The following figure shows the feature architecture:

Note

For AP to join controller using IPv6 address, ensure that you configure the preferred mode in AP profile as IPv6.

Configure SD-access wireless

Configure SD-access wireless.

Enable SD-Access wireless globally, you need to run the **wireless fabric** configuration command. During SD-Access Wireless provisioning, ensure that L2-VNID value is unique.

Configure default map server (GUI)

Configure the default map server to enable communication between fabric components using the GUI.

Set up the default map server. This action enables the wireless fabric network to properly associate controllers and devices with their respective mapping information.

Procedure

1. Click **Configuration** > **Wireless Plus** > **Fabric** > **Fabric Configuration**.
2. In the **Map Server** section, enter the IP address and preshared key details for Server 1.
3. Optional: Specify the IP address and preshared key details to configure Server 2.
4. Click **Apply**.

The default map server settings are saved, enabling fabric devices to communicate and register with the specified servers.

Configure default map server (CLI)

Use these configuration steps to configure the default map server on your wireless LAN controller and enable seamless device registration and operation in a Fabric network using commands.

Configure a default map server to ensure that wireless Fabric components in your Cisco network can register and operate as part of the control plane using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the default map server.

   Example

   ```
   Device(config)# wireless fabric control-plane map-server-name
   ```

   Here, *map-server-name* defines a pair of map servers.

3. Configure IP address for the default map server.

   Example

   ```
   Device(config-wireless-cp)# ip address ip-address key user-password
   reenter-password
   ```

4. Return to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

   ```
   Device(config-wireless-cp)# end
   ```

The default map server is configured. Wireless fabric components can now register with the control-plane infrastructure and exchange location and policy information for network operations.

```
Device# configure terminal
Device(config)# wireless fabric control-plane map-server-name
Device(config-wireless-cp)# ip address 200.0.0.0 key user-password user-password
Device(config-wireless-cp)# end
```

Configure SD-Access Wireless Profile (GUI)

Configure SD-access wireless profile using GUI.

Configure an SD-Access wireless profile to define network parameters for wireless fabric integration.

SD-Access wireless profiles are used to configure wireless fabric settings including VNID and SGT tag parameters for network segmentation.

Procedure

1. Choose **Configuration** > **Wireless** > **Fabric**.
2. On the **Fabric** page, click the **Profiles** tab and click **Add**.
3. In the **Add New Profile** window that is displayed, specify the following parameters:
   - Profile name
   - Description
   - L2 VNID; valid range is between 0 and 16777215
   - SGT tag; valid range is between 2 and 65519
4. Click **Save & Apply to Device**.

The SD-Access wireless profile is configured and applied to the device with the specified parameters.

Configure SD-Access wireless profile (CLI)

Use this task to configure an SD-Access wireless profile using commands.

Configure a wireless profile for SD-Access fabric deployment using commands.

Follow the procedure given below to configure SD-Access wireless profile:

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the SD-Access wireless profile parameters.

Example

```
Device(config)# wireless profile fabric fabric-profile-name
```

3. Configure SGT tag.

   Example

   ```
   Device(config-wireless-fabric)# sgt-tag sgt
   ```

   Here, *sgt* refers to the sgt tag value. The valid range is from 2-65519. The default value is 0.

4. Configure client L2-VNID.

   Example

   ```
   Device(config-wireless-fabric)# client-l2-vnid client-l2-vnid
   ```

   Here, *client-l2-vnid* refers to the client L2-VNID value. The valid range is from 0-16777215.

5. Return to the privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

   ```
   Device(config-wireless-fabric)# end
   ```

Configuring Map Server in Site Tag (GUI)

Configure map server in site tag using GUI.

Assign a map server to a site tag using the graphical user interface, enabling the wireless fabric to properly reference the control plane for device management.

Use this task to associate a Fabric control plane with a site tag, which is required for wireless fabric configuration. This enables seamless device communication and site identification within the wireless network.

Before you begin

Ensure that you have configured a control plane at the time of configuring Wireless Fabric.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. On the **Manage Tags** page, click the **Site** tab.
3. Click the name of the site tag.
4. In the **Edit Site Tag** window, choose the Fabric control plane name from the **Control Plane Name** drop-down list.
5. Save the configuration.

The selected site tag is now associated with the specified Fabric control plane, enabling proper device management within the wireless fabric.

Configure map server in site tag (CLI)

Configure map server in site tag using commands.

Configure the fabric control plane map server name within a site tag to establish proper control plane connectivity.

Use this procedure to associate a map server with a site tag for fabric control plane operations. The map server provides centralized mapping services for the fabric infrastructure.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the site tag.

   Example

   ```
   Device(config)# wireless tag site site-tag
   ```

   Example

   ```
   Device(config)# wireless tag site default-site-tag
   ```

   Here, *site-tag* refers to the site tag name.

3. Configure fabric control plane details.

   Example

   ```
   Device(config-site-tag)# fabric control-plane map-server-name
   ```

   Here, *map-server-name* refers to the fabric control plane name associated with the site tag.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-site-tag)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The map server is now configured in the site tag and will provide fabric control plane services for the associated site.

Configure map server per L2-VNID using GUI

Configure map server per L2-VNID using GUI.

Configure the fabric VNID mapping to establish the map server per L2-VNID.

Use this procedure to set up fabric VNID mapping through the GUI interface when you need to establish map server configuration for specific L2-VNIDs.

Procedure

1. Choose **Configuration** > **Wireless** > **Fabric**.
2. On the **Fabric Configuration** page in the **Fabric VNID Mapping** section, click **Add**.
3. In the **Add Client and AP VNID** window, specify a name for the Fabric, L2 VNID value (valid range is from 0 to 4294967295), control plane name.
4. Save the configuration.

The map server per L2-VNID is configured and the fabric VNID mapping is saved.

Configure map server per L2-VNID (CLI)

Configure map server per L2-VNID using commands.

Configure the map server to the VNID map table for proper fabric network operation.

Follow the procedure given below to configure map server in site tag.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the map server to the VNID map table.

   Example

   ```
   Device(config)# wireless fabric name fabric-name l2-vnid l2-vnid-value l3-vnid
    l3-vnid-value ip network-ip subnet-mask control-plane-name control-plane-name
   ```

   Example

   ```
   Device(config)# wireless fabric name fabric_name l2-vnid 2 l3-vnid 2 ip
   122.220.234.0 255.255.0.0 control-plane-name sample-control-plane
   ```

   - *fabric-name* refers to the fabric name.
   - *l2-VNID-value* refers to the L2 VNID value. The valid range is from 0 to 16777215.
   - *l3-VNID-value* refers to the L3 VNID value. The valid range is from 0 to 16777215.
   - *control-plane-name* refers to the control plane name.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The map server is now configured with the specified L2-VNID and L3-VNID values in the fabric network.

SD-Access wireless verification commands

Lists the commands for verifying SD-Access wireless configurations.

You can verify the SD-Access wireless configurations using these commands:

Table 179: Commands for Verifying SD-Access Wireless

Commands	Description
show wireless fabric summary	Displays the fabric status.
show wireless fabric VNID mapping	Displays all the VNID mapping details.
show wireless profile fabric detailed *fabric_profile_name*	Displays the details of a given fabric profile name.
show AP name *AP_name* **config general**	Displays the general details of the Cisco AP.
show wireless client MAC *MAC_addr* **detail**	Displays the detailed information for a client by MAC address.
show wireless tag site detailed *site_tag*	Displays the detailed parameters for a site tag.

198 Passive Client

Topics:

- Passive clients
- Enable passive client for FlexConnect mode (CLI)
- DHCP broadcast support for workgroup bridges
- Enable passive client on WLAN policy profile (GUI)
- Enable passive client on WLAN policy profile (CLI)
- Enable ARP broadcast on VLAN (GUI)
- Enable ARP broadcast on VLAN (CLI)
- Passive client in fabric deployment
- Verify passive client configuration

Passive clients

Passive Clients refers to wireless devices such as printers and devices configured using a static IP address.

A passive client is a wireless device that

- connects to the wireless network using a static IP address
- does not transmit IP information after associating with an AP, and
- requires additional mechanisms for controllers to learn its IP address (such as ARP requests or DHCP).

Feature history

Table 180: Feature history table for passive clients

Feature name	Release information	Feature description
Support for FlexConnect local switching	Cisco IOS XE 17.12.x	Passive client feature is now supported on FlexConnect local switching mode.
Passive clients	Cisco IOS XE 16.11.1	This feature enables special handling for wireless clients (such as printers and devices with static IPs) that do not transmit IP information after associating with an AP.

Passive clients are wireless devices, such as printers and devices configured using a static IP address. Such clients do no transmit any IP information after associating to an AP. That is why, the controller does not learn their IP address unless they perform the DHCP process.

In the controller, the clients just show up in the **Learn IP** state and get timed out because of the DHCP policy-timeout.

Changes in default behaviour

The Passive Client feature can be enabled on a per WLAN basis. Enabling this feature will change a few default behaviors in order to better accommodate passive clients . These changes include :

- No client will ever timeout in the IP_LEARN phase. The controller will keep on waiting to learn their IP address. Note that the idle timeout remains active and will delete the client entry after the timeout period expiry, if the client remains silent all along.
- ARP coming from the wired side is broadcasted to all the APs, if the controller does not know the client IP address, to ensure that it reaches the passive client. After this, the controller learns the client IP from the ARP response.
- In order to save air time, the controller transforms the ARP broadcast coming from the wired side or from other wireless clients and unicasts them to the wireless client it owns . This is only possible after the controller has learned the MAC-IP binding of its wireless client.
- When the controller enables ARP broadcast, the controller does not transform the ARP broadcasts into unicasts but only forwards the broadcast, thereby wasting air time for other clients (with a frame that is not acknowledgeable and therefore less reliable). This pushes the passive client to respond to the ARP request and therefore every other client benefits from learning the MAC-IP binding of the wireless client.
- When you enable IP MAC binding for clients with static IP address, the controller consumes the first ARP packet to perform IP MAC binding. This packet is not forwarded upstream.

Enable passive client for FlexConnect mode (CLI)

Enable the passive client feature when the device operates in FlexConnect mode to support client devices that do not initiate traffic themselves.

Enable the passive client feature when the device is operating in FlexConnect mode to support client devices that do not initiate traffic themselves (passive clients).

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy policy-profile
   ```

3. Enable passive client.

   Example

   ```
   Device(config-wireless-policy)# passive-client
   ```

   You can use the no form of the command to disable passive client.

4. Disable IP theft detection for static IP passive clients (local and FlexConnect configuration)

   Example

   ```
   Device(config-wireless-policy)# no ip mac-binding
   ```

   This is applicable for only IPv4 and has been designed for overlapping IP addresses.

5. Configure a VLAN and enter VLAN configuration mode.

   Example

   ```
   Device(config)# vlan configuration vlan-id
   ```

6. Broadcast ARP on VLAN, to move passive client to run state (local mode only).

   Example

   ```
   Device(config-vlan-config)# arp broadcast
   ```

7. Configure a FlexConnect profile and enter the FlexConnect profile configuration mode.

Example

```
Device(config)# wireless profile flex flex-profile
```

8. Disable ARP proxy for FlexConnect (FlexConnect mode only).

Example

```
Device(config-wireless-flex-profile)# no arp-caching
```

Passive client for FlexConnect mode is enabled.

```
Device# configure terminal
Device(config)# wireless profile policy policy-profile1
Device(config-wireless-policy)# passive-client
Device(config-wireless-policy)# no ip mac-binding
Device(config)# vlan configuration vlan-id
Device(config-vlan-config)# arp broadcast
Device(config)# wireless profile flex flex-profile1
Device(config-wireless-flex-profile)# no arp-caching
```

DHCP broadcast support for workgroup bridges

Explains how enabling the dhcp broadcast command under the FlexConnect profile ensures DHCP replies are broadcasted, addressing IP assignment issues for devices behind third-party WGBs that do not handle broadcast DHCP requests properly.

Devices placed behind a third-party WGB may fail to obtain an IP address if the WGB does not handle DHCP requests with the broadcast flag set.

- The **dhcp broadcast** command under the FlexConnect profile ensures that DHCP replies are sent as broadcasts instead of being converted to unicasts. This setting helps resolve compatibility issues, especially for some device types.
- In this scenario, you can enable this command to allow devices behind the WGB to receive IP addresses.

Enable passive client on WLAN policy profile (GUI)

Use this task to enable passive client support on a WLAN policy profile, allowing devices that do not transmit packets to remain connected on the WLAN.

Enable passive clients on a specific WLAN policy profile so devices that do not actively transmit packets can stay connected.

Use this task to enable support for passive clients on specific WLAN policy profiles.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Policy** page, click **Add** to open the **Add Policy Profile** page.
2. In the **General** tab, use the slider to enable **Passive Client**.
3. Click **Save & Apply to Device**.

The policy profile is updated to support passive clients on the WLAN.

Enable passive client on WLAN policy profile (CLI)

Use this task to enable the passive client feature on a selected WLAN policy profile using commands. This allows devices that do not actively communicate with the controller to be recognized and managed on the WLAN.

Enable passive client support for devices on a WLAN policy profile using commands.

Use the passive client feature to allow devices that do not actively communicate with the controller to be recognized and managed on the WLAN.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy policy-profile
   ```

3. Enable passive client.

   Example

   ```
   Device(config-wireless-policy)# [no] passive-client
   ```

4. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

The passive client feature is now enabled for the specified WLAN policy profile.

```
Device# configure terminal
Device(config)# wireless profile policy rr-xyz-policy-1
Device(config-wireless-policy)# [no] passive-client
Device(config-wireless-policy)# end
```

Enable ARP broadcast on VLAN (GUI)

Use this task to enable ARP broadcast functionality for VLANs through the GUI, allowing the VLAN to propagate ARP requests.

Enable ARP broadcast capability on a VLAN so ARP requests are properly propagated within the network using the GUI.

Procedure

1. Choose **Configuration** > **Layer2** > **VLAN** page, click **VLAN** tab.
2. Click **Add** to view the **Create VLAN** window.
3. Use the slider to enable **ARP Broadcast**.
4. Click **Save & Apply to Device**.

The selected VLAN now supports ARP broadcasts and propagates ARP requests.

Enable ARP broadcast on VLAN (CLI)

Configure ARP broadcast on a specified VLAN to allow devices within that VLAN to respond to ARP requests using commands.

Enable ARP broadcast on a VLAN so devices within that VLAN can communicate efficiently using ARP using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a VLAN or multiple VLANs to enter the VLAN configuration mode.

   Example

   ```
   Device(config)# vlan configuration vlan-id
   ```

3. Enable ARP broadcast on VLAN.

   Example

   ```
   Device(config-vlan)# [no] arp broadcast
   ```

4. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-vlan)# end
   ```

   You can also press **Ctrl-Z** to exit global configuration mode.

ARP broadcast is successfully enabled for the specified VLAN.

```
Device# configure terminal
Device(config)# vlan configuration 1
```

```
Device(config-vlan)# [no] arp broadcast
Device(config-vlan)# end
```

Passive client in fabric deployment

This topic outlines the characteristics and requirements for supporting passive clients within a fabric network deployment.

A passive client is a client device that

- does not send its own IP address information in packets (such as ARP requests)
- relies on the network infrastructure to discover and maintain its presence, and
- is supported in fabric deployments where special handling is required to ensure connectivity.

You need to enable these features:

- Enable ARP broadcast on VLANs to support passive client discovery.
- Enable LISP multicast to facilitate address learning. For information on LISP multicast, see https://www.cisco.com/c/en/us/td/docs/ios-xml/ios/iproute_lisp/configuration/xe-3s/irl-xe-3s-book/irl-lisp-multicast.html.

For information on LISP (Locator ID Separation Protocol), see https://www.cisco.com/c/en/us/td/docs/ios-xml/ios/iproute_lisp/configuration/xe-3s/irl-xe-3s-book/irl-cfg-lisp.html.

Enable broadcast underlay on VLAN

Use this procedure to enable broadcast underlay for a VLAN by configuring a LISP instance and ethernet service on the Fabric Edge Node using commands.

Configure LISP instance and IPv4 service (CLI)

Set up the LISP instance and enable IPv4 services to support mappings from endpoint identifier (EID) to routing locator (RLOC) in your network fabric using commands.

Perform these configuration tasks only on the Fabric Edge Node. Do not perform them from the controller.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   FabricEdge# configure terminal
   ```

2. Enter the LISP configuration mode.

   Example

   ```
   FabricEdge(config)# router lisp
   ```

3. Create a LISP EID instance to group multiple services. The configuration applied under this instance ID applies to all services in the group.

Example

```
FabricEdge(config-router-lisp)# instance-id instance
```

4. Enable Layer 3 network services for the IPv4 address family. Enter the service submode.

   Example

   ```
   FabricEdge(config-router-lisp-instance)# service ipv4
   ```

5. Configure EID to RLOC mapping relationship.

   Example

   ```
   FabricEdge(config-router-lisp-instance-dynamic-eid)# database-mapping eid
   locator-set rloc-name
   ```

6. Generate a static map request for the destination EID.

   Example

   ```
   FabricEdge(config-router-lisp-instance-service)# map-cache destination-eid
   map-request
   ```

7. Exit the service submode.

   Example

   ```
   FabricEdge(config-router-lisp-instance-service)# exit-service-ipv4
   ```

8. Exit the instance submode.

   Example

   ```
   FabricEdge(config-router-lisp-instance)# exit-instance-id
   ```

A system with a LISP instance and IPv4 service is now configured.

```
FabricEdge# configure terminal
FabricEdge(config)# router lisp
FabricEdge(config-router-lisp)# instance-id 3
FabricEdge(config-router-lisp-instance)# service ipv4
FabricEdge(config-router-lisp-instance-dynamic-eid)# database-mapping
66.66.66.64/32 locator-set rloc1
FabricEdge(config-router-lisp-instance-service)# map-cache 0.0.0.0/0 map-request
FabricEdge(config-router-lisp-instance-service)# exit-service-ipv4
FabricEdge(config-router-lisp-instance)# exit-instance-id
```

Configure Ethernet service and enable broadcast underlay (CLI)

Set up the LISP instance and enable IPv4 services to support endpoint identifier (EID) to routing locator (RLOC) mappings in the fabric.

Procedure

1. Create a LISP EID instance to group multiple services.

   Example

   ```
   FabricEdge(config-router-lisp)# instance-id instance
   ```

2. Enable Layer 2 network services and enter service submode.

   Example

   ```
   FabricEdge(config-router-lisp-instance)# service ethernet
   ```

3. Associate the LISP instance ID with a VLAN. This VLAN provides reachability to the endpoint identifier address space.

   Example

   ```
   FabricEdge(config-router-lisp-instance-service)# eid-table vlan vlan-number
   ```

4. Specify the multicast group that the underlay uses to carry broadcast traffic for the overlay Layer 2 network.

   Example

   ```
   FabricEdge(config-router-lisp-instance-service)# broadcast-underlay
   multicast-group
   ```

5. Exit the service submode.

   Example

   ```
   FabricEdge(config-router-lisp-instance-service)# exit-service-ethernet
   ```

6. Exit the instance submode.

   Example

   ```
   FabricEdge(config-router-lisp-instance)# exit-instance-id
   ```

The Ethernet service is enabled and the broadcast underlay support is configured for the specified VLAN and multicast group.

```
FabricEdge(config-router-lisp)# instance-id 101
FabricEdge(config-router-lisp-instance)# service ethernet
FabricEdge(config-router-lisp-instance-service)# eid-table vlan 101
FabricEdge(config-router-lisp-instance-service)# broadcast-underlay 239.0.0.1
FabricEdge(config-router-lisp-instance-service)# exit-service-ethernet
FabricEdge(config-router-lisp-instance)# exit-instance-id
```

Enable ARP flooding

Learn how to enable ARP flooding for IPv4 and Ethernet services on the Fabric Edge Node using commands.

Enable ARP flooding for IPv4 service (CLI)

Enable ARP flooding on the Fabric Edge Node for IPv4.

Perform these configuration tasks from Fabric Edge Node. You cannot perform them from your controller.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   FabricEdge# configure terminal
   ```

2. Enter the LISP configuration mode.

   Example

   ```
   FabricEdge(config)# router lisp
   ```

3. Create a LISP EID instance to group multiple services. This configuration applies to all services grouped under the instance-id.

   Example

   ```
   FabricEdge(config-router-lisp)# instance-id instance
   ```

4. Enable Layer 3 network services for the IPv4 address family and enter service submode.

   Example

   ```
   FabricEdge(config-router-lisp-instance)# service ipv4
   ```

5. Configure EID to RLOC mapping relationship.

   Example

   ```
   FabricEdge(config-router-lisp-instance-dynamic-eid)# database-mapping eid
   locator-set rloc1
   ```

6. Generate a static map request for the destination EID.

   Example

   ```
   FabricEdge(config-router-lisp-instance-service)# map-cache destination-eid
   map-request
   ```

7. Exit the service submode.

   Example

   ```
   FabricEdge(config-router-lisp-instance-service)# exit-service-ipv4
   ```

8. Exit the instance submode.

Example

```
FabricEdge(config-router-lisp-instance)# exit-instance-id
```

You have enabled ARP flooding on the Fabric Edge Node for IPv4.

```
FabricEdge# configure terminal
FabricEdge(config)# router lisp
FabricEdge(config-router-lisp)# instance-id instance
FabricEdge(config-router-lisp-instance)# service ipv4
FabricEdge(config-router-lisp-instance-dynamic-eid)# database-mapping
66.66.66.64/32 locator-set rloc1
FabricEdge(config-router-lisp-instance-service)# map-cache 0.0.0.0/0 map-request
FabricEdge(config-router-lisp-instance-service)# exit-service-ipv4
FabricEdge(config-router-lisp-instance)# exit-instance-id
```

What to do next

Enable ARP flooding for Ethernet service.

Enable ARP flooding for Ethernet service (CLI)

Enable ARP flooding for the Ethernet service on the Fabric Edge Node.

Procedure

---

1. Create a LISP EID instance, which groups multiple services.

   Example

   ```
   FabricEdge(config-router-lisp)# instance-id instance
   ```

2. Enable Layer 2 network services and enter service submode.

   Example

   ```
   FabricEdge(config-router-lisp-instance)# service ethernet
   ```

3. Associate the LISP instance ID you configured earlier with a VLAN. The VLAN provides access to the endpoint identifier address space.

   Example

   ```
   FabricEdge(config-router-lisp-instance-service)# eid-table vlan vlan-number
   ```

4. Enable ARP flooding.

   Example

   ```
   FabricEdge(config-router-lisp-instance-service)# flood arp-nd
   ```

5. Configure EID to RLOC mapping relationship.

Example

```
FabricEdge(config-router-lisp-instance-service)# database-mapping mac
locator-set rloc1
```

6. Exit the service submode.

Example

```
FabricEdge(config-router-lisp-instance-service)# exit-service-ethernet
```

7. Exit the instance submode.

Example

```
FabricEdge(config-router-lisp-instance)# exit-instance-id
```

You have enabled ARP flooding on the Fabric Edge Node for Ethernet service.

```
FabricEdge(config-router-lisp)# instance-id 101
FabricEdge(config-router-lisp-instance)# service ethernet
FabricEdge(config-router-lisp-instance-service)# eid-table vlan 101
FabricEdge(config-router-lisp-instance-service)# flood arp-nd
FabricEdge(config-router-lisp-instance-service)# database-mapping mac
locator-set rloc1
FabricEdge(config-router-lisp-instance-service)# exit-service-ethernet
FabricEdge(config-router-lisp-instance)# exit-instance-id
```

Verify passive client configuration

Verify passive client configuration.

To verify the status of the passive client, use this command:

```
Device# show wireless profile policy detailed sample-profile-policy
Policy Profile Name           : sample-profile-policy
Description                   : sample-policy
Status                        : ENABLED
VLAN                          : 20
Client count                  : 0
Passive Client                : ENABLED    <--------------------
WLAN Switching Policy
Central Switching           : ENABLED
Central Authentication      : ENABLED
Central DHCP                : DISABLED
Override DNS                : DISABLED
Override NAT PAT            : DISABLED
Central Assoc               : DISABLED
.
.
.
```

To verify VLANs that have ARP broadcast enabled, use this command:

```
Device# show platform software arp broadcast

Arp broadcast is enabled on vlans:
20
```

199 Fabric in a Box with External Fabric Edge

Topics:

- Fabric in a Box with external Fabric Edge

Describes the role of external fabric edge nodes in integrated wireless fabric operation, including their relationship with fabric topology, policy, site, WLAN, AP profiles, and LISP/map-server integration.

Fabric in a Box with external Fabric Edge

Explains the characteristics of Fabric in a Box topologies that incorporate external Fabric Edge Nodes for enhanced network scalability and wireless reach.

A Fabric in a Box topology is a network architecture that

- combines border node, control plane, Fabric Edge, and wireless controller in a single device
- supports external Fabric Edge Nodes to extend network capabilities, and
- enables seamless integration and roaming of APs and clients across both internal and external nodes.

Beginning with Cisco IOS XE Amsterdam 17.2.1, the Fabric in a Box (FiaB) topology supports external Fabric Edge Nodes. External Fabric Edge Nodes increase port density and extend wireless reach by adding more APs.

Configure a Fabric profile (CLI)

Configure a Fabric profile using commands to define wireless Fabric settings and client parameters.

Set up a wireless Fabric profile, assign a client L2-VNID, and add a description for organizational clarity using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the wireless Fabric profile parameters.

   Example

   ```
   Device(config)# wireless profile fabric fabric-profile-name
   ```

3. Configure client L2-VNID.

   Example

   ```
   Device(config-wireless-fabric)# client-l2-vnid client-l2-vnid
   ```

   Here, *client-l2-vnid* refers to the client L2-VNID value. The valid range is from 0 to 16777215.

4. Add a description for the Fabric profile.

   Example

   ```
   Device(config-wireless-fabric)# description description
   ```

5. Return to the privileged EXEC mode.

Example

```
Device(config-wireless-fabric)# end
```

Configure a policy profile (CLI)

Configure a wireless policy profile using commands to enable fabric deployment features and local switching.

Set up a wireless policy profile via commands to define AAA policy overrides, DHCP mode, local switching, and apply Fabric profiles for wireless networks.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure wireless policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-policy
   ```

   > **Note**
   >
   > In Fabric deployments, local mode, local authentication, and local association are not supported.

3. Configure local DHCP mode, where the DHCP is performed in an AP.

   Example

   ```
   Device(config-wireless-policy)# no central dhcp
   ```

4. Configure a WLAN for local switching.

   Example

   ```
   Device(config-wireless-policy)# no central switching
   ```

5. Apply the Fabric profile.

   Example

   ```
   Device(config-wireless-fabric)# fabric fabric-name
   ```

6. Enable the policy profile.

Example

```
Device(config-wireless-fabric)# no shutdown
```

7. Return to the privileged EXEC mode.

Example

```
Device(config-wireless-fabric)# end
```

Configure a site tag (CLI)

Use this procedure to configure a site tag for wireless APs using commands.

Set up a site tag and assign an AP profile to manage wireless APs using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure site tag and enter the site tag configuration mode.

Example

```
Device(config)# wireless tag site site-tag
```

3. Assign an AP profile to the wireless site.

Example

```
Device(config-site-tag)# ap-profile ap-profile-name
```

4. Add a description to the AP profile.

Example

```
Device(config-site-tag)# description description
```

5. Return to the privileged EXEC mode.

Example

```
Device(config-site-tag)# end
```

Configure a WLAN (CLI)

Configure a WLAN using commands.

Configure a WLAN on your device using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN and enter the WLAN configuration submode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id SSID-name
   ```

3. Enable the WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

Configure a policy tag (CLI)

Configure policy tags on a device using the commands to map policy profiles to WLAN profiles.

Set up a policy tag, and map a policy profile to a WLAN profile using the device commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure policy tag and enter the policy tag configuration mode.

   Example

   ```
   Device(config)# wireless tag policy policy-tag-name
   ```

3. Map a policy profile to a WLAN profile.

Example

```
Device(config-policy-tag)# wlan wlan-name policy profile-policy-name
```

4. Return to the privileged EXEC mode.

Example

```
Device(config-site-tag)# end
```

Configure an AP profile (CLI)

Configure an AP profile on your device using command-line interface commands.

Set up an AP profile for managing APs with specific configuration parameters using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure an AP profile and enter the AP profile configuration mode.

Example

```
Device(config)# ap profile ap-profile-name
```

3. Enter the AP configuration mode.

Example

```
Device(config-ap-profile)# ap ap-ether-mac
```

4. Specify the policy tag that is to be attached to the AP.

Example

```
Device(config-ap-profile)# policy-tag policy-tag
```

5. Return to the privileged EXEC mode.

Example

```
Device(config-ap-profile)# end
```

Configure map server and AP subnet (CLI)

Configure the map server and associated AP subnet using commands.

Enable SD-Access wireless features by configuring the map server and setting up AP subnet Layer 2 and Layer 3 VNIDs using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable SD-Access wireless globally.

   Example

   ```
   Device(config)# wireless fabric
   ```

3. Configure AP subnet Layer 2 and Layer 3 VNIDs.

   Example

   ```
   Device(config)# wireless fabric name name l2-vnid l2-vnid-value l3-vnid
   l3-vnid-value ip network-ip subnet-mask
   ```

4. Define client Layer 2 VNID AAA override.

   Example

   ```
   Device(config)# wireless fabric name name l2-vnid l2-vnid-value
   ```

5. Configure the control plane name.

   Example

   ```
   Device(config)# wireless fabric control-plane name
   ```

6. Configure the map server IP address and authentication key shared with the map server.

   Example

   ```
   Device((config-wireless-cp)# ip address ip-address key shared-key
   ```

7. Return to the privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

Alternatively, you can also press *Ctrl-Z* to exit global configuration mode.

Configure Fabric on FiaB node (CLI)

Configure the LISP Fabric and related networking features on a FiaB node using commands.

Enable Layer 2 and Layer 3 network services on a FiaB node, configure address resolution, and facilitate secure locator discovery using commands.

Procedure

1. Enter the global configuration mode. Enter the LISP configuration mode. Associate a default Virtual Routing and Forwarding (VRF) table through which the routing locator address space is reachable to a router Locator ID Separation Protocol (LISP) instantiation. Specify a named locator set and enter the LISP locator-set configuration mode. Specify an IP address of loopback or other egress tunnel router (ETR) interface. Exit the LISP locator-set configuration mode. Specify an existing locator set and enter the LISP locator-set configuration mode. Configure a locator address by creating a locator entry.

   Example

   ```
   FiaB# configure terminal
   ```

   ```
   FiaB(config)# router lisp
   ```

   ```
   FiaB(config-router-lisp)# locator-table default
   ```

   ```
   FiaB(config-router-lisp)# locator-set locator-set-name
   ```

   ```
   FiaB(config-router-lisp-locator-set)# ip-address
   ```

   ```
   FiaB(config-router-lisp-locator-set)# exit-locator-set
   ```

   ```
   FiaB(config-router-lisp)# locator-set rloc_loopback
   ```

2. Configure the ETR to auto discover the locators registered by other xTRs. (Ingress tunnel router (ITR) and an ETR are known as an xTR.). Exit LISP locator-set configuration mode. Enable Layer 3 network services for the IPv4 address family and enter the service submode. Configure VXLAN as encapsulation type for data packets. Configure map resolver address for sending map requests. Configure the map server for ETR registration. Configure a LISP ETR.

Example

```
FiaB(config-router-lisp-locator-set)# IPv4-interface interface
```

```
FiaB(config-router-lisp-locator-set)# auto-discover-rlocs
```

```
FiaB(config-router-lisp-locator-set)# exit-locator-set
```

```
FiaB(config-router-lisp)# service ipv4
```

```
FiaB(config-lisp-srv-ipv4)# encapsulation vxlan
```

```
FiaB(config-lisp-srv-ipv4)# itr map-resolver map-resolver-address
```

```
FiaB(config-lisp-srv-ipv4)# etr map-server map-server-address key key-type
authentication-key
```

3. Enable security group tag propagation in LISP-encapsulated traffic. Remove the address family-specific map cache configuration. Enable the Proxy Ingress Tunnel Router (PITR) functionality and specify the address to use when LISP encapsulating packets to LISP sites. Configure a LISP map server. Configure a LISP map resolver. Export table entries into the map cache, with the action set to send-map-request. Export LISP site registrations to the routing information base (RIB).

   Example

   ```
   FiaB(config-lisp-srv-ipv4)# etr
   ```

   ```
   FiaB(config-lisp-srv-ipv4)# sgt
   ```

   ```
   FiaB(config-lisp-srv-ipv4)# no map-cache away-eids send-map-request
   ```

   ```
   FiaB(config-lisp-srv-ipv4)# proxy-itr ip-address
   ```

   ```
   FiaB(config-lisp-srv-ipv4)# map-server
   ```

   ```
   FiaB(config-lisp-srv-ipv4)# map-resolver
   ```

   ```
   FiaB(config-lisp-srv-ipv4)# map-cache away-eids send-map-request
   ```

4. Configure LISP installed routes of type site registrations. Install the map cache to a map request for site registrations. Exit LISP service-ipv4 configuration mode. Select service type as Ethernet and enter the service submode. Configure the maximum number of dynamic local endpoint identifier (EID) prefix database entries. Configure the map-resolver address for sending map requests.

Example

```
FiaB(config-lisp-srv-ipv4)# route-export site-registrations
```

```
FiaB(config-lisp-srv-ipv4)# distance site-registrations number
```

```
FiaB(config-lisp-srv-ipv4)# map-cache site-registration
```

```
FiaB(config-lisp-srv-ipv4)# exit-service-ipv4
```

```
FiaB(config-router-lisp)# service ethernet
```

```
FiaB(config-lisp-srv-eth)# database-mapping limit dynamic limit
```

```
FiaB(config-lisp-srv-eth)# itr map-resolver map-resolver-address
```

5. Enable the LISP ITR functionality. Configure a map server for ETR registration. Enable the LISP ETR functionality. Enable the LISP map server functionality. Enable the LISP map resolver functionality. Exit LISP service-ethernet configuration mode. Create a LISP EID instance to group multiple services.

Example

```
FiaB(config-lisp-srv-eth)# itr
```

```
FiaB(config-lisp-srv-eth)# etr map-server map-server-address key key-type
authentication-key
```

```
FiaB(config-lisp-srv-eth)# etr
```

```
FiaB(config-lisp-srv-eth)# map-server
```

```
FiaB(config-lisp-srv-eth)# map-resolver
```

```
FiaB(config-lisp-srv-eth)# exit-service-ethernet
```

```
FiaB(config-router-lisp)# instance-id instance
```

6. Configure the parameters for probing of remote routing locators (RLOCs). Configure a dynamic EID and enter the dynamic EID configuration mode. Configure EID prefix and locator-set for dynamic EID. Exit LISP dynamic-eid configuration mode. Exit LISP instance-id configuration mode. Create a LISP EID instance to group multiple services. Configure parameters for probing remote RLOCs.

Example

```
FiaB(config-lisp-inst)# remote-rloc-probe on-route-change
```

```
FiaB(config-lisp-inst)# dynamic-eid dynamic-eid-name
```

```
FiaB(config-router-lisp-dynamic-eid)# database-mapping eid locator-set
rloc_loopback
```

```
FiaB(config-router-lisp-dynamic-eid)# exit-dynamic-eid
```

```
FiaB(config-router-lisp-instance)# exit-instance-id
```

```
FiaB(config-router-lisp)# instance-id instance
```

```
FiaB(config-lisp-inst)# remote-rloc-probe on-route-change
```

7. Enable Layer 2 network services and enter the service submode. Bind an EID table to VLAN. Configure an address family-specific local EID prefixes database. Exit LISP service-ethernet configuration mode. Exit LISP instance-id configuration mode. Configure a map server with open passive TCP sockets to listen for incoming connections.

   Example

   ```
   FiaB(config-lisp-inst)# service ethernet
   ```

   ```
   FiaB(config-lisp-inst-srv-eth)# eid-table vlan vlan-number
   ```

   ```
   FiaB(config-lisp-inst-srv-eth)# database-mapping mac locator-set rloc_loopbac
   ```

   ```
   FiaB(config-lisp-inst-srv-eth)# exit-service-ethernet
   ```

   ```
   FiaB(config-lisp-inst)# exit-instance-id
   ```

   ```
   FiaB(config-router-lisp)# map-server session passive-open server
   ```

8. Configure a LISP site on a map server. Specify a description text for the LISP site. Configure the authentication key used by the LISP site.

   Example

   ```
   FiaB(config-router-lisp)# site site-name
   ```

   ```
   FiaB(config-router-lisp-site)# description map-server-description
   ```

   ```
   FiaB(config-router-lisp-site)# authentication-key key
   ```

9. Accept registrations, if any, for Layer 2 EID records. Exit LISP site configuration mode. Configure the IPv4 locator address of the LISP. Configure the IPv4 source locator address of the interface. Exit LISP router-lisp configuration mode.

Example

```
FiaB(config-router-lisp-site)# eid-record instance-id instance-id address
accept-more-specifics
```

```
FiaB(config-router-lisp-site)# eid-record instance-id instance-id any-mac
```

```
FiaB(config-router-lisp-site)# exit-site
```

```
FiaB(config-router-lisp)# ipv4 locator reachability exclude-default
```

```
FiaB(config-router-lisp)# ipv4 source-locator interface-name
```

```
FiaB(config-router-lisp)# exit-router-lisp
```

Configure a Fabric Edge Node (CLI)

Configure a Fabric Edge Node using commands to enable LISP, interface settings, and network services necessary for its operation within a fabric network.

Set up a Fabric Edge Node with essential configurations for LISP operation, routing, and interface management using commands.

> **Note**
>
> You can perform these configuration tasks only from Fabric Edge Node, and not from your controller.

Procedure

1. Enter the global configuration mode. Enter the LISP configuration mode. Associate a default VRF table through which the routing locator address space is reachable to a router LISP instantiation. Specify a named locator set and enters LISP locator-set configuration mode. Configure the IPv4 address of the interface as locator. Exit the LISP locator-set configuration mode. Exit the LISP router-lisp configuration mode.

Example

```
FabricEdge# configure terminal
```

```
FabricEdge(config)# router lisp
```

```
FabricEdge(config-router-lisp)# locator-table default
```

```
FabricEdge(config-router-lisp)# locator-set rloc_loopback
```

```
FabricEdge(config-router-lisp-locator-set)# IPv4-interface interface-num
priority priority weight weight
```

```
FabricEdge(config-router-lisp-locator-set)# exit-locator-set
```

```
FabricEdge(config-router-lisp-)# exit-router-lisp
```

2. Configure an interface. Specify a description text for the interface. Set an interface MAC address manually. Configure an IP address for the interface. Specify a destination address for UDP broadcasts. Disable sending of ICMP redirect messages. Enable fast-switching cache for outgoing packets on the same interface.

Example

```
FabricEdge(config)# interface Vlan interface-num
```

```
FabricEdge(config-if)# description description
```

```
FabricEdge(config-if)# mac-address mac-address
```

```
FabricEdge(config-if)# ip address ip-address mask
```

```
FabricEdge(config-if)# ip helper-address ip-address
```

```
FabricEdge(config-if)# no ip redirects
```

```
FabricEdge(config-if)# ip route-cache same-interface
```

3. Remove liveness test on dynamic EID discovered on this interface. Allow EID mobility on the interface. Exit from the interface configuration mode. Enter the LISP configuration mode. Specify a locator set and enter the LISP locator-set configuration mode. Exit the LISP locator-set configuration mode. Enable Layer 3 network services for the IPv4 address family and enter the service submode.

Example

```
FabricEdge(config-if)# no lisp mobility liveness test
```

```
FabricEdge(config-if)# lisp mobility dynamic-eid-name
```

```
FabricEdge(config-if)# exit
```

```
FabricEdge(config)# router lisp
```

```
FabricEdge(config-router-lisp)# locator-set locator-set-name
```

```
FabricEdge(config-router-lisp-locator-set)# exit-locator-set
```

```
FabricEdge(config-router-lisp)# service ipv4
```

4. Configure the loopback IP address of the Proxy Egress Tunnel Router (PETR). Select the encapsulation type as VXLAN for data packets. Configure the map resolver address for sending map requests. Configure the map server for ETR registration. Configure the locator address of the LISP map server and the authentication key that this router, acting as a LISP ETR, will use to register with the LISP mapping system. Configure a LISP Egress Tunnel Router (ETR).

Example

```
FabricEdge(config-lisp-srv-ipv4)# use-petr ip-address
```

```
FabricEdge(config-lisp-srv-ipv4)# encapsulation vxlan
```

```
FabricEdge(config-lisp-srv-ipv4)# itr map-resolver map-resolver-address
```

```
FabricEdge(config-lisp-srv-ipv4)# etr map-servermap-server-address key key-type
 authentication-key
```

```
FabricEdge(config-lisp-srv-ipv4)# etr map-servermap-server-address proxy-reply
 authentication-key
```

```
FabricEdge(config-lisp-srv-ipv4)# etr
```

5. Enable security group tag propagation in LISP encapsulated traffic. Remove the address family-specific map cache configuration. Enable the Proxy Ingress Tunnel Router (PITR) functionality and specify the address to use when LISP encapsulating packets to LISP sites. Exit LISP service-ipv4 configuration mode. Select the service type as Ethernet. Configure the map-resolver address for sending map requests.

Example

```
FabricEdge(config-lisp-srv-ipv4)# sgt
```

```
FabricEdge(config-lisp-srv-ipv4)# no map-cache away-eids send-map-request
```

```
FabricEdge(config-lisp-srv-ipv4)# proxy-itr ip-address
```

```
FabricEdge(config-lisp-srv-ipv4)# exit-service-ipv4
```

```
FabricEdge(config-router-lisp)# service ethernet
```

```
FabricEdge(config-lisp-srv-eth)# itr map-resolver map-resolver-address
```

6. Enable the LISP ITR functionality. Configure the map server for ETR registration. Enable the LISP ETR functionality. Exit the LISP service-ethernet configuration mode. Create a LISP EID instance to group multiple services. Configure the parameters for probing remote Routing locators (RLOCs).

   Example

```
FabricEdge(config-lisp-srv-eth)# itr
```

```
FabricEdge(config-lisp-srv-eth)# etr map-server map-server-address key key-type
 authentication-key
```

```
FabricEdge(config-lisp-srv-eth)# etr
```

```
FabricEdge(config-lisp-srv-eth)# exit-service-ethernet
```

```
FabricEdge(config-router-lisp)# instance-id instance
```

```
FabricEdge(config-lisp-inst)# remote-rloc-probe on-route-change
```

7. Configure a dynamic EID and enter the dynamic EID configuration mode. Configure the EID prefix and locator set for the dynamic EID. Exit dynamic instance submode. Select service type as IPv4. Bind an EID table. Exit the LISP service-ipv4 configuration mode. Exit the LISP instance-id configuration mode.

Example

```
FabricEdge(config-lisp-inst)# dynamic-eid dynamic-eid-name
```

```
FabricEdge(config-router-lisp-dynamic-eid)# database-mapping eid locator-set
 rloc_loopback
```

```
FabricEdge(config-router-lisp-dynamic-eid)# exit-instance-id
```

```
FabricEdge(config-lisp-inst)# service ipv4
```

```
FabricEdge(config-lisp-inst-srv-ipv4)# eid-table default
```

```
FabricEdge(config-lisp-inst-srv-ipv4)# exit-service-ipv4
```

```
FabricEdge(config-lisp-inst)# exit-instance-id
```

8. Select service type as IPv4. Export away table entries into the map cache, with the action set to send-map-request. Exit LISP service-ipv4 configuration mode. Create a LISP EID instance to group multiple services. Configure parameters for probing remote RLOCs. Enable Layer 2 network services and enter the service submode. Bind an EID table to VLAN.

Example

```
FabricEdge(config-router-lisp)# service ipv4
```

```
FabricEdge(config-lisp-srv-ipv4)# map-cache away-eids map-request
```

```
FabricEdge(config-lisp-srv-ipv4)# exit-service-ipv4
```

```
FabricEdge(config-router-lisp)# instance-id instance
```

```
FabricEdge(config-lisp-inst)# remote-rloc-probe on-route-change
```

```
FabricEdge(config-lisp-inst)# service ethernet
```

```
FabricEdge(config-lisp-inst-srv-eth)# eid-table vlan vlan-number
```

9. Configure address family-specific local EID prefixes database. Exit LISP service-ethernet configuration mode. Exit from LISP instance-id configuration mode. Configure the IPv4 locator address of the LISP. Configure the IPv4 source locator address of the interface. Exit the LISP router-lisp configuration mode.

Example

```
FabricEdge(config-lisp-inst-srv-eth)# database-mapping mac locator-set
rloc_loopbac
```

```
FabricEdge(config-lisp-inst-srv-eth)# exit-service-ethernet
```

```
FabricEdge(config-lisp-inst)# exit-instance-id
```

```
FabricEdge(config-router-lisp)# ipv4 locator reachability minimum-mask-length
 length
```

```
FabricEdge(config-router-lisp)# ipv4 source-locator interface-name
```

```
FabricEdge(config-router-lisp)# exit-router-lisp
```

Verify Fabric configuration

Lists commands and sample outputs to verify LISP configuration, operational status, and site registration in Cisco Fabric environments.

Use these commands to verify the Fabric configuration.

To verify the LISP configuration on a device, use this command:

```
FabricEdge# show running-config | section router lisp

router lisp

- VLAN Groups

Configuring VLANs chapter

200 VLANs

Topics:

- Virtual Local Area Network
- Configuring normal-range VLANs
- Extended-range VLANs
- Monitor VLANs

Virtual Local Area Network

Introduces VLANs as logical networks that segment switched networks by function or application, explains their isolation and packet forwarding behavior, and outlines how VLANs relate to IP subnets and interface-based membership.

A VLAN (Virtual Local Area Network) is a type of logical network that

- segments switched networks by function, team, or application without regard to the physical locations of the users
- forwards packets (unicast, broadcast, multicast) only among end stations in the same VLAN, and
- maintains its own bridge Management Information Base (MIB) for isolation and control.

VLANs have the same attributes as physical LANs. However, you can group end stations even if they are not physically located on the same LAN segment. Each VLAN is considered a logical network. To send packets to stations outside the VLAN, use a router or a controller that supports fallback bridging.

VLANs are often associated with IP subnets. For example, all the end stations in a particular IP subnet belong to the same VLAN. Assign controller interfaces to VLANs manually to use interface-based (static) VLAN membership.

Supported VLANs

The topic describes the controller supporting VLANs.

The controller supports VLANs in VTP client, server, and transparent modes. VLANs are identified by a number from 1 to 4094.

- VLAN 1 is the default VLAN and is created during system initialization.
- All of the VLANs except 1002 to 1005 are available for user configuration.

VLAN port membership modes

This section explains VLAN port membership modes.

A VLAN port membership mode is a configuration method that

- determines how a switch port associates with one or more VLANs
- specifies the type of VLAN traffic the port can carry, and
- controls whether VLAN membership is assigned manually or dynamically.

To assign a port to a VLAN, set the membership mode. The membership mode determines which type of traffic the port carries and how many VLANs the port can join. When a port belongs to a VLAN, the controller manages the port addresses for each VLAN.

Table 181: Port Membership Modes and Characteristics

Membership Mode	VLAN Membership Characteristics	VTP Characteristics
Static-access	A static-access port can belong to one VLAN and is manually assigned to that VLAN.	VTP is not required. Set the VTP mode to transparent if you do not want VTP to propagate information globally. Participation in VTP requires at least one trunk port on the controller connected to a trunk port on a second controller.

Membership Mode	VLAN Membership Characteristics	VTP Characteristics
Trunk IEEE 802.1Q) : • IEEE 802.1Q– Industry-standard trunking encapsulation.	A trunk port is a member of all VLANs by default, including extended-range VLANs, but membership can be limited by configuring the allowed-VLAN list.	VTP maintains VLAN configuration consistency by managing the addition, deletion, and renaming of VLANs across the network. VTP exchanges VLAN configuration messages with other controllers over trunk links.

Note

If a client VLAN has both a primary and a secondary subnet, you cannot assign a static IP address on the secondary subnet.

Consider this SVI configuration example:

interface VlanX

ip address a.b.c.254 255.255.255.0 secondary

ip address a.d.e.254 255.255.255.0

In this scenario, you can't allocate the secondary subnet for clients with static IP addresses.

VLAN configuration files

This topic describes configurations for VLAN IDs 1 to 1005 are written to the vlan.dat file.

When you configure VLAN IDs 1 to 1005, your settings are saved to the vlan.dat file (VLAN database). To display these configurations, enter the show vlan privileged EXEC command. The vlan.dat file is stored in flash memory. If the VTP mode is transparent, your configurations are also saved in the controller running configuration file.

Use interface configuration mode to define the port membership mode and to add or remove ports from VLANs. The results of your commands are saved to the running-configuration file. To display the running configuration, enter the show running-config privileged EXEC command. When you save VLAN and VTP information (including extended-range VLAN configuration information) in the startup configuration file and reboot the controller, the system chooses its configuration based on several criteria.

- If the VTP mode is transparent in the startup configuration and the VLAN database and domain name match those in the startup configuration file, the device ignores the VLAN database. In this situation, the controller uses the VTP and VLAN configurations from the startup configuration file. The VLAN database revision number does not change.
- If the VTP mode or domain name in the startup configuration does not match the VLAN database, the device uses the domain name, VTP mode, and VLAN IDs 1 to 1005 configuration from the VLAN database.
- In VTP versions 1 and 2, if you set the VTP mode to server, the device uses the domain name and VLAN configuration for VLAN IDs 1 to 1005 from the VLAN database. VTP version 3 supports VLANs 1006 to 4094.

> **Note**
>
> Delete the vlan.dat file and the configuration files before you reset the switch configuration with the write erase command. This step ensures the switch reboots correctly when you reset it.

Normal-range VLAN configuration guidelines

This topic describes the guidelines to create and modify normal-range VLAN configuration.

These guidelines help you create or change normal-range VLANs in your network.

- Normal-range VLANs use numbers from 1 to 1001.
- VLAN configurations for VLANs 1 to 1005 are always saved in the VLAN database. In transparent VTP mode, both VTP and VLAN configurations are also saved in the running configuration file.
- If your controller works in VTP server mode or VTP transparent mode, you can add, change, or remove VLANs 2 to 1001 in the VLAN database. VLAN ID 1, as well as VLANs 1002 to 1005, are automatically created. You cannot remove these VLANs.
- The system does not save extended-range VLANs that you create in VTP transparent mode, and these VLANs are not shared across the network. VTP version 3, when in server mode, allows you to share extended-range VLANs (VLANs 1006 to 4094) in the database.

If clients cannot connect to the controller because of a VLAN failure, you have these options:

- Configure **ip4 dhcp required** in the policy profile to make the client start a DHCP request.
- Set up the RADIUS server to send VLAN group information, including the client's static IP VLAN, so the client can use a static IP address.
- Configure 'aaa-override vlan fallback' in the policy profile to make the controller look for the client's static IP VLAN in other VLAN groups. The client can join the network if its static IP VLAN is listed in the VLAN group set under the policy profile.

Extended-range VLAN configuration guidelines

This topic describes the guidelines to create extended-range VLAN configuration.

Extended-range VLANs are VLANs with IDs from 1006 to 4094.

Follow these guidelines when creating extended-range VLANs:

- Extended-range VLAN IDs are not saved in the VLAN database. VTP does not recognize these VLANs unless your device uses VTP version three.
- Do not include extended-range VLANs in the pruning eligible range.
- For VTP version 1 or 2, set the VTP mode to transparent in global configuration mode. Save this configuration to the startup configuration so that your device boots in VTP transparent mode. Save the configuration to avoid losing the extended-range VLAN configuration when the device resets.

Prerequisites for VLANs

The topic describes the prerequisites for VLANs.

These are the prerequisites and considerations for configuring VLANs:

- To configure VLAN through the GUI, change the number of available Virtual Terminal (VTY) sessions to 50. The Web UI processes HTTP requests using VTY lines. If several connections are open, the device's default limit of 15 VTY lines can be exceeded. Increase the number of VTY lines to 50 before using the Web UI.

  Note

  To increase the number of VTY lines on your device, enter these configuration commands.

  ```
  Device# configure terminal
  Device(config)# service tcp-keepalives in
  Device(config)# service tcp-keepalives out

  Device# configure terminal
  Device(config)# line vty 16-50
  ```

  Note

  The maximum number of SSH VTY sessions supported on the standby controller is eight.

- Decide if you will use VLAN Trunking Protocol (VTP) to manage global VLAN configuration for your network before creating VLANs.
- Create the VLAN on the device before adding it to a VLAN group.

Restrictions for VLANs

This section describes the restrictions for VLANs.

These are the restrictions for VLANs:

- You cannot delete a wireless management interface if its associated VLAN interface has already been deleted. To prevent this issue, delete the wireless management interface before deleting the VLAN interface.
- The device supports IEEE 802.1Q trunking methods for sending VLAN traffic over Ethernet ports.
- When no client VLAN is configured for a policy profile, the AP native VLAN is used.
- The behavior of VLAN 1 changes depending on the AP mode. The device handles VLAN scenarios as described here:
  - Local mode AP : If you use *vlan-name* , clients are assigned to VLAN 1. If you use *vlan-id* 1, clients are assigned to the wireless management interface.
  - FlexConnect mode AP : If you use *vlan-name* , clients are assigned to VLAN 1. If you use *vlan-id* 1, clients are assigned to the native VLAN defined in the flex profile.

  By default, the policy profile assigns vlan-id 1 so that clients can use the wireless management VLAN.
- You cannot use the same VLAN on the same SSID for both local switching and central switching.

Configuring normal-range VLANs

Guides administrators through configuring normal-range VLANs, including creating, modifying, and deleting VLANs, setting key parameters, validating settings, and maintaining VLAN database integrity to ensure proper Layer 2 network segmentation and reliable switching operation.

Summary

Configuring normal-range VLANs lets administrators create or modify VLANs within the standard allowed range. It also lets them assign key properties and ensures proper Layer 2 network segmentation. The process requires setting necessary parameters and using recommended practices to maintain VLAN database integrity. The process includes several key components.

- The network administrator manages VLAN creation, modification, and deletion.
- The switch VLAN database stores and applies VLAN configurations.
- VLAN parameters include attributes such as VLAN ID, name, type, state, and associations which define each VLAN.

Workflow

Normal-range VLANs are VLANs with IDs from 1 to 1005. Proper configuration is essential for network segmentation and security. It also helps maintain a reliable switching environment. The process consists of several stages:

1. Access the VLAN database: The administrator uses the switch's VLAN configuration mode to begin changes.
2. Identify or create the VLAN: Select an existing VLAN or specify a new VLAN ID within the normal range (1-1005).
3. Set VLAN parameters: Assign a VLAN name, choose a VLAN type (Ethernet, Token Ring Bridge Relay Function [TrBRF], or Token Ring Concentrator Relay Function [TrCRF]), and set the VLAN state (active or suspended).
4. Validate the VLAN settings: Confirm that the VLAN was created or modified as expected, using appropriate verification commands.
5. Maintain VLAN database integrity: Avoid deleting the `vlan.dat` file manually because this can cause inconsistencies. Always use standard switch commands to modify or remove VLAN configurations.

Create or modify an Ethernet VLAN (CLI)

Use this procedure to create or modify an Ethernet VLAN.

Configure a new Ethernet VLAN or update an existing one using commands on the controller.

Before you begin

With VTP version 1 and 2, the controller in VTP transparent mode allows you to assign VLAN IDs greater than 1006. However, these VLANs are not added to the VLAN database.

The controller supports only Ethernet interfaces.

Procedure

1. Enter a VLAN ID to access VLAN configuration mode. Enter a new VLAN ID to create a VLAN, or enter an existing VLAN ID to modify that VLAN.

   Example

   ```
   Device(config)# vlan 20
   ```

> **Note**
>
> The valid VLAN ID range for this command is between 1 to 4094.

2. Enter a name for the VLAN.

   Example

   ```
   Device(config-vlan)# name test20
   ```

   If you do not enter a name for the VLAN, the system appends the *vlan-id* value with leading zeros to the word VLAN.

3. Configure the VLAN media type.

   Example

   ```
   Device(config-vlan)# media {ethernet | fd-net | trn-net}
   ```

4. Verify your entries.

   Example

   ```
   Device# show vlan {name test20 | id 20}
   ```

Assign static-access ports to a VLAN (GUI)

Use this procedure to assign static-access ports to a VLAN using GUI.

Assign static-access ports to a specific VLAN from the user interface using the GUI.

Procedure

1. Choose **Configuration** > **Layer2** > **VLAN** > **VLAN**.
2. Click the **VLAN** tab.
3. To assign **Port Members**, select the desired interfaces in the **Available** list. Then, use the arrow to move them to the **Associated** list.
4. Click **Update & Apply to Device**.

Assign static-access ports to a VLAN (CLI)

Assign static-access ports to a VLAN using commands.

Assign Layer 2 switch ports to a specific VLAN for network segmentation using commands.

You can assign a static-access port to a VLAN without having VTP globally propagate VLAN configuration information by disabling VTP (VTP transparent mode). For more information on static-access ports, see *VLAN Port Membership Modes*.

If you assign an interface to a VLAN that does not exist, the new VLAN is created.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the interface to be added to the VLAN.

   Example

   ```
   Device(config)# interface gigabitethernet2/0/1
   ```

3. Define the VLAN membership mode for the port (Layer 2 access port).

   Example

   ```
   Device(config-if)# switchport mode access
   ```

4. Assign the port to a VLAN.

   Example

   ```
   Device(config-if)# switchport access vlan 2
   ```

   The valid VLAN IDs range is between 1 to 4094.

5. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-if)# end
   ```

6. Verify the VLAN membership mode of the interface.

   Example

   ```
   Device# show running-config interface interface-id
   ```

7. Verify your entries in the *Administrative Mode* and the *Access Mode VLAN* fields of the display.

   Example

   ```
   Device# show interfaces gigabitethernet2/0/1 switchport
   ```

Extended-range VLANs

Introduces extended-range VLANs, outlining their purpose, VLAN ID support, and differences in configuration storage based on VTP versions and modes.

Extended-range VLANs enable service providers to extend their infrastructure to a greater number of customers. The extended-range VLAN IDs are permitted in any **switchport** command that accepts VLAN IDs.

- With VTP version 1 or 2, extended-range VLAN configurations are not stored in the VLAN database. However, if VTP mode is set to transparent, the configurations are stored in the controller running configuration file, and you can also save them in the startup configuration file.
- For VTP version 3, extended-range VLANs are stored in the VLAN database.

Create an extended-range VLAN (GUI)

Use this procedure to create an extended-range VLAN using GUI.

Add an extended-range VLAN to your network to support larger scaling or specialized network segmentation using the GUI.

Procedure

1. Choose **Configuration** > **Layer2** > **VLAN**.
2. In the VLAN page, click **ADD**.
3. Enter the extended range VLAN ID in the **VLAN ID** field.

   The extended range is between range is 1006 and 4094.
4. Enter a VLAN name in the **Name** field.
5. Save the configuration.

Create an extended-range VLAN (CLI)

Use this procedure to create an extended-range VLAN using commands.

Create an extended-range VLAN on a device using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Enter an extended-range VLAN ID and enter the VLAN configuration mode.

   Example

   ```
   Device(config)# vlan 2000
   ```

   The range is between 1006 to 4094.
3. Verify that the VLAN has been created.

Example

```
Device# show vlan id 2000
```

Monitor VLANs

This section provides the details about monitoring VLANs.

Table 182: Privileged EXEC show commands

Command	Purpose
show interfaces [**vlan** *vlan-id*]	Displays characteristics for all interfaces or for the specified VLAN configured on the controller.
show vlan [**access-map** *name* | **brief** | **group** | **id** *vlan-id* | **ifindex** | **mtu** | **name** *name* | **summary**]	Displays parameters for all VLANs or the specified VLAN on the controller. These command options are available: • ***brief*** –Displays VTP VLAN status in brief. • ***group*** –Displays the VLAN group with its name and the connected VLANs that are available. • ***id*** –Displays VTP VLAN status by identification number. • ***ifindex*** –Displays SNMP ifIndex. • ***mtu*** –Displays VLAN MTU information. • ***name*** –Displays the VTP VLAN information by specified name. • ***summary*** –Displays a summary of VLAN information.

201 VLAN Groups

Topics:

- VLAN groups
- VLAN group support for DHCP and static IP clients

VLAN groups

Outlines the configuration and operation of VLAN groups for wireless networks, including dynamic VLAN assignment, policy profile mapping, and management of VLAN integrity using Dirty flag mechanisms based on client DHCP failures and MAC address hashing.

A VLAN group is a wireless network configuration feature that

- enables assignment of multiple VLANs to a single policy profile
- dynamically allocates a wireless client to a VLAN within the group based on the client's MAC address, and
- manages VLAN availability and integrity by marking VLANs as *Dirty* when the clients are unable to receive IP addresses using DHCP.

Whenever a client connects to a wireless network (WLAN), the client is placed in a VLAN associated with the policy profile mapped to the WLAN. In a large venues, such as an auditorium, stadiums, or conference rooms with numerous wireless clients, managing connections using only a single WLAN can be challenging.

The clients can be assigned to one of the configured VLANs. This feature maps a policy profile to a single VLAN or to multiple VLANs using VLAN groups. A VLAN is assigned to the client, and the client receives the IP address from the assigned VLAN.

The system might not clear the *Dirty* flag from the VLAN, even after 30 minutes, for a VLAN group. After 30 minutes, when the VLAN is marked as non-dirty, new clients in the IP Learn state can be assigned IP addresses from the VLAN if available IPs exist in the pool and the DHCP scope is configured correctly. This is expected because the timestamp of each interface must be checked to confirm it exceeds 30 minutes, which results in a 5-minute lag before the global timer expires.

Note

The Controller marks the VLAN interface as *Dirty* when three or more clients fail to receive IP addresses through DHCP. The VLAN interface is marked *Dirty* if the VLAN *Dirty* counter increases as a result of an ***IP Learn Failure***, which occurs when a client sends three DHCP discoveries without receiving a response. This occurs before the client is deleted due to an ***IP Learn Timeout***.

Each client receives a unique hash value derived from its MAC address. This approach ensures that clients from the same vendor, which may differ only by a few bits, do not cause incorrect *Dirty* VLAN markings.

Prerequisites for VLAN groups

This section describe a prerequisite for VLAN groups.

Review the required condition for VLAN group.

- A VLAN should be present in the device for it to be added to the VLAN group.
- IP MAC binding should be configured on a policy profile that uses a VLAN group.

Restrictions for VLAN groups

This section describes the restrictions for VLAN groups.

Follow these restrictions when configuring VLAN groups:

- If the number of VLANs in a VLAN group exceeds 32, the mobility functionality might not work as expected and Layer 2 multicast might break for some VLANs. Therefore, it is the responsibility of network administrators to configure a feasible number of VLANs in a VLAN group.
- The VLAN Groups feature works for APs in local mode.
- The VLAN Groups feature operates only in central switching mode; it cannot be used in FlexConnect local switching mode.
- The ARP Broadcast feature is not supported on VLAN groups.
- Multicast with VLAN group is only supported for access points in local mode. A multicast VLAN is required when a VLAN group is configured and multicast traffic is used.
- When configuring VLAN groups with multiple VLANs, and each VLAN is used by a different subnet, clients with static IP addresses might be assigned to an incorrect VLAN if SVIs are not present on the controller. For every VLAN in the VLAN group, configure an SVI interface with a valid IP address.

Create a VLAN Group (GUI)

Use this procedure to create a VLAN group using GUI.

Create a VLAN group to assign multiple VLAN IDs efficiently in the network using the GUI.

Procedure

1. Choose **Configuration** > **Layer2** > **VLAN Group**.
2. Click **Add**.
3. Set the **VLAN GROUP** name and the list of **VLANS**.

   This can be a range, or a set of comma-separated values.
4. Enter the VLAN name in the **Name** field.

   Configure the other parameters if required.
5. Click **Update & Apply to Device**.

Create a VLAN Group (CLI)

Use this procedure to create a VLAN group using commands.

Create a VLAN group for network segmentation and traffic management using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Create a VLAN group with the given group name and add all the VLANs listed in the command.

Example

```
Device(config)# vlan group vlangrp1 vlan-list 91-95.
```

The VLAN list ranges from 1 to 4096 and the maximum number of VLANs supported in a group is 64.

3. Exit the global configuration mode and return to the privileged EXEC mode.

Example

```
Device(config)# end
```

Alternatively, press *CTRL-Z* to exit the global configuration mode.

Add a VLAN group to policy profile (GUI)

Use this procedure to add a VLAN group to policy profile using GUI.

Assign a VLAN group to an existing policy profile, enabling client traffic association with the specified VLANs using commands.

The policy profile consists mainly of network and switching policies. The policy profile is a reusable entity that can be applied to multiple tags. When you apply a client policy to the AP or controller, the policy profile includes it. Examples are VLAN, ACL, QoS, session timeout, idle timeout, AVC profile, Bonjour profile, local profiling, device classification, and BSSID QoS. However, all security attributes and features related to wireless on the WLAN are grouped under the WLAN profile.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. On the **Policy Profile** page, click on a policy profile name.
3. Click on the **Access Policies** tab.
4. Under **VLAN** section, select a a VLAN or VLAN Group from the **VLAN/VLAN Group** drop-down list.
5. Click **Update & Apply to Device**.

Add a VLAN group to a policy profile (CLI)

Use this procedure to add a VLAN group to policy profile using commands.

Map a specific VLAN group to a WLAN policy profile using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the WLAN policy profile.

Example

```
Device(config)# wireless profile policy my-wlan-policy
```

3. Map the VLAN group to the WLAN by entering the group name.

Example

```
Device(config-wireless-policy)# vlan myvlan-group
```

4. Exit the global configuration mode and return to the privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

View the VLANs in a VLAN group

This section discusses how you can view the VLANs in a VLAN group.

These commands let you view VLAN group information and VLAN assignments:

Command	Description
show vlan group	Displays the list of VLAN groups with name and the VLANs that are configured.
show vlan group group-name *group_name*	Displays the specified VLAN group details.
show wireless client mac-address *client-mac-addr* **detail**	Displays the VLAN group assigned to the client.
show wireless vlan details	Displays VLAN details.

VLAN group support for DHCP and static IP clients

Outlines VLAN group support for assigning DHCP and static IP clients to VLANs, configuring MAC and IP bindings, enforcing network access policies, and details prerequisites and feature history for IPv4 client management.

A VLAN group feature is a network function that

- assigns clients to VLANs based on DHCP or static IP information
- restricts internet access for static IP clients whose addresses do not match the VLAN's IP list, and
- applies only to IPv4 clients with automatic enablement unless explicitly disabled by configuration.
- The VLAN Group to support DHCP and Static IP clients feature manages network access for DHCP and static IP clients.
- Ensure that the **ipv4 dhcp required** command is not configured on the wireless policy profile. If this command is present, the feature is disabled, and the client remains in the IP learn state. Ensure that the **ip mac-binding** command is configured on the wireless policy profile. This command associates VLAN information with the MAC address and IP address assigned to the client, whether assigned statically or through DHCP.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 183: Feature history for VLAN group support for DHCP and static IP clients

Feature Name	Release Information	Feature Description
VLAN group support for DHCP and static IP clients	Cisco IOS XE 17.9.1	From this release VLAN group support for DHCP and static IP clients enhances network segmentation by allowing controllers to assign both DHCP and IPv4 static IP clients to VLANs using computed logic.

Prerequisites and restrictions of VLAN Group support for DHCP and static IP clients

Prerequisites and restrictions of VLAN Group support for DHCP and static IP clients.

Prerequisites of VLAN Group support for DHCP and static IP clients

- Ensure that a switch VLAN interface (SVI) is configured with the IP address.
- Ensure that IP MAC-binding is configured on the target Policy Profile(s).

Restrictions of VLAN Group support for DHCP and static IP clients

- FlexConnect local switching and FlexConnect local authentication are not supported. Only local mode, FlexConnect central switching, and FlexConnect central authentication are supported.
- IPv6 is not supported.
- The peer controller cannot have a VLAN group in the policy profile, because a VLAN group with static IP mobility is not supported. To support VLAN group with an anchor peer controller, **static-ip-mobility** must be configured and **DHCP required** must be disabled.

Supported features

This section provides details about supported features.

This table provides details about supported features for VLAN group support for DHCP and static IP clients.

- Configure SVI with an IP address in the same subnet as the client's IP address.
- Clients are excluded if there is no matching SVI.

Feature	Support
Guest Anchor	Yes
Mobility	Yes
RLAN	Yes

SVI	Yes Ensure that you configure SVI with an IP address in the same subnet as that of the client's IP address.
IRCM support: Guest AireOS as anchor and Cisco Catalyst 9800 controller as foreign	Yes
IRCM support : Guest AireOS as foreign and Cisco Catalyst 9800 controller as anchor	Yes The client is excluded if there is no match for the SVI.

202 WLANs

Topics:

- WLANs
- How to configure WLANs

WLANs

Explains wireless local area networks that enable control of lightweight access points with configurable SSIDs and profiles.

A WLAN is a wireless network feature that

- enables control of wireless local area networks for lightweight access points
- supports up to 16 advertised WLANs per access point with up to 4096 total configurable WLANs, and
- allows selective advertisement using profiles and tags for better manageability.

An SSID identifies the specific wireless network that you want the device to access. You can configure WLANs with different SSIDs or with the same SSID.

WLAN configuration details

Each WLAN has a separate WLAN ID, a separate profile name, and a WLAN SSID.

Note

The **wireless client max-user-login concurrent** command will work as intended even if the **no configure max-user-identity response** command is configured.

Note

We recommend that you configure the **password encryption aes** and the **key config-key password-encrypt** *key* commands to encrypt your password.

Note

For C9105, C9115, and C9120 APs, when a new WLAN is pushed from the controller and if the existing WLAN functional parameters are changed, the other WLAN clients will disconnect and reconnect.

Wi-Fi multimedia (WMM) policy

Wi-Fi Multimedia (WMM) is used to prioritize different types of traffic. The WMM policy options include:

- **Disabled**: Disables WMM on the WLAN.
- **Required**: Requires client devices to use WMM. Devices that do not support WMM cannot join the WLAN.
- **Allowed**: Devices that do not support WMM can join the WLAN but will not benefit from the 802.11n rates.

> **Note**
>
> For 802.11ax APs and higher (Cisco Catalyst 9117, 9124, 913x, 916x, 917x APs), WMM can not be **Disabled**. Only **Required** or **Allowed** options are supported.

Prerequisites for WLANs

Outlines the prerequisites for configuring WLANs.

You can associate up to 16 WLANs with each access point group and assign specific access points to each group. Each access point advertises only the enabled WLANs that belong to its access point group. The access point (AP) does not advertise disabled WLANs in its access point group or WLANs that belong to another group.

We recommend that you assign one set of VLANs for WLANs and a different set of VLANs for management interfaces to ensure that devices properly route VLAN traffic.

Restrictions for WLANs

Lists restrictions for WLANs.

This reference provides restrictions and limitations that apply when configuring and managing WLANs on wireless controllers.

- Do not configure PSK as this configuration is not supported and impacts client join flow.
- Ensure that TKIP or AES ciphers are enabled with WPA1 configuration, else ISSU may break during upgrade process.
- When you change the WLAN profile name, then FlexConnect APs (using AP-specific VLAN mapping) will become WLAN-specific. If FlexConnect Groups are configured, the VLAN mapping will become Group-specific.
- Do not enable IEEE 802.1X Fast Transition on Flex Local Authentication enabled WLAN, as client association is not supported with Fast Transition 802.1X key management.
- Peer-to-peer blocking does not apply to multicast traffic.
- In FlexConnect, peer-to-peer blocking configuration cannot be applied only to a particular FlexConnect AP or a subset of APs. It is applied to all the FlexConnect APs that broadcast the SSID.
- The WLAN name and SSID can have up to 32 characters.
- WLAN and SSID names support only the following ASCII characters:
  - Numerals: 48 through 57 hex (0 to 9)
  - Alphabets (uppercase): 65 through 90 hex (A to Z)
  - Alphabets (lowercase): 97 through 122 hex (a to z)
  - ASCII space: 20 hex
  - Printable special characters: 21 through 2F, 3A through 40, and 5B through 60 hex, that is: ! " # $ % & ' ( ) * + , - . / : ; < = > ? @ [\ ] ^ _ ` { | } ~
- WLAN name cannot be a keyword; for example, if you try to create a WLAN with the name as 's' by entering the **wlan s** command, it results in shutting down all WLANs because 's' is used as a keyword for shutdown.
- You cannot map a WLAN to VLAN 0. Similarly, you cannot map a WLAN to VLANs 1002 to 1006.
- Dual stack clients with a static-IPv4 address is not supported.

- In a dual-stack with IPv4 and IPv6 configured in the Cisco 9800 controller, if an AP tries to join controller with IPv6 tunnel before its IPv4 tunnel gets cleaned, you would see a traceback and AP join will fail.
- When creating a WLAN with the same SSID, you must create a unique profile name for each WLAN.
- When multiple WLANs with the same SSID get assigned to the same AP radio, you must have a unique Layer 2 security policy so that clients can safely select between them.
- The SSID that is sent as part of the user profile will work only if **aaa override** command is configured.
- RADIUS server overwrite is not configured on a per WLAN basis, but rather on a per AAA server group basis.
- Downloadable ACL (DACL) is supported only on the central switching mode. It is not supported for Flex Local switching or on the Cisco Embedded Wireless Controller.
- You cannot mix open configuration models with CLI-based, GUI-based, or Catalyst Center-based configurations. However, if you decide to use multiple model types, they must remain independent of each other. For example, in open configuration models, you can only manage configurations that have been created using an open configuration model, not a CLI-based or GUI-based model. Configurations that are created using open configuration models cannot be modified using a GUI-based model, or CLI-based model, or any other model.
- When you are configuring **dot11bg 11g** command and **radio dot11bg** or **radio dot11g** command, the clients can still connect in 5GHz radio. In this scenario, the client association needs to be blocked. This option is only available on a 2.4-GHz radio.

> ⚠ **Caution**
>
> Some clients might not be able to connect to WLANs properly if they detect the same SSID with multiple security policies. Use this WLAN feature with care.

Band selection

Describes how band select facilitates the movement of dual-band client radios from congested frequency bands to less congested 5-GHz access points for improved network performance.

A band selection is a wireless network feature that

- facilitates the movement of dual-band client radios from congested frequency bands
- enables clients to connect to less congested 5-GHz access points for improved network performance, and
- reduces interference from other devices by optimizing which frequency band clients use.

The 2.4-GHz band is often congested. Clients using this band may experience interference from Bluetooth devices, microwave ovens, cordless phones, and co-channel interference from other access points due to the 802.11b/g channel limit of 3 nonoverlapping channels. By configuring band selection on devices, administrators can steer dual-band clients toward the 5-GHz band, improving overall network performance.

Off-channel scanning deferral

Describes a wireless network feature that temporarily postpones RRM off-channel scanning activities.

Off-channel scanning deferral is a wireless network feature that

- temporarily postpones RRM off-channel scanning activities when important data transmission occurs
- prevents performance impact on critical traffic by avoiding the normal 70-millisecond off-channel periods, and

- can be configured on a per-WLAN basis with specific WMM UP class and time threshold parameters.

Off-channel scanning operations

A lightweight access point, in normal operational conditions, periodically goes off-channel and scans another channel. This is in order to perform RRM operations such as the following:

- Transmitting and receiving Neighbor Discovery Protocol (NDP) packets with other APs.
- Detecting rogue APs and clients.
- Measuring noise and interference.

During the off-channel period, which normally is about 70 milliseconds, the AP is unable to transmit or receive data on its serving channel. Therefore, there is a slight impact on its performance and some client transmissions might be dropped.

While the AP is sending and receiving important data, it is possible to configure off-channel scanning deferral so that the AP does not go off-channel and its normal operation is not impacted. You can configure off-channel scanning deferral on a per-WLAN basis, per WMM UP class basis, with a specified time threshold in milliseconds. If the AP sends or receives, on a particular WLAN, a data frame marked with the given UP class within the specified threshold, the AP defers its next RRM off-channel scan. For example, by default, off-channel scanning deferral is enabled for UP classes 4, 5, and 6, with a time threshold of 100 millseconds. Therefore, when RRM is about to perform an off-channel scan, a data frame marked with UP 4, 5, or 6 is received within the last 100 milliseconds, RRM defers going off-channel. The AP radio does not go off-channel when a voice call sending and receiving audio samples is marked as UP class 6 for every active 20 milliseconds.

Off-channel scanning deferral does come with a tradeoff. Off-channel scanning can impact throughput by 2 percent or more, depending on the configuration, traffic patterns, and so on. Throughput can be slightly improved if you enable off-channel scanning deferral for all traffic classes and increase the time threshold. However, by not going off-channel, RRM can fail to identify AP neighbors and rogues, resulting in negative impact to security, DCA, TPC, and 802.11k messages.

DTIM period

Explains how DTIM period allows power-saving clients to wake up at the appropriate time.

A Delivery Traffic Indication Map (DTIM) period is a 802.11 network timing mechanism that

- allows power-saving clients to wake up at the appropriate time if they are expecting broadcast or multicast data
- determines when access points transmit buffered broadcast and multicast frames after beacon broadcasts, and
- coincides with the DTIM broadcast interval.

DTIM period characteristics

In the 802.11 networks, lightweight access points broadcast a beacon at regular intervals, which coincides with the Delivery Traffic Indication Map (DTIM). After the access point broadcasts the beacon, it transmits any buffered broadcast and multicast frames based on the value set for the DTIM period.

Typical DTIM values and their transmission patterns:

- DTIM value 1: Transmits broadcast and multicast frames after every beacon
- DTIM value 2: Transmits broadcast and multicast frames after every other beacon

For instance, if the beacon period of the 802.11 network is 100 ms and the DTIM value is set to 1, the access point transmits buffered broadcast and multicast frames for 10 times every second. If the beacon period is 100 ms and the DTIM value is set to 2, the access point transmits buffered broadcast and multicast frames for 5 times every second. Either of these settings are suitable for applications, including Voice Over IP (VoIP), that expect frequent broadcast and multicast frames.

However, the DTIM value can be set as high as 255 (to transmit broadcast and multicast frames after every 255th beacon). The only recommended DTIM values are 1 and 2; higher DTIM values will likely cause communications problems.

> **Note**
>
> A beacon period, which is specified in milliseconds on the device, is converted internally by the software to 802.11 Time Units (TUs), where 1 TU = 1.024 milliseconds. Depending on the AP model, the actual beacon period may vary slightly; for example, a beacon period of 100 ms may in practice equate to 104.448 ms.

WLAN radio policies

Explains the WLAN Radio Policy feature that allows broadcasting WLANs on corresponding slots.

A WLAN radio policy is a wireless network configuration feature that

- allows broadcasting the WLAN on the corresponding slot
- provides more granular control compared to existing WLAN features that broadcast on all applicable slots, and
- is supported only on 5 GHz band.

WLAN radio policy functionality

The existing WLAN feature allows you to broadcast WLAN on a specified radio on all the applicable slots. With the WLAN Radio Policy feature, you can broadcast the WLAN on the corresponding slot.

Restrictions for WLAN radio policy

Lists restrictions for WLAN radio policy.

This topic lists the restrictions that apply to WLAN radio policy configuration.

- WLAN is pushed to all the radios only if these configurations are used:
  - WPA3 + AES cipher + 802.1x-SHA256 AKM
  - WPA3 + AES cipher + OWE AKM
  - WPA3 + AES cipher + SAE AKM
  - WPA3 + CCMP256 cipher + SUITEB192-1X AKM
  - WPA3 + GCMP256 cipher + SUITEB-1X AKM
  - WPA3 + GCMP128 cipher + SUITEB192-1X AKM

Prerequisites for configuring Cisco client extensions

Outlines prerequisites for configuring Cisco client extensions.

The software supports CCX versions 1 through 5, which enables devices and their access points to communicate wirelessly with third-party client devices that support CCX. CCX support is enabled automatically for every WLAN on the device and cannot be disabled. However, you can configure Aironet information elements (IEs).

If Aironet IE support is enabled, the access point sends an Aironet IE 0x85 (which contains the access point name, load, number of associated clients, and so on) in the beacon and probe responses of this WLAN, and the device sends Aironet

IEs 0x85 and 0x95 (which contains the management IP address of the device and the IP address of the access point) in the reassociation response if it receives Aironet IE 0x85 in the reassociation request.

Peer-to-peer blocking

Explains a WLAN security feature that prevents direct communication between wireless devices within the same network.

Peer-to-peer blocking is a WLAN security feature that

- is applied to individual WLANs, where each client inherits the peer-to-peer blocking setting of the WLAN to which it is associated
- enables you to have more control over how traffic is directed by allowing you to choose to have traffic bridged locally within the device, dropped by the device, or forwarded to the upstream VLAN, and
- is supported for clients that are associated with local and central switching WLANs.

> **Note**
>
> Peer-to-peer blocking feature is VLAN-based. WLANs using the same VLAN has an impact, if Peer-to-peer blocking feature is enabled.

Diagnostic channels

Describes diagnostic channel selection for troubleshooting client WLAN communication issues.

A diagnostic channel is a troubleshooting feature that

- enables testing of client and AP communication to identify network difficulties
- allows corrective measures to be taken to make the client operational on the network, and
- provides GUI or CLI configuration options for enabling diagnostic tests.

Configuration options

You can use the device GUI or CLI to enable the diagnostic channel, and you can use the device **diag-channel** CLI to run the diagnostic tests.

> **Note**
>
> We recommend that you enable the diagnostic channel feature only for non-anchored SSIDs that use the management interface. CCX Diagnostic feature has been tested only with clients having Cisco ADU card

AP names in beacon

AP names in beacon is a feature that

- extends the maximum length for AP name from 16 to 32 characters
- prevents AP name truncation in beacons, and
- uses a vendor specific (VS) Information Element (IE) instead of CCX IEs.

The extended length matches the maximum length supported in the controller. This enhancement resolves issues where AP names were truncated due to a 16-character limit imposed by CCX Information Elements (IEs).

Feature history

Table 184: Feature history for AP names in beacons

Feature name	Release information	Feature description
AP names in beacons	Cisco IOS XE 17.18.2	AP names in beacon is a feature that allows AP names to be extended from 16 to 32 characters, prevents truncation of AP names in beacon frames, and uses a vendor-specific Information Element (IE) instead of the older CCX IEs.

How to configure WLANs

Configure WLANs to create wireless network connectivity. Define essential parameters, apply security policies, and provision access points to meet your organization's coverage and performance needs.

WLAN wizard

Explains a feature that simplifies the process of setting up a Wireless Local Area Network (WLAN).

A WLAN wizard is a simplified workflow that

- helps you quickly create a WLAN and setup some primary configurations for your specific deployment
- supports wireless deployment modes including Local mode, FlexConnect mode, and Guest CWA mode, and
- provides different authentication methods for each deployment mode.

Wireless deployment modes

The wizard supports the following wireless deployment modes:

- Local mode: In Local mode, the WLAN is broadcast in the campus locally.
- Flex Connect mode: In FlexConnect mode, the WLAN is broadcast remotely across the WAN in a branch.
- Guest CWA mode: In Guest CWA mode, the WLAN is created for guest access with Central Web Authentication (CWA).

Important

These steps help configure WLANs, otherwise an error might occur.

To configure a WLAN for your preferred wireless deployment mode using the WLAN wizard on the WebUI, go to **Configuration > Wireless Setup > WLAN Wizard**.

You can also navigate to the WLAN Wizard by these paths:

- On the Toolbar, click on the **Wireless Setup** icon and select **WLAN Wizard** from the drop-down list.

- On the left navigation pane, go to **Configuration > Tags & Profiles > WLANs** and click on **WLAN Wizard** on the top-right corner.

On the **WLAN Wizard** page, select a wireless deployment mode for the WLAN to initiate steps for setting up the WLAN with profiles, authentication methods, tags, and APs and other configurations.

Local mode

Describes the WLAN deployment configuration used in office setups with no branch offices.

Local mode is a WLAN deployment configuration that

- is used when the WLAN is present in an office setup with no branch offices
- creates two CAPWAP tunnels from an AP to the controller, one for management and the other for data traffic, and
- implements centrally switched behavior where data traffic is tunneled from the AP to the controller for routing.

Local mode traffic handling

In local mode, data traffic is tunneled (bridged) from the AP to the controller where it is then routed by some routing device. This behavior is known as "centrally switched" because the data traffic is processed at the controller level. Locally switched means the traffic is terminated at the local switch adjacent to the access point.

Authentication methods

Explains the authentication methods available for configuring a WLAN in local mode.

An authentication method is a WLAN security configuration that

- sets the method by which a client can access the WLAN
- decides the level of security on the WLAN, and
- is selected from the left panel when configuring a WLAN for local mode.

Authentication method options

The authentication method options are:

- PSK: A Pre-Shared Key (PSK) is a unique key created for individuals or groups of users on the same SSID. A client will have to enter the PSK to be authenticated and allowed to access the WLAN.
- Dot1x: The client must go through relevant EAP authentication model to start exchanging traffic in the WLAN.
- Local Web Authentication: The controller intercepts htttp(s) traffic and redirects the client to the internal web page for authentication.
- External Web Authentication: The controller intercepts htttp(s) traffic and redirects the client to the login page hosted on the external web server for authentication.
- Central Web Authentication: The controller redirects all web traffic from the client to the ISE login page for authentication.

Configure WLAN profile and policy

Configure WLAN profile and policy details including network name, SSID, and associated policy parameters.

Configure the WLAN profile and policy to define wireless network properties and network policies for client switching and AP management.

After selecting the Authentication method, click on **WLAN** on the left panel to enter the WLAN profile and policy details.

The WLAN profile defines the properties of a WLAN such as Profile Name, Status, WLAN ID, L2 and L3 Security parameters, AAA Server associated with this SSID and other parameters that are specific to a particular WLAN. The policy profile defines the network policies and the switching policies for a client (with the exception of QoS), which constitute the AP policies as well.

Procedure

1. In the **Network Name** section, enter a **WLAN profile name**, which is a unique name for your wireless network. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
2. Enter a valid **SSID** for the WLAN. A valid SSID can be up to 32 characters and can contain spaces. A valid SSID can be ASCII characters from 0 to 31, with leading and trailing spaces. This is the broadcast name for your WLAN.
3. Enter the **WLAN ID**.
4. In the **WLAN Policy** section, enter the **Policy Profile name**. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
5. Select the **VLAN** to be associated with the Policy Profile from the drop-down list.
6. To select an existing Policy Profile for the WLAN, click on **Select Existing** and choose a **Policy Profile** from the drop-down list.

The WLAN profile and policy are configured with the specified network name, SSID, WLAN ID, and associated policy parameters.

Configure authentication for WLAN

Configure authentication configurations and filters for the WLAN depending on the selected authentication method.

Set up authentication configurations to secure your WLAN and control client access based on your chosen authentication method.

Authentication configurations include keys, filters, ACLs, and parameter maps that correspond to your selected authentication method. Each authentication method requires specific configuration steps to establish secure client connections.

Follow these steps to configure authentication for your WLAN:

Procedure

1. If you have selected **PSK** as the authentication method, configure these parameters:
   a) In the **WLAN > Pre-Shared Key (PSK)** section, select the PSK format. Choose between ASCII and Hexadecimal formats.
   b) From the **PSK type** drop-down list, choose if you want the key to be unencrypted or AES encrypted.
   c) In the **Pre-Shared Key** field, enter the pass key for the WLAN.
2. If you have selected **Dot1x** as the authentication method, configure the following:
   a) In the **WLAN > AAA** tab, configure the AAA server list for the WLAN.
   b) Select any of the available AAA servers to add to the WLAN.
   c) To add a new AAA server to the list, click on Add New Server and enter the IP address and server-key.

d) To use an already configured AAA server list, click on **Use Existing** and select the appropriate list from the drop-down.

3. If you have selected **Local Web Authentication** as the authentication method, configure these parameters:
   a) In the **WLAN > Parameter Map** tab, configure the parameter map for the WLAN. A parameter map sets parameters that can be applied to subscriber sessions during authentication.
      1. In the **Global Configuration** section, configure the global parameter map.
      2. Enter an IPv4 or IPv6 address to configure a virtual IP address for redirecting the clients to the login page of the controller.
      3. From the Trustpoint drop-down list, select the trustpoint for HTTPS login page. The trustpoint corresponds to the device certificate the controller will use in conjunction with the virtual IP and hostname.
      4. In the **WLAN Specific Configuration** section, either create a new parameter map for the WLAN, or select an existing parameter map from the drop-down list.

   b) In the **WLAN > Local Users** tab, enter the username in the local database to establish a username-based authentication system.
      1. Enter the user name to be saved.
      2. From the **Password Encryption** drop-down list, choose if you want the password to be unencrypted or encrypted.
      3. In the **Password** field, specify the password the user must enter to gain access to the switch. The password must be from 1 to 25 characters and can contain embedded spaces.
      4. Click on the **+** sign to add the credentials to the database. Add as many user credentials as required.

4. If you have selected **External Web Authentication** as the authentication method, configure these parameters:
   a) In the **WLAN > Parameter Map** tab, configure the parameter map for the WLAN.
      1. In the **Global Configuration** section, configure the global parameter map.
      2. Enter an IPv4 or IPv6 address to configure the virtual IP address of the external web authentication login page to which the guest users are redirected.
      3. From the **Trustpoint** drop-down list, select the trustpoint for HTTPS login page. The trustpoint corresponds to the device certificate the controller will use in conjunction with the virtual IP and hostname.
      4. In the **WLAN Specific Configuration** section, either create a new parameter map for the WLAN, or select an existing parameter map from the drop-down list.
      5. To create a new parameter map, enter the parameter-map name.
      6. In the **Redirect URL for login** field, enter the URL of the external server that will host the authentication page for login.
      7. In the **Portal IPV4 Address** field, enter the IPv4 address of the external server to send redirects. If the external server uses an IPv6 address, in the **Portal IPV6 Address** field, enter the IPv6 address of the portal to send redirects.

   b) In the **WLAN > ACL / URL Filter** tab, configure the ACL rules and the URL filter list.
      1. In the **Pre Auth ACL** section, enter the name of the ACL.
      2. In the **IP address** field, enter the source IP address and the destination IP address. This will configure the ACL to permit packet transfer from and to the specified IP address. You can add as many IP addresses as required.
      3. In the **URL Filter** section, enter a name for the URL Filter list that you are creating.

4. Use the slider to set the list action to **Permit** or **Deny** the URLs.
5. Specify the URLs in the **URLs** box. Enter every URL on a new line.

5. If you have selected Central Web Authentication as the authentication method, configure the following:
   a) In the **WLAN > AAA/ACL** tab, configure the AAA server list and ACL for the WLAN.
   b) In the **AAA Configuration** section, select any of the available AAA servers to add to the WLAN. This will be the server where the clients will get authenticated.
   c) To add a new AAA server to the list, click on **Add New Server** and enter the IP address and server-key.
   d) To use an already configured AAA server list, click on **Use Existing** and select the appropriate list from the drop-down.
   e) In the **ACL List** section, enter the name of the ACL. This ACL will contain the rules regarding URLs that can be accessed by the client and should match the name configured on the RADIUS server.

Configure tags on WLAN

Configure tags on WLAN to define properties through associated policies that are inherited by clients and access points.

Configure tags on WLAN to define properties through associated policies that are inherited by clients and access points.

A Tag's property is defined by the policies associated to it. This property is in turn inherited by an associated client/AP. There are various type of tags, each associated to different profiles.

Procedure

1. In the **Site Configuration** section, either enter a site tag to be added, or select an existing site tag from the drop-down list. You can add as many tags as required. In the local mode, the site tag contains the AP join profile only.
2. In the **Policy Tag** section, either enter a policy tag to be added, or select an existing policy tag from the drop-down list. You can add as many tags as required. The policy tag constitutes mapping of the WLAN profile to the policy profile. The WLAN profile defines the wireless characteristics of the WLAN. The policy profile defines the network policies and the switching policies for the client.
3. In the **RF Tag** section, either enter an RF tag to be added, or select an existing RF tag from the drop-down list. You can add as many tags as required. The RF tag contains the 2.4 GHz and 5 GHz RF profiles.

The tags are successfully configured on the WLAN. The properties defined by the policies associated with these tags will be inherited by the associated clients and access points.

AP Provision

Configure access point provisioning to associate APs with WLAN tags and locations.

This task allows you to add access points to the local site and associate them with appropriate tags for WLAN configuration.

Once the Wireless network and RF characteristics are set up, access points can be added to the local site either using static AP MAC address assignment or by assigning already joined APs to a specific location.

To add tags and associate APs to the WLAN, click **AP Provisioning** from the left panel.

Procedure

1. The APs already discovered by the controller are listed in the **Provision Joined APs** tab. You can select the APs to be associated to the WLAN from this table.
2. To add tags to the selected APs, select the appropriate Policy Tag, Site Tag, and RF Tag from the respective drop-down lists. Click on **Add** to apply the tags.

3. To add APs manually, click on the **Pre-provision APs** tab. You can either add individual MAC addresses of the APs or upload a CSV file with the AP MAC addresses listed. The added APs will be listed in the table below.
4. Select the APs to be associated to the WLAN from this table.
5. To add tags to the selected APs, select the appropriate Policy Tag, Site Tag, and RF Tag from the respective drop-down lists. Click on **Add** to apply the tags.

   A table of all the APs and the tags added to them is displayed in the **Selected APs** tab.

6. Click **Apply**.

   This will create a WLAN in local mode with the authentication method, authentication filters, tags, and APs configured on it.

The access points are successfully provisioned and associated with the configured tags, creating a WLAN in local mode with the specified authentication and configuration settings.

FlexConnect mode

Describes a wireless solution for branch office and remote office deployments.

FlexConnect mode is a wireless solution that

- enables configuration and control of access points (AP) in a branch or remote office from the corporate office through a wide area network (WAN) link without deploying a controller in each office
- allows FlexConnect APs to switch client data traffic and perform client authentication locally when their connection to the controller is lost, and
- offers network survivability in the event of a loss of connection to the centralized wireless controller.

FlexConnect mode deployment

This figure shows a FlexConnect mode deployment:

Authentication methods

Describes the methods by which clients can access WLANs in FlexConnect mode and the security levels they provide.

An authentication method is a security mechanism that

- sets the method by which a client can access the WLAN
- decides the level of security on the WLAN, and
- determines how traffic is intercepted and redirected for client authentication.

Authentication method options

To configure a WLAN for FlexConnect mode, select the preferred authentication method from the left panel. The authentication method options are:

- Local Web Authentication: The controller intercepts htttp(s) traffic and redirects the client to the internal web page for authentication.

- External Web Authentication: The controller intercepts htttp(s) traffic and redirects the client to the login page hosted on the external web server for authentication.
- Central Web Authentication: The controller redirects all web traffic from the client to the ISE login page for authentication.

Configure WLAN profile and policy

Configure WLAN profile and policy settings to define network properties and switching policies for wireless networks.

Configure WLAN profile and policy settings to establish wireless network connectivity with appropriate security parameters and client policies.

After selecting the Authentication method, click on **WLAN** on the left panel to enter the WLAN profile and policy details.

The WLAN profile defines the properties of a WLAN such as Profile Name, Status, WLAN ID, L2 and L3 Security parameters, AAA Server associated with this SSID and other parameters that are specific to a particular WLAN. The policy profile defines the network policies and the switching policies for a client (with the exception of QoS), which constitute the AP policies as well.

Procedure

1. In the **Network Name** section, enter a **WLAN profile name**, which is a unique name for your wireless network.

   The name can be ASCII characters from 32 to 126, without leading and trailing spaces.

2. Enter a valid **SSID** for the WLAN.

   A valid SSID can be up to 32 characters and can contain spaces. A valid SSID can be ASCII characters from 0 to 31, with leading and trailing spaces. This is the broadcast name for your WLAN.

3. Enter the **WLAN ID**.
4. In the **WLAN Policy** section, enter the **Policy Profile name**.

   The name can be ASCII characters from 32 to 126, without leading and trailing spaces.

5. Select the **VLAN** to be associated with the Policy Profile from the drop-down list.
6. To select an existing Policy Profile for the WLAN, click on **Select Existing** and choose a **Policy Profile** from the drop-down list.

The WLAN profile and policy are configured with the specified network name, SSID, WLAN ID, and associated VLAN settings for wireless network connectivity.

Configure authentication configurations

Configure authentication settings and filters for the WLAN depending on your selected authentication method.

Configure authentication settings, keys, filters, ACLs, and parameter maps for your selected WLAN authentication method to enable secure wireless access for users.

Set up the authentication configurations and filters for the WLAN depending on the method you have chosen. These include the keys, filters, ACLs, and parameter maps as applicable to the selected authentication method.

Follow these steps to configure authentication configurations:

Procedure

1. If you have selected **Local Web Authentication** as the authentication method, configure the following:

a) In the **WLAN > Parameter Map** tab, configure the parameter map for the WLAN. A parameter map sets parameters that can be applied to subscriber sessions during authentication.

1. In the **Global Configuration** section, configure the global parameter map.
2. Enter an IPv4 or IPv6 address to configure a virtual IP address for redirecting the clients to the login page of the controller.
3. From the **Trustpoint** drop-down list, select the trustpoint for HTTPS login page. The trustpoint corresponds to the device certificate the controller will use in conjunction with the virtual IP and hostname.
4. In the **WLAN Specific Configuration** section, either create a new parameter map for the WLAN, or select an existing parameter map from the drop-down list.

b) In the WLAN > Local Users / Flex tab, configure a Flex profile and enter the username in the local database to establish a username-based authentication system.

1. In the **Flex Profile** section, enter the name of the new flex profile and the native VLAN ID.
2. To use an already existing Flex profile, click on **Select Existing** to choose a profile from the drop-down list and enter the native VLAN ID.
3. In the **Local Users** section, enter the user name to be saved.
4. From the **Password Encryption** drop-down list, choose if you want the password to be unencrypted or encrypted.
5. In the **Password** field, specify the password the user must enter to gain access to the switch. The password must be from 1 to 25 characters and can contain embedded spaces.
6. Click on the **+** sign to add the credentials to the database. Add as many user credentials as required.

2. If you have selected **External Web Authentication** as the authentication method, configure the following:

a) In the **WLAN > Parameter Map** tab, configure the parameter map for the WLAN.

1. In the **Global Configuration** section, configure the global parameter map.
2. Enter an IPv4 or IPv6 address to configure the virtual IP address of the external web authentication login page to which the guest users are redirected.
3. From the **Trustpoint** drop-down list, select the trustpoint for HTTPS login page. The trustpoint corresponds to the device certificate the controller will use in conjunction with the virtual IP and hostname.
4. In the **WLAN Specific Configuration** section, either create a new parameter map for the WLAN, or select an existing parameter map from the drop-down list.
5. To create a new parameter map, enter the parameter-map name.
6. In the **Redirect URL for login** field, enter the URL of the external server that will host the authentication page for login.
7. In the **Portal IPV4 Address** field, enter the IPv4 address of the external server to send redirects. If the external server uses an IPv6 address, in the **Portal IPV6 Address** field, enter the IPv6 address of the portal to send redirects.

b) In the **WLAN > ACL / URL Filter** tab, configure the ACL rules and the URL filter list.

1. In the **Flex Profile** section, enter the name of the new flex profile and the native VLAN ID.
2. To use an already existing Flex profile, click on **Select Existing** to choose a profile from the drop-down list and enter the native VLAN ID.
3. In the **Pre Auth ACL** section, enter the name of the ACL.

4. In the **IP address** field, enter the source IP address and the destination IP address. This will configure the ACL to permit packet transfer from and to the specified IP address. You can add as many IP addresses as required.
5. In the **URL Filter** section, enter a name for the URL Filter list that you are creating.
6. Click on **Add** to add the URLs.
7. Specify the URL to be added to the list and its preference.
8. Use the slider to set the list action to **Permit** or **Deny** the URLs.
9. Click **Save**.

   You can add as many URLs to the list as required.

c) To add a new AAA server to the list, click on Add New Server and enter the IP address and server-key.
d) To use an already configured AAA server list, click on **Use Existing** and select the appropriate list from the drop-down.

3. If you have selected **Central Web Authentication** as the authentication method, configure the following:
   a) In the **WLAN > AAA/ACL** tab, configure the AAA server list and ACL for the WLAN.
   b) In the **AAA Configuration** section, select any of the available AAA servers to add to the WLAN. This will be the server where the clients will get authenticated.
   c) To add a new AAA server to the list, click on **Add New Server** and enter the IP address and server-key.
   d) To use an already configured AAA server list, click on **Use Existing** and select the appropriate list from the drop-down.
   e) In the **Flex Profile** section, enter the name of the new flex profile and the native VLAN ID.
   f) To use an already existing Flex profile, click on **Select Existing** to choose a profile from the drop-down list and enter the native VLAN ID.
   g) In the **ACL List** section, enter the name of the ACL. This ACL will contain the rules regarding URLs that can be accessed by the client and should match the name configured on the RADIUS server.

Configure tags on WLAN

Configure tags on WLAN to define properties through associated policies that are inherited by clients and access points.

Configure tags on WLAN to define properties through associated policies that are inherited by clients and access points.

A Tag's property is defined by the policies associated to it. This property is in turn inherited by an associated client/AP. There are various type of tags, each associated to different profiles.

Follow these steps to configure tags on WLAN:

Procedure

---

1. In the **Site Configuration** section, either enter a site tag to be added, or select an existing site tag from the drop-down list. You can add as many tags as required. In FlexConnect mode, the site tag contains the AP join profile and the Flex profile.
2. In the **Policy Tag** section, either enter a policy tag to be added, or select an existing policy tag from the drop-down list. You can add as many tags as required. The policy tag constitutes mapping of the WLAN profile to the policy profile. The WLAN profile defines the wireless characteristics of the WLAN. The policy profile defines the network policies and the switching policies for the client.
3. In the **RF Tag** section, either enter an RF tag to be added, or select an existing RF tag from the drop-down list. You can add as many tags as required. The RF tag contains the 2.4 GHz and 5 GHz RF profiles.

The tags are configured on the WLAN with their associated policies and profiles.

AP Provision

Configure access point provisioning to associate APs with WLAN tags and locations.

Access point provisioning allows you to associate discovered or manually added APs with specific WLAN configurations by applying policy, site, and RF tags.

Once the Wireless network and RF characteristics are set up, access points can be added to the local site either using static AP MAC address assignment or by assigning already joined APs to a specific location.

Follow these steps to provision access points and apply tags to associate them with the WLAN:

Procedure

1. To add tags and associate APs to the WLAN, click on **AP Provisioning** from the left panel.
2. The APs already discovered by the controller are listed in the **Provision Joined APs** tab. You can select the APs to be associated to the WLAN from this table.
3. To add tags to the selected APs, select the appropriate Policy Tag, Site Tag, and RF Tag from the respective drop-down lists. Click on **Add** to apply the tags.
4. To add APs manually, click on the **Pre-provision APs** tab. You can either add individual MAC addresses of the APs or upload a CSV file with the AP MAC addresses listed. The added APs will be listed in the table below.
5. Select the APs to be associated to the WLAN from this table.
6. To add tags to the selected APs, select the appropriate Policy Tag, Site Tag, and RF Tag from the respective drop-down lists. Click on **Add** to apply the tags.

   A table of all the APs and the tags added to them is displayed in the **Selected APs** tab.
7. Click **Apply**.

   This will create a WLAN in FlexConnect mode with the authentication method, authentication filters, tags, and APs configured on it.

The access points are successfully provisioned and associated with the WLAN configuration. A WLAN in FlexConnect mode is created with the specified authentication method, authentication filters, tags, and APs.

Guest CWA mode

Explains a secure wireless guest network implementation using Central Web Authentication for accountable internet access to visitors.

Guest CWA mode is a wireless network security implementation that

- provides secure and accountable internet access to visitors using Central Web Authentication
- uses the enterprise's existing wireless and wired infrastructure to the maximum extent, and
- comprises two controllers - a Guest Foreign and a Guest Anchor.

Guest CWA mode implementation

The Guest mode addresses the need to provide internet access to guests in a secure and accountable manner with Central Web Authentication as the security method.

Controller types

Describes the types of controllers available for WLAN Guest CWA mode configuration.

A controller type is a WLAN configuration category that

- determines how controllers manage guest client connections and traffic
- defines the role each controller plays in the guest access network, and
- enables proper traffic flow and security implementation for guest WLAN services.

Controller type options

To configure a WLAN for Guest CWA mode, select the type of controller configuration you want to set up on the device from the left panel.

The controller type options are:

- Foreign: A Foreign is a controller in the WLAN that exists in the enterprise. A client sends a connection request to a Foreign controller to join the WLAN. It is a dedicated guest WLAN or SSID and is implemented throughout the campus wireless network wherever guest access is required. The Foreign controller manages the anchor controllers.
- Anchor: An Anchor is a controller or group of controllers in a WLAN that manage traffic within the network for a guest client. It provides internal security by forwarding the traffic from a guest client to a Cisco Wireless Controller in the demilitarized zone (DMZ) network.

Configure WLAN profile and policy

Configure WLAN profile and policy settings to define wireless network properties and network policies for client switching.

Configure WLAN profile and policy settings to establish wireless network connectivity and define network switching policies for clients.

After selecting the Authentication method, click on **WLAN** on the left panel to enter the WLAN profile and policy details.

The WLAN profile defines the properties of a WLAN such as Profile Name, Status, WLAN ID, L2 and L3 Security parameters, AAA Server associated with this SSID and other parameters that are specific to a particular WLAN. The policy profile defines the network policies and the switching policies for a client (with the exception of QoS), which constitute the AP policies as well.

Procedure

1. In the **Network Name** section, enter a **WLAN profile name**, which is a unique name for your wireless network. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
2. Enter a valid **SSID** for the WLAN. A valid SSID can be up to 32 characters and can contain spaces. A valid SSID can be ASCII characters from 0 to 31, with leading and trailing spaces. This is the broadcast name for your WLAN.
3. Enter the **WLAN ID**.
4. In the **WLAN Policy** section, enter the **Policy Profile name**. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
5. Select the **VLAN** to be associated with the Policy Profile from the drop-down list..

6. To select an existing Policy Profile for the WLAN, click on **Select Existing** and choose a **Policy Profile** from the drop-down list..
7. If you have selected **Foreign**, in the **Mobility Anchors** section, select the IP address of an available controller to assign it as the mobility anchor for the WLAN. This will extend the configurations on the Foreign controller onto the anchor controllers as well.

The WLAN profile and policy are configured with the specified network name, SSID, WLAN ID, and policy settings. The wireless network is ready for client connections with the defined switching policies.

Configure authentication for guest access

Configure authentication settings for guest access mode using Central Web Authentication.

Configure AAA server settings and access control lists to enable guest authentication through Central Web Authentication for WLAN access.

For the Guest access mode, the authentication method is Central Web Authentication. This configuration allows guest users to authenticate through a centralized web portal before gaining network access.

Procedure

---

1. In the **WLAN > AAA/ACL** tab, configure the AAA server list and ACL for the WLAN.
2. In the **AAA Configuration** section, select any of the available AAA servers to add to the WLAN.

   This will be the server where the clients will get authenticated.
3. To add a new AAA server to the list, click on **Add New Server** and enter the IP address and server-key.
4. To use an already configured AAA server list, click on **Use Existing** and select the appropriate list from the drop-down.
5. In the **ACL List** section, enter the name of the ACL.

   This ACL will contain the rules regarding URLs that can be accessed by the client and should match the name configured on the RADIUS server.

The WLAN is now configured with AAA authentication settings for guest access, allowing clients to authenticate through the specified AAA servers and apply the configured access control rules.

Configure tags on WLAN

Configure tags on WLAN to define properties inherited by associated clients and access points.

Configure tags to define properties that are inherited by associated clients and access points through various policy profiles.

A Tag's property is defined by the policies associated to it. This property is in turn inherited by an associated client/AP. There are various type of tags, each associated to different profiles.

Procedure

---

1. In the **Site Configuration** section, either enter a site tag to be added, or select an existing site tag from the drop-down list. You can add as many tags as required.
2. In the **Policy Tag** section, either enter a policy tag to be added, or select an existing policy tag from the drop-down list. You can add as many tags as required. The policy tag constitutes mapping of the WLAN profile to the policy profile. The WLAN profile defines the wireless characteristics of the WLAN. The policy profile defines the network policies and the switching policies for the client.

3. In the **RF Tag** section, either enter an RF tag to be added, or select an existing RF tag from the drop-down list. You can add as many tags as required. The RF tag contains the 2.4 GHz and 5 GHz RF profiles.

Tags are configured on the WLAN with site configuration, policy, and RF tags that define the properties inherited by associated clients and access points.

AP provision

Configure access point provisioning for wireless networks by adding tags and associating APs to the WLAN.

This task enables you to add access points to the local site and associate them with the wireless LAN configuration by applying appropriate tags.

Once the Wireless network and RF characteristics are set up, access points can be added to the local site either using static AP MAC address assignment or by assigning already joined APs to a specific location.

If you have selected **Foreign**, click on **AP Provisioning** from the left panel to add tags and associate APs to the WLAN.

Procedure

---

1. The APs already discovered by the controller are listed in the **Provision Joined APs** tab. You can select the APs to be associated to the WLAN from this table.
2. To add tags to the selected APs, select the appropriate Policy Tag, Site Tag, and RF Tag from the respective drop-down lists. Click on **Add** to apply the tags.
3. To add APs manually, click on the **Pre-provision APs** tab. You can either add individual MAC addresses of the APs or upload a CSV file with the AP MAC addresses listed. The added APs will be listed in the table below.
4. Select the APs to be associated to the WLAN from this table.
5. To add tags to the selected APs, select the appropriate Policy Tag, Site Tag, and RF Tag from the respective drop-down lists. Click on **Add** to apply the tags.

   A table of all the APs and the tags added to them is displayed in the **Selected APs** tab.

6. Click **Apply**.

   This will create a WLAN in Guest CWA mode with the authentication method, mobility anchors, authentication filters, tags, and APs configured on it.

The access points are successfully provisioned and associated with the WLAN configuration. A WLAN in Guest CWA mode is created with the specified authentication method, mobility anchors, authentication filters, tags, and APs.

Create WLANs (GUI)

Configure WLANs using the GUI interface.

Create wireless local area networks (WLANs) to enable network connectivity and manage wireless access configurations through the GUI interface.

Use the GUI interface to create and configure WLANs when you need to establish wireless network connectivity. This method provides a visual interface for WLAN configuration and management.

Procedure

---

1. In the **Configuration** > **Tags & Profiles** > **WLANs** page, click **Add**.

   The **Add WLAN** window is displayed.

2. Under the **General** tab and **Profile Name** field, enter the name of the WLAN. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
3. Click **Save & Apply to Device**.

The WLAN is created and applied to the device. The new WLAN appears in the WLANs list and is ready for use.

Create WLANs (CLI)

Create WLANs using commands.

Create wireless local area networks (WLANs) to provide wireless network access for clients.

You can create SSID using GUI or CLI. However, we recommend that you use CLI to create SSID. By default, the WLAN is disabled after creation.

Follow these steps to create WLANs using CLI commands:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the WLAN name and ID.

   Example

   ```
   Device(config)# wlan profile-name wlan-id [ssid]
   ```

   Example

   ```
   Device(config)# wlan profile-name wlan-id [ssid] mywlan 34 mywlan-SSID
   ```

   - For the *profile-name*, enter the profile name. The range is from 1 to 32 alphanumeric characters.
   - For the *wlan-id*, enter the WLAN ID. The range is from 1 to 512.
   - For the *ssid*, enter the Service Set Identifier (SSID) for this WLAN. If the SSID is not specified, the WLAN profile name is set as the SSID.

   Note

   - You can create SSID using GUI or CLI. However, we recommend that you use CLI to create SSID.
   - By default, the WLAN is disabled.

3. Return to privileged EXEC mode.

Example

