlan configuration vlan-id
   ```

   Example

   ```
   Device(config)# vlan configuration 20
   ```

8. Enable ARP broadcast on the VLAN.

   Example

   ```
   Device(config-vlan-config)# arp broadcast
   ```

9. Return to privileged EXEC mode.

   Example

   ```
   Device(config-vlan-config)# end
   ```

Device tracking is disabled for wireless clients, and ARP broadcast is enabled on the specified VLAN.

Verify ARP broadcast

Verify ARP broadcast to ensure that the feature is enabled and functioning as expected on the device. Use this procedure to confirm ARP broadcast status for troubleshooting or validation purposes.

Use this task to confirm whether ARP broadcast is enabled on your device. Confirming ARP broadcast helps ensure proper network communication and assists in troubleshooting connectivity issues.

Before you begin

Procedure

Use the **show platform software arp broadcast** command.

Example

```
Device# show platform software arp broadcast
Arp broadcast is enabled on vlans: 20,50
```

This command displays the ARP broadcast status and lists the VLANs where ARP broadcast is enabled.

View the ARP broadcast status and the VLANs on which it is enabled. If troubleshooting is required, proceed to the relevant troubleshooting task.

164 Disabling IP Learning in Local Mode

Topics:

- Disabling IP learning in local mode

Outlines the process and considerations for disabling Internet Protocol learning in local mode, highlighting its impact on network behavior and configuration.

Disabling IP learning in local mode

Explains how disabling IP learning in local mode prevents IP Theft events and client exclusion by stopping device tracking for clients.

A disabling IP learning in local mode feature is a WLAN security mechanism that

- uses the **no ip mac-binding** command to prevent device tracking for clients
- prevents IP Theft errors by ensuring that multiple clients do not register the same IP address, and
- allows downstream broadcast ARP traffic to reach wireless clients in the VLAN when ARP broadcast is enabled and IP MAC binding is disabled.

IP learning prevention in local mode scenarios

Describes how the controller handles IP address conflicts and ARP broadcast traffic in local mode.

Key points about IP learning prevention:

- In local mode central switching, multiple clients may have an allocated or registered IP address.
- If the controller detects more than one client using the same IP address, it discards one client as an IP Theft event, which may result in client exclusion.
- To allow downstream broadcast ARP traffic to reach wireless clients in the VLAN, enable ARP broadcast and disable IP MAC binding.
- The controller replicates broadcast ARP packets to all APs belonging to the controller when Multicast over Multicast (MOM) is disabled.
- To avoid replication, enable MOM.

> **Note**
>
> This feature is applicable only for IPv4 addresses.

Restrictions for disabling IP learning in local mode

Outlines key restrictions you must consider when disabling IP learning in local mode, including command limitations and policy incompatibilities.

Restrictions for disabling IP learning in local mode

- The **wireless client ip deauthenticate** command works by referring to the IP table binding entries directly. It does not work for clients whose IPs are not learnt.
- The L3 web authentication and other L3 policies are not supported.
- When IP Source Guard (IPSG) is enabled and multiple binding information is sent with the same IP and preference level (such as DHCP, ARP, and so on) to CPP, the CPP starts to ignore the later bindings after the first binding creation. Hence, you should not configure IPSG and disable IP MAC binding together. If IPSG and **no ip mac-binding** are configured together then IPSG does not work.

Disable IP learning in local mode (CLI)

Configure IP learning in local mode using CLI commands to control client IP address assignment and ARP broadcast behavior.

Configure the wireless policy profile to disable IP learning in local mode, ensuring proper client IP address handling and ARP broadcast support.

This task is performed when you need to prevent IP address learning for wireless clients in local mode, typically to support downstream ARP broadcast traffic and avoid MAC binding issues.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the wireless profile policy.

   Example

   ```
   Device(config)# wireless profile policy profile-policy-name
   ```

3. Disable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

   Disabling the policy profile results in associated AP and client rejoining.

4. Disable IP learning in local mode.

   Example

   ```
   Device(config-wireless-policy)# no ip mac-binding
   ```

5. Enable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

6. Exit wireless policy configuration mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

7. Configure a VLAN and enter VLAN configuration mode.

Example

```
Device(config-vlan-config)# vlan configuration vlan-id
```

To allow downstream broadcast ARP traffic to reach the wireless client in the VLAN, enable ARP broadcast and disable IP MAC binding.

8. Enable ARP broadcast on the VLAN.

Example

```
Device(config-vlan-config)# arp broadcast
```

9. Return to privileged EXEC mode.

Example

```
Device(config-vlan-config)# end
```

IP learning is disabled in local mode, allowing ARP broadcast traffic to reach wireless clients and preventing MAC binding issues.

Verify MAC entries database

Provides steps to verify MAC entries from the database.

Use the **show wireless device-tracking database mac** command to verify MAC address details stored in the device database.

To verify the MAC details from database, use the following command:

```
Device# show wireless device-tracking database mac
  MAC             VLAN  IF-HDL      IP

------------------------------------------------------------------------------------------

  6c96.cff2.889a  64    0x90000008  9.9.64.175
```

ARP broadcast verification

Provides information about how to verify ARP broadcast.

To verify the ARP broadcast, use the following command.

```
Device# show platform software arp broadcast
Arp broadcast is enabled on vlans:
20,50
```

165 Security-Enhanced Linux

Topics:

- Security-Enhanced Linux

Introduces Security-Enhanced Linux fundamentals and provides essential information about implementing mandatory access controls in Linux environments.

Security-Enhanced Linux

Describes the SELinux enhancement for Cisco IOS XE platforms.

Security-Enhanced Linux (SELinux) is a Linux kernel security solution that

- incorporates a strong, flexible Mandatory Access Control (MAC) architecture into Cisco IOS XE platforms
- provides enhanced mechanisms to enforce information separation based on confidentiality and integrity requirements, and
- confines user programs and system services to minimum privilege required to perform their assigned functionality.

SELinux functionality and modes

SELinux addresses threats of tampering and bypassing of application security mechanisms and enables the confinement of damage that malicious or flawed applications can cause.

SELinux enforces mandatory access control policies that confine user programs and system services to the minimum privilege required to perform their assigned functionality. This reduces or eliminates the ability of these programs and daemons to cause harm when compromised (for example, through buffer overflows or misconfigurations). This is a practical implementation of principle of least privilege by enforcing MAC on Cisco IOS XE platforms. This confinement mechanism works independently of the traditional Linux access control mechanisms. SELinux allows you to define policies to control the access from an application process to any resource object, thereby allowing for the clear definition and confinement of process behavior.

SELinux can operate in two modes when enabled on a system:

- **Permissive Mode**: In Permissive mode, SELinux does not enforce the policy, and only generates system logs for any denials caused by violation of the resource access policy. The operation is not denied, but only logged for resource access policy violation.
- **Enforcing Mode**: In Enforcing mode, the SELinux policy is enabled and enforced. The Enforcing mode denies resource access based on the access policy rules, and generates system logs.

SELinux is enabled in the Enforcing mode by default on supported Cisco IOS XE platforms. In the Enforcing mode, any system resource access that does not have the necessary allow policy is treated as a violation, and the operation is denied. The violating operation fails when a denial occurs, and system logs are generated. In Enforcing mode, the solution works in access-violation prevention mode.

> **Note**
>
> By default, SELinux is in the Enforcing mode.

Configure SELinux in the EXEC mode

Configure SELinux in the EXEC mode using CLI commands.

Enable and configure SELinux security policies in EXEC mode to enhance system security through access controls.

SELinux (Security-Enhanced Linux) provides mandatory access control security mechanisms. This configuration allows you to set SELinux policies in different operational modes including enforcing, permissive, or default settings.

Procedure

1. Enable privileged EXEC mode.

Example

```
Device> enable
```

Enter the password if prompted.

2. Enter global configuration mode.

Example

```
Device# configure terminal
```

3. Enable the internal commands of the network-based services.

Example

```
Device(config)# service internal
```

4. Exit from the global configuration mode.

Example

```
Device(config)# exit
```

5. Configure SELinux in the EXEC mode.

Example

```
Device# set platform software selinux {default | enforcing | permissive}
```

Example

```
Device# set platform software selinux enforcing
```

Available modes are default, enforcing, or permissive.

SELinux is now configured in the specified mode and will apply the appropriate security policies to system operations.

Configure SELinux in the global configuration mode

Configure SELinux policy in the global configuration mode using CLI commands.

This task enables you to set up SELinux security policies on the device to enhance system security through access controls.

SELinux (Security-Enhanced Linux) provides mandatory access controls that can be configured in either enforcing or permissive mode. Use this procedure when you need to establish or modify SELinux security policies on your device.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enable the internal commands of the network-based services.

Example

```
Device(config)# service internal
```

3. Configure SELinux policy.

Example

```
Device(config)# platform security selinux {enforcing | permissive}
```

```
Device(config)# platform security selinux enforcing
```

SELinux is now configured with the specified policy mode. The system will apply the selected security enforcement level to control access to system resources.

Examples for SELinux

Lists the examples for SELinux.

Provides examples of system log output when changing SELinux modes between Enforcing and Permissive states.

This example shows the output for changing the mode from Enforcing to Permissive:

```
"*Oct 20 21:44:03.609: %IOSXE-1-PLATFORM: R0/0: SELINUX_MODE_PROG: Platform
Selinux confinement mode downgraded to permissive!"
```

This example shows the output for changing the mode from Permissive to Enforcing:

```
"*Oct 20 21:44:34.160: %IOSXE-1-PLATFORM: R0/0: SELINUX_MODE_PROG: Platform
Selinux confinement mode upgraded to enforcing!"
```

Note

If you change the SELinux mode, the change is considered as a system security event, and a system log message is generated.

SELINUX syslog message reference

Lists the syslog message references for SELINUX.

Provides reference information for SELINUX syslog messages including message details, explanations, components, and recommended actions for troubleshooting security policy violations.

Facility-Severity-Mnemonic	**%SELINUX-1-VIOLATION**
Severity-Meaning	Alert Level Log
Message	N/A
Message Explanation	Resource access was made by the process for which a resource access policy does not exist. The operation was flagged, and resource access was denied. A system log was generated with information that process resource access has been denied.
Component	SELINUX
Recommended Action	Contact Cisco TAC with these relevant information as attachments: • The exact message as it appears on the console or in the system. • Output of the **show tech-support** command (text file). • Archive of the Btrace files from the box using the following command: **request platform software trace archive target** *URL* • Output of the **show platform software SELINUX** command. • Output of the **show platform software audit all | section exclude** command. • Output of the **show platform software audit summary** command.

These examples display sample syslog messages:

Example 1:

```
*Nov 14 00:09:04.943: %SELINUX-1-VIOLATION: R0/0: audispd: type=AVC
msg=audit(1699927057.934:129): avc: denied { getattr } for pid=5899 comm="ls"

path="/root/test" dev="rootfs" ino=25839
scontext=system_u:system_r:polaris_iosd_t:s0
tcontext=system_u:object_r:admin_home_t:s0 tclass=file permissive=0
```

Example 2:

```
*Nov 14 00:09:04.947: %SELINUX-1-VIOLATION: R0/0: audispd: t type=AVC
msg=audit(1699927198.486:130): avc: denied { write } for pid=6012 comm="echo"

path="/root/test" dev="rootfs" ino=25839
scontext=system_u:system_r:polaris_iosd_t:s0
tcontext=system_u:object_r:admin_home_t:s0 tclass=file permissive= 0
```

Verify count of denials

Provides command to verify the count of denials.

To verify the count of denials, use this command:

```
Device# show platform software audit summary
==================================
AUDIT LOG ON chassis 1 route-processor 0
----------------------------------
AVC Denial count: 6
```

Verify SELinux enablement

Lists the show command and its output for verifying SELinux enablement.

To verify SELinux enablement, use this command:

```
Device# show platform software selinux
=======================================
IOS-XE SELINUX STATUS
=======================================
SElinux Status : Enabled
Current Mode : Enforcing
Config file Mode : Enforcing
```

Part XI

Mobility

Topics:

- Mobility
- NAT Support on Mobility Groups
- Static IP Client Mobility
- Mobility Domain ID - 802.11i Roaming
- 802.11r Support for Flex Local Authentication
- Opportunistic Key Caching

166 Mobility

Topics:

- Mobility

Introduces the fundamental concepts and principles of network mobility, covering essential components and technologies that enable wireless connectivity and device movement across network infrastructures.

Mobility

Introduces mobility functionality including intracontroller, intercontroller, and intersubnet roaming concepts, SDA roaming capabilities, and mobility group configurations for wireless network management.

Mobility, or roaming, is the ability of a wireless LAN client to maintain a seamless and secure connection while moving from one access point to another with minimal latency.

- enables uninterrupted connectivity as clients move between access points,
- relies on controllers to manage client information, including MAC and IP addresses, security context, quality of service (QoS), wireless LAN (WLAN), and associated access point, and
- ensures secure and efficient data forwarding and traffic management for wireless clients.

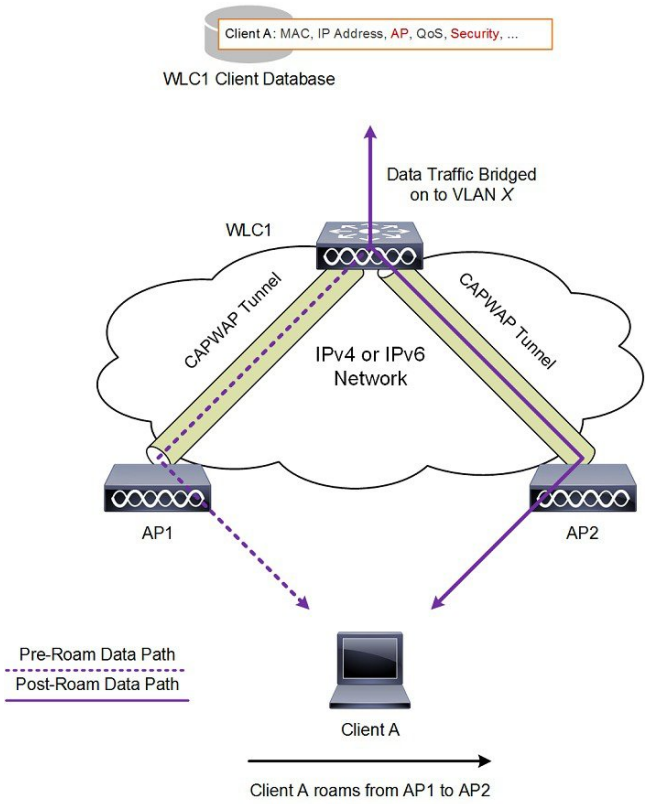
Definitions of mobility-related terms

Key mobility terms in wireless LANs include point of attachment, point of presence, and station.

- Point of Attachment: the location in the network where a station data path is first processed when it enters the network.
- Point of Presence: the point in the network where a station is advertised.
- Station: a device that connects to and requests service from a network.

Intracontroller roaming

Intracontroller roaming refers to the process by which a wireless client moves its association from one access point to another within the same controller. The controller updates the client database and establishes new security context and associations when necessary, enabling seamless connectivity.



A intracontroller roaming is a wireless network mobility process that

- enables a wireless client to move its association from one access point to another within the same controller
- allows the controller to update the client database with the new access point association, and
- maintains or reestablishes the security context and client associations to support uninterrupted connectivity.

Additional information

When a client roams between access points managed by the same controller, the controller simply updates the client database to reflect the client's new association. If required, the controller creates new security contexts and reestablishes associations to maintain connectivity.

Figure 27: Intracontroller roaming

Intracontroller roaming example

A user walking through a building with multiple access points connected to one wireless LAN controller experiences no interruption in service because intracontroller roaming automatically updates the client's association information as the device connects to new access points.

Intercontroller roaming

This concept explains intercontroller roaming events, including how clients transition between controllers, how mobility messages function, security considerations, and important authentication and SDA limitations.

An intercontroller roaming event is a wireless mobility process that provides the following functions:

- occurs when a client moves from an access point managed by one controller to an access point managed by another controller
- exchanges mobility messages between the new and original controllers to update the client database entry, and
- maintains the user network experience, making the handover transparent to the user.

- Mobility messages: specialized communications between controllers that coordinate the handover and update the client database during a roaming event.
- Client database entry: the information each controller stores about a connected client, such as security context, session details, and access point association.

Expanded explanation

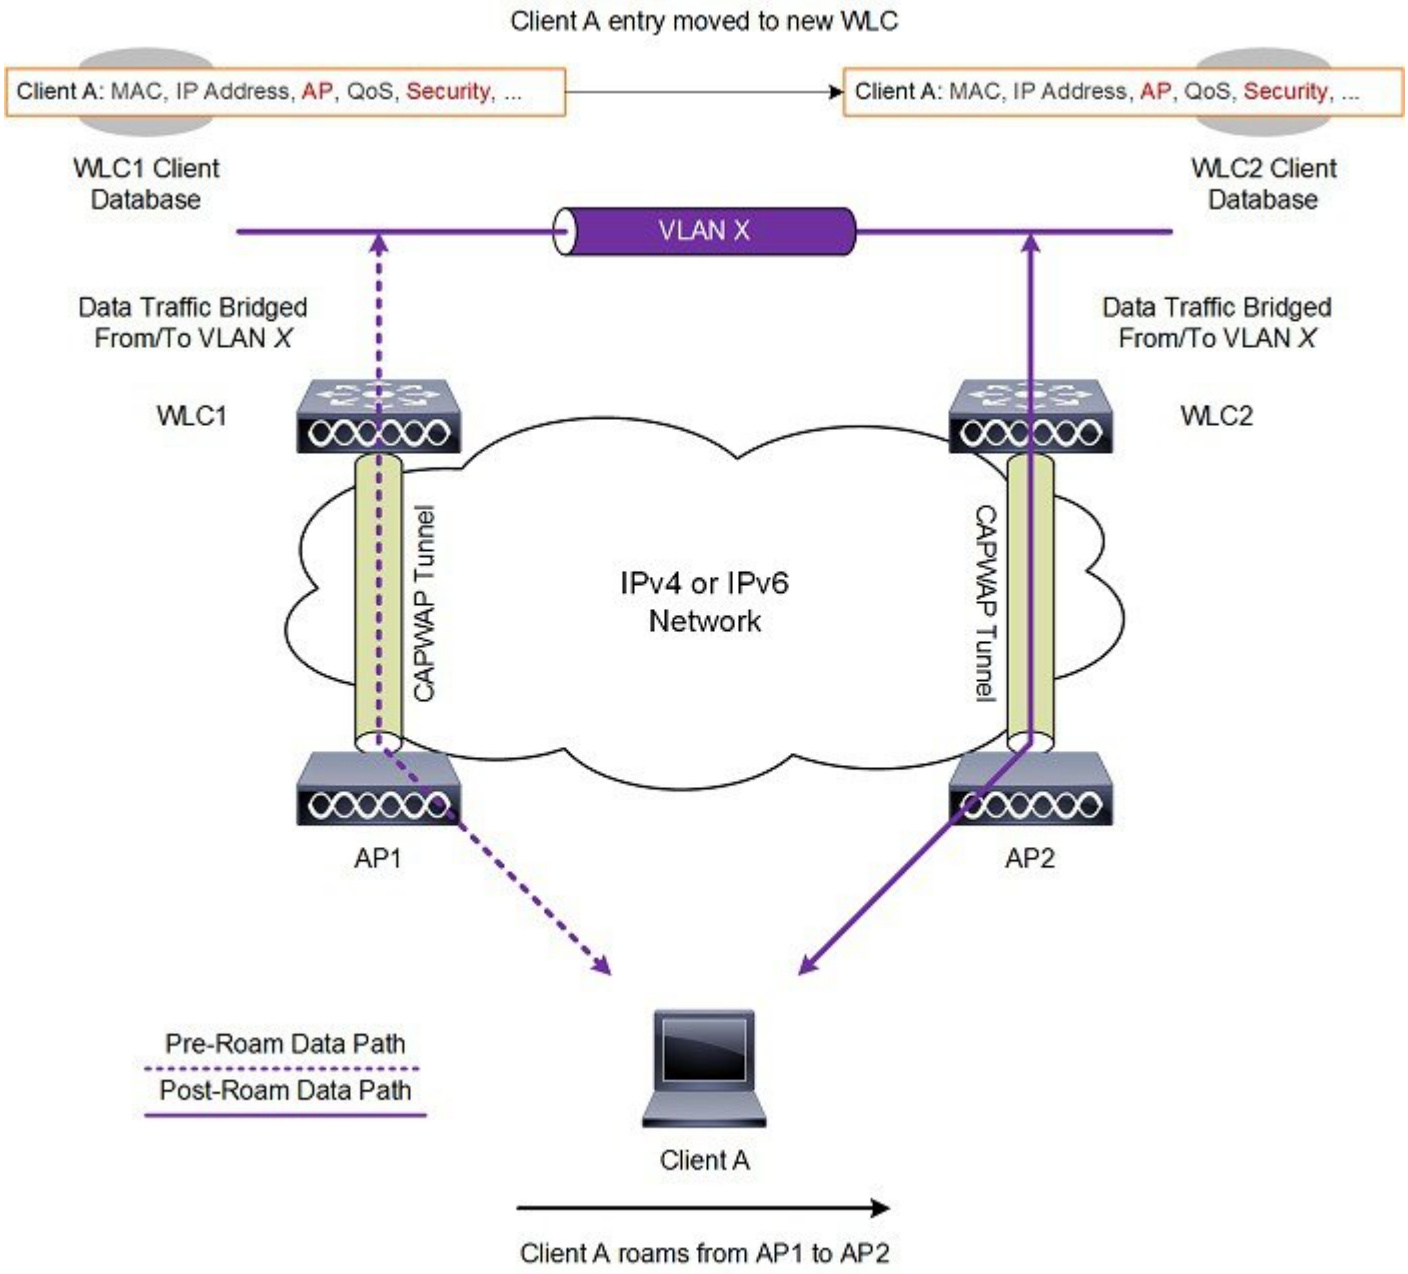
When a client device joins an access point managed by a new controller, the new controller exchanges mobility messages with the previous controller.

These messages transfer the client session information and database entry from the original controller to the new controller. The system establishes new security contexts and associations as needed.

The system updates the client database entry to reflect the new access point and controller location. This process occurs in the background and appears seamless to the user.

Note

Clients configured with 802.1X or Wi-Fi Protected Access (WPA) security complete full authentication to comply with IEEE standards.



Important

Intersubnet roaming is not supported for Software-Defined Access (SDA).

Intercontroller roaming examples

A user with a mobile device walks from one building to another on a campus network. The device switches from an access point managed by Controller A to one managed by Controller B. The client remains connected and active while the controllers complete the roaming event.

The figure shows intercontroller roaming, which occurs when wireless LAN interfaces on controllers are on the same IP subnet.

Intersubnet roaming

Learn how intersubnet roaming works in wireless LAN environments, including controller roles, client mobility behavior, and required network conditions.

An intersubnet roaming event is a wireless network mobility process that provides the following functions:

- allows wireless clients to move seamlessly between controllers on different IP subnets
- keeps the original client IP address after roaming
- uses anchor and foreign controller roles to maintain and track the client session across controllers
- Anchor controller: the original controller where the client is first authenticated and where session anchoring remains, maintaining the primary client database entry.

- Foreign controller: the new controller to which the client connects after roaming, which receives a copy of the client database entry marked as a foreign entry.

Expanded explanation

Intersubnet roaming is similar to intercontroller roaming because controllers exchange mobility messages when a client roams. Instead of transferring the client database entry to the new controller, the original controller marks the client with an anchor entry in its client database.

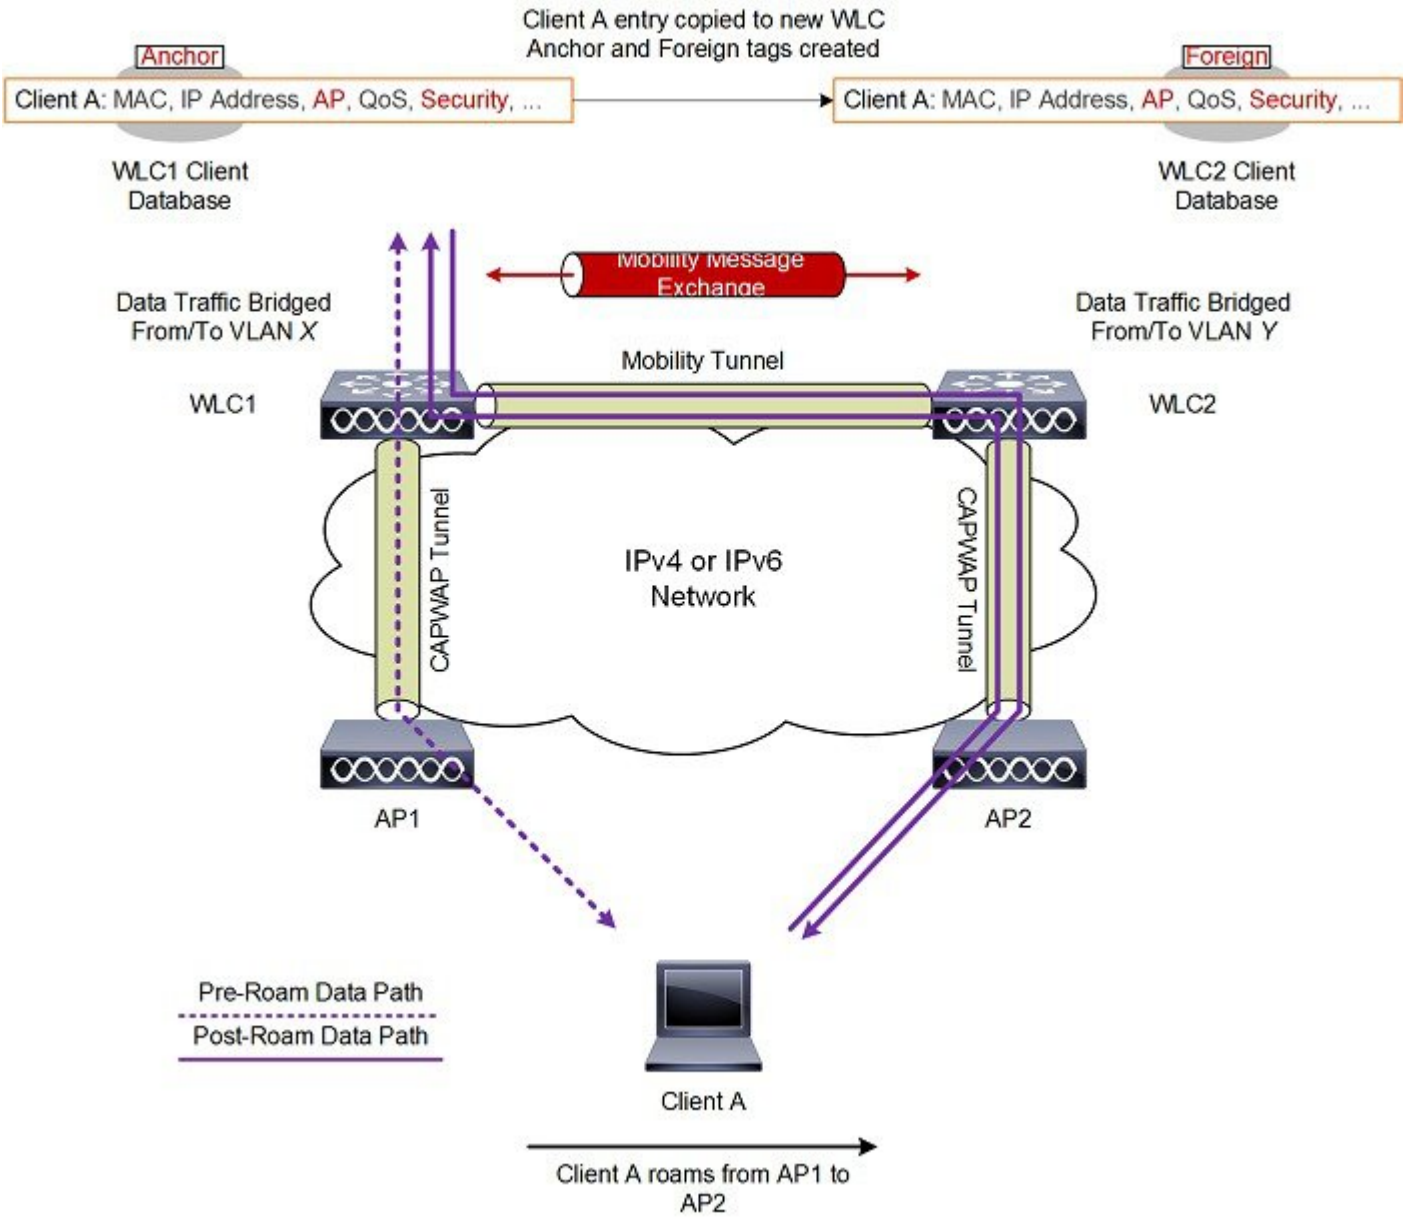
The system then copies the database entry to the new controller and marks it as a foreign entry. This process keeps the roam transparent to the wireless client and preserves the original IP address.

WLANs on both the anchor and foreign controllers must provide the same network access privileges.

Ensure that source-based routing and source-based firewalls are not configured. If they are present, clients may experience network connectivity issues after the handoff.

Additional reference information

In static anchor setups that use controllers and a RADIUS server, the following applies:



- If AAA override dynamically assigns VLAN and QoS, the foreign controller updates the anchor controller with the correct VLAN after Layer 2 authentication (802.1X).
- For Layer 3 RADIUS authentication, the anchor controller sends authentication requests.

> **Note**
>
> The Cisco Catalyst 9800 Series Wireless Controller mobility tunnel is a CAPWAP tunnel with a control path (UDP 16666) and a data path (UDP 16667). The control path uses DTLS encryption by default. You can enable DTLS on the data path when you add the mobility peer.
>
> The supported DTLS version is 1.2.

Intersubnet roaming example

This figure shows intersubnet roaming, which occurs when wireless LAN interfaces on controllers are located on different IP subnets.

Figure 28: Intersubnet roaming

SDA roaming

Learn how SDA roaming types keep wireless clients connected when they move between access points in a software-defined access (SDA) fabric. This section explains intra-xTR and inter-xTR roaming and how client location tables and data tables are updated during roaming events.

SDA roaming types keep wireless clients connected as they move across access points in a software-defined access (SDA) network. SDA roaming:

- keeps wireless clients connected within the fabric as they move across access points
- supports both intra-xTR events—within the same access switch—and inter-xTR events—across different access switches
- updates key system tables—local client database, client history table, and map server where applicable—for accurate client location tracking and ongoing connectivity
- SDA (software-defined access): An architecture that uses centralized control to automate and secure network operations across wired and wireless endpoints.

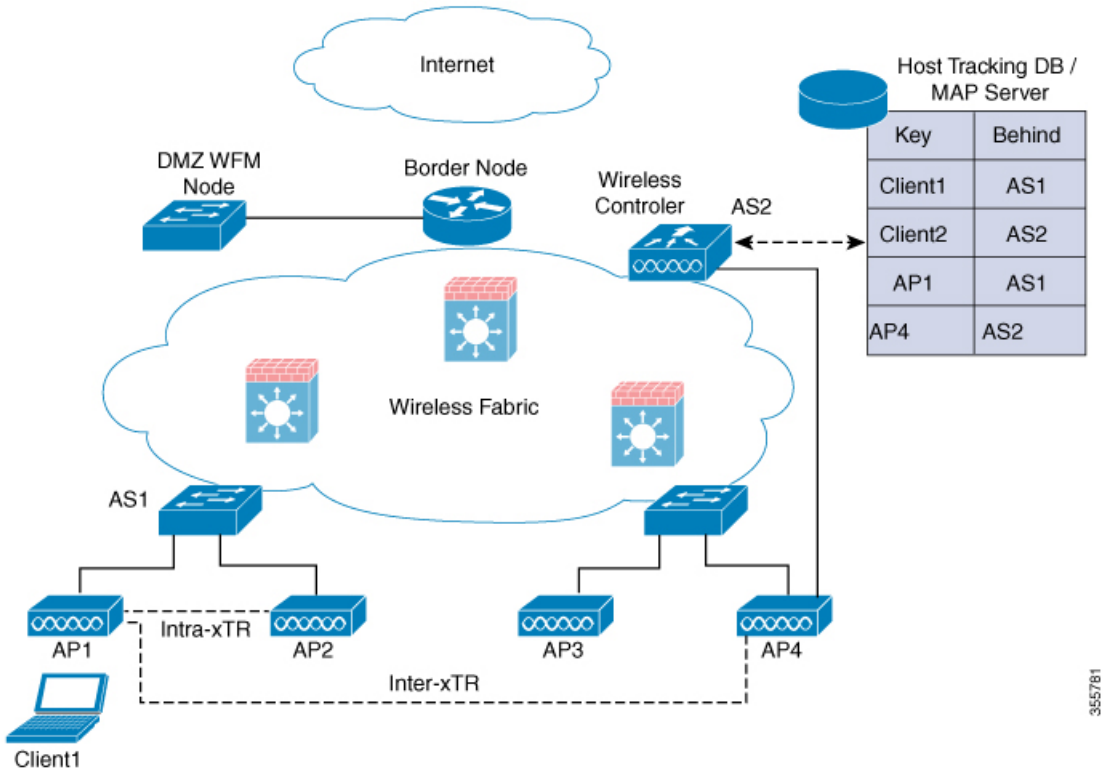
- xTR (tunnel router): In SDA, an xTR is an access switch that acts as both an ingress tunnel router and an egress tunnel router. It serves as a fabric edge node responsible for client mobility and traffic tunneling.

Expanded explanation

This section describes the two principal types of SDA roaming events:

- Intra-xTR roaming happens when your client moves between access points attached to the same access switch (xTR) in an SDA fabric-enabled WLAN. The system updates the local client database and client history table with the new access point information.
- Inter-xTR roaming happens when your client moves to an access point attached to another access switch (xTR) within the fabric. The system updates the local client database and the map server with the new location (RLOC) to show which switch the client is now using.

Note



- During intra-xTR events, the access switch updates only its internal tables.
- During inter-xTR events, the switch and the map server update their tables so the client session continues without interruption.

SDA roaming example

When a wireless client roams from Access Point A to Access Point B, both connected to the same access switch, the client experiences an intra-xTR roaming event. Only local tables are updated.

When the client moves from Access Point A to Access Point C on another access switch, the system initiates an inter-xTR roaming event. It updates both the local client database and the central map server with the new location.

The figure shows intra-xTR and inter-xTR roaming. This occurs when the client moves between access points on the same switch or on different switches in a fabric topology.

Mobility groups

This concept explains how mobility groups enable seamless roaming for wireless clients by coordinating multiple controllers within the same network realm.

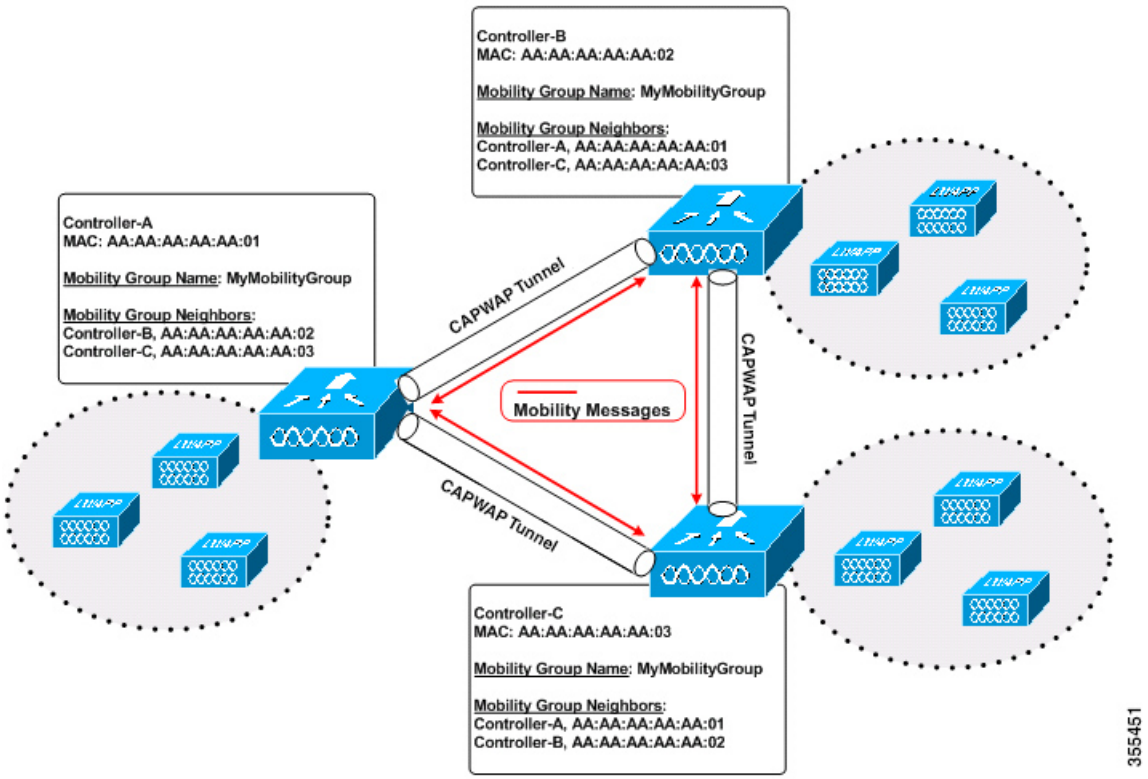
A mobility group is a wireless controller configuration that

- defines a set of controllers identified by the same mobility group name
- enables seamless roaming and state and context sharing for wireless clients, and
- allows controllers to dynamically forward data traffic and share the list of access points.

By creating a mobility group, multiple controllers in a network dynamically share information and forward data traffic when inter-controller or inter-subnet roaming occurs.

Controllers in the same mobility group share the context and state of client devices and their list of access points. This prevents controllers from identifying access points from other controllers as rogue devices. With this shared information, the network supports inter-controller wireless LAN roaming and controller redundancy.

When an access point (AP) moves from one controller to another, and both controllers are mobility peers, a client associated with controller 1 before the move might remain anchored to controller 1 after the move.



Controller 1 maintains the client entry for a timeout period to support roaming and reassociation scenarios. To prevent a client from remaining anchored to controller 1 after such a move, remove the mobility peer configuration from that controller.

> **Note**
>
> A mobility group can contain up to 24 members, while a mobility list can include up to 72 entries.

Example of a single mobility group

The figure shows that each controller is configured with a list of the other mobility group members.

Whenever a new client joins a controller, the controller sends a unicast message, or a multicast message if mobility multicast is configured, to all controllers in the mobility group. The controller that previously managed the client passes the client status to the new controller.

Supported platforms

Details platform support for mobility features, outlines guidelines and restrictions on mobility implementation, and specifies inter-release controller mobility supported platforms.

Lists the AireOS wireless controllers, Catalyst 9800 wireless controllers, and Catalyst switch platforms supported by the solution.

Review this list to confirm your device models are supported for integration and management.

Supported AireOS wireless controllers

- Cisco 3504 Wireless Controller
- Cisco 5520 Wireless Controller
- Cisco 8540 Wireless Controller

Supported Catalyst 9800 Wireless controllers

- Catalyst 9800-CL (Cloud Wireless Controller)
- Cisco Catalyst 9800-80 Wireless Controller
- Cisco Catalyst 9800-40 Wireless Controller
- Cisco Catalyst 9800-L Wireless Controller

Supported switch platforms

- **Catalyst switches**
  - Cisco Catalyst 9300 Switch
- **Catalyst 9800 controllers**
  - Catalyst 9800-CL (Cloud Wireless Controller)
  - Cisco Catalyst 9800-40 Wireless Controller

Guidelines and restrictions

This topic explains the guidelines and restrictions for mobility, including supported platforms, configuration requirements, and operational considerations for SDA Inter-Controller Mobility.

SDA Inter-Controller Mobility enables seamless client roaming across compatible Cisco wireless controllers and switch platforms. This topic describes supported hardware, operational requirements, and restrictions.

- Data DTLS Configuration: Ensure that the data DTLS configuration on Catalyst 9800 and AireOS controller platforms is identical. If the configurations do not match, the system disables the mobility data path.
- Layer 3 Roaming: In intercontroller roaming scenarios, policy profiles with different VLANs are supported for Layer 3 roaming.
- L3 Override in Guest VLANs: L3 override is not supported in guest VLANs on AireOS controllers. Trigger DHCP Discovery manually on the new VLAN because clients do not trigger it automatically.
- Policy Profile and VLAN Flexibility: Controllers that use the same WLAN profile can have different policy profile names and client VLANs.
- Intracontroller Roaming: Roaming is supported between identical policy profiles with the WLAN mapped within a single controller.

  Starting with Cisco IOS XE Amsterdam 17.3.x, seamless roaming is supported between the same WLAN associated with different policy profiles. For more information, see the Client Roaming Policy Profile feature.
- Web Authentication Roaming: If a client roams while in web authentication state, the system treats the client as a new client on the other controller rather than as a mobile client.
- DHCP Server Consistency: Mobility peer controllers must use the same DHCP server to maintain client mobility move counts on intra-VLAN.
- Data DTLS and Server Security Chip (SSC) Hash Key: Data DTLS and SSC hash key values must be identical for mobility tunnels established between controller members.
- Mobility Move Count: The system updates the move count under client details only during inter-controller roaming. For intra-controller roaming, verify the value under client statistics and mobility history.
- VLAN Mapping Differences: The Anchor VLAN on Catalyst 9800 controllers corresponds to the Access VLAN on Cisco AireOS controllers.

- Mobility Role State for Roaming Clients: Roaming clients may appear with the *Unknown* mobility role because clients in the *IP learn* state can experience frequent additions and deletions.
- WLAN Profile Mismatch: In inter-controller roaming between Catalyst 9800 and Catalyst 9800 or AireOS controllers, client roaming is not supported if there is a WLAN profile mismatch.
- IPv4 Tunnel Only: Only IPv4 tunnels are supported between Catalyst 9800 and Cisco AireOS controllers.
- High Availability Configuration: In High Availability scenarios, configure the mobility MAC address explicitly by using the `wireless mobility mac-address` command to ensure that the mobility tunnel remains up after Stateful Switchover (SSO).
- Certificate and Trustpoint Limitation: Use RSA-based certificates or RSA-based trustpoints for wireless management. Mobility tunnels do not support ECDSA-based certificates or ECDSA-based trustpoints.
- Layer 2 and Layer 3 Topology Warning: Connecting Anchor controllers and Foreign controllers in the same Layer 2 network and over a Layer 3 mobility tunnel creates a loop topology. This configuration may trigger a MAC_CONFLICT warning message each minute. The warning does not impact functionality or performance. Use a VLAN other than the management VLAN as the client VLAN.
- Tunnel Reset and Stateful Switchover (SSO): The mobility tunnel reestablishes if Stateful Switchover (SSO) is triggered due to a gateway check failure.
- AP Slot 2 and Neighbor Reporting: If the current AP has a 5 GHz slot 2 radio operating on Layer 2 or Layer 3 mobility, the WLAN BSSID is added only to the 802.11k or 802.11v neighbor information. When radio property information from APs on other controllers is unavailable, the AP uses its own radio properties.

  If the AP does not have a slot 2 radio, other APs cannot be added as neighbors. If validation fails, the system does not add that radio to the neighbor list.
- Keepalive Values Recommendation: Use the default keepalive count and interval values to reduce convergence time when setting up mobility tunnels between AireOS and Catalyst 9800 controllers.
- Client Join Times: When the mobility tunnel is up and mobility peers are configured, a new client may take up to 3 seconds to join. The system sends 3 mobile messages, 1 second apart, to verify whether the client is already part of the network.

Inter-release controller mobility supported platforms

This section lists the platforms, software versions, feature compatibility, and restrictions for Inter-Release Controller Mobility (IRCM) on Cisco Wireless Controllers.

The Inter-Release Controller Mobility (IRCM) feature is supported on these Cisco Wireless Controllers.

Cisco Catalyst 9800 series

- All Cisco Catalyst 9800 Series Wireless Controller platforms running Cisco IOS XE Software version 16.10.1 or later.
- By design, Cisco Catalyst 9800 Wireless Controllers do not include the Primary Mode configuration in the Discovery Response. The controller always sends the Discovery Response with Primary Mode enabled.

Cisco AireOS wireless controllers

- Supported AireOS Wireless Controllers running the AireOS 8.5.14x.x IRCM image based on the 8.5 maintenance release software include:
  - Cisco 3504 Wireless Controller
  - Cisco 5508 Wireless Controller
  - Cisco 5520 Wireless Controller

  - Cisco 8510 Wireless Controller
  - Cisco 8540 Wireless Controller
- Supported AireOS Wireless Controllers running AireOS 8.8.111.0 and later include:
  - Cisco 3504 Wireless Controller
  - Cisco 5520 Wireless Controller
  - Cisco 8540 Wireless Controller

Unsupported AireOS wireless controllers

You cannot use the IRCM feature on these Cisco AireOS Wireless Controllers:

- Cisco 2504 Wireless Controller
- Cisco Flex 7510 Wireless Controller
- Cisco WiSM 2

Recommended configuration for IRCM deployments

- Configure both Cisco AireOS and Cisco Catalyst 9800 Series Controllers as static RF leaders to avoid RF grouping between them.
- Configure the same RF network name on both controllers.

AireOS 9800 virtual controllers: hash command and data tunnel encryption

- If the peer Cisco Catalyst 9800 Series Wireless Controller is virtual, configure the hash using this command:

```
config mobility group member hash 172.20.227.73
3f93a86cee2039e9c3aada1822ad74b89fea30c1
```

- Enable or disable data tunnel encryption using this command:

```
config mobility group member data-dtls 00:0c:29:a8:d5:77 enable or disable
```

- Run this command on the Cisco Catalyst 9800 Series Wireless Controller to obtain the hash:

```
show wireless management trustpoint
Trustpoint Name : ewlc-tp1
Certificate Info : Available
Certificate Type : SSC
Certificate Hash : 3f93a86cee2039e9c3aada1822ad74b89fea30c1
Private key Info : Available
```

Platform and feature limitations

- IPv6 is not supported for Software Defined Access (SDA) IRCM fabric client roaming.
- IPv6 is supported for nonfabric IRCM client roaming.
- Ensure that AireOS controllers support the Encrypted Mobility feature.
- Application Visibility and Control (AVC) is not supported for IRCM.
- In mixed deployments that include Catalyst 9800 and AireOS controllers, use the same name for the WLAN profile and the policy profile. AireOS does not recognize the policy profile and uses the WLAN name for both profiles.
- Mobility group multicast is not supported because AireOS does not support mobility multicast in encrypted mobility.

- Disable Link Local bridging on the peer AireOS controller.
- IRCM is not supported in FlexConnect or FlexConnect+Bridge modes.
- If the client roaming rate is very high, the displayed client count may exceed the supported roaming scale. This occurs because the system requires time to update records. A client that appears on multiple WNCDs for a short time may be counted more than once. Wait for the system to stabilize before you verify client counts using show CLIs, WebUI, Cisco DNA Center, or SNMP.

IPv6 feature support between controllers

The following features support IPv6 client mobility between AireOS controllers and Catalyst 9800 controllers:

- Accounting
- Layer 3 security (Webauth)
- Policy (ACL and QoS)
- IP address assignment and learning through SLAAC and DHCPv6
- IPv6 Source Guard
- Multiple IPv6 address learning
- IPv6 multicast
- SISF IPv6 features include:
  - RA Guard
  - RA Throttling
  - DHCPv6 Guard
  - ND Suppress

These IPv6 features are not supported on Catalyst 9800 controllers:

- Configurable IPv6 timers
- RA Guard enabled on access points
- Global IPv6 disable
- IPv6 Central Web Authentication (CWA)
- More than eight IPv6 addresses per client

Configure the mobility feature (GUI)

Provides instructions for configuring mobility through GUI and CLI interfaces, including inter-release controller mobility setup and mobility peer configuration procedures.

Configure wireless controller mobility features to support seamless roaming and redundancy.

Procedure

1. Choose **Configuration** > **Wireless** > **Mobility**.
   The **Wireless Mobility** page appears, where you can perform global configuration and peer configuration.
2. In the **Global Configuration** section, perform these tasks:

a) Enter a name for the mobility group.
b) Enter the multicast IP address for the mobility group.
c) In the **Keep Alive Interval** field, specify how many times to send a ping request to a mobility list member before marking the member unreachable. The valid range is 3 to 20 seconds, and the default value is 3 seconds.
d) Specify the time, in seconds, between ping requests to a mobility list member in the **Mobility Keep Alive Count** field. The valid range is 1 to 30 seconds.
e) Enter the Differentiated Services Code Point (DSCP) value for the mobility group.
f) Enter the mobility MAC address.
g) Click **Apply**.

3. In the **Peer Configuration** tab, perform these tasks:
   a) In the **Mobility Peer Configuration** section, click **Add**.
   b) In the **Add Mobility Peer** window that is displayed, enter the MAC address and IP address for the mobility peer. The MAC address can be in *xx:xx:xx:xx:xx:xx*, *xx-xx-xx-xx-xx-xx*, or *xxxx.xxxx.xxxx* format.
   c) If NAT is used, enter the optional public IP address for the NAT-ed address of the mobility peer. If NAT is not used, the device displays the direct IP address of the mobility peer.
   d) Enter the mobility group to which you want to add the mobility peer.
   e) Select the required status for **Data Link Encryption**.
   f) Specify the **SSC Hash** as required.

      Secure Socket Communications (SSC) hash is required if the peer is a Cisco Catalyst 9800-CL Wireless Controller, which uses a self-signed certificate. In this case, the SSC hash provides additional validation. SSC hash is not required if the peer is an appliance because appliances have manufacturing installed certificates (MIC) or device certificates installed in the hardware.

   g) Click **Save & Apply to Device**.
   h) In the **Non-Local Mobility Group Multicast Configuration** section, click **Add**.
   i) Enter the mobility group name.
   j) Enter the multicast IP address for the mobility group.
   k) Click **Save**.

The controller applies the mobility group configuration and peer configuration, enabling mobility features for wireless devices.

Configure the mobility group (CLI)

Learn how to configure a mobility group and related parameters using CLI commands on your device.

Use this task to configure a mobility group and related parameters using CLI commands on a network device.

Procedure

---

1. Create a mobility group named **`Mygroup`**.

   Example

   ```
   Device(config)# wireless mobility group name Mygroup
   ```

2. Configure the MAC address used in mobility messages.

   Example

   ```
   Device(config)# wireless mobility mac-address mac-addr
   ```

3. Optional: Configure the mobility intercontroller DSCP value.

   Example

   ```
   Device(config)# wireless mobility dscp value-0-to-63
   ```

4. Optional: Configure the interval between two keepalives sent to a mobility member.

   Example

   ```
   Device(config)# wireless mobility group keepalive interval time-in-seconds
   ```

   The valid range is from 1 to 30 seconds.

   > **Note**
   >
   > For controllers connected through mobility tunnels, ensure that both controllers use the same keepalive interval value.

5. Optional: Configure the number of keepalive retries before a member status is set to DOWN.

   Example

   ```
   Device(config)# wireless mobility group keepalive count count
   ```

6. Add a peer IPv4 or IPv6 address to a specific group. Use one of the following options to configure IPv4 or IPv6:

   - **wireless mobility mac-address** *mac-address* **ip** *peer-ip-address* **group** *group-name* **data-link-encryption**
   - **wireless mobility mac-address** *mac-address* **ip** *peer-ip-address* **public-ip** *public-ip-address* **group** *group-name*

   Example

   ```
   Device(config)# wireless mobility mac-address 001E.BD0C.5AFF ip 9.12.32.10
   group test-group data-link-encryption
   ```

   ```
   Device(config)# wireless mobility mac-address 001E.BD0C.5AFF ip fd09:9:2:49::55
    public-ip fd09:9:2:49::55 group scalemobility
   ```

   Use the **no** form of this command to remove the peer from the local group.

7. Configure a multicast IPv4 or IPv6 address for a local or nonlocal mobility group.

   - **wireless mobility multicast** { **ipv4** | **ipv6** } *ip-address*
   - **wireless mobility group multicast-address** *group-name* { **ipv4** | **ipv6** } *ip-address*

> **Note**
>
> **Mobility Multicast** – The controller sends a multicast message instead of a unicast message to all members in the local or nonlocal mobility group when a client joins or roams.

Example

```
Device(config)# wireless mobility multicast ipv4 224.0.0.4
```

This command sets the multicast IPv4 address to 224.0.0.4 for a local mobility group.

Example

```
Device(config)# wireless mobility group multicast-address Mygroup ipv4
224.0.0.5
```

This command sets the multicast IPv4 address to 224.0.0.5 for a nonlocal mobility group.

The mobility group and related parameters are configured. Mobility services are enabled across controllers in the network.

Configure inter-release controller mobility (GUI)

Learn how to configure inter-release controller mobility using the graphical user interface (GUI) to set mobility group parameters and apply the configuration.

Configure inter-release controller mobility so devices can move between controllers running different software releases.

Configure this feature when you want to support mobility between controllers that run different software versions in your wireless infrastructure.

Procedure

---

1. Choose **Configuration** > **Wireless** > **Mobility** > **Global Configuration**.
2. Enter values for the following fields: **Mobility Group Name**, **Multicast IPv4 Address**, **Multicast IPv6 Address**, **Keep Alive Interval (sec)**, **Mobility Keep Alive Count**, **Mobility DSCP Value**, and **Mobility MAC Address**.
3. Click **Apply**.

Inter-release controller mobility is now enabled.

Configure inter-release controller mobility (CLI)

Learn how to configure inter-release controller mobility (IRCM) to enable seamless mobility and wireless services between controllers running different software releases, such as Cisco AireOS and Cisco IOS XE.

Inter-Release Controller Mobility (IRCM) provides features that allow controllers running different software releases to work together.

IRCM enables seamless mobility and wireless services between controllers running Cisco AireOS and Cisco IOS XE. For example, you can configure mobility between a Cisco 8540 WLC and Cisco Catalyst 9800 Series Wireless Controller. Supported features include Layer 2 roaming, Layer 3 roaming, guest access, and guest termination.

> **Note**
>
> To configure IRCM for different combinations of AireOS and Catalyst 9800 controllers, see the Cisco Catalyst 9800 Wireless Controller-AireOS IRCM Deployment Guide.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Add a peer IPv4 or IPv6 address to a specific group. You can configure IPv4 or IPv6 using one of the following options:

   - **wireless mobility group member mac-address** *mac-address* **ip** *peer-ip* **group** *group-name* **data-link-encryption**
   - **wireless mobility group member mac-address** *mac-address* **ip** *peer-ip-address* **public-ip** *public-ip-address* **group** *group-name*

   Example

   ```
   Device(config#) wireless mobility group member mac-address 001E.BD0C.5AFF ip
    9.12.32.10 group test-group data-link-encryption
   ```

   ```
   Device(config#) wireless mobility group member mac-address 001E.BD0C.5AFF ip
    fd09:9:2:49::55 public-ip fd09:9:2:49::55 group scalemobility
   ```

   Use the **no** form of this command to remove the peer from the local group.

3. Add a name for the local group.

   Example

   ```
   Device(config#) wireless mobility group name group-name
   ```

   The default local group name is "default".

4. Optional: Configure the MAC address used in mobility messages.

   Example

   ```
   Device(config#) wireless mobility mac-address mac-address
   ```

5. Add a peer to the local group.

Example

```
Device(config#) wireless mobility group member ip peer-ip
```

Use the **no** form of this command to remove the peer from the local group.

6. Optional: Configure the Differentiated Services Code Point (DSCP) value.

Example

```
Device(config#) wireless mobility dscp dscp-value
```

The default value is 48.

7. Configure the mobility control and data path keepalive count.

Example

```
Device(config#) wireless mobility group keepalive count count
```

The default value is 3.

8. Configure the mobility control and data path keepalive interval.

Example

```
Device(config#) wireless mobility group keepalive interval interval
```

The default value is 10.

> **Note**
>
> Ensure that both controllers use the same keepalive interval value when they are connected through mobility tunnels.

After you configure IRCM, wireless client mobility and service continuity are enabled across Cisco AireOS and Cisco IOS XE controllers in the specified mobility group.

Verify mobility

Explains monitoring procedures and commands for tracking mobility operations and performance across wireless network infrastructure.

To display the summary of the mobility manager, use this command:

```
Device# show wireless mobility summary
```

To display mobility peer information, use this command:

```
Device# show wireless mobility peer ip 10.0.0.8
```

To display the list of access points known to the mobility group, use this command:

```
Device# show wireless mobility ap-list
```

To display statistics for the mobility manager, use this command:

```
Device# show wireless stats mobility
Mobility event statistics:

```

To display mobility information of the client, use this command:

```
Device# show wireless client mac-address 00:0d:ed:dd:35:80 detail
```

To display roaming history of the active client in the subdomain, use this command:

```
Device# show wireless client mac-address 00:0d:ed:dd:35:80 mobility history
```

To display client-specific statistics for the mobility manager, use this command:

```
Device# show wireless client mac-address 00:0d:ed:dd:35:80 stats mobility
```

To verify whether intercontroller roam is successful, use these commands:

- **show wireless client mac** *mac-address* **detail**: (on the roamed-to Controller) Displays the roam type as L2 and the roam count is incremented by 1.
- **show wireless client summary** : (on the roamed-from controller) The client entry will not be there in the output.

Verify SDA Mobility

To verify whether intracontroller, intra-xTR roam is successful, use these commands:

- **show wireless client summary**: Displays the new AP if the client has roamed across the APs on the same xTR.
- **show wireless client mac** *mac-address* **detail**: Displays the same RLOC as before the roam.

To verify whether intracontroller, inter-xTR roam is successful, use these commands:

- **show wireless fabric client summary**: Displays the new AP if the client has roamed across the APs on a different xTR.
- **show wireless client mac** *mac-address* **detail**: Displays the RLOC of the new xTR to which the client has roamed to.

To check client status before and after intracontroller roaming, perform these steps:

1. Check if client is on the old AP, using **show wireless client summary** command on the controller.
2. Check whether the client MAC is listed against the old AP, using **show mac addr dyn** command on the xTR1.
3. Check whether the client IP is registered from current xTR1, and client MAC is registered from both current xTR1, and WLC1, using **show lisp site detail** command on the MAP server.
4. After the intra-WLC roam, check whether the client is on the new AP, using the **show wireless client summary** and **show mac addr dyn** commands on the WLC1 and xTR1.
5. After the Inter-xTR Roam (old and new APs on different xTRs), check whether the client is on the new AP (connected to the new xTR2), using the **show wireless client summary** and **show mac addr dyn** commands on the WLC1 and xTR2.
6. Check whether the client is registered from the new xTR2, using the **show lisp site detail** command on the MAP server.

Verify roaming on MAP werver for SDA

Run this command on the MAP server, before and after the roam, to check whether the client IP is registered from current xTR, and client MAC is registered from both current xTR, and WLC.

```
Device# show lisp site detail
```

167 NAT Support on Mobility Groups

Topics:

- NAT support for mobility groups

Explains how to configure Network Address Translation support for wireless mobility groups to enable seamless client roaming across different network segments.

NAT support for mobility groups

This concept explains how Network Address Translation (NAT) supports mobility tunnels between peer controllers in a mobility group, including scenarios in which one or both controllers are located behind a NAT device.

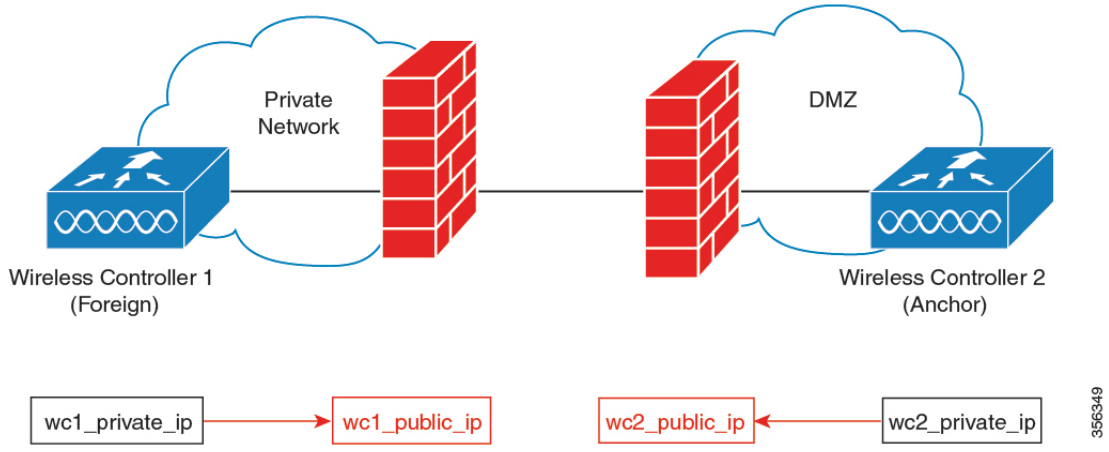
NAT support for mobility groups is a mobility architecture enhancement that

- enables mobility tunnels between peer controllers, even when one or both peers operate behind a NAT device,
- translates public and private IP addresses to maintain connectivity between controllers, and
- requires proper configuration of both addresses for NAT peers to ensure seamless mobility communication.

Additional information

Depending on the placement and number of NAT devices, translation might be required at one or both ends of the tunnel.

When you configure a NAT mobility peer, configure both the private IP address (the address used inside the network before the NAT device) and the public IP address (the address visible on the external network).



If a firewall is present between mobility group controllers, ensure that the following ports are accessible:

- Port 16666 for mobility control messages
- Port 16667 for mobility data messages

> **Note**
>
> Ensure that ports 16666 and 16667 are accessible through any firewalls between peer controllers.

This figure illustrates how public and private IP addresses are translated to establish a mobility tunnel between controllers behind NAT devices.

Figure 29: Mobility NAT

Restrictions for NAT support on mobility groups

Adhere to these restrictions when configuring NAT support on mobility groups to ensure proper controller peer connectivity and client roaming functionality.

- Only one-to-one (static) NAT entries entries can exist for the controller peers that form the mobility tunnels.
- Configuring multiple peers with the same public IP address is not supported.
- Private IP addresses of the configured peers must be unique.
- Port Address Translation (PAT) is not supported.
- If peer controllers of different types, for example, Cisco AireOS and Cisco Catalyst 9800 Series, are placed behind NAT, Inter-Release Controller Mobility (IRCM) is not supported for client roaming.
- IPv6 address translation is not supported.

Functionalities supported on mobility NAT

This topic explains the functionalities supported on mobility NAT, including supported controllers, features, and application compatibility.

This topic lists the functionalities supported on mobility NAT.

Two controllers, with the foreign controller behind a NAT device (1to1 NAT only)	Yes
Two controllers, with the anchor controller behind a NAT device (1to1 NAT only)	Yes
Two controllers, with the anchor and foreign controller behind a NAT device (1to1 NAT only)	Yes
Multiple foreign and anchor controllers behind NATs (1to1 NAT only)	Yes
Supported Cisco Catalyst 9800 Series Wireless Controllers	• Cisco Catalyst 9800-40 Wireless Controller • Cisco Catalyst 9800-80 Wireless Controller • Catalyst 9800 Wireless Controller for Cloud • Cisco Catalyst 9800-L Wireless Controller
Number of peers supported	72
Manageability using SNMP, Yang, and web UI	Yes
IRCM support for mobility	Yes
SSO	Yes
Client roaming (Layer 2 and Layer 3) between Cisco Catalyst 9800 Series Wireless Controllers	Yes
Client roaming (Layer 2 and Layer 3) between Cisco Catalyst 9800 Series Wireless Controller and AireOS controller	No

Supported applications on the mobility tunnel	• Native profiling • AP list • PMK cache • Mesh AP

Configure a mobility peer (CLI)

Configure a mobility peer by using the CLI to add a peer with a required private IP address and an optional public IP address.

Add a mobility peer to your wireless controller by specifying a required private IP address and, if needed, an optional public IP address using the CLI.

Before you begin

Ensure that both the private and public IP addresses of a mobility peer use the same type: IPv4 or IPv6.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Add a mobility peer to the list by specifying the required private IP address. Optionally, include a public IP address.

   Example

   ```
   Device(config)# wireless mobility group member mac-address peer_mac ip
   peer_private_ip [ public-ip peer_public_ip ] group group_name
   ```

   Example

   ```
   Device(config)# wireless mobility group member mac-address 001e.494b.04ff ip
    11.0.0.2 public-ip 4.0.0.112 group dom1
   ```

   Note

   You cannot configure multiple peers with the same private or public IP address.

3. Return to privileged EXEC mode.

Example

```
Device(config)# exit
```

The controller saves the mobility peer with its private IP address and, if provided, its public IP address. You can use this peer for wireless mobility group operations.

Verify NAT support on mobility groups

Verify NAT support on mobility groups.

To display the mobility information of a client, use this command:

```
Device# show wireless client mac-address 000a.bd15.0010 detail

Client MAC Address : 000a.bd15.0010
Client IPv4 Address : 100.100.0.2
Client Username: N/A
AP MAC Address : 000a.ad00.0800
AP Name: SIM-AP-7
AP slot : 1
.
.
.
```

To display mobility peer information using a private peer IP address, use this command:

```
Device# show wireless mobility peer ip 21.0.0.2

Mobility Peer Info
==================
Ip Address : 21.0.0.2
Public Ip Address : 3.0.0.22
MAC Address : cc70.ed02.c3b0
Group Name : dom1
.
.
.
```

168 Static IP Client Mobility

Topics:

- Static IP client mobility

Explains how static IP clients maintain network connectivity while moving between different network locations and access points.

Static IP client mobility

This concept explains how static IP client mobility enables seamless connectivity for wireless clients that use static IP addresses as they roam across controllers within the same mobility group.

Static IP client mobility is a wireless network capability that

- allows clients with static IP addresses to maintain connectivity when roaming between controllers
- tunnels client traffic to controllers that support the client's original subnet, and
- ensures reliable service across controllers within the same mobility group.

Behavior and configuration details for static IP client mobility

Wireless networks sometimes require clients to use static IP addresses. When these clients move within the network, they may attempt to associate with different controllers.

If a client tries to connect to a controller that does not support the subnet that matches the static IP address, the connection fails. The controller inspects ARP requests from the client to determine whether the IP address was assigned by DHCP or was statically configured.

If the ARP request contains an IP address that is not present on any of the controller's Switched Virtual Interfaces (SVIs), the client is disconnected with a VLAN_FAIL error. In this case, client traffic is backhauled without explicit disconnection. The disconnection behavior that results from a VLAN mismatch was introduced in the 17.9.1 release.

Example of static IP client mobility in action

- If a wireless client with a static IP address moves to a controller that does not support the client's subnet, the controller analyzes the ARP request. If the subnet is not recognized, the controller disconnects the client, and the client traffic is backhauled.
- When the client moves to a controller within the same mobility group that supports the correct subnet, the traffic is tunneled to the appropriate controller. As a result, the client remains connected to the network even when subnet support varies across controllers.

Restrictions for static IP client mobility

Adhere to these restrictions when configuring static IP client mobility to ensure compatibility and feature support.

- This feature is not supported on the Fabric and Cisco Catalyst 9800 Wireless Controller for Switch platforms.
- IPv6 is not supported.
- FlexConnect mode is not supported.
- WebAuth (LWA and CWA) is not supported.
- Only Open, 802.11ax, and PSK authentication mechanisms are supported.
- This feature is supported only on WLANs that do not have a mobility anchor configured. If a mobility anchor is configured on a WLAN and static IP mobility is enabled, the feature is not supported.
- This feature is supported only when all peers are configured for static IP mobility.
- IRCM is not supported.

Configure a static IP client mobility profile (GUI)

Learn how to configure static IP client mobility using the graphical user interface (GUI) by updating the policy profile and enabling the Static IP Mobility option.

Provide guidance for users to draft a clear and concise purpose and results statement, outlining the objectives and expected outcomes for their task or project.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy** .
2. On the **Policy** page, click the policy profile name or click **Add** to create a new one.
3. Click the **Mobility** tab.
4. Set the **Static IP Mobility** field to **Enabled** state.
5. Click **Update & Apply to Device** .

Static IP clients are able to roam seamlessly between access points, maintaining their network sessions and improving overall connectivity.

Configure a static IP client mobility (CLI)

Learn how to configure static IP client mobility using CLI commands on your device.

Enable wireless client devices with static IP addresses to seamlessly roam between controllers in the network while maintaining their IP configuration.

Before you begin

- Configure the SVI interface (L3 VLAN interface) to service the static IP client on at least one of the peer controllers in the network.
- For clients to join a controller, the VLAN (based on the VLAN number in the policy profile configuration) should be configured on the device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN policy profile and enter wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-policy-name
   ```

3. Enable static IP mobility.

   Example

   ```
   Device(config-wireless-policy)# static-ip-mobility
   ```

Static IP client mobility is successfully configured. Wireless clients with static IP addresses can roam across controllers without losing connectivity or their IP settings.

Verify static IP client mobility

Verify static IP client mobility.

Use these commands to verify the static IP client mobility configuration:

```
Device# show wireless profile policy detailed static-ip-policy

Policy Profile Name           : static-ip-policy

169 Mobility Domain ID - 802.11i Roaming

Topics:

- Mobility domain ID—802.11i roaming

Explains the use of Mobility Domain Identifiers in 802.11i wireless networks to enable secure and seamless client roaming between access points.

Mobility domain ID—802.11i roaming

A mobility domain is a group of access points (APs) that forms a continuous radio frequency space. This grouping allows synchronization of the Pairwise Master Key (PMK) to support fast roaming for 802.11i (WPA) and 802.11r (Fast Transition). The Mobility Domain ID (MDID) manages PMK sharing within defined AP clusters to enable efficient roaming.

A mobility domain ID is a wireless network grouping mechanism that

- enables APs to form a continuous radio frequency space for seamless client roaming,
- facilitates synchronization and sharing of Pairwise Master Keys (PMKs) across APs, and
- manages roaming boundaries by linking APs under a common mobility domain for 802.11i and WPA, as well as 802.11r (Fast Transition).

A mobility domain can be defined in two ways:

- Static configuration: APs are grouped under a common mobility domain ID (MDID).
- Dynamic computation: Spatial clustering algorithms group APs based on neighbor associations.

The MDID is used by 802.11r to define the network boundary where fast roaming is supported.

Within a mobility domain, APs share PMKs. This capability allows clients to roam quickly without fully reauthenticating.

If an MDID is configured, it overrides the site tag for PMK sharing control.

Key characteristics and functionality

- PMK sharing: When an MDID is configured for a group of APs, all APs in that group share PMK cache keys, even if they belong to different site tags. Share PMKs only within the same mobility domain to ensure fast and secure client roaming.
- Precedence: If a mobility domain is defined, the MDID takes precedence over the AP site tag for PMK caching.
- Flexibility: The MDID method supports PMK cache sharing for both central and local authentication modes.

Implementation information

- Configuration method: You can configure MDID only through the open configuration model. There is no CLI or GUI support for this feature.
- Scale: Each mobility domain (site tag or MDID) supports up to 100 APs in Cisco IOS XE 17.2.1. Each AP supports up to 1,000 PMK cache entries in this release.
- Restriction: The Mobility Domain ID–802.11i Roaming feature does not function when Flex APs operate in standalone mode because controller coordination is required for key sharing.

Historical context and release notes

- Before Cisco IOS XE 17.2.1, the PMK cache was shared across FlexConnect APs using the AP site tag. All APs in the same site tag could share the PMK cache, but this support applied only to central authentication.
- Since Cisco IOS XE 17.2.1, you can assign a unique MDID to each AP. All APs with the same MDID share PMK cache keys regardless of site tag assignment. MDID-based PMK cache sharing now works for both central and local authentication. It also ensures that APs outside an MDID do not participate in the same PMK cache, even if they are under the same site tag.

Notes

Note

- The Mobility Domain ID–802.11i Roaming feature does not function when Flex APs operate in standalone mode because controller coordination is required for key sharing.
- You can set MDID only through the open configuration model.
- In Cisco IOS XE 17.2.1, each site tag or MDID supports up to 100 APs, and each AP supports up to 1,000 PMK entries.

You can configure MDID only through open configuration models. For more information, see the Cisco IOS XE Programmability Configuration Guide at https://www.cisco.com/c/en/us/td/docs/ios-xml/ios/prog/configuration/172/b_172_programmability_cg.html.

Verify mobility domain ID - 802.11i roaming

Verify mobility domain ID - 802.11i roaming.

This examples shows how to view and verify the 802.11i roaming configuration:

```
Device#  show running-config | section specific-config
ap specific-config 58ac.70dc.xxxx hostname AP58AC.70DC.XXXX
   roaming-domain roaming_domain_2
ap specific-config 78xc.f09d.xxxx hostname AP78XC.F09D.XXXX
   roaming-domain roaming_domain_3
```

170 802.11r Support for Flex Local Authentication

Topics:

- 802.11r support for FlexConnect local authentication

802.11r support for FlexConnect local authentication

Describes the 802.11r fast transition capability for locally authenticated FlexConnect clients.

802.11r support for FlexConnect local authentication is a fast transition capability that

- enables fast roaming for locally authenticated FlexConnect clients by sharing Pairwise Master Key (PMK) cache entries
- uses site tag or Mobility Domain ID (MDID) grouping to distribute PMK cache entries across APs, and
- supports up to 100 APs per group by default and 300 with high scale mode, with a maximum of 1000 PMK entries per AP.

Implementation details

In releases prior to Cisco IOS XE Amsterdam 17.2.1, the FlexConnect mode fast transition was supported only in centrally authenticated clients. This was achieved by sharing the Pairwise Master Key (PMK) to all the FlexConnect APs in the same site tag. From Cisco IOS XE Amsterdam 17.2.1, fast transition is supported even for locally authenticated clients.

The client PMK cache entries are shared and distributed to all the APs in the same site tag. From Cisco IOS XE Amsterdam 17.2.1, another grouping called Mobility Domain ID (MDID) is introduced, for sharing the PMK cache entries. MDID can be configured for APs using the open configuration model only. There is no CLI or GUI support.

The PMK cache distribution in a FlexConnect local site (using either the site tag or MDID) is restricted to 100 APs per group by default and 300 with high scale mode, with a maximum support for 1000 PMK entries per AP.

The following are the 802.11r support guidelines:

- Supports 802.11r on FlexConnect local authentication only with Over-the-Air method of roaming. Over-the-DS (Distribution System) is not supported.
- Supports adaptive 11r for Apple clients.
- Supports both Fast Transition + 802.1x and Fast Transition + PSK.

> **Note**
>
> This is supported only when clients join the standalone mode AP.

802.11r support verification for flex local authentication

Provides commands to verify 802.11r support for flex local authentication.

Use the following commands to verify 802.11r support for flex local authentication by checking PMK caches and 802.11r flex roam attempts.

To verify the number of PMK caches, use the **show wireless pmk-cache** command:

```
Device# show wireless pmk-cache
Number of PMK caches in total : 1

Type      Station            Entry Lifetime  VLAN Override        IP Override
         Audit-Session-Id              Username
-----------------------------------------------------------------------------------------
DOT11R    74xx.bx5a.07xx      87              NA
           000000000000000FF3562B5D      jey
```

To verify the 802.11r flex roam attempts, use the **show wireless client mac-address 74xx.bx5a.07xx mobility history** command:

```
Device# show wireless client mac-address 74xx.bx5a.07xx mobility history
Recent association history (most recent on top):

AP Name                                      BSSID           AP Slot    Assoc
 Time               Instance   Mobility Role   Run Latency (ms)     Dot11 Roam
 Type

-------------------------------------------------------------------------------------------------------------------------

APM-9120-1-GCP                               d4xx.80xx.8fxx  1
12/11/2019 18:44:37      1          Local           2                   802.11R

APM-4800-3                                   f4xx.e6xx.08xx  1
12/11/2019 18:43:02      1           Local           17547                N/A

show wireless stats client detail | sec roam
Total 11r flex roam attempts                    : 1
```

171 Opportunistic Key Caching

Topics:

- Opportunistic key caching

Explains Opportunistic Key Caching technology and provides step-by-step guidance for enabling and verifying the feature through both command-line and graphical interfaces.

Opportunistic key caching

Explains the OKC technique that allows wireless clients and the WLAN infrastructure to cache only one PMK for client association with a WLAN.

Opportunistic Key Caching (OKC) is an enhancement of the WPA2 Pairwise Master Key ID (PMKID) caching method that

- allows wireless clients and the WLAN infrastructure to cache only one PMK for client association with a WLAN, even when roaming between multiple APs
- enables APs to share the original PMK that is used for the WPA2 4-way handshake, and
- works with WPA2-EAP as a fast roaming technique.

Key characteristics

OKC shares several characteristics with PMKID caching:

- The initial association to an AP is a regular first-time authentication to the corresponding WLAN, where you must complete the entire 802.1X/EAP authentication for the authentication server, and the 4-way handshake for key generation, before sending data frames.
- All APs share the original PMK from a client session under a centralized device that caches and distributes the original PMK to all the APs.
- New encryption keys are generated every time a client reassociates with APs.

OKC support varies by client type:

- Microsoft and some Android clients support OKC.
- Apple and few Android clients support 802.11r as an alternative fast roaming method.

OKC configuration characteristics:

- OKC is enabled by default on a WLAN.
- Disabling OKC on a WLAN disables the OKC even for the OKC-supported clients.
- A new configuration is introduced for each WLAN in the controller in Cisco IOS XE Amsterdam 17.2.1, to disable or enable fast and secure roaming with OKC at the corresponding AP.

Enable opportunistic key caching

Configure opportunistic key caching to improve wireless client roaming performance.

Opportunistic Key Caching (OKC) improves wireless client roaming performance by allowing clients to use cached encryption keys when moving between access points within the same mobility domain.

Use this procedure when you need to enable OKC on a WLAN to enhance client roaming experience. OKC is enabled by default on most configurations.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enter WLAN configuration submode.

   Example

   ```
   Device(config)# wlan wlan-profile-name wlan-identifier <1-4096>
   ssid-network-name
   ```

   ```
   Device(config)# wlan wlan-profile-name 18 san-ssid
   ```

3. Enable Opportunistic Key Caching, if not enabled. By default, the OKC feature is enabled.

   Example

   ```
   Device(config-wlan)# okc
   ```

   Use the **no** form of this command to disable the OKC feature.

Opportunistic Key Caching is now enabled on the specified WLAN, allowing wireless clients to experience improved roaming performance when moving between access points.

Enable opportunistic key caching (GUI)

Configure opportunistic key caching using GUI.

Enable opportunistic key caching to improve wireless network performance by allowing devices to cache encryption keys for faster roaming between access points.

Opportunistic key caching (OKC) is configured through the WLAN settings in the Advanced tab. This feature is enabled by default but can be managed based on your network security requirements.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.

   The **Add WLAN** dialog box is displayed.

3. In the **Add WLAN** dialog box, click the **Advanced** tab and complete the following procedure:
   a) In the **11ax** section, check the **OKC** check box to disable or enable the feature. By default this feature is enabled.
   b) Click **Update & Apply to Device**.

Opportunistic key caching is configured according to your selection. The WLAN settings are updated and applied to the device.

Verify opportunistic key caching

Provides commands to verify opportunistic key caching configuration.

Verify whether opportunistic key caching (OKC) is disabled for a WLAN profile using show commands.

These example shows how to verify whether OKC is disabled for a WLAN profile.

```
Device# show wlan id 18
WLAN Profile Name     : 18%wlanprofile
================================================
Identifier                                       : 18
Description                                      :
Network Name (SSID)                              : san-ssid
Status                                           : Disabled
Broadcast SSID                                   : Enabled
Advertise-Apname                                 : Disabled
Universal AP Admin                               : Disabled
Max Associated Clients per WLAN                  : 0
Max Associated Clients per AP per WLAN           : 0
Max Associated Clients per AP Radio per WLAN     : 200
OKC                                              : Disabled

Part XII

High Availability

Topics:

- High Availability
- Redundancy Management Interface

This guide provides technical procedures for configuring and managing High Availability on Cisco Catalyst 9800 Series Wireless Controllers. It enables administrators to implement robust failover mechanisms, monitor system health, and troubleshoot redundancy configurations to ensure continuous wireless network operations.

172 High Availability

Topics:

- High Availability
- Auto-upgrade feature
- Link layer discovery protocol use cases
- Reload reason history

The Cisco Catalyst 9800 Series Wireless Controller High Availability (HA) feature reduces network downtime by enabling seamless failover between active and standby controllers, preserving AP and client connectivity through stateful switchover, and mirroring AP and client databases to avoid disconnections during failover events.

High Availability

This topic explains High Availability (HA) and how it reduces wireless network downtime by enabling seamless failover between controllers, ensuring continuous service for APs and clients.

A high availability feature is a wireless controller capability that

- reduces network downtime by enabling seamless failover between active and standby controllers,
- preserves AP and client connectivity through stateful switchover by maintaining CAPWAP tunnels and client sessions during failover, and
- mirrors AP and client databases from the active controller to the standby controller to prevent APs from entering discovery state and avoid client disconnections.

Feature history for High Availability

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Table 144: Feature history

Release	Feature	Feature information
Cisco IOS XE 17.18.1	Enhanced Gateway Reachability Statistics	Improves visibility into gateway reachability and provides detailed statistics for ICMP, ARP, and ND probes. This feature enables simplified troubleshooting, greater transparency, and more reliable diagnostics for HA and RMI functionality. This command is introduced: • **show platform software rif-mgr chassis { active | standby} r0 gateway-statistics** This command is modified: • **show platform software rif-mgr chassis { active | standby} r0 resource-status**

Release	Feature	Feature information
Cisco IOS XE 17.9.1	High Availability Deployment for Application Centric Infrastructure (ACI) Network	This feature avoids interleaving traffic between the old and new active controller using these functionalities: • Bringing down Wireless Management Interface (WMI) faster. • Disabling fast switchover notification.
	Link Layer Discovery Protocol (LLDP) Support in the Standby Controller	From this release, the Link Layer Discovery Protocol (LLDP) process will be up and running in both active and standby controllers.
Cisco IOS XE 17.6.1	Standby Interface Status using Active SNMP	This feature allows the standby controller interface status to be queried at the active using SNMP.
Cisco IOS XE 17.5.1	Auto-Upgrade	The auto-upgrade feature enables the standby controller to upgrade to active controller's software image, so that both controllers can form an high availability (HA) pair.
Cisco IOS XE 17.5.1	Standby Monitoring Enhancements	The Standby Monitoring Enhancements feature monitors the standby CPU or memory information from the active controller. Also, this feature independently monitors the standby controller using SNMP for the interface MIB. The cLHaPeerHotStandbyEvent and cLHaPeerHotStandbyEvent MIB objects in CISCO-HA-MIB are used to monitor the standby HA status.
Cisco IOS XE 17.4.1	Gateway Reachability Detection	Gateway reachability feature minimizes the downtime on APs and clients when the gateway reachability is lost on the active controller.
Cisco IOS XE 17.1.1s	Redundant Management Interface	The Redundancy Management Interface (RMI) is used as a secondary link between the active and standby controllers. This interface is the same as the Wireless Management Interface and the IP address on this interface is configured in the same subnet as the Wireless Management Interface.

Additional reference information

High availability enables seamless controller failover, ensuring that APs and clients remain connected during controller outages. These notes and recommendations apply to HA deployments:

- Do not shut or unshut the RP port during controller bootup in HA mode.
- If RP communication is lost between the active and standby controllers during HA synchronization, the standby controller intentionally crashes when IPC communication fails.

  If the RP link is restored, the standby controller restarts gracefully and forms an HA pair.
- When the controller operates as a spanning tree host, configure portfast trunk on the uplink switch to ensure faster convergence. Use **spanning-tree port type edge trunk** or **spanning-tree portfast trunk**.
- You can configure FIPS in an HA setup. For information, see the Configuring FIPS in HA Setup.
- Do not configure the secondary IPv4 address. The controller uses the IPv4 secondary address internally for RMI purposes.

  Configure only one management IPv6 address on the Wireless Management Interface (WMI). The controller uses any secondary address for RMI-IPv6.

  Configuring more than one management IPv4 address or more than one management IPv6 address on the WMI may cause unpredictable behavior.

During a failover event, only one CAPWAP tunnel is maintained between APs and the active controller. This ensures zero downtime for client services and no SSID outages. Database mirroring prevents APs from entering the discovery state and ensures that clients remain connected without interruption.

Prerequisites for High Availability

This topic explains the prerequisites for high availability, including interface configuration, HA port options, and latency, bandwidth, and MTU requirements.

To ensure high availability, configure interfaces properly, select the appropriate HA port, and meet latency, bandwidth, and MTU requirements for RP links.

External interfaces and IPs

All interfaces are configured on the Active box and synchronized with the Standby box. Therefore, the same set of interfaces is present on both controller s.

External nodes connect to the same IP addresses regardless of which controller they are connected to.

APs, clients, DHCP servers, Cisco Prime Infrastructure, Cisco Catalyst Center, and Cisco Identity Services Engine (ISE) servers, as well as other controller members in the mobility group, always connect to the same IP address.

The SSO switchover is transparent to these devices. However, if TCP connections exist from external nodes to the controller , reset and reestablish those connections.

HA interfaces

The HA interface provides:

- Provides connectivity between the controller pair before an IOSd comes up,
- provides IPC transport across the controller pair, and
- enables redundancy across control messages exchanged between the controller pair. The control messages include HA role resolution, keepalive messages, notifications, HA statistics, and similar messages.

You can select an SFP or RJ-45 connection for the HA port. Supported Cisco SFPs are:

- GLC-SX-MMD
- GLC-LH-SMD

> **Note**
>
> Connect either the SFP port or the RJ-45 port to the peer. Do not connect both ports at the same time.

HA operates when either an SFP or RJ-45 connection is present between the two controllers. If you connect an SFP link while RJ-45 HA is active, the HA pair restarts. The restart occurs even if the SFP link is not connected.

> **Note**
>
> - Use a dedicated physical network interface card (NIC) and switch for the redundancy port (RP) when deploying the HA pair across two hosts. This prevents keepalive losses and false HA switchovers or alarms.
> - Disable security scans on VMware virtual instances to prevent HA issues.

> **Note**
>
> Connect RP links using switches to enable controller HA. Keep the round-trip time between the two controllers under 80 milliseconds.

Latency, bandwidth, and MTU

These are the latency, bandwidth, and MTU prerequisites for the RP link:

- The maximum supported latency for the RP link is 80 milliseconds round-trip time (RTT).
- The RP link must support a minimum bandwidth of 60 megabits per second (Mbps).
- The RP link must support a minimum maximum transmission unit (MTU) of 1500 bytes.

High Availability restrictions

Outlines restrictions and important guidelines for configuring High Availability, including synchronization requirements, interface pairing, and switchover scenarios on wireless controllers.

- Wait until configuration synchronization completes on the standby controller. Before initiating a fail-safe Stateful Switchover (SSO), ensure that the standby controller has been powered on for sufficient time (up to 24 minutes [up to 1,440 seconds] on some platforms) to achieve readiness. Use the **show wireless stats redundancy config database** command to view database statistics.
- During a switchover in local mode, NBAR engine flow states are lost. As a result, classification restarts and may lead to incorrect packet classification.
- You can use HA connections only with IPv4.

- When you perform a switchover or an active reload, the high-availability link goes down on the new primary controller.
- Do not enable hyper-threading in HA systems. If enabled, HA keepalives are lost, and a stack merge may occur.
- You cannot access the web UI from the standby RMI interface.
-
-
- Configure two HA interfaces, RMI and RP, on the same subnet. Do not share this subnet with any other interfaces on the device.
- After a switchover, you must re-establish any TCP session because synchronization is not possible.
- Client SSO does not address clients that have not reached the RUN state. These clients are removed after a switchover.
- Statistics tables are not synchronized from the active controller to the standby controller.
- Creating a machine snapshot of a VM hosting controller HA interfaces is not supported. This action may lead to a crash in the HA controller.
- Clients that are not in RUN state are reauthenticated after a switchover.
- Application classification may not be retained after SSO:
  - AVC limitation–After a switchover, context transfer or synchronization to the standby controller does not occur. The new active flow must be relearned. AVC QoS does not take effect during classification failure.
  - A voice call cannot be recognized after a switchover because a voice policy is based on RTP or RTCP protocol.
  - Auto QoS does not work due to AVC limitation.
- For virtual platforms, pair the active controller and the standby controller with the same interface. For hardware appliances, use a dedicated HA port.
- You can synchronize static IP addressing to the standby controller, but you cannot use the IP address from the standby controller.
- You can map a dedicated HA port to a 1-gigabit (1,000 Mbps) interface only.
- To use EtherChannels in HA mode in releases up to Cisco IOS XE Gibraltar 16.12.x, ensure that the channel mode is set to On.
- EtherChannel Auto-mode is not available in HA mode in releases up to Cisco IOS XE Gibraltar 16.12.x.
- LACP and PAGP protocols cannot be used in HA mode in releases up to Cisco IOS XE Gibraltar 16.12.x.
- When the controller operates as a host for spanning tree, configure portfast trunk on the uplink switch using **spanning-tree port type edge trunk** or **spanning-tree portfast trunk** command to ensure faster convergence.
- The **clear chassis redundancy** and **write erase** commands do not reset the chassis priority to the default value.
- While configuring devices in HA, ensure that members do not have wireless trustpoints with the same name but different keys. If you form an HA pair between two standalone controllers with mismatched trustpoints, the wireless trustpoint does not come up after SSO. The *rsa keypair* file exists but is incorrect because the *nvram:private-config* file is not synchronized with the actual *WLC_WLC_TP* key pair.
- Before forming HA, delete existing certificates and keys from each controller that was previously deployed as standalone. This is a best practice.
- Do not configure the WLAN or WLAN policy after a switchover while recovery is in progress. Doing so may cause the controller to crash.

- After a switchover, clients that are not in RUN state and not connected to an AP are removed after 300 seconds (5 minutes).

Best practices for RP port configuration

Use these guidelines when configuring RP ports to ensure proper redundancy and select the correct subnet for Local and Remote IP addresses.

When you configure RP ports, use these best practices:

- Ensure that the Local and Remote IP addresses are in the same subnet.
- Use the 169.254.X.X/16 subnet, deriving the last two octets from the management interface.
- Do not use the 10.10.10.x/24 subnet for the RP port.
- For more information about RMI+RP chosen as the redundancy method, see Information About Redundancy Management Interface .

Configure High Availability (CLI)

Learn how to configure high availability using CLI commands to set up device priorities, high-availability interfaces, and keepalive parameters for redundancy pairs.

Set up high availability for network redundancy and automatic failover between devices using the CLI.

Before you begin

Ensure that the active and standby controllers use the same mode—either Install mode or Bundle mode—and the same image version. Use Install mode.

Procedure

1. Optional: Configure the priority of the device.

Example

```
Device# chassis chassis-num priority chassis-priority
```

Note

From Cisco IOS XE 16.12.x onward, a device reload is not required for the chassis priority to take effect.

- *chassis-num* —Enter the chassis number (range: one to two).
- *chassis-priority* —Enter the chassis priority (range: one to two; default: one).

> **Note**
>
> If both devices boot up simultaneously, the device with the higher priority (2) becomes active. The other device becomes standby. If both devices have the same priority, the device with the smaller MAC address becomes active, and the peer device becomes standby.

2. Set the chassis high-availability parameters.

   Example

   ```
   Device# chassis redundancy ha-interface GigabitEthernet num local-ip
   local-chassis-ip-addr network-mask remote-ip remote-chassis-ip-addr
   ```

   Example

   ```
   Device# chassis redundancy ha-interface
                          GigabitEthernet 2 local-ip 4.4.4.1 /24 remote-ip
   4.4.4.2
   ```

   - *num* –GigabitEthernet interface number (range: zero to 32).
   - *local-chassis-ip-addr* –Enter the IP address of the local chassis high-availability interface.
   - *network-mask* –Enter the network mask or prefix length in slash nn or dotted decimal format.
   - *remote-chassis-ip-addr* –Enter the remote chassis IP address.

   This command is not supported on these models:

   - Cisco Catalyst CW9800H1 Wireless Controller.
   - Cisco Catalyst CW9800H2 Wireless Controller.
   - Cisco Catalyst CW9800M Wireless Controller.

   RMI-based high availability is mandatory in the Cisco Catalyst CW9800H1 Wireless Controller, Cisco Catalyst CW9800H2 Wireless Controller, and Cisco Catalyst CW9800M Wireless Controller.

3. Configure the peer keepalive timeout value.

   Example

   ```
   Device# chassis redundancy keep-alive timer timer
   ```

   Set the time interval in multiples of 100 milliseconds (ms). Enter one for the default value.

4. Set the peer keepalive retry value that determines when the system considers the peer down.

   Example

   ```
   Device# chassis redundancy keep-alive retries retry-value
   ```

The default value is five.

After you complete these steps, high availability is configured between two devices. The system uses device priorities, high-availability interfaces, and keepalive parameters to ensure redundancy and seamless failover if a device fails.

Disable High Availability

This topic explains how to disable high availability on controllers using the RP or RMI method. It includes the required commands and important considerations for supported models.

When you disable high availability, all HA-related parameters are removed and the controller returns to stand-alone mode.

- Use **clear chassis redundancy** with the RP method to clear the local IP, remote IP, HA interface, mask, timeout, and priority.
- Use **no redun-management interface vlan chassis** with the RMI method.
- After you unpair the controllers, the startup and HA configuration of the standby controller are cleared, and it enters Day zero state.

If you configure the controller using the RP method for SSO, use this command to clear all HA-related parameters: local IP, remote IP, HA interface, mask, timeout, and priority:

- **clear chassis redundancy**

If you configure the controller using the RMI method, use this command:

- **no redun-management interface vlan chassis**

Note

This command is not supported on these models:

- Cisco Catalyst CW9800H1 Wireless Controller .
- Cisco Catalyst CW9800H2 Wireless Controller .
- Cisco Catalyst CW9800M Wireless Controller .

Note

Reload your devices to apply the changes.

Before you execute the command, you see this warning on the active controller:

```
Device# clear chassis redundancy
WARNING: Clearing the chassis HA configuration will result in both the chassis
 move into
Stand Alone mode. This involves reloading the standby chassis after clearing
its HA
```

```
configuration and startup configuration which results in standby chassis coming
 up as a totally
clean after reboot. Do you wish to continue? [y/n]? [yes]:
*Apr 3 23:42:22.985: received clear chassis.. ha_supported:1yes
WLC#
*Apr 3 23:42:25.042: clearing peer startup config
*Apr 3 23:42:25.042: chkpt send: sent msg type 2 to peer..
*Apr 3 23:42:25.043: chkpt send: sent msg type 1 to peer..
*Apr 3 23:42:25.043: Clearing HA configurations
*Apr 3 23:42:26.183: Successfully sent Set chassis mode msg for chassis 1.chasfs
 file updated
*Apr 3 23:42:26.359: %IOSXE_REDUNDANCY-6-PEER_LOST: Active detected chassis 2
 is no
longer standby
```

On the standby controller, these messages indicate that the configuration is being cleared:

```
Device-stby#

Copy a WebAuth tar bundle to the standby controller (GUI)

Copy a WebAuth tar bundle to the standby controller in a high-availability configuration.

Ensure the standby controller receives the WebAuth tar bundle to maintain seamless high-availability functionality.

Copy a WebAuth tar bundle to the standby controller in a high-availability configuration.

Procedure

1. Go to **Administration** , select **Management** , and then select **Backup and Restore**.
2. Select **To Device** from the **Copy** drop-down list.
3. Select **WebAuth Bundle** from the **File Type** drop-down list.
4. Select **TFTP** , **SFTP** , **FTP** , or **HTTP** from the **Transfer Mode** drop-down list.

   The required values for the **Server IP Address** and **File Path** fields depend on the selected transfer mode.

   - **TFTP**
     - **IP Address (IPv4/IPv6)** : Enter the server IP address (IPv4 or IPv6) of the TFTP server you want to use.
     - **File Path**: Enter the file path. Start the file path with a slash, such as */path*.
     - **File Name**: Enter a file name.

       Do not use spaces in the file name. Use underscores and hyphens. Make sure the file name ends with .tar, for example, webauthbundle.tar.
   - **SFTP**
     - **IP Address (IPv4/IPv6)**: Enter the server IP address (IPv4 or IPv6) of the SFTP server that you want to use.
     - **File Path**: Enter the file path. Start the file path with a slash, such as */path*.
     - **File Name**: Enter a file name.

Do not use spaces in the file name. Only underscores and hyphens are allowed. Make sure the file name ends with .tar, for example, webauthbundle.tar.

- **Server Login Username**: Enter the SFTP server login user name.
- **Server Login Password**: Enter the SFTP server login passphrase.

- **FTP**
  - **IP Address (IPv4/IPv6)**: Enter the server IP address (IPv4 or IPv6) of the FTP server that you want to use.
  - **File Path**: Enter the file path. Start the file path with a slash, such as */path* .
  - **File Name**: Enter a file name.

    Do not use spaces in the file name. Only underscores and hyphens are allowed. Make sure the file name ends with .tar, for example, webauthbundle.tar.
  - **Logon Type**: Choose **Anonymous** or **Authenticated** . If you choose **Authenticated**, these fields are activated:
    - **Server Login Username**: Enter the FTP server login user name.
    - **Server Login Password**: Enter the FTP server login passphrase.

- **HTTP**
  - **Source File Path**: Click **Select File** to select the configuration file, and click **Open**.

5. Click the **Yes** or **No** radio button to back up the existing startup configuration to Flash.

   Save the configuration to Flash to propagate the WebAuth bundle to other members, including the standby controller.
6. Click **Download File**.

The WebAuth tar bundle is successfully copied to the standby controller, ensuring high-availability readiness.

System and network fault handling

This topic explains system and network fault handling, including controller switchover conditions and recovery scenarios for both system and network faults.

If the standby controller crashes, it reboots and comes up as the standby controller. Bulk sync follows causing the standby to become hot. If the active controller crashes, the standby becomes active. The new active controller assumes the role of primary and tries to detect a dual active.

These matrices provide a clear picture of the conditions the controller switchover would trigger:

Table 145: System and Network Fault Handling after 17.5

Number	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
1	Up	P-Reachable	G-Reachable	G-Reachable	No SSO	No Action	

Note	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
2	Up	P-Reachable	G-Reachable	G-Unreachable	No SSO	No action is required. The standby unit is not ready for SSO in this state because it does not have gateway reachability. In this scenario, the standby unit appears in standby-recovery mode. **Spring Back:** If the gateway reachability is restored (G_Reachable), the controller returns to Standby state (no reboot is necessary). **Note** RP resources and gateway resources each trigger distinct actions.	**Spring Back:** If the gateway reachability is restored (G_Reachable), the controller transitions to Standby state. A reboot is not required.
3	Up	P-Reachable	G-Unreachable	G-Reachable	SSO	The system exchanges gateway reachability messages over the RMI and RP links. When the active controller reboots, the standby controller takes over as the active controller. The RP goes down during the reboot process.	

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
							The Stack Manager sends a message to the standby controller to initiate a role change. The standby controller consults the active controller. • If the active controller responds, the standby controller determines that the active controller does not have all the required resources and allows the role change. • If the active controller does not respond, or if the RMI link is down, the standby controller proceeds with the role change because it has all the resources required to become active.
4	Up	P-Reachable	G-Unreachable	G-Unreachable	No SSO	The standby controller is not ready for SSO in this state because it does not have gateway reachability. The standby controller appears in Standby-Recovery mode.	**SpringBack:** If the gateway reachability is restored on the Standby-Recovery controller (G_Reachable), the controller transitions to the standby state.

Number	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
5	Up	P-Unreachable	G-Reachable	G-Reachable	No SSO	No action taken when RMI goes DOWN. There will be no DAD when the RMI link is DOWN.	If gateway reachability (G_Reachable) is lost, the controller transitions to Standby. This situation is managed as case (3) The active controller maintains its state when gateway reachability is lost. No action is taken when the RMI link goes down. Dual-Active Detection (DAD) does not occur when the RMI link is down.
6	Up	P-Unreachable	G-Reachable	G-Unreachable	No SSO	No Action. Standby is not ready for SSO in this state as it does not have gateway reachability. The standby shall be shown to be in standby-recovery mode.	**Spring Back:** If the gateway reachability is restored (G_Reachable), the controller shall go to Standby mode without a reload. There shall be no action if the RMI comes UP.

Number	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
7	Up	P-Unreachable	G-Unreachable	G-Reachable	SSO	A gateway reachability message is also exchanged over the RP link. The Active device reboots so that the Standby device becomes the new Active. The RP link goes down when the Active device reboots. The Stack Manager sends a message over the RP and RMI links to the Standby Controller to initiate the role change. The Standby controller consults the Active device. • If the Active responds, the Standby determines that the Active does not have all resources and allows the role change. • If the Active does not respond–possibly because the RP link is already down–the Standby allows the role change regardless of resource status.	When the active controller reboots, the RP goes down. The Stack Manager sends a message over the RP and RMI link to the standby controller to initiate a role change. The standby controller consults the active controller.

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
8	Up	P-Unreachable	G-Unreachable	G-Unreachable	No SSO	The standby controller is not ready for SSO in this state because it does not have gateway reachability. The standby controller appears in standby-recovery mode. **Spring Back:** If gateway reachability is restored on the standby-recovery controller (G_Reachable), the controller transitions to standby. Refer to step 7 for more details. The active controller does not change its state when gateway reachability is lost. No action occurs if the RMI comes up.	When the Active device reboots, the RP goes down. The Stack Manager sends a message over the RP and RMI links to the Standby Controller to initiate a role change. The Standby Controller consults the Active Controller. • If the Active responds, the Standby deduces that the Active does not have all the required resources and proceeds with the role change. • If the Active does not respond (for example, if the RP is already down), the Standby allows the role change regardless of the resource status.

Number	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
9	Down	P-Reachable	G-Reachable	G-Reachable	No SSO	When the RP is not available, the standby transitions to Standby-Recovery mode. The stack manager requests a role change when the RP goes down. If the RMI is up, the RIF manager sends a message to the active unit to check its status. If a response is received, the standby does not allow the role change and transitions to Standby-Recovery. If there is no response, such as when the active unit is down due to a crash, the role change is allowed. This scenario works differently if the RP goes down before the standby reaches Standby-Hot state. If the RP link goes down before the standby becomes Standby-Hot, the RIF sends a positive response to the stack manager, resulting in a controller reload.	**Spring Back:** If gateway reachability is restored on the Standby-Recovery (G_Reachable), the controller transitions to Standby. In this case, refer to state (7). The Active controller does not change its state when gateway reachability is lost. No action is taken if the RMI comes up.

Number	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
10	Down	P-Reachable	G-Reachable	G-Unreachable	No SSO		When the RP goes down, the stack manager requests a role change. While the RMI is operational, the RIF manager sends a message to the active controller to verify its status. If a response is received, the standby controller prevents the role change and transitions to standby-recovery. If there is no response, such as when the active controller is down due to a crash, the role change is permitted. However, if the RP goes down before the standby controller reaches the standby-hot state, the RIF manager sends a positive response to the stack manager, which results in a controller reload.

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
						The standby is not ready for SSO in this state because it does not have gateway reachability. The standby will appear in standby-recovery mode. There are two possible scenarios: • The RP goes down first, followed by the standby gateway. • The standby gateway goes down first, followed by the RP. Consider the case where the RP goes down first. In this situation, the stack manager requests a role change. However, because the standby does not have gateway reachability, it cannot allow the role change. The system starts a 30-minute timer when the RMI goes down (meaning both the RP and RMI are down). If the RP goes down before the standby is in standby-hot state, the system reloads. There are several sub-cases: • If the active unit crashes and returns within 30 minutes, the timer stops. The standby remains	

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
						in recovery and reboots when the RP is up. • If the RP stays down, no action is taken when the timer expires, provided the RMI is up. • If the active unit continuously crashes, the timer expires with the RMI down, and the standby-recovery unit reboots as the active unit. Spring Back: • If the gateway returns first, the standby-recovery unit remains in recovery. • If the RP returns first, the system reboots to standby-recovery or standby, depending on whether the gateway is reachable.	

Number	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
11	Down	P-Reachable	G-Unreachable	G-Unreachable	No SSO		

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
						Standby transitions to Standby-Recovery. Assume both controllers lose gateway, then RP goes down. Stack manager requests a role change. Because Standby lacks resources, it starts a 30-minute timer when RMI goes down (that is, RP and RMI are both down). There are three possible outcomes: • If Active recovers within 30 minutes, the timer stops. Standby remains in recovery and may reboot when RP returns. • If RP stays down, no action occurs when the timer expires, provided RMI is up. • If Active never recovers, the timer expires with RMI down, and Standby-Recovery reboots as Active. • If Active never recovers, the timer expires with RMI down, and Standby-Recovery reboots as Active. **Note**	Let us assume that both the controllers lost their GW and then the RP went DOWN. The stack manager will request for a role change when the RP goes DOWN. The standby anyway does not have all resources (Gateway Reachability at present) and hence it shall not allow role change to happen. It will start the 30 min timer when RMI goes DOWN(timer starts when RP+RMI are DOWN).There are now two possibilities: • The active suffered a software glitch (For example: a crash) in which case, it would come up within 30 minutes and the timer would be stopped. The standby will continue to be in standby-recovery. If the RP comes UP when the timer is running, the Standby-Recovery would reboot and might come up as Standby or Standby-Recovery. • Physical RP connection went down and it remains down. When the timer expires, if the RMI is UP, no

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
						If gateway reachability was not enabled, SSO is not allowed when Active is up. If Active is down and Standby is standby-hot, SSO is allowed. If RP returns before standby-hot, it reloads. Note: Recovery to Standby without reload is possible only if recovery was due solely to gateway. **Spring Back:** • If gateway returns first, the system remains in Standby-Recovery. • If RP returns first, the system reboots to Standby-Recovery and then to Standby if gateway is up.	action shall be taken. • The active continuously crashes, that is, it does not come up after 30 minutes. In this case, when the timer expires,the RMI will be DOWN. The standby-recovery shall reboot when the timer expires (and might come UP as Active.) When RP DOWN event is received, if the Gateway Reachability is not enabled, Gateway will not be considered as a resource. In this case, SSO shall not be allowed if the Active is UP. SSO shall be allowed if Active is DOWN, provided Standby is in Standby-Hot state. If the RP link goes down before the standby becomes standby-hot, it shall reload.

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information

Note

The Standby-Recovery that has lost RP is no more Standby Hot. This implies that the recovery from Standby-Recovery to Standby without a reboot (as was the case earlier in 17.2) is not possible for RP events. It is however possible for Gateway events.

Spring Back:

- When the Standby-Recovery findsGateway is UP it continues to be in Standby-Recovery if RP is still DOWN.
- When the Standby-Recovery finds that its RP is UP, it will reboot and come up as Standby-Recovery

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
13	Down	P-Unreachable	G-Reachable	G-Reachable	SSO		

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
						A double fault may result in two active controllers. When this occurs, the Standby controller becomes active, but the original Active controller may still exist. Once connectivity is restored, role negotiation ensures that the most recent Active controller is retained. In the event that RMI goes down and then RP also goes down, the stack manager requests a role change. If RMI is unavailable, Standby grants the role change only if it is in standby-hot mode; otherwise, it denies the request. If RP returns before standby-hot mode is reached, it reloads. **Spring Back:** If RMI returns, the previous Active controller enters Active-Recovery mode. When RP returns, the controller reboots and transitions to Standby. If RP goes down, RMI goes down, and the timer expires, Standby reboots as Active. The timer may be skipped in cases of a pure double fault. **Note**	Let us assume that the RMI goes DOWN first and then the RP goes DOWN. When the RP goes DOWN, the stack manager requests a role change. Since the RMI is DOWN, the standby cannot consult with the Active. The standby allows a role change to become Active, regardless of its resource state, provided the standby is in Standby-Hot. If the standby is not in Standby-Hot, a role change is not allowed. If the RP link goes down before the standby becomes Standby-Hot, the standby reloads **Spring Back:** If the RMI comes UP at any time, Old Active transitions to Active-Recovery. Active-Recovery reboots when the RP comes up, after which it will become Standby. If the RP goes DOWN first, refer to case (9). If RP_DOWN and RMI_DOWN occur in that sequence and the 30-minute timer expires, the standby shall reboot. It will come up as Active if RP and RMI continue to be DOWN. Alternatively, the 30-minute timer may not be started in this case.

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
						You may skip the timer for pure double-fault cases.	The timer can be used when the standby does not have all required resources, such as gateway reachability at present or port status and gateway reachability in the future, to take over as Active. **Note** Another option is to not start the 30-minute timer in this situation. Use the timer only if the standby does not have all the required resources to take over as active. Currently, this refers to gateway reachability; in the future, it may also include port status and gateway reachability.
14	Down	P-Unreachable	G-Reachable	G-Unreachable	No SSO		

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
						Double fault – two active controllers possible. Old Active stays Active; Standby may become Active if connectivity is not restored within a set time. If Standby is in standby-recovery due to GW loss, then RMI goes down, then RP goes down. Stack manager requests role change; no RMI means no consult, so Standby allows change. If Active crashed, it restarts as Standby; if both come up, split-brain conflict may occur.	Let us assume that the Standby is in Standby-Recovery mode as it loses GW. Let us assume that the RMI goes DOWN first and then the RP goes DOWN. The stack manager shall request role change when the RP goes DOWN. Since the RMI isDOWN, the standby cannot consult with the Active. The standby shall allow role change. **Spring Back:** If RMI returns, Old Active enters Active-Recovery and reboots on RP return to become Standby

Number	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
15	Down	P-Unreachable	G-Unreachable	G-Reachable	SSO	Double fault – two active controllers possible. Standby becomes active; old Active may still exist. Role negotiation occurs once connectivity is restored. Assume GW loss on Active, then RMI down then RP down. Stack manager requests role change; no RMI means standby allows change if in standby-hot, else reloads. If RP returns before standby-hot, it reloads. **Spring Back:** If RMI returns, old Active goes to Active-Recovery and reboots on RP return to become Standby.	Suppose the Standby is in Standby-Recovery mode after losing GW. Assume the RMI goes down first, then the RP goes down. The stack manager requests a role change when the RP goes down. Because the RMI is down, the Standby cannot consult with the Active, so it allows the role change. If the Active went down due to a software glitch, it will come up and become Standby. If no communication is established between the two controllers, both may become active, causing a network conflict **Spring Back:** If the RMI comes UP at some point of time,Old Active will go to Active-Recovery. Active-Recovery shall reboot when the RP comes up and will become Standby.

Node	RP Link	Reachability Through RMI	GW From Active	GW From Standby	SSO	Result	Additional Information
16	Down	P-Unreachable	G-Unreachable	G-Unreachable	No SSO	A double fault can result in two active controllers. The old Active remains Active, and the Standby may become Active if connectivity is not restored within a stipulated time. If both controllers lose GW and the Standby is in standby-recovery, then RMI goes down, followed by RP going down. The stack manager requests a role change. If there is no RMI, the Standby allows the change, which can cause a conflict. **Spring Back:** If RMI returns, the old Active enters Active-Recovery and, when RP returns, reboots to become Standby.	Assume that both Active and Standby lose GW, and Standby enters Standby-Recovery. If RMI goes DOWN first, followed by RP going DOWN, the stack manager requests a role change when RP goes DOWN. Since RMI is DOWN, Standby cannot consult with Active and allows the role change. This situation can cause a network conflict. **Spring Back:** If RMI comes UP at any point, the old Active transitions to Active-Recovery. Active-Recovery reboots when RP comes UP and then becomes Standby.

Handling recovery mechanism

This topic explains the Active-to-Active and Standby-to-Standby high availability (HA) recovery mechanisms and describes the system behaviors for each scenario.

This topic provides details about the Active-to-Active and Standby-to-Standby High Availability (HA) recovery mechanisms and the system behaviors for each scenario.

Active-to-Active recovery

- Active recovery occurs if the Route Processor (RP) is down but the Redundancy Management Interface (RMI) is up during boot. The system triggers active recovery after startup.
- In a stable active-standby HA state, if RMI goes down followed by RP, and RMI recovers before RP, the system enters Active-to-Active recovery. After RP is restored, the system reloads active recovery and re-establishes HA.

Standby-to-Standby recovery

- If the Gateway fails, the standby node enters standby recovery mode. In this mode, the standby node stays synchronized with the active unit but cannot become active without the Gateway. When in a hot state, the standby node is ready to take over when Gateway connectivity resumes.

- If only the Gateway is unavailable, restore the Gateway to allow HA to recover without rebooting.
- If a Route Processor (RP) failure triggers standby recovery, wait for the RP to return online. The standby node then reboots automatically, and the system restores HA.

Verify high availability configurations

Verify high availability configurations.

To view the HA configuration details, use this command:

```

To view the HA redundancy summary, use this command:

```
Device# show wireless stat redundancy summary
HA redundancy summary
---------------------

AP recovery duration (ms)        : 264
SSO HA sync timer expired        : No
```

Verify high availability

Verify high availability.

Table 146: Commands for monitoring chassis and redundancy

Command Name	Description
show chassis	Displays the chassis information. **Note** When the peer timeout and retries are configured, the **show chassis ha-status** command output may show incorrect values. To check the peer keep-alive timer and retries, use these commands: • **show platform software stack-mgr chassis active r0 peer-timeout** • **show platform software stack-mgr chassis standby r0 peer-timeout**
show redundancy	Displays details about Active box and Standby box.
show redundancy switchover history	Displays the switchover counts, switchover reason, and the switchover time.

To start the packet capture in the redundancy HA port (RP), use these commands:

- test wireless redundancy packet dump start
- test wireless redundancy packet dump stop
- test wireless redundancy packet dump start filter port 2300

```
Device# test wireless redundancy packetdump start
Redundancy Port PacketDump Start
Packet capture started on RP port.

Device# test wireless redundancy packetdump stop
Redundancy Port PacketDump Start
Packet capture started on RP port.
Redundancy Port PacketDump Stop
Packet capture stopped on RP port.
Device# dir bootflash:
Directory of bootflash:/

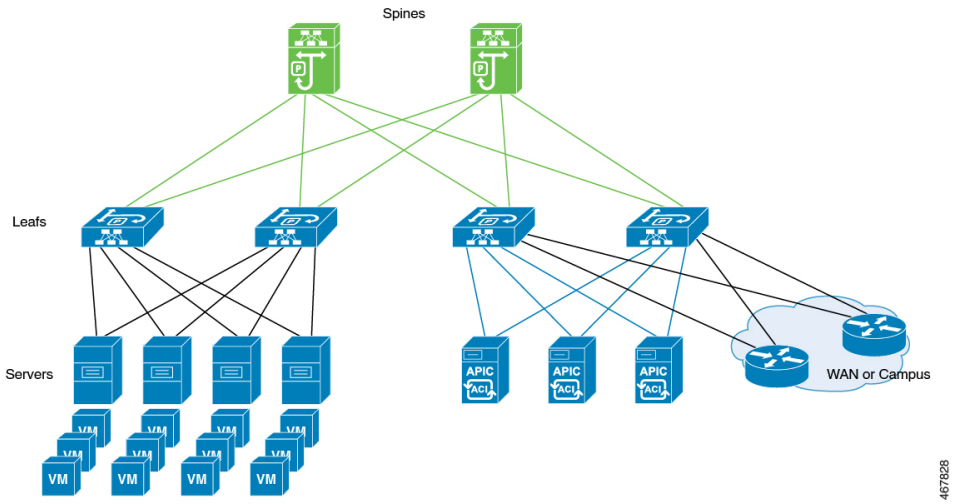
ACI network controllers

Explains Cisco Application Centric Infrastructure (ACI) network controllers, their architecture, deployment topologies, and integrated mechanisms for ensuring reliable high-availability failover.

A Cisco ACI network controller is a data center infrastructure platform that provides the following capabilities:

- integrates virtual and physical workloads across a programmable, multi-hypervisor fabric,
- supports multiservice and cloud data center environments, and
- uses a spine-and-leaf switch topology that the controller provisions and manages as a unified entity.



Additional reference information

Use Cisco Application Centric Infrastructure (ACI) technology to combine physical and virtualized environments so you can deploy programmable networking in your data center. ACI controllers help you automate deployment, streamline management, and achieve high availability and scalability.

You can use Cisco ACI in networks with the Redundancy Management Interface (RMI) to ensure resilience for mission-critical workloads.

This diagram shows separate components that the ACI controller connects in a spine-and-leaf topology and manages as a single infrastructure fabric.

Figure 30: Cisco ACI Network Deployment

Example: Avoid interleaving traffic in ACI deployments

In a high-availability data center, Cisco ACI controllers integrate multiple workloads over a unified spine-and-leaf fabric. To maximize service continuity and avoid traffic conflicts during failover, the organization accelerates the shutdown of wireless management interfaces when it detects failure.

It also disables fast switchover notifications to manage the timing of the switchover, tunes the keepalive timeout, and uses GARP burst mitigation to prevent ARP instability. These combined mechanisms ensure seamless and reliable control plane transitions.

Methods to prevent interleaving traffic during controller switchover

Provides methods to prevent interleaving traffic during controller switchover in ACI deployments, including best practices for managing wireless management interfaces, fast switchover notifications, and GARP mitigation.

To ensure a seamless controller switchover in ACI deployments and prevent disruptions for access points (APs) and clients, avoid interleaving traffic—that is, traffic originating from both the old and new active controllers at the same time. The following methods help eliminate management IP conflicts and ARP table instability during these events.

Bring down the wireless management interface faster

When a switchover occurs, APs and clients may disconnect if both controllers send traffic simultaneously. To prevent this, bring down the wireless management interface on the old active controller as soon as a failure is detected. This stops outgoing traffic from the previous controller and prevents management IP conflicts within the network. The standby controller then assumes the active role with a new IP-MAC binding.

The IP Data-Plane Learning feature in ACI tracks duplicate MAC addresses for the same IP address. It can trigger alarms and block affected IP addresses for a configurable period as a protective measure. When a failure is detected, the controller assigns the “non-participant” property to the affected chassis. The Data-Plane Learning feature monitors this status and quickly brings down the old management interface while blocking unwanted traffic, eliminating conflicts between old and new controllers.

Disable fast switchover notification

This mechanism provides more control during failover events. Normally, when a failure is detected, the active controller sends an explicit notification to the standby controller, enabling it to take over immediately. If you disable the fast switchover notification, the active controller no longer sends this alert. The standby controller instead detects the failure based solely on the keepalive timeout.

This configuration lets you control when traffic from the new active controller begins during a failure scenario. Adjusting the keepalive timeout allows you to match your operational needs. However, switchover will wait for the timeout to expire, which introduces a delay. This delay reduces the chance of overlapping traffic and minimizes the risk that both old and new controllers send management traffic at the same time.

GARP burst mitigation

During a controller switchover, a burst of Gratuitous ARP (GARP) traffic may occur. This burst can overwhelm ARP learning in ACI and destabilize ARP tables. To prevent this, the system retransmits GARP packets at a lower rate after the switchover. Lowering the GARP packet rate prevents excessive ARP table churn and supports smoother and more reliable controller transitions.

Best practices for deploying the ACI network in the controller

Use these guidelines when deploying the ACI network in the controller to ensure that the maximum supported clients and endpoint limits are not exceeded.

Check the maximum supported clients in High Availability to ensure that Cisco ACI does not exceed the configured IPv4 and IPv6 end points.

Disable the fast switchover notification mechanism (CLI)

Learn how to disable the fast switchover notification mechanism using CLI commands.

Use these instructions to disable the fast switchover notification mechanism on your network device using CLI. Disabling this feature stops your device from sending explicit fast switchover notifications, which may help in some operational scenarios.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Disable explicit fast switchover notification.

   Example

   ```
   Device(config)# no redun-management fast-switchover
   ```

   Note

   Configure the fast switchover notification mechanism only on the primary controller. You do not need to configure it on the secondary controller.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

After you complete this procedure, your device no longer sends explicit notifications for fast switchover events. Make configuration changes only on the primary controller. You do not need to make changes on the secondary controller.

Configure the gratuitous ARP (GARP) retransmit (CLI)

Learn how to configure Gratuitous ARP (GARP) retransmit using CLI commands to control the rate and interval of GARP resend operations.

Set the rate and interval for sending gratuitous ARP (GARP) packets to enhance network redundancy and update address tables.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Determine the rate at which the GARP resend performs.

Example

```
Device(config)# redun-management garp-retransmit burst packet-burst-size
interval time-interval
```

Note

- *packet-burst-size* : The valid range is from 0 to 1000. The value 0 refers to the disabled retransmit.
- *time-interval* : Refers to the time interval, in seconds. The valid range is from 0 to 5 seconds. The value 0 refers to the disabled retransmit.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The GARP retransmit settings are updated for the device.

Disable the initial GARP (CLI)

Learn how to disable the initial GARP using CLI commands on your device.

Disable the initial GARP retransmit mechanism in redundancy management to optimize ARP traffic and prevent unnecessary broadcasts.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Disable the initial GARP.

Example

```
Device(config)# no redun-management garp-retransmit initial
```

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The device will no longer send initial gratuitous ARP messages during redundancy failover, helping to minimize broadcast traffic in your network.

Configure a switchover

Configure a switchover using the redundancy force-switchover command to test high availability on Cisco Catalyst 9800 series wireless controllers.

Enable manual failover to the standby unit and verify that high availability and redundancy work as expected.

Procedure

Force a failover to the standby unit by entering this command:

Example

```
Device#redundancy force-switchover
```

After you enter this command, the standby controller takes the active role. The active controller reloads and becomes the standby controller. Use this command to test high availability cluster stability and confirm that switchovers work as expected.

Note

Use only the recommended command to test switchovers between Cisco Catalyst 9800 series wireless controllers. Using other commands, such as **reload slot X** (where X is the active controller), might cause unexpected behavior.

Note

In a scaled environment, avoid performing an immediate switchover after modifying WLAN or policy profile configurations. Doing so might cause unexpected behavior.

The system completes the switchover. The standby controller becomes active, and the previous active controller reloads to become standby. The switchover verifies high availability cluster stability.

Auto-upgrade feature

Explains the Auto-Upgrade feature that enables the standby controller to upgrade with the software image of the active controller so that both controllers form an HA pair.

The Auto-Upgrade feature is a wireless controller capability that

- enables the standby controller to upgrade with the software image of the active controller
- allows both controllers to form an HA pair, and
- supports the active controller in INSTALL mode.

Auto-upgrade feature requirements

The Auto-Upgrade feature has the following requirements:

- This feature supports the active controller in INSTALL mode.
- This feature supports Cisco Catalyst 9800 Series Wireless Controller software versions 17.5.1 and later.
- This feature is triggered in the standby controller only when the active image is in committed state.

Auto-upgrade use cases

Describes the use cases and functionalities supported by the Auto-Upgrade feature.

Auto-upgrade use cases are scenarios that

- handle software version mismatches during upgrades by copying packages between redundancy ports
- support HA pair deployments where controllers may have different versions, and
- manage SMU installations when standby controllers come online after being offline.

Auto-upgrade functionality details

The following are the use cases and functionalities supported by the Auto-Upgrade feature:

- Handling software version mismatch: During an upgrade, if one of the redundancy port is upgraded to a newer version, and the other one is not upgraded at the same time, the active port tries to copy its packages to the other port using the Auto-Upgrade feature. You can enable Auto-Upgrade in this situation using configuration or by manually running the **software auto-upgrade enable** privileged EXEC command.

  The auto-upgrade configuration is enabled by default.

  > **Note**
  >
  > Auto-upgrade upgrades the mismatched redundancy port only when both the active redundancy port and the mismatched redundancy port are in INSTALL mode.

- HA pair: If one of the controller is not upgraded successfully, use Auto-Upgrade to upgrade the controller on the newly deployed HA pair, which can each be a different version.
- SMUs (APSP, APDP, and so on): If the SMUs that are successfully installed on the active controller when the standby controller was offline. In this scenario, when the standby controller comes up online, the Auto-Upgrade copies this SMU to the standby controller and installs it.

Configuration workflow

Configure workflow.

#unique_2256

Configure auto-upgrade (CLI)

Configure auto-upgrade using commands.

Enable the Auto-Upgrade feature to automatically upgrade software when new versions become available.

The Auto-Upgrade feature is enabled by default but can be disabled. When disabled, manual upgrades must be performed using the install autoupgrade command.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable the Auto-Upgrade feature.

   Example

   ```
   Device(config)# software auto-upgrade enable
   ```

   This feature is enabled by default.

   If you disable this feature using the no form of this command, you need to manually auto upgrade using the install autoupgrade command in privileged EXEC mode.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

Auto-upgrade is now enabled and will automatically upgrade software when new versions are available.

Link layer discovery protocol use cases

Describes Link Layer Discovery Protocol (LLDP) use cases in high-availability setups.

A Link Layer Discovery Protocol (LLDP) use case is a network topology scenario that demonstrates how LLDP operates independently in high-availability wireless unit configurations where active and standby units maintain separate protocol instances.

High-availability LLDP operation

In a high-availability (HA) setup, when two wireless units act as active and standby, the LLDP still runs independently in both.

When you execute the LLDP neighbors command, the system name as the neighbor entry in the uplink switch is displayed as *hostname*-**stbdy**.

Enable LLDP (CLI)

Configure LLDP using commands.

Enable Link Layer Discovery Protocol (LLDP) to allow network devices to advertise information about themselves to other devices on the network.

LLDP is used for network topology discovery and network management. Enable LLDP when you need devices to share information such as system name, port description, and VLAN configuration with neighboring devices.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable Link Layer Discovery Protocol (LLDP).

   Example

   ```
   Device(config)# lldp run
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

LLDP is now enabled and the device will begin advertising and receiving LLDP information from neighboring devices.

Enable LLDP timers (CLI)

Configure LLDP timers using commands.

Configure LLDP timer settings to control packet transmission rates and retention periods.

LLDP timers control how frequently LLDP packets are sent, how long receivers keep packets, and initialization delays. These settings optimize LLDP performance for your network environment.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable LLDP holdtime timer.

Example

```
Device(config)# lldp holdtime time-in-seconds
```

Example

```
Device(config)# lldp holdtime 100
```

The timer decides how long the receiver must keep the packet. Valid range is from 0 to 65535 seconds.

3. Specify the delay for LLDP to initialize.

Example

```
Device(config)# lldp reinit delay-in-seconds
```

Example

```
Device(config)# lldp reinit 3
```

Valid range is from 2 to 5 seconds.

4. Specify the rate at which LLDP packets are sent.

Example

```
Device(config)# lldp timer time-in-seconds
```

Example

```
Device(config)# lldp timer 7
```

Valid range is from 5 to 65534 seconds.

5. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

LLDP timers are now configured with the specified holdtime, reinitialization delay, and transmission rate settings.

Enable LLDP TLV-Select (CLI)

Configure LLDP TLV-Select using commands.

Enable specific LLDP TLV types to control what information is advertised by the device.

LLDP TLV-Select allows you to control which Type-Length-Value elements are included in LLDP advertisements, providing granular control over the information shared with neighboring devices.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable type, length, and value (TLV) selection for LLDP.

   Example

   ```
   Device(config)# lldp tlv-select tlv-type
   ```

   Example

   ```
   Device(config)# lldp tlv-select port-vlan
   ```

   Available TLV types:

   - **mac-phy-cfg**: IEEE 802.3 MAC, physical configuration, or status TLV.
   - **management-address**: Management address TLV.
   - **port-description**: Port description TLV.
   - **port-vlan**: Port VLAN ID TLV.
   - **system-capabilities**: System capabilities TLV.
   - **system-description**: System description TLV.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The specified LLDP TLV type is now enabled and will be included in LLDP advertisements sent by the device.

LLDP verification

Lists the show commands to verify LLDP details in active and standby controllers.

Use the following **show** commands to view the LLDP details independently in the active and standby controller.

Timer and status verification

To verify the timer and status in the active and standby controller, use the following command:

```
Device# show lldp
Global LLDP Information:
    Status: ACTIVE
    LLDP advertisements are sent every 30 seconds
```

```
    LLDP hold time advertised is 120 seconds
    LLDP interface reinitialisation delay is 2 seconds
```

Neighbor details verification

To verify the neighbor details in the active controller, use the following command:

```
Device# show lldp neighbors
Capability codes:
    (R) Router, (B) Bridge, (T) Telephone, (C) DOCSIS Cable Device
    (W) WLAN Access Point, (P) Repeater, (S) Station, (O) Other
Device ID           Local Intf     Hold-time  Capability      Port ID
9500-SW             Tw0/0/0        120        B,R             Twe1/0/14
```

To verify the neighbor details in the standby controller, use the following command:

```
Device# show lldp neighbors
Capability codes:
(R) Router, (B) Bridge, (T) Telephone, (C) DOCSIS Cable Device
(W) WLAN Access Point, (P) Repeater, (S) Station, (O) Other
Device ID           Local Intf     Hold-time  Capability      Port ID
9500-SW             Tw0/0/0        120        B,R             Twe1/0/13
Total entries displayed: 1
```

LLDP neighbor TLV details verification

To verify the LLDP neighbor (TLV) detail, use the following command:

```
Device# show lldp neighbors detail
------------------------------------------------
Local Intf: Te0/0/0
Chassis id: 2cd0.2d62.be80
Port id: Te1/1
Port Description: TenGigabitEthernet1/1
System Name: HSRP-ROUTER-1-15.cisco.com

System Description:
Cisco IOS Software, IOS-XE Software, Catalyst 4500 L3 Switch  Software
(cat4500e-UNIVERSAL-M), Version 03.09.00.E RELEASE SOFTWARE (fc1)
Technical Support: http://www.cisco.com/techsupport
Copyright (c) 1986-2016 by Cisco Systems, Inc.
Compiled Tue 19-Jul

Time remaining: 99 seconds
System Capabilities: B,R
Enabled Capabilities: B,R
Management Addresses:
    IP: 8.109.0.1
    IPV6: 2001:12:1::2
Auto Negotiation - not supported
Physical media capabilities:
    Other/unknown
Media Attachment Unit type - not advertised
Vlan ID: 109
Peer Source MAC: 2cd0.2d62.be80
```

Uplink switch LLDP details verification

To verify the LLDP details in the uplink switch, use the following command:

```
Device# show lldp neighbors detail
------------------------------------------------
Local Intf: Te1/1
Chassis id: d4e8.80b3.0420
Port id: Te0/0/0
Port Description: TenGigabitEthernet0/0/0
System Name: WLC-BGL15.cisco.com

System Description:
Cisco IOS Software [Bangalore], C9800 Software (C9800_IOSXE-K9), Experimental
 Version 17.9.20220630:200739
Copyright (c) 1986-2022 by Cisco Systems, Inc.
Compiled Thu 30-Jun-22 13:19

Time remaining: 107 seconds
System Capabilities: B,R
Enabled Capabilities: R
Management Addresses:
    IP: 8.109.0.47
    IPV6: FD09:8:109::45
Auto Negotiation - not supported
Physical media capabilities - not advertised
Media Attachment Unit type - not advertised
Vlan ID: 109
```

LLDP packet errors verification

To verify LLDP packet errors, use the following command:

```
Device# show lldp errors
LLDP errors/overflows:
Total memory allocation failures: 0
Total encapsulation failures: 0
Total input queue overflows: 0
Total table overflows: 0
```

LLDP traffic statistics verification

To verify LLDP traffic statistics, use the following command:

```
Device# show lldp traffic
LLDP traffic statistics:
Total frames out: 18470
Total entries aged: 0
Total frames in: 6156
Total frames received in error: 0
Total frames discarded: 0
Total TLVs discarded: 0
Total TLVs unrecognized: 0
```

Reload reason history

Describes a diagnostic and serviceability feature that records controller reload events and maintains historical data for troubleshooting purposes.

Reload reason history is a diagnostic and serviceability feature that

- records the reasons for controller reloads
- maintains a log of the last ten reload events, and
- provides access to this data through CLI commands or programmable interfaces like NETCONF/YANG.

This feature is useful for troubleshooting abnormal reboots and understanding system behavior in production environments. Cisco introduced it in IOS XE Dublin 17.11.1, enhancing previous capabilities that only recorded the last reload reason.

View reload reason history

View the history using the **show version** command and the Network Configuration Protocol (NETCONF).

> **Note**
>
> When you reload the standby controller, the system report files are generated in the controller hard disk.

Feature history

Lists feature history for reload reason history.

This reference provides the feature history for reload reason history functionality.

Table 147: Feature history for reload reason history

Feature name	Release information	Feature description
Reload reason history	Cisco IOS XE 17.11.1	The reload reason history feature tracks the reasons for controller reload. This is done for the last 10 reloads. In Cisco IOS-XE 17.10.x and earlier releases, it was possible to track only the reason for the last reload.

Request reload reason history using YANG

Configure YANG with NETCONF and RESTCONF to request reload reason history for automated and programmable network operations.

Use YANG with NETCONF and RESTCONF to provide the desired solution for automated and programmable network operations.

Procedure

Use RPC to create a NETCONF GET request for reload history data.

Example

```
<nc:rpc xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0"
```

```
message-id="urn:uuid:da15955f-5bb7-437c-aeb5-0fc7901a1e9e">
  <nc:get>
    <nc:filter>
      <device-hardware-data
xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-device-hardware-oper">
        <device-hardware>
          <device-system-data>
            <reload-history/>
          </device-system-data>
        </device-hardware>
      </device-hardware-data>
    </nc:filter>
  </nc:get>
</nc:rpc>

<rpc-reply message-id="urn:uuid:da15955f-5bb7-437c-aeb5-0fc7901a1e9e"
xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0">

      </device-hardware>
    </device-hardware-data>
  </data>
</rpc-reply>
```

A NETCONF GET request for reload history data is created.

What to do next

Formore information about the YANG models, see these documents:

- The Cisco IOS XE Programmability Configuration Guide at https://www.cisco.com/c/en/us/support/wireless/catalyst-9800-series-wireless-controllers/products-installation-and-configuration-guides-list.html
- The YANG Data Models on Github at https://github.com/YangModels/yang/tree/main/vendor/cisco/xe.
- Contact the Developer Support Community for NETCONF and YANG features at: https://developer.cisco.com/

Reload reason history verification

Lists commands to verify reload history and reason details in the controller console.

Verify reload history and reason details using specific commands to troubleshoot controller issues and understand system behavior.

View reload history details

To view the reload history details, use this command:

```
Device# show reload-history

173 Redundancy Management Interface

Topics:

- Redundancy management interfaces

Details the Redundancy Management Interface for monitoring gateway statistics, standby controller health, and configuring redundancy parameters across network infrastructure.

Redundancy management interfaces

Explains the foundational concepts and principles of Redundancy Management Interfaces (RMI) for high availability in Cisco Catalyst 9800 Series Wireless Controllers, including pairing scenarios, gateway monitoring, and troubleshooting for IPv4 and IPv6 dual stack environments.

A redundancy management interface is a high availability feature that

- enables pairing scenarios and gateway monitoring for Cisco Catalyst 9800 Series Wireless Controllers
- supports both IPv4 and IPv6 dual stack environments, and
- facilitates dynamic pairing, upgrade/downgrade behaviors, ARP handling, and AAA integration.

Gateway monitoring

Describes a network management capability that automatically selects gateway IP addresses and provides enhanced visibility into gateway reachability and RMI state.

Gateway monitoring is a network management capability that

- selects the gateway IP based on the static routes that match the RMI subnet using the broadest mask and least gateway IP
- provides enhanced visibility and statistics related to gateway reachability and RMI state, and
- simplifies troubleshooting and control over high availability (HA) and RMI functionality by offering detailed diagnostics.

Key aspects

Gateway IP selection:

- From Cisco IOS XE 17.2.1 onwards, the **ip default-gateway gateway-ip** command is deprecated for RMI gateway configuration.
- The system automatically chooses a gateway IP by evaluating static routes and selecting the gateway that:
  - matches the RMI subnet,
  - uses the broadest subnet mask,
  - and has the lowest IP address.
- If no matching static route exists, gateway failover does not operate—even if management gateway-failover is enabled.

Enhanced statistics and transparency:

- From Cisco IOS XE 17.18.1 onwards, gateway monitoring provides improved visibility into gateway reachability, RMI state, and detailed diagnostics.
- **Benefits include:**
  - Enhanced visibility into gateway health and RMI state.
  - Simplified troubleshooting through detailed statistics and state information.
  - Greater transparency and control over HA and RMI, improving reliability and diagnostics.

Refer to the Gateway statistics monitoring on page 2132 for gateway monitoring commands.

Airport's air traffic control system

Gateway monitoring works like an airport's air traffic control system. Instead of a pilot manually selecting a runway (like using the old **ip default-gateway** command), a central system automatically identifies the best runway based on current conditions (route matching, subnet mask, and lowest IP address). It then tracks the success or failure of each takeoff and landing (probe statistics and diagnostics), making sure the whole airport runs smoothly and efficiently while providing real-time updates and troubleshooting support when issues arise.

Configure gateway monitoring interval (CLI)

Configure gateway monitoring interval using commands.

Set the interval at which the management gateway failover feature monitors gateway availability on a switch.

Adjusting the gateway monitoring interval determines how frequently the device checks gateway status to trigger failover if necessary. This procedure is performed using command-line interface (CLI) commands.

Before you begin

- Ensure you have access to the device CLI in privileged EXEC mode.
- Confirm that you have the required permissions to enter configuration mode and modify gateway monitoring settings.

Follow these steps to configure the gateway monitoring interval using the CLI:

Procedure

1. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. **management gateway-failover interval** *interval-value*

   Example

   ```
   Device(config)# management gateway-failover interval 6
   ```

   Configures the gateway monitoring interval.

   interval-value - Refers to the gateway monitoring interval. The valid range is from 6 to 12. Default value is 8.

3. **end**

   Example

   ```
   Device(config)# end
   ```

   Saves the configuration and exits configuration mode and returns to privileged EXEC mode.

The system monitors the gateway at the specified interval. Your configuration is saved, and the device returns to privileged EXEC mode.

Configure gateway monitoring (CLI)

Configure gateway monitoring on a device to ensure effective monitoring and management of gateway connections for smooth network operations.

Enable and configure gateway monitoring on a device.

This task is typically performed to ensure that network devices can effectively monitor and manage gateway connections, facilitating smooth network operations and management. Gateway monitoring involves setting up a default gateway and enabling monitoring features.

Follow these steps to configure gateway monitoring (CLI):

Procedure

1. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. **[no] management gateway-failover enable**

   Example

   ```
   Device(config)# management gateway-failover enable
   ```

   Enables gateway monitoring. (Use the **no** form of this command to disable gateway monitoring.)

3. **end**

   Example

   ```
   Device(config)# end
   ```

   Returns to privileged EXEC mode.

The gateway monitoring is enabled and configured, and the configuration changes are active.

What to do next

To save the configuration, use the **write memory** command.

Gateway statistics monitoring

Provides commands and output for displaying gateway statistics and status information.

To display detailed gateway statistics, use the **show platform software rif-mgr chassis {active | standby } r0 gateway-statistics** command and to display gateway status information, use the **show platform software rif-mgr chassis { active | standby } r0 resource-status** command.

```
Device# show platform software rif-mgr chassis active r0 gateway-statistics
```

```
Number of L2 (ARP/ND) probes sent        : 164890
Number of ICMP probes sent               : 20
Number of L2 (ARP/ND) responses received : 164878
Number of ICMP responses received        : 0
Number of L2 (ARP/ND) responses failed   : 12
Number of ICMP responses failed          : 20

Peer Gateway Status : Up
```

Gateway reachability detection

Describes a feature that minimizes the downtime on APs and clients when the gateway reachability is lost on the active controller.

Gateway reachability detection is a feature that

- minimizes the downtime on APs and clients when the gateway reachability is lost on the active controller
- enables both active and standby controllers to keep track of gateway reachability by sending Internet Control Message Protocol (ICMP) and ARP requests periodically to the gateway, and
- detects gateway failures within approximately 8 seconds using consecutive failure monitoring.

Gateway reachability detection behavior

Both active and standby controllers use the RMI IP as the source IP. The messages are sent at 1 second interval. If it takes 8 (or configured value) consecutive failures in reaching the gateway, the controller declares the gateway as non-reachable. It takes approximately 8 seconds to detect if a controller has lost gateway reachability.

Gateway monitoring with native IPv6 uses ICMP Neighbor Discovery protocols and ICMPv6 ECHO to check gateway reachability.

Therefore, you can monitor only the IPv6 gateway when RMI IPv6 is configured.

This means that only one IPv4 or IPv6 gateways can be monitored.

> **Note**
>
> If the standby controller loses gateway, the standby moves to the standby recovery mode.
>
> If the active controller loses gateway, the active reloads and standby becomes active.

Requirement: proper configuration of default gateway

Important note regarding default gateway configuration for gateway reachability check

To ensure the gateway reachability check functions correctly, configure the default gateway next hop in the same subnet as the WMI, which also serves the RMI.

If you configure the default gateway with a next hop IP address outside the WMI subnet, the controller does not send packets for the gateway reachability check. This configuration can cause failover or redundancy issues.

Configure system redundancy workflow

Describes the workflow for configuring system redundancy management interfaces and monitoring.

Summary

The key components involved in the configuration workflow are:

- Redundancy Management Interface (RMI): Provides redundancy capabilities through GUI or CLI configuration
- Controllers: Require reloading for RMI configuration to take effect
- IPv6 Static Route: Enables network routing configuration
- Gateway Monitoring Interval: Monitors gateway connectivity at specified intervals

Workflow

The configuration workflow involves these stages:

1. Configure Redundancy Management Interface using either GUI or CLI method

   For more information, see Configure redundancy management interface (GUI) on page 2156.

   > **Note**
   >
   > For RMI configuration to take effect, ensure that you reload your controllers.

2. Configure IPv6 Static Route to establish network routing

   For information, see Gateway monitoring on page 2130.

3. Configure Gateway Monitoring Interval using CLI to set monitoring parameters

   For more information, see Configure gateway monitoring interval (CLI) on page 2131.

Migrate to RMI IPv6

Configure RMI IPv6 migration from either RMI IPv4 or HA pairing without RMI.

You can migrate to RMI IPv6 from two different configurations: from RMI IPv4 or from HA pairing without RMI. The migration process varies depending on your current configuration.

Before you begin

Follow these steps to migrate to RMI IPv6:

Procedure

Determine your current configuration and follow the appropriate migration path.

- If migrating from RMI IPv4, continue with the following substeps:

  a. Unconfigure the RMI IPv4 using the following CLIs:

  ```
  Device# conf t
  Device(config)# no redun-management interface <vlan_name> chassis 1 address
   <ip_address1> chassis 2 address <ip_address2>
  ```

  > **Note**
  >
  > This CLI unconfigures RMI on both the controllers.

  b.

  > **Note**
  >
  > Take a backup of the running config on active before you reload the controller.

  Reload the controller.

  c. Copy the backed up config to the running config on the box which would have lost all the config.

  d. Configure the RMI IPv6 on both the controllers.

  e. Reload the controller.

- If migrating from HA Pairing (without RMI), for information on HA pairing, see Configuring Redundancy Management Interface (GUI).

Standby monitoring

Describes the standby monitoring feature that allows monitoring of a system on a standby controller using programmatic interfaces and commands.

Standby monitoring is a system health feature that

- monitors the health of a system on a standby controller using programmatic interfaces and commands
- allows monitoring of parameters such as CPU, memory, interface status, power supply, fan failure, and the system temperature

- is enabled when Redundancy Management Interface (RMI) is configured, and
- cannot be dynamically enabled or disabled.

Requirements and configuration

Standby Monitoring is enabled when Redundancy Management Interface (RMI) is configured, no other configuration is required. The RMI itself is used to connect to the standby and perform standby monitoring.

> **Note**
>
> The active controller uses the management or RMI IP to initiate AAA requests. Whereas, the standby controller uses the RMI IP to initiate AAA requests. Thus, the RMI IPs must be added in AAA servers for a seamless client authentication and standby monitoring.

To enable standby console, ensure that the following configuration is in place:

```
redundancy
main-cpu
secondary console enable
```

> **Note**
>
> The Standby Monitoring feature is not supported on a controller in the active-recovery and the standby-recovery modes.

The Standby Monitoring feature supports only the following traffic on the RMI interface of the standby controller:

- Address Resolution Protocol (ARP)
- Internet Control Message Protocol (ICMP)
- TCP Traffic (to or from) ports: 22, 443, 830, and 3200
- UDP RADIUS ports: 1645 and 1646
- UDP Extended RADIUS ports: 21645 to 21844

Feature scenarios include:

- Monitoring the health of the standby directly from the standby controller using Standby RMI IP
- Getting syslogs from the standby controller using the Standby RMI IP

Use cases include:

- Enabling SNMP agent and programmatic interfaces on the standby controller: You can directly perform an SNMP query or programmatic interface query to the standby's RMI IP and active controller
- Enabling syslogs on the standby controller: You can directly get the standby syslogs from the standby controller

RADIUS accounting support:

Whenever you log in to a standby device, the RADIUS start record must be sent to the external RADIUS server. Similarly, when you log out of a device, the RADIUS stop record must be sent to the external RADIUS server.

TACACS+ authentication support:

Users are authenticated through the RMI using the external TACACS+ server. The username and password are evaluated in the TACACS+ server. Depending on the response received from the server, a user will be able to log in to the standby device.

TACACS+ accounting support:

Whenever you log in to the standby device, the TACACS+ accounting start record must be sent to the external TACACS+ server. Similarly, when you log out of a device, the TACACS+ accounting stop record must be sent to the external TACACS+ server.

Note

This configuration must be in place to configure AAA to send the accounting packets:

```
aaa accounting exec {default | named-list} start-stop group {RAD |
tac-group-name}
```

Note

The TACACS+ login to the standby device is not supported when TACACS+ server is configured with hostname.

Monitor the health of standby parameters using SNMP

-

Standby monitoring using standby RMI IP

Describes standby monitoring using standby RMI IP.

Standby monitoring using standby RMI IP is a network management capability that

- enables direct SNMP queries to the standby controller's RMI IP address
- supports IF-MIB monitoring for interface statistics on standby controllers from Release 17.5 onwards, and
- automatically enables SNMP on the standby controller when SNMP agent is enabled on the active controller.

Supported mibs and monitoring capabilities

When an SNMP agent is enabled on the standby controller, you can directly perform an SNMP query to the standby's RMI IP. From Release 17.5 onwards, you can query the following MIB on the standby controller:

Table 148: MIB name and notes

MIB Name	Notes
IF-MIB	This MIB is used to monitor the interface statistics of the standby controller using the standby RMI IP address.

Note

If an SNMP agent is enabled on the active controller, by default, the SNMP is enabled on the standby controller.

Standby monitoring using the active controller

Lists MIB objects for monitoring standby controller health parameters through the active controller.

Monitor the health parameters of the standby controller, including memory, CPU, port status, power statistics, and peer gateway latencies, using various MIB objects through the active controller.

CISCO-LWAPP-HA-MIB

The CISCO-LWAPP-HA-MIB monitors the health parameters of the standby controller, that is, memory, CPU, port status, power statistics, peer gateway latencies, and so on.

You can query these MIB objects of CISCO-LWAPP-HA-MIB.

Table 149: MIB objects and notes

MIB Objects	Notes
cLHaPeerHotStandbyEvent	This object can be used to check if the standby controller has turned hot-standby or not.
cLHaBulkSyncCompleteEvent	This object represents the time at which the bulksync is completed.

CISCO-PROCESS-MIB

The CISCO-PROCESS-MIB monitors CPU and process statistics. Use it to monitor CPU-related or memory-related BINOS processes. The standby CISCO-PROCESS-MIB can be monitored using the active controller.

ENTITY-MIB

The ENTITY-MIB is used to monitor hardware details of the active and standby controllers using the active controller.

Note

The standby Route Processor (RP) sensors are appended in the active RP sensors.

Standby IOS linux syslogs

Explains how standby IOS Linux syslogs are relayed and forwarded to external servers in wireless controller HA configurations.

Standby IOS Linux syslogs are a logging mechanism that

- relay logs using the same method as on the active Cisco IOS for wireless controllers
- enable external logging from the standby IOS starting from Release 17.5 onwards, and

- forward all syslogs generated on the standby controller to the configured external server through BINOS processes.

Standby syslog behavior

From Release 17.5 onwards, external logging of syslogs from the standby IOS is enabled. As BINOS processes on standby also forwards the syslogs to Cisco IOS, all the syslogs generated on the standby controller is forwarded to the configured external server.

> **Note**
>
> RMI IP address is used for logging purpose.

The standby controller tries to send syslogs to the IPv4 server because logging is only configured on IPv4 even though IPv4 is not supported by standby. This is the expected behavior when an HA pair is configured with the RMI IPv6 address, the active controller has dual stack, and logging is configured on the IPv4 address

Standby interface status using active SNMP

Lists the MIB objects of CISCO-LWAPP-HA-MIB that can be queried for standby interface information.

The standby interface information is sent to the active controller using IPC in these scenarios:

- When there is a change in the interface status.
- When a new interface is added or deleted on the standby controller.

When the active controller receives the interface information from the standby controller, the active controller's database is populated with the standby interface information.

When an SNMP query is received for the standby interface information, the SNMP handlers corresponding to the CISCO-LWAPP-HA-MIB reads them from the standby interface database on the active and populates the MIB objects in CISCO-LWAPP-HA-MIB.

You can query the following MIB objects of CISCO-LWAPP-HA-MIB.

Table 150: MIB objects of CISCO-LWAPP-HA-MIB

MIB Object	Notes
stbyIfIndex	This is a unique value (greater than zero) for each interface of the standby controller.
stbyIfName	This is the name of the standby interface.
stbyIfPhysAddress	This is the interface address of the standby controller in the protocol sublayer.
stbyifOperStatus	This is the current operational state of the interface in the standby controller.
stbyifAdminStatus	This is the desired state of the interface of the standby controller.

To verify the logging on the active when the standby fails to send interface statistics, use this command:

```
Device# debug snmp ha-chkpt
Device# debug snmp ha-intf_db
```

Standby controller health monitoring using programmatic interfaces

Lists the programmatic interfaces that can be used to monitor the health of standby controller.

You can monitor parameters such as CPU, memory, sensors, and interface status on a standby controller using programmatic interfaces such as NETCONF and RESTCONF. The RMI IP of the standby controller can be used for access to the following operational models:

The models can be accessed through:

- Cisco-IOS-XE-device-hardware-oper.yang
- Cisco-IOS-XE-process-cpu-oper.yang
- Cisco-IOS-XE-platform-software-oper.yang
- Cisco-IOS-XE-process-memory-oper.yang
- Cisco-IOS-XE-interfaces-oper.yang

For more information on the YANG models, see the *Programmability Configuration Guide, Cisco IOS XE 17.3.x*.

Standby controller health monitoring (CLI)

Lists commands to monitor the health of standby controller.

This section describes the different commands that can be used to monitor the standby device.

You can connect to the standby controller through SSH using the RMI IP of the standby controller. The user credentials must have been configured already. Both local authentication and RADIUS authentication are supported.

> **Note**
>
> The **redun-management** command needs to be configured on both the controllers, primary and standby, prior to high availability (HA) pairing.

Port state monitoring

This is a sample output of the **show interfaces** *interface-name* command:

```
Device-standby# show interfaces GigabitEthernet1

GigabitEthernet1 is down, line protocol is down

Shadow state is up, true line protocol is up
  Hardware is CSR vNIC, address is 000c.2909.33c2 (bia 000c.2909.33c2)
  MTU 1500 bytes, BW 1000000 Kbit/sec, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full Duplex, 1000Mbps, link type is force-up, media type is Virtual
```

```
  output flow-control is unsupported, input flow-control is unsupported
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:06, output 00:00:24, output hang never
  Last clearing of "show interface" counters never
  Input queue: 30/375/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 389000 bits/sec, 410 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     3696382 packets input, 392617128 bytes, 0 no buffer
     Received 0 broadcasts (0 multicasts)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 0 multicast, 0 pause input
     18832 packets output, 1218862 bytes, 0 underruns
     Output 0 broadcasts (0 multicasts)
     0 output errors, 0 collisions, 2 interface resets
     3 unknown protocol drops
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier, 0 pause output
     0 output buffer failures, 0 output buffers swapped out
```

This is a sample output of the **show ip interface brief** command:

```
Device# show ip interface brief

Interface              IP-Address      OK? Method Status                Protocol
GigabitEthernet1       unassigned      YES unset  down                  down

GigabitEthernet0       unassigned      YES NVRAM  administratively down down

Capwap1                unassigned      YES unset  up                    up

Capwap2                unassigned      YES unset  up                    up

Capwap3                unassigned      YES unset  up                    up

Capwap10               unassigned      YES unset  up                    up

Vlan1                  unassigned      YES NVRAM  down                  down

Vlan56                 unassigned      YES unset  down                  down

> **Note**
>
> The **show environment summary** command displays data only for physical appliances such as Cisco Catalyst 9800-80 Wireless Controller, Cisco Catalyst 9800-40 Wireless Controller, Cisco Catalyst 9800-L Wireless Controller, and Cisco Catalyst 9800 Embedded Wireless Controller for Switch. The command does not display data for Cisco Catalyst 9800 Wireless Controller for Cloud.

Gateway-monitoring configuration verification

Provides commands to verify the gateway-monitoring configuration status.

Verify the status of the gateway-monitoring configuration on active and standby controllers using specific show commands.

To verify the status of the gateway-monitoring configuration on an active controller, run this command:

```
Device# show redundancy states

my state = 13 -ACTIVE
peer state = 8 -STANDBY HOT
Mode = Duplex
Unit = Primary
Unit ID = 1

Redundancy Mode (Operational) = sso
Redundancy Mode (Configured) = sso
Redundancy State = sso
Maintenance Mode = Disabled
Manual Swact = enabled
Communications = Up

client count = 129
client_notification_TMR = 30000 milliseconds
RF debug mask = 0x0
Gateway Monitoring = Disabled
Gateway monitoring interval = 8 secs
```

To verify the status of the gateway-monitoring configuration on a standby controller, run this command:

```
Device-stby# show redundancy states

my state = 8 -STANDBY HOT
peer state = 13 -ACTIVE
Mode = Duplex
Unit = Primary
Unit ID = 2

Redundancy Mode (Operational) = sso
Redundancy Mode (Configured) = sso
```

```
Redundancy State = sso
Maintenance Mode = Disabled
Manual Swact = cannot be initiated from this the standby unit
Communications = Up

client count = 129
client_notification_TMR = 30000 milliseconds
RF debug mask = 0x0
Gateway Monitoring = Disabled
Gateway monitoring interval = 8 secs
```

RMI IPv4 configuration verification

Lists commands to verify the Redundancy Management Interface (RMI) IPv4 configuration.

Verify the RMI IPv4 configuration.

```
Device# show running-config interface vlan management-vlan

Building configuration...

Current configuration : 109 bytes
!
interface Vlan90
ip address 9.10.90.147 255.255.255.0 secondary
ip address 9.10.90.41 255.255.255.0
end
```

To verify the interface configuration for a standby controller, use this command:

```
Device-stby# show running-config interface vlan 90

Building configuration...

Current configuration : 62 bytes
!
interface Vlan90
ip address 9.10.90.149 255.255.255.0
end
```

To verify the chassis redundancy management interface configuration for an active controller, use this command:

```
Device# show chassis rmi

Chassis/Stack Mac Address : 000c.2964.1eb6 - Local Mac Address
Mac persistency wait time: Indefinite
   H/W Current
Chassis# Role      Mac Address     Priority  Version  State  IP
RMI-IP
---------------------------------------------------------------------------------------
*1       Active    000c.2964.1eb6  1         V02      Ready  169.254.90.147
9.10.90.147
2        Standby   000c.2975.3aa6  1         V02      Ready  169.254.90.149
9.10.90.149
```

To verify the chassis redundancy management interface configuration for a standby controller, use this command:

```
Device-stby# show chassis rmi

Chassis/Stack Mac Address : 000c.2964.1eb6 - Local Mac Address
Mac persistency wait time: Indefinite
                                             H/W   Current
Chassis#   Role    Mac Address     Priority Version  State  IP
RMI-IP
---------------------------------------------------------------------------------------
1         Active   000c.2964.1eb6     1      V02     Ready  169.254.90.147
9.10.90.147
*2        Standby  000c.2975.3aa6     1      V02     Ready  169.254.90.149
9.10.90.149
```

To verify the ROMMON variables on an active controller, use this command:

```
Device# show romvar | include RMI

RMI_INTERFACE_NAME = Vlan90
RMI_CHASSIS_LOCAL_IP = 9.10.90.147
RMI_CHASSIS_REMOTE_IP = 9.10.90.149
```

To verify the ROMMON variables on a standby controller, use this command:

```
Device-stby# show romvar | include RMI

RMI_INTERFACE_NAME = Vlan90
RMI_CHASSIS_LOCAL_IP = 9.10.90.149
RMI_CHASSIS_REMOTE_IP = 9.10.90.147
```

To verify the switchover reason, use this command:

```
Device# show redundancy switchover history

Index  Previous  Current  Switchover             Switchover
       active    active   reason                 time
-----  --------  -------  ----------             ----------
   1       2        1     Active lost GW         17:02:29 UTC Mon Feb 3 2020
```

RMI IPv6 configuration verification

Provides commands to verify the RMI IPv6 configuration.

Verify the RMI IPv6 configuration.

To verify the chassis redundancy management interface configuration for both active and standby controllers, run this command:

```
Device# show chassis rmi

Chassis/Stack Mac Address : 00a3.8e23.a540 - Local Mac Address
Mac persistency wait time: Indefinite
Local Redundancy Port Type: Twisted Pair
                                             H/W   Current
Chassis#   Role     Mac Address    Priority Version State     IP
```

```
RMI-IP

  1        Standby  706d.1536.23c0    1      V02     Ready  169.254.254.17
2020:0:0:1::211
 *2        Active   00a3.8e23.a540    1      V02     Ready  169.254.254.18
2020:0:0:1::212
```

To verify the RMI related ROMMON variables for both active and standby controllers, run this command

```
Device# show romvar | i RMI

RMI_INTERFACE_NAME = Vlan52
RMI_CHASSIS_LOCAL_IPV6 = 2020:0:0:1::212
RMI_CHASSIS_REMOTE_IPV6 = 2020:0:0:1::211
```

Redundancy port interface configuration verification

Provides commands to verify redundancy port interface configuration.

Use these commands to verify redundancy port interface configuration for RMI and RP connections in both active and standby instances.

RMI link verification commands

To verify the RMI link re-establishment count and the time since the RMI link is Up in the active instance, run these command:

```
Device# show platform software rif-mgr chassis active R0 rmi-connection-details
RMI Connection Details
    RMI Link re-establish count : 2
    RMI Link Uptime             : 21 hours 8 minutes 43 seconds
    RMI Link Upsince            : 08/05/2021 13:46:01
```

To verify the RMI link re-establishment count and the time since the RMI link is Down in the active instance, run these command:

```
Device# show platform software rif-mgr chassis active R0 rmi-connection-details
RMI Connection Details
    RMI Link re-establish count : 1
    RMI Link Downtime           : 28 seconds
    RMI Link Downsince          : 07/16/2021 03:19:11
```

To verify the RMI link re-establishment count and the time since the RMI link is Up in the standby instance, run these command:

```
Device# show platform software rif-mgr chassis standby R0 rmi-connection-details
RMI Connection Details
    RMI Link re-establish count : 1
    RMI Link Uptime             : 1 hour 39 minute 9 seconds
    RMI Link Upsince            : 07/16/2021 01:31:41
```

To verify the RMI link re-establishment count and the time since the RMI link is Down in the standby instance, run these command:

```
Device# show platform software rif-mgr chassis standby R0 rmi-connection-details
RMI Connection Details
    RMI Link re-establish count : 1
```

```
    RMI Link Downtime           : 22 seconds
    RMI Link Downsince          : 07/16/2021 03:19:17
```

RP link verification commands

To verify the RP link re-establishment count and the time since the RP link is UP for days in the active instance, run the following command:

```
Device# show platform software rif-mgr chassis active R0 rp-connection-details
RP Connection Details
    RP Connection Uptime  : 12 days 17 hours 1 minute 39 seconds
    RP Connection Upsince : 07/03/2021 07:06:20
```

To verify the RP link re-establishment count and the time since the RP link is Down in the active instance, run the following command:

```
Device# show platform software rif-mgr chassis active R0 rp-connection-details
RP Connection Details
    RP Connection Downtime     : 4 seconds
    RP Connection Downsince    : 07/16/2021 03:33:04
```

To verify the RP link re-establishment count and the time since the RP link is UP in the standby instance, run the following command:

```
Device# show platform software rif-mgr chassis standby R0 rp-connection-details
RP Connection Details
    RP Connection Uptime  : 12 days 17 hours 2 minutes 1 second
    RP Connection Upsince : 07/03/2021 07:05:58
```

To verify the RP link re-establishment count and the time since the RP link is Down in the standby instance, run the following command:

```
Device# show platform software rif-mgr chassis standby R0 rp-connection-details
RP Connection Details
    RP Connection Downtime    : 22 seconds
    RP Connection Downsince   : 07/16/2021 03:19:17
```

RIF and stack manager internal statistics verification

To verify the RIF and stack manager internal statistics in the active instance, run the following command:

```
Device# show platform software rif-mgr chassis active R0 rif-stk-internal-stats
RIF Stack Manager internal stats

    Stack-mgr reported RP down            : False
    DAD link status reported to Stack-Mgr : True
```

To verify the RIF and stack manager internal statistics in the standby instance, run the following command:

```
Device# show platform software rif-mgr chassis standby R0 rif-stk-internal-stats
RIF Stack Manager internal stats

    Stack-mgr reported RP down            : False
    DAD link status reported to Stack-Mgr : True
```

LMP statistics verification

To verify the number of packets sent or received for each type in the active instance, run the following command:

```
Device# show platform software rif-mgr chassis active R0 lmp-statistics
LMP Statistics

Info Type Sent                    : 6
Solicit Info Type Sent            : 0
Unsolicit Info Type Sent          : 6
Reload Type Sent                  : 0
Recovery Type Sent                : 1
Gateway Info Type Sent            : 0
Enquiry Type Sent                 : 0
Solicit Enquiry Type Sent         : 0
Unsolicit Enquiry Type Sent       : 0

Info Type Received                : 5
Solicit Info Type Received        : 2
Unsolicit Info Type Received      : 3
Reload Type Received              : 0

Gateway Info Type Received        : 4
Enquiry Type Received             : 0
Solicit Enquiry Type Received     : 0
Unsolicit Enquiry Type Received   : 0
```

To verify the number of packets sent or received for each type in the standby instance, run the following command:

```
Device# show platform software rif-mgr chassis standby R0 lmp-statistics
LMP Statistics

Info Type Sent                   : 6
Solicit Info Type Sent           : 0
Unsolicit Info Type Sent         : 6
Reload Type Sent                 : 0
Recovery Type Sent               : 0
Gateway Info Type Sent           : 4
Enquiry Type Sent                : 0
Solicit Enquiry Type Sent        : 0
Unsolicit Enquiry Type Sent      : 0

Info Type Received               : 5
Solicit Info Type Received       : 3
Unsolicit Info Type Received     : 2
Reload Type Received             : 0
Recovery Type Received           : 1
Gateway Info Type Received       : 0
Enquiry Type Received            : 0
Solicit Enquiry Type Received    : 0
Unsolicit Enquiry Type Received  : 0
```

Redundancy management interfaces

A redundancy management interface is a network interface that

- acts as a secondary link between active and standby wireless controllers,
- enables resource health information exchange (such as gateway reachability), and
- assists in the detection of dual-active controller conditions to maintain high availability.

The RMI might trigger a switchover based on the gateway status of the active controller.

Subdefinitions:

- **Active controller**: Uses the management IP as the primary address and RMI as the secondary IPv4 address on the management VLAN. RMI configuration is automatic.

  Analogy: Like a city's current mayor who's in charge, but always ready to hand over leadership if needed.

- **Standby controller**: Has the RMI IP as the primary address; upon switchover, roles and addresses are swapped.

  Analogy: Like a vice-mayor who takes the mayor's seat (with all responsibilities and keys) when the mayor is away.

- **RP (Redundancy Port)**: The main dedicated physical link for state and configuration synchronization between active and standby controllers; loss of both RP and RMI links results in high availability (HA) failures.

  (Analogy: Like the main road connecting two city offices, critical for daily business and coordination).

- **WMI (Wireless Management Interface)**: The main management interface for controller operations and communications; shares its subnet with the RMI and may serve as a source address for certain types of traffic such as AAA packets.

  Analogy: Like a city's public headquarters, used for both regular operations and official correspondence.

- RMI **(Redundancy Management Interface)**: A dedicated network interface that serves as a secondary communication path between controllers for exchanging resource health information, detecting dual-active conditions, and monitoring gateway reachability; shares the same subnet as the Wireless Management Interface (WMI).

  Analogy: Like an emergency side road connecting two city halls, used for urgent official communication.

- **HA (High Availability)**: A deployment setup where controllers operate as an active-standby pair to ensure uninterrupted wireless services; relies on RP and RMI links for failover and role management.

- **ARP table**: A database on a network device such as a switch that maintains mappings between IP addresses and MAC addresses; determines how to forward traffic within the local network.

  (Analogy: Like a city map book held by delivery drivers in neighboring towns, showing them which mayor is at which city hall, so the right deliveries go to the right address.)

- **GARP (Gratuitous ARP):** A type of ARP (Address Resolution Protocol) packet broadcast by a controller, typically after a switchover, to update the ARP tables in connected network switches with the correct IP-to-MAC address mappings.

  (Analogy: Like sending out an urgent memo to all nearby towns, telling them who the new mayor is so they update their city maps immediately after a leadership change.)

- **ARP cache timeout**: The duration for which an entry in the ARP table is considered valid before it must be refreshed; reducing this value helps the network recover quickly after role or address changes in the controllers.

  (Analogy: Like setting a regular schedule for when all delivery drivers check for updates to the city map books, ensuring they quickly recognize changes in city leadership or addresses.)

- **SGACL (Security Group Access Control List)**: A policy configuration that determines which types of network traffic (e.g., ICMP, ARP) are permitted between specific interfaces or devices, such as the RMI addresses of controllers.

  (Analogy: Like special city rules that decide which types of emergency vehicles are allowed to travel the emergency road between city halls.)

- **ICMP (Internet Control Message Protocol)**: A network protocol used for sending error messages and operational information between network devices; essential for controllers to monitor each other's status over the RMI.

  (Analogy: Like sending quick bike couriers to report on the status of the roads or to alert if there's trouble between cities.)

- **AAA (Authentication, Authorization, and Accounting**): A framework for controlling user access to network resources and tracking user activity; controllers may send AAA-related packets from either the WMI IP or the RMI IP, so the AAA server must recognize both as valid.

(Analogy: Like having a security checkpoint that logs who enters or exits city buildings, whether they come from Main Street (WMI) or the emergency road (RMI).)

- **SGT (Security Group Tag)**: An identification label assigned to network devices for policy enforcement with Cisco TrustSec; mapping is applied for both RMI and WMI addresses when device SGTs are used.

  Analogy: Like giving every city vehicle a badge, so officials can enforce special rules for each group whether they use Main Street or the emergency road.

- **Cisco TrustSec**: A security architecture that uses SGTs to enforce network segmentation and access control policies; not supported on the RMI interface.

  Analogy: Like a city's security zone system—effective on main city roads, but not supported on the emergency side road.

Limitations for RMI

- Cisco TrustSec is not supported on the RMI.
- From the Cisco IOS XE 17.14.1 release onwards, RP-only SSO is not supported for CW9800H1, CW9800H2, or CW9800M Wireless Controllers. These controllers support RP+RMI SSO deployment only. In contrast, Cisco Catalyst 9800 Wireless Controllers support both RP-only SSO and RP+RMI SSO.

Best practices for RMI

- Ensure that the SGACL is defined appropriately to allow ICMP and ARP traffic between the active and standby RMI addresses when device SGT is used, since the IP-SGT mapping applies to both the RMI and WMI addresses.
- Configure the AAA server to recognize both the WMI IP and the RMI IP as valid source addresses, because AAA packets from the controller may originate from either.
- RMI-based "RP" High Availability is mandatory in the Cisco Catalyst CW9800H1 Wireless Controller, Cisco Catalyst CW9800H2 Wireless Controller and Cisco Catalyst CW9800M Wireless Controller.

Important: gateway monitoring interval and detection time

- When gateway reachability is enabled, both the active and standby controllers check gateway status through the RMI interface.
- It takes approximately the configured gateway monitoring interval to detect when a controller has lost gateway reachability.
- The default gateway monitoring interval is eight seconds, so the minimum detection time is about eight seconds unless you configure a different value.

Recommendation: set ARP cache timeout to ensure fast HA recovery:

When both the RP and RMI links are down, the HA setup breaks and both controllers become active, causing an IP conflict in the network. The HA setup is restored once the RP link is up. Depending on the external switch, its ARP table may correctly update to the new active controller or remain stale if the switch ignores GARP packets, potentially prolonging the conflict.

- We recommend setting the ARP cache timeout to a low value. This practice enables faster recovery from multiple fault scenarios.

  You should choose a timeout value that does not negatively affect network traffic. For example, 30 minutes is a suitable interval.

Analogy

Think of redundancy management interfaces (RMI) as an emergency backup road that connects two cities (the active and standby controllers). The main highway (the redundancy port, RP) handles most of the day-to-day traffic and coordination. If the main highway is blocked or damaged, the emergency road (RMI) ensures that vital information—such as each city's health, status, and road conditions—can still be exchanged quickly.

Just as emergency vehicles and communication must be allowed to travel the backup road (analogous to allowing ICMP and ARP traffic via SGACL), the RMI helps both cities detect if both try to take charge at the same time (dual-active condition) and exchange important information about the area's main gateway (gateway status). If both the highway and the emergency road are inaccessible, each city might assume it's in charge, resulting in confusion (an IP conflict). The ARP table is like city maps in other towns (switches) that may not immediately recognize which city is currently in charge after both reconnect—setting these maps to update frequently (low ARP cache timeout) allows for faster recovery from major outages.

Controller operations with Redundant Management Interface

Explains how active and standby controllers assign and manage IP addresses using the redundant management interface (RMI) in high-availability setups.

A controller operation with redundant management interface is a high-availability configuration that

- assigns the management IP address as the primary address on the active controller
- uses the secondary IPv4 address on the management VLAN as the RMI IP address for the active controller, and
- configures the RMI IP address as the primary IP address on the standby controller.

IP address assignment in controller operations

The active controller assigns IP addresses as follows:

- The primary address is the management IP address.
- The secondary IPv4 address on the management VLAN is the RMI (Redundant Management Interface) IP address for the active controller.

The standby controller manages IP addresses in a high-availability setup as follows:

- It does not have the wireless management IP configured.
- The RMI IP address is configured as the primary IP address on the standby controller.
- When the standby controller becomes active, the management IP address becomes the primary IP address, and the RMI IP address becomes the secondary IP address.
- If the interface on the active controller is administratively down, the same state is reflected on the standby controller.

> **Note**
>
> Do not configure the secondary IPv4 address explicitly. RMI automatically configures a single secondary IPv4 address under the RMI.

Dual stack configurations on management vlans with RMI

Explains the capability of the management VLAN to be configured with both IPv4 and IPv6 addresses for RMI and WMI.

A dual stack configuration is a network interface setup that

- allows both IPv4 and IPv6 addresses to be configured on the wireless management interface,
- permits monitoring only of the gateway that matches the configured RMI address family (IPv4 or IPv6), and
- restricts the visibility of the alternate family's management address on the standby controller.

Expanded explanation

- Dual stack refers to the fact that the wireless management interface can be configured with IPv4 and IPv6 addresses. If an RMI IPv4 address is configured along with an IPv4 management IP address, you can additionally configure an IPv6 management address on the wireless management interface. This IPv6 management IP address will not be visible on the standby controller.
- If an RMI IPv6 address is configured along with an IPv6 management IP address, you can additionally configure an IPv4 management address on the wireless management interface. This IPv4 management IP address will not be visible on the standby controller.
- Therefore, you can monitor only the IPv6 gateway when the RMI IPv6 address is configured, or only the IPv4 gateway when the RMI IPv4 address is configured.

> **Note**
>
> The RMI feature supports the RMI IPv4 or IPv6 addresses.

RMI-based high-availability pairings

Describes a controller deployment configuration that uses Remote Machine Interface to synchronize two controllers for redundancy and failover.

A RMI-based high-availability pair is a controller deployment configuration that

- uses Remote Machine Interface (RMI) to synchronize two controllers,
- provides redundancy by designating active and standby roles, and
- ensures failover and persistent state during controller reloads or outages.

RMI-based high-availability pairing scenarios and device support

You should consider RMI-based high-availability pairs in the following scenarios:

- Fresh installation: Configure high availability during the initial setup of controllers.
- Already paired controllers: Adjust or reconfigure pairing for controllers that are already part of a high-availability pair.
- Upgrade scenario: Maintain or update the pair relationship during software or hardware upgrades.
- Downgrade scenario: Ensure pairing remains stable and functional during downgrades.

Dynamic high-availability (HA) pairing requires both the active and standby controllers to reload. In practice, on the Cisco Catalyst 9800-L, 9800-40, and 9800-80 Wireless Controllers, dynamic pairing occurs when one controller reloads and becomes the standby member of the pair.

> **Note**
>
> Unique chassis numbers must be configured for each controller before forming an HA pair, as these numbers identify the controllers within the pair.

HA pairing without previous configuration

Describes a deployment scenario for wireless controllers that enables initial HA setup on devices without existing ROMMON variables.

A high-availability (HA) pairing without previous configuration is a deployment scenario for wireless controllers that

- initiates the HA setup on devices without existing ROMMON variables for RP (Route Processor) IP addresses
- allows selection between the soon-to-be-deprecated privileged EXEC mode RP-based commands and the newer RMI IP-based mechanisms, and
- derives RP IPs from RMI IPs after forming the HA pair, with restrictions on method transitions.

Command usage and method selection

When HA pairing is performed for the first time (without previous setup), devices do not have ROMMON variables for RP IP addresses.

After RMI-based HA pairing on a brand-new system:

- RP IPs are derived from RMI IPs and used in HA pairing.
- Privileged EXEC mode RP-based CLIs method of clearing and forming an HA pair is not allowed.
- To view the ROMMON variables, use the **show romvars** command.

> **Caution**
>
> Privileged EXEC mode RP-based commands are deprecated and will be blocked after choosing the RMI-based HA pairing.

Method selection considerations:

- You can still choose from the existing privileged EXEC mode RP-based commands or the RMI IP-based mechanisms. However, the privileged EXEC mode RP-based commands are deprecated.
- If you use Cisco Catalyst Center, you can choose the privileged EXEC mode RP-based CLI mechanism till the Cisco Catalyst Center migrates to support the RMI.
- If you choose privileged EXEC RP-based CLI mechanism, the RP IPs are configured the same way as in the 16.12 release.

Use the RMI IP-based mechanism for fresh installations, even though both RP-based and RMI methods may initially be available.

Software version requirements:

- The RMI migration is supported from Cisco Catalyst Center, 2.3.3.x release version.

- RMI-based High Availability requires Cisco IOS XE release version 17.3 or above.

Cisco Catalyst Center interoperability:

- If you use Cisco Catalyst Center, you can choose the privileged EXEC mode RP-based CLI mechanism till the Cisco Catalyst Center migrates to support the RMI.
- The RMI migration is supported from Cisco Catalyst Center, 2.3.3.x release version.

Negative cases where RMI migration fails include:

- Devices are not reachable.
- Non-Cisco Catalyst 9800 Series Wireless Controllers are in use.
- Controller is running Cisco IOS XE 17.3 or below
- High Availability is not configured.
- High Availability RMI is already configured.
- Attempting upgrade to an already failed High Availability paired controller.

> ⚠ **Caution**
>
> The controller GUI prohibits applying RMI migration configuration to High Availability failed devices.

Security system installation analogy

Establishing HA pairing without previous configuration is like setting up a new security system in a building that has never had one before.

At first, you have the choice between using an old key-based system (privileged EXEC mode RP-based commands), which will soon be phased out, or installing a new state-of-the-art digital access system (RMI IP-based mechanism).

Once you install the modern digital system and program it to generate security codes based on the latest technology (RP IPs derived from RMI IPs), the use of physical keys becomes unavailable.

If you later decide to upgrade, you can only add new features to the digital system; you cannot go back to using the old keys because the doors no longer have compatible locks.

This analogy illustrates how choosing the RMI-based approach in HA pairing establishes a new baseline that does not allow reverting to the older method.

Paired controllers

Describes a high availability infrastructure configuration that links two controllers for redundancy and failover operations.

A paired controller is a high availability (HA) infrastructure configuration that

- links two controllers to operate jointly for redundancy and failover,
- allows seamless migration from traditional EXEC mode RP-based commands to RMI-based HA pairing, and
- ensures controller identity and connectivity are maintained even when core pairing mechanisms are updated or reloaded.

Expanded explanation

When controllers are already in an HA pair, they continue to use existing EXEC mode RP-based commands unless Remote Management Interface (RMI) is enabled. Enabling RMI migrates the system to use RMI-derived HA pairing, overwriting any existing RP IPs with those derived from the RMI configuration. The HA pair remains stable immediately after this change, but the controllers only adopt the new IPs following their next reload.

RMI requires controllers to be reloaded for the changes to take effect. Once both controllers restart, they reestablish the HA pair using the new RMI-derived RP IPs. After pairing through RMI, EXEC mode RP-based commands are blocked, preventing configuration conflicts.

Examples

- Two controllers configured as a high availability pair, where enabling RMI changes the way their active-standby relationship is managed and what IPs are used for internal communication.
- An active and standby controller pair that continues functioning during migration from legacy RP-IP pairing to RMI, without disruption until reload.

Counter-examples

- Two standalone controllers operating independently without HA pairing cannot be considered paired controllers.
- A controller pair where RMI is never configured and all management remains through EXEC mode RP-based commands does not benefit from RMI-derived features.

Analogy

Imagine a paired controller setup as two co-pilots flying an airplane together (the airplane represents your network environment). Traditionally, they use walkie-talkies (EXEC mode RP-based commands) to coordinate their flying activities. If you upgrade their communication system to headsets (RMI-based pairing), the co-pilots continue flying the plane using walkie-talkies until they both put on the new headsets (after a "reload" or restart).

From that point onward, all their coordination happens via the more reliable and advanced headsets. The co-pilots' ability to work together—their partnership—remains unbroken throughout; it is only how they communicate and identify each other's messages that changes, and only becomes effective after both are using the new headsets.

Upgrade from Cisco IOS XE 16.1.x to a later release

Provides upgrade and downgrade options when migrating a system from Cisco IOS XE 16.1.x to a later release.

When upgrading a system, you have these options:

- Migrate while retaining the existing RP IP configuration: In this scenario, the current RP IP configuration remains unchanged, and future modifications will utilize EXEC mode RP-based commands.
- Migrate after clearing the HA configuration: Here, you have the choice to use either the traditional EXEC mode RP-based commands or adopt the new RMI-based RP configuration. If the previous configuration is preserved, RMI will update the RP IPs with those derived from the RMI IPs.

Downgrade scenario

Important

The downgrade scenario given below is not applicable for Cisco IOS XE 17.1.x.