```
Device# end
```

Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The WLAN is created with the specified profile name, WLAN ID, and SSID. The WLAN is disabled by default and must be enabled separately for use.

Delete WLANs (GUI)

Configure WLAN deletion using the GUI interface.

Remove unwanted or obsolete WLANs from your network configuration to maintain optimal performance and security.

Use this procedure when you need to remove WLANs that are no longer required or need to be replaced with new configurations. This task can be performed on single or multiple WLANs simultaneously.

Procedure

---

1. In the **Configuration** > **Tags & Profiles** > **WLANs** page, check the check box adjacent to the WLAN you want to delete.

   To delete multiple WLANs, select multiple WLANs check boxes.
2. Click **Delete**.
3. Click **Yes** on the confirmation window to delete the WLAN.

The selected WLAN(s) are permanently removed from the system and will no longer appear in the WLANs list.

Delete WLANs (CLI)

Configure WLAN deletion using CLI commands to remove WLAN profiles from the wireless network configuration.

Delete WLAN profiles that are no longer needed or require reconfiguration in the wireless network environment.

Use this procedure when you need to remove WLAN profiles from the wireless controller configuration. Deleting a WLAN removes the profile and associated settings from the system.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Delete the WLAN.

Example

```
Device(config)# no wlan wlan-profile-name wlan-id  [ssid]
```

```
Device(config)# no wlan test2
```

The arguments are:

- The *wlan-name* is the WLAN profile name.
- The *wlan-id* is the WLAN ID.
- The *ssid* is the WLAN SSID name configured for the WLAN.

> **Note**
>
> If you delete a WLAN that is part of an AP group, the WLAN is removed from the AP group and from the AP's radio.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The WLAN profile is deleted from the wireless controller configuration. If the WLAN was associated with an AP group, it is automatically removed from the group and the AP's radio interface.

WLAN search methods (CLI)

Lists commands for searching WLANs using the command-line interface.

To verify the list of all WLANs configured on the controller, use this command:

```
Device# show wlan summary
Number of WLANs: 4

WLAN Profile Name                     SSID                           VLAN
Status
-------------------------------------------------------------------------------
1    test1                            test1-SSID                     137  UP
3    test2                            test2-SSID                     136  UP
2    test3                            test3-SSID                     1    UP
45   test4                            test4-SSID                     1
DOWN
```

To use wild cards and search for WLANs, use this **show** command:

```
Device# show wlan summary | include test-wlan-ssid
1    test-wlan                        test-wlan-ssid                  137
 UP
```

Enable WLANs (GUI)

Enable WLANs using the graphical user interface.

Enable wireless local area networks (WLANs) to allow wireless client connections and network access through the graphical user interface.

Use this task when you need to activate WLANs that have been configured but are currently disabled, allowing wireless devices to connect to your network.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. On the **WLANs** page, click the WLAN name.
3. In the **Edit WLAN** window, toggle the **Status** button to **ENABLED**.
4. Click **Update & Apply to Device**.

The WLAN is ENABLED and wireless clients can now connect to the network through this WLAN.

Enable WLANs (CLI)

Configure WLANs using commands.

Enable previously configured WLANs to make them operational and available for client connections.

WLANs must be explicitly enabled after configuration to allow wireless clients to connect. This procedure activates a specific WLAN profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. Enter WLAN configuration submode.

   Example

   ```
   Device(config)# WLAN profile-name
   ```

   Example

   ```
   Device(config)# WLAN test4
   ```

   The *profile-name* is the profile name of the configured WLAN.

3. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

4. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The WLAN is now enabled and operational, allowing wireless clients to connect to the network.

Disable WLANs (GUI)

Configure WLAN settings to disable wireless local area networks using the GUI interface.

Disable WLANs to prevent wireless network access when maintenance is required or to temporarily suspend wireless services.

Use this procedure when you need to temporarily disable wireless networks without deleting the WLAN configuration. The WLAN settings remain intact and can be re-enabled later.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. In the **WLANs** window, click the WLAN name.
3. In the **Edit WLAN** window, set the **Status** toggle button as **DISABLED**.
4. Click **Update & Apply to Device**.

The WLAN is DISABLED and wireless clients can no longer connect to this network. The WLAN configuration is preserved and can be re-enabled when needed.

Disable WLANs (CLI)

Disable WLANs using commands.

Disable specific WLANs to prevent wireless client access when needed for maintenance or security purposes.

You may need to disable WLANs temporarily for maintenance, troubleshooting, or security reasons. This procedure shows how to disable a WLAN using the CLI and verify the change.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enter WLAN configuration submode.

Example

```
Device(config)# wlan profile-name
```

Example

```
Device(config)# wlan test4
```

The *profile-name* is the profile name of the configured WLAN.

3. Disable the WLAN.

Example

```
Device(config-wlan)# shutdown
```

4. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

5. Display the list of all WLANs configured on the device.

Example

```
Device# show wlan summary
```

You can search for the WLAN in the output to verify it has been disabled.

The specified WLAN is now disabled and will not accept wireless client connections until re-enabled.

Configure general WLAN properties (CLI)

Configure general WLAN properties using commands.

Configure media stream, broadcast SSID, and radio properties for a WLAN.

You can configure these properties: Media stream, Broadcast SSID, and Radio settings for optimal WLAN performance and visibility.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enter WLAN configuration submode.

Example

```
Device(config)# wlan profile-name
```

Example

```
Device(config)# wlan test4
```

The *profile-name* is the profile name of the configured WLAN.

3. Disable the WLAN.

Example

```
Device(config-wlan)# shutdown
```

4. Broadcast the SSID for this WLAN.

Example

```
Device(config-wlan)# broadcast-SSID
```

5. Configure the WLAN radio policy for dot11 radios.

Example

```
Device(config-wlan)# dot11bg 11g
```

Also see the section: Configuring a WLAN Radio Policy.

6. Enable multicast VLANs on this WLAN.

Example

```
Device(config-WLAN)# media-stream multicast-direct
```

7. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

8. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The WLAN is now configured with the specified general properties including media stream, broadcast SSID, and radio settings.

Configure advanced WLAN properties (CLI)

Configure advanced WLAN properties using commands.

Configure advanced WLAN properties to customize wireless network behavior and security settings.

Advanced WLAN properties provide additional configuration options for wireless networks, including coverage hole detection, client association limits, access control, and peer-to-peer blocking settings. These configurations help optimize wireless performance and security based on specific network requirements.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter WLAN configuration submode.

   Example

   ```
   Device(config)# wlan profile-name
   ```

   Example

   ```
   Device(config)# wlan test4
   ```

   The *profile-name* is the profile name of the configured WLAN.

3. Enable coverage hole detection for this WLAN.

   Example

   ```
   Device(config-wlan)# chd
   ```

4. Enable support for Aironet IEs for this WLAN.

   Example

   ```
   Device(config-wlan)# ccx aironet-iesupport
   ```

5. Set the maximum number of clients that can be configured on a WLAN. Configure limits for clients per WLAN, clients per AP, or clients per AP radio.

   Example

   ```
   Device(config-wlan)# client association limit {clients-per-WLAN | ap
   clients-per-AP-per-WLAN | radio clients-per-AP-radio-per-WLAN}
   ```

   Example

   ```
   Device(config-wlan)# client association limit AP 400
   ```

6. Configure the IPv4 WLAN web ACL.

   Example

   ```
   Device(config-wlan)# ip access-group web ACL-name
   ```

   Example

   ```
   Device(config-wlan)# ip access-group web test-ACL-name
   ```

   The *ACL-name* specifies the user-defined IPv4 ACL name.

7. Configure peer-to-peer blocking parameters.

   Example

   ```
   Device(config-wlan)# peer-blocking [allow-private-group | drop |
   forward-upstream]
   ```

   Example

   ```
   Device(config-WLAN)# peer-blocking drop
   ```

   The keywords are:

   - **allow-private-group**: Enables peer-to-peer blocking on the Allow Private Group action.
   - **drop**: Enables peer-to-peer blocking on the drop action.
   - **forward-upstream**: No action is taken and forwards packets to the upstream.

   > **Note**
   >
   > The **forward-upstream** option is not supported for Flex local switching. Traffic is dropped even if this option is configured. Also, peer to peer blocking for local switching SSIDs are available only for the clients on the same AP.

8. Set the channel scan defer priority and defer time.

   Example

   ```
   Device(config-WLAN)# channel-scan {defer-priority {0-7} | defer-time {0-6000}}
   ```

   Example

   ```
   Device(config-WLAN)# channel-scan defer-priority 6
   ```

   The arguments are:

   - **defer-priority**: Specifies the priority markings for packets that can defer off-channel scanning. The range is from 0 to 7. The default is 3.

- **defer-time**: Deferral time in milliseconds. The range is from 0 to 6000. The default is 100.

9. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The advanced WLAN properties are now configured with the specified settings for coverage hole detection, client limits, access control, peer-to-peer blocking,broadcast filtering, AAA override, session timeout, exclusion list management, and diagnostic channel support.

Configure advanced WLAN properties (GUI)

Configure advanced WLAN properties using the GUI to enable features such as coverage hole detection, Aironet IE, diagnostic channel, and 802.11v BSS Transition support.

Configure advanced WLAN properties to enable enhanced wireless network features including coverage optimization, client connection limits, BSS transition support, and 802.11ax capabilities.

Advanced WLAN properties provide additional configuration options to optimize wireless network performance and enable specific features for client management and network diagnostics.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs** .
2. Click **Add**.
3. Under the **Advanced** tab, check the **Coverage Hole Detection** check box.
4. Check the **Aironet IE** check box to enable Aironet IE on the WLAN.
5. Check the **Diagnostic Channel** check box to enable diagnostic channel on the WLAN.
6. From the **P2P Blocking Action** drop-down list, choose the required value.
7. Set the **Multicast Buffer** toggle button as enabled or diabled.
8. Check the **Media Stream Multicast-Direct** check box to enable the feature.
9. In the **Max Client Connections** section, specify the maximum number of client connections for the following:
   - In the **Per WLAN** field, enter a value. The valid range is between 0 and 10000.
   - In the **Per AP Per WLAN** field, enter a value. The valid range is between 0 and 400.
   - In the **Per AP Radio Per WLAN** field, enter a value. The valid range is between 0 and 200.
10. In the **11v BSS Transition Support** section, perform the following configuration tasks:
    a) Check the BSS Transition check box to enable 802.11v BSS Transition support.
    b) In the **Disassociation Imminent** field, enter a value. The valid range is between 0 and 3000.
    c) In the **Optimized Roaming Disassociation Timer** field, enter a value. The valid range is between 0 and 40.
    d) Select the check box to enable:
       - BSS Max Idle Service
       - BSS Max Idle Protected
       - Disassociation Imminent Service

- Directed Multicast Service
- Universal Admin
- Load Balance
- Band Select
- IP Source Guard

11. In the 11ax section, perform these configuration tasks:

a) Select the check box to enable these parameters:

- Check the **Enable 11ax** checkbox to enable 802.11ax operation status on the WLAN.
- Check the **Downlink OFDMA** and **Uplink OFDMA** check boxes to enable downlink and uplink connections that use OFDMA.

  Orthogonal Frequency Division Multiple Access (OFDMA) is a channel access mechanism that assures contention-free transmission to multiple clients in both the downlink (DL) and uplink (UL) within a respective single transmit opportunity.
- Check the **Downlink MU-MIMO** and **Uplink MU-MIMO** check boxes to enable downlink and uplink connections that use MU-MIMO.

  With Multiuser MIMO (MU-MIMO), an AP can use its antenna resources to transmit multiple frames to different clients, all at the same time and over the same frequency spectrum.
- Enable the target wake up time configuration on the WLAN by checking the **BSS Target Wake Up Time** checkbox.

  Target wake up time allows an AP to manage activity in the Wi-Fi network to minimize medium contention between stations, and to reduce the required amount of time that a station in the power-save mode needs to be awake. This is achieved by allocating stations to operate at non-overlapping times, and/or frequencies, and concentrate the frame exchanges in predefined service periods.
- Check the **Universal Admin** check box to enable Universal Admin support for the WLAN.
- Enable OKC on the WLAN by checking the **OKC** check box. Opportunistic Key Caching (OKC) allows the wireless client and the WLAN infrastructure to cache only one Pairwise Master Key (PMK) for the lifetime of the client association with this WLAN, even when roaming between multiple APs. This is enabled by default.
- Check the **Load Balance** check box to enable Aggressive Client Load Balancing. This allows lightweight access points to load balance wireless clients across access points.
- Check the **Band Select** check box to enable band selection for the WLAN. Band selection enables client radios that are capable of dual-band (2.4 and 5-GHz) operations to move to a less congested 5-GHz access point. The 2.4-GHz band is often congested with interference from other electronic devices as well as co-channel interference from other access points. Band selection helps prevent these sources of interference and improve overall network performance.
- Enable IP Source Guard on the WLAN by checking the **IP Source Guard** check box. IP Source Guard (IPSG) is a Layer 2 security feature that prevents the wireless controller from forwarding the packets with source IP addresses that are not known to it.

b) From the **WMM Policy** drop-down list, choose the policy as **Allowed**, **Disabled**, or **Required**. By default, the WMM policy is **Allowed**. Wi-Fi Multimedia (WMM) is used to prioritize different types of traffic.

- **Disabled**: Disables WMM on the WLAN.
- **Required**: Requires client devices to use WMM. Devices that do not support WMM cannot join the WLAN.
- **Allowed**: Devices that cannot support WMM can join the WLAN but will not benefit from the 802.11n rates.

c) From the **mDNS** drop-down list, choose **Bridging**, **Gateway**, or **Drop**. Multicast DNS (mDNS) provides the ability to perform DNS-like operations on the local link in the absence of any conventional Unicast DNS server.

- **Bridging**: Packets with mDNS multicast IP and multicast mac will be sent on multicast CAPWAP tunnel.
- **Gateway**: All ingress mDNS packets received from the wired network on a L3 interface (SVI or physical) would be intercepted by the Controller software and processed.
- **Drop**: All ingress mDNS packets will be dropped.

12. In the **Off Channel Scanning Defer** section, choose the appropriate **Defer Priority** values and then specify the required Scan Defer Time value in milliseconds.
13. In the **Assisted Roaming (11k)** section, choose the appropriate status for:
    - Prediction Optimization
    - Neighbor List
    - Dual-Band Neighbor List
14. In the **DTIM Period (in beacon intervals)** section, specify a value for 802.11a/n and 802.11b/g/n radios. The valid range is from 1 to 255.
15. Click **Apply to Device**.

The WLAN profile is updated with advanced properties, and features such as coverage optimization, client connection limits, enhanced roaming, and diagnostics are enabled for improved network performance.

Configure WLAN radio policy (GUI)

Configure WLAN radio policy using the GUI interface.

Configure a WLAN radio policy to define the radio bands and settings for wireless network operation through the graphical user interface.

Use this procedure when you need to set up radio policies for WLANs to control which radio bands (2.4 GHz or 5 GHz) are used and configure related settings for optimal wireless network performance.

Procedure

---

1. On the **Configuration** > **Tags & Profiles** > **WLANs** page, click **Add** to create WLANs.
2. In the **General** tab, enter a **Profile Name**, which is a unique name of the your wireless network.

   The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
3. Enter a valid **SSID** for the WLAN.

   A valid SSID can be up to 32 characters and can contain spaces. A valid SSID can be ASCII characters from 0 to 31, with leading and trailing spaces. This is the broadcast name for your WLAN.
4. Enter the **WLAN ID**.

   The valid range for the different models are listed below:

Model	WLAN ID Range
Cisco Catalyst 9800-80 Wireless Controller	1-4096
Cisco Catalyst 9800-CL Wireless Controller	1-4096

Model	WLAN ID Range
Cisco Catalyst 9800-40 Wireless Controller	1-4096
Cisco Catalyst 9800-L Wireless Controller	1-4096
Cisco Embedded Wireless Controller for an AP	1-16

5. Set the WLAN **Status** to Enabled.
6. To broadcast the SSID of the WLAN, set the status of Broadcast SSID to enabled.

   By default, this is disabled.
7. In the **Radio Policy** section, enable the desired radio band for the WLAN.
   - 2.4ghz: Configures the policy on the 2.4 GHz radio.
   - 5ghz: Configures the policy on the 5 GHz radio.
8. If you enable the 5 Ghz radio band, select the radio slot to broadcast the WLAN on.

   The options are slot 0, slot 1, and slot 2. You can select multiple slots for the WLAN.
9. From the **802.11b/g Policy** drop-down list, choose the radio policy from these options:
   - 802.11g only
   - 802.11b/g
10. Click **Apply to Device**.

The WLAN radio policy is configured and applied to the device with the specified radio bands and settings.

Configure a WLAN radio policy (CLI)

Configure WLAN radio policy using commands to enable the WLAN on specific radio bands and slots.

Configure WLAN radio policy to control which radio bands and slots the WLAN operates on.

Use this procedure to configure WLAN radio policy settings when you need to specify which radio bands (2.4 GHz, 5 GHz, or 6 GHz) and which radio slots the WLAN should use for wireless communication.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Enter WLAN configuration submode.

   Example

   ```
   Device(config)# wlan profile-name
   ```

Example

```
Device(config)# wlan test4
```

The *profile-name* is the profile name of the configured WLAN.

3. Disable the WLAN.

Example

```
Device(config-wlan)# shutdown
```

4. Enable the corresponding radio policy on the WLAN.

Example

```
Device(config-wlan)# radio policy dot11 {5ghz | 24ghz | 6ghz }
```

Example

```
Device(config-wlan)# radio policy dot11 5ghz
```

The options are:

- **2.4ghz**: Configures the WLAN on 2.4-GHz radio only.
- **5ghz**: Configures the WLAN on 5-GHz radio only.
- **6ghz**: Configures the WLAN on 6-GHz radio only.

5. Configure the WLAN radio policy on the slot that you choose.

Example

```
Device(config-wlan-radio-5ghz)# slot slot-number
```

Example

```
Device(config-wlan-radio-5ghz)# slot 1
```

The options are:

- **0**: Configures the WLAN on the 5GHz radio with radio slot 0 (if using 5GHz).
- **1**: Configures the WLAN on the 5GHz radio with radio slot 1.
- **2**: Configures the WLAN on the 5GHz radio with radio slot 2 (if present).

6. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

7. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The WLAN is now configured with the specified radio policy and will operate on the designated radio band and slot.

Configure AP name advertisement in beacons (GUI)

To enable the inclusion of the AP hostname in beacon and probe responses, preventing truncation.

This feature allows the AP name to be extended to 32 characters, matching the maximum length in the controller. The configuration is available through CLI, NETCONF-YANG, and WebUI. By default, this feature is disabled.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
   The Add WLAN page is displayed.
3. Click the **Advanced** tab.
4. Check the **Advertise AP Name** check box to include the AP hostname in beacon and probe responses. This feature is disabled by default.
5. Click **Apply to Device**.

The AP includes its hostname in beacon and probe responses.

Configure AP name advertisement in beacons

To enable the inclusion of the AP hostname in beacon and probe responses, preventing truncation.

This feature allows the AP name to be extended to 32 characters, matching the maximum length in the controller. The configuration is available via CLI, NETCONF-YANG, and WebUI. By default, this feature is disabled.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter WLAN profile configuration mode for the desired WLAN.

   Example

   ```
   Device(config)# wlan wlan-prof-name wlan-id ssid-name
   ```

3. Disable the WLAN to allow configuration changes.

Example

```
Device(config-wlan)# shutdown
```

4. Enable AP name advertisement.

Example

```
Device(config-wlan)# advertise ap-name
```

5. Enable WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The AP now includes its hostname in beacon and probe responses.

```
Device# configure terminal
Device(config)# wlan wlan-profile1 25 ssid1
Device(config-wlan)# shutdown
Device(config-wlan)# advertise ap-name
Device(config-wlan)# no shutdown
```

WLAN properties verification (CLI)

Lists commands to verify WLAN properties using CLI commands.

To verify the WLAN properties based on the WLAN ID, use this command:

```
Device# show wlan ID wlan-id
```

To verify the WLAN properties based on the WLAN name, use this command:

```
Device# show wlan name wlan-name
```

To verify the WLAN properties of all the configured WLANs, use this command:

```
Device# show wlan all
```

To verify the summary of all WLANs, use this command:

```
Device# show wlan summary
```

To verify the running configuration of a WLAN based on the WLAN name, use this command:

```
Device# show running-config wlan wlan-name
```

To verify the running configuration of all WLANs, use this command:

```
Device# show running-config wlan
```

Verify WLAN-VLAN information of an AP

Lists the command to verify operational WLAN-VLAN mappings per AP.

To verify the operational WLAN-VLAN mappings per AP, use this command:

```
Device# show AP name test wlan vlan
Policy tag mapping
------------------
WLAN Profile Name Name Policy    VLAN   Flex Central Switching  IPv4 ACL
IPv6 ACL
-----------------------------------------------------------------------------------
jey_cwa            pp-local-1     46       Enabled               jey_acl1
Not Configured
swaguest           pp-local-1     46       Enabled               jey_acl1
Not Configured
```

WLAN radio policy verification

Provides command to verify a WLAN radio policy configuration status.

To verify the WLAN radio policy configuration status, use this command:

```
Device# show wlan id 6 | sec Radio Bands
wpa3 enabled wlan:
Configured Radio Bands: All
Operational State of Radio Bands : All Bands Operational
```

```
Configured Radio Bands : All
Operational State of Radio Bands
    2.4ghz                      : UP
    5ghz                        : UP
    6ghz                        : DOWN (Required config: Disable WPA2 and
Enable WPA3 & dot11ax)
```

```
wpa3 not enabled WLAN :
Configured Radio Bands : All
Operational State of Radio Bands
2.4ghz : UP
5ghz   : UP
```

```
5ghz specify slot is enabled :
Configured Radio Bands
5ghz   : Enabled
Slot 0 : Enabled
Slot 1 : Disabled
Slot 2 : Disabled
```

```
Operational State of Radio Bands
5ghz   : UP
Slot 0 : Enabled
Slot 1 : Disabled
Slot 2 : Disabled
```

Verify AP name advertisement

To verify the AP name advertisement, use this command:

```
Device# show wlan id 1
WLAN Profile Name     : wlan-prof-name
================================================
Identifier                                    : 1
Description                                   :
Network Name (SSID)                           : cm71
Status                                        : Enabled
Broadcast SSID                                : Enabled
Advertise-Apname                              : Disabled
Universal AP Admin                            : Disabled
Max Associated Clients per WLAN               : 0
Max Associated Clients per AP per WLAN        : 0
Max Associated Clients per AP Radio per WLAN  : 200
.
.
.
```

203 WLAN Security

Topics:

- WPA1 and WPA2 security protocols
- AAA override
- Fallback for AAA-overridden VLAN
- How to configure WLAN security

Outlines wireless LAN security protocols and features, including WPA1, WPA2, and AAA override, and provides guidance for implementing Layer 2 security, VLAN overrides, prerequisites, and configuration procedures to secure wireless networks.

WPA1 and WPA2 security protocols

Describes Wi-Fi Protected Access (WPA, WPA1, and WPA2) standards-based security solutions from the Wi-Fi Alliance that provide data protection and access control for wireless LAN systems.

WPA1 and WPA2 are standards-based security solutions from the Wi-Fi Alliance that

- provide data protection and access control for wireless LAN systems
- offer different encryption methods, with WPA1 using TKIP and WPA2 using AES-CCMP, and
- support multiple authentication options including 802.1X, PSK, and Cisco Centralized Key Management.

WPA1 and WPA2 implementation details

WPA1 is compatible with the IEEE 802.11i standard but was implemented prior to the standard's ratification; WPA2 is the Wi-Fi Alliance's implementation of the ratified IEEE 802.11i standard.

By default, WPA1 uses Temporal Key Integrity Protocol (TKIP) and Message Integrity Check (MIC) for data protection while WPA2 uses the stronger Advanced Encryption Standard encryption algorithm using Counter Mode with Cipher Block Chaining Message Authentication Code Protocol (AES-CCMP). By default, both WPA1 and WPA2 use the 802.1X for authenticated key management. However, the following options are also available:

- PSK—When you choose PSK (also known as WPA preshared key or WPA passphrase), you need to configure a preshared key (or a passphrase). This key is used as the Pairwise Master Key (PMK) between clients and authentication server.
- Cisco Centralized Key Management uses a fast rekeying technique that enables clients to roam from one access point to another without going through the controller , typically in under 150 milliseconds (ms). Cisco Centralized Key Management reduces the time required by the client to mutually authenticate with the new access point and derive a new session key during reassociation. Cisco Centralized Key Management fast secure roaming ensures that there is no perceptible delay in time-sensitive applications, such as wireless Voice over IP (VoIP), Enterprise Resource Planning (ERP), or Citrix-based solutions. Cisco Centralized Key Management is a CCXv4-compliant feature. If Cisco Centralized Key Management is selected, only Cisco Centralized Key Management clients are supported.

  When Cisco Centralized Key Management is enabled, the behavior of access points differs from the controller 's for fast roaming in the following ways:

  - If an association request sent by a client has Cisco Centralized Key Management enabled in a Robust Secure Network Information Element (RSN IE) but Cisco Centralized Key Management IE is not encoded and only PMKID is encoded in RSN IE, then the controller does not do a full authentication. Instead, the controller validates the PMKID and does a four-way handshake.
  - If an association request sent by a client has Cisco Centralized Key Management enabled in RSN IE and Cisco Centralized Key Management IE is encoded and only PMKID is present in the RSN IE, then the AP does a full authentication. The access point does not use PMKID sent with the association request when Cisco Centralized Key Management is enabled in RSN IE.

- 802.1X+Cisco Centralized Key Management—During normal operation, 802.1X-enabled clients mutually authenticate with a new access point by performing a complete 802.1X authentication, including communication with the main RADIUS server. However, when you configure your WLAN for 802.1X and Cisco Centralized Key Management fast secure roaming, Cisco Centralized Key Management-enabled clients securely roam from one access point to another without the need to reauthenticate to the RADIUS server. 802.1X+Cisco Centralized Key Management is considered as an optional Cisco Centralized Key Management because both Cisco Centralized Key Management and non-Cisco Centralized Key Management clients are supported when this option is selected.

On a single WLAN, you can allow WPA1, WPA2, and 802.1X/PSK/Cisco Centralized Key Management/802.1X+Cisco Centralized Key Management clients to join. All of the access points on such a WLAN advertise WPA1, WPA2, and 802.1X/PSK/Cisco Centralized Key Management/ 802.1X+Cisco Centralized Key Management information elements in

their beacons and probe responses. When you enable WPA1 and/or WPA2, you can also enable one or two ciphers, or cryptographic algorithms, designed to protect data traffic. Specifically, you can enable AES and/or TKIP data encryption for WPA1 and/or WPA2. TKIP is the default value for WPA1, and AES is the default value for WPA2.

Restrictions for WPA2 and WPA3

Outlines restrictions for WPA2 and WPA3 configuration.

Consider these restrictions when configuring WPA2 and WPA3 security settings:

- You cannot enable security ft or ft-adaptive without enabling WPA2 or WPA3.
- You cannot enable ft-dot1x or ft-PSK without enabling WPA2 or WPA3.
- You cannot enable 802.1x or PSK simultaneously with SHA256 key derivation type without enabling WPA2 or WPA3 on a WLAN.
- You cannot configure PMF on WPA1 WLAN without WPA2 security.
- IOS APs do not support WPA3.

Prerequisites for Layer 2 Security

Lists prerequisites for layer 2 security.

WLANs with the same SSID must have unique Layer 2 security policies so that clients can make a WLAN selection based on the information advertised in beacon and probe responses.

The available Layer 2 security policies are as follows:

- None (open WLAN)
- WPA+WPA2

> **Note**
>
> - Although WPA and WPA2 cannot be used by multiple WLANs with the same SSID, you can configure two WLANs with the same SSID with WPA/TKIP with PSK and Wi-Fi Protected Access (WPA)/Temporal Key Integrity Protocol (TKIP) with 802.1X, or with WPA/TKIP with 802.1X or WPA/AES with 802.1X.
> - A WLAN configured with TKIP support will not be enabled on an RM3000AC module.

- Static WEP (not supported on Wave 2 APs)

AAA override

Describes the AAA Override option of a WLAN that enables configuration of WLAN for identity networking.

AAA override is a WLAN option that enables you to configure the WLAN for identity networking by applying VLAN tagging, Quality of Service (QoS), and Access Control Lists (ACLs) to individual clients based on the returned RADIUS attributes from the AAA server.

Configure AAA override (CLI)

Configure AAA override to allow RADIUS server policies to override local wireless policy settings.

Enable AAA override functionality to allow authentication servers to dynamically override wireless policy configurations on a per-client basis.

AAA override allows RADIUS servers to push policy attributes that supersede the locally configured wireless policy settings. This is useful for implementing dynamic policies based on user authentication results.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-policy
   ```

   Example

   ```
   Device(config)# wireless profile policy test-wgb
   ```

3. Configure AAA policy override.

   Example

   ```
   Device(config-wireless-policy)# aaa-override
   ```

   > **Note**
   >
   > If VLAN is not pushed from the RADIUS server, the VLAN Override feature can be disabled from the RADIUS server.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

   Alternatively, you can also press Ctrl-Z to exit global configuration mode.

AAA override is now enabled for the wireless policy profile, allowing RADIUS server attributes to override local policy settings for authenticated clients.

VLAN override

Describes the VLAN override feature that requires AAA Override to be enabled under the Policy Profile.

VLAN override is an authentication feature that

- requires AAA Override to be enabled under the Policy Profile
- enables VLAN assignment from the RADIUS server using IETF RADIUS attributes or Aire-Interface-Name attribute, and
- supports VLAN ID, VLAN name, or VLAN group name assignment.

VLAN assignment methods

You can assign VLAN from the RADIUS server in two ways:

- Using IEFT RADIUS attributes 64, 65, and 81—The attribute 81 can be a VLAN ID, VLAN name, or VLAN group name. Both VLAN name and VLAN group are supported. Therefore, VLAN ID does not need to be predetermined on RADIUS.

  The RADIUS user attributes used for the VLAN ID assignment are:

  - 64 (Tunnel-Type)—Must be set to VLAN (Integer = 13).
  - 65 (Tunnel-Medium-Type)—Must be set to 802 (Integer = 6).
  - 81 (Tunnel-Private-Group-ID)—Must be set to the corresponding VLAN ID, VLAN name, or VLAN group name.

- Using Aire-Interface-Name attribute—Use this attribute to assign a successfully authenticated user to a VLAN interface name (or VLAN ID) as per the user configuration. When you use this attribute, the VLAN name is returned as a string.

> **Note**
>
> If additional 802.1x authentication is executed after VLAN override in MAB authentication, the RADIUS server must be configured to return the same value in VLAN attribute even with 802.1x authentication. VLAN overridden by MAB authentication and the VLAN assigned by 802.1x authentication should have the same value.

The VLAN ID is 12-bits, and takes a value between 1 and 4094, inclusive. Because the Tunnel-Private-Group-ID is of type string, as defined in RFC2868 for use with IEEE 802.1X, the VLAN ID integer value is encoded as a string. When these tunnel attributes are sent, it is necessary to fill in the Tag field.

Configure override VLAN for central switching (CLI)

Configure override VLAN for central switching to enable RADIUS server to dynamically assign VLANs to clients.

Enable dynamic VLAN assignment from a RADIUS server for centrally switched wireless clients.

Override VLAN configuration allows the RADIUS server to dynamically assign VLANs to wireless clients during authentication, providing flexible network segmentation based on user credentials or policies.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Define VLANs that can be pushed from the RADIUS server.

Example

```
Device(config)# vlan vlan-id
```

Example

```
Device(config)# vlan 20
```

The valid VLAN ID range is 1 to 4094.

3. Optional: Change the default name of the VLAN.

Example

```
Device(config-vlan)# name vlan-name
```

Example

```
Device(config-vlan)# name vlan_ascii
```

4. Return to privileged EXEC mode.

Example

```
Device(config-vlan)# end
```

Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The override VLAN is configured and ready to accept dynamic VLAN assignments from the RADIUS server for centrally switched clients.

Configure override VLAN for local switching (CLI)

Configure Override VLAN for local switching.

Configure VLAN name to ID mapping under flex profile for local switching scenarios.

If the VLAN name ID mapping under flex profile is newly added or updated, then the WLAN policy profiles having a matching VLAN name configured, must be shut and unshut. This is to ensure that the updated WLAN-VLAN mapping is pushed to the APs and the client receives the IP address from the intended VLAN.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a Flex profile.

Example

```
Device(config)# wireless profile flex flex-profile-name
```

Example

```
Device(config)# wireless profile flex rr-xyz-flex-profile
```

3. Define VLANs that can be pushed from the RADIUS server.

Example

```
Device(config-wireless-flex-profile)# vlan-name vlan-name
```

Example

```
Device(config-wireless-flex-profile)# vlan-name vlan_123
```

4. Configure VLAN ID.

Example

```
Device(config-wireless-flex-profile-vlan)# vlan-id vlan-id
```

Example

```
Device(config-wireless-flex-profile-vlan)# vlan-id 23
```

The valid VLAN ID range is 1 to 4096.

5. Return to privileged EXEC mode.

Example

```
Device(config-wireless-flex-profile-vlan)# end
```

Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The override VLAN is now configured for local switching with the specified flex profile, enabling VLAN name to ID mapping for wireless clients.

VLAN override on Layer 3 web authentication

Describes VLAN override functionality during layer 3 web authentication processes.

VLAN override on Layer 3 web authentication is a network authentication feature that

- enables the RADIUS server to push a new VLAN assignment during Layer 3 authentication
- triggers client re-association and DHCP renewal when VLAN changes occur, and
- maintains client state during the transition process.

Authentication process and client transition

When a client gets connected to the controller and authenticated using the RADIUS server for Local Web Authentication (LWA) and Central Web Authentication (CWA), the RADIUS server pushes back in access-accept the new VLAN. If the RADIUS server pushes back a new VLAN in the access-accept, the client goes back to IP learn state on the controller. The controller de-associates the client while maintaining the client state for 30 seconds. Once the client re-associates, the client lands immediately to the new VLAN and re-triggers a new DHCP request. The client then learns a new IP and moves to the RUN state on the controller.

The VLAN Override on Layer 3 Web authentication supports:

- Local clients
- Anchored clients
- FlexConnect central authentication, central or local switching

VLAN override verification on Layer 3 web authentication

Provides commands to verify VLAN override on layer 3 web authentication.

Verify VLAN override on layer 3 web authentication using specific show commands to display override status and statistics.

To display the VLAN override after L3 authentication, use this command:

```
Device# show wireless client mac <mac> detail
[…]
        Vlan Override after L3 Auth: True
```

To display the statistics about client, use this command:

```
Device# show wireless stats client detail
[…]
      Total L3 VLAN Override vlan change received      : 1
      Total L3 VLAN Override disassociations sent      : 1
      Total L3 VLAN Override re-associations received  : 1
      Total L3 VLAN Override successful VLAN change    : 1
      […]
      L3 VLAN Override connection timeout                              : 0
```

Fallback for AAA-overridden VLAN

Describes a wireless policy profile feature that provides backup connectivity when AAA-assigned VLANs are unavailable.

Fallback for AAA-overridden VLAN is a wireless policy profile feature that provides backup network connectivity when AAA-assigned VLANs or VLAN groups become unavailable.

Fallback for AAA-overridden VLAN implementation details

From Cisco IOS XE Bengaluru 17.6.1, fallback for AAA-overridden VLAN or VLAN groups is supported on the wireless policy profile.

A new command is introduced in the wireless policy profile to configure the Fallback for AAA-Overridden VLAN feature. In Cisco IOS XE Bengaluru 17.6.1, you cannot configure the Fallback for AAA Overridden VLAN feature using the GUI.

Feature history for fallback for AAA-overridden VLAN

Lists feature history for fallback for AAA-overridden VLAN.

This table provides release and related information for the feature explained in this module.

This feature is available in all the releases subsequent to the one in which it is introduced in, unless noted otherwise.

Table 185: Feature history for fallback for AAA-overridden VLAN

Feature	Release	Feature Information
Fallback for AAA-Overridden VLAN	Cisco IOS XE Bengaluru 17.6.1	In Cisco IOS XE Bengaluru 17.5.1 and earlier releases, if there is a network with a single AAA server dictating policies that need to be applied to a client; and this client moves across different sites that have different policy definitions. If these policy definitions are not defined on the site to which the client needs to connect, the client does not get access to the network. For example, if a client is to be given access in VLAN 1, and VLAN 1 is not defined on the site to which the client connects, the client is excluded and does not get any access to the network. The Fallback for AAA-Overridden VLAN feature is introduced to allow fallback to policy profile VLAN when the overridden VLAN is not available.

Central switching and FlexConnect mode scenarios

Describes scenarios in Central Switching and FlexConnect modes when fallback is enabled for AAA-overridden VLAN or VLAN groups.

Central switching and FlexConnect mode scenarios are network configurations that

- define client VLAN assignment behavior when fallback is enabled for AAA-overridden VLAN or VLAN groups
- determine how clients receive IP addresses based on controller and FlexConnect profile configurations, and
- specify different VLAN assignment rules for Central Switching versus FlexConnect modes.

Central switching mode behavior

FlexConnect mode behavior

If fallback is enabled for AAA-overridden VLAN or VLAN groups, you might encounter these scenarios in Central Switching and FlexConnect modes.

In Central Switching mode, VLAN assignment follows these rules:

- If the AAA server gives a VLAN policy to a client, and the VLAN ID or the VLAN name is defined in the controller, the client is assigned to the VLAN specified by the AAA server.
- If the VLAN is not defined in the controller, the client is assigned to a VLAN that is configured on the wireless policy profile.

- If a VLAN group is configured on a wireless policy profile, the VLAN, as computed by the existing VLAN group logic, is assigned to the client.
- In the VLAN group case, fallback to policy profile VLAN occurs only when all the VLANs in the group are not configured in the controller, or, if the VLAN group is not defined in the controller.
- If both, AAA-overridden VLAN and the VLAN configured on the wireless policy profile are not defined in the controller, the configuration is termed as invalid, and the client is excluded.
- If a VLAN policy is not configured, or, if the default wireless policy profile is configured, the client is assigned a VLAN from the management VLAN.

If the AAA server assigns a VLAN policy to a client configured in the FlexConnect profile, the VLAN is resolved by the controller. If the VLAN is not configured on the FlexConnect profile, the behavior of the VLAN name and the VLAN ID is made consistent, with the help of the fallback feature, and the client receives the IP address from the wireless policy profile configuration.

FlexConnect mode behavior includes these characteristics:

- If AAA VLAN is defined in FlexConnect profile, the client is assigned the AAA VLAN.
- If AAA VLAN is not defined in the FlexConnect profile, FlexConnect VLAN Central Switching is configured, and VLAN is defined in the controller, and the client is assigned AAA VLAN and is centrally switched.
- If AAA VLAN is not defined in the FlexConnect profile, FlexConnect VLAN Central Switching is configured, the VLAN is not defined in the controller, and the client is assigned a VLAN from the wireless policy profile.
- If AAA VLAN is not defined in the FlexConnect profile, and FlexConnect VLAN Central Switching is not configured, the client is assigned a VLAN from the wireless policy profile.

Configure fallback for AAA-overridden VLAN (CLI)

Configure fallback for AAA-overridden VLAN using commands.

Enable fallback to the policy profile VLAN when the AAA-overridden VLAN is not available, ensuring client connectivity continuity.

When AAA servers override client VLAN assignments but the specified VLAN becomes unavailable, fallback configuration allows clients to connect using the default policy profile VLAN instead of being denied access.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile and enter wireless policy profile configuration mode.

   Example

   ```
   Device(config)# wireless profile policy wlan-policy-profile-name
   ```

3. Allow fallback to the policy profile VLAN when the overridden VLAN is not available.

Example

```
Device(config-wireless-policy)# aaa-override vlan fallback
```

The WLAN policy profile is configured with AAA override VLAN fallback, allowing clients to use the default policy VLAN when their AAA-assigned VLAN is unavailable.

Verify fallback for AAA-overridden VLAN

Provides verification commands for fallback on AAA-overridden VLAN configuration.

To verify if the fallback for AAA-overridden VLAN is enabled, use this command:

```
Device# show wireless profile policy detailed default-policy-profile | sec AAA
 Policy Params
AAA Policy Params
  AAA Override                    : DISABLED
  NAC                             : DISABLED
  AAA Policy name                 : default-aaa-policy
  AAA Vlan Fallback               : ENABLED
```

How to configure WLAN security

Configures security settings for a wireless LAN (WLAN) to protect access and data on your network.

Configure static WEP Layer 2 security parameters (GUI)

Configure static WEP layer 2 security parameters using GUI.

Configure static WEP layer 2 security parameters to secure wireless network communication using WEP encryption keys.

Use this procedure when you need to configure WEP layer 2 security for a WLAN. Static WEP provides basic encryption for wireless communications using either 40-bit or 104-bit encryption keys.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. On the **WLANs** page, click the name of the WLAN.
3. In the **Edit WLAN** window, click the **Security** tab.
4. From the **Layer 2 Security Mode** drop-down list, select the **Static WEP** option.
5. (Optional) Check the **Shared Key Authentication** check box to set the authentication type as shared. By leaving the check box unchecked, the authentication type is set to open.
6. Set the **Key Size** as either **40 bits** or **104 bits**.
   - 40 bits: The keys with 40-bit encryption must contain 5 ASCII text characters or 10 hexadecimal characters.
   - 104 bits: The keys with 104-bit encryption must contain 13 ASCII text characters or 26 hexadecimal characters.
7. Set the appropriate **Key Index**; you can choose between 1 to 4.
8. Set the **Key Format** as either **ASCII** or **Hex**.
9. Enter a valid **Encryption Key**.
   - 40 bits: The keys with 40-bit encryption must contain 5 ASCII text characters or 10 hexadecimal characters.

- 104 bits: The keys with 104-bit encryption must contain 13 ASCII text characters or 26 hexadecimal characters.

10. Click **Update & Apply to Device**.

The WLAN is configured with static WEP layer 2 security parameters. The settings are applied to the device and WEP encryption is enabled for the wireless network.

Configure static WEP layer 2 security parameters (CLI)

Configure static WEP layer 2 security parameters using commands.

Set up static WEP encryption and authentication for WLAN security.

Static WEP provides basic wireless security through shared encryption keys. This configuration is used when legacy devices require WEP compatibility, though WPA/WPA2 is recommended for better security.

Before you begin

You must have administrator privileges.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter WLAN configuration submode.

   Example

   ```
   Device# wlan profile-name wlan-id SSID-Name
   ```

   Example

   ```
   Device# wlan test4 1 test4
   ```

   profile-name is the profile name of the configured WLAN.

   wlan-id is the wireless LAN identifier. The range is 1 to 512.

   SSID_Name is the SSID which can contain 32 alphanumeric characters.

   > **Note**
   >
   > If you have already configured this command, enter **wlan** *profile-name* command.

3. Disable fast transition over the data source on the WLAN.

Example

```
Device(config-wlan)# no security ft over-the-ds
```

4. Disable 802.11r Fast Transition on the WLAN.

Example

```
Device(config-wlan)# no security ft
```

5. Disable the WPA/WPA2 support for a WLAN.

Example

```
Device(config-wlan)# no security wpa wpa1 ciphers tkip
```

6. Configure Static WEP Key authentication with authentication type.

Example

```
Device(config-wlan)# security static-wep-key authentication open
```

The keywords are as follows:

- **static-wep-key**: Configures Static WEP Key authentication.
- **authentication**: Specifies the authentication type you can set. The values are open and shared.

7. Configure Static WEP Key encryption parameters.

Example

```
Device(config-wlan)# security static-wep-key encryption 104 ascii 0
encryption-key key-index
```

Example

```
Device(config-wlan)# security static-wep-key encryption 104 ascii 0
1234567890123 1
```

The keywords are as follows:

- **static-wep-key**: Configures Static WEP Key authentication.
- **encryption**: Specifies the encryption type that you can set. The valid values are 104 and 40. 40-bit keys must contain 5 ASCII text characters or 10 hexadecimal characters. 104-bit keys must contain 13 ASCII text characters or 26 hexadecimal characters.
- **ascii**: Specifies the key format as ASCII.
- **hex**: Specifies the key format as HEX.

8. Exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

Static WEP layer 2 security is now configured on the WLAN with the specified authentication and encryption parameters.

Configure WPA + WPA2 Layer 2 security parameters (GUI)

Configure WPA + WPA2 layer 2 security parameters using GUI.

This task configures WPA + WPA2 layer 2 security parameters to secure wireless network communications using the graphical user interface.

Use this procedure when you need to set up wireless network security using both WPA and WPA2 protocols through the GUI interface. This configuration provides enhanced security for your wireless network by supporting both protocols simultaneously.

Procedure

1. Click **Configuration** > **Tags and Profiles** > **WLANs**.
2. Click **Add** to add a new WLAN Profile or click the one you want to edit.
3. In the **Edit WLAN** window, click **Security** > **Layer2**.
4. From **Layer 2 Security Mode** drop-down menu, select **WPA + WPA2**.
5. Configure the security parameters and then click **Save and Apply to Device**.

The WPA + WPA2 layer 2 security parameters are configured and applied to the device. The WLAN profile now uses both WPA and WPA2 security protocols to protect wireless network communications.

Configure WPA + WPA2 layer 2 security parameters (CLI)

Configure WPA + WPA2 layer 2 security parameters using commands.

This task configures WPA and WPA2 layer 2 security settings to secure wireless networks using command-line interface commands.

Note

The default values for security policy WPA2 are:

- Encryption is AES.
- Authentication Key Management (AKM) is dot1x.

Before you begin

You must have administrator privileges.

Follow these steps to configure WPA + WPA2 layer 2 security parameters using commands:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration submode.**wlan**

   Example

   ```
   Device(config)# wlan profile-name wlan-id SSID_name
   ```

   Example

   ```
   Device(config)# wlan test4 1 test4
   ```

   - *profile-name* is the profile name of the configured WLAN.
   - *wlan-id* is the wireless LAN identifier. The range is from 1 to 512.
   - *SSID_name* is the SSID that contains 32 alphanumeric characters.

   Note

   If you have already configured this command, enter **wlan** *profile-name* command.

3. Enables WPA or WPA2 support for WLAN.

   Example

   ```
   Device(config-wlan)# security wpa {akm | wpa1 | wpa2}
   ```

   ```
   Device(config-wlan)# security wpa
   ```

4. Enables WPA.

   Example

   ```
   Device(config-wlan)# security wpa wpa1
   ```

5. Specify the WPA1 cipher.

   Example

   ```
   Device(config-wlan)# security wpa wpa1 ciphers [aes | tkip]
   ```

   ```
   Device(config-wlan)# security wpa wpa1 ciphers aes
   ```

Choose one of the following encryption types:

- **aes**: Specifies WPA/AES support.
- **tkip**: Specifies WPA/TKIP support.

The default values are TKIP for WPA1 and AES for WPA2.

> **Note**
>
> You can enable or disable TKIP encryption only using the CLI. Configuring TKIP encryption is not supported in GUI.

When you have VLAN configuration on WGB, you need to configure the encryption cipher mode and keys for a particular VLAN, for example, **encryption VLAN 80 mode ciphers TKIP**. Then, you need to configure the encryption cipher mode globally on the multicast interface by entering the following command: **encryption mode ciphers TKIP**.

6. Enable or disable Cisco Centralized Key Management, 802.1x, 802.1x with SHA256 key derivation type, Fast Transition, PSK or PSK with SHA256 key derivation type.**security WPA AKM {CCKM| dot1x | dot1x-sha256 | ft | PSK |PSK-sha256}**

   Example

```
Device(config-wlan)# security wpa akm {cckm | dot1x | dot1x-sha256 | ft | psk
 | psk-sha256}
```

```
Device(config-wlan)# security wpa akm psk-sha256
```

> **Note**
>
> - You cannot enable 802.1x and PSK with SHA256 key derivation type simultaneously.
> - When you configure Cisco Centralized Key Management SSID, you must enable the **ccx aironet-iesupport** for Cisco Centralized Key Management to work.
> - WPA3 Enterprise dot1x-sha256 is supported only in local mode.

7. Enter this command to specify a preshared key, if you have enabled PSK.

   Example

```
Device(config-wlan)# security wpa psk set-key {ascii | hex} {0 | 8} password
```

```
Device(config-wlan)# security wpa psk set-key ascii 0 test
```

WPA preshared keys must contain 8 to 63 ASCII text characters or 64 hexadecimal characters.

> **Note**
>
> Avoid using the percent sign (%) in ASCII preshared keys. Some clients or access points may interpret this character specially, which can cause the client to fail to join the WLAN.

8. Enable or disable authentication key management suite for fast transition.

   Example

   ```
   Device(config-wlan)# security wpa akm ft {dot1x | psk | sae}
   ```

   ```
   Device(config-wlan)# security wpa akm ft psk
   ```

   > **Note**
   >
   > You can now choose between PSK and fast transition PSK as the AKM suite.

9. Enable WPA2.

   Example

   ```
   Device(config-wlan)# security wpa wpa2
   ```

10. Configure WPA2 cipher. **security wpa wpa2 ciphers aes**

    Example

    ```
    Device(config-wlan)# security wpa wpa2
    ```

    Example

    - **aes**: Specifies WPA/AES support.

11. **show wireless pmk-cache**

    Displays the remaining time before the PMK cache lifetime timer expires.

    If you have enabled WPA2 with 802.1X authenticated key management or WPA1 or WPA2 with Cisco Centralized Key Management authenticated key management, the PMK cache lifetime timer is used to trigger reauthentication with the client when necessary. The timer is based on the timeout value received from the AAA server or the WLAN session timeout setting.

    If you configure 802.1x with session timeout between 0 and 299, Pairwise Master Key (PMK) cache is created with a timer of 1 day 84600 seconds.

Note

- The command will show VLAN ID with VLAN pooling feature in VLAN-Override field.
- Sticky key caching (SKC) is not supported.

WPA and WPA2 layer 2 security parameters are configured for the WLAN. The wireless network is secured with the specified authentication and encryption settings.

204 Remote LANs

Topics:

- Remote LANs
- RLAN authentication fallback

Explains the concept of Remote LANs (RLANs) for authenticating and managing wired clients using a controller, covering limitations, profile and policy configuration, port and tag assignment, fast switching, and verification procedures.

Remote LANs

Introduces Remote LANs (RLANs), outlining their limitations, and provides instructions for enabling or disabling RLANs, creating and configuring RLAN and policy profiles through GUI and CLI, attaching policy tags, configuring fast switching, and verifying RLAN configuration.

A remote LAN is a network security feature that

- enables authentication of wired clients using the wireless controller
- switches client traffic between central and local switching modes, and
- treats wired client traffic as wireless client traffic for unified management.

Feature history

Table 186: Feature history for Remote LANs

Feature name	Release information	Feature description
Remote LANs	Cisco IOS XE 16.9.1	Remote LAN (RLAN) is a network security feature that allows authentication of wired clients using a wireless controller. It treats wired client traffic as wireless client traffic for unified management. The RLAN in an AP sends authentication requests for wired clients, similar to the process for centrally authenticated wireless clients.
Fast switching support for RLAN	Cisco IOS XE 17.15.2	Fast switching support for RLAN is a network optimization mechanism that reduces latency and improves throughput by enabling VLAN-tagged data packets to be switched directly between WAN and LAN ports using the AP's internal switch processor. This feature is supported on Cisco Catalyst 9105AXW APs starting with release 17.15.2.

The RLAN in an AP sends authentication requests for wired clients. Authentication of a wired client in an RLAN is similar to the process for a centrally authenticated wireless client.

For information about APs that support this feature, see https://www.cisco.com/c/en/us/td/docs/wireless/access_point/feature-matrix/ap-feature-matrix.html

Ethernet (AUX) port

By default, the second Ethernet port in Cisco Aironet 1850, 2800, and 3800 Series APs functions as a link aggregation (LAG) port. When LAG is disabled, you can use this port as an RLAN port.

These APs models use LAG port as an RLAN port:

- 1852E

- 1852I
- 2802E
- 2802I
- 3802E
- 3802I
- 3802P
- 4802

Role of Controller

- The controller acts as an authenticator, receiving Extensible Authentication Protocol (EAP) over LAN (EAPOL) messages from the wired client sent through an AP.
- The controller communicates with the configured Authentication, Authorization, and Accounting (AAA) server.
- The controller configures the LAN ports for an AP and pushes the configuration to the corresponding AP.

Fast switching support for RLAN

A fast switching feature is a network optimization mechanism that

- enables VLAN-tagged data packets to be switched directly between WAN and LAN ports using the access point's internal switch processor
- bypasses CPU processing to reduce latency and improve throughput, and
- supports efficient data handling for latency-sensitive applications such as gaming and video streaming.

On Cisco Catalyst 9105AXW APs from version 17.15.2, hardware fast switching for RLAN client traffic is supported. To configure this feature, enable fast switching on the controller and assign the appropriate VLAN IDs to LAN ports. This optimizes network performance and ensures seamless connectivity.

Starting with release 17.15.2, hardware fast switching for RLAN client traffic is supported on Cisco Catalyst 9105AXW APs. This feature enhances performance by reducing latency and improving throughput. The AP can switch VLAN-tagged data packets directly between WAN and LAN ports using its internal switch processor, which bypasses CPU processing. Fast switching is ideal for latency-sensitive applications such as gaming and video streaming and enables efficient data handling. To configure this feature, enable fast switching on the controller and assign the appropriate VLAN IDs to LAN ports. This optimizes network performance and ensures seamless connectivity.

Limitations of RLAN

Limitations of RLAN.

Review these limitations when using RLAN:

- RLAN supports only a maximum of four wired clients regardless of the AP model.
- RLAN support with Virtual Routing and Forwarding (VRF) is not available.
- In the Catalyst 9105 AXW AP operating in OEAP mode, only LAN1 and LAN2 are configured for RLAN. LAN3 is a local-only port and is enabled by default. Even if you disable LAN3 from the controller, the system skips payload processing for LAN3 because it is designated as a local-only port in OEAP mode.
- The RLAN feature is supported on Fabric.
- RLAN is supported in APs that have more than one Ethernet port.

- In RLAN (local mode - local switching mode), if you want to use the AP native VLAN for client IP, the VLAN should be configured as either **no vlan** or **vlan 1** in the RLAN policy profile. For example, if the native VLAN ID is 80, do not use the numeral 80 in the RLAN policy profile. Also, do not use VLAN name *VLANxxxx* to configure VLAN in the RLAN policy profile.

  When a new client is connected to an AP, the client details are available in the controller initially. However, after the CAPWAP DOWN/UP state, the client details are no longer listed in the controller.
- APs in local mode with central switching do not support VLAN-tagged traffic from RLAN clients, resulting in dropped traffic.
- A VLAN name (without any numerals) that is configured in the remote-lan-policy does not provide the mapped VLAN ID for central switching.
- RLAN does not support these features:
  - Central Web Authentication (CWA)
  - Quality of Service (QoS)
  - Bi-Directional Rate Limiting (BDRL)
  - Identity PSK (iPSK)

Consider these limitations when you use the AUX port in Cisco 2700 APs:

- RLAN supports the AUX port and a non-native VLAN for this port.
- Local mode supports wired client traffic on a central switch, but FlexConnect mode does not support a central switch.
- FlexConnect mode supports wired client traffic on the local switch, but not on the central switch.
- You cannot use the AUX port as a trunk port, and you cannot add switches or bridges behind the port.
- The AUX port does not support dot1x.

Configure remote LANs (RLANs)

Enable or disable all RLANs

Enable or disable all RLANs.

Enable remote LANs (RLANs) on the device to ensure network access for connected clients, or disable RLANs to restrict access.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable or disable all RLANs.

   Example

   ```
   Device(config)# [no] ap remote-lan shutdown
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

All RLANs on the device are enabled (or disabled), and corresponding interfaces become active (or inactive).

Create RLAN profile (GUI)

Create RLAN profile using GUI.

Define a Remote LAN (RLAN) profile so you can enable RLAN services for specific devices.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Remote LAN**.
2. Click **Add**.
3. Enter the **Profile Name**, **RLAN ID**. Enable or disable the **Status** toggle button. The profile name must contain ASCII characters from 32 to 126, without leading and trailing spaces.
4. Click **Apply to Device**.

The new RLAN profile is created and applied to the selected device.

Create RLAN profile (CLI)

Create RLAN profile using commands.

Add a new remote LAN profile for wireless device management using CLI commands.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure remote LAN profile.

   Example

   ```
   Device(config)# ap remote-lan profile-name remote-lan-profile-name rlan-id
   ```

   - *remote-lan-profile*: The remote LAN profile name. The range is from 1 to 32 alphanumeric characters.
   - *rlan-id*: The remote LAN identifier. The range is from 1 to 128.

> **Note**
>
> You can create a maximum of 128 RLANs. You cannot use the *rlan-id* of an existing RLAN while creating another RLAN.
>
> RLAN and WLAN profiles cannot have the same names. Similarly, RLAN and WLAN policy profiles must use distinct names.

The system creates the RLAN profile, making it available for configuration and assignment to APs.

```
Device# configure terminal
Device(config)# ap remote-lan profile-name rlan_profile_name 3
```

Configure RLAN profile parameters (GUI)

Configure RLAN profile parameters using GUI.

Configure Remote LAN (RLAN) profile parameters to control client associations, authentication methods, and security settings.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Remote LAN**.
2. In the **RLAN Profile** page, click **Add**.

   The **Add RLAN Profile** page is displayed.
3. In the **General** tab:
   a) Enter a **Name** and **RLAN ID** for the RLAN profile. The name must use ASCII characters with values from 32 to 126 and must not have leading or trailing spaces.
   b) Set how many clients can connect to each RLAN in the **Client Association Limit** field.
   c) To enable the profile, set the status as **Enable**.
4. In the **Security** > **Layer2** tab:
   a) To enable 802.1X for an RLAN, set the **802.1x** status as **Enabled**.

   > **Note**
   >
   > You can activate either web or 802.1x authentication list at a time.

   b) Choose the authorization list name from the **MAC Filtering** drop-down list.
   c) Choose the 802.1x for an RLAN authentication list name from the **Authentication List** drop-down list.
5. In the **Security** > **Layer3** tab:
   a) To enable web authentication for an RLAN, set the **Web Auth** status as **Enabled**.

> **Note**
>
> You can activate either web or 802.1X authentication list at a time.

b) Choose the web authentication parameter map from the **Webauth Parameter Map** drop-down list.
c) Choose the web authentication list name from the **Authentication List** drop-down list.

6. In the **Security** > **AAA** tab:
   a) Set the **Local EAP Authentication** to enabled. Also, choose the required **EAP Profile Name** from the drop-down list.
7. Save your configuration.

The configured RLAN profile is active. It is available for client associations using the specified security and authentication settings.

Configure RLAN profile parameters (CLI)

Configure RLAN profile parameters using commands.

Set up and customize Remote LAN (RLAN) profile parameters to control client access and authentication for RLAN interfaces.

Before you begin

The configurations in this section are not mandatory for an RLAN profile.

In case of central switching mode, you need to configure both central switching and central DHCP.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure remote LAN profile.

   Example

   ```
   Device(config)# ap remote-lan profile-name rlan-profile-name rlan-id
   ```

   The RLAN ID range is from 1 to 128.

3. Configure client connections per RLAN.

   Example

   ```
   Device(config-remote-lan)# client association limit client-connections
   ```

   client-connections: Is the maximum client connections per RLAN. The range is from 0 to 10000. 0 refers to unlimited.

4. Configure RLAN IP configuration commands.

Example

```
Device(config-remote-lan)# ip access-group web ipv4-acl_name
```

ipv4-acl-name: Refers to the IPv4 ACL name or ID.

5. Set EAP profile on an RLAN.

Example

```
Device(config-remote-lan)# local-auth profile-name
```

profile-name: Is the EAP profile on an RLAN.

6. Set MAC filtering support on an RLAN.

Example

```
Device(config-remote-lan)# mac-filtering mac-filter-name
```

mac-filter-name: Is the authorization list name.

7. Configure 802.1X for an RLAN.

Example

```
Device(config-remote-lan)# security dot1x authentication-list list-name
```

list-name: Is the authentication list name.

8. Configure web authentication for an RLAN.

Example

```
Device(config-remote-lan)# security web-auth authentication-list list-name
```

list-name: Is the authentication list name.

> **Note**
>
> You can activate either web or dot1x authentication list at a time.

9. Enable or disable RLAN profile.

Example

```
Device(config-remote-lan)# [no] shutdown
```

The RLAN profile is configured with your desired parameters for client access, authentication, and network policies.

Create RLAN policy profile (GUI)

Create RLAN policy profile using GUI.

Create a new Remote LAN (RLAN) policy profile for controlled wireless network access.

Procedure

1. Choose **Configuration** > **Wireless** > **Remote LAN** > **RLAN Policy**.
2. Click **Add** to create a new RLAN policy profile for the selected device..
3. In the **General** tab, enter the **Policy Name**.
4. Click **Apply to Device**.

The new RLAN policy profile is created and applied to the selected device.

Create RLAN policy profile (CLI)

Create RLAN policy profile using commands.

Configure an RLAN policy profile on a Cisco device. Wireless attributes for the RLAN are defined.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure RLAN policy profile and enter wireless policy configuration mode.

   Example

   ```
   Device(config)# ap remote-lan-policy policy-name rlan_policy_prof_name
   ```

After you complete these steps, the system creates a new RLAN policy profile. You can then assign it to remote LANs.

Configure RLAN policy profile parameters (GUI)

Configure RLAN policy profile parameters using GUI.

Configure RLAN policy profile parameters to define how Remote LAN (RLAN) networks operate.

Procedure

1. Choose **Configuration** > **Wireless** > **Remote LAN**.
2. On the **Remote LAN** page, click **RLAN Policy** tab.
3. On the **RLAN Policy** page, click the name of the **Policy** or click **Add** to create a new one.

   The **Add/Edit RLAN Policy** page is displayed.

4. In the **General** tab:

a) Enter a **Name** and **Description** for the policy profile.
b) Set **Central Authentication** to **Enabled** state.
c) Set **Central DHCP** to **Enabled** state.
d) Set the **PoE** check box to enable or disable power over Ethernet.
e) Set the status as **Enable** to activate the policy.

5. In the **Access Policies** Tab, choose the VLAN name or number from the **VLAN** drop-down list.

> **Note**
>
> When central switching is disabled, the VLAN in the RLAN policy cannot be configured as the AP's native VLAN. To use the AP native VLAN for client IP, the VLAN should be configured as either **no vlan** or **vlan 1** in the RLAN policy profile.

6. From the **Host Mode** drop-down list, choose the **Host Mode** for the remote-LAN802.1x from these options:

- Single-Host Mode: Is the default host mode. In this mode, the switch port allows only a single host to be authenticated and passes traffic one by one.
- Multi-Host Mode: The first device to authenticate opens the switch port, allowing all other devices to use the port. You do not need to authenticate other devices independently. If the authenticated device becomes unauthorized, the switch port closes.
- Multi-Domain Mode: The authenticator allows one host from the data domain and another from the voice domain. This is a typical configuration on switch ports with IP phones connected.

> **Note**
>
> - For an RLAN profile with open-auth configuration, you must map the RLAN-policy with single host mode. Mapping RLAN-policy with multi-host or multi-domain mode is not supported.
> - The controller does not assign data versus voice VLAN, based on traffic. RLAN only supports multiple VLAN assignments through 802.1x AAA override. You must create data and voice VLANs and then assign these VLANs to respective clients, based on their authentication through the 802.1x AAA override.

7. Configure IPv6 ACL or Flexible NetFlow.

- Under the **Access Policies** > **Remote LAN ACL** section, choose the **IPv6 ACL** from the drop-down list.
- Under the **Access Policies** > **AVC** > **Flow Monitor IPv6** section, check the **Egress Status** and **Ingress Status** check boxes and choose the policies from the drop-down lists.

8. Click the **Advanced** tab.

a) Configure the violation mode for Remote-LAN 802.1x from the **Violation Mode** drop-down list, choose the violation mode type from these options:

- Shutdown: Disables the port
- Replace: Removes the current session and initiates authentication for the new host. This is the default behavior.
- Protect: Drops packets with unexpected MAC addresses without generating a system message.

b) Enter the **Session Timeout (sec)** value to define the client's duration of a session.

The range is from 20 to 86400 seconds.

c) Under **AAA Policy Params** section, check the **AAA Override** check box to enable AAA override.
d) Under the **Exclusionlist Params** section, check the **Exclusionlist** check box and enter the **Exclusionlist Timeout** value.

This sets the exclusion time for a client. The range is from 0 to 2147483647 seconds. 0 refers to no timeout.

9. Save the configuration.

The RLAN policy profile is created or modified with the specified parameters, enabling precise control of RLAN behavior, access policies, and operational modes.

Configure RLAN policy profile parameters (CLI)

Configure RLAN policy profile parameters using commands.

Set up and customize a Remote LAN (RLAN) policy profile on your device.

Procedure

---

1. Configure central switching.

Example

```
Device(config-remote-lan-policy)# central switching
```

2. Configure central DHCP.

Example

```
Device(config-remote-lan-policy)# central dhcp
```

3. Set exclusion-listing on RLAN.

Example

```
Device(config-remote-lan-policy)# exclusionlist timeout timeout-value
```

timeout: Sets the duration that the client remains in the excluded state. The range is from 0 to 2147483647 seconds. 0 refers to no timeout.

4. Configures VLAN name or ID.**vlan***vlan*

Example

```
Device(config-remote-lan-policy)# vlan vlan
```

vlan: Represents the VLAN name or VLAN ID.

5. Configure AAA policy override.

Example

```
Device(config-remote-lan-policy)# aaa-override
```

6. Configure client session timeout.

   Example

   ```
   Device(config-remote-lan-policy)# session-timeout timeout in seconds
   ```

   timeout in seconds: Specifies the duration of a session. The range is from 20 to 86,400 seconds.

   > **Note**
   >
   > If the session timeout is less than 300 seconds for Dot1x clients, the session timeout is set to one day (86,400 seconds).

7. Configure host mode for remote-LAN 802.1x.

   Example

   ```
   Device(config-remote-lan-policy)# host-mode {multidomain voice domain |
   multihost | singlehost}
   ```

   voice domain: Specifies the RLAN voice domain VLAN ID. The range is from 0 to 65,535.

   You can configure these IEEE 802.1X authentication modes:

   - Multi-Domain Mode: The authenticator allows one host from the data domain and another from the voice domain. This is a typical configuration on switch ports with IP phones connected.
   - Multi-Host Mode: The first device to authenticate opens up to the switch port, so that all other devices can use the port. You need not authenticate other devices independently, if the authenticated device becomes authorized the switch port is closed.
   - Single-Host Mode: This is the default host mode. In this mode, the switch port allows only a single host to be authenticated and passes traffic one by one.

8. Configure a fabric RLAN profile by entering a name for the fabric profile.

   Example

   ```
   Device(config-remote-lan-policy)# fabric fabric-profile-name
   ```

9. Configure violation mode for Remote-LAN 802.1x.

   Example

   ```
   Device(config-remote-lan-policy)# violation-mode {protect | replace | shutdown}
   ```

   When a security violation occurs, a port is protected based on these configured violation actions:

   - Shutdown: Disables the port.
   - Replace: Removes the current session and initiates authentication for the new host. This is the default behavior.

- Protect: Drops packets with unexpected MAC addresses without generating a system message. In the single-host authentication mode, a violation is triggered when more than one device is detected in data VLAN. In a multi-host authentication mode, a violation is triggered when more than one device is detected in data VLAN or voice VLAN.

10. Enables or disables PoE.

Example

```
Device(config-remote-lan-policy)# [no] poe
```

11. Enable or disable an RLAN policy profile.

Example

```
Device(config-remote-lan-policy)# shutdown
```

12. Return to privileged EXEC mode.

Example

```
Device(config-remote-lan-policy)# end
```

The RLAN policy profile is configured as specified. Devices governed by this profile will now operate according to the parameters you set.

```
Device(config-remote-lan-policy)# central switching
Device(config-remote-lan-policy)# central dhcp
Device(config-remote-lan-policy)# exclusionlist timeout 200
Device(config-remote-lan-policy)# vlan vlan1
Device(config-remote-lan-policy)# aaa-override
Device(config-remote-lan-policy)# session-timeout 21
Device(config-remote-lan-policy)# host-mode multihost
Device(config-remote-lan-policy)# fabric fabric-profile-name
Device(config-remote-lan-policy)# violation-mode protect
Device(config-remote-lan-policy)# poe
Device(config-remote-lan-policy)# shutdown
Device(config-remote-lan-policy)# end
```

Configure policy tag and map an RLAN policy profile to an RLAN profile (CLI)

Configure policy tag and mapping an RLAN policy profile to an RLAN profile using commands.

Define a policy tag and associate your RLAN policy profile with an RLAN profile.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a policy tag and enter policy tag configuration mode.

Example

```
Device(config)# wireless tag policy policy-tag-name
```

3. Map your RLAN policy profile to an RLAN profile.

Example

```
Device(config-policy-tag)# remote-lan rlan-profile-name policy
rlan_profile_name policy rlan_policy_profile port-id port-id
```

- *remote-lan-profile-name*: The name of the RLAN profile.
- *rlan-policy-profile-name*: The name of the policy profile.
- *port-id*: The LAN port number on the AP. The port number can be any integer from 1 to 4.

4. Return to privileged EXEC mode.

Example

```
Device(config-policy-tag)# end
```

You can press **Ctrl-Z** to exit global configuration mode.

The controller maps your specified RLAN policy profile to the RLAN profile under the policy tag.

```
Device# configure terminal
Device(config)# wireless tag policy remote-lan-policy-tag
Device(config-policy-tag)# remote-lan remote-lan1 policy rlan_profile_name
port-id 2
Device(config-policy-tag)# end
```

Configure a LAN port (CLI)

Configure LAN port using commands.

Enable or disable a LAN port on an AP using commands.

Procedure

Configure a LAN port.

Example

```
Device# ap name ap-name lan port-id lan-port-id {disable | enable}
Device# ap name L2_1810w_2 lan port-id 1 enable
```

- **enable**: Enables the LAN port.
- **disable**: Disables the LAN port.

The selected LAN port on the AP is enabled or disabled as specified.

Attach policy tag to an access point (GUI)

Attach policy tag to an AP using GUI.

Assign a specific policy to an AP to enforce wireless configurations.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Select an AP.
3. Under the **Tags** section, use the **Policy** drop-down to select a policy tag.
4. Click **Update & Apply to Device**.

The AP is associated with the policy tag, and the new configuration is enforced.

Attach policy tag to an access point (CLI)

Attach policy tag to an AP using commands.

Assign a predefined policy tag to a specific AP.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an Ethernet MAC address for an AP and enter the AP configuration mode.

   Example

   ```
   device(config)# ap ap-ethernet-mac
   ```

3. Attach a policy tag to the AP.

   Example

   ```
   Device(config-ap-tag)# policy-tag remote-lan-policy-tag
   ```

   policy-tag-name: The name of the policy tag defined earlier.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-tag)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The AP is now associated with the specified policy tag.

```
Device# configure terminal
Device(config)# ap 00a2.891c.21e0
Device(config-ap-tag)# policy-tag remote-lan-policy-tag
Device(config-ap-tag)# end
```

Configure RLAN fast switching (CLI)

Enable RLAN fast switching to improve handoff performance for wireless clients on the AP.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile default-ap-profile
   ```

3. Enable RLAN fast switching.

   Example

   ```
   Device(config-ap-profile)# [no] rlan fast-switching
   ```

   Use the **no** form of this command to disable the feature.

4. Exit RLAN configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

RLAN fast switching is enabled for the selected AP profile, providing faster handoffs for wireless clients.

Verify RLAN configuration

Verify RLAN configuration.

Use this command to display the summary of all RLANs:

```
Device# show remote-lan summary

Number of RLANs: 1

RLAN        Profile Name                      Status
------------------------------------------------------------
1            rlan_test_1                       Enabled
```

Use this command to display the RLAN configuration by ID:

```
Device# show remote-lan id <id>

Remote-LAN Profile Name              : rlan_test_1
=================================================
Identifier                                  : 1
Status                                      : Enabled
Mac-filtering                               : Not Configured
Number of Active Clients                    : 1
Security_8021X                              : Disabled
8021.x Authentication list name             : Not Configured
Local Auth eap Profile Name                 : Not Configured
Web Auth Security                           : Disabled
Webauth Authentication list name            : Not Configured
Web Auth Parameter Map                      : Not Configured
Client association limit                    : 0
Ipv4 Web Pre Auth Acl                       : Not Configured
Ipv6 Web Pre Auth Acl                       : Not Configured
```

Use this command to display the RLAN configuration by profile name:

```
Device# show remote-lan name <profile-name>

Remote-LAN Profile Name     : rlan_test_1
================================================
Identifier                                     : 1
Status                                         : Enabled
Mac-filtering                                  : mac-auth
Number of Active Clients                       : 0
Security_8021x_dot1x                           : Enabled

```

```
Device# show remote-lan policy summary
Number of Policy Profiles: 1

Profile Name                      Description                          Status

-------------------------------------------------------------------------------------------
rlan_named_pp1                Testing RLAN policy profile             Enabled
```

Use this command to display the LAN port configuration of a Cisco AP:

```
Device# show ap name <ap_name> lan port summary
LAN Port status for AP L2_1815w_1
Port ID      status       vlanId      poe
---------------------------------------------
LAN1         Enabled       20          Disabled
LAN2         Enabled       20          NA
LAN3         Disabled      0           NA
```

Use this command to display the summary of all clients:

```
Device# show wireless client summary
Number of Local Clients: 1

MAC Address       AP Name        WLAN         State    Protocol    Method
 Role
-------------------------------------------------------------------------------------
d8eb.97b6.fcc6    L2_1815w_1      1           * Run     Ethernet    None
 Local
```

Use this command to display client details for the specified username:

```
Device# show wireless client username cisco
MAC Address        AP Name          Status      WLAN      Auth Protocol
-------------------------------------------------------------------------------------------
0014.d1da.a977    L2_1815w_1        Run 1 *      Yes        Ethernet
d8eb.97b6.fcc6    L2_1815w_1        Run 1 *      Yes        Ethernet
```

Use this command to display detailed information for a client by MAC address:

```
Device# show wireless client mac-address 2cea.7f18.5bb3 detail
Client MAC Address : 2cea.7f18.5bb3
Client MAC Type : Universally Administered Address
Client DUID: NA
```

```
Client IPv4 Address : 10.56.33.21
Client IPv6 Addresses : fe80::d60:2e8:4cc2:6212
Client Username: N/A
AP MAC Address : 4ca6.4d22.1a80
AP Name: AP3C57.31C5.799C
AP slot : 16
Client State : Associated
Policy Profile : fabric-rlan-policy
Flex Profile : default-flex-profile
Remote LAN Id: 1 <----------
Remote LAN Name: fabric-rlan <--------
Wireless LAN Network Name (SSID): fabric-rlan <----------
BSSID : 4ca6.4d22.1a81
Connected For : 211 seconds
Protocol : Ethernet <--------
Channel : 0
Port ID: 1 <-----------
Client IIF-ID : 0xa0000002
Association Id : 0
Authentication Algorithm : Open System
<--------o/p trimmed ------>
```

Use this command to display the summary of all AP tags:

```
Device# show ap tag summary
Number of APs: 2

AP Name             AP Mac               Site Tag Name         Policy Tag Name
         RF Tag Name               Misconfigured     Tag Source
-------------------------------------------------------------------------------------------------
L2_1810d_1        0008.3296.24c0       default-site-tag
default-policy-tag        default-rf-tag             No               Default

L2_1810w_2        00b0.e18c.5880       rlan-site-tag              rlan_pt_1
           default-rf-tag             No               Static
```

Use this command to display the summary of all policy tags:

```
Device# show wireless tag policy summary
Number of Policy Tags: 2

Policy Tag Name                   Description
------------------------------------------------------------------------
rlan_pt_1
default-policy-tag                default policy-tag
```

Use this command to display details of a specific policy tag:

```
Device# show wireless tag policy detailed <rlan_policy_tag_name>
Policy Tag Name : rlan_pt_1
Description     :

Number of WLAN-POLICY maps: 0

Number of RLAN-POLICY maps: 2
REMOTE-LAN Profile Name           Policy Name                          Port
 Id
-------------------------------------------------------------------------------------------
rlan_test_1                       rlan_named_pp1
 1
```

```
rlan_test_1                      rlan_named_pp1
 2
```

Use this command to display the fabric client summary:

```
Device# show wireless fabric client summary

Number of Fabric Clients : 0

MAC Address    AP Name                          WLAN State              Protocol
 Method     L2 VNID    RLOC IP
```

Use this command to display the RLAN client summary:

```
Device# show wireless client summary

Number of Clients: 1

MAC Address        AP Name       Type   ID  State    Protocol   Method   Role
-------------------------------------------------------------------------------
2cea.7f18.5bb3 AP3C57.31C5.799C  RLAN    1    Run    Ethernet   None    Local

Number of Excluded Clients: 0
```

RLAN authentication fallback

Introduces RLAN authentication fallback, explaining how client authentication dynamically switches between 802.1X and MAB on OEAP RLAN ports, details prerequisites and operational behavior, and highlights feature availability in Cisco IOS XE Cupertino 17.8.1 and later.

An RLAN authentication fallback is a WLAN authentication mechanism that

- enables client authentication to switch between 802.1X and MAC authentication bypass (MAB) when the initial method fails
- supports dynamic fallback from 802.1X to MAB and vice versa according to client status and registration, and
- requires that both 802.1X and MAB are enabled for fallback support.

Feature history

Table 187: Feature history for RLAN authentication fallback

Feature name	Release information	Feature description
RLAN authentication fallback	Cisco IOS XE 17.8.x	RLAN authentication fallback alternates client authentication between 802.1X and MAC authentication bypass (MAB) when the initial method fails. It dynamically switches based on client status and registration, requiring both 802.1X and MAB to be enabled. From Cisco IOS XE Cupertino 17.8.1, Remote LAN (RLAN) ports on OfficeExtend Access Points (OEAPs) support authentication fallback.

How RLAN authentication fallback works

From Cisco IOS XE Cupertino 17.8.1, Remote LAN (RLAN) ports on OfficeExtend Access Points (OEAPs) support authentication fallback. If a client using IEEE 802.1X fails to authenticate, the system attempts MAC authentication bypass (MAB). Conversely, if the client's MAC address is not registered for MAC authentication bypass, the system falls back to IEEE 802.1X. Enable both methods to ensure successful authentication.

By default, the RLAN fallback mechanism is disabled. You must explicitly enable this mechanism. When both 802.1X and MAB are enabled, the device must succeed in both authentication methods for successful authentication.

Configure RLAN authentication fallback (CLI)

Configure RLAN authentication fallback using commands.

Enable authentication fallback for remote LAN (RLAN) profiles on your device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a remote LAN profile.

   Example

   ```
   Device(config)# ap remote-lan profile-name rlan_profile_name rlan-id
   ```

3. Enable 802.1X authentication on MAC filter failure.

   Example

   ```
   Device(config-remote-lan)# security {dot1x on-macfilter-failure | mac-filter
    on-dot1x-failure}
   ```

   Note

   You can either configure 802.1X authentication on MAC filter failure or MAC filter authentication on 802.1X failure. You cannot configure both.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-remote-lan)# end
   ```

If the primary authentication method fails, the RLAN profile attempts an alternative authentication method."

```
Device# configure terminal
Device(config)# ap remote-lan profile-name rlan_profile_name 3
Device(config-remote-lan)# security dot1x on-macfilter-failure
Device(config-remote-lan)# end
```

Modify 802.1X EAP timers for RLAN clients

Modify 802.1X EAP timers for RLAN clients.

Adapt 802.1X EAP authentication timers for remote LAN (RLAN) clients to ensure successful endpoint authentication.

To adapt the 802.1X EAP timers for RLAN clients, use this procedure:

> **Note**
>
> When you modify the 802.1X EAP timers, ensure that the timer is long enough to allow 802.1X-capable endpoints to authenticate. A timer that is too short may result in 802.1X-capable endpoints being subject to a fallback authentication or authorization technique.
>
> If 802.1X EAP timers are not configured using this procedure, the timer configuration done using the **wireless security dot1x request** and **wireless security dot1x identity-request** commands are applied.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the remote LAN profile.

   Example

   ```
   Device(config)# ap remote-lan profile-name rlan_profile_name rlan-id
   ```

3. Configure the maximum number of EAP ID request retransmissions.

   Example

   ```
   Device(config-remote-lan)# security dot1x identity-request retries retry-num
   ```

   The valid range is from 1 to 20.

4. Configure the EAP ID request-timeout value in seconds.

   Example

   ```
   Device(config-remote-lan)# security dot1x identity-request timeout
   timeout-value
   ```

The valid range is from 1 to 120.

5. Configure the maximum number of EAP request retransmissions.

   Example

   ```
   Device(config-remote-lan)# security dot1x request retries retry-num
   ```

   The valid range is from 0 to 20.

6. Configure the EAP request retransmission timeout value in seconds.

   Example

   ```
   Device(config-remote-lan)# security dot1x request timeout timeout-value
   ```

   The valid range is from 1 to 120.

7. Return to privileged EXEC mode.

   Example

   ```
   Device(config-remote-lan)# end
   ```

The EAP authentication timers for RLAN clients are adapted to your specified values, improving authentication reliability for 802.1X-capable endpoints.

```
Device# configure terminal
Device(config)# ap remote-lan profile-name rlan_profile_name 3
Device(config-remote-lan)# security dot1x identity-request retries 20
Device(config-remote-lan)# security dot1x identity-request timeout 120
Device(config-remote-lan)# security dot1x request retries 20
Device(config-remote-lan)# security dot1x request timeout 120
Device(config-remote-lan)# end
```

Verify RLAN authentication fallback

Verify RLAN authentication fallback.

Use this command to check the status of the fallback authentication mechanism.

```
Device# show remote-lan all

Remote-LAN Profile Name     : rlan_profile_name
================================================
Identifier                                    : 3

```

205 RLAN External Module

Topics:

- External module

External module

Explains the External Module feature that enables traffic to flow in and out from the Cisco Aironet Developer Platform module.

The External Module feature is a traffic management capability that

- enables traffic to flow in and out from the Cisco Aironet Developer Platform module
- operates when an access point (AP) is in both local and flex connect mode, and
- provides connectivity for external platform modules through the AP infrastructure.

Requirement: Prerequisites for configuring external module

Outlines the prerequisites that must be met before configuring an external module.

Before you begin, you must ensure the following:

- The external module is powered on.
- The RLAN status is enabled.

Configure external module (GUI)

Configure external module using GUI to assign RLAN policy profiles and profiles to external module ports through policy tags.

This task allows you to configure external module settings through the graphical user interface by creating policy tag mappings that associate RLAN profiles and policy profiles with external module ports.

Before you begin

Follow these steps to configure external module using GUI:

Procedure

1. Choose **Configuration** > **Tags & Profiles > Tags**.
2. In the **Policy** tab, select one of the **Policy Tag Name** and click **Add**.
3. In **Add Policy Tag** page and **RLAN-POLICY Maps** section, click **Add**.
4. From the **Port ID** drop-down list, choose **ext-module**.
5. From the **RLAN Profile** drop-down list, choose an RLAN profile.
6. From the **RLAN Policy Profile** drop-down list, choose an RLAN policy profile.
7. Click the check mark icon.

The external module is configured with the selected RLAN profile and policy profile through the policy tag mapping.

Configure external module (CLI)

Configure external module using commands.

Configure external module settings to enable remote LAN functionality on wireless devices.

External modules provide additional capabilities for remote LAN connectivity in wireless networks. This configuration assigns policy tags and remote LAN policies to external modules.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a policy tag to the external module for the remote LAN.

   Example

   ```
   Device(config)# wireless tag policy default-policy-tag
   ```

3. Configure a remote LAN policy to the external module.

   Example

   ```
   Device(default-policy-tag)# remote-lan rlan-profile policy rlan-policy
   ext-module
   ```

   Example

   ```
   Device(default-policy-tag)# remote-lan rlan policy abc ext-module
   ```

The external module is now configured with the specified policy tag and remote LAN policy, enabling remote LAN functionality.

External module verification

Provides commands to verify external module configuration and inventory details.

Verify external module configuration and inventory details using show commands.

To view the external module remote LAN configuration, use the following command:

```
Device# show ap name ap_name lan port summary

LAN Port status for AP ap_name

Port ID      status      vlanId      poe        power-level     RLAN
-------------------------------------------------------------------
ext-module   Enabled     39          NA         NA              Enabled
```

To view the external module inventory details, use the following command:

```
Device# show ap name abc inventory
NAME: AP3800, DESCR: Cisco Aironet 3800 Series (IEEE 802.11ac) Access Point
PID: AIR-AP3802I-D-K9, VID: 01, SN: xxxxxxxxxxx

MODULE NAME: Expansion Module, DESCR: Cisco HDK Module (rev2)
```

```
PID: Unknown, SN: xxxxxxxxxxx, MaxPower: 2700mW
VersionID: V22, Capabilities: RLAN (UP)
```

206 802.11ax Per WLAN

Topics:

- 802.11ax mode per WLAN

802.11ax mode per WLAN

Explains how 802.11ax mode is configured per WLAN to provide more granular control over wireless network settings.

An 802.11ax mode per WLAN is a wireless configuration feature that

- enables or disables 802.11ax functionality at the individual WLAN level rather than per radio band
- provides granular control over 11ax settings for specific SSIDs
- allows mixed 11ax and legacy client connectivity on the same access point.

Configuration evolution and behavior

Prior to Cisco IOS XE Bengaluru Release 17.4.1, the 802.11ax mode was configured per radio band. In this configuration, the 11ax mode was either enabled or disabled for all WLANs (AP) that were configured per radio, all at once. When 11ax was enabled per radio, the 11ac clients were not able to scan or connect to the SSID if the beacon had 11ax information elements. Client could not probe an access point (AP), if the beacon has 11ax IE.

Therefore, a 11ax configuration knob per AP is introduced, from Cisco IOS XE Bengaluru Release 17.5.1. This knob is introduced under the WLAN profile. By default, the 11ax knob per WLAN is now enabled on the controller.

> **Note**
>
> For 6-GHz radio, the 802.11ax parameters are taken from the multi BSSID profile tagged to the corresponding 6-GHz RF profile of the AP. So, the WLAN dot11ax parameters are overridden by multi BSSID profile parameters in the case of 6-GHz. There are no changes for 2.4 and 5-GHz band WLANs. They continue to use the WLAN parameters for 802.11ax.

Configure 802.11ax mode per WLAN (GUI)

Configure 802.11ax mode per WLAN using GUI.

Enable or disable 802.11ax mode on a specific WLAN to control Wi-Fi 6 functionality.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.

   The **Add WLAN** window is displayed.
3. Click the **Advanced** tab.
4. In the **11ax** section, check the **Enable 11ax** check box to enable 802.11ax operation status on the WLAN.

> **Note**
>
> When 11ax is disabled, beacons will not display 11ax IE, and all the 11ax features will be operationally disabled on the WLAN.

5. Click **Apply to Device**.

The 802.11ax mode is now configured or disabled on the specified WLAN according to your requirements.

Configure 802.11ax mode per WLAN (CLI)

Configure 802.11ax mode per WLAN using commands.

Enable or disable 802.11ax mode on a specific WLAN to control Wi-Fi 6 functionality.

802.11ax (Wi-Fi 6) provides improved performance and efficiency. This configuration allows you to enable or disable 802.11ax mode on individual WLANs based on your network requirements.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the WLAN name and enter the WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan-profile-name
   ```

3. Configure 802.11ax on a WLAN.

   Example

   ```
   Device(config-wlan)# dot11ax
   ```

4. Disable 802.11ax on the WLAN profile.

   Example

   ```
   Device(config-wlan)# no dot11ax
   ```

The 802.11ax mode is now configured or disabled on the specified WLAN according to your requirements.

Verify 802.11ax mode per WLAN

This topic explains how to verify 802.11ax mode per WLAN to confirm the operational status of 802.11ax parameters.

This topic verifies the operational status of 802.11ax parameters for a specific WLAN configuration to ensure the wireless network is operating with the expected 802.11ax features enabled.

Verify 802.11ax mode per WLAN

To display the status of the 11ax parameter, use this command:

```
Device# show wlan id 6
            WLAN Profile Name     : power
            ================================================
            Identifier                                    : 6
            Description                                   :
            Network Name (SSID)                           : power
            Status                                        : Enabled
            Broadcast SSID                                : Enabled
            Advertise-Apname                              : Disabled
            Universal AP Admin                            : Disabled
            Max Associated Clients per WLAN               : 0
            Max Associated Clients per AP per WLAN        : 0
            Max Associated Clients per AP Radio per WLAN  : 200
            .
            .
            .
            802.11ac MU-MIMO                              : Enabled
            802.11ax parameters
            802.11ax Operation Status                  : Enabled
            OFDMA Downlink                             : Enabled

207 BSS Coloring

Topics:

- BSS coloring

BSS coloring

Describes a Wi-Fi 6 mechanism that allows devices to distinguish between packets from their own BSS and overlapping BSS by using color values in the PHY header.

BSS coloring is a Wi-Fi 6 mechanism that

- allows devices operating in the same frequency space to quickly distinguish between packets from their own BSS and packets from an Overlapping BSS (OBSS) by looking at the BSS color value in the HE PHY header
- enables spatial reuse opportunities where devices can transmit simultaneously with OBSS packets instead of deferring transmissions due to legacy interference thresholds, and
- increases power savings by allowing devices to drop non-BSS packets earlier without demodulating the entire packet.

BSS coloring background information

The 802.11 Wi-Fi standard minimizes the chance of multiple devices interfering with one another by transmitting at the same time. This carrier-sense multiple access with collision avoidance (CSMA/CA) technology is based on static thresholds that allow Wi-Fi devices to avoid interfering with each other on air. However, with an increase in density and the number of Wi-Fi devices, these static thresholds often lead to CSMA/CA causing devices to defer transmissions unnecessarily.

For example, if two devices that are associated with different BSS, can hear every transmission from each other at relatively low signal strengths, each device should defer its transmission when it receives a transmission from the other. But if both the devices were to transmit at the same time, it is likely that neither would cause enough interference at the other BSS' receiver to cause reception failure for either transmission.

Devices today must demodulate packets to look at the MAC header in order to determine whether or not a received packet belongs to their own BSS. This process of demodulation consumes power, which can be saved if devices can quickly identify the BSS by looking at the PHY header alone, and subsequently drop packets that are from a different BSS. Prior to Wi-Fi 6, there was no provision for devices to do this.

The new 802.11ax (Wi-Fi 6) standard addresses both of the issues discussed above, through the new BSS Coloring and Spatial Reuse mechanism. Since every Wi-Fi 6 device understands the BSS color, it can be leveraged to increase power savings by dropping packets earlier, and to identify spatial reuse opportunities.

BSS coloring

Explains a method used to differentiate between the BSS of access points and their clients on the same RF channel.

BSS coloring is a Wi-Fi 6 method that

- differentiates between the BSS of access points and their clients on the same RF channel
- enables each AP radio to assign a value (from 1 to 63), known as BSS color, to be included in the PHY header of all HE transmissions from devices in its BSS, and
- allows devices to quickly and easily distinguish transmissions coming from their BSS from those of neighboring BSS.

Supported platforms

The following platforms support this feature:

- Cisco Catalyst 9800 Series Wireless Controllers
- Cisco Catalyst 9115 Access Points
- Cisco Catalyst 9120AX Series Access Points
- Cisco Catalyst 9124AX Series Access Points

- Cisco Catalyst 9130AX Access Points

OBSS-PD and spatial reuse

Explains OBSS-PD spatial reuse technology that improves Wi-Fi 6 network efficiency by allowing controlled transmission over inter-BSS packets.

OBSS-PD is a Wi-Fi packet detection mechanism that

- uses a more aggressive packet detect threshold for inter-BSS packets, typically higher than the legacy -82 dBm
- identifies inter-BSS packets by comparing the BSS color in the HE PHY header with the device's BSS color, and
- enables Wi-Fi 6 or 802.11ax devices to transmit over inter-BSS packets with RSSI below the OBSS-PD threshold to improve throughput and network efficiency.

> **Note**
>
> Cisco Catalyst 9120AX Series Access Points do not support OBSS-PD.

Configure BSS color on AP (GUI)

Configure BSS color on AP using GUI.

Procedure

1. Choose **Configuration > Wireless > Access Points**.
2. Click the **5 GHz Radios** section or the **2.4 GHz Radios** section.

   The list of the AP radios in the band is displayed.
3. Click the required AP name.

   The **Edit Radios** window is displayed.
4. From the **Edit Radios** window, select the **Configure** tab.

   The general information, Antenna Parameters, RF Channel Assignment, Tx Power Level Assignment, and BSS Color are displayed.
5. In the **BSS Color** area and from the **BSS Color Configuration** drop-down list, choose **Custom** configuration
   - **Custom**: To manually select the BSS color configuration for the AP radio.
     a. Click the **BSS Color Status** field to disable or enable the feature.
     b. In the **Current BSS Color** field, specify a corresponding BSS color for the AP radio. The valid range is between 1 and 63.
6. Click **Update & Apply to Device**.

Configure BSS color in the privileged EXEC mode

Configure BSS color in the privileged EXEC mode.

Procedure

1. **enable**

   Example

   ```
   Device> enable
   ```

   Enables privileged EXEC mode. Enter your password, if prompted.

2. **ap name** *ap-name* **dot11 24ghz 5ghz 6ghz | dual-band slot** *slot-id* **dot11ax bss-color** *<1-63>*

   Example

   ```
   Device#ap name apn dot11 24ghz slot 0 dot11ax bss-color 12
   ```

   Sets the BSS color on the 2.4-GHz, 5-GHz, 6-GHz, or dual-band radio, for a specific access point on the following slots:

   - 5 GHz: Slot 1 and 2
   - 2.4 GHz: Slot 0
   - 6-GHz: Slot 3
   - Dual-band: Slot 0

   Use the **no** form of this command to disable BSS color.

   Example

   ```
   Device#ap name apn no dot11 24ghz slot 0 dot11ax bss-color
   ```

Configure BSS color globally

Configure BSS color globally using GUI.

Procedure

1. Choose **Configuration > Radio Configurations > Parameters**.
2. In the **11ax Parameters** section, enable BSS color globally for the 5 GHz and 2.4 GHz radios by checking the **BSS Color** check box.

Configure BSS color in the configuration mode

Configure BSS color in the configuration mode.

Enable 802.11ax BSS color functionality to improve spatial reuse and reduce interference in wireless networks.

BSS color is used in 802.11ax networks to distinguish between overlapping basic service sets, allowing devices to better manage interference and improve overall network performance.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password if prompted.
2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Enable the 802.11ax BSS color on all radios for the specified frequency band.

   Example

   ```
   Device(config)# [no] ap dot11 {24ghz | 5ghz | 6ghz} dot11ax bss-color
   ```

   Example

   ```
   Device(config)# ap dot11 24ghz dot11ax bss-color
   ```

   Use the `no` form of this command to disable BSS color.

BSS color is now enabled on the specified frequency band, improving spatial reuse and network efficiency for 802.11ax devices.

Configure overlapping BSS packet detect (GUI)

Configure overlapping BSS packet detect using GUI.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **Parameters**.

   The parameters page is displayed where you can configure global parameters for 5 GHz Band and 2.4 GHz Band radios.
2. In the **11ax Parameters** section, check the **OBSS PD** check box to enable the overlapping BSS packet detect (OBSS PD) feature.
3. In the **Non-SRG OBSS PD Max Threshold** field, enter the threshold in decibel-milliwatts. Value range is between -82 dBm and -62 dBm.

Configure OBSS-PD spatial reuse globally (CLI)

Configure OBSS-PD spatial reuse globally using commands.

Enable 802.11ax OBSS-PD spatial reuse functionality to improve network efficiency by allowing concurrent transmissions when interference levels are acceptable.

OBSS-PD (Overlapping Basic Service Set Packet Detection) spatial reuse is an 802.11ax feature that improves network capacity by allowing access points to transmit simultaneously when the detected interference is below a specified threshold. Configure this feature globally across all radios of a specific frequency band.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure 802.11ax OBSS PD based spatial reuse on all 2.4 GHz or 5 GHz radios.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} dot11ax spatial-reuse obss-pd
   ```

   Example

   ```
   Device(config)# ap dot11 24ghz dot11ax spatial-reuse obss-pd
   ```

   Use the `no` form of this command to disable this feature.