In a downgrade scenario, only EXEC mode RP-based commands are available. The downgrade process may follow one of these paths:

- If the upgraded system used the RMI-based RP configuration.
- If the upgraded system continued to use the EXEC mode RP-based commands.

In the above cases, the downgraded system uses the EXEC mode RP-based commands to modify the configuration. However, the downgraded system will continue to use the new derived RP IPs.

In both of these cases, the system will revert to EXEC mode RP-based commands for configuration alterations, yet will still utilize the newly derived RP IPs.

> **Note**
>
> When you downgrade the Cisco Catalyst 9800 Series Wireless Controller to any version below Cisco IOS XE 17.1 and if the mDNS gateway is enabled on the WLAN/RLAN/GLAN interfaces, the mdns-sd-interface gateway goes down after the downgrade.
>
> To enable the mDNS gateway on the WLAN/RLAN/GLAN interfaces in Cisco IOS XE 16.12 and earlier versions, use these commands:
>
> **wlan test 1 test**
>
> **mdns-sd gateway**
>
> To enable the mDNS gateway on the WLAN/RLAN/GLAN interfaces from version Cisco IOS XE 17.1 onwards, use these command:
>
> **mdns-sd-interface gateway**

Configure redundancy management interface (GUI)

Configure redundancy management interface using GUI to enable failover capabilities on Cisco Catalyst 9800 Series Wireless Controllers.

Enable redundancy management for Cisco Catalyst 9800 Series Wireless Controllers using the graphical user interface (GUI).

Use this task to configure the redundancy management interface (RMI) and set up either RMI+RP or RP redundancy pairing on Cisco Catalyst 9800 Series Wireless Controllers. Configuring redundancy improves system availability and failover capabilities.

Before you begin

Ensure that Wireless Management Interface (WMI) is available before configuring RMI + RP using the GUI.

Follow these steps to configure redundancy management interface using GUI:

Procedure

1. In the **Administration > Device > Redundancy** window, perform the following:
   a. Set the **Redundancy Configuration** toggle button to **Enabled** to activate redundancy configuration.
   b. In the **Redundancy Pairing Type** field, select **RMI+RP** to perform RMI+RP redundancy pairing as follows:
      - In the **RMI IP for Chassis 1** field, enter the RMI IP address for chassis 1.
      - In the **RMI IP for Chassis 2** field, enter the RMI IP address for chassis 2.
      - From the **HA Interface** drop-down list, choose one of the HA interfaces.

You can select the HA interface only for Cisco Catalyst 9800 Series Wireless Controllers.

- Set the **Management Gateway Failover** toggle button to **Enabled** to activate management gateway failover.
- In the **Gateway Failure Interval** field, enter an appropriate value. The valid range is 6–12 seconds (default 8 seconds).

c. In the **Redundancy Pairing Type** field, select **RP** to perform RP redundancy pairing as follows:

- In the **Local IP** field, enter an IP address for the local chassis.
- In the **Netmask** field, enter the subnet mask assigned to all wireless clients.
- From the **HA Interface** drop-down list, choose one of the HA interfaces.

  You can select the HA interface only for Cisco Catalyst 9800 Series Wireless Controllers.
- In the **Remote IP** field, enter an IP address for the remote chassis.

d. In the **Keep Alive Timer** field, enter an appropriate timer value (1–10 × 100 milliseconds).

e. In the **Keep Alive Retries** field, enter an appropriate retry value (3–10 seconds).

f. In the **Active Chassis Priority** field, enter a value.

2. Click **Apply** and reload controllers.

The redundancy management interface is configured, and redundancy pairing is established based on your chosen method. The controller is now set up for improved high availability and failover.

Configure redundancy management interface (CLI)

Configure redundancy management interface using commands.

Configure a Redundancy Management Interface (RMI) on Cisco Catalyst 9800 controllers using CLI commands to support high availability (HA) between two devices.

Use this task when you want to set up high availability and redundancy between two Catalyst 9800 series controllers. The RMI coordinates HA communication and failover, ensuring service continuity in case of device failure.

Before you begin

- Ensure both controllers are cabled and powered on.
- Verify you have administrator access to both devices via CLI.
- Gather the following information:
  - Chassis number (1 or 2 for each controller)
  - Desired chassis priority for HA (if overriding default)
  - A dedicated GigabitEthernet interface for HA communication (required for 9800-CL controllers)
  - Management VLAN and corresponding IP addresses for each chassis

Procedure

---

1. Optional: Configure the priority of the specified device.

Example

```
Device# chassis chassis-num priority chassis-priority
```

Example

```
Device# chassis 1 priority 1
```

From Cisco IOS XE Gibraltar 16.12.x onwards, device reload is not required for the chassis priority to become effective.

- *chassis-num*–Enter the chassis number. The range is from 1 to 2.
- *chassis-priority*–Enter the chassis priority. The range is from 1 to 2. The default value is 1.

When both the devices boot up at the same time, the device with higher priority becomes active, and the other one becomes standby. If both the devices are configured with the same priority value, the one with the smaller MAC address acts as active and its peer acts as standby.

2. Create an HA interface for your controller.

Example

```
Device# chassis redundancy ha-interface GigabitEthernet interface-number
```

Example

```
Device# chassis redundancy ha-interface
GigabitEthernet 3
```

- *interface-number*: GigabitEthernet interface number. The range is from 1 to 32.

This step is applicable only for Cisco Catalyst 9800-CL Series Wireless Controllers. The chosen interface is used as the dedicated interface for HA communication between the 2 controllers.

3. Enter global configuration mode.

Example

```
Device# configure terminal
```

4. Configure Redundancy Management Interface.

Example

```
Device(config)# redun-management interface vlan vlan-interface-number chassis
 chassis-number address ip-address chassis chassis-number address ip-address
```

Example

```
Device(config)# redun-management interface
Vlan 200 chassis 1 address 9.10.90.147
chassis 2 address 9.10.90.149
```

- *vlan-interface-number*: VLAN interface number. The valid range is from 1 to 4094.

Here, the *vlan-interface-number* is the same VLAN as the Management VLAN. That is, both must be on the same subnet.

- *chassis-number*: Chassis number. The valid range is from 1 to 2.
- *ip-address*: Redundancy Management Interface IP address.

Each controller must have a unique chassis number for RMI to form the HA pair. The chassis number can be observed as SWITCH_NUMBER in the output of **show romvar** command. Modification of SWITCH_NUMBER is currently not available through the web UI.

To disable the HA pair, use the **no redun-management interface vlan chassis** command.

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

6. Save the configuration.

   Example

   ```
   Device# write memory
   ```

7. Reload the controllers.

   Example

   ```
   Device# reload
   ```

   When the RMI configuration is done, you must reload the controllers for the configuration to take effect.

   For Cisco Catalyst 9800-CL Wireless Controller VM, both the active and standby controllers reload automatically. In the case of hardware platforms, you should reload the active controller manually, as only standby the controller reloads automatically.

The redundancy management interface is configured. After reload, an HA pair is established between the two controllers, enabling redundancy and failover support.

Part XIII

Quality of Service

Topics:

- Quality of Service

- Native Profiling
- Air Time Fairness
- IPv6 Non-AVC QoS Support
- QoS Basic Service Set Load

Configuring QoS

174 Quality of Service

Topics:

- Wireless Quality of Service
- Bidirectional rate limiting
- Per-client bidirectional rate limiting
- How to configure wireless QoS

This chapter explains how to configure and apply wireless QoS on Cisco Catalyst 9800 controllers, including metal policies, DSCP/User Priority mappings, bidirectional and per-client rate limiting, GUI/CLI procedures, and related prerequisites and restrictions.

Wireless Quality of Service

Introduces the fundamentals of wireless QoS, including target selection for SSID and clients, supported QoS features, mobility considerations, metal policy options, prerequisites, and operational restrictions, with details on client connectivity and TCP packet handling on CWA SSID.

A wireless Quality of Service policy is a network management policy that

- prioritizes specific types of wireless traffic by giving preferential treatment
- applies different rules to SSID and client targets in both upstream and downstream directions, and
- supports traffic marking, rate limiting (policing), mobility features, and compatibility with advanced controller functions.

- Upstream traffic: The flow of data from a wireless source to a wired target.
- Downstream traffic: The flow of data from a wired source to a wireless target.
- Target: The entity (SSID or client) where the QoS policy is enforced.

Additional reference information

- Without QoS, network devices transmit packets with best-effort service, offering no guarantees for reliability, delay bounds, or throughput. Wireless QoS policies enhance the network by ensuring that traffic with higher priority receives preferential treatment. This policy improves overall performance for critical applications.
- Applying a wireless QoS policy to prioritize voice traffic on an SSID ensures that calls suffer less latency or jitter compared to general web browsing traffic.
- Rate limiting is used to prevent a single client from consuming excessive bandwidth and to maintain fair usage for all wireless clients.
- A network with no configured QoS policies treats all wireless traffic equally, which can lead to poor performance for delay-sensitive applications.
- QoS policies designed for wired networks do not automatically apply to wireless environments, as wireless traffic has unique constraints.

Wireless QoS targets

This section describes the various wireless QoS targets available on a device.

Service set identifiers policies

SSID policies.

An Service Set Identifiers (SSID) policy is a wireless network configuration policy that

- controls the application of QoS settings to a wireless SSID in both ingress and egress directions
- applies per AP and per SSID, and
- allows configuration of policing and marking actions on SSID traffic.

If an SSID policy is not configured, no QoS policy is applied to the SSID.

Client policies

Wireless QoS mobility enables configuration of QoS policies so that the network provides the same service anywhere in the network.

Client policies are applicable in the ingress and egress direction. You can configure policing and marking policies on clients. AAA override is also supported.

Supported QoS features on wireless targets

The precious metal policies are system-defined policies that are available on the controller.

Wireless controllers support various QoS features to manage traffic and ensure optimal performance for both SSIDs and client devices. These tables show the supported features, applicable directions, and configuration modes for wireless targets.

Table 151: QoS features available on wireless targets

This table describes the various features available on wireless targets.

Target	Features	Direction where policies Are applicable
SSID	• Set • Police • Drop	Upstream and downstream
Client	• Set • Police • Drop	Upstream and downstream

Table 152: QoS policy actions

This table describes the various features available on wireless targets.

Policy action types	Wireless target support	
	Local mode	FlexConnect Mode
Police	Supported	Supported with restrictions **Note** Per-SSID policing is not supported for FlexConnect locally switched traffic.
Set	Supported	Supported

Table 153: QoS policy set actions

This table describes the various features available on wireless targets.

Set action types	Supported	
	Local mode	FlexConnect mode
set dscp	Supported	Supported

Set action types	Supported	
	Local mode	FlexConnect mode
set qos-group	Supported	Not Supported
set wlan user-priority (downstream only)	Supported (BSSID only)	Supported (BSSID only)

Wireless QoS mobility

Wireless Quality of Service (QoS) mobility enables you to configure QoS policies so that the network provides the same service anywhere in the network.

A wireless QoS mobility feature is a network mobility mechanism that

- enables configuration of QoS policies to provide consistent service for wireless clients
- supports seamless roaming between different access points and network devices and
- maintains the same service levels no matter where the client connects in the network.

Wireless client roaming can occur in two forms:

- Intra-device roaming: Roaming across access points managed by the same device.
- Inter-device roaming: Roaming across access points managed by different devices.

Additional reference information

Note

- In a foreign wireless LAN controller (WLC), client statistics are not displayed.
- Make sure that all client policies are available on every device in the mobility group.
- Apply the same Service Set Identifier (SSID) policy to every device in the mobility group to ensure clients receive consistent treatment.

Precious metal policies for wireless QoS

Precious metal policies for wireless QoS.

Precious metal policies for wireless QoS are system-defined QoS policies

- assign different service levels to wireless network traffic based on pre-set categories,
- remain unmodifiable, cannot be removed by administrators, and
- affect packet attributes, such as 802.11e (WMM) and DSCP fields, when policies are applied.

- Platinum: Used for VoIP clients, assigns the highest priority.
- Gold: Used for video clients, assigns high priority, lower than platinum.
- Silver: Used for best-effort traffic, assigns standard priority.

- Bronze: Used for Non-Real-Time (NRT) traffic, assigns the lowest priority.

Additional reference information

Preconfigured precious metal policies are available on wireless controllers. Administrators cannot modify or delete these policies. AAA mechanisms may push client metal policies. These policies determine packet scheduling and marking on the network.

In FlexConnect local switching mode, APs do not enforce QoS metal policy ceiling limits for upstream traffic. Limit enforcement occurs at the controller exit point. The AP does not change DSCP values.

See the Metal policy format section for more information about metal policy formats.

See the Metal policy map section for more information about metal policies.

> **Note**
>
> In FlexConnect local switching mode, default precious metal QoS policies are not pushed to access points. To apply QoS in FlexConnect local switching deployments, configure and apply custom QoS profiles.

Precious metal policies for wireless QoS

- Assigning the platinum policy to VoIP devices ensures minimal latency for voice communication.
- Assigning the gold policy to video streaming clients optimizes traffic for media applications.
- The silver policy applied to laptops browsing the internet handles general best-effort data.
- The bronze policy used for devices performing background updates minimizes their network priority.
- Custom user-defined QoS policies that administrators can modify or remove are not considered precious metal policies.
- Policies that do not map traffic types to platinum, gold, silver, or bronze levels are not included.

Prerequisites for wireless QoS

Prerequisites for wireless QoS.

Before you configure wireless QoS, make sure you understand key concepts and network factors to ensure effective deployment.

The required prerequisites include:

- Understand wireless concepts and network topologies.
- Understand QoS implementation.
- Modular QoS CLI (MQC). To learn more about Modular QoS CLI, see the MQC guide.
- Understand the types of applications used and the traffic patterns on your network.
- Understand your network's bandwidth requirements and speed.

Restrictions for QoS on wireless targets

Restrictions for QoS on wireless targets.

QoS policy application on wireless targets (such as SSIDs, BSSIDs, and wireless clients) has these key restrictions and considerations.

General Restrictions

- QoS policy application on wireless targets (such as Service Set Identifier (SSID), BSSID, and wireless clients) includes these key restrictions and considerations:

Hierarchical (parent policy and child policy) QoS is not supported.

- QoS policy maps and class maps that are created or customized through the CLI may include options or policy variations that are not supported for modification through the GUI. To modify QoS policy maps and class maps that were created or customized through the CLI, use the CLI.
- Configure SSID and client targets only with marking and policing policies.
- You can assign only one policy per target for each direction.
- Although class maps in a policy map can have different types of filters, only one marking action (set dscp) is supported.
- Only one set action per class is supported.
- You cannot use access group matching.
- Access points in flex mode do not support Access Control List (ACL) matching for local switching traffic.
- SIP Call Admission Control (CAC) is not supported on central switching mode.
- From Cisco IOS XE Amsterdam 17.3.1 and later, SIP Call Admission Control (CAC) is not supported.
- Do not apply QoS on the WMI interface because it may reboot the controller.
- AP QoS statistics for each radio stop updating after 32,768 minutes (546 hours). At that point, the offered rate shows zero and the minute counter stops increasing.

  The system calculates rates within a 32,768-minute window (546 hours). After 32,768 minutes, the data rate calculation is zero.

  To reset the statistics, run this command to clear the QoS statistics for the target policy map and SSID:

```
show policy-map interface wireless ssid profile-name <wlan_profile_name>
radio type <radio_type> ap name <AP_name> input clear
```

AP Side Restrictions

- In Cisco Embedded Wireless Controller, FlexConnect local switching, and Software-Defined Access (SDA) deployments, the AP enforces QoS policies and rate-limiting actions at the per-flow (5-tuple) level, not per client.
- For FlexConnect local switching with local authentication and AAA override enabled (using an external AAA server), you can use only air space VLAN and ACL as AAA overrides. QoS and other overrides are not available.
- Rate limiting per SSID is not supported in FlexConnect local switching mode. For rate limiting to work as expected, FlexConnect central switching mode should be used.
- In FlexConnect local switching mode, per-SSID QoS policies that use a policing action (**police cir**) are not supported. Use FlexConnect central switching when per-SSID traffic policing is required.

Control Plane Rate Limiting and Policing

You do not need to configure control plane rate limiting or policing. Built-in mechanisms, such as policers, protect the CPU from control plane traffic. Migrations from AireOS to IOS-XE handle this automatically.

Restriction: Client connectivity and TCP packet drops on SSIDs with AAA rate limiting

Outlines restrictions for troubleshooting client connectivity and TCP packet drops on local-mode APs with CWA SSIDs, especially when rate limits and AAA overrides are configured.

Do not configure rate limits or AAA overrides on Cisco ISE for any SSID where AAA rate limiting is applied. These settings can cause the APs in local mode to drop TCP packets. In such a scenario, use Modular QoS CLI (MCQ)-based method only for configuring Quality of Service (QoS) and rate limiting.

Behavior explanation

When a client connects to an SSID with AAA rate limiting configured on APs in local mode, the AP forwards ICMP, DHCP, and DNS packets to the controller but drops TCP packets. This issue is caused when rate limits are configured on Cisco ISE and AAA overrides are in place. You can verify that TCP packets are dropped using the **show datapath drop trace** comand.

Workaround

Review the configuration of rate limits and consider removing them or adjusting the settings to avoid dropping TCP packets. Use Modular QoS CLI (MCQ)-based method only for configuring Quality of Service (QoS) and rate limiting. For more information about the MCQ-based method, see Configure QoS Rate Limit on Catalyst 9800 Wireless Controllers.

Verify client connectivity

- To observe the AP configuration, use this command.

```
show ap dot11 5ghz network
```

- To verify the AP configuration, use this command.

```
show ap dot11 5ghz network
```

- To check the client summary, use this command.

```
show wireless client summary
```

- To verify client details and troubleshoot connectivity issues, use this command:

```
show wireless client mac-address MAC-address detail
```

Bidirectional rate limiting

Explains bi-directional rate limiting concepts and outlines prerequisites, application of metal policies, configuration steps for SSID and client, and traffic-classification-based rate limiting, including procedures for applying policy maps to profiles.

A bidirectional rate limit is a wireless network traffic management feature that

- establishes configurable rate limits for both upstream and downstream traffic directions
- enables administrators to set individual limits per direction directly on the WLAN, overriding QoS profile values, and global controller configurations, and
- supports prioritization of client groups by assigning them to specific QoS profiles.

QoS profiles

There are four distinct QoS profiles to configure rate limits:

- Gold

- Platinum
- Silver
- Bronze

Additional reference information

- Apply rate limiting directly to a WLAN. This action overrides both global QoS settings and QoS profiles for the controller and clients.
- Bidirectional rate limits apply to all clients associated with a given SSID. Every client connected to the same SSID has identical rate restrictions.
- Set throughput limits to control wireless client performance for both traffic directions. Assign service priority to specific client sets for prioritization.

Configuration guidance

- Select a QoS profile and configure the rate limiting parameters for upstream and downstream directions. Setting a parameter to `0` disables rate limiting for that direction.
- Assign a QoS profile to each WLAN to determine the rate limits for all connected clients.

Scenario considerations

- Configure bidirectional rate limits on both the Anchor and Foreign controllers in mobility Anchor–Foreign controller setups. Use identical configuration across both controllers to prevent feature failure.
- The feature is supported in guest anchor scenarios, including IRCM guest deployments where AireOS devices function as guest anchor or guest foreign.
- Cisco Catalyst 9800 Series Wireless Controller uses a policing option to enforce bidirectional rate limits.

Bidirectional rate limiting

If a guest SSID uses the Bronze QoS profile and sets both upstream and downstream limits to specific values, all guests on that SSID have consistent rate restrictions, regardless of any global QoS or profile settings.

Apply metal policy with bidirectional rate limiting

Summary

Applying metal policies with bidirectional rate limiting involves configuring network policies to manage bandwidth usage and enforce traffic control on both upload and download directions.

Workflow

To apply metal policy with bidirectional rate limiting, perform these tasks:

1. Configure Metal Policy on SSID.
2. Configure Metal Policy on Client.
3. Configure bidirectional rate limiting for all traffic.
4. Configure bidirectional rate limiting Based on traffic classification.
5. Apply bidirectional rate limiting policy map to policy profile.
6. Apply Metal Policy with bidirectional rate limiting.

Result

The network enforces metal policies with bidirectional rate limiting, providing effective traffic management and resource fairness across SSIDs and client devices.

Requirements for bidirectional rate limiting configuration

Prerequisites for bidirectional rate limiting.

Ensure you meet the essential requirements before configuring bidirectional rate limiting.

To configure bidirectional rate limiting, ensure these prerequisites are met:

- Apply the client metal policy through AAA override.
- Specify the metal policy on the Identity Services Engine (ISE) server.
- Enable AAA override on the policy profile.

Configure the metal policy on the SSID

Configure the metal policy on the SSID.

Apply a metal service policy to a wireless SSID using a WLAN policy profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN policy profile and enter wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy policy-profile-name
   ```

3. Add a user-defined description to the new wireless policy.

   Example

   ```
   Device(config-wireless-policy)# description description
   ```

4. Set the platinum policy for input.

   Example

   ```
   Device(config-wireless-policy)# service-policy input input-policy
   ```

5. Set the platinum policy for output.

Example

```
Device(config-wireless-policy)# service-policy output output-policy
```

The system applies the configured policy profile to the SSID. It enforces platinum-level input and output service policies.

Configure a metal policy on your client device

Configure a metal policy on your client device.

Set up a wireless metal policy profile that uses AAA override on your client device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile and enter wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy policy-profile-name
   ```

3. Add a user-defined description to the new wireless policy.

   Example

   ```
   Device(config-wireless-policy)# description description
   ```

4. Enable AAA override on your WLAN.

   Example

   ```
   Device(config-wireless-policy)# aaa-override
   ```

   Note

   After you enable AAA override and the ISE server starts sending policy, the client policy defined in the service-policy client does not take effect.

With AAA override enabled, your wireless policy profile allows external RADIUS authentication and policy control.

Configure bidirectional rate limiting for all traffic

Configure bidirectional rate limiting for all traffic.

Enforce bidirectional rate limiting on all traffic by using policy maps.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a named object to apply policies to traffic classes.

   Example

   ```
   Device(config)# policy-map policy-map
   ```

   Policy-map names can contain alphabetic, hyphen, or underscore characters. The names are case sensitive. Names can be up to 40 characters long.

3. Associate a class map with the policy map and enter policy-map class configuration mode.

   Example

   ```
   Device(config-pmap)# class class-map-name
   ```

4. Configure traffic policing for your traffic class.

   Example

   ```
   Device(config-pmap-c)# police rate
   ```

   Valid values are 8,000 to 200,000,000 bps.

The bidirectional rate limiting policy limits all traffic that matches the class map.

Configure Bi-Directional Rate Limiting Based on Traffic Classification

Configure bi-directional rate limiting based on traffic classification.

Procedure

1. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. **policy-map** *policy-map*

   Example

   ```
   Device(config)# policy-map policy-sample2
   ```

   Creates a named object representing a set of policies that are to be applied to a set of traffic classes. Policy-map names can contain alphabetic, hyphen, or underscore characters, are case sensitive, and can be up to 40 characters.

3. **class** *class-map-name*

   Example

   ```
   Device(config-pmap)# class class-sample-youtube
   ```

   Associates a class map with the policy map, and enters policy-map class configuration mode.

4. **police** *rate*

   Example

   ```
   Device(config-pmap-c)# police 1000000
   ```

   Configures traffic policing (average rate, in bits per second). Valid values are 8000 to 200000000.

5. **conform-action drop**

   Example

   ```
   Device(config-pmap-c-police)# conform-action drop
   ```

   Specifies the drop action to take on packets that conform to the rate limit.

6. **exceed-action drop**

   Example

   ```
   Device(config-pmap-c-police)# exceed-action drop
   ```

   Specifies the drop action to take on packets that exceeds the rate limit.

7. **exit**

   Example

   ```
   Device(config-pmap-c-police)# exit
   ```

   Exits the policy-map class configuration mode.

8. **set dscp default**

   Example

   ```
   Device(config-pmap-c)# set dscp default
   ```

   Sets the DSCP value to default.

9. **police** *rate*

   Example

   ```
   Device(config-pmap-c)# police 500000
   ```

   Configures traffic policing (average rate, in bits per second). Valid values are 8000 to 200000000.

10. **exit**

    Example

    ```
    Device(config-pmap-c)# exit
    ```

    Exits the policy-map class configuration mode.

11. **exit**

    Example

    ```
    Device(config-pmap)# exit
    ```

    Exits the policy-map configuration mode.

12. **class-map match-any** *class-map-name*

    Example

    ```
    Device(config)# class-map match-any class-sample-youtube
    ```

    Selects a class map.

13. **match protocol** *protocol*

    Example

    ```
    Device(config-cmap)# match protocol youtube
    ```

    Configures the match criteria for a class map on the basis of the specified protocol.

Apply bidirectional rate limiting policy map to policy profile

Apply bidirectional rate limiting policy map to policy profile.

Apply bidirectional rate limiting to your wireless network by attaching a policy map to a policy profile.

Procedure

1. Enter global configuration mode to begin setup.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile to enter wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy policy-profile-name
   ```

3. Add a user-defined description to your new wireless policy.

   Example

   ```
   Device(config-wireless-policy)# description description
   ```

4. Set the input client service policy to platinum.

   Example

   ```
   Device(config-wireless-policy)# service-policy client input platinum-up
   ```

5. Set the output client service policy to platinum.

   Example

   ```
   Device(config-wireless-policy)# service-policy client output output-policy
   ```

6. Set the input service policy to platinum.

   Example

   ```
   Device(config-wireless-policy)# service-policy input input-policy
   ```

7. Set the output service policy to platinum.

   Example

   ```
   Device(config-wireless-policy)# service-policy output platinum
   ```

Your wireless policy profile applies bidirectional rate limiting based on the service policies you set.

Apply metal policy with bidirectional rate limiting

Apply metal policy with bidirectional rate limiting.

Use a metal policy to enforce bidirectional bandwidth limits on wireless traffic.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy policy-profile-name
   ```

3. Add a description for the new wireless policy.

   Example

   ```
   Device(config-wireless-policy)# description description
   ```

4. Assign 'platinum' as the input client service policy.

   Example

   ```
   Device(config-wireless-policy)# service-policy client input input-policy
   ```

5. Assign 'platinum' as the output client service policy.

   Example

   ```
   Device(config-wireless-policy)# service-policy client output output-policy
   ```

6. Assign 'platinum' as the input service policy.

   Example

   ```
   Device(config-wireless-policy)# service-policy input input-policy
   ```

7. Assign 'platinum' as the output service policy.

   Example

   ```
   Device(config-wireless-policy)# service-policy output platinum
   ```

8. Exit the policy configuration mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

9. Create a named object to apply policies to traffic classes.

   Example

   ```
   Device(config)# policy-map policy-sample 1
   ```

   Policy map names can contain alphabetic characters, hyphens, or underscores. They are case sensitive and can be up to 40 characters long.

10. Associate a class map with the policy map, and enter configuration mode for the specified system class.

Example

```
Device(config-pmap)# class class-map-name
```

11. Configure traffic policing.

Example

```
Device(config-pmap-c)# police 500,000
```

Valid values range from 8,000 to 200,000,000 bytes.

The metal policy enforces bidirectional rate limiting so wireless traffic meets the input and output bandwidth limits you specified.

Per-client bidirectional rate limiting

Describes per-client bi-directional rate limiting, presenting use cases, process workflows, prerequisites, restrictions, GUI-based configuration, AAA override integration, and verification procedures for policy enforcement.

A per-client bidirectional rate limit is a wireless traffic control feature that

- enforces, for each wireless client, bandwidth caps separately on both upstream and downstream traffic,
- ensures that each client receives a single aggregate limit, no matter how many concurrent flows or streams are active,
- addresses limitations of legacy per-flow rate limiting on 802.11ac Wave 2 APs in Flex local switching mode.

Additional reference information

Previously, per-flow rate limiting capped each client stream, such as a YouTube stream or an FTP transfer, independently. As a result, clients could exceed the intended per-client bandwidth limit.

With per-client bidirectional rate limits, the total bandwidth used by all of a client's streams cannot exceed the configured limit. This restriction applies no matter how many streams are active.

Per-client bidirectional rate limiting

If a controller limits each client to 1000 Kbps (1 megabit per second), and a client initiates both a YouTube and an FTP stream, both streams together will share the 1000 Kbps (1 megabit per second) limit, ensuring the client cannot exceed the cap.

Use case for per-client bidirectional rate limiting

Use case 1: configuring only default class map

If you configure the policy map with only the default class map and map it to the QoS client policy, the AP applies a per-client rate limit to each connected client.

Use case 2: changing from per client rate limit to per flow rate limit

If you configure the policy map with an additional class map along with the default class map and map it to the QoS client policy, the AP applies a per-flow rate limit to each client. Because the policy map includes multiple class maps, the AP clears any previously configured per-client rate limit values.

When the policy map includes more than one class map, the rate limit changes from per-client to per-flow, and the AP deletes the per-client rate limit values from the rate information token bucket.

Use case 3: changing from per flow rate limit to per client limit

If you remove the additional class map and the policy map contains only the default class map, the AP applies a per-client rate limit to each client.

Process for per-client bidirectional rate limiting

Process for per-client bidirectional rate limiting.

Summary

This section covers the high-level steps for per client bidirectional rate limiting.

Workflow

1. Configure a policy map for the WLAN using the policy profile.
2. Map the QoS-related policy map to the WLAN.
3. Configure policy map with the default class map.
4. Configure a different police rate value for the class default map.

> **Note**
>
> If the policy map has a class default with a valid police rate value, the AP applies that rate limit to the overall client data traffic flow.

5. Apply the policy map with class Default to the QoS client policy in the WLAN policy profile.

Prerequisites for per-client bidirectional rate limiting

Prerequisites for per-client bidirectional rate limiting.

- You can use this feature only with a QoS client policy. Ensure the policy profile contains only a QoS Policy or a policy target as client.
- If the policy map includes class default with a valid police rate value, the access point applies this rate limit to the the data traffic flow for the client.

Restrictions on per-client bidirectional rate limiting

Restrictions on per-client bidirectional rate limiting.

- If the policy map has a class map other than the Default class map, the per-client rate limit does not work on the AP.
- From Cisco IOS XE 17.5.x onwards, use AAA override to push attributes and achieve a per-client rate limit.

Configure per-client bidirectional rate limiting (GUI)

Configure per-client bidirectional rate limiting for each client by using the GUI.

Set limits on upload and download data rates for each client. This ensures fair bandwidth distribution.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click the Policy Profile Name.

   The **Edit Policy Profile** window is displayed.

   > **Note**
   >
   > The **Edit Policy Profile** window is displayed and configured in default class map only.

3. Choose the **QOS And AVC** tab.
4. In the **QoS Client Policy** settings, choose the policies from the **Egress** and **Ingress** drop-down lists.

   > **Note**
   >
   > You need to apply the default policy map to the QoS Client Policy.

5. Click **Update & Apply to Device**.

The selected policies in the policy profile enforce bidirectional rate limiting for each client.

Verify per client bi-directional rate limiting

Verify per client bi-directional rate limiting.

To verify whether per client is applied in AP, use this command:

```
Device# show rate-limit client
Config:
              mac vap rt_rate_out rt_rate_in rt_burst_out rt_burst_in
nrt_rate_out nrt_rate_in nrt_burst_out nrt_burst_in
A0:D3:7A:12:6C:5E   0           0           0            0           0
    0           0             0            0
Statistics:
            name     up down
        Unshaped      0    0
  Client RT pass 697610 8200
 Client NRT pass      0    0
 Client RT drops      0    0
Client NRT drops      0   16
               9    180    0
Per client rate limit:
              mac vap rate_out rate_in            policy
A0:D3:7A:12:6C:5E   0       88      23 per_client_rate_2
```

Configure bi-directional rate limiting using AAA override (CLI)

Configure BDRL using AAA override.

Enable WLAN policy profiles to enforce upstream and downstream bandwidth limits based on RADIUS server (e.g., Cisco ISE) attributes through AAA override.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile and enter wireless policy configuration mode.

   Example

   ```
   Device (config)# wireless profile policy profile-name
   ```

3. Configure AAA override to apply policies coming from the AAA server or Cisco Identity Services Engine (ISE) server.

   Example

   ```
   Device(config-wireless-policy)# aaa-override
   ```

   These attributes are available in the RADIUS server:

   - Airespace-Data-Bandwidth-Average-Contract: 8001
   - Airespace-Real-Time-Bandwidth-Average-Contract: 8002
   - Airespace-Data-Bandwidth-Burst-Contract: 8003
   - Airespace-Real-Time-Bandwidth-Burst-Contract: 8004
   - Airespace-Data-Bandwidth-Average-Contract-Upstream: 8005
   - Airespace-Real-Time-Bandwidth-Average-Contract-Upstream: 8006
   - Airespace-Data-Bandwidth-Burst-Contract-Upstream: 8007
   - Airespace-Real-Time-Bandwidth-Burst-Contract-Upstream: 8008

   Note

   8001, 8002, 8003, 8004, 8005, 8006, 8007, and 8008 are example rate-limit values.

The WLAN policy profile is configured to honor bi-directional rate limiting instructions received via AAA override from the RADIUS server.

Verify bi-directional rate-limit

Verify bi-directional rate-limit.

To verify the bi-directional rate limit, use this command:

```
Device# show wireless client mac-address E8-8E-00-00-00-71 detailClient MAC
Address : e88e.0000.0071

Client RT drops 0 0
Client NRT drops 0 0
```

```
Per client rate limit:
mac vap rate_out rate_in policy
```

How to configure wireless QoS

Provides instructions for configuring wireless QoS, including policy maps with class maps for voice and video, GUI and CLI steps for applying QoS policies to profiles and tags, AP policy tag attachment, and advanced mapping options such as DSCP to UP exception and trust upstream DSCP values.

Configure a policy map with class map (GUI)

Configure a policy map with class map using GUI.

Define and apply a QoS policy map with associated class maps to control network traffic behavior.

Use this task when you need to create or update a QoS policy map containing class maps, specifying how different types of network traffic are marked, policed, or dropped.

> **Note**
>
> Do not configure the Police (kbps) action for an SSID QoS policy used with FlexConnect local switching. Use FlexConnect central switching when per-SSID policing is required.

Before you begin

Use these steps to configure a policy map with class map using the GUI.

Procedure

1. Choose **Configuration** > **Services** > **QoS**.
2. Click **Add** to view the **Add QoS** window.
3. In the text box next to **Policy Name**, enter the name of the new policy map.
4. Click **Add Class-Maps**.
5. Configure **AVC** based policies or **User Defined** policies. To enable **AVC** based policies, and configure the following:
   a) Choose either **Match Any** or **Match All**.
   b) Choose the required **Mark Type**. If you choose **DSCP** or **User Priority**, you must specify the appropriate **Mark Value**.
   c) Check the **Drop** check box to drop traffic from specific sources.

      > **Note**
      >
      > When **Drop** is enabled, the **Mark Type** and **Police(kbps)** options are disabled.

   d) Select the required protocols from the **Available Protocol(s)** list based on the chosen **Match Type**. Move them to the **Selected Protocol(s)** list. The system drops traffic from these selected protocols.
   e) Click **Save**.

> **Note**
>
> To add more Class Maps, repeat steps 4 and 5.

> **Note**
>
> To add more Class Maps, repeat steps 4 and 5.

6. To enable the **User-Defined** QoS policy, configure these options:
   a) Choose either **Match Any** or **Match All**.
   b) From the drop-down list, choose either **ACL** or **DSCP** as the **Match Type**. Specify the appropriate **Match Value**.
   c) Choose the required **Mark Type** to associate with the mark label. If you choose *DSCP*, you must specify an appropriate **Mark Value**.
   d) Check the **Drop** check box to drop traffic from specific sources.

   > **Note**
   >
   > When **Drop** is enabled, the **Mark Type** and **Police(kbps)** options are disabled.

   e) Click **Save**.

   > **Note**
   >
   > To define actions for all the remaining traffic, in the Class Default, choose either **Mark**, **Police(kbps)**, or both as appropriate.

7. Click **Save & Apply to Device**.

The system deploys the defined policy map with its class maps and associated actions. QoS settings are enforced on network traffic as specified.

Configure a class map (CLI)

Configure a class map using commands.

Define and customize a class map to identify and match specific network traffic, such as voice and video, using CLI commands.

Use this procedure to configure class maps for voice and video traffic:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a class map.

   Example

   ```
   Device(config)# class-map class-map-name
   ```

3. Match the DSCP value in IPv4 and IPv6 packets.

   Example

   ```
   Device(config-cmap)# match dscp dscp-value
   ```

   > **Note**
   >
   > By default, the class map uses match-all.

4. Exit class map configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-cmap)# end
   ```

5. Verify class map details.

   Example

   ```
   Device# show class-map class_map_name
   ```

You have configured the class map with the specified matching criteria. It is ready for use in traffic policies.

Configuring Policy Profile to Apply QoS Policy (GUI)

Configure policy profile to apply QoS policy using GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. On the **Policy Profile** page, click the name of the policy profile.
3. In the **Edit Policy Profile** window, click the **QoS and AVC** tab.

4. Under **QoS SSID Policy**, choose the appropriate **Ingress** and **Egress** policies for WLANs.

> **Note**
>
> The ingress policies can be differentiated from the egress policies by the suffix *-up*. For example, the Platinum ingress policy is named *platinum-up*.

5. Under **QoS Client Policy**, choose the appropriate **Ingress** and **Egress** policies for clients.
6. Click **Update & Apply to Device**.

> **Note**
>
> Only custom policies are displayed under **QoS Client Policy**. AutoQoS policies are auto generated and not displayed for user selection.

Configure policy profile to apply QoS policy (CLI)

Configure policy profile to apply QoS policy using commands.

Apply a QoS policy to a WLAN policy profile using CLI.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the WLAN policy profile. Enter the wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy profile-policy
```

3. Apply the policy.

Example

```
Device(config-wireless-policy)# service-policy client input policy-map-client
```

These options are available:

- **input**–Assigns the client policy for ingress direction on the policy profile.
- **output**–Assigns the client policy for egress direction on the policy profile.

4. Apply the policy to the Basic Service Set Identifier (BSSID).

   Example

   ```
   Device(config-wireless-policy)# service-policy input output policy-name
   ```

   These options are available:

   - **input**–Assigns the policy-map to all clients in WLAN.
   - **output**–Assigns the policy-map to all clients in WLAN.

5. Enable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

The specified QoS policy is applied to the WLAN policy profile, and all clients associated with the WLAN receive the defined QoS treatment.

Apply policy profile to policy tag (GUI)

Apply a policy profile to a policy tag by using the GUI.

Associate a policy profile with a policy tag to manage network behavior for specific WLANs.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. On the **Manage Tags** page in the **Policy** tab, click **Add**.
3. In the **Add Policy Tag** window, enter a name and description for the policy tag.
4. Map the required WLAN IDs and WLAN profiles with appropriate policy profiles.
5. Click **Update & Apply to Device**.

The device applies the specified policy profile to the policy tag and controls WLAN behavior based on the configuration.

Apply policy profile to policy tag (CLI)

Apply policy profile to policy tag using commands.

Associate a policy profile with a policy tag through command-line configuration to enforce desired wireless policy settings.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure policy tag and enter the policy tag configuration mode.

   Example

   ```
   Device(config-policy-tag)# wireless tag policy policy-tag-name
   ```

3. Map a policy profile to a WLAN profile.

   Example

   ```
   Device(config-policy-tag)# wlan test policy profile-policy-name
   ```

4. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

   Example

   ```
   Device(config-policy-tag)# end
   ```

5. Display the configured policy tags.

   Example

   ```
   Device# show wireless tag policy summary
   ```

   Note

   To view the detailed information of a policy tag, use the **show wireless tag policy detailed** *policy-tag-name* command.

The policy profile is applied to the policy tag. You can verify the configuration through summary and detailed display commands.

Attach policy tag to an AP

Attach a policy tag to an AP.

Assign a policy tag to a wireless AP to determine its network and functional behavior.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the AP, then enter the AP profile configuration mode.

Example

```
Device(config)# ap F866.F267.7DFB
```

3. Map a policy tag to the AP.

Example

```
Device(config-ap-tag)# policy-tag policy-tag-name
```

4. Save the configuration. Exit configuration mode. Return to privileged EXEC mode.

Example

```
Device(config-ap-tag)# end
```

5. Display the AP details and the tags associated with it.

Example

```
Device# show ap tag summary
```

The specified AP is associated with the chosen policy tag. You can verify the mapping by displaying the AP details.

Configure custom QoS mapping (CLI)

Configure custom QoS mapping.

Create a custom mapping between IP DSCP values and 802.11e user priorities to support Hotspot 2.0 interworking on the WLAN.

The system creates a map between the 802.11e user priorities and the IP differentiated services code point (DSCP) for interworking with IP networks. Enable Hotspot 2.0 on the WLAN to support mapping exception.

> **Note**
>
> Custom QoS mapping applies only to Hotspot 2.0.

Specify the mapping by assigning DSCP ranges to individual user priority values, and set exceptions by mapping DSCP values to UP values one-to-one. If you enable a QoS map and do not add custom mappings, the system uses default values.

> **Note**
>
> Egress = Downstream = Output; and Ingress = Upstream = Input

The table shows a QoS map, where an AP provides a wireless client with the required mapping from IP DSCP to 802.11e user priority.

Table 154: Default DSCP-Range-to-User Priority Mapping

IP DSCP Range	802.11e User Priority
0-7	0
8-15	1
16-23	2
24-31	3
32-39	4
40-47	5
48-55	6
56-63	7

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

3. Configure DSCP-to-user priority mapping.

   Example

   ```
   Device(config-ap-profile)# qos-map dscp-to-up-range user-priority up-to-dscp
    dscp-start dscp-end
   ```

   You can configure up to eight entries–one for each *user-priority* value. If you do not configure a custom value, the system sends a non-configured value (0xFF) to the AP.

Use the **no** form of this command to disable the configuration. To delete all the custom mappings, use the **no dscp-to-up-range** command.

When you apply custom DSCP to user priority mappings for an AP profile, the system translates the QoS policy correctly for Hotspot 2.0 clients.

Configure a DSCP-to-user priority mapping exception

Configure DSCP-to-user priority mapping exception.

Define custom exceptions so you can map IP DSCP values to 802.11e user priorities in an AP profile. This provides control over QoS behavior.

When you configure a QoS mapping or exception, the system creates a custom QoS map. The map is sent to the corresponding AP.

If you do not configure DSCP-to-user priority mapping or exception entries, the system uses an empty QoS map.

The table displays exceptions with a one-to-one mapping between DSCP values and user priority values.

Table 155: Default DSCP-Range-to-User Priority Mapping Exceptions

IP DSCP	802.11e User Priority
0	0
2	1
4	1
6	1
10	2
12	2
14	2
18	3
20	3
22	3
26	4
34	5
46	6
48	7
56	7

> **Note**
>
> Disable voice admission control for user priorities 6 and 7 using the controller GUI. To disable **Admission Control (ACM)**, choose **Configuration** > **Radio Configurations** > **Media Parameters**.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap profile name
   ```

3. Configure a DSCP-to-user priority exception.

   Example

   ```
   Device(config-ap-profile)# qos-map dscp-to-up-exception dscp-num user-priority
   ```

With these settings, your AP profile has customized DSCP-to-user priority mapping exceptions. This configuration provides tailored QoS mapping for wireless clients.

Configure trust upstream DSCP value

Configure trust upstream DSCP value.

Configure the wireless controller to trust the upstream DSCP value, not the user priority. This optimizes end to end QoS marking.

The controller marks the 802.11 user priority value in Traffic Identifier (TID) field based on the DSCP value in IP header.

> **Note**
>
> The AP forwards the DSCP value to Air when the 802.11 user priority value is set.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure an AP profile and enter AP profile configuration mode.

Example

```
Device(config)# ap profile ap profile-name
```

3. Configure the AP to trust upstream DSCP instead of user priority.

Example

```
Device(config-ap-profile)# qos-map trust-dscp-upstream
```

Use the **no** form of the command to disable the configuration.

> **Note**
>
> Starting with Cisco IOS XE 17.4.1 release, **qos-map trust-dscp-upstream** is the default setting. As a result, client DSCP is maintained all the way through by default.

> **Note**
>
> When you enable the **trust-dscp-upstream** command, the DSCP value is 18. If you do not configure any value, Silver is the default.

The AP profile is set to trust upstream DSCP values, ensuring that client QoS markings are preserved from end to end.

175 Wireless Auto-QoS

Topics:

- Auto QoS information

This chapter explains how to enable, disable, clear, view, and rollback AutoQoS on wireless policy profiles using CLI and GUI, automating QoS deployment and allowing manual override or troubleshooting.

Auto QoS information

Lists wireless Auto QoS features that automate deployment of wireless QoS policies and traffic prioritization.

Wireless Auto QoS automates deployment of wireless QoS features. It has a set of predefined profiles which can be further modified by the customer to prioritize different traffic flows. Auto-QoS matches traffic and assigns each matched packet to qos-groups. This allows the output policy map to put specific qos-groups into specific queues, including into the priority queue.

Autoqos policy configuration
Table 156: Autoqos policy configuration

Mode	Client Ingress	Client Egress	BSSID Ingress	BSSID Egress	Port Ingress	Port Egress	Radio
Voice	N/A	N/A	P3	P4	N/A	P7	ACM on
Guest	N/A	N/A	P5	P6	N/A	P7	
Fastlane	N/A	N/A	N/A	N/A	N/A	P7	edca-parameters fastlane
Enterprise-avc	N/A	N/A	P1	P2	N/A	P7	

P1	AutoQos-4.0-wlan-ET-SSID-Input-AVC-Policy
P2	AutoQos-4.0-wlan-ET-SSID-Output-Policy
P3	platinum-up
P4	platinum
P5	AutoQos-4.0-wlan-Dot1x-Output-Policy
P6	AutoQos-4.0-wlan-GT-SSID-Output-Policy
P7	AutoQos-4.0-wlan-Port-Output-Policy

Configure wireless auto-QoS on profile policy (CLI)

Configure wireless Auto QoS to automate deployment of wireless QoS features.

You can enable AutoQoS on a profile policy to automate deployment of wireless QoS features.

You can enable AutoQoS on a profile policy.

Procedure

1. Enable privileged EXEC mode.

Example

```
Device# enable
```

Enter your password if prompted.

2. Configure AutoQoS wireless policy.

Example

```
Device# wireless autoqos policy-profile test-profile mode voice
```

- **enterprise-avc**–Enables AutoQoS Wireless Enterprise AVC Policy.
- **fastlane**–Enable AutoQoS Wireless Fastlane Policy.
- **guest**–Enable AutoQoS Wireless Guest Policy.
- **voice**–Enable AutoQoS Wireless Voice Policy.

> **Note**
>
> AutoQoS MIB attribute does not support full functionality with service policy. Service policy must be configured manually. Currently, there is only support for AutoQoS mode.

What to do next

> **Note**
>
> After enabling AutoQoS, we recommend that you wait for a few seconds for the policy to install and then try and modify the AutoQoS policy maps if required; or retry if the modification is rejected.

Disable wireless autoqos

Disable wireless AutoQoS globally on the device.

Disable wireless AutoQoS functionality to manually control QoS parameters or troubleshoot QoS-related issues.

Wireless AutoQoS automatically configures QoS settings for optimal wireless performance. You may need to disable it when implementing custom QoS policies or when troubleshooting network issues.

Procedure

1. Enable privileged EXEC mode.

Example

```
Device> enable
```

Enter your password if prompted.

2. Shut down the policy profile.

Example

```
Device# shutdown
```

Shuts down the policy profile.

3. Globally disable wireless AutoQoS.

Example

```
Device# wireless autoqos disable
```

Globally disables wireless AutoQoS.

4. Enable the wireless policy profile.

Example

```
Device# no shutdown
```

Enables the wireless policy profile.

> **Note**
>
> Disabling Auto QoS does not reset global radio configurations like CAC and EDCA parameters.

Wireless AutoQoS is now disabled globally, allowing for manual QoS configuration or troubleshooting without automatic QoS interference.

Rollback auto-QoS configuration (GUI)

Configure the rollback of AutoQoS settings using the GUI interface.

Before you begin

Follow these steps to rollback AutoQoS configuration using the GUI:

Procedure

---

1. Choose **Configuration** > **Services** > **QoS**.
2. Click **Disable AutoQoS**.
3. Click **Yes** to confirm.

Rollback AutoQoS configuration (CLI)

Configure the reset of AutoQoS configuration templates to restore default settings.

Before you begin

> **Note**
>
> AutoQoS MIB attribute does not support the full functionality with service policy. Currently, there is only support for AutoQoS mode. Service policy must be configured manually.

Follow these steps to rollback AutoQoS configuration:

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Reset AutoQoS configuration.

   Example

   ```
   Device# clear platform software autoqos config template guest
   ```

   - enterprise-avc–Resets AutoQoS Enterprise AVC Policy Template.
   - guest–Resets AutoQoS Guest Policy Template.

Clear wireless autoqos policy profile (GUI)

Configure wireless AutoQoS policy profile to remove automatic Quality of Service settings using the GUI.

Before you begin

Follow these steps to clear wireless AutoQoS policy profile using the GUI

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click on the **Policy Profile Name**.
3. Go to **QOS and AVC** tab.
4. From the **Auto Qos** drop-down list, choose **None**.
5. Click **Update & Apply to Device**.

Clear wireless autoqos policy profile (CLI)

Clear wireless AutoQoS policy profile using commands.

Clear the AutoQoS configuration from a wireless policy profile to reset or remove QoS settings.

Use this procedure when you need to remove AutoQoS settings from a wireless policy profile, typically during reconfiguration or troubleshooting scenarios.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Shut down the policy profile.

   Example

   ```
   Device# shutdown
   ```

3. Clear the configured AutoQoS wireless policy.

   Example

   ```
   Device# wireless autoqos policy-profile policy-name mode clear
   ```

   Example

   ```
   Device# wireless autoqos policy-profile test-profile mode clear
   ```

4. Enable the wireless policy profile.

   Example

   ```
   Device# no shutdown
   ```

The AutoQoS configuration is cleared from the specified wireless policy profile, and the profile is re-enabled.

View Auto-QoS on policy profile (CLI)

Configure AutoQoS viewing on policy profile to display detailed parameters and configurations.

Before you begin

AutoQoS is supported on the local mode and flex mode. AutoQoS configures a set of policies and radio configurations depending on the template. It is possible to override the service-policy that is configured by AutoQoS. The latest configuration takes effect, with AAA override policy being of highest priority.

Follow these steps to view AutoQoS on policy profile:

Procedure

1. **enable**

   Example

   ```
   Device#enable
   ```

   Enables privileged EXEC mode. Enter your password if prompted.

2. **show wireless profile policy detailed** *policy-profile-name*

   Example

   ```
   Device# show wireless profile policy detailed testqos
   ```

   Shows policy-profile detailed parameters.

   Note

   When the AutoQoS mode is configured to voice within the policy profile, any modifications to the global ACM settings require a shutdown and subsequent no shutdown operation on the policy profile to activate the changes. Without performing this shut and no shut cycle, the updated ACM configurations are not applied to the beacon frames. This causes the beacon to continue broadcasting the old ACM values.

   This process ensures that the revised ACM settings are correctly propagated and reflected throughout the wireless environment, thereby maintaining accurate call admission control enforcement.

176 Native Profiling

Topics:

- Native profiling

This chapter guides administrators through configuring and verifying device-based profiling using HTTP/DHCP: creating class maps, service templates, parameter maps and policy maps, enabling profiling in local mode, and applying service templates to enforce per-device policies.

Native profiling

Describes the native profiling feature that allows device profiling based on HTTP and DHCP to identify end devices and enforce device-based policies.

Native profiling is a network security feature that

- profiles devices based on HTTP and DHCP to identify end devices on the network
- configures device-based policies and enforces these policies per user or per device policy on the network, and
- allows profiling of mobile devices and basic onboarding of the profiled devices to a specific VLAN.

Native profiling characteristics

Policies assign ACL and QoS or configure session timeouts.

The policies are defined based on the following attributes:

- User group or user role
- Device type such as Windows clients, smartphones, tablets, and so on
- Service Set Identifier (SSID)
- Location, based on the access point group that the end point is connected to
- Time of the day
- Extensible Authentication Protocol (EAP) type, to check what EAP method that the client is getting connected to

When a wireless client joins an access point, certain QoS policies get enforced on the access point. One such feature is the native profiling for both upstream and downstream traffic at AP. The native profiling feature when clubbed with AAA override supports specific set of policies based on the time of day and day of week. The AAA override then applies these policies coming from a RADIUS server to the access point.

Let's consider a use case of time of the day in conjunction with user role. Usually, the user role is used as an extra matching criteria along with the time of day. You can club the time of day usage with any matching criteria to get the desired result. The matching will be performed when the client joins the controller .

You can configure policies as two separate components:

- Defining policy attributes as service templates that are specific to clients joining the network and applying policy match criteria
- Applying match criteria to the policy.

> **Note**
>
> Before proceeding with the native profile configuration, ensure that HTTP Profiling and DHCP Profiling are enabled.

> **Note**
>
> Native profiling is not supported with FlexConnect Local Authentication and Local Switching. Hence, do not configure **no central switching**, **no central authentication**, and **subscriber-policy-name** *name* commands together. ISSU will fail for this type of configuration. Ensure that you remove the configuration before attempting ISSU.

To configure Native Profiling, use one of the following procedures:

- Create a service template
- Create a class map

  > **Note**
  >
  > You can apply a service template using either a class map or parameter map.

- Create a parameter-map and associate the service template to parameter-map
  - Create a policy map
    1. If class-map has to be used: Associate the class-map to the policy-map and associate the service-template to the class-map.
    2. If parameter-map has to be used: Associate the parameter-map to the policy-map
  - Associate the policy-map to the policy profile.

Create a class map (GUI)

Configure a class map using GUI.

Procedure

1. Click **Configuration** > **Services** > **QoS**.
2. In the **QoS – Policy** area, click **Add** to create a new QoS Policy or click the one you want to edit.
3. Add **Add Class Map** and enter the details.
4. Click **Save**.
5. Click **Update and Apply to Device**.

Create a class map (CLI)

Configure a class map using commands for more granular control than GUI options.

> **Note**
>
> Configuration of class maps via CLI offer more options and can be more granular than GUI.

Before you begin

Follow these steps to create a class map using CLI commands:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the class map type and name.

   Example

   ```
   Device(config)# class-map type control subscriber match-any cls_user
   ```

3. Specify the class map attribute filter criteria.

   Example

   ```
   Device(config-filter-control-classmap)# match username ciscoise
   ```

4. Specify the class map type and name.

   Example

   ```
   Device(config)# class-map type control subscriber match-any cls_userrole
   ```

5. Specify the class map attribute filter criteria.

   Example

   ```
   Device(config-filter-control-classmap)# match user-role engineer
   ```

6. Specify the class map type and name.

   Example

   ```
   Device(config)# class-map type control subscriber match-any cls_oui
   ```

7. Specify the class map attribute filter criteria.

   Example

   ```
   Device(config-filter-control-classmap)# match oui 48.f8.b3
   ```

8. Specify the class map type and name.

   Example

   ```
   Device(config)# class-map type control subscriber match-any cls_mac
   ```

9. Specify the class map attribute filter criteria.

   Example

   ```
   Device(config-filter-control-classmap)# match mac-address 0040.96b9.4a0d
   ```

10. Specify the class map type and name.

    Example

    ```
    Device(config)# class-map type control subscriber match-any cls_devtype
    ```

11. Specify the class map attribute filter criteria.

    Example

    ```
    Device(config-filter-control-classmap)# match device-type windows
    ```

12. Specify the class map type and name.

    Example

    ```
    Device(config)# class-map type control subscriber match-all match_tod
    ```

13. Specify a match to the time of day.

    Example

    ```
    Device(config-filter-control-classmap)# match join-time-of-day 10:30 12:30
    ```

    Here, join time is considered for matching. For example, if the match filter is set from 11:00 am to 2:00 pm, a device joining at 10:59 am is not considered, even if it acquires credentials after 11:00 am.

    Here,

    start-time and *end-time* specifies the 24-hour format.

    Use the **show class-map type control subscriber name** *name* command to verify the configuration.

> **Note**
>
> You should also disable AAA override for this command to work.

14. Match name using the device type.

Example

```
Device(config-filter-control-classmap)# match device-type android
```

Type a question mark (?) after the device type and select the device from the list.

> **Note**
>
> You should enable the device classifier for the device list to be populated.

Create a service template (GUI)

Create a service template using the GUI interface to define network security policies.

Procedure

1. Choose **Configuration** > **Security** > **Local Policy**.
2. On the **Local Policy** page, **Service Template** tab, click **ADD**.
3. In the **Create Service Template** window, enter the following parameters:
   - **Service Template Name:** Enter a name for the template.
   - **VLAN ID:** Enter the VLAN ID for the template. Valid range is between 1 and 4094.
   - **Session Timeout (secs):** Sets the timeout duration for the template. Valid range is between 1 and 65535.
   - **Access Control List:** Choose the Access Control List from the drop-down list.
   - **Ingress QOS:** Choose the input QoS policy for the client from the drop-down list
   - **Egress QOS:** Choose the output QoS policy for the client from the drop-down list.
4. Click **Save & Apply to Device**.

Create a service template (CLI)

Configure a service template using CLI commands to define network parameters and policies.

Before you begin

Follow these steps to create a service template using CLI commands:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter service template configuration mode.

   Example

   ```
   Device(config)# service-template svc1
   ```

3. Specify the VXLAN network identifier (VNID).

   Example

   ```
   Device(config-service-template)# vnid test
   ```

   Use the **show service-template** *service-template-name* command to verify the configuration.

4. Specify the access list to be applied.

   Example

   ```
   Device(config-service-template)# access-group acl-auto
   ```

5. Specify VLAN ID.

   Example

   ```
   Device(config-service-template)# vlan 10
   ```

   Valid range is from 1-4094.

6. Specify session timeout value for a service template.

   Example

   ```
   Device(config-service-template)# absolute-timer 1000
   ```

   Valid range is from 1-65535.

7. Configure an input QoS policy for the client.

   Example

   ```
   Device(config-service-template)# service-policy qos input in_qos
   ```

8. Configure an output QoS policy for the client.

Example

```
Device(config-service-template)# service-policy qos output out_qos
```

Create a parameter map (CLI)

Configure a parameter map to specify attribute filter criteria and associated service templates.

Before you begin

Follow these steps to create a parameter map:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the parameter map type and name.

   Example

   ```
   Device(config)# parameter-map type subscriber attribute-to-service param
   ```

3. Specify the parameter map attribute filter criteria.

   Example

   ```
   Device(config-parameter-map-filter)# 1 map device-type eq "windows"
   mac-address eq 3c77.e602.2f91 username eq "cisco"
   ```

   Multiple filters are used in the example provided here.

4. Specify the service template and its precedence.

   Example

   ```
   Device(config-parameter-map-filter-submode)# 1 service-template svc1 precedence
    150
   ```

Create a policy map (GUI)

Configure a policy map using the GUI to define service templates and match criteria for devices.

Before you begin

Follow these steps to create a policy map using the GUI:

Procedure

1. Choose **Configuration** > **Security** > **Local Policy** > **Policy Map** tab.
2. Enter a name for the Policy Map in the **Policy Map Name** text field.
3. Click **Add**
4. Choose the service template from the **Service Template** drop-down list.
5. For the following parameters select the type of filter from the drop-down list and enter the required match criteria
   - Device Type
   - User Role
   - User Name
   - OUI
   - MAC Address
6. Click **Add Criteria**
7. Click **Update & Apply to Device**.

Create a policy map (CLI)

Configure a policy map using commands.

Create and configure a policy map to control subscriber behavior and apply service templates in wireless environments.

Policy maps define how the system responds to specific events and conditions. This procedure creates a subscriber control policy map that can be applied to wireless profiles for client management and service provisioning.

Before you begin

Before removing a policy map or parameter map, you should remove it from the target or shut down the WLAN profile or delete the session.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the policy map type.

   Example

   ```
   Device(config)# policy-map type control subscriber policy-map-name
   ```

   Example

   ```
   Device(config)# policy-map type control subscriber polmap5
   ```

3. Specify the match criteria to the policy map.

Example

```
Device(config-event-control-policymap)# event identity-update match-all
```

4. You can apply a service template using either a class map or a parameter map, as shown here.
   - Configure the local profiling policy class map number and specify how to perform the action.
   - Activate the service template.
   - Map an identity-update attribute to an auto-configured template.

   Example

   The following example shows how a class-map with a service-template has to be applied:

   ```
   Device(config-class-control-policymap)# class-num class class-map-name
   do-until-failure
   Device(config-action-control-policymap)# action-index activate service-template
    service-template-name
   ```

   Example

   The following example shows how a parameter map has to be applied (service template is already associated with the parameter map 'param' while creating it):

   ```
   Device(config-action-control-policymap)# action-index map attribute-to-service
    table parameter-map-name
   ```

5. Exit configuration mode.

   Example

   ```
   Device(config-action-control-policymap)# end
   ```

6. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

7. Configure a wireless policy profile.

   Example

   ```
   Device(config)# wireless profile policy wlan-policy-profile-name
   ```

   > ⚠ **Caution**
   >
   > Do not configure aaa-override for native profiling under a named wireless profile policy. Native profiling is applied at a lower priority than AAA policy. If aaa-override is enabled, the AAA policies will override native profile policy.

8. Add a description for the policy profile.

Example

```
Device(config-wireless-policy)# description profile-policy-description
```

Example

```
Device(config-wireless-policy)# description "default policy profile"
```

9. Configure DHCP TLV caching on a WLAN.

Example

```
Device(config-wireless-policy)# dhcp-tlv-caching
```

10. Configure client HTTP TLV caching on a WLAN.

Example

```
Device(config-wireless-policy)# http-tlv-caching
```

11. Configure the subscriber policy name.

Example

```
Device(config-wireless-policy)# subscriber-policy-name policy-name
```

Example

```
Device(config-wireless-policy)# subscriber-policy-name polmap5
```

12. Configure a VLAN name or VLAN ID.

Example

```
Device(config-wireless-policy)# vlan vlan-id
```

Example

```
Device(config-wireless-policy)# vlan 1
```

13. Save the configuration.

Example

```
Device(config-wireless-policy)# no shutdown
```

The policy map is created and configured with the specified parameters, and the wireless policy profile is activated with the associated subscriber policy.

Configure native profiling in local mode (CLI)

Learn how to configure native profiling in local mode by enabling central switching in the policy profile.

To enable native profiling for wireless users in local mode by updating the policy profile configuration.

To configure native profiling in the local mode, you must follow the steps described in Create a policy map (CLI) on page 2211 . In the policy profile, you must enable central switching as described in the step given below in order to configure native profiling.

Procedure

Enable central switching.

Example

```
Device(config-wireless-policy)# central switching
```

Native profiling is now enabled in local mode. The device uses central switching, allowing profiling information to be collected and used for network management.

Verify native profile configuration

Verify native profile configuration.

Use these **show** commands to verify the native profile configuartion:

```
Device# show wireless client device summary

Active classified device summary
MAC Address       Device-type                       User-role
            Protocol-map
-------------------------------------------------------------------------------------
1491.82b8.f94b    Microsoft-Workstation             sales
                        9
1491.82bc.2fd5    Windows7-Workstation              sales
                       41
```

```
Device# show wireless client device cache

Cached classified device info

MAC Address       Device-type                       User-role
            Protocol-map
-------------------------------------------------------------------------------------
2477.031b.aa18    Microsoft-Workstation
                        9
30a8.db3b.a753    Un-Classified Device
                        9
4400.1011.e8b5    Un-Classified Device
                        9
980c.a569.7dd0    Un-Classified Device
```

```
Device# show wireless client mac-address 4c34.8845.e32c detail | s
Session Manager:
  Interface :
  IIF ID            : 0x90000002
  Device Type       : Microsoft-Workstation
  Protocol Map      : 0x000009
  Authorized        : TRUE
  Session timeout   : 1800
  Common Session ID: 78380209000000174BF2B5B9
  Acct Session ID   : 0
  Auth Method Status List
   Method : MAB
    SM State         : TERMINATE
    Authen Status    : Success
  Local Polices:
   Service Template : wlan_svc_C414.3CCA.0A51 (priority 254)
    Absolute-Timer   : 1800
  Server Polices:
  Resultant Policies:
  Filter-ID         : acl-auto
  Input QOS         : in_qos
  Output QOS        : out_qos
  Idle timeout      : 60 sec
  VLAN               : 10
  Absolute-Timer    : 1000
```

Use this **show** command to verify the class map details for a class map name:

```
Device# show class-map type control subscriber name test
Class-map              Action                        Exec  Hit  Miss  Comp
---------               ------                       ----  ---  ----   ---
match-any test     match day Monday                    0     0    0     0
match-any test     match join-time-of-day 8:00 18:00   0     0    0     0
Key:
  "Exec" - The number of times this line was executed
  "Hit"  - The number of times this line evaluated to TRUE
  "Miss" - The number of times this line evaluated to FALSE
  "Comp" - The number of times this line completed the execution of its
       condition without a need to continue on to the end
```

177 Air Time Fairness

Topics:

- Air time fairness

Air time fairness

Describes how Cisco ATF allows administrators to prioritize device categories, ensuring selected groups receive WLAN traffic more frequently.

Cisco Air Time Fairness (ATF) is a WLAN management feature that

- allocates Wi-Fi air time for user groups or device categories
- allows network administrators to group devices of a defined category and enables some groups to receive traffic from the WLAN more frequently than other groups
- provides air time fairness defined by the network administrator and not by the network, and
- dynamically adapts to changing conditions in a WLAN.

Air time fairness capabilities

Cisco ATF provides these additional capabilities:

- Provides a simplified mechanism for allocating air time.
- Enables a more efficient fulfillment of service-level agreements.
- Augments standards-based Wi-Fi QoS mechanisms.

By enabling network administrators to define what fairness means in their environments with regards to the amount of air time per client group, the amount of traffic is also controlled.

To control air time on a percentage basis, the air time including both uplink and downlink transmissions of a client or SSID is continuously measured.

Only air time in the downlink direction, that is AP to client, can be controlled accurately by the AP. Although air time in the uplink direction, that is client to AP can be measured, it cannot be controlled. Although the AP can constrain air time for packets that it sends to clients, the AP can only measure air time for packets that it hears from clients because it cannot strictly limit their air time.

Cisco ATF establishes air time limits (defined as a percentage of total air time) and applies those limits on a per SSID basis, where the SSID is used as a parameter to define a client group. Other parameters can be used as well to define groups of clients. Furthermore, a single air time limit can be applied to individual clients.

If the air time limit for an SSID (or client) is exceeded, the packets in the downlink direction are dropped. Dropping downlink packets (AP to client) frees up air time whereas dropping uplink packets (client to AP) does not do anything to free up air time because the packet has already been transmitted over the air by the client.

Client fair sharing ensures that all clients in an SSID or WLAN are treated equally based on their utilization of the radio bandwidth:

- The percentage of air time to be given to each client is recomputed every time a client connects or disconnects.
- Client fair sharing is applicable only to downstream traffic.
- Clients can be categorized into usage groups at the policy level.
- Client-based ATF metrics accumulation is performed in the transmit complete routine. This allows the air time that is unused by clients in low-usage or medium-usage groups to be accumulated to a common share pool bucket where the high-usage clients can be replenished.

Cisco ATF is supported on the following APs:

- Cisco Aironet 2700 Series Access Points
- Cisco Aironet 3700 Series Access Points

- Cisco Aironet 2800 Series Access Points
- Cisco Aironet 3800 Series Access Points
- Cisco Aironet 4800 Series Access Points
- Cisco Aironet 1540 Series Access Points
- Cisco Aironet 1560 Series Access Points

Note

Cisco ATF is supported on MESH, if APs support ATF. ATF is supported on FlexConnect mode and the Local mode.

Note

Cisco Catalyst APs offer capabilities that are equivalent to ATF by leveraging the enhancements in the Wi-Fi 6 and 6E protocols. 802.11ax features such as OFDMA, bidirectional MU-MIMO, and BSS coloring, combined with the advanced QoS features in the Cisco Catalyst 9800 Series Wireless Controllers, help resolve scheduling and congestion problems, accommodate multiple users at the same time, and allocate bandwidth more efficiently.

Cisco ATF operates in the following modes:

- Monitor mode: View the air time, report air time usage for all AP transmissions, view reports per SSID or WLAN, view reports per site group/tag, report air time usage at periodic intervals. No enforcement as part of Monitor mode.
- Enforce Policy mode: Enforce air time based on configured policy, enforce air time on a WLAN, all APs connected in a Cisco Catalyst 9800 Series Wireless Controller network, or per site group/tag.

Restrictions on Cisco air time fairness

Lists the restrictions on Cisco Air Time Fairness implementation and configuration.

This reference provides the specific restrictions that apply when implementing and configuring Cisco Air Time Fairness (ATF) functionality.

- Cisco ATF can be implemented only on data frames in the downstream direction.
- When ATF is configured in per-SSID mode, all the WLANs are disabled before you enter any ATF configuration commands. The WLANs are enabled after you enter all the ATF commands.

Cisco air time fairness use cases

Describes common deployment scenarios for Cisco Air Time Fairness (ATF) in various network environments.

A Cisco Air Time Fairness use case is a deployment scenario that

- demonstrates how air time allocation can be partitioned between different user groups or service providers in shared WLAN environments
- addresses specific network sharing requirements in venues such as public hotspots, educational institutions, enterprises, and managed hotspot services, and

- enables fair distribution of wireless bandwidth resources based on business or operational requirements.

Common ATF deployment scenarios

The following scenarios illustrate typical ATF implementations across different environments:

- **Public hotspots (stadium/airport/convention center/other)**: A public network is sharing a WLAN between two (or more) service providers and the venue. Subscribers to each service provider can be grouped and allocated a certain percentage of air time.
- **Education**: A university is sharing a WLAN between students, faculty, and guests. The guest network can be further partitioned by the service provider, for distribution of bandwidth privileges to the guests. Each group can be assigned a certain percentage of air time.
- **Enterprise/hospitality/retail**: The venue is sharing a WLAN between employees and guests. The guest network can be further partitioned by service provider. The guests could be sub-grouped by tier of service type with each subgroup being assigned a certain percentage of air time, for example a paid group is entitled for more air time than the free group.
- **Time shared managed hotspot**: The business entity managing the hotspot, such as a service provider or an enterprise, can allocate and subsequently lease air time to other business entities.

Configure Cisco air time fairness

Describes the high-level steps to configure Cisco Air Time Fairness (ATF) including policy creation, WLAN configuration, and monitoring.

Summary

The key components involved in configuring Cisco Air Time Fairness are:

- Monitor mode: Optional network usage determination tool
- Cisco ATF policies: Configuration rules that define air time allocation
- WLAN ATF policy assignment: Network or site group/tag level policy application
- Optimization settings: Performance enhancement configurations
- ATF statistics monitoring: Ongoing performance tracking and validation

Workflow

The configuring Cisco Air Time Fairness process involves these stages:

1. Enable Monitor mode to determine network usage.
2. Create Cisco ATF policies.
3. Add WLAN ATF policies per network or per site group/tag.
4. Determine, if optimization must be enabled.
5. Periodically check the Cisco ATF statistics.

Create a Cisco ATF profile (GUI)

Configure a Cisco ATF profile using the GUI.

Before you begin

Follow these steps to create a Cisco ATF profile using the GUI:

Procedure

1. Choose **Configuration** > **Wireless** > **Air Time Fairness**.
2. Click the **Profiles** tab and click the **Add** button, to create a new ATF policy.

   The **Add ATF Policy** window is displayed.
3. Specify a name, ID, and weight to the ATF policy.

   Weighted ratio is used instead of percentages so that the total can exceed 100. The minimum weight that you can set is 5. For example, if you configure the weight as 50, this means that the air time for this ATF profile is 50% when applied to an policy profile.
4. Use the slider to enable or disable the **Client Sharing** feature.

   When you enable this option in the Web UI, the default ATF configuration is set to **Enforce** and not **Monitor**.
5. Click **Apply to Device**.

Create Cisco ATF profile (CLI)

Create a Cisco ATF profile using commands.

Create and configure a Cisco ATF (Airtime Fairness) profile to manage airtime allocation and ensure fair distribution of wireless resources among clients.

Cisco ATF profiles are used to control how airtime is allocated among wireless clients on an access point. This helps ensure that slower clients do not monopolize airtime at the expense of faster clients, improving overall network performance.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Create a new Cisco ATF policy.

   Example

   ```
   Device(config)# wireless profile airtime-fairness atf-policy-name
   atf-profile-id
   ```

   Example

   ```
   Device(config)# wireless profile airtime-fairness atf-policy-name 1
   ```

   - *atf-policy-name*–Enters the ATF profile name.
   - *atf-profile-id*–Enters the ATF profile ID. Range is from 0 to 511.
3. Add a weight to the Cisco ATF policy.

Example

```
Device(config-config-atf)# weight policy-weight
```

Example

```
Device(config-config-atf)# weight 5
```

- *policy-weight*–Enters the policy weight. Range is from 5 to 100.

4. Enable client sharing for Cisco ATF policy.

Example

```
Device(config-config-atf)# client-sharing
```

5. Return to privileged EXEC mode.

Example

```
Device(config-config-atf)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The Cisco ATF profile is created and configured with the specified weight and client sharing settings, ready to be applied to wireless policies for airtime management.

Attach Cisco ATF profile to a policy profile (GUI)

Configure Cisco ATF profile attachment to a policy profile using GUI.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click **Add**.

   The **Add Policy Profile** window is displayed.
3. Click the **Advanced** tab.
4. Under the **Air Time Fairness Policies** section, select the required policy for 2.4 GHz and 5 GHz policies.
5. Click **Apply to Device**.

Attach Cisco ATF profile to a policy profile (CLI)

Configure attachment of a Cisco ATF profile to a policy profile using commands.

Attach a Cisco ATF profile to a policy profile to enable airtime fairness management for wireless clients.

This procedure is used when you need to associate an existing ATF policy with a policy profile to control airtime allocation across wireless clients on specific radio bands.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create policy profile for the WLAN.

   Example

   ```
   Device(config)# wireless profile policy profile-name
   ```

   The *profile-name* is the profile name of the policy profile.

3. Configure air time fairness policy for 2.4- or 5-GHz radio.

   Example

   ```
   Device(config-wireless-policy)# dot11 band airtime-fairness atf-policy-name
   ```

   Example

   ```
   Device(config-wireless-policy)# dot11 24ghz airtime-fairness atf-policy-name
   ```

   The *band* can be either 24ghz or 5ghz. The *atf-policy-name* is the name of the air time fairness policy.

   > **Note**
   >
   > You can assign the same ATF policy to both 2.4-GHz and 5-GHz radios (or) have two different ATF policies as well.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The Cisco ATF profile is now attached to the policy profile, enabling airtime fairness management for the specified radio band.

Enable ATF in the RF profile (GUI)

Configure ATF in the RF profile using GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF**.
2. Click **Add**.
   The **Add RF Profile** window is displayed.
3. Click the **Advanced** tab.
4. Under the **ATF Configuration** section, complete the following :
   a) Use the slider to enable or disable the **Status**. The **Mode** field is displayed.
   b) Click the **Monitor** mode or **Enforced** mode radio option. If you enable the **Enforced** mode, use the slider to enable or disable **Optimization**.
   c) Use the slider to enable to disable **Bridge Client Access**. This is applicable for mesh mode APs. Bridge Client Access determines the percentage of the ATF policy weight that is allocated to clients connected to the mesh APs.
5. Specify the **Airtime Allocation** value between 5 and 90.
6. Click **Apply to Device**.

Enable ATF in the RF profile (CLI)

Configure ATF in the RF profile using commands.

Enable Cisco ATF on 2.4 GHz or 5 GHz radios to manage air time allocation and improve network performance.

Cisco ATF must be enabled on 2.4 GHz or 5 GHz radios separately. Use this procedure when you need to configure air time fairness policies to ensure optimal wireless network performance and client experience.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an RF profile for 2.4- or 5-GHz radio.

   Example

   ```
   Device(config)# ap dot11 frequency-band rf-profile rf-profile-name
   ```

   Example

   ```
   Device(config)# ap dot11 24ghz rf-profile rfprof24_1
   ```

   Where *frequency-band* is either 24ghz or 5ghz.

3. Configure air time fairness mode.

   Example

   ```
   Device(config-rf-profile)# airtime-fairness mode mode-type
   ```

Example

```
Device(config-rf-profile)# airtime-fairness mode enforce-policy
```

Configures air time fairness in either of the modes:

- Enforce-policy–This mode signifies that the ATF is operational.
- Monitor–This mode gathers information about air time and reports air time usage.

4. Enable the air time fairness optimization.

Example

```
Device(config-rf-profile)# airtime-fairness optimization
```

Optimization is effective when the current WLAN reaches the air time limit and the other available WLANs does not use air time to its full extent.

5. Return to privileged EXEC mode.

Example

```
Device(config-rf-profile)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

ATF is now enabled in the RF profile and will manage air time allocation according to the configured policy mode.

Cisco ATF configuration verification

Lists commands to verify Cisco ATF configurations.

You can verify Cisco ATF configurations using these commands:

Table 157: Commands for verifying Cisco ATF configurations

Commands	Description
show wireless profile airtime-fairness summary	Displays the summary of air time fairness profiles.
show wireless profile airtime-fairness mapping	Displays the ATF policy mapping with the wireless profiles.
show ap airtime-fairness summary	Displays the ATF configuration summary of all radios.
show ap dot11 24ghz airtime-fairness	Displays the ATF configuration for 2.4-GHz radio.
show ap dot11 5ghz airtime-fairness	Displays the ATF configuration for 5-GHz radio.
show ap name *ap-name* **airtime-fairness**	Displays the ATF configuration or statistics for an AP.
show ap name *ap-name* **dot11 {24ghz | 5ghz} airtime-fairness statistics summary**	Displays the ATF statistics of 2.4- or 5GHz radio.

Cisco ATF statistics verification

Lists the commands available to verify Cisco ATF statistics.

Use these commands to verify Cisco ATF statistics for WLANs, ATF policies, and individual clients.

Table 158: ATF statistics per WLAN

Commands	Description
show ap name *ap-name* **dot11** {**24ghz** | **5ghz**} **airtime-fairness wlan** *wlan_name* **statistics**	Displays the ATF statistics related to a WLAN.

Table 159: ATF statistics per ATF policy

Commands	Description
show ap name *ap-name* **dot11** {**24ghz** | **5ghz**} **airtime-fairness policy** *policy-name* **statistics**	Displays the ATF statistics related to an ATF policy.

Table 160: ATF statistics per client

Commands	Description
show ap airtime-fairness statistics client *mac_address*	Displays the ATF statistics related to a client.

178 IPv6 Non-AVC QoS Support

Topics:

- IPv6 non-AVC QoS support

This chapter explains configuring IPv6 QoS on access points, including DSCP marking, packet dropping, and policing for Fabric and FlexConnect local switching, with CLI procedures and verification commands.

IPv6 non-AVC QoS support

IPv6 non-AVC QoS support enables Quality of Service (QoS) for IPv6 traffic on Fabric and FlexConnect local switching and offers the same functionality as IPv4 QoS starting from Cisco IOS XE 17.2.1.

IPv6 non-AVC QoS support is a wireless network feature that

- enables QoS for IPv6 traffic on Fabric and FlexConnect local switching,
- performs QoS processing at the access point (AP), and
- offers the same functionality as IPv4 QoS starting from Cisco IOS XE 17.2.1.

Supported actions for IPv6 non-AVC QoS

You can use IPv6 non-AVC QoS to:

- mark the Differentiated Services Code Point (DSCP) value for IPv6 packets,
- drop IPv6 packets based on the DSCP value,
- police IPv6 traffic.

Platform limitations

IPv6 non-AVC QoS is not supported on Cisco Aironet 1700, 2700, or 3700 Series Access Points.

Mark DSCP values in an IPv6 packet (CLI)

Learn how to mark DSCP values for an IPv6 packet using the CLI by configuring a policy map and setting the DSCP value in the packet.

Assign differentiated services code point (DSCP) values to IPv6 packets for traffic classification and Quality of Service (QoS).

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a policy map.

   Example

   ```
   Device(config)# policy-map policy-map-name
   ```

3. Specify the class map criteria for the policy.

   Example

   ```
   Device(config-pmap)#class class-map-name
   ```

4. Set the DSCP value in an IPv6 packet.

   Example

   ```
   Device(config-pmap-c)#set dscp <0-63>
   ```

   DSCP values must be in the range of 0 to 63.

The selected DSCP value is assigned to matching IPv6 packets, enabling traffic classification and QoS handling according to your policy.

Drop an IPv6 packet with DSCP values (CLI)

Learn how to drop an IPv6 packet with DSCP values using CLI commands.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a policy map.

   Example

   ```
   Device(config)# policy-map policy-map-name
   ```

3. Create a policy criteria.

   Example

   ```
   Device(config-pmap)#class class-map-name
   ```

4. Police the committed information rate.

   Example

   ```
   Device(config-pmap-c)#police cir <8000 - 10000000000>
   ```

   the committed information rate is between 8000 and 10000000000. Target bit rate (Bits per second).

5. Configure the **conform-action drop** command.

   Example

   ```
   Device(config-pmap-c-police)#conform action drop
   ```

   This command is the action when the rate is less than the conform burst.

6. Configure the **exceed-action drop** command.

Example

```
Device(config-pmap-c-police)#exceed-action drop
```

This command is the action when the rate is within the conform and conform plus exceed burst.

Configure policing for IPv6 traffic (CLI)

Learn how to police IPv6 traffic by configuring a policy map, class map, and policing actions on your device.

Police IPv6 traffic by enforcing bandwidth limits and actions for conforming and exceeding packets.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a policy map.

   Example

   ```
   Device(config)# policy-map policy-map-name
   ```

3. Create a policy criteria.

   Example

   ```
   Device(config-pmap)#class class-map-name
   ```

4. Specify the committed information rate.

   Example

   ```
   Device(config-pmap-c)#police cir <8000 - 10000000000>
   ```

   The CIR (committed information rate) sets the allowed bits per second; choose a value between 8000 and 10,000,000,000.

5. Configure the **conform-action transmit** command, for transmitting packets.

   Example

   ```
   Device(config-pmap-c-police)#conform-action transmit
   ```

6. Configure the **exceed-action drop** command.

   Example

   ```
   Device(config-pmap-c-police)#exceed-action drop
   ```

This command specifies the action taken when the packet rate exceeds the CIR but is within conform plus exceed burst.

IPv6 traffic is policed according to your defined bandwidth and actions. The device transmits packets within the CIR and drops packets that exceed the specified rate.

IPv6 non-AVC QoS verification

Verify IPv6 non-AVC QoS.

- To verify the DSCP values for IPv6 packets, IPv6 packets that are dropped, and the policing of IPv6 traffic, use the **show policy-map** command:

  This is a sample output of the **show** command that verifies the DSCP value for an IPv6 packet:

```
Device# show policy-map
1 policymaps
Policy Map Set-dscp type:qos client:default
 Class Set-dscp1_ADV_UI_CLASS
 set dscp af41 (34)
 Class class-default
 no actions
```

- This is a sample output of the **show** command that verifies the IPv6 packets that are dropped:

```
Device# show policy-map
1 policymaps
Policy Map Drop-dscp type:qos client:default
        Class Drop-dscp1_ADV_UI_CLASS
        drop

        Class class-default
        no actions
```

- This is a sample output of the **show** command that verifies the policing of IPv6 traffic:

```
Device# show policy-map
1 policymaps
Policy Map Drop-traffic type:qos client:default
        Class Drop-traffic1_ADV_UI_CLASS
        police rate 2000000 bps (250000Bytes/s)
        conform-action
        exceed-action

        Class class-default
        no actions
```

179 QoS Basic Service Set Load

Topics:

- QoS basic set service load

This chapter explains QBSS IE behavior across Cisco IOS XE releases and provides CLI steps to enable or disable QBSS load and WMM on WLANs, configure policy profiles and VLANs, and verify QBSS load status.

QoS basic set service load

Explains the per-WLAN configuration knob that controls QBSS IE advertisement in beacon frames and probe responses.

A QoS Basic Set Service (QBSS) information element (IE) knob is a per-WLAN configuration feature that

- controls the inclusion or exclusion of the QBSS IE in beacon frames and probe responses
- advertises channel load information of an AP through the QBSS IE, and
- is enabled by default to provide QoS load information to wireless clients.

QBSS load behavior changes

The relationship between WMM and QBSS load advertisement has evolved across Cisco IOS XE releases.

Until Cisco IOS XE 17.1.1s, the enablement of Wi-Fi Multimedia (WMM) automatically enabled the QBSS load advertisement in the probes and beacons and there was no separate knob to turn on QBSS load IE. However, from Cisco IOS XE 17.2.1, this behavior has changed with the introduction of a separate configuration knob.

The behavior until Cisco IOS XE 17.1.1s:

- When WMM was enabled on WLAN, QBSS load was advertised in the beacon and probe frames.
- When WMM was disabled on WLAN, QBSS IE was not advertised in the beacon and probe frames.

The behavior from Cisco IOS XE 17.2.1:

- When you enable WMM and QBSS ID on WLAN, QBSS IE is advertised in the beacon and probe frames.
- When you enable WMM on WLAN and disable QBSS load IE on WLAN, QBSS load is not advertised in the beacon and probe frames.
- When you disable WMM on WLAN and enable QBSS load IE on WLAN, QBSS IE is advertised in the beacon and probe frames.

> **Note**
>
> By default, QBSS load IE is enabled. The behavior can be configured on policy profile.

Configure Wi-Fi multimedia (CLI)

Configure Wi-Fi multimedia on a WLAN to enable quality of service features for multimedia traffic.

Enable Wi-Fi Multimedia (WMM) on a WLAN to provide quality of service features for multimedia applications.

Create a WLAN and then enable WMM to prioritize multimedia traffic and improve network performance for applications that require specific bandwidth or latency requirements.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Specify the WLAN name and ID.

Example

```
Device(config)# wlan profile-name wlan-id ssid
```

Example

```
Device(config)# wlan mywlan 34 mywlan-ssid
```

Where:

- *profile-name*: Profile name of the WLAN. You can use between 1 to 32 alphanumeric characters.
- *wlan-id*: WLAN ID. You can use between 1 to 512 alphanumeric characters.
- *ssid*: Service Set Identifier (SSID) for this WLAN. If the SSID is not specified, the WLAN profile name is set as the SSID.

> **Note**
>
> By default, the WLAN is disabled.

3. Disable WPA2 ciphers for Advanced Encryption Standard (AES).

Example

```
Device(config-wlan)# no security wpa wpa2 ciphers aes
```

4. Disable security AKM for dot1x.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

5. Configure WMM and allow WMM on the WLAN.

Example

```
Device(config-wlan)# wmm allowed
```

6. Enable WLAN.

Example

```
Device(config-wlan)# no shutdown
```

WMM is now enabled on the WLAN, providing quality of service features for multimedia traffic prioritization.

Enable QoS basic set service load (CLI)

Configure QoS basic set service load to provide enhanced QoS information element functionality on the WLAN.

Enable QBSS load to provide QoS enhanced basic service set information element functionality on the WLAN.

QBSS load enables the transmission of enhanced QoS information elements that help optimize wireless network performance. Perform this procedure to enable QBSS load on a wireless policy profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-policy
   ```

   Example

   ```
   Device(config)# wireless profile policy rr-xyz-policy-1
   ```

3. Configure VLAN name or VLAN ID.

   Example

   ```
   Device(config-wireless-policy)# vlan vlan-id
   ```

   Example

   ```
   Device(config-wireless-policy)# vlan 24
   ```

4. Enable QoS enhanced basic service set information element.

   Example

   ```
   Device(config-wireless-policy)# qbss-load
   ```

   Use the **no** form of this command to disable the feature.

5. Save the configuration and exit configuration mode.

Example

```
Device(config-wireless-policy)# no shutdown
```

QoS basic set service load is now enabled on the wireless policy profile. The configuration is saved and you have returned to privileged EXEC mode.

What to do next

1. Create a policy tag. For more information about creating policy tags, refer to *Configuring a Policy Tag (CLI)*.
2. Map the policy tag to the AP. For more information about mapping a policy tag to the AP, refer to *Attaching a Policy Tag and Site Tag to an AP (CLI)*.

QoS basic set service load verification

Verify QoS basic set service load.

To verify if QBSS load is enabled, use the **show wireless profile policy detailed** *named-policy-profile* command:

```
Device# show wireless profile policy detailed named-policy-profileshow wireless
profile policy detailed named-policy-profile
Policy Profile Name                 : named-policy-profile
Description                         :
Status                              : ENABLED
VLAN                                : 91
Multicast VLAN                      : 0
OSEN client VLAN                    :
Multicast Filter                    : DISABLED
QBSS Load                           : ENABLED
Passive Client                      : DISABLED
ET-Analytics                        : DISABLED
StaticIP Mobility                   : DISABLED
WLAN Switching Policy
  Flex Central Switching            : ENABLED
  Flex Central Authentication       : ENABLED
  Flex Central DHCP                 : ENABLED
  Flex NAT PAT                      : DISABLED
  Flex Central Assoc                : ENABLED
```

Part XIV

IPv6

Topics:

- IPv6 Client IP Address Learning
- IPv6 ACL
- Configuring IPv6 Mobility
- IPv6 Support on Flex and Mesh
- IPv6 CAPWAP UDP Lite Support
- Neighbor Discovery Proxy
- Address Resolution Protocol Proxy
- IPv6 Ready Certification

180 IPv6 Client IP Address Learning

Topics:

- IPv6 client address learning
- IPv6 address tracking for wireless clients
- Native IPv6

This chapter explains how to discover, track, and manage IPv6 addresses for wireless clients, and provides configuration steps (CLI and GUI) for SLAAC, DHCPv6, RA guard/throttle, ND suppression, and related IPv6 interface and DHCP settings.

IPv6 client address learning

Explains how wireless controllers learn IPv6 client addresses and the mechanisms clients use to acquire them.

A client address learning mechanism is a wireless controller feature that

- identifies and stores IPv4 and IPv6 addresses for wireless clients
- maintains the client's transition state during association and timeout, and
- operates through monitoring relevant network protocols.

There are three ways for an IPv6 client to acquire IPv6 addresses:

- Stateless Address Auto-Configuration (SLAAC)
- Stateful DHCPv6
- Static Configuration

In all of these methods, the IPv6 client always sends a Neighbor Solicitation Duplicate Address Detection (DAD) request to ensure that there is no duplicate IP address on the network. The device monitors Neighbor Discovery Protocol (NDP) and DHCPv6 packets from the client to learn its IP addresses.

Prerequisites for IPv6 client address learning

This topic outlines the requirements you must meet before configuring IPv6 client address learning

- Before configuring IPv6 client address learning, configure the clients to support IPv6.
- To enable wireless IPv6 client connectivity, the underlying wired network must support IPv6 routing and an address assignment mechanism, such as SLAAC or DHCPv6. The wireless LAN controller must have L2 adjacency to the IPv6 router.

> **Note**
>
> The AP learns the IPv6 client address based on the source IP address, even though neighbor advertisements can hold the remaining IPv6 addresses. The AP does not examine neighbor advertisements to learn the IPv6 address acquired by the client. This behavior occurs only with Apple clients and not with Microsoft Windows clients.

Configure IPv6 interface on a switch (GUI)

Configure an IPv6 interface on a switch by specifying VLAN, interface details, and IPv6 settings using the GUI.

Enable IPv6 connectivity on a switch interface by assigning IPv6 addresses and configure related settings via the GUI.

Procedure

1. Choose **Configuration** > **Layer2** > **VLAN** > **SVI**.
2. Click **Add**.
3. Enter **VLAN Number**, **Description** and **MTU (Bytes)**.
4. Enable or disable the **Admin Status** toggle button.
5. In **IP Options**, check the **IPv6** check box.

6. Select the type of **Static** address from the drop-down list and enter the static address.
7. Check or uncheck the **DHCP**, **Autoconfig** and **Act as an IPv6 DHCP client** check boxes.

   If you check the **DHCP** check box, the **Rapid Commit** check box is displayed. Check or uncheck the **Rapid Commit** check box.
8. Click **Apply to Device**.

Configure IPv6 on Interface (CLI)

Use this procedure to configure IPv6 addresses on a interface using the commands.

Use this procedure to assign IPv6 addresses to a specific controller interface using commands.

Before you begin

Enable IPv6 on the client and IPv6 support on the wired infrastructure.

Procedure

1. Enable the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password, if prompted.
2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
3. Create an interface and enter the interface configuration mode.

   Example

   ```
   Device(config)# interface vlan vlan-id
   ```
4. Configure IPv6 address on the GigabitEthernet interface using the link-local option.

   Example

   ```
   Device(config-if)# ip address 198.51.100.1 255.255.255.0
   Device(config-if)# ipv6 address fe80::1 link-local
   Device(config-if)# ipv6 address 2001:DB8:0:1:FFFF:1234::5/64
   Device(config-if)# ipv6 address 2001:DB8:0:0:E000::F/64
   ```
5. Optional: Enable IPv6 on the GigabitEthernet interface.

   Example

   ```
   Device(config)# ipv6 enable
   ```

6. Exit interface mode.

Example

```
Device(config)# end
```

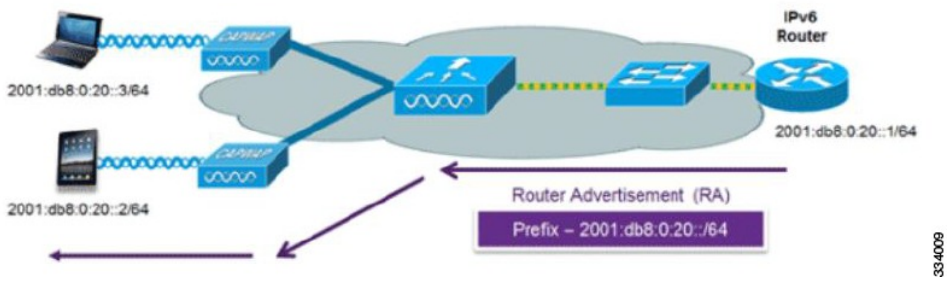
Address assignment using SLAAC

This topic explains how IPv6 address assignment works using SLAAC, including algorithm options and router configuration..

A SLAAC address assignment is an IPv6 address configuration mechanism that

- enables clients to automatically generate their own addresses based on a network prefix
- provides plug-and-play connectivity without requiring manual configuration, and
- utilizes router advertisements to communicate the IPv6 prefix and default gateway to clients.

SLAAC is configured as follows:



- A host sends a Router Solicitation message.
- The host waits for a Router Advertisement message.
- The host takes the first 64 bits of the IPv6 prefix from the Router Advertisement message and combines it with the 64-bit EUI-64 address (in the case of Ethernet, this is created from the MAC address) to create a global unicast address. The host also uses the source IP address in the IP header of the Router Advertisement message as its default gateway.
- IPv6 clients perform Duplicate Address Detection to ensure that randomly chosen addresses do not conflict with those of other clients.

Note

The last 64 bits of the IPv6 address can be learned by using one of these algorithms:

- EUI-64, which is based on the MAC address of the interface
- Private addresses that are randomly generated

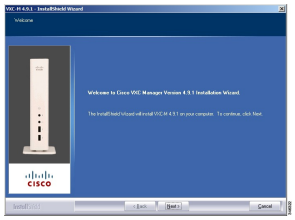
Figure 31: Address Assignment Using SLAAC

These Cisco IOS configuration commands from a Cisco-capable IPv6 router are used to enable SLAAC addressing and router advertisements:

```
ipv6 unicast-routing
    interface Vlan20
    description IPv6-SLAAC
    ip address 192.168.20.1 255.255.255.0
    ipv6 address FE80:DB8:0:20::1 linklocal
    ipv6 address 2001:DB8:0:20::1/64
    ipv6 enable
    end
```

Stateful DHCPv6 address assignment

This topic explains how stateful DHCPv6 assigns IPv6 addresses to clients and its operational differences compared to stateless DHCPv6.



A stateful DHCPv6 address assignment is an IPv6 address management method that

- assigns unique IPv6 addresses to clients from a DHCPv6 pool
- enables the router or external DHCPv6 server to manage address state and lease information, and
- provides additional configuration details, including domain names and DNS servers.

There are two modes of operation for DHCPv6: Stateless and Stateful.

The DHCPv6 Stateless mode is used to provide clients with additional network information that is not available in the router advertisement, but not an IPv6 address, becuase this is already provided by SLAAC. This information includes the DNS domain name, DNS servers, and other DHCP vendor-specific options.

Figure 32: Stateful DHCPv6 Address Assignment

Configure the interface as shown to implement stateless DHCPv6 with SLAAC enabled on your Cisco IOS IPv6 router.

```
ipv6 unicast-routing
ipv6 dhcp pool IPV6_DHCPPOOL
address prefix 2001:db8:5:10::/64
domain-name cisco.com
dns-server 2001:db8:6:6::1
interface Vlan20
description IPv6-DHCP-Stateless
ip address 192.168.20.1 255.255.255.0
ipv6 nd other-config-flag
ipv6 dhcp server IPV6_DHCPPOOL
ipv6 address 2001:DB8:0:20::1/64
end
```

Configure DHCP pool on switch (GUI)

Configure a DHCP pool on a switch by specifying IP address ranges, subnet mask, lease times, and other related settings using the GUI.

Set up DHCP pools to automatically assign IP addresses to devices on your network using the GUI.

Procedure

1. Choose **Administration** > **DHCP**. Click the **Add** button. The **Create DHCP Pool** dialog box appears.
2. Enter a pool name in the **DHCP Pool Name** field. The pool name must not exceed 236 characters.
3. Select either **IPv4** or **IPv6** from the **IP Type** drop-down list.
4. Enter an IP address in the **Network** field.
5. Select a subnet mask from the **Subnet Mask** drop-down list.
6. Enter an IP address in the **Starting ip** field amd enter an IP address in the **Ending ip** field.
7. Optional: Set the status of the **Reserved Only** field to **Enabled** to reserve the DHCP pool. Select the desired option from the **Lease** drop-down list.
8. Selecting the **User Defined** option from the **Lease** drop-down list enables the **(0-365 days)**, **(0-23 hours)**, and **(0-59 minutes)** fields. Enter appropriate values. Click the **Save & Apply to Device** button.
9. For IPv6, enter the **DNS Server, DNS Domain Name, and Ipv6 Address Allocation**.

Configure DHCP pool on Switch (CLI)

Configure a DHCP pool on a switch using commands to enable automatic IP address assignment to connected devices.

Set up a DHCP pool so that devices connected to the switch automatically receive IP addresses and network configuration using commands.

Follow the procedure given below to configure DHCP Pool on an interface:

Procedure

1. Enable the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Enter the configuration mode and configure the IPv6 DHCP pool on the VLAN.

   Example

   ```
   Device(config)# ipv6 dhcp pool vlan-id
   ```

4. Enter the configuration-DHCP mode and configure the address pool and its lifetime on a VLAN.

Example

```
Device(config-dhcpv6)# address prefix 2001:DB8:0:1:FFFF:1234::/64 lifetime
300 10
```

5. Configure the DNS servers for the DHCP pool.

   Example

   ```
   Device(config-dhcpv6)# dns-server 2001:20:21::1
   ```

6. Configure the domain name to complete unqualified host names.

   Example

   ```
   Device(config-dhcpv6)# domain-name example.com
   ```

7. Return to the privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press ***Ctrl-Z*** to exit global configuration mode.

Configure stateless auto address configuration without DHCP on Switch (CLI)

Use this task to configure IPv6 stateless address autoconfiguration (SLAAC) on a switch interface without using DHCP.

Configure IPv6 addresses using stateless auto address configuration without enabling DHCP on the switch using commands.

Procedure

---

1. Enable the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Create an interface and enter the interface configuration mode.

   Example

   ```
   Device# interface vlan 1
   ```

4. Configure IPv6 address on the GigabitEthernet interface using the link-local option.

   Example

   ```
   Device(config-if)# ip address 198.51.100.1 255.255.255.0
   Device(config-if)# ipv6 address fe80::1 link-local
   Device(config-if)# ipv6 address 2001:DB8:0:1:FFFF:1234::5/64
   Device(config-if)# ipv6 address 2001:DB8:0:0:E000::F/64
   ```

5. Optional: Enable IPv6 on the GigabitEthernet interface.

   Example

   ```
   Device(config)# ipv6 enable
   ```

6. Ensure the attached hosts do not use stateful autoconfiguration to obtain addresses.

   Example

   ```
   Device(config)# interface vlan 1
   Device(config-if)# no ipv6 nd managed-config-flag
   ```

7. Ensure the attached hosts do not use stateful autoconfiguration to obtain non-address options from DHCP (domain etc).

   Example

   ```
   Device(config-if)# no ipv6 nd other-config-flag
   ```

8. Return to the privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press ***Ctrl-Z*** to exit global configuration mode.

Configure stateless auto address configuration with DHCP on Switch

Configure IPv6 stateless auto addressing with DHCP on a switch using the commands.

Enable IPv6 stateless auto address configuration so attached hosts can receive IPv6 addresses and additional information from DHCP without stateful address assignment using commands.

Procedure

---

1. Enable the privileged EXEC mode and enter the global configuration mode.

Example

```
Device# enable
```

```
Device# configure terminal
```

Enter your password if prompted.

2. Create an interface and enter the interface configuration mode.

Example

```
Device(config)# interface vlan 1
```

3. Configure IPv6 address on the GigabitEthernet interface using the link-local option.

Example

```
Device(config-if)# ip address 198.51.100.1 255.255.255.0
Device(config-if)# ipv6 address fe80::1 link-local
Device(config-if)# ipv6 address 2001:DB8:0:1:FFFF:1234::5/64
Devicec(config-if)# ipv6 address 2001:DB8:0:0:E000::F/64
```

4. Configure IPv6 address on the GigabitEthernet interface using the link-local option.

Example

```
Device(config-if)# ip address 198.51.100.1 255.255.255.0
Device(config-if)# ipv6 address fe80::1 link-local
Device(config-if)# ipv6 address 2001:DB8:0:1:FFFF:1234::5/64
Device(config-if)# ipv6 address 2001:DB8:0:0:E000::F/64
```

5. Optional: Enable IPv6 on the GigabitEthernet interface.

Example

```
Device(config)# ipv6 enable
```

6. Specify a subnet prefix.

Example

```
Device(config)# ipv6 nd prefix 2001:9:3:54::/64 no-advertise
```

7. Ensure the attached hosts do not use stateful autoconfiguration to obtain addresses.

Example

```
Device(config)# interface vlan 1
Device(config-if)# no ipv6 nd managed-config-flag
```

8. Ensure the attached hosts do not use stateful autoconfiguration to obtain non-address options from DHCP (domain etc).

Example

```
Device(config-if)# no ipv6 nd other-config-flag
```

9. Display the configuration parameters and exit the interface mode.

Example

```
Device(config)# ipv6 dhcp server servername
```

```
Device(config)# end
```

Configure stateless address auto configuration without DHCP on Switch (CLI)

Configure IPv6 stateless address autoconfiguration (SLAAC) without DHCP for hosts on a switch using commands.

Set up IPv6 addresses for hosts on a switch using SLAAC, ensuring they do not rely on DHCP for address or configuration using commands.

Procedure

---

1. Enable the privileged EXEC mode.

Example

```
Device# enable
```

Enter your password if prompted.

2. Enter the global configuration mode.

Example

```
Device# configure terminal
```

3. Create an interface and enter the interface configuration mode.

Example

```
Device(config)# interface vlan 1
```

4. Configure IPv6 address on the GigabitEthernet interface using the link-local option.

Example

```
Device(config-if)# ip address 198.51.100.1 255.255.255.0
Device(config-if)# ipv6 address fe80::1 link-local
Device(config-if)# ipv6 address 2001:DB8:0:1:FFFF:1234::5/64
Device(config-if)# ipv6 address 2001:DB8:0:0:E000::F/64
```

5. Optional: Enable IPv6 on the GigabitEthernet interface.

Example

```
Device(config)# ipv6 enable
```

6. Ensure the attached hosts do not use stateful autoconfiguration to obtain addresses.

   Example

   ```
   Device(config)# interface vlan 1
   Device(config-if)# no ipv6 nd managed-config-flag
   ```

7. Ensure the attached hosts do not use stateful autoconfiguration to obtain non-address options from DHCP (domain etc).

   Example

   ```
   Device(config-if)# no ipv6 nd other-config-flag
   ```

8. Return to the privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press ***Ctrl-Z*** to exit global configuration mode.

Router solicitation

This topic explains how router solicitation messages prompt routers to advertise configuration information for local routing and address auto-configuration.

A router solicitation message is a network communication signal that

- is issued by a host controller to locate local routers
- prompts routers to transmit Router Advertisement messages, and
- facilitates the host in obtaining routing information or performing stateless auto-configuration.

Router Advertisements are transmitted periodically. The host triggers an immediate Router Advertisement using a Router Solicitation, for example, when it boots or after a restart operation.

Router advertisement

A Router Advertisement message is issued periodically by a router or in response to a Router Solicitation message from a host.

A Router advertisement is a type of message

- that is sent by IPv6 routers either periodically or in response to Router Solicitation messages from hosts, and
- communicates essential information such as network prefixes, default gateway availability, and configuration flags.

Router advertisement messages enable hosts to perform stateless autoconfiguration and update their routing tables with current network settings.

Router advertisement guard

This topic explains how router advertisement guards increase IPv6 network security by blocking rogue router advertisements from wireless clients.

A router advertisement guard is a security feature that

- examines incoming router advertisement messages from IPv6 devices
- drops unwanted or rogue router advertisements coming from wireless clients, and
- protects legitimate IPv6 routers and the network from misconfigured or malicious IPv6 clients.

By default, RA guard is always enabled on the controller.

- Port on which the frame is received
- IPv6 source address
- Prefix list
- Trusted or Untrusted ports for receiving the router advertisement guard messages
- Trusted/Untrusted IPv6 source addresses of the router advertisement sender
- Trusted/Untrusted Prefix list and Prefix ranges
- Router preference

Router advertisement throttling

This topic explains how router advertisement throttling limits the frequency of RA packets and maintains IPv6 connectivity for clients.

A router advertisement throttle is a network control mechanism that

- enforces limits on the frequency of router advertisement (RA) packets sent toward the wireless network
- ensures routers that send multiple RA packets are restricted to a minimum frequency required for IPv6 client connectivity, and
- maintains uninterrupted IPv6 connectivity for new or roaming clients by allowing RA packets in response to Router Solicitation (RS) packets.

If a client sends an RS packet, the router sends an RA back to the client. The controller allows this RA to pass and delivers it as a unicast message to the client. This process ensures that new or roaming clients are not affected by RA throttling.

Configure RA throttle policy (CLI)

Configure Router Advertisement (RA) throttle policies to enforce limits for IPv6 multicast RA traffic to wireless clients using commands

Restrict the frequency and quantity of multicast Router Advertisements (RAs) sent to wireless clients for improved network performance and client behavior using commands.

Configure RA Throttle policy to allow the enforce the limits

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Define the router advertisement (RA) throttler policy name and enter IPv6 RA throttle policy configuration mode.

   Example

   ```
   Device(config)# ipv6 nd ra-throttler policy ra-throttler1
   ```

3. Configure the throttle period in an IPv6 RA throttler policy.

   Example

   ```
   Device(config-nd-ra-throttle)# throttle-period 500
   ```

   The throttle period is measured in seconds. It is the duration during which the controller does not forward RA to wireless clients.

4. Limit multicast RAs per VLAN per throttle period.

   Example

   ```
   Device(config-nd-ra-throttle)# max-through 15
   ```

5. Limit the number of multicast RAs per device per throttle period in an RA throttler policy.

   Example

   ```
   Deviceconfig-nd-ra-throttle)# allow at-least 5 at-most 10
   ```

Apply RA throttle policy on VLAN (GUI)

Apply a Router Advertisement (RA) throttle policy to a VLAN through the GUI to control the rate of RA packets on your network.

Apply a Router Advertisement (RA) throttle policy to a VLAN through the GUI to control the rate of RA packets on your network.

Procedure

---

1. Choose **Configuration** > **Services** > **RA Throttle Policy**.
2. Click **Add**. The **Add RA Throttle Policy** dialog box appears.
3. Enter a name for the policy in the **Name** field.
4. Select the desired option from the **Medium Type** drop-down list.
5. Enter a value in the **Throttle Period** field. RA throttling takes place only after the **Max Through** limit is reached for the VLAN or the **Allow At-Most** value is reached for a particular router.
6. Enter a value for the **Max Through** field, which is the maximum number of RA packets on a VLAN that can be sent before throttling takes place. The **No Limit** option allows an unlimited number of RA packets through with no throttling.
7. Choose an **Interval Option**. The device acts differently based on the RFC 3775 value set in IPv6 RA packets. Options include:

- Ignore: Causes the RA throttle to treat packets with the interval option as a regular RA and subjects them to throttling if in effect.
- Passthrough: Allows any RA messages with the RFC 3775 interval option to go through without throttling.
- Throttle: Causes the RA packets with the interval option to always be subject to rate limiting.

8. Enter the minimum number of RA packets per router that can be sent as multicast before throttling takes place in the **At Least Multicast RAs** field.
9. Enter the maximum number of RA packets per router that can be sent as multicast before throttling takes place in the **At Most Multicast RAs** field. The **No Limit** option allows an unlimited number of RA packets through the router. Click the **Add & Apply to Device** button.

Apply RA throttle policy on a VLAN (CLI)

Configure an RA throttle policy for a VLAN using commands to limit Router Advertisement (RA) packet frequency.

Control and optimize IPv6 Router Advertisement (RA) packet frequency within a VLAN, ensuring efficient IPv6 client connectivity using commands.

Applying the RA Throttle policy on a VLAN. Enabling RA throttling reduces the frequency of router advertisement packets while still maintaining IPv6 client connectivity.

Procedure

---

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a VLAN or a collection of VLANs and enter the VLAN configuration mode.

   Example

   ```
   Device(config)# vlan configuration 1
   ```

3. Attach an IPv6 RA throttler policy to a VLAN or a collection of VLANs.

   Example

   ```
   Device(config-vlan)# ipv6 nd ra throttler attach-policy ra-throttler1
   ```

Neighbor discovery

IPv6 Neighbor Discovery is a protocol that enables IPv6 nodes to discover other nodes on the local network, determine their link-layer addresses, and maintain reachability information.

IPv6 Neighbor Discovery (ND) is a suite of messages and processes

- that allows devices on an IPv6 network to discover neighbors, determine their link-layer addresses, identify routers, and

- maintain information about routes and reachability replacing several IPv4 mechanisms, including the Address Resolution Protocol (ARP), ICMP Router Discovery, and ICMP Redirect.

IPv6 neighbor discovery inspection analyzes neighbor discovery messages to build a trusted binding table database. IPv6 Neighbor Discovery packets that do not comply with requirements are dropped. The neighbor binding table in the tracks each IPv6 address and its associated MAC address. The table removes clients according to the neighbor-binding timers.

Neighbor discovery suppression

This topic explains how neighbor discovery suppression improves wireless device efficiency by selectively responding to multicast requests.

A neighbor discovery suppression mechanism is a network optimization feature that

- caches IPv6 addresses of wireless clients when they reach RUN state
- selectively converts multicast Neighbor Solicitation (NS) requests to unicast or replies directly, depending on configuration, and
- forwards NS multicast requests to the wired side when the target address is not in the device's cache.

The same behavior applies to ARP requests for IPv4 addresses, where the device maintains the IPv4 address of the wireless client in the cache.

If neither configuration is enabled, and the device receives a Non-DAD or DAD NS multicast searching for an IPv6 address, and the target address is known to the device and belongs to one of its clients, the device converts the multicast NS to a unicast NS. It replaces the destination MAC address with the client's MAC address and forwards the unicast packet to the client.

If full proxy is enabled, and the device receives a Non-DAD or DAD NS multicast searching for an IPv6 address, and the target address is known to the device and belongs to one of its clients, the device replies with an NA message on behalf of the client.

Use the **ipv6 nd proxy** command to enable or disable DAD or full proxy.

When the device receives an DAD-NS multicast looking for an IPv6 address, and if the target address is known to the device and belongs to one of its clients, the device will reply with an NA message on behalf of the client.

If the device receives a DAD-NS multicast searching for an IPv6 address, and the target address is known to the device and belongs to one of its clients, the device replies with an NA message on behalf of the client.

If the device does not have the IPv6 address of a wireless client, it does not respond with NA; instead, it forwards the NS packet to the wired side. This is because all wireless client IPv6 addresses and their corresponding MAC addresses should be available in the controller. If an IPv6 address required by the NS is not available, the address is assumed not to belong to a wireless client, so the request is forwarded to the wired side.

IPv6 address tracking for wireless clients

Explains how Cisco wireless controllers track IPv6 addresses for wireless clients, the operational limits, and the impact of new software releases on address tracking and feature compatibility.

A wireless client's IPv6 addresses are network configuration parameters that

- enable a controller to identify and monitor multiple IPv6 addresses used by a single wireless device
- are stored and tracked by the controller to enforce policy and facilitate client management, and
- are subject to a fixed limit that influences feature availability and network behavior.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 161: Feature history for IPv6 Address Tracking for Wireless Clients

Feature Name	Release Information	Feature Description
IPv6 Address Tracking for Wireless Clients	Cisco IOS XE Cupertino 17.9.2	In this release, the controller allows data traffic from wireless clients with new IPv6 source addresses, even after eight addresses have been learned for each client. The controller continues to learn new IPv6 addresses from the clients' control traffic (IPv6 NS/NA and DHCPv6) and keeps track of only a maximum of eight addresses per wireless client.
IPv6 Address Tracking for Wireless Clients	Cisco IOS XE Cupertino 17.9.1	Until this release, the controller supported a maximum of eight IPv6 addresses per wireless client. After eight IPv6 addresses were learned for a wireless client, the controller dropped any data traffic from that client with new IPv6 source addresses.

To forward multicast neighbor solicitation (NS) queries for unknown IPv6 target addresses those not tracked by the controller to wireless clients, you must enable the **wireless ipv6 nd ns-forward** configuration.

Important

Configure IPv6 Multicast over Multicast (MoM) tunnel along with the **wireless ipv6 nd ns-forward** configuration.

Note

In Cisco IOS XE 17.9.2, because the controller allows IPv6 traffic without address tracking beyond the eight-address limit, some features such as User Defined Network, iPSK Peer-to-Peer Blocking, Management over Wireless, Neighbor Discovery Suppression, and IP Theft Detection may not work for clients using more than eight addresses. You can disable the new behavior by enabling the IP Source Guard feature https://www.cisco.com/c/en/us/td/docs/wireless/controller/9800/17-9/config-guide/b_wl_17_9_cg/m_ipsg_ewlc.html?bookSearch=true.

Configure unknown address multicast neighbor solicitation forwarding (CLI)

Configure your wireless controller to forward multicast neighbor solicitation (NS) messages for unknown IPv6 client addresses.

Enable the controller to forward multicast NS queries for wireless clients whose IPv6 addresses are not tracked, ensuring proper neighbor discovery on the network using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable forwarding of the multicast neighbor solicitation (NS) messages for unknown IPv6 target addresses, specifically, the addresses of wireless clients that are not tracked by the controller to wireless clients.

   Example

   ```
   Device (config)# wireless ipv6 nd ns-forward
   ```

   Note

   We recommend configuring IPv6 Multicast over Multicast (MoM) tunnel together with this command.

Native IPv6

Enables seamless communication by using IPv6 as the exclusive protocol throughout a network, eliminating the need for IPv4 translation or tunneling mechanisms.

IPv6

IPv6 is a packet-based protocol used to exchange data, voice, and video traffic over digital networks.

IPv6 (Internet Protocol version 6) is a

- packet-based communications protocol developed to exchange data, voice, and video traffic over digital networks, and
- successor to IPv4, offering a much larger address space and several functional enhancements to support the growing requirements of modern networks.

IPv6 is based on IP, but adds a much larger address space and improvements such as a simplified main header and extension headers. The architecture of IPv6 helps existing IPv4 users transition to IPv6. It allows continued use of services such as end-to-end security, quality of service (QoS), and globally unique addresses. The larger IPv6 address space allows networks to scale and provide global reachability.

> **Note**
>
> Features and functions that work on IPv4 networks with IPv4 addresses also work on IPv6 networks with IPv6 addresses.

General guidelines and unsupported features of IPv6

This topic outlines the recommended guidelines for configuring IPv6 on controller or embedded wireless controllers and highlights unsupported IPv6 features you should avoid.

- For IPv6 functionality, disable IPv6 multicast routing.
- The Wireless Management interface must have only one static IPv6 address.
- Router advertisements should be suppressed on the wireless management interface and on client VLANs, if IPv6 is configured on the client VLAN.
- The preferred mode is a setting within the AP join profile. When you configure the preferred mode as IPv6, an AP attempts to join over IPv6 first. If it fails, the AP falls back to IPv4.
- You should use MAC addresses for RA tracing of APs and clients.
- APs can join IPv6 controllers only with a static IPv6 address. If you have a controller with auto configurations and multiple IPv6 addresses, APs cannot join those IPv6 controllers.

Unsupported Feature

- UDP Lite is not supported.
- AP sniffer over IPv6 is not supported.
- IPv6 is not supported for the HA port interface.
- Auto RF grouping over IPv6 is not supported. Only static RF grouping is supported.

Configure IPv6 addressing (CLI)

Configure IPv6 addressing for network interfaces using commands.

Enable IPv6 communication and routing capabilities on physical and VLAN interfaces using commands.

> **Note**
>
> All features and functions that operate on IPv4 networks with IPv4 addresses also function on IPv6 networks with IPv6 addresses.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure IPv6 for unicasting.

Example

```
Device(config)# ipv6 unicast-routing
```

3. Create an interface and enter the interface configuration mode.

Example

```
Device(config)# interface vlan 1
```

4. Specify a global IPv6 address.

Example

```
Device(config-if)# ipv6 address FD09:9:2:49::53/64
```

5. Enable IPv6 on the interface.

Example

```
Device(config-if)# ipv6 enable
```

6. Suppress IPv6 router advertisement transmissions on the interface.

Example

```
Device(config-if)# ipv6 nd ra suppress all
```

7. Return to the global configuration mode and configure the ports that are connected to the supported APs with the wireless management interface.

Example

```
Device(config-if)# exit
```

```
Device(config)# wireless management interface gigabitEthernet vlan 64
```

8. Specify IPv6 static routes.

Example

```
Device(config)# ipv6 route ::/0 FD09:9:2:49::1
```

Create an AP join profile (GUI)

Configure an AP join profile through the GUI to set parameters for AP joining.

Set up an AP join profile that controls AP joining behavior and preferences using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. On the **AP Join Profile** window, click the **General** tab and click **Add**.
3. In the **Name** field, enter a name for the AP join profile.
4. Optional: Enter a description for the AP join profile.
5. Choose **CAPWAP** > **Advanced**.
6. Select **IPv6** from the **Preferred Mode** drop-down list under the **Advanced** tab to set the preferred mode of APs to IPv6.
7. Click **Save & Apply to Device**.

Create an AP join profile (CLI)

Create an AP join profile using commands.

Create an AP join profile using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile
   ```

3. Add a description for the AP profile.

   Example

   ```
   Device(config-ap-profile)# description ap-profile-name
   ```

4. Set the preferred mode of APs as IPv6.

   Example

   ```
   Device(config-ap-profile)# preferred-mode ipv6
   ```

Configure the primary and backup Controller (GUI)

Use this task to configure both the primary and backup embedded wireless controllers in the GUI for high availability.

Set up a reliable wireless network by designating primary and backup controllers to ensure continuous connectivity in case of failures using the GUI.

Before you begin

Ensure that you have configured an AP join profile prior to configuring the primary and backup controller s.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. On the **AP Join Profile** window, click the AP join profile name.
3. In the **Edit AP Join Profile** window, click the **CAPWAP** tab.
4. In the **High Availability** tab, under **Backup Controller Configuration**, check the **Enable Fallback** check box.
5. Enter the primary and secondary controller names and IP addresses.
6. Click **Update & Apply to Device**.

Configure primary and backup controller (CLI)

Use this procedure to configure the primary and backup controllers for a selected AP using commands.

Set up failover by designating primary and backup controllers on an AP to ensure continuous operation if the primary controller becomes unavailable using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

3. Configure AP CAPWAP parameters with the primary backup controller's name.

   Example

   ```
   Device(config)# capwap backup primary primary-controller-name
   primary-controller-ip
   ```

> **Note**
>
> Enable fast heartbeat so that **capwap backup primary** and **capwap backup secondary** work.
>
> The AP may disconnect if the link between the controller and the AP is unreliable and fast heartbeat is enabled.

4. Configure AP CAPWAP parameters with the secondary backup controller's name.

   Example

   ```
   Device(config)# capwap backup secondary secondary-controller-name
   secondary-controller-ip
   ```

5. Configure the system logging settings for the APs.

   Example

   ```
   Device(config)# syslog host ip-address
   ```

6. Initiate AP image downgrade from a TFTP server for all the APs.

   Example

   ```
   Device(config)# tftp-downgrade tftp-server-ip imagename
   ```

Verify IPv6 configuration

This section lists the commands and interface summaries used to verify IPv6 configuration on wireless devices.

Use these **show** command to verify the IPv6 configuration:

```
Device# show wireless interface summary
Wireless Interface Summary
Interface Name Interface Type VLAN ID IP Address     IP Netmask    MAC Address
-------------------------------------------------------------------------------
Vlan49         Management     49      0.0.0.0       255.255.255.0
001e.f64c.1eff
                                      fd09:9:2:49::54/64
```

181 IPv6 ACL

Topics:

- IPv6 ACL
- Configure IPv6 ACLs
- Verify IPv6 ACL

This chapter explains how to configure, apply, and verify IPv6 access control lists on Cisco devices, detailing ACL types, CLI/GUI procedures, interface application, RA/ND protections, and troubleshooting commands.

IPv6 ACL

Introduces IPv6 access control lists (ACLs), describing their purpose, configuration, and how they compare to IPv4 ACLs in managing network access and data traffic.

An access control list (ACL) is a set of rules used to control or restrict access to a network interface that

- are configured on the device and can be applied to various interfaces such as the management interface, AP-manager interface, dynamic interfaces, or on WLANs, and
- regulate data traffic to and from wireless clients or to protect the controller's central processing unit (CPU).

You can also create a preauthentication ACL for web authentication. Such an ACL is used to allow certain types of traffic before authentication is complete.

IPv6 ACLs support the same options as IPv4 ACLs including source, destination, source and destination ports.

> **Note**
>
> To enable only IPv4 traffic in your network, block all IPv6 traffic. Configure an IPv6 ACL to deny all IPv6 traffic, and apply it to specific WLANs or to all WLANs.

Understand IPv6 ACLs

Understanding IPv6 ACLs.

Types of ACL

Types of ACL.

Per user IPv6 ACL

Per user IPv6 ACL.

- For the per-user ACL, the complete access control entries (ACEs) are configured as text strings on the RADIUS server.
- The ACCESS-Accept attribute contains the ACE, which is then sent to the device and applied directly to the client. When a wireless client roams to a foreign device, the foreign device receives the ACEs as an AAA attribute in the mobility handoff message. Output direction using per-user ACL is not supported.

Filter ID IPv6 ACL

Filter ID IPv6 ACL.

- For the filter-Id ACL, the complete ACEs and the ACL name `filter-id` are configured on the Cisco 9800 controller. Only the filter-id is configured on the RADIUS server.
- The `filter-id` is sent to the device in the ACCESS-Accept attribute. The device looks up the `filter-id` to find the ACEs, and then applies the ACEs to the client. When the client roams at Layer 2 to the foreign device, only the filter-id is sent to the foreign device in the mobility handoff message. Using output filtered ACLs with per-user ACLs is not supported.

Prerequisites for configuring IPv6 ACL

Prerequisites for configuring IPv6 ACL.

- To filter IP Version 6 (IPv6) traffic, create IPv6 access control lists (ACLs) and apply them to interfaces, using the same process as for IP Version 4 (IPv4) named ACLs.
- You can also create and apply input router ACLs to filter Layer 3 management traffic when the switch is running the Network Essentials license.

Restrictions for configuring IPv6 ACL

Restrictions for configuring IPv6 ACL.

With IPv4, you can configure standard and extended numbered IP ACLs, named IP ACLs, and MAC ACLs. IPv6 supports only named ACLs. The IPv6 ACL does not support FlexConnect mode.
The device supports most of the Cisco IOS-supported IPv6 ACLs, with some exceptions:

- The controller does not support routing, and only inbound ACLs are supported for wireless clients.
- The device does not support matching on these keywords: flowlabel, routing header, and undetermined-transport.
- The device does not support reflexive ACLs (the reflect keyword).
- The device does not apply MAC-based ACLs on IPv6 frames.
- There is no restriction on the keywords entered in the ACL, even if they are not supported on the platform. When you apply the ACL to an interface that requires hardware forwarding (physical ports or SVIs), the device checks if the ACL is supported on the interface. If not, attaching the ACL is rejected.
- If not, the device rejects attaching the ACL. If an ACL is already applied to an interface and you attempt to add an access control entry (ACE) with an unsupported keyword, the device does not allow the ACE to be added to the ACL currently attached to the interface.

Configure IPv6 ACLs

Use this task to filter IPv6 traffic by configuring and applying IPv6 access control lists (ACLs) to router interfaces.

Block or permit IPv6 traffic based on policies using ACLs.

To filter IPv6 traffic, perform these steps:

Before you begin

Procedure

1. Create an IPv6 ACL, and enter the IPv6 access list configuration mode.
2. Configure the IPv6 ACL to block (deny) or pass (permit) traffic.
3. Apply the IPv6 ACL to the interface where traffic will be filtered.
4. For router ACLs, assign an IPv6 address to the Layer 3 interface where the ACL is applied.

Default IPv6 ACL configuration

This topic provides the default configuration settings for IPv6 access control lists (ACLs).

There are no IPv6 ACLs configured or applied.

Interact with other features and switches

This topic provides details on how access control lists (ACLs) interact with other features and switch hardware, including supported protocols, error conditions, and software fallback behaviors.

Access control lists (ACLs) on switches interact with other features and platform behaviors in these ways:

- If a port ACL is configured to drop a bridged frame, the frame is not bridged.
- You can create IPv4 and IPv6 ACLs, and apply both to the same interface.
- Each ACL must have a unique name; if not, you receive an error message.
- Different commands are required to create and attach IPv4 and IPv6 ACLs. Using the incorrect command results in an error.
- MAC ACLs cannot filter IPv6 frames; MAC ACLs are for non-IP frames.
- When hardware memory or TCAM is full, additional ACLs are processed in software by the CPU. A console message indicates the ACL has been unloaded and packets will be handled in software.
- Only packets matching the ACL type (IPv4, IPv6, or MAC) that could not be added will be processed in software.
- If the TCAM is full, additional configured ACLs result in packets being forwarded to the CPU, and the ACLs are applied in software.

Create an IPv6 ACL (GUI)

Configure a new IPv6 access control list (ACL) using the GUI for secure network traffic filtering.

Define and apply an IPv6 ACL to control permitted or denied network traffic based on source, destination, protocol, and other parameters using the GUI.

Procedure

1. Choose **Configuration** > **Security** > **ACL**.
2. Click **Add**.
3. In the **Add ACL Setup** dialog box, enter these parameters.
   - ACL Name: Enter the name for the ACL
   - ACL Type: IPv6
   - Sequence: The valid range is between 100 and 199 or 2000 and 26991.
   - Action: Select **Permit** or **Deny** the packet flow from the drop-down list.
   - Source Type: Choose **any**, **Host** or **Network** from which the packet is sent.
   - Destination Type: Choose **any**, **Host** or **Network** to which the packet is sent.
   - Protocol: Select a protocol from the drop-down list.
   - Log: Enable or disable logging.
   - DSCP: Enter to match packets with the DSCP value.
4. Click **Add**.
5. Add the rest of the rules and click **Apply to Device**.

Create an IPv6 ACL (CLI)

Configure an IPv6 Access Control List (ACL) in Cisco IOS using commands to filter IPv6 traffic by protocol, address, port, and conditions.

Define rules to permit or deny IPv6 packets based on specific criteria, enhancing network security and control using commands.

Procedure

1. Enable the privileged EXEC mode and enter the global configuration mode.

   Example

   ```
   Device# enable
   ```

   ```
   Device# configure terminal
   ```

   Enter your password if prompted.

2. Use a name to define an IPv6 access list and enter the IPv6 access-list configuration mode.

   Example

   ```
   Device# ipv6 access-list acl_name
   ```

3. Enter deny or permit to specify whether to deny or permit the packet if conditions are matched.

   Example

   ```
   {deny | permit} protocol {source-ipv6-prefix/prefix-length | any | host
   source-ipv6-address}
   [operator [port-number]]{destination-ipv6-prefix/prefix-length | any |host
   destination-ipv6-address}
   [operator [port-number]][dscp value] [fragments][log] [log-input]
   [routing][sequence value]
   [time-range name]
   ```

   These are the conditions:

   - To set the protocol, enter the name or number of an Internet protocol (ahp, esp, icmp, ipv6, pcp, stcp, tcp, or udp), or enter an integer from 0 to 255 to represent an IPv6 protocol number.
   - Specify the source-ipv6-prefix/prefix-length or destination-ipv6-prefix/prefix-length as the source or destination IPv6 network or network class to set deny or permit conditions. Enter values in hexadecimal, using 16-bit segments separated by colons, as described in RFC 2373.
   - Enter any as an abbreviation for the IPv6 prefix ::/0.
   - For host source-ipv6-address or destination-ipv6-address, enter the specific IPv6 host address. Enter values in hexadecimal, using 16-bit segments separated by colons, to set deny or permit conditions.
   - Specify an operator to compare the source or destination ports of the protocol. Valid operators are lt (less than), gt (greater than), eq (equal), neq (not equal), and range.

   When the operator is placed after the source-ipv6-prefix/prefix-length argument, it matches the source port. When the operator is placed after the destination-ipv6-prefix/prefix-length argument, it matches the destination port.

- The port number can be a decimal value from 0 to 65535 or a TCP or UDP port name. Use TCP port names only for TCP filtering, and UDP port names only for UDP filtering.
- Enter a DSCP value to match a differentiated services code point against the traffic class value in each IPv6 packet header. The valid range is 0 to 63.
- To check noninitial fragments, enter the keyword fragments. This option is available only when the protocol is IPv6.
- To send a log message to the console for matching packets, enter log. To include the input interface in the log entry, enter log-input. Logging is supported only for router ACLs.
- Enter routing to enable IPv6 packet routing.
- Enter a sequence value to assign a sequence number to the access list statement. Valid values range from 1 to 4,294,967,295.
- Enter a time-range name to apply a specific time range to the deny or permit statement.

4. Define a TCP access list and the access conditions.

Example

```
{deny | permit} tcp {source-ipv6-prefix/prefix-length | any |
hostsource-ipv6-address}
[operator [port-number]]{destination-ipv6-prefix/prefix-length | any
|hostdestination-ipv6-address}
[operator [port-number]][ack] [dscp value][established] [fin]
[log][log-input] [neq {port |protocol}] [psh] [range{port | protocol}]
[rst][routing] [sequence value]
[syn] [time-range name][urg]
```

Enter tcp for Transmission Control Protocol. The parameters are the same as those described in Step 3, with these additional optional parameters:

- ack: Acknowledgment bit set.
- established: An established connection. A match occurs if the TCP datagram has the ACK or RST bits set.
- fin: Finished bit set; no more data from sender.
- neq {port | protocol}: Matches only packets that are not on a given port number.
- psh: Push function bit set.
- range {port | protocol}: Matches only packets in the port number range.
- rst: Reset bit set.
- syn: Synchronize bit set.
- urg: Urgent pointer bit set.

5. Define a UDP access list and the access conditions.

Example

```
{deny | permit} udp {source-ipv6-prefix/prefix-length | any |
hostsource-ipv6-address}
[operator [port-number]]{destination-ipv6-prefix/prefix-length | any |
hostdestination-ipv6-address}
[operator [port-number]][dscp value] [log][log-input]
```

```
[neq {port |protocol}] [range {port |protocol}] [routing][sequence
value][time-range name]
```

Enter udp for the User Datagram Protocol. The UDP parameters are similar to those for TCP. However, the operator [port] must specify a UDP port number or name, and the established parameter cannot be used with UDP.

6. Define an ICMP access list and the access conditions.

   Example

   ```
   {deny | permit} icmp {source-ipv6-prefix/prefix-length | any |
   hostsource-ipv6-address}
   [operator [port-number]] {destination-ipv6-prefix/prefix-length | any |
   hostdestination-ipv6-address}
   [operator [port-number]][icmp-type [icmp-code] |icmp-message] [dscpvalue]
   [log] [log-input]
   [routing] [sequence value][time-range name]
   ```

   Enter icmp for Internet Control Message Protocol. The ICMP parameters are the same as those for most IP protocols in Step 3a. However, ICMP includes additional parameters for message type and code. These optional keywords have these meanings:

   - icmp-type: Enter to filter by ICMP message type, a number from 0 to 255.
   - icmp-code: Enter to filter ICMP packets by the ICMP message code type, a number from 0 to 255.
   - icmp-message: Enter to filter ICMP packets by the ICMP message type name or the ICMP message type and code name. To view a list of ICMP message type names and code names, use the ? key or consult the command reference for this release.

7. Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

8. Verify the access list configuration.

   Example

   ```
   show ipv6 access-list
   ```

9. Optional: Save your entries in the configuration file.

   Example

   ```
   copy running-config startup-config
   ```

Create WLAN IPv6 ACL (GUI)

Create a WLAN IPv6 Access Control List (ACL) using the GUI to apply IPv6 traffic controls to a wireless LAN.

Create a WLAN IPv6 Access Control List (ACL) using the GUI to apply IPv6 traffic controls to a wireless LAN.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name** , the **SSID** and the **WLAN ID**.
4. Choose **Security** > **Layer3** tab. Click **Show Advanced Settings**. Under the **Preauthenticated ACL** settings, select the ACL from the **IPv6** drop-down list.
5. Click **Apply to Device**.

Create WLAN IPv6 ACL (CLI)

Configure IPv6 ACLs on a WLAN using commands to secure and control network traffic.

Create and apply a WLAN IPv6 Access Control List (ACL) to define traffic rules and enforce security for wireless clients using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create policy profile for the WLAN.

   Example

   ```
   Device(config)# wireless profile policy profile-name
   ```

   The *profile-name* is the profile name of the policy profile.

3. Create a named WLAN ACL.

   Example

   ```
   Device(config-wireless-policy)# ipv6 acl acl_name
   ```

4. Create a pre-authentication ACL for web authentication.

   Example

   ```
   Device(config-wlan)# ipv6 traffic-filter web acl_name-preauth
   ```

Verify IPv6 ACL

Verify IPv6 ACL.

Display IPv6 ACLs (CLI)

Learn how to use commands to view IPv6 access control lists configured on a network device.

View all IPv6 access lists or a specific access list by name for verification and troubleshooting using commands.

Procedure

1. Enable the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Display all access lists configured on the device

   Example

   ```
   Device# show access-lists
   ```

4. Display all configured IPv6 access list or the access list specified by name.

   Example

   ```
   Device# show ipv6 access-list acl_name
   ```

Example: Create an IPv6 ACL

Example for creating an IPv6 ACL.

This example configures the IPv6 access list named CISCO. The first deny entry denies all packets with a destination TCP port number greater than 5000. The second deny entry denies packets with a source UDP port number less than 5000. The second deny entry also logs all matches to the console. The first permit entry permits all ICMP packets. The second permit entry permits all other traffic. The second permit entry is necessary because each IPv6 access list ends with an implicit deny all condition.

> **Note**
>
> Logging is supported only on Layer 3 interfaces.

```
Device(config)# ipv6 access-list CISCO
```

```
Device(config-ipv6-acl)# deny tcp any any gt 5000
Device(config-ipv6-acl)# deny ::/0 lt 5000 ::/0 log
Device(config-ipv6-acl)# permit icmp any any
Device(config-ipv6-acl)# permit any any
```

Example: Apply an IPv6 ACL to a policy profile in a wireless environment

This topic explains the examples for applying an IPv6 ACL to a policy profile.

These example shows how to apply an IPv6 ACL to a policy profile in a wireless environment.

> **Note**
>
> All IPv6 ACLs must be associated to a policy profile.

1. Create an IPv6 ACL.

```
Device
                              (config)# ipv6 access-list <acl-name>

Device
                              (config-ipv6-acl)# permit tcp 2001:DB8::/32 any

Device
                              (config-ipv6-acl)# permit udp 2001:DB8::/32 any
```

2. Apply the IPv6 ACL to a policy profile.

```
Device
                               (config)# wireless profile policy
<policy-profile-name>
Device
                              (config-wireless-policy)# shutdown

Device
                              (config-wireless-policy)# ipv6 acl <acl-name>

Device
                          (config-wireless-policy)# no shutdown
```

Display IPv6 ACLs (CLI)

This topic shows you how to display all configured IPv6 access control lists (ACLs) or a specific ACL by using commands on your device.

This topic shows you how to display all configured IPv6 access control lists (ACLs) or a specific ACL by using commands on your device.

To display IPv6 ACLs, perform this procedure:

Procedure

1. Display all access lists configured on the device.

   Example

   ```
   Device# show access-lists
   ```

2. Display all configured IPv6 access list or the access list specified by name.

   Example

   ```
   Device# show ipv6 access-list acl_name
   ```

Example: Display IPv6 ACLs

Example for displaying IPv6 ACLs.

This is an example of the output from the **show access-lists** privileged EXEC command. The output shows all access lists that are configured on the switch or switch stack .

```
Device# show access-lists
Extended IP access list hello
10 permit ip any any
IPv6 access list ipv6
permit ipv6 any any sequence 10
```

This is an example of the output from the **show ipv6 access-lists** privileged EXEC command. The output shows only IPv6 access lists configured on the switch or switch stack.

```
Device# show ipv6 access-list
IPv6 access list inbound
permit tcp any any eq bgp (8 matches) sequence 10
permit tcp any any eq telnet (15 matches) sequence 20
permit udp any any sequence 30
IPv6 access list outbound
deny udp any any sequence 10
deny tcp any any eq telnet sequence 20
```

Example: Configure RA throttling

This task describes how to create and apply an RA throttle policy using the controller.

Configure router advertisement (RA) throttling and neighbor solicitation (NS) suppression to prevent power-saving wireless clients from being disturbed by frequent unsolicited RA messages using commands.

This task describes how to create an RA throttle policy in order to help the power-saving wireless clients from being disturbed by frequent unsolicited periodic RA's. The unsolicited multicast RA is throttled by the controller .

Before you begin

Enable IPv6 on the client machine.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a RA throttler policy called Mythrottle.

   Example

   ```
   Device(config)# ipv6 nd ra-throttler policy Mythrottle
   ```

3. Determine the time interval segment during which throttling applies.

   Example

   ```
   Device(config-nd-ra-throttle)# throttle-period 20
   ```

4. Determine how many initial RA's are allowed.

   Example

   ```
   Device(config-nd-ra-throttle)# max-through 5
   ```

5. Determine how many RA's are allowed after the initial RAs have been transmitted, until the end of the interval segment.

   Example

   ```
   Device(config-nd-ra-throttle)# allow at-least 3 at-most 5
   ```

6. Create a per VLAN configuration.

   Example

   ```
   Device(config)# vlan configuration 100
   ```

7. Enable the router advertisement throttling.

   Example

   ```
   Device(config)# ipv6 nd ra-throttle attach-policy attach-policy_name
   ```

8. Return to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

182 Configuring IPv6 Mobility

Topics:

- IPv6 client mobility

IPv6 client mobility

Explains how IPv6 client mobility enables seamless Layer 2 and Layer 3 roaming for IPv6-only and dual-stack wireless nodes, providing consistent connectivity and correct IP address management.

A client mobility is a wireless network feature that

- supports seamless Layer 2 and Layer 3 roaming for IPv6-only and dual-stack clients
- manages IPv6 client addresses and Neighbor Discovery (NDP) packet handling across controllers, and
- retains the client's IP address and application connectivity as they move between access points and switches in the mobility group.

Link layer mobility is not sufficient for wireless client Layer 3 applications to work seamlessly while roaming. Cisco IOSd's wireless mobility module uses mobility tunneling to retain seamless connectivity for the client's Layer 3 PoP (point of presence) when the client roams across different subnets on different switches.

IPv6 is the next-generation network layer Internet protocol intended to replace IPv4 in the TCP/IP suite of protocols. This new version increases the global internet address space to accommodate users and applications that require unique global IP addresses. IPv6 incorporates 128-bit source and destination addresses, which provide significantly more addresses than the 32-bit IPv4 addresses.

To support IPv6 clients across controllers, ICMPv6 messages must be handled in a specific way to ensure the IPv6 client remains on the same Layer 3 network. The device keeps track of IPv6 clients by intercepting ICMPv6 messages to provide seamless mobility and protect the network from network attacks. Neighbor Discovery Protocol (NDP) packets are converted from multicast to unicast and delivered individually to each client. This unique solution ensures that Neighbor Discovery and Router Advertisement packets are not leaked across VLANs. Clients receive specific Neighbor Discovery and Router Advertisement packets, ensuring correct IPv6 addressing and avoiding unnecessary multicast traffic.

The configuration for IPv6 mobility is the same as for IPv4 mobility and does not require separate software on the client side to achieve seamless roaming. The device must be part of the same mobility group. Both IPv4 and IPv6 client mobility are enabled by default.

IPv6 client mobility provides these features:

- Retains multiple client IPv6 addresses during Layer-2 and Layer-3 roaming.
- Manages IPv6 Neighbor Discovery Protocol (NDP) packets.
- Learns client IPv6 addresses.

> **Note**
>
> The configuration for IPv6 mobility in SDA wireless and Local mode is the same as for IPv4 mobility and does not require different software configuration on the client side to achieve seamless roaming. Refer to the IPv4 mobility section for configuration information.

> **Note**
>
> f an IPv6 address is configured on the SVI, configure the **ipv6 nd ra suppress all** command on all client VLAN SVI interfaces on the controller. This prevents multiple devices from advertising themselves as routers.

Using router advertisement

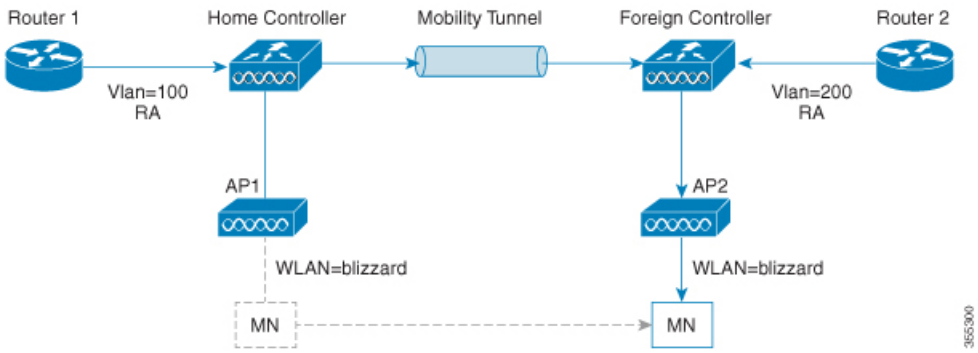
This topic describes how Router Advertisement (RA) messages in the IPv6 Neighbor Discovery Protocol (NDP) enable wireless client mobility and IPv6 address acquisition in converged access network environments.

The Neighbor Discovery Protocol (NDP) is a protocol that

- operates at the link layer and manages the discovery of other nodes on the network link
- determination of their link-layer addresses, identification of available routers, and
- the maintenance of reachability information for neighboring nodes.

A Router Advertisement (RA) is an IPv6 Neighbor Discovery Protocol (NDP) message

- sent by routers to communicate network parameters such as available routers
- network prefixes for IPv6 address configuration, and
- link MTU information to hosts on the link.



RAs play a vital role in this process by allowing hosts to detect routers, generate IPv6 addresses, and configure other connection parameters.

Routers send RAs either on a regular basis or in response to Router Solicitation messages from hosts.

IPv6 wireless client mobility manages the IPv6 RA packet. The device forwards the link-local all-nodes multicast RA packets to both local and roaming wireless nodes mapped on the same VLAN where the RA was received.

Figure 1 illustrates how a roaming client “MN” receives RA from VLAN 200 in a foreign controller and how it acquires an new IP address and breaks into L3 mobility's point of presence.

Figure 33: Roaming Client Receives Valid RA from Router 1

Router advertisement throttling

This topic explains how router advertisement throttling limits the frequency of RA packets and maintains IPv6 connectivity for clients.

A router advertisement throttle is a network control mechanism that

- enforces limits on the frequency of router advertisement (RA) packets sent toward the wireless network
- ensures routers that send multiple RA packets are restricted to a minimum frequency required for IPv6 client connectivity, and
- maintains uninterrupted IPv6 connectivity for new or roaming clients by allowing RA packets in response to Router Solicitation (RS) packets.

If a client sends an RS packet, the router sends an RA back to the client. The controller allows this RA to pass and delivers it as a unicast message to the client. This process ensures that new or roaming clients are not affected by RA throttling.

IPv6 address learning

This topic explains how IPv6 clients obtain their addresses and how network devices detect and record these address assignments.

IPv6 address learning is the process

- by which IPv6 clients acquire IP addresses, and
- network devices such as switches or controllers, observe and record these assignments.

There are three ways for an IPv6 client to acquire IPv6 addresses:

- Stateless Address Auto-Configuration (SLAAC)
- Stateful DHCPv6
- Static configuration

For these methods, the IPv6 client always sends NS DAD (duplicate address detection) to ensure that there is no duplicated IP address on the network. The device snoops the client's NDP and DHCPv6 packets to learn about the client's IP addresses. It then updates the controller's database. The database then informs the controller about the client's new IP address.

Handling multiple IP addresses

This concept explains how IP addresses are managed for network clients, including their assignment, update, and provisioning to external systems.

An IP address is a network identifier that

- uniquely distinguishes a device on a network
- supports both IPv4 and IPv6 formats, and
- can be dynamically assigned, updated, or displayed for client devices.

If a new IP address is received after the RUN state, whether it is an addition or removal, the controller updates its local database with the new IP addresses for display purposes. IPv6 uses the same PEM state machine code flow as IPv4. When external entities, such as Prime Infrastructure, request IP addresses, the controller includes all available IPv4 and IPv6 addresses in the API or SPI interface response.

An IPv6 client can acquire multiple IP addresses from the stack for different purposes. For example, a client may have a link-local address for local traffic and a routable unique local or global address.

When the client is in the DHCP request state and the controller receives the first IP address notification from the database, for either an IPv4 or IPv6 address, the PEM moves the client into the RUN state.

If a new IP address is received after the RUN state, whether it is an addition or removal, the controller updates its local database with the new IP addresses for display purposes.

When external entities, such as Prime Infrastructure, request IP addresses, the controller provides all available IPv4 and IPv6 addresses.

IPv6 configuration

This topic explains the key attributes of IPv6 configurations in a switch controller device, including client support, VLAN setup, and packet handling

A IPv6 configuration is a network setup that

- enables seamless support for IPv6 clients alongside IPv4 clients
- requires manual VLAN configuration by the administrator to activate IPv6 features, and
- implements snooping and throttling functionality to manage NDP packets between the switch controller device and its clients.

Prerequisites for IPv6 client mobility

This topic explains the prerequisites for IPv6 client mobility.

Wireless IPv6 client mobility requires the wired and wireless network infrastructure to support IPv6 routing, suitable address assignment mechanisms, and compatible device configurations.

- To enable wireless IPv6 client connectivity, the underlying wired network must support IPv6 routing and an address assignment mechanism, such as SLAAC or DHCPv6. The device must have Layer 2 adjacency to the IPv6 router. The VLAN should be tagged when packets enter the device. APs do not require connectivity on an IPv6 network because all traffic is encapsulated inside the IPv4 CAPWAP tunnel between the AP and the device.
- Ensure that all clients support IPv6 address assignment using either stateless autoconfiguration, such as Windows XP clients, or stateful DHCPv6 IP addressing, such as Windows 7 clients.

  Verify that your network switch or router supports the DHCP for IPv6 feature and is configured as a DHCPv6 server, such as a Cisco Catalyst 3850 or 5700 switch. Alternatively, use a dedicated server, such as a Windows 2008 server with a built-in DHCPv6 server.

Monitor IPv6 client mobility

This section provides a list of commands used to monitor IPv6 client mobility on the device, including their functions and descriptions.

- This table lists the commands available for monitoring IPv6 client mobility and their corresponding descriptions:

Commands	Description
show wireless client summary	Displays the wireless specific configuration of active clients.
show wireless client mac-address	Displays the wireless specific configuration of active clients based on their MAC address.

183 IPv6 Support on Flex and Mesh

Topics:

- IPv6 support on FlexConnect + mesh deployment

This chapter shows how to enable and configure IPv6 for FlexConnect with mesh on Cisco wireless controllers, covering CLI and GUI steps to set IPv6 addresses, AP preferred-mode, PIM dense-mode, and verification.

IPv6 support on FlexConnect + mesh deployment

Explains IPv6 support and traffic handling when using FlexConnect and mesh deployments with Cisco Catalyst Wireless Controllers.

A FlexConnect and mesh deployment is a wireless network configuration that

- enables IPv6 as the primary backhaul transport for service provider
- supports IPv6 clients connecting via WLANs on the Cisco Catalyst 9800 series wireless controller and Cisco Embedded Wireless controller on Catalyst APs, and
- forwards IPv6 client traffic efficiently to the network core.

Configure IPv6 support for FlexConnect + Mesh (CLI)

This topic enables IPv6 routing and multicast features on controller-based FlexConnect and Mesh interfaces by guiding you through the required commands.

Follow these steps to enable IPv6 routing and multicast features for FlexConnect and Mesh on a controller using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create an interface and enter the interface configuration mode.

   Example

   ```
   Device(config)#interface vlan vlan-interface-number
   ```

3. Disable the interface configuration.

   Example

   ```
   Device(config-if)#shutdown
   ```

4. Optional: Enable IPv6 on the interface.

   Example

   ```
   Device(config-if)#ipv6 enable
   ```

5. Configure IPv6 address on the interface using the IPv6 prefix option.

   Example

   ```
   Device(config-if)#ipv6 address X:X:X:X::X/<0-128>
   ```

6. Enable the IPv6 address.

   Example

   ```
   Device(config-if)#no shutdown
   ```

7. Enable the PIM dense-mode operation.

   Example

   ```
   Device(config-if)#no shutdown
   ```

8. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-if)#end
   ```

9. Verify your entries and check the gateway connectivity.

   Example

   ```
   Device# show ipv6 interface brief
   ```

   ```
   Device# ping ipv6 destination-address or hostname
   ```

Configure preferred IP address as IPv6 (GUI)

Configure your AP join profile to use IPv6 as the preferred IP address mode in Cisco Wireless Controller GUI.

Set the preferred IP address mode to IPv6 for APs joining the controller using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. Click the AP Join Profile Name. The **Edit AP Join Profile** window is displayed.
3. Choose **CAPWAP** > **Advanced**.
4. Select **IPV6** from the **Preferred Mode** drop-down list.
5. Click **Update & Apply to Device**.

Configure preferred IP address as IPv6 (CLI)

Configure an AP profile so that the preferred IP address is set to IPv6 on a controller using commands.

Set the AP to use IPv6 as its preferred IP address when joining the controller using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile default-ap-profile
   ```

3. Use IPv6 to join the controller .

   Example

   ```
   Device(config-ap-profile)# preferred-mode ipv6
   ```

4. Exit the configuration mode and return to the privileged EXEC mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

Verify IPv6 on FlexConnect + Mesh

This topic provides commands and output examples for verifying IPv6 configuration and interface status on a controller embedded wireless controller operating with FlexConnect and Mesh.

To verify the IPv6 configuration on the controller , use this **show** command:

```
Device# show ip interface brief
Interface              IP-Address      OK? Method Status                Protocol
GigabitEthernet2       unassigned      YES unset  up                    up

GigabitEthernet0       unassigned      YES NVRAM  administratively down down

Capwap1                unassigned      YES unset  up                    up

184 IPv6 CAPWAP UDP Lite Support

Topics:

- UDP Lite

This chapter describes how to enable and verify UDP Lite for IPv6 CAPWAP on controllers and APs using commands, explains firewall considerations, and notes limitations such as lack of support for mobility IPv6 tunnels.

UDP Lite

Describes UDP Lite support, its purpose in IPv6 environments for controllers and APs, and important operational impacts and restrictions.

UDP Lite Support is an enhancement to the IPv6 functionality on controllers and APs

- that enables support for the UDP Lite protocol, and
- minimizes performance impact by restricting the checksum calculation coverage for the UDP Lite header to 8 bytes rather than requiring a complete payload checksum as standard UDP over IPv6 does.

This feature applies only to the IPv6 addresses of the controller and APs. IPv6 mandates a complete payload checksum for UDP.

Intermediate firewalls must allow UDP Lite protocol (protocol ID 136) packets when using the UDP Lite Support feature. Some firewalls might not provide the option to open specific ports on UDP Lite protocol. In these cases, the administrator must open all ports on UDP Lite.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 162: Feature history for IPv6 CAPWAP UDP Lite support

Feature Name	Release Information	Feature Description
IPv6 CAPWAP UDP Lite support	Cisco IOS XE Cupertino 17.1.1s	From this release, the UDP Lite support feature is an enhancement to the existing IPv6 functionality to support the UDP Lite protocol.

Restrictions for UDP Lite support

- Mobility IPv6 tunnels do not support the UDP Lite support feature.

Enable UDP lite support (CLI)

Use this procedure to enable UDP Lite for IPv6 CAPWAP data packets on an AP profile using commands.

Enable UDP Lite, allowing APs to handle IPv6 CAPWAP data packets using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

Example

```
Device(config)# ap profile ap-profile
```

3. Enable IPv6 CAPWAP UDP lite on the AP.

Example

```
Device(config-ap-profile)# capwap udplite
```

> **Note**
>
> This message is displayed after the configuration:
>
> ```
> This feature is supported only for IPv6 data packets, APs will be rebooted.
> ```

4. Return to the privileged EXEC mode.

Example

```
Device(config-ap-profile)# end
```

Alternatively, you can also press *Ctrl-Z* to exit global configuration mode.

Verify UDP lite support configuration

This section lists the command and output used to verify UDP Lite support configuration on a device.

To verify the CAPWAP UDP Lite status, use this command:

```
Device# show ap profile name default-ap-profile detailed

CAPWAP UDP-Lite                 : ENABLED
Lawful-Interception             : ENABLED
LI timer                      : 60
AWIPS                           : DISABLED
AWIPS Forensic                  : Unknown
Client RSSI Statistics
Reporting                     : ENABLED
Reporting Interval            : 30 seconds
```

185 Neighbor Discovery Proxy

Topics:

- Neighbor discovery

This chapter explains configuring a controller's IPv6 neighbor discovery and duplicate address detection proxies in central switching mode, detailing behavior, use cases, and commands to enable full-proxy and DAD-proxy functions.

Neighbor discovery

Explains how the Neighbor Discovery Protocol enables IPv6 nodes to signal their presence on a network link and obtain information about nearby systems.

A neighbor discovery protocol (NDP) is a communication protocol that

- uses ICMPv6 messages to allow nodes within the same IPv6 network link to detect and signal their presence
- employs solicited-node multicast addresses to track and discover other IPv6 hosts connected to network interfaces, and
- facilitates address resolution and reachability checks between nodes using neighbor solicitation (NS) and neighbor advertisement (NA) messages.

Neighbor discovery proxy

This concept explains how neighbor discovery proxies operate in wireless controller environments to manage IPv6 neighbor solicitation messages and reduce multicast traffic to wireless clients.

A neighbor discovery proxy is a controller feature that

- intercepts IPv6 neighbor solicitation packets destined for wireless client
- responds on behalf of the clients to reduce unnecessary multicast traffic, and
- operates only in central switching mode for efficient network management.

If neighbor discovery proxy is not enabled, the multicast neighbor solicitation is converted into unicast neighbor solicitation with the MAC address of the target client and is forwarded to that client.

> **Note**
>
> A controller does not proxy the neighbor solicitation packet if the destination address is not that of a wireless client.

Configure neighbor discovery proxy (CLI)

This topic explains IPv6 neighbor discovery (ND) proxy functionality on a device using commands.

Follow these steps to configure the neighbor discovery proxy using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy policy policy-name
```

3. Enable ND proxy.

Example

```
Device(config-wireless-policy)# ipv6 nd proxy full-proxy
```

Duplicate address detection proxy

The IPv6 duplicate address detection (DAD) proxy feature ensures that IP addresses assigned to wireless devices are unique by intercepting and responding to DAD requests on their behalf.

IPv6 duplicate address detection (DAD) is a mechanism that is

- used to verify that an IPv6 address is unique on a network segment before it is assigned to a device
- acts on behalf of wireless clients to ensure no duplicate addresses are assigned, and
- the proxy responds to DAD neighbor solicitation (NS) messages, preventing address conflicts among wireless clients.

DAD verifies whether a host address is unique. The IPv6 DAD Proxy feature responds on behalf of the address owner when an address is in use.

However, in a scenario where nodes are restricted from talking to each other at Layer 2, DAD cannot detect a duplicate address. If the DAD proxy is disabled, the multicast packet is converted into a unicast packet and sent to the target client.

Note

- DAD proxy is applicable only in central switching mode.
- A controller does not proxy the DAD NS packet if the destination address is not that of a wireless client.

Configure duplicate address detection proxy (CLI)

Configure a duplicate address detection (DAD) proxy for IPv6 networks using commands.

Enable DAD proxy to prevent duplicate IPv6 address assignment by monitoring and responding to neighbor discovery requests using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a WLAN policy profile and enter the wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy policy-profile-name
```

3. Enable DAD proxy.

Example

```
Device(config-wireless-policy)# ipv6 nd proxy dad-proxy
```

> **Note**
>
> Full proxy configuration includes both ND proxy and DAD proxy configurations. To enable DAD proxy, use the **ipv6 nd proxy full-proxy** command.

186 Address Resolution Protocol Proxy

Topics:

- Address resolution protocol

This chapter explains how a wireless controller handles ARP requests for wireless clients, describing ARP proxy behavior, broadcast suppression, and command steps to enable ipv4 arp-proxy in a WLAN policy profile.

Address resolution protocol

Explains how the Address Resolution Protocol (ARP) maps IP network addresses to hardware addresses used by data link protocols.

An address resolution protocol is a network protocol that

- maps IP network addresses to hardware (MAC) addresses used by data link protocols
- enables devices in a local network to discover the physical address associated with an IP address, and
- facilitates communication by resolving addresses required for packet delivery on the network.

The Address Resolution Protocol (ARP) is used by the Internet Protocol (IP) [RFC826], specifically in IPv4 networks. When a wireless client sends an ARP request for an IP address of interest, the controller performs a search for that address in its database. If an entry is found in the controller database, then the ARP is converted to unicast and forwarded to that particular client. If there is no entry in the controller's database, the ARP request is flooded out to the VLAN wired ports.

Address resolution protocol proxy

This topic explains how proxy ARP enables a controller to respond to ARP requests for wireless clients, helping manage broadcast traffic and enhance network efficiency.

A proxy ARP operation is a wireless controller feature that

- responds to ARP request packets on destined for wireless clients
- minimizes broadcast traffic by limiting ARP requests to appropriate clients, and
- is applicable only in central switching mode for wireless client destinations.

ARP Proxy enables the controller to respond to ARP request packets destined for wireless clients. During broadcast suppression, the controller checks if proxy is enabled for the destined wireless clients. If proxy is enabled, the controller drops the ARP request packet and generates a response to the source so that the packet appears to come from the wireless client. This helps in limiting the traffic to the wireless clients.

If ARP Proxy is not enabled, the broadcast ARP request is converted into a unicast ARP request with the MAC address of the target client and forwarded only to that client.

> **Note**
>
> A device will not proxy the ARP request if the destination address does not belong to a wireless client.

Configure address resolution protocol proxy (CLI)

Learn how to configure the Address Resolution Protocol (ARP) proxy on a wireless policy profile using commands.

Enable ARP proxying for client devices on a WLAN by updating the relevant policy profile settings using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a WLAN policy profile and enter the wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy policy-profile-name
```

3. Enable ARP proxy.

Example

```
Device(config-wireless-policy)# ipv4 arp-proxy
```

187 IPv6 Ready Certification

Topics:

- IPv6 ready certification

This chapter describes the IPv6 RFC-compliance features added in Cisco IOS XE Bengaluru 17.6.1, packet fragmentation rules, neighbor discovery handling, MTU behavior, hop-by-hop processing, and route information option configuration and verification to enable secure, standards-based IPv6 deployment.

IPv6 ready certification

Explains the IPv6 features required for IPv6 Ready Certification compliance in Cisco IOS XE Bengaluru, 17.6.1.

A functionality is a network capability that

- enables compliance with the latest RFC specifications for IPv6
- supports key IPv6 packet and protocol operations, and
- ensures robust and secure IPv6 communication in modern network environments

Starting with Cisco IOS XE Bengaluru, 17.6.1, these IPv6 functionalities are implemented:

- **Fragment Processing and Reassembly (RFC8200)**: The first fragment must contain the mandatory extension header up to the first upper level protocol (ULP) header as specified in RFC 8200.
- **Handling Atomic Fragments in Neighbor Discovery (RFC6980)**: Fragmented neighbor discovery packets must be dropped.
- **Packet too Big (RFC8201)**: Atomic fragmentation is not supported. Packets that do not meet the IPv6 MTU requirement of 1280 bytes are dropped.
- **Route Information Options (RIO) in IPv6 Router Advertisements (RFC4191)**: A new RIO is added to the IPv6 Router Advertisement message to communicate specific routes from routers to hosts. Explicit route configuration ensures that only necessary routes are advertised.
- **IPv6 Hop-by-Hop Processing (RFC 8200)**: This enhancement allows explicit configuration of nodes along the delivery path for packets that require hop-by-hop options header processing.

Feature History for IPv6 ready certification

This table provides release and related information for the feature explained in this module.

This feature is available in all the releases subsequent to the one in which it is introduced in, unless noted otherwise.

Table 163: Feature History for IPv6 ready certification

Release	Feature	Feature Information
Cisco IOS XE Bengaluru 17.6.1	IPv6 ready certification	This feature is enhanced with the implementation of various IPv6 functionalities that are required to comply with the latest RFC specifications.

Configure IPv6 route information (CLI)

Configure the route information option (RIO) in IPv6 router advertisement messages so hosts can receive specific routes and select the optimal default router.

Ensure that IPv6 hosts, especially those on multihomed networks, receive required explicit routes to improve their ability to select the appropriate default router.

The Route Information Option (RIO) in the IPv6 router advertisement messages helps in communicating specific routes from routers to hosts. This improvement enables a host to select an appropriate default router when it is multihomed and the routers are on different links. Only necessary routes are advertised to the hosts because of the explicit route configuration.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the interface and enter the interface configuration mode.

   Example

   ```
   Device(config)# interface gigabitethernet1.1
   ```

3. Configure RIO in IPv6 router advertisement messages.

   Example

   ```
   Device(config-if)# ipv6 nd ra specific-route prefix/length lifetime
   lifetime/infinity [ preference preference]
   ```

   For more information, see the ipv6 nd ra specific route command.

Verify IPv6 route information

This section list the command you can use to view IPv6-specific routes in router advertisements and to examine hop-by-hop processing in an IPv6 node.

To identify the specific routes that are sent in the router advertisements, use this command:

```
Device# show ipv6 nd ra specific-route
IPv6 Prefix/Length Lifetime Preference Interface
---------------------------------------- -------- ---------- ---------
1234::12/127 1000 High GigabitEthernet2
```

- Persistent Device Avoidance
- Spectrum Intelligence
- Spectrum Analysis

188 Cisco CleanAir

Topics:

- Cisco CleanAir
- Configure CleanAir
- CleanAir Pro scanning
- Verify CleanAir parameters
- CleanAir FAQs

Cisco CleanAir

Introduces Cisco CleanAir technology, describing key terminology, system components, and comparisons with Wi-Fi chip-based RF management. Explains persistent device handling, spontaneous interference, device merging, EDRRM and AQR update modes, high availability, and important operational considerations.

A Cisco CleanAir system is a wireless spectrum management solution that

- identifies and monitors all users and interferers in the industrial, scientific, and medical (ISM) bands
- provides real-time radio frequency (RF) visibility and actionable interference information, and
- enables the network to automatically or manually respond to interference, improving wireless performance.

Table 164: Feature history for Cisco CleanAir

Release	Feature	Feature Information
Cisco IOS XE 17.13.1	EDRRM Support for 6 GHz Band Radio	The Event-Driven Radio Resource Management (EDRRM) is enabled in the 6 GHz band radio of AP.

Cisco CleanAir systems consist of CleanAir-enabled APs and a Cisco Catalyst 9800 Series Wireless Controller. The APs gather device information across the ISM bands, detect and evaluate interference sources, and forward this information to the controller. The controller manages the APs and displays detected interference devices.

For devices operating in the unlicensed band, Cisco CleanAir systems provide detailed information about device identity, interference impact, and recommended actions to mitigate issues. CleanAir simplifies RF management, allowing users to maintain optimal wireless performance without requiring deep RF expertise.

Components of Cisco CleanAir systems

Cisco CleanAir systems are comprised of several key hardware and software elements:

- **Cisco CleanAir-enabled APs**: These devices actively scan the wireless spectrum for all active transmitters.
- **Wireless controllers**: Cisco Catalyst 9800 Series Wireless Controller.
- **Management platforms**: Provides centralized management and visualization of spectrum and interference data forwarded by the controllers.

How Cisco CleanAir systems detect and respond to interference

1. **Always-On spectrum awareness**: Cisco CleanAir-enabled APs scan the industrial, scientific, and medical (ISM) bands, identifying and evaluating all radio devices that may cause interference.
2. **Unified control and interference intelligence**: The controller controls the access points and displays the interference devices.
3. **Actionable insight for every interferer**: For every device operating in the unlicensed band, Cisco CleanAir provides information about what it is, how it is impacting your wireless network, and what actions you or your network should take. It simplifies RF so that you do not have to be an RF expert.

Benefits of Cisco CleanAir systems

- **Simplifies spectrum management**: Provides visibility into interference without requiring advanced RF expertise.
- **Improves network reliability**: Automatically detects and resolves issues affecting Wi-Fi performance.

- **Supports advanced WLAN services**: Ensures quality for voice over wireless and IEEE 802.11 operations by minimizing RF interference.

Detecting and mitigating interference

In a busy office environment, multiple devices such as microwave ovens, cordless phones, and Bluetooth devices operate in the 2.4-GHz and 5-GHz ISM bands. These can disrupt Wi-Fi communication. Cisco CleanAir systems detect these interferers, identify their impact, and automatically adjust wireless channels or prompt users to take corrective action.

A basic wireless LAN without CleanAir functionality cannot detect, identify, or respond to environmental interference in real time, meaning performance issues can go unnoticed and unresolved.

Cisco CleanAir systems function like air quality sensors in a smart building—they continuously monitor the environment, detect harmful agents, and trigger responses to ensure optimal conditions for all users.

Cisco CleanAir-related terms

Cisco CleanAir-related terms.

Table 165: Cisco CleanAir-related terms

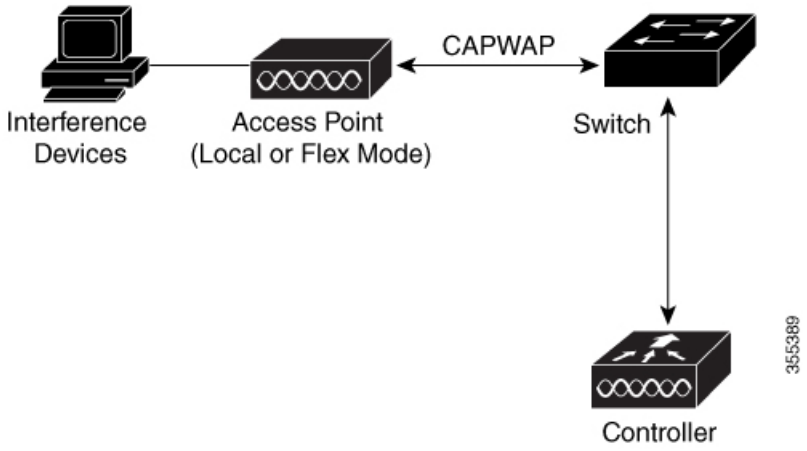
Term	Description
AQI	Air Quality Index. The AQI indicates air quality based on RF interference. An AQI of zero is considered poor, and an AQI greater than eighty-five is considered good.
AQR	Air Quality Report. An AQR shows total interference from all sources, including major categories. The system sends an AQR every 15 minutes and every 30 seconds in Rapid mode.
DC	Duty Cycle. Indicates the percentage of time your device uses the channel.
EDRRM	Event-Driven RRM. When needed, EDRRM enables your access point to skip normal RRM intervals and immediately change channels.
IDR	Interference Device Reports that an AP sends to the controller .
ISI	Interference Severity Index. The ISI is an indicator of the severity of the interference.
RSSI	Received Signal Strength Indicator. RSSI measures the power in a received signal. It indicates the level detected by an access point from an interfering device.

Cisco CleanAir components

This process shows how the main Cisco CleanAir components cooperate to monitor, analyze, and mitigate RF interference in wireless networks. It outlines each component's role and the sequence of operations in the CleanAir system.

Summary

Cisco CleanAir technology uses a coordinated set of hardware and software components to detect, report, and address wireless interference. Each part of the system contributes to maintaining optimal air quality and reliable wireless performance.



The key components involved in the process are:

- Cisco CleanAir-enabled AP: Collects information about Wi-Fi interference sources and processes it. The AP collects and sends the Air Quality Report (AQR) and Interference Device Report (IDR) to the controller .
- Controller: Controls and configures CleanAir-capable access points, collects and processes spectrum data, provides user interfaces (GUI and CLI), and detects, merges, and mitigates interference devices. The controller also detects, merges, and mitigates interference devices using RRM TPC and DCA For details, see Interference Device Merging.

CleanAir technology ensures wireless networks remain reliable by automatically detecting sources of interference and providing tools for administrators to analyze and respond to RF threats.

Workflow

Figure 34: Cisco CleanAir Solution

These stages describe the operation of Cisco CleanAir components in the system.

1. Configuration: Configures Cisco CleanAir capabilities on the APs.
2. Detection: Cisco CleanAir-enabled APs continuously scan the wireless environment for interference sources and assess air quality.
3. Reporting: APs generate reports such as Air Quality Reports (AQRs) and Interference Device Reports (IDRs), which summarize detected interference and air quality indexes.
4. Aggregation: Wireless controllers collect AQRs and IDRs from all APs, process the data, and store it in relevant databases.
5. Analysis and Response: Controllers use built-in mechanisms (like Radio Resource Management) to mitigate interference and maintain optimal RF conditions.
6. Advanced Services: Cisco Spaces or CMX tracks interference devices over time and location, merges data from multiple controllers, and provides comprehensive threat detection with adaptive Wireless Intrusion Prevention System (WIPS).
7. Specialized Troubleshooting (optional): For in-depth RF analysis, an administrator can connect a CleanAir-enabled AP directly to a PC running Cisco Spectrum Expert.

Result

The Cisco CleanAir system delivers end-to-end automated detection, analysis, and mitigation of wireless interference, enabling proactive network management and high-quality wireless performance.

Prerequisites for CleanAir

Details the prerequisites required for deploying Cisco CleanAir, outlining supported configurations and hardware, and specifies relevant operational restrictions for successful implementation.

You can configure Cisco CleanAir only on CleanAir-enabled access points.

Only Cisco CleanAir-enabled access points in these access point modes can perform Cisco CleanAir spectrum monitoring:

- **Local**: In this mode, each Cisco CleanAir-enabled access point radio provides air quality and interference detection reports for the current operating channel only. An AP measures air quality and interference only when it is not transmitting Wi-Fi frames. When channel utilization is high, CleanAir detects less interference.
- **FlexConnect**: When a FlexConnect access point is connected to the controller, its Cisco CleanAir functionality is identical to local mode.

- **Monitor**: When Cisco CleanAir is enabled in monitor mode, the access point provides air quality and interference detection reports for all monitored channels.
  - **All**: All channels
  - **DCA**: Channel selection governed by the DCA list
  - **Country**: All channels are legal within a regulatory domain

Restrictions for CleanAir

Restrictions for CleanAir.

Access points in monitor mode do not transmit Wi-Fi traffic or 802.11 packets. They are excluded from radio resource management (RRM) planning and are not included in the neighbor AP list. IDR clustering depends on the device 's ability to detect neighboring in-network APs. Correlating interference device detections from multiple APs is limited between monitor-mode APs.

CleanAir is not supported where the channel width is 160 MHz.

Difference between Spectrum Intelligence and Cisco CleanAir

Difference betwen

Feature	Spectrum Intelligence	Cisco CleanAir
Noise identification	Reports broad, often vague RF noise without pinpointing sources	Precisely identifies interference type, source, potential impact to a WLAN
Noise measurement method	Relies on long-term averaging, which smooths out important details and reduces resolution of measurements	Captures real-time events with full granularity
Response style	Primarily reacts after interference is noticed	Enables proactive, context-aware mitigation allowing for intelligent, proactive decisions.
Transient interference handling	Averaging measurements reduces resolution of measurements, and disruptive signals do not appear to need mitigation.	Flags brief, spontaneous interference events immediately

Cisco CleanAir access points can detect and report severity of the interference .

Spectrum event-driven RRM is one such mitigation strategy.

> **Note**
>
> Spectrum event-driven RRM can be triggered only by Cisco CleanAir-enabled access points in local mode.

Persistence interference

This section explains persistent device avoidance, a feature in Cisco CleanAir that ensures sustained interference mitigation from devices like microwave ovens.

A persistent device avoidance is a wireless interference mitigation feature that

- identifies and continuously tracks intermittent interference sources such as microwave ovens,
- maintains channel avoidance for affected APs even if the interference is not constantly present, and
- automatically updates Radio Resource Management (RRM) whenever the interfering device or related access points are moved.

For example, if a microwave oven operates in a break room only for a few minutes at a time, Cisco CleanAir identifies the microwave as an interference source, locates the affected portion of the band and APs most severely affected, and directs RRM to avoid those channels persistently. Even if the microwave is not active all day, the system maintains avoidance as long as the device is periodically detected. If you move either the microwave oven or the surrounding access points, the algorithm updates RRM automatically

Classes of persistent interference sources

Certain devices, once detected, are likely to remain in place and may cause ongoing interference. Cisco CleanAir can bias the affected channel in Radio Resource Management (RRM) so that CleanAir "remembers" the potential for interference. See Radio Resource Management White Paper.

These device classes qualify as persistent interference sources:

- Microwave ovens
- Outdoor Ethernet bridges
- WiMax fixed and mobile devices
- Motorola Canopy systems

Special case: Bluetooth devices

Bluetooth devices are detected and reported as interference only when actively transmitting. They often enter power-save modes, so interference may only be noticed during active streaming of data or voice.

Persistent devices detection

Persistent devices detection.

CleanAir-capable Monitor Mode AP collects information about persistent devices on all configured channels and store the information in controller . Local or Bridge mode AP detects interference devices on the serving channels only.

Persistent device avoidance

Persistent device avoidance.

When a Persistent Device (PD) is detected in the CleanAir module, it is reported to the RRM module on the MA. This information is used in the channel selection by the subsequent EDRRM Event Driven RRM (ED-RRM) signal sent to the RRM module.

Spontaneous interference

Spontaneous interference is interference that appears suddenly on a network and may jam one or more channels. With Cisco CleanAir spectrum, event-driven RRM, you can set a threshold for air quality, abbreviated as AQ. If air quality drops below this threshold, the system immediately changes the affected AP's channel. Although most RF management systems avoid interference, they require time for information to spread before channels update. Cisco CleanAir uses AQ measurements to continually check the spectrum and can switch channels within **30 seconds**.

For example, if your AP detects interference from a device such as a video camera, it switches channels within **30 seconds** after the interference begins. Cisco CleanAir also helps you identify and locate the interference source so you can take permanent steps to resolve the issue later.

EDRRM and AQR update mode

This section explains EDRRM and AQR update modes, which allow wireless APs to respond rapidly to interference by bypassing standard Radio Resource Management intervals..

An EDRRM and AQR update mode is a wireless network feature set that

- enables APs experiencing severe interference (“in distress”) to bypass normal RRM intervals and immediately change channels,
- requires CleanAir technology for monitoring and reporting classified interference devices, and
- provides fast action and remote configuration through control messages and local spectrum management.
- **EDRRM (Event Driven Radio Resource Management):** A function that allows an AP to react instantly to excessive interference by changing channels immediately instead of waiting for scheduled RRM intervals.
- **AQR (Air Quality Reporting) update mode**: A process by which CleanAir APs monitor air quality and report classified interference devices every 15 minutes; when interference causes substantial air quality degradation, EDRRM is triggered.

If a classified interference device severely degrades the air quality on an active channel, EDRRM triggers an immediate channel change so that no clients are stranded on an unusable channel.

Think of a city’s scheduled traffic lights as the normal RRM intervals, allowing cars (data) to move in an orderly, timed way. Normally, everyone waits for the green light, moving only at the set intervals. EDRRM is like having an emergency override for ambulances (APs in distress): if there’s a medical emergency (severe interference), the control center can change the lights to green immediately—regardless of the normal schedule—so the ambulance can take an alternate, clear route (new channel). Air Quality Reporting (AQR) acts like real-time traffic cameras detecting and reporting sudden blockages (classified interference devices) so that the emergency override can be triggered if road conditions (channel quality) deteriorate unexpectedly.

Restrictions for EDRRM and AQR update mode

- EDRRM is not enabled by default; you must first enable CleanAir and then enable EDRRM.
- If an interfering device is operating on an active channel and causes enough AQ degradation to trigger an EDRRM, then no clients will be able to use that channel or the AP. You must remove the AP from the channel.

Configure CleanAir

Explains step-by-step procedures to enable and configure CleanAir on 2.4-GHz and 5-GHz bands using both GUI and CLI, set up air quality alarms, configure interference reporting, EDRRM, Persistent Device Avoidance, and manage CleanAir on controllers and access points.

Enable CleanAir for the 2.4-GHz band (GUI)

Learn how to activate CleanAir spectrum intelligence for 2.4-GHz radios using the web interface to monitor and mitigate wireless interference.

Enable CleanAir on 2.4-GHz band radios for real-time interference detection.

Use this procedure to activate Cisco CleanAir technology on APs operating in the 2.4-GHz spectrum using the GUI.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **CleanAir**.

2. On the **CleanAir** window, click the **2.4 GHz Band** > **General** tab.
3. Check the **Enable CleanAir** checkbox.
4. Click **Apply**.

CleanAir is enabled on all selected 2.4-GHz radios, and spectrum analysis begins for those devices.

Enable CleanAir for the 2.4-GHz band (CLI)

This topic provides step-by-step procedure to configure CleanAir on the controller using commands.

Enable CleanAir technology on APs operating in the 2.4-GHz band radios for real-time interference detection using commands.

Procedure

Enable the CleanAir feature on the 802.11b network.

Example

```
Device(config)#ap dot11 24ghz cleanair
Device(config)#no ap dot11 24ghz cleanair
```

Run the **no** form of this command to disable CleanAir on the 802.11b network.

CleanAir is enabled on all selected 2.4-GHz radios, and spectrum analysis begins for those devices.

Configure a CleanAir alarm for 2.4-GHz air-quality and devices (CLI)

Configure CleanAir alarms for specific air quality thresholds and device interference types on 2.4-GHz radios using the commands.

Set up alarms that notify you when air quality drops or when certain device types are detected on the 2.4-GHz band using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the alarm for the threshold value for air-quality for all the 2.4-GHz devices.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm air-quality threshold
   threshold_value
   ```

   Add the **no** form of this command to disable the alarm.