3. Configure 802.11ax non-SRG OBSS PD max on all 2.4-GHz or 5-GHz radios.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} dot11ax spatial-reuse obss-pd
   non-srg-max threshold-value
   ```

   Example

   ```
   Device(config)# ap dot11 24ghz dot11ax spatial-reuse obss-pd non-srg-max -62
   ```

   The default value is -62. The valid range is -82 to -62 dBm.

OBSS-PD spatial reuse is now configured globally on the specified frequency band, allowing access points to optimize concurrent transmissions based on the configured interference threshold.

Configure OBSS PD in an RF profile (GUI)

Configure OBSS PD in an RF profile using GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF**.
2. On the **RF Profile** page, click **Add** to configure the following:

- General
- 802.11
- RRM
- Advanced

3. In the **Advanced** tab, under the **11ax Parameters** section, complete the following:
   a) Use the toggle button to enable or disable the **OBSS PD** field.
   b) In the **Non-SRG OBSS PD Max Threshold (dBm)**, enter the threshold value. The default value is -62 dBm. Values range between -82 dBm and -62 dBm.
4. Click **Save & Apply to Device**.

Configure OBSS-PD spatial reuse in the RF profile mode (CLI)

Configure OBSS-PD spatial reuse in the RF profile mode using commands.

Enable OBSS-PD spatial reuse functionality on access points to improve network efficiency by allowing concurrent transmissions in overlapping basic service sets.

OBSS-PD spatial reuse is an 802.11ax feature that helps optimize spectrum utilization in dense wireless environments by dynamically adjusting transmission thresholds based on neighboring network activity.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an RF profile and enter RF profile configuration mode.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rf-profile rf-profile-name
   ```

   Example

   ```
   Device(config)# ap dot11 24ghz rf-profile rfprof24_1
   ```

3. Configure 802.11ax OBSS PD based spatial reuse in the RF profile configuration mode.

   Example

   ```
   Device(config-rf-profile)# dot11ax spatial-reuse obss-pd
   ```

   Use the no form of this command to disable this feature.

4. Configure 802.11ax non-SRG OBSS PD maximum threshold.

Example

```
Device(config-rf-profile)# dot11ax spatial-reuse obss-pd non-srg-max
threshold-value
```

Example

```
Device(config-rf-profile)# dot11ax spatial-reuse obss-pd non-srg-max -62
```

The valid range is -82 to -62 dBm. The default value is -62.

OBSS-PD spatial reuse is configured on the RF profile and will be applied to all access points using this profile, enabling improved spectrum efficiency in overlapping coverage areas.

BSS color and OBSS-PD verification

Lists commands to verify BSS color and OBSS-PD configuration and status.

This reference provides commands to verify if the global per-band BSS color and OBSS-PD are enabled, view RF profile OBSS-PD configuration, check BSS color configuration of all AP radios on a band, and examine BSS color configuration and capability of specific AP radios.

To verify if the global per-band BSS color and OBSS-PD are enabled, use the following **show** command:

```
Device# show ap dot11 24ghz network
802.11b Network                              : Enabled
11gSupport                                   : Enabled
11nSupport                                   : Enabled
.
.
.
802.11ax                                     : Enabled
  DynamicFrag                                : Enabled
  MultiBssid                                 : Enabled
  Target Wakeup Time                         : Enabled
  Target Wakeup Time Broadcast               : Enabled
  BSS Color                                  : Enabled
  OBSS PD                                    : Enabled
  Non-SRG OBSS PD Max                        : -62 dBm
802.11ax MCS Settings:
  MCS  7, Spatial Streams = 1                : Supported
.
.
.
```

To view the RF profile OBSS-PD configuration, use the following **show** command:

```
Device# show ap rf-profile name rf-profile-name detail
Description                       : pre configured rfprofile for 5gh radio
RF Profile Name                   : rf-profile-name
Band                              : 5 GHz
Transmit Power Threshold v1       : -65 dBm
Min Transmit Power                : 7 dBm
Max Transmit Power                : 30 dBm
.
.
.
802.11ax
```

```
  OBSS PD                          : Enabled
  Non-SRG OBSS PD Max              : -62 dBm
NDP mode                           : Auto
```

To view the BSS color configuration of all the AP radios on a band in the summary list, along with Channel, TX Power and so on, use the following **show** command:

```
Device# show ap dot11 24ghz summary extended
AP Name                          Mac Address     Slot    Admin State    Oper
 State    Width  Txpwr           Channel                        BSS Color
-----------------------------------------------------------------------------------------------

208 DHCP for WLANs

Topics:

- Dynamic Host Configuration Protocol
- Configure DHCP for WLANs
- Configure internal DHCP server
- Configure DHCP-Required for FlexConnect

Dynamic Host Configuration Protocol

Describes a network protocol that dynamically assigns IP addresses to devices on a network for IP communication.

Dynamic Host Configuration Protocol (DHCP) is a network protocol that

- dynamically assigns IP addresses to devices on a network for IP communication
- enables configuration of WLANs to use the same or different DHCP servers or no DHCP server, and
- provides two types of DHCP servers: internal and external.

Internal DHCP servers

Describes internal DHCP servers that are typically used in branch offices without a dedicated DHCP server.

An internal DHCP server is a device-based DHCP service that

- provides DHCP addresses to wireless clients, direct-connect APs, and DHCP requests that are relayed from APs
- supports only lightweight APs, and
- requires SVI configuration for the client VLAN with the IP address set as DHCP server IP address.

General guidelines

The device contains an internal DHCP server. This server is typically used in branch offices that do not have a DHCP server.

DHCP option 43 is not supported on the internal server. Therefore, the APs must use an alternative method to locate the management interface IP address of the device, such as local subnet broadcast, Domain Name System (DNS), or priming.

When clients use the internal DHCP server of the device, IP addresses are not preserved across reboots. As a result, multiple clients can be assigned to the same IP address. To resolve any IP address conflicts, clients must release their existing IP address and request a new one.

Key configuration requirements:

- Internal DHCP server serves both wireless client and wired client (wired client includes AP).
- To serve wireless client with internal DHCP server, an unicast DHCP server IP address must be configured for wireless client. Internal DHCP server IP address must be configured under the server facing interface, which can be loopback interface, SVI interface, or L3 physical interface.
- To use internal DHCP server for both wireless and wired client VLAN, an IP address must be configured under client VLAN SVI interface.
- For wireless client, in DHCP helper address configuration, the IP address of the internal DHCP server must be different from address of wireless client VLAN SVI interface.
- For wireless client with internal DHCP server support, the internal DHCP server can be configured using global configuration command, under the client VLAN SVI interface or under the wireless policy profile.
- An internal DHCP server pool can also serve clients of other controllers .

Note

- VRF is supported in the internal DHCP servers.
- DHCPv6 is not supported in the internal DHCP servers.

External DHCP servers

Explains external DHCP servers that dynamically assign IP addresses within a network from a separate server outside the device.

An external DHCP server is a separate server outside the device that

- dynamically assigns IP addresses within a network
- operates with industry-standard DHCP Relay support, and
- maintains client IP addresses during roaming scenarios.

External DHCP server operation

The operating system is designed to appear as a DHCP relay to the network and as a DHCP server to clients with industry-standard external DHCP servers that support DHCP Relay, which means that each controller appears as a DHCP relay agent to the DHCP server, and as a DHCP server in the virtual IP address to wireless clients.

Because the controller captures the client IP address that is obtained from a DHCP server, it maintains the same IP address for that client during intra controller, inter controller, and inter-subnet client roaming.

Note

External DHCP servers support DHCPv6.

DHCP assignments

Describes DHCP server configuration options on a per-interface or per-WLAN basis.

A DHCP assignment is a network configuration method that

- configures DHCP servers on a per-interface or per-WLAN basis,
- allows assignment of primary and secondary DHCP servers to individual interfaces, and
- enables DHCP server definition on WLANs to override interface-level DHCP server addresses.

DHCP assignment configuration

Security considerations

You can configure DHCP on a per-interface or per-WLAN basis. We recommend that you use the primary DHCP server address that is assigned to a particular interface.

You can assign DHCP servers for individual interfaces. You can configure the management interface, AP manager interface, and dynamic interface for a primary and secondary DHCP server, and configure the service-port interface to enable or disable DHCP servers. You can also define a DHCP server on a WLAN (in this case, the server overrides the DHCP server address on the interface assigned to the WLAN).

For enhanced security, we recommend that you ask all clients to obtain their IP addresses from a DHCP server. To enforce this requirement, you can configure all the WLANs with a DHCP Address. Assignment Required setting, which disallows client static IP addresses. If DHCP Address Assignment Required is selected, clients must obtain an IP address through DHCP. Any client with a static IP address is not allowed on the network. The controller monitors DHCP traffic because it acts as a DHCP proxy for the clients.

Note

- WLANs that support management over wireless must allow management (device-servicing) clients to obtain an IP address from a DHCP server.
- The operating system is designed to appear as a DHCP relay to the network and as a DHCP server to clients with industry-standard external DHCP servers that support DHCP relay. This means that each controller appears as a DHCP relay to the DHCP server and as a DHCP server at the virtual IP address to wireless clients.

You can create WLANs with DHCP Address Assignment Required disabled. If you do this, clients have the option of using a static IP address or obtaining an IP address from a designated DHCP server. However, note that this might compromise security.

Note

DHCP Address Assignment Required is not supported for wired guest LANs.

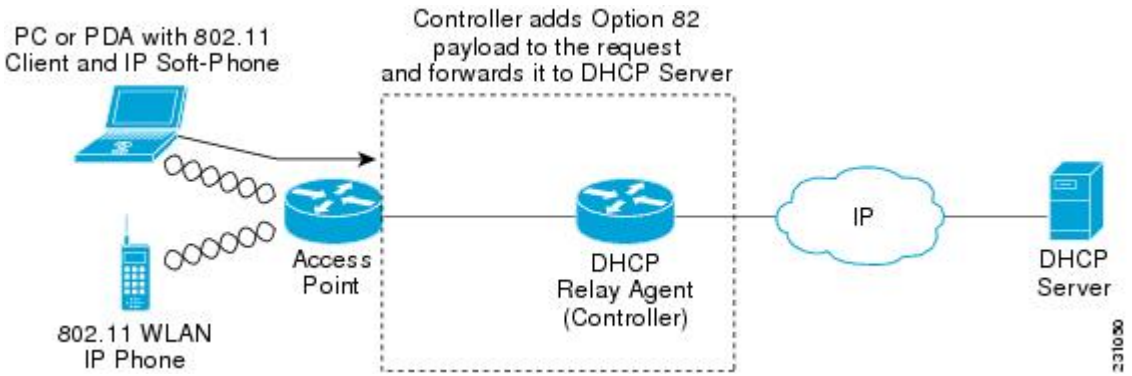
You can create separate WLANs with DHCP Address Assignment Required configured as disabled. This is applicable only if DHCP proxy is enabled for the controller. You must not define the primary or secondary configuration DHCP server instead you should disable the DHCP proxy. These WLANs drop all the DHCP requests and force clients to use a static IP address. These WLANs do not support management over wireless connections.

DHCP option 82

Describes additional security when DHCP is used to allocate network addresses.

DHCP option 82 is a DHCP relay agent feature that

- provides additional security when DHCP is used to allocate network addresses
- enables the controller to act as a DHCP relay agent to prevent DHCP client requests from untrusted sources, and
- allows the controller to add option 82 information to DHCP requests from clients before forwarding the requests to the DHCP server.



DHCP option 82 operation

The AP forwards all the DHCP requests from a client to the controller. The controller adds the DHCP option 82 payload and forwards the request to the DHCP server. The payload can contain the MAC address or the MAC address and SSID of the AP, depending on how you configure this option.

> **Note**
>
> DHCP packets that already include a relay agent option are dropped at the controller.

For DHCP option 82 to operate correctly, DHCP proxy must be enabled.

Figure 36: DHCP Option 82

Restrictions for configuring DHCP for WLANs

Outlines restrictions for configuring DHCP for WLANs.

When configuring DHCP for WLANs, ensure proper server reachability and service enablement to avoid connectivity issues.

- If you override the DHCP server in a WLAN, you must ensure that you configure the underlying Cisco IOS configuration to make sure that the DHCP server is reachable.
- WLAN DHCP override works only if DHCP service is enabled on the controller.

  You can configure DHCP service in either of the following ways:

  - Configuring the DHCP pool on the controller.
  - Configuring a DHCP relay agent on the SVI. Note that the VLAN of the SVI must be mapped to the WLAN where DHCP override is configured.

Guidelines for DHCP relay configuration

Outlines the guidelines for configuring DHCP relay agent source IP and server addresses to ensure proper functionality.

Relay agent source IP

Configure the relay agent source IP according to the following precedence order to ensure proper DHCP relay functionality.

- If you configure source interface VLAN in the SVI interface, the IP address of the VLAN interface configured as source is used.
- If the Relay Agent source IP is not mentioned, the IP address of the SVI interface created for the corresponding client's VLAN is used.
- If the Relay Agent source IP is not mentioned, the source address specified at the global level is used.

DHCP server

Configure DHCP server addresses according to the following precedence order to ensure proper server selection.

- If the DHCP server address is configured in the wireless policy profile, the server address configured in the policy profile takes precedence.
- If the DHCP server address is not configured in the policy profile, the server address configured in SVI takes precedence.

> **Note**
>
> You can configure two server addresses in the SVI. In this case, the DHCP packets from the client are sent to both the servers.
>
> The Option 82 configured in policy profile, SVI, and globally is considered and honored together.

These guidelines apply to central DHCP and local switching configurations. The DHCP packets are sourced from the IP address of the Wireless Management Interface (WMI), if VLAN is not configured in the policy profile and AAA override. The SVI interface configuration is mandatory to achieve the DHCP relay functionality in central DHCP or local switching. Even though many interface options are available in the **ip dhcp relay source-interface** <> command, only VLAN interface is applicable.

Configure DHCP for WLANs

Provides instructions for configuring DHCP scopes using GUI and CLI, including setting IP address ranges, subnet masks, lease options, and network parameters such as routers, DNS and NetBIOS name servers, domains, and DHCP options for wireless clients.

Configure DHCP scopes (GUI)

Configure DHCP scopes using the graphical user interface to manage IP address assignment and network configuration parameters for wireless clients.

Configure DHCP scopes to automatically assign IP addresses and network configuration parameters to wireless clients on your network.

DHCP scopes define the range of IP addresses available for assignment to clients, along with associated network configuration parameters such as subnet masks, default routers, and DNS servers.

Procedure

1. Choose **Administration > DHCP Pools**.
2. In the **Pools** section, click **Add** to add a new DHCP pool.

   The **Create DHCP Pool** dialog box is displayed.
3. In the **DHCP Pool Name** field, enter a name for the new DHCP pool.
4. From the **IP Type** drop-down list, choose the IP address type.
5. In the **Network** field, enter the network served by this DHCP scope.

   This IP address is used by the management interface with netmask applied, as configured in the **Interfaces** window.
6. In the **Subnet Mask** field, enter the subnet mask assigned to all the wireless clients.
7. In the **Starting IP** field, enter the starting IP address.

8. In the **Ending IP** field, enter the trailing IP address.
9. In the **Reserved Only** field, enable or disable it.
10. From the **Lease** drop-down list, choose the lease type as either **User Defined** or **Never Expires**.

    If you choose User Defined, you can enter the amount of time that an IP address is granted to a client.

11. To perform advanced configuration for DHCP scope, click **Advanced**.
12. Check the **Enable DNS Proxy** check box to enable DNS proxy.
13. In the **Default Router(s)** field, enter the IP address of the optional router or routers that connect to the device and click the **+** icon to add them to the list.

    Each router must include a DHCP forwarding agent that enables a single device to serve the clients of multiple devices.

14. In the **DNS Server(s)** field, enter the IP address of the optional DNS server or servers and click the **+** icon to add them to the list.

    Each DNS server must be able to update a client's DNS entry to match the IP address assigned by the DHCP scope.

15. In the **NetBios Name Server(s)** field, enter the IP address of the optional Microsoft NetBIOS name server or servers, such as Microsoft Windows Internet Naming Service (WINS) server, and click the **+** icon to add them to the list.
16. In the **Domain** field, enter the optional domain name of the DHCP scope for use with one or more DNS servers.
17. To add **DHCP** options, click **Add** in the **DHCP Options List** section.

    DHCP provides an internal framework for passing configuration parameters and other control information, such as DHCP options, to the clients on your network. DHCP options carry parameters as tagged data stored within protocol messages exchanged between the DHCP server and its clients.

18. Enter the **DHCP** option that you want to add.
19. Click **Save & Apply to Device**.

The DHCP scope is configured and ready to assign IP addresses and network configuration parameters to wireless clients.

Configure DHCP scopes (CLI)

Configure DHCP scopes using commands.

Set up DHCP scopes to automatically assign IP addresses and network configuration to client devices.

DHCP scopes define the range of IP addresses and network parameters that a DHCP server can assign to clients. This configuration is essential for automated network address management in enterprise environments.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the DHCP pool address.

   Example

   ```
   Device(config)# ip dhcp pool pool-name
   ```

Example

```
Device(config)# ip dhcp pool test-pool
```

3. Specify the network number in dotted-decimal notation and the mask address.

Example

```
Device(dhcp-config)# network network-name mask-address
```

Example

```
Device(dhcp-config)# network 209.165.200.224 255.255.255.0
```

4. Specify the DNS name server.

Example

```
Device(dhcp-config)# dns-server hostname
```

Example

```
Device(dhcp-config)# dns-server example.com
```

You can specify an IP address or a hostname.

5. Return to privileged EXEC mode.

Example

```
Device(dhcp-config)# end
```

The DHCP scope is now configured and ready to assign IP addresses, network masks, and DNS server information to DHCP clients.

Configure internal DHCP server

Provides instructions for configuring an internal DHCP server to automatically assign IP addresses to wireless clients. It includes steps for adjusting DHCP settings within a wireless policy profile using both the web interface and CLI commands. The configuration covers setting up centralized DHCP services, defining network pools, exclusions, and static IP reservations. Additionally, it outlines commands for verifying the DHCP configuration, including client binding checks and analyzing DHCP relay and packet punt statistics.

Configure the internal DHCP server under client VLAN SVI (GUI)

Configure the internal DHCP server under client VLAN SVI using GUI.

This task configures the internal DHCP server settings for a client VLAN Switched Virtual Interface (SVI) to enable DHCP relay functionality.

Use this procedure when you need to set up DHCP relay on an SVI to forward DHCP requests to a designated helper address. This configuration is typically performed on network switches to enable DHCP services across VLANs.

Procedure

1. Choose **Configuration** > **Layer2** > **VLAN** > **SVI**.
2. Click an SVI.
3. Click the **Advanced** tab.
4. Under **DHCP Relay** settings, enter the **IPV4 Helper Address**.
5. Click **Update & Apply to Device**.

The internal DHCP server is configured under the client VLAN SVI with the specified helper address, enabling DHCP relay functionality for the selected SVI.

Configure the internal DHCP server under client VLAN SVI (CLI)

Configure the internal DHCP server under client VLAN SVI using commands.

Set up an internal DHCP server to provide IP address assignment for wireless and wired clients through the client VLAN SVI configuration.

The internal DHCP server can be configured under the client VLAN SVI to serve both wireless and wired clients. This configuration requires proper IP addressing and helper configuration to function correctly with the wireless infrastructure.

Before you begin

- For wireless clients, only two DHCP servers are supported.
- To use the internal DHCP server for both wireless and wired client VLAN, an IP address must be configured under the client VLAN SVI.
- For wireless clients, the IP address of the internal DHCP server must be different from the address of the wireless client VLAN SVI (in the DHCP helper address configuration).
- For wireless clients, the internal DHCP server can be configured under the client VLAN SVI or under the wireless policy profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a loopback interface and enter interface configuration mode.

   Example

   ```
   Device(config)# interface loopback interface-number
   ```

   Example

   ```
   Device(config)# interface Loopback0
   ```

3. Configure the IP address for the interface.

Example

```
Device(config-if)# ip address ip-address subnet-mask
```

Example

```
Device(config-if)# ip address 10.10.10.1 255.255.255.255
```

4. Exit interface configuration mode.

Example

```
Device(config-if)# exit
```

5. Configure the VLAN ID.

Example

```
Device(config)# interface vlan vlan-id
```

Example

```
Device(config)# interface vlan 32
```

6. Configure the IP address for the interface.

Example

```
Device(config-if)# ip address ip-address subnet-mask
```

Example

```
Device(config-if)# ip address 192.168.32.100 255.255.255.0
```

7. Configure the destination address for UDP broadcasts.

Example

```
Device(config-if)# ip helper-address ip-address
```

Example

```
Device(config-if)# ip helper-address 10.10.10.1
```

> **Note**
>
> If the IP address used in the **IP helper-address** command is an internal address of the controller an internal DHCP server is used. Otherwise, the external DHCP server is used.

8. Disable the Maintenance Operation Protocol (MOP) for an interface.

   Example

   ```
   Device(config-if)# no mop enabled
   ```

9. Disable the task of sending MOP periodic system ID messages.

   Example

   ```
   Device(config-if)# no mop sysid
   ```

10. Exit interface configuration mode.

    Example

    ```
    Device(config-if)# exit
    ```

11. Specify the IP address that the DHCP server should not assign to DHCP clients.

    Example

    ```
    Device(config)# ip dhcp excluded-address ip-address
    ```

    Example

    ```
    Device(config)# ip dhcp excluded-address 192.168.32.1
    ```

12. Specify the IP addresses that the DHCP server should not assign to DHCP clients.

    Example

    ```
    Device(config)# ip dhcp excluded-address ip-address
    ```

    Example

    ```
    Device(config)# ip dhcp excluded-address 192.168.32.100
    ```

13. Configure the DHCP pool address.

    Example

    ```
    Device(config)# ip dhcp pool pool-name
    ```

Example

```
Device(config)# ip dhcp pool pool-vlan32
```

14. Specify the network number in dotted-decimal notation, along with the mask address.

Example

```
Device(dhcp-config)# network network-address subnet-mask
```

Example

```
Device(dhcp-config)# network 192.168.32.0 255.255.255.0
```

15. Specify the IP address of the default router for a DHCP client.

Example

```
Device(dhcp-config)# default-router ip-address
```

Example

```
Device(dhcp-config)# default-router 192.168.32.1
```

16. Exit DHCP configuration mode.

Example

```
Device(dhcp-config)# exit
```

17. Configure the WLAN policy profile and enter wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy profile-policy
```

Example

```
Device(config)# wireless profile policy default-policy-profile
```

18. Configure central association for locally switched clients.

Example

```
Device(config-wireless-policy)# central association
```

19. Configure the central DHCP for locally switched clients.

Example

```
Device(config-wireless-policy)# central dhcp
```

20. Configure WLAN for central switching.

    Example

    ```
    Device(config-wireless-policy)# central switching
    ```

21. Add a description for the policy profile.

    Example

    ```
    Device(config-wireless-policy)# description "policy-profile-description"
    ```

    Example

    ```
    Device(config-wireless-policy)# description "default policy profile"
    ```

22. Assign the profile policy to the VLAN.

    Example

    ```
    Device(config-wireless-policy)# vlan vlan-id
    ```

    Example

    ```
    Device(config-wireless-policy)# vlan 32
    ```

23. Enable the wireless profile policy.

    Example

    ```
    Device(config-wireless-policy)# no shutdown
    ```

The internal DHCP server is now configured under the client VLAN SVI and can provide IP address assignment to both wireless and wired clients connected to the specified VLAN.

Configure the internal DHCP server under a wireless policy profile (GUI)

Configure the internal DHCP server under a wireless policy profile using the GUI.

Configure DHCP settings to enable automatic IP address assignment for wireless clients connected to the network under a specific policy profile.

Use this procedure when you need to set up internal DHCP server functionality within a wireless policy profile to provide IP address allocation for connected wireless devices.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click a policy name.
3. Click the **Advanced** tab.

4. Under **DHCP** settings, check or uncheck the **IPv4 DHCP Required** check box and enter the **DHCP Server IP Address**.
5. Click **Update & Apply to Device**.

The internal DHCP server is configured under the wireless policy profile and the settings are applied to the device.

Configure the internal DHCP server under a wireless policy profile (CLI)

Configure the Internal DHCP server under a wireless policy profile.

Enable DHCP services for wireless clients by configuring an internal DHCP server within a wireless policy profile.

The internal DHCP server provides IP address assignment and network configuration to wireless clients. This configuration includes setting up loopback and VLAN interfaces, defining DHCP pools, and associating the DHCP server with a wireless policy profile.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a loopback interface and enter interface configuration mode.

   Example

   ```
   Device(config)# interface loopback interface-number
   ```

   Example

   ```
   Device(config)# interface Loopback0
   ```

3. Configure the IP address for the interface.

   Example

   ```
   Device(config-if)# ip address ip-address subnet-mask
   ```

   Example

   ```
   Device(config-if)# ip address 10.10.10.1 255.255.255.255
   ```

4. Exit interface configuration mode.

   Example

   ```
   Device(config-if)# exit
   ```

5. Configure the VLAN ID.

Example

```
Device(config)# interface vlan vlan-id
```

Example

```
Device(config)# interface vlan 32
```

6. Configure the IP address for the interface.

Example

```
Device(config-if)# ip address ip-address subnet-mask
```

Example

```
Device(config-if)# ip address 192.168.32.100 255.255.255.0
```

7. Disable the Maintenance Operation Protocol (MOP) for an interface.

Example

```
Device(config-if)# no mop enabled
```

8. Disable the task of sending MOP periodic system ID messages.

Example

```
Device(config-if)# no mop sysid
```

9. Exit interface configuration mode.

Example

```
Device(config-if)# exit
```

10. Specify the IP address that the DHCP server should not assign to DHCP clients.

Example

```
Device(config)# ip dhcp excluded-address ip-address
```

Example

```
Device(config)# ip dhcp excluded-address 192.168.32.100
```

11. Configure the DHCP pool address.

Example

```
Device(config)# ip dhcp pool pool-name
```

Example

```
Device(config)# ip dhcp pool pool-vlan32
```

12. Specify the network number in dotted-decimal notation along with the mask address.

Example

```
Device(dhcp-config)# network network-address subnet-mask
```

Example

```
Device(dhcp-config)# network 192.168.32.0 255.255.255.0
```

13. Specify the IP address of the default router for a DHCP client.

Example

```
Device(dhcp-config)# default-router ip-address
```

Example

```
Device(dhcp-config)# default-router 192.168.32.1
```

14. Exit DHCP configuration mode.

Example

```
Device(dhcp-config)# exit
```

15. Configure a WLAN policy profile and enter wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy profile-policy
```

Example

```
Device(config)# wireless profile policy default-policy-profile
```

16. Configure central association for locally switched clients.

Example

```
Device(config-wireless-policy)# central association
```

17. Configure local switching.

Example

```
Device(config-wireless-policy)# central switching
```

18. Add a description for the policy profile.

Example

```
Device(config-wireless-policy)# description "policy-profile-name"
```

Example

```
Device(config-wireless-policy)# description "default policy profile"
```

19. Enable DHCP Option 82 for the wireless clients.

Example

```
Device(config-wireless-policy)# ipv4 dhcp opt82
```

20. Enable ASCII on DHCP Option 82.

Example

```
Device(config-wireless-policy)# ipv4 dhcp opt82 ascii
```

21. Enable VLAN ID.

Example

```
Device(config-wireless-policy)# ipv4 dhcp opt82 format vlan-id
```

Example

```
Device(config-wireless-policy)# ipv4 dhcp opt82 format vlan32
```

22. Support the addition of Cisco 2-byte Remote ID (RID) for DHCP Option 82.

Example

```
Device(config-wireless-policy)# ipv4 dhcp opt82 rid
```

23. Configure the WLAN's IPv4 DHCP server.

Example

```
Device(config-wireless-policy)# ipv4 dhcp server ip-address
```

Example

```
Device(config-wireless-policy)# ipv4 dhcp server 10.10.10.1
```

24. Assign the profile policy to the VLAN.

Example

```
Device(config-wireless-policy)# vlan vlan-id
```

Example

```
Device(config-wireless-policy)# vlan 32
```

25. Enable the wireless profile policy.

Example

```
Device(config-wireless-policy)# no shutdown
```

The internal DHCP server is now configured and operational within the wireless policy profile, ready to provide IP addresses and network configuration to wireless clients.

Configure the internal DHCP server globally (GUI)

Configure the internal DHCP server globally using GUI.

Configure a DHCP pool to enable automatic IP address assignment for network devices through the internal DHCP server.

Use this procedure when you need to set up centralized IP address management for your network infrastructure using the GUI interface.

Procedure

---

1. Choose **Administration** > **DHCP Pools** > **Pools**.
2. Click **Add**.

   The **Create DHCP Pool** window is displayed.
3. Enter the **DHCP Pool Name**, **Network**, **Starting IP**, and **Ending IP**.
4. From the **IP Type**, **Subnet Mask**, and **Lease** drop-down lists, choose a value.
5. Click the **Reserved Only** toggle button.
6. Click **Apply to Device**.

The DHCP pool is created and applied to the device, enabling automatic IP address assignment within the specified range.

Configure the internal DHCP server globally (CLI)

Configure the internal DHCP server globally using commands.

Enable centralized DHCP services for wireless clients by configuring the internal DHCP server with appropriate network pools and policies.

The internal DHCP server configuration allows the wireless controller to provide IP addresses to wireless clients directly, eliminating the need for external DHCP servers in certain network deployments.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a loopback interface and enter interface configuration mode.

   Example

   ```
   Device(config)# interface loopback interface-number
   ```

   Example

   ```
   Device(config)# interface Loopback0
   ```

3. Configure the IP address for the interface.

   Example

   ```
   Device(config-if)# ip address ip-address subnet-mask
   ```

   Example

   ```
   Device(config-if)# ip address 10.10.10.1 255.255.255.255
   ```

4. Exit interface configuration mode.

   Example

   ```
   Device(config-if)# exit
   ```

5. Configure the VLAN ID.

   Example

   ```
   Device(config)# interface vlan vlan-id
   ```

   Example

   ```
   Device(config)# interface vlan 32
   ```

6. Configure the IP address for the interface.

   Example

   ```
   Device(config-if)# ip address ip-address subnet-mask
   ```

Example

```
Device(config-if)# ip address 192.168.32.100 255.255.255.0
```

7. Disable the Maintenance Operation Protocol (MOP) for an interface.

Example

```
Device(config-if)# no mop enabled
```

8. Disable the task of sending the MOP periodic system ID messages.

Example

```
Device(config-if)# no mop sysid
```

9. Exit the interface configuration mode.

Example

```
Device(config-if)# exit
```

10. Specify the target DHCP server parameters.

Example

```
Device(config)# ip dhcp-server ip-address
```

Example

```
Device(config)# ip dhcp-server 10.10.10.1
```

11. Specify the IP address that the DHCP server should not assign to DHCP clients.

Example

```
Device(config)# ip dhcp excluded-address ip-address
```

Example

```
Device(config)# ip dhcp excluded-address 192.168.32.100
```

12. Configure the DHCP pool address.

Example

```
Device(config)# ip dhcp pool pool-name
```

Example

```
Device(config)# ip dhcp pool pool-vlan32
```

13. Specify the network number in dotted-decimal notation along with the mask address.

Example

```
Device(dhcp-config)# network network-address subnet-mask
```

Example

```
Device(dhcp-config)# network 192.168.32.0 255.255.255.0
```

14. Specify the IP address of the default router for a DHCP client.

Example

```
Device(dhcp-config)# default-router ip-address
```

Example

```
Device(dhcp-config)# default-router 192.168.32.1
```

15. Exit DHCP configuration mode.

Example

```
Device(dhcp-config)# exit
```

16. Configure a WLAN policy profile and enter wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy profile-policy
```

Example

```
Device(config)# wireless profile policy default-policy-profile
```

17. Configure central association for locally switched clients.

Example

```
Device(config-wireless-policy)# central association
```

18. Configure central DHCP for locally switched clients.

Example

```
Device(config-wireless-policy)# central dhcp
```

19. Configure local switching.

Example

```
Device(config-wireless-policy)# central switching
```

20. Add a description for the policy profile.

Example

```
Device(config-wireless-policy)# description policy-profile-description
```

Example

```
Device(config-wireless-policy)# description "default policy profile"
```

21. Assign the profile policy to the VLAN.

Example

```
Device(config-wireless-policy)# vlan vlan-id
```

Example

```
Device(config-wireless-policy)# vlan 32
```

22. Enable the profile policy.

Example

```
Device(config-wireless-policy)# no shutdown
```

The internal DHCP server is now configured globally with the specified pool, exclusions, and wireless policy profile settings to serve DHCP requests from wireless clients.

Configure IP reservations in the internal DHCP server (CLI)

Configure IP reservations in the internal DHCP server using CLI steps.

Reserve specific IP addresses for clients in the internal DHCP server to ensure consistent address assignment.

IP reservations allow DHCP servers to assign the same IP address to specific clients based on their client ID or MAC address. This is useful for servers, printers, or other devices that require consistent network addressing.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the DHCP pool address.

Example

```
Device(config)# ip dhcp pool pool-name
```

Example

```
Device(config)# ip dhcp pool dhcp-pool-add
```

3. Specify the network number in dotted-decimal notation along with the mask address.

Example

```
Device(dhcp-config)# network network-address mask-address
```

Example

```
Device(dhcp-config)# network 192.168.32.0 255.255.255.0
```

4. Configure a reserved address using either the client ID or the MAC address.

Example

```
Device(dhcp-config)# address ip-address client-id client-id
```

Example

```
Device(dhcp-config)# address ip-address hardware-address client-mac-id
```

Example

```
Device(dhcp-config)# address 209.165.200.224 client-id dhcp-client-id
```

> **Note**
>
> The IP reservation is contingent on the type of identifier, be it the client ID or the MAC address that the client provides. If the client sends its DHCP DISCOVER or REQUEST using the client ID, set your IP reservation using the client ID and not the hardware address.

IP reservations are configured in the internal DHCP server, ensuring that specified clients receive consistent IP addresses based on their identifiers.

Verify internal DHCP configuration

Provides commands to verify internal DHCP configuration.

Verify internal DHCP configuration using specific show commands to check client binding, DHCP relay statistics for wireless clients, and DHCP packet punt statistics.

Client binding verification

To verify client binding, use this command:

```
Device# show ip dhcp binding

Bindings from all pools not associated with VRF:
IP address      Client-ID/              Lease expiration        Type
State      Interface
                Hardware address/
                User name
192.168.32.3    0130.b49e.491a.53       Mar 23 2018 06:42 PM    Automatic
Active     Loopback0
```

DHCP relay statistics verification

To verify the DHCP relay statistics for a wireless client, use this command:

```
Device# show wireless dhcp relay statistics

DHCP Relay Statistics
---------------------

DHCP Server IP :   10.10.10.1

Message               Count
-------------------------
DHCPDISCOVER      :  1
BOOTP FORWARD     :  137
BOOTP REPLY       :  0
DHCPOFFER         :  0
DHCPREQUEST       :  54
DHCPACK           :  0
DHCPNAK           :  0
DHCPDECLINE       :  0
DHCPRELEASE       :  0
DHCPINFORM        :  82

Tx/Rx Time :
------------
LastTxTime : 18:42:18
LastRxTime : 00:00:00

Drop Counter :
-------------
TxDropCount : 0
```

DHCP packet punt statistics verification

To verify the DHCP packet punt statistics in CPP, use this command:

```
Device# show platform hardware chassis active qfp feature wireless punt
statistics

CPP Wireless Punt stats:

                                App Tag     Packet Count
                                -------     ------------
         CAPWAP_PKT_TYPE_DOT11_PROBE_REQ            14442
```

```
            CAPWAP_PKT_TYPE_DOT11_MGMT              50
            CAPWAP_PKT_TYPE_DOT11_IAPP            9447
            CAPWAP_PKT_TYPE_DOT11_RFID               0
             CAPWAP_PKT_TYPE_DOT11_RRM               0
          CAPWAP_PKT_TYPE_DOT11_DOT1X                0
    CAPWAP_PKT_TYPE_CAPWAP_KEEPALIVE             2191
CAPWAP_PKT_TYPE_MOBILITY_KEEPALIVE                   0
      CAPWAP_PKT_TYPE_CAPWAP_CNTRL                7034
       CAPWAP_PKT_TYPE_CAPWAP_DATA                   0
   CAPWAP_PKT_TYPE_MOBILITY_CNTRL                    0
                  WLS_SMD_WEBAUTH                    0
                SISF_PKT_TYPE_ARP                5292
               SISF_PKT_TYPE_DHCP                 140
             SISF_PKT_TYPE_DHCP6                 1213
          SISF_PKT_TYPE_IPV6_ND                   350
        SISF_PKT_TYPE_DATA_GLEAN                   44
     SISF_PKT_TYPE_DATA_GLEAN_V6                   51
        SISF_PKT_TYPE_DHCP_RELAY                  122
  CAPWAP_PKT_TYPE_CAPWAP_RESERVED                   0
```

Configure DHCP-Required for FlexConnect

Details the FlexConnect DHCP-required feature, ensuring wireless clients in local switching mode obtain IP addresses through DHCP. Includes FlexConnect-specific restrictions and limitations. Configuration is possible through the GUI or commands, with specific commands available for verification.

FlexConnect DHCP-Required

Describes a FlexConnect feature that enforces DHCP IP address acquisition for wireless clients in local switching mode.

FlexConnect DHCP-Required is a policy profile feature that

- forces connected wireless clients to obtain IP addresses from DHCP
- creates IP-MAC bindings by tracking IP addresses learned by the AP or controller, and
- maintains client connectivity during roaming within the same L2 network without requiring DHCP renegotiation.

FlexConnect DHCP-Required operation

When the DHCP-Required knob on a policy profile is enabled, a connected wireless client must get the IP address from DHCP. When the client completes the DHCP process and acquires an IP address, this IP address is learnt by the controller and only then the client traffic is switched on to the network. The DHCP-Required feature is already supported in central switching.

In Cisco IOS XE Amsterdam 17.2.1, the feature is supported on FlexConnect local switching clients. Prior to Release 17.2.1, DHCP-Required was not enforced on FlexConnect local switching clients. The IP address learnt by the AP or the controller for the wireless client is tracked to create an IP-MAC binding. As part of this feature, when a FlexConnect local switching client roams from one AP to another, the client need not do the DHCP again in the same L2 network, because the controller tracks the IP address and pushes the binding to the newly roaming AP.

The FlexConnect DHCP-Required feature can be configured from open configuration models, CLI, and from the GUI. The CLI and GUI configurations are described in this chapter. For more information about the open configuration modes, see the https://www.cisco.com/c/en/us/td/docs/ios-xml/ios/prog/configuration/172/b_172_programmability_cg.html.

Restrictions for FlexConnect DHCP-Required

Restrictions and limitations for FlexConnect DHCP-required.

- The DHCP-Required feature is applicable for IPv4 addresses only.
- The IP-MAC binding can be pushed to other APs only through the custom policy profile. IP-MAC binding is not available in the default policy. The mapping is propagated to all the APs in the same custom policy profile.
- The DHCP-Required feature works on IP-MAC binding basis and is not supported with third party workgroup bridge (WGB), where WGB wired client information is not shared to AP by the WGB.
- Cisco Wave 2 APs take 180 seconds to remove a client entry with static IP, when DHCP-required is enabled.

Caution: Enabling IP-MAC address binding in SDA can cause high CAPWAP control traffic and CPU spikes

If you enable the **ipv4 dhcp required** setting with client IP-MAC address binding in Software-Defined Access (SDA) environments, then:

- Expect high CAPWAP control traffic during client join or slow roaming events.
- Be aware that Wireless Network Controller Device (WNCD) CPU utilization may spike above 95%, which can cause client connectivity issues.

  .
- Monitor your system for spikes in client count and CPU utilization per WNCD, especially during roaming events, and be prepared to respond if performance issues occur.

Normally, WNCD CPU utilization should remain consistent between SDA and non-SDA networks.

These are the symptoms.

- WLC CPU utilization may spike above 90% temporarily during client roaming events.
- High CAPWAP control traffic is observed due to distribution of client IP-MAC mappings to all APs in the flex group of the currently connected AP.

Conditions affected include:

- Cisco Catalyst 9800-40 controller
- SDA enabled with **ipv4 dhcp required** configured
- 9120 or 9130 APs, approximately 250 APs per WNCD
- SDA-enabled SSID

Monitoring steps:

1. Monitor client count and CPU utilization per WNCD.
2. Observe CPU utilization spikes during roaming events. CPU usage should stabilize after roaming ends.

Configure FlexConnect DHCP-Required (GUI)

Configure FlexConnect DHCP-required using GUI.

This task enables the FlexConnect DHCP-Required feature through the GUI interface to ensure proper DHCP configuration for FlexConnect access points.

Use this procedure when you need to configure the FlexConnect DHCP-Required feature through the GUI interface for policy profiles.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.

2. On the **Policy** window, click the name of the corresponding Policy Profile.
   The **Edit Policy Profile** window is displayed.
3. Click the **Advanced** tab.
4. In the **DHCP** section, check the **IPv4 DHCP Required** check box to enable the feature.
5. Click **Update & Apply to Device**.

The FlexConnect DHCP-Required feature is now enabled for the selected policy profile, and the configuration is applied to the associated devices.

Configure FlexConnect DHCP-required (CLI)

Configure FlexConnect DHCP-required using commands.

Enable the FlexConnect DHCP-required feature to ensure clients obtain IP addresses through DHCP before being allowed network access.

FlexConnect DHCP-required forces clients to obtain an IP address through DHCP before they can communicate on the network. This configuration is performed through the CLI on a WLAN policy profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-policy
   ```

   Example

   ```
   Device(config)# wireless profile policy rr-xyz-policy-1
   ```

3. Enable the FlexConnect DHCP-Required feature.

   Example

   ```
   Device(config-wireless-policy)# ipv4 dhcp required
   ```

4. Save the configuration.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

FlexConnect DHCP-required is now configured on the policy profile, requiring clients to obtain IP addresses through DHCP before network access is granted.

Verify FlexConnect DHCP-required

Lists commands to verify FlexConnect DHCP-required functionality.

Verify FlexConnect DHCP-required functionality using wireless client commands to confirm IP address learning and client states.

- To verify the IP address learnt for a client on an IP DHCP-Required policy-enabled WLAN, use the **show wireless client summary** command:

> **Note**
>
> The controller or AP does not learn the IP address through other means such as ARP or data gleaning, when IPv4 DHCP-Required is enabled.

```
Device# show wireless client summary
Number of Clients: 1
MAC Address          AP Name            Type   ID  State          Protocol
Method     Role
-------------------------------------------------------------------------------------------
1cXX.bXXX.59XX       APXXXX.7XXX.4XXX   WLAN   3   IP Learn       11ac
Dot1x      Local
```

- This example shows that the client IP is in the **Run** state, indicating that the client has received the IP address from DHCP:

```
Device# show wireless client summary
Number of Clients: 1
MAC Address        AP Name              Type        ID        State
Protocol       Method      Role
-------------------------------------------------------------------------------------------
5XXX.37XX.c3XX     APXXXX.4XXX.4XXX     WLAN        3         Run          11n(5)
          None         Local
```

209 Aironet Extensions IE (CCX IE)

Topics:

- Cisco Aironet Extensions Information Element

Use this procedure to enable Aironet extensions IE for a WLAN using the graphical user interface.

Cisco Aironet Extensions Information Element

Explains the Cisco Aironet Extensions Information Element (IE), an attribute used by Cisco devices for better connectivity.

The Cisco Aironet Extensions Information Element (IE) is an attribute that

- contains information such as the AP name, device type, radio type, AP load, and the number of associated clients in the beacon and probe responses of the WLAN
- is used by Cisco devices for better connectivity, and
- provides information that Cisco Client Extensions use to associate with the best AP.

Configuration characteristics

The Aironet Extensions IE configuration has the following characteristics:

- Configuration is disabled by default
- Allows setting the AP name without enabling the whole IE extension by just inserting the AP name

> **Note**
>
> WLAN shutdown is required only when configuring Aironet Extensions (CCX IE) through the CLI. If CCX IE is enabled through the WebUI, WLAN shutdown is not necessary.

Configure Aironet Extensions IE using GUI

Configure Aironet extensions IE using GUI.

Enable Aironet extensions IE to enhance WLAN interoperability and support Aironet-specific features.

Before you begin

Follow these steps to configure Aironet Extensions IE using GUI:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs** .
2. In the **WLANs** window, click **Add**.
3. In the **Add WLAN** window, under the **Advanced** tab, check the **Aironet IE** check box to enable Aironet IE on the WLAN.
4. Click **Apply to Device**.

The WLAN is updated to include Aironet extensions IE, enabling enhanced interoperability.

Configure Aironet Extensions IE (CLI)

Configure Aironet extensions IE using commands.

Enable the Aironet Extensions IE feature on a WLAN to support enhanced Cisco client capabilities.

Perform this procedure to create a WLAN and enable the Aironet Extensions IE feature on the WLAN. For more information about the open configuration models, refer to the Programmability Configuration Guide, Cisco IOS XE Amsterdam 17.1.x.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the WLAN name and ID.

   Example

   ```
   Device(config)# wlan profile-name wlan-id ssid
   ```

   Example

   ```
   Device(config)# wlan mywlan 34 mywlan-ssid
   ```

   - *profile-name*: Profile name. The range is from 1 to 32 alphanumeric characters.
   - *wlan-id*: WLAN ID. The range is from 1 to 512.
   - *ssid*: Service Set Identifier (SSID) for this WLAN. If the SSID is not specified, the WLAN profile name is set as the SSID.

   Note

   By default, the WLAN is disabled.

3. Configure the Cisco Client Extensions option and set the support of Aironet IE on the WLAN.

   Example

   ```
   Device(config-wlan)# ccx aironet-iesupport
   ```

   Use the **no** form of this command to disable the configuration.

The WLAN is created with Aironet Extensions IE enabled, allowing enhanced capabilities for Cisco wireless clients. You must now create a policy tag and map it to the AP to complete the configuration.

AP name addition verification

Provides verification of the AP name addition.

Verify the addition of AP name using Open Configuration in the beacon without enabling IE.

This example shows how to verify the addition of the AP Name (using Open Configuration) in the beacon without enabling IE:

```
Device# show wlan id 1
WLAN Profile Name     : wlan-test
================================================
Identifier                                    : 1
Description                                   :
Network Name (SSID)                           : wlan2
Status                                        : Disabled
Broadcast SSID                                : Enabled
Advertise-Apname                              : Enabled
Universal AP Admin                            : Disabled
Max Associated Clients per WLAN               : 0
Max Associated Clients per AP per WLAN        : 0
Max Associated Clients per AP Radio per WLAN  : 200
OKC                                           : Enabled
Number of Active Clients                      : 0
CHD per WLAN                                  : Enabled
WMM                                           : Allowed
Channel Scan Defer Priority:
  Priority (default)                          : 5
  Priority (default)                          : 6
Scan Defer Time (msecs)                       : 100
Media Stream Multicast-direct                 : Disabled
CCX - AironetIe Support                      : Enabled
Peer-to-Peer Blocking Action                  : Disabled
```

210 Device Analytics

Topics:

- Device analytics
- Adaptive 802.11r

Device analytics

Describes the Device Analytics feature that enhances the enterprise Wi-Fi experience for client devices to ensure seamless connectivity.

Device Analytics is a feature that

- enhances the enterprise Wi-Fi experience for client devices to ensure seamless connectivity
- provides a set of data analytics tools for analyzing wireless client device behavior, and
- encrypts exchanged data using AES-256-CBC to ensure device security when device profiling is enabled.

Device support information

The Device Analytics feature supports different device types with specific compatibility requirements:

Starting from Cisco IOS XE Bengaluru 17.6.1, this feature is supported on Intel devices with AC9560, AC8561, AX201, AX200, AX1650, AX210, AX211, and AX1675 chipsets. Device information and other information received from the Intel devices are shared with Cisco Catalyst Center. It will also be used to enhance device profiling on the controller.

> **Note**
>
> From Cisco IOS XE Dublin 17.12.1, MacBook Analytics is supported on the controller when the MacBook device sends 11k action frames along with the model information.

> **Note**
>
> Apple clients such as iPhones and iPads use 802.11k action frames to send device information to the controller. When they fail to send 802.11k action frames, the controller will not perform device classification based on the 802.11 protocol. Hence, this falls back to legacy device classification which is based on HTTP and DHCP protocols.

Restrictions for device analytics

Outlines the restrictions and requirements for implementing device analytics functionality.

Observe these restrictions when implementing device analytics:

- This feature is applicable only for Cisco device ecosystem partners.
- This feature is supported only on the 802.11ax and Wave 2 APs.
- This feature is supported using central authentication in either local mode or FlexConnect mode.
- To support Intel devices, AP should have PMF capability and PMF should set to optional or required on the WLAN.

Configure device analytics (GUI)

Configure device analytics using the GUI to enable wireless device monitoring and data collection.

Configure device analytics to monitor wireless device performance and collect analytical data for network optimization.

Device analytics provides insights into wireless device performance and network behavior. This configuration is performed at the WLAN level to control which wireless networks support analytics features.

Before you begin

Follow these steps to configure device analytics using the GUI:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. On the **WLANs** page, click the name of the WLAN.
3. In the **Edit WLAN** page, click the **Advanced** tab.
4. In the **Device Analytics** section, select the **Advertise Support** check box.
5. Select the **Advertise PC Analytics Support** check box to enable PC analytics on the WLAN.
6. Optional: In the **Device Analytics** section, select the **Share Data with Client** check box.
7. Click **Update & Apply to Device**.

Device analytics is configured for the WLAN and will begin collecting performance data from connected wireless devices.

Configure device analytics (CLI)

Configure device analytics using commands.

Enable device analytics on a WLAN to collect and optionally export device information for network analysis and optimization.

Device analytics allows the network to collect information from connected devices, which can be used for network monitoring and analysis. This feature can be enabled per WLAN and optionally configured to export information to compatible clients.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id SSID-name
   ```

   Example

   ```
   Device(config)# wlan device_analytics 1 device_analytics
   ```

   - *WLAN-name*: Enter the profile name. The range is from 1 to 32 alphanumeric characters.
   - *WLAN-ID*: Enter the WLAN ID. The range is from 1 to 512.
   - *SSID-name*: Enter the Service Set Identifier (SSID) for this WLAN. If the SSID is not specified, the WLAN profile name is set as the SSID.

> **Note**
>
> If you have already configured WLAN, enter the **wlan** *wlan-name* command.

3. Set the maximum number of clients, clients per AP, or clients per AP radio that can be configured on a WLAN.

   Example

   ```
   Device(config)# client association limit {clients-per-wlan | ap
   clients-per-ap-per-wlan | radio clients-per-ap-radio-per-wlan}
   ```

   Example

   ```
   Device(config)# client association limit 1 1
   ```

4. Enable or disable device analytics. WLANs advertise analytics capability in beacons & probe responses.

   Example

   ```
   Device(config)# [no] device-analytics
   ```

   This is enabled by default.

5. Configure device analytics export option.

   Example

   ```
   Device(config)# [no] device-analytics [export]
   ```

   Example

   ```
   Device(config)# device-analytics export
   ```

   When export option is set, the information from Cisco devices are shared with compatible clients (such as, Samsung devices). Here, information from Cisco devices refer to the Cisco controller details, AP version, and model number.

   This configuration is disabled by default.

6. Enable PC analytics on the WLAN.

   Example

   ```
   Device(config)# device-analytics pc-analytics
   ```

   Enables PC analytics on the WLAN. WLANs advertise analytics capability in beacons & probe responses.

7. Enable the WLAN.

   Example

   ```
   Device(config)# no shutdown
   ```

8. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Device analytics is now configured on the WLAN, enabling the collection of device information and optionally exporting data to compatible clients.

Verify device analytics

Verify device analytics reports and client properties for wireless clients.

Verify device analytics to review client properties, statistics, and PC Analytics reports including neighbor AP information, candidate BSSIDs, and various diagnostic reports.

Use this procedure to access and review comprehensive analytics data for wireless clients, including connection quality metrics and troubleshooting information.

Procedure

1. On the **Monitoring > Wireless > Clients** page, click on a client in the table to view its properties and statistics.
2. In the **General** tab, click **Client Properties** to view the **PC Analytics** reports. This section displays the neighbor AP information, candidate BSSIDs, and reports for low RSSI, beacon miss, failed APs, and unknown APs.

The PC Analytics reports display comprehensive information about the selected client, including neighbor AP data, candidate BSSIDs, and diagnostic reports for connectivity issues such as low RSSI, beacon misses, failed APs, and unknown APs.

Verify device analytics configuration

Lists commands to verify device analytics configuration and view client device information.

This reference provides commands to verify device analytics configuration status, view client device information, check last disconnect reasons, and examine per-client pc-analytics reports.

Device analytics status verification

To view the status of device analytics export, use this command:

```
Device# show wlan 1 test-wlan

WLAN Profile Name     : test-wlan
================================================
Identifier                       : 1
Description                      :
Network Name (SSID)              : test-open-ssid
Status                           : Enabled
Broadcast SSID                   : Enabled
Advertise-Apname                 : Disabled
Universal AP Admin               : Disabled

Device Analytics
    Advertise Support            : Enabled
```

```
    Share Data with Client      : Disabled
```

Client device information

To view client device information, use this command:

```
Device# show device classifier mac-address 0040.96ae.xxx detail

  Client Mac: 0040.96ae.xxxx
  Device Type: Samsung Galaxy S10e(Phone)
  Confidence Level: 40
  Device Name: android-dhcp-9
  Software Version(Carrier Code): SD7(TMB)
  Device OS: Android 9
  Device Vendor: android-dhcp-9
  Country: US
```

Last disconnect reason

To view the last disconnect reason, use this command:

```
Device# show device classifier mac-address 0040.96ae.xxxx detail

Client MAC Address : 0040.96ae.xxxx
Client IPv4 Address : 12.1.0.52
Client IPv6 Addresses : fe80::631b:5b4f:f9b6:53cc
Client Username: N/A
AP MAC Address : 7069.5a51.53c0
AP Name: AP4C77.6D9E.61B2
AP slot : 1
Client State : Associated

Assisted Roaming Neighbor List
Nearby AP Statistics:
EoGRE : No/Simple client
Last Disconnect Reason : User initiated disconnection - Device was powered off
 or Wi-Fi turned off
```

Per-client pc-analytics reports

To view the per client pc-analytics reports, use this command:

```
Device# show wireless client mac-address 3413.e8b6.xxxx stats pc-analytics

-------------------------
Neighbor APs Info:
-------------------------
Reported time:: 06/21/2021 18:50:34
-------------------------
Roaming Reasons:
-------------------------
Selected AP RSSI:: -67
Candidate BSSIDs:
-----------------
Neighbor AP RSSI(dB)
a4b2.3903.d10e -70
-------------------------
```

```
PC Analytics report stats
-------------------------
------------------------------------------------------------------------
Report Type Processed Reports Dropped Reports
------------------------------------------------------------------------

STA Info 1 0
Neigh AP 1 0
Low RSSI 0 0
Beacon Miss 0 0
Failed AP 0 0
Unknown APs 0 0
```

Adaptive 802.11r

Describes the adaptive 802.11r functionality that enables device ecosystem partnerships and supports 802.11r-compatible devices on Cisco networks.

Adaptive 802.11r is a WLAN feature that

- enables device ecosystem partnerships for 802.11r functionality
- allows information sharing between client devices and the controller and AP, and
- is enabled by default when creating a WLAN.

Adaptive 802.11r functionality

The Cisco device ecosystem partner now supports 11r functionality on an adaptive 802.11r SSID. Samsung is one of the partners.

> **Note**
>
> The Adaptive 802.11r is enabled by default. This means that when you create a WLAN, the adaptive 802.11r is configured by default.

Client device information such as its model number, supported operating system is shared with the controller and AP while the device receives information such as controller and AP type, software release, etc. Also, this enables 802.11r-compatible devices to benefit from adaptive 802.11r on Cisco networks. This ecosystem comes handy especially for troubleshooting device disconnection from the AP as the controller receives information such as the disconnect reason code from the client device.

> **Note**
>
> Devices without 11r support cannot join an SSID where 11r is enabled.
>
> To use the 11r functionality on devices, you need to create a separate SSID with 11r enabled and another with 11r disabled to support the non-11r devices in the network.
>
> Adaptive dot11r is supported by Apple iPad, Apple iPhone, and Samsung S10 devices. However; some software update creates a MIC mismatch error in these devices. But these errors are transient and clients will successfully be able to associate to the SSID in subsequent results.

Configure adaptive 802.11r (GUI)

Configure adaptive 802.11r using GUI.

Configure adaptive 802.11r to enable fast roaming capabilities for wireless clients while maintaining backward compatibility with devices that do not support 802.11r.

Adaptive 802.11r allows wireless networks to automatically detect client capabilities and enable fast transition features when supported, providing seamless roaming without requiring separate WLAN configurations.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. On the **WLANs** page, click the name of the WLAN.
3. In the **Edit WLAN** window, click the **Security** > **Layer2** tab.
4. In the **WPA Parameters** section and **Fast Transition** drop-down list, choose **Adaptive Enabled**.
5. Click **Update & Apply to Device**.

The WLAN is configured with adaptive 802.11r, enabling automatic fast transition capabilities for compatible clients while maintaining connectivity for non-802.11r devices.

Adaptive 802.11r verification

Provides the command to verify adaptive 802.11r configuration.

Verify adaptive 802.11r configuration using command line interface.

To view the details, use this command:

```
Device# show running-config all
wlan test-psk 2 test-psk
 security ft adaptive
"adaptive" is  optional
```

Note

This command is used to enable or disable adaptive 11r:

[no] security ft adaptive

This command is used to enable or disable 802.11r:

[no] security ft

211 Device Classifier Dynamic XML Support

Topics:

- Device classifier dynamic XML support

Introduces the dynamic XML support feature for device classifier functionality and explains how it enables flexible device identification and classification.

Device classifier dynamic XML support

Explains device classifier dynamic XML support that enables better device classification without upgrading the device to a new release.

Device classifier dynamic XML support is a feature that

- enables better device classification without upgrading the device to a new release
- allows updating XML files with new rules, checks, and profiles based on connected devices, and
- provides dynamic device classification by copying XML files to the device file system.

Device classification workflow and configuration

The current device classifier uses static XML file wherein you define checks, rules, and profiles based on MAC, DHCP, and HTTP TLVs in wireless devices. The static XML file is converted to a text file and integrated with the image. When you enable the device classified functionality using **device classifier** command, the contents in the text file is read and populated into the device classifier structures.

> **Note**
>
> The subsequent device classification is based on the populated device classifier structures.

Presently, if you find any unclassified devices in a controller, the static XML file is updated with the new rules, checks, and profiles to get the devices classified. You will need to wait till the subsequent release as the static XML file is integrated with the image and cannot be changed from the controller.

The device classifier dynamic XML support enhancement addresses this problem for device classifier dynamic XML file.

With the introduction of dynamic XML support, you are provided with a new dynamic device classifier XML file support.

> **Note**
>
> The filename will be **dc_user_profiles.XML** and you can update the dynamic XML file with the new rules, checks, and profiles based on the devices connected and according to the provided schema.You can then copy this XML file to the device file system to enable better device classification without the need to upgrade the device to a new release.

The static XML file support is still available. If a device is connected, its TLVs are checked with the dynamic XML user profiles first and if it matches it is classified as per that profile. If you search for non-static XML profiles and if it matches it is classified as per that profile.

Workflow to classify unclassified devices with dynamic XML file:

1. The dynamic XML filename must be **dc_user_profiles.XML**.

> **Note**
>
> Files with any other name are not read and parsed even if they have the correct schema.

2. Copy the sample dynamic XML file to your system using this command:

   copy {flash:} {ftp: | tftp:}

3. Provide a new version for the dynamic XML file:

   <Version>1.1</Version>

4. Edit the dynamic XML file with the new rules, checks, and profiles as defined in the schema after examining the TLV values of the unclassified devices.

   > **Note**
   >
   > To check the TLV values, use this command:
   >
   > **show wireless client MAC-address** *MAC* **detail**

5. Copy the dynamic XML file to the device flash using this command:

   copy {ftp: | tftp:} {flash:}

Once the file is copied to the device file system, the newly connected clients are classified according to the new profiles defined in the dynamic XML file. You need to reconnect the already unclassified devices to send the DHCP and HTTP TLVs, and then classify them according to the new profiles. The already classified devices remain as classified until they are reconnected.

Note

The sample dynamic XML file is available in the device at *flash:dc_profile_dir/*. You can consider these sample dynamic XML file schema and copy this to your system using **copy {flash:} {ftp: | tftp:}** command, and append or replace the content with your own profiles, rules, and checks:

```
<?xml version="1.0" encoding="UTF-8"?>

                   <RuleName>Sample_Rule_1</RuleName>
                   <RuleOperator>OR</RuleOperator>
                   <RuleCertaintyMetric>20</RuleCertaintyMetric>
                   <Check>
                              <Protocol>DHCP</Protocol>
                              <TLV-Type>12</TLV-Type>
                              <TLV-Value-Type>String</TLV-Value-Type>
                              <TLV-Value>test</TLV-Value>
                   </Check>
                   <Check>
                              <Protocol>HTTP</Protocol>
                              <TLV-Type>3</TLV-Type>
                              <TLV-Value-Type>Integer</TLV-Value-Type>
                              <TLV-Value>23</TLV-Value>
                    </Check>
             </Device>
             <Device>
                  <DeviceType>Sample_Profile_2</DeviceType>
                  <RuleName>Sample_Rule_2</RuleName>
                  <RuleOperator>AND</RuleOperator>
                  <RuleCertaintyMetric>30</RuleCertaintyMetric>
                  <Check>
                         <Protocol>DHCP</Protocol>
                        <TLV-Type>12</TLV-Type>
                        <TLV-Value-Type></TLV-Value-Type>
                        <TLV-Value>test</TLV-Value>
                  </Check>
                  <Check>
                         <Protocol>MAC</Protocol>
                         <TLV-Value-Type>String</TLV-Value-Type>
                         <TLV-Value>Cisco</TLV-Value>
                   </Check>
</Device>
</DeviceList>
```

Each time you copy a new dynamic XML file, the older user profiles are erased completely and newer profiles are populated. After copying the dynamic XML files, only the newly connected clients are classified based on the new dynamic file whereas the already classified devices still remain as classified with older profiles until they are reconnected.

MAC OUI-based profiles configuration

The Organizational Unique Identifier (OUI) of a MAC address is part of the MAC address that identifies the vendor of the network adapter. The OUI is the first three bytes of the six-byte field and administered by the IEEE.

To define MAC-based profiles in the dynamic XML file, see https://standards-oui.ieee.org/.

For example, if the Client MAC address is **7035.094d.000**, then OUI is **0x703509**. You can find the corresponding entry in the https://standards-oui.ieee.org/ as shown below:

```
70-35-09   (hex)  Cisco Systems, Inc
703509     (base 16)    Cisco Systems, Inc
      80 West Tasman Drive
      San Jose  CA  94568
      US
```

Feature history for device classifier dynamic XML support

Lists feature history for device classifier dynamic XML support.

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 188: Feature history for device classifier dynamic XML support

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.10.1	Device Classifier Dynamic XML Support	You can: • Add rules, checks, and profile name to an XML file. • Upload the XML file to the device file system. This feature enables better device classification without upgrading the device to a new release. **Note** Device classifier dynamic XML support is applicable for these: • Devices that are not classified previously: The classification takes effect from the latest file without any reboot. • Devices that are already classified: The clients have to rejoin for the classification to take effect. • Client previously classified with higher protocol values such as DHCP + HTTP: If the same client wants to be classified with only DHCP, use the **clear wireless client device cache** command.

Enable device classifier (CLI)

Enable device classifier using commands.

Enable the device classifier feature to automatically identify and classify attached devices on the network.

Device classifier is used to identify and classify devices that are connected to the network based on their behavior and characteristics. This feature helps with network management and policy enforcement.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enable the classification of attached devices.

Example

```
Device(config)# device classifier
```

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Device classifier is now enabled and will automatically identify and classify devices that connect to the network.

Update dynamic XML file

Configure dynamic XML file for device classification.

Update the dynamic XML file to classify devices by adding device configuration information.

Device classification requires specific XML entries in the dynamic XML file to properly identify and categorize devices.

Procedure

Add these lines in the dynamic XML file to classify a device:

Example

```
<DeviceList>
          <CopyRight>Copyright (c) 2021-2022 by Cisco Systems, Inc. All rights
 reserved.</CopyRight>
           <Version>1.1</Version>
           <Device>
                  <DeviceType>Device-test"</DeviceType>
                 <RuleName>Rule-Test</RuleName>
                <RuleOperator>AND</RuleOperator>
                <RuleCertaintyMetric>20</RuleCertaintyMetric>
                <Check>
                        <Protocol>DHCP</Protocol>
                        <TLV-Type>12</TLV-Type>
                       <TLV-Value-Type>String</TLV-Value-Type>
                       <TLV-Value>test</TLV-Value>
                 </Check>
          </Device>

.............................
</DeviceList>
```

The dynamic XML file is updated with the device classification configuration.

Verify TLV value

Provides the command to verify TLV values.

To verify the TLV values, use this command:

```
Device# show  wireless  client  mac-address 7035.094d.0001 detail
Client MAC Address : 7035.094d.0001

……

Nearby AP Statistics:

     |

Max Client Protocol Capability: Wi-Fi6 (802.11ax)
```

Old classification cache clearing

Provides the command to clear old classification cache when classified clients use type-length-values with lower combination values.

If an already classified client uses any of the three type-length-values (TLVs) [OUI, DHCP, or HTTP] and if the combination value is lower, the existing value is ignored. To avoid such a scenario, use the clear wireless client device cache command.

```
Device# clear wireless client device cache
```

Note

The priority of the TLVs is as follows:

- OUI
- DHCP
- HTTP

After executing the clear command, you must rejoin the client to get it classified as per the latest XML file.

212 BSSID Counters

Topics:

- BSSID counters

BSSID counters

Explains a feature that helps to retrieve the BSSID statistics at certain intervals for a client associated with a WLAN.

A BSSID counter is a statistical feature that

- retrieves BSSID statistics when a client is associated with a WLAN for every configured interval
- requires configuration in the controller per AP profile to enable or disable BSSID statistics on the access points, and
- is disabled by default.

BSSID counter limitations

BSSID counter is not supported on the Cisco Aironet 1800 series APs and Cisco Catalyst 9100 series APs.

Enable BSSID statistics and BSSID neighbor statistics (CLI)

Configure BSSID statistics and BSSID neighbor statistics to monitor wireless network performance and neighboring access points.

Enable BSSID statistics collection and neighbor statistics reporting to monitor AP performance and neighboring wireless networks.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the AP profile configuration submode.

   Example

   ```
   Device(config)# ap profile ap-profile-name
   ```

   ap-profile-name is the profile name of the configured AP.

3. Enable BSSID statistics.

   Example

   ```
   Device(config-ap-profile)# bssid-stats
   ```

   Use the **no** form of the command to disable the feature.

4. Set the BSSID stats frequency timer.

   Example

   ```
   Device(config-ap-profile)# bssid-stats bssid-stats-frequency
   bssid-timer-seconds
   ```

Example

```
Device(config-ap-profile)# bssid-stats bssid-stats-frequency 40
```

BSSID statistics frequency timer is in the range of 1 to 180 seconds.

5. Enable BSSID neighbor statistics.

Example

```
Device(config-ap-profile)# bssid-neighbor-stats
```

Use the **no** form of the command to disable the feature.

6. Set the interval at which BSSID neighbor statistics is sent from the AP.

Example

```
Device(config-ap-profile)# bssid-neighbor-stats interval bssid-interval
```

Example

```
Device(config-ap-profile)# bssid-neighbor-stats interval 50
```

The BSSID neighbor stats interval is in the range of 1 to 180 seconds.

BSSID statistics and BSSID neighbor statistics are now enabled and will be collected at the specified intervals for network monitoring and analysis.

BSSID statistics verification on the controller

Lists commands to verify BSSID statistics on the controller.

To verify the BSSID statistics on the controller, use these commands:

- **show wireless stats ap name** *ap-name* **dot11 24ghz slot** *0***wlan-id** *<wlan-id>* **statistics**

```
Device# show wireless stats ap name APXXXX.6DXX.58XX dot11 24ghz slot 0

213 Fastlane+

Topics:

- Fastlane+

Introduces the Fastlane+ feature for enhanced network performance and provides comprehensive guidance on configuration, monitoring, and verification across both command-line and graphical interfaces.

Fastlane+

Describes the Fastlane+ feature that improves the effectiveness of estimating the uplink buffer status for clients.

Fastlane+ is a feature that

- improves the effectiveness of estimating the uplink buffer status for clients
- enhances the user experience for latency-sensitive applications, and
- allows scheduled access-based uplink transmissions by periodically collecting buffer status reports from clients.

Fastlane+ configuration and support

The Fastlane+ feature can be enabled or disabled on a per-WLAN basis. Support for this feature is indicated in the beacons and probe responses transmitted by an AP.

> **Note**
>
> This feature works only if Protected Management Frame (PMF) is configured as optional or mandatory for a WLAN.

Configure Fastlane+ on a WLAN (CLI)

Configure Fastlane+ on a WLAN using commands.

This task enables the Fastlane+ feature on a WLAN to optimize wireless network performance and user experience.

Use this procedure when you need to enable Fastlane+ on a specific WLAN through the command-line interface.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN and enters WLAN configuration submode.

   Example

   ```
   Device(config)# wlan profile-name WLAN-ID SSID-name
   ```

   Example

   ```
   Device(config)# wlan wlan-test 3 ssid-test
   ```

> **Note**
>
> If you have already configured a WLAN, enter the **WLAN** *profile-name* command.

3. Configure Fastlane+ feature on a WLAN.

Example

```
Device(config-wlan)# scheduler asr
```

Fastlane+ is now configured on the specified WLAN. The WLAN will use optimized scheduling to improve wireless performance.

Configure Fastlane+ on a WLAN (GUI)

Configure Fastlane+ on a WLAN using the GUI.

Enable advanced scheduling requests handling on a per-WLAN basis to optimize wireless network performance through Fastlane+ configuration.

Fastlane+ provides enhanced scheduling capabilities for wireless networks. This feature can be configured on individual WLANs to improve network efficiency and client experience.

Procedure

1. Choose **Configuration > Tags & Profiles > WLANs**.
2. Select a WLAN.
3. Click **Advanced** tab.
4. Check the **Advanced Scheduling Requests Handling** check box to enable the feature on a per-WLAN basis.
5. Click **Update & Apply to Device**.

Fastlane+ is now enabled on the selected WLAN with advanced scheduling requests handling configured.

Monitor Fastlane+ (GUI)

Monitor Fastlane+ client statistics and capabilities through the wireless client monitoring interface.

This task enables you to monitor Fastlane+ client performance and view uplink latency statistics and client capabilities information.

Use this procedure to access and review Fastlane+ monitoring data for wireless clients, including latency distribution and feature-related capabilities.

Procedure

1. Choose **Monitoring > Wireless > Clients**.
2. Click a client name from the client list.

The **Client** window with multiple tabs is activated.

3. Click **General** tab.
4. Click **Client Statistics** tab.

   The most recent uplink latency statistics received from the client is displayed in the **Uplink Latency Distribution** section.

5. Click **Client Properties** tab.

   The Fastlane+ feature-related client capabilities information is displayed at the bottom of the window.

You can now view Fastlane+ client statistics including uplink latency distribution and client capabilities information through the monitoring interface.

Fastlane+ verification

Lists commands to verify Fastlane+ configuration, capability information, and statistics.

Verify whether Fastlane+ is enabled or disabled for a WLAN, capability information, client uplink latency statistics, and scheduling statistics for Fastlane+ clients.

WLAN Fastlane+ status verification

This example shows how to verify whether Fastlane+ is enabled or disabled for a WLAN:

```
Device# show wlan 2 | include ASR

Advanced Scheduling Requests Handling : Enabled
```

Client capability and latency statistics

This example shows how to verify Fastlane+ capability information and the most recent client uplink latency statistics:

```
Device# show wireless client mac-address f45c.89b0.xxxx detail
.
.
.
Regular ASR support: : ENABLED
Non-default Fastlane Profile: : Active
Range Voice Video Background Best-Effort
----------------------------------------------------------------------------------------
[0-20ms] 400 300 200 100
[20-40ms] 401 301 201 101
[40-100ms] 402 302 202 102
[>100ms] 403 303 203 103
```

All clients statistics verification

This example shows how to verify Fastlane+ statistics along with Fastlane+ capability and uplink latency statistics for all the Fastlane+ clients on a WLAN.

> **Note**
>
> **show interfaces dot11radio asr-info all** is an AP command, and does not work on the controller.

```
Device# show interfaces Dot11Radio 1 asr-info all

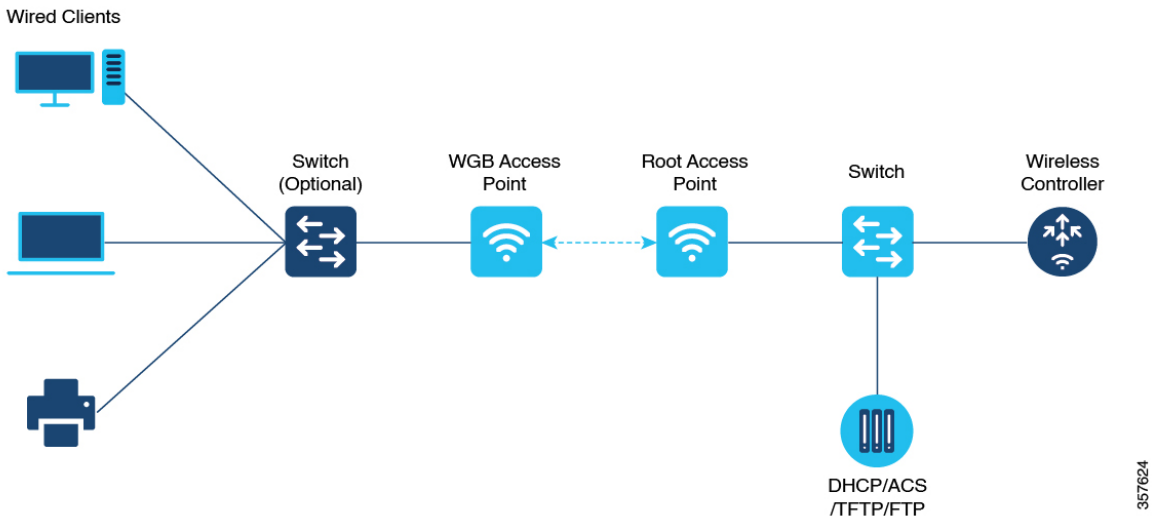
214 Workgroup Bridges

Topics:

- Cisco Workgroup Bridges
- Configure AP as WGB
- Simplified WGB configuration

This chapter describes configuring and managing Cisco Workgroup Bridges (WGB), including supported platforms, WLAN and SSID setup, radio and timeout settings, certificate enrollment, RADIUS/EAP configuration, and verification commands to bridge wired clients over wireless

Cisco Workgroup Bridges



Introduces Cisco Workgroup Bridges, describing key operational concepts, listing restrictions, and providing instructions for configuring Workgroup Bridge on WLAN as well as monitoring status for effective network integration.

A workgroup bridge (WGB) is an access point mode that

- provides wireless connectivity to wired clients connected on its Ethernet port
- connects a wired network to an existing wireless infrastructure through a single wireless segment, and
- learns the MAC addresses of its wired clients and reports them to the wireless LAN controller (WLC) using IAPP messaging.

The WGB establishes a single wireless connection to the root access point (AP). The root AP treats the WGB as a wireless client, allowing the wired devices behind the WGB to access the wireless network seamlessly. Suppose you have a group of wired devices in a conference room with no Ethernet drop available. You can connect these devices to a WGB, which allows them to communicate over the enterprise wireless network as if they were wireless clients.

Figure 37: Example of a WGB

Starting from Cisco IOS XE Cupertino 17.8.1, WGB is supported on the following Cisco Catalyst 9100 Series Access Points.

- Cisco Catalyst 9105
- Cisco Catalyst 9115
- Cisco Catalyst 9120

Starting from Cisco IOS XE Dublin 17.10.1, WGB is supported on the following Cisco Catalyst 9100 Series Access Points.

- Cisco Catalyst 9124
- Cisco Catalyst 9130

From Cisco IOS XE Cupertino 17.9.1 onwards, WGB supports one radio for uplink (backhaul) connectivity and another radio for serving wireless clients. This feature is supported on the Cisco 11AX APs such as Cisco Catalyst 9105 APs, Cisco Catalyst 9115 APs, Cisco Catalyst 9120 APs.

OPEN and PSK security (WPA2 Personal) based wireless clients can be associated to WGB independent of its uplink connectivity, but they will not be able to pass traffic unless WGB has uplink connectivity. Radius server must be configured

and the WGB should have uplink connectivity for authentication of wireless clients to 802.1x security (WPA2 Enterprise) WLAN. Both IPv4 and IPv6 traffic forwarding is supported for wireless clients. Static IP and Passive Client support is enabled by default on these WLANs.

These features are supported for use with WGB:

Table 189: WGB Feature Matrix

Feature	Cisco Wave 2 APs	Cisco 11AX APs
802.11r	Supported	Supported
QOS	Supported	Supported
UWGB mode	Supported	Not supported
IGMP Snooping or Multicast	Supported	Supported
802.11w	Supported	Supported
PI support (without SNMP)	Not supported	Not supported
IPv6	Supported	Supported
VLAN	Supported	Supported
802.11i (WPAv2)	Supported	Supported
Broadcast tagging/replicate	Supported	Supported
Unified VLAN client	Supported	Supported
WGB client	Supported	Supported
802.1x - PEAP, EAP-FAST, EAP-TLS	Supported	Supported
NTP	Supported	Supported
Wired client support on all LAN ports	Supported in all Wired-0, 1 and LAN ports 1, 2, and 3	Supported in all Wired-0, 1 and LAN ports 1, 2, and 3
Second radio wireless client support	Not supported	Supported

This table shows the supported and unsupported authentication and switching modes for Cisco APs when connecting to a WGB.

> **Note**
>
> Workgroup Bridge mode is supported on the WiFi6 Pluggable Module from Cisco IOS XE Bengaluru 17.6.1.

Table 190: Supported Access Points and Requirements

Access Points	Requirements
Cisco Aironet 2800, 3800, 4800, 1562, and Cisco Catalyst 9105, 9115, 9120, 9124, and 9130, IW6300 and ESW6300 Series	CAPWAP image starting from Cisco AireOS 8.8 release.

Restrictions for WGB

These are the restrictions for WGB:

- Cisco Wave 2 and 802.11ax APs operating in WGB mode can connect only to a Cisco root APs with Aironet IE/CCX enabled on the WLAN. WGB connectivity to a non-Cisco root access point is not supported in this mode.

  For non-Cisco root AP connectivity, use uWGB mode where applicable. However, uWGB mode supports only one wired client behind the WGB.

- MAC filtering is not supported for wired clients.
- Idle timeout is not supported for both WGB and wired clients.
- Session timeout is not applicable for wired clients.
- Web authentication is not supported.
- The total number of clients supported by WGB (wired + wireless) is limited to 20 clients.
- If you want to use a chain of certificates, copy all the CA certificates to a file and install it under a trust point on the WGB, else server certificate validation may fail.
- Wired clients connected to a WGB inherit the WGB's QoS and AAA override attributes.
- To enable the WGB to communicate with the root AP, create a WLAN and make sure that Aironet IE is enabled under the Advanced settings.
- WPA2 Enterprise security works only if the uplink WLAN is enabled for FlexConnect local switching or Fabric enabled WLAN.
- Radius override is not supported for wireless clients that are associated with WGB WLANs.
- WGB does not support 802.1X wired client authentication when used with power injector.

  The power-injector drops all EAPOL packets received from the wired client and does not forward it to the WGB's wired0 interface. In such cases, use PoE plus hub behind the wired0 interface and connect the wired clients to the hub.

- After WGB reload, the WGB 802.1X wired clients behind a hub do not trigger authentication automatically, unless done manually.

  After WGB is reloaded the WGB dot1x wired clients which are behind a hub remain authenticated or connected on their side and do not get notified that the WGB is reloaded. Clients are also not shown on the WGB bridge table. The client interfaces must be manually disabled and enabled back to trigger authentication.

- When the 802.1X wired client Ethernet interface is disabled and then enabled again, client authentication might fail for some of dot1x wired clients, at times.

Configure a WGB on a WLAN (CLI)

Use this procedure to configure a workgroup bridge (WGB) on a WLAN to enable network connectivity for wired devices through a wireless link.

Deploy a WGB so that connected wired devices can access the network via WLAN.

WGBs allow wired devices to join a wireless network by bridging their wired connections over Wi-Fi. This configuration is used in environments where direct wireless capability is not available for all devices.

Before you begin

Ensure WLAN security (such as authentication and encryption) is already configured.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter WLAN configuration submode.

   Example

   ```
   Device(config)# wlan profile-name
   ```

   The *profile-name* is the profile name of the configured WLAN.

3. Configure the Cisco Client Extensions option and sets the support of Aironet IE on the WLAN.

   Example

   ```
   Device(config-wlan)# ccx aironet-iesupport
   ```

4. Exit the WLAN configuration submode.

   Example

   ```
   Device(config-wlan)# exit
   ```

5. Configure WLAN policy profile and enters the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-policy
   ```

6. Add a description for the policy profile.

Example

```
Device(config-wireless-policy)# description "test-wgb"
```

7. Assign the profile policy to the VLAN.

   Example

   ```
   Device(config-wireless-policy)# vlan vlan-no
   ```

8. Configure WGB VLAN client support.

   Example

   ```
   Device(config-wireless-policy)# wgb vlan
   ```

9. Configure WGB broadcast tagging on a WLAN.

   Example

   ```
   Device(config-wireless-policy)# wgb broadcast-tagging
   ```

10. Restart the policy profile.

    Example

    ```
    Device(config-wireless-policy)# no shutdown
    ```

11. Exit the wireless policy configuration mode.

    Example

    ```
    Device(config-wireless-policy)# exit
    ```

12. Configure policy tag and enters policy tag configuration mode.

    Example

    ```
    Device(config)# wireless tag policy policy-tag
    ```

13. Map a policy profile to a WLAN profile.

    Example

    ```
    Device(config-policy-tag)# wlan profile-name policy profile-policy
    ```

14. Exit policy tag configuration mode, and returns to privileged EXEC mode.

    Example

    ```
    Device(config-policy-tag)# end
    ```

The WGB is now configured and can join the designated WLAN, bridging its wired clients to the wireless network.

Verify WGB status on the controller

Lists commands to verify the status of a workgroup bridge on the controller.

Use these commands to verify the status of a WGB.

To display the wireless-specific configuration of active clients, use this command:

```
Device# show wireless client summary
```

To display the WGBs on your network, use this command:

```
Device# show wireless wgb summary
```

To display the details of wired clients that are connected to a particular WGB, use this command:

```
Device# show wireless wgb mac-address 00:0d:ed:dd:25:82 detail
```

Configure AP as WGB

Guides configuration of access points as Workgroup Bridges, including tasks to enter autonomous mode, set up Wave 2 APs, configure SSID and EAP profiles, authentication servers, 802.1X credentials, certificate enrollment, radio interface, timeouts, and bridge forwarding using CLI commands.

Configure Cisco Wave 2 APs or 11AX APs in WGB or CAPWAP AP mode (CLI)

Learn how to configure Cisco Wave 2 or 11AX Access Points as workgroup bridges or CAPWAP APs using command-line interface (CLI) commands.

Set up the AP mode and management configuration for Cisco APs using the CLI.

This task is applicable when you need to quickly reconfigure the AP operation mode between Workgroup Bridge and CAPWAP using the AP's command-line interface.

Procedure

1. Enter the privileged mode of the AP.

   Example

   ```
   Device> enable
   ```

2. Move the AP in to the Workgroup Bridge mode.

   Example

   ```
   Device# ap-type workgroup-bridge
   ```

3. Configure DHCP or static IP address using the **configure ap address ipv4 dhcp** or **configure ap address ipv4 static***ip-address netmask gateway-ipaddress* command.

Example

DHCP IP Address

```
Device# configure ap address ipv4 dhcp
```

Static IP Address

```
Device# configure ap address ipv4 static 10.10.10.2 255.255.255.234 192.168.4.1
```

4. Configure an username for the AP management.

Example

```
Device# configure ap management add username username password password secret
 secret
```

5. Configure the AP hostname.

Example

```
Device# configure ap hostname host-name
```

The AP is successfully configured in the selected mode with the desired network and management settings.

Configure an SSID profile for Cisco Wave 2 and 11AX APs (CLI)

Configure an SSID profile for Cisco Wave 2 and 11AX APs using CLI commands on the AP console.

Set up secure Wi-Fi profiles for Wave 2 and 11AX APs, allowing client authentication and traffic management using the AP CLI.

This configuration is performed on the AP console and does not apply to the controller CLI. Choose authentication and QoS settings best suited for your environment.

Before you begin

Ensure you have access to the AP console and any preshared keys or EAP profiles needed for authentication.

Procedure

---

1. Create an SSID profile and specify authentication (open, PSK, or EAP) and key management options.

Example

SSID profile with open authentication:

```
Device# configure ssid-profile test WRT s1 authentication open
```

SSID profile with PSK authentication:

```
Device# configure ssid-profile test WRT s1 authentication psk 1234
key-management dot11r
```

SSID profile with EAP authentication:

```
Device# configure ssid-profile test WRT s1 authentication eap profile test2
key-management dot11r
```

Choose the authentication protocol that matches your deployment requirements.

2. Attach the SSID profile to a radio interface.

Example

```
Device# configure dot11radio radio-interface mode wgb ssid-profile profle-name
```

Binds the SSID profile for wireless bridge operations.

3. Optional: Configure the DTIM period for the SSID profile.

Example

```
Device# configure ssid-profile profile-name ssid ssid-name dtim-period
ssid-name
```

Sets the delivery traffic indication message interval for broadcast/multicast traffic.

> **Note**
>
> Supported for wireless clients from Cisco IOS XE Cupertino 17.9.1 onwards.

4. Optional: Create a QoS profile.

Example

```
Device# configure qos profile qos-profile gold
```

Gold, silver, platinum, and bronze options are available to prioritize traffic.

5. Optional: Map the QoS profile to the SSID profile.

Example

```
Device# configure ssid-profile profile-name ssid ssid-name qos profile
qos-profile-name
```

Enables traffic prioritization for the specified SSID profile.

> **Note**
>
> Supported for wireless clients from Cisco IOS XE Cupertino 17.9.1 onwards.

6. Optional: Delete an SSID profile.

Example

```
Device# configure ssid-profile profile-name delete
```

7. Optional: Display summary of configured and connected SSIDs.

Example

```
Device# show wgb ssid
```

8. Optional: Display management, control, and data packet statistics for WGB SSIDs.

Example

```
Device# show wgb packet statistics
```

The SSID profile is configured for the AP and mapped to the desired radio interface. Wireless clients can now connect using the specified authentication mode, traffic is prioritized according to QoS settings, and you can monitor SSID and packet statistics as needed.

Configure the authentication server (CLI)

Configure the authentication server on the device using command-line interface (CLI) commands.

Set up a primary or secondary RADIUS authentication server for network access control using CLI.

RADIUS servers provide centralized authentication, authorization, and accounting (AAA) management for users connecting to the network.

Before you begin

Ensure you have the IP address, port number, and shared secret for the RADIUS server you are configuring.

Procedure

Configure a RADIUS authentication server with a primary or secondary role, IP version (IPv4 or IPv6), port, server address, and shared secret.

Example

```
Device# configure radius authentication primary | secondary add ipv4|ipv6
address radius-server-ip-address port radius-server-port-number secret
radius-secret
```

```
Device# configure radius authentication primary add ipv4 address 192.168.1.2
port 1812 secret Cisco123
```

a. **primary | secondary**: specifies if the RADIUS server is primary or secondary.

b. **ipv4 | ipv6**: identifies the IP address type.

c. **radius-server-ip-address**: is the management IP address of the RADIUS server.

d. **radius-server-port-number**: is typically 1812 for authentication.

e. **radius-secret**: is a shared secret between the device and the RADIUS server (case-sensitive).

The RADIUS authentication server is now configured. The device can authenticate users against the designated server.

Configure dot1X credential (CLI)

Use this procedure to configure a Dot1X credential using CLI commands on your device.

Configure or remove a Dot1X credential profile, and manage WGB client authentication using CLI commands.

Dot1X credentials are used to authenticate devices securely to the network. You can create or remove these credentials as required, and clear authenticated Workgroup Bridge (WGB) clients using dedicated commands.

Before you begin

Ensure the device is in global configuration mode before issuing these commands.

Procedure

1. Configure a dot1X credential profile with username and password.

   Example

   ```
   Device(config)# configure dot1x credential profile-name username username
   password password
   ```

2. Delete a dot1X credential profile.

   Example

   ```
   Device(config)# configure dot1x credential profile-name delete
   ```

3. Deauthenticate a WGB client by clearing a WGB client session based on MAC address or clear all WGB clients.

   Example

   ```
   Device# clear wgb client single mac-address
   ```

   To clear all WGB clients, use:

   ```
   Device# clear wgb client all
   ```

Dot1X credentials and WGB client sessions are managed according to your chosen operations.

Configure an EAP profile (CLI)

Configure an EAP profile using commands.

Use this procedure to create, manage, or delete EAP profiles on your device for authentication using the CLI.

An EAP profile defines the authentication method for wireless users. You can configure various methods and associate Trustpoints or credentials to strengthen security for wireless authentication.

Before you begin

Enable global configuration mode on the device and verify access to CLI.

Procedure

1. Configure an EAP profile and set the EAP method.

   Example

   ```
   Device# configure eap-profile profile-name method method-name
   ```

   Configures an EAP profile with the chosen method.

   The method-name can be:

   - **fast**
   - **peap**
   - **tls**

2. Associate a Trustpoint with the EAP profile. Use either the default or a specific name.

   Example

   EAP profile to Trustpoint with MIC Certificate:

   ```
   Device# configure eap-profile profile-name trustpoint default
   ```

   EAP profile to Trustpoint with CA Certificate:

   ```
   Device# configure eap-profile profile-name trustpoint name trustpoint-name
   ```

   Configures an EAP profile with a Trustpoint for authentication.

3. Attach a CA Trustpoint to the EAP profile.

   Example

   ```
   Device# configure eap-profile profile-name trustpoint {default | name
   trustpoint-name}
   ```

   Attaches the CA Trustpoint.

> **Note**
>
> With the default profile, WGB uses the internal MIC certificate for authentication.

4. Configure the 802.1X credential profile for the EAP profile.

   Example

   ```
   Device# configure eap-profile profile-name dot1x-credential profile-name
   ```

   Configures the 802.1X credential profile associated with the EAP profile.

5. Optional: Delete an EAP profile.

   Example

   ```
   Device# configure eap-profile profile-name delete
   ```

6. Optional: Display the WGB EAP dot1x credential profile summary.

   Example

   ```
   Device# show wgb eap dot1x credential profile
   ```

7. Optional: Display the EAP profile summary.

   Example

   ```
   Device# show wgb eap profile
   ```

8. Optional: Display all configured EAP and dot1x profiles.

   Example

   ```
   Device# show wgb eap profile all
   ```

The EAP profile is now configured as required. You can display or modify EAP profiles as needed to support different authentication strategies.

Configure manual-enrollment of a Trustpoint for WGB (CLI)

Use this procedure to configure manual enrollment of a Trustpoint for workgroup bridge (WGB) using CLI commands.

Manually configure and enroll a Trustpoint on a WGB to enable certificate-based security authentication via CLI.

A Trustpoint defines a Certification Authority (CA) used to issue certificates for device authentication. Manual enrollment is used when automatic enrollment via HTTP/SCEP is not available.

Before you begin

Ensure that the WGB configuration is complete and the required CA certificate is accessible. You must have administrator access to the CLI and all necessary server and certificate information.

Procedure

1. Configure a Trustpoint on the WGB and set the enrollment method to terminal.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name enrollment terminal
   ```

   Defines a new Trustpoint and specifies that certificate content will be entered manually.

2. Authenticate the Trustpoint and input the base 64 encoded CA certificate.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name authenticate
   ```

   Authenticates a Trustpoint by pasting the CA-signed certificate. End certificate input by typing **quit** on a new line.

3. Configure the private key size for the Trustpoint.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name key-size key-length
   ```

   Sets the RSA key pair length for the Trustpoint's private key.

4. Configure the subject name attributes for the Trustpoint's certificate.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name subject-name name
   2ltr-country-code state-name locality org-name org-unit email
   ```

   Example

   ```
   Device# configure crypto pki trustpoint
   ca-server-US subject-name test US CA abc cisco AP test@cisco.com
   ```

   Specifies certificate subject fields, matching your organization's naming policy.

5. Generate a Certificate Signing Request (CSR) on the WGB and enroll the Trustpoint.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name enroll
   ```

   Generates the private key and a CSR; provide the CSR output to your CA server for certificate signing.

6. Import the signed certificate from the CA back into the WGB Trustpoint.

Example

```
Device# configure crypto pki trustpoint ca-server-name import certificate
```

Installs the issued device certificate. End certificate input with the **quit** command on a new line.

7. Optional: Delete the Trustpoint if reconfiguration is needed.

Example

```
Device# configure crypto pki trustpoint ca-server-name delete
```

Removes a Trustpoint configuration from the device.

8. Optional: Display the Trustpoint summary.

Example

```
Device# show crypto pki trustpoint
```

Shows all Trustpoints configured on the device.

9. Optional: Display certificates associated with a Trustpoint.

Example

```
Device# show crypto pki trustpoint ca-server-name certificate
```

Inspect the contents of certificates for a specific Trustpoint.

Manual Trustpoint enrollment is now complete on the WGB. The device can use the certificates for secure authentication and establish connections as required for network operation.

Configure auto-enrollment of a Trustpoint for workgroup bridge (CLI)

Use this procedure to configure auto-enrollment of a Trustpoint for a workgroup bridge (WGB) using CLI commands.

Enable automatic certificate enrollment for secure communication by configuring a Trustpoint and CA enrollment in a WGB deployment.

Auto-enrollment of a Trustpoint streamlines certificate management for workgroup bridges by allowing automatic acquisition and renewal of CA certificates.

Before you begin

Ensure the device is running the appropriate WGB image and has connectivity to the CA server.

Procedure

---

1. Configure the Trustpoint and specify the CA server enrollment URL.

Example

```
Device# configure crypto pki trustpoint ca-server-name enrollment url
ca-server-url
```

Enrolls a Trustpoint in WGB using the CA server URL.

2. Authenticate the Trustpoint by fetching the CA certificate from the CA server.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name authenticate
   ```

   Fetches the CA certificate for Trustpoint authentication.

3. Set the private key size for the Trustpoint.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name key-size key-length
   ```

   Example

   ```
   Device# configure crypto pki trustpoint
   ca-server-Us key-size 60
   ```

4. Configure the subject name for the trustpoint.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name subject-name name
   2ltr-country-code state-name locality org-name org-unit email
   ```

   Example

   ```
   Device# configure crypto pki trustpoint
   ca-server-US subject-name test US CA abc cisco AP test@cisco.com
   ```

   Customize the subject name parameters as needed for your deployment.

5. Enroll the Trustpoint to request a signed certificate from the CA server.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name enroll
   ```

   Initiates the certificate enrollment request to the CA server.

6. Enable auto-enrollment and specify the renewal percentage threshold.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name auto-enroll enable
   renew-percentage
   ```

   Example

   ```
   Device# configure crypto pki trustpoint
   ca-server-US auto-enroll enable  10
   ```

Use **disable** to turn off auto-enroll if needed.

7. Optional: Delete the Trustpoint if it is no longer required.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name delete
   ```

   Removes the Trustpoint from the configuration.

8. Optional: Display the summary of Trustpoints.

   Example

   ```
   Device# show crypto pki trustpoint
   ```

   Lists all configured Trustpoints and their status.

9. Optional: Display the certificate for a specific Trustpoint.

   Example

   ```
   Device# show crypto pki trustpoint ca-server-name certificate
   ```

   Shows the certificate configured for the specified Trustpoint.

10. Optional: Display the PKI timer information.

    Example

    ```
    Device# show crypto pki timers
    ```

    Displays timer settings related to PKI operations.

The Trustpoint is now auto-enrolled and managed on the WGB, ensuring secure and automated certificate renewal.

Configure manual certificate enrollment using TFTP server (CLI)

Learn how to configure manual certificate enrollment using TFTP server commands.

Manual certificate enrolment allows devices to obtain certificates from a TFTP server, which is essential for secure communications.

Procedure

---

1. Specify the enrollment method to retrieve the CA certificate and client certificate for a Trustpoint in WGB.

   Example

   ```
   Device# configure crypto pki trustpoint
   ca-server-name enrollment addr/file-name
   ```

2. Authenticate the CA certificate from the specified TFTP server.

Example

```
Device# configure crypto pki trustpoint
ca-server-name authenticate
```

Retrieves the CA certificate and authenticates it from the specified TFTP server. If the file specification is included, the WGB will append the extension ".ca" to the specified filename.

3. Configure the private key size for the Trustpoint.

Example

```
Device# configure crypto pki trustpoint
ca-server-name key-size key-length
```

4. Set the subject name for the Trustpoint.

Example

```
Device# configure crypto pki trustpoint
ca-server-name subject-name test US CA abc cisco AP test@cisco.com
```

5. Generate a private key and certificate signing request (CSR).

Example

```
Device# configure crypto pki trustpoint
ca-server-name enroll
```

Generate a private key and Certificate Signing Request (CSR) and write the request out to the TFTP server. The filename to be written is appended with the extension ".req".

6. Import the signed certificate into WGB using TFTP at the console terminal, which retrieves the granted certificate.

Example

```
Device# configure crypto pki trustpoint
ca-server-name import certificate
```

The WGB will attempt to retrieve the granted certificate using TFTP using the same filename and the file name appended with ".crt" extension.

7. Optional: Display the Trustpoint summary.

Example

```
Device# show crypto pki trustpoint
```

8. Optional: Display the content of the certificates that are created for a Trustpoint.

Example

```
Device# show crypto pki trustpoint trustpoint-name certificate
```

Import the PKCS12 format certificates from the TFTP server (CLI)

Import the PKCS12 format certificates from the TFTP server using commands.

Importing PKCS12 format certificates is essential for establishing secure communications in network devices.

Procedure

1. Import the PKCS12 format certificate from the TFTP server.

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-name import pkcs12 tftp
   addr/file-name password pwd
   ```

   Example

   ```
   Device# configure crypto pki trustpoint ca-server-US import pkcs12
   tftp://10.8.0.6/all_cert.p12 password ******
   ```

2. Optional: Display the Trustpoint summary.

   Example

   ```
   Device# show crypto pki trustpoint
   ```

3. Optional: Display the content of the certificates created for a Trustpoint.

   Example

   ```
   Device# show crypto pki trustpoint trustpoint-name certificate
   ```

   Example

   ```
   Device# show crypto pki trustpoint ca-server-US certificate
   ```

Configure radio interface for workgroup bridges (CLI)

Configure radio interface for workgroup bridges using commands.

From the available two radio interfaces, before configuring WGB or UWGB mode on one radio interface, configure the other radio interface to root AP mode.

Procedure

1. Configure a radio interface as root AP.

   Example

   ```
   Device# configure dot11Radio radio-int mode root-ap
   ```

Example

```
Device# configure dot11Radio 0/3/0 mode root-ap
```

Maps a radio interface as root AP.

> **Note**
>
> When an active SSID or EAP profile is modified, you need to reassociate the profile to the radio interface for the updated profile to be active.

2. Configure the WLAN at the root AP mode radio.

Example

```
Device# configure dot11radio value wlan add ssid-profile-name ssid-number
```

Example

```
Device# configure dot11radio dotradiovalue wlan add ssid-profile-name
ssid-number
```

Enter the SSID profile name and SSID number between 1 and 16. Value can be 0 or 1.

3. Delete WLAN from the radio configuration.

Example

```
Device# configure dot11radio dotradiovalue wlan delete ssid-profile-name
```

Enter the SSID profile name. Value can be 0 or 1.

4. Configure a radio channel to broadcast the SSID.

Example

```
Device# configure dot11radio value channel channel-number width
```

Example

```
Device# configure dot11radio value channel channel-number width
```

The channel numbers are between 1 and 173. The channel width values are 20, 40, 80, and 160.

> **Note**
>
> - Only 20MHz channel width is supported on radio 0 (2.4-GHz band).
> - If radar is detected on a configured channel on radio 1, then the channel automatically changes to a non-DFS channel with a channel width of 20MHz. The administrator must reset the radio to bring it back to the configured channel.

5. Configure the periodic beacon interval in milliseconds.

   Example

   ```
   Device# configure dot11radio dotradiovalue beacon-period beacon-interval
   ```

   The value range is from 2 to 2000 milliseconds.

6. Map a radio interface to a WGB SSID profile.

   Example

   ```
   Device# configure dot11Radio 0/3/0 mode wgb ssid-profile ssid-profile-name
   ```

7. Map a radio interface to a UWGB SSID profile.

   Example

   ```
   Device# configure dot11Radio radio-int mode uwgb mac-addr ssid-profile
   ssid-profile-name
   ```

8. Configure a radio interface.

   Example

   ```
   Device# configure dot11Radio radio-int mode enable
   ```

   After configuring the uplink to the SSID profile, we recommend that you disable and enable the radio for the changes to be active.

9. Configure a radio antenna.

   Example

   ```
   Device# configure dot11Radio radio-int antenna a-antenna
   ```

10. Configure the radio interface encryption mode.

    Example

    ```
    Device# configure dot11Radio radio-int encryption mode ciphers aes-ccm
    ```

11. Configure the device channel rate.

Example

```
Device# configure wgb mobile rate basic 6 9 18 24 36 48 54
```

12. Configure the threshold duration and signal strength to trigger scanning.

Example

```
Device# configure wgb mobile period seconds thres-signal
```

13. Configure the static roaming channel.

Example

```
Device# configure wgb mobile station interface dot11Radio 0/3/0 scan
channel-number add
```

14. Optional: Delete the mobile channel.

Example

```
Device# configure wgb mobile station interface dot11Radio 0/3/0 scan
channel-number delete
```

15. Optional: Disable the mobile channel.

Example

```
Device# configure wgb mobile station interface dot11Radio 0/3/0 scan disable
```

16. Optional: Configure the beacon miss-count.

Example

```
Device# configure wgb beacon miss-count value
```

> **Note**
>
> When you set the beacon miss-count value to 10 or lower, then the beacon miss-count gets disabled. Set the value to 11 or higher to enable this function.

17. Optional: Display the Wi-Fi station statistics.

Example

```
Device# show wgb wifi wifi-interface stats
```

18. Optional: Display the radio antenna statistics.

Example

```
Device# show controllers dot11Radio radio-interface antenna
```

19. Optional: Display the mobile station channels scan configuration.

Example

```
Device# show wgb mobile scan channel
```

20. Optional: Display the configuration that is stored in the NV memory.

Example

```
Device# show configuration
```

21. Optional: Display the running configuration in the device.

Example

```
Device# show running-config
```

Configure workgroup bridge timeouts (CLI)

Configure timeouts for workgroup bridge features using CLI commands.

Use this task to configure various timeout values that control workgroup bridge (WGB) behavior, improving reliability and performance.

- Set specific timeout limits for association, authentication, EAP, DHCP response, and channel scan processes.

Timeout values affect how long the WGB waits for events before triggering corrective actions or failure notices.

This task applies to Cisco devices in environments where precise timeout management is needed for workgroup bridge operations and troubleshooting.

Before you begin

Ensure you have privileged EXEC access on the device.

- Verify device compatibility and active WGB configuration.

Procedure

1. Configure the WGB association response timeout.

Example

```
Device# configure wgb association response timeout response-millisecs
```

The valid range is 300 to 5000 milliseconds. The default value is 5000 milliseconds.

2. Configure the WGB authentication response timeout.

Example

```
Device# configure wgb authentication response timeout response-millisecs
```

The valid range is 300 to 5000 milliseconds. The default value is 5000 milliseconds.

3. Configure the Universal WGB client response timeout.

Example

```
Device# configure wgb uclient timeout timeout-secs
```

The valid range is 1 to 65535 seconds. The default value is 60 seconds.

4. Configure the WGB EAP timeout.

Example

```
Device# configure wgb eap timeout timeout-secs
```

The valid range is 2 to 60 seconds. The default value is 3 seconds.

5. Configure the WGB channel scan timeout.

Example

```
Device# configure wgb channel scan timeout {fast | slow | medium}
```

Select scan speed according to site requirements.

6. Configure the WGB DHCP response timeout.

Example

```
Device# configure wgb dhcp response timeout timeout-secs
```

The valid range is 1000 to 60000 milliseconds. The default value is 60 seconds.

7. Display the WGB association summary.

Example

```
Device# show wgb dot11 association
```

Display associated WGB clients and related statistics.

The configured timeout parameters apply immediately and affect how the WGB responds to events and failures.

For example, to set the WGB association response timeout to 4000 milliseconds:

```
Device# configure wgb association response timeout 4000
```

What to do next

Verify timeout settings by using display commands and monitoring WGB behavior.

- Adjust timeouts as needed for specific network or client stability.

Configure bridge forwarding for workgroup bridge (CLI)

Configure bridge forwarding for workgroup bridge using commands.

Before you begin

The Cisco Wave 2 and 11AX APs as Workgroup Bridge recognizes the Ethernet clients only when the traffic has the bridging tag.

We recommend setting the WGB bridge client timeout value to default value of 300 seconds, or less in environment where change is expected, such as:

- Ethernet cable is unplugged and plugged back.
- Endpoint is changed.
- Endpoint IP is changed (static to DHCP and vice versa).

If you need to retain the client entry in the WGB table for a longer duration, we recommend you increase the client WGB bridge timeout duration.

Procedure

1. Add a WGB client using the MAC address.

   Example

   ```
   Device# configure wgb bridge client add mac-address
   ```

   Example

   ```
   Device# configure wgb bridge client add F866.F267.7DFB
   ```

2. Configure the WGB bridge client timeout. Default timeout value is 300 seconds. The valid range is from 10 to 1000000 seconds.

   Example

   ```
   Device# configure wgb bridge client timeout timeout-secs
   ```

   Example

   ```
   Device# configure wgb bridge client timeout 400
   ```

3. Display the WGB wired clients over the bridge.

   Example

   ```
   Device# show wgb bridge
   ```

4. Display the WGB Gigabit wired clients over the bridge.

Example

```
Device# show wgb bridge wired gigabitEthernet interface
```

Example

```
Device# show wgb bridge wired gigabitEthernet 0/1
```

5. Display the WGB bridge radio interface summary.

Example

```
Device# show wgb bridge dot11Radio interface-number
```

Example

```
Device# show wgb bridge dot11Radio 0/3/1
```

Simplified WGB configuration

Describes the capability to configure workgroup bridge (WGB) settings across multiple Cisco access points simultaneously using configuration import methods.

Simplified WGB configuration is a network deployment capability that

- enables configuration of WGB in multiple Cisco access points (APs) simultaneously
- allows deployment of multiple WGBs in a network through configuration import, making them operational quicker
- eliminates the need to configure multiple Cisco APs using CLIs after logging into each one individually.

Configuration deployment methods

A network administrator can onboard Cisco APs using either of these methods:

- Upload the working configuration from an existing Cisco AP to a server and download it to the newly deployed Cisco APs.
- Send a sample configuration to all the Cisco APs in the deployment.

This feature is supported only on these Cisco APs:

- Cisco Aironet 1562 Access Points
- Cisco Aironet 2800 Access Points
- Cisco Aironet 3800 Access Points
- Cisco Catalyst 9105 Access Points
- Cisco Catalyst 9115 Access Points
- Cisco Catalyst 9120 Access Points
- Cisco Catalyst IW6300 Series Heavy Duty Access Points

For latest support information on various features in Cisco Wave 2 and 802.11ax (Wi-Fi 6) Access Points in Cisco IOS XE releases, see the Feature Matrix for Wave 2 and 802.11ax (Wi-Fi 6) Access Points document.

Configure multiple WGBs (CLI)

Configure multiple WGBs using commands.

Configure multiple WGBs efficiently by uploading and downloading configuration files via SFTP or TFTP.

Perform this procedure on the APs in WGB mode when you need to deploy the same configuration across multiple workgroup bridges or update their settings remotely.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Create upload configuration file and upload to the SFTP or TFTP server.

   Example

   ```
   Device# copy configuration upload {sftp:|tftp:} ip-address [directory]
   [file-name]
   ```

   Example

   ```
   Device# copy configuration upload sftp: 10.10.10.1 C:sample.txt
   ```

3. Download the configuration file and replace the old configuration in the AP.

   Example

   ```
   Device# copy configuration download {sftp:|tftp:} ip-address [directory]
   [file-name]
   ```

   Example

   ```
   Device# copy configuration download sftp: 10.10.10.1 C:sample.txt
   ```

   The device reboots and applies the new configuration when it restarts.

4. Display the WGB uplink information.

   Example

   ```
   Device# show wgb dot11 association
   ```

5. Display the AP software information.

Example

```
Device# show version
```

Multiple WGBs are configured with the uploaded configuration files, and you can verify their status using the show commands.

Verify WGB configuration

Lists the debug log output that confirms successful WGB configuration download and application.

After completing the configuration download and reboot of the AP, the WGB rejoins the network. Use the **show logging** command to list and verify the download events that are captured in the debug logs:

```
Device# show logging

215 Peer-to-Peer Client Support

Topics:

- Peer-to-peer client support

Introduces peer-to-peer client support functionality and guides through configuration processes while outlining system restrictions and limitations.

Peer-to-peer client support

Describes granular control over how traffic is directed in wireless networks.

Peer-to-peer client support is a WLAN feature that

- provides granular control over how traffic is directed
- can be applied to individual WLANs with each client inheriting the peer-to-peer blocking setting of the WLAN to which it is associated
- allows traffic to be bridged locally within a device, dropped by a device, or forwarded to the upstream VLAN.

Peer-to-peer blocking support details

Peer-to-peer blocking is supported for clients that are associated with local and central switching WLANs.

These restrictions apply to peer-to-peer client support:

- Peer-to-peer blocking does not apply to multicast traffic.
- Peer-to-peer blocking is not enabled by default.
- In FlexConnect, peer-to-peer blocking configuration cannot be applied only to a particular FlexConnect AP or a subset of APs. It is applied to all the FlexConnect APs that broadcast the SSID.
- FlexConnect central switching clients supports peer-to-peer upstream-forward. However, this is not supported in the FlexConnect local switching. This is treated as peer-to-peer drop and client packets are dropped.

  FlexConnect central switching clients supports peer-to-peer blocking for clients associated with different APs. However, for FlexConnect local switching, this solution targets only clients connected to the same AP. FlexConnect ACLs can be used as a workaround for this limitation.

Configure peer-to-peer client support

Configure peer-to-peer client support to control how client traffic flows between devices on the same WLAN.

Enable peer-to-peer blocking policies to control communication between wireless clients on the same WLAN.

Peer-to-peer blocking allows you to control whether wireless clients can communicate directly with each other or must route traffic through the upstream network infrastructure. This feature is useful for security and traffic management in enterprise environments.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter WLAN configuration submode.

   Example

   ```
   Device(config)# wlan profile-name
   ```

   The *profile-name* is the profile name of the configured WLAN.

3. Configure peer-to-peer blocking parameters.

   Example

   ```
   Device(config-wlan)# peer-blocking allow-private-group | drop |
   forward-upstream
   ```

   Example

   ```
   Device(config-wlan)# peer-blocking drop
   ```

   The keywords are:

   - **allow-private-group**: Enables peer-to-peer blocking on the Allow Private Group action.
   - **drop**: Enables peer-to-peer blocking on the drop action.
   - **forward-upstream**: No action is taken and forwards packets to the upstream.

     Note

     The **forward-upstream** option is not supported for Flex local switching. Traffic is dropped even if this option is configured. Also, peer to peer blocking for local switching SSIDs are available only for the clients on the same AP.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

5. Display the details of the selected WLAN.

   Example

   ```
   Device# show wlan id wlan-id
   ```

   Example

   ```
   Device# show wlan id 12
   ```

Peer-to-peer client support is now configured on the WLAN with the specified blocking behavior for client-to-client communication.

216 Deny Wireless Client Session Establishment Using Calendar Profiles

Topics:

- Denial of wireless client session establishment

Denial of wireless client session establishment

Describes a controller feature that stops client session establishment based on scheduled time periods to enable controlled network management without manual intervention.

Denial of wireless client session establishment is a controller feature that

- allows the controller to stop client session establishment based on a particular time
- helps control the network in efficient and controlled manner without any manual intervention, and
- supports daily, weekly, and monthly recurrence schedules through calendar profiles mapped to policy profiles.

Supported recurrence types

In Cisco Catalyst 9800 Series Wireless Controller , you can deny the wireless client session based on these recurrences:

- Daily
- Weekly
- Monthly

The Calendar Profiles created are then mapped to the policy profile. By attaching the calendar profile to a policy profile, you will be able to create different recurrences for the policy profile using different policy tag.

Note

You need to create separate Calendar Profile for Daily, Weekly, and Monthly sub-categories.

The following is the workflow for denial of wireless client session establishment feature:

- Create a calendar profile.
- Apply the calendar profile to a policy profile.

Note

A maximum of 100 calendar profile configuration and 5 calendar profile association to policy profile is supported.

Configuration limits and timing considerations:

- Feature activation: If you boot up your controller, the denial of client session establishment feature kicks in after a minute from the system boot up.
- Time change adaptation: If you change the system time after the calendar profile is associated to a policy profile, you can expect a maximum of 30 second delay to adapt to the new clock timings.

> **Note**
>
> You cannot use the **no action deny-client** command to disable action while associating the calendar profile to a policy profile.
>
> If you want to disable the action command, you need to disassociate the calendar profile from the policy profile, and re-configure again.

Guidelines and limitations

Guidelines and limitations

-
-

Guidelines and limitations

-
-

Configure daily calendar profile (CLI)

Configure daily calendar profile to set scheduled time periods for wireless operations.

Set up a calendar profile that defines daily recurring time periods for wireless network operations and power management.

Calendar profiles allow you to schedule specific time periods for wireless operations, such as controlling when certain wireless features are active. Daily calendar profiles apply the same time schedule every day.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a calendar profile.

   Example

   ```
   Device(config)# wireless profile calendar-profile name calendar-profile-name
   ```

   Example

   ```
   Device(config)# wireless profile calendar-profile name daily_calendar_profile
   ```

   The *calendar-profile-name* refers to the name of the calendar profile.

3. Configure start and end time for the calendar profile.

Example

```
Device(config-calendar-profile)# start start-time end end-time
```

Example

```
Device(config-calendar-profile)# start 09:00:00 end 17:00:00
```

The *start-time* is the start time for the calendar profile. You need to enter start time in **HH:MM:SS** format.

The *end-time* is the end time for the calendar profile. You need to enter end time in **HH:MM:SS** format.

4. Configure daily recurrences for the calendar profile.

Example

```
Device(config-calendar-profile)# recurrence daily
```

5. Return to privileged EXEC mode.

Example

```
Device(config-calendar-profile)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

> **Note**
>
> When the calendar profile kicks in, the AP power profile rules (for example, radio state and USB device state) that are defined for the Ethernet speed are not applied and continue to be as per the fixed power profile.

The daily calendar profile is configured and will apply the specified time schedule every day for wireless operations.

Configure weekly calendar profile (CLI)

Configure weekly calendar profile to define specific time windows and recurring schedules for network operations.

Create a weekly calendar profile that defines recurring time windows for scheduled network operations or policies.

Calendar profiles allow network administrators to schedule when certain policies or operations should be active. A weekly calendar profile provides recurring time windows that repeat on specified days of the week, enabling automated time-based network management.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a calendar profile.

   Example

   ```
   Device(config)# wireless profile calendar-profile name name
   ```

   Example

   ```
   Device(config)# wireless profile calendar-profile name weekly_calendar_profile
   ```

   The *name* refers to the name of the calendar profile.

3. Configure start and end time for the calendar profile.

   Example

   ```
   Device(config-calendar-profile)# start start-time end end-time
   ```

   Example

   ```
   Device(config-calendar-profile)# start 18:00:00 end 19:00:00
   ```

   The *start-time* is the start time for the calendar profile in **HH:MM:SS** format.

   The *end-time* is the end time for the calendar profile in **HH:MM:SS** format.

4. Configure weekly recurrences for the calendar profile.

   Example

   ```
   Device(config-calendar-profile)# recurrence weekly
   ```

5. Configure days when the weekly calendar needs to be active.

   Example

   ```
   Device(config-calendar-profile)# day {friday | monday | saturday | sunday |
   thursday | tuesday | wednesday}
   ```

   Example

   ```
   Device(config-calendar-profile)# day friday
   Device(config-calendar-profile)# day monday
   ```

   > **Note**
   >
   > You can configure multiple days using this command.

6. Return to privileged EXEC mode.

Example

```
Device(config-calendar-profile)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The weekly calendar profile is now configured and can be applied to network policies that require time-based scheduling and recurring weekly activation windows.

Configure monthly calendar profile (CLI)

Configure monthly calendar profile for scheduling network operations.

Create a monthly calendar profile to schedule recurring network operations or denial of service events on specific dates each month.

Monthly calendar profiles enable you to define time-based policies that recur on specific dates within a month. This is useful for scheduled maintenance windows or automated network policy enforcement.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a calendar profile.

   Example

   ```
   Device(config)# wireless profile calendar-profile name profile-name
   ```

   Example

   ```
   Device(config)# wireless profile calendar-profile name monthly_calendar_profile
   ```

   The *profile-name* refers to the name of the calendar profile.

3. Configure start and end time for the calendar profile.

   Example

   ```
   Device(config-calendar-profile)# start start-time end end-time
   ```

   Example

   ```
   Device(config-calendar-profile)# start 18:00:00 end 19:00:00
   ```

   The *start-time* is the start time for the calendar profile. You need to enter start time in **HH:MM:SS** format.

   The *end-time* is the end time for the calendar profile. You need to enter end time in **HH:MM:SS** format.

4. Configure monthly recurrences for the calendar profile.

Example

```
Device(config-calendar-profile)# recurrence monthly
```

5. Configure a date for the calendar profile.

Example

```
Device(config-calendar-profile)# date date-value
```

Example

```
Device(config-calendar-profile)# date 25
```

> **Note**
>
> If the requirement is to perform denial of service in certain timing, such as, 2,10, and 25 of every month, all three days need to be configured using the **date** command. There is no range for date. You need to configure the dates as per your requirement.

6. Return to privileged EXEC mode.

Example

```
Device(config-calendar-profile)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The monthly calendar profile is configured and can be applied to schedule recurring network operations on the specified dates and times each month.

Map daily calendar profile to policy profile (CLI)

Configure mapping of a daily calendar profile to a policy profile to control client access based on time schedules.

Enable time-based access control by associating a calendar profile with a policy profile to manage client session establishment during specific time intervals.

Calendar profiles define time-based restrictions that can be applied to policy profiles. When mapped together, they allow administrators to automatically deny or allow client connections based on scheduled time slots, providing granular control over network access.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Create policy profile for the WLAN.

   Example

   ```
   Device(config)# wireless profile policy profile-name
   ```

   Example

   ```
   Device(config)# wireless profile policy default-policy-profile
   ```

   The *profile-name* is the profile name of the policy profile.

3. Map a calendar profile to a policy profile.

   Example

   ```
   Device(config-wireless-policy)# calender-profile name calendar-profile-name
   ```

   Example

   ```
   Device(config-wireless-policy)# calender-profile name daily_calendar_profile
   ```

   The *calendar-profile-name* is the name of the calendar profile name created in the daily calendar profile configuration task.

   > **Note**
   >
   > You need to disable Policy Profile before associating a calendar profile to a policy profile. Run this command:
   >
   > ```
   > Device(config-wireless-policy)# shutdown
   > ```

4. Configure deny client session establishment during calendar profile interval.

   Example

   ```
   Device(config-policy-profile-calender)# action deny-client
   ```

   > **Note**
   >
   > Client associations are denied daily between timeslot 9:00:00 to 17:00:00. For start and end time details, see the daily calendar profile configuration task.

5. Return to privileged EXEC mode.

Example

```
Device(config-policy-profile-calender)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The daily calendar profile is successfully mapped to the policy profile, enabling time-based client access control according to the configured schedule.

Map weekly calendar profile to policy profile (CLI)

Configure a weekly calendar profile mapping to a policy profile to control client session establishment during specific time periods.

Control wireless client access by mapping time-based calendar profiles to policy profiles, enabling scheduled denial of client sessions.

Weekly calendar profiles allow administrators to define specific time periods when client associations should be denied. This configuration is useful for implementing access control policies based on business hours or maintenance windows.

Before you begin

Ensure that a weekly calendar profile has been created before mapping it to a policy profile.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create or enter the policy profile configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-name
   ```

   Example

   ```
   Device(config)# wireless profile policy default-policy-profile
   ```

3. Map a calendar profile to the policy profile.

   Example

   ```
   Device(config-wireless-policy)# calender-profile name calendar-profile-name
   ```

   Example

   ```
   Device(config-wireless-policy)# calender-profile name weekly_calendar_profile
   ```

> **Note**
>
> You need to disable Policy Profile before associating a calendar profile to a policy profile. Use this command:
>
> ```
> Device(config-wireless-policy)# shutdown
> ```

4. Configure the action to deny client session establishment during calendar profile intervals.

   Example

   ```
   Device(config-policy-profile-calender)# action deny-client
   ```

   > **Note**
   >
   > Client associations are denied daily between timeslot 9:00:00 to 17:00:00. For start and end time details, see the weekly calendar profile configuration task.
   >
   > On Monday and Tuesday, clients are denied between 17:30:00 and 19:00:00 besides regular time 9:00:00 to 17:00:00.
   >
   > On 25th of every month, clients are denied between 18:00:00 and 19:00:00 besides regular time 9:00:00 to 17:00:00.

5. Exit to privileged EXEC mode.

   Example

   ```
   Device(config-policy-profile-calender)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The weekly calendar profile is now mapped to the policy profile, and client session establishment will be denied during the configured time periods defined in the calendar profile.

Map monthly calendar profile to policy profile (CLI)

Configure policy profile calendar mapping to control client access based on monthly calendar schedules.

Control client session establishment by mapping calendar-based time restrictions to wireless policy profiles.

Monthly calendar profiles define time-based access restrictions that can be applied to wireless policy profiles. This allows administrators to automatically deny client associations during specified time periods based on daily, weekly, or monthly schedules.

Before you begin

A monthly calendar profile must be created before it can be mapped to a policy profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create or enter policy profile configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-name
   ```

   Example

   ```
   Device(config)# wireless profile policy default-policy-profile
   ```

   The *profile-name* is the profile name of the policy profile.

3. Map a calendar profile to the policy profile.

   Example

   ```
   Device(config-wireless-policy)# calender-profile name calendar-profile-name
   ```

   Example

   ```
   Device(config-wireless-policy)# calender-profile name monthly_calendar_profile
   ```

   The *calendar-profile-name* is the name of the calendar profile name created in the monthly calendar profile configuration task.

4. Configure deny client action for the calendar profile interval.

   Example

   ```
   Device(config-policy-profile-calender)# action deny-client
   ```

   Note

   Every day client associations are denied between timeslot 9:00:00 to 17:00:00. For start and end time details, see the monthly calendar profile configuration task.

   On Monday and Tuesday, clients are denied between 17:30:00 and 19:00:00 besides regular time 9:00:00 to 17:00:00.

   On 25th of every month, clients are denied between 18:00:00 and 19:00:00 besides regular time 9:00:00 to 17:00:00.

5. Return to privileged EXEC mode.

Example

```
Device(config-policy-profile-calender)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The monthly calendar profile is now mapped to the policy profile and will automatically deny client sessions during the configured time intervals.

Verify calendar profile configuration

Lists commands to verify calendar profile configuration.

Verify calendar profile configuration using show commands to view profile summaries and detailed information for specific profiles.

To view the summary of calendar profiles, use this command:

```
Device# show wireless profile calendar-profile summary
Number of Calendar Profiles: 3

Profile-Name
--------------------------------
monthly_25_profile
weekly_mon_profile
daily_calendar_profile
```

To view the calendar profile details for a specific profile name, use this command:

```
Device# show wireless profile calendar-profile detailed daily_calendar_profile
Calendar profiles                          : daily_calendar_profile
-------------------------------------------------------------------
Recurrence                                 : DAILY
Start Time                                 : 09:00:00
End Time                                   : 17:00:00
```

Verify policy profile configuration

Provides commands to verify policy profile configuration.

Verify policy profile configuration using specific show commands to view detailed parameters and calendar profile information.

To view the detailed parameters for a specific policy profile, use this command:

```
Device# show wireless profile policy detailed default-policy-profile
Tunnel Profile
  Profile Name                     : Not Configured
Calendar Profile
  Profile Name                     : monthly_25_profile
  Wlan Enable                      : Not Configured
  Client Block                     : Client Block Configured
  ------------------------------------------------
  Profile Name                     : weekly_mon_profile
  Wlan Enable                      : Not Configured
  Client Block                     : Client Block Configured
  ------------------------------------------------
```

```
  Profile Name                        : daily_calendar_profile
  Wlan Enable                         : Not Configured
  Client Block                        : Client Block Configured
  ----------------------------------------------------
Fabric Profile
  Profile Name                        : Not Configured
```

To view the configured calendar profile information under policy profile, use this command:

```
Device# show wireless profile policy all
Tunnel Profile
Profile Name : Not Configured
Calendar Profile
Profile Name : daily_calendar_profile
Wlan Enable : Not Configured
Client Block : Client Block Configured
----------------------------------------------------
Profile Name : weekly_calendar_profile
Wlan Enable : Not Configured
Client Block : Client Block Configured
----------------------------------------------------
Fabric Profile
Profile Name : Not Configured
```

Note

The anchor priority is always displayed as local. Priorities can be assigned on the foreign controller.

217 Ethernet over GRE

Topics:

- Ethernet over GRE

Introduces Ethernet over Generic Routing Encapsulation tunnels and guides through configuring tunnel gateways, domains, profiles, and wireless policy associations for secure network connectivity.

Ethernet over GRE

Describes Ethernet over GRE aggregation solution for grouping Wi-Fi traffic from hotspots.

Ethernet over GRE (EoGRE) is an aggregation solution that

- groups Wi-Fi traffic from hotspots
- enables customer premises equipment (CPE) devices to bridge Ethernet traffic coming from an end-host and encapsulate the traffic in Ethernet packets over an IP Generic Routing Encapsulation (GRE) tunnel, and
- forwards end-host traffic and initiates subscriber sessions when IP GRE tunnels are terminated on a service provider's broadband network gateway.

Client IPv6 traffic

Client IPv6 traffic is supported on IPv4 EoGRE tunnels. A maximum of eight different client IPv6 addresses are supported per client. Wireless controllers send all the client IPv6 addresses that they have learned to the accounting server using the accounting update message. All RADIUS or accounting messages exchanged between controllers and tunnel gateways or RADIUS servers are outside the EoGRE tunnel.

To enable EoGRE for a WLAN, the wireless policy profile should be mapped to a tunnel profile, which may contain:

- AAA override: Allows you to bypass rule filtering for a client.
- Gateway RADIUS proxy: Allows forwarding of AAA requests to tunnel gateways.
- Tunnel rules: Defines the domain to use for each realm. They also define VLAN tagging for the client traffic towards tunnel gateways.
- DHCP option 82: Provides a set of predefined fields.

EoGRE deployment with multiple tunnel gateways

The wireless controller sends keepalive pings to the primary and secondary tunnel gateways and keeps track of the missed pings. When a certain threshold level is reached for the missed pings, switchover is performed and the secondary tunnel is marked as active. This switchover deauthenticates all the clients to enable them to rejoin the access points (APs). When the primary tunnel come back online, all the client traffic are reverted to the primary tunnel. However, this behavior depends on the type of redundancy.

Load balancing in EtherChannels

Load balancing of tunneled traffic over Etherchannels works by hashing the source or destination IP addresses or MAC addresses of the tunnel endpoint pair. Because the number of tunnels is very limited when compared to clients (each tunnel carries traffic for many clients), the spreading effect of hashing is highly reduced and optimal utilization of Etherchannel links can be hard to achieve.

Using the EoGRE configuration model, you can use the *tunnel source* option of each tunnel interface to adjust the load-balancing parameters and spread tunnels across multiple links.

You can use different source interfaces on each tunnel for load balancing based on the source or destination IP address. For that choose the source interface IP address in such a way that traffic flows take different links for each src-dest IP pair. This is an example with four ports:

```
Client traffic on Tunnel1 – Src IP: 40.143.0.72  Dest IP: 40.253.0.2
Client traffic on Tunnel2 – Src IP: 40.146.0.94  Dest IP: 40.253.0.6
Client traffic on Tunnel3 – Src IP: 40.147.0.74  Dest IP: 40.253.0.10
```

Use the **show platform software port-channel link-select interface port-channel 4 ipv4** *src_ip dest_ip* command to determine the link that a particular flow will take.

EoGRE configuration

Describes EoGRE configuration methods and deployment options.

EoGRE configuration is a network deployment approach that

- supports two different deployment modes: Central-Switching and Flex or Local-Switching
- uses tunnel gateways, tunnel domains, and tunnel profiles to manage client traffic, and
- enables secure tunneling through policy profiles mapped to WLANs using policy tags.

EoGRE deployment modes

The EoGRE solution can be deployed in two different ways:

- Central-Switching: EoGRE tunnels connect the controller to the tunnel gateways.
- Flex or Local-Switching: EoGRE tunnels are initiated on the APs and terminated on the tunnel gateways.

To configure EoGRE, perform these tasks:

1. Create a set of tunnel gateways.
2. Create a set of tunnel domains.
3. Create a tunnel profile with rules that define how to match clients to domains.
4. Create a policy profile and attach the tunnel profile to it.
5. Map the policy profile to WLANs using policy tags.

> **Note**
>
> The EoGRE tunnel fallback to the secondary tunnel is triggered after the *max-skip-count* ping fails in the last measurement window. Based on the starting and ending instance of the measurement window, the fall-back may take more time than the duration that is configured.

EoGRE supports multiple authentication methods:

Table 191: EoGRE authentication methods

Method Name	First Supported Release	Mode
PSK	17.2.1	Local/Flex (central authentication)
Open	16.12.1	Local/Flex (central authentication)
LWA	16.12.1	Local/Flex (central authentication)
Dot1x	16.12.1	Local/Flex (central authentication)
CWA	16.12.1	Local/Flex (central authentication)

Create a tunnel gateway (CLI)

Configure a tunnel gateway to establish network connectivity between remote sites.

Establish a tunnel gateway for secure communication between network segments.

In the controller, a tunnel gateway is modeled as a tunnel interface.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a tunnel interface and enter interface configuration mode.

   Example

   ```
   Device(config)# interface tunnel tunnel-number
   ```

   Example

   ```
   Device(config)# interface tunnel 21
   ```

3. Set the source address of the tunnel interface.

   Example

   ```
   Device(config-if)# tunnel source source-interface
   ```

   Example

   ```
   Device(config-if)# tunnel source 22
   ```

   The source interface can be VLAN, Gigabit Ethernet or loopback.

4. Set the destination address of the tunnel.

   Example

   ```
   Device(config-if)# tunnel destination tunnel-address
   ```

   Example

   ```
   Device(config-if)# tunnel destination 10.11.12.13
   ```

5. Set the encapsulation mode of the tunnel to Ethernet over GRE IPv4 or Ethernet over GRE IPv6.

   Example

   ```
   Device(config-if)# tunnel mode ethernet gre {ipv4 | ipv6} p2p
   ```

Example

```
Device(config-if)# tunnel mode ethernet gre ipv4 p2p
```

The tunnel gateway is configured and ready to establish secure connections between network segments.

Configure the tunnel gateway (GUI)

Configure the tunnel gateway using GUI.

Configure the tunnel gateway to establish network tunneling connections through the graphical user interface.

Use the GUI to set up tunnel gateway parameters including tunnel identification, destination addressing, source interface selection, and AAA proxy configuration when needed.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **EoGRE**.
2. Click the **Gateways** tab.

   The **Add Gateway** window is displayed.
3. In the **Tunnel ID** field, specify the tunnel ID.
4. In the **Destination address (IPv4/IPv6)** field, specify the IPv4 or IPv6 address.
5. From the **Source Interface** drop-down list, select an interface.
6. In the **AAA Proxy** section, slide the **AAA Proxy** slider to **Enabled**. When AA Proxy is enabled, complete these steps:
   a) From the **ENCRYPTION Type** drop-down list, select either **UNENCRYPTED** or **AES ENCRYPTION**.
   b) In the **Key Phrase** field, specify the key phrase.
7. Click **Apply to Device**.

The tunnel gateway is configured with the specified parameters and applied to the device.

Configure a tunnel domain (CLI)

Configure a tunnel domain.

This task creates a tunnel domain to group tunnels for redundancy purposes, ensuring High Availability by designating primary and secondary tunnels with specific failover behavior.

> **Note**
>
> Tunnel domains are a redundancy grouping of tunnels. This configuration procedure specifies a primary and a secondary tunnel, along with a redundancy model.

At any point of time, only one tunnel will be active per domain. The primary tunnel will be active when tunnel domain is setup. When the primary tunnel goes down (heartbeats are skipped), a switchover to the secondary tunnel is performed.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure EoGRE redundancy domain. **tunnel eogre domain** *domain*

   Example

   ```
   Device(config)# tunnel eogre domain domain
   ```

   ```
   Device(config)# tunnel eogre domain dom1
   ```

3. Configure the primary tunnel.

   Example

   ```
   Device(config-eogre-domain)# primary tunnel primary-tunnel_intf
   ```

   ```
   Device(config-eogre-domain)# primary tunnel 21
   ```

4. Configure the secondary tunnel.

   Example

   ```
   Device(config-eogre-domain)# secondary tunnel secondary-tunnel_intf
   ```

   ```
   Device(config-eogre-domain)# secondary tunnel 22
   ```

5. Set the redundancy model as revertive.

   Example

   ```
   Device(config-eogre-domain)# redundancy revertive
   ```

   When redundancy is set to revertive and the primary tunnel goes down, a switchover to secondary tunnel is performed. When the primary tunnel comes back up, a switchover to the primary tunnel is performed, because the primary tunnel has priority over the secondary tunnel.

   When redundancy is not set to revertive, tunnels will have the same priority, and a switchover to the primary tunnel is not performed if the active tunnel is the secondary tunnel and the primary tunnel comes back up.

The tunnel domain is configured with designated primary and secondary tunnels. The primary tunnel will be active initially, and automatic failover to the secondary tunnel will occur if the primary tunnel becomes unavailable. If revertive redundancy is configured, the system will switch back to the primary tunnel when it becomes available again.

Configure tunnel domain (GUI)

Configure tunnel domain using GUI.

Configure the tunnel domain to establish EoGRE connectivity with primary and secondary tunnel gateways.

Use this procedure to set up tunnel domains through the graphical user interface, including gateway selection and redundancy options.

Follow these steps to configure the tunnel domain:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **EoGRE**.
2. Click the **Domains** tab.

   The **Add Domain** window is displayed.
3. In the **Name** field, specify the domain name.

   The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
4. From the **Primary Tunnel Gateway** drop-down list, choose an option.
5. From the **Secondary Tunnel Gateway** drop-down list, choose an option.
6. Slide the **Status** button to **Enabled**, to activate the domain status.
7. Slide the **Revertive Redundancy** button to **Enabled**, to activate revertive redundancy.
8. Click **Apply to Device**.

The tunnel domain is configured with the specified settings and applied to the device.

Configure EoGRE global parameters CLI)

Configure EoGRE global parameters to establish tunnel communication settings and AAA proxy configuration.

Establish EoGRE tunnel parameters including heartbeat intervals, skip counts, source interfaces, and AAA proxy keys for proper tunnel operation.

EoGRE (Ethernet over Generic Routing Encapsulation) global parameters control tunnel behavior across the network. These settings ensure reliable tunnel communication and proper failover handling.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Set EoGRE tunnel heartbeat periodic interval.

   Example

   ```
   Device(config)# tunnel eogre heartbeat interval interval-value
   ```

   Example

   ```
   Device(config)# tunnel eogre heartbeat interval 600
   ```

3. Set the maximum number of tolerable dropped heartbeats.

   Example

   ```
   Device(config)# tunnel eogre heartbeat max-skip-count skip-count
   ```

   Example

   ```
   Device(config)# tunnel eogre heartbeat max-skip-count 7
   ```

   After reaching the maximum number of heartbeats that can be dropped, the tunnel is declared as down and a switchover is performed.

4. Set the tunnel EoGRE source interface.

   Example

   ```
   Device(config)# tunnel eogre source loopback tunnel-source
   ```

   Example

   ```
   Device(config)# tunnel eogre source loopback 12
   ```

5. Optional: Configure AAA proxy RADIUS key for the AAA proxy setup.

   Example

   ```
   Device(config)# tunnel eogre interface tunnel tunnel-intf aaa proxy key key
   key-name
   ```

   Example

   ```
   Device(config)# tunnel eogre interface tunnel 21 aaa proxy key 0 mykey
   ```

   Note

   When the tunnel gateway is behaving as the AAA proxy server, only this step is required for the configuration.

EoGRE global parameters are configured with the specified heartbeat interval, maximum skip count, source interface, and optional AAA proxy key settings.

Configure EoGRE global parameters (GUI)

Configure EoGRE global parameters using GUI.

The EoGRE global parameters define the network-wide settings for Ethernet over Generic Routing Encapsulation tunnels, including heartbeat intervals and interface assignments.

Use this task to establish the fundamental EoGRE configuration parameters that will apply across your network infrastructure.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **EoGRE**.

   The EoGRE **Global Config** tab is displayed.
2. In the **Heartbeat Interval (seconds)** field, specify an appropriate timer value for heartbeat interval. The valid range is from 60 to 600 seconds.
3. In the **Max Heartbeat Skip Count** field, specify the maximum heartbeat skip count. The valid range is from 3 to 10.
4. From the **Interface Name** drop-down list, choose an interface name.
5. Click **Apply**.

The EoGRE global parameters are configured and applied to your network infrastructure.

Configure a tunnel profile (CLI)

Configure a tunnel profile using commands.

Create and configure a tunnel profile to manage client traffic routing and authentication through tunneled connections.

Tunnel profiles define how client traffic is handled when using tunneled connections, including DHCP options, AAA overrides, and RADIUS proxy settings. This configuration is essential for managing client authentication and traffic routing in wireless environments.

Before you begin

Ensure that you define the destination VLAN on the controller. If you do not define the VLAN, clients will not be able to connect.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Configure a WLAN policy profile.

   Example

   ```
   Device(config)# wireless profile policy profile-policy-name
   ```

   Example

   ```
   Device(config)# wireless profile policy eogre_policy
   ```
3. Create a tunnel profile.

   Example

   ```
   Device(config-wireless-policy)# tunnel-profile tunnel-profile-name
   ```

Example

```
Device(config-wireless-policy)# tunnel-profile tunnel1
```

4. Return to global configuration mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

5. Configure a wireless tunnel profile.

   Example

   ```
   Device(config)# wireless profile tunnel tunnel-profile-name
   ```

   Example

   ```
   Device(config)# wireless profile tunnel wl-tunnel-1
   ```

6. Activate DHCP Option 82 for the tunneled clients.

   Example

   ```
   Device(config-tunnel-profile)# dhcp-opt82 enable
   ```

7. Configure Remote ID options.

   Example

   ```
   Device(config-tunnel-profile)# dhcp-opt82 remote-id remote-id
   ```

   Example

   ```
   Device(config-tunnel-profile)# dhcp-opt82 remote-id vlan
   ```

   Choose from the comma-separated list of options such as **ap-mac**, **ap-ethmac**, **ap-name**, **ap-group-name**, **flex-group-name**, **ap-location**, **VLAN**, **ssid-name**, **ssid-type**, and **client-mac**.

8. Enable AAA policy override.

   Example

   ```
   Device(config-tunnel-profile)# aaa-override
   ```

9. Enable the gateway RADIUS proxy.

   Example

   ```
   Device(config-tunnel-profile)# gateway-radius-proxy
   ```

10. Enable the gateway accounting RADIUS proxy.

Example

```
Device(config-tunnel-profile)# gateway-accounting-radius-proxy
```

11. Create a rule to choose a domain, using the realm filter, for client Network Access Identifier (NAI), tunneling domain name, and destination VLAN.

Example

```
Device(config-tunnel-profile)# rule priority realm-filter realm domain
domain-name vlan vlan-id
```

Example

```
Device(config-tunnel-profile)# rule 12 realm-filter realm domain dom1 vlan 5
```

The tunnel profile is now configured with the specified settings for DHCP options, AAA overrides, RADIUS proxy, and filtering rules, enabling proper client traffic management through tunneled connections.

Configure the tunnel profile (GUI)

Configure a tunnel profile using GUI.

Configure a tunnel profile to define the parameters and settings for establishing tunnel connections in the EoGRE environment.

Use this procedure to create and configure tunnel profiles that manage tunnel connections and their associated settings through the graphical user interface.

Follow these steps to configure the tunnel profile:

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **EoGRE**.
2. Click the **Tunnel Profiles** tab.
3. Click the **Add** button.

   The **Add Tunnel Profile** window is displayed.

4. Click the **General** tab and complete these steps:
   a) In the **Name** field, specify the tunnel profile name. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
   b) In the **Status** field, slide the button to change the status to **Enabled**.
   c) In the **Central Forwarding** field, slide the button to **Enabled**, to enable the feature.
   d) In the **DHCP Option-82** section, change the **Status** field and the **ASCII** field to **Enabled**, as per requirement.
   e) In the **Delimiter** field, specify the delimiter.
   f) From the **Circuit ID Available Services** list, select an available services and click the > sign to add the services to the assigned list.
   g) From the **Remote ID Available Services** list, select an available services and click the > sign to add the services to the assigned list.
   h) In the **AAA** section, choose an appropriate status for the **Radius Proxy** field, the **Accounting Proxy** field, and the **Override** field.

5. Click the **Rules** tab, and complete these steps:
   a) Click the **Add Rules** button.
   b) In the **Priority** field, specify the priority of the rule from a range of 1 to 100.
   c) In the **Realm** field, specify a realm.
   d) From the **Domain** drop-down list, choose a domain.
   e) In the **VLAN ID** field, specify the VLAN ID that ranges from 1 to 4094.
   f) Click **Save**.
6. Click **Apply to Device**.

The tunnel profile is successfully configured and applied to the device with the specified settings for tunnel connections.

Associate WLAN to a wireless policy profile (CLI)

Configure the association of a WLAN to a wireless policy profile.

Associate a WLAN with a wireless policy profile to apply specific policies and configurations to wireless network traffic.

When managing wireless networks, you need to associate WLANs with policy profiles to ensure proper traffic handling and security configurations are applied to wireless clients.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a policy tag and enter policy tag configuration mode.

   Example

   ```
   Device(config)# wireless tag policy policy-tag-name
   ```

   Example

   ```
   Device(config)# wireless tag policy eogre_tag
   ```

3. Map an EoGRE policy profile to a WLAN profile.

   Example

   ```
   Device(config-policy-tag)# wlan wlan-name policy profile-policy-name
   ```

   Example

   ```
   Device(config-policy-tag)# wlan eogre_open_eogre policy eogre_policy
   ```

4. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

Example

```
Device(config-policy-tag)# end
```

The WLAN is now associated with the specified wireless policy profile, and the configured policies will be applied to wireless traffic on that WLAN.

Attach a policy tag and a site tag to an AP

Configure an access point with policy and site tags to define its network behavior and location-based settings.

Associate policy and site tags with an AP to apply specific network policies and location-based configurations.

Policy tags define network behaviors and WLAN mappings for APs, while site tags specify location-based settings like DNS servers and local switching parameters. Both tags must be attached to APs to ensure proper network operation.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap mac-address
   ```

   Example

   ```
   Device(config)# ap 80E8.6FD4.0BB0
   ```

3. Map the policy tag to the AP.

   Example

   ```
   Device(config-ap-tag)# policy-tag policy-tag-name
   ```

   Example

   ```
   Device(config-ap-tag)# policy-tag eogre_tag
   ```

4. Map a site tag to the AP.

   Example

   ```
   Device(config-ap-tag)# site-tag site-tag-name
   ```

Example

```
Device(config-ap-tag)# site-tag sp-flex-site
```

5. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

Example

```
Device(config-ap-tag)# end
```

The AP is now configured with the specified policy tag and site tag, enabling it to apply the associated network policies and location-based settings.

Verify EoGRE tunnel configuration

Verify the EoGRE tunnel configuration.

The `show tunnel eogre` command displays the EoGRE clients, domains, gateways, global-configuration, and manager information in the local mode.

To display the EoGRE domain summary in the local mode, use this command:

```
Device# show tunnel eogre domain summary
Domain Name          Primary GW   Secondary GW      Active GW      Redundancy
-------------------------------------------------------------------------------
domain1             Tunnel1      Tunnel2           Tunnel1        Non-Revertive
eogre_domain        Tunnel1      Tunnel2           Tunnel1        Non-Revertive
```

To display the details of an EoGRE domain in the local mode, use this command:

```
Device# show tunnel eogre domain detailed domain-name
 Domain Name    : eogre_domain
 Primary GW     : Tunnel1
 Secondary GW   : Tunnel2
 Active GW      : Tunnel1

The `show ap tunnel eogre` command displays the tunnel domain information, EoGRE events, and the tunnel gateway status on the APs, in the flex mode.

To view the summary information of an EoGRE tunnel gateway in the flex mode, use this command:

```
Device# show ap tunnel eogre domain summary
AP MAC          Domain                              Active Gateway
-------------------------------------------------------------------------------
80e8.6fd4.9520  eogre_domain                        Tunnel1
```

To view the wireless tunnel profile summary, use this command:

```
Device# show wireless profile tunnel summary
Profile Name                     AAA-Override AAA-Proxy DHCP Opt82 Enabled
-------------------------------- ------------ --------- ---------- --------
eogre_tunnel                               No        No        Yes      Yes
eogre_tunnel_set                           No        No        Yes       No
eogre_tunnel_snmp                          No        No         No       No
```

To view a wireless tunnel profile's details, use this command:

```
Device# show wireless profile tunnel detailed profile-name
Profile Name : eogre_tunnel
Status : Enabled
 AAA-Proxy/Accounting-Proxy: Disabled / Disabled
 AAA-Override : Disabled
 DHCP Option82 : Enabled
  Circuit-ID : ap-mac,ap-ethmac,ap-location,vlan
  Remote-ID : ssid-name,ssid-type,client-mac,ap-name
Tunnel Rules
Priority Realm                Vlan Domain (Status/Primary GW/Secondary GW)
-------- -------------------- ---- ---------------------------------------------
1        *                    2121 eogre_domain (Enabled/Tunnel1/Tunnel2)
```

To view detailed information about an EoGRE tunnel domain's status, use this command:

```
Device# show ap tunnel eogre domain detailed
Domain     : eogre_domain
AP MAC     : 80e8.6fd4.9520
Active GW  : Tunnel1
```

To view the EoGRE events on an AP, use this command:

```
Device# show ap tunnel eogre events
AP 80e8.6fd4.9520  Event history
Timestamp               #Times   Event                RC Context
----------------------- -------- -------------------- --
----------------------------------------
02/18/2019 23:50:26.341 6        IAPP_STATS            0 GW Tunnel2 uptime:0s

```

To view detailed information about an EoGRE tunnel gateway's status on an AP, use this command:

```
Device# show ap name ap-name tunnel eogre gateway detailed gateway-name
Gateway : Tunnel2
 Mode   : IPv4
 IP     : 9.51.1.12
 State  : Down
 MTU    : 0
 AP MAC : 80e8.6fd4.9520
 Clients
  Total Number of Wireless Clients      : 0
 Traffic
  Total Number of Received Packets      : 0
  Total Number of Received Bytes        : 0
  Total Number of Transmitted Packets   : 0
  Total Number of Transmitted Bytes     : 0
  Total Number of Lost Keepalive        : 151
```

218 Wireless Guest Access

Topics:

- Wireless guest access
- Configure guest access using different security methods

Guides the configuration and management of wireless guest access, including mobility tunnels, load balancing, and guest anchor setups for secure visitor connectivity.

Wireless guest access

Explains the Wireless Guest Access feature that provides internet access to guests in a secure and accountable manner.

Wireless guest access is a network security feature that

- provides internet access to guests in a secure and accountable manner
- uses the enterprise's existing wireless and wired infrastructure to the maximum extent, and
- reduces the cost and complexity of building a physical overlay network.

Wireless guest access architecture and components

The Wireless Guest Access solution comprises of two controllers - a Guest Foreign and a Guest Anchor. An administrator can limit bandwidth and shape the guest traffic to avoid impacting the performance of the internal network.

Note

- When a client joins through a capwap tunnel from an AP, the RADIUS NAS-Port-Type is set as "wireless 802.11". Here, Point of Attachment (PoA) and Point of Presence (PoP) is the same.
- When a client joins through a mobility tunnel, the RADIUS NAS-Port-Type is set as "virtual". Here, PoA is the Foreign controller and PoP is the Anchor controller as the client is anchored. For information on the standard types, see the following link:

  https://www.iana.org/assignments/radius-types/radius-types.xhtml#radius-types-13

Wireless Guest Access feature comprises these functions:

- Guest Anchor controller is the point of presence for a client.
- Guest Anchor Controller provides internal security by forwarding the traffic from a guest client to a Cisco Wireless Controller in the demilitarized zone (DMZ) network through the anchor controller.
- Guest Foreign controller is the point of attachment of the client.
- Guest Foreign Controller is a dedicated guest WLAN or SSID and is implemented throughout the campus wireless network wherever guest access is required. A WLAN with mobility anchor (guest controller) configured on it identifies the guest WLAN.
- Guest traffic segregation implements Layer 2 or Layer 3 techniques across the campus network to restrict the locations where guests are allowed.
- Guest user-level QoS is used for rate limiting and shaping, although it is widely implemented to restrict the bandwidth usage for a guest user.
- Access control involves using embedded access control functionality within the campus network, or implementing an external platform to control guest access to the Internet from the enterprise network.
- Authentication and authorization of guests that are based on variables, including date, duration, and bandwidth.
- An audit mechanism to track who is currently using, or has used, the network.
- A wider coverage is provided by including areas such as lobbies and other common areas that are otherwise not wired for network connectivity.
- The need for designated guest access areas or rooms is removed.

> **Note**
>
> To use IRCM with AireOS in your network, contact Cisco TAC for assistance.

This table shows controller support for guest access functions.

Table 192: Supported controllers

Controller Name	Supported as Guest Anchor	Supported as Guest Foreign
Cisco Catalyst 9800-40 Wireless Controller	Yes	Yes
Cisco Catalyst 9800-80 Wireless Controller	Yes	Yes
Cisco Catalyst 9800-CL Wireless Controller	Yes	Yes
Cisco Catalyst 9800-L Wireless Controller	Yes	Yes
Cisco Catalyst 9800 Embedded Wireless Controller for Switch	No	No
Cisco Catalyst 9800 Embedded Wireless Controller on Cisco Catalyst 9100 Series APs	No	No

This is a list of features supported by Cisco Guest Access:

- Sleeping Clients
- FQDN
- AVC (AP upstream and downstream)
- Native Profiling
- Open Authentication
- OpenDNS
- Supported Security Methods:
  - MAB Central Web Authentication (CWA)
  - Local Web Authentication (LWA)
  - LWA on MAB Failure
  - 802.1x + CWA
  - 802.1x
  - PSK
  - 802.1x + LWA
  - PSK + CWA

- PSK + LWA
- iPSK + CWA
- MAB Failure + PSK
- MAB Failure + OWE
- MAB Failure + SAE

- SSID QoS Upstream and Downstream (Foreign)
- AP/ Client SSO
- Static IP Roaming
- Client IPv6
- Roaming across controllers
- RADIUS Accounting

> **Note**
>
> In a guest access scenario, accounting is always performed at the foreign controller for all authentication methods.

- QoS: Client-Level Rate Limiting
- Guest Anchor Load Balancing
- Workgroup Bridges (WGB)

> **Note**
>
> To enable the controller to support multiple VLANs from a WGB, use **wgb vlan** command.

Foreign map

Explains the foreign map feature that supports guest access using policy profile and WLAN profile configuration models.

A foreign map is a guest access feature that

- supports guest access using Policy Profile and WLAN Profile configuration models in the controller
- is achieved with policy profile and WLAN profile config model, and
- configures two different WLAN profiles on two Guest Foreigns where seamless roaming is not allowed between them.

Foreign map configuration

Foreign Map support in Cisco Catalyst 9800 Series Wireless Controller is achieved with the policy profile and WLAN profile configuration model.

Foreign map commands

- Guest Foreign commands:
  - **Foreign1: wlanProf1 PolicyProf1**

- **Foreign2: wlanProf2 PolicyProf2**

- Guest Anchor commands:
  - **wlanProf1, wlanProf2**
  - **PolicyProf1: Vlan100 - subnet1**
  - **PolicyProf2: Vlan200 - subnet2**

Foreign map roaming

Configure two different WLAN profiles on the two Guest Foreigns and seamless roaming is not allowed between them. This is expected configuration. However, seamless roaming is allowed if the same WLAN profile is configured on two Guest Foreigns, but it prevents Foreign Map feature from working.

Wireless Guest Access: Use Cases

The wireless guest access feature can be used to meet different requirements. Some of the possibilities are shared here.

Scenario One: Providing Secured Network Access During Company Merger

This feature can be configured to provide employees of **company A** who are visiting **company B** to access company A resources on company B network securely.

Scenario Two: Shared Services over Existing Setup

Using this feature, you can provide multiple services using multiple vendors piggy backing on the existing network. A company can provide services on an SSID which is anchored on the existing controller. This is while the existing service continues to serve over the same controller and network.

Guidelines for wireless guest access

Outlines guidelines and limitations for wireless guest access.

Match the security profiles under WLAN on both Guest Foreign, and Guest Anchor.

- Match the policy profile attributes such as NAC and AAA Override on both Guest Foreign, and Guest Anchor controllers.
- On Export Anchor, the WLAN profile name and Policy profile name is chosen when a client joins at runtime and the same should match with the Guest Foreign controller.

Recommendation: troubleshooting IPv6

Consider these workarounds when a guest export client cannot get a routable IPv6 address through SLAAC or cannot pass traffic when the IPv6 address is learned through DHCPv6.

When a guest export client cannot get a routable IPv6 address through SLAAC or cannot pass traffic when the IPv6 address is learned through DHCPv6, you can use these workarounds:

- On IPv6 Routers: You can work around the RA multicast to unicast conversion by modifying behavior on the IPv6 gateway. Depending on the product, this may be the default behavior or may require configuration.
- On Cisco IPv6 Routers: Configure unicast RA depending on your platform.
- On non-Cisco IPv6 Routers: If non-Cisco network devices do not support configuration command to enable solicited unicast RA then a work around does not exist.

For Cisco IPv6 Routers:

- Cisco Nexus platform: Has solicited unicast RA enabled by default to help with wireless deployment.
- Cisco IOS-XE platform: Use the following configuration command to turn on unicast RA to help with wireless deployment:

  ipv6 nd ra solicited unicast

Load balancing among multiple guest controllers

Describes load balancing among multiple guest controllers.

Load balancing among multiple guest controllers is a network configuration feature that

- distributes large guest client volumes across up to 72 controllers for a single export foreign guest WLAN configuration
- supports priority-based anchor configuration with primary anchors (priority 1,3) and backup anchors for failure scenarios, and
- automatically handles failover by disconnecting clients from failed primary anchors and redirecting them to secondary anchors.

Configuration and failover behavior

To configure mobility guest controllers, use **mobility anchor** *ip address*.

You can specify primary anchors with priority (1,3) and choose another anchor as backup in case of failure.

In a multi-anchor scenario, when the primary anchor goes down, the clients get disconnected from the primary anchor and joins the secondary anchor.

When the highest priority anchor goes down before the keep-alive timeout completes, the export anchor request for new clients fails, and Foreign selects the next highest priority Anchor in the list to export the clients.

Configure mobility tunnel for guest access (GUI)

Configure mobility tunnel for guest access using GUI.

Enable secure guest network access by establishing a mobility tunnel that allows traffic to traverse between network segments while maintaining security policies.

Use this procedure when setting up guest network access that requires mobility tunneling to route guest traffic through designated mobility anchors in your wireless infrastructure.

Procedure

1. Choose **Configure** > **Tags and Profiles** > **WLANs**.
2. In the **Wireless Networks** area, click the relevant WLAN or RLAN and click **Mobility Anchor**.
3. In the **Wireless Network Details** section, choose a device from the **Switch IP Address** drop-down list.
4. Click **Apply**.

The mobility tunnel for guest access is configured and the selected switch is designated as the mobility anchor for the wireless network.

Configure mobility tunnel for guest access (CLI)

Configure mobility tunnel for guest access using commands.

Configure a mobility tunnel to enable guest access across mobility groups.

Follow the procedure given below to configure a mobility tunnel. This allows guest clients to roam between access points in different mobility groups while maintaining their network session.

Procedure

1. Configure a mobility group.

   Example

   ```
   Device(config)# wireless mobility group name group-name
   ```

   Example

   ```
   Device(config)# wireless mobility group name mtunnelgrp
   ```

2. Configure a mobility MAC address.

   Example

   ```
   Device(config)# wireless mobility mac-address mac-address
   ```

   Example

   ```
   Device(config)# wireless mobility mac-address 0d:4c:da:3a:f2:21
   ```

3. Configure a mobility peer.

   Example

   ```
   Device(config)# wireless mobility group member mac-address mac-address ip
   ip-address group group-name
   ```

   Example

   ```
   Device(config)# wireless mobility group member mac-address df:07:a1:a7:a8:55
    ip 206.223.123.2 group mtgrp
   ```

The mobility tunnel is now configured, allowing guest clients to seamlessly roam between controllers in the mobility group.

Configure guest access policy (GUI)

Configure guest access policy using GUI.

Configure guest access policies to manage how guest users connect to and use your wireless network.

Guest access policies define the network access parameters and security settings for temporary users who need network connectivity without full user credentials.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.

2. Click **Add**.
3. In the **General** tab, enter the **Name** and enable the **Central Switching** toggle button.
4. In the **Access Policies** tab, under the **VLAN** settings, choose the vlans from the **VLAN/VLAN Group** drop-down list.
5. In the **Mobility** tab, under the **Mobility Anchors** settings, check the **Export Anchor** check box.
6. In the **Advanced** tab, under the **WLAN Timeout** settings, enter the **Idle Timeout (sec)**.
7. Click **Apply to Device**.

The guest access policy is configured and applied to the device, allowing guest users to access the network according to the defined parameters.

Configure guest access policy (CLI)

Configure guest access policy using commands.

Create and configure a guest access profile policy to enable guest networking on wireless clients.

Follow the procedure given below to create and configure the guest access profile policy. Alternately, you may use the existing default policy profile after configuring the mobility anchor to that policy.

You can only configure anchors which are peers. Ensure that the IP address that is used is a mobility peer and is included in the mobility group. The system shows an invalid anchor IP address error message when any other IP address is used.

To delete the mobility group, ensure that the mobility peer which is also a mobility anchor is removed from the policy profile.

Note

- No payload is sent to Guest Foreign to display the VLAN.
- To avoid a client exclusion from occurring due to VLAN, Cisco Catalyst 9800 Series Controllers need to define VLAN along with the associated name being pushed from ISE.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the policy profile and enter wireless profile configuration mode.

   Example

   ```
   Device(config)# wireless profile policy wlan-policy-profile
   ```

   Example

   ```
   Device(config)# wireless profile policy guest-test-policy
   ```

> **Note**
>
> - You can use the **default-policy-profile** to configure the profile policy.

3. Shut down the policy if it exists before configuring the anchor.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

4. Optional: Enable central switching.

   Example

   ```
   Device(config-wireless-policy)# central switching
   ```

5. Configure Guest Foreign or Guest Anchor.
   - Configure Guest Foreign with anchor IP address
   - Configure Guest Anchor

   Example

   For Guest Foreign:

   ```
   Device(config-wireless-policy)# mobility anchor anchor-ip-address
   ```

   For Guest Anchor:

   ```
   Device(config-wireless-policy)# mobility anchor
   ```

   Example

   For Guest Foreign:

   ```
   Device(config-wireless-policy)# mobility anchor 19.0.2.1
   ```

   For Guest Anchor:

   ```
   Device(config-wireless-policy)# mobility anchor
   ```

6. Optional: Configure duration of idle timeout, in seconds.

   Example

   ```
   Device (config-wireless-policy)# idle-timeout timeout
   ```

   Example

   ```
   Device (config-wireless-policy)# idle-timeout 1000
   ```

7. Configure VLAN name or VLAN ID.

   Example

   ```
   Device(config-wireless-policy)# vlan vlan-id
   ```

   Example

   ```
   Device(config-wireless-policy)# vlan 2
   ```

   > **Note**
   >
   > VLAN is optional for a Guest Foreign controller.

8. Enable policy profile.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

9. Exit the configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

10. Optional: Display the configured profiles.

    Example

    ```
    Device# show wireless profile policy summary
    ```

11. Optional: Display detailed information of a policy profile.

    Example

    ```
    Device# show wireless profile policy detailed policy-profile-name
    ```

    Example

    ```
    Device# show wireless profile policy detailed guest-test-policy
    ```

The guest access policy is configured and enabled, allowing guest clients to connect using the specified mobility anchor and VLAN settings.

View guest access debug information (CLI)

Lists commands to view guest access debug information.

View guest access debug information using commands.

- To display client level detailed information about mobility state and the anchor IP address, use this command:

  show wireless client mac-add *mac-address* **detail**

- To display the client mobility statistics, use this command:

  show wireless client mac-address *mac-address* **mobility statistics**

- To display client level roam history for an active client in sub-domain, use this command:

  show wireless client mac-address *mac-address* **mobility history**

- To display detailed parameters of a given profile policy, use this command:

  show wireless profile policy detailed *policy-name*

- To display the global level summary for all mobility messages, use this command:

  show wireless mobility summary

- To display the statistics for the Mobility manager, use this command:

  show wireless stats mobility

Verify wireless guest access enablement

Provides verification that wireless guest access is enabled.

To check if wireless guest access is enabled, run this command.

```
Device# show platform hardware chassis  active  qfp feature sw client vlan all

------------------------------------------------------------
Vlan : 666
Learning Enabled : true
DHCPSN Enabled : true
Non IP Multicast Enabled : false
Broadcast Enabled : false
Wireless Passive Client Enabled : false
Guest-Lan Enabled : true
MTU : 65535
Input UIDB : 65503
Output UIDB : 65497
Flood List : 0XB8658A0
```

Configure guest access using different security methods

Describes how to configure guest access using various security methods and provides detailed information about different configuration options and implementation approaches.

These sections provide information about:

Open authentication

Describes how to configure guest access using open authentication by setting up the WLAN profile, with no tag requirements unless Application Visibility and Control (AVC) is enabled.

To configure the guest access with open authentication, follow the steps:

1. Configure the WLAN Profile

2. Configure access policy profile

> **Note**
>
> No tag is required unless AVC is enabled.

Configure a WLAN profile for guest access with open authentication (GUI)

Configure a WLAN profile that enables guest access using open authentication through the graphical user interface.

Create a WLAN profile that allows guest users to connect to the wireless network without requiring authentication credentials, providing open access for temporary or visitor use.

Guest access with open authentication is commonly used in public areas, visitor networks, or temporary access scenarios where security requirements are minimal and ease of access is prioritized.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID** and the **WLAN ID**. Choose the radio policy from the **Radio Policy** drop-down list. Enable or disable the **Status** and **Broadcast SSID** toggle buttons.
4. Choose **Security** > **Layer2** tab. Uncheck the **WPA Policy**, **WPA2 Policy**, **AES** and **802.1x** check boxes.
5. Click **Apply to Device**.

The WLAN profile is created and configured for guest access with open authentication. Guest users can now connect to the wireless network without providing authentication credentials.

Configure a WLAN profile for guest access with open authentication (CLI)

Configure a WLAN profile with open authentication to provide unrestricted network access for guest users.

Establish a guest access WLAN that allows users to connect without authentication credentials.

Open authentication WLANs are commonly used for guest networks where ease of access is prioritized over security. This configuration removes all security barriers, making it suitable for public or temporary access scenarios.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN and SSID.

   Example

   ```
   Device(config)# wlan profile-name wlan-id ssid-name
   ```

Example

```
Device(config)# wlan mywlan 34 mywlan-ssid
```

3. Disable WPA security.

Example

```
Device(config-wlan)# no security wpa
```

4. Disable security AKM for dot1x.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

5. Disable WPA2 security.

Example

```
Device(config-wlan)# no security wpa wpa2
```

6. Disable WPA2 ciphers for AES.

Example

```
Device(config-wlan)# no security wpa wpa2 ciphers aes
```

7. Save the configuration.

Example

```
Device(config-wlan)# no shutdown
```

The WLAN profile is now configured with open authentication, allowing guest users to connect without any security credentials.

Configure a policy profile (CLI)

Configure a WLAN policy profile to define network connectivity and mobility settings for wireless clients.

Create a policy profile that establishes WLAN connectivity rules and mobility configurations for wireless network access.

Policy profiles define how wireless clients connect to and interact with the network, including VLAN assignments, mobility settings, and switching behavior. Configure these profiles to control client access and network segmentation.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy wlan-policy-profile
```

Example

```
Device(config)# wireless profile policy open_it
```

3. Configure Guest Foreign or Guest Anchor. Choose the first option to configure a Guest Foreign or second option to configure a Guest Anchor:
   - **mobility anchor** *anchor-ip-address*
   - **mobility anchor**

Example

For Guest Foreign:

```
Device (config-wireless-policy)# mobility anchor anchor-ip-address
```

For Guest Anchor:

```
Device (config-wireless-policy)# mobility anchor
```

Example

For Guest Foreign:

```
Device (config-wireless-policy)# mobility anchor 19.0.2.1
```

For Guest Anchor:

```
Device (config-wireless-policy)# mobility anchor
```

4. Enable Central switching.

Example

```
Device(config-wireless-policy)# central switching
```

5. Configure a VLAN name or VLAN ID.

Example

```
Device(config-wireless-policy)# vlan id
```

Example

```
Device(config-wireless-policy)# vlan 16
```

> **Note**
>
> VLAN is optional for a Guest Foreign controller.

6. Enable the policy profile.

Example

```
Device(config-wireless-policy)# no shutdown
```

The policy profile is now configured and enabled, ready to be applied to WLAN configurations for wireless client connectivity.

Local web authentication

Describes the configuration steps for Local Web Authentication (LWA), including setting up parameter maps, WLAN profiles, policy profiles, and AAA servers to enable web-based authentication for wireless clients.

To configure LWA, follow these steps:

1. Configure the Parameter Map.
2. Configure the WLAN Profile.
3. Applying Policy Profile on a WLAN
4. Configure the AAA Server.

Configure a parameter map (GUI)

Configure a parameter map for web authentication through the graphical user interface.

Configure a parameter map to define web authentication settings including connection limits and timeout values.

Parameter maps are used to configure web authentication parameters that control how users authenticate through the web interface. This configuration is performed through the device's graphical user interface.

Procedure

---

1. Choose **Configuration** > **Security** > **Web Auth**.
2. Click **Add**.
3. Enter the **Parameter-map name**, **Maximum HTTP connections**,**Init-State Timeout(secs)** and choose **webauth** in the **Type** drop-down list.
4. Click **Apply to Device**.

The parameter map is configured and applied to the device with the specified web authentication settings.

Configure a parameter map (CLI)

Configure a parameter map to define web authentication settings and timeout parameters for client authentication.

Define web authentication parameters and timeout settings to control client authentication behavior.

Parameter maps are used to configure global web authentication settings that control how clients authenticate and how long they remain in various authentication states.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a parameter map and enter parameter-map WEBAUTH configuration mode.

   Example

   ```
   Device(config)# parameter-map type webauth global
   ```

3. Configure the WEBAUTH type parameter.

   Example

   ```
   Device(config-params-parameter-map)# type webauth
   ```

4. Configure the WEBAUTH timeout in seconds.

   Example

   ```
   Device(config-params-parameter-map)# timeout init-state sec timeout-seconds
   ```

   Example

   ```
   Device(config-params-parameter-map)# timeout init-state sec 3600
   ```

   Valid range for time is from 60 to 3932100 seconds.

5. Configure a virtual IP address.

   Example

   ```
   Device(config-params-parameter-map)# virtual-ip ipv4 virtual-IP-address
   ```

   Example

   ```
   Device(config-params-parameter-map)# virtual-ip ipv4 209.165.201.1
   ```

The parameter map is configured with web authentication settings, timeout values, and virtual IP address for client authentication.

Configure a WLAN profile for guest access with local web authentication (GUI)

Configure a WLAN profile to enable guest access using local web authentication through the GUI interface.

Configure a WLAN profile to enable guest access with local web authentication, allowing temporary network access for visitors while maintaining security controls.

Use this procedure when you need to provide internet access to guests through a web-based authentication portal. This configuration enables controlled access for users who do not have permanent network credentials.

Follow these steps to configure a WLAN profile for guest access with local web authentication:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click on the **WLAN** name.
3. Choose **Security** > **Layer3**.
4. Check the **Web Policy** check box.
5. Choose a parameter map from the **Web Auth Parameter Map** drop-down list.
6. Choose an authentication list from the **Authentication List** drop-down list.
7. Click **Update & Apply to Device**.

The WLAN profile is configured with local web authentication for guest access. Guest users connecting to this WLAN will be redirected to a web authentication portal where they can obtain network access.

Configure a WLAN profile for guest access with local web AUTHENTICATION (CLI)

Configure local web AUTHENTICATION for a WLAN profile to enable guest access through the command-line interface.

This task configures a WLAN profile with local web AUTHENTICATION to provide secure guest access to the wireless network.

Local web AUTHENTICATION allows guest users to access the network through a web-based AUTHENTICATION portal. This configuration is typically used in guest access scenarios where users need to authenticate via a web interface before gaining network access.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN and SSID.

   Example

   ```
   Device# Device(config)# wlan mywlan 38 mywlan-ssid1
   ```

3. Enable web authentication for a WLAN.

Example

```
Device(config-wlan)# security web-auth
```

4. Configure the default parameter map.

Example

```
Device(config-wlan)# security web-auth parameter-map default
```

> **Note**
>
> When **security web-auth** is enabled, you get to map the **default authentication-list** and global **parameter-map**. This is applicable for authentication-list and parameter-map that are not explicitly mentioned.

5. Configure the global parameter map.

Example

```
Device(config-wlan)# security web-auth parameter-map global
```

6. Set the authentication list for IEEE 802.1x.

Example

```
Device(config-wlan)# security web-auth authentication-list lwa-authentication
```

The WLAN profile is configured with local web AUTHENTICATION for guest access. Guest users will now be prompted to authenticate through a web interface when connecting to the wireless network.

Configure an AAA server for local web authentication (GUI)

Configure AAA server settings for local web authentication through the GUI interface.

This task allows you to set up AAA server configuration for local web authentication using the graphical user interface.

Use this procedure when you need to configure authentication and authorization settings for local web authentication through the device's web interface.

Procedure

---

1. Choose **Configuration** > **Security** > **AAA** > **AAA Advanced** > **Global Config**.
2. Choose the options from the **Local Authentication**, **Authentication Method List**, **Local Authorization** and **Authorization Method List** drop-down lists.
3. Enable or Disable the **Radius Server Load Balance** using toggle button.
4. Check the **Interim Update** check box.
5. Click **Apply**.

The AAA server configuration for local web authentication is now configured with your selected settings.

Configure an AAA server for local web authentication (CLI)

Configure an AAA server for local web authentication using CLI commands.

Configure Authentication, Authorization, and Accounting (AAA) server settings to enable local web authentication on the device.

Use this procedure when you need to set up local authentication and authorization for web-based user access on your device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. **aaa authentication login** *lwa-authentication* **local**

   Example

   ```
   Device(config)#aaa authentication login lwa-authentication local
   ```

   Defines the authentication method at login.

3. **aaa authorization network default local if-authenticated**

   Example

   ```
   Device(config)#aaa authorization network default local if-authenticated
   ```

   Sets the authorization method to local if the user has authenticated.

The AAA server is configured for local web authentication. Users can now authenticate locally when accessing the device through web interface.

Configure global settings (CLI)

Configure global system settings including user authentication and HTTP server parameters.

Establish basic global configuration settings for system access and HTTP server functionality.

Global configuration sets system-wide parameters that affect device operation and user access methods.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set the clear text password for the user.

Example

```
Device(config)# username name password 0 clear-text-password
```

Example

```
Device(config)# username base password 0 pass1
```

3. Enable the HTTP server.

Example

```
Device(config)# ip http server
```

4. Set the HTTP server authentication method to local.

Example

```
Device(config)# ip http authentication local
```

> **Note**
>
> You will get the admin access rights regardless of the user privilege, if the **ip http authentication local** is disabled and username is the same as enable password.

Global configuration settings are now applied, enabling HTTP server access with local authentication and user password configuration.

Central web authentication

Describes a security method that redirects unauthenticated users to a centralized web portal for credential verification before granting network access, commonly used in guest networks and BYOD environments.

Configure WLAN profile for guest access with central web authentication (GUI)

Configure a WLAN profile for guest access with central web authentication using the GUI interface.

Configure a WLAN profile that enables guest access using central web authentication to provide secure network access for guest users.

Guest access with central web authentication allows visitors to access the network through a web-based authentication portal while maintaining security controls through MAC filtering and authorization lists.

Before you begin

Follow these steps to configure a WLAN profile for guest access with central web authentication:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.

2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID**, and the **WLAN ID**.
4. To enable the WLAN, set **Status** as **Enabled**.
5. From the **Radio Policy** drop-down list, select the radio policy.
6. To enable the **Broadcast SSID**, set the status as **Enabled**.
7. Choose **Security** > **Layer2** tab. Uncheck the **WPA Policy**, **WPA2 Policy**, **AES** and **802.1x** check boxes.
8. Check the **MAC Filtering** check box to enable the feature. With MAC Filtering enabled, choose the Authorization list from the **Authorization List** drop-down list.
9. Click **Apply to Device**.

The WLAN profile is configured for guest access with central web authentication. The profile is now available for guest users to connect through the web authentication portal.

Configure a WLAN profile for guest access with central web authentication (CLI)

Configure a WLAN profile to enable guest access using central web authentication for secure network access.

Set up a WLAN profile that allows guest users to access the network through central web authentication, providing controlled access while maintaining security.

Guest access with central web authentication is used when you need to provide network access to temporary users while maintaining control and security through web-based authentication portals.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN and SSID.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id ssid-name
   ```

   Example

   ```
   Device(config)# wlan mywlan 38 mywlan-ssid1
   ```

3. Enable MAB authentication for the remote RADIUS server.

   Example

   ```
   Device(config-wlan)# mac-filtering remote-authorization-list-name
   ```

   Example

   ```
   Device(config-wlan)# mac-filtering auth-list
   ```

4. Disable WPA security.

   Example

   ```
   Device(config-wlan)# no security wpa
   ```

5. Disable security AKM for dot1x.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

6. Disable WPA2 security.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2
   ```

7. Disable WPA2 ciphers for AES.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2 ciphers aes
   ```

8. Save the configuration and activate the WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

The WLAN profile is configured for guest access with central web authentication, allowing guest users to connect and authenticate through the web portal.

Configure AAA server (GUI)

Configure RADIUS server groups and servers for AAA authentication using the GUI interface.

Configure RADIUS server groups and individual RADIUS servers to enable AAA authentication for network access control and user authentication.

AAA (Authentication, Authorization, and Accounting) servers provide centralized authentication services for network devices. RADIUS servers must be properly configured with server groups to ensure reliable authentication services.

Procedure

---

1. Choose **Configuration** > **Security** > **AAA** > **Servers/Groups** > **RADIUS** > **Server Groups**.
2. Click the RADIUS server group.
3. From the **MAC-Delimiter** drop-down list, choose an option.
4. From the **MAC-Filtering** drop-down list, choose an option.
5. Enter the **Dead-Time (mins)**.
6. From the **Available Servers** on the left, move the servers you need to **Assigned Servers** on the right.

7. Click **Update & Apply to Device**.
8. Choose **Configuration** > **Security** > **AAA** > **Servers/Groups** > **RADIUS** > **Servers**.
9. Click the RADIUS server.
10. Enter the **IPv4/IPv6 Server Address**, **Auth Port**, **Acct Port**, **Server Timeout (seconds)** and **Retry Count**.
11. Check or uncheck the **PAC Key** checkbox and choose the Key Type from the **Key Type** drop-down list. Enter the **Key** and **Confirm Key**.
12. Enable or disable the **Support for CoA** toggle button.
13. Click **Update & Apply to Device**.

The RADIUS server groups and servers are configured and applied to the device. AAA authentication is now available using the configured RADIUS servers.

Configure AAA server (CLI)

Configure AAA server settings using the command line interface for authentication and authorization services.

Set up AAA server configuration to enable authentication and authorization for network access control.

Configure AAA server for Guest Foreign only. This configuration establishes RADIUS server groups and authorization methods for network access control.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set the authorization method to local.

   Example

   ```
   Device(config)# aaa authorization network authorization-list local group
   server-group-name
   ```

   Example

   ```
   Device(config)# aaa authorization network cwa local group ise
   ```

3. Configure RADIUS server group definition.

   Example

   ```
   Device(config)# aaa group server radius server-group-name
   ```

   Example

   ```
   Device(config)# aaa group server radius ise
   ```

> **Note**
>
> *server-group-name* refers to the server group name. The valid range is from 1 to 32 alphanumeric characters.

4. Configure the RADIUS server name.

   Example

   ```
   Device(config-sg-radius)# server name radius-server-name
   ```

   Example

   ```
   Device(config-sg-radius)# server name ise1
   ```

5. Set the MAC address as the password.

   Example

   ```
   Device(config-sg-radius)# subscriber mac-filtering security-mode mac
   ```

6. Set the MAC address delimiter to colon.

   Example

   ```
   Device(config-sg-radius)# mac-delimiter colon
   ```

7. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

   Example

   ```
   Device(config-sg-radius)# end
   ```

8. Set the RADIUS server name.

   Example

   ```
   Device(config)# radius server name
   ```

   Example

   ```
   Device(config)# radius server ISE1
   ```

9. Configure the RADIUS server IP address authentication and accounting ports.

   Example

   ```
   Device(config-radius-server)# address ipv4 radius-server-ipaddress auth-port
    port-number acct-port port-number
   ```

Example

```
Device(config-radius-server)# address ipv4 209.165.201.1 auth-port 1635
acct-port 33
```

The AAA server configuration is now complete with RADIUS server group settings, authentication methods, and MAC filtering parameters established for Guest Foreign access control.

Configure 802.1x with local web authentication

Configure 802.1x authentication combined with local web authentication for enhanced WLAN security.

Configure dual authentication mechanism using 802.1x and local web authentication for comprehensive WLAN security.

This configuration combines 802.1x network access control with local web authentication, providing layered security for wireless clients. This is typically used when both network-level and user-level authentication are required.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN and SSID.

   Example

   ```
   Device(config)# wlan wlan-profile wlan-id ssid
   ```

   Example

   ```
   Device(config)# wlan testwprofile 22 ssid-3
   ```

3. Configure 802.1X for the WLAN.

   Example

   ```
   Device(config-wlan)# security dot1x authentication-list
   authentication-list-name
   ```

   Example

   ```
   Device(config-wlan)# security dot1x authentication-list default
   ```

4. Enable authentication list for web authentication security on the WLAN.

   Example

   ```
   Device(config-wlan)# security web-auth authentication-list
   authentication-list-name
   ```

Example

```
Device(config-wlan)# security web-auth authentication-list default
```

5. Configure the global parameter map for web authentication.

Example

```
Device(config-wlan)# security web-auth parameter-map global
```

6. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The WLAN is configured with both 802.1x and local web authentication, providing dual-layer security for wireless clients.

Configure local web authentication with PSK protocol (CLI)

Configure local web authentication with PSK protocol to enable secure access to the wireless network through web-based authentication combined with pre-shared key security.

Enable secure wireless network access using both PSK encryption and web-based authentication for enhanced security.

Local web authentication with PSK protocol combines pre-shared key security with web-based user authentication, providing a dual-layer security approach for wireless networks where traditional enterprise authentication methods are not required.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the WLAN and SSID.

Example

```
Device(config)# wlan wlan-profile wlan-id ssid
```

Example

```
Device(config)# wlan psksec-profile 22 ssid-4
```

3. Disable WPA security.

Example

```
Device(config-wlan)# no security wpa
```

4. Disable WPA2 security.

Example

```
Device(config-wlan)# no security wpa wpa2
```

5. Disable security AKM for dot1x.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

6. Enable the security type as PSK.

Example

```
Device(config-wlan)# security wpa akm psk
```

7. Configure the PSK shared key.

Example

```
Device(config-wlan)# security wpa akm psk set-key {ascii | hex} key
```

Example

```
Device(config-wlan)# security wpa akm psk set-key asci 0
```

8. Enable the web authentication for the WLAN.

Example

```
Device(config-wlan)# security web-auth
```

9. Enable authentication list for the WLAN.

Example

```
Device(config-wlan)# security web-auth authentication-list default
```

10. Configure the global parameter map.

Example

```
Device(config-wlan)# security web-auth parameter-map global
```

The WLAN is now configured with local web authentication using PSK protocol, requiring users to authenticate through a web portal while maintaining PSK encryption for wireless traffic.

Central web authentication with PSK protocol

Describes the configuration process for Central Web Authentication using Pre-Shared Key protocol, including steps to configure WLAN profiles and apply policy profiles to wireless networks.

To configure the CWA with PSK security protocol, follow the steps:

1. Configure the WLAN Profile.
2. Applying Policy Profile on a WLAN

Configure WLAN profile for central web authentication with PSK protocol (CLI)

Configure a WLAN profile to support central web authentication using pre-shared key (PSK) protocol for wireless clients.

Set up central web authentication with PSK to provide secure wireless access with web-based client authentication.

Central web authentication with PSK allows wireless clients to connect using a shared key and then authenticate through a web portal. This configuration is useful in guest networks or environments requiring web-based user authentication while maintaining PSK connectivity.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN and SSID.

   Example

   ```
   Device(config)# wlan wlan-profile wlan-id ssid
   ```

   Example

   ```
   Device(config)# wlan cwasec-profile 27 ssid-5
   ```

3. Disable WPA security.

   Example

   ```
   Device(config-wlan)# no security wpa
   ```

4. Disable WPA2 security.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2
   ```

5. Disable security AKM for dot1x.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

6. Enable the security type as PSK.

Example

```
Device(config-wlan)# security wpa psk
```

7. Configure the PSK shared key.

Example

```
Device(config-wlan)# security wpa psk set-key {ascii | hex} key
```

Example

```
Device(config-wlan)# security wpa psk set-key asci 0
```

8. Enable MAC filtering for PSK web authentication.

Example

```
Device(config-wlan)# mac-filtering authorization-list-name
```

Example

```
Device(config-wlan)# mac-filtering cwa-list
```

The WLAN profile is configured for central web authentication with PSK protocol, allowing clients to connect using the shared key and authenticate via web portal.

Central web authentication with iPSK protocol

Describes how to configure Central Web Authentication (CWA) with individual Pre-Shared Key (iPSK) protocol by setting up the WLAN profile and applying the appropriate policy profile to the wireless LAN.

To configure the CWA with iPSK security protocol, follow the steps:

1. Configure the WLAN Profile.

Configure WLAN profile for central web authentication with iPSK protocol

Configure a WLAN profile that uses central web authentication with iPSK protocol for secure guest access.

This task configures a WLAN profile that enables central web authentication with iPSK (Identity Pre-Shared Key) protocol, providing secure guest access while maintaining centralized authentication control.

Use this configuration when you need to provide guest wireless access with pre-shared key authentication combined with central web authentication. This approach allows for individualized keys per device while maintaining centralized authentication oversight.

Procedure

1. Configure guest WLAN.

   Example

   ```
   config# wlan guest-wlan-name wlan-id ssid
   ```

   ```
   config# wlan ipsk-cwa-profile 28 ssid-6
   ```

2. Disable security AKM for 802.1x.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

3. Configure the PSK AKM shared key.

   Example

   ```
   Device(config-wlan)# security wpa akm psk set-key {asci | hex} key
   ```

   ```
   Device(config-wlan)# security wpa akm psk set-key asci 0
   ```

4. Enable MAC filtering for iPSK authentication.

   Example

   ```
   Device(config-wlan)# mac-filtering authorization_list_name
   ```

   ```
   Device(config-wlan)# mac-filtering cwa-list
   ```

The WLAN profile is configured for central web authentication with iPSK protocol. Guest devices can now connect using pre-shared keys while being subject to centralized web authentication control and MAC filtering.

Configure web authentication on MAC address bypass failure (GUI)

Configure Web Authentication to handle MAC address bypass failures through the WLAN profile settings.

This task configures Web Authentication to handle situations where MAC address filtering fails, providing an alternative authentication method for network access.

When MAC filtering is enabled but a device's MAC address is not in the authorization list, you can configure the system to fall back to Web Authentication instead of denying access completely.

Procedure

1. Click **Configuration** > **Tags and Profiles** > **WLANs**.
2. Click **Add** to add a new WLAN Profile or click the one you want to edit.
3. In the **Edit WLAN** window, complete the following steps:

a) Choose **Security** > **Layer2** and check the **MAC Filtering** check box to enable MAC filtering.
b) From the **Authorization List** drop-down list, select a value.
c) Choose the **Layer3** tab.
d) Click **Show Advanced Settings** and check the **On MAC Filter Failure** checkbox.

Web Authentication is now configured to activate when MAC address filtering fails, allowing devices not on the authorization list to authenticate through the web interface.

Configure web authentication on MAC address bypass failure (CLI)

Configure authentication to fall back to web authentication if a client cannot authenticate using MAC filter while trying to connect to a WLAN.

Enable web authentication fallback when MAC filter authentication fails to avoid client disassociations due to MAC filter authentication failures.

You can configure authentication to fall back to web authentication, if a client cannot authenticate using MAC filter (Local or RADIUS), while trying to connect to a WLAN. To enable this feature, configure both MAC filtering and Web Authentication on the device. This can also avoid disassociations that happen only because of MAC filter authentication failure.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy policy-name
   ```

   Example

   ```
   Device(config)# wireless profile policy cwa
   ```

3. Enable Central switching.

   Example

   ```
   Device(config-wireless-policy)# central switching
   ```

4. Configure Guest Foreign or Guest Anchor.
   - mobility anchor *anchor-ip-address*
   - mobility anchor

Example

For Guests Foreign:

```
Device (config-wireless-policy)# mobility anchor anchor-ip-address
```

For Guest Anchor:

```
Device (config-wireless-policy)# mobility anchor
```

Example

For Guests Foreign:

```
Device (config-wireless-policy)# mobility anchor 19.0.2.1
```

For Guest Anchor:

```
Device (config-wireless-policy)# mobility anchor
```

5. Configure a VLAN name or VLAN ID.

Example

```
Device(config-wireless-policy)# vlan name
```

Example

```
Device(config-wireless-policy)# vlan 16
```

> **Note**
>
> VLAN is optional for a Guest Foreign controller.

6. Enable the policy profile.

Example

```
Device(config-wireless-policy)# no shutdown
```

7. Configure guest WLAN.

Example

```
config# wlan guest-wlan-name wlan-id ssid
```

Example

```
config# wlan test-wlan-guest 10 wlan-ssid
```

8. Configure MAC filtering support on WLAN.

Example

```
config-wlan# mac-filtering mac-auth-listname authorization-override
```

9. Enable web authentication.

   Example

   ```
   config-wlan# security web-auth
   ```

10. Enable web authentication if MAC filter authentication fails.

    Example

    ```
    config-wlan# security web-auth on-macfilter-failure
    ```

Web authentication fallback is now configured for MAC filter authentication failures, preventing client disconnections when MAC authentication fails.

Configure WLAN for web authentication on MAC authentication bypass failure with pre-shared key (CLI)

Enable web authentication for clients who fail MAC authentication bypass on a WLAN, using a pre-shared key, through the CLI.

Use this configuration to ensure clients who do not pass MAC authentication bypass are redirected to a web authentication portal with a secure pre-shared key.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN.

   Example

   ```
   Device(config)# wlan wlan-name wland-id SSID-name
   ```

   - **wlan-name** is the name of the configured WLAN.
   - **wlan-id** is the WLAN identifier. The range is one to 512.
   - **SSID-name** is the SSID name which can have up to 32 alphanumeric characters.

   If you have already created and configured the WLAN, use the **wlan** *wlan-name* command.

3. Set the MAC filtering parameters.

Example

```
Device(config-wlan)# mac-filtering test-auth-list
```

4. Configure the PSK AKM shared key using the command.

Example

```
Device(config-wlan)# ecurity wpa psk set-key {ascii | hex} key password
```

```
Device(config-wlan)# security wpa psk set-key ascii 0 PASSWORD
```

5. Disable the security AKM for 802.1X.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

6. Configure PSK support.

Example

```
Device(config-wlan)# security wpa akm psk
```

7. Enable the authentication list for 802.1X security.

Example

```
Device(config-wlan)# security web-auth authentication-list
authenticate-list-name
```

8. Enable the authorization list for 802.1X security.

Example

```
Device(config-wlan)# security web-auth authorization-list authorize-list-name
```

9. Enable web authentication on MAC filter failure.

Example

```
Device(config-wlan)# security web-auth on-macfilter-failure
```

10. Configure the parameter map.

Example

```
Device(config-wlan)# security web-auth parameter-map parameter-map-name
```

> **Note**
>
> If a parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

11. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The WLAN is configured to perform web authentication for clients failing MAC authentication bypass, securing access with a pre-shared key.

Configure WLAN with web authentication for MAB failures using a pre-shared key (CLI)

Enable web authentication for clients who fail MAC authentication bypass (MAB) on a WLAN, using a pre-shared key through the CLI.

Use this configuration to ensure that clients who do not pass MAC authentication bypass are redirected to a web authentication portal protected by a secure pre-shared key.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the WLAN.

Example

```
Device(config)# wlan wlan-name wland-id SSID-name
```

- **wlan-name** is the name of the configured WLAN.
- **wlan-id** is the WLAN identifier. The range is one to 512.
- **SSID-name** is the SSID name which can have up to 32 alphanumeric characters.

If you have already created and configured the WLAN, use the **wlan** *wlan-name* command.

3. Set the MAC filtering parameters.

Example

```
Device(config-wlan)# mac-filtering auth-list-name
```

4. Disable security AKM for dot1x.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

5. Enable WPA3 support.

   Example

   ```
   Device(config-wlan)# security wpa wpa3
   ```

6. Enable WPA3 OWE support.

   Example

   ```
   Device(config-wlan)# security wpa akm owe
   ```

7. Enable authentication list for 802.1X security.

   Example

   ```
   Device(config-wlan)# security web-auth authentication-list
   authenticate-list-name
   ```

8. Enable authorization list for 802.1X security.

   Example

   ```
   Device(config-wlan)# security web-auth authorization-list authorize-list-name
   ```

9. Enable web authentication on MAC filter failure.

   Example

   ```
   Device(config-wlan)# security web-auth on-macfilter-failure
   ```

10. Configure the parameter map.

    Example

    ```
    Device(config-wlan)# security web-auth parameter-map parameter-map-name
    ```

    If a parameter map is not associated with a WLAN, the system uses the configuration from the global parameter map.

11. Enable the WLAN.

    Example

    ```
    Device(config-wlan)# no shutdown
    ```

The WLAN now performs web authentication for clients who fail MAC authentication bypass and secures access with a pre-shared key.

Configure WLAN for web authentication on MAB failure with SAE (CLI)

Configure a WLAN using the CLI. If MAC Authentication Bypass (MAB) fails, users are directed to web authentication with Simultaneous Authentication of Equals (SAE) enabled.

Use this task when you require a WLAN that supports MAC authentication. If MAC authentication fails, the controller falls back to web authentication with SAE.

This setup strengthens security by ensuring that only authorized users can access the network. It also supports modern authentication protocols.

Before you begin

Prepare the names of the authentication and authorization lists and the parameter map, if needed.

Procedure

1. Configure the WLAN.

   Example

   ```
   Device(config)# wlan wlan-name wland-id SSID-name
   ```

   - **wlan-name** is the name of the configured WLAN.
   - **wlan-id** is the WLAN identifier. The range is one to 512.
   - **SSID-name** is the SSID name which can have up to 32 alphanumeric characters.

   If you have already created and configured the WLAN, use the **wlan** *wlan-name* command.

2. Set the MAC filtering parameters.

   Example

   ```
   Device(config-wlan)# mac-filtering test-auth-list
   ```

3. Disable security AKM for 802.1X.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

4. Enable WPA3 support.

   Example

   ```
   Device(config-wlan)# security wpa wpa3
   ```

5. Enable AKM SAE support.

Example

```
Device(config-wlan)# security wpa akm sae
```

6. Enable authentication list for 802.1X security.

   Example

   ```
   Device(config-wlan)# security web-auth authentication-list
   authenticate-list-name
   ```

7. Enable authorization list for 802.1X security.

   Example

   ```
   Device(config-wlan)# security web-auth authorization-list authorize-list-name
   ```

8. Enable web authentication on MAC filter failure.

   Example

   ```
   Device(config-wlan)# security web-auth on-macfilter-failure
   ```

9. Configure the parameter map.

   Example

   ```
   Device(config-wlan)# security web-auth parameter-map parameter-map-name
   ```

   If a parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

The WLAN is configured to use MAC authentication. If MAC authentication fails, users are redirected to web authentication, with WPA3 and SAE enabled.

Configure WLAN for web authentication on MAC authentication failure with Dot1x (CLI)

Configure a WLAN to use web authentication as a fallback mechanism when MAC filtering fails, while maintaining 802.1x as the primary authentication method.

Enable web authentication fallback for clients that fail MAC filtering on a WLAN configured with 802.1x authentication.

This configuration allows clients to authenticate via a web portal when they cannot pass MAC filtering, providing a secondary authentication path while maintaining 802.1x as the primary security mechanism.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create or enter WLAN configuration submode.

Example

```
Device(config)# wlan profile-name wlan-id ssid-name
```

Example

```
Device(config)# wlan wlan-test 3 ssid-test
```

- *profile-name*: Profile name of the configured WLAN.
- *WLAN-id*: Wireless LAN identifier. Range is from 1 to 512.
- *SSID_Name*: SSID that can contain 32 alphanumeric characters.

> **Note**
>
> If you have already configured a WLAN, enter the profile name of the configured WLAN in the command (**WLAN** *profile-name*) and continue with the rest of the configuration steps.

3. Configure MAC filtering parameters.

Example

```
Device(config-wlan)# mac-filtering auth-list-name
```

Example

```
Device(config-wlan)# mac-filtering test-auth-list
```

4. Configure 802.1x authentication.

Example

```
Device(config-wlan)# security dot1x authentication-list
dot1x-authentication-list
```

5. Enable the web authentication list.

Example

```
Device(config-wlan)# security web-auth authentication-list
authenticate-list-name
```

Example

```
Device(config-wlan)# security web-auth authentication-list default
```

6. Enable web authentication on MAC filter failure.

Example

```
Device(config-wlan)# security web-auth on-macfilter-failure
```

7. Configure the web authentication parameter map.

Example

```
Device(config-wlan)# security web-auth parameter-map parameter-map-name
```

Example

```
Device(config-wlan)# security web-auth parameter-map WLAN1_MAP
```

> **Note**
>
> If a parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

8. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The WLAN is configured to use 802.1x as the primary authentication method, with web authentication as a fallback for clients that fail MAC filtering.

219 Wired Guest Access

Topics:

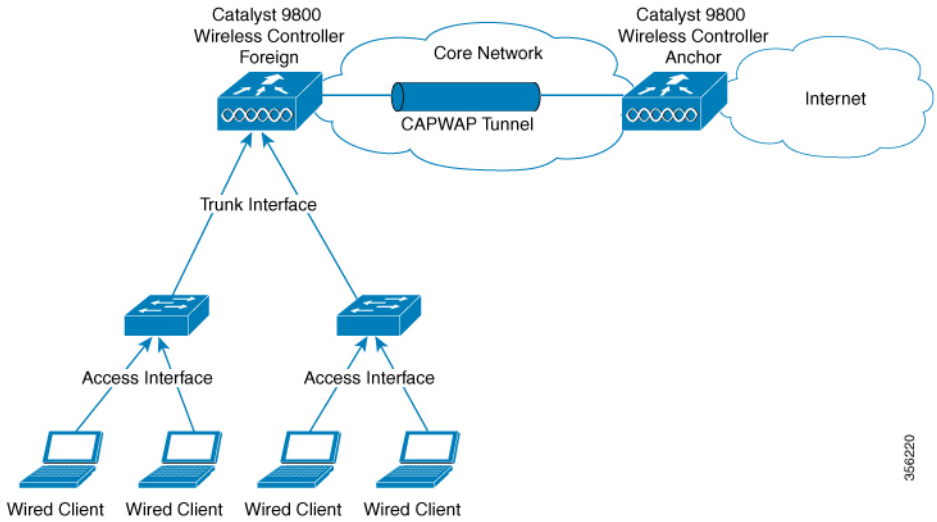
- Wired guest access

Guides the configuration of wired guest access through foreign and anchor controllers, detailing authentication methods and session management for secure guest connectivity.

Wired guest access

Describes a feature that allows guest users in an enterprise network to connect to a designated guest access network.

Wired guest access is a network feature that



- enables guest users of an enterprise network that supports both wired and wireless access to connect to the guest access network
- allows wired guest clients to connect from designated and configured wired Ethernet ports for guest access after they complete the configured authentication methods, and
- directs wired session guests to a wireless guest controller in a demilitarized zone (DMZ) through a Control And Provisioning of Wireless Access Points (CAPWAP) tunnel.

Wired guest access configuration and architecture

Wired guest access can be configured in a dual-controller configuration that uses both an anchor controller and a foreign controller. A dual-controller configuration isolates wired guest access traffic from the enterprise user traffic.

The wired session guests are provided open or web-authenticated access from the wireless controller.

Figure 38: Guest access architecture

IPv6 Router Advertisement forwarding for wired guests

- **Guest Anchor Controller**: Guest anchor controller forwards the RA packets, from the receiving VLAN, to all the foreign controllers using the mobility data tunnel. The RA packets are tagged with the anchor VLAN to ensure the message is forwarded to the correct clients using the foreign controller data path.
- **Guest Foreign Controller**: Guest foreign controller forwards the received RAs from the guest anchor to the wired ports on which the wired guest clients are connected. To forward the RAs to the intended clients, the guest foreign controller keeps a track of the wired guest clients-per interface, access VLANs, and anchor VLANs.

Wired clients get the IPv6 based connectivity when they receive the IPv6 Router Advertisement (RA) message. The IPv6 router sends these RA messages and it contains information such as IPv6 prefix and router link-local address.

These RA messages are sent as Unicast or Multicast messages. The Unicast RA messages are routed as same as the client directed traffic. The Multicast RA messages are forwarded to all the clients present in the intended VLAN. RA message forwarding is enabled by default and requires no specific configuration.

Supported features

Supported features include:

- Cisco Catalyst 9800 Series Wireless Controllers-Anchor
- Cisco AireOS Wireless Controllers-Anchor
- Cisco Catalyst 9800 Series Wireless Controllers-Foreign
- Cisco AireOS Wireless Controllers-Foreign
- Dual controller solution (foreign + anchor) and access switch
- Trunk Ports
- Open Authentication
- Local Web Authentication
- Scale max 2k clients and 5 guest-LANs (5 VLANs max)
- Client IPv6 support
- Idle Timeout and Session Timeout
- Accounting on Foreign
- Manageability (SNMP/Yang/WebUI)
- QoS Rate-Limiting and MQC Policies (Upstream at foreign, Upstream, and Downstream at the anchor)
- QoS support with AireOS Anchor setup
- Stateful Switch Over (SSO)
- Port Channel support on Anchor and Foreign with no restrictions to the controller's role.
- Access Port on Foreign
- Cisco Umbrella (not supported in AireOS Anchor)
- ACL support at anchor
- Fully Qualified Domain Name (FQDN) URL filtering is supported at Anchor controller.
- IP theft detection
- Sleeping Client

Local web authentication options:

- Local Web Authentication (web consent)

> **Note**
>
> In AireOS, this is referred to as **web pass-through**.

- Local Web Authentication + ISE (External Web Authentication).
- LWA (local web authentication), with a username and a password.
- Web consent (LWA + consent), that is with a username, a password and the check box of acceptance.

To configure Web Authentication, see Web-based Authentication section of the Cisco Catalyst 9800 Series Wireless Controller Software Configuration Guide.

Note

Statistics computation not supported.

Note

QoS rate-limiting supports bps rate-limiting, pps rate-limiting is not supported.

Restrictions for wired guest access

Outlines the configuration and deployment restrictions for wired guest access implementation.

- A maximum of five guest LANs are supported on the foreign controller.
- A maximum of 2000 clients per foreign are supported.
- No Multicast or Broadcast support.
- You can map only one wired VLAN to a guest LAN.
- You can map only one guest LAN to one policy profile.
- Every guest LAN has a unique name and this name cannot be shared with RLAN or WLAN.
- Ensure that the Anchor VLAN ID and the wired VLAN ID configured on the Foreign controller is not the same.
- QoS is not supported on VLAN and on physical interfaces of the controller.

Configure access switch for wired guest client (CLI)

Configure access switch for wired guest client connectivity.

Set up an access switch to provide network connectivity for wired guest clients through VLAN assignment and port configuration.

Wired guest clients require dedicated VLAN assignment on access switches to segregate guest traffic from corporate network traffic and provide appropriate network access controls.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create the VLAN ID.

Example

```
Device(config)# vlan vlan-id
```

Example

```
Device(config)# vlan 200
```

3. Return to configuration mode.

Example

```
Device(config)# exit
```

4. Enter the interface to be added to the VLAN.

Example

```
Device(config)# interface GigabitEthernetinterface-number
```

Example

```
Device(config)# interface GigabitEthernet1/0/1
```

5. Assign the port to a VLAN.

Example

```
Device(config-if)# switchport access vlan vlan-id
```

Example

```
Device(config-if)# switchport access vlan 200
```

The valid VLAN IDs range is from 1 to 4094.

6. Define the VLAN membership mode for the port.

Example

```
Device(config-if)# switchport mode access
```

7. Disable CDP on the interface.

Example

```
Device(config-if)# no cdp enable
```

8. Save the configuration and exit to privileged EXEC mode.

Example

```
Device(config-if)# end
```

The access switch is configured with the appropriate VLAN assignment and port settings to provide network connectivity for wired guest clients.

Configure access switch for foreign controller (CLI)

Configure access switch for foreign controller.

Configure an access switch to support communication with a foreign controller by setting up appropriate VLAN and trunk configurations.

This configuration is needed when setting up an access switch to work with a foreign controller in a wireless network deployment. The switch must be configured with the proper VLAN and trunk settings to enable communication.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create the VLAN ID.