3. Configure the alarm for the 2.4-GHz devices using this command.

Example

```
Device(config)# ap dot11 24ghz cleanair alarm device {bt-discovery | bt-link
 | canopy | cont-tx | dect-like | fh | inv | jammer | mw-oven | nonstd |
report | superag | tdd-tx | video | wimax-fixed | wimax-mobile | xbox | zigbee}
```

Add the **no** form command to disable the alarm.

- bt-discovery: Bluetooth Discovery and bt-link: Bluetooth Link.
- canopy: Canopy devices and cont-tx: Continuous Transmitter.
- dect-like: Digital Enhanced Cordless Communication (DECT)-like phone and fh: 802.11 frequency hopping devices.
- inv: Devices using spectrally inverted WiFi signals and jammer: Jammer.
- mw-oven: Microwave oven and nonstd: Devices using non standard Wi-Fi channels.
- report: Interference device reporting and superag: 802.11 SuperAG devices.
- tdd-tx: TDD Transmitter and video: Video cameras.
- wimax-fixed: WiMax Fixed and wimax-mobile: WiMax Mobile.
- xbox: Xbox and zigbee: 802.15.4 devices.

4. Return to the privileged EXEC mode.

Example

```
Device(config)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Configure interference reporting for a 2.4-GHz device (GUI)

Configure interference reporting for a 2.4-GHz device using GUI.

Configure which types of interference are detected by a 2.4-GHz device using the CleanAir GUI. This task guides you through selecting and applying specific interference types to monitor.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **CleanAir**.
2. Click the **2.4 GHz Band** tab.
3. Choose the interference types and add them to the **Interference Types to detect** section.

   These interference types are available:

   - BLE Beacon: Bluetooth low energy beacon and Bluetooth Discovery.
   - Bluetooth Link and Canopy.
   - Continuous Transmitter and DECT-like Phone: Digital Enhanced Cordless Technology phone.
   - 802.11 FH: 802.11 frequency hopping device and WiFi Inverted: Device using spectrally inverted Wi-Fi signals.
   - Jammer and Microwave Oven.

- WiFi Invalid Channel: Device using nonstandard Wi-Fi channels and TDD Transmitter.
- Video Camera and SuperAG: 802.11 SuperAG device.
- WiMax Mobile and WiMax Fixed.
- 802.15.4, Microsoft Device and SI_FHSS.

4. Click **Apply**.

Configure interference reporting for a 2.4-GHz device (CLI)

Configure interference reporting for a 2.4-GHz device using commands.

Configure a 2.4-GHz device to report interference using commands. This process enables devices to detect and provide information about various sources of wireless interference.

Procedure

1. Configure the 2.4-GHz interference devices to report to the device using the command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair device {ble-beacon | bt-discovery |
   bt-link | canopy | cont-tx | dect-like | fh | inv | jammer | mw-oven | nonstd
    | report | superag | tdd-tx | video | wimax-fixed | wimax-mobile | xbox |
   zigbee | alarm}
   ```

   Run the **no** form of this command to disable the configuration.

   These are the list of the keyword descriptions:

   - ble-beacon: Bluetooth low energy beacon.
   - bt-discovery: Bluetooth discovery and bt-link: Bluetooth link.
   - canopy: Canopy device and cont-tx: Continuous transmitter.
   - dect-like: Digital Enhanced Cordless Communication-like phone and fh: 802.11-frequency hopping device.
   - inv: Device using spectrally inverted Wi-Fi signals and jammer: Jammer.
   - mw-oven: Microwave oven, nonstd: Device using nonstandard Wi-Fi channels and report: Interference device reporting.
   - superag: 802.11 SuperAG device, tdd-tx: TDD transmitter and video: Video camera.
   - wimax-fixed: WiMax Fixed and wimax-mobile: WiMax Mobile.
   - microsoft xbox: Microsoft Xbox device and zigbee: 802.15.4 device.

2. Return to the privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Enable CleanAir for the 5-GHz band (GUI)

Learn how to enable CleanAir for the 5-GHz band to improve wireless interference detection and spectrum analysis.

Enable CleanAir to improve 5-GHz wireless interference detection and spectrum analysis using the GUI.

Perform this task when you need enhanced monitoring and automated mitigation of interference on 5-GHz wireless networks.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **CleanAir**.
2. On the **CleanAir** page, choose the **5 GHz Band** > **General** tab.
3. Check the **Enable CleanAir** checkbox.
4. Click **Apply**.

CleanAir is enabled for the 5-GHz band, enhancing the detection and mitigation of wireless interference.

Enable CleanAir for the 5-GHz band (CLI)

Configure CleanAir on a 5-GHz 802.11a network to enhance wireless interference detection and mitigation using the commands.

Enable the CleanAir feature to monitor and mitigate wireless interference on 5-GHz wireless networks using commands.

Procedure

Enable the CleanAir feature on a 802.11a network.

Example

```
Device(config)# ap dot11 5ghz cleanair
```

Run the **no** form of this command to disable CleanAir on the 802.11a network.

CleanAir is enabled for the 5-GHz band, enhancing the detection and mitigation of wireless interference.

Configure interference reporting for a 5-GHz device (GUI)

Learn how to set up interference reporting on your 5-GHz device to identify and detect various wireless interference sources.

Enable detection and reporting of selected interference types for better network performance.

Use this procedure when you need to monitor wireless interference on 5-GHz band devices using CleanAir technology.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **CleanAir**.

2. Click the **5 GHz Band** tab.
3. Choose the interference types and add them to the **Interference Types to detect** section.

   These interference types are available:

   - Canopy
   - Continuous Transmitter
   - DECT-like Phone–Digital Enhanced Cordless Technology phone
   - 802.11 FH–802.11 frequency hopping device
   - WiFi Inverted–Device using spectrally inverted Wi-Fi signals
   - Jammer
   - WiFi Invalid Channel–Device using nonstandard Wi-Fi channels
   - SuperAG–802.11 SuperAG device
   - TDD Transmitter
   - WiMax Mobile
   - WiMax Fixed
   - Video Camera

4. Click **Apply**.

Your 5-GHz device now detects and reports the selected interference types.

Configure interference reporting for a 5-GHz device (CLI)

Configure interference reporting for a 5-GHz device using commands.

Procedure

---

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a 5-GHz interference device to report to the **ap dot11 5ghz cleanair device{canopy | cont-tx | dect-like | inv | jammer | nonstd | report | superag | tdd-tx | video | wimax-fixed | wimax-mobile}** command.

   Example

   ```
   Device(config)#ap dot11 5ghz cleanair device canopy
   Device(config)#ap dot11 5ghz cleanair device cont-tx
   Device(config)#ap dot11 5ghz cleanair device dect-like
   Device(config)#ap dot11 5ghz cleanair device inv
   ```

```
Device(config)#ap dot11 5ghz cleanair device jammer
Device(config)#ap dot11 5ghz cleanair device nonstd

Device(config)#ap dot11 5ghz cleanair device report
Device(config)#ap dot11 5ghz cleanair device superag
Device(config)#ap dot11 5ghz cleanair device tdd-tx
Device(config)#ap dot11 5ghz cleanair device video
Device(config)#ap dot11 5ghz cleanair device wimax-fixed
Device(config)#ap dot11 5ghz cleanair device wimax-mobile
Device(config)#ap dot11 5ghz cleanair device si_fhss
Device(config)#ap dot11 5ghz cleanair device alarm
```

Device. Run the **no** form of this command to disable interference device reporting.

This is a list of the keyword descriptions:

- **canopy**–Canopy device
- **cont-tx**–Continuous transmitter
- **dect-like**–Digital Enhanced Cordless Communication-like phone
- **fh**–802.11-frequency hopping device
- **inv**–Device using spectrally-inverted Wi-Fi signals
- **jammer**–Jammer
- **nonstd**–Device using nonstandard Wi-Fi channels
- **superag**–802.11 SuperAG device
- **tdd-tx**–TDD transmitter
- **video**–Video camera
- **wimax-fixed**–WiMax fixed
- **wimax-mobile**–WiMax mobile

3. Return to the privileged EXEC mode.

Example

```
Device(config)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Configure event driven RRM for a CleanAir event (GUI)

Configure event driven Radio Resource Management (RRM) to automatically adjust wireless channels in response to interference detected by CleanAir-enabled access points.

Configure event driven Radio Resource Management (RRM) to respond to CleanAir-detected interference.

Use this feature to optimize channel assignment automatically when a CleanAir-enabled access point detects significant interference.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **RRM**.
   The **Radio Resource Management** window is displayed.
2. Click the **DCA** tab.
3. In the **Event Driven RRM** section, check the **EDRRM** check box to run RRM when CleanAir-enabled AP detects a significant level of interference.
4. Configure the **Sensitivity Threshold** level at which RRM has to be invoked from the following options:
   - **Low**: Represents a decreased sensitivity to changes in the environment and its value is set at 35.
   - **Medium**: Represents medium sensitivity to changes in the environment at its value is set at 50.
   - **High**: Represents increased sensitivity to changes in the environment at its value is set at 60.
   - **Custom**: If you choose this option, you must specify a custom value in the **Custom Threshold** box.
5. To configure rogue duty cycle, check the **Rogue Contribution** check box and then specify the **Rogue Duty-Cycle** in terms of percentage. The default value of rogue duty cycle is 80 percent.

   Note

   Rogue Contribution is a new component in ED-RRM functionality. It enables ED-RRM to respond to Rogue Channel Utilization, which operates independently from CleanAir metrics. Rogue Duty Cycle is derived from standard off-channel RRM metrics and triggers a channel change when neighboring rogue interference is detected. Since this process relies on RRM metrics rather than CleanAir, the timing depends on normal 180-second off-channel intervals, with a maximum delay of three minutes. Rogue Contribution is configured separately from CleanAir ED-RRM and is disabled by default. This feature allows each AP to respond to Wi-Fi interference originating outside the local network, with measurements taken at every individual AP.

   Rogue Contribution is a new component in ED-RRM functionality. It enables ED-RRM to respond to detected Rogue Channel Utilization, which functions separately from CleanAir metrics.

6. Save the configuration.

The controller now automatically triggers RRM based on CleanAir or optionally, rogue channel utilization events.

Configure EDRRM for a CleanAir event (CLI)

Use this procedure to enable and configure Event-Driven Radio Resource Management (EDRRM) CleanAir event detection on an access point through the CLI.

Enable automated, event-driven dynamic RRM adjustments in response to CleanAir events.

EDRRM allows the AP to adjust its channel management dynamically in response to detected interference or CleanAir events. This ensures better wireless performance and mitigation of interference.

Before you begin

Verify the AP supports CleanAir and EDRRM features.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# conf t
   ```

   Run the **no** form of this command to disable EDRRM.

2. Enable EDRRM CleanAir event.

   Example

   ```
   Device (config)#ap dot11 24ghz rrm channel cleanair-event
   Device(config)#no ap dot11 24ghz rrm channel cleanair-event
   ```

   Run the **no** form of this command to disable EDRRM.

3. Configure the EDRRM sensitivity of the CleanAir event.

   Example

   ```
   Device(config)#ap dot11 24ghz rrm channel cleanair-event sensitivity high
   ```

   This a list of the keyword descriptions:

   - Custom–Specifies custom sensitivity to non-Wi-Fi interference as indicated by the AQ value.
   - High–Specifies the most sensitivity to non-Wi-Fi interference as indicated by the AQ value.
   - Low–Specifies the least sensitivity to non-Wi-Fi interference as indicated by the AQ value.
   - Medium–Specifies medium sensitivity to non-Wi-Fi interference as indicated by the AQ value.

EDRRM CleanAir event detection and response is enabled with your selected sensitivity, improving dynamic channel management during interference events.

Verify CleanAir support on connected APs

Lists the methods for determining CleanAir support status on connected access points.

Provide information and methods to help users identify which connected access points support Cisco CleanAir technology, enabling informed network management and planning.

To verify CleanAir support on connected APs, use this command:

```
Device# show ap dot11 24ghz cleanair summary
                                                Spectrum  Spectrum     Spectrum
    Spectrum
```

```

CleanAir Pro scanning

Describes CleanAir Pro scanning features, detailing how to enable scanning via CLI, monitor scanning statistics through GUI, and verify operational details for enhanced RF interference detection and analysis.

A CleanAir Pro feature is a wireless monitoring capability that

- monitors and reports different categories of non-Wi-Fi interference across supported 2.4-GHz, 5-GHz, and 6-GHz band frequency bands
- generates detailed Interference Device Reports (IDRs) including interferer type, severity, and impacted channels, and
- calculates air quality (AQ) metrics for each dynamic channel assignment (DCA) channel to support intelligent channel management by the controller.

Table 166: Feature history for CleanAir Pro scanning

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.10.1	CleanAir Support for 6-GHz	The CleanAir is enabled in 6-GHz band radio of AP only if CleanAir is enabled globally in 6-GHz band in the controller and 6-GHz radio of individual AP. Cisco IOS XE Cupertino 17.9.1 supports 6-GHz only for spectral analysis on Cisco Catalyst Center. IDR and AQ are not supported for the 6-GHz band in Cisco IOS XE Cupertino 17.9.1.
Cisco IOS XE Cupertino 17.9.1	CleanAir Pro Scanning	The CleanAir Pro Scanning feature monitors and reports the different categories of non-Wi-Fi interference in the 2.4-GHz and 5-GHz bands.

Controller behavior for interferer and channel monitoring

The controller manages interferer information and channel selection using these methods:

- **Interferer database management**: The controller maintains a database of active interferers reported by each access point (AP) on the network.

- **Interferer merging**: If the same interferer is detected by multiple APs, the controller merges these records so the interferer is tracked as a single entity across the network.
- **Air quality tracking**: The controller monitors air quality metrics for each channel. These metrics are used during dynamic channel assignment (DCA) to select optimal channels for each AP.

> **Note**
>
> The CleanAir Pro Scanning feature is applicable only for APs with CleanAir Pro-supported radios.

Channel-list configuration command keywords for CleanAir Pro scanning

CleanAir Pro Scanning scans channels in the slots or bands currently enabled on an AP. Here are certain commands used to enable scannig.

- **ap dot11 rrm monitor channel-list dca**: Scans only channels enabled under DCA.
- **ap dot11 rrm monitor channel-list country**: Scans all regulatory channels permitted in the site's country setting.
- **ap dot11 rrm monitor channel-list country all**: Scans every channel available to the radio, without regard to regulatory constraints.

Contents and event types in IDR

APs detect non-Wi-Fi interferers and report this data to the controller through Interference Device Report (IDR) such as

- duty cycle,
- Received Signal Strength Indicator (RSSI) in dBm, and
- a calculated Severity metric.

The controller receives IDR messages and uses event types to track the status of each interferer:

- **UP**: The interferer is first detected.
- **UPDT**: The interferer's status is updated.
- **DOWN**: The interferer is no longer observed.

The controller maintains a list of interferers along with the channels affected for each AP. Within an AP, interferers are merged if they share the same channel, RSSI, and device signature. Across multiple APs, a controller merges interferers reported as the same type.

These processes enable accurate tracking and consolidation of interferer data throughout the network.

Air quality index reports

The Air Quality Index (AQ) metric quantifies interference levels detected by each access point (AP) in a Cisco wireless network.

AQ calculation: AQ starts at 100 (optimal) for each AP and is decremented by the cumulative severity values of all detected interference sources.

Air Quality Metric Calculation

For example, if three Bluetooth devices are reported by an AP, each with a severity of two, this results in an overall cell AQ of 94 (2x3 BT = 6, 100 – 6 = AQ of 94).

Enable CleanAir Pro scan features (CLI)

Learn how to enable CleanAir Pro scan features using the CLI for 2.4, 5, and 6 GHz radios.

Enable spectrum monitoring and interference detection across all supported wireless radios.

Use this procedure when you want to configure CleanAir Pro scanning and alarms on Cisco wireless devices using CLI.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the CleanAir features for the 2.4-GHz , 5-GHz, or 6-GHz radios using the **ap dot11** {**24ghz** | **5ghz** | **6ghz**} **cleanair** command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair
   ```

3. Configure CleanAir alarm for air quality in the 2.4-GHz, 5-GHz, or 6-GHz radiosusing the **ap dot11** {**24ghz** | **5ghz** | **6ghz**} **cleanair alarm air-quality** command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm air-quality
   ```

4. Configure the air quality threshold value of CleanAir alarm in the 2.4-GHz , 5-GHz, or 6-GHz radios using the **ap dot11** {**24ghz** | **5ghz** | **6ghz**} **cleanair alarm air-quality threshold** *threshold-value* command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm air-quality threshold 25
   ```

   The valid range is between 1 and 100.

5. Configure the continuous transmitter as the interference device CleanAir alarm in the 2.4-GHz , 5-GHz, or 6-GHz radios using the **ap dot11** {**24ghz** | **5ghz** | **6ghz**} **cleanair alarm device cont-tx** command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm device cont-tx
   ```

6. Configure the air quality alarm on exceeding unclassified category severity using the **ap dot11** {**24ghz** | **5ghz** | **6ghz**} **cleanair alarm unclassified** command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm unclassified
   ```

7. Configure the air quality alarm on exceeding unclassified category severity threshold using the **ap dot11** {**24ghz** | **5ghz** | **6ghz**} **cleanair alarm unclassified threshold** *threshold-value*command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm unclassified threshold 15
   ```

   The valid range is between 1 and 100.

8. Configure continuous transmitter as the CleanAir interference device type using the **ap dot11** {**24ghz** | **5ghz** | **6ghz**} **cleanair device cont-tx** command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair device cont-tx
   ```

CleanAir Pro scan features are active, with alarms configured according to your settings.

Monitor CleanAir Pro statistics (GUI)

Use this procedure to monitor CleanAir Pro statistics and interference reports using the graphical user interface.

Review CleanAir Pro statistics for air quality, interference, and radio channels across your wireless network.

This task helps you assess wireless spectrum health, identify interference sources, and check air quality metrics for monitored access points.

Procedure

---

1. Choose **Monitoring** > **Wireless** > **CleanAir Statistics**.
   The **CleanAir Statistics** window is displayed.
2. Click the **2.4 GHz Band**, **5 GHz Band**, or **6 GHz Band** tab.
   The **CleanAir Interference Devices** window is selected by default. You can monitor and detect the cluster IDs, the interferer type, severity, the affected channels, and so on, for the listed APs.
3. Click the listed devices under the **CleanAir Interference Devices** tab to view the **CleanAir Interference Charts** that displays the **AQ Graph** and the **Interference Power**.
4. Click the **Air Quality** tab to monitor the channel, the average and minimum AQ, number of interferers, the time at which the interference was detected, and the spectrum AP type.
5. Click the **Worst Air Quality Report** tab to view the AQ report, with details of the AP that reported the worst AQ, the radio channel number with the worst-reported air quality, the minimum and the average AQ index, the interference device count, and the spectrum AP type.

You have reviewed CleanAir Pro statistics to monitor air quality, interference, and device-specific spectrum data across selected wireless bands.

Verify CleanAir Pro scanning details

Verify CleanAir Pro scanning details using GUI.

To view the CleanAir Air Quality (AQ) data, run this command:

```
Device# show ap dot11 {24ghz | 5ghz | 6ghz} cleanair air-quality summary
```

To view the CleanAir Air Quality (AQ) worst data, run this command:

```
Device# show ap dot11 {24ghz | 5ghz | 6ghz} cleanair air-quality worst
```

To view the CleanAir device cluster information, run this command:

```
Device# show ap dot11 {24ghz | 5ghz | 6ghz} cleanair device cluster cluster-id
```

To view the CleanAir interferers of a device type, run this command:

```
Device# show ap dot11 {24ghz | 5ghz | 6ghz} cleanair device type
```

To view the CleanAir configuration for a specific AP, run this command:

```
Device# show ap name ap-name dot11 {24ghz | 5ghz | 6ghz} cleanair air-quality
Device# show ap name ap-name dot11 {24ghz | 5ghz | 6ghz} cleanair device
```

To view the continuous transmitter as the CleanAir interference device type, run this command:

```
Device# show ap dot11 6ghz cleanair device type cont-tx
```

Configuration examples for CleanAir

Configuration examples for CleanAir.

This example shows how to enable CleanAir on the 2.4-GHz band and an AP operating in the channel:

```
Device#configure terminal
Device(config)#ap dot11 24ghz cleanair
Device(config)#exit
Device#ap name TAP1 dot11 24ghz cleanair
Device#end
```

This example shows how to enable an EDRRM CleanAir event in the 2.4-GHz band and configure high sensitivity to non-Wi-Fi interference:

```
Device#configure terminal
Device(config)#ap dot11 24ghz rrm channel cleanair-event
Device(config)#ap dot11 24ghz rrm channel cleanair-event sensitivity high
Device(config)#end
```

This example shows how to enable an AP in the monitor mode:

```
Device#ap name <ap-name> mode monitor
```

CleanAir Pro scanning

Describes CleanAir Pro scanning features, detailing how to enable scanning via CLI, monitor scanning statistics through GUI, and verify operational details for enhanced RF interference detection and analysis.

A CleanAir Pro feature is a wireless monitoring capability that

- monitors and reports different categories of non-Wi-Fi interference across supported 2.4-GHz, 5-GHz, and 6-GHz band frequency bands
- generates detailed Interference Device Reports (IDRs) including interferer type, severity, and impacted channels, and

- calculates air quality (AQ) metrics for each dynamic channel assignment (DCA) channel to support intelligent channel management by the controller.

Table 167: Feature history for CleanAir Pro scanning

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.10.1	CleanAir Support for 6-GHz	The CleanAir is enabled in 6-GHz band radio of AP only if CleanAir is enabled globally in 6-GHz band in the controller and 6-GHz radio of individual AP. Cisco IOS XE Cupertino 17.9.1 supports 6-GHz only for spectral analysis on Cisco Catalyst Center. IDR and AQ are not supported for the 6-GHz band in Cisco IOS XE Cupertino 17.9.1.
Cisco IOS XE Cupertino 17.9.1	CleanAir Pro Scanning	The CleanAir Pro Scanning feature monitors and reports the different categories of non-Wi-Fi interference in the 2.4-GHz and 5-GHz bands.

Controller behavior for interferer and channel monitoring

The controller manages interferer information and channel selection using these methods:

- **Interferer database management**: The controller maintains a database of active interferers reported by each access point (AP) on the network.
- **Interferer merging**: If the same interferer is detected by multiple APs, the controller merges these records so the interferer is tracked as a single entity across the network.
- **Air quality tracking**: The controller monitors air quality metrics for each channel. These metrics are used during dynamic channel assignment (DCA) to select optimal channels for each AP.

Note

The CleanAir Pro Scanning feature is applicable only for APs with CleanAir Pro-supported radios.

Channel-list configuration command keywords for CleanAir Pro scanning

CleanAir Pro Scanning scans channels in the slots or bands currently enabled on an AP. Here are certain commands used to enable scannig.

- **ap dot11 rrm monitor channel-list dca**: Scans only channels enabled under DCA.
- **ap dot11 rrm monitor channel-list country**: Scans all regulatory channels permitted in the site's country setting.
- **ap dot11 rrm monitor channel-list country all**: Scans every channel available to the radio, without regard to regulatory constraints.

Contents and event types in IDR

APs detect non-Wi-Fi interferers and report this data to the controller through Interference Device Report (IDR) such as

- duty cycle,
- Received Signal Strength Indicator (RSSI) in dBm, and
- a calculated Severity metric.

The controller receives IDR messages and uses event types to track the status of each interferer:

- **UP**: The interferer is first detected.
- **UPDT**: The interferer's status is updated.
- **DOWN**: The interferer is no longer observed.

The controller maintains a list of interferers along with the channels affected for each AP. Within an AP, interferers are merged if they share the same channel, RSSI, and device signature. Across multiple APs, a controller merges interferers reported as the same type.

These processes enable accurate tracking and consolidation of interferer data throughout the network.

Air quality index reports

The Air Quality Index (AQ) metric quantifies interference levels detected by each access point (AP) in a Cisco wireless network.

AQ calculation: AQ starts at 100 (optimal) for each AP and is decremented by the cumulative severity values of all detected interference sources.

Air Quality Metric Calculation

For example, if three Bluetooth devices are reported by an AP, each with a severity of two, this results in an overall cell AQ of 94 (2x3 BT = 6, 100 – 6 = AQ of 94).

Enable CleanAir Pro scan features (CLI)

Learn how to enable CleanAir Pro scan features using the CLI for 2.4, 5, and 6 GHz radios.

Enable spectrum monitoring and interference detection across all supported wireless radios.

Use this procedure when you want to configure CleanAir Pro scanning and alarms on Cisco wireless devices using CLI.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the CleanAir features for the 2.4-GHz , 5-GHz, or 6-GHz radios using the **ap dot11** {**24ghz** | **5ghz** | **6ghz**} **cleanair** command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair
   ```

3. Configure CleanAir alarm for air quality in the 2.4-GHz, 5-GHz, or 6-GHz radiosusing the **ap dot11 {24ghz | 5ghz | 6ghz} cleanair alarm air-quality** command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm air-quality
   ```

4. Configure the air quality threshold value of CleanAir alarm in the 2.4-GHz , 5-GHz, or 6-GHz radios using the **ap dot11 {24ghz | 5ghz | 6ghz} cleanair alarm air-quality threshold** *threshold-value* command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm air-quality threshold 25
   ```

   The valid range is between 1 and 100.

5. Configure the continuous transmitter as the interference device CleanAir alarm in the 2.4-GHz , 5-GHz, or 6-GHz radios using the **ap dot11 {24ghz | 5ghz | 6ghz} cleanair alarm device cont-tx** command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm device cont-tx
   ```

6. Configure the air quality alarm on exceeding unclassified category severity using the **ap dot11 {24ghz | 5ghz | 6ghz} cleanair alarm unclassified** command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm unclassified
   ```

7. Configure the air quality alarm on exceeding unclassified category severity threshold using the **ap dot11 {24ghz | 5ghz | 6ghz} cleanair alarm unclassified threshold** *threshold-value*command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair alarm unclassified threshold 15
   ```

   The valid range is between 1 and 100.

8. Configure continuous transmitter as the CleanAir interference device type using the **ap dot11 {24ghz | 5ghz | 6ghz} cleanair device cont-tx** command.

   Example

   ```
   Device(config)# ap dot11 24ghz cleanair device cont-tx
   ```

CleanAir Pro scan features are active, with alarms configured according to your settings.

Monitor CleanAir Pro statistics (GUI)

Use this procedure to monitor CleanAir Pro statistics and interference reports using the graphical user interface.

Review CleanAir Pro statistics for air quality, interference, and radio channels across your wireless network.

This task helps you assess wireless spectrum health, identify interference sources, and check air quality metrics for monitored access points.

Procedure

1. Choose **Monitoring** > **Wireless** > **CleanAir Statistics**.
   The **CleanAir Statistics** window is displayed.
2. Click the **2.4 GHz Band**, **5 GHz Band**, or **6 GHz Band** tab.
   The **CleanAir Interference Devices** window is selected by default. You can monitor and detect the cluster IDs, the interferer type, severity, the affected channels, and so on, for the listed APs.
3. Click the listed devices under the **CleanAir Interference Devices** tab to view the **CleanAir Interference Charts** that displays the **AQ Graph** and the **Interference Power**.
4. Click the **Air Quality** tab to monitor the channel, the average and minimum AQ, number of interferers, the time at which the interference was detected, and the spectrum AP type.
5. Click the **Worst Air Quality Report** tab to view the AQ report, with details of the AP that reported the worst AQ, the radio channel number with the worst-reported air quality, the minimum and the average AQ index, the interference device count, and the spectrum AP type.

You have reviewed CleanAir Pro statistics to monitor air quality, interference, and device-specific spectrum data across selected wireless bands.

Verify CleanAir Pro scanning details

Verify CleanAir Pro scanning details using GUI.

To view the CleanAir Air Quality (AQ) data, run this command:

```
Device# show ap dot11 {24ghz | 5ghz | 6ghz} cleanair air-quality summary
```

To view the CleanAir Air Quality (AQ) worst data, run this command:

```
Device# show ap dot11 {24ghz | 5ghz | 6ghz} cleanair air-quality worst
```

To view the CleanAir device cluster information, run this command:

```
Device# show ap dot11 {24ghz | 5ghz | 6ghz} cleanair device cluster cluster-id
```

To view the CleanAir interferers of a device type, run this command:

```
Device# show ap dot11 {24ghz | 5ghz | 6ghz} cleanair device type
```

To view the CleanAir configuration for a specific AP, run this command:

```
Device# show ap name ap-name dot11 {24ghz | 5ghz | 6ghz} cleanair air-quality
Device# show ap name ap-name dot11 {24ghz | 5ghz | 6ghz} cleanair device
```

To view the continuous transmitter as the CleanAir interference device type, run this command:

```
Device# show ap dot11 6ghz cleanair device type cont-tx
```

Verify CleanAir parameters

Outlines methods for monitoring CleanAir deployment, including configuring air quality traps, tracking interference devices, viewing worst air quality metrics by radio band via GUI, and referencing practical configuration examples.

You can verify CleanAir parameters using these commands:

Table 168: Commands for verifying CleanAir

Command Name	Description
show ap dot11 24ghz cleanair device type all	Displays all the CleanAir interferers for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type ble-beacon	Displays all the Bluetooth Low Energy (BLE) beacons for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type bt-discovery	Displays CleanAir interferers of type BT Discovery for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type bt-link	Displays CleanAir interferers of type BT Link for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type canopy	Displays CleanAir interferers of type Canopy for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type cont-tx	Displays CleanAir interferers of type Continuous transmitter for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type dect-like	Displays CleanAir interferers of type Digital Enhanced Cordless Telecommunications (DECT) Like for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type fh	Displays CleanAir interferers of type 802.11FH for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type inv	Displays CleanAir interferers of type Wi-Fi Inverted for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type jammer	Displays CleanAir interferers of type Jammer for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type mw-oven	Displays CleanAir interferers of type MW Oven for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type nonstd	Displays CleanAir interferers of type Wi-Fi inverted channel for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type superag	Displays CleanAir interferers of type SuperAG for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type tdd-tx	Displays CleanAir interferers of type TDD Transmit for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type video	Displays CleanAir interferers of type Video Camera for the 2.4-GHz band.
show ap dot11 24ghz cleanair device type wimax-fixed	Displays CleanAir interferers of type WiMax Fixed for the 2.4-GHz band.

Configure air quality traps (CLI)

Configure SNMP traps to monitor air quality index (AQI) and generate alerts when thresholds are exceeded.

Set up SNMP traps so that you receive alerts when the air quality falls below a specified threshold.

Procedure

1. Configure the trap **ciscoLwappSiAqLowSeverityHigh** to generate an alert when air quality goes beyond a given threshold.

   On the controller GUI, navigate to **Configuration** > **Radio Configurations** > **Configuration** > **CleanAir** > **Trap configuration**.

   The trap **ciscoLwappSiAqLowSeverityHigh** (OID: 1.3.6.1.4.1.9.9.513.1.6.1.0.5) is used to monitor air quality and generate alerts when the air quality index exceeds a specified threshold.

2. Send the trap from the controller CLI. From the global configuration mode, enable SNMP traps for air quality index (AQI).

   Example

   ```
   Device# snmp-server enable traps wireless SI
   ```

SNMP traps are configured, and the device sends alerts when air quality index thresholds are exceeded.

What to do next
Monitor SNMP alerts to ensure notifications are received as expected.

Monitor with CleanAir device clusters

This section explains CleanAir device clusters and how they manage detections of interferer devices by merging multiple sensor reports into unified records

A CleanAir device cluster is a spectrum monitoring feature that

- merges detections of the same interference device from multiple sensors into a single cluster,
- assigns and maintains a unique cluster ID for each device, and
- preserves device history by keeping cluster IDs active during temporary lapses in detection.

How CleanAir handles interference device monitoring

Some devices conserve power by limiting the transmit time until actually needed, which results in the spectrum sensor to stop detecting the device temporarily. This device is then correctly marked as down and removed from the spectrum database.

In cases when all the interferer detections for a specific device are reported, the cluster ID is kept alive for an extended period of time to prevent possible device-detection bouncing. If the same device is detected again, it is merged with the original cluster ID and the device-detection history is preserved.

> **Note**
>
> You can configure Cisco CleanAir only on CleanAir-enabled APs.

: Bluetooth headset power management

Some Bluetooth headsets operate on battery power and employ methods to reduce power consumption, such as turning off the transmitter when not needed. Such devices can appear to come and go from the classification. To manage these devices, CleanAir keeps the cluster IDs for longer and they are remerged into a single record upon detection. This process smoothens the user records and accurately represents the device history.

CleanAir FAQs

Provides answers to frequently asked questions about Cisco CleanAir, addressing common operational scenarios, troubleshooting steps, and best practices for efficient RF interference management.

Multiple access points detect the same interference device. However, the device shows them as separate clusters or different suspected devices clustered together. Why does this happen?

Access points must be RF neighbors for the device to consider merging the devices that are detected by these access points. An access point takes time to establish neighbor relationships. A few minutes after the device reboots or after there is a change in the RF group, and similar events, clustering will not be very accurate.

How do I view neighbor access points?

To view neighbor access points, use the **show ap** *ap_name* **auto-rf dot11 24ghz 5ghz** command.

This example shows how to display the neighbor access points:

```
Device#show ap name AS-5508-5-AP3 auto-rf dot11 24ghz

What are the AP debug commands available for CleanAir?

The AP debug commands for CleanAir are:

- **debug cleanair bringup event logdebug low major nsi offchan**
- **debug rrm neighbor off-channel reports**

189 Bluetooth Low Energy

Topics:

- Bluetooth low energy

Explains how Bluetooth Low Energy beacons work with Cisco CleanAir to enable location-based services, asset tracking, and device detection.

Bluetooth low energy

Details core concepts and characteristics of Bluetooth Low Energy, outlining device roles, communication models, and application scenarios for low-power wireless connectivity.

A Bluetooth low energy device is a wireless personal area network technology that

- enables enhanced location services for mobile devices
- transmits universally unique identifiers (UUIDs), major and minor fields for device identity and context, and
- allows smartphones and APs to detect BLE signals for various use cases, including interferer identification, asset tracking, and targeted notifications.

These details are picked up by Bluetooth-enabled smartphones and devices. The location information of these devices is sent to the corresponding back-end server. Relevant advertisements and other important information are then delivered to the devices using this location-specific information.

Additionally, information about missing tags can be obtained. This feature can determine rogue and malicious tags using the unique identifier associated with each tag (or family of tags) against a predetermined allowed list from a customer. The management function can display or send email alerts based on rogue tags, missing tags, or moved tags.

Note

This feature is not related to the Indoor IoT Services feature set that is part of Cisco Spaces.

It describes how APs and Catalyst 9800 detect BLE devices as wireless interferers using CleanAir, rather than the BLE radio available on some AP models. This feature is not intended for BLE-based asset tracking, environmental monitoring, or tag management use cases. These use cases are powered by Cisco Spaces.

For details about the full functionality of BLE-related use cases in the Cisco solution, refer to the Cisco Spaces configuration guides for Indoor IoT services.

Limitations of BLE Feature

- The wireless infrastructure must support Cisco CleanAir.
- The feature supports a maximum of only 250 unique BLE beacons (cluster entries) and 1,000 device entries.
- The Cisco CleanAir feature is supported only on Cisco Aironet 3700 Series APs with Hyperlocation module RM3010. On Wave 2 and Wi-Fi 6 APs, the BLE feature works differently (through cloud beacon center) and is not covered by this feature.

Areas of Use

The BLE feature provides granular location details of devices, such as smartphones or Bluetooth-enabled devices, which helps deliver context-sensitive advertising and other information to users. Possible areas of application include retail stores, museums, zoos, healthcare, fitness centers, security, and advertising.

Enable Bluetooth low energy beacon (GUI)

Learn how to enable the Bluetooth low energy beacon detection using the CleanAir feature in the GUI.

Enable detection of Bluetooth low energy (BLE) beacons in your wireless network for enhanced interference management using the GUI.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **CleanAir** > **2.4 GHz Band** > **General**.
2. Check the **Enable CleanAir** check box.
3. From the **Available Interference Types** list, select and move **BLE Beacon** to the **Interference Types to Detect** list.
4. Click **Apply**.

Enable Bluetooth low energy beacon (CLI)

Use this task to enable Bluetooth low energy beacon detection on your Cisco controller using commands.

Bluetooth low energy (BLE) detection is enabled by default. Use the procedure given below to enable BLE when it is disabled.

Before you begin

- The wireless infrastructure must support Cisco CleanAir.
- Cisco CleanAir configuration and show commands are available only in Mobility Controller (MC) mode.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Controller# configure terminal
   ```

2. Enable the BLE feature on the 802.11b network.

   Example

   ```
   Controller(config)# ap dot11 24ghz cleanair device ble-beacon
   ```

   Use the **no** form of the command to disable BLE feature on the 802.11b network.

3. Return to the privileged EXEC mode.

   Example

   ```
   Controller(config)# exit
   ```

4. Optional: Display the BLE beacon configuration.

   Example

   ```
   Controller# show ap dot11 24ghz cleanair config
         Interference Device Settings:
         Interference Device Reporting..............  : Enabled
         Bluetooth Link.........................  : Enabled
         Microwave Oven.........................  : Enabled
         BLE Beacon.............................  : Enabled
   ```

5. Optional: Display the BLE beacon device-type information.

Example

```
Controller# show ap dot11 24ghz cleanair device type ble-beacon
      DC    = Duty Cycle (%)
      ISI   = Interference Severity Index (1-Low Interference, 100-High
Interference)
      RSSI  = Received Signal Strength Index (dBm)
      DevID = Device ID
      No    ClusterID          DevID  Type           AP Name
ISI  RSSI  DC   Channel

-------------------------------------------------------------------------------------

--   -74   0    unknown
```

190 Persistent Device Avoidance

Topics:

- Cisco persistent device avoidance

This chapter explains how to enable and verify CleanAir's persistent device avoidance on supported Cisco APs, showing commands and controller output to detect, record, and mitigate recurring non-WiFi interference for optimized channel planning.

Cisco persistent device avoidance

Explains how persistent device avoidance improves WLAN performance by detecting and mitigating interference from periodic devices.

A persistent device avoidance feature is a spectrum management capability that

- detects persistent, periodic interference devices (such as outdoor bridges and microwave ovens) that are usually missed by other RF metrics
- stores device information on the controller to allow mitigation of affected channels, and
- dynamically alters channel plans to minimize interference and optimize WLAN performance because short-duration and periodic operations remain largely undetected by normal RF management metrics.

With Cisco CleanAir, the RRM dynamic channel allocation (DCA) algorithm can detect, measure, register, and remember the impact of interference. It then adjusts the RRM DCA algorithm accordingly. The PDA process minimizes the use of channels affected by persistent devices in the channel plan. This adjustment remains local to the interference source. CleanAir detects and stores persistent device information in the controller. This information is used to mitigate the interfering channels.

Persistent Devices Detection: CleanAir-capable monitor mode APs collect information about persistent devices on all the configured channels and store the information in the controller. Local or bridge mode APs detect interference devices only on the serving channels.

The PDA feature works seamlessly on all platforms. All AP models that support CleanAir and Spectrum Intelligence also support the PDA feature.

The supported platforms are:

- Cisco Aironet 1852 & 1832 APs
- Cisco Aironet 2700 Series APs
- Cisco Aironet 2800 Series APs
- Cisco Aironet 3700 Series APs
- Cisco Aironet 3800 & 4800 Series APs
- Cisco Catalyst 9115 & 9117 Series APs
- Cisco Catalyst 9120AX Series APs
- Cisco Catalyst 9124AX Series APs
- Cisco Catalyst 9130AX APs

Configure persistent device avoidance (GUI)

Configure persistent device avoidance to minimize interference from persistent non-WiFi sources during dynamic channel assignment in the network using the GUI..

Procedure

1. Choose **Configurations** > **Radio Configurations** > **RRM**.
2. Click the **5 GHz Band** tab or the **2.4 GHz Band**, and click the **DCA** tab.
3. In the **DCA** window, under the **Dynamic Channel Assignment Algorithm** section, check the **Avoid Persistent Non-WiFi Interference** check box to enable the device to ignore persistent non-WiFi interference.

4. Click **Apply**.

Configure persistent device avoidance (CLI)

Configure persistent device avoidance using commands.

Configure persistent device avoidance (PDA) on your device using commands.

You can enable and disable the PDA feature and PDA propagation configuration mode through the RRM Manager.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure persistent non-WiFi device avoidance in the 802.11a or 802.11b channel assignment.

   Example

   ```
   Device# [no] ap dot11 24ghz rrm channel device
   ```

   Use the **no** form of this command to negate the command or to set its defaults.

Verify persistent device avoidance

This topic provides instructions to verify that persistent interference devices are detected and avoided by the system using commands.

To verify the current state of **Device Aware** detail of the channel, use this command:

```
Device#show ap dot11 24ghz channel

191 Spectrum Intelligence

Topics:

- Spectrum Intelligence

This chapter explains how to enable and configure Spectrum Intelligence on compatible Cisco APs to detect and classify non-Wi-Fi interference across 2.4 and 5-GHz bands, and how to verify and debug related reports.

Spectrum Intelligence

Explains how Spectrum Intelligence features analyze radio frequencies to detect non-Wi-Fi interference on 2.4-GHz and 5-GHz bands.

A spectrum intelligence feature is a radio analysis tool that

- scans 2.4-GHz and 5-GHz bands for non-Wi-Fi radio interference
- detects and classifies interference types such as microwave, continuous wave (like video bridge and baby monitor), Wi-Fi, and frequency hopping (Bluetooth and frequency-hopping spread spectrum (FHSS) cordless phone), and
- provides detailed radio utilization, noise, air quality, and interference reports for compatible Cisco APs.

For information about APs that support this feature, see the relevant documentation. https://www.cisco.com/c/en/us/td/docs/wireless/access_point/feature-matrix/ap-feature-matrix.html.

Note

You must enable the Spectrum Intelligence feature on Cisco Aironet 1832 and 1852 series APs to view radio details such as noise, air quality, interference, and radio utilization in Cisco Catalyst Center Assurance AP health.

Restrictions

- SI APs report only a single interference type in Local mode.
- SI does not support high availability for air quality or interference reports. High availability is not supported because the interference report or device report will not be copied to standby after switchover. The AP is expected to send the report again if the interfering device is still present.
- Spectrum Intelligence detects only three types of devices:
  - Microwave
  - continuous wave (such as video recorder, baby monitor)
  - SI-FHSS (Bluetooth and frequency hopping Digital European Cordless Telecommunications [DECT] phones).

Configure spectrum intelligence (CLI)

Use this process to enable or disable the Spectrum Intelligence (SI) feature on a Cisco AP using commands. This procedure applies to both 2.4-GHz and 5-GHz radio networks.

Enable network administrators to monitor and analyze the radio frequency (RF) environment by configuring the Spectrum Intelligence (SI) feature on Cisco APs.

Follow the procedure given below to configure spectrum intelligence:

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the 2.4-GHz or 5-GHz spectrum intelligence feature on the 802.11a or 802.11b network.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz} SI
```

Add **no** form of the command to disable SI on the 802.11a or 802.11b network.

Verify spectrum intelligence information

Verify spectrum intelligence information by running key Cisco device commands to check CleanAir and SI status, device types, and interference details for both 2.4-GHz and 5-GHz bands.

Use these commands to verify spectrum intelligence information:

To display the SI information for a 2.4-GHz or 5-GHz band, use this command:

```
Device# show ap dot11 24ghz SI config

SI Solution..................................... : Enabled
Interference Device Settings:
SI_FHSS............................... : Enabled
Interference Device Types Triggering Alarms:
SI_FHSS............................... : Disabled
```

```
Device# show ap dot11 5ghz SI device type
RSSI  = Received Signal Strength Index (dBm)
DevID = Device ID
PD    = Persistent Device
Mac Address        DevID  Type          PD   AP Name
 RSSI  Channel              Last Update Time
------------------------------------------------------------------------------------------
3400.0401.0006     0x0006 BT Discovery   No   RRM-TSIM-3
  -88   40                 12/16/2020 18:11:28 UTC
```

To display SI interferers of type continuous transmitter for a 2.4-GHz band, use this command:

```
Device# show ap dot11 24ghz SI device type cont_tx

RSSI  = Received Signal Strength Index (dBm)
DevID = Device ID
Mac Address        DevID  Type          AP Name                          RSSI
  Channel
-------------------------------------------------------------------------------------
xxxx.xxxx.xxxx     0xf001 Continuous TX Cisco-AP                       -47
```

To display 802.11a interference devices information for the given AP for 5-GHz, use this command:

```
Device# show ap dot11 5ghz SI device type ap

DC    = Duty Cycle (%)
ISI   = Interference Severity Index (1-Low Interference, 100-High Interference)
```

```
RSSI  = Received Signal Strength Index (dBm)
DevID = Device ID
AP type = CA, clean air, SI spectrum intelligence
No  ClusterID/BSSID    DevID  Type    AP Type AP Name                  ISI
RSSI  DC   Channel
--- ------------------ ------ ------- ------  ------------------------ ----
----- ---- ----------
```

To display SI interferers of type continuous transmitter for a 5-GHz band, use this command:

```
Device# show ap dot11 5ghz SI device type cont_tx

RSSI  = Received Signal Strength Index (dBm)
DevID = Device ID
Mac Address        DevID  Type          AP Name                          RSSI
  Channel
-------------------------------------------------------------------------------
xxxx.xxxx.xxx1     0xf001 Continuous TX Cisco-AP                          -88

xxxx.xxxx.xxx2     0xf002 Continuous TX Cisco-AP                          -88
```

To display all Cisco CleanAir interferers for a 2.4-GHz band, use this command:

```
Device# show ap dot11 24ghz cleanair device type all
```

Debugg spectrum intelligence on supported APs (CLI)

Learn how to debug Spectrum Intelligence features on supported APs using commands.

Enable troubleshooting and log generation for Spectrum Intelligence on supported APs using commands.

Procedure

1. Generate major Spectrum Intelligence logs for an AP by entering this command.

   Example

   ```
   debug cleanair major
   ```

2. Verify the Spectrum Intelligence scan schedule of 5 seconds on an AP by entering this command

   Example

   ```
   debug cleanair event
   ```

3. Generate logs at 10-minute interval, when interference is not detected or reported by the AP, by entering this command.

   Example

   ```
   debug cleanair raw 10
   ```

   This command creates three files under **/tmp** directory from dev shell.

   - spectrum.fft
   - spectrum.dbg

- spectrum.int

4. View the Spectrum Intelligence detected interfering devices by entering this command.

   Example

   ```
   show cleanair interferers
   ```

5. View the Spectrum Intelligence configuration status by entering this command.

   Example

   ```
   show cleanair status
   ```

192 Spectrum Analysis

Topics:

- Spectrum analysis

This chapter explains how to enable and use AP radio monitoring GUI and commands and live captures in Cisco Catalyst Center to detect RF interference, interpret persistence, waterfall, and interference charts, and verify settings.

Spectrum analysis

Explains how spectrum analysis charts help network administrators identify RF violations and interpret spectrum data using the Cisco Catalyst Center.

A spectrum analysis chart is a graphical visualization tool that

- Cisco Catalyst Center receives and displays real-time spectrogram streams from APs
- aggregates spectrum data into distinct chart types for network administrators, and
- helps identify and analyze RF violations using color-coded, interactive visual outputs.

To analyze a violation, you should select the corresponding AP and analyze the spectrogram stream.

Each AP uses a specific channel to communicate with clients, depending on whether the setting is global or specific to a channel.

When many clients join the same AP, frames are more likely to be dropped. If clients disconnect quickly or cannot join, perform spectrum analysis to check if the channels are congested.

You can enable spectrum analysis on each AP listed in the web UI and view graphs for the selected AP. When spectrum analysis is enabled, APs send spectrum data to Cisco Catalyst Center, which aggregates it into three distinct charts.

You can view these charts while performing a spectrum analysis:

- Persistence charts plot the amplitude-to-power ratio of each signal at each channel for five minutes. The chart uses blue to represent one signal and red to represent many signals. It also uses opacity to show the age of signal data within the five-minute interval; older data appears more transparent.
- Waterfall charts plot all signals analyzed in the channel for five minutes, with intensity on the X-axis and time on the Y-axis. The chart uses blue for low values and red for high values.
- Interference and Duty charts plot the severity of detected interference for each channel band and list the interference type. Interference appears as a circle; the center indicates severity and the radius shows the affected section of the channel band. The impact is measured by severity values, ranging from 0 to 100. Cisco Catalyst Center determines the interference type from the RF signature using Cisco CleanAir technology.

Live spectrum analysis

This topic explains how live spectrum analyses enable real-time monitoring and visualization of radio frequency interference and usage on APs.

A live spectrum analysis is a radio monitoring feature that

- enables real-time inspection of the spectrum of frequencies generated by AP radios
- displays consolidated interference views across both the 2.4 GHz and 5 GHz ranges when using radio 2, and
- allows users to select an AP radio in the web UI and view its associated live spectrum for a configurable duration for 10 minutes.

You can perform a live spectrum analysis of the AP radios using the web UI, which allows you to monitor the spectrum of frequencies generated by the associated AP radios. The live spectrum capture uses radio 2 if it is available. Otherwise, both radio 0 and radio 1 are used. However, if the feature is enabled on radio 0 or radio 1, you can view only the part of the spectrum associated with those radios.

Perform AP spectrum analysis (GUI)

Learn how to analyze AP spectrum using the Cisco Catalyst Center GUI to evaluate wireless performance using the GUI.

Identify radio frequency interference and optimize wireless network performance using AP spectrum analysis using the GUI.

Before you begin

Use the Cisco Catalyst Center discovery functionality to locate an AP to perform a spectrum analysis.

Procedure

1. Choose **Provision > Inventory**.

   The **Inventory** window is displayed.

2. Click **AP Name**.

   The **360 degree Device** window is displayed.

3. Click **Intelligent Capture**.
4. Click **Spectrum Analysis** to view the graphs.
5. From the **Radio** drop-down list, select a radio.
6. Click **Start Spectrum Analysis**.

   The graphs are displayed on the Web UI for you to analyze.

   To stop the analysis, click **Stop Spectrum Analysis**.

Configure spectrum analysis (CLI)

Configure spectrum analysis on a wireless access point using commands.

Enable spectrum analysis to monitor and troubleshoot RF interference on wireless APs using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure spectrum analysis on the AP.

   Example

   ```
   Device# icap subscription ap rf spectrum enable
   ```

3. Select a radio slot to enable spectrum analysis.

   Example

   ```
   Device# icap subscription ap rf spectrum slot number
   ```

Verify spectrum analysis

Verify spectrum analysis.

This is a sample output of the command that verifies spectrum analysis on a selected AP:

```
Device# show ap icap subscription name
Subscription list
-----------------
Full Pkt Capture : Disabled
Partial Pkt Capture : Enabled
Anomaly Event : Enabled
Debug : Disabled
Stats : Disabled
Ap Operational Data : Disabled
Sensor Message : Enabled
RRM Operational Data : Disabled
Client Events : Disabled
aWIPS Forensic Pkts: Disabled
MAC and Filters subscription list
---------------------------------
Full-packet-trace: None
Partial-packet-trace: None
Filters: None
Anomaly Detection: None
Client Stats
------------
None
RF Spectrum
-----------
Radio Slot(s): 1
```

Part XVI

Mesh Access Points

Topics:

- Mesh Access Points
- Redundant Root Access Point (RAP) Ethernet Daisy Chaining

193 Mesh Access Points

Topics:

- Mesh network
- Mesh Authorization and Security
- Bridge group names
- Mesh background scanning
- Mesh serial backhaul
- Mesh backhaul RRM
- Mesh backhaul at 2.4 GHz and 5 GHz
- Ethernet bridging
- DHCP and NAT functionality on root AP (RAP)
- Mesh convergence
- Mesh daisy chaining
- FlexConnect + bridge mode
- Mesh AP Roles and Topology
- Link test
- Air time fairness on mesh
- Mesh call admission control
- Fast teardown for a mesh deployment

Mesh network

Introduces mesh architecture, RRM feature support, restrictions, country codes, controller interoperability, enabling mesh profiles, associating mesh features, and verifies mesh configuration for foundational understanding and initial setup.

A mesh network is a wireless network topology that

- uses interconnected Cisco Aironet outdoor mesh APs and indoor mesh APs to relay data
- provides scalability, central management, and seamless mobility between indoor and outdoor deployments, and
- is coordinated and provisioned using Cisco Wireless Controller and Cisco Prime Infrastructure.

The Control and Provisioning of Wireless Access Points (CAPWAP) protocol manages the connection of mesh access points to the network, ensuring secure and efficient network operations.

End-to-end security

End-to-end security within the mesh network is supported by employing Advanced Encryption Standard (AES) encryption between wireless mesh APs and Wi-Fi Protected Access 2 (WPA2) clients. For connections to a mesh AP (MAP) wireless client, such as MAP-to-MAP and MAP-to-root access point, WPA2 is applicable.

Wireless mesh termination points

The wireless mesh terminates at two points on the wired network. The first location is where the root access point (RAP) is attached and all bridged traffic connects to the wired network. The second location is where the CAPWAP controller connects to the wired network. At this location, the WLAN client traffic from the mesh network connects to the wired network. The WLAN client traffic from CAPWAP is tunneled to Layer 2. Matching WLANs should terminate on the same switch VLAN as the wireless controllers. The security and network configuration for each of the WLANs on the mesh depend on the security capabilities of the network to which the wireless controller is connected.

In the new configuration model, the controller has a default mesh profile. This profile is mapped to the default AP-join profile, which is in turn is mapped to the default site tag. If you are creating a named mesh profile, ensure that these mappings exist and that the corresponding AP is added to the appropriate site-tag.

Mesh scenarios in IRCM

Important

These are the mesh scenarios in IRCM from Cisco IOS XE Amsterdam 17.3 up to Cisco IOS XE Cupertino 17.9, for the Cisco Wave 1 APs that are not supported:

- Cisco Wave 1 APs are not supported in the releases after Cisco IOS XE Amsterdam 17.3. This includes mesh support as well. Therefore, it is not possible for a Cisco Wave 1 AP to join a Cisco Catalyst 9800 Series Wireless Controller (controller) with Cisco IOS XE Amsterdam 17.4 and later versions. We recommend this deployment mode for Cisco Wave 1 APs.
- In the case of Cisco mesh deployments, these are the deployment limitations to be aware of when the system is deployed:
  - MAP roaming is not allowed between Cisco Catalyst 9800 Series Wireless Controllers, if the controllers run different Cisco IOS XE versions (running on versions Cisco IOS XE Amsterdam 17.3 or Cisco IOS XE Cupertino 17.9) for any of the Cisco Wave 1 APs and Cisco Wave 2 APs.
  - You cannot have Cisco Wave 1 APs and Cisco Catalyst 9124 Series APs in the same mesh tree, in the releases post Cisco IOS XE Amsterdam 17.3.x. This can be achieved in 17.3.x, starting with the 17.3.6 (upcoming) release.

- The whole mesh tree containing Cisco Wave 1 APs must be joined to the 17.3 controller, by running the **strict-bgn** and **mac filtering** commands.

> **Note**
>
> The limitations mentioned above are not valid for the Cisco Industrial Wireless 3702 Series Access Points, which are supported until the Cisco IOS XE Cupertino 17.9 release.

Mesh RRM feature support and evolution across AP generations

Describes the Mesh RRM feature support and the evolution across AP generations.

This topic describes the mesh Radio Resource Management (RRM) feature support, its evolution across different generations of Cisco APs, differences between AP families, key features, and the progression of mesh RRM capabilities in various software releases.

Mesh AP families

The two families of mesh APs available are the Cisco Wave 1 APs and the Cisco Wave 2 APs and the AX APs. These families have different capabilities and features, and they are not fully compatible with each other. The Cisco Wave 1 APs do not support the same feature set as the Cisco Wave 2 and AX APs.

Both families of APs support background scanning. However, their implementations are not interoperable, so you cannot use both in a single mesh deployment.

Evolution in the mesh RRM feature across AP generations

Cisco Wave 1 APs have not received significant mesh RRM feature updates after the Cisco IOS XE Amsterdam 17.3 release. Mesh RRM features on Cisco Wave 2 and AX APs have gained many improvements in recent releases.

- Cisco IOS XE Cupertino 17.9.1 introduced mesh RRM DCA using radio information only from RAPs.
- Cisco IOS XE Dublin 17.11 introduced mesh background scanning and FastaAncestor find mode.
- Cisco IOS XE 17.14 introduced mesh RRM DCA that uses radio information from the entire mesh tree.

Restrictions for mesh access points

Outlines restrictions and considerations for mesh access points configuration and deployment.

Feature restrictions

For information about APs that support Mesh feature, see https://www.cisco.com/c/en/us/td/docs/wireless/access_point/feature-matrix/ap-feature-matrix.html.

- Serial backhaul AP support with separate backhaul radios for uplink and downlink.
- Public Safety channels (4.9-GHz band) support.
- Passive Beaconing (Anti-Stranding)

Configuration considerations

Only Root APs support SSO. MAPs will disconnect and rejoin after SSO.

- In a mixed regulatory domain mesh AP deployment, ensure that the Dynamic Channel Assignment (DCA) allowed channel list is supported by MAPs.
- When you disable the admin state on the 2.4-GHz radio of mesh APs, and the root AP (RAP) backhaul radio is switched to 2.4-GHz, RAP will still use 2.4-GHz radio to serve the mesh backhaul connections, inspite of 2.4-GHz radio being in the disabled state.

The AP Stateful Switch Over (SSO) feature allows the access point (AP) to establish a CAPWAP tunnel with the Active controller and share a mirror copy of the AP database with the Standby controller. The overall goal for the addition of AP SSO support to the controller is to reduce major downtime in wireless networks due to failure conditions that may occur due to box failover or network failover.

Country codes

This concept explains how country codes ensure that controllers and access points (APs) meet local regulatory compliance, including broadcast frequencies, channels, and power levels.

A country code is a regulatory compliance setting that

- allows specification of the intended country of operation for controllers and APs
- ensures adherence to local regulations about broadcast frequencies, channels, and power levels, and
- maintains correct assignment of regulatory domains for each device.

In certain countries, there is a difference for indoor and outdoor APs in these areas:

- Regulatory domain code
- Set of channels supported
- Transmit power level

Controllers and APs are designed for use in many countries with varying regulatory requirements. At the factory, the radios within the APs are assigned to a specific regulatory domain (such as -E for Europe). The country code then enables you to specify a particular country of operation (such as FR for France or ES for Spain). Configuring a country code ensures that the broadcast frequency bands, interfaces, channels, and transmit power levels of each radio are compliant with country-specific regulations.

Mesh interoperability between controllers

This concept explains mesh interoperabilities between controllers, detailing how mesh access points (MAPs) and parent controllers interact across AireOS and Catalyst 9800 networks.

Mesh interoperability between controllers is a wireless mesh network capability that

- enables MAPs to join an AireOS controller through a mesh network formed by APs connected to a Cisco Catalyst 9800 Series Wireless Controller
- allows MAPs to join a Cisco Catalyst 9800 Series Wireless Controller through a mesh network formed by APs connected to an AireOS controller, and
- supports MAP roaming between parent mesh APs connected to AireOS and Cisco Catalyst 9800 Series Wireless Controller using PMK cache.

> **Note**
>
> For seamless interoperability, the AireOS controller and the Cisco Catalyst 9800 Series Wireless Controller must be in the same mobility group. Both controllers should use image versions that support Inter-Release Controller Mobility (IRCM).

Indoor mesh interoperability with outdoor mesh

This concept explains how indoor and outdoor MAPs extend wireless coverage and interoperate in a mesh network.

A mesh network is a wireless connectivity architecture that

- enables both indoor and outdoor MAPs to connect and share coverage
- allows seamless mobility groups between the two environments, and
- supports management of all MAPs through a single controller.

The system supports interoperability between indoor MAPs and outdoor APs. By default, you should use indoor MAPs inside buildings. Deploy them outside only for temporary, short-haul coverage extensions, such as connecting a building to a nearby parking lot.

You can share mobility groups between indoor and outdoor networks, and you can manage all devices with a single controller. The same WLANs that you configure can be broadcast from both indoor and outdoor MAPs.

Enable wireless mesh profile (CLI)

Enable wireless mesh profile.

To enable and configure a wireless mesh profile to support mesh networking functionality on your device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile and enter mesh profile configuration mode.

   Example

   ```
   Device(config)# wireless profile mesh profile-name
   ```

3. Enable the fast teardown of mesh network and configure the parameters of the feature.

   Example

   ```
   Device(config-wireless-profile-mesh)# fast-teardown
   ```

The wireless mesh profile is enabled and configured with the fast teardown feature.

```
Device# configure terminal
Device(config)# wireless profile mesh mesh1
Device(config-wireless-profile-mesh)# fast-teardown
```

Associate wireless mesh to an AP profile (CLI)

Learn how to associate a wireless mesh profile with an AP profile using CLI commands.

Associate a mesh profile with an AP profile to enable mesh capabilities on compatible APs through CLI configuration.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the AP profile to enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile default-ap-profile
   ```

3. In AP profile configuration mode, configure the mesh profile.

   Example

   ```
   Device(config-ap-profile)# mesh-profile mesh-profile-name
   ```

The AP profile now uses the specified mesh profile. All APs using this profile inherit mesh configuration parameters.

```
Device# configure terminal
Device(config)# ap profile default-ap-profile
Device(config-ap-profile)# mesh-profile test1
```

Verify mesh configuration

Verify mesh configuration.

Use these **show** commands to verify the various aspects of mesh configuration:

- **show wireless mesh stats** *ap-name*
- **show wireless mesh security-stats** {*all* | *ap-name*}
- **show wireless mesh queue-stats** {*all* | *ap-name*}
- **show wireless mesh per-stats summary** {*all* | *ap-name*}
- **show wireless mesh neighbor summary** {*all* | *ap-name*}
- **show wireless mesh neighbor detail** *ap-name*

- **show wireless mesh ap summary**
- **show wireless mesh ap tree**
- **show wireless mesh ap backhaul**
- **show wireless mesh config**
- **show wireless mesh convergence detail** *bridge-group-name*
- **show wireless mesh convergence subset-channels**
- **show wireless mesh neighbor**
- **show wireless profile mesh detailed** *mesh-profile-name*
- **show wireless stats mesh security**
- **show wireless stats mesh queue**
- **show wireless stats mesh packet error**
- **show wireless mesh ap summary**
- **show ap name** *ap-name* **mesh backhaul**
- **show ap name** *ap-name* **mesh neighbor detail**
- **show ap name** *ap-name* **mesh path**
- **show ap name** *ap-name* **mesh stats packet error**
- **show ap name** *ap-name* **mesh stats queue**
- **show ap name** *ap-name* **mesh stats security**
- **show ap name** *ap-name* **mesh stats**
- **show ap name** *ap-name* **mesh bhrate**
- **show ap name** *ap-name* **config ethernet**
- **show ap name** *ap-name* **cablemodem**
- **show ap name** *ap-name* **environment**
- **show ap name** *ap-name* **gps location**
- **show ap name** *ap-name* **environment**
- **show ap name** *ap-name* **mesh linktest data** *dest-mac*
- **show ap environment**
- **show ap gps location**

For details about these commands, see the *Cisco Catalyst 9800 Series Wireless Controller Command Reference* document.

MAC authorization

Use this **show** command to verify the MAC authorization configuration:

```
Device# show run aaa
aaa authentication dot1x CENTRAL_LOCAL local
aaa authorization credential-download CENTRAL_AUTHOR local
```

```
username 002cc8de4f31 mac
username 00425a0a53b1 mac

ewlc_eft#sh wireless profile mesh detailed madhu-mesh-profile

PSK provisioning

Use this **show** command to verify PSK provisioning configuration:

```
Device# show wireless mesh config
Mesh Config
  Backhaul RRM                                  : ENABLED
  Mesh CAC                                      : DISABLED
  Outdoor Ext. UNII B Domain channels(for BH)   : ENABLED
  Mesh Ethernet Bridging STP BPDU Allowed       : ENABLED
  Rap Channel Sync                              : ENABLED

Mesh Alarm Criteria
  Max Hop Count                                 :  4
  Recommended Max Children for MAP              : 10
  Recommended Max Children for RAP              : 20
  Low Link SNR                                  : 12
  High Link SNR                                 : 60
  Max Association Number                        : 10
  Parent Change Number                          :  3

Mesh PSK Config
  PSK Provisioning                              : ENABLED
  Default PSK                                   : ENABLED
  PSK In-use key number                         : 1
  Provisioned PSKs(Maximum 5)

  Index    Description
  ------   ------------
  1         key1
```

Bridge group name

Use this **show** command to verify the bridge group name configuration:

```
Device# show wireless profile mesh detailed abc-mesh-profile
Mesh Profile Name             : abc-mesh-profile
-----------------------------------------------
Description                   :
Bridge Group Name             : bgn-abc
Strict match BGN              : ENABLED
Amsdu                         : ENABLED
```

```
Background Scan                : ENABLED
Channel Change Notification    : DISABLED
Backhaul client access         : ENABLED
Ethernet Bridging              : ENABLED
Ethernet Vlan Transparent      : DISABLED
Full Sector DFS                : ENABLED
IDS                            : ENABLED
Multicast Mode                 : In-Out
Range in feet                  : 12000
Security Mode                  : EAP
Convergence Method             : Fast
LSC only Authentication        : DISABLED
Battery State                  : ENABLED
Authorization Method           : CENTRAL_AUTHOR
Authentication Method          : CENTRAL_LOCAL
Backhaul tx rate(802.11bg)     : auto
Backhaul tx rate(802.11a)      : 802.11n mcs15
```

Backhaul client access

Use this **show** command to verify the backhaul client access configuration:

```
Device# show wireless profile mesh detailed abc-mesh-profile
Mesh Profile Name              : abc-mesh-profile
-------------------------------------------------
Description                    :
Bridge Group Name              : bgn-abc
Strict match BGN               : ENABLED
Amsdu                          : ENABLED
Background Scan                : ENABLED
Channel Change Notification    : DISABLED
Backhaul client access         : ENABLED
Ethernet Bridging              : ENABLED
Ethernet Vlan Transparent      : DISABLED
...
Backhaul tx rate(802.11bg)     : auto
Backhaul tx rate(802.11a)      : 802.11n mcs15
```

Wireless backhaul data rate

Use this **show** command to verify the wireless backhaul data rate configuration:

```
Device# show wireless profile mesh detailed abc-mesh-profile
Mesh Profile Name              : abc-mesh-profile
-------------------------------------------------
Description                    :
Bridge Group Name              : bgn-abc
Strict match BGN               : ENABLED
...
Authorization Method           : CENTRAL_AUTHOR
Authentication Method          : CENTRAL_LOCAL
Backhaul tx rate(802.11bg)     : auto
Backhaul tx rate(802.11a)      : 802.11n mcs15
```

Dynamic frequency selection

Use this **show** command to verify the dynamic frequency selection configuration:

```
Device# show wireless profile mesh detailed abc-mesh-profile
Mesh Profile Name             : abc-mesh-profile
-------------------------------------------------
Description                   :
Bridge Group Name             : bgn-abc
Strict match BGN              : ENABLED
Amsdu                         : ENABLED
Background Scan               : ENABLED
Channel Change Notification   : DISABLED
Backhaul client access        : ENABLED
Ethernet Bridging             : ENABLED
Ethernet Vlan Transparent     : DISABLED
Full Sector DFS               : ENABLED
...
Backhaul tx rate(802.11a)     : 802.11n mcs15
```

Intrusion detection system

Use this **show** command to verify the wireless backhaul data rate configuration:

```
Device# show wireless profile mesh detailed abc-mesh-profile
Mesh Profile Name             : abc-mesh-profile
-------------------------------------------------
Description                   :
Bridge Group Name             : bgn-abc
Strict match BGN              : ENABLED
Amsdu                         : ENABLED
Background Scan               : ENABLED
Channel Change Notification   : DISABLED
Backhaul client access        : ENABLED
Ethernet Bridging             : ENABLED
Ethernet Vlan Transparent     : DISABLED
Full Sector DFS               : ENABLED
IDS                           : ENABLED
Multicast Mode                : In-Out
...
Backhaul tx rate(802.11a)     : 802.11n mcs15
```

Ethernet bridging

Use this **show** command to verify ethernet bridging configuration:

```
Device# show wireless profile mesh detailed abc-mesh-profile
Mesh Profile Name             : abc-mesh-profile
-------------------------------------------------
Description                   :
Bridge Group Name             : bgn-abc
Strict match BGN              : ENABLED
Amsdu                         : ENABLED
Background Scan               : ENABLED
Channel Change Notification   : DISABLED
Backhaul client access        : ENABLED
Ethernet Bridging             : ENABLED
Ethernet Vlan Transparent     : DISABLED
Full Sector DFS               : ENABLED
IDS                           : ENABLED
Multicast Mode                : In-Out
```

```
...
Backhaul tx rate(802.11a)     : 802.11n mcs15
```

Multicast over mesh

Use this **show** command to verify multicast over Mesh configuration:

```
Device# show wireless profile mesh detailed abc-mesh-profile
Mesh Profile Name             : abc-mesh-profile
-------------------------------------------------
Description                   :
Bridge Group Name             : bgn-abc
Strict match BGN              : ENABLED
Amsdu                         : ENABLED
Background Scan               : ENABLED
Channel Change Notification   : DISABLED
Backhaul client access        : ENABLED
Ethernet Bridging             : ENABLED
Ethernet Vlan Transparent     : DISABLED
Full Sector DFS               : ENABLED
IDS                           : ENABLED
Multicast Mode                : In-Out
...
Backhaul tx rate(802.11a)     : 802.11n mcs15
```

RRM on mesh backhaul

Use this **show** command to verify RRM on Mesh backhaul configuration:

```
Device# show wireless mesh config
Mesh Config
  Backhaul RRM                                    : ENABLED
  Mesh CAC                                        : DISABLED
  Outdoor Ext. UNII B Domain channels(for BH)     : ENABLED
  Mesh Ethernet Bridging STP BPDU Allowed         : ENABLED
  Rap Channel Sync                                : ENABLED

Mesh Alarm Criteria
  Max Hop Count                                   :  4
  Recommended Max Children for MAP                : 10
  Recommended Max Children for RAP                : 20
  Low Link SNR                                    : 12
  High Link SNR                                   : 60
  Max Association Number                          : 10
  Parent Change Number                            :  3

Mesh PSK Config
  PSK Provisioning                                : ENABLED
  Default PSK                                     : ENABLED
  PSK In-use key number                           : 1
  Provisioned PSKs(Maximum 5)

  Index    Description
  ------   ------------
  1         key1
```

Preferred parent selection

Use this **show** command to verify preferred parent configuration:

```
Device# show wireless mesh ap tree
=================================================================================
AP Name [Hop Ctr,Link SNR,BG Name,Channel,Pref Parent,Chan Util,Clients]
=================================================================================

[Sector 1]
-----------
1542-RAP [0, 0, bgn-madhu, (165), 0000.0000.0000, 1%, 0]
   |-MAP-2700 [1, 67, bgn-madhu, (165), 7070.8b7a.6fb8, 0%, 0]

Number of Bridge APs : 2
Number of RAPs : 1
Number of MAPs : 1

(*)  Wait for 3 minutes to update or Ethernet Connected Mesh AP.
(**) Not in this Controller
```

AP role change

Use this **show** command to verify AP role change configuration:

```
Device# show wireless mesh ap summary
AP Name                          AP Model BVI MAC        BGN        AP Role
-------                          -------- -------        ---        -------
1542-RAP                         1542D    002c.c8de.1338 bgn-abc  Root AP
MAP-2700                         2702I    500f.8095.01e4 bgn-abc  Mesh AP

Number of Bridge APs         :   2
Number of RAPs               :   1
Number of MAPs               :   1
Number of Flex+Bridge APs    :   0
Number of Flex+Bridge RAPs   :   0
Number of Flex+Bridge MAPs   :   0
```

Mesh leaf node

Use this **show** command to verify mesh leaf node configuration:

```
Device# show ap name MAP-2700 config general
Cisco AP Name   : MAP-2700
=================================================

Cisco AP Identifier                             : 7070.8bbc.d3e0

  PSK Provisioning                                  : ENABLED
  Default PSK                                       : ENABLED
  PSK In-use key number                             : 1
  Provisioned PSKs(Maximum 5)

  Index    Description
  ------   ------------
  1         key1
```

Provisioning LSC for bridge-mode and mesh APs

Use this **show** command to verify the provisioning LSC for Bridge-Mode and Mesh AP configuration:

```
Device# show wireless profile mesh detailed default-mesh-profile
Mesh Profile Name             : default-mesh-profile
-------------------------------------------------
```

```
Description                    : default mesh profile
Bridge Group Name              : bgn-abc
Strict match BGN               : DISABLED
Amsdu                          : ENABLED
Background Scan                : ENABLED
Channel Change Notification    : ENABLED
Backhaul client access         : ENABLED
Ethernet Bridging              : DISABLED
Ethernet Vlan Transparent      : ENABLED
Full Sector DFS                : ENABLED
IDS                            : DISABLED
Multicast Mode                 : In-Out
Range in feet                  : 12000
Security Mode                  : EAP
Convergence Method             : Fast
LSC only Authentication        : DISABLED
Battery State                  : ENABLED
Authorization Method           : default
Authentication Method          : default
Backhaul tx rate(802.11bg)     : auto
Backhaul tx rate(802.11a)      : auto
```

Specify backhaul slot for root AP

Use this **show** command to verify the backhaul slot for the Root AP configuration:

```
Device# show ap name 1542-RAP mesh backhaul
MAC Address : 380e.4d85.5e60
  Current Backhaul Slot: 1
  Radio Type: 0
  Radio Subband: All
  Mesh Radio Role: DOWNLINK
  Administrative State: Enabled
  Operation State: Up
  Current Tx Power Level:
  Current Channel: (165)
  Antenna Type: N/A
  Internal Antenna Gain (in .5 dBm units): 18
```

Use a link test on mesh backhaul

Use this **show** command to verify the use of link test on mesh backhaul configuration:

```
Device# show ap name 1542-RAP mesh linktest data 7070.8bbc.d3ef
380e.4d85.5e60 ==> 7070.8bbc.d3ef

Started at : 05/11/2020 20:56:28
Status: In progress

Configuration:
==============
Data rate:  Mbps
Packets per sec: : 234
Packet Size: : 1200
Duration: : 200
```

Mesh CAC

Use this **show** command to verify mesh CAC configuration:

```
Device# show wireless mesh config
Mesh Config
  Backhaul RRM                                    : ENABLED
  Mesh CAC                                        : DISABLED
  Outdoor Ext. UNII B Domain channels(for BH)     : ENABLED
  Mesh Ethernet Bridging STP BPDU Allowed         : ENABLED
  Rap Channel Sync                                : ENABLED

Mesh Alarm Criteria
  Max Hop Count                                   :  4

Mesh Authorization and Security

Covers MAC, EAP, and preshared-key authentication, certificate provisioning, and intrusion detection for mesh APs.

MAC authorization

MAC authorization controls whether a MAP can join a wireless controller by checking the AP's MAC address.

A MAC authorization is a security mechanism that

- restricts MAPs from joining a controller unless their MAC address is pre-approved
- ensures only authorized mesh APs participate in the wireless network, and
- can be handled using either an internal list or an external AAA server.

You must enter the MAC address of an AP in the controller for a MAP to join the controller. The controller responds only to CAPWAP requests from MAPs listed in its authorization list. Remember to use the MAC address provided on the back of the AP.

MAC authorization for MAPs connected to the controller over Ethernet occurs during the CAPWAP join process. For MAPs joining the controller over radio, MAC authorization occurs when the corresponding AP attempts to secure an adaptive wireless path protocol (AWPP) link with the parent MAP. AWPP operates as the protocol for Cisco mesh networks.

The Cisco Catalyst 9800 Series Wireless Controller supports MAC authorization internally as well as using an external AAA server.

Configure MAC authorization (GUI)

Configure MAC authorization using GUI.

Enable MAC-based authorization for wireless mesh networks. Specify which devices can connect by entering their MAC addresses.

Procedure

1. Choose **Configuration** > **Security** > **AAA** > **AAA Advanced** > **Device Authentication**.
2. Click **Add**.
   The **Quick Step: MAC Filtering** page is displayed.
3. In the **Quick Step: MAC Filtering** page, complete these steps:
   a) Enter the **MAC Address** . The MAC address can be in either *xx:xx:xx:xx:xx:xx* , *xx-xx-xx-xx-xx-xx* , or *xxxx.xxxx.xxxx* format.
   b) Choose the **Attribute List Name** from the drop-down list.
   c) Choose the **WLAN Profile Name** from the drop-down list.
   d) Click **Apply to Device**.

   Both WebUI and CLI support MAC user configuration in these formats: xxxxxxxxxxxx, xx:xx:xx:xx:xx:xx, xx-xx-xx-xx-xx-xx, or xxxx.xxxx.xxxx. The AP sends the default MAC address without any delimiter. If the MAC address is configured with a delimiter, AP authorization fails unless it uses the xxxxxxxxxxxx format.
4. Choose **Configuration** > **Security** > **AAA** > **AAA Method List** > **Authorization**.
5. Click **Add**.
   The **Quick Step: AAA Authorization** window is displayed.
6. In the **Quick Step: AAA Authorization** page, complete these actions:
   a) Enter the **Method List Name**.
   b) Choose the **Type** from the drop-down list.
   c) Choose the **Group Type** from the drop-down list.
   d) Check the **Fallback to Local** check box.
   e) Check the **Authenticated** check box.
   f) Move the required servers from the **Available Server Groups** to the **Assigned Server Groups.**
   g) Click **Apply to Device**.
7. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
8. Click the mesh profile.
   The **Edit Mesh Profile** page is displayed.
9. Click the **Advanced** tab.
10. In the **Security** settings, from the **Method** drop-down list, choose **EAP**.
11. Choose the **Authentication Method** from the drop-down list.
12. Choose the **Authorization Method** from the drop-down list.
13. Click **Update & Apply to Device**.

Authorized devices with the specified MAC addresses can connect to the wireless mesh network.

Configure MAC authorization (CLI)

Use this procedure to configure MAC authorization for bridge mode access points (APs) using CLI commands on the controller.

Enable MAC authorization for bridge mode APs by configuring the credentials and authorization methods needed.

Add the MAC address of a bridge mode AP to the controller to allow authentication.

Before you begin

- MAC filtering for bridge mode APs is enabled by default on the controller. Configure only the MAC address. Find the MAC address on the back of the AP.
- MAC authorization is supported using both internal and external AAA servers.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure username authentication for MAC filtering, using the MAC address as the username.

   Example

   ```
   Device(config)# username user-name
   ```

3. Set the authorization method list to use local credentials.

   Example

   ```
   Device(config)# aaa authorization credential-download method-name local
   ```

4. Set the authorization method list to use a RADIUS server group. The command supports up to 14 lines.

   Example

   ```
   Device(config)# aaa authorization credential-download method-name radius group
    server-group-name
   ```

5. Configure a mesh profile to access mesh profile configuration mode.

   Example

   ```
   Device(config)# wireless profile mesh mesh-profile-name
   ```

6. Configure the authorization method for mesh APs.

   Example

   ```
   Device(config-wireless-mesh-profile)# method authorization method-name
   ```

You have successfully configured MAC authorization for bridge mode access points using the CLI on the controller.

```
Device# configure terminal
Device(config)# username username1
Device(config)# aaa authorization credential-download list1 local
Device(config)# aaa authorization credential-download auth1 radius group
radius-server-1
```

```
Device(config)# wireless profile mesh mesh-profile
Device(config-wireless-mesh-profile)# method authorization auth1
```

EAP authentication

EAP authentication methods are used to provide secure user and device authentication to wireless networks.

A EAP authentication is a wireless network authentication method that

- allows users and wireless clients to be authenticated locally on a controller
- removes dependence on external authentication servers, and
- supports additional modules such as LSC-based authentication for enhanced security.

Use Local EAP in remote offices to maintain connectivity during backend disruptions. The controller acts as both a server and a user database, retrieving user credentials locally or through LDAP. Local EAP supports the EAP-FAST method for MAP authentication.

An LDAP backend database allows the controller to query an LDAP server for the credentials (username and password) of a particular user. The controller uses these credentials to authenticate the user.

> **Note**
>
> If you configure RADIUS servers on the controller, it will first authenticate the wireless clients using those servers. Local EAP is attempted only if RADIUS servers are not found, timed out, or were not configured.

Locally significant certificate-based (LSC) EAP authentication

A locally significant certificate-based authentication is a WLAN security method that

- authenticates network devices (such as APs and controllers) using locally generated digital certificates
- allows both locally significant certificates (LSCs) and manufacturing installed certificates (MICs) to coexist (with LSCs taking precedence), and
- supports advanced security features, like mesh EAP authentication and master session key generation.

LSC-based EAP authentication requires a public key infrastructure (PKI). This establishes certification authorities, defines policies, and sets validity periods and restrictions.

Certificates (LSCs) must be generated and installed on Access Points and controllers. If an Access Point is provisioned with an LSC, the MIC certificate is not used during boot-up. Changes from LSC to MIC require the Access Point to reboot. LSC-based EAP authentication is supported for mesh Access Points (MAPs). The controller supports mesh security with EAP authentication to a designated server to authenticate mesh child Access Points and generate master session keys for packet encryption.

If a customer installs an LSC (certificate they generate), the AP will use that certificate for authentication and not the factory-installed MIC. Mesh child APs can use LSC EAP authentication to securely join the network and establish encrypted sessions.

The controller also supports mesh security with EAP authentication to a designated server in order to:

- Authenticate the mesh child AP
- Generate a master session key (MSK) for packet encryption.

Configure MAP authorization - EAP (GUI)

Configure MAP authorization - EAP using GUI.

Enable secure authentication for mesh access points by configuring MAP authorization to use EAP (Extensible Authentication Protocol) through the graphical user interface (GUI).

Procedure

1. Choose **Configuration** > **Security** > **AAA** > **AAA Method List** > **Device Authentication**.
2. Click **Add**.
3. Enter **Method List Name**.
4. Choose **Type** as dot1x and **Group Type** from the drop-down lists.
5. Check or uncheck the **Fallback to Local** check box.
6. Move the required servers from the **Available Server Groups** to the **Assigned Server Groups.**
7. Click **Apply to Device**.
8. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
9. Click the mesh profile. The **Edit Mesh Profile** page is displayed.
10. Choose the **Advanced** tab.
11. In the **Security** settings, from the **Method** drop-down list, choose **EAP**.
12. Choose the options from the **Authentication Method** and **Authorization Method** drop-down lists.
13. Click **Update & Apply to Device**.

MAP authorization with EAP is now active for the selected mesh profile.

Configure MAP authorization (CLI)

Use this procedure to configure MAP authorization with EAP or PSK authentication for mesh access points using CLI commands.

Set up mesh access point (MAP) authentication for mesh access points using either Extensible Authentication Protocol (EAP) or Pre-Shared Key (PSK) methods.

Select and configure an authentication method—EAP or PSK—for MAP authentication.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set an authentication method list to use a RADIUS server group. This is required for EAP authentication.

   Example

   ```
   Device(config)# aaa authentication dot1x method-name radius group
   server-group-name
   ```

For local authentication:

```
Device(config)# aaa authentication dot1x auth1 local
```

3. Set an authorization method list to use local credentials.

   Example

   ```
   Device(config)# wireless profile mesh profile-name local
   ```

4. Configure the mesh security EAP or PSK for mesh AP.

   Example

   ```
   Device(config-wireless-mesh-profile)# security eap server-group-name
   ```

5. Configure the authentication method for mesh AP authentication.

   Example

   ```
   Device(config-wireless-mesh-profile)# method authentication method-name
   ```

You have configured MAP authorization for mesh access points using your chosen authentication method (EAP or PSK).

```
Device# configure terminal
Device(config)# aaa authentication dot1x auth1 local
Device(config)# wireless profile mesh mesh1
Device(config-wireless-mesh-profile)# security eap / psk
Device(config-wireless-mesh-profile)# method authentication auth1
```

Preshared key provisioning

PSKs allow for controlled mesh deployments and enhance MAPs security beyond the default configuration.

A preshared key (PSK) is a mesh security credential that

- provides authentication between Mesh Access Points (MAPs), RAPs, and controllers
- allows for custom configuration to restrict network access, and
- enhances security compared to default or wildcard provisioning based on MAC addresses.

In mesh deployments, the MAPs might leave the network and join other mesh networks if both mesh deployments use AAA with wildcard MAC filtering to allow MAP association.

Since MAPs might use EAP-FAST, you cannot control this because EAP uses a combination of MAC address and AP type for authentication, and there are no controlled configuration options available. If you use the PSK option with a default pass phrase, you create a security risk.

This issue frequently occurs in overlapping deployments of two service providers when MAPs are used in moving vehicles, such as ferries, ships, or other public transportation.

In these scenarios, your MAPs are not restricted to your service provider mesh network. As a result, another service provider's network can hijack MAPs, preventing them from serving your customers.

The PSK key provisioning feature enables network administrators to assign unique preshared keys from the controller to MAPs. This ensures that only authorized MAPs can authenticate to specific RAPs and controllers. These measures prevent accidental or malicious association with unauthorized mesh networks and protect service provider deployments.

Configure PSK provisioning (CLI)

Use this procedure to configure a pre-shared key (PSK) for wireless mesh access points using CLI commands. This enables secure authentication for mesh APs, and streamlines the provisioning process.

When you enable PSK provisioning, your APs join using the default PSK. After you set the PSK provisioning key, the system pushes the configured key to each newly joined AP.

Complete these steps to configure a PSK:

Before you begin

Confirm that you have pushed the provisioned PSK to every AP configured with PSK as mesh security.

Note

- PSKs are saved across reboots in the controller as well as on the corresponding mesh AP.
- A controller can have a total of five PSKs and one default PSK.
- A mesh AP deletes the provisioned PSK only during a factory reset.
- A mesh AP never uses the default PSK after receiving the first provisioned PSK.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the security method for wireless as PSK.

   Example

   ```
   Device(config)# wireless mesh security psk provisioning
   ```

   Note

   The controller pushes the provisioned PSK only to APs configured with PSK as the mesh security method.

3. Configure a new PSK for mesh APs.

Example

```
Device(config)# wireless mesh security psk provisioning key index {0 | 8}
preshared-key description
```

4. Enable default PSK-based authentication.

Example

```
Device(config)# wireless mesh security psk provisioning default-psk
```

5. Specify the PSK to be actively used.

Example

```
Device(config)# wireless mesh security psk provisioning inuse index
```

> **Note**
>
> You should explicitly specify the in-use key index in the global configuration to point to the PSK index.

The controller provisions the specified pre-shared key on the mesh APs, sets the active key, and distributes it accordingly.

```
Device# configure terminal
Device(config)# wireless mesh security psk provisioning
Device(config)# wireless mesh security psk provisioning key 1 0 secret
secret-key
Device(config)# wireless mesh security psk provisioning default-psk
Device(config)# wireless mesh security psk provisioning inuse 1
```

Provision LSC for bridge-mode and mesh APs (GUI)

Use this procedure to provision Local Significant Certificates (LSC) for bridge-mode and mesh APs using the graphical user interface.

Provision LSCs. This action secures communication for bridge-mode and mesh APs.

Procedure

---

1. Choose **Configuration** > **Wireless** > **Access Points** > **LSC Provision**.
2. In the **Add APs to LSC Provision List** settings, click the **Select File** option to upload a CSV file that contains AP details.
3. Click **Upload File**.
4. You can also use the **AP MAC Address** field to search for APs by MAC address and add them. The system displays APs added to the provision list in the **APs in Provision List** list.
5. Click **Apply**.
6. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
7. Click **Add**.

8. In the **General** tab, enter the **Name** of the mesh profile and check the **LSC** check box.
9. In the **Advanced** tab, under the **Security** settings, choose the authorization method from the **Authorization Method** drop-down list.
10. Click **Apply to Device**.

The system successfully applies LSC provisioning to the specified bridge-mode and mesh APs.

Provision LSC for bridge-mode and mesh APs

Provision Locally Significant Certificates (LSC) for bridge-mode and mesh Access Points (APs) using CLI commands.

- Configuring a Locally Significant Certificate (LSC) will not remove preexisting certificates from an AP.
- An AP can have both LSC and Message Integrity Check (MIC) certificates. However, when you provision an AP with LSC, the MIC certificate is not used when the AP starts. If you switch from LSC to MIC, reboot the AP.

To configure LSC for bridge-mode and mesh APs, use this procedure:

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure LSC provisioning for an AP.

   Example

   ```
   Device(config)# ap lsc-provision
   ```

   Note

   This step is applicable only for mesh APs.

3. Optional: Configure LSC provisioning for all APs in the provision list.

   Example

   ```
   Device(config)# ap lsc-provision provision-list
   ```

4. Configure a named authorization list to download EAP credentials from the RADIUS group server.

   Example

   ```
   Device(config)# aaa authentication dot1x auth-list radius group
   radius-server-grp
   ```

5. Create a mesh profile to enter mesh profile configuration mode.

   Example

   ```
   Device(config)# wireless profile mesh mesh-profile-name
   ```

6. Set mesh security for LSC-only MAP authentication.

   Example

   ```
   Device(config-wireless-mesh-profile)# lsc-only-auth
   ```

   All the mesh APs reboot after you run this command.

7. Configure an authorization method for mesh APs.

   Example

   ```
   Device(config-wireless-mesh-profile)# method authorization local
   ```

All bridge-mode and mesh APs are provisioned with Locally Significant Certificates (LSC).

```
Device# configure terminal
Device(config)# ap lsc-provision
Device(config)# ap lsc-provision provision-list
Device(config)# aaa authentication dot1x list1 radius group sg1
Device(config)# wireless profile mesh mesh1
Device(config-wireless-mesh-profile)# lsc-only-auth
Device(config-wireless-mesh-profile)# method authorization list1
```

Intrusion detection system

This concept explains how intrusion detection systems protect computer networks by monitoring, detecting, and responding to unauthorized or malicious activities to enhance network security.

Cisco Intrusion Detection System/Intrusion Prevention System (CIDS/CIPS) is a network security solution that

- monitors network traffic and system activities for signs of suspicious behavior
- detects and classifies potential security threats such as malware or unauthorized access, and
- responds to attacks or alerts administrators to enable prevention or mitigation actions.

CIDS can block specific clients from your wireless network if it detects attacks involving them in network layers 3 to 7. This feature helps you detect, classify, and stop threats such as worms, spyware, adware, network viruses, and application abuse.

Configure the intrusion detection system (CLI)

Learn how to configure intrusion detection system reporting for mesh APs using CLI commands.

Enable intrusion detection system monitoring and reporting on mesh APs to enhance network security.

When enabled, the intrusion detection system generates reports for all client access traffic. This feature does not apply to backhaul traffic.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile and enter mesh profile configuration mode.

   Example

   ```
   Device(config)# wireless profile mesh profile-name
   ```

3. Configure intrusion detection system reporting for mesh APs.

   Example

   ```
   Device(config-wireless-mesh-profile)# ids
   ```

The device is now configured to report intrusion detection events for mesh APs.

```
Device# configure terminal
Device(config)# wireless profile mesh mesh-ids
Device(config-wireless-mesh-profile)# ids
```

Bridge group names

Explains how bridge group names organize mesh APs and manage parent-child associations, including procedures for configuring bridge group names through both GUI and CLI interfaces.

A bridge group name (BGN) is a mesh network configuration parameter that

- controls the association of Mesh Access Points (MAPs) to a parent mesh AP
- allows logical grouping of radios to isolate different networks on the same channel, and
- allows MAPs to join networks before you assign a custom BGN.

BGNs can logically group radios to avoid two networks on the same channel from communicating with each other. The setting is useful when your network contains multiple RAPs in the same sector (area). A BGN is a string containing up to 10 characters.

A BGN of *NULL VALUE* is assigned by default during manufacturing. This value is not visible to you, but it allows a MAP to join the network before you assign a network-specific BGN.

If you have two RAPs in your network in the same sector, we recommend that you configure the two RAPs with the same BGN, on different channels.

When Strict Match BGN is enabled on a MAP, the MAP scans ten times to find a matching BGN parent. If the AP does not find a parent with a matching BGN after ten scans, it connects to a nonmatching BGN and maintains the connection for 15 minutes. After 15 minutes, the AP scans ten times again, and this cycle continues. The default BGN functionality does not change when Strict Match BGN is enabled.

In Cisco Catalyst 9800 Series Wireless Controller, the BGN is configured on the mesh profile. When a MAP joins the controller, the system pushes the configured BGN on the mesh profile to the AP.

Preferred parent selection

A preferred parent selection is a mesh network configuration method that

- enables enforcement of linear topology in a mesh environment
- allows administrators to override the AWPP-defined (Adaptive Wireless Path Protocol) parent selection algorithm, and
- supports explicit specification of the uplink path for the MAP in mesh deployments.

For Cisco Wave 1 APs, when you configure a preferred parent, ensure that you specify the MAC address of the actual mesh neighbor for the desired parent. This MAC address is the base radio MAC address that has the letter "f" as the final character. For example, if the base radio MAC address is 00:24:13:0f:92:00, then you must specify 00:24:13:0f:92:0f as the preferred parent.

```
Device# ap name ap1 mesh parent preferred 00:24:13:0f:92:0f
```

For Cisco Wave 2 APs, when you configure a preferred parent, the MAC address is the base radio MAC address that has "0x11" added to the last two characters. For example, if the base radio MAC address is 00:24:13:0f:92:00, then you must specify 00:24:13:0f:92:11 as the preferred parent.

```
Device# ap name ap1 mesh parent preferred 00:24:13:0f:92:11
```

Configure a bridge group name (GUI)

Configure a bridge group name using GUI.

Configure a bridge group name to organize and manage wireless mesh network profiles efficiently.

Procedure

1. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
2. Click **Add**.
3. In the **Advanced** tab, under the **Bridge Group** settings, enter the **Bridge Group Name**.
4. Under the **Bridge Group** settings, check the **Strict Match** check box to enable the feature. The MAP scans ten times to find a matching BGN parent when you enable **Strict Match** BGN.
5. Click **Apply to Device**.

The system assigns and applies a new bridge group name to the mesh profile you selected.

Configure a bridge group name (CLI)

Use this procedure to configure a bridge group name on an AP using CLI commands.

Configure a bridge group name (BGN) for a mesh profile on a wireless LAN controller using CLI commands.

- If a BGN is configured on a mesh profile, whenever a MAP joins the controller, it pushes the BGN configured on the mesh profile to the AP.
- Whenever a mesh AP moves from AireOS controller to the Cisco Catalyst 9800 Series Wireless Controller, the BGN configured on the mesh profile is pushed to that AP and stored there.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile and enter mesh profile configuration mode.

   Example

   ```
   Device(config)# wireless profile mesh mesh-profile-name
   ```

3. Configure a bridge group name.

   Example

   ```
   Device(config-wireless-mesh-profile)# bridge-group name bridge-grp-name
   ```

4. Configure bridge group strict matching.

   Example

   ```
   Device(config-wireless-mesh-profile)# bridge-group strict-match
   ```

The bridge group name is assigned to the mesh profile and applied to all associated mesh APs.

```
Device# configure terminal
Device(config)# wireless profile mesh mesh-profile-bgn
Device(config-wireless-mesh-profile)# bridge-group name bgn-grp-name
Device(config-wireless-mesh-profile)# bridge-group strict-match
```

Mesh background scanning

Describes background channel scanning and MAP fast ancestor find mode for rapid failover, including configuration and verification procedures through both GUI and CLI.

A mesh background scan is a mesh networking feature that

- enables mesh access points (MAPs) to find and connect to better potential parents across channels
- maintains stable uplinks by proactively scanning for available parent nodes, and
- reduces reconnection delay after parent loss by using a neighbor list instead of scanning all channels.

When background scanning is disabled, a MAP has to scan all the channels of the regulatory domain after detecting a parent loss in order to find a new parent and go through the authentication process. This delays the time taken for the mesh AP to connect back to the controller.

When background scanning is enabled, a MAP can avoid scanning across the channels to find a parent after detecting a parent loss, and select a parent from the neighbor list and establish the Adaptive Wireless Path Protocol (AWPP) link.

Background scanning and MAP fast ancestor find mode

Describes mechanisms that optimize MAP connectivity and parent selection in Cisco mesh wireless networks.

Background scanning and MAP fast ancestor finding are features that

- optimize MAP connectivity and parent selection in Cisco mesh wireless networks
- minimize mesh tree convergence time when MAPs lose connectivity with their parents, and
- reduce the need for beacon transmission during network formation.

Background scanning and MAP fast ancestor finding details

Cisco mesh access points (MAPs) perform the following functions:

- Interconnects over wireless links in a tree topology,
- Uses Adaptive Wireless Path Protocol (AWPP) to create and maintain their topology, and
- Supports additional features: Background Scanning and MAP Fast Ancestor Finding.

When a MAP comes up, it tries to look for another MAP (parent) to join and reach the gateway through a RAP. The same happens when a MAP loses connectivity with its existing parent. This procedure is known as mesh tree convergence.

The Background scanning feature:

- Updates MAPs about neighboring channels and helps find new parents swiftly by scanning all available channels.
- Minimizes the time spent during scan-and-seek phases when a MAP loses its current parent.
- Does not speed up the authentication process to the new parent.

A child MAP maintains its uplink with its parent by using the AWPP adjacency request/response messages, which act as keepalive signals. If consecutive response messages are lost, the parent is considered lost, and the child MAP searches for a new parent. A MAP maintains a list of neighbors ON the current ON channel. If the AP loses its current parent, it roams to the next best potential neighbor. If no other neighbors are found, the AP scans or seeks across all the channels or subset channels to find a parent. This process is time-consuming.

The MAP Fast Ancestor Finding feature enables a method to reduce the need for sending or receiving beacons during network formation, while starting or deploying a new mesh network.

Configure background scanning (GUI)

Configure background scanning using GUI.

Enable background scanning on a wireless mesh profile to improve network performance and reliability.

Procedure

1. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
2. Select your desired profile.
3. In **General** tab, check the **Background Scanning** check box.
4. Click **Update & Apply to Device**.

You have activated background scanning for the selected wireless mesh profile.

Configure background scanning

Use this procedure to configure background scanning in mesh deployments so that mesh access points (MAPs) can scan neighboring channels to find better parent nodes and maintain optimal uplink connections.

To enable background scanning in mesh deployments so that mesh access points (MAPs) can detect neighboring channels and identify better parent nodes, maintaining optimal uplink connections.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile and enter the mesh profile configuration mode.

   Example

   ```
   Device(config)# wireless profile mesh mesh-profile-name
   ```

3. Configure background scanning to enable mesh access points to find better parent nodes and maintain optimal connections.

   Example

   ```
   Device(config-wireless-mesh-profile)# background-scanning
   ```

Background scanning is enabled in the mesh profile. Mesh APs scan neighboring channels to find better parent nodes. This helps maintain optimal uplink performance in the mesh network.

```
Device# configure terminal
Device(config)# wireless profile mesh mesh-profile-name
Device(config-wireless-mesh-profile)# background-scanning
```

Configure AP fast ancestor find mode (GUI)

Configure AP fast ancestor find mode using GUI.

Enable a child MAP to synchronize with any neighbor parent MAP across all channels.

Use the GUI to configure the MAP Fast Ancestor Find feature within a mesh profile.

Follow these steps to configure AP fast ancestor find mode through the GUI:

Procedure

1. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
2. Click **Add**.
   The **Add Mesh Profile** page is displayed.
3. In the **Add Mesh Profile** page, click the **General** tab.

4. In the **Name** field, enter the mesh profile name.
5. In the **Description** field, enter a description for the mesh profile.
6. Check the **MAP Fast Ancestor Find** check box to enable a MAP (child) to synchronize with any neighbor MAP (parent) across all channels.
7. Click **Apply to Device** to save the configuration.

The MAP Fast Ancestor Find feature is enabled for the specified mesh profile.

Configure background scanning and MAP fast ancestor find mode (Task)

Configure background scanning and MAP fast ancestor find mode using commands.

Configure background scanning and MAP fast ancestor find mode using the CLI within a mesh profile for detailed configuration options.

Follow these steps to configure background scanning and MAP fast ancestor find mode through the CLI:

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile and enter mesh profile configuration mode.

   Example

   ```
   Device# wireless profile mesh default-mesh-profile
   ```

3. Enable background scanning in mesh deployments.

   Example

   ```
   Device(config-wireless-mesh-profile)# background-scanning
   ```

   > **Note**
   >
   > In Cisco Catalyst 9124 Series Access Points, a dedicated RF ASIC radio is used for background scanning.

4. Enable fast ancestor find mode.

   Example

   ```
   Device(config-wireless-mesh-profile)# map-fast-ancestor-find
   ```

Background scanning and MAP fast ancestor find mode are enabled for the specified mesh profile.

Example

```
Device# configure terminal
Device# wireless profile mesh default-mesh-profile
Device(config-wireless-mesh-profile)# background-scanning
Device(config-wireless-mesh-profile)# map-fast-ancestor-find
```

Verify background scanning and MAP fast ancestor find

Provides verification methods for background scanning and MAP Fast Ancestor Find features.

To verify whether the Background Scanning and MAP Fast Ancestor Find features are enabled, run the **show wireless profile mesh detailed** command.

To verify the background scan, use this command:

```
Device# show wireless profile mesh detailed Mesh_Profile | i Background Scan
Background Scan               : ENABLED
```

To verify MAP Fast Ancestor Find, use this command:

```
Device# show wireless profile mesh detailed Mesh_Profile | i MAP fast ancestor
 find
MAP fast ancestor find        : ENABLED
```

Mesh serial backhaul

Covers wireless and serial backhaul operation, client access, radio selection, enabling serial backhaul in radio profiles, and verification for robust mesh connectivity options.

A mesh serial backhaul is a wireless mesh networking feature that

- enables separate uplink and downlink channels on dedicated radios to improve backhaul bandwidth
- allows inbound and outbound traffic to use exclusive communication paths for better performance (one radio is used as the uplink radio and a different one is used as the downlink radio), and
- supports universal access by extending network reach and avoiding shared-channel interference.

The Mesh Serial Backhaul feature is supported in the controller from Cisco IOS XE Cupertino 17.7.1 onwards for Cisco Catalyst 9124AXE outdoor APs. To enable this feature, associate a radio profile with a radio frequency (RF) tag. When you enable this feature, all APs with the same mesh profile share the mesh configuration. All APs with the same radio profile share the radio configuration.

The 2.4-GHz and 5-GHz radios, which are not used in serial backhaul, provide basic client access functionality. The downlink radio provides universal access.

> **Note**
>
> Slot 1 and slot 0 are supported as mesh backhaul. Slot 2 is not supported as a mesh backhaul. You can utilize slot 2 for client serving or for serial backhaul downlink.

Channel assignment

For the Mesh Serial Backhaul feature, channels are assigned according to these rules:

- Uplink and downlink channels are different.
- All the 5-GHz radios maintain a frequency guard between their operating channels. For example, 100-MHz channel spacing between radios in Cisco Catalyst 9124AXE outdoor APs.
- Dynamic Frequency Selection (DFS) channels are supported.

In a root access point, the controller assigns channels because the uplink is wired. A mesh access point uses the last channel configured by the controller for this radio or uses the default channel. If the channel used by the MAP is not compatible with the uplink, the MAP picks a valid random channel and notifies the controller. In another scenario, when the MAP receives a channel change alert on the uplink radio, it randomly picks a new downlink channel. The MAP checks the validity of the downlink radio. If the current channel is not compatible, the MAP picks a random channel.

Prerequisites for channel assignment

Ensure that these prerequisites are met before channel assignment:

- Enable tri-radio globally by running the **Device# ap tri-radio** command.
- Enable the dual radio on the APs by running the **Device# ap name** *ap-name* **dot11 5ghz dual-radio mode enable**command.

Use cases

These are some of the use cases for the Mesh Serial Backhaul feature:

- **Maximize throughput** : Serial backhaul allows the 5-GHz backhaul to operate on different channels, thereby maximizing throughput over multiple mesh hops.
- **Network segregation**: APs that have serial backhaul enabled, segregate backhaul channel on mesh topographies. This avoids localized link interferences.

Enable serial backhaul in radio profile (GUI)

Enable serial backhaul in radio profile using GUI.

Enable mesh backhaul features on a specific radio profile to support serial backhaul in mesh deployments.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF/Radio** > **Radio**.
2. Click **Add** to add a radio profile.
   The **Add Radio Profile** page is displayed.
3. In the **Add Radio Profile** page, enter the name, and description.
4. In the **Mesh Backhaul** field, choose the **Enabled** radio button to enable the feature.

5. In the **Mesh Designated Downlink** field, choose the **Enabled** radio button to enable the feature.

> **Note**
>
> Mesh Designated Downlink is supported only on slot number 2 of Mesh APs. Radio profiles must be matched carefully to RF tag slots.

6. Click **Apply to Device**.

The radio profile is updated, enabling serial backhaul for selected mesh APs.

Enable mesh configurations in radio profile (CLI)

Enable mesh configurations in radio profile using commands.

Configure your Cisco wireless AP to enable mesh backhaul and designate downlink radio slots in a radio profile.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure wireless radio profile and enter the radio-profile configuration mode.

Example

```
Device(config)# wireless profile radio radio-profile-name
```

3. Enable mesh backhaul.

Example

```
Device(config-wireless-radio-profile)# mesh backhaul
```

By default, this command is enabled. Mesh backhaul can be disabled on a specific slot, to stop the specific slot from being the backhaul candidate.

4. Enable the radio slot as a designated downlink.

Example

```
Device(config-wireless-radio-profile)# mesh designated downlink
```

By default, this command is disabled. It is enabled only for slot 2 of mesh APs. If another slot is configured as the designated downlink, a warning message appears: `Designated downlink is supported only on slot 2 of mesh APs. Associate in the RF tag accordingly.`

By default, all the radio slots are mesh-enabled and not designated as downlink.

The mesh backhaul and designated downlink configurations are now applied to your selected radio profile.

Enable serial backhaul (CLI)

Learn how to configure a wireless profile to designate a radio as a mesh downlink backhaul.

Configure a wireless profile to designate a radio as a mesh downlink backhaul.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the wireless RF tag to enter wireless RF tag profile configuration mode.

   Example

   ```
   Device(config)# wireless profile radio radio-profile-name
   ```

3. Enable the specified radio as a designated mesh downlink backhaul.

   Example

   ```
   Device(config-wireless-radio-profile)# mesh designated downlink
   ```

   The designated downlink is enabled in the radio profile only for slot 2.

4. Exit the submode and return to global configuration mode.

   Example

   ```
   Device(config-wireless-radio-profile)# exit
   ```

5. Configure the wireless RF tag to enter wireless RF tag profile configuration mode.

   Example

   ```
   Device(config)# wireless tag rf rf-profile-name
   ```

   The designated downlink is enabled in the radio profile only for slot 2.

6. Configure the designated downlink radio for serial backhaul.

   Example

   ```
   Device(config-wireless-rf-tag)# dot11 5ghz {slot1 | slot2} radio-profile
   radio-profile-name
   ```

> **Note**
>
> In mesh APs, the uplink and downlink are in the same slot by default. When you configure a designated downlink, the mesh AP is forced to use a specific radio as downlink.

The specified radio is now configured as a designated mesh downlink, and the mesh AP is forced to use that radio for downlink backhaul.

Fallback Mode

> **Note**
>
> If you configure at least one radio as a designated downlink, that radio will not be available for uplink. To prevent a configuration mistake, such as configuring the uplink radio as the designated downlink, the mesh AP uses a fallback timer. If the mesh AP cannot join the controller within 10 minutes, the designated configurations are cleared, and all radios become uplink-capable.

```
Device# configure terminal
Device(config)# wireless profile radio radio-mesh-downlink
Device(config-wireless-radio-profile)# mesh designated downlink
Device(config-wireless-radio-profile)# exit
Device(config)# wireless tag rf radio profile rf-map-tag
Device(config-wireless-rf-tag)# dot11 5ghz slot2 radio-profile
radio-mesh-downlink
```

Mesh serial backhaul - configuration example

This section presents commands for configuring mesh APs to enable only slot 0 and slot 1 for backhaul use.

This example explains how to configure mesh APs to allow only slot 0 and slot 1 for backhaul connectivity:

```
Device# configure terminal
Device(config)# wireless profile radio radio-mesh-downlink
Device(config-wireless-radio-profile)# no mesh backhaul
Device(config-wireless-radio-profile)# exit
```

```
Device(config)# wireless tag rf rf-map-tag
Device(config-wireless-rf-tag)# dot11 5ghz slot2 radio-profile mesh-disabled
```

Verify mesh serial backhaul

Lists commands to verify mesh serial backhaul configuration and status.

This reference provides commands to verify mesh AP serial backhaul configuration and operational status on wireless devices.

To verify mesh AP serial backhaul, run this command:

```
Device# show ap name MAP-SB config slot 2 | inc Mesh
Mesh Radio Role : Downlink Access
Mesh Backhaul : Enabled
Mesh Designated Downlink : Enabled
```

To verify serial backhaul enabled on a specific AP, run this command:

```
Device# show ap name MAP-SB mesh backhaul
MAC Address : 4cxx.4dxx.f4xx
Current Backhaul Slot: 1
Radio Type: Main
Radio Subband: All
Mesh Radio Role: Uplink Access <<<<<<
Administrative State: Enabled
Operation State: Up
Current Tx Power Level: 6
Current Channel: (104) <<<<<<
Antenna Type:
Internal Antenna Gain (in .5 dBm units): 1
MAC Address : 4cxx.4dxx.f4xx
Current Backhaul Slot: 2
Radio Type: Slave
Radio Subband: All
Mesh Radio Role: Downlink Access <<<<<<
Administrative State: Enabled
Operation State: Up
Current Tx Power Level: 8
Current Channel: (149) <<<<<<
Antenna Type:
Internal Antenna Gain (in .5 dBm units): 1
```

To verify mesh serial backhaul, run this command:

```
Device# show wireless profile radio detailed radio-mesh-downlink
Radio Profile name                              : radio-mesh-downlink
Description                                     :
Beam-Selection                                  : Not configured
Number of antenna to be enabled                 : 0
Mesh Backhaul                                   : Enabled
Mesh Designated Downlink                        : Enabled
```

Mesh backhaul RRM

Explains how mesh backhaul RRMs optimize wireless mesh network performance by dynamically selecting the best backhaul channels and reducing interference.

A mesh backhaul RRM is a wireless network optimization mechanism that

- continuously evaluates channel conditions to identify the least congested backhaul channels
- reduces interference and enhances mesh network stability, and
- automates channel selection for root and mesh access points (APs).

Root access points (RAPs) choose backhaul channels to operate in mesh networks. Until Cisco IOS XE Cupertino 17.8.1, this operation occurred by an explicit configuration, a least congested scan during RAP boot time, during the initial radio resource management (RRM) run without mesh access points (MAPs) connected, or a backhaul channel that was chosen at random. As a result, a poor backhaul channel selection resulted in poor performance.

From Cisco IOS XE Cupertino 17.9.1 onwards, RRM DCA is run on mesh backhaul, in auto mode, in FlexConnect or centralized networks. For APs that do not have dedicated (RHL) radios, DCA is triggered by running commands in the privilege EXEC mode.

RRM continuously evaluates the channel conditions to ensure that the network utilizes the least congested channels. The network uses the transmission static power if it is configured, or falls back to the default level. This is supported on APs that have dedicated radios to scan channel conditions, without any user perceptible interruption to the mesh network traffic.

In the mesh backhaul RRM feature, the RRM DCA decides all the downlink channels in a steady network. However, if an AP detects a change in its uplink roam or radar detection response, the AP chooses the best downlink to converge faster.

APs choosing the best possible downlink is limited to serial backhaul enabled APs only.

To avoid a poor channel backhaul selection, from Cisco IOS XE Dublin 17.14.1 onwards, the RRM DCA optimizes the RAP backhaul radio channel of a mesh subtree by considering the noise, interference, load, and the RF parameter measurements only from the RAP. The RRM DCA on Mesh Backhaul feature enables DCA to make better channel assignment for a mesh subtree, by having continuous measurements and inputs from the whole mesh tree required to run DCA.

To enable RRM DCA on a full mesh tree run the **wireless mesh backhaul rrm auto-dca** command. To trigger DCA once, run the **ap dot11 [5ghz | 2.4 ghz] rrm channel-update mesh** command.

To understand what happened during a DCA run on the mesh backhaul, use the **show wireless mesh rrm dca status** and **show wireless mesh rrm dca changed** commands.

Note

- In a topology with mixed APs (RF ASIC capable and non-capable APs), only inputs from the RF ASIC capable APs apply for **auto-dca** .
- All mesh APs in a subtree should be configured to belong to the same site-tag for DCA to work properly.
- This feature is limited to RF ASIC capable APs, such as Cisco Catalyst 9124 Series APs and Cisco Catalyst 9130 Series APs.

Radio Resource Management on mesh

This concept explains how Radio Resource Management (RRM) acts as a built-in RF engineer to provide real-time RF management of a wireless network.

Radio resource management (RRM) features are wireless network management functions that

- enable real-time RF management of the wireless network
- monitor lightweight APs for traffic load, interference, noise, and coverage, and
- operate automatically through embedded controller software.

The RRM measurement in the mesh AP backhaul is enabled based on these conditions:

- Mesh AP has the Root AP role.
- Root AP has joined using Ethernet link.
- Root AP does not serve any child AP.

Configure RRM on mesh backhaul (CLI)

Use this task to enable Radio Resource Management (RRM) on the mesh backhaul interface of your wireless access points using CLI commands. This configuration allows mesh root access points with Ethernet uplink and no child APs to report RRM noise information for optimized network management.

RRM measurement in the mesh AP backhaul is enabled if your access point meets these conditions:

- Mesh AP has the Root AP role.
- The Root AP has joined the network using an Ethernet link.
- Root AP does not serve any child AP.

Complete the steps to enable RRM in the mesh backhaul:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure RRM on the mesh backhaul.

   Example

   ```
   Device(config)# wireless mesh backhaul rrm
   ```

RRM is enabled on the mesh backhaul for APs.

```
Device# configure terminal
Device(config)# wireless mesh backhaul rrm
```

Configure RRM channel assignment for root access points globally

Use these tasks to configure the channel assignment of the RAP in privileged EXEC mode and globally through RRM.

Configure Radio Resource Management (RRM) channel assignment policies for all root access points. This configuration optimizes wireless performance, minimizes interference, and maintains network stability across your deployment.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure RRM for mesh backhaul.

Example

```
Device(config)# wireless mesh backhaul rrm
```

3. Optional: Configure auto DCA for RF Application Specific Integrated Circuit (ASIC) integrated RAPs.

Example

```
Device(config)# wireless mesh backhaul rrm auto-dca
```

All RAPs adopt the configured RRM channel assignment settings globally. This change results in improved channel distribution, reduced interference, and more reliable wireless connectivity across the network.

```
Device# configure terminal
Device(config)# wireless mesh backhaul rrm
Device(config)# wireless mesh backhaul rrm auto-dca
```

Complete these steps to configure the initial channel assignment of the RAP in privileged EXEC mode through RRM and to initiate channel selection for each bridge group.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device> enable
```

2. Initiate the update of the 802.11, 802.11a, or 802.11b channel selection for every mesh Cisco AP.

Example

```
Device# ap dot11 {24ghz | 5ghz | 6ghz} rrm channel-update mesh
```

3. Initiate the update of the 802.11, 802.11a, or 802.11b channel selection for mesh AP in the bridge group.

Example

```
Device# ap dot11 {24ghz | 5ghz | 6ghz} rrm channel-update mesh bridge-group
bridge-group-name
```

RRM completes the channel assignment for the RAP in privileged EXEC mode.

```
Device> enable
Device# ap dot11 5ghz rrm channel-update mesh
Device# ap dot11 5ghz rrm channel-update mesh bridge-group cisco-bridge-group
```

Configure RRM channel assignment for an AP

Use this task to manually trigger Radio Resource Management (RRM) channel assignment for a specific access point (AP) to optimize wireless performance.

Assign RRM channels to an AP. This action helps you optimize wireless channel usage and reduce interference.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Trigger the RRM DCA process for your AP.

   Example

   ```
   Device# ap name Cisco-ap-name dot11 {24ghz | 5ghz | 6ghz} rrm channel update
    mesh
   ```

After you trigger the process, the system starts the RRM DCA process and updates the channel assignment for your selected radio band.

```
Device> enable
Device# ap name Cisco-ap-name dot11 5ghz rrm channel update mesh
```

RRM DCA status verification

Lists commands to verify the RRM DCA status.

Verify the RRM DCA status for mesh access points using specific commands and understand the output differences between manual and automatic DCA triggers.

To view the status of the DCA that is run for mesh APs, run this command:

```
Device# show ap name Cisco-AP config general | inc Mesh
Mesh profile name                               : default-mesh-profile
Mesh DCA Run Status:                            : Not Running
Last Mesh DCA Run                               : 02/07/2022 01:21:56
```

To verify the status of the last DCA run per radio, run this command:

```
Device# show wireless mesh rrm dca status
```

> **Note**
>
> The output for the **show AP config general | i Mesh** and the **show AP name <AP name> config general | i Mesh** command displays only the status for manual RRM DCA triggers performed with the **AP name <AP name> dot11 RRM channel update mesh** command.
>
> The output for the **show AP config general | i Mesh** and the **show AP name <AP name> config general | i Mesh** commands, does not update if only the global mesh RRM DCA is enabled (auto-DCA).

Dynamic frequency selection

This concept explains Dynamic Frequency Selection (DFS) and how it protects radar services by requiring compliant radio devices to detect, avoid, and switch away from radar-occupied frequencies.

A dynamic frequency selection (DFS) is a wireless communication protocol that

- enables radio devices to detect radar signals
- requires devices to cease transmission when radar is detected, and
- requires selecting and monitoring a new channel before resuming transmission.

Regulatory bodies enforce DFS to prevent interference with radar services in shared frequency bands by unlicensed wireless devices.

To protect radar services, regulatory bodies require devices on newly opened frequency sub-bands to operate using DFS. Your radio device must detect radar signals as required. If a radar event is detected in any AP within a sector, mesh access points immediately switch channels to maintain compliance.

For instance, When a radio detects a radar signal, the radio should stop transmitting for at least 30 minutes to protect that service. The radio should then select a different channel to transmit on, but only after monitoring it. If no radar is detected on the projected channel for at least one minute, the new radio service device can begin transmissions on that channel.

Configure dynamic frequency selection (CLI)

Use this procedure to configure dynamic frequency selection (DFS) for mesh profiles using command-line interface commands.

Configure dynamic frequency selection (DFS) on your device to enable radar detection and meet DFS requirements.

DFS specifies the types of radar waveforms that should be detected and the timers that must be used for operation in the DFS channel.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile and enter mesh profile configuration mode.

Example

```
Device(config)# wireless profile mesh profile-name
```

3. Enable DFS.

Example

```
Device(config-wireless-mesh-profile)# full-sector-dfs
```

> **Note**
>
> DFS functionality allows a MAP that detects a radar signal to transmit this information to the RAP. The RAP treats this as a radar detection and moves the sector. This process is called the coordinated channel change. The coordinated channel change feature is always enabled on Cisco Wave 2 and newer APs. You can disable this feature only on Cisco Wave 1 APs.

Dynamic Frequency Selection is enabled for your mesh profile. Your mesh profile is now ready to operate and meets radar detection requirements.

```
Device# configure terminal
Device(config)# wireless profile mesh dfs-mesh-profile
Device(config-wireless-mesh-profile)# full-sector-dfs
```

Spectrum Intelligence for mesh

This concept explains Spectrum Intelligence features for mesh networks, including how they detect non-Wi-Fi interference, leverage CleanAir technology, and support radio management and mitigation in client and backhaul radio bands

A Spectrum Intelligence feature is a wireless network monitoring capability that

- scans 2.4 GHz and 5 GHz bands for non-Wi-Fi radio interference
- provides device and air quality reports using Cisco CleanAir technology, and
- includes mitigation features like Event-Driven Radio Resource Management (EDRRM) and Persistent Device Avoidance (PDA) that require CleanAir data.

The Spectrum Intelligence feature supports both client serving and monitor modes. CleanAir technology in mesh backhaul and access radios generates Interference Device Reports (IDR) and Air Quality Index (AQI). In mesh networks, you use mitigation features with client-access radios in the same way as with non-mesh networks. However, in backhaul radios, reports are controller-only and do not trigger ED-RRM actions. You cannot enable or disable CleanAir on mesh APs (MAPs) because configuration options are not available.

For more information about Spectrum Intelligence, see Configure spectrum intelligence (CLI) on page 2344 section.

Mesh backhaul at 2.4 GHz and 5 GHz

Explains how mesh backhauls connect wireless devices and affect throughput in network environments.

A backhaul is a wireless network interface that

- creates the connection between Mesh Access Points (MAPs)
- operates over 802.11a/n/ac/g, depending on the AP, and
- typically defaults to the 5-GHz frequency band.

Selecting the appropriate backhaul rate is important for efficient spectrum use. It can directly affect client device throughput, a critical metric in evaluating wireless performance.

Mesh backhaul is supported at 2.4 GHz and 5 GHz. By default, the backhaul interface for mesh APs uses 802.11a/ac/ax. In some countries, mesh networks cannot use a 5 GHz backhaul. In countries where 5 GHz is allowed, using 2.4 GHz radio frequencies achieves more extensive mesh or bridge distances.

When a RAP receives a slot-change configuration, the RAP propagates it to all child MAPs. All MAPs disconnect and join the newly configured backhaul slot.

For information about APs that support mesh backhaul, see https://www.cisco.com/c/en/us/td/docs/wireless/access_point/feature-matrix/ap-feature-matrix.html .

Note

In Israel, you must ensure that you run the **ap country IO** command to enable the outdoor country code for the selected radio. After you configure using the **ap country IO** command, the 2.4-GHz radio is enabled and 5-GHz radio is disabled.

Configure mesh backhaul (CLI)

Configure mesh backhaul using commands.

Set the mesh backhaul frequency for an access AP using CLI commands.

Procedure

Change the mesh backhaul to 2.4 GHz.

Example

```
Device # ap name test-ap mesh backhaul radio dot11 24ghz
```

The specified access point now uses 2.4 GHz as its mesh backhaul radio frequency.

Specify the backhaul slot for the root AP (GUI)

Use this task to configure the backhaul slot for a root access point using the web interface.

Configure the backhaul slot for a root access point to optimize wireless mesh connectivity and ensure reliable network communication.

Procedure

1. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.

2. Click **Add**.
3. In the **General** tab, enter the **Name** of the mesh profile.
4. In the **Advanced** tab, select the rate types for **5 GHz Band Backhaul** and **2.4 GHz Band Backhaul** from the **Rate Types** drop-down list.
5. Click **Apply to Device**.

The system updates the root access point with the specified backhaul slot settings. It uses the selected rate types for 5 GHz and 2.4 GHz band backhaul connections.

Specify the backhaul slot for the root AP (CLI)

Learn how to specify the mesh backhaul slot for a root AP using Command-Line Interface (CLI) commands to optimize wireless mesh connectivity.

Assign a specific radio slot (2.4 GHz or 5 GHz) to the mesh backhaul of your root access point to optimize wireless connectivity and network performance.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Specify the mesh backhaul radio slot for your root AP.

   Example

   ```
   Device# ap name ap-name mesh backhaul radio dot11 {24ghz | 5ghz} [slot slot-id]
   ```

Assign a radio slot (2.4 GHz or 5 GHz) to the mesh backhaul of your root access point to improve wireless connectivity and network performance.

```
Device> enable
Device# ap name rap1 mesh backhaul radio dot11 24ghz slot 2
```

Mesh backhaul verification

Provides commands to verify mesh backhaul configuration and status.

Use the **show AP name mesh backhaul** command to view details of the mesh backhaul at 2.4 GHz.

```
Device# show ap name test-ap mesh backhaul

MAC Address : xxxx.xxxx.xxxx
Current Backhaul Slot: 0
Radio Type: 0
Radio Subband: All
Mesh Radio Role: DOWNLINK
Administrative State: Enabled
Operation State: Up
```

```
Current Tx Power Level:
Current Channel: (11)
Antenna Type: N/A
Internal Antenna Gain (in .5 dBm units): 0
```

Use the **show wireless mesh AP backhaul** command to view the mesh backhaul details.

```
Device# show wireless mesh ap backhaul

MAC Address : xxxx.xxxx.0x11
Current Backhaul Slot: 1
Radio Type: Main
Radio Subband: All
Mesh Radio Role: Downlink
Administrative State: Enabled
Operation State: Up
Current Tx Power Level: 6
Current Channel: (100)*
Antenna Type: N/A
Internal Antenna Gain (in .5 dBm units): 10
```

Use the **show AP summary** command to view the radio MAC address and the corresponding AP name.

```
Device# show ap summary
Number of APs: 1
AP Name    Slots  AP Model         Ethernet       MAC Radio MAC  Location
     Country IP Address   State
-------------------------------------------------------------------------------
AP-Cisco-1  2     AIR-APXXXXX-E-K9 xxxx.xxxx.xxd4 xxxx.xxxx.0x11 default
location  DE     10.11.70.170 Registered
```

Backhaul client access

This concept explains how enabling Backhaul Client Access allows wireless client association over the backhaul radio.

Backhaul client access is a wireless networking feature that

- allows wireless clients to associate with mesh APs using the backhaul radio
- supports both 2.4 GHz and 5 GHz backhaul radios, and
- permits the backhaul radio to carry both client traffic and backhaul traffic simultaneously.

When backhaul client access is disabled, only backhaul traffic is sent over the backhaul radio, and client association is performed only over the access radio.

> **Note**
>
> Backhaul client access is disabled by default. After you enable backhaul client access, all MAPs except the subordinate AP and its child APs in a daisy-chained deployment reboot.

Configure backhaul client access (GUI)

Configure backhaul client access using GUI.

Enable backhaul client access for mesh device profiles.

Procedure

1. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
2. Choose a profile.
3. In **General** tab, check the **Backhaul Client Access** check box.
4. Click **Update & Apply to Device**.

The system updates the profile and enables backhaul client access for devices that use the selected mesh profile.

Configure backhaul client access (CLI)

Configure backhaul client access using commands.

Enable backhaul client access on a mesh profile. This allows client devices to connect to the APs through the mesh backhaul. The result is increased network flexibility and coverage.

> **Note**
>
> Backhaul client access is disabled by default. After you enable it, all MAPs reboot, except for the subordinate AP and its child APs in a daisy-chained deployment.

Complete these steps to enable backhaul client access on a mesh profile:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile and enter mesh profile configuration mode.

   Example

   ```
   Device(config)# wireless profile mesh profile-name
   ```

3. Configure backhaul with client access AP.

   Example

   ```
   Device(config-wireless-mesh-profile)# client-access
   ```

You have enabled backhaul client access on the selected mesh profile.

```
Device# configure terminal
Device(config)# wireless profile mesh profile-name
Device(config-wireless-mesh-profile)# client-access
```

Configure dot11ax rates on mesh backhaul per AP (GUI)

Configure Dot11ax rates on mesh backhaul per access point using GUI.

This task enables you to configure specific dot11ax (Wi-Fi 6) rates for mesh backhaul connections on individual APs.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
   The **All Access Points** section, which lists all the configured APs in the network, is displayed with their corresponding details.
2. Select the mesh AP that has been configured.
   The **Edit AP** page is displayed.
3. Choose the **Mesh** tab.
4. In the **General** section, under the **Backhaul** section, the default **Backhaul Radio Type** , **Backhaul Slot ID** , and **Rate Types** field details are displayed. Note that the values for **Backhaul Radio Type** and **Backhaul Slot ID** can be changed only for a root AP.
5. From the **Rate Types** drop-down list, choose the backhaul rate type.

   Based on the choice, enter the details for the corresponding fields that are displayed.The backhaul interface varies between auto and the 802.11a/b/g/n/ac/ax rates, depending on the AP. The Cisco Catalyst 9124AX Outdoor AP is the only AP that supports 11ax backhaul rates on the mesh backhaul.
6. In the **Backhaul MCS Index** field, enter the Modulation Coding Scheme (MCS) rate, that can be transmitted between the APs. The valid range is from 0 to 11, on both bands.
7. In the **Spatial Stream** field, enter the number of spatial streams that are supported. The maximum number of spatial streams supported on a single radio in a 5 GHz radio band is 8, while 2.4 GHz radio band supports 4 spatial streams.
8. Click **Update and Apply to Device**.

After you complete the steps, the selected mesh access point operates using the configured dot11ax rates for its backhaul link.

Configure Dot11ax rates on mesh backhaul in mesh profile (GUI)

Configure Dot11ax rates on mesh backhaul in mesh profile using the GUI to optimize data transmission between access points.

This task allows you to configure Dot11ax rates on mesh backhaul in mesh profile to optimize data transmission between access points using advanced wireless standards.

Use this procedure when you need to configure mesh backhaul rates using the Dot11ax standard. This configuration is specifically supported on Cisco Catalyst 9124AXI/D Series outdoor Access Points and allows for enhanced wireless mesh networking performance.

Procedure

1. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
2. Click **Add**.

The **Add Mesh Profile** window is displayed.

3. In the **Add Mesh Profile** window, click the **General** tab.
4. In the **Name** field, enter the mesh profile name.
5. Click the **Advanced** tab.
6. In the **5 GHz Band Backhaul** section and the **2.4 GHz Band Backhaul** section, choose the **dot11ax** backhaul rate type from **Rate Types** the drop-down list.

> **Note**
>
> Cisco Catalyst 9124AXI/D Series outdoor Access Point is the only AP to support 11ax backhaul rates on the mesh backhaul.

7. In the **Dot11ax MCS index** field, specify the MCS rate at which data can be transmitted between the APs. The value range is between 0 to 11, on both the radio bands.
8. In the **Spatial Stream** field, enter a value. The maximum number of spatial streams supported on a single radio in a 5-GHz radio band is 8, while 2.4- GHz radio band supports 4 spatial streams.
9. Click **Update and Apply to Device**.

The Dot11ax rates are now configured on the mesh backhaul in the mesh profile. The mesh network will use the specified MCS rates and spatial stream configuration for data transmission between access points.

Configure wireless backhaul data rate (CLI)

Use this procedure to configure the wireless backhaul data rate for access points using CLI commands, which helps optimize network coverage and performance based on your deployment requirements.

Configure the data transmission rate for wireless backhaul connections between APs using CLI commands to optimize wireless network performance, coverage, and spectrum use.

Use backhaul to create a wireless connection between APs. Depending on the AP, the backhaul interface can be 802.11bg, 802.11a, 802.11n, or 802.11ac. Selecting a rate lets you use the available RF spectrum effectively.

Data rates can also affect the RF coverage and network performance. Lower data rates, for example, 6 Mbps, can extend farther from the AP than higher data rates, for example, 1300 Mbps. As a result, the data rate affects cell coverage, and consequently, the number of APs required.

> **Note**
>
> You can configure backhaul data rate, preferably, through the mesh profile. In certain cases, where a specific data rate is needed, use the command to configure the data rate per AP.

Follow this procedure to configure wireless backhaul data rate in privileged EXEC mode or in mesh profile configuration mode.

Procedure

1. Enter privileged EXEC mode.

Example

```
Device> enable
```

2. Configure backhaul transmission rate.

Example

```
Device# ap name ap-name mesh backhaul rate {auto | dot11abg | dot11ac | dot11n}
```

3. Configure a mesh profile and enter mesh profile configuration mode.

Example

```
Device(config)# wireless profile mesh profile-name
```

4. Configure backhaul transmission rate.

Example

```
Device(config-wireless-mesh-profile)# backhaul rate dot11  { 24ghz | 5ghz |
6ghz} dot11n RATE_6M
```

> **Note**
>
> Ensure the rate you configure on the AP (step 2) matches the rate you configure on the mesh profile (step 4).

After you configure the wireless backhaul data rate, your APs will balance coverage area and performance for your deployment.

```
Device> enable
Device# ap name ap1 mesh backhaul rate auto
Device(config)# wireless profile mesh mesh1
Device(config-wireless-mesh-profile)# backhaul rate dot11 5ghz dot11n mcs 31
```

Configure data rate per AP (CLI)

Learn how to configure data rates for each access point using CLI commands to optimize wireless network performance

Configure data transmission rates for each AP on mesh backhaul for the 2.4 GHz and 5 GHz bands using the command-line interface.

Procedure

1. Enter privileged EXEC mode.

Example

```
Device> enable
```

2. Configure the 802.11ax mesh backhaul rates for the 2.4 GHz and 5 GHz bands.

Example

```
Device# ap name ap-name mesh backhaul rate dot11ax mcs <0-11> ss <1-8>
```

The AP uses the configured backhaul data rates for 2.4 GHz and 5 GHz bands.

```
Device> enable
Device# ap name ap-name mesh backhaul rate dot11ax mcs 5 ss 4
```

Configure data rate using mesh profile (CLI)

Use this procedure to configure the backhaul data rate for mesh profiles using command-line interface commands on your device.

Set specific data rates for 2.4 GHz and 5 GHz backhaul communication in mesh profiles to optimize wireless mesh network performance.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a mesh profile and enter mesh profile configuration mode.

Example

```
Device(config)# wireless profile mesh profile-name
```

3. Configure the backhaul transmission rate for the 2.4 GHz band and the 5 GHz band. For the 2.4 GHz band, set the 802.11ax spatial stream value from 1 to 4. For the 5 GHz band, set the spatial stream value from 1 to 8.

Example

```
Device(config-wireless-mesh-profile)# backhaul rate dot11 {24ghz | 5ghz}
dot11ax mcs <0-11> spatial-stream <1-8>
```

The mesh profile is updated with the configured data rate for the specified frequency band and spatial streams.

```
Device# configure terminal
Device(config)# wireless profile mesh profile-name
```

```
Device(config-wireless-mesh-profile)# backhaul rate dot11 5ghz dot11ax mcs 5
spatial-stream 6
```

Verify dot11ax rates on mesh backhaul

Lists commands to verify 802.11ax rates on mesh backhaul.

To verify the 802.11ax rates on mesh backhaul in the mesh profile, use this command:

```
Device# show wireless profile mesh detailed default-mesh-profile
Mesh Profile Name              : default-mesh-profile
-----------------------------------------------
Description                    : default mesh profile
.
.
Backhaul tx rate(802.11bg)     : 802.11ax mcs7 ss1
Backhaul tx rate(802.11a)      : 802.11ax mcs9 ss2
```

To verify the 802.11ax rates on mesh backhaul in the general configuration of an AP, use this command:

```
Device# show ap config general
Cisco AP Identifier             : 5c71.0d17.49e0
.
.
Backhaul slot id                : 1
Backhaul tx rate                : 802.11ax mcs7 ss1
```

Ethernet bridging

Explains Ethernet bridging across a mesh network, covering configuration tasks for bridging, multicast forwarding, and workgroup-bridge support to extend network connectivity.

An Ethernet bridge is a network device that

- enables you to secure activation of Ethernet ports on MAPs
- supports both tagged and untagged packets for flexible deployment, and
- allows segmenting application traffic with VLAN tagging between wireless and wired LANs.

For security, the Ethernet port on all MAPs is disabled by default. They can be enabled only through Ethernet bridging configuration on both the root and respective MAP.

Secondary Ethernet interfaces support both tagged and untagged packets.

In a point-to-point bridging, a Cisco Aironet 1500 Series MAP can extend remote networks by using the backhaul radio to bridge multiple segments of a switched network. This is fundamentally a wireless mesh network with one MAP and no WLAN clients.

In point-to-multipoint networks, client access can still be provided with Ethernet bridging enabled, although if bridging between buildings, MAP coverage from a high rooftop might not be suitable for client access. To use an Ethernet-bridged application, enable the bridging feature on the RAP and on all the MAPs in that sector.

In a mesh environment, with VLAN support for Ethernet bridging, the secondary Ethernet interfaces on MAPs are assigned a VLAN individually from the controller. Wired and wireless backhaul links operate as trunks with all VLANs allowed. Non-Ethernet bridged traffic, as well as untagged Ethernet bridged traffic travels along the mesh using the native VLAN of the APs in the mesh. It is similar for all the traffic to and from the wireless clients that the APs are servicing. The VLAN-tagged packets are tunneled through AWPP over wireless backhaul links.

> **Note**
>
> Ensure Ethernet bridging is enabled for every parent mesh AP along the data path to the controller.

Ethernet bridging should be enabled for these scenarios:

- Use mesh nodes as bridges.
- Connect Ethernet devices, such as a video camera on a MAP using its Ethernet port.

VLAN tagging for MAP Ethernet clients

Primary interfaces refer to mesh AP backhauls, and secondary interfaces refer to other AP interfaces.

Ethernet VLAN tagging segments application traffic within a mesh and forwards it to a wired LAN (access mode) or another wireless mesh network (trunk mode).

Configure Ethernet bridging (GUI)

Enable Ethernet bridging on a mesh profile via the configuration interface.

Enable Ethernet bridging on a mesh profile so that network traffic can be transparently passed between Ethernet segments.

Procedure

1. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
2. Click **Add**.
3. In **General** tab, enter the **Name** of the mesh profile.
4. In the **Advanced** tab, check the **VLAN Transparent** check box to enable VLAN transparency.
5. In **Advanced** tab, check the **Ethernet Bridging** check box.
6. Click **Apply to Device**.

Ethernet bridging is now enabled for the selected mesh profile.

Configure Ethernet bridging (CLI)

Learn how to configure Ethernet bridging on access points using CLI commands to enable device connectivity.

Configure Ethernet bridging on mesh access points (APs) to allow Ethernet devices to connect through AP ports.

The Ethernet ports on MAPs are disabled by default. To enable them, configure Ethernet bridging on the Root AP and the relevant MAPs.

You can enable Ethernet bridging to:

- Use the mesh nodes as bridges.
- Connect Ethernet devices, such as a video camera, on a MAP using the MAP's Ethernet port.

Before you begin

- Ensure that you configure these commands under the mesh profile configuration for Ethernet bridging to be enabled:
  - **ethernet-bridging**: Enables the Ethernet Bridging feature on an AP.

- **no ethernet-vlan-transparent**: Makes the wireless mesh bridge VLAN aware. VLAN filtering is allowed with this AP command: **[no] mesh ethernet { 0 | 1 | 2 | 3 } mode trunk vlan allowed .**

  Note

  If you want all VLANs bridged (the bridge acts like a piece of wire), enable VLAN transparency to allow all VLANs to pass. To avoid unnecessary traffic flooding the network, filter VLANs on the wired side when using VLAN transparent mode.

- Configure the switch port that connects to the root AP as a trunk port so Ethernet bridging works.
- For Bridge mode APs, use the **ap name** *name-of-rap* **mesh vlan-trunking native** *vlan-id* command to configure a trunk VLAN on the corresponding RAP. You must configure this command to enable the Ethernet Bridging feature on the AP.
- For FlexConnect+Bridge APs, configure the native VLAN ID under the corresponding flex profile.

e

Note

To ensure that the MAPs apply the Ethernet VLAN configuration on the controller, configure the native VLAN on the RAP by running this command:

```
Device# ap name ap-name no mesh vlan-trunking
Device# ap name ap-name mesh vlan-trunking native 247
```

Alternatively, you can configure native VLAN on the RAP and then the MAP in this order:

```
Device# ap name ap-name no mesh vlan-trunking
Device# ap name ap-name mesh vlan-trunking native vlan_id
Device# ap name ap-name mesh ethernet 1 mode trunk vlan native native
Device# ap name ap-name mesh ethernet 0 mode trunk vlan allowed allowed
```

To verify the status of RAP and MAP, run this command:

```
Device# show mesh forwarding all
```

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Configure the Ethernet port of the AP and set the mode.

Example

```
Device# ap name ap-name mesh ethernet {0 | 1 | 2 | 3} mode access vlan-id
```

3. Set the native VLAN for the trunk port.

Example

```
Device# ap name ap-name mesh ethernet {0 | 1 | 2 | 3} mode trunk vlan native
 21
```

4. Configure the allowed VLANs for the trunk port.

Example

```
Device# ap name ap1 mesh ethernet  { 0 | 1 | 2 | 3 } mode trunk vlan allowed
 vlan-id
```

This command permits VLAN filtering on an Ethernet port of any Mesh or Root Access Point. It is active only when VLAN transparency is disabled in the mesh profile.

Ethernet bridging is enabled on the AP, allowing devices to communicate through configured VLANs.

```
Device> enable
Device# ap name ap1 mesh ethernet 1 mode access 21
Device# ap name ap1 mesh ethernet 1 mode trunk vlan native 21
Device# ap name ap1 mesh ethernet 1 mode trunk vlan allowed 21
```

Multicast over mesh Ethernet bridging network

This concept explains the mesh multicast modes available for bridging-enabled APs in mesh Ethernet networks and how each mode manages multicast and broadcast packet transmission.

A mesh multicast mode is a traffic management setting for bridging-enabled APs that

- determine how multicast and broadcast packets are forwarded across the mesh Ethernet network
- manage only non-CAPWAP multicast traffic, and
- help optimize bandwidth by reducing unnecessary multicast transmissions.

Mesh multicast modes

Mesh multicast modes determine how bridging-enabled APs such as MAP and RAP send multicast packets among Ethernet LANs within a mesh network. Mesh multicast modes manage only non-CAPWAP multicast traffic. CAPWAP multicast traffic is governed by a different mechanism.

Three different mesh multicast modes are available to manage multicast and broadcast packets on all MAPs. Enabling these modes ensures that unnecessary multicast transmissions within the mesh network are reduced and backhaul bandwidth is conserved.

The three mesh multicast modes are:

- Regular mode: In regular mode, bridging-enabled RAP and MAP multicast data across the entire mesh network and all its segments.

- In-only mode: When a MAP receives multicast packets from the Ethernet, it forwards them to the corresponding RAP's Ethernet network. No additional forwarding occurs. This setting ensures that the RAP does not send non-CAPWAP multicasts back to the MAP Ethernet networks within the mesh network (their point of origin). The system filters out MAP to MAP multicasts so these do not occur.
- In-out mode: The RAP and MAP multicast in different ways.
  - If a MAP receives multicast packets over Ethernet, it sends them to the RAP. The MAP does not send these packets to other MAPs over Ethernet; the system filters MAP-to-MAP packets from the multicast stream.
  - If a RAP receives multicast packets over Ethernet, it sends them to all the MAPs and their respective Ethernet networks. When in-out mode operates, partition your network to ensure a multicast sent by one RAP is not received by another RAP on the same Ethernet segment and then sent back into the network.

Configure multicast modes over mesh

Use this procedure to configure multicast operation modes on a mesh network.

Enable multicast forwarding behavior so that your wireless mesh network operates efficiently.

- If multicast packets are received at a MAP over Ethernet, the MAP sends them to the RAP. The MAP does not send them to other MAPs; it filters out MAP-to-MAP packets from the multicast.
- If multicast packets are received at a RAP over Ethernet, they are sent to all the MAPs and their respective Ethernet networks.
- The *in-out* mode is the default mode. To prevent a multicast sent by one RAP from being received by another RAP on the same Ethernet segment and then sent back into the network, properly partition your network when the *in-out* mode is in operation.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile and enter mesh profile configuration mode.

   Example

   ```
   Device(config)# wireless profile mesh profile-name
   ```

3. Configure mesh multicast mode.

   Example

   ```
   Device(config-wireless-mesh-profile)# multicast {in-only | in-out | regular}
   ```

You have set the mesh profile to the multicast mode you want. This setting controls how multicast packets are routed in the network.

```
Device# configure terminal
Device(config)# wireless profile mesh mesh-multicast
Device(config-wireless-mesh-profile)# multicast regular
```

Workgroup bridge

This concept explains how workgroup bridges (WGBs) connect wired networks over a single wireless segment and their key operational attributes.

A workgroup bridge (WGB) is a wireless networking device that

- connects wired networks over a single wireless segment
- informs the corresponding mesh access point (MAP) of all wired clients on its segment through IAPP messages, and
- uses an additional MAC address header to route packets to and from wired clients.

Data packets for WGB clients contain an extra MAC address in the 802.11 header (four MACs, instead of the usual three), with the extra address being that of the WGB itself. The extra MAC in the header is the address of the workgroup bridge itself. This extra MAC address is used to route a packet to and from the corresponding clients.

You can configure APs as workgroup bridges. You need only one radio interface for controller connectivity. Use the Ethernet interface for wired client connectivity and another radio interface for wireless clients.

In Cisco Catalyst 9800 Series Wireless Controllers, WGB acts as a client association that allows wired clients behind the WGB to pass data over the mesh network. Wired clients with different VLANs behind a WGB are also supported.

DHCP and NAT functionality on root AP (RAP)

Describes integrated DHCP server and NAT functions provided by root APs, including operational processes, configuration steps, and verification commands for network service delivery.

DHCP and NAT functionality is a wireless network feature that

- assigns private IPv4 addresses to client devices using DHCP
- translates these private addresses to public addresses for network access with NAT, and
- enables root APs (RAPs) to provide seamless connectivity for clients in a mesh network.

The APs associated with a mesh network can play one of the two roles:

- Root Access Point (RAP) – An AP can be a root AP for multiple mesh networks.
- Mesh Access Point (MAP) – An AP can be a mesh AP for only one mesh network at a time.

> **Note**
>
> This feature is applicable for Cisco Aironet 1542 series outdoor APs.

How DHCP and NAT functionalities work on root AP - IPv4 scenario

Learn how root access points (RAPs) in mesh networks assign private IP addresses to your devices and help you securely access external networks using DHCP and NAT.

In wireless mesh networking, root APs (RAPs) can be enabled to provide both DHCP (Dynamic Host Configuration Protocol) and NAT (Network Address Translation) functionalities. This feature enables the controller to send a TLV to RAP when a new RAP joins the controller.

Summary

RAPs use integrated DHCP and NAT functionalities to assign private IPv4 addresses to wireless clients and provide secure, translated access to external networks. The process orchestrates communication between the network controller, RAP, and client device.

Workflow

The workflow consists of these steps:

1. The controller sends a TLV to configure the RAP with DHCP and NAT functionalities when a RAP joins the network.
2. A client device associates to the RAP's SSID.
3. The RAP assigns a private IPv4 address to the client using its DHCP functionality.
4. The RAP applies NAT to translate the client's private address, enabling secure access to external networks.

Result

Wireless clients that connect to RAPs receive private IPv4 addresses and can securely access external networks using DHCP and NAT services managed by the RAP.

Configure DHCP server on root AP (CLI)

Configure DHCP server on RAP.

Configure a DHCP server on the root AP.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile.

   Example

   ```
   Device(config)# ap profile ap-profile-name
   ```

3. Configure the DHCP server on the root AP.

Example

```
Device(config-ap-profile)# dhcp-server
```

4. Exit the configuration mode.

Example

```
Device(config-ap-profile)# end
```

The system saves the configuration, exits configuration mode, and returns to privileged **EXEC** mode.

The root AP is now configured as a DHCP server and assigns IP addresses to associated clients.

DHCP server for root AP configuration verification

Provides verification of DHCP server for RAP configuration.

To verify the DHCP server for root AP configuration, use this command:

```
Device# show ap config general
Cisco AP Name   : AP4C77.6DF2.D588
================================================
<SNIP>
Dhcp Server                                     : Enabled
```

Mesh convergence

Explains mesh convergence, including failure detection, alternate path selection, fast network recovery mechanisms, and configuration and verification of parent loss detection and gateway reachability.

A mesh convergence event is a network recovery mechanism that

- allows MAPs to re-establish connection with a controller after losing the backhaul link to the current parent
- enables the use of a maintained subset of channels for future scanning and parent identification, and
- supports multiple convergence methods to optimize reconnection time.

The table presents the supported convergence methods.

Table 169: Mesh convergence

Mesh convergence	Parent Loss Detection / Keepalive Timers
Standard	21 seconds / 3 seconds
Fast	7 seconds / 3 seconds
Very Fast	4 seconds / 2 seconds
Noise-tolerant-fast	21 seconds / 3 seconds

Noise-tolerant fast detection

Learn how noise-tolerant fast detections are used for parent loss detection in network environments, focusing on their mechanisms for evaluating connectivity and triggering recovery actions.

A noise-tolerant fast detection is a detection method that

- monitors the response to Adaptive Wireless Path Protocol (AWPP) neighbor requests at specified intervals
- identifies parent connectivity loss through missed responses, and
- initiates network recovery actions such as roaming or full scans when loss is detected.

Noise-tolerant fast detection occurs when there is no response to an AWPP neighbor request. In the standard method, the system evaluates the current parent every 2 1 seconds. Each neighbor receives a unicast request every three seconds, and the parent also receives a request. If the parent does not respond, the device either roams to an available neighbor on the same channel or performs a full scan to find a new parent.

Configure mesh convergence (CLI)

Configure mesh convergence using commands.

This section provides information about how to configure mesh convergence.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a mesh profile.

   Example

   ```
   Device(config)# wireless profile mesh profile-name
   ```

3. Configure mesh convergence method in a mesh profile.

   Example

   ```
   Device(config-wireless-mesh-profile)# convergence {fast | noise-tolerant-fast
    | standard | very-fast}
   ```

You have successfully configured mesh convergence for the specified mesh profile on the device.

```
Device# configure terminal
Device(config)# wireless profile mesh mesh1
Device(config-wireless-mesh-profile)# convergence fast
```

Mesh convergence verification

Provides commands to verify mesh convergence configuration and status.

Verify mesh convergence configuration and view subset channels for bridge groups using command-line interface commands.

This example shows the output from the **show wireless profile mesh detailed** command, which displays the mesh convergence method.

```
Device# show wireless profile mesh detailed default-mesh-profile

Mesh Profile Name             : default-mesh-profile
-------------------------------------------------
Description                 : default mesh profile
Convergence Method          : Fast
```

This example shows the output from **show wireless mesh convergence subset-channels** command, which displays the subset channels for the selected bridge group name.

```
Device# show wireless mesh convergence subset-channels

Bridge group name                Channel
-----------------------------------------
Default                          132
```

Mesh network recovery mechanisms

Learn the mechanisms that improve mesh network recovery by rapidly detecting uplink gateway reachability failures in mesh APs.

A mesh network recovery mechanism is a network self-healing feature that

- rapidly detects uplink gateway reachability failures in mesh APs
- automatically triggers alternate uplink selection to maintain connectivity, and
- uses ICMP pings to default gateways to verify uplink status after failover events or controller disconnections.

In all 802.11ac Wave 2 and 802.11ax mesh APs, detecting uplink gateway failures quickly speeds up mesh network recovery. Mesh APs use ICMP ping to the default gateway, either IPv4 or IPv6, to check uplink gateway reachability.

Reachability checks for mesh APs work

A mesh AP triggers the reachability check in two scenarios:

- After a new uplink is selected and before the mesh AP joins the controller

  After a new uplink is selected, the mesh AP has a 45-second window to reach the gateway (through static IP or DHCP) through the selected uplink. If the mesh AP does not reach the gateway within 45 seconds, the system blocks the current uplink and starts selecting a new uplink. If the AP joins the controller during this window, it stops the reachability check. The system does not perform gateway reachability checks during normal operations.

- As soon as the mesh AP times out its connection with the controller

  When the mesh AP times out its connection with the controller and fails to reach the gateway within 5 seconds, the system marks the current uplink as blocked and starts the uplink selection process.

Mesh daisy chaining

Describes Ethernet daisy chaining among mesh APs, presenting prerequisites, restrictions, configuration procedures, enabling on specific AP models, and verification for chained connectivity.

A mesh daisy chain is a wireless networking topology that

- connects mesh APs in series to relay data
- enables both serial backhaul communication and network extension for client access, and
- supports flexible deployment by allowing MAPs to connect in different modes and power configurations.

Mesh APs can daisy chain when operating as Mesh APs. In a daisy chain configuration, MAPs function as either serial backhaul links—using different channels for uplink and downlink to increase backhaul bandwidth—or as extensions of universal network access. Extending universal access allows a local mode or FlexConnect mode Mesh AP to connect to the Ethernet port of a MAP, expanding network reach for client devices.

Wired daisy-chained APs require specific cabling based on power source:

- If an AP uses DC power, connect an Ethernet cable from the LAN port of the Primary AP directly to the PoE-in port of the Subordinate AP.

Prerequisites for mesh Ethernet daisy chaining

This topic outlines the essential requirements that must be met before implementing mesh Ethernet daisy chaining.

Before you deploy mesh Ethernet daisy chaining, complete several configuration steps and verify specific settings on your APs. These prerequisites include designating AP roles, enabling relevant features, configuring VLAN support, and using the proper cabling to ensure optimal system performance and compatibility.

- Ensure that you have configured the AP role as root AP.
- Ensure that you have enabled Ethernet bridging and Strict Wired Uplink on the corresponding AP.
- Ensure that you have disabled VLAN transparency.
- To enable VLAN support on each root AP operating in bridge mode, use the **ap name** *name-of-rap* **mesh vlan-trunking [native]** *vlan-id* command. This command configures a trunk VLAN on the corresponding RAP.
- To enable VLAN support on each root AP, for Flex+Bridge APs, you must configure the native VLAN ID under the corresponding Flex profile.
- Ensure that you use 4-pair cables that support 1000 Mbps. This feature does not work properly with 2-pair cables that support 100 Mbps.

Restrictions for mesh Ethernet daisy chaining

This topic outlines the essential requirements you must meet before implementing mesh Ethernet daisy chaining on Cisco Industrial Wireless APs.

Review and meet these requirements before you configure mesh Ethernet daisy chaining:

- This feature is applicable to the Cisco Industrial Wireless 3702 AP and Cisco Catalyst 9124 Series APs.
- This feature is applicable to APs operating in Bridge mode and Flex+Bridge mode only.
- In Flex+Bridge mode, if local switching WLAN is enabled, the work group bridge (WGB) multiple VLAN is not supported.
- For Ethernet daisy chain topology, connect a power injector as the power supply for the AP. Do not connect the Cisco Industrial Wireless 3702 PoE out port to the PoE in port of another Cisco Industrial Wireless 3702 AP.

- The network convergence time increases as the number of APs in the chain increases.
- Any EWC-capable AP that is part of daisy chaining and has been assigned the RAP role must operate in CAPWAP mode (ap-type capwap).

Configure mesh Ethernet daisy chaining (CLI)

Configure mesh ethernet daisy chaining using commands.

This section provides information about how to configure the Mesh Ethernet Daisy Chaining feature on a mesh AP.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the AP profile.

   Example

   ```
   Device(config)# ap profile default-ap-profile
   ```

3. Configure persistent SSID broadcast and ensure strict wired uplink. RAP will not switch to wireless backhaul when you configure this command.

   Example

   ```
   Device(config-ap-profile)# ssid broadcast persistent
   ```

Mesh Ethernet daisy chaining is successfully enabled on the mesh AP. The SSID broadcast is persistent and the RAP uses a strict wired uplink.

Enable mesh Ethernet daisy chaining

Enable mesh ethernet daisy chaining.

This section describes how to enable the Mesh Ethernet Daisy Chaining feature on a Cisco IW 3702 AP.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a mesh profile.

Example

```
Device(config)# wireless profile mesh default-mesh-profile
```

3. Connect remote wired networks to each other.

Example

```
Device(config)# ethernet-bridging
```

4. Disable VLAN transparency to ensure that the bridge is VLAN aware.

Example

```
Device(config)# no ethernet-vlan-transparent
```

The Ethernet daisy chaining feature is enabled.

Mesh Ethernet daisy chaining verification

Provides commands to verify mesh ethernet daisy chaining configuration and status.

Use these commands to verify mesh ethernet daisy chaining configuration and check the Persistent SSID broadcast status for access points.

Use the **show AP config general** command to find out if a Persistent SSID is configured for an AP.

```
Device# show ap 3702-RAP config general

Persistent SSID Broadcast                  Enabled/Disabled
```

Use the **show wireless mesh persistent-SSID-broadcast summary** command to view the Persistent SSID broadcast status for all bridge root APs

```
Device# show wireless mesh persistent-ssid-broadcast summary

 AP Name     AP Model BVI MAC        BGN        AP Role              Persistent
 SSID state
-------     -------- -------        ---        -------
---------------------
3702-RAP     3702     5c71.0d07.db50 ap_name    Root AP               Enabled
1560-RAP    1562E    380e.4dbf.c6b0 ap_name    Root AP              Disabled
```

FlexConnect + bridge mode

Covers resilient mesh deployments using FlexConnect and bridge-mode APs, including configuration of flex profiles, site tags, mesh profiles, AP associations, and verification for enhanced redundancy.

A FlexConnect bridge mode is a wireless network configuration that

- enables FlexConnect capabilities on mesh (bridge mode) APs,
- allows mesh APs to inherit VLANs from the root AP, and

- supports VLAN trunking and native VLAN ID configuration per AP.

FlexConnect + bridge mode enables FlexConnect capabilities on mesh (bridge mode) APs. Mesh APs inherit VLANs from the root AP to which they are connected.

Any EWC-capable AP in FlexConnect mode connected to a MAP should be in CAPWAP mode (AP-type CAPWAP).

You can enable or disable VLAN trunking and configure a native VLAN ID on each AP for any of these modes:

- FlexConnect
- FlexConnect + bridge (FlexConnect + mesh)

Flex resilient with Flex and bridge modes

Explains Flex Resilient deployment with Flex and bridge mode APs, detailing configuration steps for Flex and mesh profiles, site tag and mesh associations, switch interface setup, AP attachment, and verification of resilient configurations.

A flex resilient system in flex and bridge modes is a network feature that

- operates within a configuration involving both flex and bridge mode APs
- allows the primary functionality of APs as mesh links between a root access point (RAP) and mesh access point (MAP), and
- ensures that the feature's operations are limited to flex and bridge mode APs.

Additional reference information

- Flex+Bridge Mode: A configuration mode combining the flexibility of standalone (local) management for APs with stable mesh network connectivity through root and mesh APs.
- Mesh Link Operation: Exists between RAP and MAP, allowing communication and bridging.
- Client Connectivity:
  - No new or disconnected clients can associate with a Mesh AP in flex+bridge mode.
  - Ongoing connections are maintained until a loss of the parent link for a child MAP.
- In a locally switching WLAN, the client traffic of a Flex+Bridge MAP is sent to the RAP's switchport.
- A child MAP that loses its parent connection cannot connect to a new parent without reacquiring a connection to the CAPWAP controller.
- The feature does not operate on non-Flex+Bridge mode APs.
- A new or disconnected wireless client cannot associate with a Mesh AP when in this mode.

Configure a flex profile (GUI)

Configure a flex profile using GUI.

Set up a flex profile to enhance network resilience and enable local authentication.

Use these steps to configure a flex profile using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Flex**.

2. Click a **Flex Profile Name**. The **Edit Flex Profile** dialog box appears.
3. Under the **General** tab, choose the **Flex Resilient** check box to enable the Flex Resilient feature.
4. Under the **VLAN** tab, choose the required VLANs.
5. (Optionally) Under the **Local Authentication** tab, choose the desired server group from the **Local Accounting RADIUS Server Group** drop-down list. Also, choose the **RADIUS** check box.
6. Click **Update & Apply to Device**.

The flex profile is successfully configured and updated in the system.

Configure a Flex profile (CLI)

Configure a Flex Profile using commands.

Configure a Flex Profile using commands on a network device to enable specific features and settings.

Use these steps to configure a flex profile using the CLI.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a flex profile and enters flex profile configuration mode using the **wireless profile flex** *flex-profile* command.

   Example

   ```
   Device(config)# wireless profile flex new-flex-profile
   ```

3. Enable ARP caching.

   Example

   ```
   Device(config-wireless-flex-profile)# arp-caching
   ```

4. Enable default parameters for the Flex profile using the **description** *description* command.

   Example

   ```
   Device(config-wireless-flex-profile)# description "new flex profile"
   ```

5. Configure native vlan-id information.

   Example

   ```
   Device(config-wireless-flex-profile)# native-vlan-id 2660
   ```

6. Enable the resilient feature.

Example

```
Device(config-wireless-flex-profile)# resilient
```

7. Configure VLAN name using the **vlan-name** *vlan_name* command.

   Example

   ```
   Device(config-wireless-flex-profile)# vlan-name VLAN2659
   ```

8. Configure the VLAN ID.

   Example

   ```
   Device(config-wireless-flex-profile)# vlan-id 2659
   ```

   The valid VLAN ID ranges from 1 to 4096.

9. Exit the configuration mode and return to the privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

The Flex profile is configured on the network device with the specified settings and features.

Configure a site tag (CLI)

Configure a Site Tag using commands.

Configure a site tag on a network device to manage wireless networks efficiently and map APs to specific site tags. Use these steps to configure a site tag using CLI.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a site tag and enter site tag configuration mode using the **wireless tag site** *site-name* command.

   Example

   ```
   Device(config)# wireless tag site new-flex-site
   ```

3. Configure a flex profile using the **flex-profile** *flex-profile-name* command.

Example

```
Device(config-site-tag)# flex-profile new-flex-profile
```

4. Remove **Local site** configured from the site tag.

Example

```
Device(config-site-tag)# no local-site
```

5. Map a site tag to an AP using the **site-tag** *site-tag-name* command.

Example

```
Device(config-site-tag)# site-tag new-flex-site
```

6. Exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-site-tag)# end
```

The site tag is configured and mapped to the specified AP, facilitating effective management of wireless networks within the defined site tag.

Configure a mesh profile (CLI)

Configure a mesh profile using commands.

Configure a mesh profile on a network device to enable communication between mesh nodes, ensuring VLAN awareness and connectivity management.

Use these steps to configure a mesh profile using CLI commands.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a mesh profile and enter the mesh profile configuration mode using the **wireless profile mesh** *profile-name* command.

Example

```
Device(config)# wireless profile mesh Mesh_Profile
```

3. Disable VLAN transparency to ensure that the bridge is VLAN aware.

Example

```
Device(config-wireless-profile-mesh)# no ethernet-vlan-transparent
```

4. Exit the configuration mode and return to the privileged EXEC mode.

Example

```
Device(config-wireless-profile-mesh)# end
```

The mesh profile is configured, VLAN transparency is disabled to ensure VLAN awareness, and the device returns to privileged EXEC mode.

Associate the wireless mesh to an AP profile (CLI)

Associate Wireless Mesh to an AP Profile using commands.

Associate a wireless mesh to an AP profile to ensure proper configuration and management of AP.

Use these steps to associate the wireless mesh to an AP profile.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the AP profile and enter AP profile configuration mode using the **ap profile** *ap-profile-name* command.

Example

```
Device(config)# ap profile new-ap-join-profile
```

3. Configure the mesh profile in AP profile configuration mode using the **mesh-profile** *mesh-profile-name* command.

Example

```
Device(config-ap-profile)# mesh-profile Mesh_Profile
```

4. Configure the Secure Shell (SSH).

Example

```
Device(config-ap-profile)# ssh
```

5. Specify the AP management username and password for managing APs using the **mgmtuser username** *username* **password** {**0** | **8**} *password* command.

Example

```
Device(config-ap-profile)# mgmtuser username Cisco password 0 Cisco secret 0
 Cisco
```

- **0**: Specifies an UNENCRYPTED password.
- **8**: Specifies an AES encrypted password.

> **Note**
>
> While configuring a username, ensure that special characters are not used as they can lead to configuration errors.

6. Exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-ap-profile)# end
```

The AP profile is configured with the wireless mesh, allowing for proper management and operation of the AP.

Attach site tag to an access point (CLI)

Attach site tag to an AP using commands.

Attach a site tag for AP identification and configuration management.

Use these steps to attach a site tag to an AP:

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure APs and enters ap-tag configuration mode using the **ap** *mac-address* command.

Example

```
Device(config)# ap F866.F267.7DFB
```

3. Map a site tag to the AP using the**site-tag** *site-tag-name* command.

Example

```
Device(config-ap-tag)# site-tag new-flex-site
```

> **Note**
>
> Associating Site Tag causes the associated AP to reconnect.

4. Exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-ap-tag)# end
```

The AP is now associated with the specified site tag and will reconnect.

Configure switch interface for APs (CLI)

Configure Switch Interface for APs using commands.

Configure a switch interface for APs using CLI to ensure proper VLAN assignment and trunk settings.

Use these steps to configure switch interface for APs:

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enter the interface to be added to the VLAN.

Example

```
Device(config)# interface <int-id>
```

3. Assign the allowed VLAN ID to the port using the **switchport trunk native vlan** *vlan-id* command.

Example

```
Device(config-if)# switchport trunk native vlan 2660
```

4. Assign the allowed VLAN ID to the port using the **switchport trunk allowed vlan** *vlan-id* command.

Example

```
Device(config-if)# switchport trunk allowed vlan 2659,2660
```

5. Sets the trunking mode to trunk unconditionally.

Example

```
Device(config-if)# switchport mode trunk
```

Note

When the controller works as a host for spanning tree, ensure that you configure portfast trunk, using **spanning-tree portfast trunk** command, in the uplink switch to ensure faster convergence.

6. Exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-if)# end
```

The switch interface is successfully configured for AP connectivity, enabling effective VLAN management and ensuring faster network convergence for connected APs.

Flex resilient with flex and bridge mode AP configuration verification

Provides commands to verify Flex Resilient with Flex and Bridge Mode AP Configuration.

Use the verification commands to view details about AP mode and model, MAP mode details, RAP mode details, and the status of the Flex Profile–Resilient feature.

Use this command to view details about the AP mode and model.

```
Device# show ap name <ap-name> config general | inc AP Mode
AP Mode                                          : Flex+Bridge
AP Model                                         : AIR-CAP3702I-A-K9
```

Use this command to view the MAP mode details.

```
Device# show ap name MAP config general | inc AP Mode
AP Mode                                          : Flex+Bridge
AP Model                                         : AIR-CAP3702I-A-K9
```

Use this command to view the RAP mode details.

```
Device# show ap name RAP config general | inc AP Mode
AP Mode                                          : Flex+Bridge
AP Model                                         : AIR-AP2702I-A-K9
```

Use this command to check the status of the Flex Profile–Resilient feature.

```
Device# show  wireless profile flex detailed FLEX_TAG | inc resilient
Flex resilient                 : ENABLED
```

Mesh AP Roles and Topology

Describes AP roles, preferred-parent selection, leaf nodes, channel synchronization, and battery-state settings.

Select a preferred parent (GUI)

Configure the preferred parent MAC address for an access point in mesh mode to optimize wireless connectivity.

Direct a mesh-capable AP to use a designated parent for uplink within the wireless topology.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click the AP.
3. In the **Mesh** tab, enter the **Preferred Parent MAC**.
4. Click **Update & Apply to Device**.

The AP uses the specified preferred parent MAC address for uplink, optimizing connectivity in the mesh network.

Select a preferred parent (CLI)

Learn how to configure a mesh access point (AP) to use a specific preferred parent by entering CLI commands.

To configure a preferred parent for a MAP, complete these steps.

You can override the AWPP-defined parent selection and assign a specific preferred parent to a mesh AP using this mechanism.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Configure mesh parameters for the AP and set the mesh-preferred parent MAC address.

   Example

   ```
   Device# ap name ap-name mesh parent preferred mac-address
   ```

> **Note**
>
> Ensure that you use the radio MAC address of the preferred parent.
>
> For Cisco Wave 1 APs, specify the MAC address of the actual mesh neighbor as the preferred parent. Use the base radio MAC address that ends with the letter "f". For example, if the base radio MAC address is 00:24:13:0f:92:00, then you must specify 00:24:13:0f:92:0f as the preferred parent.
>
> ```
> Device# ap name ap1 mesh parent preferred 00:24:13:0f:92:0f
> ```
>
> For Cisco Wave 2 APs, specify the MAC address for the preferred parent by adding "0x11" to the last two characters of the base radio MAC address. For example, if the base radio MAC address is 00:24:13:0f:92:00, then you must specify 00:24:13:0f:92:11 as the preferred parent.
>
> ```
> Device# ap name ap1 mesh parent preferred 00:24:13:0f:92:11
> ```

The mesh AP is configured to use the specified MAC address as its preferred parent.

```
Device> enable
Device# ap name ap1 mesh parent preferred 00:0d:ed:dd:25:8F
```

Change the role of an AP (GUI)

Change the role of an AP using GUI.

Change the operational role of an AP to support different network topologies.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click the **Access Point**.
3. In the **Mesh** tab, choose **Root** or **Mesh** from the **Role** drop-down list.
4. Click **Update & Apply to Device**.

The AP automatically restarts to apply the new role configuration.

Change the role of an AP (CLI)

Learn how to change the role of a Cisco access point (AP) between mesh and root modes using CLI commands to adapt your wireless network configuration.

Change your Cisco access point (AP) role between mesh AP (MAP) and root AP (RAP) using command-line interface (CLI) commands.

To change the AP from MAP to RAP or the reverse, follow this procedure. By default, your AP joins the controller in the mesh AP role.

Procedure

1. Enter privileged EXEC mode.

Example

```
Device> enable
```

2. Change the role of the Cisco bridge mode AP. The AP reboots after the role change.

Example

```
Device# ap name ap-name role {mesh-ap | root-ap}
```

The specified AP reboots and operates in its new role. After rebooting, it connects and functions in your wireless mesh network.

```
Device> enable
Device# ap name ap1 role root-ap
```

Mesh leaf node

Learn how mesh leaf nodes operate in a wireless mesh network and describes why lower performance Mesh Access Points (MAPs) are configured as leaf nodes.

A mesh leaf node is a type of mesh access point (MAP) that

- operates only as a child node within a wireless mesh network
- is typically assigned to MAPs with lower performance, and
- cannot serve as a parent MAP, ensuring wireless backhaul performance is not degraded.

Leaf nodes maintain stable network throughput by preventing low-performance devices from acting as wireless backhaul links for other MAPs.

Configure mesh leaf node (CLI)

Use this procedure to configure a mesh leaf node using CLI commands.

Set an AP as a mesh leaf node. Other mesh APs cannot select this AP as a parent MAP.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device> enable
```

2. Configure the AP to operate only as a leaf node. Other MAPs cannot select this AP as a parent MAP.

Example

```
Device# ap name ap-name mesh block-child
```

Use the **no** form of this command to change it to a regular AP.

The AP operates solely as a mesh leaf node and cannot be selected as a parent MAP.

```
Device> enable
Device# ap name ap1 mesh block-child
```

Configure the mesh leaf node (GUI)

Configure the mesh leaf node using GUI.

Configure a mesh leaf node so that it blocks child connections to enforce network segmentation.

Procedure

---

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click the AP.
3. In the **Mesh** tab, check the **Block Child** check box.
4. Click **Update & Apply to Device**.

Your mesh leaf node now blocks child connections.

Configure subset channel synchronization

Learn how to configure subset channel synchronization for a mobility group to ensure faster mesh AP convergence.

Enable synchronization of mesh subset channels to ensure efficient convergence of RAPs and MAPs.

The controller sends all channels used by RAPs to MAPs for future seeking and convergence. The controller keeps a list of subset channels for each Bridge Group Name (BGN) and shares this list across all controllers in a mobility group.

The subset channel list includes channels where RAPs within a Bridge Group Name (BGN) operate. This list is distributed to all mesh access points (MAPs) within controllers and across controllers. Maintaining a subset channel list helps Mesh APs converge faster. You can select the convergence method in the mesh profile. The system sends the subset channel list to MAPs if the convergence method is non-standard.

Follow these steps to configure subset channel synchronization for a mobility group.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure subset channel synchronization for a mobility group.

Example

```
Device(config)# wireless mesh subset-channel-sync mac
```

The mobility group synchronizes subset channels, which enables mesh APs to converge faster.

```
Device# configure terminal
Device(config)# wireless mesh subset-channel-sync mac
```

Configure battery state for mesh AP (GUI)

Use this procedure to configure the battery state for a mesh access point using the GUI.

Configure the battery state on a mesh AP using the web interface.

Procedure

1. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
2. Select a profile.
3. On the **General** tab, check the **Battery State for an AP** check box.
4. Click **Update & Apply to Device**.

After you configure the profile, the profile displays the battery state for the selected mesh AP.

Configure battery state for mesh AP (CLI)

Use this task to configure the battery backup feature for outdoor mesh APs to provide temporary power during outages and support external devices, using CLI commands.

Some outdoor APs come with the option of battery backup. The AP also includes a POE-out port that powers a video surveillance camera. The integrated battery provides temporary backup power during external power interruptions.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile, and enter mesh profile configuration mode.

   Example

   ```
   Device(config)# wireless profile mesh profile-name
   ```

3. Configure the battery state for an AP.

Example

```
Device(config-wireless-mesh-profile)# battery-state
```

You have configured the battery state for the mesh AP, so backup power is now available when required.

```
Device# configure terminal
Device(config)# wireless profile mesh mesh-profile-name
Device(config-wireless-mesh-profile)# battery-state
```

Link test

Explains procedures for testing and assessing mesh backhaul link quality and performance, including GUI and CLI-based link test configurations.

A link test is a radio communication diagnostic tool that

- determines the radio link quality between two devices
- supports both ping and CCX test types for different directions, and
- allows both APs and clients to act as initiators and responders.

Two types of link-test packets are transmitted during a link test: request and response. Any radio that receives a link-test request packet fills in the appropriate text boxes. It then echoes the packet back to the sender with the response type set. The radio link quality in the client-to-access point direction can differ from that in the access point-to-client direction. This difference occurs because transmit power and receive sensitivity are distributed asymmetrically on both sides.

Types of link tests

The two types of link tests that you can perform are:

- **Ping link test**: With the ping link test, the controller tests link quality in the client-to-access point direction. The controller polls the RF parameters of the ping reply packets received by the AP to determine the client-to-access point link quality.
- **CCX link test**: With the CCX link test, the controller can also test the link quality in the access point-to-client direction. The controller sends link-test requests to the client. The client records RF parameters, such as received signal strength indicator (RSSI) and signal-to-noise ratio (SNR), in the response packet. Both requestor and responder roles exist on the AP and controller. You can initiate a link test from the AP, controller, or a CCX v4 or v5 client.

Use a link test on mesh backhaul (GUI)

Use this procedure in the graphical user interface to run a link test on a mesh backhaul connection. The task enables measurement of wireless link quality, packet loss, and connectivity between mesh access points to help ensure optimal network performance.

Network administrators can validate wireless mesh backhaul connectivity and signal strength with this task. Running a link test enables proactive identification of performance issues, ensures reliable mesh network operation, and helps troubleshoot weak connections.

Procedure

1. Choose **Monitoring** > **Wireless** > **AP Statistics** > **General**.

2. Select the Access Point.
3. Choose **Mesh** > **Neighbor** > **Linktest**.
4. Select the desired values from the **Date Rates**, **Packets to be sent (per second)**, **Packet Size (bytes)**, and **Test Duration (seconds)** drop-down lists.
5. Click **Start**.

You can see the detailed link test results for the selected mesh backhaul connection.

Use a link test on mesh backhaul

Use a link test on mesh backhaul using commands.

To initiate a link test between neighbor mesh APs, complete these steps.

> **Note**
>
> Use the **test mesh linktest mac-address** *neighbor-ap-mac* **rate** *data-rate* **fps** *frames-per-second* **frame-size** *frame-size* command to perform link test from an AP.

Procedure

1. Enters privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Set the link test parameters.

   Example

   ```
   Device# ap name ap-name mesh linktest H.H.H data-rate packet-per-sec
   packet-size test-duration
   ```

   - *H.H.H*: Specify the destination AP MAC address.
   - *data-rate*: Specify the data rates in Mbps. The values are 1, 2, 5, 6, 9, 11, 12, 18, 24, 36, 48, 54, 108, or m0 through m15.
   - *packet-per-sec*: Specify the packets to be sent per second. The range is from 1 to 25,000.
   - *packet-size*: Specify the packet size in bytes. The range is from 1 to 1,500.
   - *test-duration*: Specify the test duration in seconds. The range is from 10 to 300.

The system displays test results, including throughput, loss, and latency metrics, to verify link quality between access points.