   Example

   ```
   Device(config)# vlan vlan-id
   ```

   Example

   ```
   Device(config)# vlan 200
   ```

3. Return to configuration mode.

   Example

   ```
   Device(config)# exit
   ```

4. Enter the interface to be added to the VLAN.

   Example

   ```
   Device(config)# interface GigabitEthernetinterface-number
   ```

   Example

   ```
   Device(config)# interface GigabitEthernet1/0/2
   ```

5. Assign the allowed VLAN ID to the port when it is in trunking mode.

   Example

   ```
   Device(config-if)# switchport trunk allowed vlan vlan-id
   ```

   Example

   ```
   Device(config-if)# switchport trunk allowed vlan 200
   ```

6. Set the trunking mode to trunk unconditionally.

   Example

   ```
   Device(config-if)# switchport mode trunk
   ```

7. Save the configuration and exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-if)# end
   ```

The access switch is now configured with the appropriate VLAN and trunk settings to support communication with a foreign controller.

Configure foreign controller with open authentication (GUI)

Configure foreign controller with open authentication using GUI.

Configure a foreign controller with open authentication to enable wireless guest access through the GUI interface.

Foreign controllers allow guest clients to connect through external wireless controllers while maintaining centralized policy management. This configuration uses open authentication without web authentication requirements.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click on a **Policy Name**.
3. Go to the **Mobility** tab.
4. In the **Mobility Anchors** section, check the **Export Anchor** check box.
5. Click **Apply to Device**.
6. Choose **Configuration** > **Wireless** > **Guest LAN** > **Guest LAN Configuration**
7. Click **Add**.
8. In the **General** tab, enter the **Profile Name**, **Guest LAN ID**, **Client Association Limit**.
9. Choose the desired mode from the **mDNS Mode** drop-down list.
10. Enable or disable the **Status** and **Wired VLAN Status** toggle button.
11. In the **Security** tab, disable the **Web Auth** toggle button.
12. Click **Apply to Device**.
13. Choose **Configuration** > **Wireless** > **Guest LAN** > **Guest LAN Map Configuration**

14. Click **Add Map**.
15. In the Add Guest LAN Map window, enter the **Guest LAN Map**.
16. Click **Apply to Device**.
17. Click **Add**.
18. Choose the values from the **Profile Name** and **Policy Name** drop-down lists.
19. Click **Save**.

The foreign controller is configured with open authentication. Guest clients can now connect through the configured guest LAN without requiring web authentication.

Configure foreign controller with open authentication (CLI)

Configure foreign controller with open authentication using commands.

Set up a foreign controller with open authentication to enable guest access through mobility anchor configuration.

Foreign controllers are used in mobility deployments where guest traffic is tunneled to a designated anchor controller. This configuration establishes the necessary mobility anchor relationship and guest LAN settings for open authentication.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile.

   Example

   ```
   Device(config)# wireless profile policy wlan-policy-profile-name
   ```

   Example

   ```
   Device(config)# wireless profile policy testpro-1
   ```

3. Configure the mobility anchor and set its priority.

   Example

   ```
   Device(config-wireless-policy)# mobility anchor non-local-mobility-cntlr-ip
   priority priority
   ```

   Example

   ```
   Device(config-wireless-policy)# mobility anchor 192.168.201.111 priority 1
   ```

4. Enable the configuration.

Example

```
Device(config-wireless-policy)# no shutdown
```

5. Return to configuration mode.

Example

```
Device(config-wireless-policy)# exit
```

6. Configure guest LAN profile with a wired VLAN.

Example

```
Device(config)# guest-lan profile-name guest-profile-name guest-lan-id
wired-vlan wired-vlan-id
```

Example

```
Device(config)# guest-lan profile-name gstpro-1 1 wired-vlan 25
```

> **Note**
>
> Configure the wired VLAN only for the Guest Foreign controller.

7. Disable web-authentication.

Example

```
Device(config-guest-lan)# no security web-auth
```

8. Enable the guest LAN.

Example

```
Device(config-guest-lan)# no shutdown
```

9. Return to configuration mode.

Example

```
Device(config-guest-lan)# exit
```

10. Configure a guest LAN map.

Example

```
Device(config)# wireless guest LAN map gst-map-name
```

Example

```
Device(config)# wireless guest LAN map gstmap-1
```

11. Attach a guest LAN map to the policy profile.

Example

```
Device(config-guest-lan-map)# guest-lan guest-profile-name policy
wlan-policy-profile-name
```

Example

```
Device(config-guest-lan-map)# guest-lan gstpro-1 policy testpro-1
```

12. Return to configuration mode.

Example

```
Device(config-guest-lan-map)# exit
```

The foreign controller is now configured with open authentication, and guest traffic will be tunneled to the designated mobility anchor controller.

Configure foreign controller with local web authentication (GUI)

Configure foreign controller with local web authentication using GUI.

Configure a foreign controller to enable local web authentication for guest access through the graphical user interface.

Local web authentication allows guest users to authenticate through a web portal when connecting to the wireless network. This configuration involves setting up mobility anchors, guest LAN configuration, and guest LAN mapping to enable the authentication process.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Select a **Policy Name**.
3. Go to the **Mobility** tab.
4. In the **Mobility Anchors** section, check the **Export Anchor** check box.
5. Click **Update & Apply to Device**.
6. Choose **Configuration** > **Wireless** > **Guest LAN** > **Guest LAN Configuration**
7. Click **Add**.
8. In the **General** tab, enter the **Profile Name**, **Guest LAN ID**, **Client Association Limit**.
9. Choose the desired mode from the **mDNS Mode** drop-down list.
10. Enable or disable the **Status** and **Wired VLAN Status** using toggle button.
11. Go to the **Security** tab.
12. Enable the **Web Auth** using toggle button.
13. Choose the values from the **Web Auth Parameter Map**, **Authentication List** and **Authorization List** drop-down lists.

14. Click **Apply to Device**.
15. Choose **Configuration** > **Wireless** > **Guest LAN** > **Guest LAN Map Configuration**
16. Click **Add Map**.
17. In the Add Guest LAN Map window, enter the **Guest LAN Map**.
18. Click **Apply to Device**.
19. Click **Add**.
20. Choose the values from the **Profile Name** and **Policy Name** drop-down lists.
21. Click **Save**.

The foreign controller is successfully configured with local web authentication. Guest users can now authenticate through the web portal when connecting to the wireless network.

Configure foreign controller with local WEB authentication (CLI)

Configure foreign controller with local WEB authentication using commands.

Enable foreign controller functionality with local WEB authentication to provide secure guest access through mobility anchoring.

Foreign controllers work with anchor controllers in mobility scenarios to provide seamless roaming and secure guest access. This configuration establishes the necessary policy profiles and guest LAN mappings for local WEB authentication.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile.

   Example

   ```
   Device(config)# wireless profile policy wlan-policy-profile-name
   ```

   Example

   ```
   Device(config)# wireless profile policy testpro-1
   ```

3. Configure the mobility anchor and set its priority.

   Example

   ```
   Device(config-wireless-policy)# mobility anchor non-local-mobility-cntlr-ip
   priority priority
   ```

   Example

   ```
   Device(config-wireless-policy)# mobility anchor 192.168.201.111 priority 1
   ```

4. Enable the configuration.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

5. Return to configuration mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

6. Configure guest LAN profile with a wired VLAN.

   Example

   ```
   Device(config)# guest-lan profile-name guest-profile-name guest-lan-id
   wired-vlan wired-vlan-id
   ```

   Example

   ```
   Device(config)# guest-lan profile-name gstpro-2 3 wired-vlan 26
   ```

7. Enable WEB-authentication.

   Example

   ```
   Device(config-guest-lan)# security web-auth
   ```

8. Configure the authentication list for a IEEE 802.1x network.

   Example

   ```
   Device(config-guest-lan)# security web-auth authentication-list auth-list-name
   ```

   Example

   ```
   Device(config-guest-lan)# security web-auth authentication-list default
   ```

9. Configure the security WEB-auth parameter map.

   Example

   ```
   Device(config-guest-lan)# security web-auth parameter-map parameter-map-name
   ```

   Example

   ```
   Device(config-guest-lan)# security web-auth parameter-map global
   ```

10. Enable the guest LAN.

Example

```
Device(config-guest-lan)# no shutdown
```

11. Return to configuration mode.

Example

```
Device(config-guest-lan)# exit
```

12. Configure a guest LAN map.

Example

```
Device(config)# wireless guest-lan map gst-map-name
```

Example

```
Device(config)# wireless guest-lan map gstmap-2
```

13. Attach a guest LAN map to the policy profile.

Example

```
Device(config-guest-lan-map)# guest-lan guest-lan-profile-name policy
policy-profile-name
```

Example

```
Device(config-guest-lan-map)# guest-lan gstpro-2 policy testpro-1
```

14. Return to configuration mode.

Example

```
Device(config-guest-lan-map)# exit
```

The foreign controller is now configured with local WEB authentication, enabling secure guest access through the mobility anchor setup and guest LAN mapping.

What to do next
For more information about Local WEB Authentication, see https://www.cisco.com/c/en/us/td/docs/wireless/controller/9800/config-guide/b_wl_16_10_cg/wireless-web-authentication.html

Configure anchor controller with open authentication (GUI)

Configure anchor controller with open authentication using GUI.

This task configures an anchor controller with open authentication to enable guest access and mobility management for wireless clients.

Use this procedure when you need to set up mobility anchoring for guest users without requiring web authentication. This configuration creates a policy profile with mobility anchor settings and a corresponding guest LAN for open authentication.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click **Add**.
3. In the **General** tab, enter the **Name**.
4. Go to the **Access Policies** tab.
5. Under the **VLAN** settings, choose the vlans from the **VLAN/VLAN Group** drop-down list.
6. Go to the **Mobility** tab.
7. Under the **Mobility Anchors** settings, check the **Export Anchor** check box.
8. Click **Apply to Device**.
9. Choose **Configuration** > **Wireless** > **Guest LAN**.
10. Click **Add**.
11. In the **General** tab, enter the **Profile Name**, the **Guest LAN ID** and the **Client Association Limit**.
12. In the **Security** tab, under the **Layer3** settings, disable the **Web Auth** toggle button.
13. Click **Apply to Device**.

The anchor controller is now configured with open authentication. The policy profile with mobility anchor settings and the guest LAN are created and applied to the device.

Configure anchor controller with open authentication (CLI)

Configure anchor controller with open authentication using commands.

Enable anchor controller functionality with open authentication for guest access scenarios.

Anchor controllers provide centralized guest access management by terminating guest traffic at a designated controller while maintaining security isolation from the main network.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile.

   Example

   ```
   Device(config)# wireless profile policy wlan-policy-profile-name
   ```

   Example

   ```
   Device(config)# wireless profile policy testpro-2
   ```

3. Configure the mobility anchor.

Example

```
Device(config-wireless-policy)# mobility anchor
```

4. Configure a VLAN name or a VLAN ID.

Example

```
Device(config-wireless-policy)# vlan vlan-id
```

Example

```
Device(config-wireless-policy)# vlan 29
```

5. Enable the configuration.

Example

```
Device(config-wireless-policy)# no shutdown
```

6. Return to configuration mode.

Example

```
Device(config-wireless-policy)# exit
```

7. Configure the guest LAN profile with a wired VLAN.

Example

```
Device(config)# guest-lan profile-name guest-profile-name guest-lan-id
```

Example

```
Device(config)# guest-lan profile-name testpro-2 1
```

8. Configure the maximum client connections per guest LAN.

Example

```
Device(config-guest-lan)# client association limit guest-lan-client-limit
```

The valid range is from 1 to 2000.

9. Disable web authentication.

Example

```
Device(config-guest-lan)# no security web-auth
```

10. Enable the guest LAN.

Example

```
Device(config-guest-lan)# no shutdown
```

11. Return to configuration mode.

Example

```
Device(config-guest-lan)# exit
```

The anchor controller is now configured with open authentication, allowing guest clients to access the network through the designated guest LAN profile with the specified VLAN assignment.

Configure anchor controller with local web authentication (GUI)

Configure anchor controller with local web authentication using GUI.

Configure an anchor controller with local web authentication to establish mobility anchoring for guest access control.

Use this procedure when you need to set up an anchor controller that handles local web authentication for guest users in a wireless network environment.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click **Add**.
3. In the **General** tab, enter the **Name**.
4. Go to the **Access Policies** tab.
5. Under the **VLAN** settings, choose the vlans from the **VLAN/VLAN Group** drop-down list.
6. Go to the **Mobility** tab.
7. Under the **Mobility Anchors** settings, check the **Export Anchor** check box.
8. Click **Apply to Device**.
9. Choose **Configuration** > **Wireless** > **Guest LAN**.
10. Click **Add**.
11. In the **General** tab, enter the **Profile Name**, the **Guest LAN ID** and the **Client Association Limit**.
12. In the **Security** tab, under the **Layer3** settings, enable the **Web Auth** toggle button. Choose the Parameter map from the **Web Auth Parameter Map** drop-down list and the authentication list from the **Authentication List** drop-down list.
13. Click **Apply to Device**.

The anchor controller is configured with local web authentication. The policy profile and guest LAN configuration are applied to the device and ready to handle guest user authentication.

Configure anchor controller with local web authentication (CLI)

Configure anchor controller with local web authentication using commands.

Establish an anchor controller configuration with local web authentication to manage client connectivity and security.

Anchor controllers provide centralized authentication and policy enforcement for wireless clients across multiple wireless LAN controllers. This configuration enables local web authentication for guest access scenarios.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile.

   Example

   ```
   Device(config)# wireless profile policy wlan-policy-profile-name
   ```

   Example

   ```
   Device(config)# wireless profile policy testpro-2
   ```

3. Configure the mobility anchor.

   Example

   ```
   Device(config-wireless-policy)# mobility anchor
   ```

4. Configure a VLAN name or a VLAN ID.

   Example

   ```
   Device(config-wireless-policy)# vlan vlan-id
   ```

   Example

   ```
   Device(config-wireless-policy)# vlan 30
   ```

5. Enable the configuration.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

6. Return to configuration mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

7. Configure a guest LAN profile with a wired VLAN.

   Example

   ```
   Device(config)# guest-lan profile-name guest-profile-name guest-lan-id
   ```

Example

```
Device(config)# guest-lan profile-name testpro-2 1
```

8. Configure the maximum client connections per guest LAN.

Example

```
Device(config-guest-lan)# client association limit guest-lan-client-limit
```

The valid range is between 1 and 2000.

9. Configure web authentication.

Example

```
Device(config-guest-lan)# security web-auth
```

10. Configure the security web-auth parameter map.

Example

```
Device(config-guest-lan)# security web-auth parameter-map parameter-map-name
```

Example

```
Device(config-guest-lan)# security web-auth parameter-map testmap-1
```

11. Configure the authentication list for the IEEE 802.1x network.

Example

```
Device(config-guest-lan)# security web-auth authentication-list
authentication-list-name
```

Example

```
Device(config-guest-lan)# security web-auth authentication-list testlwa-1
```

12. Enable the guest-LAN.

Example

```
Device(config-guest-lan)# no shutdown
```

13. Return to configuration mode.

Example

```
Device(config-guest-lan)# exit
```

The anchor controller is now configured with local web authentication, enabling secure guest access through the designated guest LAN profile with web-based authentication.

Configure session timeout for a profile policy (CLI)

Configure session timeout for a profile policy.

Configure session timeout values for wired guests to control the duration of their network sessions.

Session timeout for a wired guest is set to infinite by default. Use this procedure to configure specific timeout values for wired guests.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile.

   Example

   ```
   Device(config)# wireless profile policy wlan-policy-profile-name
   ```

   Example

   ```
   Device(config)# wireless profile policy testpol-1
   ```

3. Enable the client session timeout on the guest LAN.

   Example

   ```
   Device(config-wireless-policy)# guest-lan enable-session-timeout
   ```

4. Configure the client session timeout in seconds.

   Example

   ```
   Device(config-wireless-policy)# session-timeout timeout-duration
   ```

   Example

   ```
   Device(config-wireless-policy)# session-timeout 1000
   ```

   The valid range is from 0 to 86400 seconds.

Session timeout is now configured for the profile policy, controlling how long wired guest sessions remain active before automatic disconnection.

Configure global settings (GUI)

Configure global settings including user administration and HTTP/HTTPS access using the GUI.

Configure global system settings to establish user accounts and manage HTTP/HTTPS access for device management.

Global configuration includes setting up user administration and configuring HTTP/HTTPS access settings for secure device management.

Procedure

1. Choose **Administration** > **User Administration**.
2. Click **Add**.
3. Enter the **Username**, **Password** and **Confirm Password**.
4. Choose the desired value from the **Policy** and **Privilege** drop-down lists.
5. Click **Apply to Device**.
6. Choose **Administration** > **Management** > **HTTP/HTTPS/Netconf**.
7. In the **HTTP/HTTPS Access Configuration** settings, enable or disable the **HTTP Access**, **HTTPS Access** and **Personal Identity Verification** toggle buttons.
8. Enter the **HTTP Port** and **HTTPS Port**.
9. Click **Apply**.

The global configuration is applied with the new user account created and HTTP/HTTPS access settings configured according to your specifications.

Verify wired guest configurations

Provides commands to verify wired guest configurations.

This reference provides commands to verify wired guest configurations and view guest-LAN details and client information.

To validate the wireless configuration, use this command:

```
Device# wireless config validate

Wireless Management Trustpoint Name: 'WLC-29c_WLC_TP'
        Trustpoint certificate type is WLC-SSC
    Wireless management trustpoint config is valid

Jan 22 07:49:15.371: %CONFIG_VALIDATOR_MESSAGE-5-EWLC_GEN_ERR: Chassis 1 R0/0:
 wncmgrd:
Error in No record found for VLAN 9, needed by Guest-LAN open-wired
```

To display the summary of all Guest-LANs, use this command:

```
Device# show guest-lan summary

Number of Guest LANs: 1

GLAN  GLAN Profile Name                  Status
-----------------------------------------------
1     wired_guest_open                   UP
```

To view the detailed output of all Guest-LANs, use this command:

```
Device# show guest-lan all

Guest-LAN Profile Name     : open
================================================
Guest-LAN ID                                  : 1
Wired-Vlan                                    : 200
Status                                        : Enabled
Number of Active Clients                      : 1
Max Associated Clients                        : 2000
Security
    WebAuth                                   : Enabled
    Webauth Parameter Map                     : global
    Webauth Authentication List               : LWA-AUTHENTICATION
    Webauth Authorization List                : LWA-AUTHENTICATION
```

To view the guest-LAN configuration by ID, use this command:

```
Device# show guest-lan id 1
Guest-LAN Profile Name     : open
================================================
Guest-LAN ID                                  : 1

Wired guest access use cases

Describes use cases for wired guest access.

Wired guest access use cases are network scenarios that utilize wired guest access functionality to meet specific operational requirements beyond standard guest network access.

Equipment software update scenario

Video streaming scenario

This feature can be configured to allow the wired port to connect to the manufacture or vendor website for equipment maintenance, software, or firmware updates.

This feature can be configured to allow devices that are connected to a wired port to stream video to visitor information screens.

220 Data Rate Selection at SSID Level

Topics:

- Legacy data rate selection at SSID level

Legacy data rate selection at SSID level

This section explains legacy data rate selection at SSID level.

Legacy data rate selection at SSID level is a wireless configuration feature that:

- allows the configuration of 802.11a/b/g (legacy) data rates per WLAN or Virtual AP (VAP)
- specifies the minimum bit rate to be used by each radio for a specific SSID, and
- ensures that the AP does not advertise rates lower than the configured minimum, even if those rates are enabled in the RF profile.

Previously, you managed legacy data rate configurations at the global or RF profile level. This feature provides granular control at the SSID level, which is useful for deployments requiring specific performance thresholds for different user groups or applications.

Bit rate defaults and ranges

The values to configure a legacy date rate in RF profile configuration depends on the frequency band:

- For 2.4 GHz, the default is 1 Mbps. The valid range is 1 to 54 Mbps.
- For 5 GHz, the default is 6 Mbps. The valid range is 6 to 54 Mbps.

> **Note**
>
> This configuration does not apply to the 6 GHz radio band.

Feature history for legacy data rate selection at SSID level

This section explains the feature history details of the legacy data rate selection at SSID level feature.

- This table provides release and related information for the feature explained in this module.
- This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 193: Feature history for legacy data rate selection at SSID level

Feature Name	Release Information	Feature Description
Legacy data rate selection at SSID level	Cisco IOS XE 26.1.1	SSID-level legacy data rate selection enables the customization of legacy 802.11a/b/g speeds for individual WLANs or Virtual APs. This feature enforces a minimum bit rate for each radio, ensuring the AP does not advertise any speeds below that threshold, even if those lower rates are permitted in the general RF profile.

Guidelines for legacy data rate selection

This section explains the guidelines for legacy data rate selection

Requirement: Radio band applicability

Ensure that minimum data rate configurations apply only to the 2.4 GHz and 5 GHz bands. This feature does not support or impact the 6 GHz radio band.

RF profile precedence

The minimum data rate configured at the SSID level acts as a threshold. The AP does not advertise legacy rates lower than this threshold, even if those rates are marked as supported or mandatory in the RF profile.

Mandatory rate alignment

At least one mandatory rate in the RF profile must be higher than the minimum data rate set for the SSID. If no mandatory rate is higher than the SSID minimum data rate, the configuration fails and an error appears.

Configure the minimum data rate (GUI)

Use this procedure to configure the minimum data rate using the GUI.

Set a minimum legacy bit rate threshold for a specific WLAN to control which data rates the AP advertises.

Use this task to ensure that clients can only connect using data rates above a specific threshold for a SSID. This setting overrides broader RF profile settings.

Before you begin

Make sure you have created and can access the WLAN. Determine the minimum bit rate that meets your use case to improve cell efficiency.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click the **WLAN Name** you want to configure, or click **Add** to create a new one.
3. In the **Edit WLAN** or **Add WLAN** window, click the **Advanced** tab.
4. Locate the **Minimum Data Rates At SSID Level** section.
5. From the **2.4 GHz Data Rate** and **5 GHz Data Rate** drop-down lists, select the desired minimum bit rate.
6. Click **Update & Apply to Device**.

The WLAN is updated with the new minimum data rate thresholds. The APs broadcasting this SSID now advertise legacy rates at or above the minimum values you set.

Configure the minimum data rate (CLI)

Use this procedure to configure the minimum data rate using commands.

Configure the minimum data rate for 2.4 GHz and 5 GHz radios on your WLAN using commands.

Minimum data rate settings control which devices connect to a WLAN and at what speeds. These settings help remove support for slower rates and improve throughput.

Before you begin

Make sure you can access the CLI on your wireless controller. Know your WLAN profile name, SSID, and preferred data rate values for 2.4 GHz and 5 GHz radios.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN network and enter the WLAN profile name.

   Example

   ```
   Device(config)# wlan (default-wlan-profile)
   ```

   You can use up to 32 alphanumeric characters for the WLAN profile name.

3. Create WLAN identifier and enter the SSID (network) name.

   Example

   ```
   Device(config)# wlan (default-wlan-profile) <1-4096> SSID50
   ```

   The valid WLAN identifier range is 1 to 4096. You can use up to 32 alphanumeric characters for the SSID name.

4. Configure 802.11 parameters.

   Example

   ```
   Device(config-wlan)# dot11
   ```

5. Configure 802.11a and 802.11b parameters and data rates.

   Example

   ```
   Device(config-wlan)# dot11 5ghz data-rate
   ```

   ```
   Device(config-wlan)# dot11 24ghz data-rate
   ```

6. Configure minimum data rate and set the minimum data rate for 2.4 GHz and 5 GHz radios.

   Example

   ```
   Device(config-wlan)# dot11 24ghz data-rate min RATE_9M
   ```

   ```
   Device(config-wlan)# dot11 5ghz data-rate min RATE_12M
   ```

   The minimum data rate for 2.4 GHz radio is 9 Mbps. The minimum data rate for 5 GHz radio is 12 Mbps.

7. Exit the global configuration mode.

Example

```
Device(config-wlan)# end
```

Verify RF profile and radio slot status

This section provides how to verify RF profile and radio slot status details.

Use this command to verify if the RF profile is assigned to the radio and to also check the radio slot status.

- **show ap rf-profile summary**

To verify if the RF profile is assigned to the radio and to also check the radio slot status, enter this command from the console:

```
Device# show ap rf-profile summary

Number of RF-profiles: 17
RF Profile Name                  Band     Description
  State
------------------------------------------------------------------------------------

```

221 User Defined Network

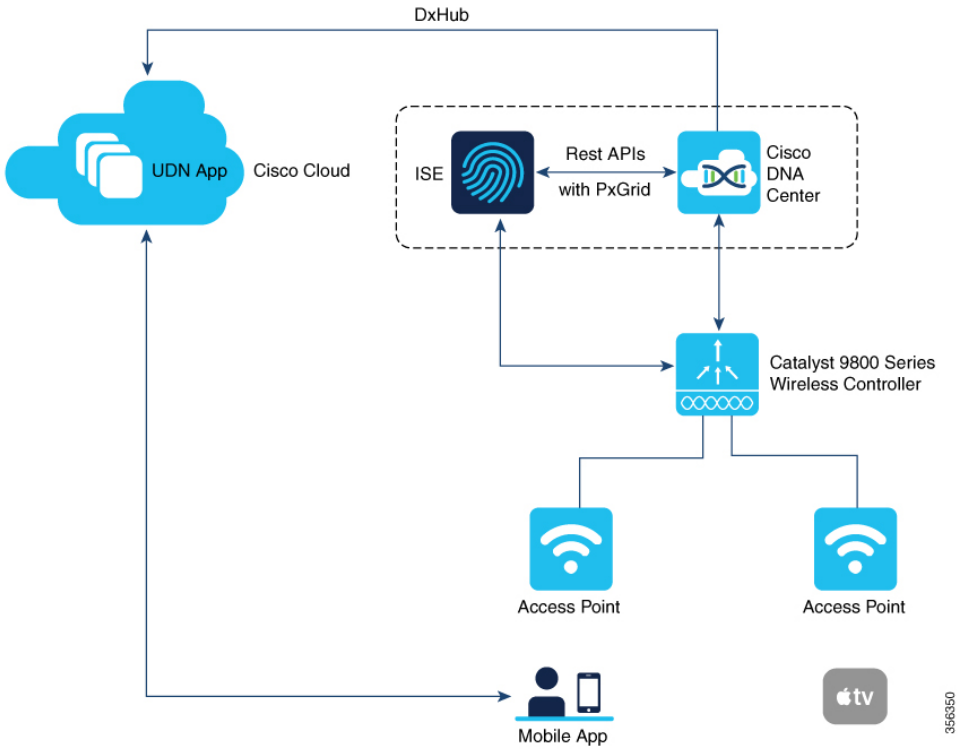
Topics:

- User defined networks

Introduces User Defined Network capabilities, allowing administrators to create customized network topologies and configurations tailored to specific organizational requirements.

User defined networks

Describes a solution that provides secure and remote on-boarding of devices in shared service environments.



A user defined network (UDN) is a solution that

- provides secure and remote on-boarding of devices in shared service environments like dormitory rooms, resident halls, class rooms and auditoriums
- allows users to securely use Simple Discovery Protocols (SDP) like Apple Bonjour and mDNS-based protocols (Air Play, Air Print, Screen Cast, Print, and so on.), and UPnP based protocols to interact and share information with only their registered devices in a shared environment, and
- enables the users to share their devices and resources with friends and roommates securely.

UDN solution features

The UDN solution provides an easy way to create a virtual segment that allows user to create a private segment to add their devices. Traffic (unicast, non-Layer 3 multicast, or broadcast) to these devices can be seen only by other devices and users in the private segment. This feature also eliminates the security concern where users knowingly or unknowingly take control of devices that belong to other users in a shared environment. As of now, the UDN is supported only in local mode.

Figure 39: User defined network topology

The User Defined Network solution workflow includes the following steps:

1. User Defined Network is enabled on the controller, using policy profile, and the policy configuration is pushed to all the WLANs on a site.
2. User Defined Network association is automatically generated by the UDN cloud service and is inherited by all the devices belonging to an user.

3. Users can add or modify devices to the User Defined Network assigned to them by using a web portal or a mobile application. Users can also add devices to another User Defined Network, if they are invited to join that User Defined Network.
4. The controller is updated with the client or resource information assigned to the User Defined Network.

> **Note**
>
> Cisco Identity Services Engine (ISE) policy infrastructure is not used to update User Defined Network information. Whenever, there is a change in the User Defined Network, the ISE updates the controller with an explicit or a separate Change of Authorization (CoA) containing only the change of the User Defined Network ID.

Restrictions for User Defined Network

Outlines restrictions and limitations for User Defined Network feature implementation and deployment.

Consider these restrictions when implementing User Defined Network:

- A user can be associated to only one UDN. Roaming across controllers is not supported.
- This feature is not applicable for Cisco Mobility Express and Cisco AireOS platforms. Hence, IRCM is not supported.
- This feature is supported only in local mode on the Wave 2 access points and Cisco Catalyst 9100 series access points.
- This feature is supported only for centrally switched SSIDs.
- This feature is not supported for Flex mode APs, Fabric SSIDs, Guest Anchor scenario, Layer 2 and Layer 3 roaming.
- Layer 3 multicast (except SSDP/UPnP) containment using UDN is not supported, L3 multicast will continue to work as it is today.
- It is not recommended to enable user-defined **drop unicast** option in GUI if UDN is disabled.
- It is recommended to disable UDN from policy profile in SSIDs when integrating UDN+ solution with Cisco exclusive partner Splash Access.

  > **Note**
  >
  > The UDN+ simplifies the solution and brings the same unique user experience for both Meraki and Cisco Catalyst 9800 Series Wireless Controller based deployments.

- For user defined network plus deployments, do not configure **peer-blocking drop** or **peer-blocking allow-private-group** on the WLAN used for UDN. These settings can prevent UDN from functioning.

  For user defined network plus deployments, do not configure **user-defined-network drop-unicast** in the wireless policy profile. This setting can prevent UDN from functioning, even when peer blocking is not configured.

Configure a user defined network (CLI)

Configure a user defined network to enable site-based policy enforcement across WLANs with mDNS filtering based on UDN-ID.

Deploy user defined network configuration to enforce policies across all clients or devices in a network for a site.

The User Defined Network configuration is site based and is added as part of a policy profile. When applied, the policy is enforced to all the clients or devices in a network for a site, across WLANs. When enabled, the policy profile also enforces the filtering of mDNS queries based on the UDN-ID.

Before you begin

- RADIUS server should be configured for the UDN solution to work.
- Configure **aaa-override** in the policy profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a policy profile.

   Example

   ```
   Device(config)# wireless profile policy profile-name
   ```

   ```
   Device(config)# wireless profile policy policy-wpn
   ```

   profile-name is the profile name of the policy profile.

3. Enable user defined private-network.

   Example

   ```
   Device(config-wireless-policy)# user-defined-network
   ```

4. Set action to drop unicast traffic.

   Example

   ```
   Device(config-wireless-policy)# user-defined-network drop-unicast
   ```

   By default, unicast traffic is allowed across UDN.

   > ⚠ **Caution**
   >
   > If you enable **user-defined-network drop-unicast**, it can disrupt UDN operation and affect client connectivity.

5. Exit to global configuration mode.

Example

```
Device(config-wireless-policy)# exit
```

6. Configure a remote LAN policy profile.

Example

```
Device(config)# ap remote-lan-policy policy-name policy-name
```

```
Device(config)# ap remote-lan-policy policy-name policy-wpn
```

7. Enable user defined private-network for remote LAN policy.

Example

```
Device(config-remote-lan-policy)# user-defined-network
```

8. Set action to drop unicast traffic for remote LAN policy.

Example

```
Device(config-remote-lan-policy)# user-defined-network drop-unicast
```

The user defined network is configured with both wireless policy profile and remote LAN policy, enabling site-based enforcement and mDNS filtering based on UDN-ID across all network clients.

Configure a user defined network (GUI)

Configure a user defined network using GUI.

Configure a user defined network to enable a user personal network and control unicast traffic behavior.

Use this procedure when you need to enable user defined networks and configure unicast traffic handling through the GUI interface.

Procedure

---

1. Choose **Configuration > Tags & Profiles > Policy**.
2. In the **Policy Profile** window, select a policy profile.
3. In the **Edit Policy Profile** window, click the **Advanced** tab.
4. In the **User Defined Network** section, check the **Status** check box to enable a user personal network.
5. Check the **Drop Unicast** check box to set the action to Drop Unicast traffic.

   By default, unicast traffic is not contained.

The user defined network is configured with the specified unicast traffic handling settings.

Verify user defined network configuration

Lists commands to verify user defined network configuration status and client information.

Use the commands in this reference to verify the status of the User Defined Network (UDN) feature, view client UDN information, check UDN payloads, and examine mDNS service instances for private networks.

To view the status of the UDN feature (either enabled or disabled) and also information about the drop unicast flag, use this command:

```
Device# show wireless profile policy detailed default-policy-profile

User Defined (Private) Network                : Enabled
User Defined (Private) Network Unicast Drop   : Enabled
```

To view the name of the UDN to which the client belongs, use this command:

```
Device# show wireless client mac-address 00:0d:ed:dd:35:80 detailed

User Defined (Private) Network : Enabled
User Defined (Private) Network Drop Unicast : Enabled
               Private group name: upn*group*7
               Private group id : 7777
               Private group owner: 1
               Private group name: upn*group*7
               Private group id : 7777
               Private group owner:
```

To view the UDN payload sent from an AP to the controller, use this command:

```
Device# show wireless stats client detail | inc udn

Total udn payloads sent                           : 1
```

When mDNS gateway is enabled on the controller, the mDNS services are automatically filtered based on the user private network ID for all the clients on the WLANs where user private network is enabled.

To view the service instances of a private network, use this command:

```
Device# show mdns-sd cache udn 7777 detail

Name: _services._dns-sd._udp.local
  Type: PTR
  TTL: 4500
  WLAN: 2
  WLAN Name: mdns-psk
  VLAN: 16
  Client MAC: f4f9.51e2.a6a6
  AP Ethernet MAC: 002a.1087.d68a
  Remaining-Time: 4486
  Site-Tag: default-site-tag
  mDNS Service Policy: madhu-mDNS-Policy
  Overriding mDNS Service Policy: NO
  UDN-ID: 7777
  UDN-Status: Enabled
  Rdata: _airplay._tcp.local
.
.
.
```

To view the service instances that are learnt from a shared UDN ID, use this command:

```
Device# show mdns-sd cache udn shared
```

```

To view the multicast DNS (mDNS) Service Discovery cache detail, use this command:

```
Device# show mdns-sd cache detail

Name: _printer._tcp.local
  Type: PTR
  TTL: 4500
  VLAN: 21
  Client MAC: ace2.d3bc.047e
  Remaining-Time: 4383
  mDNS Service Policy: default-mdns-service-policy
  Rdata: HP OfficeJet Pro 8720 [BC047E] (2)._printer._tcp.local
```

222 Hotspot 2.0

Topics:

- Hotspot 2.0

Hotspot 2.0

Explains the Hotspot 2.0 feature that enables IEEE 802.11 devices to interwork with external networks.

Hotspot 2.0 is a network interworking feature that

- enables IEEE 802.11 devices to interwork with external networks
- provides network discovery and selection services, and
- allows mobile devices to join Wi-Fi networks automatically, including during roaming.

Hotspot 2.0 components

The Hotspot 2.0 feature has four distinct parts:

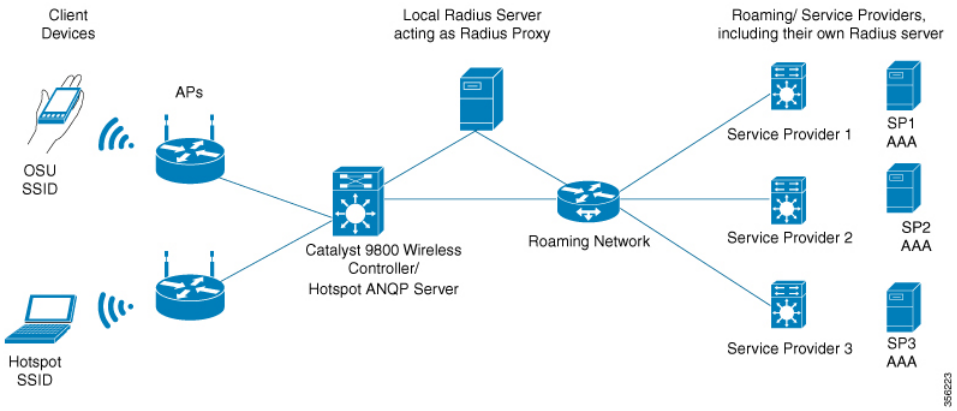
- Hotspot 2.0 Beacon Advertisement: Allows a mobile device to discover Hotspot 2.0-compatible and 802.11u-compatible WLANs.
- Access Network Query Protocol (ANQP) Queries: Sends queries about the networks from IEEE 802.11 devices, such as network type (private or public); connectivity type (local network, internet connection, and so on), or the network providers supported by a given network.
- Online Sign-up: Allows a mobile device to obtain credentials to authenticate itself with the Hotspot 2.0 or WLAN.
- Authentication and Session Management: Provides authentication (802.1x) and management of the STA session (session expiration, extension, and so on).

Hotspot 2.0, also known as HS2 and Wi-Fi Certified Passpoint, is based on the IEEE 802.11u and Wi-Fi Alliance Hotspot 2.0 standards. It seeks to provide better bandwidth and services-on-demand to end users.

The interworking service aids network discovery and selection, enabling information transfer from external networks. It provides information to the stations about the networks before association.

Interworking not only helps users within the home, enterprise, and public access domains, but also assists manufacturers and operators to provide common components and services for IEEE 802.11 customers. These services are configured on a per-WLAN basis on the Cisco Wireless Controller (controller).

In order to mark a WLAN as Hotspot 2.0-compatible, the 802.11u-mandated information element and the Hotspot 2.0 information element is added to the basic service set (BSS) beacon advertised by the corresponding AP, and in WLAN probe responses.



Note

The Hotspot 2.0 feature supports only local mode or FlexConnect mode (central switching and central authentication).

FlexConnect local switching is only supported when the Open Roaming configuration template is set up using the **wireless hotspot ANQP-server** *server-name* **type open-roaming** command. If the configuration diverges from this template, FlexConnect local switching will not be supported.

This figure shows a standard deployment of the Hotspot 2.0 network architecture:

Figure 40: Hotspot 2.0 Deployment Topology

Hotspot 2.0 enhancements

From Cisco IOS XE Amsterdam 17.3.1, the Hotspot 2.0 feature has been enhanced with these options:

- New ANQP elements:
  - Advice of charge: Provides information on the financial charges for using the SSID of the NAI realm
  - Operator icon metadata
  - Venue URL: Defines an optional URL for each of the configured venue names
- Introduction of Terms and Conditions: This requires a user to accept certain Terms and Conditions before being allowed internet access, after connecting to a Hotspot SSID.
- Integration of OSEN security and WPA2 security on the same SSID.

From Cisco IOS XE Amsterdam 17.3.1 onwards, two encryption methods are supported on a single SSID, namely WPA2 802.1x for Hotspot 2.0 and OSEN for online sign-up. Based on the type of encryption selected during client association, the client will be put on Hotspot 2.0 VLAN or online sign-up VLAN.

In WPA2 802.1x authentication, a client should match the credentials provisioned on a device. In online sign-up, a service provider WLAN is used by a client to perform online sign-up. For Hotspot 2.0 SSIDs, the RADIUS server enforces the terms and conditions before allowing internet connectivity to clients.

This release also supports OSEN-specific VLAN in a policy profile. If an OSEN VLAN is defined in a policy profile, OSEN clients are added to the VLAN. Otherwise, clients are added to the regular policy profile VLAN or to the default VLAN. If OSEN is enabled with WPA2 on an SSID, it is mandatory to define an OSEN VLAN in the policy profile. Otherwise, clients cannot join the VLAN.

In FlexConnect mode, if an OSEN VLAN is defined in a policy profile, the same VLAN needs to be added to the flex profile. Failing to do so excludes the clients from the VLAN.

Note

When Hotspot 2.0 is enabled in a WLAN, the Wi-Fi direct clients that support cross-connect feature should not be allowed to associate to the Hotspot 2.0 WLAN. To make sure this policy is enforced, ensure that the following configuration is in place:

```
wlan <wlan-name> <wlan-name> <ssid>
wifi-direct policy xconnect-not-allow
```

Restrictions

- Clients are excluded if an OSEN VLAN is not added to a flex profile.
- In FlexConnect mode, clients are excluded if an OSEN VLAN is not added in a flex profile.
- In FlexConnect deployments, the URL filter should reference an existing URL filter (configured using the **urlfilter list** *urlfilter-name* command). Otherwise, a client is added to the excluded list, after authentication.
- Only central authentication is supported.
- Fragmented ANQP replies are not synchronized to the standby controller in high-availability mode. Therefore, clients have to re-issue a query if there is a switchover.

Open roaming

Describes a configuration feature that enables mobile users to automatically and seamlessly roam across Wi-Fi and cellular networks.

Open roaming is a configuration feature that

- enables mobile users to automatically and seamlessly roam across Wi-Fi and cellular networks
- simplifies the task of setting up a Hotspot 2.0 ANQP server with a new configuration template, and
- is supported from Cisco IOS XE Amsterdam Release 17.2.1 on the controller.

Open roaming configuration options

When you configure open roaming, fixed ANQP parameters are automatically populated.

You can configure different identity types by defining roaming organizational identifiers. The organizational unique identifier (OUI) is a three-octet number that identifies the type of organizations available in a given roaming consortium. The OUI list determines the type of identities allowed to roam into the network. The default configuration allows all the identities on the access network. However, access networks can customize the Roaming Consortium Organization Identifier (RCOI) they advertise.

You can configure three types of policies for access networks:

- **Allow all**: Accepts users from any identity provider (IDP), with any privacy policy.
- **Real ID**: Accepts users from any IDP, but only with a privacy policy that shares real identity (anonymous not accepted).
- **Custom**: Accepts users of select identity types and privacy policies associated with the identity types; basically all the other RCOIs.

Users can select the following privacy modes:

- Anonymous
- Share real identity

The list of currently defined organizational identifiers and their aliases are given in the following table.

Table 194: Roaming organizational identifiers and aliases

Description	Roaming Organizational Identifier	WBA Value	Display Name
All	004096	5A03BA0000	All
All with real ID	00500b	5A03BA1000	All with real-ID only

SP paid Gold QoS real ID	-	BAA2D05100	SP paid Gold QoS real ID
Government ID free	-	5A03BA0400	Government ID free

Description	Roaming Organizational Identifier	WBA Value	Display Name
Automotive ID free	-	5A03BA0500	Automotive ID free
Automotive Paid	-	BAA2D00500	Automotive Paid
Education or Research ID free	-	5A03BA0800	Education or Research ID free
Cable ID free	-	5A03BA0900	Cable ID free

Configure Hotspot 2.0

Configure an access network query protocol server (CLI)

Configure an access network query protocol server.

Set up an Access Network Query Protocol (ANQP) server to define and advertise services offered by an AP at Wi-Fi Hotspot 2.0 locations.

The Access Network Query Protocol Server (ANQP) is a query and response protocol that defines the services offered by an AP, usually at a Wi-Fi Hotspot 2.0.

> **Note**
>
> When configuring roaming-OI in the ANQP server, ensure that you set the **beacon** keyword for at least one roaming-OI, as mandated by the 802.11u standard.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Hotspot 2.0 ANQP server.

   Example

   ```
   Device(config)# wireless hotspot anqp-server server-name
   ```

   Example

   ```
   Device(config)# wireless hotspot anqp-server my_server
   ```

3. Add a description for the ANQP server.

Example

```
Device(config-wireless-anqp-server)# description description
```

Example

```
Device(config-wireless-anqp-server)# description "My Hotspot 2.0"
```

4. Configure a 802.11u Third Generation Partnership Project (3GPP) cellular network.

   Example

   ```
   Device(config-wireless-anqp-server)# 3gpp-info mobile-country-code
   mobile-network-code
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# 3gpp-info us mcc
   ```

   The *mobile-country-code* should be a 3-digit decimal number. The *mobile-network-code* should be a 2-digit or 3-digit decimal number.

5. Configure the ANQP reply fragmentation threshold, in bytes.

   Example

   ```
   Device(config-wireless-anqp-server)# anqp fragmentation-threshold
   threshold-value
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# anqp fragmentation-threshold 100
   ```

   The ANQP protocol can be customized by setting the fragmentation threshold, after which the ANQP reply is split into multiple messages.

   > **Note**
   >
   > We recommend that you use the default values for the deployment.

6. Configure the Hotspot 2.0 ANQP domain identifier.

   Example

   ```
   Device(config-wireless-anqp-server)# anqp-domain-id domain-id
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# anqp-domain-id 100
   ```

7. Configure the 802.11u network authentication type.

   Example

   ```
   Device(config-wireless-anqp-server)# authentication-type {dns-redirect |
   http-https-redirect | online-enrollment | terms-and-conditions}
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# authentication-type online-enrollment
   ```

   Depending on the authentication type, a URL is needed for HTTP and HTTPS.

8. Configure the Hotspot 2.0 protocol and port capabilities.

   Example

   ```
   Device(config-wireless-anqp-server)# connection-capability ip-protocol
   port-number {closed|open|unknown}
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# connection-capability 12 40 open
   ```

   Note

   Hotspot 2.0 specifications require that you predefine some open ports and protocols. Ensure that you meet these requirements in order to comply with the Hotspot 2.0 specifications. See the **connection-capability** command in the *Cisco Catalyst 9800 Series Wireless Controller Command Reference* document for a list of open ports and protocols.

9. Configure an 802.11u domain name.

   Example

   ```
   Device(config-wireless-anqp-server)# domain domain-name
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# domain my-domain
   ```

   You can configure up to 32 domain names. The *domain-name* should not exceed 220 characters.

10. Configure an 802.11u IPv4 address type in the Hotspot 2.0 network.

    Example

    ```
    Device(config-wireless-anqp-server)# ipv4-address-type ipv4-address-type
    ```

Example

```
Device(config-wireless-anqp-server)# ipv4-address-type public
```

11. Configure an 802.11u IPv6 address type in the Hotspot 2.0 network.

Example

```
Device(config-wireless-anqp-server)# ipv6-address-type ipv6-address-type
```

Example

```
Device(config-wireless-anqp-server)# ipv6-address-type available
```

12. Configure an 802.11u NAI realm profile that identifies the realm that is accessible using the AP.

Example

```
Device(config-wireless-anqp-server)# nai-realm realm-name
```

Example

```
Device(config-wireless-anqp-server)# nai cisco.com
```

13. Configure a Hotspot 2.0-operating class identifier.

Example

```
Device(config-wireless-anqp-server)# operating-class class-id
```

Example

```
Device(config-wireless-anqp-server)# operating-class 25
```

14. Configure a Hotspot 2.0 operator-friendly name in a given language.

Example

```
Device(config-wireless-anqp-server)# operator operator-name language-code
```

Example

```
Device(config-wireless-anqp-server)# operator XYZ-operator eng
```

Use only the first three letters of the language, in lower case, for the language code. For example, use *eng* for English.

To see the full list of language codes, go to: http://www.loc.gov/standards/iso639-2/php/code_list.php.

> **Note**
>
> You can configure only one operator per language.

15. Configure the SSID that wireless clients will use for OSU.

Example

```
Device(config-wireless-anqp-server)# osu-ssid SSID
```

Example

```
Device(config-wireless-anqp-server)# osu-ssid test
```

The SSID length can be up to 32 characters.

16. Configure the 802.11u roaming organization identifier.

Example

```
Device(config-wireless-anqp-server)# roaming-oi OI-value [beacon]
```

Example

```
Device(config-wireless-anqp-server)# roaming-oi 24 beacon
```

If the **beacon** keyword is specified, the roaming OUI is advertised in the AP WLAN beacon or probe response. Otherwise, it will only be returned while performing the roaming OUI ANQP query.

> **Note**
>
> The hex string of a roaming OUI should contain only lowercase letters.

17. Configure the 802.11u venue information.

Example

```
Device(config-wireless-anqp-server)# venue venue-name language-code
```

Example

```
Device(config-wireless-anqp-server)# venue bank eng
```

The *venue-name* should not exceed 220 characters and the *language-code* should only be 2 or 3 lowercase letters (a-z) in length.

The ANQP server is configured and will advertise the specified network services and capabilities to wireless clients performing 802.11u queries at the Hotspot 2.0 location.

Configure ANQP global server settings (GUI)

Configure ANQP global server settings using the GUI interface.

Configure ANQP (Access Network Query Protocol) global server settings to define network parameters and connection types for wireless hotspot services.

Use this procedure to configure global server settings for ANQP, which enables wireless clients to discover network services and connection information before associating with the access point.

Procedure

1. Choose **Configuration > Wireless > Hotspot/OpenRoaming**.
2. Select an existing server from the list of servers.
3. Click the **Server Settings** tab.
4. Go to the **Global Server Settings** section.
5. From the **IPv4 Type** drop-down list, choose an IPv4 type.
6. From the **IPv6 Type** drop-down list, choose an IPv6 type.
7. In the **OSU SSID** field, enter the SSID that wireless clients will use for Online Sign-Up (OSU).
8. Click the **Show Advanced Configuration** link to view the advanced options.
   - In the **Fragmentation Threshold (bytes)** field, enter the fragmentation threshold.

     Note

     Packets that are larger than the size you specify here will be fragmented.

   - In the **GAS Request Timeout (ms)** field, enter the number of Generic Advertisement Services (GAS) request action frames sent that can be sent to the controller by an AP in a given interval.
9. Click **Apply to Device**.

The ANQP global server settings are configured and applied to the device. Wireless clients can now query the access point for network information using the configured parameters.

Configure open roaming (CLI)

Configure open roaming using commands.

Set up a Hotspot 2.0 ANQP server with open roaming configuration to enable seamless wireless connectivity across participating networks.

The new configuration template of the open roaming ANQP server simplifies the task of setting up a Hotspot 2.0 ANQP server. When you configure open roaming using this template, default ANQP parameters are automatically populated. The default values defined in the template always override any user-defined configuration values.

For example, these are the default values enforced with the type open-roaming template:

- nai-realm open.openroaming.org

- eap-method eap-tls
- eap-method eap-ttls
- inner-auth-non-eap mschap-v2
- inner-auth-non-eap pap
- eap-method eap-aka

You can add more fields to the existing template, but ensure that they do not overlap with the existing default values. Also, if you change any of these default values, you will need to re-configure every time you enter in ANQP type open-roaming config.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Hotspot 2.0 ANQP server with open roaming.

   Example

   ```
   Device(config)# wireless hotspot anqp-server server-name type open-roaming
   ```

   Example

   ```
   Device(config)# wireless hotspot anqp-server my-server type open-roaming
   ```

3. Set the open roaming element alias.

   Example

   ```
   Device(config-wireless-anqp-server)# open-roaming-oi alias
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# open-roaming-oi allow-all
   ```

4. Configure a preferred domain name to ensure that clients roam into a preferred network.

   Example

   ```
   Device(config)# domain domain-name
   ```

   Example

   ```
   Device(config)# domain my-domain
   ```

You can configure up to 32 domain names. The domain-name should not exceed 220 characters.

The open roaming ANQP server is configured with the specified settings, enabling clients to seamlessly roam across participating open roaming networks.

Configure open roaming (GUI)

Configure open roaming using GUI.

Configure an ANQP server as an open roaming server to enable seamless connectivity for users across different networks without requiring separate authentication credentials.

Use this procedure when you need to set up open roaming functionality through the GUI interface to allow automatic network access for compatible devices.

Procedure

---

1. Choose **Configuration > Wireless > Hotspot/OpenRoaming**.
2. Click **Add**.

   The **Add New ANQP Server** window is displayed.
3. In the **Name** field, enter a name for the server.
4. In the **Description** field, enter a description for the server.
5. Check the **OpenRoaming Server** check box to use the server as an open roaming server.

   > **Note**
   >
   > You can set the server as an open roaming server only at the time of server creation.

6. Check the **Internet Access** check box to enable internet access for the server.
7. From the **Network Type** drop-down list, choose the network type.
8. Click **Apply to Device**.

The ANQP server is configured as an open roaming server and applied to the device, enabling seamless network access for compatible client devices.

Configure NAI realms (GUI)

Configure NAI realms using the GUI to define authentication parameters for OpenRoaming networks.

Configure NAI realms to define Network Access Identifier realms for OpenRoaming authentication, specifying supported EAP methods and credential types for wireless clients.

NAI realms are used in 802.11u networks to specify authentication parameters and supported EAP methods for network access. This configuration is essential for OpenRoaming implementations where clients need to understand available authentication options.

Procedure

---

1. Choose **Configuration > Wireless > Hotspot/OpenRoaming**.

2. Select an existing server from the list of servers.
3. Go to the **NAI Realms** section.
4. Click **Add**.

   The **Add NAI Realm** window is displayed.

5. In the **NAI Realm Name** field, enter an 802.11u NAI realm of the OSU operator.
6. In the **EAP Methods** section, use the toggle button to enable the required EAP methods.

   After an EAP method is enabled, a pane is displayed to configure the details. Users are shown a configuration section where they can enable *credential*, *inner-auth-EAP*, *inner-auth-non-EAP*, *tunneled-EAP-credential*. The user can select multiple options for each of the configuration.

   - The **Credential** window has options such as certificate, hw-token, nfc, none, sim, softoken, username-password, and usim. Check the corresponding check box.
   - The **inner-auth-EAP** window has options such as EAP-aka, EAP-fast, EAP-sim, EAP-tls, EAP-ttls, EAP-leap, and EAP-peap. Check the corresponding check box.
   - The **inner-auth-EAP** window has options such as EAP-aka, EAP-fast, EAP-sim, EAP-tls, EAP-ttls, EAP-leap, and EAP-peap. Check the corresponding check box.
   - The **tunneled-EAP-credential** window has options such as anonymous, certificate, hw-token, nfc, sim, softoken, username-password, and usim. Check the corresponding check box.
   - Click **Save**.

7. Click **Apply to Device**.

The NAI realm is configured with the specified authentication methods and applied to the device, enabling OpenRoaming clients to identify supported authentication options for network access.

Configure organizational identifier alias (GUI)

Configure organizational identifier alias using the GUI to enable roaming organization identifiers and domain names for hotspot and OpenRoaming functionality.

Configure organizational identifier alias to enable proper roaming functionality and domain management for wireless hotspot and OpenRoaming services.

Use this procedure when you need to set up roaming organization identifiers and domain names for wireless hotspot or OpenRoaming configurations through the graphical user interface.

Procedure

---

1. Choose **Configuration > Wireless > Hotspot/OpenRoaming**.
2. Select an existing server from the list of servers.
3. In the **Roaming OIs** area, enter an 802.11u roaming organization identifier in the **Roaming OI** field.
4. Check the **Beacon State** check box to enable the beacon.

   If the beacon is specified, the roaming OUI is advertised in the AP WLAN beacon or probe response. Otherwise, it will only be returned while performing the roaming OUI ANQP query.

> **Note**
>
> Only three OUIs can be enabled in the beacon state.

5. Click **Add** to add a roaming OI.
6. In the **Available OpenRoaming OI** window, select an organizational identifier and click the right arrow to add an **OpenRoaming OI**.
7. In the **Domains** area, enter an 802.11u domain name in the **Domain Name** field.
8. Click **Add** to use the domain name that you have entered as the preferred domain.
9. Click **Apply to Device**.

The organizational identifier alias is configured with the specified roaming OIs and domain names. The configuration is applied to the device and roaming functionality is enabled for the wireless hotspot or OpenRoaming service.

Configure WAN metrics (GUI)

Configure WAN metrics using the GUI to set downlink and uplink parameters for hotspot servers.

Configure WAN metrics to define network performance parameters including downlink load, downlink speed, upload load, upload speed, and link status for hotspot servers.

WAN metrics configuration allows you to specify network performance characteristics that affect how the hotspot server manages wireless connections and traffic flow.

Procedure

---

1. Choose **Configuration > Wireless > Hotspot/OpenRoaming**.
2. Select an existing server from the list of servers.
3. Click the **Server Settings** tab.
4. Go to the **WAN Metrics** area.
5. In the **Downlink Load** field, enter the WAN downlink load.
6. In the **Downlink Speed (kbps)** field, enter the WAN downlink speed, in kbps.
7. In the **Load Duration (100ms)** field, enter the load duration.
8. In the **Upload Load** field, enter the WAN upload load.
9. In the **Upload Speed (kbps)** field, enter the WAN upload speed, in kbps.
10. From the **Link Status** drop-down list, choose the link status.
11. Use the **Full Capacity Link** toggle button to enable the WAN link to operate at its maximum capacity.
12. Click **Apply to Device**.

The WAN metrics configuration is applied to the selected hotspot server, and the network performance parameters are updated according to your specified settings.

Configure WAN metrics

Configure WAN metrics using commands.

Set up Wide Area Network (WAN) parameters such as uplink and downlink speed, link status, and load for Hotspot 2.0 ANQP server configuration.

This procedure shows you how to configure the Wide Area Network (WAN) parameters such as uplink and downlink speed, link status, load, and so on.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Hotspot 2.0 ANQP server.

   Example

   ```
   Device(config)# wireless hotspot anqp-server server-name
   ```

   Example

   ```
   Device(config)# wireless hotspot anqp-server my_server
   ```

3. Configure the WAN downlink load.

   Example

   ```
   Device(config-wireless-anqp-server)# wan-metrics downlink-load load-value
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# wan-metrics downlink-load 100
   ```

4. Configure the WAN downlink speed, in kbps.

   Example

   ```
   Device(config-wireless-anqp-server)# wan-metrics downlink-speed speed
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# wan-metrics downlink-speed 1000
   ```

5. Configure the WAN link to operate at its maximum capacity.

   Example

   ```
   Device(config-wireless-anqp-server)# wan-metrics full-capacity-link
   ```

6. Set the WAN link status.

Example

```
Device(config-wireless-anqp-server)# wan-metrics link-status
{down|not-configured|test-state|up}
```

Example

```
Device(config-wireless-anqp-server)# wan-metrics link-status down
```

7. Configure the uplink or downlink load measurement duration.

Example

```
Device(config-wireless-anqp-server)# wan-metrics load-measurement-duration
duration
```

Example

```
Device(config-wireless-anqp-server)# wan-metrics
load-measurement-duration 100
```

8. Configure the WAN uplink load.

Example

```
Device(config-wireless-anqp-server)# wan-metrics uplink-load load-value
```

Example

```
Device(config-wireless-anqp-server)# wan-metrics uplink-load 100
```

9. Configure the WAN uplink speed, in kbps.

Example

```
Device(config-wireless-anqp-server)# wan-metrics uplink-speed speed
```

Example

```
Device(config-wireless-anqp-server)# wan-metrics uplink-speed 1000
```

The WAN metrics are now configured for the Hotspot 2.0 ANQP server with the specified parameters for network performance monitoring and reporting.

Configure beacon parameters (GUI)

Configure beacon parameters using the GUI interface to set up hotspot and OpenRoaming settings for wireless networks.

This task allows you to configure beacon parameters for hotspot and OpenRoaming functionality on wireless networks, including setting the homogenous extended service set identifier, domain identifier, and venue information.

Use this procedure when you need to establish beacon parameters for wireless hotspot services or OpenRoaming configurations through the web-based GUI interface.

Procedure

1. Choose **Configuration > Wireless > Hotspot/OpenRoaming**.
2. Select an existing server from the list of servers.
3. Click **Server Settings** tab.
4. Go to the **Beacon Parameters** section.
5. In the **Hess ID** field, enter the homogenous extended service set identifier. The Hess ID can be either in *xx:xx:xx:xx:xx:xx*, *xx-xx-xx-xx-xx-xx*, or *xxxx.xxxx.xxxx* format.
6. In the **Domain ID** field, enter the domain's identifier.
7. From the **Venue Type** drop-down list, select the venue.

   Choosing a venue activates the subvenue type.
8. From the **subvenue-type** drop-down list, select the sub-venue.
9. Click **Apply to Device**.

The beacon parameters are configured and applied to the device. The wireless network will now broadcast the specified hotspot and OpenRoaming configuration settings.

Configure authentication and venue (GUI)

Configure authentication and venue using the GUI.

Configure authentication types, venue details, and connection capabilities for Hotspot/OpenRoaming services through the wireless controller GUI.

Use this procedure to set up authentication methods, venue information, and connection capabilities for wireless hotspot services. This configuration ensures compliance with Hotspot 2.0 specifications and provides proper authentication and venue identification for wireless clients.

Procedure

1. Choose **Configuration > Wireless > Hotspot/OpenRoaming**.
2. Select an existing server from the list of servers.
3. Click the **Authentication/Venue** tab.
4. Under the **Network Auth Types** section, check the **DNS Redirect**, **Online Enrolment**, **HTTP/HTTPS Redirect**, **Terms and Conditions** check boxes.

   For **HTTP/HTTPS Redirect** and **Terms and Conditions**, the URL field is enabled after selecting them.
5. Add the URL for the corresponding authentication type.
6. Click **Apply**.
7. Go to the **Venues** section and click **Add**.

   The **Venue Details** pane is displayed.
8. In the **Language Code** field, enter the language code.

   Use the first two or three letters of the language, in lower case, for the language code. For example, use *eng* for English. To see the full list of language codes, go to: http://www.loc.gov/standards/iso639-2/php/code_list.php.
9. In the **Venue URL** field, enter the URL of the venue.

10. In the **Venue Name** field, enter the name of the venue.
11. Click check mark icon to add the venue details.
12. Go to the **Connection Capability** section and click **Add**.

    The **Connection Capabilities** pane is displayed. See the **connection-capability** command in the *Cisco Catalyst 9800 Series Wireless Controller Command Reference* document for a list of open ports and protocols.

13. In the **Port Number** field, enter the port number.
14. From the **Connection Status** drop-down list, choose a connection status.
15. In the **IP Protocol** field, enter the IP protocol number.

    Hotspot 2.0 specifications require that you predefine some open ports and protocols. Ensure that you meet these requirements in order to comply with the Hotspot 2.0 specifications. See the **connection-capability** command in the *Cisco Catalyst 9800 Series Wireless Controller Command Reference* document for a list of open ports and protocols.

16. Click the check mark icon to add the connection details.
17. Click **Apply to Device**.

The authentication types, venue details, and connection capabilities are configured and applied to the wireless controller. The hotspot service is now configured with the specified authentication methods and venue information.

Configure 3GPP/operator (GUI)

Configure 3GPP/operator using the GUI interface.

This task allows you to configure 3GPP cellular networks and Hotspot 2.0 operators for wireless hotspot and OpenRoaming functionality.

Use this configuration when you need to set up 3GPP cellular network information and operator details for wireless hotspot services. This configuration includes operating class indicators, mobile country and network codes, and operator language settings.

Procedure

---

1. Choose **Configuration > Wireless > Hotspot/OpenRoaming**.
2. Select an existing server from the list of servers.
3. Go to the **3GPP/Operator** tab.
4. In the **Operating Class Indicator** field, enter the operating class identifier and click the + icon.

   The operating class identifier is added and displayed in the pane below. Use the delete icon to delete them, if required.

   > **Note**
   >
   > Class IDs should be in the following ranges: 81-87, 94-96, 101-130, 180, and 192-254.

5. Go to the **3GPP Cellular Networks** section and click **Add**.

   The **3GPP Network Details** pane is displayed.

6. In the **Mobile Country Code (MCC)** field, enter the mobile country code, which should be a 3-digit decimal number.

7. In the **Mobile Network Code (MNC)** field, enter the mobile network code, which should be a 2 or 3-digit decimal number.

   For the list of Mobile Country Codes (MCC) and Mobile Network Codes (MNC), see the following links: https://www.itu.int/pub/T-SP-E.212B-2018 or https://www.MCC-MNC.com.

8. Click check mark icon to add the network details.
9. Go to the **Hotspot 2.0 Operators** section and click **Add**.

   The **Operator Details** pane is displayed.

10. In the **Language Code** field, enter the language code.

    Use only the first three letters of the language, in lower case, for the language code. For example, use *eng* for English. To see the full list of language codes, go to: http://www.loc.gov/standards/iso639-2/php/code_list.php.

11. In the **Name** field, enter the name of the OSU operator.
12. Click check mark icon to add the operator details.
13. Click **Apply to Device**.

The 3GPP/operator configuration is applied to the device. The configured operating class indicators, cellular network details, and operator information are now active for wireless hotspot and OpenRoaming services.

Configure OSU provider (GUI)

Configure OSU provider using GUI.

Configure an OSU (Online Sign-Up) provider to enable wireless clients to connect and provision network access through the Hotspot/OpenRoaming service.

Use this procedure to set up an OSU provider with the necessary configuration parameters including provider name, NAI realm, authentication methods, server URI, icon configuration, and friendly names for different languages.

Before you begin

Follow these steps to configure OSU provider using GUI:

Procedure

---

1. Choose **Configuration > Wireless > Hotspot/OpenRoaming**.
2. Select an existing server from the list of servers.
3. Go to the **OSU Provider** tab.
4. Click **Add**.

   The **General Config** pane is displayed.

5. In the **Provider Name** field, enter the OSU provider name.
6. In the **NAI Realm** field, enter the Network Access Identifier (NAI) realm of the OSU operator.
7. From the **Primary Method** drop-down list, choose the primary supported OSU method of the OSU operator.

   This activates the **Secondary Method** drop-down list. If you choose *None* as the primary supported OSU method, you will not get the secondary method.

8. (Optional) From the **Secondary Method** drop-down list, choose the secondary supported OSU method of the OSU operator.
9. In the **Server URI** field, enter the server Uniform Resource Identifier (URI) of the OSU operator.
10. Click **Icon Config** tab.

11. Click **Add**.
12. From the **Icon Name** drop-down list, choose the icon name.
13. Click **Save**.
14. Click **Friendly Names** tab.
15. Click **Add**.
16. In the **Language** field, enter the language code.
17. In the **Name** field, enter the name of the OSU operator.
18. In the **Description** field, enter the description for the OSU operator.
19. Click **Save**.
20. Click the check mark icon to save.
21. Click **Apply to Device**.

The OSU provider is configured and applied to the device, enabling wireless clients to use the Online Sign-Up service for network provisioning.

Configure OSU provider (CLI)

Configure OSU provider using CLI.

Configure an OSU (Online Sign-Up) provider to enable wireless clients to connect and provision network access through the Hotspot/OpenRoaming service.

Use this procedure to set up an OSU provider with the necessary configuration parameters including provider name, NAI realm, authentication methods, server URI, icon configuration, and friendly names for different languages.

Before you begin

Follow these steps to configure OSU provider using CLI:

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an icon for Hotspot 2.0 and its parameters, such as media type, language code, icon width, and icon height.

   Example

   ```
   Device(config)# wireless hotspot icon bootflash:system-file-name media-type
   language-code icon-width icon-height
   ```

   ```
   Device(config)# wireless hotspot bootflash:logo1 image eng 100 200
   ```

3. Configure a Hotspot 2.0 ANQP server.

Example

```
Device(config)# wireless hotspot anqp-server server-name
```

```
Device(config)# wireless hotspot anqp-server my_server
```

4. Configure a Hotspot 2.0 OSU provider name.

   Example

   ```
   Device(config-wireless-anqp-server)# osu-provider osu-provider-name
   ```

   ```
   Device(config-wireless-anqp-server)# osu-provider my-osu
   ```

5. Configure the name of the OSU operator in a given language.

   Example

   ```
   Device(config-anqp-osu-provider)# name osu-operator-name lang-code description
   ```

   ```
   Device(config-anqp-osu-provider)# name xyz-oper eng xyz-operator
   ```

   The OSU operator name and description should not exceed 220 characters. The language code should be 2 or 3 lower-case letters (a-z).

6. Configure the server Uniform Resource Identifier (URI) of the OSU operator.

   Example

   ```
   Device(config-anqp-osu-provider)# server-uri server-uri
   ```

   ```
   Device(config-anqp-osu-provider)# server-uri cisco.com
   ```

7. Configure the primary supported OSU method of the OSU operator.

   Example

   ```
   Device(config-anqp-osu-provider)# method {oma-dm | soap-xml-spp}
   ```

   ```
   Device(config-anqp-osu-provider)# method oma-dm
   ```

8. Configures the Network Access Identifier (NAI) realm of the OSU operator.

   Example

   ```
   Device(config-anqp-osu-provider)# nai-realm nai-realm
   ```

   ```
   Device(config-anqp-osu-provider)# nai-realm cisco.com
   ```

   The *nai-realm* should not exceed 220 characters.

9. Configure the icon for the OSU provider.

Example

```
Device(config-anqp-osu-provider)# icon file-name
```

```
Device(config-anqp-osu-provider)# icon xyz.jpeg
```

The *file-name* should not exceed 100 characters.

The OSU provider is configured and applied to the device, enabling wireless clients to use the Online Sign-Up service for network provisioning.

Configure Hotspot 2.0 WLAN

Configure Hotspot 2.0 WLAN.

Set up a Hotspot 2.0 enabled WLAN to provide standardized Wi-Fi access for mobile devices.

Hotspot 2.0 WLANs enable automatic network discovery and connection for compatible devices, providing a seamless wireless experience in public and enterprise environments.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN and enter WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id ssid
   ```

   Example

   ```
   Device(config)# wlan hs2 1 hs2
   ```

3. Configure random GTK for hole 196 mitigation.

   Example

   ```
   Device(config-wlan)# security wpa
   wpa2 gtk-randomize
   ```

   Hole 196 is the name of WPA2 vulnerability.

4. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The Hotspot 2.0 WLAN is configured and enabled, allowing compatible devices to automatically discover and connect to the network.

Configure an online subscription with encryption WLAN (CLI)

Configure an online subscription with encryption WLAN.

Enable secure onboarding for Hotspot 2.0 networks by configuring an OSEN WLAN to obtain necessary credentials.

Online subscription with Encryption (OSEN) WLAN is used to onboard a Hotspot 2.0 network (to get the necessary credentials) in a secure manner.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN and enter WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id ssid
   ```

   Example

   ```
   Device(config)# wlan hs2 1 hs2
   ```

3. Enable WPA OSEN security support.

   Example

   ```
   Device(config-wlan)# security wpa osen
   ```

   Note

   OSEN and robust security network (RSN) are mutually exclusive. If RSN is enabled on a WLAN, OSEN cannot be enabled on the same WLAN.

4. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The OSEN WLAN is configured and enabled, allowing secure onboarding for Hotspot 2.0 network credentials. Note that you cannot apply a policy profile to the OSEN WLAN if a Hotspot 2.0 server is enabled on the WLAN.

Attach an ANQP server to a policy profile (CLI)

Configure an ANQP server attachment to a policy profile for Hotspot 2.0 functionality.

Enable Hotspot 2.0 functionality by attaching an ANQP server to a wireless policy profile.

ANQP (Access Network Query Protocol) servers provide network information to Hotspot 2.0 clients during the discovery and authentication process. This configuration is required for implementing Hotspot 2.0 services.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a policy profile.

   Example

   ```
   Device(config)# wireless profile policy policy-profile-name
   ```

   Example

   ```
   Device(config)# wireless profile policy policy-hotspot
   ```

3. Disable the policy profile.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

4. Attach the Hotspot 2.0 ANQP server to the policy profile.

   Example

   ```
   Device(config-wireless-policy)# hotspot anqp-server server-name
   ```

   Example

   ```
   Device(config-wireless-policy)# hotspot anqp-server my-server
   ```

5. Enable the policy profile.

Example

```
Device(config-wireless-policy)# no shutdown
```

The ANQP server is successfully attached to the policy profile. You must then attach the policy profile to the WLAN to make the WLAN Hotspot 2.0 enabled.

What to do next
Attach the policy profile to the WLAN to make the WLAN Hotspot 2.0 enabled.

Configure interworking for Hotspot 2.0

Configure interworking for Hotspot 2.0.

Enable Hotspot 2.0 interworking capabilities to provide seamless wireless network access for mobile devices.

Hotspot 2.0 interworking allows mobile devices to automatically discover and connect to Wi-Fi networks that provide internet access. This configuration sets up the ANQP (Access Network Query Protocol) server and defines network characteristics for Hotspot 2.0 compliance.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Hotspot 2.0 ANQP server.

   Example

   ```
   Device(config)# wireless hotspot anqp-server server-name
   ```

   Example

   ```
   Device(config)# wireless hotspot anqp-server my_server
   ```

3. Configure a 802.11u network type.

   Example

   ```
   Device(config-wireless-anqp-server)# network-type network-type internet-access
    access-level
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# network-type guest-private
   internet-access allowed
   ```

   The access-level can be allowed or forbidden.

4. Optional: Configure a homogenous extended service set.

Example

```
Device(config-wireless-anqp-server)# hessid HESSID-value
```

Example

```
Device(config-wireless-anqp-server)# hessid 12.13.14
```

5. Select a group type and venue type from the list of available options.

Example

```
Device(config-wireless-anqp-server)# group venue-group venue-type
```

Example

```
Device(config-wireless-anqp-server)# group business bank
```

Hotspot 2.0 interworking is now configured with the specified ANQP server, network type, and venue information, enabling automatic network discovery and connection for compatible mobile devices.

Configure the Generic Advertisement Service rate limit (CLI)

Configure the generic advertisement service rate limit.

Control the rate of Generic Advertisement Services (GAS) request action frames to prevent network congestion and optimize performance.

GAS rate limiting helps manage the volume of hotspot service requests processed by the controller and APs, ensuring stable network performance in high-density environments.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure an AP profile and enter AP profile configuration mode.

Example

```
Device(config)# ap profile profile-name
```

Example

```
Device(config)# ap profile hs2-profile
```

3. Configure the number of Generic Advertisement Services (GAS) request action frames sent to the controller by an AP in a given interval.

Example

```
Device(config-ap-profile)# gas-ap-rate-limit request-number interval
```

Example

```
Device(config-ap-profile)# gas-ap-rate-limit 20 120
```

4. Return to global configuration mode.

Example

```
Device(config-ap-profile)# exit
```

5. Configure the number of GAS request action frames to be processed by the controller.

Example

```
Device(config)# wireless hotspot gas-rate-limit gas-requests-to-process
```

Example

```
Device(config)# wireless hotspot gas-rate-limit 100
```

The GAS rate limiting is configured to control the processing of hotspot service requests at both the AP and controller levels.

Configure global settings (GUI)

Configure global settings for wireless hotspot and OpenRoaming functionality.

Configure global settings to manage GAS rate limits and icon configurations for wireless hotspot and OpenRoaming services.

Use this task to set up global parameters that control the behavior of wireless hotspot and OpenRoaming features across your network.

Procedure

---

1. Choose **Configuration > Wireless > Hotspot/OpenRoaming > Global Settings**.
2. In the **GAS Rate Limit (Requests per sec)** field, enter the number of GAS request action frames to be processed by the controller.
3. Go to the **Icons Configuration** area.
4. Click **Add**.

   The **Add Global Icon** window is displayed.

5. From the **System Path** drop-down list, choose the path.
6. In the **Icon Name** field, enter the icon name.
7. In the **Icon Type** field, enter the icon type.
8. In the **Language Code** field, enter the language code.
9. In the **Icon Height** field, enter the icon height.

10. In the **Icon Width** field, enter the icon width.
11. Click **Apply to Device**.

The global settings for wireless hotspot and OpenRoaming are configured with the specified GAS rate limit and icon parameters applied to the device.

Configure advice of charge

Configure advice of charge information for using the SSID of the Network Access Identifier (NAI) realm.

Configure advice of charge to provide information on financial charges for using the SSID of the NAI realm in Hotspot 2.0 networks.

Advice of charge provides clients with information about the financial costs associated with using a particular SSID or NAI realm. This configuration is used in Hotspot 2.0 deployments where operators need to inform users about data usage charges.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Hotspot 2.0 ANQP server.

   Example

   ```
   Device(config)# wireless hotspot anqp-server server-name
   ```

   Example

   ```
   Device(config)# wireless hotspot anqp-server my_server
   ```

3. Configure advice of charge for data usage.

   Example

   ```
   Device(config-wireless-anqp-server)# advice-charge type
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# advice-charge data
   ```

   Advice of charge provides information on the financial charges for using the SSID of the NAI realm.

4. Configure advice of charge information, which includes language, currency, and plan information.

   Example

   ```
   Device(config-anqp-advice-charge)# plan language currency info plan-info-file
   ```

Example

```
Device(config-anqp-advice-charge)# plan eng eur info bootflash:plan_eng.xml
```

Note

You can configure up to 32 plans.

5. Configure NAI realm for this advice of charge.

Example

```
Device(config-anqp-advice-charge)# nai-realm nai-realm
```

Example

```
Device(config-anqp-advice-charge)# nai-realm cisco
```

Note

You can configure up to 32 realms.

The advice of charge is now configured with the specified language, currency, plan information, and NAI realm, providing clients with financial charge information for network usage.

Configure terms and conditions (CLI)

Configure terms and conditions for Hotspot 2.0 ANQP server.

Set up terms and conditions configuration for wireless hotspot clients to ensure compliance and proper authentication.

Terms and conditions configuration is required for Hotspot 2.0 deployments where clients must acknowledge specific terms before accessing network resources. This configuration includes specifying the terms file, timestamp, and associated URL filtering policies.

Before you begin

Define a URL filter list, as shown in this example:

```
urlfilter list url-filter-name
    action permit
    filter-type post-authentication
    url allow-url
```

For information on configuring an URL list, see the *Defining URL Filter List* section.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Hotspot 2.0 ANQP server.

   Example

   ```
   Device(config)# wireless hotspot anqp-server server-name
   ```

   Example

   ```
   Device(config)# wireless hotspot anqp-server my_server
   ```

3. Configure the terms and conditions filename for the clients.

   Example

   ```
   Device(config-wireless-anqp-server)# terms-conditions filename file-name
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# terms-conditions filename xyz-file
   ```

4. Configure the terms and conditions timestamp.

   Example

   ```
   Device(config-wireless-anqp-server)# terms-conditions timestamp date time
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# terms-conditions timestamp 2020-02-20
   20:20:20
   ```

5. Configure the terms and conditions URL filter list name.

   Example

   ```
   Device(config-wireless-anqp-server)# terms-conditions urlfilter list
   url-filter-list
   ```

   Example

   ```
   Device(config-wireless-anqp-server)# terms-conditions urlfilter list filter-yy
   ```

The terms and conditions are now configured for the Hotspot 2.0 ANQP server, enabling proper client authentication and compliance verification.

Define ACL and URL filter in AP for FlexConnect

Configure ACL and URL filter policies in AP for FlexConnect to control network access and web filtering for wireless clients.

Configure ACL and URL filter policies for FlexConnect access points to provide network access control and web content filtering for wireless clients.

FlexConnect allows access points to locally switch wireless traffic and apply policies when the connection to the wireless LAN controller is limited or unavailable. This configuration defines access control lists and URL filters that will be applied at the access point level.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Define an extended UDP access list and set access conditions for BOOTP client to server traffic.

   Example

   ```
   Device(config-ext-nacl)# sequence-number permit udp any eq bootpc any eq
   bootps
   ```

   Example

   ```
   Device(config-ext-nacl)# 10 permit udp any eq bootpc any eq bootps
   ```

   Sets access conditions to match only the packets on a given port number of bootstrap protocol (BOOTP) clients from any source host to match only the packets on a given port number of the bootstrap protocol (BOOTP) server of a destination host.

3. Define an extended UDP access list for BOOTP server to client traffic.

   Example

   ```
   Device(config-ext-nacl)# sequence-number permit udp any eq bootps any eq
   bootpc
   ```

   Example

   ```
   Device(config-ext-nacl)# 20 permit udp any eq bootps any eq bootpc
   ```

   Sets access conditions to match only the packets on a given port number of bootstrap protocol (BOOTP) server from any source host to match only the packets of a given port number of the bootstrap protocol (BOOTP) clients of a destination host.

4. Define an extended UDP access list for DNS traffic.

Example

```
Device(config-ext-nacl)# sequence-number permit udp any eq domain any eq
domain
```

Example

```
Device(config-ext-nacl)# 30 permit udp any eq domain any eq domain
```

Sets access conditions to match a destination host Domain Name Service (DNS) with only the packets from a given port number of the source DNS.

5. Define an extended IP access list to permit traffic from any source to a specific destination host.

Example

```
Device(config-ext-nacl)# sequence-number permit ip any host dest-address
```

Example

```
Device(config-ext-nacl)# 40 permit ip any host 10.10.10.8
```

Forwards packets from a source host to a single destination host.

6. Define an extended IP access list to permit traffic from a specific source host to any destination.

Example

```
Device(config-ext-nacl)# sequence-number permit ip host dest-address any
```

Example

```
Device(config-ext-nacl)# 50 permit ip host 10.10.10.8 any
```

Forwards packets from a single source host to a destination host.

7. Exit access list configuration mode and return to global configuration mode.

Example

```
Device(config-ext-nacl)# exit
```

8. Configure a new FlexConnect policy profile.

Example

```
Device(config)# wireless profile flex flex-profile-name
```

Example

```
Device(config)# wireless profile flex test-flex-profile
```

Enters wireless flex profile configuration mode.

9. Configure an ACL policy for the FlexConnect profile.

   Example

   ```
   Device(config-wireless-flex-profile)# acl-policy acl-policy-name
   ```

   Example

   ```
   Device(config-wireless-flex-profile)# acl-policy acl_name
   ```

10. Apply a URL filter list to the FlexConnect profile.

    Example

    ```
    Device(config-wireless-flex-profile)# urlfilter list url-filter-name
    ```

    Example

    ```
    Device(config-wireless-flex-profile)# urlfilter list urllist_flex
    ```

11. Configure a production VLAN name.

    Example

    ```
    Device(config-wireless-flex-profile)# vlan-name prod-vlan-name
    ```

    Example

    ```
    Device(config-wireless-flex-profile)# vlan-name test-vlan
    ```

    Ensure that filter-type post-authentication configuration is in place for the URL filter to work. For information on configuring URL filter list, see the Defining URL Filter List section of the chapter DNS-Based Access Control Lists.

12. Create a production VLAN ID.

    Example

    ```
    Device(config-wireless-flex-profile-vlan)# vlan-id prod-vlan-id
    ```

    Example

    ```
    Device(config-wireless-flex-profile-vlan)# vlan-id 10
    ```

13. Configure an OSU VLAN name.

    Example

    ```
    Device(config-wireless-flex-profile)# vlan-name osu-vlan-name
    ```

Example

```
Device(config-wireless-flex-profile)# vlan-name test-vlan
```

14. Create an OSU VLAN ID.

Example

```
Device(config-wireless-flex-profile-vlan)# vlan-id osu-vlan-id
```

Example

```
Device(config-wireless-flex-profile-vlan)# vlan-id 20
```

The FlexConnect profile is configured with ACL and URL filter policies, enabling local switching and policy enforcement at the access point level for wireless clients.

Configure an OSEN WLAN - single SSID (CLI)

Configure an OSEN WLAN (single SSID).

Configure an OSEN WLAN with single SSID to enable secure wireless access using OSEN encryption.

OSEN (OSU Server-only Authenticated L2 Encryption Network) provides secure connectivity for Hotspot 2.0 deployments. This configuration enables a single SSID WLAN with OSEN security capabilities.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a WLAN and enter WLAN configuration mode.

Example

```
Device(config)# wlan wlan-name wlan-id ssid
```

Example

```
Device(config)# wlan hs2 1 hs2
```

3. Disable fast transition over the data source on the WLAN.

Example

```
Device(config-wlan)# no security ft over-the-ds
```

4. Disable adaptive 11r.

Example

```
Device(config-wlan)# no security ft adaptive
```

5. Enable WPA2 security.

   Example

   ```
   Device(config-wlan)# security wpa wpa2
   ```

6. Enable WPA2 ciphers for AES.

   Example

   ```
   Device(config-wlan)# security wpa wpa2 ciphers aes
   ```

7. Enable WPA OSEN security support.

   Example

   ```
   Device(config-wlan)# security wpa osen
   ```

8. Enable the WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

9. Return to global configuration mode.

   Example

   ```
   Device(config-wlan)# exit
   ```

10. Configure a policy profile.

    Example

    ```
    Device(config)# wireless profile policy policy-profile-name
    ```

    Example

    ```
    Device(config)# wireless profile policy policy-hotspot
    ```

11. Attach the Hotspot 2.0 ANQP server to the policy profile.

    Example

    ```
    Device(config-wireless-policy)# hotspot anqp-server server-name
    ```

Example

```
Device(config-wireless-policy)# hotspot anqp-server my-server
```

12. Configure the VLAN ID with OSEN encryption for single SSID.

Example

```
Device(config-wireless-policy)# vlan vlan-id encryption osen
```

Example

```
Device(config-wireless-policy)# vlan 10 encryption osen
```

The OSEN WLAN with single SSID is now configured and enabled, providing secure wireless access using OSEN encryption for Hotspot 2.0 deployments.

Verify Hotspot 2.0 configuration

Lists commands to verify Hotspot 2.0 configuration.

Use these **show** commands to verify the quality of service (QoS) and AP GAS rate limit.

To view whether a QoS map ID is user configured or the default one, use this command:

```
Device# show ap profile <profile name> detailed

QoS Map                         : user-configured
```

To view the QoS map values used and their source, use this command:

```
Device# show ap profile <profile name> qos-map

QoS Map                         : default
DSCP ranges to User Priorities
 User Priority   DSCP low   DSCP high   Upstream UP to DSCP
-------------------------------------------------------------
             0          0           7                     0
             2         16          23                    10
             3         24          31                    18
             4         32          39                    26
             5         40          47                    34
             6         48          55                    46
             7         56          63                    48

DSCP to UP mapping exceptions
 DSCP   User Priority
---------------------
    0               0
    2               1
    4               1
    6               1
   10               2
   12               2
   14               2
   18               3
   20               3
```

```
   22               3
```

To view the AP rate limiter configuration, use this command:

```
Device# show ap name AP0462.73e8.f2c0 config general | i GAS

GAS rate limit Admin status                     : Enabled
Number of GAS request per interval              : 30
GAS rate limit interval (msec)                  : 100
```

Verify client details

Provides command to verify wireless-specific configuration of active clients.

To verify the wireless-specific configuration of active clients based on their MAC address, use this command:

```
Device# show wireless client mac 001e.f64c.1eff detail
.
.
.
Hotspot version : Hotspot 2.0 Release 2
Hotspot PPS MO ID :
Hotspot Terms and Conditions URL :
http://host1.ciscohotspot.com/terms.php?addr=b8:27:eb:5a:dc:39&ap=123
.
.
.
Policy Type : OSEN (within RSN)
Resultant Policies:
    VLAN Name        : VLAN0010
    VLAN             : 10
```

223 Client Roaming Across Policy Profile

Topics:

- Client roaming policy profile

Introduces client roaming across policy profiles, outlining concepts, configuration steps, and verification procedures essential for ensuring seamless client mobility in network environments.

Client roaming policy profile

The client roaming policy profile enables seamless client transition between different profiles.

A client roaming policy profile is a wireless controller configuration element.

- Defines the rules for client transitions between different wireless policy profiles
- determines whether seamless roaming is permitted between WLANs with differing policy profiles, and
- evaluates and implements policy settings during client movement across access points.
- Policy profile: a set of network policies configured by an administrator and associated with a WLAN, governing client access and behavior.
- Policy tag: an identifier that links a WLAN to a specific policy profile in the Cisco Catalyst 9800.

Policy profile roaming behavior and exceptions

In Cisco Catalyst 9800 Series Wireless Controllers, each WLAN associates with a policy profile through a policy tag. By default, the controller does not allow seamless client roaming between the same WLANs when those WLANs are associated with different policy profiles. When this occurs, clients disconnect and must reauthenticate.

When you enable roaming across policy profiles, seamless roaming is allowed only if the profiles differ in a few settings, such as VLAN, ACLs, and session parameters. The controller retains the client's original IP address and applies all new attributes except the VLAN.

Seamless roaming is allowed if the two policy profiles differ only in the following settings:

- Accounting list
- Cisco TrustSec (CTS)
- DHCP TLV caching
- Dot11 5 GHz airtime fairness
- Dot11 2.4 GHz airtime fairness
- ET analytics enable
- HTTP TLV caching
- Idle threshold
- Idle timeout
- mDNS SD service policy
- IPv4 ACL
- IPv6 ACL
- QBSS load
- RADIUS profiling
- Session timeout
- SIP CAC disassociation client
- SIP CAC send-486busy
- VLAN

When a client attempts to roam across policy profiles, the system increments the roam across policy profiles counter for each attempt. If the roam is denied, the system increments the roam across policy profile deny delete reason counter.

> **Note**
>
> This feature is not supported on fabric or on Cisco Catalyst 9800 FlexConnect.

This example shows a client attempting to roam across policy profiles PP1 and PP2 when the roam is denied.

```
wireless profile policy PP1
vlan 42
no shutdown
wireless profile policy PP2
aaa-override
vlan 43
no shutdown
```

Configure client roaming across policy profile

Configure client roaming across policy profiles.

Allow wireless clients to maintain connectivity when moving between different policy profiles by enabling VLAN persistence.

Before you begin

Use these steps to configure client roaming across policy profiles.

Procedure

1. Enable configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable client roaming across different policy profiles.

   Example

   ```
   Device(config) # wireless client vlan-persistent
   ```

3. End the session.

   Example

   ```
   Device(config) # end
   ```

Wireless clients can retain their VLAN assignment as they roam between policy profiles, improving session continuity across the network.

Verify client roaming across policy profiles

Verify client roaming across policy profiles.

These show the client roaming from policy profile PP1 configured with VLAN 42 to policy profile PP2 configured with VLAN 43.

This is the sample output of the **show wireless client mac-address xxxx.xxxx.xxxx detail** command that shows the client is connected to policy profile PP1.

```
Device#show wireless client mac-address xxxx.xxxx.xxxx detail

Client MAC Address : xxxx.xxxx.xxxx

224 Assisted Roaming

Topics:

- 802.11k neighbor list and assisted roaming

Explains how assisted roaming technology improves wireless client connectivity by enabling access points to guide devices toward optimal connection points within the network.

802.11k neighbor list and assisted roaming

Describes the 802.11k standard that allows an AP to inform 802.11k-capable clients of neighboring BSSIDs and help them optimize scanning and roaming behavior.

The 802.11k neighbor list and assisted roaming is a wireless roaming optimization feature that

- allows an AP to inform 802.11k-capable clients of neighboring BSSIDs (APs in the same SSID)
- helps clients optimize their scanning and roaming behavior, and
- includes Assisted Roaming Prediction Optimization for non-802.11k clients to discourage roaming to suboptimal APs.

Prediction based roaming for non-802.11k clients

You can optimize roaming for non-802.11k clients by generating a prediction neighbor list for each client without sending an 802.11k neighbor list request. When prediction based roaming enables a WLAN, after each successful client association/re-association, the same neighbor list optimization applies on the non-802.11k client to generate and store the neighbor list in the mobile station software data structure. Clients at different locations have different lists because the client probes are seen with different RSSI values by the different neighbors as the clients usually probe before any association or re-association. This list is created with the most updated probe data and predicts the next AP that the client is likely to roam to.

The wireless infrastructure discourages clients from roaming to those less desirable neighbors by denying association if the association request to an AP does not match the entries on the stored prediction neighbor list.

Key configuration parameters for prediction based roaming:

- Denial count: Maximum number of times a client is refused association.
- Prediction threshold: Minimum number of entries required in the prediction list for the assisted roaming feature to activate.

> **Note**
>
> We recommend not configuring two SSIDs with the same name in the controller, which may cause roaming issues.

For more information, see https://www.cisco.com/c/en/us/td/docs/wireless/controller/8-5/Enterprise-Mobility-8-5-Design-Guide/Enterprise_Mobility_8-5_Deployment_Guide/Chapter-11.html#pgfId-1140097.

Restrictions for assisted roaming

Outlines the restrictions and limitations for implementing assisted roaming functionality.

- This feature is supported only on 802.11n capable indoor access points. For a single band configuration, a maximum of 6 neighbors are visible in a neighbor list. For dual band configuration, a maximum of 12 neighbors are visible.
- You can configure assisted roaming only using the CLI.

Configure assisted roaming (GUI)

Configure assisted roaming using GUI to optimize client roaming for both 802.11k and non-802.11k clients.

Configure assisted roaming to enable clients to request neighbor reports containing information about known neighbor access points that are candidates for a service set transition.

Assisted roaming allows clients to request neighbor reports containing information about known neighbor access points that are candidates for a service set transition.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLAN** and click **Add** to add a WLAN or select an existing WLAN.
2. On the **Advanced** tab, go to the **Assisted Roaming (11K)** and select the **Prediction Optimization** checkbox to optimize roaming for non 802.11k clients by generating a prediction neighbor list for each client without sending an 802.11k neighbor list request.
3. Select the **Neighbor List** checkbox to optimize roaming for 802.11K clients by generating a neighbor list for each client without sending an 802.11k neighbor list request. By default, the neighbor list contains only neighbors in the same band with which the client is associated. However, if you select the Dual Band Neighbor List checkbox, it allows 802.11k to return neighbors in both bands.
4. Click **Apply to Device**.

Assisted roaming is configured for the WLAN with the selected optimization options for both 802.11k and non-802.11k clients.

Configure assisted roaming (CLI)

Configure assisted roaming using commands.

Enable assisted roaming to improve client roaming performance by providing neighbor AP information and prediction capabilities.

Assisted roaming helps wireless clients make better roaming decisions by providing neighbor lists, dual-band lists, and prediction features. This configuration improves overall wireless network performance and client experience.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure neighbor floor label bias.

   Example

   ```
   Device(config)# wireless assisted-roaming floor-bias dBm-value
   ```

   Example

   ```
   Device(config)# wireless assisted-roaming floor-bias 20
   ```

   The valid range is from 5 to 25 dBm, and the default value is 15 dBm.

3. Enter WLAN configuration submode.

Example

```
Device(config)# wlan wlan-id
```

Example

```
Device(config)# wlan wlan1
```

The *wlan-id* is the profile name of the configured WLAN.

4. Configure an 802.11k neighbor list for a WLAN.

Example

```
Device(wlan)# assisted-roaming neighbor-list
```

By default, assisted roaming is enabled on the neighbor list when you create a WLAN. The **no** form of the command disables assisted roaming neighbor list.

5. Configure a dual-band 802.11k dual list for a WLAN.

Example

```
Device(wlan)# assisted-roaming dual-list
```

By default, assisted roaming is enabled on the dual list when you create a WLAN. The **no** form of the command disables assisted roaming dual list.

6. Configure assisted roaming prediction list feature for a WLAN.

Example

```
Device(wlan)# assisted-roaming prediction
```

By default, the assisted roaming prediction list is disabled.

> **Note**
>
> A warning message is displayed and load balancing is disabled for the WLAN if load balancing is already enabled for the WLAN.

7. Configure the minimum number of predicted APs required for the prediction list feature to be activated.

Example

```
Device# wireless assisted-roaming prediction-minimum count
```

The default value is 3.

> **Note**
>
> If the number of the AP in the prediction assigned to the client is less than the number that you specify, the assisted roaming feature will not apply on this roam.

8. Configure the maximum number of times a client can be denied association if the association request is sent to an AP that does not match any AP on the prediction.

   Example

   ```
   Device# wireless assisted-roaming denial-maximum count
   ```

   Example

   ```
   Device# wireless assisted-roaming denial-maximum 8
   ```

   The valid range is from 1 to 10, and the default value is 5.

9. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

Assisted roaming is now configured with the specified parameters, enabling improved client roaming performance through neighbor lists, dual-band support, and prediction capabilities.

Verify assisted roaming

Lists the command to verify assisted roaming configuration on a WLAN.

This command can be used to verify assisted roaming configured on a WLAN:

Command	Description
show WLAN id *WLAN-id*	Displays the WLAN parameters on the WLAN.

Configuration examples for assisted roaming

Provides configuration examples for assisted roaming.

Configuration examples for assisted roaming demonstrate the necessary commands and syntax to configure neighbor floor label bias, disable neighbor list on specific WLANs, configure prediction lists, and set prediction thresholds and maximum denial counts.

This example shows how to configure the neighbor floor label bias:

```
Device# configure terminal
Device(config)# wireless assisted-roaming floor-bias 10
```

```
Device(config)# end
Device# show wlan id 23
```

This example shows how to disable neighbor list on a specific WLAN:

```
Device# configure terminal
Device(config)# wlan test1
Device(config (wlan)# no assisted-roaming neighbor-list
Device(config)(wlan)# end
Device# show wlan id 23
```

This example shows how to configure the prediction list on a specific WLAN:

```
Device# configure terminal
Device(config)# wlan test1
Device(config)(wlan)# assisted-roaming prediction
Device(config)(wlan)# end
Device# show wlan id 23
```

This example shows how to configure the prediction list based on assisted roaming prediction threshold and maximum denial count on a specific WLAN:

```
Device# configure terminal
Device(config)# wireless assisted-roaming prediction-minimum 4
Device(config)# wireless assisted-roaming denial-maximum 4
Device(config)# wlan wlan-name
Device(config)(wlan)# end
Device# show wlan id 23
```

225 802.11r BSS Fast Transition

Topics:

- 802.11r Fast Transition
- 802.11r Fast Transition for SAE authenticated clients

Explains the 802.11r Fast Transition feature for seamless wireless roaming and provides configuration procedures for various security methods including Dot1x, PSK, and SAE authentication.

802.11r Fast Transition

Describes a roaming mechanism that enables initial handshake with a new AP before the client roams to the target access point.

802.11r Fast Transition is a roaming mechanism that

- enables the initial handshake with a new AP even before the corresponding client roams to the target access point
- allows a client and the access points to do the Pairwise Transient Key (PTK) calculation in advance, and
- applies PTK keys to the client and the access points after the client responds to the reassociation request or responds to the exchange with new target AP.

802.11r Fast Transition features

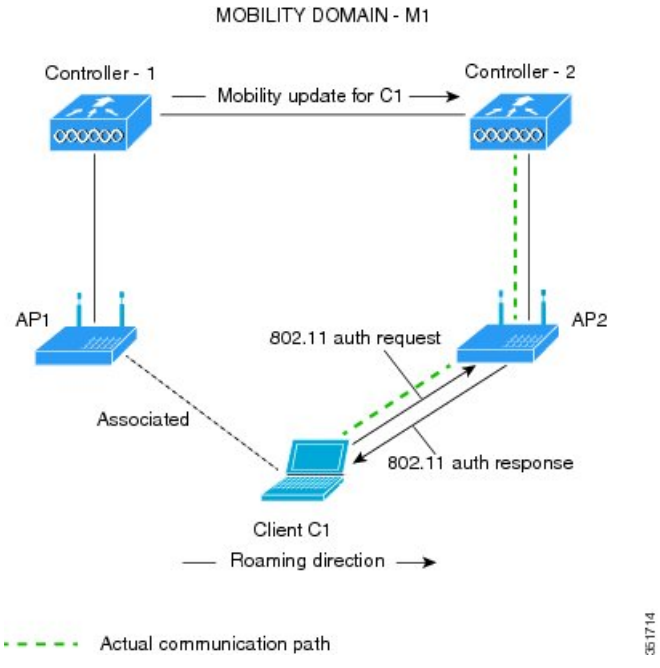
The FT key hierarchy is designed to allow clients to make fast BSS transitions between APs without requiring reauthentication at every AP. WLAN configuration contains a new Authenticated Key Management (AKM) type called Fast Transition (FT).

Client roaming

For a client to move from its current AP to a target AP using the FT protocols, message exchanges are performed using one of these methods:

- Over-the-Air: The client communicates directly with the target AP using IEEE 802.11 authentication with the FT authentication algorithm.
- Over-the-Distribution System (DS): The client communicates with the target AP through the current AP. The communication between the client and the target AP is carried in FT action frames between the client and the current AP and is then sent through the device.

Figure 41: Message exchanges when over–the–air client roaming is configured



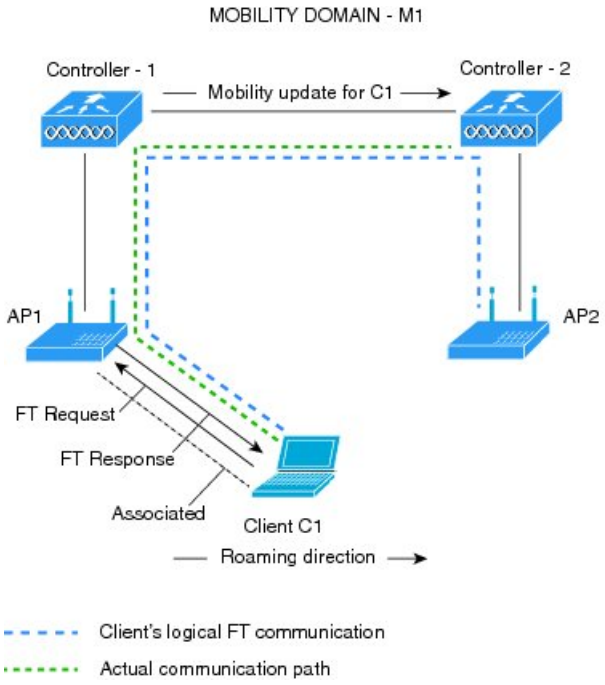


Figure 42: Message exchanges when over–the–DS client roaming is configured

Note

The 802.11r Fast Transition for SAE (FT-SAE) is not restricted to inter controller roaming.

Restrictions for 802.11r Fast Transition

Consider these restrictions when configuring 802.11r Fast Transition.

Consider these restrictions when implementing 802.11r Fast Transition:

- EAP LEAP method is not supported.
- Traffic Specification (TSPEC) is not supported for 802.11r fast roaming. Therefore, RIC IE handling is not supported.
- If WAN link latency exists, fast roaming is also delayed. Voice or data maximum latency should be verified. The Cisco WLC handles 802.11r Fast Transition authentication requests during roaming for both Over-the-Air and Over-the-DS methods.
- Legacy clients cannot associate with a WLAN that has 802.11r enabled if the driver of the supplicant that is responsible for parsing the Robust Security Network Information Exchange (RSN IE) is old and not aware of the additional AKM suites in the IE. Due to this limitation, clients cannot send association requests to WLANs. These clients, however, can still associate with non-802.11r WLANs. Clients that are 802.11r-capable can associate as 802.11i clients on WLANs that have both 802.11i and 802.11r Authentication Key Management Suites enabled.

  The workaround is to enable or upgrade the driver of the legacy clients to work with the new 802.11r AKMs, after which the legacy clients can successfully associate with 802.11r-enabled WLANs.

  Another workaround is to have two SSIDs with the same name, but with different security settings (FT and non-FT).
- Fast Transition resource-request protocol is not supported because clients do not support this protocol. Also, the resource-request protocol is an optional protocol.
- To avoid any Denial of Service (DoS) attack, each Cisco WLC allows a maximum of three Fast Transition handshakes with different APs.

- Non-802.11r-capable devices will not be able to associate with FT-enabled WLAN.
- We recommend 802.11r FT Over-the-Air roaming for FlexConnect deployments.
- FT-SAE Over-the-DS roam is not supported in FlexConnect local authentication mode.
- 802.11r FT-over-DS is enabled by default, when a WLAN is created in the controller. In Cisco Wave 2 APs, local switching local authentication with 802.11r is not supported. To make the local switching local authentication work with Cisco Wave 2 APs, explicitly disable 802.11r in WLAN. A sample configuration is given below:

```
wlan local-dot1x 24 local-dot1x
no security ft over-the-ds
no security ft adaptive
security dot1x authentication-list spwifi_dot1x
no shutdown
```

Monitor 802.11r fast transition

Lists the CLI commands to monitor 802.11r fast transition.

These commands can be used to monitor 802.11r Fast Transition:

Command	Description
show WLAN name *WLAN-name*	Displays a summary of the configured parameters on the WLAN.

Command	Description
show wireless client mac-address *mac-address*	Displays the summary of the 802.11r authentication key management configuration on a client.

```

Configure 802.11r Fast Transition in an open WLAN (CLI)

Configure 802.11r Fast Transition on an open WLAN using commands.

Enable 802.11r Fast Transition capabilities on an open WLAN to improve roaming performance for wireless clients.

802.11r Fast Transition allows wireless clients to roam between access points more quickly by pre-authenticating with target access points. This configuration is performed on an open WLAN without WPA security.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enter WLAN configuration submode.

Example

```
Device# wlan profile-name
```

Example

```
Device# wlan test4
```

The *profile-name* is the profile name of the configured WLAN.

3. Associate the client VLAN to the WLAN.

Example

```
Device(config-wlan)# client vlan vlan-id
```

Example

```
Device(config-wlan)# client vlan 0120
```

4. Disable WPA security.

Example

```
Device(config-wlan)# no security wpa
```

5. Disable security AKM for dot1x.

Example

```
Device(config-wlan)# no security wpa akm dot1x
```

6. Disable WPA2 security.

Example

```
Device(config-wlan)# no security wpa wpa2
```

7. Disable WPA2 ciphers for AES.

Example

```
Device(config-wlan)# no security wpa wpa2 ciphers aes
```

8. Enable 802.11r Fast Transition parameters.

Example

```
Device(config-wlan)# security ft
```

9. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

10. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

Alternatively, you can also press Ctrl-z to exit global configuration mode

---

The WLAN is now configured with 802.11r Fast Transition enabled, allowing wireless clients to perform faster roaming between access points.

Configure 802.11r BSS Fast Transition on a Dot1x security enabled WLAN (CLI)

Configure 802.11r Fast Transition in an open WLAN using commands.

Enable 802.11r BSS Fast Transition on a WLAN with 802.1x authentication to provide seamless roaming for wireless clients.

802.11r Fast Transition reduces the time required for wireless clients to roam between access points by enabling pre-authentication and key caching. This configuration is particularly useful in environments where clients need to maintain connectivity while moving between coverage areas.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enter WLAN configuration submode.

Example

```
Device# wlan profile-name
```

```
Device# wlan wlan-bss-ft
```

The *profile-name* is the profile name of the configured WLAN.

3. Associate the client VLAN to this WLAN.

Example

```
Device(config-wlan)# client vlan vlan-name
```

Example

```
Device(config-wlan)# client vlan 0120
```

4. Enable the local auth EAP profile.

   Example

   ```
   Device(config-wlan)# local-auth local-auth-profile-eap
   ```

5. Enable security authentication list for dot1x security.

   Example

   ```
   Device(config-wlan)# security dot1x authentication-list default
   ```

   The configuration is similar for all dot1x security WLANs.

6. Enable 802.11r Fast Transition on the WLAN.

   Example

   ```
   Device(config-wlan)# security ft
   ```

7. Enable 802.1x security on the WLAN.

   Example

   ```
   Device(config-wlan)# security wpa akm ft dot1x
   ```

8. Enable the WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

9. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wlan)# end
   ```

   Alternatively, you can also press Ctrl-z to exit global configuration mode

---

Configure 802.11r Fast Transition on a PSK security–enabled WLAN (CLI)

Configure 802.11r Fast Transition on a PSK security-enabled WLAN using commands.

Enable 802.11r Fast Transition capability on a WLAN that uses PSK security to improve roaming performance for wireless clients.

802.11r Fast Transition reduces the time required for client devices to roam between access points by pre-authenticating with neighboring APs. This configuration is performed on WLANs that use pre-shared key (PSK) authentication.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan-profile-name
   ```

3. Associate the client VLAN to this WLAN.

   Example

   ```
   Device(config-wlan)# client vlan vlan-name
   ```

   Example

   ```
   Device(config-wlan)# client vlan 0120
   ```

4. Disable security AKM for dot1x.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

5. Configure Fast Transition PSK support.

   Example

   ```
   Device(config-wlan)# security wpa akm ft psk
   ```

6. Configure PSK AKM shared key.

   Example

   ```
   Device(config-wlan)# security wpa akm psk set-key {ascii {0 | 8} | hex {0 |
   8}} key-value
   ```

   Example

   ```
   Device(config-wlan)# security wpa akm psk set-key ascii 0 test
   ```

7. Configure 802.11r Fast Transition.

   Example

   ```
   Device(config-wlan)# security ft
   ```

8. Enable the WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

9. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wlan)# end
   ```

   Alternatively, you can also press Ctrl-Z to exit global configuration mode.

The WLAN is now configured with 802.11r Fast Transition support using PSK authentication, enabling faster client roaming between access points.

Disable 802.11r fast transition (GUI)

Configure the system to disable 802.11r Fast Transition using the GUI interface.

Disable 802.11r Fast Transition functionality on a WLAN configuration to prevent automatic roaming assistance between access points.

Use this procedure when you need to turn off Fast Transition capabilities for a specific WLAN. Note that fast transition cannot be enabled or disabled if you have configured an SSID with Open Authentication.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. On the **WLANs** page, click the WLAN name.
3. In the **Edit WLAN** window, click the **Security** > **Layer2** tab.
4. From the **Fast Transition** drop-down list, choose **Disabled**.

   > **Note**
   >
   > You cannot enable or disable Fast Transition, if you have configured an SSID with Open Authentication.

5. Click **Update & Apply to Device**.

The 802.11r Fast Transition feature is disabled for the selected WLAN, and the configuration changes are applied to the device.

Disable 802.11r Fast Transition (CLI)

Configure 802.11r Fast Transition disablement using commands.

Disable 802.11r Fast Transition on WLANs to prevent Fast Transitions in 802.11r-enabled networks.

Use this procedure when you need to prevent Fast Transitions in 802.11r-enabled WLANs using the command line interface.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration submode.

   Example

   ```
   Device(config)# wlan profile-name
   ```

   ```
   Device(config)# wlan wlan-test4
   ```

3. Disable the FT AKMs that are enabled before disabling FT.

   Example

   ```
   Device(config-wlan)# no security wpa akm ft dot1x
   ```

   The available FT AKMs are: SAE-FT, SAE-EXT-FT and 802.1x-FT.

4. Disable 802.11r Fast Transition on the WLAN.

   Example

   ```
   Device(config-wlan)# no security ft {adaptive | over-the-ds |
   reassociation-timeout timeout-in-seconds}
   ```

   ```
   Device(config-wlan)# no security ft over-the-ds
   ```

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

802.11r Fast Transition is disabled on the WLAN and Fast Transitions will no longer occur for clients connecting to this network.