```
Device> enable
Device# ap name ap1 mesh linktest F866.F267.7DFB 24 234 1200 200
```

Air time fairness on mesh

Explains how ATF on mesh ensures fair airtime distribution and optimizes performance wirelessly in mesh networks.

Air time fairness (ATF) on mesh is a wireless quality of service feature that

- regulates downlink airtime distribution in mesh networks using token bucket mechanisms
- ensures fair access to radio airtime across mesh access points and their clients, and
- operates on both client access radios and backhaul radios to provide network-wide fairness.

ATF on mesh operation details

The Air Time Fairness (ATF) on Mesh feature is conceptually similar to the ATF feature for local access points (APs). ATF is a form of wireless quality of service (QoS) that regulates downlink airtime (as opposed to egress bandwidth). Before a frame is transmitted, the ATF budget for that SSID is checked to ensure that there is sufficient airtime budget to transmit the frame. Each SSID can be thought of as having a token bucket (1 token = 1 microsecond of airtime). If the token bucket contains enough airtime to transmit the frame, it is transmitted over air. Otherwise, the frame can either be dropped or deferred. Deferring a frame means that the frame is not admitted into the Access Category Queue (ACQ). Instead, it remains in the Client Priority Queue (CPQ) and transmitted at a later time when the corresponding token bucket contains a sufficient number of tokens (unless the CPQ reaches full capacity, at which point, the frame is dropped). The majority of the work involved in the context of ATF takes place on the APs. The wireless controller is used to configure the ATF on Mesh and display the results.

In a mesh architecture, the mesh APs (parent and child MAPs) in a mesh tree access the same channel on the backhaul radio for mesh connectivity between parent and child MAPs. The root AP is connected by wire to the controller, and MAPs are connected wirelessly to the controller. Hence, all the CAPWAP and Wi-Fi traffic are bridged to the controller through the wireless backhaul radio and through RAP. In terms of physical locations, normally, RAPs are placed at the roof top and MAPs in multiple hops are placed some distance apart from each other based on the mesh network segmentation guidelines. Hence, each MAP in a mesh tree can provide 100 percent of its own radio airtime downstream to its users though each MAP accessing the same medium. Compare this to a non-mesh scenario, where neighboring local-mode unified APs in the arena next to each other in different rooms, serving their respective clients on the same channel, and each AP providing 100% radio airtime downstream. ATF has no control over clients from two different neighboring APs accessing the same medium. Similarly, it is applicable for MAPs in a mesh tree.

For outdoor or indoor mesh APs, ATF must be supported on client access radios that serve regular clients similarly to how it is supported on ATF on non-mesh unified local mode APs to serve the clients. Additionally, it must also be supported on backhaul radios which bridge the traffic to/from the clients on client access radios to RAPs (one hop) or through MAPs to RAPs (multiple hops). It is a bit tricky to support ATF on the backhaul radios using the same SSID/Policy/Weight/Client fair-sharing model. Backhaul radios do not have SSIDs and it always bridge traffic through their hidden backhaul nodes. Therefore, on the backhaul radios in a RAP or a MAP, the radio airtime downstream is shared equally, based on the number of backhaul nodes. This approach provides fairness to users across a wireless mesh network, where clients associated to second-hop MAP can stall the clients associated to first-hop MAP where second-hop MAP is connected wireless to first-hop MAP through backhaul radio even though the Wi-Fi users in the MAPs are separated by a physical location. In a scenario where a backhaul radio has an option to serve normal clients through universal client access feature, ATF places the regular clients into a single node and groups them. It also enforces the airtime by equally sharing the radio airtime downstream, based on the number of nodes (backhaul nodes plus a single node for regular clients).

Configure ATF on mesh (GUI)

Configure ATF on mesh using GUI.

Configure ATF to optimize bandwidth allocation among clients on a mesh network.

Procedure

1. Choose **Configuration** > **Wireless** > **Airtime Fairness** > **Global Config**.
2. For **5 GHz Band** and **2.4 GHz Band**, enable the **Status** and the **Bridge Client Access** toggle button.
3. To select the **Mode**, click the **Monitor** or **Enforced** radio button.
4. Enable or disable the **Optimization** toggle button.
5. Enter **Airtime Allocation**.
6. Click **Apply to Device**.

The ATF settings are applied and mesh APs operate with the new airtime fairness parameters.

Configure ATF on mesh

Configure ATF on mesh using commands.

Ensure fair airtime allocation and optimize wireless performance for mesh environments.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an RF profile to enter RF profile configuration mode.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6gh} rf-profile rf-profile1
   ```

3. Configure airtime allocation weight percentage for mesh APs.

   Example

   ```
   Device(config-rf-profile)# airtime-fairness bridge-client-access
   airtime-allocation allocation-weight-percentage
   ```

You have now configured mesh APs for ATF. Balanced airtime allocation improves wireless network efficiency.

```
Device# configure terminal
Device(config)# ap dot11 24ghz rf-profile rfprof24_1
Device(config-rf-profile)# airtime-fairness bridge-client-access
airtime-allocation 10
```

Create an ATF policy for a MAP

Learn how to create an ATF (Airtime Fairness) policy for a MAP using command line interface commands.

Define and enable an Airtime Fairness (ATF) policy for a Mesh Access Point (MAP). This policy optimizes wireless network performance and ensures equitable airtime distribution among connected clients.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile to enter wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy  rr-xyz-policy-1
   ```

3. Enable ATF in the existing RF profile.

   Example

   ```
   Device(config-wireless-policy)# dot11 24ghz airtime-fairness atf-policy
   ```

Airtime Fairness is applied to the specified MAP when the policy is enabled.

```
Device# configure terminal
Device(config)# wireless profile policy rr-xyz-policy-1
Device(config-wireless-policy)# dot11 24ghz airtime-fairness atf-policy1
```

Create an ATF policy (GUI)

Create an ATF policy for a MAP using GUI.

Create a new Air Time Fairness (ATF) policy and apply it to a MAP (Managed Access Point) for optimal client traffic sharing.

Procedure

1. Choose **Configuration** > **Air Time Fairness** > **Profiles**.
2. On the **Profiles** window, click **Add**.
3. In the **Add ATF Policy** window, specify a name, ID, and weight for the ATF policy.

> **Note**
>
> A weighted ratio is used instead of percentages, allowing the total to exceed 100. The minimum weight that you can set is 5.

4. Use the slider to enable or disable the **Client Sharing** feature.
5. Click **Save & Apply to Device** to save your ATF configuration.
6. Optional: To delete a policy, check the check box next to the appropriate policy and click **Delete**.
7. Optional: To edit an existing ATF policy, select the check box next to the policy you want to edit.

   In the **Edit ATF Policy** window that is displayed, you can modify the weight and client sharing details for the policy.

You have created and applied the new ATF policy to the selected MAP.

Add an ATF to a policy profile (GUI)

Add an ATF to a policy profile using GUI.

Enable ATF on your selected policy profiles to assign fair radio resource allocation policies to wireless clients.

Procedure

---

1. Choose **Configuration > Tags & Profiles > Policy**.
2. Click the name of your policy profile.
3. Click the **Advanced** tab.
4. In the **Air Time Fairness Policies** section, choose the appropriate status for the 2.4 GHz Policy and 5 GHz Policy.
5. Click **Update & Apply to Device**.

Your selected policy profile is updated and now includes the ATF settings you chose.

Enable ATF mode in an RF profile (GUI)

Enable ATF mode in an RF profile using GUI.

Enable Airtime Fairness mode to distribute wireless bandwidth more equitably among clients in an RF profile.

Procedure

---

1. Choose **Configuration > Tags & Profiles > RF**.
2. Click the name of the corresponding RF profile.
3. In the **RF Profile** window, click the **Advanced** tab.
4. In the **ATF Configuration** section, choose the appropriate status:
   - **Status**: If you choose **Enabled** as the status, select the **Mode** as either **Monitor** or **Enforced**. You can also enable or disable optimization for this mode.
   - **Bridge Client Access**

- **Airtime Allocation**: Enter the allocation value. You can set the value only after you enable the **Bridge Client Access**.

5. Click **Update & Apply to Device**.

ATF mode is enabled for the selected RF profile, and the corresponding settings are applied to the device.

Verify ATF configuration on mesh

Verify ATF configuration on mesh.

You can verify Cisco ATF configurations on mesh APs using these commands.

Use this **show** command to display the ATF configuration summary of all the radios:

```
Device# show ap airtime-fairness summary

AP Name                           MAC Address       Slot Admin    Oper
Mode           Optimization
-------------------------------- ----------------- ---- -------- -----------
-------------- ------------
ap1/2                             6c:99:89:0c:73:a0 0    ENABLED  DOWN
Enforce-Policy Enabled
ap1/2                             6c:99:89:0c:73:a0 1    ENABLED  UP
Enforce-Policy Enabled
ap1/3                             6c:99:89:0c:73:a1 0    ENABLED  DOWN
Enforce-Policy Enabled
ap1/3                             6c:99:89:0c:73:a1 1    ENABLED  UP
Enforce-Policy Enabled
```

Use this **show** command to display the ATF configuration for a 2.4-GHz radio:

```
Device# show ap dot11 24ghz airtime-fairness

AP Name                           MAC Address       Slot Admin    Oper
Mode           Optimization
-------------------------------- -----------------   ---- -------- -----------
-------------- ------------
ap1/2                             6c:99:89:0c:73:a0 1    ENABLED  UP
Enforce-Policy Enabled
```

Use this **show** command to display the ATF WLAN statistics:

```
Device# show ap name ap1 dot11 24ghz airtime-fairness wlan 12 statistics

AP Name                           MAC Address       Slot Admin    Oper
Mode           Optimization
-------------------------------- ----------------- ---- -------- -----------
-------------- ------------
ap1/2                             6c:99:89:0c:73:a0 0    ENABLED  DOWN
Enforce-Policy Enabled
ap1/2                             6c:99:89:0c:73:a0 1    ENABLED  UP
Enforce-Policy Enabled      Network level
```

Use this **show** command to display the wireless mesh summary:

```
Device# show wireless profile mesh summary

Number of Profiles: 2
```

```
Profile-Name                        BGN         Security  Bh-access  Description
------------------------------------------------------------------------------------------
mesh1                                             EAP       DISABLED

default-mesh-profile                              EAP       DISABLED   default
mesh profile
```

Use this **show** command to display the mesh ATF client access information:

```
Device# show mesh atf client-access

AP Name              Client Access Allocation   Override   Current nodes
                      Default %    Current %
------------------   ---------    ---------    --------   -------------
RAP                      25           40        Enabled          4
RAP                      33           40        Enabled          3
```

Mesh call admission control

Describes call admission control (CAC) for mesh, outlining how real-time session admission is controlled to prevent bandwidth oversubscription and includes configuration steps.

A mesh call admission control is a quality of service mechanism that

- continuously monitors bandwidth available to mesh access points
- regulates voice call admissions to maintain acceptable call quality, and
- rejects calls when bandwidth or resource limits are reached.

Call Admission Control (CAC) enables a mesh AP to maintain controlled quality of service (QoS) on the controller. This management helps maintain voice quality on the mesh network. Bandwidth-based, or static, CAC enables the client to specify how much bandwidth or shared medium time is required to accept a new call. Each AP determines whether it can accommodate a call by checking the available bandwidth and comparing it to the bandwidth required for the call. If there is not enough bandwidth available to maintain the maximum allowed number of calls with acceptable quality, the mesh AP rejects the call.

Mesh CAC is not supported in these scenarios.

- APs in a Mesh tree assigned with different site tags.
- APs in a Mesh tree assigned with the default site tag.

Configure mesh CAC (CLI)

Configure mesh CAC using commands.

Enable mesh CAC to manage call admission and ensure quality over wireless mesh links.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enable mesh CAC mode.

Example

```
Device(config)# wireless mesh cac
```

Mesh CAC is activated. Only the supported number of concurrent calls can occur over mesh links, which preserves call quality.

Fast teardown for a mesh deployment

Explains the fast teardown procedure for mesh deployments, detailing how failed mesh relationships are swiftly removed, with steps for configuration and verification to accelerate recovery and topology rebuilding.

A fast teardown is a mesh deployment feature that

- enables rapid detection of root AP uplink failures
- helps restore or reconfigure network service when the uplink is lost, and
- applies to mesh deployments with unreliable uplinks, such as wireless microwave links.

Fast teardown for mesh APs is not supported on Cisco Industrial Wireless (IW) 3702 Access Points.

Configure fast teardown for a mesh AP profile (GUI)

Learn how to enable fast teardown for a mesh AP profile to accelerate recovery from uplink failures in mesh networks.

Use this procedure to configure mesh AP profiles for rapid detection of uplink failures and improve mesh network resiliency.

Procedure

1. Choose **Configuration** > **Wireless** > **Mesh** > **Profiles**.
2. Click **Add**.
3. In the **Add Mesh Profile** window, click **Advanced**.
4. Select a security mode, an authentication method, and an authorization method.
5. Enable **Ethernet bridging** if it is required.
6. Enter the bridge group name. Then enable Strict Match BGN.
7. Select a band backhaul transmission rate for your radio.
8. Perform these actions in the **Fast Roaming** section:
   - Check the **Fast Teardown** check box to detect the root AP uplink failure faster in a mesh deployment and to address fast teardown of the mesh network when an uplink failure occurs.
   - In the **Number of Retries** field, enter the number of retries allowed until gateway is considered unreachable. The valid range is from 1 to 10.
   - In the **Interval value** field, enter the retry value. The valid range is from 1 to 10 seconds.

- In the **Latency Threshold** field, enter the threshold for a round-trip latency between the AP and the controller. The valid range is from 1 and 500 milliseconds.
- In the **Latency Exceeded Threshold** field, enter the latency interval in which at least one ping must succeed in less than the specified time. The valid range is from 1 to 30 seconds.
- In the **Uplink Recovery Interval** field, enter the time during which root AP uplink must be stable in order to accept the child connections. The valid range is from 1 and 3600 seconds.

9. Click **Apply to Device**.

Your mesh AP profile now supports fast teardown. This configuration enables the system to detect uplink failures more quickly, helping your devices recover rapidly.

Configure fast teardown for a mesh AP profile (CLI)

Use this task to configure the fast teardown feature for a mesh AP profile using CLI commands to improve recovery times in mesh networks.

Enable and configure fast teardown for a mesh AP profile to reduce network restoration time and increase network reliability.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile and enter the mesh profile configuration mode.

   Example

   ```
   Device(config)# wireless profile mesh profile-name
   ```

3. Enable the fast teardown of mesh network and configure the feature's parameter.

   Example

   ```
   Device(config-wireless-mesh-profile)# fast-teardown
   ```

4. Enable the fast teardown feature.

   Example

   ```
   Device(config-wireless-mesh-profile-fast-teardown)# enabled
   ```

5. Optional: Configure the retry interval.

   Example

   ```
   Device(config-wireless-mesh-profile-fast-teardown)# interval duration
   ```

The valid range is from 1 to 10 seconds.

6. Optional: Set the latency interval so that at least one ping succeeds within your chosen threshold time.

   Example

   ```
   Device(config-wireless-mesh-profile-fast-teardown)# latency-exceeded-threshold
    duration
   ```

   The valid range is from 1 to 30 seconds.

7. Optional: Specify the latency threshold.

   Example

   ```
   Device(config-wireless-mesh-profile-fast-teardown)# latency-threshold
   threshold-range
   ```

   The valid range is from 1 to 500 milliseconds.

8. Optional: Specify the number of retries until the gateway is considered unreachable.

   Example

   ```
   Device(config-wireless-mesh-profile-fast-teardown)# retries retry-limit
   ```

   The valid range is from 1 to 10.

9. Optional: Specify the time during which root access point uplink has to be stable to accept child connections.

   Example

   ```
   Device(config-wireless-mesh-profile-fast-teardown)# uplink-recovery-intervals
    recovery interval
   ```

   The valid range is from 1 to 3600 seconds.

You have configured the mesh AP profile with fast teardown enabled and applied custom parameters. This configuration improves your network's responsiveness to disruptions.

```
Device# configure terminal
Device(config)# wireless profile mesh mesh1
Device(config-wireless-mesh-profile)# fast-teardown
Device(config-wireless-mesh-profile-fast-teardown)# enabled
Device(config-wireless-mesh-profile-fast-teardown)# interval 5
Device(config-wireless-mesh-profile-fast-teardown)# latency-exceeded-threshold
 20
Device(config-wireless-mesh-profile-fast-teardown)# latency-threshold 20
Device(config-wireless-mesh-profile-fast-teardown)# retries 1
Device(config-wireless-mesh-profile-fast-teardown)# uplink-recovery-intervals
 1
```

Fast teardown verification with default mesh profile

Provides verification of fast teardown with default mesh profile.

To verify the fast teardown with the default mesh profile, use this command:

```
Device# show wireless profile mesh detailed default-mesh-profile
Mesh Profile Name            default-mesh-profile
------------------------------------------------
Fast Teardown                          : ENABLED
Number of Retries                      : 4
Interval in sec                        : 1
Latency Threshold in msec              : 10
Latency Exceeded Threshold in sec      : 8
Uplink Recovery Interval in sec        : 60
```

194 Redundant Root Access Point (RAP) Ethernet Daisy Chaining

Topics:

- Redundant RAP Ethernet daisy chaining

Redundant RAP Ethernet daisy chaining

Explains how redundant RAP Ethernet daisy chains allow RAPs to be connected using wired Ethernet to avoid latency in backhaul link failure recovery.

A redundant RAP Ethernet daisy chain is a network topology feature that

- connects Root APs (RAPs) in a sequence using wired Ethernet links
- provides redundant paths with two switches acting as designated ports for failover, and
- minimizes latency in backhaul link failure recovery by reversing data flow through a new STP root.

This feature proposes a redundancy in the daisy chain, wherein two switches act as a redundant Designated Port, each connected to either end of the daisy chain. In case of a link failure, the link direction is reversed using a new STP root.

A redundant RAP Ethernet daisy chain shares capabilities with the mesh daisy chain feature. Both topologies provide redundancy and improve network resiliency. In the redundant RAP Ethernet daisy chain topology, each AP encapsulates a packet with a CAPWAP header and forwards it from its wireless client to the controller. The AP bridges the packet from its secondary Ethernet interface to its primary Ethernet interface, including CAPWAP packets sent from other APs' wireless clients. Both 2.4 GHz and 5 GHz radios are available for client access.

Redundant RAP Ethernet daisy chain is supported on the IW6300 AP model.

The daisy chain strict RAP configuration is applicable to Cisco IOS APs only.

If a CAPWAP loss occurs on the first RAP connected to the switch in an Ethernet daisy chain topology, the entire chain loses its uplink, causing a long recovery time. When the RAP Ethernet daisy chain is enabled, the CAPWAP data keepalive interval increases threefold.

> **Note**
>
> Only the wired uplink configuration is valid when an AP is configured as a Bridge or Flex Bridge mode Root AP.

Prerequisites for redundant RAP Ethernet daisy chaining support

This topic outlines the requirements you must meet before enabling redundant RAP Ethernet daisy chaining support.

To successfully configure redundant RAP Ethernet daisy chaining, ensure that you:

- Enable Ethernet bridging.
- Enable the strict-wired-uplink feature.

Configure redundant RAP Ethernet daisy chaining support (CLI)

Use this procedure to configure redundant RAP Ethernet daisy chaining using CLI commands.

Enable redundant RAP Ethernet daisy chaining on a mesh profile to provide link redundancy in wireless mesh networks.

Use this configuration to improve network robustness by allowing redundant paths in the RAP Ethernet daisy chain topology.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a mesh profile and enter mesh profile configuration mode.

Example

```
Device(config)# wireless profile mesh profile-name
```

3. Configure daisy chain STP redundancy.

Example

```
Device(config-wireless-mesh-profile)# daisychain-stp-redundancy
```

Redundant RAP Ethernet daisy chaining is enabled for the specified mesh profile.

```
Device# configure terminal
Device(config)# wireless profile mesh default-mesh-profile
Device(config-wireless-mesh-profile)# daisychain-stp-redundancy
```

Verify daisy chain redundancy

Verify daisy chain redundancy using commands.

To verify the ethernet daisy chain summary, use this command:

```
Device# show wireless mesh ethernet daisy-chain summary

AP Name      BVI MAC          BGN     Backhaul      Ethernet          STP Red
-------------------------------------------------------------------------------
RAP4        683b.78bf.15f0    IOT     Ethernet0     Up  Up  Dn  Dn   Enabled
RAP3        683b.78bf.1634    IOT     Ethernet0     Up  Up  Dn  Dn   Enabled
RAP1        6c8b.d383.b4d4    IOT     Ethernet0     Up  Up  Dn  Dn   Enabled
RAP2        6c8b.d383.b4e8    IOT     Ethernet0     Up  Up  Up  Dn   Enabled
```

To verify the ethernet daisy chain Bridge Group Name (BGN) details, use this command:

```
Device# show wireless mesh ethernet daisy-chain bgn <IOT>

AP Name   BVI MAC          BGN    Backhaul    Ethernet          STP Red
-------------------------------------------------------------------------------
RAP4     683b.78bf.15f0    IOT    Ethernet0   Up  Up  Dn  Dn   Enabled
RAP3     683b.78bf.1634    IOT    Ethernet0   Up  Up  Dn  Dn   Enabled
RAP1     6c8b.d383.b4d4    IOT    Ethernet0   Up  Up  Dn  Dn   Enabled
RAP2     6c8b.d383.b4e8    IOT    Ethernet0   Up  Up  Up  Dn   Enabled
```

To verify the mesh profile, use this command:

```
Device# show wireless profile mesh detailed default-mesh-profile

Mesh Profile Name : default-mesh-profile
-----------------------------------------------
Description : default mesh profile
Bridge Group Name : IOT
```

```
Strict match BGN : ENABLED

Ultra-Reliable Wireless Backhaul Background

Ultra-Reliable Wireless Backhaul (URWB) is a wireless technology that delivers highly reliable, low-latency network connectivity for critical applications and devices, using IEEE 802.11 standards in the 5 GHz band.

Ultra-Reliable Wireless Backhaul (URWB) is a wireless technology developed for mission and business critical applications that demand high reliability, low latency, and robust performance. It operates in the 5 GHz frequency band and is based on the widely adopted IEEE 802.11 standards. Leveraging the 802.11 framework simplifies implementation for Information Technology (IT) and Operational Technology (OT) teams. As a result, URWB enables greater deployment flexibility, reduced infrastructure costs, and accelerated installation when connecting fixed and mobile devices.

URWB is designed for wireless connectivity needs that are an integral part of your network infrastructure, rather than connecting end users like Wi-Fi technology is commonly used for.

URWB provides scalability without compromising reliability, delivering low latency and high availability. These characteristics are essential for mobile device use cases where stable connections and minimal latency are critical to ensuring safety and maintaining operational efficiency.

URWB supports two distinct connectivity models:

- Mobility: Provides seamless and uninterrupted connectivity to moving devices. Commonly used for Autonomous Guided Vehicles (AGV), autonomous mobile robots (AMR), trains, and other mobile devices.
- Fixed infrastructure: Establishes connectivity between radios attached to stationary structures such as poles, towers, or buildings. This architecture is frequently used for wireless backhaul and physical surveillance.

Mobility roles

1. Base (Infrastructure – AP role)

   Behavior: Serves as a fixed access point that mobile clients connect to.

2. Base-Relay (Infrastructure – Relay role)

   Behavior: A stationary infrastructure node that extends wireless coverage by relaying traffic between bases and clients.

3. Client (Mobile/Vehicle)

   Behavior: A moving node (e.g., mounted on a vehicle/crane/AGV) that actively scans for, connects to, and roams between infrastructure nodes.

Topologies

URWB supports multiple network configurations, including:

- Fixed Mesh: Multiple nodes are interconnected, allowing data to be routed dynamically through the most efficient path. Ideal for large industrial sites or campuses where redundancy and self-healing capabilities are required.
- Point-to-Multipoint (PTMP): A single central node connects to multiple remote nodes. Common in scenarios like wireless backhaul for several field devices or edge networks connecting to a central hub.
- Mobility: Supports connectivity to moving assets such as vehicles or robots. Essential for use cases requiring continuous, low-latency communication while in motion.

Benefits

- ultra-low latency,
- seamless handoffs, even at high speed (220mph - 350Km/h),
- high-throughput,

- high-availability with ultra-fast failover, and
- supports both fixed and mobile devices.

Limitations and restrictions

The following limitations exist for this release:

- Compatibility- URWB on Cisco Wireless project supports select access points. For complete information on AP devices use case and country support, see the guide "URWB on Cisco Wireless Use Case and Country".
- Mobility architectures extending over Layer 3 networks are not supported. Mobility deployments must be deployed with all Base access points in the same network segment.
- 6 GHz Standard Power is not supported on URWB radios.
- URWB supports up to two radio slots per access point.
- 2.4 GHz radios are not supported.
- SD Access (Wireless Fabric) is not supported.
- URWB supports one wired network port on each access point. LAN ports, on applicable access points, are not supported.
- Throughput on URWB is subject to processing limitations, which varies per access point platform.

Configure URWB using the controller

Configures URWB network settings and parameters using the wireless controller interface. This process enables centralized management and deployment of ultra-reliable wireless backhaul profiles for optimized connectivity in mission-critical environments.

Create URWB network profile (GUI)

Describes how to create URWB network profile for APs in the GUI.

A URWB Network Profile is a configuration framework designed to enable the setup of an Ultra-Reliable Wireless Backhaul (URWB) network for APs. This profile allows APs to form a wireless mesh network with enhanced reliability, performance, and security.

Complete these steps to configure URWB network profile:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **URWB Network Profile**.
2. Click **Add**.

   The **Add URWB Network Profile** page is displayed.

3. In the **General** tab, complete the following:
   a) To edit the profile, enable the **URWB Status** check box.
   b) Enter the **URWB Network Profile Name**.
   c) Enter the description of the profile name.
   d) Check the **Strong Network Key** check box, to configure a strong password evaluation for the network key. If you enable strong network key, it means that the network key must contain atleast one uppercase, lowercase alphabets, and digits.

e) Select either **Unencrypted** or **AES** from the **Network Key Type** drop-down list. You can use only **Unencrypted** for configuration.
f) Enter the **Network-Key**.

The network key must be between 8 and 63 characters long. Only uppercase alphabets, lowercase alphabets, digits, or special characters are allowed in the network key.

4. Click the **Mobility** tab and select one of the following **Mobility Roles**:
   - Base
   - Base Relay
   - Client
5. To edit the MPO attributes, click the **MPO** tab.

> **Note**
>
> To edit the MPO attributes, select an option other than **Disabled** in the **Packet Duplication Mode**. MPO is not mandatory to make the system operate.

a) In the **Class of Service** field, enter a value from 0 to 6.

This value indicates the number of packets that need to be duplicated. The default value is 6.

b) In the **Number of Paths** field, enter a value from 1 to 4.

This value indicates the number of independent paths to be established for traffic duplication. The default value is 1.

c) In the **Minimum SNR** field, enter a value from 0 to 96.

This value indicates the minimum SNR for a wireless link to be considered for building a redundant path. The default value is 20.

d) To enable telemetry, check the **Enable Telemetry** check box.

6. Complete the following details in the **Advanced** tab:

> **Note**
>
> You can leave the advanced parameters at their default settings; you do not need to configure them.

a) In the **Ethernet Protocols** area, select the **Allow Ether Types** from the drop-down list.

Select **List** from the **Allow Ether Types** drop-down list to allow only custom Ether values.

b) Check the **Legacy Ethernet** check box to allow Ethernet I frames fowarding.
c) In the **Unicast** area, check the **Unicast Flood** check box to enable unicast flood and enter unicast flood limitation.
d) Check the **Unicast Flood Limitation** check box to flood one packet every 5 seconds.
e) Select the **Multicast** option from the drop-down list.

7. Select the **Multicast** option from the drop-down list.

8. Check the **High Availability Enabled** check box to enable the redundancy support for devices in the same class (coordinator, vehicle devices, and point-to-multi-point base).
9. Click **Apply to Device**.

The URWB network profile is created.

Configure URWB network profile (CLI)

Describes the CLI steps to create a URWB network profile

Configure the URWB network key in the URWB pofile. The URWB profile is a wireless profile type that contains the URWB configuration parameters. All the APs with the same site-tag are configured with the URWB configurations defined in the URWB profile.

Complete the following steps to create a URWB network profile and configure the URWB network key:

Procedure

---

1. Enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter a profile name to create a URWB profile.

   Example

   ```
   Device(config)# wireless profile urwb urwb-profile-name
   ```

   This command creates a URWB profile and enters into the wireless URWB profile configuration mode.

3. Optional: Configure a strong password evaluation for the network key.

   Example

   ```
   Device(config-wireless-urwb-profile)# strong-network-key
   ```

   If you enable strong network key, it means that the network key must contain at least one uppercase, lowercase alphabets, and digits.

4. Configure a network key for secure communication between the URWB nodes.

   Example

   ```
   Device(config-wireless-urwb-profile)# network-key key {0 | 8}<network-key>
   ```

   Here, **0** indicates that you must enter an unencrypted network key; and **8** indicates an AES encrypted network key.

> **Note**
>
> You can only use type 0 for configuration. If you configure the encryption command (**password encryption aes**) in the configuration mode, the output of the **show running-config** command displays the details of the encrypted network key (8 xxxx).
>
> For more information, see Setting a Private Configuration Key for Password Encryption.

> **Note**
>
> The network key supports all the printable ASCII characters except the following special characters: ~ | ; $ < > & ^ ` ? \ and ".

5. Enable the URWB profile in the wireless URWB profile configuration mode.

   Example

   ```
   Device(config-wireless-urwb-profile)# no shutdown
   ```

   To disable the URWB profile, use the **shutdown** command.

6. Exit the sub-mode.

   Example

   ```
   Device(config-wireless-urwb-profile)# exit
   ```

The URWB network profile is created and the network key is configured in the wireless profile.

Example

```
Device# configure terminal
Device(config)# wireless profile urwb urwb-profile-name
Device(config-wireless-urwb-profile)# strong-network-key
Device(config-wireless-urwb-profile)# network-key network-key-type 0
<network-key>
Device(config-wireless-urwb-profile)# no shutdown
Device(config-wireless-urwb-profile)# exit
```

Configure URWB mobility backhaul check (CLI)

Complete the following steps to configure mobility role and backhaul check:

Procedure

---

1. Enter configuration mode.

Example

```
Device# configure terminal
```

2. Enter a profile name to create a URWB profile.

   Example

   ```
   Device(config)# wireless profile urwb urwb-profile-name
   ```

   This command creates a URWB profile and enters into the wireless URWB profile configuration mode.

3. Configure URWB mobility role.

   Example

   ```
   Device(config-wireless-urwb-profile)# mobility role {base| base-relay | client}
   ```

4. Configure URWB mobility backhaul-check when coordinator is unreachable

   Example

   ```
   Device(config-wireless-urwb-profile)# [no] mobility backhaul-check
   coordinator-down {handoff-inhibition | relay-switch}
   ```

   This command configures the handoff and handoff-inhibition when coordinator is unreachable. The relay-switch configuration switches to Infrastructure Wireless Relay mode if the coordinator is unreachable.

   Use the **no** form of this command to disable URWB mobility backhaul-check with coordinator-down

5. Configure URWB mobility backhaul-check when Ethernet ports are down.

   Example

   ```
   Device(config-wireless-urwb-profile)# [no] mobility backhaul-check eth-down
   {handoff-inhibition|relay-switch}
   ```

   This command configures the handoff and handoff-inhibition when when all Ethernet ports are disconnected. The relay-switch configuration switches to Infrastructure Wireless Relay mode if all Ethernet ports are down.

   Use the **no** form of this command to disable URWB mobility backhaul-check when Ethernet ports are down.

The URWB mobility role and backhaul check is configured.

Example

```
Device# configure terminal
Device(config)# wireless profile urwb urwb-profile-name
Device(config-wireless-urwb-profile)# mobility role {base| base-relay | client}
Device(config-wireless-urwb-profile)# [no] mobility backhaul-check
coordinator-down {handoff-inhibition | relay-switch}
Device(config-wireless-urwb-profile)# [no] mobility backhaul-check eth-down
{handoff-inhibition|relay-switch}
```

URWB Backhaul Check

The Backhaul Check feature monitors the connectivity status of infrastructure (base/base_relay) units' wired Ethernet ports and/or mesh-end connectivity. When backhaul connectivity is lost, the feature prevents mobile units from handing off to that infrastructure unit. This process ensures that traffic is not routed to a 'dead end' in the network.

Purpose

In a Fluidity/URWB network, infrastructure units (track-side radios) provide wireless coverage to mobile units (vehicle radios). These infrastructure units typically connect to the wired network via Ethernet. If an infrastructure unit loses its wired backhaul connection, it becomes a 'black hole.' Mobile units could connect to it wirelessly, but their traffic would have no path to the network.

Standard (Ethernet Port) Backhaul Check vs. Mesh-End Backhaul Check

This feature supports two operational modes: Standard Backhaul Check and Mesh-End Backhaul Check.

Standard Backhaul Check

What it monitors: The physical Ethernet port status on the infrastructure unit itself.

Use case: The infrastructure unit has a direct wired Ethernet connection to the backbone network. If that cable or port fails, the unit has no backhaul.

Mesh-End Backhaul Check

What it monitors: The logical reachability to the mesh-end (coordinator) via the wired AutoTAP probing mechanism – essentially checking if a pseudowire path to the coordinator still exists.

Use case: The infrastructure unit does NOT have a direct Ethernet connection to the backbone. Instead it reaches the network through a chain of other infrastructure units (e.g., a base-relay daisy chain). Even if its own Ethernet port is operational or does not exist, the path to the coordinator or mesh-end may be broken further upstream.

Configure URWB mobility MPO parameters (CLI)

Complete the following steps to configure URWB mobility MPO parameters.

Procedure

1. Enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter a profile name to create a URWB profile.

   Example

   ```
   Device(config)# wireless profile urwb urwb-profile-name
   ```

   This command creates a URWB profile and enters into the wireless URWB profile configuration mode.

3. Enable URWB mobility multipath operation (MPO).

   Example

   ```
   Device(config-wireless-urwb-profile)# mobility mpo enable {rx-only | tx-rx}
   ```

   This command enables MPO Receive Only or MPO Bidirectional.

4. Configure URWB mobility MPO traffic CoS.

Example

```
Device(config-wireless-urwb-profile)# mobility mpo cos cos-value
```

Here, the CoS value is between 0 to 7.

5. Configure URWB mobility MPO maximum paths (maximum number of MPO links).

Example

```
Device(config-wireless-urwb-profile)# mobility mpo path number of links
```

Here, the number of links are between 1 to 4.

6. Configure URWB mobility MPO RSSI.

Example

```
Device(config-wireless-urwb-profile)# mobility mpo rssi rssi-value
```

This command configures minimum RSSI to establish MPO redundant links. Here, the RSSI value is between 0 to 96.

7. Configure URWB mobility MPO telemetry.

Example

```
Device(config-wireless-urwb-profile)# [no] mobility mpo telemetry
```

The URWB mobility MPO parameters are configured.

Example

```
Device# configure terminal
Device(config)# wireless profile urwb urwb-profile-name
Device(config-wireless-urwb-profile)# [no] mobility mpo enable rx-only
Device(config-wireless-urwb-profile)# mobility mpo path 4
Device(config-wireless-urwb-profile)# mobility mpo rssi 4
Device(config-wireless-urwb-profile)# [no] mobility mpo telemetry
```

Configure URWB mobility scan parameters (CLI)

Before you begin

The mobility scan parameters are strictly connected to the channel list configuration. Together with this parameter, you must also configure the channel list for scanning. To configure the channel list, see the Configure URWB channel list (CLI) section.

Procedure

---

1. Enter configuration mode.

Example

```
Device# configure terminal
```

2. Enter a profile name to create a URWB profile.

   Example

   ```
   Device(config)# wireless profile urwb urwb-profile-name
   ```

   This command creates a URWB profile and enters into the wireless URWB profile configuration mode.

3. Configure URWB mobility scan.

   Example

   ```
   Device(config-wireless-urwb-profile)# mobility scan {isolation scan-wait-time
    0-65535| periodic scan-period 0-65535 | rssi-threshold threshold-value 0-96}
   Device(config-wireless-urwb-profile)# no mobility scan isolation
   Device(config-wireless-urwb-profile)# no mobility scan periodic
   ```

   Use the **no** form of the command to disable isolation and periodic time for scanning.

The URWB mobility scan parameters are configured.

Example

```
Device# configure terminal
Device(config)# wireless profile urwb urwb-profile-name
Device(config-wireless-urwb-profile)# mobility scan {isolation scan-wait-time
 0-65535| periodic scan-period 0-65535 | rssi-threshold threshold-value 0-96}
Device(config-wireless-urwb-profile)# no mobility scan isolation
Device(config-wireless-urwb-profile)# no mobility scan periodic
```

Configure URWB MPLS parameters (CLI)

Complete the following steps to configure URWB MPLS dataframe packets for a specified device:

Procedure

---

1. Enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter a profile name to create a URWB profile.

   Example

   ```
   Device(config)# wireless profile urwb urwb-profile-name
   ```

   This command creates a URWB profile and enters into the wireless URWB profile configuration mode.

3. Configure MPLS Ethernet filter, filtering method.

Example

```
Device(config-wireless-urwb-profile)# [no] mpls ether-filter ethertypes
filtering {allow-all | use-allow-list}
```

This command allows all ethertypes or uses the configured ethertypes allowed list.

Use the **no** form of the command to disable MPLS ether-filter filtering method.

4. Configure Ethernet filter allow-list and add the Ethernet type value to the allow-list.

Example

```
Device(config-wireless-urwb-profile)# [no] mpls ether-filter ethertypes
allow-list add ether-type-value
```

Here, the value of the Ethernet type is from 0 to 65535.

Use the **no** form of the command to remove ether-type from URWB ether-filter. allow-list .

5. Configure ethernet I frames forwarding.

Example

```
Device(config-wireless-urwb-profile)# [no] mpls ether-filter ethernet-I
```

Here, the value of the Ethernet type is from 0 to 65535.

Use the **no** form of the command to disable ether-filter Ethernet-I frames.

6. Configure high-availability.

Example

```
Device(config-wireless-urwb-profile)# mpls high-availability
Device(config-wireless-urwb-profile)# [no] mpls high-availability
```

Use the **no** form of the command to disable high-availability.

7. Configure high-availability time out for device failure detection.

Example

```
Device(config-wireless-urwb-profile)# mpls high-availability timeout
timeout-value
```

Here, the *timeout-value* is the high-availability node failure detection timeout. The value is from 0 to 65535 ms.

The URWB MPLS parameters are configured.

Example

```
Device# configure terminal
Device(config)# wireless profile urwb urwb-profile-name
Device(config-wireless-urwb-profile)# [no] mpls ether-filter ethertypes
filtering allow-all
Device(config-wireless-urwb-profile)# [no] mpls ether-filter ethertypes
allow-list add 50
```

```
Device(config-wireless-urwb-profile)# [no] mpls ether-filter ethernet-I
Device(config-wireless-urwb-profile)# mpls high-availability
Device(config-wireless-urwb-profile)# mpls high-availability timeout 54
Device(config-wireless-urwb-profile)# [no] mpls high-availability
```

Configure multicast for URWB profile (CLI)

Complete the following steps to configure the multicast settings for URWB profile:

Procedure

1. Enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter a profile name to create a URWB profile.

   Example

   ```
   Device(config)# wireless profile urwb urwb-profile-name
   ```

   This command creates a URWB profile and enters into the wireless URWB profile configuration mode.

3. Configure multicast settings.

   Example

   ```
   Device(config-wireless-urwb-profile)# multicast {all | coordinator-only}
   Device(config-wireless-urwb-profile)# [no] multicast
   ```

   This command enables multicast rule to all devices or only to the coordinator device.

   Use the **no** form of the command to disable multicast.

The URWB multicast settings are configured.

Example

```
Device# configure terminal
Device(config)# wireless profile urwb urwb-profile-name
Device(config-wireless-urwb-profile)# multicast coordinator-only
Device(config-wireless-urwb-profile)# [no] multicast
```

Limitations and guidelines for secondary Ethernet ports

The limitations and guidelines for secondary Ethernet ports highlight key operational constraints and configuration considerations to ensure proper deployment and functionality of the feature.

When deploying secondary Ethernet ports, observe these constraints:

- **Redundancy Impact** : Activating the secondary Ethernet port disables dual-Ethernet redundancy (backup mode).
- **VLAN Configuration**: The primary and secondary Ethernet ports must share an identical VLAN configuration.

- **State Changes**: Any modification to the secondary port state (enabled or disabled) requires a device reboot for the change to take effect.
- **Model-Specific Restrictions**: For the Cisco Catalyst 9124AX Series model, the third port (LAN1) is limited to client connections or daisy-chaining and cannot operate as a root port.
- **Mobility Infrastructure Limitation**: In a mobility-configured network with two mesh-end devices, the mobility infrastructure must be deployed using a ring topology. The two mesh-end APs must be positioned as the first and last APs in the ring and must be directly connected to the controller. Additionally, both mesh-end APs are required to reach the controller through the same wired port, designated as the root port, to ensure proper network operation and failover capabilities.

Configure secondary Ethernet port (GUI)

Configure the secondary Ethernet port on supported access point models to enable wired client connectivity and optional PoE functionality.

Configure the secondary Ethernet port to enable wired client connectivity and optional PoE functionality.

From release 26.2.1, the URWB stack supports permanently enabling two wired interfaces, allowing independent management of Wired0 and Wired1 ports and enabling daisy-chaining or mesh ring deployments without external switches. This feature restores parity with standalone Industrial Wireless software and enhances flexibility and cost efficiency in URWB deployments. Enable optional PoE on the secondary Ethernet port to provide wired client support and power to downstream devices.

Before you begin

Ensure that your access point model supports configuration of a secondary Ethernet port and Power over Ethernet (PoE). Only the Cisco Catalyst 9124AX series supports PoE on port ID 2.

Procedure

1. Log in to the Controller web interface.
2. Choose **Configuration > Tags & Profiles > URWB Network Profile**.
3. Select the **Wired Clients** tab.
4. Go to the **Ethernet settings** section.
5. Choose the physical port ID to map as the secondary logical interface or disable the secondary Ethernet interface.
6. Enable the **LAN Port PoE** toggle if your device model supports powering downstream devices.

   > **Note**
   >
   > PoE functionality is supported only on LAN1 port of Cisco Catalyst 9124AX series.

7. Click **Save**.
8. Reboot the device.

What to do next

1. Navigate to **Monitoring > Wireless > AP Statistics** on the wireless controller interface.
2. Select the specific AP under the **General** tab to access its detailed statistics.

3. Click the **URWB** sub-tab to confirm that the secondary Ethernet configuration changes have been correctly applied after the device reboot.

> **Note**
>
> Hot configuration support is limited to changing the mapping of the secondary URWB port to a different physical port (e.g., from LAN1 to LAN2).

Configure secondary Ethernet port (CLI)

Configure the secondary Ethernet port on supported Cisco access points using CLI commands to enable wired client connectivity and optional PoE functionality.

Configure the secondary LAN port ID on compatible Cisco access points. Enable optional PoE on the secondary Ethernet port to provide wired client support and power to downstream devices.

Before you begin

- Identify the correct LAN Port ID for your hardware (supported range: 1 to 4). You can use the **show interface status** command in privileged EXEC mode to list the LAN Port IDs of the device.
- Ensure that your access point model supports configuration of a secondary Ethernet port and Power over Ethernet (PoE). Only the Cisco Catalyst 9124AX series supports PoE on port ID 2.

Procedure

1. Use the **wireless profile urwb** *profile-name* command to enter the URWB profile configuration mode.

   Example

   ```
   Device# wireless profile urwb Cisco-AP
   ```

2. Use the **ethernet secondary lan id** *port-id* command to configure the secondary LAN.

   Example

   ```
   Device# ethernet secondary lan id 1
   ```

   The supported port ID range is 0 to 4. On most supported access point models, Port ID 1 corresponds to the secondary Ethernet port. Setting the port ID to zero effectively disables the secondary port in URWB.

3. (Optional) Use the **ethernet secondary lan poe** command to enable PoE-out on the secondary port.

   Example

   ```
   Device# ethernet secondary lan poe
   ```

> **Note**
>
> PoE functionality is supported only for the Cisco Catalyst 9124AX access point series on port ID 2.

4. (Optional) Use the **show ap name** *ap_name* **urwb info** command to verify that the secondary Ethernet port is active and configured correctly.

Example

```
Device# show ap name Cisco-AP urwb info
```

```
Secondary Ethernet
  Port state                          : Disabled
  PoE out                             : Disabled
```

Create URWB radio profile (GUI)

Describes the steps to create a URWB radio profile.

The URWB wireless radio profile is used to configure a particular radio slot for the URWB backhaul operation. The URWB wireless radio profile, when applied to a radio interface on a device, is relevant only if the device is in the URWB mode.

To set up a backhaul link with URWB, configure the URWB radio profile to a radio interface. Follow these steps to create a URWB radio profile:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF/Radio**.
2. Click the **Radio** tab.
3. Click **Add**.

   The **Add Radio Profile** window is displayed.
4. In the **Add Radio Profile** window, click the **General** tab and enter the radio profile name.
5. Click the **URWB** tab.
6. From the **URWB Radio Role** drop-down list, choose one of the options:
   - Disabled: Disables the URWB radio role. This is the default value.
   - Fixed
   - Mobility
   - Fixed Point to Multi Point
7. From the **Radio Band** drop-down list, choose one of the radios:
   - 5 GHz
   - 6 GHz

8. From the **Channel** drop-down list, choose the appropriate channel.
9. From the **Channel width** drop-down list, choose one of the channel widths:
   - 20 MHz
   - 40 MHz
   - 80 MHz
   - 160 MHz
10. In the **Encryption** section, choose a type of encryption from the **AES** drop-down list.
   - Disabled: Disables the encryption. This is the default value.
   - Fixed Key
   - Rotating Key: When you choose the Rotating Key encryption, enter the **Key Rotation Timeout** in seconds. The value must be in the range of 1 to 65,535. The default is 15.

> **Note**
>
> Configuring the rotating key can impact mobility performance.

11. In the **Fixed Point to Multi Point** section, configure the following:
   a) Check the **Auto Scan** check box to allow clients to perform frequency scanning when the RSSI from the base is below the threshold or when there is no signal.
   b) Enter the cluster ID to identify a cluster formed of base(s) and client(s).

> **Note**
>
> Devices with different cluster IDs do not connect in one topology.

   c) Enter the tower ID.

> **Note**
>
> Redundant pair of base(s) must be assigned the same unique tower ID.

   d) Enter the **RSSI Threshold** to build a path to the base. The range is from 0 to 100. The default is 0.
12. Click **Apply to Device** to save the configuration.

The URWB radio profile has been created.

What to do next

Assign the URWB profiles to the wireless RF tag.

Create RF tags and assign profiles (GUI)

Complete these steps to create RF tags and assign profiles:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**, click the **RF** tab, and then click **Add**.

   The **Add RF Tag** page is displayed.
2. In the **Add RF Tag** page, enter the name and description of the RF tag.
3. Select the required **6 GHz Band RF Profile**, **5 GHz Band RF Profile**, and **2.4 GHz Band RF Profile** to be associated with the RF tag.
4. Select an appropriate **URWB Network Profile** for the RF tag.
5. Choose the required **6 GHz Radio Profile**, **5 GHz Radio Profile**, and **2.4 GHz Radio Profile** to be associated with the RF tag.
6. Click **Apply to Device** to save the configuration.

The RF tags are created and profiles are assigned.

Create URWB radio profile (CLI)

Describes the CLI steps to create a URWB radio profile.

Complete the following steps to configure the URWB radio profile:

Procedure

1. Enter configuration mode to start creating a URWB radio profile.

   Example

   ```
   Device# configure terminal
   ```
2. Enter a profile name to create a wireless radio profile.

   Example

   ```
   Device(config)# wireless profile radio urwb-radio-profile-name
   ```

   This command creates a wireless radio profile and enters into the wireless profile radio configuration mode.
3. Configure URWB channel radios in the 5-GHz or 6-GHz bands.

   Example

   ```
   Device(config-wireless-radio-profile)# urwb channel {5ghz | 6ghz} channel
   ```

   The channel range is from 1 to 233.
4. Configure URWB channel width.

Example

```
Device(config-wireless-radio-profile)# urwb cwidth {160MHz | 20MHz | 40MHz |
 80MHz}
```

The valid channel widths are 160MHz, 20MHz, 40MHz, and 80MHz.

5. Configure URWB role of the radio, as fixed, mobility, or point-to-multi-point.

Example

```
Device(config-wireless-radio-profile)# urwb role {fixed | point-to-multi-point
 | mobility}
```

6. Exit the sub-mode.

Example

```
Device(config-wireless-radio-profile)# exit
```

The URWB radio profile is created.

Example

```
Device# configure terminal
Device(config)# wireless profile radio urwb-radio-profile-name
Device(config-wireless-radio-profile)# urwb channel 5ghz 120
Device(config-wireless-radio-profile)# urwb cwidth 160MHz
Device(config-wireless-radio-profile)# urwb role fixed
Device(config-wireless-radio-profile)# exit
```

Configure URWB point-to-multi-point parameters (CLI)

Complete the following steps to configure the URWB fixed point-to-multi-point (PTMP) parameters:

Procedure

---

1. Enter configuration mode to create a URWB radio profile.

Example

```
Device# configure terminal
```

2. Enter a profile name to create a wireless radio profile.

Example

```
Device(config)# wireless profile radio urwb-radio-profile-name
```

This command enters into the wireless profile radio configuration mode.

3. Configure URWB PTMP cluster ID to identify a cluster formed of base(s) and client(s).

Example

```
Device(config-wireless-radio-profile)# urwb ptmp cluster-id cluster-id
```

The maximum length of the cluster ID is 64 characters long.

> **Note**
>
> You must not set the cluster ID as an empty value or with ''.

Cluster ID: When more than one point-to-multipoint cluster operates in the same location, each cluster can be logically separated from every other cluster by using a cluster ID value that is unique to that cluster. A Fixed client radio will only communicate wirelessly with a Fixed Base radio that shares the same cluster ID.

> **Note**
>
> This setting is applicable only if the URWB role is set to point-to-multi-point.

4. Enable URWB PTMP autoscan for radio slot.

Example

```
Device(config-wireless-radio-profile)# [no] urwb ptmp autoscan
```

Use the **no** for of this command to disable URWB PTMP autoscan.

> **Note**
>
> This setting is applicable only if the URWB role is set to point-to-multi-point and if the URWB PTMP role is secondary.

5. Set the URWB PTMP tower ID for radio slot.

Example

```
Device(config-wireless-radio-profile)# [no] urwb ptmp tower-id tower-id
```

Use the **no** for of this command to disable URWB PTMP tower ID.

> **Note**
>
> This setting is applicable only if URWB role is set to point-to-multi-point and if URWB PTMP role is Fixed Base.

Tower ID: To avoid connectivity issues when multiple towers are serving the same cluster, the **tower-id** parameter can be enabled on Base radios.

All radios mounted on the same tower share the same tower ID. Even if two base radios see each other through a physical link and wirelessly, they know that they are on a different tower and will continue to advertise themselves.

When a client is connected to one tower (Tower 1) and moves close to another one (Tower 2), it automatically connects to a new base on Tower 2. This gives a wider coverage area and continuous connectivity. The same tower design, with different tower IDs, can be replicated to provide more coverage zones.

6. Configure URWB PTMP RSSI threshold for radio slot.

   Example

   ```
   Device(config-wireless-radio-profile)# [no] urwb ptmp rssi-threshold
   threshold-value
   ```

   Use the **no** form of this command to disable URWB PTMP RSSI threshold.

   Note

   This setting is appliable only if URWB role is set to point-to-multi-point and if URWB PTMP role is Fixed Client.

The URWB PTMP parameters are configured.

Example

```
Device# configure terminal
Device(config)# wireless profile radio urwb-radio-profile-name
Device(config-wireless-radio-profile)# urwb ptmp cluster-id cluster-id
Device(config-wireless-radio-profile)# [no] urwb ptmp autoscan
Device(config-wireless-radio-profile)# [no] urwb ptmp tower-id tower-id
Device(config-wireless-radio-profile)# [no] urwb ptmp rssi-threshold
threshold-value
```

Configure URWB encryption parameters (CLI)

Complete the following steps to configure the URWB encryption parameters:

Procedure

---

1. Enter configuration mode to create a URWB radio profile.

   Example

   ```
   Device# configure terminal
   ```

2. Enter a profile name to create a wireless radio profile.

   Example

   ```
   Device(config)# wireless profile radio urwb-radio-profile-name
   ```

   This command creates a wireless radio profile and enters into the wireless profile radio configuration mode.

3. Configure AES-based encryption policy with fixed key or rotating key.

Example

```
Device(config-wireless-radio-profile)# urwb crypto policy {none | fixed-key
| rotating-key}
```

Use the **none** command to disable the AES-based encryption.

4. Configure AES-based encryption rotating key timeout.

Example

```
Device(config-wireless-radio-profile)# urwb crypto rotating-key-timeout timeout
```

Here, the *timeout* range is from 0 to 65535 seconds.

> **Note**
>
> This setting is applicable only if the URWB crypto policy is set to **rotating-key**.

The URWB encryption parameters are configured.

Example

```
Device# configure terminal
Device(config)# wireless profile radio urwb-radio-profile-name
Device(config-wireless-radio-profile)# urwb crypto policy {none | fixed-key |
 rotating-key}
Device(config-wireless-radio-profile)# urwb crypto rotating-key-timeout 120
```

Configure URWB channel list (CLI)

Complete the following steps to configure the URWB channel list for mobility scanning:

Procedure

1. Enter configuration mode to create a URWB radio profile.

Example

```
Device# configure terminal
```

2. Enter a profile name to create a wireless radio profile.

Example

```
Device(config)# wireless profile radio urwb-radio-profile-name
```

This command creates a wireless radio profile and enters into the wireless profile radio configuration mode.

3. Add channel or channel-width to URWB channel list for radio slot.

Example

```
Device(config-wireless-radio-profile)# [no] urwb chan-list channel channel
cwidth channel_width
```

Use the **no** for of this command to remove channel or channel-width from the URWB channel list for radio slot.

The URWB channel list is configured for mobility scanning.

Example

```
Device# configure terminal
Device(config)# wireless profile radio urwb-radio-profile-name
Device(config-wireless-radio-profile)# [no] urwb chan-list channel 100 cwidth
 40MHz
```

Create RF tags and assign profiles (CLI)

Complete the following steps to map the radio profile to RF tag and radio slot:

Procedure

---

1. Enter configuration mode to create wireless RF tags.

   Example

   ```
   Device# configure terminal
   ```

2. Enter a profile name and create a wireless RF tag.

   Example

   ```
   Device(config)# wireless tag rf rf-profile-name
   ```

   This command configures the wireless RF tag and goes into the wireless RF tag profile configuration mode.

3. Configure URWB profile.

   Example

   ```
   Device(config-wireless-rf-tag)# urwb-profile urwb_profile
   ```

4. Configure the URWB radio profile to the RF tag.

   Example

   ```
   Device(config-wireless-rf-tag)# dot11 5ghz slot1 radio-profile
   urwb-radio-profile-name
   ```

> **Note**
>
> Use the `dot11 6ghz <slot> radio-profile radio-profile-name` command to attach radio profile to a 6 GHz radio configuration. For example, `Device(config- wireless-rf-tag)# dot11 6ghz slot3 radio-profile urwb_radio_profile`

5. Exit the sub-mode.

Example

```
Device(config-wireless-rf-tag)# exit
```

The RF tags are created and assigned to the URWB profiles.

Example

```
Device# configure terminal
Device(config)# wireless tag rf rf-profile-name
Device(config-wireless-rf-tag)# urwb-profile urwb_profile
Device(config-wireless-rf-tag)# dot11 5ghz slot1 radio-profile
urwb-radio-profile-name
Device(config-wireless-rf-tag)# exit
```

> **Note**
>
> In the RF tag configuration, if you assign radio profiles on 2 radio slots in 5-GHz band (**dot11 5ghz slot# radio-profile** *profile-name*. Following restrictions apply:
>
> - The channels configured are separated by 100 MHz.
> - The channels cannot be in the same UNII2 Ext channels.

What to do next

- Assign the URWB coordinator role to one of the APs.
- Configure URWB DFS parameters.
- Assign the URWB Fixed Base role to the selected APs.

Configure URWB parameters in the privileged EXEC mode

Describes the process to configure URWB parameters in the Privileged EXEC mode.

The URWB parameters in the EXEC mode are Fixed Base and Fixed Point-to-Multipoint.

- Fixed Base in a point-to-multipoint topology, is the radio selected by the clients to connect to. Clients only connect to Fixed Base radios.
- If Fixed Point-to-Multipoint is enabled, at least one AP has to be configured as a Fixed Base.

Configure URWB parameters per radio (GUI)

Describes the steps to configure the URWB parameters per radio using GUI steps.

Complete the following steps to configure URWB parameters per radio:

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click the **5 GHz Radios** section.
3. Select an AP from the list of APs displayed.

   The edit page is displayed.
4. In the **URWB** section, use the toggle button to enable or disable the **Fixed Point to Multipoint Base [Config on WLC]** parameter.

   > **Note**
   >
   > Reboot the AP for F**ixed Point to Multipoint Base** configuration on the controller to synchronize with the configuration on the AP.
5. Click **Update & Apply to Device**.
6. Click **All Access Points** and select the required AP.

   The **Edit AP**page is displayed.
7. Click the **URWB** tab.
8. In the **URWB Coordinator [Config on WLC]** section, check the **Coordinator** check box to configure the AP as a coordinator.

   This option tags a device to the coordinator role. Coordinators are the entry or exit points of the traffic to or from the infrastructure side.

   Reboot the AP to synchronize configurations.
9. Optional: Check the **Wired-Only** coordinator, and select either **Fixed** or **Mobility**.

   The **URWB Coordinator [Config on AP]** section displays the coordinator status on the AP.
10. Click **Update & Apply to Device** to save the configuration.

The URWB parameters are configured per radio.

Configure URWB parameters in the privileged EXEC mode (CLI)

Describes the steps to configure URWB parameters in the privileged EXEC mode.

Procedure

1. Configure URWB PTMP parameters.

Example

```
Device# ap name Cisco-AP dot11 5ghz slot slot-number urwb ptmp base
Device# ap name Cisco-AP no dot11 5ghz slot slot-number urwb ptmp base
```

2. Configure URWB DFS parameters.

Example

```
Device# ap name Cisco-AP dot11 5ghz slot slot-number urwb dfs {auto | primary
 | secondary}
```

3. Configure URWB coordinator mode.

Example

```
Device# ap name Cisco-AP urwb mode coordinator
Device# ap name Cisco-AP no urwb mode coordinator
```

4. Configure URWB coordinator radio-off mode.

Example

```
Device# ap name Cisco-AP urwb mode coordinator radio-off {fixed | mobility}
```

The URWB parameters are configured in the privileged EXEC mode.

Example

```
Device# ap name Cisco-AP dot11 5ghz slot slot-number urwb ptmp base
Device# ap name Cisco-AP no dot11 5ghz slot slot-number urwb ptmp base
Device# ap name Cisco-AP dot11 5ghz slot slot-number urwb dfs {auto | primary
 | secondary}
Device# ap name Cisco-AP urwb mode coordinator
Device# ap name Cisco-AP no urwb mode coordinator
Device# ap name Cisco-AP urwb mode coordinator radio-off fixed
```

Verify URWB details

Describes the verification section of the URWB feature.

Verify URWB profile details

To display the profile details specific to a URWB profile, use the following command:

```
Device# show wireless profile urwb detailed urwb-profile
```

Verify details about specific wireless radio profile

To display details about specific wireless radio profile, including the URWB information, use the following command:

```
Device# show wireless profile radio detailed radio_profile_name
```

Verify URWB details for a specific AP

To display the URWB details for a specific AP, use the following command:

```
Device# show ap name ap_name urwb info
```

Verify the configuration status from a URWB AP

To display the configuration status from a URWB AP, use the following command:

```
Device# show ap urwb status
```

Verify URWB details for an AP in a radio band

To display the URWB details for an AP in a radio band, use the following command:

```
Device# show ap name Cisco-AP dot11 band slot slot-id urwb detail
```

URWB telemetry protocol

URWB telemetry protocol provides real-time wireless network performance monitoring by sending structured UDP packets containing key metrics such as signal strength, latency, jitter, and packet loss.

The URWB telemetry protocol feature performs external monitoring of real-time wireless performance. This feature sends pre-defined, structured UDP packets at regular intervals, and these packets contain network metrics. Third-party and custom applications can use telemetry data. An application that receives this data can interpret it live or capture and process it later. The telemetry UDP packets includes:

- signal strength and Link Error Rate,
- latency,
- jitter,
- packet throughput,
- number of transmissions and retransmissions,
- modulation rate,
- details of packet loss,
- operating frequency of each radio, and
- information about the events that record the network.

Configure URWB telemetry protocol using AP CLI

Enable or disable URWB telemetry protocol

Perform this task to manage the URWB telemetry export functionality on the device. Enabling or disabling the protocol ensures the telemetry export aligns with your network management requirements.

Procedure

Use the configure **urwb telemetry export enable** command to enable the URWB telemetry export.

```
Device#configure urwb telemetry export enable
```

Or

Use the **configure urwb telemetry export disable** command to disable the URWB telemetry export.

```
Device#configure urwb telemetry export disable
```

Configure URWB telemetry server

Before you begin

Perform this task to configure the address and port number of the URWB telemetry server, ensuring successful communication between the device and the server.

Procedure

1. Use the **configure urwb telemetry server address** command to configure the server address.

   ```
   Device#configure urwb telemetry server a.b.c.d
   ```

2. Use the **configure urwb telemetry server address Port number** command to configure port number of telemetry server.

   ```
   Device#configure urwb telemetry server a.b.c.d 30000
   ```

   Example

   ```
   Device#configure urwb telemetry server a.b.c.d <0-65535>
   ```

   Example

   ```
   Device#configure urwb telemetry server
     x.x.x.x  IP address of telemetry server (A.B.C.D)
   Device#configure urwb telemetry server a.b.c.d
     <0-65535>  Port number of telemetry server (NUM)
     <cr>
   Device#configure urwb telemetry server a.b.c.d 9
     <cr>
   ```

> **Note**
>
> Port number valid range is from 0 to 65535.

Verify telemetry configuration

This task ensures that the telemetry configuration is correctly set up on the device, allowing for proper monitoring and reporting of telemetry data.

Procedure

Use the **show urwb telemetry config** command to view the telemetry configuration.

Example

```
Device#show urwb telemetry config

Telemetry export: disabled, current (live): disabled

Telemetry server: 0.0.0.0 30000, current (live): 0.0.0.0 30000

Telemetry level: default, current (live): default
```

Monitor URWB network information using Controller (GUI)

Describes the GUI steps to monitor URWB network information using the controller.

Complete these steps to monitor the URWB network information:

Procedure

1. Choose **Monitoring** > **Wireless** > **URWB Monitoring** to view the URWB network statistics.

   The **URWB Network Topology** page is displayed.

   The **URWB Network Topology** page displays a graphical representation of the network that includes AP nodes. The page also features the **URWB Coordinator** drop-down list.

   > **Note**
   >
   > The **Coordinator** or mesh-end is responsible for collecting and sending the URWB network statistics to the controller.

2. From the **URWB Coordinator** drop-down list, select the coordinator AP Name to view the network topology graph associated with the selected coordinator.

The page features the total number of APs connected, and the type of link used to connect to the AP nodes.

3. Click individual nodes or APs in the graph to view specific details, such as:
   - **Mesh ID**
   - **AP Name**
   - **IP Address**
   - **Device Model**
   - **AP Role**
   - **Connected Devices Count**

> **Note**
>
> The connections or links between APs could be either wired or wireless. Wireless links are represented in blue and wired links are represented in black.

4. Click the wireless link to view the **Uplink** and **Downlink** statistics for the link, such as:
   - **Throughput(Mbps)**
   - **LER**: Link Error Rate - Measurement of link errors
   - **PER**: Packet Error Rate - Percentage of packets with errors
   - **RSSI**: Received Signal Strength Indicator
   - **MCS | Rate**: Modulation and coding scheme

The refresh interval for monitoring statistics is two seconds

Verify AP URWB information

To display the AP URWB information, use these commands:

Table 170: AP URWB commands and description

Show commands	Description
show ap name *ap-name* **urwb coord-routes**	Displays the URWB coordinator routes.
show ap name *ap-name* **urwb fixed-links**	Displays the URWB fixed links reported by the coordinator AP.
show ap name *ap-name* **urwb mobility-links**	Displays the URWB mobility links reported by the coordinator AP.
show ap name *ap-name* **urwb network**	Displays the URWB network nodes reported by the coordinator AP.
show ap name *ap-name* **wireless-stats**	Displays the URWB wireless link statistics reported by the coordinator AP.

URWB recovery

URWB recovery enables access points to automatically troubleshoot and restore their connection to the network controller, ensuring seamless connectivity and efficient operations in wireless networks.

The URWB recovery commands are supported on access point (APs) to troubleshoot and restore connectivity when communication with the controller is lost. These commands facilitate the recovery process and ensure that APs can reconnect and resume normal operations.

URWB recovery includes these main features:

- Helps APs troubleshoot connectivity issues.
- Automatically downloads the correct configuration after the connection is restored and eliminates the need for manual intervention.
- Returns the AP to a fully functional state after recovery.

Configure URWB recovery to maintain network efficiency and seamless connectivity.

Prerequisites

- If the device has a CAPWAP connection, the URWB recovery commands are rejected.
- Ensure you have physical access to the AP's console.
- Know the correct alpha-2 country code for the AP's deployment location.

Configure the URWB recovery using AP CLI

Complete these steps to configure the URWB recovery using AP commands.

Procedure

1. Use the **configure urwb recovery conf-reset** command to reset the URWB configuration and disable the URWB mode.

   Example

   ```
   Device#configure urwb recovery conf-reset
   ```

   Warning

   In URWB mode, this command erases all configurations and resets the device to factory default settings in CAPWAP mode.

2. Use the **configure urwb country-code** *country-code* command to configure the country code for initial provisioning.

   Example

   ```
   Device#configure urwb recovery country-code US
   ```

> **Note**
>
> - Enter the correct Alpha-2 country code (for example, US, IN, GB).
> - Set the country code before changing the radio slot to ensure correct application of the parameters.
> - For WiFi-7 PIDs, the device will prompt you to reload the AP.

3. Use the **configure urwb recovery network-key** *key* command to configure the network-key on the radio interface.

   Example

   ```
   Device#configure urwb recovery network-key 123456789
   ```

   > **Note**
   >
   > The network-key must contain at least 8 characters and can be up to 64 characters. Special characters such as "~|;$<>&^`?/ and "" are not permitted.

4. Use the **configure urwb recovery dot11Radio** *interface* **role {fixed | mobility-client}** command to configure the role on the radio interface. It can be either fixed or mobility-client.

   Example

   ```
   Device#configure urwb recovery dot11Radio 1 role fixed
   ```

   > **Note**
   >
   > If you need to change both the country code and the radio slot role, set the country code first to ensure the correct application of the parameters.

5. Use the **configure urwb recovery dot11Radio** *interface* **band** *band* **channel** *channel* **bandwidth** *bandwidth* command to configure the radio interface settings.

   Example

   ```
   Device#configure urwb recovery dot11Radio 1 band 5ghz channel 36 bandwidth
   20
   ```

   - The radio *interface* supports 5 GHz and 6 GHz bands. Set the band ID is correctly before configuration.
   - Operating *channel* range is 1 to 256.
   - Supported radio *bandwidth* options are 20 MHz, 40 MHz, 80 MHz, and 160 MHz.

6. Use the **configure urwb recovery dot11Radio** *interface* **encryption {aes-fixed-key | aes-rotating-key | disable}** command to assign an encryption to the selected radio interface.

   Example

   ```
   Device#configure urwb recovery dot11Radio 1 encryption aes-fixed-key
   ```

7. Use the **reload** command to apply the changes.

   Example

   ```
   Device#reload
   ```

   Note

   The configuration is saved automatically.

8. Use **configure urwb recovery dot11Radio** *interface* **dual-band** *band* **{5GHz | 6GHz | 24GHz}**command to configure the URWB dual-band mode.

   Example

   ```
   Device#configure urwb recovery dot11Radio 1 dual-band 5ghz
   ```

9. Use **configure urwb recovery dot11Radio** *interface* **dual-radio mode** *mode* **{enable disable}**command to configure the URWB dual-radio mode.

   Example

   ```
   Device#configure urwb recovery dot11Radio 1 dual-radio mode enable
   ```

Country code behavior on AP models

The behavior of the country code, when configured through the recovery CLI, depends on the Access Point (AP) model.

Country code behavior on WiFi-6 PIDs (IW916x -ROW models)

Note

The recovery CLI does not support country code configuration for non-ROW Wi-Fi 6 PIDs.

- Country code configuration is applicable for ROW PIDs.
- The system prevents configuration for non-ROW PIDs.
- The country code you configure determines the valid frequencies and bandwidths allowed in the regulatory domain.

Country code behavior on WiFi-7 PIDs

> **Note**
>
> For WiFi-7 PIDs, reboot the AP after configuring the country code through the recovery CLI. This ensures the changes take effect.

- The configured country code is used only for the initial connection.
- After the AP joins the controller, the regulatory configuration received from the controller is automatically applied to the AP.
- If the country code has already been programmed through the controller, this initial configuration step is not necessary.

URWB recovery configuration example

These commands allow users to quickly configure and customize the URWB recovery settings for optimal wireless network operation during recovery scenarios.

Procedure

1. Use the **configure urwb recovery dot11Radio 1** command to select the radio interface for configuration.

   Example

   ```
   Device#configure urwb recovery dot11Radio 1
   ```

2. Use the **configure urwb recovery dot11Radio 1 role** *radio-role* command to set the radio role.

   Example

   ```
   Device#configure urwb recovery dot11Radio 1 role ptmp
   ```

   The radio role is set to Point-to-Multipoint (PtMP)

3. Use the **configure urwb recovery dot11Radio 1 role** *radio-role* **cluster-id** *id* command to assign a cluster ID to the radio interface.

   Example

   ```
   Device#configure urwb recovery dot11Radio 1 role ptmp cluster-id test
   ```

4. Use the **configure urwb recovery dot11Radio 1 band** *band* **channel** *channel* **bandwidth** *bandwidth* command to configure the frequency and channel parameters.

   Example

   ```
   Device#configure urwb recovery dot11Radio 1 band 5ghz channel 36 bandwidth
   20
   ```

5. Use the **reload** command to apply the configuration and restart the access point.

Example

```
Device#reload
```

The access point restarts and the new recovery settings take effect.

Dynamically configure URWB parameters

Adjust URWB parameters dynamically on APs without rebooting, improving network management and reducing service interruptions.

This feature allows you to adjust certain Ultra-Reliable Wireless Backhaul (URWB) configuration parameters on supported access points (APs) without needing to reboot the device. This makes network management smoother and reduces service interruptions.

Hot-configurable URWB parameters

These URWB parameters can be updated dynamically, without requiring a device reboot.

- Radio frequency and bandwidth
- Radio DFS role
- Radio DFS backup channel list
- Radio crypto and key-control rotation timeout
- Network key
- MPLS ethertype
- MPLS allow Ethernet I
- MPLS ether filter method
- MPLS unicast flood
- MPLS unicast flood limitation
- Mobility role (base / base-relay)
- Mobility scan parameters (idle, after, RSSI threshold)
- Mobility RSSI hysteresis
- Mobility times (warmup, timeout)
- Mobility backhaul checks
- P2MP primary
- P2MP parameters (RSSI threshold, autoscan, cluster ID, tower ID)
- High-availability enablement
- High-availability timeout
- Multicast
- MPO enablement
- MPO fine-tuning parameters (maximum links, minimum RSSI, QoS classification)

- MPO telemetry enablement

Parameters requiring a device reload

These URWB parameters cannot be changed dynamically. The device must be rebooted for the changes to take effect. You can use either the **reload** command or use the **Reload** button in the **URWB** tab of the **Monitoring > Wireless > AP Statistics** page.

- URWB global enablement
- Coordinator mode
- Switch between P2MP base and P2MP client
- Radio role (disabled, fixed, P2MP, mobility)
- Band ID

> **Note**
>
> Changing the country code requires a device reload.

Configure URWB parameters using CLI

This task helps you modify hot-configurable URWB parameters and safely apply them to the network device.

> **Note**
>
> To prevent partial or inconsistent configurations, changes are first staged, and then explicitly applied.

Before you begin

- Confirm the parameters you intend to update are hot-configurable. See the Hot-configurable URWB parameters section for the supported list of parameters.
- Ensure that the required APs are operating in URWB mode.

Follow these steps to apply configuration changes to URWB parameters:

Procedure

1. Select the AP to which the configuration is to be applied.

> **Note**
>
> When updating configurations in a wireless mesh network, apply the configuration to the remote devices first, and then to the Coordinator AP. This helps prevent loss of connectivity to the rest of the network during the update.

2. After making the required configuration changes, verify that the Config Status field is set to 'Live update required.'

   See the View Configuration Update Status Summary section on how to view the summary of the configuration updates.

3. Apply the configuration changes using the **ap name** *ap-name* **urwb apply-running-config** command.

   > **Note**
   >
   > The Config Status field transitions to 'In progress.'

4. After the configuration is successfully applied, confirm that the Config Status field is set to 'Up to date.'

   See the View Configuration Update Status Summary section on how to view the summary of the configuration updates.

Configure URWB parameters using GUI

This task helps you modify hot-configurable URWB parameters and apply them to the network device.

Procedure

1. Choose **Configuration > Tags & Profiles > URWB Network Profile**.
2. Click the URWB Network Profile name to open the **Edit URWB Network Profile** page.
3. Select the appropriate tab and make the necessary changes.
4. Click **Update and Apply on Device**. The system displays a message confirming successful configuration.
5. Choose **Monitoring > Wireless > AP Statistics**, and select the **URWB** tab.

6. Activate the configuration using one of these methods:

   - Click the  buttom displayed on the URWB Configuration Status field of the AP.

- Select the AP and click the 

button on the page.

7. (Optional) Reload the device. Use this option only if URWB parameter changes require a device reboot. Use one of these methods:
   - Click the  button displayed on the URWB Configuration Status field of the AP.
   - Select the AP name and click the 

button on the page.

View configuration update summary

You can view the summary of the configuration updates status using the command given here.

- show ap urwb status

```
controller# show ap urwb status

*If configuration error is 'Present' please run 'show ap urwb err-status' for
 details

AP name          Coordinator name Config status Config error RF tag
   Radio roles
-----------------------------------------------------------------------------------------

AP345D.A812.0B6C AP345D.A812.0B6C Up to date                cm_p2mp_rf_tag_me
  PTMP Base
APC828.E536.7920 AP345D.A812.0B6C Up to date               cm_p2mp_rf_tag_mp2
 PTMP Secondary
APE4A4.1CD8.1700 AP345D.A812.0B6C Up to date               cm_p2mp_rf_tag_mp1

```

Controller-directed URWB traffic

Introduces controller-directed URWB traffic, enabling communication across broadcast domains and infrastructure subnets, centralizing traffic forwarding, preserving seamless mobility, and maintaining vehicle location and VLAN context for Layer 3 mobility.

This feature enables communication between different broadcast domains and infrastructure subnets.

It allows URWB vehicles and their wired clients to communicate across multiple infrastructure subnets and reduces broadcast domains while preserving seamless mobility.

In controller-directed mode, the controller maintains awareness of vehicle location, client association, and VLAN context as vehicles move. This enables Layer 3 mobility across infrastructure segments while keeping forwarding decisions centralized.

URWB clients

Introduces URWB clients as controller-managed entities representing vehicle APs and wired endpoints behind them, and explains how they enable consistent mobility, policy enforcement, and VLAN handling as vehicles move across network segments.

A URWB client is a controller-managed client type that represents either:

- a vehicle AP participating in the URWB network, or
- a wired endpoint connected behind a vehicle AP.

On the controller, URWB clients are tracked similarly to wireless clients for mobility, policy, and forwarding purposes. This allows the controller to apply consistent VLAN, policy, and roaming behavior as the vehicle moves between segments.

URWB clients

- Vehicle AP: A mobile AP mounted on a vehicle and joined to the URWB network.
- Wired URWB client: A camera, sensor, or other Ethernet-connected device behind the vehicle AP.

URWB traffic egress point

Outlines the configuration of the URWB traffic egress point, including profile setup, WLAN and policy profile creation, and policy tag mapping for proper mobility, policy handling, and traffic forwarding.

To enable the Controller-directed URWB Traffic feature, the URWB profile must be configured with the appropriate traffic egress point. When the traffic egress point is set to controller, it automatically generates the "cisco-urwb-client "WLAN and the corresponding "cisco-urwb-client" policy profile.

The policy tag must then be configured correctly to map the "cisco-urwb-client" WLAN to the "cisco-urwb-client" policy profile. This mapping is required for URWB client mobility, policy handling, and traffic forwarding to work as expected.

URWB client WLANs

Introduces system-generated URWB client WLANs, explaining their automatic creation, controller-based mobility and policy handling, and the use of the associated policy profile for mapping policies and forwarding contexts.

A URWB client WLAN (cisco-urwb-client) is a system-generated controller construct used to manage URWB clients. The system creates this WLAN automatically when a user changes the traffic egress point in a URWB profile to controller.

It supports controller-based mobility and policy handling for URWB clients and binds URWB clients to the required policy and forwarding context.

In addition to the WLAN, the system also creates a policy profile named "cisco-urwb-client" automatically. Use this policy profile to create the required mapping between the policy profile and the WLAN.

URWB mobility across subnets

Introduces URWB mobility across subnets, explaining how vehicle APs and wired devices maintain connectivity during intra-segment and inter-segment handoffs, with controller-managed forwarding updates ensuring uninterrupted client access as the AP roams between infrastructure segments.

URWB mobility across subnets allows a vehicle AP and the wired devices behind it to remain reachable while moving between infrastructure segments.

Mobility cases:

- **Intra-segment handoff**: Roaming within the same subnet, with traffic continuing through the same segment.
- **Inter-segment handoff**: Roaming across different subnets, requiring controller-directed traffic handling and forwarding updates.

When inter-segment handoff occurs, the controller updates the forwarding path based on the vehicle AP's new location while preserving client connectivity.

Limitations of Controller-directed URWB traffic

Outlines the limitations of controller-directed URWB traffic in release 26.2.1, including controller, mode, high availability, IPv6, IGMP snooping requirements, and lack of wireless relay support.

This feature has the following limitations in release 26.2.1:

- Only a single controller is supported.
- Only local mode is supported, FlexConnect is not supported.
- Controller high availability for controllers are not supported.
- IPv6 for the management network is not supported.
- IGMP snooping must be disabled on VLANs used by mobile APs and URWB wired clients. You can use the **no ip igmp snooping vlan** *vlan* command for this.
- Wireless relay is not supported.

How URWB client mobility works

Explains how URWB client mobility enables vehicle APs and their wired clients to stay connected while moving across network segments, describing the roles of the vehicle AP, coordinator AP, and controller, and outlining the stages that maintain uninterrupted connectivity.

URWB client mobility allows vehicle APs and their downstream wired clients to maintain connectivity while moving between network segments.

The key components involved in the process are:

- **Vehicle AP**: The mobile AP that moves between infrastructure subnets.
- **Coordinator AP**: The AP that aggregates URWB traffic within a local segment.
- **Wireless LAN Controller**: The device that tracks client location and updates forwarding behavior.

The process involves the following stages:

1. The vehicle AP connects through a coordinator AP and is identified by the controller as a URWB client.
2. The controller tracks the vehicle AP location, client state, and VLAN context.
3. When the vehicle AP roams to a new segment, the controller updates the forwarding path.
4. Traffic for the vehicle AP and wired clients continues without manual reconfiguration.

Result: Clients remain connected and reachable as vehicles move across subnets.

Create VLAN for vehicle AP and wired client (GUI)

This task creates the necessary VLANs on the controller to segment and manage traffic for URWB clients and mobile APs, ensuring proper routing and mobility support within the network.

Creating dedicated VLANs ensures that traffic from vehicle-based wired clients (such as VLAN 110) and mobile AP management traffic (such as VLAN 111) are correctly identified, segmented, and forwarded by the controller.

Procedure

1. Choose **Configuration** > **Layer2** > **VLAN**.
2. Click the **VLAN** tab and click the **Add** button.

The **Create VLAN** page is displayed.

3. Select the **Create a single VLAN** option and enter these parameters:
   a) **VLAN ID**: Create separate VLAN IDs for vehicle AP and wired clients. For example, enter 111 as the VLAN ID for vehicle AP and 110 for the wired client.
   b) **Name**: Enter appropriate names for the VLAN. Ensure that the length of the VLAN name is less than 20 characters.

   > **Note**
   >
   > Disable VTPv1 and VTPv2 or switch to VTPv3 before configuring a VLAN name longer than 32 characters.

4. Click **Apply to Device**.

The VLANs are created on the controller, segmenting traffic for vehicle APs and wired clients and enabling proper routing and mobility support.

Create VLAN for vehicle AP and wired client

This task creates the necessary VLANs on the controller to segment and manage traffic for URWB clients and mobile APs, ensuring proper routing and mobility support within the network.

Establish the necessary network segments on the controller to support URWB client data and mobile AP management traffic.

When implementing controller-directed URWB traffic, the controller must be aware of the specific subnets used by mobile devices. Creating dedicated VLANs ensures that traffic from vehicle-based wired clients (such as VLAN 110) and mobile AP management traffic (such as VLAN 111) are correctly identified, segmented, and forwarded by the controller.

Procedure

---

1. Use the **configure terminal** command to enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Use the **vlan** *vlan-id* command to create VLAN for the vehicle AP.

   Example

   ```
   Device(config)# vlan 111
   ```

3. Use the **vlan** *vlan-id* command to create VLAN for wired clients behind the vehicle AP.

   Example

   ```
   Device(config)# vlan 110
   ```

4. Use the **end** command to return to the privileged EXEC mode.

Example

```
Device(config)# end
```

Create URWB profile for mobility role base and client (GUI)

This task configures the URWB network profiles to establish the controller as the central traffic egress point and defines the necessary mobility roles for mobile clients.

Set up URWB network profiles to ensure centralized traffic management and assign correct mobility roles for mobile clients.

Use this task when you want to establish the controller as the central traffic egress point for mobile clients by defining appropriate URWB profiles and mobility roles.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **URWB Network Profile**.
2. In the **General** tab, enable the **URWB Status** and enter the **URWB Network Profile Name**.
3. Click the **Mobility** tab, and complete these steps:
   a) From the **Mobility Role** drop-down list, select either **Base**, **Base Relay**, or **Client**.

   > **Note**
   >
   > When you select **Base** or **Base Relay** as the mobility role, the **Wired Ports** tab is displayed. When you select **Client** as the mobility role, the **Wired Clients** tab is displayed.

   b) From the **Traffic Egress Point** drop-down list select one of these egress points:
      1. **Coordinator**: Specifies coordinator as the URWB traffic egress point.
      2. **WLC**: Specifies wireless LAN controller as the URWB traffic egress point.

   c) In the **Fast Drop Count** field, configure the fast wireless disconnect feature by entering the drop count. The range is 0 to 65535. The default value is 0.
4. In the **Advanced** section, under the **Mobility Backhaul Check** area, complete these steps:
   a. From the **Coordinator Down** drop-down list, select either **Disabled**, **Handoff-Inhibition**, or **Relay-Switch**, to configure hand-off when the coordinator is unreachable.
   b. From the **Ethernet Down** drop-down list, select either **Disabled**, **Handoff-Inhibition**, or **Relay-Switch**, to configure hand-off when all the Ethernet ports are disconnected.
5. In the **Mobility Scan** section, configure the scan parameters:
   a. **Isolation**: Scanning takes place when the device is disconnected from the infrastructure. The maximum waiting time before the scanning is triggered is 0 to 65535 ms. The default value is 0.
   b. **Periodic**: Scanning takes place periodically. The value range is 0 to 65535 seconds. The default value is 0.

c. **RSSI Threshold**: Scanning takes place when the RSSI value falls below threshold. The value range is 0 to 96. The default value is 0.

6. Click **Apply to Device**.

The URWB network profiles are configured, and the controller functions as the central traffic egress point. Mobility roles for mobile clients are defined, ensuring proper traffic routing and client management.

Configure wired ports (GUI)

Configure which physical Ethernet interface on the URWB device operates as the Secondary LAN Port. This provides an additional wired connection for the network profile.

When you select **Base** or **Base Relay** as the mobility role, the **Wired Ports** tab is displayed. Under Ethernet settings, the secondary port can be disabled or assigned to LAN 1, LAN 2, LAN 3, or LAN 4. Changes may require configuration activation or a reload of the associated AP(s).

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **URWB Network Profile**.
2. Select the required URWB profile from the displayed list.
3. Click the **Wired Ports** tab
4. In the **Ethernet Settings** section, complete these steps:
   a) From the **Secondary LAN Port** drop-down list, select a secondary LAN port to enable LAN port PoE.
   b) Check the **LAN Port PoE** check box to enable the LAN port PoE.

   > **Note**
   >
   > The Secondary LAN Port and LAN Port PoE configuration has no effect on unsupported APs. This feature is currently supported on Cisco Catalyst 9124AX series APs.

5. Click **Apply to Device** to save the configuration.

The selected LAN interface is configured as the secondary LAN port and applied to the device, potentially requiring configuration activation or an AP reload.

Configure wired clients (GUI)

Configure devices directly connected to URWB access point LAN ports, including cameras, sensors, and industrial controllers.

Enable and manage connectivity, authentication, and NAT configuration for wired devices connected to URWB access points.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **URWB Network Profile**.
2. Select the required URWB profile from the displayed list.
3. Click the **Wired Ports** tab

4. In the **Ethernet Settings** section, complete these steps:
   a) From the **Secondary LAN Port** drop-down list, select a secondary LAN port to enable LAN port PoE.
   b) Check the **LAN Port PoE** check box to enable the LAN port PoE. The Secondary LAN Port and LAN Port PoE configuration has no effect on unsupported APs.
5. In the **Local Authentication** section, select the RADIUS server group used to authenticate wired clients. The blue shortcut icon opens the RADIUS configuration area if a group must be created or reviewed.

   The selected RADIUS servers must be reachable from the network and already contain the appropriate client credentials or policies.
6. In the **NAT** section, check the **Enable NAT** check box to enable the NAT feature.
7. In **NAT Address**, enter the IPv4 address of the AP facing the on-board local network and then enter the subnet mask associated with that address.
8. Enter the **Outside Port Range**. The NAT outside port range is from 1 to 65535 unless both are 0.
9. In the **NAT Rules** section, click **Add** and complete these steps to add new rules:
   a) Select the required protocol, normally TCP or UDP.
   b) Enter the outside port on which the NAT address receives the connection. The range for NAT rule outside port is from 1 to 65535.
   c) Enter the IPv4 address of the wired device as the inside IPv4 address.
   d) Enter the inside port on that wired device.
10. Click **Save**. The newly added rule is displayed in a table.

Wired devices are configured and connected, authenticated (if required), and NAT rules are applied. The configuration is saved and displayed in the profile.

Create URWB profile for mobility role base and client

This task configures the URWB network profiles to establish the controller as the central traffic egress point and defines the necessary mobility roles for mobile clients.

Configure URWB network profiles so that the controller is the traffic egress point for both the base role and the client role.

This configuration is required to shift traffic handling from the local coordinator to the controller, enabling centralized traffic management for mobile subnets. Both the mobility role base and client need to configure the egress point to controller.

Before you begin

- In controller-directed deployments, both profiles must use the traffic egress point `WLC`.
- The base profile must use mobility role `Base` and the client profile must use mobility role `Client`

Procedure

---

1. Use the **configure terminal** command to enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Use the **wireless profile urwb** *profile* command to create or edit the base URWB profile.

Example

```
Device(config)# wireless profile urwb mb-base-urwb-profile
```

3. Use the **mobility traffic-egress wlc** command to set the controller as the traffic egress point.

   Example

   ```
   Device(config-wireless-urwb-profile)# mobility traffic-egress wlc
   ```

4. Use the **exit** command to return to the global configuration mode.

   Example

   ```
   Device(config-wireless-urwb-profile)# exit
   ```

5. Use the **wireless profile urwb** *profile* command to create or edit the client URWB profile.

   Example

   ```
   Device(config)# wireless profile urwb mb-client-urwb-profile
   ```

6. Use the **mobility traffic-egress wlc** command to set the controller as the traffic egress point for the client.

   Example

   ```
   Device(config-wireless-urwb-profile)# mobility traffic-egress wlc
   ```

7. Use the **mobility role client** command to set the mobility role for the client profile.

   Example

   ```
   Device(config-wireless-urwb-profile)# mobility role client
   ```

8. Use the **end** command to return to the privileged EXEC mode.

   Example

   ```
   Device(config-wireless-urwb-profile)# end
   ```

9. (Optional) Use the **show wireless profile urwb detailed** *profile* command to verify the configuration and operating status.

   Example

   ```
   Device# show wireless profile urwb detailed mb-base-urwb-profile

   Profile Name                        : mb-base-urwb-profile
   Description                         :
   Status                              : Disabled
   Multicast                           : Disabled
   RADIUS server group name            :

   Mobility
   ```

```

```

Create policy tag profile (GUI)

This task creates and configures a policy tag to associate the default URWB WLAN and policy profile with the coordinator APs through the WebUI.

Associate the automatically generated URWB WLAN and policy profile with a policy tag.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
   The **Policy Tag** page is displayed.
2. Click **Add**.

   The **Add Policy Tag** page is displayed.
3. Enter the policy tag name and the description.
4. In the **WLAN-POLICY Maps** section, click **Add**.

   The **Map WLAN and Policy** section is displayed.
5. From the **WLAN Profile** and **Policy Profile** drop-down lists, map the WLAN and policy profile names, and click the tick-mark button.
6. Click **Apply to Device**.

The policy tag profile is successfully created and associated with the default URWB WLAN and policy profile, enabling efficient management of coordinator APs.

Create policy tag profile

This task creates and configures a policy tag to associate the default URWB WLAN and policy profile with the coordinator APs.

Associate the automatically generated URWB WLAN and policy profile with a policy tag.

After enabling the controller-directed URWB feature, the system generates a default WLAN and policy profile (cisco_urwb_client). You cannot modify these parameters. These must be mapped to a policy tag so they can be assigned to the coordinator APs.

Procedure

1. Use the **configure terminal** command to enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Use the **wireless tag policy** *policy-tag* command to create or edit the policy tag.

   Example

   ```
   Device(config)# wireless tag policy urwb-base-policy-tag
   ```

   When the feature is enabled in the URWB profile, the system automatically creates a policy profile (cisco_urwb_client) and a WLAN profile (cisco_urwb_client).
3. Use the **wlan** *wlan-profile* **policy** *policy-profile* command to map the system-created URWB WLAN and policy profile to the policy tag.

   Example

   ```
   Device(config-policy-tag)# wlan cisco-urwb-client policy cisco-urwb-client
   ```

4. Use the **end** command to return to privileged EXEC mode.

Example

```
Device(config-policy-tag)# end
```

Bind policy tag to coordinator APs (GUI)

This task binds the created URWB policy tag to the coordinator APs to apply the necessary WLAN and policy configurations using GUI.

Assign the configured URWB policy tag to the coordinator APs to activate the URWB feature on those devices

After creating the policy tag containing the required URWB WLAN and policy profile, you must bind it to the specific coordinator APs to ensure they apply the correct configuration settings.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click an AP from the list of displayed APs.
   The **Edit AP** page is displayed.
3. Click the **General** tab.
4. In the **General** section, enter the AP name and specify location at which the AP is present.
5. In the **Tags** section, select the appropriate **Policy**, **Site**, and **RF** tags that you created in the **Configuration** > **Tags & Profiles** > **Tags** page.
6. Click **Update & Apply to Device**.

The selected coordinator APs now apply the URWB policy tag and activate their WLAN and policy configurations.

Bind the policy tag to coordinator APs

This task binds the created URWB policy tag to the coordinator APs to apply the necessary WLAN and policy configurations.

Assign the URWB policy tag to the coordinator APs so they apply the required URWB WLAN and policy configuration.

After creating the policy tag containing the required URWB WLAN and policy profile, you must bind it to the specific coordinator APs to ensure they apply the correct configuration settings.

Procedure

1. Use the **configure terminal** command to enter configuration mode.

Example

```
Device# configure terminal
```

2. Use the **ap** *ap-mac* command to enter AP configuration mode for the target coordinator AP.

Example

```
Device(config)# ap 0011.2233.4455
```

3. Use the **policy-tag** *urwb-policy-tag* command to apply the policy tag to the AP.

Example

```
Device(config-ap-tag)# policy-tag urwb-base-policy-tag
```

4. Use the **end** command to return to privileged EXEC mode.

Example

```
Device(config-ap-tag)# end
```

Configure VLAN tagging for vehicle AP (GUI)

Configure VLAN tagging on a vehicle access point to enable segmented network traffic for different applications.

Enable and assign a VLAN tag to a vehicle access point (AP) so that it can support separate network segments for improved traffic management.

Use this task when you need to assign VLAN tags to vehicle access points to support network segmentation, which can be necessary for isolating traffic types.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click an AP from the list of displayed APs.
   The **Edit AP** page is displayed.
3. Click the **Advanced** tab.
4. In the **VLAN Tag** section, check the **VLAN Tag** check box to enable the VLAN tag.

> **Note**
>
> When changing the VLAN tag, there is a momentary loss of association of the AP with the controller.

   The **VLAN Tag ID** is displayed.
5. In the **VLAN Tag ID** field, enter the VLAN tag ID. The range is from 1 to 4094.
6. Click **Update & Apply to Device**.

The vehicle AP is updated with the new VLAN tag.

Configure VLAN tagging for the vehicle AP

This task assigns a specific VLAN tag to a vehicle AP to ensure it operates on the correct subnet for controller-directed traffic.

Enable VLAN tagging on the vehicle AP so it joins the correct infrastructure VLAN for mobility and traffic handling.

In controller-directed URWB traffic scenarios, vehicle APs operate on different subnets and VLANs than infrastructure coordinators. You must enable VLAN tagging for these APs to maintain correct network segmentation and roaming capabilities.

The configured tag VLAN must not be the same as the wireless management VLAN configured on the controller.

Procedure

Use the **ap name** *ap_name* **vlan-tag** *vlan-number* command to assign the specific VLAN tag to the vehicle AP.

Example

```
Device# ap name Vehicle-AP-01 vlan-tag 111
```

View the client type information

This section provides diagnostic commands to verify URWB client identification, tunnel status, and hardware/software processing states on the controller.

Use these commands to verify that the controller has correctly identified and programmed the URWB client.

Procedure

1. Use the **show wireless client mac-address** *mac* **detail** command to confirm that the device is correctly identified as a URWB client. You can view the general client details, including the client type and authentication state.

   Example

   ```
   Device# show wireless client mac-address 5x13.d5f6.264a detail | sec Type

   Client MAC Type              : Universally Administered Address
   Client Type                  : URWB Client
   Mobility Roam Type           : None
   Policy Type                  : N/A
   EAP Type                     : Not Applicable
   ```

2. Use the **show platform hardware chassis active qfp feature wireless wlclient cpp-client mac** *mac* **details** command to verify the data path tunnel type and confirm that the client is correctly processed by the hardware.

   Example

   ```
   Device# show platform hardware chassis active qfp feature wireless wlclient
   cpp-client mac 5x13.d5f6.264a details | sec Type

     POA Tunnel Type     : DATA
     Client Type         : URWB Client
     P2P Type            : BLOCKING DISABLE
   ```

3. Use the **show platform software wireless-client chassis active f0 mac-address** *mac* command to view the global WLAN ID, SSID, and mobility state for a specific URWB client.

   Example

```
Device# show platform software wireless-client chassis active f0 mac-address
 5x13.d5f6.264a

ID                            : 0xa0000003
MAC address                   : 5x13.x5x6.264a
Type                          : URWB Client
Global WLAN ID                : 5
SSID                          : cisco_urwb_client
Client index                  : 0
Mobility state                : Local
Authentication state          : Run
```

Support for 6 GHz Low Power Indoor mode

Supports the operation of Catalyst IW916x access points in 6 GHz Low Power Indoor (LPI) mode for enhanced wireless performance and regulatory compliance in indoor environments.

LPI mode is a specific operating class within the 6 GHz band. In this mode, access points are restricted to lower power levels and are intended exclusively for indoor use.

From Release 26.2.1, these platforms support 6-GHz LPI mode in Korea domain:

- IW9167EH - LPI AP
- IW9167I - LPI AP
- IW9165D - LPI AP
- IW9165E - LPI AP and client

Introduction of 6 GHz LPI mode

Starting with Cisco IOS XE Release 17.18.1, this feature allows the APs to operate exclusively in the 6 GHz frequency band in LPI mode as a mobility client.

In this configuration, the AP serves as a mobility client, connecting to a mobility base role on the infrastructure side. You must set up the URWB profile and radio profile for both the infrastructure device and the client device.

An infrastructure device refers to a controller that provides centralized management, routing, and coordination for the network.

A client device refers to an AP that connects to the network through an infrastructure device.

Default band operation

By default, the APs operates in the 5 GHz band but can be configured for 6 GHz LPI operations.

6GHz LPI on radio2 for URWB uplink

The 6 GHz LPI radio operates on Slot 2 as a dual-band XOR Radio. Activating the 6 GHz band of Radio 2 allows for URWB operation and enhances the performance and capabilities of the AP.

URWB role for LPI mode

To enable the 6 GHz LPI mode, the AP must be assigned the URWB role via the radio profile. Once set to the URWB role, the URWB stack manages the radio by disabling all Radio Resource Management (RRM) functions and automatically selecting the LPI mode.

Supported sub-channels and frequency range

In 6 GHz LPI mode, the AP supports the U-NII-5, U-NII-6, U-NII-7, and U-NII-8 sub-channels. These sub-channels cover a frequency range of 5925 MHz to 7125 MHz, aligning with the Wi-Fi 6E band.

Restrictions

Outlines operational limitations and compliance requirements for APs operating as 6 GHz mobility clients.

When operating as a 6 GHz mobility client, the AP is subject to specific restrictions to ensure compliance with regulatory requirements and operational guidelines:

- Supports only LPI mode as a 6 GHz AP.
- URWB mobility clients do not support manual configuration of 6 GHz TX power, or RRM and 6 GHz SP mode.

How 6 GHz mobility clients operate

Describes how Cisco Catalyst APs operate as 6 GHz mobility clients to establish efficient, interference-free wireless connections, ensuring compliance with spectrum regulations.

The AP functions as a 6 GHz mobility client. It uses advanced wireless protocols and scanning mechanisms to establish interference-free and efficient connections with parent APs. This process ensures both seamless operation and adherence to spectrum regulations.

The key components involved in this process are:

- Cisco Catalyst APs: Operates as the 6 GHz mobility client, scanning channels and connecting to a parent AP.
- Carrier-Sense Multiple Access with Collision Avoidance (CSMA/CA): This protocol prevents interference by detecting channel availability before the device transmits.
- Listen Before Talk (LBT): Ensures compliance by avoiding interference with licensed services in the spectrum.
- Parent AP: Acts as the central access point to which the AP connects for continued operation.
- Received Signal Strength Indicator (RSSI): Evaluated by the AP to determine signal quality for connection.
- URWB network key: Used by the AP to authenticate and select the optimal parent AP.

These stages describe how 6 GHz mobility clients operate:

1. Scanning channels: The AP scans dedicated 6 GHz channels, listens for beacons, and evaluates the RSSI and URWB network key.
2. Protocol compliance: The device uses CSMA/CA and LBT protocols to detect and avoid interference with nearby licensed services.
3. Parent AP selection: The AP evaluates the RSSI and other parameters to select the optimal parent AP for connection.

> **Note**
>
> When the parent AP is in LPI mode, the maximum EIRP is limited to 24 dBm.

4. Connection establishment: The AP refrains from transmitting any packets until a connection with the parent AP is successfully established.
5. Transition to legacy mode: After connecting to the parent AP, the device transitions to legacy mode and continues operation under the parent AP.

Result

The process enables the AP to operate efficiently and interference-free as a 6 GHz mobility client, ensuring reliable connections with parent APs and adherence to spectrum regulations.

Configure the 6-GHz LPI mode

The 6-GHz LPI mode enables access points to provide secure, low-power wireless connectivity in indoor environments and supports advanced radio profiles and tag assignments.

Perform these steps on the wireless controller to configure the 6-GHz LPI mode.

Before you begin

Ensure that the AP is connected to the controller through a wired link in the provision mode.

Procedure

1. Configure the URWB network profile on the infrastructure device and on the client device.
2. Configure the radio profile on the infrastructure device and on the client device..
3. Create an RF tag and assign radio profile and URWB profiles on the infrastructure device and on the client device.
4. Apply the RF tag of the infrastructure device and the client device to the access point.
5. (Optional) Verify 6-GHz LPI mode on the AP in mobility client role.

Configure the URWB radio profile

Procedure

Create a radio profile which specifies URWB 6-GHz channel and URWB channel width and URWB role. Ensur that you use the same URWB profile id that you create here, when attaching the wireless RF tag.

For CLI configuration steps, refer to Create URWB radio profile (CLI) and for GUI configuration stepsrefer to Create URWB radio profile (GUI).

Configure URWB network profile

Complete the following steps to configure the URWB network profile:

Before you begin

Ensure that you use the same URWB profile id that you create here, when attaching the wireless RF tag.

Procedure

1. Enter configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter a profile name to create a URWB profile.

   Example

   ```
   Device(config)# wireless profile urwb urwb-profile-name
   ```

   This command creates a URWB profile and enters into the wireless URWB profile configuration mode.

3. Configure a network key.

   Example

   ```
   Device(config-wireless-urwb-profile)# network-key network-key-type {0 |
   8}<network-key>
   ```

   This command configures the shared secret for secure communication between the URWB nodes. The network key can be saved as encrypted or unencrypted type.

   Here, **0** indicates that you must enter an unencrypted network key; and **8** indicates that you must enter an AES encrypted network key.

   > **Note**
   >
   > The network key must not contain special characters.

4. Configure URWB mobility role to base for the AP.

   Example

   ```
   Device(config-wireless-urwb-profile)# mobility role base
   ```

5. Enable the URWB profile.

   Example

   ```
   Device(config-wireless-urwb-profile)# no shutdown
   ```

   This command enables the URWB profile in the wireless URWB profile configuration mode.

   To disable the URWB profile, use the **shutdown** command.

6. Optional: Configure a strong password evaluation for the network key.

Example

```
Device(config-wireless-urwb-profile)# strong-network-key
```

Configure the radio profile for infrastructure device

Use this procedure to configure the radio profile for infrastructure device.

Before you begin

Ensure that you use the same radio profile name that you create here, when attaching the wireless RF tag.

Procedure

---

1. Use the **wireless profile radio** *radio-profile-name* command to create the radio profile for the infrastructure device.

Example

```
Device(config)#wireless profile radio 6g-radio-infra
```

2. Use the **urwb role** *mobility* command to configure the URWB radio role.

Example

```
Device(config-wireless-radio-profile)#urwb role mobility
```

3. Use the **urwb channel** *radio-band channel-number* command to configure the 6 GHz radio band and the channel number.

Example

```
Device(config-wireless-radio-profile)#urwb channel 6ghz 145
```

4. Use the **urwb cwidth** *channel-width* command to configure the channel width.

Example

```
Device(config-wireless-radio-profile)#urwb cwidth 160MHz
```

5. Use the **urwb crypto policy** *policy-name* command to configure the encryption.

Example

```
Device(config-wireless-radio-profile)#urwb crypto policy none
```

6. Use the **exit** *policy-name* command to return to global configuration.

Example

```
Device(config-wireless-radio-profile)#exit
```

Configure the radio profile for the client device

Use this procedure to configure the radio profile for client device.

Before you begin

Ensure that you use the same radio profile name that you create here, when attaching the wireless RF tag.

Procedure

---

1. Use the **wireless profile radio** *radio-profile-name* command to create the radio profile for the client device.

   Example

   ```
   Device(config)#wireless profile radio 6g-radio-vehicle
   ```

2. Use the **urwb role** *mobility* command to configure the URWB radio role.

   Example

   ```
   Device(config-wireless-radio-profile)#urwb role mobility
   ```

3. Use the **urwb channel** *radio-band channel-number* command to configure the 6 GHz radio band and the channel number.

   Example

   ```
   Device(config-wireless-radio-profile)#urwb channel 6ghz 145
   ```

4. Use the **urwb cwidth** *channel-width* command to configure the channel width.

   Example

   ```
   Device(config-wireless-radio-profile)#urwb cwidth 160MHz
   ```

5. Use the **urwb crypto policy** *policy-name* command to configure the encryption.

   Example

   ```
   Device(config-wireless-radio-profile)#urwb crypto policy none
   ```

6. Use the **exit** *policy-name* command to return to global configuration.

Example

```
Device(config-wireless-radio-profile)#exit
```

Create the RF tag and assign radio profile and URWB profiles for the infrastructure device

Use this procedure to create the RF tag and attach radio profile and URWB profiles for the infrastructure device.

Procedure

1. Use the **wireless tag rf** *rf-profile-name* command to create an RF tag for the infrastructure device.

   Example

   ```
   Device(config)#wireless tag rf 6g-infra
   ```

2. Use the **dot11 6ghz slot2 radio-profile** *radio-profile-name* command to attach radio profile to a 6 GHz radio configuration.

   Example

   ```
   Device(config-wireless-rf-tag)#dot11 6ghz slot2 radio-profile 6g-radio-infra
   ```

3. Use the **urwb-profile***urwb-network-profile-name* command to attach URWB profile to a 6 GHz radio configuration.

   Example

   ```
   Device(config-wireless-rf-tag)#urwb-profile mobility-VE-infra
   ```

4. Use the **exit** command to return to global configuration.

   Example

   ```
   Device(config-wireless-urwb-profile)#exit
   ```

Create an RF tag and assign radio profile and URWB profiles for the client device (CLI)

Complete the following steps to create the RF tag and attach radio profile and URWB profiles for the client device.

Procedure

For CLI configuration steps, refer to Create RF tags and assign profiles (CLI) on page 2470.

Apply RF tag of the infrastructure device to access point

Use this procedure to apply the RF tag and attach radio profile and URWB profiles of the client device to access point.

Procedure

1. Use the **ap** *mac-address* command to configure the MAC address of the infrastructure device.

   Example

   ```
   Device(config)#ap fc58.9a16.e570
   ```

2. Use the **rf-tag** *rf-tag-id* command to apply RF tag of the infrastructure device to access point.

   Example

   ```
   Device(config)#rf-tag 6g-infra
   ```

Apply RF tag of the client device to access point

Use this procedure to apply the RF tag and attach radio profile and URWB profiles of the client device to access point.

Procedure

1. Use the **ap** *mac-address* command to configure the MAC address of the client device.

   Example

   ```
   Device(config)#ap  fc58.9a17.xxxx
   ```

2. Use the **rf-tag** *rf-tag-id* command to apply RF tag of the client device to access point.

   Example

   ```
   Device(config)#rf-tag 6g-vehicle
   ```

Verify 6 GHz Low Power Indoor on AP in mobility client role

Verify the 6 GHz Low Power Indoor (LPI) mode on an access point operating as a mobility client.

Use this procedure to verify 6 GHz LPI on AP in mobility client role.

Procedure

Use the **show urwb dot11Radio 2 config** command to verify the 6 GHz LPI mode on AP in mobility client role.

Example

```
Device# show urwb dot11Radio 2 config
Interface:              enabled

Mode:                   fluidity
```

NAT/PAT for URWB

Outlines NAT/PAT functionality for URWB networks, including support for AGV mobility, IP and port mapping to WAN addresses, traffic flow management, policy-based configuration, and port address translation for accessing multiple services via single external IPs.

Network address translation for URWB is a networking feature that:

- provides NAT/PAT functionality for AGV use cases when the URWB mobility feature is enabled,
- allows network administrators to map local IP addresses and ports to wide area network (WAN) addresses, and

- manages traffic flow between on-board local networks and external systems.

Key features of NAT/PAT for URWB

Policy-based management: NAT/PAT configuration is integrated into the URWB network profile, ensuring consistent application across devices.

Port address translation: Enables multiple internal services to be reached via a single external IP address using different port mappings.

Guidelines for NAT/PAT configuration

Outlines key guidelines for effective NAT/PAT configuration, including avoiding port overlap with reserved system ports, adhering to rule limits per device, and monitoring translation table size to ensure stable performance.

Follow these guidelines to ensure stable NAT/PAT performance:

- Avoid port overlap: When defining the NAT outside port range, ensure that the selected range does not overlap with reserved system ports. The following ports are strictly reserved for internal system operations and must be excluded from your configuration: 651, 5246, 5247, 6600, and 6610. Configuring a range that includes these ports will result in a validation error.
- Observe rule limits: You can configure a maximum of 100 rules per device.
- Monitor table size: To prevent resource exhaustion, the NAT translation table is limited to 4096 entries.

Configure NAT/PAT for URWB (GUI)

Provides instructions for configuring NAT and PAT on URWB systems using the graphical user interface, including step-by-step guidance for setup and management.

Enable and configure NAT/PAT translation rules for URWB mobile units.

Use this task to allow communication between devices on an on-board local network and the WAN. This configuration is managed within the URWB network profile.

Before you begin

- Ensure the URWB mobility feature is enabled on the access point.
- Identify the IP address and netmask for the local network.

Follow these steps to configure NAT/PAT for URWB:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **URWB Network Profile**.
2. Click **Add** or select an existing profile.
3. In the **General** tab, enable the URWB status to edit the profile.
4. In the **Mobility** tab, from the **Mobility Role** drop-down list, choose **Client**.
    - **Base**
    - **Base Relay**
    - **Client**

    When you select **Base** or **Base Relay** as the mobility role, the **Wired Ports** tab is displayed. When you select **Client** as the mobility role, the **Wired Clients** tab is displayed.

5. In the **Wired Clients** tab, under the **NAT** section, check the **NAT** check box to enable Network and Port Address Translation (NAT/PAT) feature.
6. In **NAT Address**, enter the IPv4 address of the AP facing the on-board local network and enter the subnet mask associated with the NAT address.
7. Enter the **Outside Port Range**. Specify the minimum and maximum port range for outside port rule value. The range is from 1 to 65535 unless both are 0.
8. In the NAT rules section, click the **Add Rule** button to add a NAT/PAT configuration rule that contains protocol information, **Inside IP Address**, **Inside Port**, and **Outside Port**. The range for the port numbers is from 1 to 65535.

   Note

   You can configure up to 100 rules. The target host shall be located within the configured inside network address space.

9. Click **Save** to add the new rules to the table and then click **Update & Apply to Device**.

NAT/PAT translation rules are applied, enabling devices on the local on-board network to communicate with external networks through the WAN.

Configure NAT/PAT for URWB

Guides users through command-line procedures for configuring NAT and PAT in URWB environments, covering essential steps for implementation and verification.

Enable and configure NAT/PAT translation rules for URWB mobile units.

Use this task to allow communication between devices on an on-board local network and the WAN. This configuration is managed within the URWB network profile.

Before you begin

- Ensure the URWB mobility feature is enabled on the access point.
- Identify the IP address and netmask for the local network.

Follow these steps to configure NAT/PAT for URWB:

Procedure

1. Use the **configure terminal** command to enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Use the **wireless profile urwb** *urwb_profile_name* command to access the URWB profile configuration mode.

   Example

   ```
   Device(config)# wireless profile urwb URWB_PROFILE
   ```

3. Use the **nat enable** command to enable the NAT feature.

Example

```
Device(config-wireless-urwb-profile)# nat enable
```

4. Use the **nat address** *ip_address* **netmask** *netmask* command to define the inside IP address and netmask for the local network.

   Example

   ```
   Device(config-wireless-urwb-profile)# nat address 192.168.0.1 netmask
   255.255.255.0
   ```

5. Use the **nat rule** {**tcp**| **udp**} *outside-port* **inside** *inside-ip inside-port* command to add NAT port forwarding rules.

   Example

   ```
   Device(config-wireless-urwb-profile)# nat rule tcp 30022 inside 192.168.0.58
    22
   ```

   In this example, TCP traffic received on outside port 30022 is forwarded to 192.168.0.58 on port 22.

   The target host shall be located within the configured inside network address space.

6. (Optional) Use the **nat outside range min** *min* **max** *max* command to set the outside port range.

   Example

   ```
   Device(config-wireless-urwb-profile)# nat outside range min 25001 max 30000
   ```

7. Use the **end** command to exit to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-urwb-profile)# end
   ```

8. (Optional) Use the **show wireless profile urwb detailed** *urwb_profile_name* command to verify the configuration.

   Example

   ```
   Device# show wireless profile urwb detailed URWB_PROFILE
   ```

9. (Optional) Use the **show ip nat translations** command to display the current NAT translation mappings on the AP.

   Example

   ```
   Device# show ip nat translations
   ```

Digital I/O ports

Introduces digital I/O port functionality, explaining their features, operational characteristics, and integration within system architectures.

A digital I/O port is a software interface that:

- enables control of external hardware signals,
- facilitates the monitoring of input status, and
- allows for the management of status indicators such as LEDs.

The IW9165E supports mapping GPIO pins to character devices (e.g., `/dev/dio-x`). These devices are exposed to the IOx framework, enabling customer-developed applications to programmatically access and manage digital I/O interfaces for external hardware control.

Best practices for digital I/O control

To ensure reliable and consistent operation of digital I/O ports, follow these best practices:

- Use standardized paths: Always interact with the `/dev/dio-x` paths to ensure compatibility with the system's hardware abstraction layer.
- Verify status: Read the exposed Digital I/O status using the supported device interface or status file for your application.

Control digital I/O ports

Provides instructions for controlling digital I/O ports, including step-by-step procedures for configuring, monitoring, and operating ports within various deployment scenarios.

Manage external hardware signals and indicators through the command line interface.

You can use the character device interface to send high or low signals to hardware components or monitor the status of connected inputs.

Before you begin

Ensure the application environment is configured to access the `/dev/` directory.

Follow these steps to control digital I/O ports:

Procedure

1. Use the **echo** command to set the output state of a digital I/O port.
   - To set a port to high, use: echo 1 > /dev/dio-1
   - To set a port to low, use: echo 0 > /dev/dio-1

   Example

   ```
   Device# echo 1 > /dev/dio-1
   ```

   Example

   ```
   Device# echo 0 > /dev/dio-1
   ```

2. Monitor the input status of a port by using the corresponding device file.
   - To monitor the digital I/O output port status (high), use: echo 1 > /dev/dio-3
   - To monitor the digital I/O output port status (low), use: echo 0 > /dev/dio-4

Example

```
Device# echo 1 > /dev/dio-3
```

Example

```
Device# echo 0 > /dev/dio-4
```

3. Control an LED by writing to the associated device file.
   - To turn on the LED (1), use: echo 1 > /dev/dio-5
   - To turn off the LED (1), use: echo 0 > /dev/dio-5

Example

```
Device# echo 1 > /dev/dio-5
```

Example

```
Device# echo 0 > /dev/dio-5
```

Digital I/O device mapping

Details digital I/O device mapping, describing how devices are associated with I/O ports and offering reference information for hardware and logical mappings.

The table lists the software-exposed device nodes used by the application environment.

- Each entry specifies the device file corresponding to a digital I/O port configured for input or output and the device file that controls an LED indicator.
- Mapping device files is essential for managing and interacting with hardware interfaces through programs or command-line operations.

Table 171: Device file mapping for digital I/O ports and LEDs

GPIOs	Digital I/O ports	Function
GPIO29	/dev/dio-1	Digital I/O 1 output
GPIO31	/dev/dio-2	Digital I/O 2 output
GPIO38	/dev/dio-3	Digital I/O 1 output
GPIO39	/dev/dio-4	Digital I/O 2 output
GPIO51	/dev/dio-5	LED 1
GPIO48	/dev/dio-6	LED 2

> **Note**
>
> The GPIOs in the table are the logical device nodes exposed to IOx.

Power saving modes

Outlines power saving modes, explaining methods, criteria, and operational impact of reducing power consumption for digital I/O devices.

From release 26.2.1, Cisco IW9165E AP supports power saving modes through the exposed low-power control interface.

A power saving mode is a configuration state that

- reduces energy consumption for devices powered by external battery sources,
- maintains essential connectivity for remote management, and
- enables automated control of connected peripherals.

Sleep modes

The AP supports two types of power saving modes:

- Light sleep: In this mode, the device keeps the URWB backhaul radio on, and other radios and ethernet ports are shut down. The users can restore the device to active mode at any time via the backhaul radio. Enabling this mode reduces power consumption by 1.5 W to 2.4 W, depending on the traffic load.
- Deep sleep: This mode is not supported in release 26.2.1.

Features of power saving modes

- Automated control: Network administrators can use custom IOx applications to manage power states and control connected devices.
- Application integration: The Cisco App-hosting Framework (CAF) facilitates communication between control systems and IOx applications to execute power-saving logic.

> **Note**
>
> Power saving modes are not persistent. The device will default to active mode after a reload or power cycle.

Manage power saving modes

Provides instructions for managing power saving modes, including procedures for enabling and configuring energy-saving features on digital I/O devices.

Transition the device into a low-power state to conserve battery life during periods of inactivity.

Use this task when the device is deployed in mobile environments where power efficiency is required.

Before you begin

- Ensure the IOx application is deployed and configured to communicate with your control system.

- Verify that the necessary digital I/O interfaces are mapped to your IOx application. See Digital I/O device mapping section.

Follow these steps to manage power saving modes:

Procedure

1. Access your control system interface.

   Example

   ```
   Engineering: How to access the control system interface?
   ```

2. Send the sleep command to the IOx application.

   Example

   ```
   Device#: echo 1 > /mnt/host_cpu/low_power_mode
   ```

   The IOx application executes the power-saving logic to transition the device to light sleep mode.

3. Send the wake-up command from your control system to the IOx application to restore full functionality.

   Example

   ```
   Device# echo 0 > /mnt/host_cpu/low_power_mode
   ```

   The IOx application executes the power-saving logic to transition the device to active mode.

IOx frameworks

Introduces IOx frameworks, describing the core concepts, architecture, and operational principles that support IOx application deployment and management on network devices.

An IOx framework is an application hosting environment that

- provides a containerized platform for running applications directly on network devices,
- extends device functionality beyond standard networking tasks, and
- enables edge computing by processing data locally at the network edge.

From release 26.2.1, Cisco IW9165E AP supports IOx. IOx combines Cisco IOS-XE with Linux. This combination allows developers to build and run applications in a secure, isolated environment. IOx leverages container technology such as Docker. This enables the deployment of custom code, analytics, and third-party software on Cisco hardware. As a result, the network device becomes a compute node.

IOx resource specifications for IW9165E

Details IOx resource specifications for IW9165E, outlining hardware requirements, resource limits, and supported configurations necessary for effective deployment and operation of IOx applications on the device.

The IW9165E supports application hosting with the following resource specifications:

- The Max Memory and Max App Size are dependent on the actual memory and storage available at run time in IW9165E

Table 172: IOx resource specifications

CPU Architecture	CPU Allocated (MFLOPS)	Max Memory Allocated (RAM)	Application Type	Max Number of Apps	Max APP size
ARM 64-bit	4800	100 MB	Docker	2	20 MB

Enable IOx using controller

Provides instructions for enabling IOx through a network controller, covering the procedures necessary to activate and configure IOx services via centralized management interfaces.

Enable the IOx framework on the IW9165E access point to support application hosting.

IOx is disabled by default on the IW9165E. You can enable it either through the Wireless Controller or directly via the AP CLI.

Before you begin

Ensure you have administrative access to the Wireless Controller or the AP console.

Follow these steps to enable IOx via the Wireless Controller:

Procedure

1. Use the **configure terminal** command to enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Use the **ap profile** *ap-profile-name* command to configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile iox
   ```

3. Use the **apphost** command to enable the apphost framework on Cisco APs.

   Example

   ```
   Device(config-ap-profile)# apphost
   ```

   This step enables IOx allowing for application hosting.

Enable IOx using AP

Guides the process of enabling IOx directly on an AP, including step-by-step procedures to activate, configure, and verify IOx capability locally on the access point.

Enable the IOx framework on the IW9165E access point to support application hosting.

IOx is disabled by default on the IW9165E. You can enable it either through the Wireless Controller or directly via the AP CLI.

Before you begin

Ensure you have administrative access to the Wireless Controller or the AP console.

Follow these steps to enable IOx via the AP CLI:

Procedure

1. Access the AP console
2. Use the **configure iox{enable| disable}** command to enable or disable IOx.

   Example

   ```
   Device# configure iox enable
   ```

3. (Optional) Use the **show iox status** command to view the status of IOx.

   Example

   ```
   Device# show iox status
   ```

   The system displays the current enabled or disabled status of the IOx framework.

URWB topology awareness

Explains how URWB topology awareness works across multiple controllers in a mobility group to ensure unified network visibility and high availability.

The URWB topology awareness feature is a mobility group capability that

- provides all the controllers in a mobility group with visibility into URWB telemetry across the entire group,
- synchronizes URWB topology information between peer controllers to ensure consistent network state.

Additional reference information

The URWB topology awareness feature allows controllers to share telemetry data within the mobility infrastructure. A controller that receives telemetry forwards it to all other controllers in the mobility group. Each peer then updates its local URWB telemetry database. This synchronizes topology information across the group, enabling consistent monitoring and troubleshooting.

In URWB deployments, a controller learns the network topology from the coordinator AP. When a single URWB network spans multiple controllers, only the controller receiving the telemetry from the coordinator AP has full visibility of the network nodes and links. Without synchronization, other controllers lack the URWB topology information and cannot provide a unified network view.

Configure URWB topology awareness (CLI)

Configure the coordinator Access Point (AP) to assign a unique URWB network name and enable topology awareness for telemetry across multiple controllers.

Set up URWB topology awareness on the Coordinator Access Point (AP) to help identify the network and improve telemetry reporting across multiple controllers.

Configuring topology awareness ensures the Coordinator AP can be easily identified in the network.

Before you begin

- Ensure the AP is in coordinator mode.
- Verify the AP has an active connection to the controller.

Follow these steps to configure the URWB network name and enable telemetry reporting on the coordinator AP.

Procedure

Use the **ap name** *ap-name* **urwb mode coordinator nwname** *network-name* command to configure the AP in coordinator mode and assign a unique network name to the URWB network.

Example

```
Device# ap name coordinator urwb mode coordinator nwname PTP1
```

Note

For wired-only coordinator configurations, use the **ap name** *ap-name* **urwb mode coordinator wired-only fixed nwname** *network-name* or **ap name** *ap-name* **urwb mode coordinator wired-only mobility nwname** *network-name* commands.

Configure URWB topology awareness (GUI)

Configure the URWB network name for an access point using the wireless management GUI

Use the wireless device management interface to assign a unique URWB network name. Assigning a unique name is essential for proper network coordination and grouping access points in URWB environments.

Before you begin

Ensure you have access credentials for the wireless management interface.

Procedure

1. Navigate to **Configuration** > **Wireless** > **Access Points**.
2. Select the desired **Access Point** from the list to open the **Edit AP** window.
3. Click the **URWB tab** to access the URWB configuration settings.
4. Select the **Coordinator** check box to enable the coordinator role for the selected AP.
5. Enter the unique identifier in the **URWB Network Name** field.

   The **URWB Network Name** field is mandatory and must be between 1 and 32 characters in length. Only alphanumeric characters, hyphens (-), dots (.), and underscores (_) are supported. Ensure the network name adheres to these requirements to avoid configuration errors.

6. Click **Update and Apply to Device** to save the configuration and push the changes to the coordinator AP.

Verify URWB network information on the coordinator AP

Use the show urwb network command to view the URWB network name and detailed topology information.

This task allows you to quickly verify URWB network details, such as name, coordinator, status, and last update, from the controller. This helps you troubleshoot and monitor your access point efficiently.

Procedure

1. Use the **show ap name** *ap-name* command to view the URWB network name and topology identifier information.

   Example

```
Device# show ap name coordinator urwb network
Mesh ID                           : 5.190.114.16

11.1.1.11       05/25/26 06:05:37
```

2. Use the **show ap name coordinator urwb info** command to display URWB information for the coordinator.

   Example

```
Device# show ap name coordinator urwb info
URWB Status                       : Enabled
Radio MAC                         : aaa.bbb.ccc
URWB Profile Inuse                : URWB_PAIR1
Mesh ID                           : 5.190.114.16

Config errors from AP             : None

Network-key hash                  :
7fd211ec1ed86daa0d9cf3b0cf245c5ee8a8added48d966a3b9c61d7d2237b06
```

```
Coordinator Mode                  : Enabled
Network Name in Use               : newux
Multicast                         : Disabled
```

3. Use the **show wireless urwb network summary** command to display all the URWB networks configured on the controller.

   Example

```
Device# show wireless urwb network summary
URWB Networks

Network Name         Network ID            Coordinator MAC       Coordinator
 Mesh ID
-------------------------------------------------------------------------------------------
coordinator         5957441956030247710       aaa.bbb.ccc
5.190.114.16
```

4. Use the **show wireless urwb network detail** *nw-name* command to display URWB network details.

   Example

```
Device# show wireless urwb network detail coordinator
URWB Network Detail

Network Name                    : coordinator
Network ID                      : 5957441956030247710
Coordinator MAC                 : aaa.bbb.ccc
Coordinator Mesh ID             : 5.190.114.16
```

Ethernet port authentication

Explains how 802.1X authentication secures Ethernet ports in vehicle ground access scenarios by validating hardware and managing access through industry-standard protocols.

802.1X authentication on Ethernet ports is a security mechanism designed for vehicle devices that

- Validates wired clients through a centralized RADIUS server.
- Ensures that only authenticated hardware gains access to network resources.
- Secures Ethernet LAN ports in industrial vehicle-to-ground deployment scenarios.

Key features

Authenticating 802.1X on an Ethernet port provides these benefits:

- Prevents unauthorized devices from accessing the network by requiring authentication before allowing data traffic on the Ethernet port.
- You can validate client credentials using industry-standard protocols such as PEAP, EAP-TLS, and EAP-FAST.
- Tailored for Vehicle Ground Access scenarios, including robotic or autonomous vehicle fleets, where physical port security is critical.

Table 173: Hardware and software compatibility

Attribute	Requirement
Software Release	26.2.1 or later
Operating Mode	Wireless Backhaul (URWB)
Hardware Models	Supported on all URWB-capable Cisco Catalyst and Industrial Wireless (IW) series PIDs
Configuration	Managed via Wireless Backhaul Network Profile

Guidelines and limitations

Outlines the key guidelines and limitations you should follow when configuring 802.1X on Ethernet ports.

Before you configure 802.1X on Ethernet ports, follow these guidelines:

- Only one wired client per LAN port is supported in this release.
- Multiple clients behind a single LAN port (e.g., via a switch) are not supported
- Authentication protocols supported are limited to PEAP, EAP-TLS, and EAP-FAST.
- You can configure a maximum of two RADIUS servers.
- The RADIUS server group can be configured only when the URWB mobility role is set to client.
- IPv6 is not supported for RADIUS server group configurations.
- Extended information parameters such as coa_port, retransmit, interim interval, and timeout are not supported.
- The accounting mechanism is also not supported in this context.

Configure a RADIUS server and group

Configure a RADIUS server and group to enable centralized authentication for users and devices.

Configure a RADIUS server and group (CLI)

Configure a RADIUS server and assign it to a server group to enable authentication services on network devices

Define a RADIUS server and assign it to a server group to enable authentication services.

This configuration is a prerequisite for enabling 802.1x authentication on Ethernet ports.

Before you begin

Ensure you have the RADIUS server IPv4 address, authentication port, and shared secret (key).

Perform these steps to configure a RADIUS server and group.

Procedure

1. Use the **configure terminal** command to enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Use the **RADIUS server** *radius_name* command to initiate the RADIUS server configuration. Define the server name, IPv4 address, and shared secret.

   Example

   ```
   Device(config)# radius server <radius-name>
   ```

3. Use the **address ipv4** {*ip-address* | *hostname*}[**auth-port** *port-number*] command to specify the server address and ports.

   Example

   ```
   Device(config)# address ipv4 xx.x.x.xx auth-port 1812
   ```

4. Use the **key** *shared_secret* command to set the shared secret.

   Example

   ```
   Device(config)# key Cisco123!
   ```

5. Use the **aaa group server** *group-name* command to create a server group and assign the defined RADIUS server to it.

   Example

   ```
   Device(config)# aaa group server radius <group-name>
   ```

6. Use the **server name** *radius-name* command to associate a RADIUS server with a RADIUS server group.

   Example

   ```
   Device(config-sg-radius)# server name <radius-name>
   ```

The RADIUS server is configured and assigned to a server group, enabling authentication services for network devices.

Configure a RADIUS server and group (GUI)

Configure a RADIUS server and server group to enable authentication management in your network device.

Establish centralized authentication by configuring a RADIUS server and creating server groups for robust network security

Use this task before enabling 802.1x authentication on Ethernet ports. A properly configured RADIUS setup ensures that network devices authenticate users and devices through a central server.

Before you begin

Configure a RADIUS server and group before enabling the 802.1x authentication on Ethernet ports using this procedure.

Procedure

1. Navigate to **Configuration** > **Security** > **AAA** > **Servers/Groups**
2. Under the **RADIUS** > **Servers** tab and click **Add**, define the Server name, IPv4 address, shared secret, and authentication port
3. Under the **RADIUS** > **Server Groups** tab and click **Add**, name the group and add the previously created RADIUS server to the assigned list.

The device is ready to use the configured RADIUS server and group for authentication processes across network interfaces.

Enable 802.1x authentication on Ethernet ports

Configure your Ethernet ports to require secure 802.1x authentication, ensuring only authorized devices access the network.

Enable 802.1X authentication on Ethernet ports (CLI)

Configure 802.1X authentication to secure the Ethernet LAN port on a vehicle device using CLI.

Enable 802.1X authentication for Ethernet LAN ports to enforce secure network access for wired clients.

This task enforces network access control for wired clients (such as robots or onboard controllers) by requiring authentication via a RADIUS server before permitting network access.

Before you begin

- Ensure the backhaul network is established.
- Have your RADIUS server IP, port, and shared secret ready.
- Verify the wired client supports PEAP, EAP-TLS, or EAP-FAST.

To enable 802.1X authentication on Ethernet ports, perform these steps

Procedure

1. Use the **configure terminal** and enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Use the **wireless profile urwb** *urwb-profile_name* command to access the wireless backhaul network profile.

   Example

   ```
   Device(config)# wireless profile urwb <urbw-profile_name>
   ```

3. Use the **local-auth radius-server-group** *radius-server-group_name* command to add the RADIUS server group to the profile.

   Example

   ```
   Device(config-wireless-urwb-profile)# local-auth radius-server-group
   <radius-group-name>
   ```

To remove the RADIUS server group association, use the **no local-auth radius-server-group** *<radius-server-group_name>* command.

4. Use the **end write memory** command to exit configuration mode and save your settings.

Example

```
Device(config-wireless-urwb-profile)# end
```

5. Use the **show ap name** *ap_name* **urwb info** command to confirm that the RADIUS server details and port settings are correctly pushed to the AP.

Example

```
Device# show ap name <ap_name> urwb info
```

Verify the status of the secondary Ethernet port if the client is connected to port 1.

802.1X authentication is enabled on the specified Ethernet port. Wired clients connecting to this port must successfully authenticate via the configured RADIUS server before gaining network access.

Enable 802.1X authentication on Ethernet ports (GUI)

Configure 802.1X authentication on Ethernet ports to secure wired network access using a RADIUS server.

Enable port-based authentication for wired clients. This ensures that only authorized devices can connect to the network.

802.1X authentication provides port-based network access control for wired clients. The system enforces authentication before granting network access. You must associate the Ethernet ports with a RADIUS server group to handle authentication requests.

Before you begin

- Ensure you have the RADIUS server IP address, port number, and shared secret.
- Verify that the wired client supports one of the EAP methods: PEAP, EAP-TLS, or EAP-FAST.
- Confirm that the RADIUS server is properly configured and reachable from the controller.

Procedure

---

1. Navigate to **Configuration** > **Tags and Profiles** > **URWB Network Profile**
2. Edit the **URWB Network Profile** and go to **Wired Clients** > **Local Authentication** > **RADIUS Server Group**
3. Choose your **RADIUS Server Group**
4. Click **Update and Apply to Device**

Wired clients must authenticate with the specified RADIUS server before accessing the network. Only authorized devices will be permitted, enhancing security for your wired infrastructure.

Troubleshoot RADIUS authentication with debug commands

Configure debug commands to identify errors, events, and packet-level issues during RADIUS authentication on Ethernet ports.

Enable and disable debug commands to gain visibility into the authentication process, helping you pinpoint causes of RADIUS authentication failures.

RADIUS authentication issues may occur during device access via Ethernet ports. Debug commands provide detailed logs to assist in troubleshooting. Use these steps when authentication errors or unexpected network events occur.

Before you begin

Follow these steps to troubleshoot RADIUS authentication on Ethernet ports using debug commands:

Procedure

1. Use the **debug urwb radius eth** command to enable specific debugging levels.

   Example

   ```
   Device# debug urwb radius eth {error | events | info | packet}
   ```

   - **error**: Displays RADIUS authentication error messages.
   - **events**: Logs authentication-related events.
   - **info**: Provides informative authentication details.
   - **packet**: Shows packet-level debugging output.

2. To disable the debugging, use the **no** form of the command.

   Example

   ```
   Device# no debug urwb radius eth {error | events | info | packet}
   ```

Debug logs are generated based on the selected level, helping you identify RADIUS authentication problems on Ethernet ports.

Verify RADIUS authentication status on an AP

Verify RADIUS authentication and view active authentication tables on an AP using show commands.

Ensure that wired client authentication on the AP is correctly configured and operating by checking RADIUS settings and active authentication tables.

Perform this task to maintain network security and troubleshoot authentication issues for wired clients by validating RADIUS configuration and monitoring active client authentication tables.

Before you begin

Ensure that RADIUS authentication is enabled for wired clients on the access point.

Follow these steps to verify RADIUS authentication and view wired client tables on the AP:

Procedure

1. Use the **show urwb wired radius config** command to display the current RADIUS configuration settings for the wired interface.

Example

```
Device# show urwb wired radius config
```

2. Use the **show urwb wired radius tables** command to view the active RADIUS authentication tables, which contain information about the wired clients currently being processed or authenticated.

   Example

   ```
   Device# show urwb wired radius tables
   ```

---

ou can review the RADIUS configuration and authentication tables, ensuring all settings are correct and wired clients are properly authenticated.

Part XVIII

VideoStream

Topics:

- VideoStream

196 VideoStream

Topics:

- Media stream

Media stream

Use the Media Stream feature to improve wireless multicast delivery. This feature converts multicast traffic to unicast and enables reliable packet acknowledgment by clients.

A Media Stream feature is a multicast delivery solution that

- converts IP multicast traffic into unicast frames for transmission over the air
- enables each wireless client to acknowledge receipt of video multicast data, and
- increases the reliability and quality of the media stream delivery in wireless networks.

The IEEE 802.11 wireless multicast delivery mechanism does not provide a reliable way to acknowledge lost or corrupted packets. As a result, if a multicast packet is lost during transmission, the system does not resend it, which may prevent you from viewing the IP multicast stream.

Cisco IOS XE Gibraltar 16.12.1 and later support IPv6 multicast addresses with the Media Stream feature. To configure media stream on IPv6 networks, specify IPv6 multicast addresses instead of IPv4 multicast addresses.

Prerequisites for media stream

This section lists the prerequisites that must be met before configuring media stream functionality, including network settings, controller mode, and client requirements.

These prerequisites must be satisfied before you configure media stream:

- Enable the multicast feature. Configure IP multicast on the controller in multicast-multicast mode.
- Check the IP address on the client machine. Verify that the client machine's IP address belongs to the appropriate VLAN.
- Verify that the access points have joined the controllers .

How to configure media stream

-

Configure the general parameters for a media stream (GUI)

Use this procedure to configure general parameters for a media stream in the wireless controller GUI.

Specify the parameters required to enable and manage multicast media streams for your network.

Procedure

1. Choose **Configuration** > **Wireless** > **Media Stream**.
2. In the **General** tab, check the **Multicast Direct Enable** check box.
3. In the **Session Message Config** section, check the **Session Announcement State** check box to enable the session announcement mechanism. The wireless controller applies the new general parameters for media streaming, and and notifies clients.
4. In the **Session Announcement URL** field, enter the URL where the client can find more information when an error occurs during the multicast media stream transmission.
5. In the **Session Announcement Email** field, enter the email address that users can contact for assistance.
6. In the **Session Announcement Phone** field, enter a phone number that users can call for assistance.
7. In the **Session Announcement Note** field, enter the reason why a client cannot be served with a multicast media.

8. Click **Apply**.

The wireless controller applies the new general parameters for media streaming, and clients are notified accordingly.

Configure multicast-direct globally for media stream (CLI)

Use this procedure to configure multicast-direct globally for media streams using CLI commands.

Enable and configure multicast-direct globally for all media streams on the wireless controller using CLI commands.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable multicast for wireless forwarding.

   Example

   ```
   Device(config)# wireless multicast
   ```

3. Enable IGMP snooping for each VLAN. If the global setting is disabled, all VLANs are considered disabled, regardless of their individual settings.

   Example

   ```
   Device(config)# ip igmp snooping
   ```

4. Enable a snooping querier on an interface when there is no multicast router in the VLAN to generate queries.

   Example

   ```
   Device(config)#ip igmp snooping querier
   ```

5. Configure the global multicast-direct on the controller.

   Example

   ```
   Device(config)# wireless media-stream multicast-direct
   ```

6. Configure the message configuration parameters, such as phone number, URL, email address, and notes.

   Example

   ```
   Device(config)# wireless media-stream message
   ```

   When a media stream is refused due to bandwidth constraints, a message can be sent to the affected user. These parameters define the IT support email address, explanatory notes to be displayed for the user, the redirect URL, and the phone number that users can contact regarding the refused stream.

7. Configure each media stream and its parameters, such as expected multicast destination addresses, stream bandwidth consumption, and stream priority parameters.

   Example

   ```
   Device(config)# wireless media-stream group grp-name startIp endIp
   ```

8. Return to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

The controller is now configured for multicast-direct for media streams as specified.

```
Device# configure terminal
Device(config)# wireless multicast
Device(config)# ip igmp snooping
Device(config)#ip igmp snooping querier
Device(config)# wireless media-stream multicast-direct
Device(config)# wireless media-stream message
 Email  Configure Session Announcement Email
 Notes  Configure Session Announcement notes
 URL    Configure Session Announcement URL
 phone  Configure Session Announcement Phone number
 <cr>
Device(config)# wireless media-stream group grp1 231.1.1.1 239.1.1.3
 avg-packet-size Configure average packet size
 default Set a command to its defaults
 exit Exit sub-mode
 max-bandwidth Configure maximum expected stream bandwidth in Kbps
 no Negate a command or set its defaults
 policy Configure media stream admission policy
 priority Configure media stream priority, <1:Lowest - 8:Highest>
 qos Configure over the air QoS class, <'video'> ONLY
 rrc-evaluation Configure RRC re-evaluation admission
 violation Configure stream violation policy on periodic re-evaluation
Device(config)# end
```

Configure media stream for 802.11 bands (CLI)

Learn how to configure media streams for 802.11 bands using CLI commands.

Enable and optimize media stream handling for 802.11 wireless bands by configuring relevant settings and parameters using CLI commands.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure whether media stream (multicast to unicast) is allowed for the 802.11 band.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} media-stream multicast-direct
```

You must disable the 802.11 network to enable media stream.

3. Optional: Configure the redirection of unicast video traffic to the best-effort queue.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} media-stream video-redirect
   ```

4. Configure the media stream to be sent through the best-effort queue if that media stream cannot be prioritized due to bandwidth-availability limitations.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} media-stream multicast-direct
   admission-besteffort
   ```

   Run the **no** form of the command to drop the stream if the media stream cannot be prioritized due to bandwidth-availability limitations.

5. Configure the maximum number of media streams allowed per client.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} media-stream multicast-direct
   client-max value
   ```

   The maximum is 15 and the default is 0. The value of 0 denotes unlimited streams.

6. Configure the maximum number of radio streams.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} media-stream multicast-direct
   radio-maximum value
   ```

   The valid range is from 1 to 20. The default is 0. The value of 0 denotes unlimited streams.

7. Configure maximum media (voice and video) bandwidth as a percentage.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} cac multimedia max-bandwidth
   bandwidth
   ```

   The range is from 5 percent to 85 percent.

8. Configure the minimum PHY rate needed for a client to send a media stream as unicast. If a client communicates below this rate, it will not receive the media stream as a unicast flow.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} cac media-stream multicast-direct
    min_client_rate dot11_rate
   ```

Typically, this PHY rate is equal to or higher than the rate at which multicast frames are sent.

9. Configure Call Admission Control (CAC) parameters for the media stream access category.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} cac media-stream
   ```

10. Configure CAC parameters for media access category used for voice and video.

    Example

    ```
    Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} cac multimedia
    ```

11. Configure CAC parameters for voice access category.

    Example

    ```
    Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} cac voice
    ```

12. Return to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

    Example

    ```
    Device(config)# end
    ```

The 802.11 bands are configured to handle media streams according to your specified parameters, enabling efficient multicast-to-unicast conversion and optimized bandwidth management for media traffic.

```
Device# configure terminal
Device(config)# ap dot11 24ghz media-stream multicast-direct
Device(config)# ap dot11 24ghz media-stream video-redirect
Device(config)# ap dot11 24ghz media-stream multicast-direct
admission-besteffort
Device(config)# ap dot11 24ghz media-stream multicast-direct client-max 15
Device(config)# ap dot11 24ghz media-stream multicast-direct radio-maximum 20
Device(config)# ap dot11 24ghz cac multimedia max-bandwidth 60
Device(config)# ap dot11 24ghz cac media-stream multicast-direct min_client_rate
Device(config)# ap dot11 5ghz cac media-stream
Device(config)# ap dot11 5ghz cac multimedia
Device(config)# ap dot11 5ghz cac voice
Device(config)# end
```

Configure a WLAN to stream video (GUI)

This task explains how to enable video streaming on a WLAN using the web GUI, so clients can access multicast video streams efficiently.

Procedure

---

1. Choose **Configuration** > **Wireless** > **WLANs** > **Wireless Networks**.
2. Select a **WLAN** to view the **Edit WLAN** window.

3. Click the **Advanced** tab.
4. Check the **Media Stream Multicast-Direct** check box to enable the feature.
5. Click **Update & Apply to Device**.

The selected WLAN now supports multicast-direct video streaming, allowing wireless clients to receive optimized video streams.

Configure WLAN to stream video (CLI)

Use this procedure to configure a WLAN for video streaming using command-line interface commands.

Enable video streaming functionality on a WLAN by configuring multicast-direct media streaming.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan_name
   ```

3. Disable WLAN for configuring its parameters.

   Example

   ```
   Device(config-wlan)# shutdown
   ```

4. Configure the multicast-direct media stream for the WLAN.

   Example

   ```
   Device(config)# media-stream multicast-direct
   ```

5. Enable the WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

6. Return to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

The WLAN is configured to support optimized video streaming via multicast-direct media streams.

```
Device# configure terminal
Device(config)# wlan wlan50
Device(config-wlan)# shutdown
Device(config)# media-stream multicast-direct
Device(config-wlan)# no shutdown
Device(config)# end
```

Enable a media stream per WLAN (GUI)

Use this procedure to enable a media stream for each WLAN using the GUI.

You can prioritize media streams over each WLAN to improve video and audio transmission quality.

Perform this task when you need to ensure media streaming is supported and optimized on specific WLANs.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. On the **WLANs** page, click the name of the **WLAN** or click **Add** to create a new one.
3. In the **Add/Edit WLAN** window that is displayed, click the **Advanced** tab.
4. Check the **Enabling a Media Stream for each WLAN** check box to enable the media stream on the WLAN.
5. Save the configuration.

You have enabled media streaming for the selected WLAN. Streaming traffic is now optimized.

Enable a media stream per WLAN (CLI)

Use this procedure to enable a media stream for a WLAN using CLI commands. This procedure allows you to provide multicast-direct media streaming on a per-WLAN basis.

Enable multicast media streaming functionality for a specified WLAN.

Perform this procedure when you need to configure multicast media streaming on individual WLANs in your wireless network environment.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan-name
   ```

3. Disable the WLAN for configuring its parameters.

Example

```
Device(config-wlan)# shutdown
```

4. Configure multicast-direct for the WLAN.

Example

```
Device(config-wlan)# media-stream multicast-direct
```

5. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The WLAN is now enabled with multicast-direct media streaming.

```
Device# configure terminal
Device(config)# wlan wlan5
Device(config-wlan)# shutdown
Device(config-wlan)# media-stream multicast-direct
Device(config-wlan)# no shutdown
```

Configure the general parameters for a media stream (GUI)

Use this procedure to configure general parameters for a media stream in the wireless section. This ensures correct setup of session announcements and global multicast settings through the GUI.

Configure the general parameters for a media stream to enable wireless multicast functionality and session announcement options. This helps you ensure the media stream operates correctly in your wireless network environment.

Procedure

---

1. Choose **Configuration** > **Wireless** > **Media Stream**.
2. Check the **Multicast Direct Enable** check box to enable multicast direct globally on the local mode.
3. In the **Session Message Config** section, enter values for these parameters:
   - Session Announcement URL
   - Session Announcement Email
   - Session Announcement Phone
   - Session Announcement Note
4. Save the configuration.

The system saves and applies the general parameters for the media stream.

Configure the general parameters for a media stream (CLI)

Use this procedure to configure the general parameters for a media stream using CLI commands.

Configure phone, URL, email, and notes for a media stream and enable multicast direct globally in a local wireless environment.

Perform this procedure when you want to apply or change general configuration parameters for a media stream through the CLI.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure various message configuration parameters, such as phone, URL, email, and notes.

   Example

   ```
   Device(config)# wireless media-stream message {url url | email email-address
    | phone phone-number | notes notes}
   ```

3. Enable multicast direct globally for local mode.

   Example

   ```
   Device(config)# wireless media-stream multicast-direct
   ```

   > **Note**
   >
   > This configuration will not impact flex and fabric media-stream configurations.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# exit
   ```

The general parameters for the media stream are now configured, and multicast direct is enabled for local mode.

```
Device# configure terminal
Device(config)# wireless media-stream message url www.xyz.com
Device(config)# wireless media-stream multicast-direct
Device(config)# exit
```

Add media stream (CLI)

Use this task to add a media stream by entering the appropriate commands on the CLI.

Configure media streams to manage multicast traffic efficiently on the device.

Media streams help you improve multicast traffic performance for applications such as streaming video or audio over wireless networks. Use media streams to reserve resources and prioritize bandwidth.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure each media stream and set parameters such as multicast destination addresses, bandwidth consumption, and priority.

   Example

   ```
   Device(config)# wireless media-stream group groupName startIpAddr endIpAddr
   ```

3. Configure the average packet size.

   Example

   ```
   Device(media-stream)# avg-packet-size packetsize
   ```

4. Configure the maximum expected stream bandwidth, in Kbps.

   Example

   ```
   Device(media-stream)# max-bandwidth bandwidth
   ```

5. Configure the media stream admission policy.

   Example

   ```
   Device(media-stream)# policy {admit | deny}
   ```

6. Configure the over-the-air QoS class as "video".

   Example

   ```
   Device(media-stream)# qos video
   ```

7. Configure the violation mode.

   Example

   ```
   Device(media-stream)# violation {drop | fallback}
   ```

8. Configure Resource Reservation Control (RRC) re-evaluation admission to provide initial or periodic admission evaluation. This process occurs at intervals of 2, 4, 8, or more seconds.

Example

```
Device(media-stream)# rrc-evaluation {initial | periodic}
```

9. Set the priority value. The valid range is 1 to 8, where 1 is the lowest.

Example

```
Device(media-stream)# priority priority-value
```

The system configures the media stream using your parameters and activates it for use.

```
Device# configure terminal
Device(config)# wireless media-stream group group1 224.0.0.0 224.0.0.223
Device(media-stream)# avg-packet-size 100
Device(media-stream)# max-bandwidth 80
Device(media-stream)# policy admit
Device(media-stream)# qos video
Device(media-stream)# violation drop
Device(media-stream)# rrc-evaluation initial
Device(media-stream)# priority 6
```

Delete a media stream (GUI)

Use this procedure to delete a media stream in the user interface when it is no longer needed.

Remove an existing media stream to keep only necessary and relevant streams in the system.

Procedure

---

1. Choose **Configuration** > **Wireless** > **Media Stream**.
2. Click the **Streams** tab.
3. Check the check box next to the stream name you want to delete.

   To delete multiple streams, select the checkboxes next to each stream name.
4. Click **Delete**.
5. Click **Yes** in the confirmation window to delete the media stream.

The selected media stream is permanently deleted from the system. It is no longer available for use or configuration.

Delete a media stream (CLI)

Use this procedure to delete a configured media stream from your device using CLI commands when the media stream is no longer needed or must be reconfigured.

Remove a configured media stream from the device using CLI commands when the media stream is no longer required or needs to be reconfigured.

Before you begin

Before you delete a media stream, make sure it is enabled and configured.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Delete the media stream identified by the command.

   Example

   ```
   Device(config)# no wireless media-stream group media_stream_name
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The specified media stream is removed from the device configuration and is no longer active.

```
Device# configure terminal
Device(config)# no wireless media-stream group grp1
Device(config)# end
```

Configure multicast direct admission control (GUI)

Use the GUI to enable and configure multicast direct admission control settings, improving media stream management on wireless networks.

This task explains how to enable and configure multicast direct admission control using the GUI.

Procedure

1. Choose **Configuration** > **Wireless** > **Media Stream**.
2. Check the **Media Stream Admission Control (ACM)** check box to enable multicast direct admission control.
3. In the **Maximum Media Stream RF bandwidth (%)** field, enter the percentage of maximum bandwidth for media applications on this radio band. The valid range is 5 to 85. If your client reaches the specified value, new calls on this radio band are rejected.
4. In the **Maximum Media Bandwidth (%)** field, enter the bandwidth. The valid range is 5 percent to 85 percent.
5. From the **Client Minimum Phy Rate** drop-down list, select the minimum transmission data rate in kilobits per second that the client can use. If the transmission data rate is below the physical rate, video does not start or your client is classified as a bad client. The system then demotes the video for better effort quality of service (QoS) or denies it.
6. In the **Maximum Retry Percent (%)** field, enter the percentage of maximum retries that are allowed. The default value is 80. If the value exceeds 80, video does not start or your client might be classified as a bad client. The system can demote the video for better effort QoS or deny it.

7. Click **Apply**.

You have activated multicast direct admission control.

Configure multicast direct admission control (CLI)

Learn how to configure multicast direct admission control using commands.

Configure multicast direct admission control to:

- ensure that media streams are efficiently delivered to wireless clients
- maintain optimal bandwidth allocation for multicast video and audio traffic, and
- enforce admission control policies that prevent network congestion and protect media quality.

To configure multicast direct admission control, perform these steps:

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Disable the 802.11 network.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} shutdown
   ```

3. Configure the redirection of the unicast video traffic to the best effort queue.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} media-stream video-redirect
   ```

4. Enable admission control on the media-stream access category.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} cac media-stream acm
   ```

5. Configure the maximum media bandwidth, in percent.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} cac media-stream max-bandwidth
    bandwidth
   ```

   The range is from 5 percent to 85 percent.

6. Configure the maximum bandwidth allocated for media to Wi-Fi Multimedia (WMM) clients.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} cac multimedia max-bandwidth
bandwidth
```

The range is from 5 percent to 85 percent.

7. Configure the minimum PHY rate needed for a client to receive media stream as unicast.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} cac media-stream multicast-direct
 min-client-rate dot11Rate
```

If your client communicates below this rate, it will not receive the media stream as a unicast flow. Usually, this PHY rate is equal to or higher than the rate multicast frames are sent.

8. Configure the maximum retry percent CAC parameter for multicast-direct streams.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} cac media-stream multicast-direct
 max-retry-percent retryPercent
```

9. Configure the maximum number of radio streams.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} media-stream multicast-direct
radio-maximum value
```

The valid range is 1 to 20. Default is 0. Value 0 denotes unlimited streams.

10. Configure the maximum number of allowed media streams for each client.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} media-stream multicast-direct
client-maximum value
```

The maximum value is 15, and the default is 0. A value of 0 denotes unlimited streams.

11. Configure the media stream so that it is sent through the best effort queue if it cannot be prioritized due to limited bandwidth.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} media-stream multicast-direct
admission-besteffort
```

Add **no** in the command to drop the stream when the media stream cannot be prioritized because bandwidth is unavailable.

12. Enable the 802.11 network.

Example

```
Device(config)# no ap dot11 {24ghz | 5ghz| 6ghz} shutdown
```

You have successfully configured multicast direct admission control on the specified wireless network interface.

```
Device# configure terminal
Device(config)# ap dot11 24ghz shutdown
Device(config)# ap dot11 24ghz media-stream video-redirect
Device(config)# ap dot11 24ghz cac media-stream acm
Device(config)# ap dot11 24ghz cac media-stream max-bandwidth 65
Device(config)# ap dot11 24ghz cac multimedia max-bandwidth 65
Device(config)# ap dot11 24ghz cac media-stream multicast-direct min-client-rate
 800
Device(config)# ap dot11 24ghz cac media-stream multicast-direct
max-retry-percent 50
Device(config)# ap dot11 24ghz media-stream multicast-direct radio-maximum 10
Device(config)# ap dot11 24ghz media-stream multicast-direct client-maximum
12
Device(config)# ap dot11 24ghz media-stream multicast-direct
admission-besteffort
Device(config)# no ap dot11 24ghz shutdown
```

Create and attach policy-based QoS profile

Create and attach policy-based QoS profile.

The high-level steps to create and attach policy-based QoS profile are as follows:

1. Create a QoS profile
2. Create a service template
3. Map the service template to thepPolicy map
4. Map the policy map to the policy profile

Create a QoS profile (GUI)

Learn how to create a QoS profile using the web interface to prioritize network traffic according to business needs.

Define and apply policies that optimize network resource allocation for various types of traffic.

Procedure

---

1. Click **Configuration** > **Services** > **QoS**.
2. Click **Add** to create a new QoS Policy.
3. Enter a **Policy Name**.
4. Enter a **Description** for the policy.
5. In the **Class Default** section, choose a value in the **Mark** drop-down list.
6. Enter the **Police (kbps)** value.
7. Click **Apply to Device**.

The new QoS profile is deployed to the selected devices. It enforces your traffic priorities immediately.

Create a QoS profile (CLI)

Learn how to create a QoS profile using commands.

Use this procedure to configure a custom Quality of Service (QoS) profile on your device by using the CLI. This configuration lets you manage network traffic according to your needs.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a policy map.

   Example

   ```
   Device(config)# policy-map policy-map-name
   ```

3. Add a description to the policy map.

   Example

   ```
   Device(config-pmap)# description description
   ```

4. Create policy criteria.

   Example

   ```
   Device(config-pmap)# class class-map-name
   ```

5. Set the committed information rate for policing.

   Example

   ```
   Device(config-pmap-c)# police cir committed-information-rate
   ```

6. Configure what action occurs when the rate is less than the conform burst value.

   Example

   ```
   Device(config-pmap-c-police)# conform-action drop
   ```

7. Configure what action occurs when the rate is between the conform burst and the sum of conform burst and exceed burst values.

   Example

   ```
   Device(config-pmap-c-police)# exceed-action drop
   ```

8. Return to privileged EXEC mode.

Example

```
Device(config-pmap-c-police)# end
```

The device creates and stores the QoS profile. Display the policy map and class map with the appropriate CLI commands to verify your configuration.

```
Device# configure terminal
Device(config)# policy-map QoS_Drop_Youtube
Device(config-pmap)# description QoS_Drop_Youtube
Device(config-pmap)# class QoS_Drop_Youtube1_AVC_UI_CLASS
Device(config-pmap-c)# police cir 8000
Device(config-pmap-c-police)# conform-action drop
Device(config-pmap-c-police)# exceed-action drop
Device(config-pmap-c-police)# end
```

Create a service template (GUI)

Use this procedure to create a new service template using GUI, specifying VLAN, session timeout, access controls, and QoS options for network clients.

Create a reusable configuration profile that defines network service attributes–such as VLAN, session timeout, access controls, and Quality of Service (QoS) policies–for consistent and efficient assignment to one or more devices.

Procedure

1. Choose **Configuration** > **Security** > **Local Policy**.
2. On the **Local Policy** page, **Service Template** tab, click **Add**.
3. In the **Create Service Template** window, configure these parameters:
   - **Service Template Name**: Enter a name for the template.
   - **VLAN ID**: Enter the VLAN ID for the template. The valid range is 1 to 4,094.
   - **Session Timeout (secs)**: Set the timeout duration for the template. The valid range is 1 to 65,535.
   - **Access Control List**: Select the Access Control List from the drop-down list.
   - **Ingress QOS**: Select the input QoS policy for the client from the drop-down list.
   - **Egress QOS**: Select the output QoS policy for the client from the drop-down list.
4. Click **Apply to Device**.

The new service template is created and available for assignment to network devices.

Map the service template to the policy map (CLI)

Map the service template to the policy map using commands.

Map a service template to a policy map using CLI commands to enable attribute-driven service control.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Specify the parameter map type and name.

Example

```
Device(config)# parameter-map type subscriber attribute-to-service
parameter-map-name
```

3. Specify the parameter map attribute filter criteria. Multiple filters are used in the example provided here.

Example

```
Device(config-parameter-map-filter)# map-index map device-type eq filter-name
 user-role eq user-name
```

4. Specify the service template.

Example

```
Device(config-parameter-map-filter-submode)# map-index service-template
service-template-name precedence precedence-num
```

5. Return to privileged EXEC mode.

Example

```
Device(config-parameter-map-filter-submode)# end
```

6. Enter global configuration mode.

Example

```
Device# configure terminal
```

7. Specify the policy map type.

Example

```
Device(config)# policy-map type control subscriber policy-map-name
```

8. Specify the match criteria to the policy map.

Example

```
Device(config-event-control-policymap)# event identity-update match-all
```

9. Apply a class map using a service template.

Example

```
Device(config-event-control-policymap)# class-num class always do-until-failure
```

10. Apply the parameter map.

Example

```
Device(config-event-control-policymap)# action-index map attribute-to-service
 table parameter-map-name
```

The service template is successfully mapped to the specified policy map.

```
Device# configure terminal
Device(config)# parameter-map type subscriber attribute-to-service
QoS-Policy_Map-param
Device(config-parameter-map-filter)# 1 map device-type eq "Android" user-role
 eq "student"
Device(config-parameter-map-filter)# 1 service-template Qos_template
Device(config-parameter-map-filter-submode)# end
Device# configure terminal
Device(config)# policy-map type control subscriber QoS-Policy_Map
Device(config-event-control-policymap)# event identity-update match-all
Device(config-event-control-policymap)# 1 class always do-until-failure
Device(config-event-control-policymap)# 1 map attribute-to-service table
QoS-Policy_Map-param
```

Map service template to the policy map (GUI)

Use this procedure to map a service template to a policy map using GUI.

Map a service template to an existing policy map. This enables deployment of predefined configurations.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. On the **Policy Profile** page, select the **Policy Profile** to be mapped.
3. In the **Edit Policy Profile** window, click the **Access Policies** tab.
4. Use the **Local Subscriber Policy Name** drop-down list to select the policy name.
5. Click **Update & Apply to Device**.

The selected service template is now mapped to the policy map and applied to the device.

Map the service template to policy map (CLI)

Use this task to map a service template to a policy map by entering the required commands in the CLI. This enables the policy map to apply the service template's configurations to network traffic.

Map a service template to a policy map so the policy map automatically applies the desired service configurations to targeted network traffic.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the parameter map type and name.

   Example

   ```
   Device(config)# parameter-map type subscriber attribute-to-service
   parameter-map-name
   ```

3. Specify the parameter map attribute filter criteria. You can use multiple filters.

   Example

   ```
   Device(config-parameter-map-filter)# map-index map device-type eq filter-name
    user-role eq user-name
   ```

4. Specify the service template.

   Example

   ```
   Device(config-parameter-map-filter-submode)# map-index service-template
   service-template-name [precedence precedence-num]
   ```

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-parameter-map-filter-submode)# end
   ```

6. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

7. Specify the type of policy map.

   Example

   ```
   Device(config)# policy-map type control subscriber policy-map-name
   ```

8. Specify the match criteria to the policy map.

   Example

   ```
   Device(config-event-control-policymap)# event identity-update match-all
   ```

9. Apply a class map with a service template.

   Example

```
Device(config-event-control-policymap)# class-num class always do-until-failure
```

10. Apply a parameter map.

    Example

```
Device(config-event-control-policymap)# action-index map attribute-to-service
 table parameter-map-name
```

The policy map is associated with the service template. It enforces the defined service configurations on specified network traffic."

```
Device# configure terminal
Device(config)# parameter-map type subscriber attribute-to-service
QoS-Policy_Map-param
Device(config-parameter-map-filter)# 1 map device-type eq "Android" user-role
 eq "student"
Device(config-parameter-map-filter-submode)# 1 service-template Qos_template
Device(config-parameter-map-filter-submode)# end
Device# configure terminal
Device(config)# policy-map type control subscriber QoS-Policy_Map
Device(config-event-control-policymap)# event identity-update match-all
Device(config-event-control-policymap)# 1 class always do-until-failure
Device(config-event-control-policymap)# 1 map attribute-to-service table
QoS-Policy_Map-param
```

Map the policy map (GUI)

Learn how to map a policy map using the GUI in order to apply service templates and criteria to device policies.

Map a new policy map so that you can enforce local security and service templates based on device and user attributes.

Procedure

---

1. Choose **Configuration** > **Security** > **Local Policy** > **Policy Map** tab.
2. Click **Add**.
3. Enter a name in the **Policy Map Name** text field.
4. Click **Add** to add the matching criteria information.
5. Select the service template from the **Service Template** drop-down list.
6. Select the filters from **Device Type**, **User Role**, **User Name**, **OUI**, and **MAC Address** drop-down lists.
7. Click **Add Criteria**.
8. Click **Apply to Device**.

The new policy map is created and applied according to the specified criteria.

Map the policy map (CLI)

Use this procedure to map a policy map to a wireless profile policy using CLI commands.

Map a policy map to a wireless policy profile using CLI commands to apply specific subscriber policies.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a wireless policy profile.

   Example

   ```
   Device(config)# wireless profile policy wlan-policy-profile-name
   ```

3. Add a description for the policy profile.

   Example

   ```
   Device(config-wireless-policy)# description profile-policy-description
   ```

4. Configure the subscriber policy name.

   Example

   ```
   Device(config-wireless-policy)# subscriber-policy-name policy-name
   ```

After you complete these steps, the policy map is mapped to the wireless policy profile, and the configuration becomes active on the device.

```
Device# configure terminal
Device(config)# wireless profile policy wireless-policy-profile
Device(config-wireless-policy)# description "wireless policy profile"
Device(config-wireless-policy)# subscriber-policy-name QoS-Policy_Map
```

Monitor media streams

This section lists the commands used to monitor media streams and provides their descriptions.

To provide reference information about the available commands used to monitor media streams on wireless devices, including a description of each command to assist users in understanding and using these monitoring tools effectively.

Table 174: Commands for monitoring media streams

Commands	Description
show wireless media-stream client detail *group name*	Displays media stream client details of the particular group.
show wireless media-stream client summary	Displays the media stream information of all the clients.
show wireless media-stream group detail *group name*	Displays the media stream configuration details of the particular group.

Commands	Description
show wireless media-stream group summary	Displays the media stream configuration details of all the groups.
show wireless media-stream message details	Displays the session announcement message details.
show wireless multicast	Displays the multicast-direct configuration state.
show ap dot11 {24ghz | 5ghz} media-stream rrc	Displays 802.11 media resource reservation control configurations.

Verify media stream information

View media stream information.

Use these **show** commands to view the media stream information.

To view general media stream information and status, use these commands:

```
Device# show wireless media-stream multicast-direct state

Multicast-direct State..................... : enabled
Allowed WLANs:
WLAN-Name                                          WLAN-ID
-------------------------------------------------------
zsetup_mc                                          1
vwlc-mc_mo                                         3
mcuc_test1                                         4
mcuc_test2                                         5
```

```
Device# show wireless media-stream group summary

Number of Groups: 4

Stream Name          Start IP                End IP            Status
------------------------------------------------------------------------------
new2                 231.2.2.3               231.2.4.4         Enabled
my234                234.0.0.0               234.10.10.10      Enabled
uttest2              235.1.1.20              235.1.1.25        Enabled
uttest3              235.1.1.40              235.1.1.200       Enabled
```

To view the details of a particular media stream, use the **show wireless media-stream client detail** *media_stream_name* command:

```
Device# show wireless media-stream group detail uttest2

Media Stream Name         : uttest2
Start IP Address          : 235.1.1.20
End IP Address            : 235.1.1.25
RRC Parameters:
 Avg Packet Size(Bytes)   : 1200
 Expected Bandwidth(Kbps) : 1000
 Policy                   : Admitted
```

```
 RRC re-evaluation        : Initial
 QoS                      : video
 Status                   : Multicast-direct
 Usage Priority           : 4
 Violation                : Drop
```

To view RRC information for a dot11 band, use the **show ap dot11 {24ghz | 5ghz | 6ghz} mediastream rrc** command:

```
Device# show  ap dot11 5ghz media-stream rrc

Multicast-direct                 : Enabled
Best Effort                      : Disabled
Video Re-Direct                  : Disabled
Max Allowed Streams Per Radio    : Auto
Max Allowed Streams Per Client   : 5
Max Media-Stream Bandwidth       : 5
Max Voice Bandwidth              : 50
Max Media Bandwidth              : 43
Min PHY Rate (Kbps)              : 6000
Max Retry Percentage             : 5
```

To view session announcement message details, use the **show wireless media-stream message details** command:

```
Device# show wireless media-stream message details
URL          :
Email        : abc@cisc
Phone        :
Note         :
State        : Disabled
```

To view the list of clients in the blocked list database, use the **show ip igmp snooping igmpv2-tracking** command:

```
Device# show ip igmp snooping igmpv2-tracking

Client to SGV mappings
----------------------

```

Part XIX

Software-Defined Access Wireless

Topics:

- Software-Defined Access Wireless
- Passive Client
- Fabric in a Box with External Fabric Edge

Introduces Software-Defined Access wireless architecture and provides guidance on configuring, monitoring, and managing wireless mesh networks with inter-fabric edge switch roaming protection.

197 Software-Defined Access Wireless

Topics:

- Software-defined access wireless
- SD-Access wireless mesh inter fabric edge switch roaming protection
- Configure SD-access wireless
- SD-Access wireless verification commands

Introduces Software-Defined Access wireless architecture and provides guidance on configuring, monitoring, and managing wireless mesh networks with inter-fabric edge switch roaming protection.

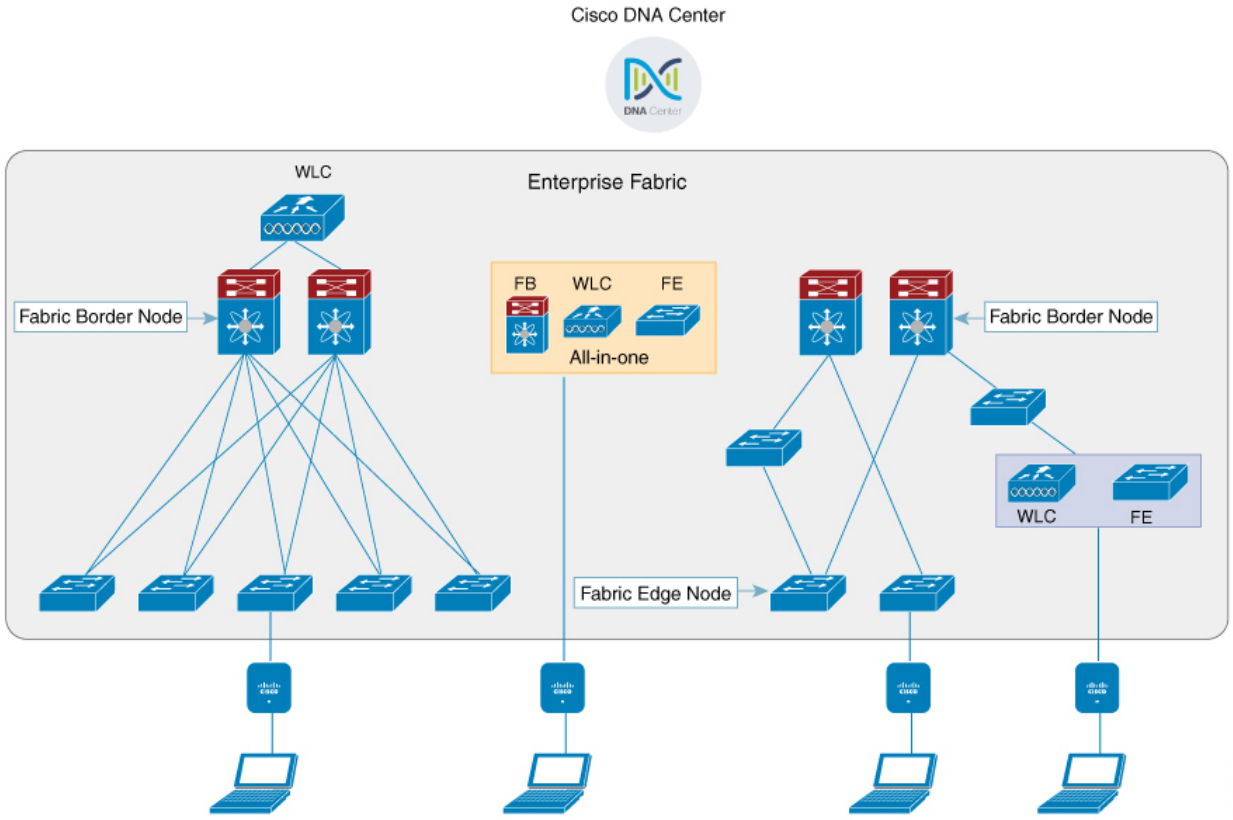
Software-defined access wireless

Explains software-defined access wireless network topology and its components.

Software-defined access wireless is a network topology that

- passes traffic through inter-connected switches while providing the abstraction of a single Layer 2 or Layer 3 device
- provides seamless connectivity with policy application and enforcement at the edge of the fabric
- uses IP overlay to make the network appear as a single virtual entity without clustering technologies, and
- moves the enterprise network from VLAN-centric architecture to user group-based enterprise architecture with flexible Layer 2 extensions.

Network components and architecture



The Enterprise Fabric provides end-to-end enterprise-wide segmentation, flexible subnet addressing, and controller-based networking with uniform enterprise-wide policy and mobility. It moves the enterprise network from current VLAN-centric architecture to a user group-based enterprise architecture, with flexible Layer 2 extensions within and across sites.

The following definitions are used for fabric nodes:

- **Enterprise Fabric**: A network topology where traffic is passed through inter-connected switches, while providing the abstraction of a single Layer 2 or Layer 3 device.
- **Fabric Domain**: An independent operation part of the network. It is administered independent of other fabric domains.
- **End Points**: Hosts or devices that connect to the fabric edge node are known as end points (EPs). They directly connect to the fabric edge node or through a Layer 2 network.

This figure shows the components of a typical SD-Access Wireless. It consists of Fabric Border Nodes (BN), Fabric Edge Nodes (EN), Wireless Controller, Cisco Catalyst Center, and Host Tracking Database (HDB).

Figure 35: Software-Defined Access Wireless

The figure covers the following deployment topologies:

- All-IN-one Fabric–When we have all Fabric Edge, Fabric Border, Control-Plane and controller functionality enabled on a Cat 9K switch.

  This topology is depicted IN the mid part of the figure.

- Split topology–When we have Fabric Border, or Control Plane, or controller on a Cat 9K switch with separate Fabric Edge. This topology is depicted IN the left-most part of the figure.

- Co-located Fabric Edge and Controller–When we have Fabric Edge and controller on a Cat 9K switch. This topology is depicted IN the right-most part of the figure.

Cisco Catalyst Center: Is an open, software-driven architecture built on a set of design principles with the objective of configuring and managing Cisco Catalyst 9800 Series Wireless Controllers.

Control Plane: This database allows the network to determine the location of a device or user. When the EP ID of a host is learnt, other end points can query the database about the location of the host. The flexibility of tracking subnets helps IN summarization across domains and improves the scalability of the database.

Fabric Border Node (Proxy Egress Tunnel Router [PxTR or PITR/PETR] IN LISP): These nodes connect traditional Layer 3 networks or different fabric domains to the enterprise fabric domain. If there are multiple fabric domains, these nodes connect a fabric domain to one or more fabric domains, which could be of the same or different type. These nodes are responsible for translation of context from one fabric domain to another. When the encapsulation is the same across different fabric domains, the translation of fabric context is generally 1:1. The fabric control planes of two domains exchange reachability and policy information through this device.

Fabric Edge Nodes (Egress Tunnel Router [ETR] or Ingress Tunnel Router [ITR] IN LISP): These nodes are responsible for admitting, encapsulating or decapsulating, and forwarding of traffic from the EPs. They lie at the perimeter of the fabric and are the first points of attachment of the policy. EPs could be directly or indirectly attached to a fabric edge node using an intermediate Layer 2 network that lies outside the fabric domain. Traditional Layer 2 networks, wireless access points, or end hosts are connected to fabric edge nodes.

Wireless Controller: The controller provides AP image and configuration management, client session management and mobility. Additionally, it registers the MAC address of wireless clients IN the host tracking database at the time of client join, as well as updates the location at the time of client roam.

Access Points: AP applies all the wireless media specific features. For example, radio and SSID policies, webauth punt, peer-to-peer blocking, and so on. It establishes CAPWAP control and data tunnel to controller. It converts 802.11 data traffic from wireless clients to 802.3 and sends it to the access switch with VXLAN encapsulation.

The SDA allows to simplify:

- Addressing IN wireless networks
- Mobility IN wireless networks
- Guest access and move towards multi-tenancy
- Leverage Sub-net extension (stretched subnet) IN wireless network
- Provide consistent wireless policies

Note

Role co-location between wireless controller and fabric edge is supported.

Platform support information for software-defined access wireless includes compatibility with various Catalyst switches and wireless controllers.

Table 175: Supported platforms for software-defined access wireless

Platforms	Support
Catalyst 9300	Yes
Catalyst 9400	Yes
Catalyst 9500H	Yes
Cisco Catalyst 9800 Series Wireless Controller for Cloud	Yes
Cisco Catalyst 9800-40 Series Wireless Controller	Yes
Cisco Catalyst 9800-80 Series Wireless Controller	Yes

Table 176: Multi-instance support

Multi-instance	Support
Multiple LISP sessions	Yes
Emulated database support	Yes
Client roaming between WNCd instances	Yes

Table 177: Feature support

Feature	Support
Inter-WLC roam for IRCM	Only L2 mobility is supported as VLAN is stretched across the fabric.
DNS-IPv4-ACL	• ACLs are enforced at AP. • Controller needs to push the DNS-ACL information to AP.
IPv6 ACL for clients	Yes. Open, 802.11x, WebAuth, PSK WLANs, IPv6 address visibility are also supported.
Location tracking/Hyperlocation	Yes
Multicast Video-Stream (IPv4)	Yes
Smart Licensing	Yes

Table 178: Outdoor access points support

AP	Support
1542	Yes
1560	Yes

SD-Access wireless mesh inter fabric edge switch roaming protection

Describes SD-Access wireless mesh inter fabric edge switch roaming protection functionality.

SD-Access wireless mesh inter fabric edge switch roaming protection is a wireless mesh feature that

- prevents mesh access points from roaming to root access points or other mesh access points connected to different fabric edge switches under normal conditions
- allows roaming when the current mesh access point link quality degrades significantly below established thresholds, and
- maintains wireless client connectivity by restarting CAPWAP tunnels after roaming across fabric edge switches.

Roaming behavior and criteria

When a Mesh AP (MAP) finds a Root AP (RAP) or other MAP with better adjacency, it roams to that RAP or MAP. However, a MAP cannot roam to another MAP or RAP connected to a different fabric edge switch due to wireless client connectivity loss. The reason being the VXLAN tunnels of the wireless client cannot be moved to another fabric edge switch.

However, if the current MAP link is much worse than the link to RAP or MAP connected to a different fabric edge switch, then the MAP roams and restart its CAPWAP tunnel.

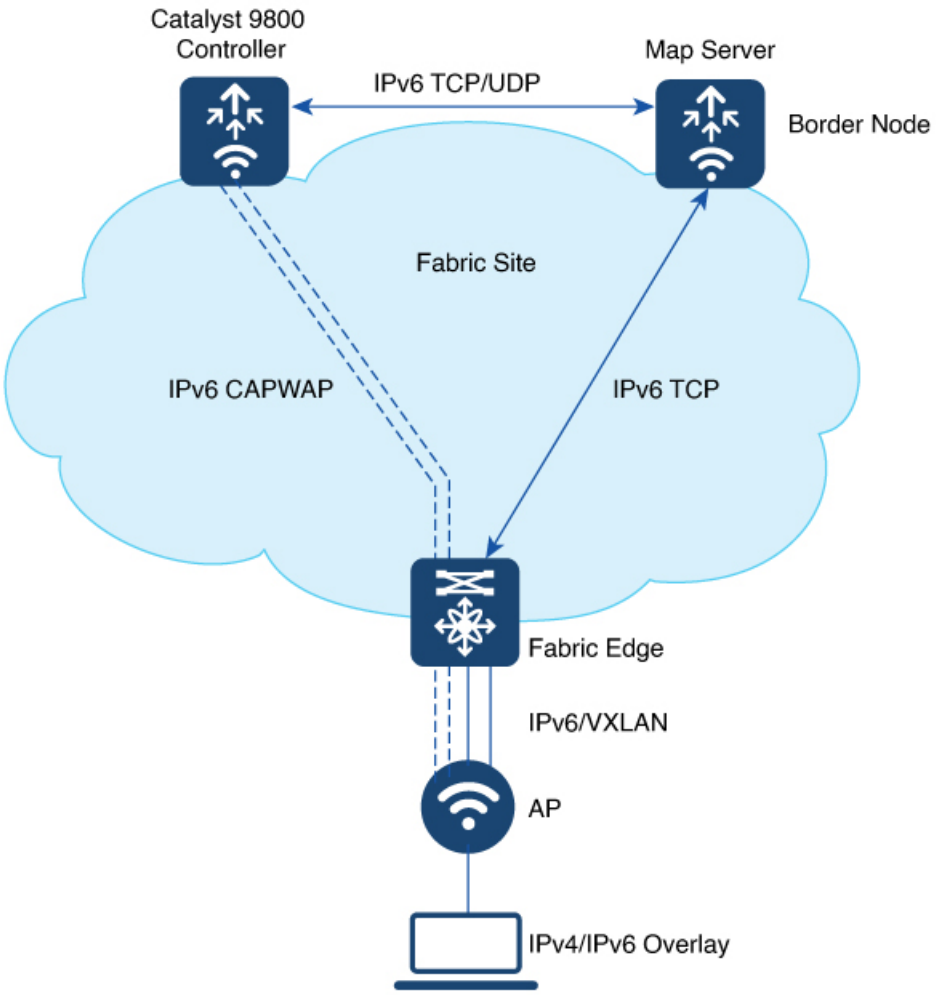
Thus, all the MAPs connected to the MAP restarts the CAPWAP tunnels as well. This allows the wireless clients to connect again and creates wireless client VXLAN tunnels in the fabric edge.

Note

The criteria for a MAP roaming to a RAP or MAP connected to a different fabric edge switch are the same as the mesh preferred parent. They are:

- If the current link SNR is worse than 12 dB and there is another better link. (Or)
- If the current link SNR is worse than 20 dB and there is another link with 20% or better SNR.

The mesh daisy chain roaming is not supported in RAP or MAP connected to different fabric edge switches.



SDA IPv6 underlay support

This feature provides a wireless SDA IPv6 underlay support to enable IPv6-based communications in a fabric site. IPv6 is used to establish LISP connections between the controller and MAP server as well as between the MAP server and Fabric Edge. IPv6 underlay is also used to construct a VXLAN tunnel between the Fabric Edge and the AP.

The feature implementation is as follows:

- **Catalyst 9800 Controller**:
  - The controller manages IPv6-based LISP sessions to the MAP server
  - Encodes, decodes, and processes LISP messages through IPv6 TCP/UDP sockets.)
  - Communicates RLOC IPv6 address to the AP for VXLAN creation and client tunnel mapping
- **Fabric Edge**:
  - Processes MAP notification from MAP server
  - Creates IPv6 VXLAN tunnel
  - Maps client to IPv6 VXLAN tunnel
  - Encapsulates and decapsulates client traffic into and out of VXLAN tunnel
- **Access Points**:
  - Processes fabric TLV from the controller
  - Creates IPv6 VXLAN tunnel
  - Encapsulates and decapsulates client traffic into and out of VXLAN tunnel