802.11r Fast Transition for SAE authenticated clients

Explains fast transition feature support for Simultaneous Authentication of Equals-based (SAE-based) fast roaming along with Pairwise Master Key (PMK) caching.

802.11r Fast Transition for SAE authenticated clients is a wireless security feature that

- supports Simultaneous Authentication of Equals-based (SAE-based) fast roaming support along with Pairwise Master Key (PMK) caching
- is an addition to the existing PMK caching-based fast roaming support, and
- is available from Cisco-IOS XE 17.9.1 release onwards.

Fast Transition protocol

During a Base Station Subsystem (BSS) transition, the Fast BSS transition feature reduces the connectivity time loss between an Station (STA) and Direct Switching. The Fast Transition protocols are part of the reassociation service, and apply to the STA transitions between the APs in the same mobility domain and Exteneded Service Set (ESS). The Fast Transition protocols need information to be exchanged during the initial association (or a later reassociation) between an STA and an AP. The initial exchange is referred to as the *FT initial mobility domain association*. Similarly, subsequent reassociations to the APs in the same mobility domain use the Fast Transition protocols.

Note

STA is known as Fast Transition Originator.

These are the FT protocols:

- **Fast Transition Protocol**: This protocol is executed when a Fast Transition Originator makes a transition to a target AP and does not require a resource request before its transition.
- **Fast Transition Resource Request Protocol**: This protocol is executed when a Fast Transition Originator requires a resource request prior to its transition.
- **Over-the-Air**: The Fast Transition Originator communicates with the target AP using IEEE 802.11 authentication with Fast Transition authentication algorithm.
- **Over-the-DS**: The Fast Transition Originator communicates with the target AP using the current AP. The communication between the Fast Transition Originator and target AP is carried in Fast Transition action frames between the Fast Transition Originator and the current AP.

The Fast Transition feature supports a new AKM for FT-SAE, specifically the **00-0F-AC:9**.

Fast Transition initial mobility domain association

An STA includes Mobility Domain Element (MDE) and Robust Security Network Element (RSNE) in the (re)association request frame. The AP responds by including FTE, MDE, and RSNE in the (re)association response frame.

That is, an STA initiates the Fast Transition initial mobility domain association procedures by performing an IEEE 802.11 authentication using the SAE algorithm.

After successful SAE authentication, the STA and AP perform a Fast Transition four-way handshake.

> **Note**
>
> - If the MDE that is received by an AP or a controller does not match the contents advertised in the beacon and probe response frames, the AP or controller rejects the (re)association request frame with the STATUS_INVALID_MDE code.
> - If an MDE is available in the (re)association request frame and the contents of RSNE do not indicate a negotiated SAE AKM of Fast BSS Transition (00-0F-AC:9 suite type), the AP rejects with STATUS_INVALID_AKMP code.
>
> After an SAE authentication, the controller receives the PMK, resulting in the successful completion of SAE.

Feature history for 802.11r Fast Transition

Lists the feature history for 802.11r fast transition.

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 195: Feature History for 802.11r Fast Transition

Feature	Release	Feature Information
802.11r Fast Transition for SAE (FT-SAE) Authenticated Clients	Cisco IOS XE Cupertino 17.9.1	From Cisco-IOS XE 17.9.1 release onwards, the Fast Transition supports SAE-based Fast Roaming support along with PMK caching. This feature is an addition to the existing PMK caching-based fast roam support.

Configure 802.11r Fast Transition on a SAE security-enabled WLAN (GUI)

Configure 802.11r fast transition on a SAE security-enabled WLAN using GUI.

This task configures 802.11r Fast Transition on a SAE (Simultaneous Authentication of Equals) security-enabled WLAN to enable seamless roaming for wireless clients.

802.11r Fast Transition reduces the time required for client authentication when roaming between access points in the same mobility domain. When combined with SAE security (WPA3), it provides both security and seamless connectivity for wireless clients.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
3. In the **General** tab, enter the **Profile Name**, the **SSID**, and the **WLAN ID**.
4. Choose **Security** > **Layer2** tab.
5. Click the **WPA3** radio button as security mode.
6. Check the required **WPA Parameters** check boxes and the **AES(CCMP128)** check box.

7. From the **Status** drop-down list, choose **Enabled**.
8. Check the **FT+SAE** check box.
9. Enter the **Pre-Shared Key**.
10. From the **PSK Format** drop-down list, choose PSK Format and from the **PSK Type** drop-down list, choose PSK Type.
11. Click **Apply to Device**.

The WLAN is configured with 802.11r fast transition and SAE security enabled. Wireless clients can now roam seamlessly between access points in the mobility domain while maintaining WPA3 security.

Configure 802.11r Fast Transition on an SAE security-enabled WLAN (CLI)

Configure 802.11r Fast Transition on an SAE security-enabled WLAN using commands.

Enable 802.11r Fast Transition capabilities on a WLAN that uses SAE (WPA3) security to provide seamless roaming for wireless clients.

802.11r Fast Transition reduces the time required for clients to roam between access points by pre-authenticating with neighboring access points. This configuration is particularly useful in environments where clients need to maintain connectivity while moving between coverage areas.

Procedure

---

1. Enable privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Configure the WLAN and SSID.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id ssid
   ```

   Example

   ```
   Device(config)# wlan wlan-ft-sae 10 wlan-ft-sae
   ```

4. Enable 802.11r Fast Transition on the WLAN.

   Example

   ```
   Device(config-wlan)# security ft
   ```

5. Disable WPA2 security.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2
   ```

6. Configure the preshared key on a WLAN.

   Example

   ```
   Device(config-wlan)# security wpa psk set-key ascii encryption-type key-string
   ```

   Example

   ```
   Device(config-wlan)# security wpa psk set-key ascii 0 123456789
   ```

   Note

   WPA preshared keys must contain 8 to 63 ASCII text characters or 64 hexadecimal characters.

7. Disable security AKM for dot1x.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

8. Configure 802.11r Fast Transition on an SAE security-enabled WLAN.

   Example

   ```
   Device(config-wlan)# security wpa akm ft sae
   ```

9. Enable WPA3 support.

   Example

   ```
   Device(config-wlan)# security wpa wpa3
   ```

10. Require clients to negotiate 802.11w PMF protection on a WLAN.

    Example

    ```
    Device(config-wlan)# security pmf mandatory
    ```

11. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

The WLAN is now configured with 802.11r Fast Transition and SAE security, enabling secure and seamless client roaming between APs.

Verify 802.11r Fast Transition SAE

Lists commands to verify 802.11r fast transition SAE configuration and status.

Use these verification commands to confirm 802.11r Fast Transition SAE is working correctly and to view related client details, authentication information, and statistics.

Client summary verification

To view the Fast Transition SAE details, use this command:

```
Device# show wireless client summary
Number of Clients: 1

226 802.11v

Topics:

- 802.11v amendment

Outlines 802.11v capabilities, focusing on prerequisites, restrictions, BSS Transition Management features, and step-by-step procedures for configuring and enabling 802.11v BSS Transition Management on wireless networks using both GUI and CLI methods.

802.11v amendment

Introduces the 802.11v amendment, highlighting its enhancements for wireless network management, including network assisted power savings, network assisted roaming, Directed Multicast Service, and BSS max idle period to optimize client battery life and improve connectivity.

The 802.11v amendment is a wireless network standard that

- describes numerous enhancements to wireless network management
- enables Network assisted Power Savings which helps clients to improve the battery life by enabling them to sleep longer, and
- enables Network assisted Roaming which enables the WLAN to send requests to associated clients, advising the clients as to better APs to associate to, for both load balancing and in directing poorly connected clients.

802.11v network assisted power savings

Wireless devices consume battery to maintain their connection to the clients, in several ways:

- By waking up at regular intervals to listen to the access point beacons containing a DTIM, which indicates buffered broadcast or multicast traffic that the access point delivers to the clients.
- By sending null frames to the access points, in the form of keepalive messages– to maintain connection with access points.
- Devices also periodically listen to beacons (even in the absence of DTIM fields) to synchronize their clock to that of the corresponding access point.

All these processes consume battery and this consumption particularly impacts devices (such as Apple), because these devices use a conservative session timeout estimation, and therefore, wake up often to send keepalive messages. The 802.11 standard, without 802.11v, does not include any mechanism for the controller or the access points to communicate to wireless clients about the session timeout for the local client.

To save the power of clients due to the mentioned tasks in wireless network, these features in the 802.11v standard are used:

- Directed multicast service
- Base station subsystem (BSS) max idle period

Directed multicast service:

Using Directed Multicast Service (DMS), the client requests the access point to transmit the required multicast packet as unicast frames. This allows the client to receive the multicast packets it has ignored while in sleep mode and also ensures Layer 2 reliability. Furthermore, the unicast frame is transmitted to the client at a potentially higher wireless link rate which enables the client to receive the packet quickly by enabling the radio for a shorter duration, thus also saving battery power. Since the wireless client also does not have to wake up at each DTIM interval in order to receive multicast traffic, longer sleeping intervals are allowed.

BSS max idle period:

The BSS max idle period is the timeframe during which an access point (AP) does not disassociate a client due to nonreceipt of frames from the connected client. This helps ensure that the client device does not send keepalive messages frequently. The idle period timer value is transmitted using the association and reassociation response frame from the access point to the client. The idle time value indicates the maximum time that a client can remain idle without transmitting any frame to an access point. As a result, the clients remain in sleep mode for a longer duration without transmitting the keepalive messages often. This in turn contributes to saving battery power.

Prerequisites for configuring 802.11v

Outlines prerequisites for configuring 802.11v.

Requirements for configuring 802.11v support in your wireless network environment.

- Applies for Apple clients like Apple iPad, iPhone, and so on, that run on Apple iOS version 7 or later.
- Supports local mode; also supports FlexConnect access points in central authentication modes only.

Restrictions for 802.11v

Describes the limitations and requirements for implementing 802.11v, specifically that client devices must support BSS Transition capabilities for proper functionality.

Client needs to support 802.11v BSS Transition.

802.11v BSS transition management

Describes 802.11v BSS transition management scenarios and functionality.

802.11v BSS transition management

- enables clients to request better AP options before roaming
- allows APs to suggest client transitions for load balancing, and
- supports optimized roaming based on RSSI and rate requirements.

802.11v BSS transition scenarios

802.11v BSS Transition is applied in these three scenarios:

- Solicited request: Client can send an 802.11v Basic Service Set (BSS) Transition Management Query before roaming for a better option of AP to reassociate with.
- Unsolicited Load Balancing request: If an AP is heavily loaded, it sends out an 802.11v BSS Transition Management Request to an associated client.
- Unsolicited Optimized Roaming request: If a client's RSSI and rate do not meet the requirements, the corresponding AP sends out an 802.11v BSS Transition Management Request to this client.

> **Note**
>
> 802.11v BSS Transition Management Request is a suggestion (or advice) given to a client, which the client can choose to follow or ignore. To force the task of disassociating a client, turn on the disassociation-imminent function. This disassociates the client after a period if the client is not reassociated to another AP.

Configure 802.11v BSS transition management (GUI)

Configure 802.11v BSS transition management using GUI.

Enable and customize 802.11v BSS transition management features for a particular WLAN to improve client roaming, battery life, and network efficiency.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add** to create WLANs.

   The **Add WLAN** page is displayed.
3. In the **Advanced** tab and **11v BSS Transition Support** section, select the **BSS Transition** check box to enable BSS transition per WLAN.
4. Enable the **Dual Neighbor List** check box to include the neighbors of other radio slots of the same AP in the BSS transition response.

   Note

   This is applicable only for 2.4 GHz and 5 GHz radio slots.
5. Enable the **BSS Max Idle Service** check box to help clients and APs efficiently decide how long to remain associated when no traffic is being transmitted. The device uses this information to preserve device battery life.
6. Enable the **BSS Max Idle Protected** check box to enable the AP to accept only authenticated frames (encrypted with Robust Security Network (RSN) information) from the client to reset the BSS Max Idle period counter. Without protected mode, any data or management frame (encrypted or unencrypted) sent by the client will reset the idle timer for the client.
7. Enable the **Directed Multicast Service** check box to request the AP to send a multicast stream as unicast, to any DMS capable client on this WLAN.
8. Click **Save & Apply to Device**.

The selected WLAN is now configured with 802.11v BSS transition management features. Clients benefit from improved roaming and battery conservation, and multicast streams can be delivered more efficiently.

Configure 802.11v BSS transition management (CLI)

Configure 802.11v BSS transition management using commands.

Enable 802.11v BSS transition management on a WLAN to improve client roaming and load balancing.

802.11v BSS transition management allows access points to provide roaming assistance to clients by suggesting better access points and triggering client roaming decisions. This feature is applied in scenarios where network optimization and seamless client mobility are required.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Configure WLAN profile and enter the WLAN profile configuration mode.

Example

```
Device(config)# wlan profile-name
```

Example

```
Device(config)# wlan test-wlan
```

3. Shutdown the WLAN profile.

Example

```
Device(config-wlan)# shutdown
```

4. Configure BSS transition per WLAN.

Example

```
Device(config-wlan)# bss-transition
```

5. Configure BSS transition disassociation imminent per WLAN.

Example

```
Device(config-wlan)# bss-transition disassociation-imminent
```

6. Enable the WLAN profile.

Example

```
Device(config-wlan)# no shutdown
```

7. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

Alternatively, you can press CTRL + Z to exit global configuration mode.

802.11v BSS transition management is now configured on the WLAN, enabling improved client roaming assistance and network optimization.

227 Virtual Routing and Forwarding

Topics:

- VRF support

Outlines Virtual Routing and Forwarding implementation, including creation and configuration of VRF definitions, mapping to switched virtual interfaces, and DHCP relay integration.

VRF support

Explains Virtual Routing and Forwarding (VRF) support functionality for wireless controllers.

Virtual Routing and Forwarding (VRF) support is a logical representation feature that

- groups Layer 3 entities such as IP addresses and routes
- provides the controller with the capability to split the control plane and data plane into multiple segregated logical instances within the same controller platform
- makes these planes VRF aware.

VRF use cases

VRF plays a crucial role in these use cases:

- Enabling flexible routing in infrastructure services such as AAA, DHCP, DNS, and more.
- Facilitating support for overlapping IP addresses.
- Permitting traffic from VRF-A to VRF-B using GRT. Route leak between two VRFs (VRF-A and VRF-B) is possible using a Global Routing Table (GRT). The direct route leak between VRFs are not supported.

> **Note**
>
> Direct route leakage between VRFs is not permitted. It should proceed from VRF A to GRT, then to the intended destination, VRF B.

For a multitenant network such as an airport, this allows you to provide wireless services to different tenants (including airlines and shops) at the airport by supporting two clients with different MAC addresses using the same IP address. With VRF support, AP in local mode or AP in FlexConnect mode with central switching policy can have two clients with the same IP even if they belong to different VRFs.

> **Note**
>
> - From Cisco IOS XE Dublin 17.12.1, overlapping IP address can be supported without disabling device tracking, by using VRF.
> - The configuration of VRF is not exclusive to this release, but its effectiveness begins from this release.

VRFs supported per platform:

- Cisco Catalyst 9800-80 Wireless Controller: 8181
- Cisco Catalyst 9800-40 Wireless Controller: 8181
- Cisco Catalyst 9800-L Wireless Controller: 8181

Guidelines and restrictions for VRF support

Outlines guidelines and restrictions for VRF support.

Follow these guidelines and restrictions when implementing VRF support:

- Supports only Local mode and FlexConnect mode (central DHCP and central switching).
- Supports only one VRF per WLAN.

> **Note**
>
> The maximum number of VRFs supported on a platform depends on the number of WLANs supported on the hardware platform.

- Supports static VRF ID allocation. All the configured VRFs should be associated with an SVI.
- Supports switch virtual interfaces (SVI) other than Wireless Management Interface (WMI).
- Supports only external DHCP servers.
- mDNS gateway is not supported.
- We recommend using commands to configure the feature because all VRF configurations are currently not supported through GUI.

Create a VRF instance

Configure a VRF instance to create isolated routing tables for network segmentation.

Create a VRF instance to enable network virtualization and traffic isolation within a single physical device.

VRF (Virtual Routing and Forwarding) instances allow you to create multiple virtual routers within a single physical router, providing network segmentation and isolation. This is useful for service providers or enterprises that need to maintain separate routing domains.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a VRF instance and enter VRF configuration mode.

   Example

   ```
   Device(config)# vrf definition vrf-name
   ```

   Example

   ```
   Device(config)# vrf definition red-vrf
   ```

3. Set an IPv4 address family.

   Example

   ```
   Device(config-vrf)# address-family ipv4
   ```

4. Exit from VRF address-family configuration submode.

   Example

   ```
   Device((config-vrf-af)# exit-address-family
   ```

5. Set an IPv6 address family.

   Example

   ```
   Device(config-vrf)# address-family ipv6
   ```

6. Exit from VRF address-family configuration submode.

   Example

   ```
   Device((config-vrf-af)# exit-address-family
   ```

7. Return to privileged EXEC mode.

   Example

   ```
   Device(config-vrf)# end
   ```

The VRF instance is created with both IPv4 and IPv6 address families configured, providing isolated routing tables for network segmentation.

Map VRF to SVI

Configure VRF mapping to an SVI interface.

Associate a VRF with a VLAN interface to enable Layer 3 separation and routing isolation.

Mapping a VRF to an SVI allows you to create isolated routing domains where traffic from different VRFs remains separated. This configuration is used when implementing network segmentation or multi-tenancy scenarios.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the VLAN interface to be associated with the VRF. Enter the interface configuration mode for the specified VLAN interface.

Example

```
Device(config)# interface interface-type-number
```

Example

```
Device(config)# interface vlan181
```

3. Associate the VRF with the Layer 3 interface.

Example

```
Device(config-if)# vrf forwarding vrf-name
```

Example

```
Device(config-if)# vrf forwarding red-vrf
```

This command activates multiprotocol VRF on the interface.

4. Disable proxy ARP.

Example

```
Device(config-if)# no ip proxy-arp
```

5. Enable the interface.

Example

```
Device(config-if)# no shutdown
```

6. Return to privileged EXEC mode.

Example

```
Device(config-if)# end
```

The VRF is now mapped to the SVI, and the interface is configured for VRF-aware routing with proxy ARP disabled.

Add VRF name through Option 82 for DHCP relay

Configure VRF name transmission through Option 82 for DHCP relay.

Enable the transmission of VRF name through Option 82 during DHCP relay operations.

VRF-based Sub Option 151 allows DHCP relay agents to include VRF information in Option 82, helping DHCP servers identify the originating VRF for client requests. This configuration is performed on wireless profile policies.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enable configuration for the specified profile policy.

   Example

   ```
   Device(config)# wireless profile policy policy-name
   ```

   Example

   ```
   Device(config)# wireless profile policy red-vrf
   ```

3. Shut down the wireless profile policy.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

4. Enable VRF-based Sub Option 151.

   Example

   ```
   Device(config-wireless-policy)# ipv4 dhcp opt82 VRF
   ```

5. Enable the wireless profile policy.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

6. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

The wireless profile policy is now configured to transmit VRF name through Option 82 during DHCP relay operations.

Add VRF name to DHCP server for DHCP relay

Configure VRF name to DHCP server for DHCP relay to enable separate VRF configuration between the DHCP server and client.

Enable separate VRF configuration between the DHCP server and client in DHCP relay scenarios.

When implementing DHCP relay, this procedure allows you to configure the DHCP server's VRF separately from the VRF of the client.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable configuration for the specified profile policy.

   Example

   ```
   Device(config)# wireless profile policy policy-name
   ```

   Example

   ```
   Device(config)# wireless profile policy red-vrf
   ```

3. Shut down the wireless profile policy.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

4. Configure the WLAN's IPv4 DHCP server IP address and VRF name.

   Example

   ```
   Device(config-wireless-policy)# ipv4 dhcp server ip-address vrf vrf-name
   ```

   Example

   ```
   Device(config-wireless-policy)# ipv4 dhcp server 1.2.3.4 vrf red-vrf
   ```

5. Enable the wireless profile policy.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

6. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

The DHCP server VRF is now configured separately from the client VRF, enabling proper DHCP relay functionality between different VRF domains.

VRF support verification

Lists commands to verify VRF support and check VRF and client overlap IP addresses.

To verify the VRF support, use these commands:

```
Device# show wireless client mac-address aaaa.facc.cccc detail

Client MAC Address : MAC XX
Client MAC Type : Universally Administered Address
Client DUID: NA
Client IPv4 Address : IP XX
Client Username : vrf1
AP MAC Address : aaa.bbb.ccc
AP Name: VRF_TEST_AP
AP slot : 1
Client State : Associated
Policy Profile : VRF_TEST_1
Flex Profile : N/A
Wireless LAN Id: 111
WLAN Profile Name: VRF_TEST_1
Wireless LAN Network Name (SSID): VRF_TEST_1
BSSID : aaa.bbb.ccc
Connected For : 543 seconds
Protocol : 802.11ax - 5 GHz
Channel : 44
Client IIF-ID : xxx
Association Id : 2
Authentication Algorithm : Open System
Idle state timeout : N/A
Re-Authentication Timeout : 43200 sec (Remaining time: 42670 sec)
Session Warning Time : Timer not running
Input Policy Name  : None
Input Policy State : None
Input Policy Source : None
Output Policy Name  : None

228 Automated Frequency Coordination

Topics:

- Automated frequency coordination
- AP height configuration through priming profile

Introduces Automated Frequency Coordination technology and guides users through configuring access point height settings via priming profiles for optimal wireless performance.

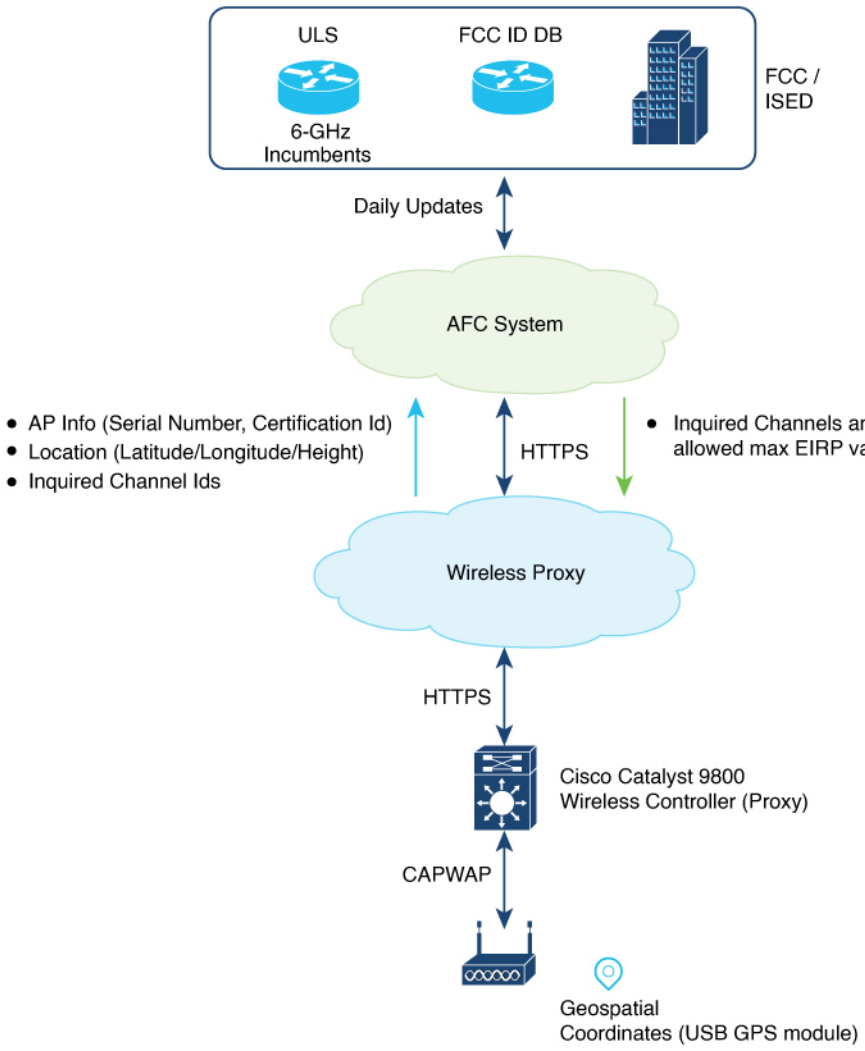
Automated frequency coordination

Describes an advanced system for coordinating spectrum allocation and utilization for access points operating within the 6-GHz band.

Automated Frequency Coordination (AFC) is an advanced system that

- coordinates the allocation and utilization of spectrum for access points (APs) that operate within the 6-GHz band
- utilizes the Universal Licensing System (ULS) as a regulatory database (encompassing a wide range of frequency bands used by various radio frequency services within a specific region), which is updated daily by the FCC, the regultory body, and
- ensures seamless and efficient management of spectrum resources, enabling optimal utilization of spectrum and minimizing interference among different radio frequency services.

AFC system benefits and operation



The FCC's decision to open the 6-GHz band for unlicensed Wi-Fi usage brings about significant advantages, including accelerated connectivity and expanded capacity. By unlocking the potential of the 6-GHz band, you can experience unprecedented performance and seamless connectivity, effortlessly engage in data-intensive activities and enjoy immersive online experiences.

Several other technologies, including fixed satellite services (FSS) used in the broadcast and cable industries, are already active in the 6-GHz band. To ensure that the new unlicensed Wi-Fi entrants do not interfere with current services, FCC has implemented the AFC system for Wi-Fi operation within this band. Indoor APs operate at reduced power levels and are less likely to interfere with current 6-GHz users. The outdoor or standard power APs have a higher probability of causing interference with the existing 6-GHz users. These APs are permitted to operate only within the frequency ranges allocated to each country. For example, in the US, APs are authorized to function in the 5.925-6.425 GHz and 6.525-7.125 GHz bands.

Under the AFC system, a new wireless device is required to verify its compatibility with the existing services. This is done by accessing a registered database of the local AFC system provided by an AFC service provider before starting data transmission. This compatibility check ensures that the device's operation does not cause any interference with the current services. To facilitate the compatibility check, the AFC provider maintains an extensive database containing information about the existing 6-GHz operators, including geolocation details, frequencies in use, power levels, antenna coverage, and other relevant data. For areas where an AFC service is available, outdoor or standard power 6-GHz Wi-Fi deployments are only authorized if they comply with the AFC guidelines.

Individual standard power APs are exempt from interfacing directly with the AFC system, if the necessary registration data is communicated by a proxy device such as the wireless controller. Still, APs are responsible for providing their precise location information. In return, they receive a designated set of available frequencies suitable for that specific location.

Figure 43: AFC architecture

AFC architecture includes these components:

- Cisco Catalyst APs supporting 6-GHz
- Cisco Catalyst 9800 Series Wireless Controller acting as AFC proxy
- A cloud-based wireless proxy tunneling the communication between the AFC proxy and the AFC system
- AFC System

The 6-GHz AFC workflow operates as follows:

1. A standard power AP joins the system. Before enabling standard power, the AP must get the available frequencies and the power in each frequency range from the AFC system.
2. The AFC proxy sends the AP information to the AFC system.
3. The AFC system computes the available frequencies and maximum allowable power based on the information provided by the regulatory body (FCC for United States).
4. The response is sent back to controller, which may assign a standard power channel to the AP based on the allowed channel list returned by the AFC system.

Supported APs

These Wi-Fi 7 APs support AFC:

Table 196: Supported APs

AP Model	9136I	9166I	9163E	9166D1	9164I	9162I	9178I	9176D1	9172I	9179F	9171I	9174I	9174E
First Supported Release	17.13.1, 17.12.3	17.13.1, 17.12.3	17.13.1, 17.12.3	17.14.1, 17.12.3	17.14.1, 17.12.3	17.14.1, 17.12.3	17.15.2	17.15.2	17.15.2, 17.17.1	17.18.1	17.18.2	17.18.2	17.18.2
6GHz/6E slots in AP	3	2	2	2	2	2	3	2	2	3	1	2	2
LPI and SP Support	LPI, SP	LPI, SP	SP only	LPI, SP	LPI, SP	LPI, SP	LPI, SP	LPI, SP	LPI, SP	LPI, SP	LPI, SP	LPI, SP	SP only
AP Type	Indoor	Indoor	Outdoor	Indoor	Indoor	Indoor	Indoor	Indoor	Indoor	Indoor/Outdoor	Indoor	Indoor	Indoor
GNSS	External	External	External	External	External	External	Internal	Internal	External	Internal	External	External	External

Note

The Cisco Wireless 9178I, 9176I, 9176D1, and 9172I Wi-Fi 7 Access Points are not applicable for 17.16.1 release.

Standard power enablement using AFC for US and Canada

Table 197: AFC power enablement: US and Canada

Country	Regulatory Body	Supported Bands	Power Levels	Supported Release
United States (US)	FCC	UNII-5, UNII-7	PSD 23dBm/MHz EIRP 36dBm	17.12.3 onwards
Canada (CA)	ISED	UNII-5, UNII-6, and UNII-7	PSD 23dBm/MHz EIRP 36dBm	17.17.1 onwards

> **Note**
>
> AFC is applicable or active for FCC (US) and Canada. You can verify this using the **show wireless afc ap** and **show wireless afc statistics** commands. In countries where AFC is not required, these commands will show no queries or responses for any access points, indicating that AFC is inactive inthat region.

Feature history for automated frequency coordination

Describes the release history and supported access points for the Automated Frequency Coordination feature, which manages spectrum allocation for 6-GHz band operations.

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 198: Feature history for automated frequency coordination

Release	Feature	Feature Information
Cisco IOS XE 17.12.3	Automated Frequency Coordination	Automated Frequency Coordination (AFC) is an advanced system for coordinating the allocation and utilization of spectrum for access points (APs) that operate within the 6-GHz band. This feature is supported on the following APs: • Cisco Catalyst Wireless 9136I Access Point • Cisco Catalyst Wireless 9163E Access Point • Cisco Catalyst Wireless 9166D Access Point • Cisco Catalyst Wireless 9166I Access Point • Cisco Catalyst Wireless 9162I Access Point • Cisco Catalyst Wireless 9164I Access Point • Cisco Catalyst Wireless 9167IW IIoT Access Point

Prerequisites for Automated Frequency Coordination

These are the prerequisites for Automated Frequency Coordination:

- Ensure that there is cloud connectivity from the controller to the cloud, with a DNS entry in place. AFC operates through either the management port or data ports.

  The AFC request is sent only when the controller is onboarded with cloud. This is automatic for hardware platforms like 9800-80, 9800-40 and 9800-L. For cloud controller, you have to manually enter a one-time password (OTP). See Onboarding the Cloud Controller.

- Before sending an AFC request, check whether the AFC service can be requested by using the show wireless afc ap command. If command output shows yes or up status for all the parameters of an AP, then request is sent out.
- Standard APs must register with the AFC system by providing these parameters:
  - Geographic coordinates (latitude and longitude)
  - Antenna height above ground level and tolerance as uncertainty height
  - FCC identification number
  - Manufacturer's unique serial number
  - Firewall Requirements - Ensure your network firewall allows outbound traffic to:
    - dnaservices.cisco.com on port 443
    - commercial.ocsp.identrust.com on port 80

Restrictions for Automated Frequency Coordination

These are the restrictions for AFC:

- AFC is not supported on Embedded Wireless Controller (EWC).

Onboard the cloud controller (GUI)

Configure the cloud controller onboarding process by generating and importing a one-time password (OTP).

Onboarding the cloud controller requires the generation of a one-time password (OTP). Controller must register with cloud framework to access any cloud service. The cloud service provides identity management services to the controller and securely authenticates the device.

> **Note**
>
> These steps apply only to the Cisco Catalyst 9800-CL Wireless Controller for Cloud, and are not applicable to the hardware-based Catalyst 9800 Wireless Controllers.

Follow these steps to onboard the cloud controller:

Procedure

1. Go to **Cisco DNA portal**.
2. Click **Application/Products**.
3. Select **Region** using the drop-down and click Register.
4. Click **Register**.
5. Enter the product details such as **Host Name/IP**, **Product Name**, and **Description**.

6. Click **Register**.

   This generates an OTP.

   The OTP token is a BASE64 encoded JSON payload. A sample OTP token is given below:

   Example

   ```
   eyJiYXNlX3VybCI6ICJodHRwczovL21hZ2xldi5tYWdsZXZjbG91ZDMudGVzc2VyYWN0
   aW50ZXJuYWwuY29tIiwib3RwIjogImNjNDY3ZDA5NzE1ZjQ3ZWI4NzhhN2UyOTA2YjllNzE0MTYzY
   mQzZjA1MWExNDUxZjg2ODViMjVhZDhmNWNkMTQifQo=
   ```

7. Copy the OTP.
8. Go to the controller console.
9. Run **cloud otp token import** command.
10. Paste the OTP copied in **Step 7** to the console.

This completes the onboarding procedure. Wait for a few minutes to complete the process.

Configure DNA services (GUI)

Configure DNA Service using GUI.

Set up integration with the Cisco DNA Cloud by configuring service connection parameters and authentication details for secure operation.

Procedure

1. Choose **Configuration > Services > Cloud Services**.
2. Click **DNA Services Configuration** tab.

   The DNA Services Configuration section displays these details:

   > **Note**
   >
   > We recommend that you retain default values for URL, API endpoint path and certificate bundle path.

   - **URL**: The base web address of the Cisco DNA Cloud instance that issued the token. This will be used to address the enrollment request.
   - **API Endpoint Path**: An API path that allows client applications like AFC to register for notifications for any Cloud state change.
   - **Certificate Bundle Path**: The path for certificate-based authentication. In addition to OTP-based authentication, you can use certificate-based authentication.
   - **HTTP Proxy (Hostname/IP)**: The HTTP proxy that serves incoming HTTPs requests from clients and processes received HTTPs responses.

3. In the **DNA OTP Configuration** section and under **Generate OTP**, select the link provided to navigate to the Cisco DNA website to generate an OTP.
4. Enter the generated OTP in the **OTP Token** field.

5. Click **Submit OTP**.

DNA services are configured. The system establishes a secure connection with the Cisco DNA Cloud, enabling authorized access to cloud-managed services and device management features.

Configure power mode per RF profile (CLI)

Configure Power Mode per RF Profile using commands.

Allow or disallow standard power mode in configuration per RF profile for 6-GHz band APs.

You can allow or disallow standard power mode in configuration per RF profile. However, the operating mode for each RF profile is determined based on the configuration, the capabilities of the AP, and the response from the AFC system regarding channel and transmit power values. If there is no connection with the AFC system or if the received Tx power values are extremely low, the AP might automatically switch from standard-power mode to low-power mode as a fallback.

If the standard power granted by the AFC server is greater than the low power, the radio is switched to standard power mode in the case of mixed-mode APs. If the granted standard power is equal to or greater than the low power, the radio is switched to standard power mode.

Note

As outdoor APs operate only in standard power mode, the RF profile configuration for the standard power mode is not evaluated.

Note

We recommend using standard power indoors for unparalleled speed and coverage. While the client and vendor ecosystem is evolving, the current Cisco standard power technology continues to provide advantages for existing standard power and dual-mode clients. Low-power clients will default to 2.4/5GHz until they are fully upgraded to standard power by the client vendors.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the RF profile and enter RF profile configuration mode.

Example

```
Device(config)# ap dot11 6ghz rf-profile rf-profile-name
```

Example

```
Device(config)# ap dot11 6ghz rf-profile prof-afc
```

3. Configure standard-power mode for 6 GHz band for APs that are capable of low power (LP) and standard power (SP).

   Example

   ```
   Device(config-rf-profile)# tx-power standard
   ```

   APs that support only SP mode are not affected by this setting (SP mode is always enabled).

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-rf-profile)# end
   ```

The RF profile is configured with standard power mode for the 6 GHz band, allowing APs to operate in standard power mode when conditions permit.

Configure power mode per RF profile (GUI)

Configure power mode per RF profile using the GUI to allow dual-power mode APs to operate as standard power APs in the 6 GHz spectrum.

This task enables standard-power service for dual-power mode APs to operate as standard power APs in the 6 GHz spectrum, allowing access to external AFC service through cloud.

The AP can access the external AFC service through cloud. Based on geographical coordinates and spectrum-inquiry requests from APs, the AFC provides responses on the available frequencies and the maximum permissible power in each frequency range.

Procedure

---

1. Go to **Configuration > Tags & Profiles > RF/Radio**.
2. Click **RF** tab.

   To add a new RF profile, see *Configuring an RF Profile (GUI)*. To modify an existing RF profile, select the required RF profile.

3. Enable **Standard-Power Service** to allow dual-power (low power or standard power) mode APs to operate as standard power APs in the 6 GHz spectrum.

   The AP can access the external AFC service through cloud. Based on geographical coordinates and spectrum-inquiry requests from APs, the AFC provides responses on the available frequencies and the maximum permissible power in each frequency range.

> **Note**
>
> - This setting is available for the 6-GHz band radio and standard-power supported APs only.
> - DNA services need to be configured to connect to AFC. You can configure DNA services in **Configuration > Services > Cloud Services > DNA Services** page.

4. Click **Apply to Device**.

Dual-power mode APs are now configured to operate as standard power APs in the 6 GHz band. They can access external AFC service through the cloud, with available frequencies and maximum permissible power determined by AFC responses.

Configure AP parameters (GUI)

Configure AP parameters using GUI.

AFC requires the longitude, latitude, and height of the AP to determine the geolocation of the AP. Longitude and latitude of the AP will be automatically calculated based on one of the following methods:

- From an internal or external GPS attached to the AP.
- From an another AP with GPS (also known as anchor AP) and the distance between the two APs.

> **Note**
>
> Only a few APs on a floor require the GPS unit. The remaining APs can derive their location from the AP with the GPS unit.
>
> You can use bulk AP provisioning to configure multiple AP parameters for multiple APs simultaneously. GUI path is **Configure > Wireless > Bulk AP Provisioning**.

Procedure

---

1. Go to **Configuration > Wireless > Access Points**.
2. In the **All Access Points** section, select a supported AP.
3. In the **Geolocation** tab, enter these details:
   a) In the **Height Configuration** section, enter the above ground level height in meters. The range is from -100 to 1000. Enter the tolerance as uncertainty height in meters. The range is from 1 to 100.
   b) In the **GNSS External Antenna Configuration** section, enter the cable length in meters.The range is from 1 to 100, with a default of 10. We recommend that you keep the default value of 10 meters with the Cisco provided external antenna.

> **Note**
>
> This option is available on selected models that support an external antenna.

4. Click **Apply to Device**.

The AP geolocation and antenna parameters are updated. APs without direct GPS will derive their location from anchor APs as needed. Bulk provisioning allows you to configure multiple APs efficiently.

Configure AP parameters (CLI)

Configure the height and GNSS antenna details of the AP.

Set up AP geolocation parameters including height and GNSS antenna configuration for accurate positioning.

To configure the height and GNSS antenna details of the AP, use the following procedure:

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Configure the AP Above Ground Level (AGL) height in meters.

   Example

   ```
   Device# ap name ap-name geolocation height height uncertainty uncertainty
   ```

   Example

   ```
   Device# ap name cisco-ap1 geolocation height 100 uncertainty 10
   ```

   The value range for height is -100 to 1000 meters. The valid range for height uncertainty is 1 to 100 meters.

3. Optional: Configure AP GNSS antenna external cable length, in meters.

   Example

   ```
   Device# ap name ap-name geolocation gnss antenna external cable-length length
   ```

   Example

   ```
   Device# ap name cisco-ap1 geolocation gnss antenna external cable-length 10
   ```

   The value range for cable length is 1 to 100, with a default value of 10.

> **Note**
>
> This configuration step is required only if GNSS is using an external antenna.

The AP geolocation parameters are now configured with the specified height and GNSS antenna settings.

AFC details verification

Lists the commands to verify AFC details and configuration information.

Use the verification commands to check AFC statistics, channel information, request status, responses, AP geolocation data, and power mode settings for troubleshooting and monitoring AFC functionality on 6 GHz APs.

AFC statistics verification

To see AFC statistics information, use this command:

```
Device# show wireless afc statistics

Total number of 6GHz APs : 4
Number of APs requiring AFC service : 4
Messages sent to AFC : 229
Successful messages received from AFC : 229
Errored AFC messages : 0
AFC messages pending : 0
Last InquiredChannel message sent:
requestId : 12195125900336565222
AP MAC : 10f9.20fd.54e0
Sent timestamp : 08/09/2023 15:14:20
Last InquiredChannel message received:
requestId : 12195125900336565222
AP MAC : 10f9.20fd.54e0
Received timestamp : 08/09/2023 15:14:21
Minimum response time (ms) : 337
Maximum response time (ms) : 40842
Average response time (ms) : 1315
Health check query : Idle
Health check status : OK
Health check timestamp : 08/09/2023 14:58:50
Number of times health check went down : 0

Health check event history

AP height configuration through priming profile

Describes how to configure AP height through priming profile for AFC 6-GHz channel availability requests.

AP height configuration through priming profile is a provisioning method that

- enables configuration of the Z coordinate (height) for multiple access points through a centralized profile approach
- provides pre-provisioning capabilities for seamless addition of new APs to the network, and
- ensures guaranteed configuration push when APs join the controller, overcoming the limitations of individual AP height configuration in Privileged EXEC mode.

Height configuration methods comparison

Until Cisco IOS XE 17.14.1, Automated Frequency Coordination (AFC) used geolocation attributes (X,Y, and Z) for an AP to be determined, to request for 6 GHz channel availability from the AFC server, for a given location. As per the regulatory requirement, the X and Y coordinates are obtained autonomously through GPS or GNSS directly, or through derivation. The Z coordinate (mandatory parameter), which refers to the height, is configured manually. In case of the controller, the height is programmed per AP, in the Privileged EXEC mode.

In this approach, the AP is joined, in order to configure height, and additional parameters that are configured in the Privileged EXEC mode.

However, following are the restrictions to the current implementation:

- There is no guarantee that all the APs will be configured with height. APs may flap during configuration, failing to set the height.
- Provisioning height individually for an AP in a large scale deployment could become cumbersome.
- The height once configured is persistent. Therefore, if you move an AP across floors, you must reprovision height as well.
- The AP height should be reprovisioned when a new AP is added to the network.

To overcome these constraints, from Cisco IOS XE 17.15.1 onwards, AP height is configured through priming profile.

These are the advantages when you configure the height of the AP through priming profile:

- Easy to update the height for a group of APs
- Pre-Provisioning feature
- Guaranteed configuration push when AP joins
- Moving around APs across different floors inherit the consistent configurations based on the filter
- Seamless addition of new APs

Guidelines for AP height configuration through priming profile

Outlines guidelines for AP height configuration through priming profile.

Follow these guidelines when configuring AP height through priming profile:

- If the height attribute is configured under the priming profile, the Priming Override attribute replaces the already configured height of the AP.
- The Priming Override attribute is unique for each priming profile, therefore, all the attributes within the priming profile are overwritten.
- Removal of height related configuration through priming profile has no effect on the configured height, but the configuration attributes are removed. The last configured height is retained.
- During an upgrade, if the height is not configured in the priming profile, it does not replace the already configured height.

Configure AP height through priming profile (GUI)

Configure the height and height uncertainty for access points through the AP priming profile to enable geolocation services.

Use this task to set the height and height uncertainty values for access points, which are required for geolocation services. The height is measured in relation to the main ground surface (Above Ground Level - AGL).

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Priming**.
2. Click **Add**.

   The **Add New AP Priming Profile** window is displayed.
3. In the **Add New AP Priming Profile** window, complete the following steps:
   a) In the **Profile Name** field, enter the new AP priming profile name.
   b) Enter the **Primary Controller Name**, **Primary Controller IP**, **Secondary Controller Name**, **Secondary Controller IP**, **Tertiary Controller Name**, **Tertiary Controller IP** details.
   c) Check the **Geolocation** check box to configure the geolocation details.
   d) In the **Height** field, enter the height of the AP in meters. The default value is 0.

   > **Note**
   >
   > Configure **Height** together with **Height Uncertainty**.
   >
   > The height of the AP is measured in relation to the main ground surface, also known as Above Ground Level (AGL). Remove height and uncertainty values to clear the height configuration.

   e) In the **Height Uncertainty** field, enter the height uncertainty in meters. The default value is 1.

   > **Note**
   >
   > Configure **Height Uncertainty** together with **Height**.
4. Use the **Priming Override** slider to enable or disable priming override.

   > **Note**
   >
   > When the Priming Override features is enabled, all the attributes configured under priming profile is pushed to AP.
5. Click **Apply to Device**.

The AP priming profile with height configuration is created and applied to the device.

Configure AP height through priming profile (CLI)

Configure AP height parameters using a priming profile to set geolocation coordinates for access points.

Set AP height and uncertainty values through a priming profile to enable accurate geolocation tracking.

Use priming profiles to configure AP height parameters when you need to establish geolocation coordinates for access points in your wireless network deployment.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a profile to prime APs and enter priming configuration mode.

   Example

   ```
   Device(config)# wireless profile ap priming priming-profile-name
   ```

3. Configure the AP geolocation height and uncertainty, in meters.

   Example

   ```
   Device(config-priming)# geolocation height ap-geolocation-height uncertainty
    height-uncertainty
   ```

   Example

   ```
   Device(config-priming)# geolocation height 372 uncertainty 64
   ```

4. Override the existing priming configuration.

   Example

   ```
   Device(config-priming)# priming-override
   ```

   Note

   The height and uncertainty for an AP is updated only if priming-override is enabled.

The AP priming profile is configured with height parameters and can be applied to access points to set their geolocation coordinates.

Apply priming profile using filters (GUI)

Configure priming profile application to access points using filter-based rules through the graphical user interface.

Configure and apply a priming profile to selected access points efficiently.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.

2. Click the **AP** tab and then click the **Filter** tab.
3. Click **Add**.

   The **Associate Tags to AP** window is displayed.
4. In the **Associate Tags to AP** window, complete the following steps:
   a) In the **Rule Name** field, enter the rule name.
   b) Use the **Active** slider to indicate if the rule is active or not.
   c) In the **Priority** field, set a priority for the active rule. The valid range is between 0 and 1023.
   d) From the **Tag** drop-down list, choose **Priming**.
   e) From the **Priming Profile** drop-down list, choose the priming profile, or, search by navigating to the **Priming Profile configuration** window.
5. Click **Apply to Device**.

The priming profile is applied to access points matching the filter criteria.

Apply priming profile using filter (CLI)

Configure a priming profile using filters to automatically provision access points with specific configurations.

Apply priming profiles to APs using filters to automate the provisioning process based on AP naming patterns.

Priming profiles allow you to pre-configure access points with specific settings before they join the network. Using filters based on AP names enables automatic application of these profiles to matching access points.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Configure a filter to prime APs and enter the AP priming filter configuration mode.

   Example

   ```
   Device(config)# ap filter name ap-filter-name type priming
   ```

   Priming filter is always persistent on the AP.

   > **Note**
   >
   > Assign filter priority after filter creation.
3. Configure a filter based on the AP name regular expression match.

   Example

   ```
   Device(config-ap-pr-filter)# ap name-regex ap-filter-string
   ```

4. Map the priming profile to the filter.

   Example

   ```
   Device(config-ap-pr-filter)# profile priming-profile-name
   ```

5. Return to global configuration.

   Example

   ```
   Device(config-ap-pr-filter)# exit
   ```

6. Configure priority for the named AP filter.

   Example

   ```
   Device(config)# ap filter priority priority-value filter-name filter-name
   ```

   Example

   ```
   Device(config)# ap filter priority 2 filter-name height_filter
   ```

The priming profile is now applied using the filter configuration, and matching access points will automatically receive the specified profile settings when they join the network.

Apply priming profile statically (GUI)

Configure static priming profile associations for access points using the GUI interface.

Establish static associations between access points and priming profiles using the graphical user interface.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. Click the **AP** tab and then click the **Static** tab.
3. Click **Add**.

   The **Associate Tags to AP** window is displayed.

4. In the **Associate Tags to AP** window, complete the following steps:
   a) In the **AP MAC Address** field, enter the AP MAC address.
   b) From the **Policy Tag Name** drop-down list, choose the required tag name or search by navigating to the **Policy Tag Configuration** window.
   c) From the **Site Tag Name** drop-down list, choose the required tag name or search by navigating to the **Site Tag Configuration** window.
   d) From the **RF Tag Name** drop-down list, choose the required tag name or search by navigating to the **RF Tag Configuration** window.
   e) From the **Priming Profile** drop-down list, choose the priming profile, or, search by navigating to the **Priming Profile Configuration** window.
5. Click **Apply to Device**.

The static priming profile association is now configured for the selected access point.

Apply priming profile statically (CLI)

Configure a priming profile to be statically applied to an access point using CLI commands.

Apply a priming profile to an AP to configure its initial settings and behavior.

Priming profiles allow you to statically configure APs with specific settings before deployment. This is useful for standardizing AP configurations across your network infrastructure.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the Ethernet MAC address of the AP.

   Example

   ```
   Device(config)# ap H.H.H
   ```

   Example

   ```
   Device(config)# ap CC-XX-3E-XX-FC-XX
   ```

3. Map a priming profile to the AP.

   Example

   ```
   Device(config-ap-tag)# priming priming-profile-name
   ```

   Example

   ```
   Device(config-ap-tag)# priming priming-profile-height
   ```

The priming profile is now statically applied to the specified AP, configuring it with the predefined settings from the profile.

AP priming profile verification

Lists commands to verify AP priming profile configurations and geolocation information.

Verify AP priming profile configurations, including all profiles overview, detailed profile information, AP configuration details, and geolocation data.

Verify all priming AP profiles

To verify all AP priming profiles, use this command:

```
Device# show wireless profile ap priming all
Profile Name                 Primary Controller Name       Primary Controller
 IP     Secondary Controller Name    Secondary Controller IP      Tertiary
Controller Name     Tertiary Controller IP          Height       Uncertainty
       Type        Override
--------------------------------------------------------------------------------
priming_profile_height        8GBXXX                          9.9.XX.XX
                                          0.0.0.0
                     0.0.0.0                          372           64
       AGL           Enabled
```

Verify AP priming profile details

To verify the details of an AP priming profile, use this command:

```
Device# show wireless profile ap priming detailed priming_profile_height
Profile Name                          : priming_profile_height
Primary Controller Name               : 8GBXXX
Primary Controller IP                 : 9.9.XX.XX
Secondary Controller Name             :
Secondary Controller IP               : 0.0.0.0
Tertiary Controller Name              :
Tertiary Controller IP                : 0.0.0.0
Height                                : 372
Uncertainty                           : 64
Type                                  : AGL
Override                              : Enabled
```

Verify AP information

To verify information of a Cisco AP, which includes the AP priming details, use this command:

```
Device# show ap name Cisco-AP conf general | sec Prim
Priming Profile                                 : priming_profile_height
Priming Override                                : Enabled
Priming Source                                  : Filter
Priming Filter name                             : height_filter
```

Verify AP geolocation information

To verify the detailed information of the AP geolocation, use this command:

```
Device# show ap name Cisco-AP geolocation detail
AP Name                          : Cisco-AP
GNSS present                     : No
Location                         : NA
Height type                      : AGL
 Source                          : Manual
 Height (meters)                 : 372
 Uncertainty (meters)            : 64
 Last update                     : 05/22/2024 08:54:34
```

229 Cisco DNA Service for Bonjour Solution Overview

Topics:

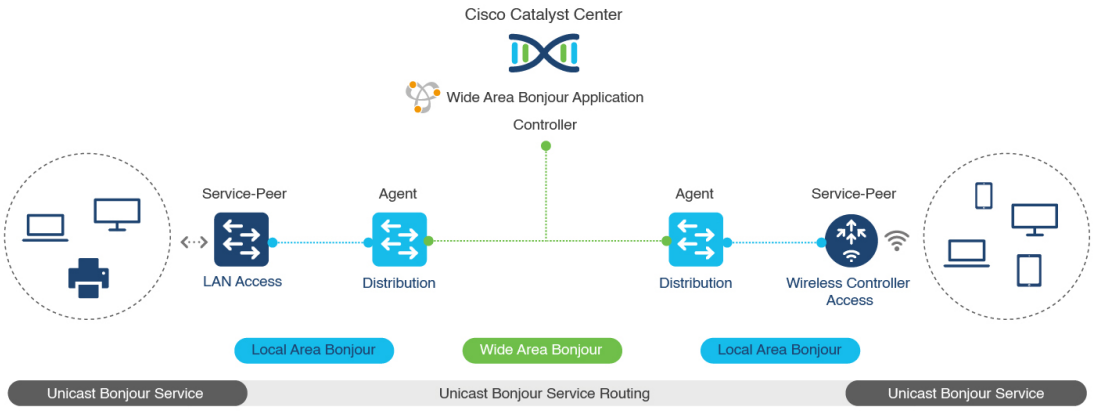
- Cisco DNA Service for Bonjour Solution

Cisco DNA Service for Bonjour Solution

Explains the Cisco Catalyst Center service for Bonjour solution, including its architecture, service routing, and interoperability across enterprise-grade wired and wireless networks.

A Cisco DNA Service for Bonjour solution is a network service architecture that

- eliminates the single Layer 2 domain constraint and expands service discovery to enterprise-grade wired and wireless networks
- enables mDNS service routing to advertise and discover services across distributed networks, and
- supports interoperability with RFC 6762-based multicast DNS (mDNS) compatible wired and wireless consumer products in enterprise environments.



Service routing domains in the Cisco DNA Service for Bonjour solution

The Apple Bonjour protocol is a zero-configuration solution that simplifies rich services and enables intuitive experience between connected devices, services, and applications. Using Bonjour, you can discover and use IT-managed, peer-to-peer, audio and video, or Internet of Things (IoT) services with minimal intervention and technical knowledge. Bonjour is originally designed for single Layer 2 small to mid-size networks, such as home or branch networks. The Cisco DNA Service for Bonjour solution eliminates the single Layer 2 domain constraint and expands the matrix to enterprise-grade traditional wired and wireless networks, including overlay networks such as Cisco Software-Defined Access (SD-Access) and industry-standard BGP EVPN with VXLAN. The Cisco Catalyst 9000 Series LAN switches, Cisco Nexus 9300 Series Switches, and Cisco Catalyst 9800 Series Wireless Controller follow the industry standard, RFC 6762-based multicast DNS (mDNS) specification to support interoperability with various compatible wired and wireless consumer products in enterprise networks.

The Cisco Wide Area Bonjour application on Catalyst Center enables mDNS service routing to advertise and discover services across enterprise-grade wired and wireless networks. The distributed architecture eliminates mDNS flood boundaries and transitions to unicast-based service routing, providing policy enforcement points and enabling management of Bonjour services.

The following figure illustrates how the Cisco Wide Area Bonjour application operates across two integrated service-routing domains.

Figure 44: Cisco Wide Area Bonjour Solution architecture

- **Local Area Service Discovery Gateway Domain - Unicast Mode**: The enhanced Layer 2 unicast policy-based deployment model. mDNS service discovery and distribution using Layer 2 unicast address enables flood-free LAN and wireless networks. Cisco Catalyst 9000 Series Switches and Cisco Catalyst 9800 Series Wireless Controller in Layer 2 mode introduce a new service-peer role, replacing the classic flood-n-learn, for unicast-based service routing support. The service-peer switch and wireless controller replace mDNS flood-n-learn with unicast-based communication with any RFC 6762 mDNS-compatible wired and wireless endpoints.

- **Wide-Area Service Discovery Gateway Domain**: The Wide Area Bonjour domain is a controller-based solution. The Bonjour gateway role and responsibilities of Cisco Catalyst and Cisco Nexus 9300 Series Switches are extended from a single SDG switch to an SDG agent, enabling Wide Area Bonjour service routing beyond a single IP gateway. Distributed SDG agent devices establish a lightweight, stateful, and reliable communication channel with a centralized Catalyst Center controller running the Cisco Wide Area Bonjour application. SDG agents route locally discovered services based on the export policy.

> **Note**
>
> The classic Layer 2 multicast flood-n-learn continues to be supported on wired and wireless networks with certain restrictions to support enhanced security and location-based policy enforcement. The Cisco Catalyst and Cisco Nexus 9300 Series Switches at Layer 3 boundary function as an SDG to discover and distribute services between local wired or wireless VLANs based on applied policies.

Solution components

Explains key components and system roles that enable unicast-based service routing across the local area and Wide Area Bonjour domain.

A solution component is a system element that

- enables unicast-based service routing across the local area and Wide Area Bonjour domain
- includes Cisco Service Peer, Cisco SDG Agent, Catalyst Center controller, and endpoints, and
- supports integration with RFC 6762-compliant Bonjour services.

Service peer, SDG agent, controller, and endpoints

The Cisco DNA Service for Bonjour solution is an end-to-end solution that includes the following key components and system roles to enable unicast-based service routing across the local area and Wide Area Bonjour domain:

- **Cisco Service Peer**: Cisco Catalyst Switches and Cisco Wireless Controllers in Layer 2 access function in service peer mode to support unicast-based communication with local attached endpoints and export service information to the upstream Cisco Catalyst SDG agent in the distribution layer.

> **Note**
>
> Cisco Nexus 9300 Series Switches don't support unicast-based service routing with downstream Layer 2 access network devices.

- **Cisco SDG Agent**: Cisco Catalyst and Cisco Nexus 9300 Series Switches function as an SDG agent and communicate with the Bonjour service endpoints in Layer 3 access mode. At the distribution layer, the SDG agent aggregates information from the downstream Cisco service peer switch and wireless controller, or local Layer 2 networks, and exports information to the central Catalyst Center controller.

> **Note**
>
> Cisco Nexus 9300 Series Switches don't support multilayer LAN-unicast deployment mode.

- Catalyst Center controller: The Catalyst Center controller builds the Wide Area Bonjour domain with network-wide and distributed trusted SDG agents using a secure communication channel for centralized services management and controlled service routing.
- **Endpoints**: A Bonjour endpoint is any device that advertises or queries Bonjour services conforming to RFC 6762. The Bonjour endpoints can be in either LANs or WLANs. The Cisco Wide Area Bonjour application is designed to integrate with RFC 6762-compliant Bonjour services, including AirPlay, Google Chrome cast, AirPrint, and so on.

Supported platforms

Lists supported platforms for Cisco DNA Service for Bonjour solution.

The following tables list the supported controllers, hardware, software versions, and SDG agents for the Cisco DNA Service for Bonjour solution.

Supported controllers, hardware, and software versions

Table 199: Supported Controllers with Supported Hardware and Software Versions

Supported Controller	Hardware	Software Version
Catalyst Center appliance	DN2-HW-APL DN2-HW-APL-L DN2-HW-APL-XL	Catalyst Center, Release 2.3.7.6
Catalyst Center on ESXi	–	Catalyst Center, Release 2.3.7.6
Cisco Wide Area Bonjour application on Catalyst Center	–	2.4.718.75196
Cisco Wide Area Bonjour application on Catalyst Center on ESXi	–	2.718.77018

Supported SDG agents, licenses, and software requirements

Table 200: Supported SDG Agents with Supported License and Software Requirements

Supported Platform	Supported Role	Local Area SDG	Wide Area SDG	Minimum Software
Cisco Catalyst 9200 Series Switches	SDG agent Service peer	Cisco DNA Advantage	Cisco DNA Advantage	Cisco IOS XE Release 17.11.1
Cisco Catalyst 9200L Series Switches	SDG agent Service peer	Cisco DNA Advantage	Cisco DNA Advantage	Cisco IOS XE Release 17.11.1

Supported Platform	Supported Role	Local Area SDG	Wide Area SDG	Minimum Software
Cisco Catalyst 9300 and 9300-X Series Switches	Service peer SDG agent	Cisco DNA Advantage	Cisco DNA Advantage	Cisco IOS XE Release 17.11.1
Cisco Catalyst 9400 and 9400-X Series Switches	Service peer SDG agent	Cisco DNA Advantage	Cisco DNA Advantage	Cisco IOS XE Release 17.11.1

Supported network designs

Explains the types of enterprise-grade networks that support the Cisco Catalyst Center Service for Bonjour, including traditional, Cisco SD-Access, and BGP EVPN-enabled wired and wireless networks.

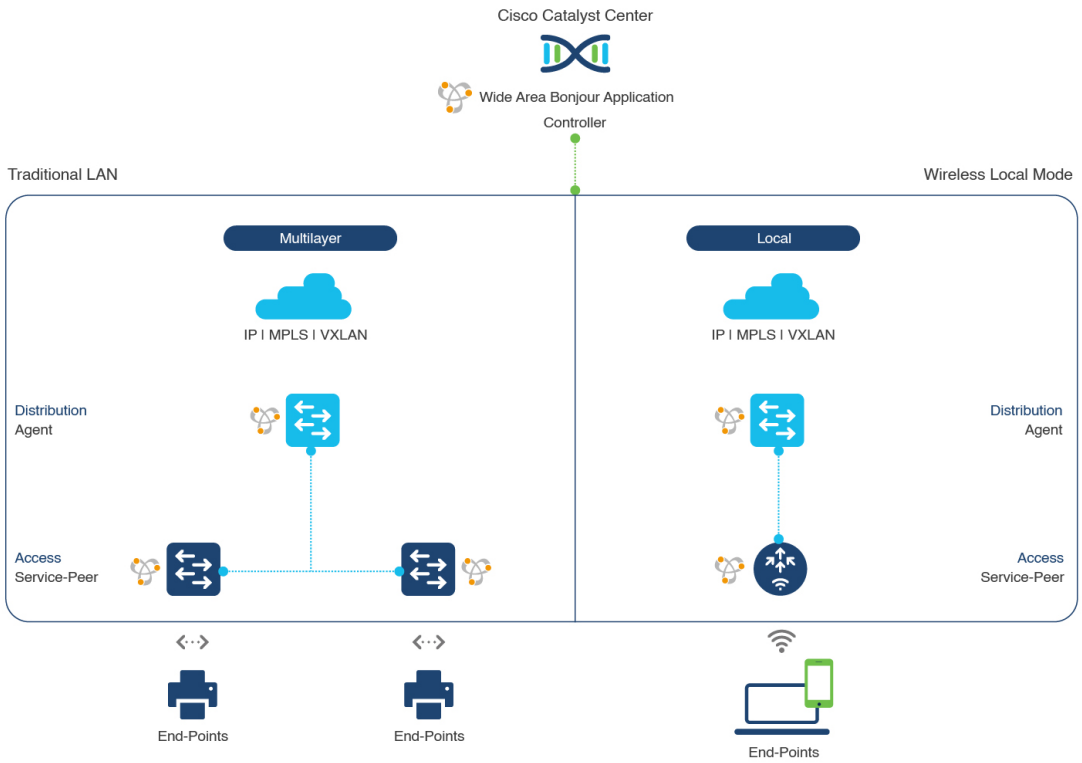
TheCisco DNA Service for Bonjouris supported on traditional, Cisco SD-Access, and BGP EVPN-enabled wired and wireless networks.

The end-to-end unicast-based Bonjour service routing is supported on traditional, Cisco SD-Access, and BGP EVPN-enabled wired and wireless networks.

Traditional wired and wireless networks

Explains traditional networks as classic Layer 2 or Layer 3 networks for wired and wireless modes deployed in enterprise environments.

A traditional wired and wireless network is a network architecture that



- uses classic Layer 2 or Layer 3 designs for wired and wireless modes, and
- is deployed in enterprise networks.

Network design features

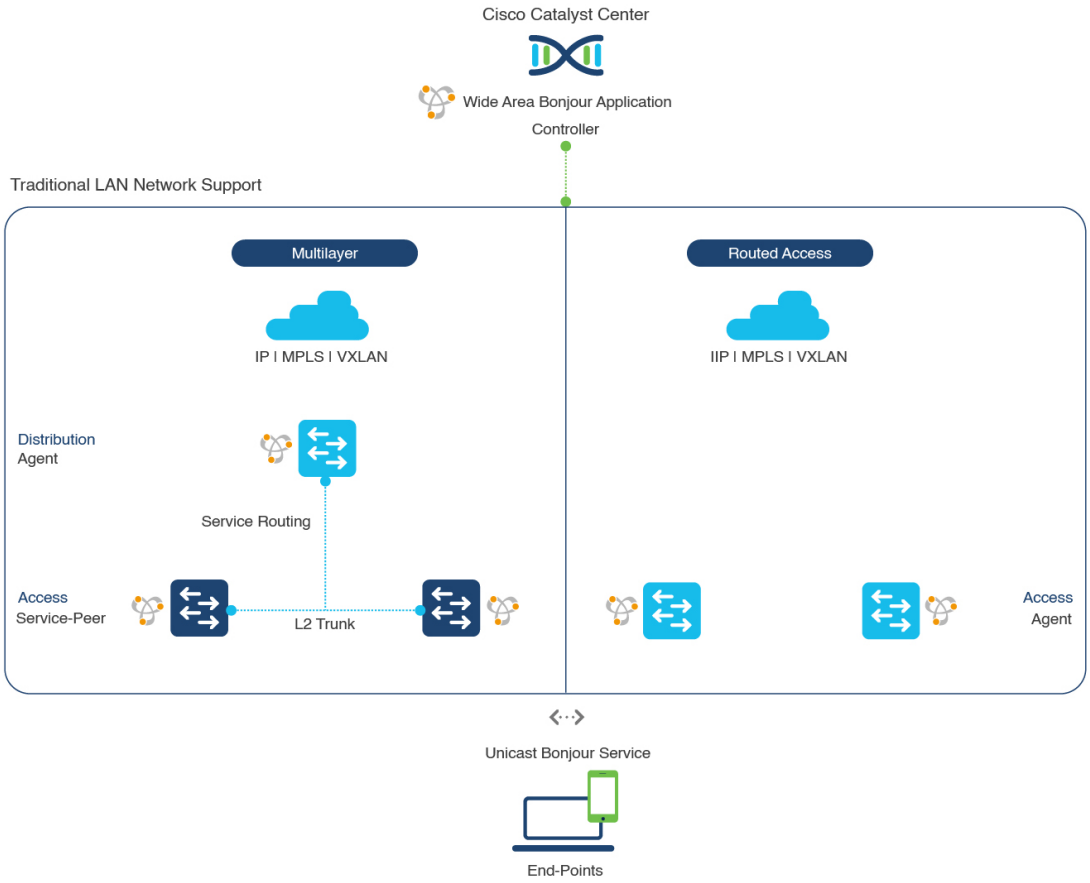
Cisco DNA Service for Bonjour supports a broad range of network designs to enable end-to-end service routing and replace flood-n-learn-based deployment with a unicast mode-based solution.

Traditional LAN and central-switching wireless local mode network designs are commonly deployed in enterprise environments.

Figure 45: Enterprise traditional LAN and wireless local mode network design

Wired networks

Explains supported traditional LAN network designs that are commonly deployed in an enterprise.



A wired network is a LAN network design that

- supports traditional enterprise deployments
- uses Cisco Catalyst or Cisco Nexus 9300 Series Switches in SDG agent role to provide Bonjour gateway functions, and
- enables IP gateway functionality for wired endpoints in multilayer or Layer 3 routed access network designs.

Enterprise wired multilayer and routed access network designs

The following figure shows the supported traditional LAN network designs that are commonly deployed in an enterprise.

Figure 46: Enterprise wired multilayer and routed access network design

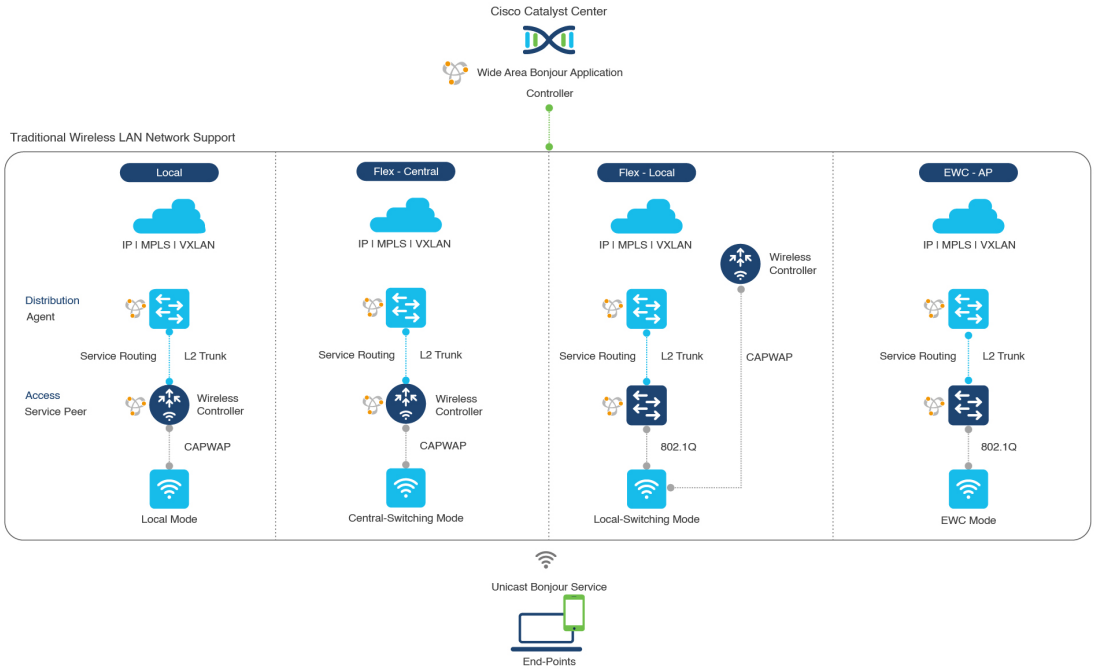
The Cisco Catalyst or Cisco Nexus 9300 Series Switches in SDG agent role that provide Bonjour gateway functions are typically IP gateways for wired endpoints that could reside in the distribution layer in multilayer network designs, or in the access layer in Layer 3 routed access network designs:

- **Multilayer LAN–Unicast mode**: In this deployment mode, the Layer 2 access switch provides the first-hop mDNS gateway function to locally attached wired endpoints. In unicast mode, the mDNS services are routed to the distribution layer systems providing IP gateway and SDG agent mode. The policy-based service routing between the SDG agents is performed by the Catalyst Center controller.
- **Multilayer LAN–Flood-n-Learn mode**: In this deployment mode, the Layer 2 access switch or wireless controller are in mDNS passthrough modes with the Cisco Catalyst or Cisco Nexus 9300 Series Switches operating in the SDG agent mode. The mDNS gateway function at distribution layer in a network enables inter-VLAN mDNS local proxy. It also builds stateful Wide Area Bonjour unicast service routing with the Catalyst Center to discover or distribute mDNS services beyond a single IP gateway.
- **Routed access**: In this deployment mode, the first-hop Cisco Catalyst or Cisco Nexus 9300 Series Switch is an IP gateway boundary and, therefore, it must also perform the SDG agent role. The policy-based service routing between the SDG agents is performed by the Catalyst Center controller.

Wireless networks

Explains modes for wireless LAN networks supported by Cisco Catalyst Center Service for Bonjour.

A wireless network is a network architecture that



- enables wireless LAN connectivity for enterprise environments
- supports mDNS gateway functions for service discovery, and
- offers multiple deployment modes for flexible integration with Cisco Catalyst Center Service for Bonjour.

Supported wireless LAN network designs

The Cisco DNA Service for Bonjour extends the single wireless controller mDNS gateway function into the Wide Area Bonjour solution. The mDNS gateway on Cisco Catalyst 9800 Series Wireless Controller can be deployed in an enhanced mode as a service peer. In this mode, the wireless controller builds unicast service routing with an upstream Cisco Catalyst gateway switch for end-to-end mDNS service discovery. It replaces the classic flood-n-learn mDNS services from wired network using mDNS AP or other methods.

The following figure shows the supported traditional wireless LAN network designs that are commonly deployed in an enterprise. Based on the wireless network design, the mDNS gateway function may be on the wireless controller, or first-hop Layer 2 or Layer 3 Ethernet switch of an Access Point in local-switching mode.

Figure 47: Enterprise traditional wireless LAN network design

The Cisco DNA Service for Bonjour supports the following modes for wireless LAN networks:

- **Local mode**: In the central switching wireless deployment mode, the m-DNS traffic from local mode Cisco access points is terminated on the Cisco Catalyst 9800 Series Wireless Controller. The Cisco Catalyst 9800 Series Wireless Controller extends the mDNS gateway function to the new service peer mode. The wireless controller can discover and distribute services to local wireless users and perform unicast service routing over a wireless management interface to the upstream Cisco Catalyst Switch in the distribution layer, which acts as the IP gateway and the SDG agent.
- **FlexConnect–central**: The mDNS gateway function for Cisco access point in FlexConnect central switch SSID functions consistently as described in **Local mode**. The new extended mDNS gateway mode on the Cisco Wireless Controller and upstream service routing with SDG agent operate consistently to discover services across network based on policies and locations.
- **FlexConnect–local**: In FlexConnect local switching mode, the Layer 2 access switch in mDNS gateway service peer mode provides the policy-based mDNS gateway function to locally attached wired and wireless users. The Cisco Catalyst Switches in the distribution layer function as SDG agents and enable mDNS service-routing across all Layer 2 ethernet switches to support unicast-based service routing to LAN and wireless LAN user groups.
- **Embedded Wireless Controller–access point**: The Layer 2 access switch in service peer mode provides unified mDNS gateway function to wired and wireless endpoints associated with Cisco Embedded Wireless Controller on Cisco Catalyst 9100 Series Access Points. The SDG agent in the distribution layer provides unicast service routing across all Layer 2 service peer switches in the Layer 2 network block without any mDNS flooding.

Cisco SD-Access wired and wireless networks

Explains how Cisco SD-Access-enabled wired and wireless networks support Cisco Catalyst Center Service for Bonjour across fabric networks, providing secure and segmented mDNS service discovery and distribution management.

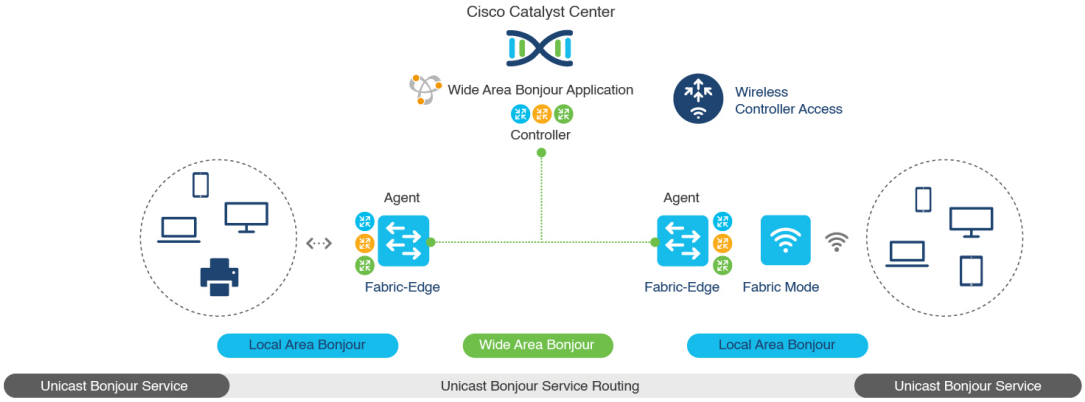
A Cisco SD-Access wired and wireless network is a network infrastructure solution that

- supports Cisco DNA Service for Bonjour across fabric networks
- provides VRF-aware Wide Area Bonjour service routing for secure and segmented mDNS service discovery and distribution management, and
- eliminates the need to extend Layer 2 flooding, improving the scale and performance of the fabric core network and endpoints.

Network design alternatives for Cisco SD-Access wired and wireless networks

Cisco SD-Access supports flexible wired and wireless network design alternatives to manage fully distributed, integrated, and backward-compatible traditional network infrastructure. Wide Area Bonjour service routing is supported in all network designs providing intuitive user experience.

Figure 48: Cisco SD-Access Wired and wireless network design



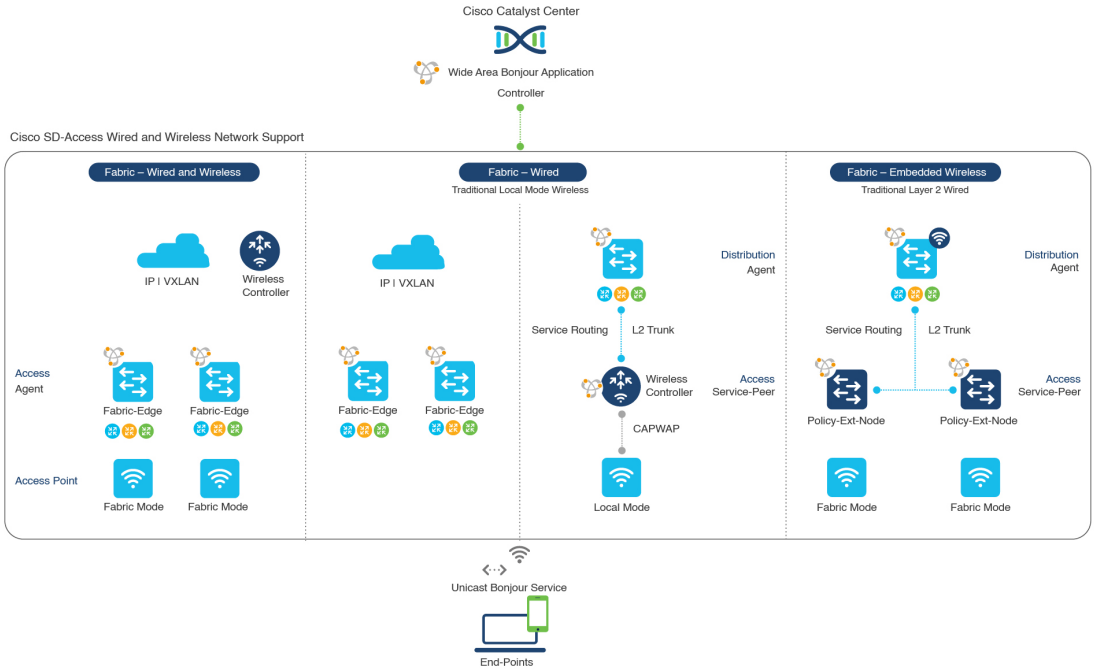


Figure 49: Cisco SD-Access Wired and wireless network design alternatives

The Cisco DNA Service for Bonjour for SD-Access enabled wired and fabric, or traditional mode-wireless networks use two-tier service routing providing end-to-end unicast-based mDNS solution. Based on the network design, each solution component is enabled in a unique role to support the Wide Area Bonjour domain:

- **Fabric Edge SDG Agent**: The Layer 3 Cisco Catalyst Fabric Edge switch in the access layer configured as SDG agent provides unicast-based mDNS gateway function to the locally attached wired and wireless endpoints. The VRF-aware mDNS service policy provides network service security and segmentation in a virtual network environment. The mDNS services can be locally distributed and routed through centralized Catalyst Center.
- **Policy Extended Node**: The Layer 2 Cisco Catalyst access layer switch enables first-hop mDNS gateway function without flooding across the Layer 2 broadcast domain. The unicast-based service routing with upstream Fabric Edge switch in the distribution layer enables mDNS service routing within the same Layer 2 network block. It can also perform remote service discovery and distribution from centralized Catalyst Center.
- Cisco Wireless Controller: Based on the following wireless deployment modes, Cisco Wireless Controller supports unique function to enable mDNS service routing in Cisco SD-Access enabled network:
  - **Fabric-Enabled Wireless**: Cisco Wireless Controller doesn't require any mDNS gateway capability to be enabled in distributed fabric-enabled wireless deployments.
  - **Local Mode Wireless**: As Cisco Wireless Controller provides central control and data plane termination, it provides mDNS gateway in service peer mode for wireless endpoints. The wireless controller provides mDNS gateway between locally associated wireless clients. The wireless controller builds service routing with upstream SDG agent Catalyst switch providing IP gateway and service routing function for wireless endpoints.
  - **Embedded Wireless Controller–Switch**: The Cisco Embedded Wireless Controller solution enables the lightweight integrated wireless controller function within the Cisco Catalyst 9300 Series Switch. The Cisco Catalyst switches in the distribution layer function as SDG agents to the wired and wireless endpoints. The SDG agent in the distribution layer provides unicast service routing across all wireless access points and Layer 2 service peer switches without mDNS flooding.
- Catalyst Center controller: The Cisco Wide Area Bonjour application on Catalyst Center supports policy and location-based service discovery, and distribution between network-wide distributed Fabric Edge switches in SDG agent mode.

The Wide Area Bonjour communication between the SDG agent and controller takes place through the network underlay. Based on policies, the SDG agent forwards the endpoint announcements or queries to the Catalyst Center. After discovering

a service, the endpoints can establish direct unicast communication through the fabric overlay in the same virtual network. The inter-virtual network unicast communication takes place through the Fusion router or external Firewall system. This communication is subject to the configured overlay IP routing and Security Group Tag (SGT) policies.

SD-Access enabled network example

In a Cisco SD-Access enabled network, the Fabric Edge SDG Agent provides unicast-based mDNS gateway function to locally attached wired and wireless endpoints, while the Policy Extended Node enables first-hop mDNS gateway function without flooding across the Layer 2 broadcast domain.

Non-SD-Access network example

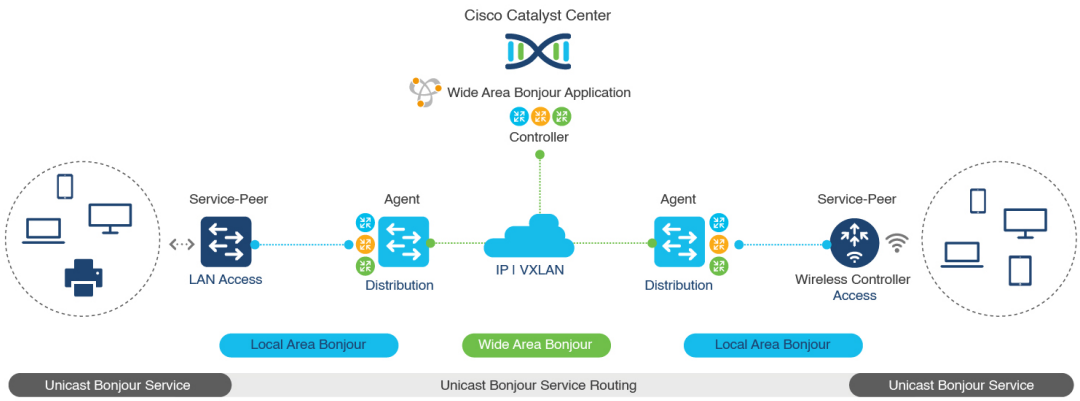
Traditional networks without SD-Access do not provide VRF-aware mDNS service routing or eliminate Layer 2 flooding, resulting in less secure and less scalable service discovery.

SD-Access network analogy

A Cisco SD-Access wired and wireless network is like a gated community where each resident (endpoint) can securely discover and communicate with services without unnecessary traffic flooding the neighborhood.

BGP EVPN networks

Explains how BGP EVPN-based technology provides flexible Layer 3 segmentation and Layer 2 extension overlay networks, supporting secure and segmented mDNS service routing in enterprise environments.



A BGP EVPN network is an overlay network technology that

- provides flexible Layer 3 segmentation and Layer 2 extension overlays
- enables secure and segmented mDNS service routing using VRF and EVPN VXLAN-aware Wide Area Bonjour service routing, and
- eliminates mDNS flooding and solves service reachability challenges for Layer 3 segmented routed networks in the fabric.

Overlay service routing in BGP EVPN networks

The BGP EVPN leaf switch in the distribution layer supports overlay Wide Area Bonjour service routing for BGP EVPN-enabled traditional Layer 2 wired access switches and traditional wireless local mode enterprise networks interconnected through various types of Layer 2 networks and Layer 3 segmented VRF-enabled networks.

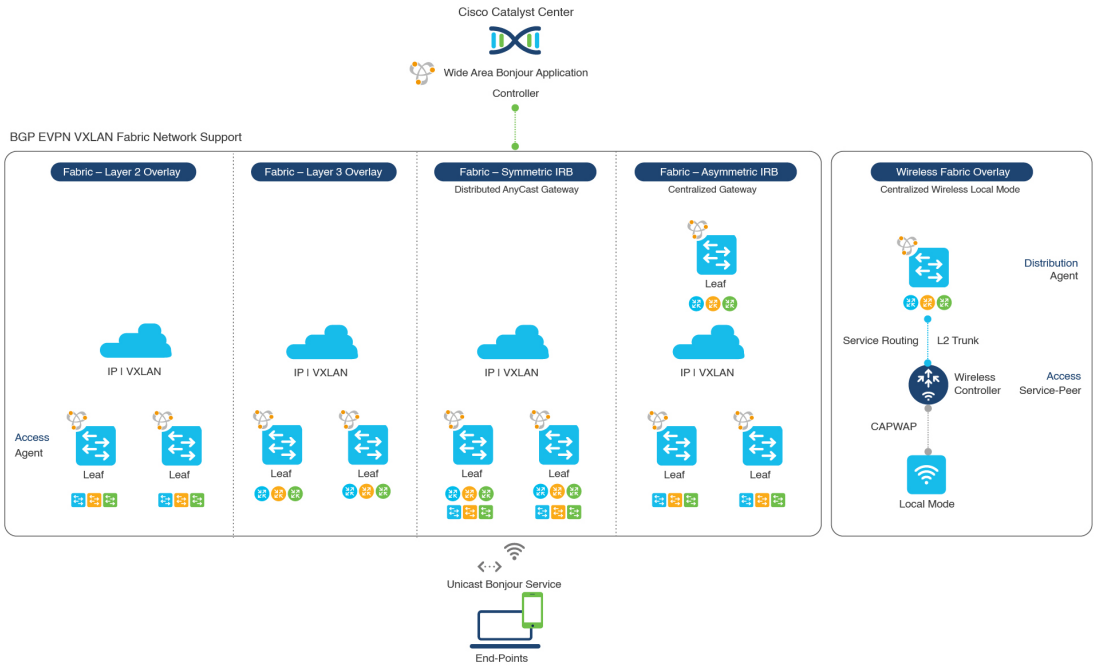


Figure 50: Overlay Bonjour service for a BGP EVPN-enabled enterprise network

Cisco DNA Service for Bonjour supports all industry-standard overlay network designs, enabling end-to-end unicast-based mDNS service routing and preventing flooding and service boundary limitations across wired and wireless networks.

The following figure illustrates various BGP EVPN VXLAN reference overlay network design alternatives. This network design enables end-to-end mDNS service discovery and distribution based on overlay network policies.

Figure 51: BGP EVPN VXLAN wired and wireless design alternatives

The Cisco Catalyst and Cisco Nexus 9000 Series Switches can be deployed in Layer 2 or Layer 3 leaf roles supporting mDNS service routing for a broad range of overlay networks. In any role, mDNS communication is limited locally and supports end-to-end unicast-based service routing across Wide Area Bonjour domain:

- **Layer 2 leaf SDG agent**: The Cisco Catalyst or Cisco Nexus switches can be deployed as Layer 2 leaf supporting end-to-end bridged network with IP gateway within or beyond BGP EVPN VXLAN fabric network. By default, mDNS is flooded as Broadcast, Unknown Unicast, Multicast (BUM) over the fabric-enabled core network. This mDNS flooding may impact network performance and security. The Layer 2 leaf, enabled as SDG agent, prevents mDNS flooding over VXLAN and supports unicast-based service routing.
- **Layer 3 leaf SDG agent**: The Cisco Catalyst or Cisco Nexus switches can be deployed as SDG agent supporting Layer 3 overlay network in BGP EVPN VXLAN fabric. The IP gateway and mDNS service boundary is terminated at the SDG agent switches and remote services can be discovered or distributed through centralized Catalyst Center.
- **Local mode wireless**: The centralized wireless local mode network can be terminated within or outside the EVPN VXLAN fabric domain to retain network segmentation and service discovery for wireless endpoints. The Cisco Catalyst 9800 Series Wireless Controller in service peer mode can build unicast service routing with distribution layer IP and SDG agent Cisco Catalyst switch to discover services from BGP EVPN VXLAN fabric overlay network.
- Catalyst Center: Catalyst Center supports Wide Area Bonjour capability to dynamically discover and distribute mDNS services based on Layer 2 or Layer 3 Virtual Network ID (VNID) policies to route the mDNS services between SDG agent switches in the network.

For more information about BGP EVPN networks, see *Cisco DNA Service for Bonjour Configuration Guide, Cisco IOS XE Bengaluru 17.6.x (Catalyst 9600 Switches)*.

BGP EVPN overlay network example

The overlay Bonjour service for a BGP EVPN-enabled enterprise network demonstrates how mDNS service routing is supported for both wired and wireless access switches interconnected through Layer 2 and Layer 3 segmented VRF-enabled networks.

Non-EVPN overlay network limitations

Traditional Layer 2 networks without BGP EVPN overlays may experience mDNS flooding and lack segmentation, resulting in service reachability challenges.

Overlay network analogy

A BGP EVPN overlay network is like a highway system that enables secure and segmented traffic flow, preventing congestion and ensuring efficient service delivery across different routes.

230 Configuring Local and Wide Area Bonjour Domains

Topics:

- Cisco DNA Service for Bonjour Solution Overview
- Configure local and wide area Bonjour domains
- Verify local area bonjour in multicast DNS mode for LAN and wireless networks
- Additional references for DNA Service for Bonjour

Guides the setup and configuration of Bonjour service discovery across local and wide area networks, including service routing and redundancy protocols.

Cisco DNA Service for Bonjour Solution Overview

Describes the Cisco DNA Service for Bonjour solution that enables Apple devices to discover and connect to network services across subnets in enterprise environments. Explains how the service facilitates seamless device connectivity while maintaining network security and performance.

Restrictions for Cisco DNA service for Bonjour solution

Consider these restrictions when implementing Cisco DNA Service for Bonjour Solution.

Review platform compatibility requirements before deployment. Cisco Service Discovery Gateway (SDG) and Wide Area Bonjour gateway function is supported on Cisco Catalyst Switch and Cisco ISR 4000 series routers. See Solution components on page 3053 for the complete list of supporting platforms, software versions and license levels.

- Use the new **mdns-sd gateway** method for Bonjour configuration policies. Cisco IOS supports classic and new method of building local Bonjour configuration policies. The classic method is based on **service-list mdns-sd** CLI whereas the new method is based on **mdns-sd gateway**. We recommend using the new **mdns-sd gateway** method since the classic configuration support will be deprecated in near future releases.
- Plan for manual migration when converting from classic to new method CLI. The classic to new method CLI migration is manual procedure to convert the configuration.
- Understand that Bonjour service policies on Cisco SDG Gateways are effective between local VLANs. In addition to these, a specific egress policy controls the type of services to be exported to the controller. The Layer 2 Multicast-DNS Bonjour communication between two end-points on same broadcast domain is transparent to gateway.
- Disable mDNS Snooping on Cisco WLC controller for wireless networks. To enable end-to-end Wide Area Bonjour solution on Wireless networks, the Cisco WLC controller must not enable mDNS Snooping function. The upstream IP gateway on the dedicated Cisco Catalyst switch must have the Bonjour gateway function enabled for wireless clients.
- Enable AP Multicast with unique Multicast group on Cisco Wireless LAN Controller. Cisco Wireless LAN Controller must enable AP Multicast with unique Multicast group. Without AP joining WLC Multicast group the mDNS messages will not be processed between client and gateway switch. Multicast on Client SSID or VLAN is optional for other multicast applications and not mandatory or required for Bonjour solution.
- Note the limitations of Cisco Catalyst 9800 WLC as mDNS Gateway. Cisco Catalyst 9800 WLC can be configured as mDNS Gateway. In this mode, the Cisco Catalyst 9800 WLC supports Local-Area Bonjour gateway solution limited to Wireless only networks. Cisco Catalyst 9800 does not support Wide Area Bonjour. For end-to-end Wired and Wireless Bonjour support, we recommend using upstream Cisco Catalyst Switch as IP and Bonjour gateway.

How Cisco Wide Area Bonjour services work

Describes how the Cisco wide area Bonjour solution follows a client-server model for service announcement and discovery in IP networks.

The Cisco Wide Area Bonjour solution follows a client-server model. The SDG Agent functions as a client and the Cisco Wide Area Bonjour application Cisco Catalyst Center functions as a server.

Summary

The key components involved in the Cisco Wide Area Bonjour service workflow are:

- Endpoint devices (Source): Send service announcements to the SDG Agent specifying what services they offer
- SDG Agent: Functions as a client, listens to announcements and matches them against configured policies
- Endpoint device (Receiver): Sends Bonjour queries to discover available services using mDNS protocol
- Cisco Wide Area Bonjour application: Functions as a server for service routing and distribution

Workflow

These stages describe the workflow of service announcement and discovery in the IP network:

1. Endpoint devices announce services to the network through the SDG Agent.
   - The endpoint devices (Source) in the Local Area Bonjour domain send service announcements to the SDG Agent and specify what services they offer. For example, _airplay._tcp.local, _raop._tcp.local, _ipp._tcp.local, and so on.
   - The SDG Agent listens to these announcements and matches them against the configured Local Area SDG Agent policies. If the announcement matches the configured policies, the SDG Agent accepts the service announcement and routes the service to the controller.
2. Endpoint devices discover services available in the network through the SDG Agent.
   - The endpoint device (Receiver) connected to the Local Area SDG Agent sends a Bonjour query to discover the services available, using the mDNS protocol.
   - If the query conforms to configured policies, SDG Agent responds with the services obtained from appropriate service routing via the Wide Area Bonjour Controller.
3. Wide Area Bonjour multi-tier policies control the service announcements and queries.

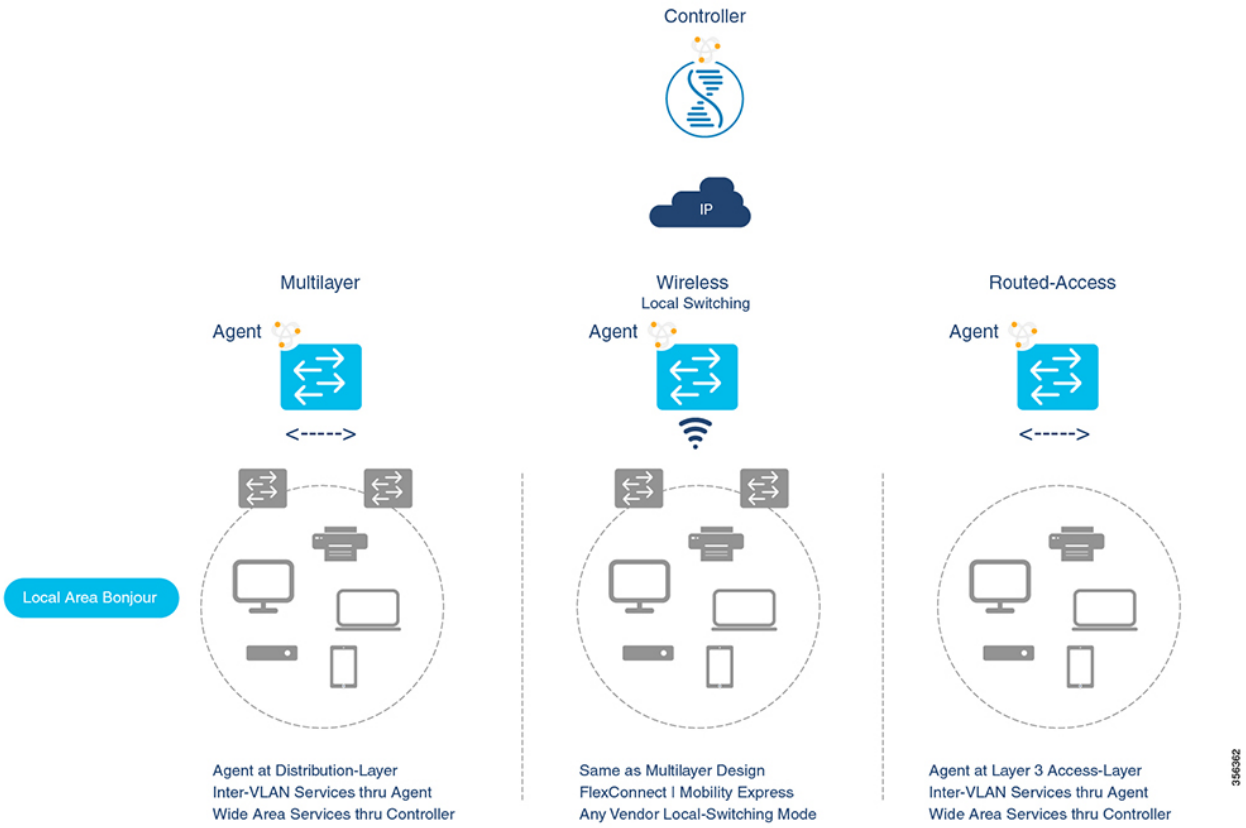
   The various policies that can be used to control the Bonjour announcements and queries are classified as these:
   - **Local Area SDG Agent Filters**: Enforced on the SDG Agent in Layer-2 Network Domain. These bi-directional policies control the Bonjour announcements or queries between the SDG Agents and the Bonjour endpoints.
   - **Wide Area SDG Agent Filters**: Enforced on the SDG Agent for export control to the Controller. This egress unidirectional policy controls the service routing from the SDG Agent to the controller.
   - **Cisco Wide Area Bonjour Policy**: Enforced on Controller for global service discovery and distribution. Policy enforcement, between the controller and the IP network is bi-directional.

Cisco wide area Bonjour supported network design

Describes the network design considerations and architectures that support Cisco wide area Bonjour implementations across distributed enterprise environments.

Traditional wired and wireless networks

Explains the various LAN network designs that Cisco DNA Service for Bonjour supports in enterprise deployments.



Traditional wired and wireless networks are enterprise network architectures that

- support various LAN network designs commonly deployed in the enterprise with Cisco DNA Service for Bonjour
- utilize SDG Agents that provide Bonjour gateway functions as IP gateways for endpoints, and
- enable consistent Bonjour gateway functions across both wired and wireless network deployments.

Network deployment modes

The SDG Agent providing Bonjour gateway functions is typically an IP gateway for wired end-points that could be residing in the distribution layer in multilayer network designs, or in the access layer in routed access network designs.

The following figure shows various topologies which are explained further in the section.

Cisco DNA Service for Bonjour supports these network deployment modes:

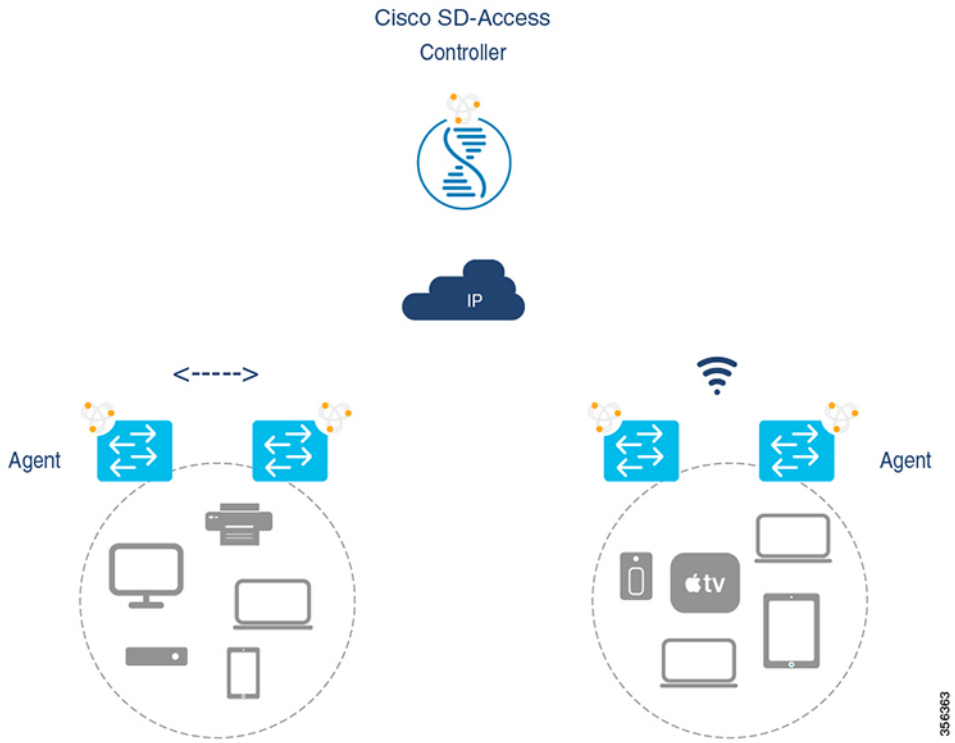
- **Multilayer LAN**: In this deployment mode, the Layer 2 Access switch provides the transparent bridging function of Bonjour services to Distribution-layer systems that act as the IP gateway and SDG Agent. There is no additional configuration or new requirement to modify the existing Layer-2 trunk settings between the Access and Distribution Layer Cisco Catalyst Switches.
- **Routed Access**: In this deployment mode, the first-hop switch is an IP gateway boundary and therefore, it must be combined with the SDG Agent role.

The Cisco DNA Service for Bonjour also supports various Wireless LAN network designs commonly deployed in the Enterprise. The SDG Agent provides consistent Bonjour gateway functions for the wireless endpoints as in wired networks. In general, the IP gateway of the wireless clients is also a Bonjour gateway. However, the placement of the SDG Agent may vary depending on the Wireless LAN deployment mode.

Cisco SD Access wired and wireless networks

Describes how Wide Area Bonjour integrates with Cisco SD-Access fabric-enabled wired and wireless networks using SDG Agents and Controllers.

Cisco SD Access wired and wireless networks are fabric-enabled network architectures that



- configure the Fabric Edge switch as the SDG Agent for both wired and wireless endpoints
- require Wide Area Bonjour policies to align with SD-Access network policies regarding Virtual Networks and SGT policies, and
- enable service discovery communication through fabric underlay while maintaining data communication through fabric overlay.

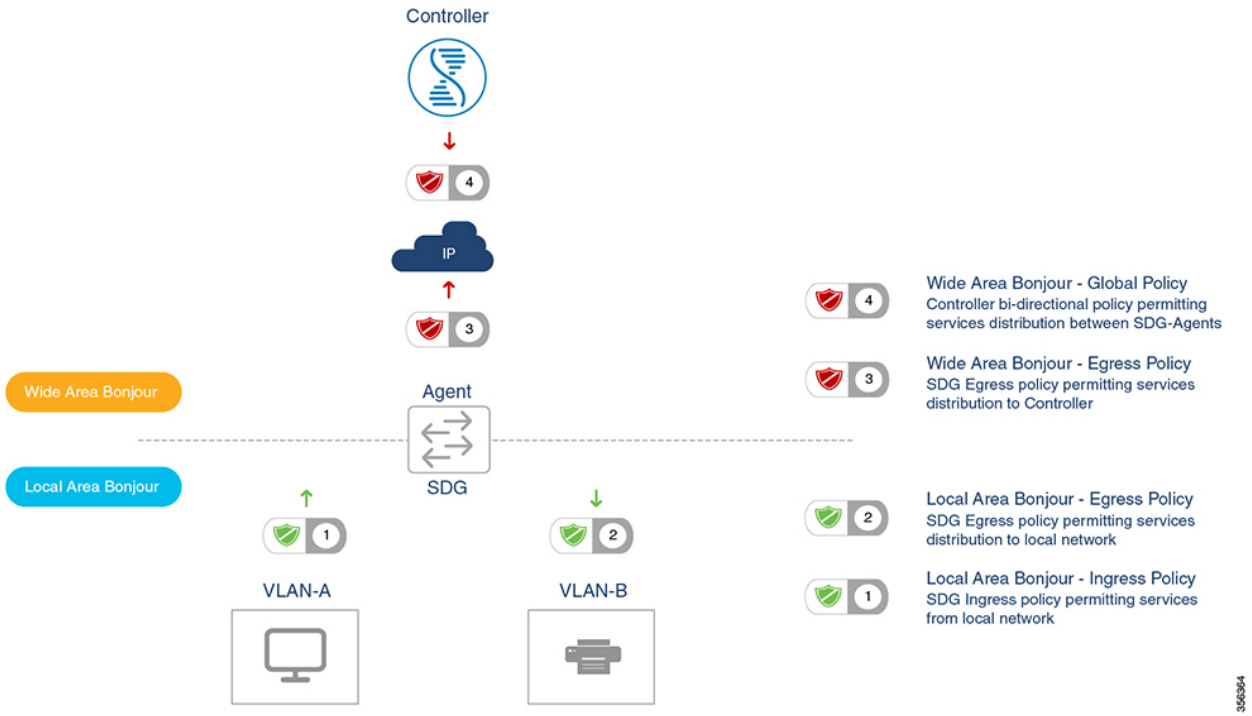
Wide Area Bonjour logical components

Wide Area Bonjour uses two logical components in a network:

- SDG Agent: The Fabric Edge switch is configured as the SDG Agent, and the configuration is added only after the SD-Access is configured.
- Wide Area Bonjour Controller: The Wide Area Bonjour application in the Cisco Catalyst Center acts as the Controller.

The Wide Area Bonjour communication between the SDG Agent and the Controller takes place through the network underlay. The SDG Agent forwards the endpoint announcements or queries to the Controller through the fabric underlay. After discovering a service, a Bonjour-enabled application establishes direct unicast communication with the discovered device through the fabric overlay. This communication is subject to any configured routing and SDG policies.

Local and wide area Bonjour policies



Describes Cisco Wide Area Bonjour policy functions that enable policy-based Bonjour services discovery and distribution in two-tier domains.

A Cisco Wide Area Bonjour policy is a network configuration mechanism that

- enables policy-based Bonjour services discovery and distribution in two-tier domains
- divides functionality into four unique functions for comprehensive service management, and
- allows network administrators to identify Bonjour services and set discovery boundaries limited to local or global based on requirements.

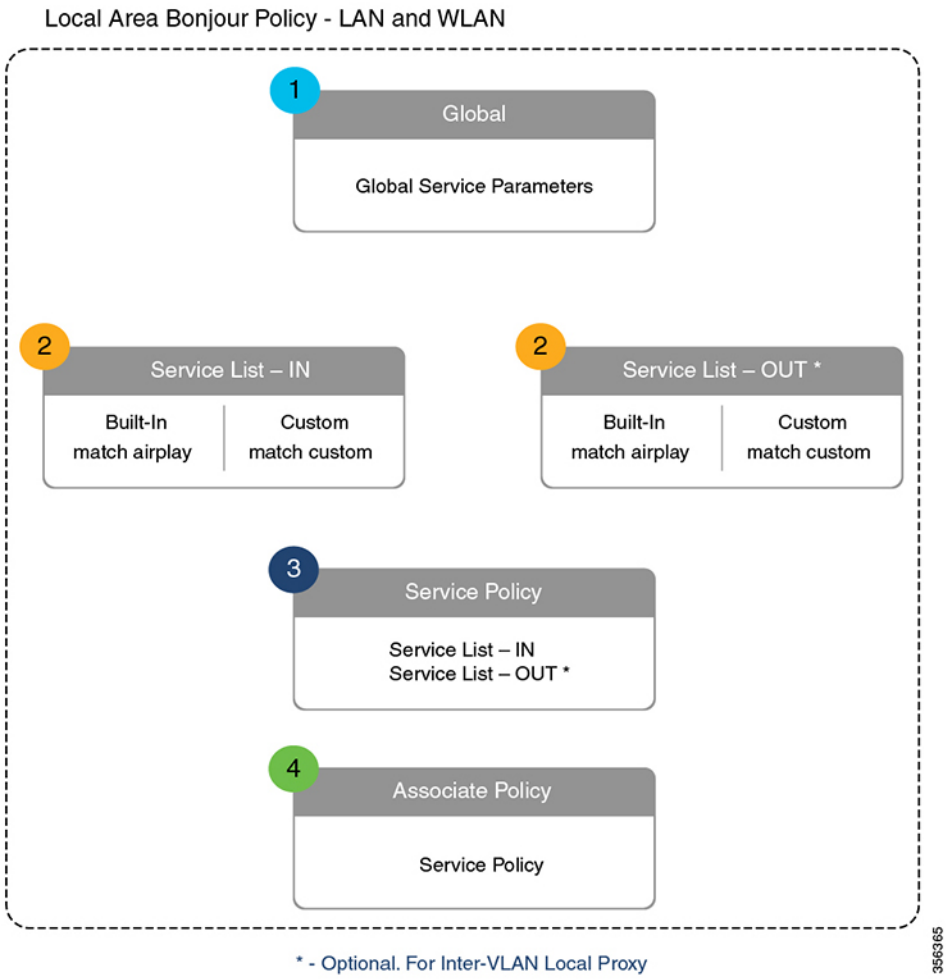
Policy enforcement points

The policy enforcement occurs at the SDG Agent level and in Cisco Catalyst Center Wide Area Bonjour application. This illustration shows enforcement point and direction of all four types of Bonjour policies:

Local area Bonjour policies

Explains the simplified and scalable Cisco IOS Bonjour policy structure with the new configuration mode.

A local area Bonjour policy is a network configuration framework that



- enables service distribution with intuitive user-friendly service-types instead of individual mDNS PoinTeR (PTR) records types
- provides built-in service-types for common Enterprise services and allows custom service-type creation for network administrators, and
- requires a mandatory three-step configuration process for Local Area Bonjour domain management.

Local area Bonjour policy configuration

The Cisco IOS Bonjour policy structure is greatly simplified and scalable with the new configuration mode. The services can be enabled with intuitive user-friendly service-type instead individual mDNS PoinTeR (PTR) records types, for example select AirPlay that automatically enables video and audio service support from Apple TV or equivalent capable devices. Several common types of services in Enterprise can be enabled with built-in service-types. If built-in service type is limited, network administrator can create custom service-type and enable the service distribution in the network.

The policy configuration for the Local Area Bonjour domain is mandatory, and is a three step process. This illustration shows the step-by-step procedure to build the Local-Area Bonjour policy, and apply to enable the gateway function on selected local networks:

Figure 52: Local Area Bonjour Policy Hierarchy

To configure local area bonjour policies, enable mDNS globally. For the device to receive mDNS packets on the interface, configure mDNS gateway on the interface. Create a service-list by using filter options within IT allow services into or OUT of a device or interface. After enabling mDNS gateway globally and on the interface, you can apply filters (IN-bound filtering or OUT-bound filtering) on service discovery information by using **service-policy** commands.

Built-in service lists

The Cisco IOS software includes built-in list of services that may consist of one more Bonjour service-type. A single service-list may contain more than one service-type entries with default rule to accept service announcement from service-provider and the service query request from receiver end-points. If selected service-type contains more than one Bonjour service-types (PTR), then a service announcement or a service query is honored when the announcement/query is for any one of these included Bonjour service-types. For example, Apple Time Capsule Data service-type consists of both_adisk and _afpovertcp built-in PTRs, however if any end-point announces or requests for only _afpovertcp service, then SDG Agent will successfully classify and process the announcement or request. The service-list contains implicit-deny for all un-defined built-in or custom services entries.

This table illustrates complete list of built-in Bonjour services that can be used to create policies in local area Bonjour.

Table 201: Cisco IOS Built-In Bonjour Service Database

Service	Service Name	mDNS PTRs
Airplay	airplay	_airplay._tcp.local

Service	Service Name	mDNS PTRs
Apple TV	apple-tv	_airplay._tcp.local _raop._tcp.local
Audinate	audinate	_dante-safe._udp.local _dante-upgr._udp.local _netaudio-arc._udp.local _netaudio-chan._udp.local _netaudio-cmc._udp.local _netaudio-dbc._udp.local
AirServer Mirroring Service	airserver	_airplay._tcp.local _airserver._tcp.local
Apple AirTunes	airtunes	_raop._tcp.local
Amazon Fire TV	amazon-fire-tv	_amzn-wplay._tcp.local
Apple AirPrint	apple-airprint	_ipp._tcp.local _universal._sub._ipp._tcp.local
Apple TV 2	apple-continuity	_companion-link._tcp.local
Apple File Share	apple-file-share	_afpovertcp._tcp.local
Apple HomeKit	apple-homekit	_homekit._ipp.local _hap._tcp.local
Apple iTunes Library	apple-itunes-library	_atc._tcp.local
Apple iTunes Music	apple-itunes-music	_daap._tcp.local
Apple iTunes Photo	apple-itunes-photo	_dpap._tcp.local
Apple KeyNote Remote Control	apple-keynote	_keynotecontrol._tcp.local _keynotepair._tcp.local
Apple Remote Desktop	apple-rdp	_afpovertcp._tcp.local _net-assistant._tcp.local
Apple Remote Event	apple-remote-events	_eppc._tcp.local
Apple Remote Login	apple-remote-login	_sftp-ssh._tcp.local _ssh._tcp.local
Apple Screen Share	apple-screen-share	_rfb._tcp.local
Google Expeditions	google-expeditions	_googexpeditions._tcp.local
Apple Time Capsule Data	apple-timecapsule	_adisk._tcp.local _afpovertcp._tcp.local

Service	Service Name	mDNS PTRs
Apple Time Capsule Management	apple-timecapsule-mgmt	_airport._tcp.local
Apple MS Window File Share	apple-windows-fileshare	_smb._tcp.local
Fax	fax	_fax-ipp._tcp.local
Google ChromeCast	google-chromecast	_googlecast._tcp.local _googlerpc._tcp.local _googlezone._tcp.local
Apple HomeSharing	homesharing	_home-sharing._tcp.local
Apple iTunes Data Sync	itune-wireless-devicesharing2	_apple-mobdev2._tcp.local
Multifunction Printer	multifunction-printer	_ipp._tcp.local _scanner._tcp.local _fax-ipp._tcp.local
Phillips Hue Lights	phillips-hue-lights	_hap._tcp.local
Printer – Internet Printing Protocol	printer-ipp	_ipp._tcp.local
Printer – IPP over SSL	printer-ipps	_ipps._tcp.local
Linux Printer – Line Printer Daemon	printer-lpd	_printer._tcp.local
Printer Socket	printer-socket	_pdl-datastream._tcp.local
Roku Media Player	roku	_rsp._tcp.local
Scanner	scanner	_scanner._tcp.local
Spotify Music Service	spotify	_spotify-connect._tcp.local
Web-Server	web-server	_http._tcp.local
WorkStation	workstation	_workstation._tcp.local

Service Status Timer Management

The Bonjour service-provider end-points may announces one or more services in the network combining mDNS records and time-to-live (TTL) service timers for each record. The TTL value provides assurance of end-point availability and serviceability in the network. The SDG Agents ensures that IT contains up to date information in its local and updates global services in Controller based on TTL and other events in Local Area Bonjour domain. The network administrator must configure the service status timer where service-provider endpoint discovery is permitted.

Wide Area Bonjour policies

Describes Wide Area Bonjour policies that enable service routing over IP networks without network boundaries.

A Wide Area Bonjour policy is a network service control mechanism that

- requires controller bound service export policy to control routing local services and discover remote services from Cisco Catalyst Center

- enables SDG-Agent to build trusted communication channels with remote service responses implicitly permitted, and
- operates unidirectionally requiring only egress service policy towards the controller.

Policy structure and configuration

The Wide Area Bonjour policy hierarchy and structure is identical as described in Local Area Bonjour Policy structure section. This section provides step-by-step reference configuration to build and enforce the policy to enable the successful communication with Wide Area Bonjour App in Cisco Catalyst Center.

Policy configuration components:

- **Service List**: Network administrators must create new controller bound egress service lists for the Wide Area Bonjour domain. In most common network deployment models, the Wide Area Bonjour service list may contain same service-types as the Local Area Bonjour to implement common services between both domains. Based on requirements, certain services can be limited to Local Area and prevent routed in Wide Area Domain, then by default only allowed service list entries are permitted and rest are dropped with implicit deny rule.
- **Ingress Policy Direction**: The ingress service policy for Wide Area Bonjour domain is not required and cannot be associated to the controller.
- **Egress Policy Direction**: The Bonjour policy structure between Local Area and Wide Area is consistent, however the enforcement point is different. Cisco recommends configuring separate Service-List and Service-Policy for Wide Area Bonjour domain as this helps building unique policy sets for each domain.
- **Conditional Egress Service List**: The Wide Area Bonjour egress service list configuration can be customized to conditionally route the service or query request to the Cisco Catalyst Center. With this alternative configuration setting, network administrators can route the service or query the request in Wide Area Bonjour domain from specific local source VLAN networks instead globally from the entire system.

Service timer management:

The Cisco Catalyst Center centralizes services information from large scale distributed SDG-Agents across the network. To maintain scale and performance of the controller, services routing information is transmitted and synchronized periodically by each SDG-Agent network device. To protect system and network performance, the scheduler base service information exchange allows graceful and reliable way to discover and distribute Bonjour services across Wide Area Bonjour domain.

> **Note**
>
> In most large-scale network environments, the default Bonjour service timers on SDG-Agents are fine-tuned and may not need any further adjustments. Cisco recommends retaining the interval timer values to default and adjust only based on any user experience issue and consider modified parameters do not introduce scale and performance impact.

Default mDNS service configurations

Explains the default mDNS service configurations that accelerate solution adoption, increase user productivity, and reduce operation overhead through a default service policy.

Default mDNS service configurations are an intuitive approach to configuring mDNS services that

- accelerates solution adoption, increases user productivity, and reduces operation overhead through a default service policy
- creates a service list with default service-types that is automatically enforced in the ingress or egress direction, and

- allows you to define a custom policy and service list with custom-defined service types.

Default mDNS service configurations details

Starting with Cisco IOS XE Bengaluru 17.6.1, the default mDNS service configuration is introduced. The default service configuration contains a default service policy that creates a service list with default service-types that is automatically enforced in the ingress or egress direction.

Additionally, you can define a custom policy and service list with custom-defined service types, and enforce it in the ingress or egress direction.

Figure 53: Default mDNS service configurations

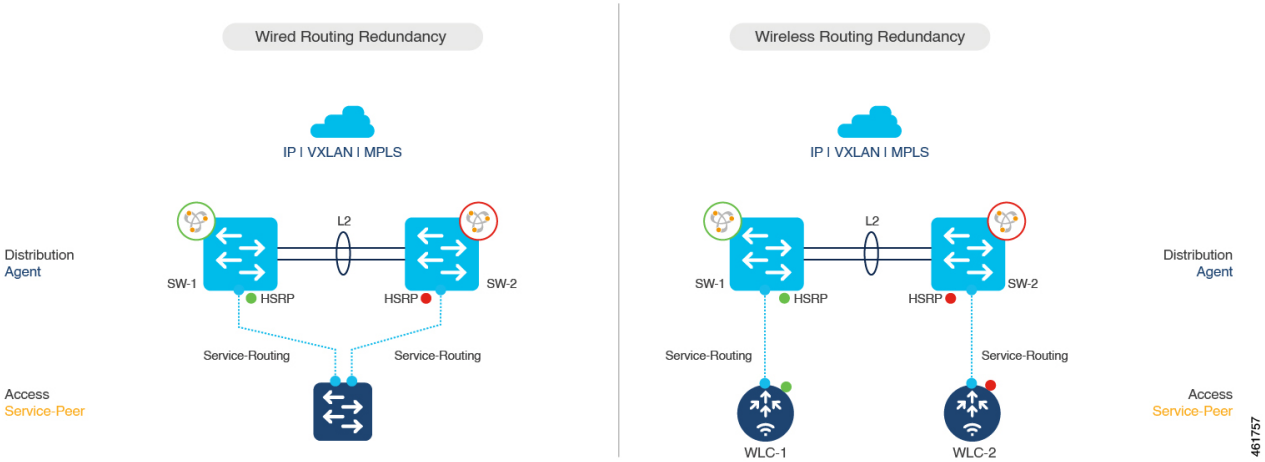
HSRP-aware mDNS service-routing

Explains Hot Standby Router Protocol-aware (HSRP-aware) mDNS Service-Routing that is supported between Service Peers and SDG agents in a multilayer network.

HSRP-Aware mDNS Service-Routing is a network protocol feature that

- maintains uninterrupted service-routing sessions between Service Peers and SDG agents during primary SDG agent failures
- enables automatic establishment of sessions with new primary SDG agents and cache information resyncing during changeouts, and
- uses HSRP virtual IP addresses on management VLANs to provide automatic gateway selection and rapid switchover capabilities.

HSRP-Aware mDNS Service-Routing configuration



Starting from Cisco IOS XE Bengaluru 17.6.1, Hot Standby Router Protocol-aware (HSRP-aware) mDNS Service-Routing is supported between Service Peers and SDG agents in a multilayer network. During a changeover, that is when the primary SDG agent fails and the secondary SDG agent becomes the new primary, the service-routing session between the Service Peer and the SDG agent remains uninterrupted. The new primary SDG agent establishes a session with the Service Peer and cache information is resynced.

The HSRP virtual IP address of the management VLAN is enabled on the SDG agent using the **standby** *group_number* **IP** *ip_address* command. The HSRP virtual IP address needs to configured on the Service Peer as the IP address of the SDG agent.

> **Note**
>
> The HSRP virtual IP address must be reachable and in active state during a changeover.

This figure illustrates a wired and wireless network that supports HSRP-aware mDNS Service-Routing:

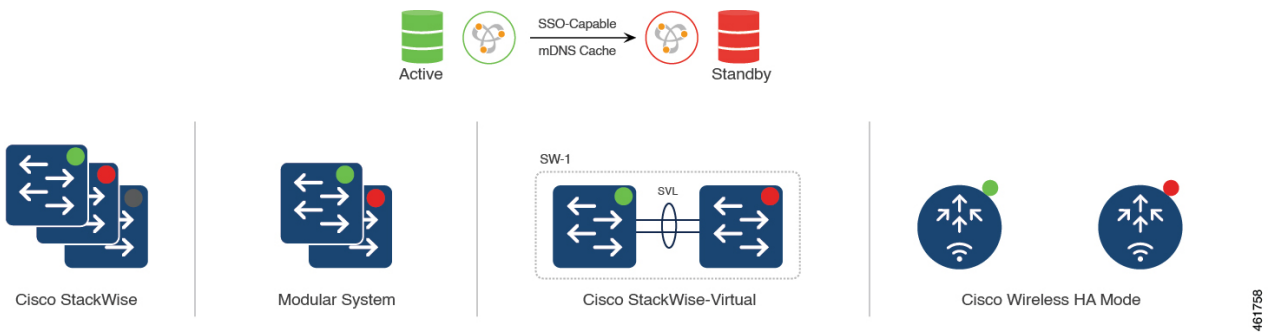
Figure 54: HSRP-Aware mDNS Service-Routing

The HSRP offers these advantages:

- Automatic gateway selection.
- Rapid switchover.
- Reduces service convergence.

mDNS service-gateway SSO support

Explains mDNS Stateful Switchover (SSO) support on network devices configured in Service Peer role.



mDNS service-gateway SSO support is a high availability feature that

- enables mDNS Stateful Switchover (SSO) on network devices configured in Service Peer role
- synchronizes cache information between active and standby devices, and
- ensures continuous mDNS service discovery when the active device fails.

Service-gateway SSO operation

Starting from Cisco IOS XE Bengaluru 17.6.1, mDNS Stateful Switchover (SSO) is supported on network devices configured in Service Peer role. In SSO-enabled devices, one device is selected as an active device and the other as a standby device. The cache information learnt by the active device is synced with the standby device. When the active device fails, the standby device becomes the new active device and continues the mDNS service discovery process.

Figure 55: MDNS Service-Gateway SSO

Configure local and wide area Bonjour domains

Describes how to configure local and wide area Bonjour domains to enable service discovery and communication across different network segments and geographic locations.

How to configure multicast DNS mode for LAN and wired networks

Explains how to configure multicast DNS mode for Local Area Bonjour on LAN and wired networks, providing step-by-step configuration procedures for enabling this network discovery protocol.

This section provides information about how to configure Local Area Bonjour in multicast DNS mode.

Enable mDNS gateway on the device

Configure mDNS gateway on the device to enable multicast DNS functionality.

Enable mDNS gateway functionality on the device to allow multicast DNS service discovery across network segments.

mDNS gateway enables devices to discover and communicate with services across different network segments using multicast DNS protocols.

Before you begin

Follow these steps to configure mDNS on the device:

Procedure

1. **enable**

   Example

   ```
   Device> enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **mdns-sd gateway**

   Example

   ```
   Device(config)# mdns-sd gateway
   ```

   Enables mDNS on the device and enters mDNS gateway configuration mode.

   Enter the following commands in mDNS gateway configuration mode to enable the respective functionalities:

   - **air-print-helper**: Enables IOS devices like iPADs to discover and use older printers that support Bonjour
   - **cache-memory-max**: Configures the percentage memory for cache
   - **ingress-client**: Configures Ingress Client Packet Tuners
   - **rate-limit**: Enables rate limiting of incoming mDNS packets
   - **service-announcement-count**: Configures maximum service advertisement count
   - **service-announcement-timer**: Configures advertisements announce timer periodicity
   - **service-query-count**: Configures maximum query count
   - **service-query-timer**: Configures query forward timer periodicity

   The following CLIs are effective only in service-peer mode:

   - **query-response**
   - **sdg-agent**
   - **service-announcement-count**
   - **service-announcement-timer**
   - **service-mdns-query**
   - **service-query-count**
   - **service-query-timer**
   - **service-receiver-purge**
   - **active-response**

   > **Note**
   >
   > For **cache-memory-max**, **ingress-client**, **rate-limit**, **service-announcement-count**, **service-announcement-timer**, **service-query-count**, and **service-query-timer** commands, you can retain the default value of the respective parameter for general deployments. Configure a different value, if required, for a specific deployment.

4. **exit**

   Example

   ```
   Device(config-mdns-sd)# exit
   ```

Exits mDNS gateway configuration mode.

---

mDNS gateway is now enabled on the device and ready to facilitate multicast DNS service discovery across network segments.

Create custom service definition (GUI)

Configure custom service definition using GUI.

Create a custom service definition to define specific mDNS services that can be discovered and used within your network environment.

Custom service definitions allow you to specify particular service types that devices on your network can advertise and discover through mDNS (multicast Domain Name System). This is useful for managing which services are available for discovery in your network infrastructure.

Before you begin

Follow these steps to create custom service definition using GUI:

Procedure

---

1. Choose **Configuration** > **Services** > **mDNS** > **Service Policy** > **Service Definition**.
2. Click **Add**.
3. Enter the **Service Definition Name** and **Description**.
4. Enter the **Service Type** and click the **+** icon.
5. Click **Apply to Device**.

The custom service definition is created and applied to the device. The new service definition will be available for use in mDNS service policies and can be discovered by devices on the network.

Create custom service definition

Configure custom service definition using commands.

Create a custom service definition to provide an admin-friendly name to one or more mDNS service types or PTR Resource Record Names.

Service definition is a construct that provides an admin friendly name to one or more mDNS service types or PTR Resource Record Name. By default, a few built-in service definitions are already predefined and available for admin to use. In addition to built-in service definitions, admin can also define custom service definitions.

Procedure

---

1. **enable**

Example

```
Device> enable
```

Enables privileged EXEC mode.

Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **mdns-sd service-definition** *service-definition-name*

   Example

   ```
   Device(config)# mdns-sd service-definition CUSTOM1
   ```

   Configures mDNS service definition.

   > **Note**
   >
   > All the created custom service definitions are added to the primary service list. Primary service list comprises of a list of custom and built-in service definitions.

4. **service-type** *string*

   Example

   ```
   Device(config-mdns-ser-def)# service-type _custom1._tcp.local
   ```

   Configures mDNS service type.

5. Repeat step 4 to configure more than one service type in the custom service definition.
6. **exit**

   Example

   ```
   Device(config-mdns-ser-def)# exit
   ```

   Exit mDNS service definition configuration mode.

The custom service definition is created and added to the primary service list, making it available for use in mDNS configurations.

Create a service list (GUI)

Configure a service list using the GUI interface.

Create service lists to control mDNS service discovery by specifying which services are allowed or denied in the network.

Service lists provide a mechanism to filter mDNS services based on service types and message types, helping you manage service discovery traffic in your network.

Procedure

1. Choose **Configuration** > **Services** > **mDNS** > **Service Policy** > **Service List**.
2. Click **Add**.
3. Enter the **Service List Name** and choose the direction from the **Direction** drop-down list.
4. Click **Add Service**.
5. Choose the service from the **Available Services** drop-down list and the message type from the **Message Type** drop-down list.
6. Click **Save**.
7. Click **Apply to Device**.

The service list is created and applied to the device, enabling mDNS service filtering based on your configured parameters.

Create service list

Configure mDNS service list using commands.

Create an mDNS service list to organize service definitions and control service discovery traffic.

mDNS service list is a collection of service definitions. Use service lists to manage which services are allowed IN or OUT of specific network segments.

Before you begin

Follow these steps to create a service list:

Procedure

1. **enable**

   Example

   ```
   Device> enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **mdns-sd service-list** *service-list-name* {**IN** | **OUT**}

   Example

   ```
   Device(config)# mdns-sd service-list VLAN100-list in
   ```

   Configures mDNS service list.

4. **match** *service-definition-name* [**message-type** {**any** | **announcement** | **query**}]

Example

```
Device(config-mdns-sl-in)# match PRINTER-IPPS message-type announcement
```

Matches the service to the message type. Here, *service-definition-name* refers to the names of services, such as, airplay, airserver, airtunes, and so on.

> **Note**
>
> To add a service, the service name must be part of the primary service list.
>
> If the mDNS service list is set to IN, the applicable command syntax is: **match** *service-definition-name* [**message-type** {**any** | **announcement** | **query**}].
>
> If the mDNS service list is set to OUT, the applicable command syntax is: **match** *service-definition-name* [**message-type** {**any** | **announcement** | **query**}] [**location-filter** *location-filter-name*] [**source-interface** {*mDNS-VLAN-number* | *mDNS-VLAN-range*}].

5. **exit**

Example

```
Device(config-mdns-sl-in)# exit
```

Exits mDNS service list configuration mode.

The mDNS service list is created and configured with the specified service definitions and message types.

Create service policy (GUI)

Create service policy using GUI.

Create a service policy to manage mDNS services and control service discovery between network segments.

Service policies define how mDNS services are handled across different network locations by specifying input and output service lists.

Procedure

---

1. Choose **Configuration** > **Services** > **mDNS** > **Service Policy** > **Service Policy**.
2. Click **Add**.
3. Enter the **Service Policy Name**.
4. Choose the service list input from the **Service List Input** drop-down list.
5. Choose the service list output from the **Service List Output** drop-down list.
6. Choose the location from the **Location** drop-down list.
7. Click **Apply to Device**.

The service policy is created and applied to the device. The mDNS service discovery is now controlled according to the configured policy parameters.

Create service policy

Configure service policy using commands.

Create a service policy to specify allowed Bonjour service announcements or queries that should be processed IN ingress or egress directions.

A Service Policy that is applied to an interface specifies the allowed Bonjour service announcements or the queries of specific service types that should be processed, IN ingress direction or egress direction or both. For this, the service policy specifies two service-lists, one each for ingress and egress directions. IN the Local Area Bonjour domain, the same service policy can be attached to one or more Bonjour client VLANs; however, different VLANs may have different service policies.

Before you begin

Follow these steps to configure service policy with service lists:

Procedure

1. **enable**

   Example

   ```
   Device> enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **mdns-sd service-policy** *service-policy-name*

   Example

   ```
   Device(config)# mdns-sd service-policy mdns-policy1
   ```

   Configures mDNS service policy.

4. **service-list** *service-list-name* {**IN** | **OUT**}

   Example

   ```
   Device(config-mdns-ser-pol)# service-list VLAN100-list in
   ```

   ```
   Device(config-mdns-ser-pol)# service-list VLAN300-list out
   ```

   Configures service lists for IN and OUT directions.

5. **exit**

Example

```
Device(config-mdns-ser-pol)# exit
```

Exits mDNS service policy configuration mode.

The mDNS service policy is created and configured with service lists for ingress and egress directions.

Associate service policy to an interface

Configure mDNS gateway on an interface and associate service policy to enable mDNS functionality.

Associate a service policy to an interface to enable mDNS (multicast DNS) functionality and govern Bonjour announcements and queries.

mDNS configuration on the device requires associating service policies to interfaces to control Bonjour service behavior on VLANs.

Before you begin

Follow these steps to configure mDNS on the device:

Procedure

---

1. **enable**

   Example

   ```
   Device> enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **interface** *interface-name*

   Example

   ```
   Device(config)# interface Vlan 601
   ```

   Enters interface mDNS configuration mode and enables interface configuration.

4. **mdns-sd gateway**

   Example

   ```
   Device(config-if)# mdns-sd gateway
   ```

Configures mDNS gateway on the interface.

Enter these commands in the interface mDNS gateway configuration mode to enable the respective functionalities:

- **active-query**: Sets the time interval for SDG agent to refresh the active status of connected Bonjour client services. The timer value ranges from 60 to 3600 seconds.

  > **Note**
  >
  > This configuration is mandatory only on VLANs whose Bonjour policy is configured to accept Bonjour service announcements from connected Bonjour clients. If the VLAN is configured to only accept Bonjour queries but not Bonjour service announcements, this configuration is optional.

- **service-instance-suffix**(Optional) : Appends the service instance suffix to any announced service name that is forwarded to the controller.
- **service-mdns-query** [**PTR** | **all**]: Configures mDNS query request message processing for the specified query types. This command is applicable when the controller is in service-peer mode.

  > **Note**
  >
  > By default, the **service-mdns-query** command allows only PTR queries. If you need to respond to all (PTR, SRV, and TXT) queries, you need to execute this command:
  >
  > **service-mdns-query all**

- **service-policy** *policy-name*: Attaches the specified service policy to the VLAN. Bonjour announcements, and queries received by and sent from the VLAN are governed by the policies configured in the service policy. This configuration is mandatory for all VLANs.

  > **Note**
  >
  > Service policies can only be attached at interface level.

- **transport** [**all** | **ipv4** | **ipv6**] (Optional): Configures BCP parameter.

  It is recommended to use **transport ipv4** command, except in those networks where the Bonjour clients send only IPv6 announcements and queries.

5. **exit**

Example

```
Device(config-if-mdns-sd)# exit
```

Exits mDNS gateway configuration mode.

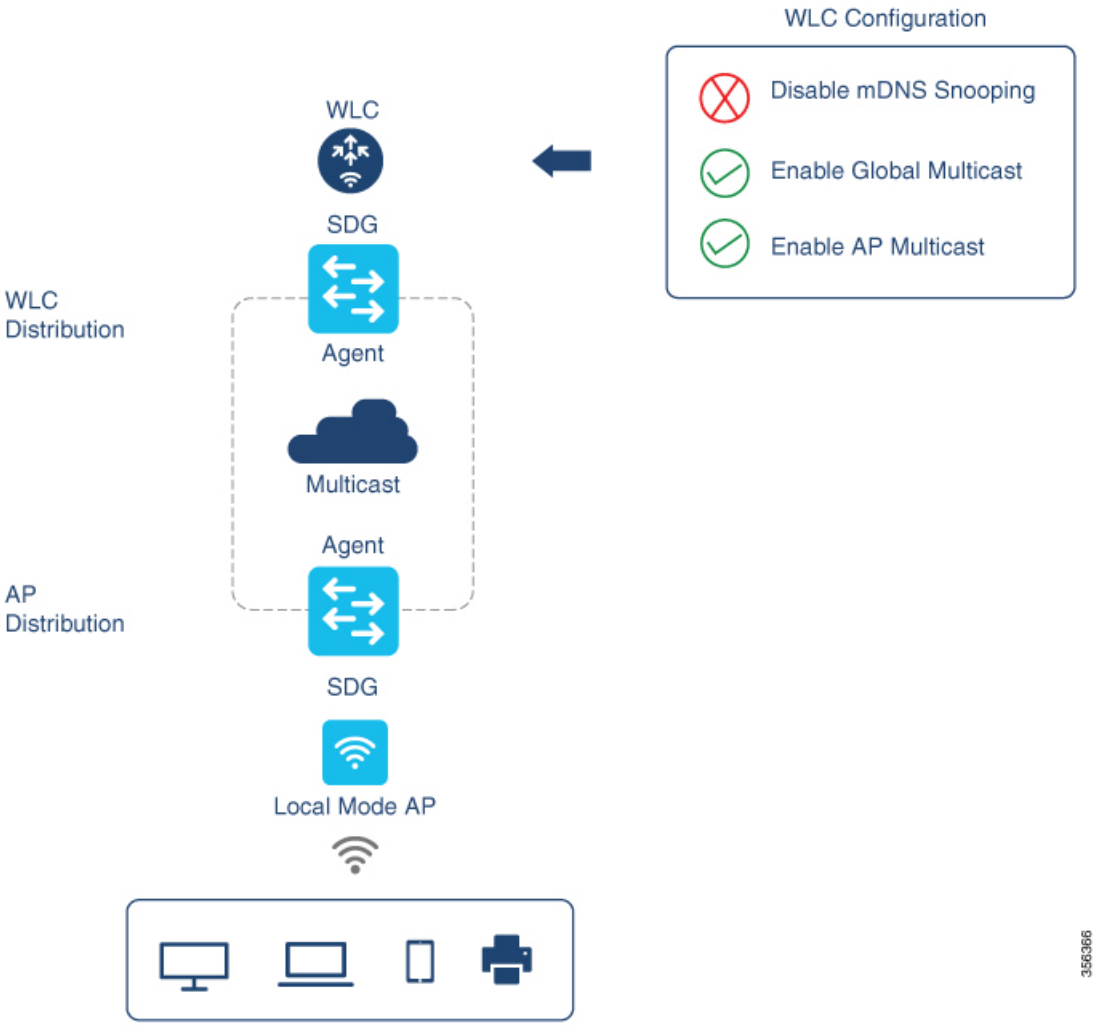
The mDNS gateway is configured on the interface with the service policy attached. The interface can now process Bonjour announcements and queries according to the configured policies.

Local area Bonjour in multicast DNS mode for wireless networks

Describes the configuration requirements for enabling local area Bonjour in multicast DNS mode within wireless network environments. This process ensures seamless communication between wireless endpoints and SDG Agent switches.

Local area Bonjour in multicast DNS mode is a service discovery framework that relies on mDNS messages transmitted over UDP port 5353 to facilitate communication between network endpoints.

- Operates using service announcements and queries sent to mDNS IPv4 address 224.0.0.251 and IPv6 address FF02::FB.
- Functions as a Layer 2 protocol, requiring clients to reside within the same Layer 2 domain for service discovery.
- Requires transparent mDNS transmission support from intermediate WLCs to bridge wireless endpoints and SDG Agents.



Wireless Network Configuration Requirements

To enable mDNS communication between wireless endpoints and a Cisco Catalyst switch acting as an SDG Agent, perform the following configuration steps:

1. Disable mDNS Snooping on Cisco AireOS based WLCs.
2. Enable the mDNS Gateway feature on Cisco Catalyst 9800 series WLCs.
3. Set the AP Multicast Mode to Multicast.

The following figure illustrates the prerequisite configuration for wireless networks to enable communication between SDG-Agent switches and wireless endpoints.

Figure 56: Wireless Network Prerequisite Configuration

The configuration of local area Bonjour on a switch that acts as the SDG Agent in a wireless network involves the same set of procedures that are used to configure local area Bonjour on a switch that acts as the SDG Agent in a wired network.

The Bonjour protocol operates on service announcements and queries. Each query or advertisement is sent to the mDNS IPv4 address 224.0.0.251 and IPv6 address FF02::FB. The mDNS messages are carried over well-known industry standard UDP port 5353, over both Layer 3 transport types.

The Layer 2 address used by the Bonjour protocol is link-local multicast address and therefore it's only forwarded to the same Layer 2 network. As multicast DNS (mDNS) is limited to a Layer 2 domain, for a client to discover a service, it has to be a part of the same Layer 2 domain. This isn't always possible in a large-scale deployment or enterprise.

To enable mDNS communication between Wireless endpoints and Cisco Catalyst switch that acts as an SDG Agent, the intermediate WLC must transparently allow the network to transmit and receive mDNS messages.

Hence, for a Multicast DNS Mode Wireless network deployment, disable the mDNS Snooping on Cisco AireOS based WLC and enable mDNS Gateway feature on Cisco Catalyst 9800 series WLC and set the AP Multicast Mode to Multicast.

The Cisco WLC and Access Points by default prevent the forwarding of Layer 2 or Layer 3 Multicast frames between Wireless and Wired network infrastructure. The forwarding is supported with stateful capabilities enabled using AP Multicast. The network administrator must globally enable Multicast and configure a unique Multicast Group to advertise in the network. This multicast group is only required for Cisco Access Points to enable Multicast over Multicast (MCMC) capabilities across the LAN network. The Bonjour solution doesn't require any Multicast requirements on Wireless Client VLAN; thus, it's optional and applicable only for other Layer 3 Multicast applications.

The core network must be configured with appropriate Multicast routing to allow the Access Points to join WLC Multicast Group. The Multicast configuration must be enabled on Cisco WLC management VLAN and on the Cisco Access Points of their respective distribution layer switch.

Associate service policy with wireless profile policy

Configure association of service policy with wireless profile policy to override the default mDNS service policy.

This task allows you to override the default mDNS service policy with a custom service policy of your choice.

A default mDNS service policy is already attached once the wireless profile policy is created. Use this procedure to override the default mDNS service policy with any of your service policy.

Before you begin

Follow these steps to associate service policy with wireless profile policy:

Procedure

1. **enable**

   Example

   ```
   Device> enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **wireless profile policy** *profile-policy-name*

   Example

   ```
   Device(config)# wireless profile policy default-policy-profile
   ```

   Configures wireless profile policy.

4. **mdns-sd service-policy** *custom-mdns-service-policy*

   Example

   ```
   Device(config-wireless-policy)# mdns-sd service-policy
   custom-mdns-service-policy
   ```

   Associates an mDNS service policy with the wireless profile policy.

   The default mDNS service policy name is **default-mdns-service-policy**.

5. **exit**

Example

```
Device(config-wireless-policy)# exit
```

Exits wireless profile policy configuration mode.

The custom mDNS service policy is now associated with the wireless profile policy, overriding the default service policy.

Configure wide area Bonjour domain

Describes how to configure wide area Bonjour domain parameters on the controller, including service types to export from the SDG Agent using service-lists and egress policies.

The Wide Area Bonjour domain configuration specifies the parameters of the controller, that is the Wide Area Bonjour Application running on Cisco Catalyst Center, as well as the service types that need to be exported to it from the SDG Agent. Configuring Wide Area Bonjour Domain involves creating service-lists and service policy similar to those created in Local Area Bonjour configuration; however, only egress policy from SDG Agent to controller is applicable.

Associate service policy with the controller in wide area Bonjour domain

Configure service policy association with the controller in wide area Bonjour domain for global service management.

This task enables the association of service policies with controllers in Wide Area Bonjour domains to manage service discovery and distribution across the network.

In Wide Area Bonjour, the service policy is configured globally and does not get associated with a VLAN as in the case of Local Area Bonjour.

Before you begin

Follow these steps to configure service policy globally:

Procedure

---

1. **enable**

   Example

   ```
   Device> enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **service-export mdns-sd controller** *controller name*

Example

```
Device(config)# service-export mdns-sd controller Cisco Catalyst
Center-BONJOUR-CONTROLLER
```

Specifies a name for the controller and enters service-export mode

4. **controller-address** *ipv4-address*

   Example

   ```
   Device(config-mdns-sd-se)# controller-address 199.245.1.7
   ```

   Specifies the controller address.

5. **controller-port** *port-number*

   Example

   ```
   Device(config-mdns-sd-se)# controller-port 9991
   ```

   Specifies the port number on which the controller is listening.

6. **controller-source-interface** *interface-name*

   Example

   ```
   Device(config-mdns-sd-se)# controller-source-interface Loopback0
   ```

   Specifies the source-interface for the controller.

7. **controller-service-policy** *service-policy-name* **OUT**

   Example

   ```
   Device(config-mdns-sd-se)# controller-service-policy policy1 OUT
   ```

   Specifies the service policy to be used by the controller.

   > **Note**
   >
   > Only OUT policy is applicable for Wide Area Bonjour.

8. **exit**

   Example

   ```
   Device(config-mdns-sd)# exit
   ```

   Exits controller service export configuration mode.

9. **mdns-sd gateway**

Example

```
Device(config)# mdns-sd gateway
```

Enters mDNS gateway configuration mode.

10. **ingress-client query-suppression enable**

Example

```
Device(config-mdns-sd)# ingress-client query-suppression enable
```

Enables ingress query suppression for better scale and performance.

11. **exit**

Example

```
Device(config-mdns-sd)# exit
```

Exits mDNS gateway configuration mode.

The service policy is successfully associated with the controller in the Wide Area Bonjour domain, enabling global service discovery management and ingress query suppression.

Configure HSRP-aware mDNS service-routing on SDG

Lists the configuration guides for hot standby router protocol-aware (HSRP-aware) mDNS service-routing on SDG.

Configure hot standby router protocol-aware (HSRP-aware) mDNS service-routing on SDG using the referenced configuration guides for Catalyst switch platforms.

For information, see these guides:

- Software Configuration Guide, Cisco IOS XE Bengaluru 17.6.x (Catalyst 9300 Switches)
- Software Configuration Guide, Cisco IOS XE Bengaluru 17.6.x (Catalyst 9400 Switches)
- Software Configuration Guide, Cisco IOS XE Bengaluru 17.6.x (Catalyst 9600 Switches)

Configure HSRP-aware mDNS service-routing on service-peer

Configure hot standby router protocol-aware (HSRP-aware) mDNS service-routing on service-peer using commands.

Configure HSRP-aware mDNS service-routing on service-peer to enable multicast DNS gateway functionality with hot standby router protocol awareness.

Use this procedure when you need to configure mDNS gateway in service-peer mode with HSRP awareness to provide redundancy and high availability for mDNS services.

Before you begin

Follow these steps to configure hot standby router protocol-aware mDNS service-routing on service-peer:

Procedure

---

1. **configure terminal**

Example

```
Device# configure terminal
```

Enters global configuration mode.

2. **mdns-sd gateway**

   Example

   ```
   Device(config)# mdns-sd gateway
   ```

   Enables mDNS on the device and enters mDNS gateway configuration mode.

3. **mode service-peer**

   Example

   ```
   Device(config-mdns-sd)# mode service-peer
   ```

   Enables mDNS gateway in service-peer mode.

4. **source-interface vlan** *vlan-interface-number*

   Example

   ```
   Device(config-mdns-sd)# source-interface vlan 23
   ```

   Configures source interface to communicate between SDG Agent and service-peer.

   > **Note**
   >
   > *vlan-interface-number*- The valid range is from1 to 4094.

5. **SDG-agent** *IP-address*

   Example

   ```
   Device(config-mdns-sd)# sdg-agent 9.6.16.10
   ```

   Configures SDG agent IPv4 or IPv6 address.

   > **Note**
   >
   > The *IP-address* refers to the HSRP-enabled IP address.

6. **end**

Example

```
Device(config-mdns-sd)# end
```

Exits server group configuration mode and enters privileged EXEC mode.

The device is configured with HSRP-aware mDNS service-routing on service-peer mode, enabling multicast DNS gateway functionality with hot standby router protocol support.

Verify local area bonjour in multicast DNS mode for LAN and wireless networks

Describes how to verify Local Area Bonjour in multicast DNS mode for both LAN and wireless networks to ensure proper service discovery functionality.

This section shows how to verify Local Area Bonjour in Multicast DNS mode for LAN and Wireless networks.

Verify SDG-agent status

Provides SDG-agent status verification information.

Use the sample outputs to verify SDG-agent status and understand the command output format for various mDNS service discovery commands.

This is a sample output of the **show mdns-sd service-list***service-list-name* {**in** | **out**} command.

```
Name            Direction  Service    Message-Type     Source
=============================================================
VLAN100-list     In         Printer   Announcement      -
                 In         Airplay   Query             -
                 In         CUSTOM1   Any               -
VLAN300-list     Out        Printer   Announcement     Vl200
```

This is a sample output of the **show mdns-sd service-definition***service-definition-name***service-type** {*custom* | *built-in*} command.

```
Service                 PTR                          Type
=====================================================================
apple-tv                _airplay._tcp.local          Built-In
                         _raop._tcp.local
apple-file-share       _afpovertcp._tcp.local       Built-In
CUSTOM1                _custom1._tcp.local          Custom
CUSTOM2                _customA._tcp.local          Custom
                       _customA._tcp.local
```

This is a sample output of the **show mdns-sd***service-policy-name***interface***interface-name* command.

```
Name   Service-List-In   Service-List-Out
================================================
mdns-policy-1  VLAN100-list   VLAN300-list
mdns-policy-2  VLAN400-list   VLAN400-list
```

This is a sample output of the **show mdns-sd summary** command.

```
mDNS Gateway: Enabled
Mode: Service Peer
Service Announcement Periodicity(in seconds): 30
Service Announcement Count: 50
Service Query Periodicity(in seconds): 15
Service Query Count: 50
Active Response Timer (in seconds): Disabled
ANY Query Forward: Disabled
SDG Agent IP: 9.8.57.10
Active Query Periodicity (in minutes): 30
mDNS Query Type: PTR only
Transport Type: IPv4
mDNS AP service policy: default-mdns-service-policy
```

This is a sample output of the **show mdns-sd sp-SDG statistics** command.

```
mDNS SP Statistics
last reset time: 07/27/21 15:36:33
Messages sent:
Query : 122
ANY query : 35
Advertisements : 12

Resync response : 3
Srvc Discovery response : 0
Keep-Alive : 2043
Messages received:
Query response : 0
ANY Query response : 0
Cache-sync : 9
Get service-instance : 0
Srvc Discovery request : 0
Keep-Alive Response : 2042
```

Verify wide area Bonjour controller status

Provides commands and sample outputs to verify wide area Bonjour controller status.

Verify wide area Bonjour controller status using show commands to display controller summary, export summary, statistics, and detailed information.

This is a sample output of the **show mdns controller summary** command.

```
Device# show mdns controller summary

Controller Summary
====================================
 Controller Name  :   Cisco Catalyst Center-BONJOUR-CONTROLLER
 Controller IP    :   10.104.52.241
 State            :   UP
 Port             :   9991
 Interface        :   Loopback0
 Filter List      :   policy1
 Dead Time        :   00:01:00
```

This is a sample output of the **show mdns controller export-summary** command.

```
Device# show mdns controller export-summary

Controller Export Summary
=========================
 Controller IP    :   10.104.52.241
 State            :   UP
 Filter List      :   policy1
 Count            :   100
 Delay Timer      :   30 seconds
 Export           :   300
 Drop             :   0
 Next Export      :   00:00:01
```

This is a sample output of the **show mdns controller statistics** command.

```
Device# show mdns controller statistics

Total BCP message sent           : 47589
  Total BCP message received       : 3
  Interface WITHDRAW messages sent : 0
  Clear cache messages sent        : 0
  Total RESYNC state count         : 0
  Last successful RESYNC           : Not-Applicable

  Service Advertisements:

```

Verify mDNS cache configurations

Provides verification commands for mDNS cache configurations.

This reference helps you verify mDNS cache configurations using show commands that display cache information from both Active and Standby devices.

These show commands display cache from both Active and Standby devices using the chassis option:

```
Device# show mdns-sd cache chassis active R0

------------------------------------------------------------ PTR Records
------------------------------------------------------------
RECORD-NAME                                  TTL      TYPE      ID
CLIENT-MAC       RR-RECORD-DATA
------------------------------------------------------------------------------------------------------------
_home-sharing._tcp.local                     4500     WLAN      1
0205.2c23.0001   AP6B8B4567-sta00001._home-sharing._tcp.local

------------------------------------------------------------ SRV Records
------------------------------------------------------------
RECORD-NAME                                  TTL      TYPE      ID
CLIENT-MAC       RR-RECORD-DATA
------------------------------------------------------------------------------------------------------------
AP6B8B4567-sta00001._home-sharing._tcp.local   4500     WLAN      1
0205.2c23.0001   0 0 5353 AP6B8B4567-sta00001.local

------------------------------------------------------------ A/AAAA Records

```

Verify additional mDNS cache configurations

Lists commands to verify additional mDNS cache configurations from Active and Standby databases.

This reference provides commands to verify mDNS cache configurations from both Active and Standby database states.

Commands for Active DB verification

To verify the cache from the Active DB, use these commands:

```
show mdns-sd cache ap-mac 0a0b.0cf0.000e chassis active R0
show mdns-sd cache client-mac 0269.fe06.0023 chassis active R0
show mdns-sd cache detail chassis active R0
show mdns-sd cache glan-id <> chassis active R0
show mdns-sd cache glan-id <> detail chassis active R0
show mdns-sd cache location-group <> chassis active R0
show mdns-sd cache location-group <> detail chassis active R0
show mdns-sd cache mdns-ap <> detail chassis active R0
show mdns-sd cache mdns-ap <> chassis active R0
show mdns-sd cache rlan-id <> detail chassis active R0
show mdns-sd cache rlan-id <> chassis active R0
show mdns-sd cache type TXT chassis active R0
show mdns-sd cache type A-AAAA detail chassis active R0
show mdns-sd cache wired chassis active R0
show mdns-sd cache wired detail chassis active R0
show mdns-sd cache wlan-id 10 chassis active R0
show mdns-sd cache wlan-id 1 detail chassis active R0
```

Commands for Standby DB verification

To verify the cache from the Standby DB, use these commands:

```
show mdns-sd cache ap-mac <> chassis standby R0
show mdns-sd cache client-mac <> chassis standby R0
```

```
show mdns-sd cache detail chassis standby R0
show mdns-sd cache glan-id <> chassis standby R0
show mdns-sd cache glan-id <> detail chassis standby R0
show mdns-sd cache location-group <> chassis standby R0
show mdns-sd cache location-group <> detail chassis standby R0
show mdns-sd cache mdns-ap <> detail chassis standby R0
show mdns-sd cache mdns-ap <> chassis standby R0
show mdns-sd cache rlan-id <> detail chassis standby R0
show mdns-sd cache rlan-id <> chassis standby R0
show mdns-sd cache type [A-AAAA|PTR|SRV|TXT] chassis standby R0
show mdns-sd cache type [A-AAAA|PTR|SRV|TXT] detail chassis standby R0
show mdns-sd cache wired chassis standby R0
show mdns-sd cache wired detail chassis standby R0
show mdns-sd cache wlan-id <> chassis standby R0
show mdns-sd cache wlan-id <> detail chassis standby R0
```

Verify local area Bonjour configuration for LAN and wireless networks

Provides verification of local Area Bonjour configuration for LAN and wireless networks.

This reference provides sample output of the **show run** command to verify local area Bonjour configuration for LAN and wireless networks.

```
mdns-sd gateway

mdns-sd service-definition custom1
 service-type _airplay._tcp.local
 service-type _raop._tcp.local

mdns-sd service-list list1 IN
 match custom1
mdns-sd service-list list2 OUT
 match custom1

mdns-sd service-policy policy1
service-list list1 IN
service-list list2 OUT

service-export mdns-sd controller Cisco Catalyst Center-CONTROLLER-POLICY
controller-address 99.99.99.10
controller-service-policy policy1 OUT
controller-source-interface Loopback0
```

Additional references for DNA Service for Bonjour

Provides supplementary reference materials and feature history information for local and wide area Bonjour implementations.

This reference provides additional resources for DNA service for Bonjour, including related documentation and MIB information.

MIB	MIBs Link
CISCO-SDG-MDNS-MIB	This MIB module defines objects describing the statistics of 63 local area and wide area MDNS SDG agent. Statistics could be 64 either global or per interface specific.

Feature history for Cisco DNA service for Bonjour

Lists release information about Cisco DNA service for Bonjour features and platform support.

This table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Release	Modification
Cisco IOS 15.2(6) E2	Cisco DNA Service for Local Area Bonjour and Wide Area Bonjour was introduced on the following platforms: • Cisco Catalyst 2960-X Series Switches • Cisco Catalyst 2960-XR Series Switches
Cisco IOS 15.5(1)SY4	Cisco DNA Service for Local Area Bonjour and Wide Area Bonjour was introduced on Cisco Catalyst 6800 Series Switches.
Cisco IOS XE 3.11.0 E	Cisco DNA Service for Local Area Bonjour and Wide Area Bonjour was introduced on the following platforms: • Cisco Catalyst 4500-E Series Switches • Cisco Catalyst 4500-X Series Switches

Release	Modification
Cisco IOS XE Gibraltar 16.11.1	Cisco DNA Service for Local Area Bonjour and Wide Area Bonjour was introduced on the following platforms: • Cisco Catalyst 3650 Series Switches • Cisco Catalyst 3850 Series Switches • Cisco Catalyst 9300 Series Switches • Cisco Catalyst 9400 Series Switches • Cisco Catalyst 9500 Series Switches • Cisco Catalyst 9500 Series Switches - High Performance • Cisco Catalyst 9600 Series Switches • Cisco Catalyst 9800 Series Wireless Controllers • Cisco 5500 Series Wireless Controllers • Cisco 8540 Wireless Controllers • Cisco 4000 Series Integrated Services Routers (ISR)
Cisco IOS XE Amsterdam 17.1.1	Cisco DNA Service for Local Area Bonjour and Wide Area Bonjour was introduced on Cisco Catalyst 9200 Series Switches.
Cisco IOS XE Amsterdam 17.2.1	Introduced Cisco DNA Service for Bonjour support for the following: • SD-Access network • Unicast mode for LAN network
Cisco IOS XE Amsterdam 17.3.2a	Introduced Cisco DNA Service for Bonjour support for the following: • Multilayer networks • Location grouping in wired networks • mDNS AP group in wireless networks

Release	Modification
Cisco IOS XE Bengaluru 17.6.1	Introduced support for the following features for Local Area Bonjour in Unicast Mode for LAN networks: • Default mDNS Service Configurations • HSRP-Aware mDNS Service-Routing • mDNS Service-Gateway SSO Support

231 Configuring Local Area Bonjour for Wireless Local Mode

Topics:

- Local area Bonjour for wireless local mode
- Wireless AP multicast
- Configure local area Bonjour for wireless local mode
- Verify mDNS gateway configuration

Local area Bonjour for wireless local mode

Explains Local Area Bonjour functionality for wireless local mode, detailing prerequisites, operational restrictions, and fundamental concepts for implementation planning.

Local Area Bonjour for wireless local mode is a network functionality that

- introduces unicast mode function in Local Area Bonjour network domain
- enables enhanced gateway function at the first hop of Wired and Wireless networks to communicate directly with any industry standard RFC 6762 compliant Multicast DNS (mDNS) end point in Layer 2 Unicast mode, and
- introduces new service-peer mode expanding classic single-gateway controller to end-to-end service-routing with upstream SDG agent switch to enable unicast-mode, increased scale, performance and resiliency in the network.

Prerequisites for local area Bonjour for wireless local mode

Outlines prerequisites for local area Bonjour for wireless local mode.

Ensure that the Cisco Catalyst 9800 series controller is successfully configured and operational before implementing Cisco Local Area Bonjour for local mode wireless networks. This is necessary for the controller to be deployed in service-peer mode

- Ensure that the targeted controller for the service-peer role has the required Cisco IOS-XE software version. See *Supported SDG Agents with Supported Licenses and Software Requirements* table in Cisco DNA Service for Bonjour Solution Overview chapter.
- Ensure that the controller runs a valid Cisco DNA-Advantage license.
- Ensure that the upstream distribution-layer Cisco Catalyst switch in SDG agent mode runs a valid Cisco DNA-Advantage license.
- Ensure that the controller is interconnected as Layer 2 trunk in static 802.1Q mode, when Layer 2 Unicast service-routing is running between SDG agent in distribution-layer and the controller service-peer.
- Ensure that the controller has IP reachability to upstream Cisco Catalyst 9000 series switches in SDG agent mode over same the IPv4 wireless management subnet.
- Ensure that global multicast is enabled on the controller and AP is set to multicast mode. All local mode APs must join the multicast group in the network to successfully process mDNS messages.

Restrictions for local area Bonjour for wireless local mode

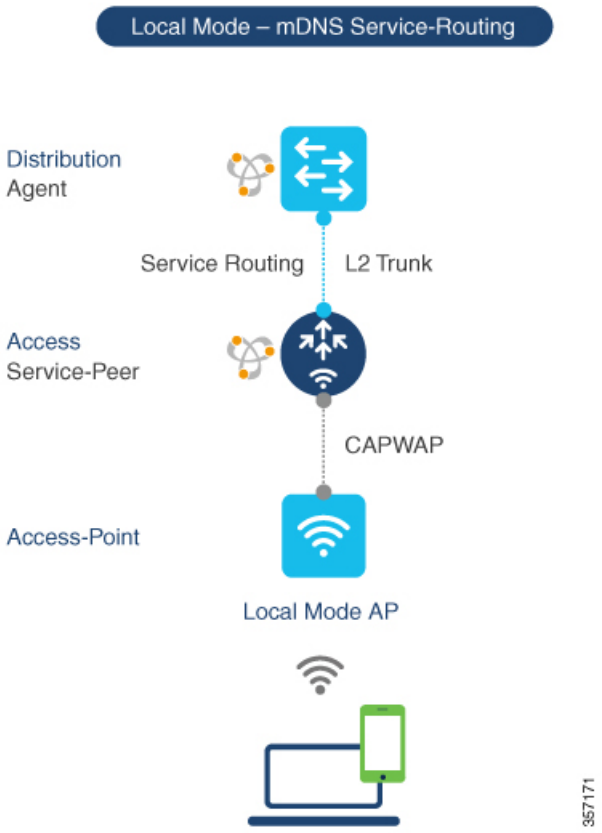
Outlines restrictions for local area Bonjour for wireless local mode.

- Controller management port is not supported for service-routing with upstream Catalyst SDG Agent switch.
- The controller in service peer mode supports location-based service for access points in local mode and FlexConnect central switching mode.
- The controller supports location-based capabilities only between wireless connected service provider and the receiver.
- The controller does not support service-routing configuration using GUI.

Local area Bonjour for wireless local mode

Explains local area Bonjour for wireless local mode.

Local area Bonjour for wireless local mode is a network service that



- enables distributed Bonjour gateway function at the network edge through unified Cisco IOS-XE operating system across Cisco Catalyst 9000 series LAN switches and Cisco Catalyst 9800 series controller
- supports mDNS gateway function to wireless users in local mode with service-routing peering to upstream Cisco Catalyst 9000 series switch for network-wide services discovery and distribution, and
- eliminates mDNS flooding over Layer 2 trunk ports through unicast based service-routing between the controller and upstream SDG-Agent switch.

Local area Bonjour capabilities

The traditional wireless controller supported mDNS snooping function with various advancements for wireless networks. As the enterprise requirements expands, IT drives the IT organization to introduce new network deployment models, supporting mobile devices and distributed zero-configuration services with increased scale, granular security control and resiliency for mission critical networks. With end-to-end Wide Area Bonjour service-routing, the new solution enables service-oriented enterprise networks with intuitive user-experience.

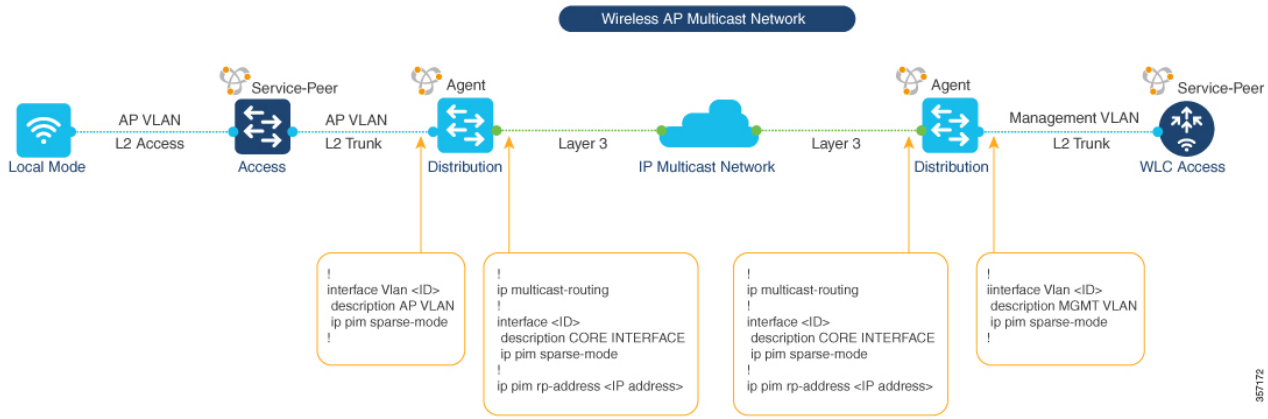
The controller platform supporting mDNS gateway function builds service-routing peering with upstream Cisco Catalyst 9000 series switch for network-wide services discovery and distribution based on IT-managed granular policies and locations. The unicast based service-routing between the controller in service-peer mode and upstream SDG-Agent switch provides increased bandwidth and eliminates mDNS flood over wireless networks and Layer 2 trunk to upstream network.

Figure 57: Cisco Catalyst 9800 series controller local area Bonjour for wireless local mode

Wireless AP multicast

Describes the configuration of wireless AP multicast settings through GUI and CLI interfaces, including IP network multicast configuration procedures.

Wireless AP multicast is a network feature that



- enables forwarding of Layer 2 or Layer 3 multicast frames between wireless and wired network infrastructure with stateful capabilities
- requires configuration of a unique AP multicast group on the controller to advertise in the IP core network, and
- supports mDNS message processing over a wireless network when multicast is enabled.

Wireless AP multicast requirements

The controller and AP by default prevents forwarding of Layer 2 or Layer 3 Multicast frames between wireless and wired network infrastructure. The forwarding is supported with stateful capabilities enabled using AP multicast. To allow mDNS message processing over a wireless network, multicast must be enabled and unique AP multicast group must be configured on the controller to advertise in IP core network. This AP multicast group is only required for APs to enable Multicast over Multicast (MCMC) capabilities in the network. The Bonjour solution do not require any other multicast requirements on wireless client VLAN; thus, it is optional and applicable only for other Layer 3 multicast applications.

End-to-end wireless multicast configuration is required to ensure wireless APs successfully join the controller-announced multicast group.

Figure 58: Multicast routing in IP core network

Configure wireless AP multicast (GUI)

Configure wireless AP multicast using GUI.

Configure wireless AP multicast settings to enable multicast communication on a controller in service-peer mode.

This procedure configures wireless AP multicast on a controller in service-peer mode.

Procedure

1. Choose **Configuration** > **Services** > **Multicast**.
2. Set the **Global Wireless Multicast Mode** to **Enabled**.
3. From the AP Capwap Multicast drop-down list, select **Multicast**.

4. Enter a unique IP address at **AP Capwap IPv4 Multicast group Address**.
5. Click **Apply**.
6. Click **Save**.

The wireless AP multicast configuration is applied and saved on the controller.

Configure wireless AP multicast (CLI)

Configure wireless AP multicast using commands.

This task configures wireless AP multicast to enable communication between access points and the controller using multicast addresses.

This procedure configures wireless AP multicast on a controller in service-peer mode.

Procedure

---

1. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. **wireless multicast**

   Example

   ```
   Device(config)# wireless multicast
   ```

   Enable global IP multicast processing.

3. **wireless multicast** *IPv4-multicast-address*

   Example

   ```
   Device(config)# wireless multicast 239.254.254.1
   ```

   Enables AP CAPWAP mode to Multicast with unique IPv4 multicast address configurations.

4. **exit**

   Example

   ```
   Device(config-mdns-sd)# exit
   ```

   Exits mDNS gateway configuration mode.

Wireless AP multicast is configured on the controller, enabling multicast communication between access points.

Configure multicast in IP network (CLI)

Configure multicast in IP network using commands.

Configure IP Multicast under AP VLAN, Management VLAN and IP core interfaces on upstream Catalyst LAN distribution-layer switch to enable multicast traffic processing in the network infrastructure.

This procedure configures IP Multicast under AP VLAN, Management VLAN and IP core interfaces on upstream Catalyst LAN distribution-layer switch.

Procedure

1. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. **IP multicast-routing**

   Example

   ```
   Device(config)# ip multicast-routing
   ```

   Enables IP multicast processing.

3. **interface** *interface-id*

   Example

   ```
   Device(config)# interface TenGigabitEthernet 1/0
   ```

   Selects an interface that is connected to hosts and network devices on which PIM can be enabled.

4. **IP PIM sparse-mode**

   Example

   ```
   Device(config-if)# ip pim sparse-mode
   ```

   Enables IP Multicast on Layer 3 interfaces of distribution and core layer network switches:

   - **AP VLAN**- Enables IP multicast on SVI interface on VLAN assigned to wireless APs of wireless AP distribution layer switch.
   - **Management VLAN**- Enables IP multicast on SVI interface on VLAN assigned to controller management VLAN of wireless distribution layer switch.
   - **Layer 3 Interface**- Enable IP multicast routing on all core network devices and Layer 3 interfaces.

5. **exit**

Example

```
Device(config-if)# exit
```

Exits interface configuration mode.

6. **IP PIM RP-address** *RP-address*

Example

```
Device(config)# ip pim rp-address 239.254.254.100
```

Configures IP Multicast RP address on core and distribution network switches. IP network may have alternate multicast routing method.

IP multicast routing is enabled on the device with PIM sparse-mode configured on the specified interface and the RP address configured for multicast group management.

Configure local area Bonjour for wireless local mode

Provides comprehensive mDNS configuration procedures, including service policies, custom service definitions, WLAN gateway setup, service-routing, and location-based mDNS on service-peers via GUI and CLI.

This section provides configuration guidelines to implement Cisco Catalyst 9800 series controller as mDNS gateway and enable service-peer mode to enable service-routing with upstream distribution-layer Cisco Catalyst 9000 series switch in SDG-Agent mode to build Local Area Bonjour.

Configure mDNS service policy (GUI)

Configure mDNS service policy using GUI.

Configure mDNS service policy to control multicast DNS service discovery traffic on wireless networks.

The mDNS service policy consists of creating a service-list to permit built-IN or user-defined custom service-types, associate service-list to a service-policy to enforce IN ingress or egress direction and apply the service-policy to targeted Wireless Profile. This configuration is common on the controller IN service peer or single-gateway solution for wireless networks.

This procedure configures mDNS Service-Policy on a controller IN service-peer mode.

Procedure

---

1. Choose **Configuration** > **Services** > **mDNS**.
2. Set the mDNS Gateway button to **Enabled**.
3. Click **Service Policy** Tab.
4. Click **Service List** and click **Add**.

   This activates the Service List window.

5. IN the **Service List Name** field, enter a unique name with alphanumeric value.
6. From the **Direction** drop-down list, select service list policy direction. Use **IN** for ingress or **OUT** for egress mDNS message matching policy.
7. Click **+Add Services** to add mDNS service-types IN selected service list.
8. From the **Available Services** drop-down list, select built-IN or custom mDNS service-type.

9. From the **Message Type** drop-down list, select **Announcement** to accept service advertisement or **Query** to permit service discovery from the network. Default message-type is **any**.
10. Click **Save** button to add mDNS service-type entry.

> **Note**
>
> Repeat Step-7 to Step-9 to add more mDNS service-types IN selected service list.

11. Click **Apply to Device**.

    This creates a new mDNS Service List for selected direction.

> **Note**
>
> Repeat Step-5 to Step-11 for bi-directional service list.

12. Click **Service-Policy** tab.
13. Click **+Add** to create new mDNS service-policy.
14. IN the **Service Policy Name** field, enter a unique mDNS service policy name.
15. From the **Service List Input** drop-down list, select ingress mDNS service list input to enforce mDNS policies on ingress direction from wireless networks.
16. From the **Service List Output** drop-down list, select mDNS policies on egress direction to wireless networks.
17. Click **Apply to Device**.

    This creates a new mDNS service policy.

18. Choose **Configuration** > **Tags & Profiles** > **Policy**
19. Choose or create a new **Policy Profile**.
20. Click **Advanced** tab.
21. From the **mDNS Service Policy** drop-down list, select an mDNS service policy.

    Refer to Cisco Catalyst 9800 Series Configuration Guide to configure other policy profile parameters.

22. Click **Apply to Device** button.

    This creates a new policy profile or updates an existing policy profile with mDNS service policy.

23. Click **Save**.

The mDNS service policy is successfully configured and applied to the policy profile, enabling controlled multicast DNS service discovery on the wireless network.

Configure mDNS service policy using CLI

Configure mDNS service policy using CLI commands.

Configure mDNS service policy to build and apply service-policies on target wireless profile in service-peer mode.

This procedure builds and applies service-policies on target wireless profile in service-peer mode.

Procedure

1. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. **mdns-sd service-list** *service-list-name* **in out**

   Example

   ```
   Device(config)# mdns-sd service-list VLAN100-LIST-IN in
   Device(config)# mdns-sd service-list VLAN100-LIST-OUT out
   ```

   Configures mDNS service-list to classify one or more service-types. Unique service-list is required to process incoming mDNS message and outbound response to requesting end points.

3. **match service-definition-name message-type any announcement query**

   Example

   ```
   Device(config)# mdns-sd service-list VLAN100-LIST-IN in
   Device(config-mdns-sl-in)# match APPLE-TV
   Device(config-mdns-sl-in)# match PRINTER-IPPS message-type announcement
   ```

   Matches inbound service-list. The controller validates to accept or drop incoming mDNS service-type (for example, Apple TV) advertisement or query matching message type. The service-list contains implicit deny at the end. Default message-type is “any”.

4. **match service-definition-name message-type any announcement query**

   Example

   ```
   Device(config)# mdns-sd service-list VLAN100-LIST-OUT out
   Device(config-mdns-sl-in)# match APPLE-TV
   Device(config-mdns-sl-in)# match PRINTER-IPPS
   ```

   Matches an outbound service-list. The controller provides local service proxy function by responding matching service-type to the requesting end points. For example, the Apple-TV and Printer learnt from VLAN 100 will be distributed to receiver in same VLAN 100. The service-list contains implicit deny at the end.

   The message-type for outbound service-list is not required.

5. **exit**

   Example

   ```
   Device(config-mdns-sl-in)# exit
   ```

   Returns to global configuration mode.

6. **mdns-sd service-policy** *service-policy-name*

Example

```
Device(config)# mdns-sd service-policy VLAN100-POLICY
```

Creates a unique mDNS service-policy.

7. **service-list** *service-list-name* **in out**

Example

```
Device(config-mdns-ser-policy)# service-list VLAN100-LIST-IN in
Device(config-mdns-ser-policy)# service-list VLAN100-LIST-OUT out
```

Configure mDNS service-policy to associate service-list for each direction.

8. **exit**

Example

```
Device(config-mdns-ser-policy)# exit
```

Exits mDNS service policy configuration mode.

9. **wireless profile policy** *policy-name*

Example

```
Device(config)# wireless profile policy WLAN-PROFILE
```

Configures unique wireless profile policy name to associate mDNS service-policy.

10. **mdns-sd service-policy** *service-policy*

Example

```
Device(config-wireless-policy)# mdns-sd service-policy VLAN100-POLICY
```

Associates mDNS service-policy to configured VLAN IDs.

> **Note**
>
> This step requires wireless profile policy to be administratively shutdown prior association service-policy and re-activate with no shutdown to make service-policy effective.

11. **exit**

Example

```
Device(config-mdns-sd)# exit
```

Exits mDNS gateway configuration mode.

The mDNS service policy is configured and associated with the wireless profile policy. The controller can now process incoming mDNS messages and provide outbound responses based on the configured service lists and policy.

Configuring custom service definition (GUI)

Configure custom service definition using GUI.

Create custom mDNS service definition with matching mDNS PTR records to enable end mDNS service-routing in the network.

The Cisco IOS-XE supports various built-in well-known mDNS service-definition types mapping to key mDNS PTR records to user-friendly names. For example, built-in Apple-TV service-type is associated with _airplay. _tcp.local and _raop. _tcp.local PTR records to successfully enable service in the network. The network administrator can create custom service-definition with matching mDNS PTR records to enable end mDNS service-routing in the network.

This procedure configures custom mDNS service definition and applies it to policy.

Procedure

1. Choose **Configuration** > **Services** > **mDNS**.
2. Set the mDNS Gateway button to **Enabled**.
3. Click **Service Policy** Tab.
4. Click **Add** to create new custom mDNS service-list definition.

   This activates Service Definition window.
5. In the **Service Definition Name** filed, enter a unique aplhanumeric value.
6. (Optional) In the **Description** field, enter a description for the service definition.
7. In the **Service Type** field, enter single mDNS PoinTeR (PTR) record entry in *_<service-type>. _<protocol>.local* regular expression format. For example, _airplay. _tcp.local
8. Click **+** to add custom mDNS service-type in selected definition list.

   Note

   Repeat Steps 7 and Step 8 to add more custom service-type in selected definition list.
9. Click **Apply**.
10. Perform steps give in *Configuring mDNS Service Policy (GUI)* by selecting built-in or custom service-type to configure service list.
11. Click **Save**.

Custom mDNS service definition is configured and applied to the service policy.

Configure custom service definition (CLI)

Configure custom service definition using commands to discover mDNS services from local wireless networks.

This task creates custom service-definition configuration to discover mDNS services from local wireless networks.

Use custom service definitions when you need to configure mDNS service discovery for services that are not predefined in the system.

Procedure

1. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. **mdns-sd service-definition-name** *service-definition-name*

   Example

   ```
   Device(config)# mdns-sd service-definition APPLE-CLASSROOM
   ```

   Creates unique service-definition name for custom service-types.

3. **service-type** *custom-mDNS-PTR*

   Example

   ```
   Device(config-mdns-ser-def)# service-type _classroom._tcp.local
   ```

   Configure an regular-expression string for custom mDNS PoinTeR(PTR) record.

4. **exit**

   Example

   ```
   Device(config-mdns-ser-def)# exit
   ```

   Returns to global configuration mode.

The custom service definition is created and configured for mDNS service discovery on local wireless networks.

Configure mDNS gateway on WLAN (GUI)

Configure mDNS gateway on WLAN using GUI.

Configure mDNS gateway to activate mDNS processing for wireless clients associated with a WLAN.

The mDNS gateway activation on targeted WLAN is required to start processing incoming mDNS messages from associated wireless clients. To activate mDNS gateway the WLAN must be administratively shutdown and re-enable thus it may require network downtime planning.

This procedure configures custom mDNS gateway and required policies.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click to enable the mDNS Gateway on existing **WLAN** row of Catalyst 9800 controller. Click **+ Add** button to create new WLAN if required. Refer to Catalyst 9800 Series Wireless Controller Configuration Guide for step-by-step WLAN configuration.

3. Click **Advanced** tab.
4. From the **mDNS Mode** drop-down list, select **Gateway** to activate mDNS Gateway on the selected WLAN.
5. Click **Apply to Device**.
6. Click **Save**.

The mDNS gateway is configured and activated on the WLAN, enabling mDNS message processing for associated wireless clients.

Configure mDNS gateway on WLAN (CLI)

Configure mDNS gateway on WLAN using commands.

This task implements mDNS gateway functionality on a targeted WLAN to enable multicast DNS service discovery across network segments.

This procedure implements mDNS gateway on a targeted WLAN of the controller in service-peer mode.

Procedure

1. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. **WLAN** *profile-name WLAN-ID SSID-name*

   Example

   ```
   Device(config)# wlan WLAN-PROFILE 1 blizzard
   ```

   Creates a unique WLAN.

3. **mdns-sd-interface gateway**

   Example

   ```
   Device(config-wlan)# mdns-sd-interface gateway
   ```

   Configure mDNS gateway on targeted WLAN.

   > **Note**
   >
   > This step requires wireless profile policy to be administratively shutdown prior association service-policy and re-activate with no shutdown to make service-policy effective.

4. **exit**

Example

```
Device(config-wlan)# exit
```

Returns to global configuration mode.

The mDNS gateway is configured on the WLAN and will enable multicast DNS service discovery functionality once the wireless profile policy is properly activated.

Configure service-routing on service-peer

Configure service-routing on service-peer to extend mDNS service discovery and distribution boundary beyond single controller to global IP network.

Configure the controller in service peer mode to extend mDNS service discovery and distribution boundary beyond single controller to global IP network using unicast based service-routing.

The controller deployed in Service-Peer mode extends mDNS service discovery and distribution boundary beyond single controller to global IP network using on unicast based service-routing. The controller service peer must establish IP based unicast service-routing with Cisco Catalyst 9000 series switch in distribution layer network for global service-routing.

This procedure configures the controller in service peer mode.

Procedure

---

1. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. **mdns-sd gateway**

   Example

   ```
   Device(config)# mdns-sd gateway
   ```

   Enables mDNS and enters in mDNS gateway configuration mode. The following optional parameters are available:

   - **active-query**: Periodic mDNS query to refresh dynamic cache.
   - **active-response**: Periodic active mDNS response instead per request processing.
   - **mode**: Set Catalyst 9800 in service-peer mode.
   - **SDG-agent**: Unicast service-routing with targeted SDG-Agent.
   - **service-announcement-count**: Configures maximum advertisements in service-routing to SDG-Agent.
   - **service-announcement-timer**: Configures advertisements announce timer periodicity in service-routing to SDG-Agent.
   - **service-query-count**: Configures maximum queries in service-routing to SDG-Agent.
   - **service-query-timer**: Configures query forward timer periodicity in service-routing to SDG-Agent.
   - **service-type-enumeration**: Configures service enumeration.

- **source-interface**: Configures the source interface. If the source interface is configured, it will be used for all mDNS transactions. By default, wireless management interface will be used.
- **transport**: Use IPv4 (default) or IPv6 transport for mDNS messaging to end points.

> **Note**
>
> For **rate-limit**, **service-announcement-count**, **service-announcement-timer**, **service-query-count** and **service-query-timer** commands, you can retain the default value of the respective parameter for general deployments. Configure a different value, if required, for a specific deployment.

3. **mode service-peer**

   Example

   ```
   Device(config-mdns-sd)# mode service-peer
   ```

   Configure mDNS gateway in service-peer mode.

4. **SDG-agent IPv4 Address**

   Example

   ```
   Device(config-mdns-sd)# sdg-agent 10.0.2.254
   ```

   Configure SDG Agent IPv4 address. Typically, the management VLAN gateway address. If FHRP mode, then use FHRP Virtual-IP address of management VLAN.

5. **exit**

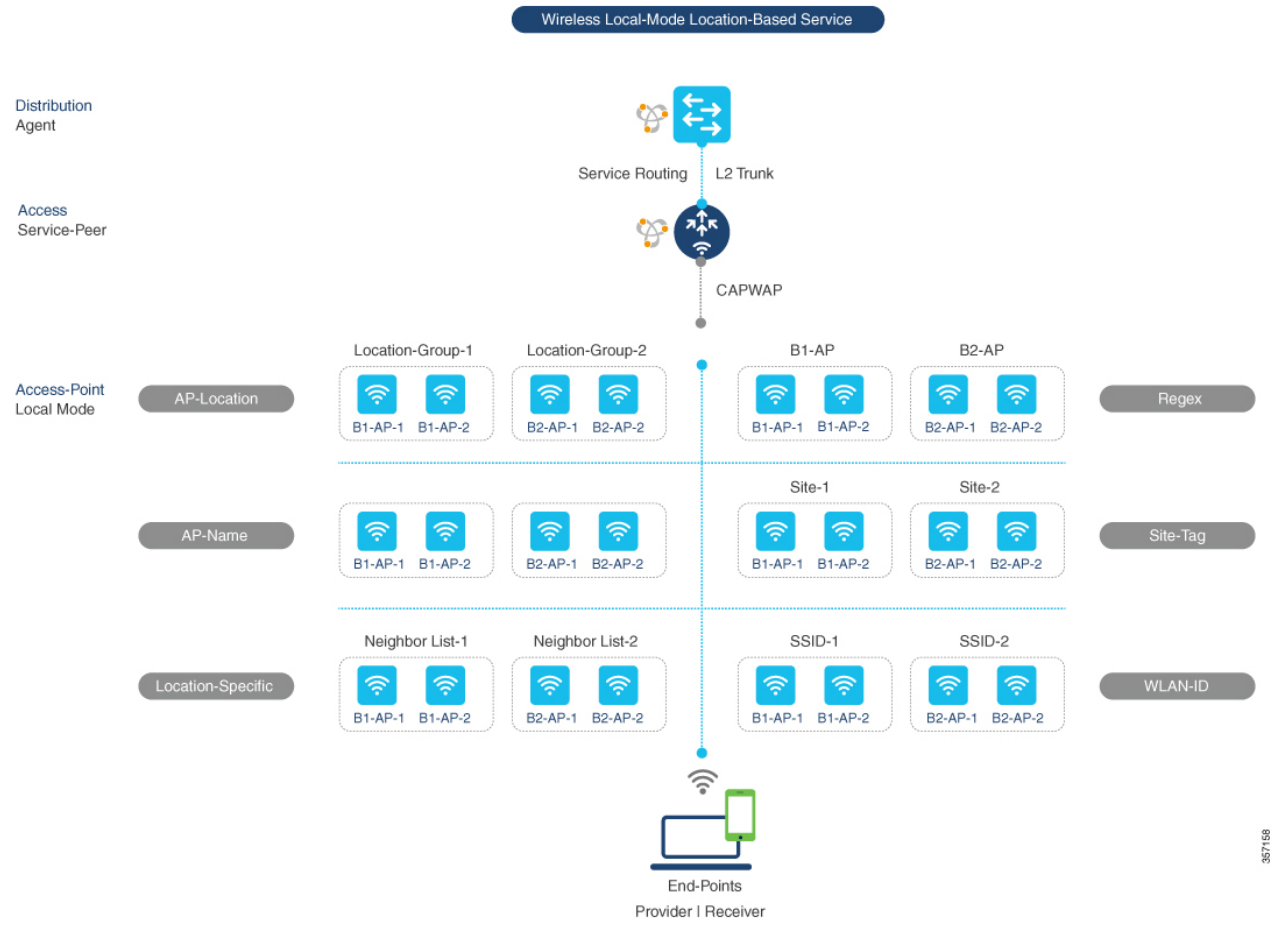
   Example

   ```
   Device(config-mdns-sd)# exit
   ```

   Returns to global configuration mode.

The controller is configured in service peer mode with unicast based service-routing to extend mDNS service discovery beyond the single controller to the global IP network.

Configure location-based mDNS on service-peer (GUI)



Configure location-based mDNS on service-peer using GUI.

This task configures location-based mDNS service policy to enable service discovery and distribution between wireless service provider and receiver endpoints using policy-based service distributions IN wireless networks.

Cisco Catalyst 9800 series controller supports location-based mDNS service discovery and distribution between wireless service provider and receiver endpoints. The location-based mDNS service support can be implemented using multiple supporting AP classification methods to implement policy-based service distributions IN wireless networks. The location-based mDNS service is effective and supported on wireless APs IN Local-Mode or FlexConnect Central Switching modes.

The figure given below illustrates various LSS based mDNS service mode discovery and distribution support:

Figure 59: Location-Based mDNS gateway

Before you begin

Follow these steps to configure location-based mDNS service policy:

Procedure

1. Choose **Configuration** > **Services** > **mDNS**.
2. Set the mDNS Gateway button to **Enabled**.
3. Click **Service Policy** Tab.
4. Click **Service List** and click **Add**.

   This activates the Service List window.
5. IN the **Service List Name** field, enter a unique name with alphanumeric value.
6. From the **Direction** drop-down list, select service list policy direction. Use **IN** for ingress or **OUT** for egress mDNS message matching policy.
7. Click **+Add Services** to add mDNS service-types IN selected service list.
8. From the **Available Services** drop-down list, select built-IN or custom mDNS service-type.
9. From the **Message Type** drop-down list, select **Announcement** to accept service advertisement or **Query** to permit service discovery from the network. Default message-type is **any**.
10. Click **Save** button to add mDNS service-type entry.

> **Note**
>
> Repeat Step-7 to Step-9 to add more mDNS service-types IN selected service list.

11. Click **Apply to Device**.

    This creates a new mDNS Service List for selected direction.

> **Note**
>
> Repeat Step-5 to Step-11 for bi-directional service list.

12. Click **Service-Policy** tab.
13. Click **+Add** to create new mDNS service-policy.
14. IN the **Service Policy Name** field, enter a unique mDNS service policy name.
15. From the **Service List Input** drop-down list, select ingress mDNS service list input to enforce mDNS policies on ingress direction from wireless networks.
16. From the **Service List Output** drop-down list, select mDNS policies on egress direction to wireless networks.
17. Click **Apply to Device**.

    This creates a new mDNS service policy.

18. Choose **Configuration** > **Tags & Profiles** > **Policy**
19. Choose or create a new **Policy Profile**.
20. Click **Advanced** tab.
21. From the **mDNS Service Policy** drop-down list, select an mDNS service policy.

    Refer to Cisco Catalyst 9800 Series Configuration Guide to configure other policy profile parameters.

22. Click **Apply to Device** button.

    This creates a new policy profile or updates an existing policy profile with mDNS service policy.

23. Click **Save**.

The location-based mDNS service policy is configured and applied to the policy profile, enabling policy-based mDNS service discovery and distribution IN the wireless network.

Configure location-based mDNS on service-peer (CLI)

Configure location-based mDNS on service-peer using commands.

This procedure implements LSS based mDNS service discovery and distribution between wireless endpoints on the targeted WLAN of the controller in service-peer mode.

Location-based mDNS filtering allows for targeted service discovery within specific network segments or geographic locations, improving network efficiency and security by limiting service advertisements to relevant areas.

Procedure

1. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. **mdns-sd service-policy** *service-policy-name*

   Example

   ```
   Device(config)# mdns-sd service-policy VLAN100-POLICY
   ```

   Creates a unique mDNS service-policy.

3. **location AP-location AP-name LSS regex site-tag SSID**

   Example

   ```
   Device(config-mdns-ser-policy)# location ap-location
   ```

   Creates a unique mDNS service-policy.

   - **AP-location**: Enables mDNS service discovery and distribution between wireless service provider and receiver connected to one or more AP configured in the same location name. The mDNS services from non-matching AP location is automatically filtered.
   - **AP-name**: Enables mDNS service discovery and distribution between wireless service provider and receiver connected to single AP matching same AP name. The mDNS services from non-matching AP name is automatically filtered.
   - **LSS**: Enables mDNS service discovery and distribution between wireless service provider and receiver connected to same and neighboring one or more AP based on RRM. The mDNS services from non-matching AP neighbor-list is automatically filtered.
   - **regex**: Enables mDNS service discovery and distribution between wireless service provider and receiver connected to one or more AP configured within matching AP name or AP Location name using regular-expression string. The mDNS services from non-matching AP names is automatically filtered.
   - **site-tag**: Enables mDNS service discovery and distribution between wireless service provider and receiver connected to one or more AP configured same site tag name. The mDNS services from non-matching site tag is automatically filtered.
   - **SSID**: Enables mDNS service discovery and distribution between wireless service provider and receiver connected to one or more AP configured same SSID name. The mDNS services from non-matching SSID is automatically filtered.

4. **exit**

   Example

   ```
   Device(config-mdns-ser-policy)# exit
   ```

Exits mDNS service policy configuration mode.

The location-based mDNS service policy is configured and will filter mDNS services based on the specified location criteria.

Verify mDNS gateway configuration

Lists verification procedures and reference commands to confirm proper mDNS gateway configuration and operational status.

This section provides guidelines to verify various Local Area Bonjour domain mDNS service configuration parameters, cache records, statistics and more on the controller in service peer mode.

Command or Action	Purpose
show mdns-sd cache AP-MAC client-MAC detail glan-ID mdns-AP rlan-ID statistics type UDN wired wlan-ID	Displays available mDNS cache records supporting multiple variables providing granular source details: • **AP-MAC**: Displays one or more mDNS service instance cache records discovered from provided AP MAC address. • **client-MAC**: Displays one or more mDNS service instance(s) cache records discovered from service provider wireless client MAC address. • **detail**: Displays mDNS record detail information combined with client and network attributes and other service parameters. • **glan-ID**: Displays one or more mDNS service instance(s) cache records discovered from provided Wired Guest LAN ID MAC address. • **mdns-AP**: Displays one or more mDNS service instance(s) cache records discovered from provided Wireless mDNS AP MAC address. • **rlan-ID**: Displays one or more mDNS service instances(s) cache records discovered from provided Wired Remote LAN ID. Range 1-128. • **statistics**: Displays detail global bi-directional mDNS statistics for IPv4 and IPv6 transports with packet processing count for each mDNS record-type. • **type**: Displays one or more service-instance(s) cache records matching mDNS record-type, i.e., A-AAAA, PTR, SRV and TXT. • **UDN**: Displays one or more mDNS service instance(s) cache records discovered from segmented Wireless service provider in User-Defined-Group (UDN) or shared-services. • **wired**: Displays one or more mDNS service instance(s) cache records discovered from upstream Layer 2 wired network. • **wlan-ID**: Displays one or more mDNS service instance(s) cache records discovered from matching provided wlan-ID. Range 1-4096.
show mdns-sd statistics debug flexconnect glan-ID rlan-ID wired wlan-ID	Displays detailed mdns statistics processed bi-directionally by system on each mDNS gateway enabled VLAN configured mDNS in Unicast mode. The expanded keyword of mDNS statistics can provide detail view on interface, policy, service-list and services.
show mdns-sd summary	Displays brief information about mDNS gateway and key configuration status on all VLANs and interfaces of the system.

Verify Catalyst WLC service-peer configuration

This section provides guidelines to verify service peer service configuration and statistics.

Command or Action	Purpose
show mdns-sd sp-SDG statistics	Displays mDNS service-routing statistics between Catalyst 9800 service-peer and upstream SDG Agent switch for global service discovery and distribution.
show mdns-sd summary	Displays brief information about mDNS gateway and key configuration status and parameters of the system.

Reference

Reference for mDNS gateway.

232 Configuring Local Area Bonjour for Wireless FlexConnect Mode

Topics:

- Local area Bonjour for wireless FlexConnect mode
- Local area Bonjour for wireless FlexConnect mode

Guides through the setup and configuration of Local Area Bonjour for Wireless FlexConnect Mode, including prerequisites, multicast Domain Name System gateway alternatives, and verification procedures.

Local area Bonjour for wireless FlexConnect mode

Introduces core concepts of Local Area Bonjour in Wireless FlexConnect environments, explains restrictions and prerequisites, and compares mDNS gateway alternatives to facilitate effective service discovery and network design understanding.

Local area Bonjour for wireless FlexConnect mode is a network service feature that

- introduces unicast mode function in Local Area Bonjour network domain
- enables enhanced gateway function at the first hop of Wired and Wireless networks to communicate directly with any industry standard RFC 6762 compliant Multicast DNS (mDNS) end point in Layer 2 Unicast mode, and
- provides service-peer mode expanding single-gateway to end-to-end service-routing with upstream SDG-Agent switch to enable unicast-mode, increased scale, performance and resiliency in the network.

Restrictions for local area Bonjour for wireless FlexConnect mode

Outlines restrictions for local area Bonjour for wireless FlexConnect mode.

In FlexConnect mode network deployments, the mDNS gateway and service-peer mode on the controller must not be configured and must be in disabled state.

Prerequisites for local area Bonjour for wireless FlexConnect mode

Outlines prerequisites for local area Bonjour for wireless FlexConnect mode.

The Cisco Catalyst 9800 series controller must be successfully configured and operational before implementing Cisco Local Area Bonjour for FlexConnect mode wireless networks.

Here are the prerequisites to enable successful mDNS gateway solution for Wireless FlexConnect:

- Ensure that the targeted Layer 2 Catalyst 9000 Series Ethernet switch is configured in service-peer role and running the required Cisco IOS-XE software version.
- Ensure that the Catalyst 9000 Series Ethernet switch runs a valid Cisco DNA-Advantage license.
- Ensure that the upstream distribution-layer Cisco Catalyst switch for Wired and FlexConnect Local Switching Wireless networks is configured in SDG-Agent mode and runs a valid Cisco DNA-Advantage license.

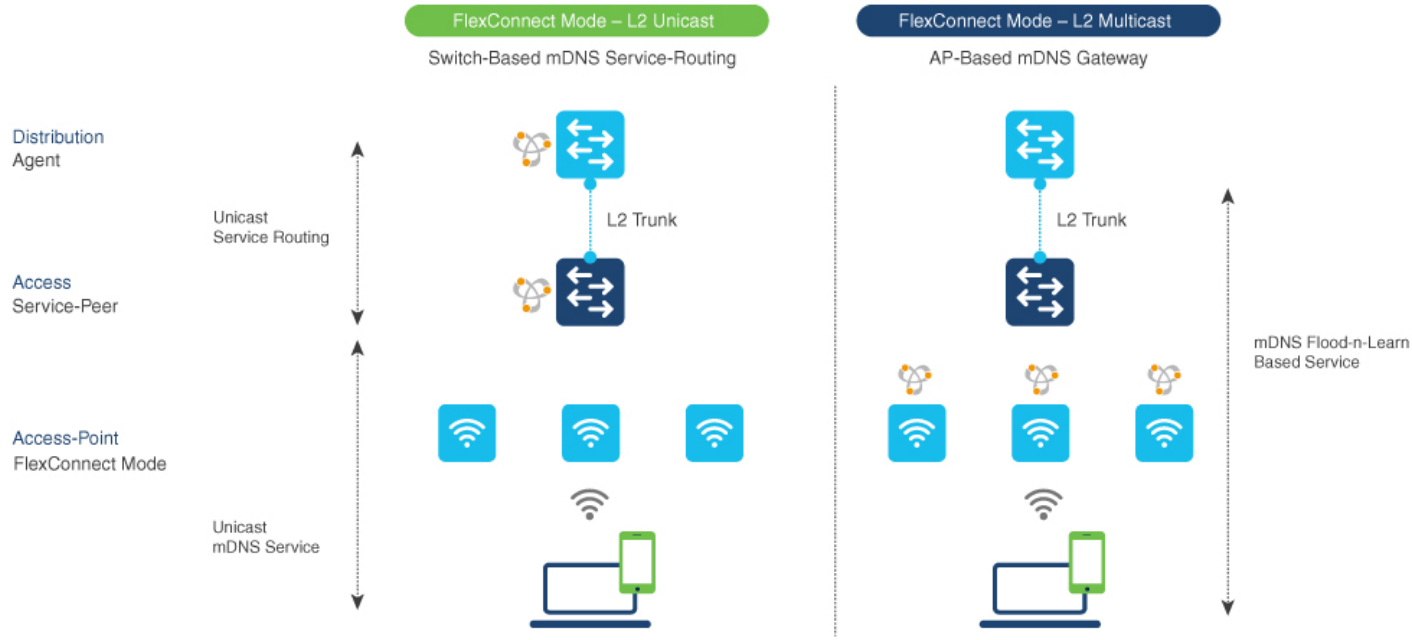
mDNS gateway alternatives for wireless FlexConnect mode

Explains mDNS gateway alternatives for wireless FlexConnect mode.

mDNS gateway alternatives for wireless FlexConnect mode are implementation methods that

- address evolving business and technical requirements in Enterprise networks
- enable service discovery and distribution in FlexConnect Local Switching based wireless networks, and
- provide two distinct approaches based on the operating network environment.

Implementation methods



Based on the operating network environment, the mDNS gateway for FlexConnect mode wireless network can be implemented in one of the methods to address service discovery and distribution:

- **Switch Based mDNS Gateway**–In Layer 2 access, the Cisco Catalyst 9000 series Ethernet switch must be implemented as mDNS gateway in Service-Peer role. The key benefits are:

- Replaces flood-n-learn with the new enhanced Unicast-based mDNS communication with FlexConnect mode wireless users.
- Eliminates mDNS flood with Unicast service-routing to LAN distribution. The Unicast service-routing between LAN distribution and Layer 2 access layer switches forms Local Area Bonjour domain to enable policy and location-based service discovery and distribution. The Unicast based service-routing over Layer 2 trunk eliminates mDNS flood-free and enables service-oriented wireless networks.
- Eliminates the requirement to forward wired network traffic to wireless Access Points improving wireless scale, performance, and network reliability.

- **AP Based mDNS Gateway**–The Cisco FlexConnect mode wireless access points can alternatively be implemented as mDNS gateway when connected to unsupported LAN access switch. In this method, the mDNS service discovery and distribution follows flood-n-learn mechanism over the Layer 2 wireless network. To implement AP based mDNS gateway, see the Multicast Domain Name System chapter.

Figure 60: mDNS gateway alternatives for FlexConnect mode

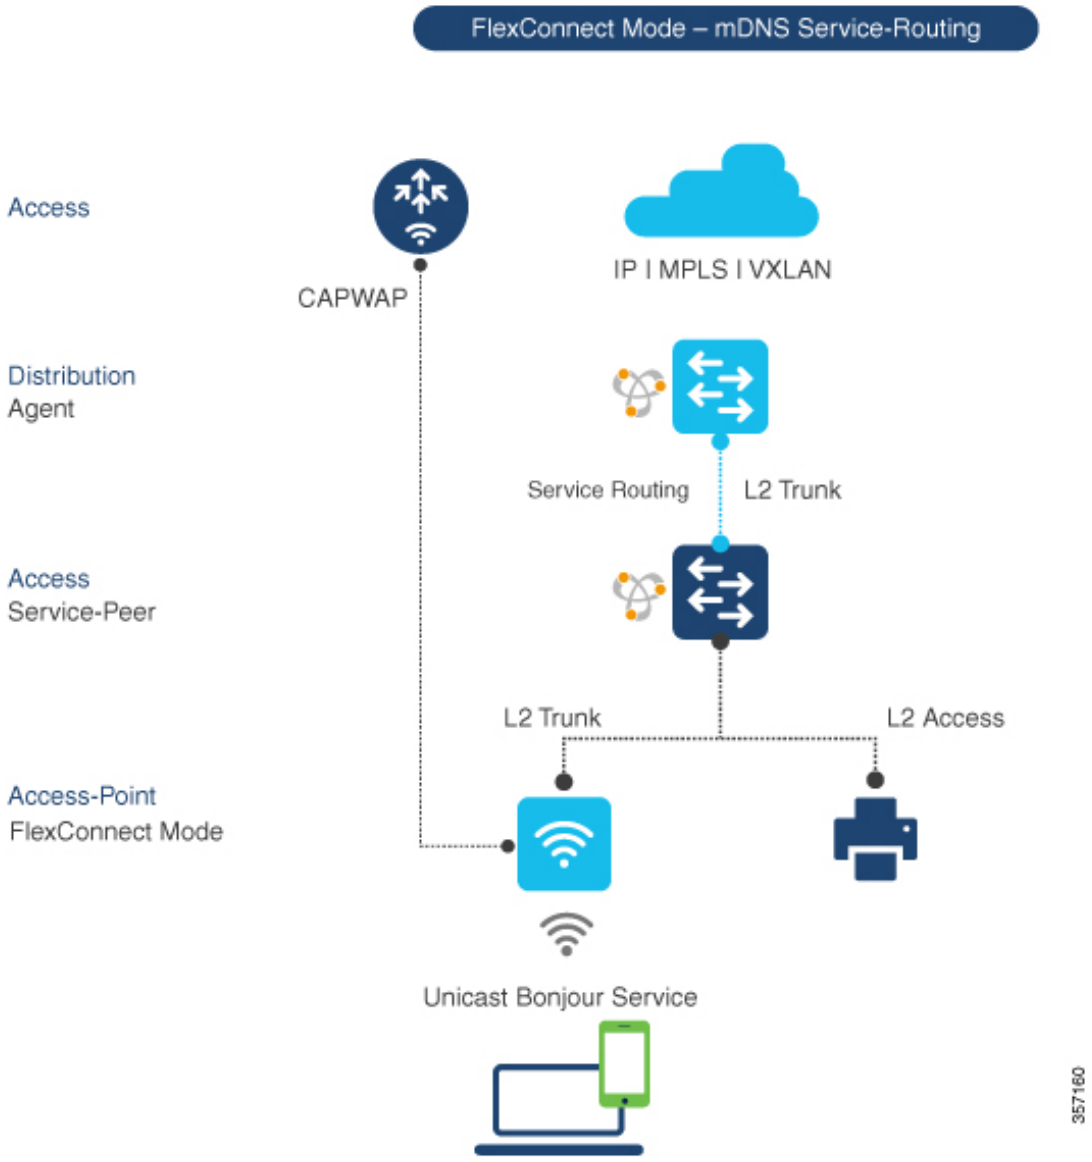
Local area Bonjour for wireless FlexConnect mode

Explains local area Bonjour for wireless FlexConnect mode.

Local area Bonjour for wireless FlexConnect mode is a mDNS gateway function that

- supports various advancements for broad range of wireless networks with distributed zero-configuration services
- enables distributed Bonjour gateway function at network edge through common unified Cisco IOS-XE operating system across Cisco Catalyst 9000 series LAN switches and Cisco Catalyst 9800 series controller
- provides end-to-end Wide Area Bonjour service-routing for service-oriented enterprise networks with intuitive user-experience.

mDNS gateway modes



The Cisco Catalyst 9000 series switches in the Layer 2 access layer and Layer 3 distribution layer must be configured in specific mDNS gateway modes to enable Unicast-based mDNS service-routing between wired and FlexConnect Local Switching mode wireless users within the same Layer 2 network block:

- **Service-Peer** - The Layer 2 access switch connecting wireless access point in FlexConnect Local Switching mode must be configured with mDNS gateway in Service-Peer mode. Each Layer 2 access switch provides mDNS gateway function between locally attached wired and FlexConnect mode wireless users. The Unicast-based mDNS service discovery and distribution within same or different VLANs is supported with bi-directional mDNS policies on single Layer 2 access switch.
- **SDG Agent** - The mDNS flood-n-learn based method in Layer 2 network is replaced with simple Unicast based service-routing between Layer 2 access switch in Service-Peer mode and upstream distribution-layer in mDNS gateway SDG Agent mode. The Unicast based mDNS service-routing eliminates mDNS flood over Layer 2 trunk ports providing increased bandwidth, enhanced security, location-based services, and flood control management in wired and FlexConnect wireless network.

Controller mDNS gateway function architecture

This figure illustrates how the controller connected to wireless access points support mDNS gateway function to wireless users in FlexConnect Local Switching mode.

Figure 61: Cisco Catalyst 9800 series controller local area Bonjour for wireless - FlexConnect mode

Local area Bonjour for wireless FlexConnect mode

Details the end-to-end configuration of Local Area Bonjour in Wireless FlexConnect mode, providing step-by-step CLI-based procedures for gateway modes, service policies, location filtering, custom service definitions, service routing, wired integration, and verification methods.

Local area Bonjour for wireless FlexConnect mode is a network configuration that enables service discovery and routing across distributed wireless infrastructure by implementing Cisco Catalyst 9000 series Ethernet switches as mDNS gateways with service-peer and SDG Agent mode capabilities to build service-routing connections with upstream distribution-layer switches.

Configuration guidelines

This configuration enables service-peer and SDG Agent mode to enable service-routing with upstream distribution-layer Cisco Catalyst 9000 series switch in SDG Agent mode to build Local Area Bonjour.

Configure mDNS gateway mode (CLI)

Configure mDNS gateway mode using CLI commands to enable mDNS gateway and Service-Peer mode on Layer 2 access switch and SDG Agent mode on Layer 3 distribution layer switch.

This task enables mDNS gateway functionality on network switches to facilitate multicast DNS service discovery across network segments.

Use this procedure when you need to enable mDNS gateway and Service-Peer mode on Layer 2 access switch and SDG Agent mode on Layer 3 distribution layer switch.

Procedure

1. **enable**

   Example

   ```
   Device# enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **mdns-sd gateway**

   Example

   ```
   Device(config)# mdns-sd gateway
   ```

   Enables mDNS on the Layer 2 Catalyst switch and enters the mDNS gateway configuration mode.

   (Optional) You can configure additional parameters:

   - **air-print-helper**: Enables communication between Apple iOS devices like iPhone or iPad to discover and use older printers that does not support driverless AirPrint function.
   - **cache-memory-max**: Configures the percentage memory for cache.
   - **ingress-client**: Configures Ingress client packet tuners.
   - **rate-limit**: Enables rate limiting of incoming mDNS packets.
   - **service-announcement-count**: Configures maximum advertisements.
   - **service-announcement-timer**: Configures advertisements announcement timer periodicity.
   - **service-query-count**: Configures maximum queries.
   - **service-query-timer**: Configures query forward timer periodicity.
   - **service-type-enumeration**: Configures service enumeration.

> **Note**
>
> For **cache-memory-max**, **ingress-client**, **rate-limit**, **service-announcement-count**, **service-announcement-timer**, **service-query-count**, **service-query-timer**, and **service-type-enumeration** commands, you can retain the default value of the respective parameter for general deployments. Configure a different value, if required, for a specific deployment.

4. **mode {service-peer | SDG-agent}**

   Example

   ```
   Device(config-mdns-sd)# mode service-peer
   ```

   ```
   Device(config-mdns-sd)# mode sdg-agent
   ```

   Configure mDNS gateway in one of these modes based on the system settings:

   - **service-peer**- Enables Layer 2 Catalyst access switch in mDNS Service-Peer mode.
   - **SDG-agent**- Default. Enables Layer 3 distribution layer Catalyst switch in SDG Agent mode to peer with central Cisco Catalyst Center controller for Wide Area Bonjour service routing.

5. **exit**

   Example

   ```
   Device(config-mdns-sd)# exit
   ```

   Exits mDNS gateway configuration mode.

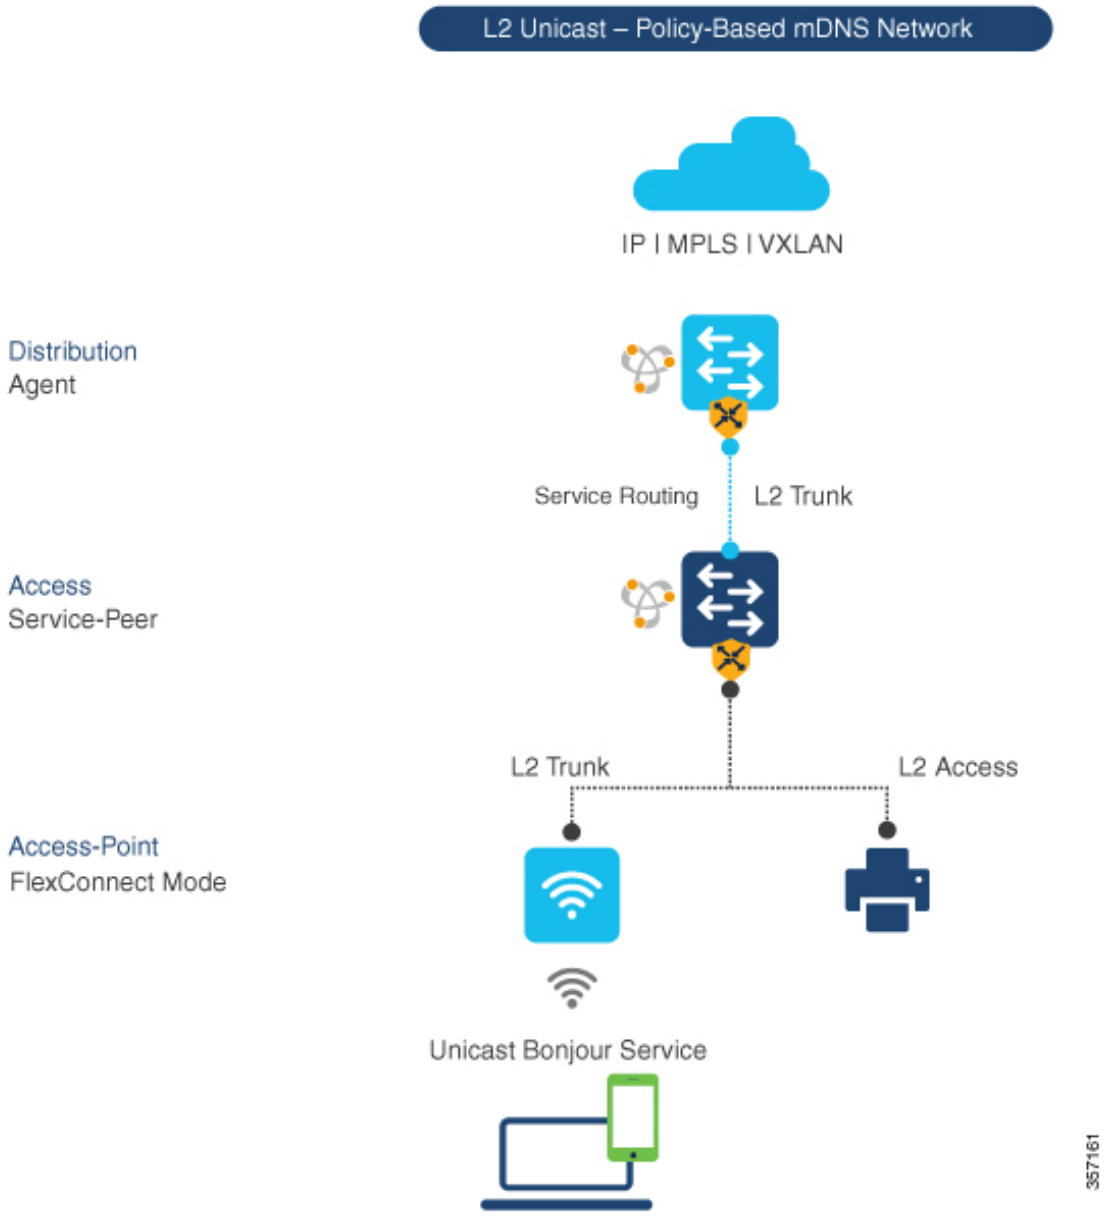
The mDNS gateway mode is configured on the switch. The switch can now facilitate mDNS service discovery across network segments based on the configured mode.

Configure mDNS service policy (CLI)

Configure mDNS service policy using commands to enable multicast DNS service discovery and proxy functionality on Catalyst switches.

Configure mDNS service policy to enable multicast DNS service discovery and proxy functionality on Catalyst switches, allowing service advertisement and discovery across VLANs in both Service-Peer and SDG agent modes.

You need to perform this configuration to enable mDNS service policy on Catalyst switches. This configuration is required in Service-Peer mode for Layer 2 Catalyst switches and SDG agent mode for Layer 3 Catalyst switches.



You need to perform the following to configure an mDNS service policy:

1. Create service-list to permit built-in or user-defined custom service types.
2. Associate service-list to a service-policy to enforce ingress or egress direction.
3. Apply the service policy to the new VLAN configuration mode.

> **Note**
>
> You will need this configuration in Service-Peer mode for Layer 2 Catalyst switch and SDG agent mode for Layer 3 Catalyst switch.

The figure shows how to configure mDNS policies on Catalyst switch in Service-Peer and SDG agent modes.

Figure 62: mDNS service policy configuration on Catalyst switch in Service-Peer and SDG agent modes

This procedure builds and applies service-policies on target VLAN in service-peer and SDG agent modes.

Before you begin

Follow these steps to configure mDNS service policy using CLI commands:

Procedure

1. **enable**

   Example

   ```
   Device# enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **mdns-sd service-list** *service-list-name* {**in** | **out**}

   Example

   ```
   Device(config)# mdns-sd service-list VLAN100-LIST-IN in
   ```

   ```
   Device(config)# mdns-sd service-list VLAN100-LIST-OUT out
   ```

   Configure mDNS service-list to classify one or more service types. Unique service-list is required to process incoming mDNS message and outbound response to request locally connected wired or FlexConnect wireless end points.

4. **match** *service-definition-name* [**message-type** {**any** | **announcement** | **query**}]

   Example

   ```
   Device(config)# mdns-sd service-list VLAN100-LIST-IN in
   ```

   ```
   Device(config-mdns-sl-in)# match APPLE-TV
   ```

   ```
   Device(config-mdns-sl-in)# match PRINTER-IPPS message-type announcement
   ```

   Matches inbound service-list.

   The Catalyst switch validates to accept or drop incoming mDNS service-type (such as, Apple TV) advertisement or query matching message type from locally connected wired or FlexConnect wireless end points. The service-list contains implicit deny at the end.

   The default message-type used is **any**.

5. **match** *service-definition-name* [**message-type** {**any** | **announcement** | **query**}]

Example

```
Device(config)# mdns-sd service-list VLAN100-LIST-OUT out
```

```
Device(config-mdns-sl-in)# match APPLE-TV
```

```
Device(config-mdns-sl-in)# match PRINTER-IPPS
```

Matches outbound service-list.

The Catalyst switch provides local service proxy function by responding matching service-type to the requesting end point(s). For example, the Apple-TV and Printer learnt from VLAN 100 will be distributed to FlexConnect wireless receiver in same VLAN 100. The service-list contains implicit deny at the end.

The message-type for outbound service-list is not required.

6. **mdns-sd service-policy** *service-policy-name*

Example

```
Device(config)# mdns-sd service-policy VLAN100-POLICY
```

Creates unique mDNS service-policy in global configuration mode.

7. **service-list** *service-list-name* **{in | out}**

Example

```
Device(config)# mdns-sd service-policy VLAN100-POLICY
```

```
Device(config-mdns-ser-policy)# service-list VLAN100-LIST-IN in
```

```
Device(config-mdns-ser-policy)# service-list VLAN100-LIST-OUT out
```

Configures mDNS service-policy to associate service-list for each direction.

8. **VLAN configuration** *ID*

Example

```
Device(config)# vlan configuration 100
```

Enables wired or wireless FlexConnect user VLAN configuration for advanced service parameters. One or more VLANs can be created for the same settings.

Here, *ID* refers to the VLAN configuration ID. The range is from 101 to 110 and 200. This range allows to configure consecutive and non-consecutive VLAN ID(s).

9. **mdns-sd gateway**

Example

```
Device(config-vlan)# mdns-sd gateway
```

Enables mDNS gateway on configured wired or FlexConnect wireless user VLAN ID(s).

10. **service-policy** *service-policy-name*

    Example

    ```
    Device(config-vlan-mdns)# service-policy VLAN100-POLICY
    ```

    Associates mDNS service-policy to the configured wired or FlexConnect wireless user VLAN ID(s).

11. **exit**

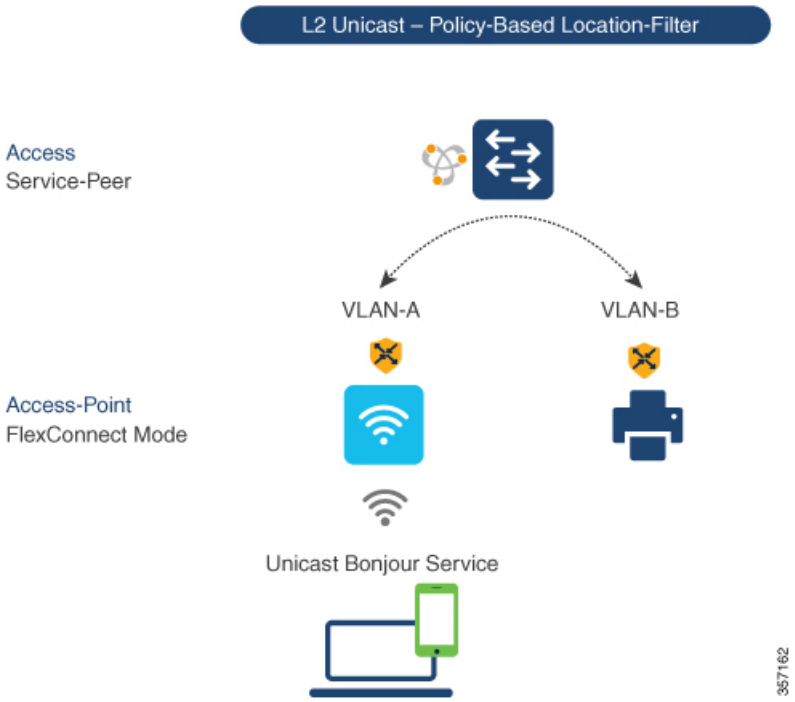
    Example

    ```
    Device(config-vlan-mdns)# exit
    ```

    Exits mDNS gateway configuration mode.

The mDNS service policy is successfully configured and applied to the specified VLAN. The Catalyst switch can now process mDNS service advertisements and queries according to the configured service lists and policy rules.

Configure mDNS Location-Filter (CLI)



Configure mDNS location-filter using commands to allow service discovery and distribution between locally configured VLAN IDs associated to FlexConnect wireless user networks.

Configure mDNS location-filter to enable local service proxy on Cisco Catalyst switch in Service-Peer mode and discover mDNS services between local wired and wireless FlexConnect user VLANs.

Optionally, you can configure mDNS location-filter to allow service discovery and distribution between locally configured VLAN IDs associated to FlexConnect wireless user networks.

The following figure illustrates and references location-filter policy on Catalyst switch in Service-Peer mode permitting to discover and distribute mDNS services between wired and FlexConnect wireless user VLANs.

Figure 63: Catalyst Service-Peer mDNS Location-Filter configuration

Before you begin

Follow these steps to enable local service proxy on Cisco Catalyst switch in Service-Peer mode and discover mDNS services between local wired and wireless FlexConnect user VLANs:

Procedure

1. **enable**

   Example

   ```
   Device# enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **mdns-sd location-filter** *location-filter-name*

   Example

   ```
   Device(config)# mdns-sd location-filter LOCAL-PROXY
   ```

   Configures a unique location-filter in global configuration mode.

4. **match location-group {all | default | ID} VLAN** [*ID*]

   Example

   ```
   Device(config-mdns-loc-filter)# match location-group default vlan 100
   ```

   ```
   Device(config-mdns-loc-filter)# match location-group default vlan 101
   ```

   Configures the match criteria to mutually distribute the permitted services between grouped VLANs. For example, mDNS services can be discovered and distributed using the Unicast mode between wireless FlexConnect user VLAN ID 100 and wired user VLAN ID 101.

5. **mdns-sd service-list** *service-list-name* **{in | out}**

   Example

   ```
   Device(config)# mdns-sd service-list VLAN100-LIST-OUT out
   ```

   Configures the mDNS service-list to classify one or more service types.

   The **service-list** configuration is required to process any incoming or outgoing mDNS messages.

6. **match** *service-definition-name* [**message-type {any | announcement | query}**]

   Example

   ```
   Device(config)# mdns-sd service-list VLAN100-LIST-OUT out
   ```

   ```
   Device(config-mdns-sl-out)# match APPLE-TV location-filter LOCAL-PROXY
   ```

   Associates location-filter to one or more service types to enable local proxy between local VLANs. For example, the Apple-TV learnt from VLAN 100 and VLAN 101 will be distributed to receiver in VLAN 100.

   > **Note**
   >
   > You do not require a **message-type** for the outbound service-list.

7. **mdns-sd service-policy** *service-policy-name*

   Example

   ```
   Device(config)# mdns-sd service-policy VLAN100-POLICY
   ```

   Creates unique mDNS service-policy in global configuration mode.

8. **service-list** *service-list-name* **{in | out}**

Example

```
Device(config)# mdns-sd service-policy VLAN100-POLICY
```

```
Device(config-mdns-ser-policy)# service-list VLAN100-LIST-OUT out
```

Configures mDNS service-policy to associate service-list for each direction.

9. **VLAN configuration** *ID*

Example

```
Device(config)# vlan configuration 100
```

Enables VLAN configuration for advanced service parameters. You can create one or more VLANs with the same settings.

Here, *ID* refers to the VLAN configuration ID. The range is from 101 to 110 and 200. This range allows to configure consecutive and non-consecutive VLAN ID(s).

10. **mdns-sd gateway**

Example

```
Device(config-vlan-config)# mdns-sd gateway
```

Enables mDNS gateway on configured VLAN ID(s).

11. **service-policy** *service-policy-name*

Example

```
Device(config-vlan-mdns-sd)# service-policy VLAN100-POLICY
```

Associates mDNS service-policy to the configured VLAN ID(s).

12. **exit**

Example

```
Device(config-vlan-mdns-sd)# exit
```

Exits mDNS gateway configuration mode.

---

mDNS location-filter is successfully configured to enable local service proxy between the specified VLANs. The mDNS services can now be discovered and distributed between wired and FlexConnect wireless user VLANs.

Configure custom service definition (CLI)

Configure custom service definition using commands to enable end mDNS service-routing in the network.

Create custom service-definition with matching mDNS PTR records to enable end mDNS service-routing in the network.

The Cisco IOS-XE supports mapping of various built-in well-known mDNS service-definition types to key mDNS PTR records and user-friendly names. For example, built-in Apple-TV service-type is associated with _airplay. _tcp.local and

_raop. _tcp.local PTR records to successfully enable service in the network. Network administrators create custom service-definition with matching mDNS PTR records to enable end mDNS service-routing in the network.

Procedure

1. **enable**

   Example

   ```
   Device# enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **mdns-sd service-definition** *service-definition-name*

   Example

   ```
   Device(config)# mdns-sd service-definition APPLE-CLASSROOM
   ```

   Creates a unique service-definition name for custom service-types.

4. **service-type** *custom-mDNS-PTR*

   Example

   ```
   Device(config-mdns-ser-def)# service-type _classroom. _tcp.local
   ```

   Configures a regular-expression string for custom mDNS PoinTeR(PTR) record.

5. **exit**

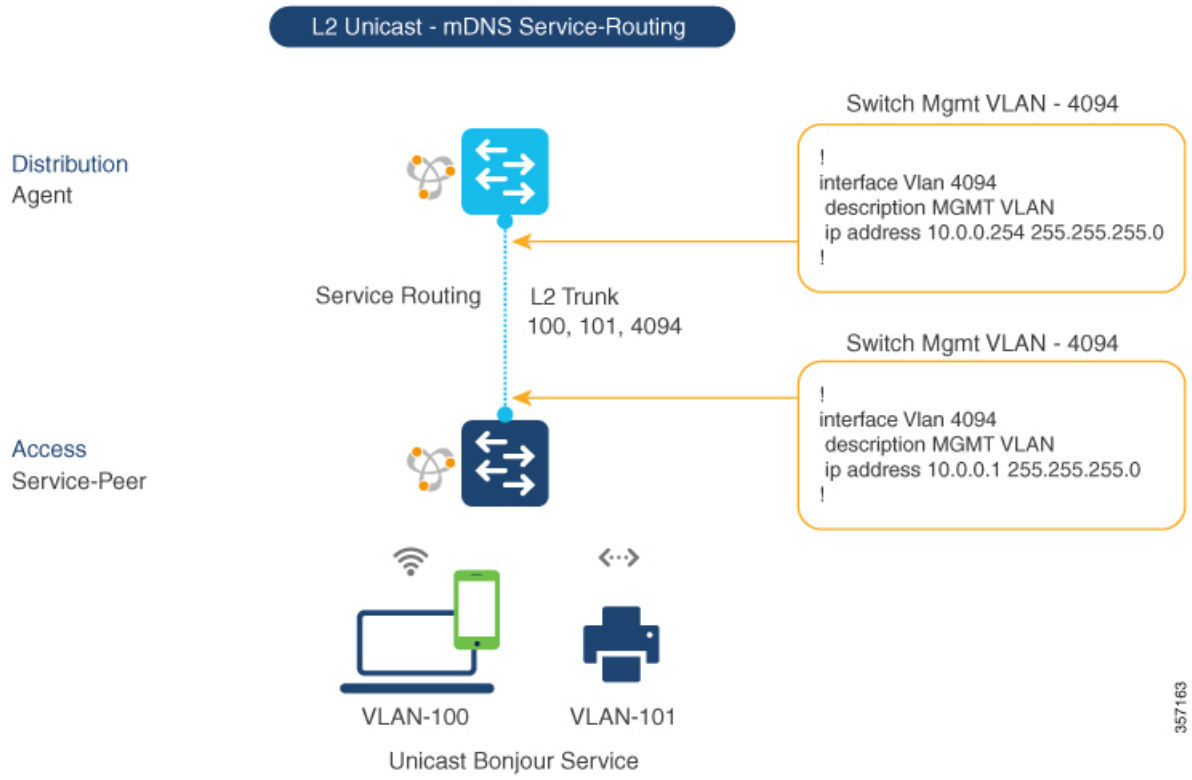
   Example

   ```
   Device(config-mdns-ser-def)# exit
   ```

   Exits mDNS gateway configuration mode.

The custom service-definition is configured and can be associated to the service-list to enable mDNS service-routing functionality in the network.

Configure service-routing on service-peer using CLI



Configure service-routing on service-peer using CLI commands to establish communication with an upstream SDG Agent switch.

Configure service-routing on a Layer 2 Cisco Catalyst switch in Service-Peer mode to establish communication with an upstream distribution-layer switch in SDG Agent mode and enable mDNS trust interface settings.

The Layer 2 Cisco Catalyst switch in Service-Peer mode builds a service-routing with an upstream distribution-layer switch in the SDG Agent mode. To build service-routing, the Layer 2 Cisco Catalyst switch requires at least one interface with valid IP address to reach the upstream SDG Agent Catalyst switch. The switch management port is unsupported.

The following figure illustrates the topology to enable unicast-based service-routing over Layer 2 trunk between access-layer Catalyst switch in the Service-Peer mode and distribution-layer Catalyst switch in SDG Agent mode.

Figure 64: Catalyst Service-Peer Service-Routing configuration

Before you begin

Follow these steps to configure service-routing on Cisco Catalyst switch in Service-Peer mode and setup mDNS trust interface settings:

Procedure

1. **enable**

   Example

   ```
   Device# enable
   ```

   Enables Privileged EXEC mode. Enter your password, if prompted.

2. **configure terminal**

Example

```
Device# configure terminal
```

Enters the global configuration mode.

3. **VLAN configuration** *ID*

   Example

   ```
   Device(config)# vlan configuration 100
   ```

   Enables Wired and FlexConnect user VLAN configuration for advanced service parameters. One or more VLANs can be created for the same settings.

   Here, *ID* refers to the VLAN configuration ID. For example, *VLAN configuration 101-110, 200* range, allows to configure consecutive and non-consecutive VLAN ID(s).

4. **mdns-sd gateway**

   Example

   ```
   Device(config-vlan-config)# mdns-sd gateway
   ```

   Enables mDNS gateway on configured VLAN ID(s).

   To enable the respective functionalities, enter these commands in the mDNS gateway configuration mode:

   - **active-query timer [sec]**: Configure to enable refresh discovered services and their records with periodic mDNS Query message for permitted service types. The valid range is from 60 to 3600 seconds. The recommended value is 3600 seconds.
   - **service-mdns-query {PTR | srv | txt}**: Permits processing specific Query type. The default query type is PTR.
   - **transport {ipv4 | ipv6 | both}**: Permits processing for IPv4, IPv6, or both. It is recommended to use one network type to reduce redundant processing and respond with the same information over two network types. The default network type is IPv4.

5. **source-interface** *ID*

   Example

   ```
   Device(config-vlan-mdns-sd)# source-interface vlan 4094
   ```

   Selects the interface with a valid IP address to source service-routing session with the upstream Cisco Catalyst SDG Agent switch. Typically, the management VLAN interface can be used.

6. **SDG-agent** [*IPv4_address*]

   Example

   ```
   Device(config-vlan-mdns-sd)# sdg-agent 10.0.0.254
   ```

   Configures the SDG Agent IPv4 address, typically, the management VLAN gateway address. If FHRP mode, then use the FHRP virtual IP address of the management VLAN.

7. **exit**

Example

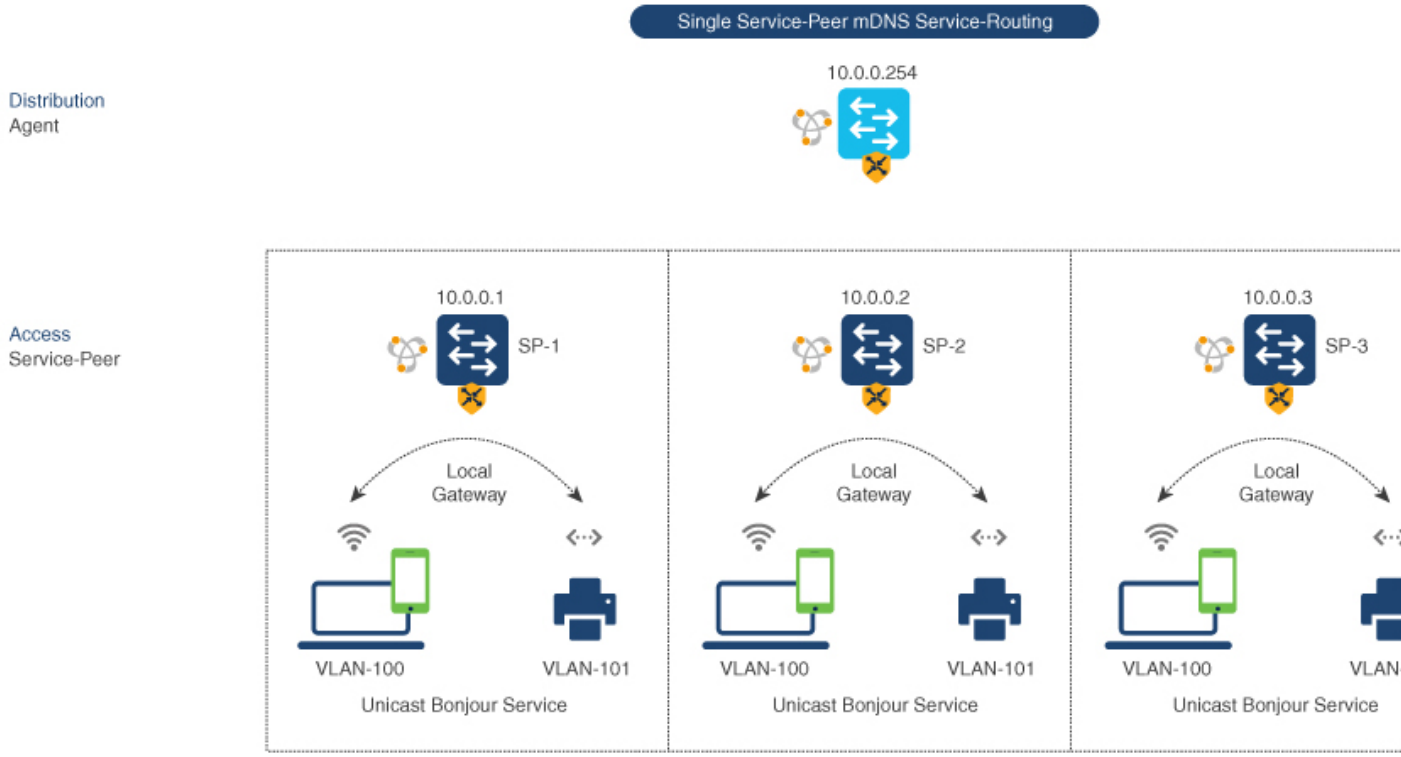
```
Device(config-vlan-mdns-sd)# exit
```

Exits the mDNS gateway configuration mode.

Service-routing is configured on the service-peer, establishing communication with the upstream SDG Agent switch and enabling mDNS gateway functionality on the specified VLAN.

Location-based mDNS

Describes the default per-switch mDNS discovery and distribution functionality for FlexConnect wireless users on Layer 2 Catalyst switches.



Location-based mDNS is a network service discovery mechanism that

- enables per-switch mDNS discovery and distribution for FlexConnect wireless users attached locally to Layer 2 Catalyst switches in Service-Peer mode by default
- supports user mobility across multiple Layer 2 Catalyst switches even when FlexConnect user VLANs are extended between switches, and
- requires mDNS service-policy configuration on the SDG Agent to accept policy-based service provider and receiver information from downstream Service-Peer access-layer switches.

Per-switch location-based FlexConnect configuration

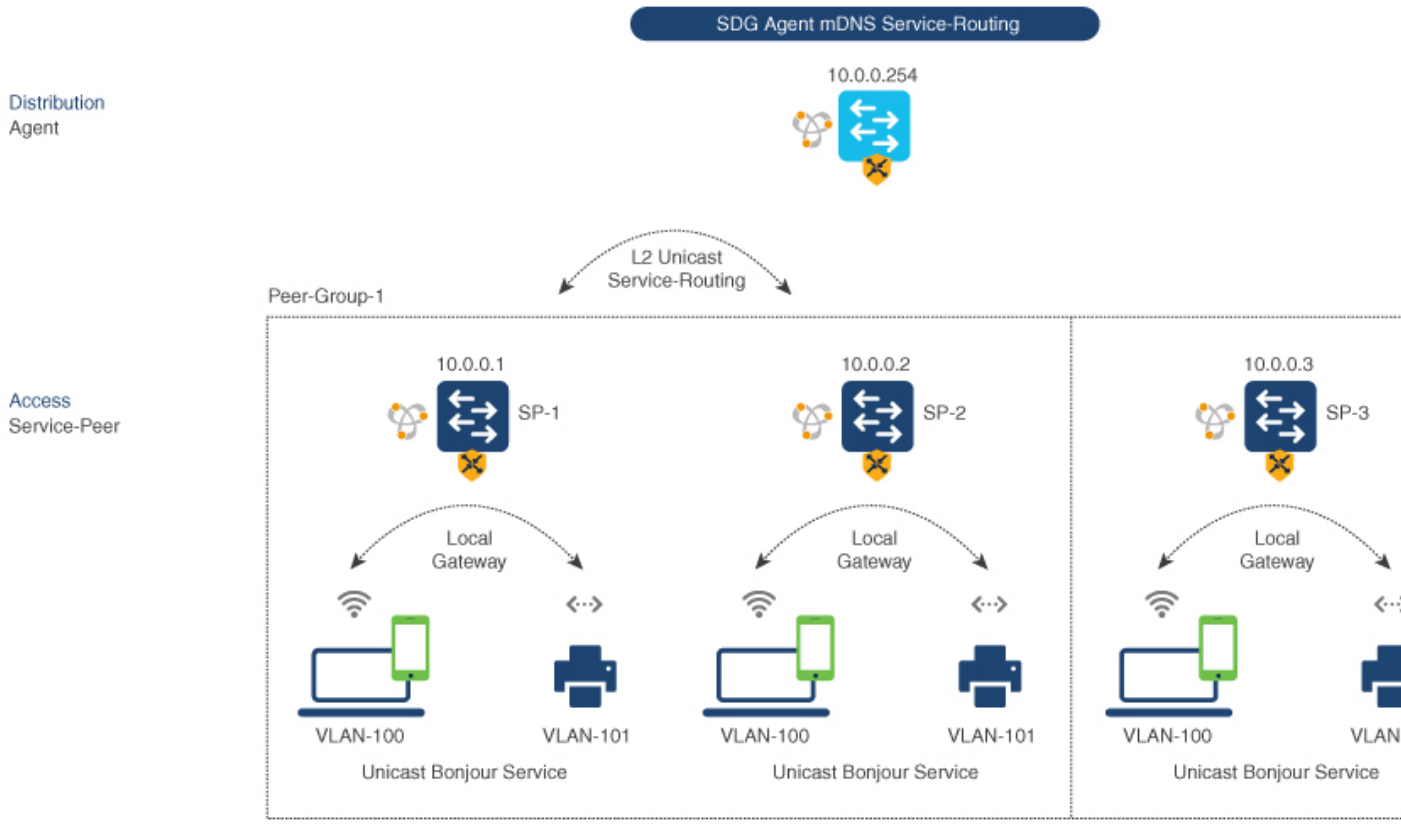
The following figure shows the per-switch location-based FlexConnect configuration topology.

Figure 65: Per-Switch Location-Based FlexConnect configuration

> **Note**
>
> Configure the mDNS service policy on the distribution layer SDG Agent switch before proceeding to the next configuration step. For more information, see the Configuring mDNS Service Policy section.

Configure service-routing on SDG agent (CLI)

Configure service-routing on SDG agent using CLI commands to enable Unicast mode Bonjour service-routing with downstream Layer 2 access-layer switches.



Configure service-routing on SDG agent to enable Unicast mode Bonjour service-routing with downstream Layer 2 access-layer Ethernet switches connected to FlexConnect wireless users.

The Cisco Catalyst 9000 series switches support SDG Agent mode automatically at the distribution layer and enables Unicast mode Bonjour service-routing with the downstream Layer 2 access-layer Ethernet switches connected to the FlexConnect wireless users. The SDG Agent must be configured with mDNS service-policy on wireless FlexConnect user VLAN to accept mDNS service cache from downstream Service-Peer switches.

This section provides step-by-step configuration guidelines to enable policy-based service discovery and distribution between locally paired Layer 2 access network switches in the Service-Peer mode.

The following figure illustrates unicast service-routing on SDG Agent and downstream Layer 2 access network switches in the Service-Peer mode.

Figure 66: Catalyst SDG agent Service-Routing configuration

Before you begin

> **Note**
>
> Configure the mDNS service policy on the distribution layer SDG Agent switch before proceeding to the next configuration step. For more information, see the Configuring mDNS Service Policy section.

Follow these steps to enable the mDNS service policy and peer-group on SDG Agent switch, and enable Unicast mode service-routing with Layer 2 access network switches in Service-Peer mode:

Procedure

1. **enable**

   Example

   ```
   Device# enable
   ```

   Enables privileged EXEC mode.

   Enter your password, if prompted.

2. **configure terminal**

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

3. **mdns-sd service-peer group** *service-peer-group-name*

   Example

   ```
   Device(config)# mdns-sd service-peer group group_1
   ```

   Configures a unique Service-Peer group.

4. **peer-group** [*ID*]

   Example

   ```
   Device(config-mdns-svc-peer)# peer-group 1
   ```

   Assigns a unique peer-group ID to the Service-Peers pair permitting mDNS service discovery and distribution within the assigned group list.

   The valid peer-group range is from 1 to 1000 for each SDG Agent switch.

5. **service-policy** *service-policy-name*

   Example

   ```
   Device(config-mdns-svc-peer-grp)# service-policy VLAN100-POLICY
   ```

Associates an mDNS service policy to accept service advertisements and query from the paired Service-Peers.

6. **service-peer** [*IPv4_address*] **location-group** {**all** | **default** | **ID**}

   Example

   ```
   Device(config-mdns-svc-peer-grp)# service-peer 10.0.0.1 location-group default
   ```

   ```
   Device(config-mdns-svc-peer-grp)# service-peer 10.0.0.2 location-group default
   ```

   Configures at least one Service-Peer to accept the mDNS service advertisement or query message. When a group has more than one Service-Peers, the SDG Agent provides Layer 2 Unicast mode routing between the configured peers.

   For example, the SDG Agent provides Unicast based service gateway function between three (10.0.0.1 and 10.0.0.2) Layer 2 Service-Peer switches matching the associated service-policy.

   The mDNS service information from the unpaired Layer 2 Service-Peer (10.0.0.3) cannot announce or receive mDNS services with the other grouped Service-Peers (10.0.0.1 and 10.0.0.2).

7. **exit**

   Example

   ```
   Device(config-mdns-svc-peer-grp)# exit
   ```

   Exits mDNS gateway configuration mode.

The SDG Agent is configured with service-routing to enable Unicast mode service-routing with downstream Layer 2 access network switches in Service-Peer mode.

Verify local area Bonjour in service-peer mode

Provides guidelines to verify various Local Area Bonjour domain mDNS service configuration parameters in service-peer mode.

This section provides guidelines to verify various Local Area Bonjour domain mDNS service configuration parameters, cache records, statistics and more on the controller in service-peer mode.

Command or Action	Purpose
show mdns-sd cache {all | interface | MAC | name | service-peer | static | type | VLAN}	Displays available mDNS cache records supporting multiple variables providing granular source details received from wired or wireless FlexConnect user VLANs. The variables are as follows: • all – Displays all available cache records discovered from multiple source connections of a system. • interface – Displays available cache records discovered from the specified Layer 3 interface. • MAC – Displays available cache records discovered from the specified MAC address. • name – Displays available cache records based on the service provider announced name. • service-peer – Displays available cache records discovered from the specified Layer 2 Service-Peer. • static – Displays locally configured static mDNS cache entry. • type – Displays available cache records based on the specific mDNS record type, such as, PTR, SRV, TXT, A or AAAA. • VLAN – Displays available cache records discovered from the specified Layer 2 VLAN ID in the Unicast mode.
show mdns-sd service-definition {name | type}	Displays built-in and user-defined custom service-definition that maps service name to the mDNS PTR records. The service-definition can be filtered by name or type.
show mdns-sd service-list {direction | name}	Displays inbound or outbound direction list of configured service-list to classify matching service-types for service-policy. The list can be filtered by name or specific direction.
show mdns-sd service-policy {interface | name}	Displays list of mDNS service-policy mapped with inbound or outbound service-list. The service-policy list can be filtered by an associated specified interface or name.

Command or Action	Purpose
show mdns-sd statistics {all | cache | debug | interface | service-list | service-policy | services | VLAN}	Displays detailed mDNS statistics processed bi-directionally by the system on each mDNS gateway enabled VLAN configured mDNS in Unicast mode. The expanded keyword for mDNS statistics can provide detailed view on interface, policy, service-list, and services. **Note** This command displays all mDNS packets received from directly connected (Local Mode) or Flex clients in WLAN.
show mdns-sd summary {interface | VLAN}	Displays brief information about mDNS gateway and key configuration status on all wired and wireless FlexConnect user VLANs, and interfaces of the system.

Verify local area Bonjour in SDG agent mode

Provides guidelines to verify various local area Bonjour domain mDNS service configuration parameters in SDG agent mode.

This section provides guidelines to verify various Local Area Bonjour domain mDNS service configuration parameters, cache records, statistics and more on the controller in SDG Agent mode

Command or Action	Purpose
show mdns-sd cache {all | interface | MAC | name | service-peer | static | type | VLAN | VRF}	Displays available mDNS cache records supporting multiple variables providing granular source details. The variables are as follows: • all – Displays all available cache records discovered from multiple source connections of a system. • interface – Displays available cache records discovered from the specified Layer 3 interface. • MAC – Displays available cache records discovered from the specified MAC address. • name – Displays available cache records based on the service provider announced name. • service-peer – Displays available cache records discovered from the specified Layer 2 Service-Peer. • static – Displays locally configured static mDNS cache entry. • type – Displays available cache records based on the specific mDNS record type, such as, PTR, SRV, TXT, A or AAAA. • VLAN – Displays available cache records discovered from the specified Layer 2 VLAN ID in the Unicast mode. • VRF – Displays per-VRF available cache records based on specific mDNS record type, i.e., PTR, SRV, TXT, A or AAAA.
show mdns-sd service-definition {name | type}	Displays built-in and user-defined custom service-definition that maps service name to the mDNS PTR records. The service-definition can be filtered by name or type.
show mdns-sd service-list {direction | name}	Displays inbound or outbound direction list of the configured service-list to classify matching service-types for service-policy. The list can be filtered by name or specific direction.
show mdns-sd service-policy {interface | name}	Displays list of mDNS service-policy mapped with inbound or outbound service-list. The service-policy list can be filtered by an associated specified interface or name.
show mdns-sd statistics {all | cache | debug | interface | service-list | service-policy | services | VLAN}	Displays detailed mDNS statistics processed bi-directionally by the system on each mDNS gateway enabled VLAN configured mDNS in Unicast mode. The expanded keyword for mDNS statistics can provide detailed view on interface, policy, service-list, and services.
show mdns-sd summary {interface | VLAN}	Displays brief information about mDNS gateway and key configuration status on all VLANs and interfaces of the system.

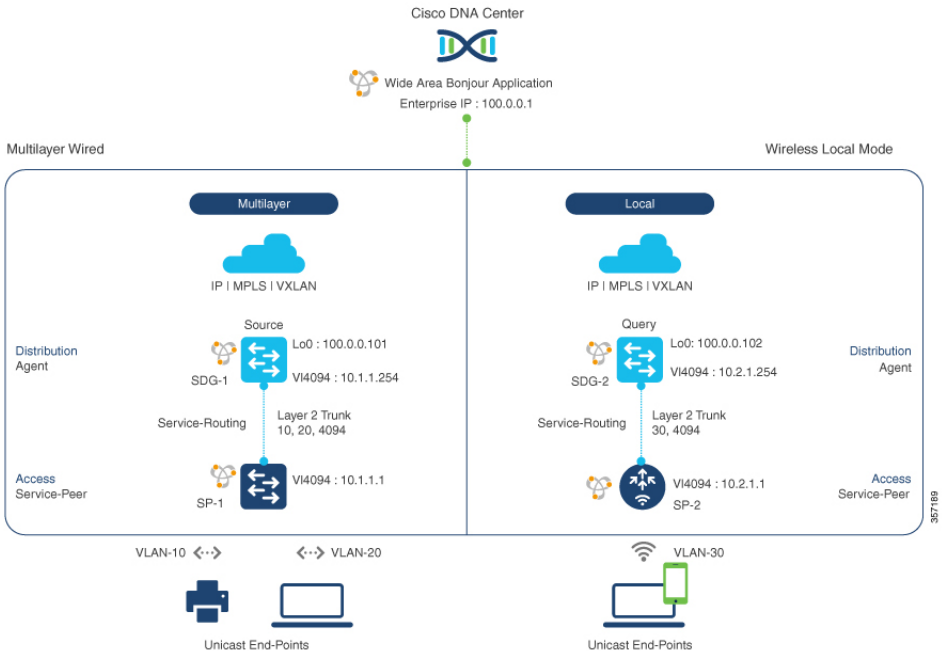
233 Configuration Example for Local Mode - Wireless and Wired

Topics:

- Overview

Demonstrates a practical configuration scenario for implementing local mode deployment across both wireless and wired network infrastructure components.



Overview

Introduces the framework for local mode deployments across multilayer wired and wireless environments, including wireless AP multicast configuration, Wide Area Bonjour examples with default and customized service lists, Cisco Catalyst Center traditional setups, verification procedures, and supporting reference material.

This chapter provides configuration guidelines to implement Wide Area Bonjour enabling end-to-end policy-based mDNS service discovery and distribution across multilayer wired and wireless local mode. The first hop mDNS gateway at Layer 2 access switch and the controller must be implemented in service peer mode and paired with LAN and wireless distribution-layer switch in SDG agent role. The network-wide distributed SDG agent must be paired with the Cisco Catalyst Center to enable mDNS service-routing across IP core network based on multiple services and network attributes.

The following figure illustrates unicast mode bonjour network environment with AirPrint capable printer and user computer (macOS, Microsoft Windows, etc.) connected to same Ethernet switch. The computers and mobile devices of the wireless user are associated to wireless AP in local mode across multi-hop IP boundary from printers.

Figure 67: Wide Area Bonjour Service-Routing Multilayer Wired and Wireless Local Mode

Configuring Wireless AP Multicast Mode

Configure wireless AP multicast mode.

This procedure configures wireless AP multicast on the controller for local mode APs and IP network.

The controller must be configured with unique IP multicast address for wireless AP in local mode to permit mDNS communication across wired and wireless networks.

Step	Controller Service Peer Configuration
Step-1 Enable global IP Multicast on Cisco Catalyst 9800 series controller.	``` ! wireless multicast ! ```
Step-2 Configure Wireless AP mode to Multicast with unique IP Multicast address.	``` ! wireless multicast 239.254.254.1 ! ```

The following table provides step-by-step IP multicast configuration guidelines on SDG agent (SDG-1 and SDG-2) at the distribution layer network.

Step	Switch SDG Agent Configuration	WLC SDG Agent Configuration
Step-1 Enable IP multicast-routing on distribution layer switches connecting Cisco Wireless Local Mode Access Point and Cisco Wireless LAN Controller.	``` ! ip multicast-routing ! ```	``` ! ip multicast-routing ! ```
Step-2 Configure IP PIM Rendezvous-Point (RP) on distribution layer switches.	``` ! ip pim rp-address 10.150.255.1 ! ```	``` ! ip pim rp-address 10.150.255.1 ! ```
Step-3 Enable IP PIM on SVI Interface of distribution layer switches connected Cisco Wireless Local Mode Access Point and Cisco WLC Management VLAN.	``` ! interface Vlan 101 description CONNECTED TO WIRELESS AP - LOCAL MODE ip pim sparse-mode ! ```	``` ! interface Vlan 4094 description CONNECTED TO WIRELESS MGMT - WLC ip pim sparse-mode ! ```
Step-4 Enable IP PIM on Layer 3 uplink Interface of distribution layer switches connected Cisco Wireless Local Mode Access Point and Cisco WLC Management VLAN.	``` ! interface range FortyGigabitEthernet 1/1/1 - 2 description CONNECTED TO IP CORE NETWORK ip pim sparse-mode ! ```	``` ! interface range FortyGigabitEthernet 1/1/1 - 2 description CONNECTED TO IP CORE NETWORK ip pim sparse-mode ! ```

Note

IP Multicast must be enabled in the Layer 3 core network to allow Cisco wireless APs in local mode to successfully join the WLC announced multicast group. For more information, refer to the Cisco online documentation to implement IP multicast networks.

Configuration Example for Default Service List and Policy in Wide Area Bonjour Between Multilayer Wired and Wireless Endpoints

Configuration example for default service list and policy in wide area bonjour between multilayer wired and wireless endpoints.

This section provides guidance on configuring Service-Peer, SDG Agent, and Cisco Catalyst Center, allowing the wired and wireless endpoints to dynamically discover default service list using Layer 2 unicast and policy.

Example: Wired and Wireless Access Layer Service Peer Configuration

Example for wired and wireless access layer service peer configuration.

The following table provides a sample configuration of wired and wireless controller access layer service peer.

Table 204: Configuring Wired and Wireless Access Layer Service Peer

Configuration Step	Sample Configuration: SP-1 Service-Peer Configuration	Sample Configuration: SP-2 Service-Peer Configuration
Step-1: Enable mDNS gateway and set the gateway mode. **Note** In wireless controller, service peer mode is enabled by default with mDNS gateway configuration.	```! mdns-sd gateway mode service-peer !```	```! mdns-sd gateway mode service-peer !```
Step-2: Activate unicast mDNS gateway and attach service policy on wired VLAN and wireless FlexConnect user VLAN of SP-1 and SP-2 Layer 2 access switch.	```! vlan configuration 10, 30 mdns-sd gateway service-policy LOCAL-AREA-POLICY active-query timer 3600 !```	```! vlan configuration 20, 30 mdns-sd gateway service-policy LOCAL-AREA-POLICY active-query timer 3600 !```
Step-3: Enable unicast service routing between wired and wireless service peer and SDG agent using wired management source VLAN ID and IP address.	```vlan configuration 10, 30 mdns-sd gateway source-interface vlan 4094 sdg-agent 10.1.1.254 !```	```! vlan configuration 20, 30 mdns-sd gateway source-interface vlan 4094 sdg-agent 10.1.1.254 !```

Example: Wired and Wireless Distribution Layer SDG Agent Configuration

Example for wired and wireless distribution layer SDG agent configuration.

The following table provides a sample configuration of distribution layer SDG agent.

Table 205: Configuring Wired and Wireles Distribution Layer SDG Agent

Configuration Step	Sample Configuration: SDG-1 – SDG Agent
Step-1: Enable mDNS gateway and set the gateway mode. The default mode is sdg-agent.	`! mdns-sd gateway !`
Step-2: Activate unicast mDNS gateway on wired VLAN and wireless user VLAN on SDG agents.	`! vlan configuration 10, 20, 30  mdns-sd gateway !`
Step-3: Configure the service peer-group and attach service-policy on the SDG agent distribution switch and enable service-routing between the assigned Service Peer switch group.	`! mdns-sd service-peer group  peer-group 1   service-policy LOCAL-AREA-POLICY  service-peer 10.1.1.1 location-group  default  service-peer 10.1.1.2 location-group  default !`
Step-4: Associate outbound service-list to a unique service-policy.	`! mdns-sd service-policy WIDE-AREA-POLICY  service-list WIDE-AREA-SERVICES-OUT !`
Step-5: Enable Wide Area Bonjour service-routing with service export configuration association controller IP Address, source interface for stateful connection, and mandatory egress policy for Wide Area service-routing.	`! service-export mdns-sd controller DNAC-CONTROLLER-POLICY  controller-address 100.0.0.1  controller-source-interface LOOPBACK  0  controller-service-policy WIDE-AREA-POLICY !`

Configuration Example for Customized Service List and Policy in Wide Area Bonjour Between Multilayer Wired and Wireless Endpoints

Configuration example for customized service list and policy in wide area Bonjour between multilayer wired and wireless endpoints.

This section provides guidance on configuring Service-Peer, SDG Agent and Cisco Catalyst Center, allowing the wired and wireless endpoints to dynamically discover printer using Layer 2 unicast and policy.

Example: Wired and Wireless Access Layer Service Peer Configuration

Example for wired and wireless access layer service peer configuration.

The following table provides a sample configuration of wired and wireless controller access layer service peer.

Table 206: Configuring Wired and Wireless Access Layer Service Peer

Configuration Step	Sample Configuration: Switch Service Peer	Sample Configuration: Wireless Controller Service Peer
Step-1: Enable mDNS gateway and set the gateway mode. **Note** In wireless controller, service peer mode is enabled by default with mDNS gateway configuration.	``` ! mdns-sd gateway mode service-peer ! ```	``` ! mdns-sd gateway ! ```
Step-2: Create unique mDNS inbound policy to permit ingress AirPrint service announcement on the Catalyst Switch and wireless controller in service peer mode.	``` ! mdns-sd service-list LOCAL-AREA-SERVICES-IN in match printer-ipp ! ```	``` ! mdns-sd service-list LOCAL-AREA-SERVICES-IN in match printer-ipp ! ```
Step-3: Create unique mDNS outbound policy to permit egress AirPrint service response on the Catalyst Switch and wireless controller in service peer mode	``` ! mdns-sd service-list LOCAL-AREA-SERVICES-OUT out match printer-ipp ! ```	``` ! mdns-sd service-list LOCAL-AREA-SERVICES-OUT out match printer-ipp ! ```
Step-4: Associate inbound and outbound service list to a unique service policy.	``` ! mdns-sd service-policy LOCAL-AREA-POLICY service-list LOCAL-AREA-SERVICES-IN service-list LOCAL-AREA-SERVICES-OUT ! ```	``` mdns-sd service-policy LOCAL-AREA-POLICY service-list LOCAL-AREA-SERVICES-IN service-list LOCAL-AREA-SERVICES-OUT ! ```

Step-5: Activate unicast mDNS gateway and attach service policy on wired VLAN and WLAN.
• **Switch**: Activate mDNS gateway per VLAN.
• **Controller**: Activate mDNS gateway per WLAN policy profile and SSID
	``

Configuration Step	Sample Configuration: Switch Service Peer	Sample Configuration: Wireless Controller Service Peer
Step-6: (Optional) Enable service routing on wired service peer mDNS between local VLANs. Also, enable location-based wireless service on the controller. • **Switch**: Configure location filter group to discover and distribute between paired local VLAN. • **Controller**: Configure wireless location-based services.	```! mdns-sd location-filter LOCAL-PROXY match location-group default vlan 10 match location-group default vlan 20 ! mdns-sd service-list LOCAL-AREA-SERVICES-OUT OUT match printer-ipps location-filter LOCAL-PROXY !```	```! mdns-sd service-policy LOCAL-AREA-POLICY location ap-location !```
Step-7: Enable unicast service routing between wired and wireless service peer and SDG agent. • **Switch**: Configure SDG agent IP and wired management source VLAN ID and IP address. • **Controller**: Configure SDG Agent IP and wireless management source VLAN ID and IP address.	```vlan configuration 10, 20 mdns-sd gateways source-interface vlan 4094 sdg-agent 10.1.1.254 !```	```! mdns-sd gateway source-interface vlan 4094 sdg-agent 10.2.1.254 !```

Example: Wired and Wireless Distribution Layer SDG Agent Configuration

Example for wired and wireless distribution layer SDG agent configuration.

The following table provides a sample configuration of distribution layer SDG agent.

Table 207: Configuring Distribution Layer SDG Agent

Configuration Step	Sample Configuration: Wired SDG Agent	Sample Configuration: Wireless SDG Agent
Step-1: Enable mDNS gateway and set the gateway mode.	```! mdns-sd gateway !```	```! mdns-sd gateway !```
Step-2: Activate unicast mDNS gateway on wired VLAN and wireless user VLAN on respective SDG agents.	```! vlan configuration 10, 20 mdns-sd gateway !```	```! vlan configuration 30 mdns-sd gateway !```
Step-3: Create unique controller bound mDNS policy to permit egress AirPrint service discovery and distribution from Catalyst Switch in SDG agent mode. Inbound policy towards controller is not required.	```! mdns-sd service-list WIDE-AREA-SERVICES-OUT out match printer-ipp !```	```! mdns-sd service-list WIDE-AREA-SERVICES-OUT out match printer-ipp !```
Step-4: Associate outbound service-list to a unique service-policy.	```! mdns-sd service-policy WIDE-AREA-POLICY service-list WIDE-AREA-SERVICES-OUT !```	```! mdns-sd service-policy WIDE-AREA-POLICY service-list WIDE-AREA-SERVICES-OUT !```
Step-5: Enable Wide Area Bonjour service-routing with service export configuration association controller IP Address, source interface for stateful connection and mandatory egress policy for Wide Area service-routing.	```! service-export mdns-sd controller DNAC-CONTROLLER-POLICY controller-address 100.0.0.1 controller-source-interface LOOPBACK 0 controller-service-policy WIDE-AREA-POLICY !```	```! service-export mdns-sd controller DNAC-CONTROLLER-POLICY controller-address 100.0.0.1 controller-source-interface LOOPBACK 0 controller-service-policy WIDE-AREA-POLICY !```

Cisco Catalyst Center Traditional Multilayer Wired and Wireless Configuration

Cisco DNA center traditional multilayer wired and wireless configuration.

Configuring Service Filters for Traditional Multilayer Wired and Wireless - Local Mode (GUI)

Configure service filters for traditional multilayer wired and wireless in local mode using GUI.

This procedure implements global service filters, which permit the Cisco Wide Area Bonjour application to dynamically discover and distribute service information between trusted Cisco Catalyst SDG agent switches across the IP network.

Procedure

1. Navigate to the **Configuration** tab in the Wide Area Bonjour application.
2. From the sidebar, select the subdomain for which you want to create the service filter.
3. Check the **Service Filter** box.
4. Click **Service Filter** icon from the topology to view a list of the service filters for the selected domain. You can also manually edit existing service filters from this list.
5. Click **Create Service Filter**.
6. From the **Network Mode** drop-down list, choose **Traditional** (the default mode).
7. Enter a unique name for the service filter.
8. (Optional) Enter a description for the service filter.
9. Select one or more service types to permit announcements and queries.
10. Enable or disable service filters after creating them. By default, service filters are enabled.

Configuring Source SDG Agents in Traditional Multilayer Wired and Wireless - Local Mode (GUI)

Configure source SDG agents in traditional multilayer wired and wireless - local mode using GUI.

This procedure configures discovery of wired printer sources from the LAN distribution switches paired with Layer 2 Catalyst Switches in a service peer role. The wireless distribution switches paired with a controller in a service peer role receive query responses for wired printers and distribute the responses to querying devices over the wireless local mode network.

Procedure

1. Click **Add** in the upper-right portion of the Catalyst Center Policy screen.
2. Select the **Query SDG agent** radio button. By default, the **Source** radio button is selected.
3. From the **SDG Agent/IP** drop-down list, select an SDG agent (100.0.0.101) which announces the services, for example, Printer.
4. Select **Peer** from the **Service Layer** drop-down list.
5. Uncheck the box **Any**. By default, this is enabled.
6. Select the query **VLAN** (Vlan-10) to distribute services (Printer) from a specific network.
7. Enable or disable services from the selected query IPv4 subnet. By default, this is enabled.
8. Enable or disable services from the selected query IPv6 subnet. By default, this is enabled.
9. Enter the **service peer IPv4 address** (10.1.1.1).
10. Click the **+** icon to add more service peers, if any. Select **Any** to accept services from any peer on a selected VLAN.
11. (Optional) Click **Add Next** to add more source SDG agents. (Repeat the preceding steps.)
12. Click **DONE**.
13. Click **CREATE**.

Configuring Query SDG Agents in Traditional Multilayer Wired and Wireless - Local Mode (GUI)

Configure query SDG agents in traditional multilayer wired and wireless - local mode using GUI.

This procedure configures distributed services to query SDG agents connected to a controller in service peer mode, based on a policy.

Procedure

1. Click **Add** in the upper-right portion of the DNA-Center Policy screen.
2. Select the **Query SDG agent** radio button. By default, the **Source** radio button is selected.
3. From the **SDG Agent/IP** drop-down list, select an SDG agent (100.0.0.102) that receives queries for the services (Printer).
4. Select **Peer** from the **Service Layer** drop-down list.
5. Uncheck the box **Any**. By default, this is enabled.
6. Select the query **VLAN** (Vlan-30) to distribute services (Printer) to a specific network.
7. Enable or disable services from the selected query IPv4 subnet. By default, this is enabled.
8. Enable or disable services from the selected query IPv6 subnet. By default, this is enabled.
9. Enter the **service peer IPv4 address** (10.2.1.254).
10. Click the **+** icon to add more service-peers, if any. Select **Any** to accept services from any peer on a selected VLAN.
11. (Optional) Click **Add Next** to add more query agents. (Repeat the preceding steps.)
12. Click **DONE**.
13. Click **CREATE**.

Verifying Wide Area Bonjour Between Multilayer Wired and Wireless Local Mode

Verify wide area Bonjour between multilayer wired and wireless local mode.

This section provides step-by-step mDNS configuration and service discovery and distribution status based on applied policy on Wired Layer 2 access switch in service peer and SDG agent mode.

Verifying Wired Service-Peer Configuration

Verify wired service-peer configuration.

Use the following commands on the Cisco Catalyst switch in service peer (SP-1) mode to determine the operational status after applying configuration and discovering the AirPrint service from the local network.

```
Device# show mdns-sd summary vlan 10

VLAN: 10
========================================

Verifying Cisco Catalyst Center Configuration and Service-Routing Status

Verify Cisco DNA-Center configuration and service-routing status.

The Cisco Wide Area Bonjour application supports comprehensive assurance capabilities to manage service-routing with network-wide distributed Cisco Catalyst switches in SDG-Agent role and mDNS services discovered over Wide Area Bonjour domain. The assurance capabilities in Cisco Wide Area Bonjour provides ability to determine service-routing state, mDNS service state and many more information at various levels for day-2 operations, analysis and troubleshooting. Each category serves unique function to manage and troubleshoot Wide Area Bonjour service-routing for day-2 operation.

This sub-section provides brief overview for each category of monitor function:

- **Dashboard**: The landing page of Cisco Wide Area Bonjour application provides key statistics in various formats to quickly determine service-routing health across the network. The network administrator can monitor operational status of service-routing with SDG Agent devices, historical chart of service discovery request, processing and drops from network-wide distributed devices and top five talkers across the network.
- **Sub-Domain 360°** : The network administrator can briefly collect statistics and status counts in 360° view. The left-panel monitoring, and configuration bar is automatically open upon clicking selected sub-domain to verify configured policies, discovered service-instances on per sub domain basis of the configuration section.
- **Monitor**: A comprehensive 3-tier monitoring and troubleshooting function of Cisco Wide Area Bonjour application for various day-2 operations. The detail view of SDG Agent, Service-Instance and advanced Troubleshooting capabilities allows network administrator to manage and troubleshoot Wide Area Bonjour domain with single of glass on Cisco Catalyst Center.

For more information, see Cisco Wide Area Bonjour on Cisco Catalyst Center User Guide, Release 2.3.3 guide. The assurance capabilities and operation details are explained in Monitor the Cisco Wide Area Bonjour Application chapter to manage Cisco Wide Area Bonjour application with various supporting service-routing assurance function.

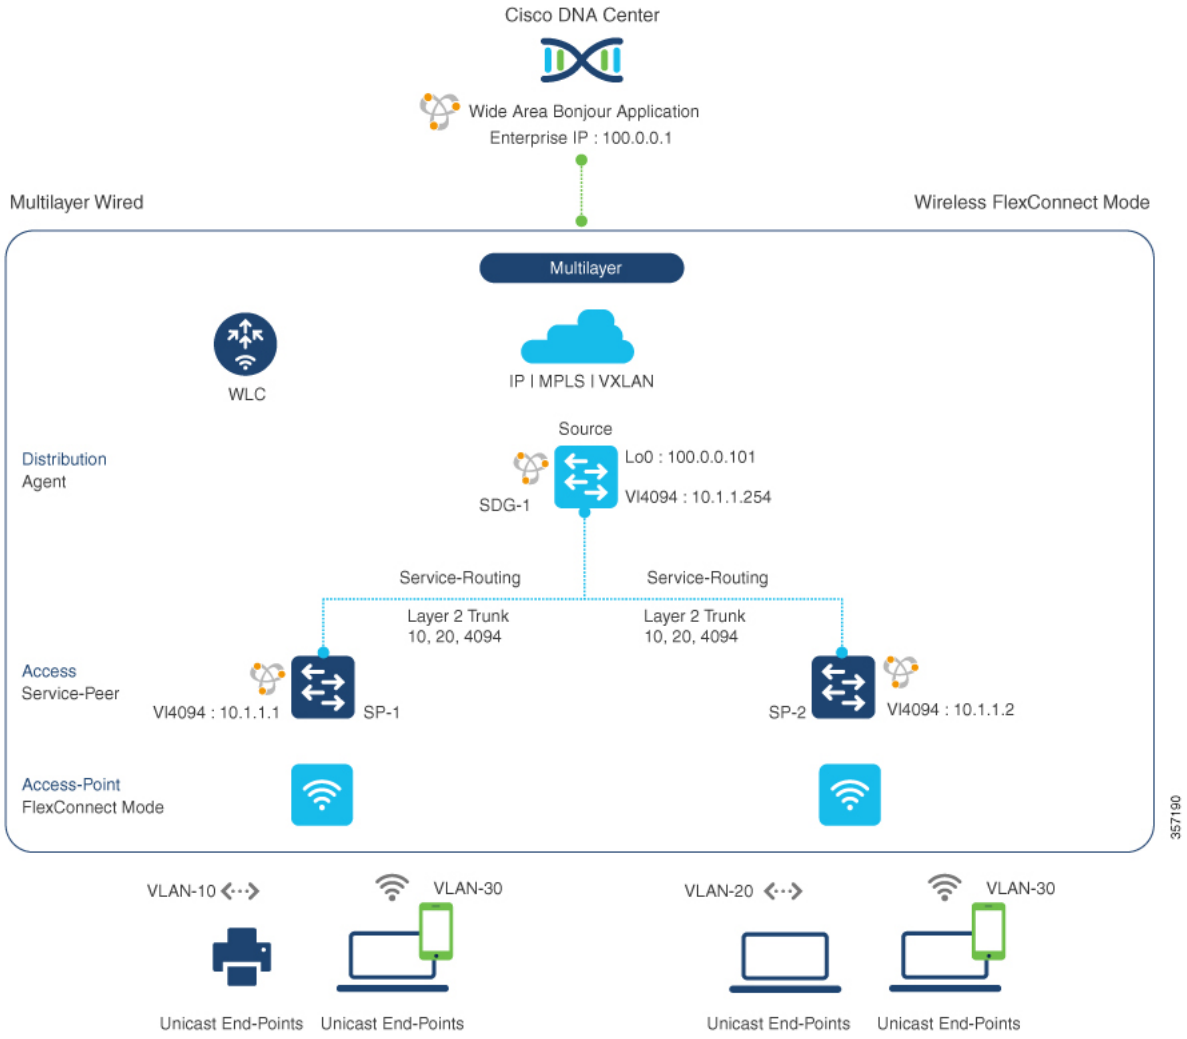
234 Configuration Example for FlexConnect Mode - Wireless and Wired

Topics:

- Overview



Overview

Introduces FlexConnect mode fundamentals for wireless and wired scenarios, presenting default and customized service list and policy configurations, detailed examples for access and distribution layers, traditional multilayer integration steps, verification commands, and supporting references to streamline deployment and management.

This chapter provides configuration guidelines to implement Local Area Bonjour enabling end-to-end policy-based mDNS service discovery and distribution across multilayer wired and wireless FlexConnect local-switching mode. The first hop mDNS gateway at Layer 2 access switch must be implemented in service peer mode and paired with common distribution-layer switch in SDG agent role IP gateway function to wired and wireless clients. The network-wide distributed SDG agent can be paired alternatively with the Cisco Catalyst Center to enable mDNS service-routing across IP core network providing mDNS service assurance, monitoring and troubleshooting.

The following figure illustrates unicast mode bonjour network environment with AirPrint capable printer and wireless user computer (macOS, Microsoft Windows, and so on.) connected to the same Ethernet switch. The network administrator implements the policy permitting additional endpoints associated to nearby location Ethernet switch to discover and use remote AirPrint capable Printer without flooding mDNS over wired and wireless networks.

Figure 68: Local Area Bonjour Service-Routing Multilayer Wired and Wireless FlexConnect Local-Switching Mode

Configuration Example for Default Service List and Policy in FlexConnect Mode - Wireless and Wired

Configuration example for default service list and policy in FlexConnect mode - wireless and wired.

This section provides guidance on configuring Service-Peer, SDG Agent, and Cisco Catalyst Center, allowing the wired and wireless endpoints to dynamically discover the default service list using Layer 2 unicast and policy.

Example: Wired and Wireless Access Layer Service Peer Configuration

Example for wired and wireless access layer service peer configuration.

The following table provides a sample configuration of wired and wireless controller access layer service peer.

Table 209: Configuring Wired and Wireless Access Layer Service Peer

Configuration Step	Sample Configuration: SP-1 Service-Peer Configuration	Sample Configuration: SP-2 Service-Peer Configuration
Step-1: Enable mDNS gateway and set the gateway mode.	```! mdns-sd gateway mode service-peer !```	```! mdns-sd gateway mode service-peer !```
Step-2: Create unique mDNS inbound policy to permit ingress AirPrint service announcement and query on the Catalyst Switch in service peer mode.	```! mdns-sd service-list LOCAL-AREA-SERVICES-IN in match printer-ipp !```	```! mdns-sd service-list LOCAL-AREA-SERVICES-IN in match printer-ipp !```
Step-3: Create unique mDNS outbound policy to permit egress AirPrint service response on the Catalyst Switch in service peer mode	```! mdns-sd service-list LOCAL-AREA-SERVICES-OUT out match printer-ipp !```	```! mdns-sd service-list LOCAL-AREA-SERVICES-OUT out match printer-ipp !```
Step-4: Associate inbound and outbound service list to a unique service policy.	```! mdns-sd service-policy LOCAL-AREA-POLICY service-list LOCAL-AREA-SERVICES-IN service-list LOCAL-AREA-SERVICES-OUT !```	```mdns-sd service-policy LOCAL-AREA-POLICY service-list LOCAL-AREA-SERVICES-IN service-list LOCAL-AREA-SERVICES-OUT !```
Step-5: Activate unicast mDNS gateway and attach service policy on wired VLAN and wireless FlexConnect user VLAN of SP-1 and SP-2 Layer 2 access switch.	```! vlan configuration 10, 30 mdns-sd gateway service-policy LOCAL-AREA-POLICY active-query timer 3600 !```	```! vlan configuration 20, 30 mdns-sd gateway service-policy LOCAL-AREA-POLICY active-query timer 3600 !```

Configuration Step	Sample Configuration: SP-1 Service-Peer Configuration	Sample Configuration: SP-2 Service-Peer Configuration
Step-6: Enable service routing on wired service peer mDNS between mDNS source and receiver local VLANs. **Note** This step is optional for SP-2 switch as it does not have local mDNS service provider endpoints or VLANs.	``` ! mdns-sd location-filter LOCAL-PROXY match location-group default vlan 10 match location-group default vlan 30 ! mdns-sd service-list LOCAL-AREA-SERVICES-OUT OUT match printer-ipps location-filter LOCAL-PROXY ! ```	

Step-7: Enable unicast service routing between wired and wireless service peer and SDG agent using wired management source VLAN ID and IP address.	```
	vlan configuration 10,

Example: Wired and Wireless Distribution Layer SDG Agent Configuration

Example for wired and wireless distribution layer SDG agent configuration.

The following table provides a sample configuration of distribution layer SDG agent.

Table 210: Configuring Wired and Wireless Distribution Layer SDG Agent

Configuration Step	Sample Configuration: SDG-1 – SDG Agent
Step-1: Enable mDNS gateway and set the gateway mode. The default mode is sdg-agent.	`! mdns-sd gateway !`
Step-2: Create a unique mDNS inbound policy to permit ingress AirPrint service announcement and query the Catalyst Switch in Service-Peer mode.	`! mdns-sd service-list LOCAL-AREA-SERVICES-IN in  match printer-ipp !`
Step-3: Create a unique mDNS outbound policy to permit egress AirPrint service response on Catalyst Switch in Service-Peer mode.	`! mdns-sd service-list LOCAL-AREA-SERVICES-OUT out  match printer-ipp !`
Step-4: Associate the inbound and outbound service-list to a unique service-policy.	`! mdns-sd service-policy LOCAL-AREA-POLICY  service-list LOCAL-AREA-SERVICES-IN  service-list LOCAL-AREA-SERVICES-OUT !`
Step-5: Activate unicast mDNS gateway on wired VLAN and wireless user VLAN on SDG agents.	`! vlan configuration 10, 20, 30  mdns-sd gateway !`
Step-6: Configure the service peer-group and attach service-policy on the SDG agent distribution switch and enable service-routing between the assigned Service Peer switch group.	`! mdns-sd service-peer group  peer-group 1   service-policy LOCAL-AREA-POLICY   service-peer 10.1.1.1 location-group  default   service-peer 10.1.1.2 location-group  default !`
Step-7: Create a unique controller bound mDNS policy to permit egress AirPrint service discovery and distribution from Catalyst Switch in SDG agent mode. Inbound policy towards controller is not required.	`! mdns-sd service-list WIDE-AREA-SERVICES-OUT out  match printer-ipp !`

Configuration Step	Sample Configuration: SDG-1 – SDG Agent
Step-8: Associate outbound service-list to a unique service-policy.	``` ! mdns-sd service-policy WIDE-AREA-POLICY service-list WIDE-AREA-SERVICES-OUT ! ```
Step-9: Enable Wide Area Bonjour service-routing with service export configuration association controller IP Address, source interface for stateful connection, and mandatory egress policy for Wide Area service-routing.	``` ! service-export mdns-sd controller DNAC-CONTROLLER-POLICY controller-address 100.0.0.1 controller-source-interface LOOPBACK 0 controller-service-policy WIDE-AREA-POLICY ! ```

Configuration Example for Customized Service List and Policy in FlexConnect Mode - Wireless and Wired

Configuration example for customized service list and policy in FlexConnect mode - wireless and wired.

This section provides guidance on configuring Service-Peer, SDG Agent, and Cisco Catalyst Center, allowing the wired and wireless endpoints to dynamically discover printer using Layer 2 unicast and policy.

Example: Wired and Wireless Access Layer Service Peer Configuration

Example for wired and wireless access layer service peer configuration.

The following table provides a sample configuration of wired and wireless controller access layer service peer.

Table 211: Configuring Wired and Wireless Access Layer Service Peer

Configuration Step	Sample Configuration: SP-1 Service-Peer Configuration	Sample Configuration: SP-2 Service-Peer Configuration
Step-1: Enable mDNS gateway and set the gateway mode.	! mdns-sd gateway mode service-peer !	! mdns-sd gateway mode service-peer !
Step-2: Create unique mDNS inbound policy to permit ingress AirPrint service announcement and query on the Catalyst Switch in service peer mode.	! mdns-sd service-list LOCAL-AREA-SERVICES-IN in match printer-ipp !	! mdns-sd service-list LOCAL-AREA-SERVICES-IN in match printer-ipp !
Step-3: Create unique mDNS outbound policy to permit egress AirPrint service response on the Catalyst Switch in service peer mode	! mdns-sd service-list LOCAL-AREA-SERVICES-OUT out match printer-ipp !	! mdns-sd service-list LOCAL-AREA-SERVICES-OUT out match printer-ipp !
Step-4: Associate inbound and outbound service list to a unique service policy.	! mdns-sd service-policy LOCAL-AREA-POLICY service-list LOCAL-AREA-SERVICES-IN service-list LOCAL-AREA-SERVICES-OUT !	mdns-sd service-policy LOCAL-AREA-POLICY service-list LOCAL-AREA-SERVICES-IN service-list LOCAL-AREA-SERVICES-OUT !
Step-5: Activate unicast mDNS gateway and attach service policy on wired VLAN and wireless FlexConnect user VLAN of SP-1 and SP-2 Layer 2 access switch.	! vlan configuration 10, 30 mdns-sd gateway service-policy LOCAL-AREA-POLICY active-query timer 3600 !	! vlan configuration 20, 30 mdns-sd gateway service-policy LOCAL-AREA-POLICY active-query timer 3600 !

Configuration Step	Sample Configuration: SP-1 Service-Peer Configuration	Sample Configuration: SP-2 Service-Peer Configuration
Step-6: Enable service routing on wired service peer mDNS between mDNS source and receiver local VLANs. **Note** This step is optional for SP-2 switch as it does not have local mDNS service provider endpoints or VLANs.	``` ! mdns-sd location-filter LOCAL-PROXY match location-group default vlan 10 match location-group default vlan 30 ! mdns-sd service-list LOCAL-AREA-SERVICES-OUT OUT match printer-ipps location-filter LOCAL-PROXY ! ```

Step-9: Enable Wide Area Bonjour service-routing with service export configuration association controller IP Address, source interface for stateful connection, and mandatory egress policy for Wide Area service-routing.	```! service-export mdns-sd controller DNAC-CONTROLLER-POLICY controller-address 100.0.0.1 controller-source-interface LOOPBACK 0 controller-service-policy WIDE-AREA-POLICY !```

Cisco Catalyst Center Traditional Multilayer Wired and Wireless Configuration

Cisco DNA Center traditional multilayer wired and wireless configuration.

Configuring Service Filters for Traditional Multilayer Wired and Wireless FlexConnect Local- Switching Mode (GUI)

Configure service filters for traditional multilayer wired and wireless FlexConnect local- switching mode using GUI.

This procedure implements global service filters, which permit the Cisco Wide Area Bonjour application to dynamically discover and distribute service information between trusted Cisco Catalyst SDG agent switches across the IP network.

Procedure

1. Navigate to the **Configuration** tab in the Wide Area Bonjour application.
2. From the sidebar, select the sub-domain for which you want to create the service filter.
3. Check the **Service Filter** box.
4. Click **Service Filter** icon from the topology to view a list of the service filters for the selected domain. You can also manually edit existing service filters from this list.
5. Click **Create Service Filter**.
6. From the **Network Mode** drop-down list, choose **Traditional** (the default mode).
7. Enter a unique name for the service filter.
8. (Optional) Enter a description for the service filter.
9. Select one or more service types to permit announcements and queries.
10. Enable or disable service filters after creating them. By default, service filters are enabled.

Configuring Source SDG Agents in Traditional Multilayer Wired and Wireless FlexConnect Local- Switching Mode (GUI)

Configure source SDG agents in traditional multilayer wired and wireless FlexConnect local- switching mode using GUI.

This procedure configures discovery of wired printer sources from the LAN distribution switches paired with Layer 2 Catalyst Switches in a service peer role. The wireless distribution switches paired with a controller in a service peer role receive query responses for wired printers and distribute the responses to querying devices over the wireless FlexConnect local switching mode network.

Procedure

1. Click **Add** on the upper-right of Cisco Catalyst Center.
2. Click the **Source** radio button to select a source SDG agent. By default, this radio button is selected.
3. From the **SDG Agent/IP** drop-down list, select an SDG agent (100.0.0.101) which announces the services, for example, Printer.
4. Select **Peer** from the **Service Layer** drop-down list.
5. Uncheck the box **Any**. By default, this is unchecked.
6. Select the query **VLAN** (Vlan-10) to distribute services (Printer) from a specific network.
7. Enable or disable services from the selected query IPv4 subnet. By default, this is enabled.
8. Enable or disable services from the selected query IPv6 subnet. By default, this is enabled.
9. Enter the **service peer IPv4 address** (10.1.1.1).

> **Note**
>
> Select **Any** to accept services from any peer on a selected VLAN.

10. (Optional) Click **Add Next** to add more source SDG agents. (Repeat the preceding steps.)
11. Click **DONE**.
12. Click **CREATE**.

Configuring Query SDG Agents in Traditional Multilayer Wired and Wireless FlexConnect Local- Switching Mode (GUI)

Configure query SDG agents in traditional multilayer wired and wireless FlexConnect local- switching mode using GUI.

This procedure configures distributed services to query SDG agents connected to a controller in service peer mode, based on a policy.

f you are using wide area network, see the *Cisco Wide Area Bonjour on Cisco Catalyst Center User Guide* at https://www.cisco.com/c/en/us/support/cloud-systems-management/dna-center/products-user-guide-list.html.

Procedure

1. Click **Add** on the upper-right of Cisco Catalyst Center.
2. Select the **Query SDG agent** radio button. By default, the **Source** radio button is selected.
3. From the **SDG Agent/IP** drop-down list, select an SDG agent (100.0.0.102) that receives queries for the services (Printer).
4. Select **Peer** from the **Service Layer** drop-down list.
5. Uncheck the box **Any**. By default, this is enabled.
6. Select the query **VLAN** (Vlan-30) to distribute services (Printer) to a specific network.
7. Enable or disable services from the selected query IPv4 subnet. By default, this is enabled.
8. Enable or disable services from the selected query IPv6 subnet. By default, this is enabled.
9. Enter the **service peer IPv4 address** (10.2.1.254).
10. Click the **+** icon to add more service-peers, if any. Select **Any** to accept services from any peer on a selected VLAN.
11. (Optional) Click **Add Next** to add more query agents. (Repeat the preceding steps.)
12. Click **DONE**.

13. Click **CREATE**.

Verifying Configuration Example for FlexConnect Mode - Wireless and Wired

Verify configuration example for FlexConnect mode - wireless and wired.

This section provides step-by-step mDNS configuration and service discovery and distribution status based on applied policy on Wired Layer 2 access switch in service peer and SDG agent mode.

Verifying Wired Service-Peer Configuration

Verify wired service-peer configuration.

Use the following commands on the Cisco Catalyst switch in service peer (SP-1 and SP-2) mode to determine the operational status after applying configuration and discovering the AirPrint service from the local network.

```
Device# show mdns-sd summary vlan 10

VLAN: 10
========================================
mDNS Gateway: Enabled
mDNS Service Policy: LOCAL-AREA-POLICY
Active Query: Enabled
            : Periodicity 3600 Seconds
Transport Type: IPv4
Service Instance Suffix: Not Configured
mDNS Query Type: ALL
SDG Agent IP: 10.1.1.254
Source Interface: Vlan4094

Device# show mdns-sd service-policy name LOCAL-AREA-POLICY

Verifying Cisco Catalyst Center Configuration and Service Routing Status

Verify Cisco DNA Center configuration and service routing status.

The Cisco Wide Area Bonjour application supports comprehensive assurance capabilities to manage service routing with network-wide distributed Cisco Catalyst switches in SDG Agent role and mDNS services discovered over Wide Area Bonjour domain. The assurance capabilities in Cisco Wide Area Bonjour provides the ability to determine service routing state, mDNS service state, and many more information at various levels for day-2 operations, analysis and troubleshooting. Each category serves unique function to manage and troubleshoot Wide Area Bonjour service routing for day-2 operation.

This sub-section provides brief overview for each category of monitor function:

- **Dashboard**: The landing page of Cisco Wide Area Bonjour application provides key statistics in various formats to quickly determine service routing health across the network. The network administrator can monitor operational status of service routing with SDG Agent devices, historical chart of service discovery request, processing and drops from network-wide distributed devices and top five talkers across the network.
- **Sub-Domain 360°** : The network administrator can briefly collect statistics and status counts in 360° view. The left-panel monitoring, and configuration bar is automatically open upon clicking selected sub-domain to verify configured policies, discovered service-instances on per sub-domain basis of the configuration section.
- **Monitor**: A comprehensive 3-tier monitoring and troubleshooting function of Cisco Wide Area Bonjour application for various day-2 operations. The detail view of SDG Agent, Service-Instance, and advanced Troubleshooting capabilities allows network administrator to manage and troubleshoot Wide Area Bonjour domain with a single pane of glass on Cisco Catalyst Center.

For more information, see Cisco Wide Area Bonjour on Cisco Catalyst Center User Guide, Release 2.1.2 guide. The assurance capabilities and operation details are explained in **Monitor the Cisco Wide Area Bonjour Application** chapter to manage Cisco Wide Area Bonjour application with various supporting service routing assurance function.

Part XXIII

Multicast Domain Name System

Topics:

- Multicast Domain Name System

235 Multicast Domain Name System

Topics:

- mDNS Gateway
- Location based service filtering
- Nearest mDNS based wired service filtering

This chapter explains how to configure and manage mDNS gateway and AP features on Cisco controllers to enable cross-subnet Bonjour service discovery, apply location- and policy-based filtering, and verify/debug wired and wireless mDNS behavior.

mDNS Gateway

Explains how mDNS gateways enable service discovery across different network segments by bridging multicast DNS traffic, facilitating interoperability in large or segmented networks.

A mDNS gateway is an Apple service discovery protocol that

- listens for multicast DNS (mDNS) service announcements and queries from local domains with the use of mDNS service records
- caches and forwards mDNS advertisements between segmented Layer 2 networks or subnets, and
- enables devices and services to be discovered even when clients and sources reside in different network segments.

The Bonjour protocol operates using service announcements and queries. Each query or advertisement is sent to the Bonjour multicast address IPv4 224.0.0.251 or IPv6 FF02::FB. The protocol uses mDNS on UDP port 5353.

The address used by the Bonjour protocol is a link-local multicast address and is therefore only forwarded to the local Layer 2 network. Because multicast DNS is limited to a Layer 2 domain, a client must be part of the same Layer 2 domain to discover a service. However, this requirement is not always practical in large-scale deployments or enterprises.

To address this issue, the Cisco Catalyst 9800 Series Wireless Controller acts as a Bonjour Gateway. The controller then listens for Bonjour services and caches these Bonjour advertisements (AirPlay, AirPrint, and so on) from the source or host. For example, Apple TV responds to Bonjour clients when requested for a service. This allows sources and clients to exist in different subnets.

By default, the mDNS gateway is disabled on the controller. To enable mDNS gateway functionality, you must explicitly configure the mDNS gateway using the CLI or Web UI.

The source IP address of all outgoing mDNS packets uses the mDNS source interface VLAN SVI IP address. By default, wireless management interface will be the source interface.

Guidelines and restrictions for configuring mDNS AP

This topic describes how configuring mDNS APs involves understanding both operational guidelines and inherent restrictions to ensure scalability, reliability, and optimal network performance.

Guidelines for configuring mDNS AP

- Cisco recommends deploying scalable Wide Area Bonjour to route mDNS service between wired and wireless networks. Cisco Catalyst 9800 Series Wireless LAN Controller introduces a new mDNS gateway, called Service-Peer mode, which replaces the classic mDNS flood-n-learn and supports enterprise-grade, scalable, stateful, and reliable complete unicast-based mDNS service-routing with upstream gateway Cisco Catalyst 9000 Series Switches. For more information, see Part: Cisco DNA Service for Bonjour .
- The mDNS AP (classic flood-and-learn based feature) is enhanced with complete unicast-based service-routing using Cisco Wide Area Bonjour. This enhancement supports flood-free wired and wireless networks and helps overcome several operational, scalability, and service resiliency challenges. The mDNS AP extends the mDNS flood from Wired VLANs to the AP. It further extends this traffic over the CAPWAP tunnel to the controller for central processing across the core network. Cisco recommends using the mDNS AP only for small network environments.
- The wired mDNS service-provider VLANs must be extended to flood mDNS traffic up to the mDNS AP Ethernet port in trunk mode. The wired VLAN extension to the mDNS AP may include other wired flood traffic, such as broadcast, unknown unicast, and Layer 2 multicast. This additional traffic can affect the mDNS AP's scale and performance.
- It is recommended to deploy at least one mDNS AP for each Layer 3 Access switch. All wired mDNS traffic is flooded using alternate L2 methods if a single mDNS AP is shared between multiple Layer 3 Access switches.
- The old wired mDNS service entry continues to be advertised to all wireless users for up to 4500 seconds, based on the mDNS cache timers on the controller. Stale entries require manual clearing from the local cache in the controller.

-
- Wireless multicast link-local is enabled by default. When wireless link-local is enabled, only mDNS Bridging mode is supported. If you require mDNS Gateway for wired services, disable wireless link-local.
- The controller sends mDNS queries with the "QU" (Query Unicast) flag at regular intervals. This flag instructs mDNS service providers (mDNS-SP) to respond with an mDNS advertisement via unicast reply. Beginning with the Cisco Catalyst IOS XE 17.9.x release, these queries are generated from the WMI interface. This change eliminates the need for interface VLANs where Service Providers are connected.
- If your Service Provider honors the "QU" flag and sends a unicast reply to the controller, you may see the mDNS-AP entries on your controller change to wired entries. You see this change because the controller receives the advertisement from the wired infrastructure. If the Service Provider does not honor the "QU" flag, you will not encounter this issue, such as on Apple devices.

> **Note**
>
> RFC 6762 compliance: RFC 6762 states that the service provider may choose not to respond to queries from the WMI, because these queries are outside the service provider's link-local scope. The controller is unable to learn about such service providers due to this limitation.

Restrictions for configuring mDNS AP

- The mDNS AP is supported only in Local and Monitor modes. If the Cisco Wireless AP operates in FlexConnect mode, the Fabric mode AP does not support the mDNS AP feature. For information about enabling mDNS service routing for various distributed wireless modes, refer to Part: Cisco DNA Service for Bonjour. If you use a FlexConnect AP as an mDNS gateway, do not use a period (.) in the service provider name, as this is not supported.
- Wireless users connected to mDNS AP may not be able to browse the Wired mDNS services across flooded Wired VLAN to mDNS AP.
- The mDNS AP scale limit for each Cisco Catalyst 9800 Series Wireless LAN Controller is restricted. The maximum mDNS Wired VLAN count for each controller is limited. The mDNS AP does not support mDNS query packet suppression or rate-limiter in AP. The wired mDNS flood from all wired VLANs is forwarded to the controller for central policy enforcement.
- The maximum number of flooded packets processed per second from wired VLANs to the mDNS AP is limited. The performance and reliability of the mDNS AP may decrease in large network environments. A maximum of 10 Wired VLANs' mDNS flood can be extended to mDNS AP. A combination of large wired VLAN scale and mDNS AP scale may impact performance in both the AP and controller.
- Only one mDNS AP is supported for each wired VLAN. Configuring multiple mDNS APs to map the same wired VLAN ID causes service instability and duplicate processing. Only one wired mDNS service policy is supported for all network-wide mDNS APs.
- High availability is not supported for multiple mDNS APs. mDNS services across wired and wireless networks are disrupted when connectivity to an mDNS AP is lost due to any type of failure.
- These limitations apply when an mDNS AP introduces LSS-based mDNS service filtering between flooded wired VLANs and wireless networks:
  - A single mDNS AP with LSS enabled can distribute wired mDNS services only to nearby APs in its neighbor list. Wireless users connected to APs not in the neighbor list may not be able to discover any wired mDNS services.
  - Only one mDNS AP can be deployed in each Wired VLAN. Wired VLANs must be reconfigured across the LAN to enable unique LSS-based mDNS APs in specific locations. For example, to achieve mDNS service discovery on each floor, each floor must have a dedicated wired VLAN or subnet, with one mDNS AP per floor to discover all other APs as neighbors on the same floor.

- The mDNS AP does not support IPv6 for wired mDNS service providers or service receivers. Only IPv4 is supported. The mDNS AP does not support role-based mDNS service filtering between wired and wireless networks. The mDNS AP does not detect or automatically resolve duplicate mDNS service instance names across wired VLANs. The Cisco Catalyst 9800 Series Wireless LAN Controller discovers and records the first service instance with a unique name in its local cache database. If a duplicate service instance name is discovered, the controller rejects the duplicate name and does not distribute it to wireless clients.
- In mDNS gateway mode, the controller does not support service discovery from mDNS messages that use multiple IP fragments.

Enable mDNS Gateway (GUI)

Learn how to enable the mDNS gateway using the GUI interface.

Enable or disable the mDNS gateway for service discovery using the GUI.

Procedure

1. Choose **Configuration** > **Services** > **mDNS**.
2. In the **Global** section, toggle the slider to enable or disable the **mDNS Gateway**.
3. From the **Transport** drop-down list, select one of these types:
   - **ipv4**
   - **ipv6**
   - **both**
4. Enter an appropriate timer value in **Active-Query Timer**. The valid range is between 1 to 120 minutes. The default is 30 minutes.
5. From the **mDNS-AP Service Policy** drop-down list, select an mDNS service policy.

   Note

   Service policy is optional only if mDNS-AP is configured. If mDNS-AP is not configured, the system uses default-service-policy.

6. Click **Apply**.

Enable or disable mDNS Gateway (GUI)

Follow these steps to enable or disable the mDNS Gateway using the GUI.

Use this procedure to configure or change mDNS service discovery for your device using the GUI.

Procedure

1. Choose **Configuration** > **Services** > **mDNS** > **Global**.
2. Enable or disable the **mDNS Gateway** toggle button.
3. Select **ipv4** or **ipv6** or **both** from the **Transport** drop-down list.

4. Enter the **Active-Query Timer**.
5. Click **Apply**.

Enable or disable mDNS Gateway (CLI)

Configure the mDNS gateway feature using commands to enable or disable service discovery on your controller

Enable or disable mDNS gateway to control multicast DNS service discovery for wireless devices using commands.

Note

- mDNS gateway is disabled by default globally on the controller.
- You need both global and WLAN configurations to enable mDNS gateway.

Procedure

1. Enable the privileged exec mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Enable mDNS gateway.

   Example

   ```
   Device(config)# mdns-sd gateway
   ```

4. Filter the mDNS gateway based on location.

   Example

   ```
   Device(config-mdns-sd)# location {ap-location | ap-name | location-group |
   lss | regex | site-tag | ssid}
   ```

   Here,

   - **ap-location** signifies location-based filtering using AP location.
   - **ap-name** signifies location-based filtering using AP name.
   - **location-group** signifies location-based filtering using location group.

- **lss** signifies location-based filtering using Location Specific Services (LSS).
- **regex** signifies location-based filtering using Regular Expression.
- **site-tag** signifies location-based filtering using site tag.
- **ssid** signifies location-based filtering using SSID.

> **Note**
>
> The **lss** is the default location filter, if mDNS gateway is configured globally.

5. Process mDNS message on a specific transport.

   Example

   ```
   Device(config-mdns-sd)# transport {ipv4 | ipv6 | both}
   ```

   Here,

   ipv4 signifies that the IPv4 mDNS message processing is enabled. This is the default value.

   ipv6 signifies that the IPv6 mDNS message processing is enabled.

   both signifies that the IPv4 and IPv6 mDNS message is enabled for each network.

6. Change the periodicity of mDNS multicast active query.

   Example

   ```
   Device(config-mdns-sd)# active-query timer active-query-periodicity
   ```

   > **Note**
   >
   > An active query is a periodic mDNS query to refresh dynamic cache.

   Here, *active-query-periodicity* refers to the active query periodicity in minutes. The valid range is from 1 to 120 minutes. Active query runs with a default periodicity of 30 minutes.

7. Configure the source interface to communicate between SDG agent and service peer.

   Example

   ```
   Device(config-mdns-sd)# source-interface vlan vlan-id
   ```

   By default, wireless management interface is used. The interface that you configure is used for all mDNS transactions.

8. Return to the global configuration mode.

Example

```
Device(config-mdns-sd)# exit
```

Create default service policy

This topic outlines the default mDNS service policy behavior and guides you in overriding it with a custom service policy if needed.

Outlines the default mDNS service policy behavior and guides you in overriding it with a custom service policy if needed.

When the mDNS gateway is enabled on any of the WLANs by default, mdns-default-service-policy is associated with it. Default service policy consists of default-service-list and their details are explained in this section. You can override the default service policy with a custom service policy.

Procedure

1. Create a service-definition if the service is not listed in the preconfigured services.
2. Create a service list for IN and OUT by using the service-definitions.
3. Use the existing service list to create a new service. For more information, refer to *Creating Service Policy* section.
4. Attach the *mdns-service-policy* to the profile or VLAN that needs to be enforced.
5. To check the default-mdns-service list, use this command:
   show mdns-sd default-service-list

Create custom service definition (GUI)

Configure a custom service definition using the GUI.

Create a service definition that specifies custom settings for mDNS through the GUI for device configuration.

Procedure

1. Choose **Configuration** > **Services** > **mDNS**.
2. In the **Service Definition** section, click **Add**.
3. In the **Quick Setup: Service Definition** page that is displayed, enter a name and description for the service definition.
4. Enter a service type and click **+** to add the service type.
5. Click **Apply to Device**.

Create custom service definition (CLI)

Configure a custom mDNS service definition using commands.

Add a custom service definition for mDNS, allowing you to associate user-friendly names with service types or PTR resource records using commands.

A service definition is a construct that provides an admin-friendly name to one or more mDNS service types or to a pointer (PTR) resource record name.

By default, a few built-in service definitions are already available for the admin to use.

In addition to built-in service definitions, the admin can define custom service definitions.

You can execute this command to view all service definitions (built-in and custom):

```
Device# show mdns-sd master-service-list
```

Procedure

1. Enable the privileged exec mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Configure mDNS service definition.

   Example

   ```
   Device(config)# mdns-sd service-definition service-definition-name
   ```

   Note

   - All the created custom service definitions are added to the primary service list.
   - Primary service list comprises of a list of custom and built-in service definitions.

4. Configure mDNS service type.

   Example

   ```
   Device(config-mdns-ser-def)# service-type string
   ```

5. Return to the global configuration mode.

   Example

   ```
   Device(config-mdns-ser-def)# exit
   ```

Create service list (GUI)

Use this task to configure a service list for mDNS filtering in the GUI, specifying direction, services, and message types, and applying the configuration to the device.

Define and manage which mDNS services and message types are allowed or filtered for inbound or outbound traffic using the GUI.

Procedure

1. Choose **Configuration** > **Services** > **mDNS**.
2. In the **Service List** section, click **Add**.
3. In the **Quick Setup: Service List** page that is displayed, enter a name for the service list.
4. From the **Direction** drop-down list, select **IN** for inbound filtering or **OUT** for outbound filtering.
5. From the **Available Services** drop-down list, select a service type to match the service list.

   Note

   To allow all services, select the **all** option.

6. Click **Add Services**.
7. From the **Message Type** drop-down list, select the message type to match from the following options:
   - **any**: To allow all messages.
   - **announcement**: To allow only service advertisements or announcements for the device.
   - **query**: To allow only a query from the client for a service in the network.
8. Click **Save** to add services.
9. Click **Apply to Device**.

Create service list (CLI)

Configure a custom mDNS service list to filter service announcements or queries for use with mDNS service policies using commands.

Create an mDNS service list in Cisco IOS XE to filter mDNS service announcements or queries for inbound or outbound traffic using commands.

mDNS service list is a collection of service definitions.

Procedure

1. Enable the privileged exec mode.

   Example

```
Device> enable
```

Enter your password, if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Configure mDNS service list.

   Example

   ```
   Device(config)# mdns-sd service-list service-list-name {IN | OUT}
   ```

   - **IN**: provides inbound filtering.
   - **Out**: provides outbound filtering.

4. Match the service to the message type.

   Example

   ```
   Device(config-mdns-sl-in)# match service-definition-name message-type
   {announcement | query}
   ```

   Here, *service-definition-name* refers to the names of services, such as, airplay, airserver, airtunes, and so on.

   > **Note**
   >
   > To add a service, the service name must be part of the primary service list.
   >
   > If the mDNS service list is set to IN, you get to view this command: **match service-definition-name message-type {announcement | any | query}**.
   >
   > If the mDNS service list is set to OUT, you get to view this command: **match service-definition-name**.

   (OR)

5. Match all services to the message type.

   Example

   ```
   Device(config-mdns-sl-in)# match all message-type {announcement | any | query}
   ```

> **Note**
>
> To add a service, the service name must be part of the primary service list.
>
> If the mDNS service list is set to IN, you get to view this command: **match all message-type {announcement | any | query}**.
>
> If the mDNS service list is set to OUT, you get to view this command: **match all**.

In case of IN or OUT filter, if any of the service contains the same or subset of the message type (query or announcement), the **match all** is not allowed unless the existing services are removed.

6. Display inbound or outbound direction list of the configured service-list to classify matching service-types for service-policy.

   Example

   ```
   Device(config-mdns-sl-in)# show mdns-sd service-list {direction | name }
   ```

   The list can be filtered by name or specific direction.

7. Return to the global configuration mode.

   Example

   ```
   Device(config-mdns-sl-in)# exit
   ```

Create service policy (GUI)

Learn how to create a service policy using the GUI to define input and output service lists for a specified location.

Create a service policy and associate service lists with a specific location through the GUI.

Procedure

1. Choose **Configuration** > **Services** > **mDNS**.
2. In the **Service Policy** section, click **Add**.
3. In the **Quick Setup: Service Policy** page that is displayed, enter a name for the service policy.
4. From the **Service List Input** drop-down list, select one of the types.
5. From the **Service List Output** drop-down list, select one of the types.
6. From the **Location** drop-down list, select the location you want to associate with the service list.
7. Click **Apply to Device**.

Create service policy (CLI)

Configure an mDNS service policy using commands to control mDNS service filtering, define location-based rules, and manage service-list directions.

Create and apply an mDNS service policy for service filtering and control of mDNS learning and responses using commands. mDNS service policy is used for service filtering while learning services or responding to queries.

Procedure

1. Enable the privileged exec mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Enable mDNS service policy.

   Example

   ```
   Device(config)# mdns-sd service-policy service-policy-name
   ```

4. Filter mDNS service types based on location filter.

   Example

   ```
   Device(config-mdns-ser-pol)# location {ap-location | ap-name | location-group
    | lss | regex | site-tag | ssid}
   ```

   Note

   - If a location filter is not applied during the service policy, the system uses the global location filter, which is set to **lss** by default.
   - The location filter specified in the service policy takes precedence, even when a global location filter is configured.
   - In Location Specific Services (LSS) based filtering, the mDNS gateway responds with the service instances learned from the neighboring APs of the querying client AP. The mDNS gateway filters service instances from all other APs.
   - In Site tag based filtering, the mDNS gateway responds with the service instances that belong to the same site-tag as the querying client.
   - The mDNS gateway provides wired services, even when location based filtering is enabled.

5. Configure various service-list names for IN and OUT directions.

Example

```
Device(config-mdns-ser-pol)# service-list service-list-name {IN | OUT}
```

Note

If an administrator creates or uses a custom service policy, the policy must have service-lists for both IN and OUT directions. Without an IN service-list, the mDNS Gateway cannot learn services. Without an OUT service-list, the mDNS Gateway cannot reply to or announce services it has learned.

6. Return to the global configuration mode.

Example

```
Device(config-mdns-ser-pol)# exit
```

Configure a local or native profile for an mDNS policy (CLI)

Configure a native profile on a device to apply an mDNS policy when AAA servers do not supply one using commands.

Ensure mDNS packets are processed based on locally defined profiles when external AAA servers do not provide a policy using commands.

When an administrator configures local authentication and authorization and does not expect to get any mDNS policy from the AAA server, the administrator can configure a local or native profile. This profile selects a mDNS policy based on user, role, or device type. When this local or native profile is mapped to the wireless profile policy, the mDNS service policy is applied to the mDNS packets that are processed on that WLAN.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the service-template or identity policy.

Example

```
Device(config)# service-template template-name
```

3. Configure the mDNS policy.

Example

```
Device(config-service-template)# mdns-service-policy mdns-policy-name
```

4. Return to the global configuration mode.

Example

```
Device(config-service-template)# exit
```

Configure an mDNS FlexConnect profile (GUI)

Configure an mDNS FlexConnect profile through the GUI to manage multicast DNS services on FlexConnect-enabled devices.

Set up and apply an mDNS FlexConnect profile to define multicast DNS settings for FlexConnect devices using the GUI.

Procedure

1. Choose **Configuration** > **Services** > **mDNS**.
2. In the **mDNS Flex Profile** section, click **Add**.
   The **Add mDNS Flex Profile** window is displayed.
3. In the **Profile Name** field, enter the FlexConnect mDNS profile name.
4. In the **Service Cache Update Timer** field, specify the service cache update time. The default value is 1 minute. The valid range is from 1 to 100 minutes.
5. In the **Statistics Update Timer** field, specify the statistics update timer. The default value is 1 minute. The valid range is from 1 to 100 minutes.
6. In the **VLANs** field, specify the VLAN ID. You can enter multiple VLAN IDs separated by commas, or enter a range of VLAN IDs. Maximum number of VLANs allowed is 16.
7. Click **Apply to Device**.

Configure an mDNS FlexConnect Profile (CLI)

Configure an mDNS FlexConnect profile using commands to manage multicast DNS settings for FlexConnect-enabled devices.

Configure an mDNS FlexConnect profile using commands to manage multicast DNS settings for FlexConnect-enabled devices. This procedure enables customization of service cache timers, statistics timers, and wired VLAN range for optimal mDNS performance.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the mDNS FlexConnect profile mode.

   Example

   ```
   Device(config)# mdns-sd flex-profile mdns-flex-profile-name
   ```

3. Configure the mDNS update service cache timer for the FlexConnect profile.

Example

```
Device(config-mdns-flex-profile)# update-timer service-cache service-cache
timer-value <1-100>
```

The default value is 1 minute. Value range is between 1 minute and 100 minutes.

4. Configure the mDNS update statistics timer for the FlexConnect profile.

Example

```
Device(config-mdns-flex-profile)# update-timer statistics statistics
timer-value <1-100>
```

The default value is 1 minute. The valid range is from 1 to 100 minutes.

5. Configure the mDNS wired VLAN range for the FlexConnect profile between 10 - 20.

Example

```
Device(config-mdns-flex-profile)# wired-vlan-range wired-vlan-range value
```

Apply an mDNS FlexConnect profile to a wireless FlexConnect profile (GUI)

Apply an mDNS FlexConnect profile to a wireless FlexConnect profile using the GUI.

Apply an mDNS FlexConnect profile to a wireless FlexConnect profile using the GUI. This procedure enables mDNS service discovery for wireless devices connected via FlexConnect.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Flex**.
2. Click **Add**.
   The **Add Flex Profile** window is displayed.
3. Under the **General** tab, from the **mDNS Flex Profile** drop-down list, select a FlexConnect profile name from the list.
4. Click **Apply to Device**.

Apply an mDNS FlexConnect profile to a Wireless FlexConnect profile (CLI)

Use this task to apply an mDNS FlexConnect profile to a Wireless FlexConnect profile using commands

Enable mDNS features for all APs in the Wireless FlexConnect profile using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Enter the wireless FlexConnect profile configuration mode.

Example

```
Device# wireless profile flex wireless-flex-profile-name
```

3. Enable the mDNS features for all the APs in the profile.

Example

```
Device(config-wireless-flex-profile)# mdns-sd mdns-flex-profile
```

Enable the mDNS gateway on the VLAN interface (CLI)

Configure the mDNS service policy for a specific VLAN interface to control mDNS traffic at the VLAN level using commands.

Enable multicast DNS (mDNS) gateway functions on a chosen VLAN interface, allowing granular service policy control for mDNS packets using commands.

This procedure configures the mDNS service policy for a specific VLAN. This allows the administrator to configure different settings to the mDNS packets on per VLAN interface basis and not on per WLAN basis.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a VLAN ID and enter the interface configuration mode.

Example

```
Device(config)# interface vlan vlan-interface-number
```

3. Configure the IP address for the interface.

Example

```
Device(config-if)# ip address ip-address subnet-mask
```

4. Enable mDNS configuration on a VLAN interface.

Example

```
Device(config-if)# mdns-sd gateway
```

5. Configure the service policy.

   Example

   ```
   Device(config-if-mdns-sd)# service-policy service-policy-name
   ```

   > **Note**
   >
   > If you do not define a specific **service-policy name**, the VLAN uses the **default-mDNS-service-policy** by default.
   >
   > The system automatically creates the **default-mDNS-service-policy**, which uses the **default-mDNS-service-list** configuration to filter mDNS service announcements and queries.

6. Returns to the privileged EXEC mode.

   Example

   ```
   Device(config-if-mdns-sd)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Configure mDNS AP (CLI)

Configure the mDNS gateway and enable mDNS on an AP using commands.

Enable Multicast DNS (mDNS) services on a specific AP and configure permitted service VLANs using commands.

In most of the deployments, the services may be available in VLANs that the APs can hear in the wired side (allowed in the switchport where the AP is directly connected: its own VLAN, or even more VLANs if switchport is a trunk).

This procedure shows how to configure mDNS AP:

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the mDNS gateway.

   Example

   ```
   Device(config)# mdns-sd gateway
   ```

3. Enable mDNS on the AP, and configure a VLAN for the mDNS AP.

Example

```
Device# ap name ap-name mdns-ap enable vlan vlan-id
```

4. Add a VLAN to the mDNS AP.

   Example

   ```
   Device# ap name ap-name mdns-ap vlan add vlan-id
   ```

   The *vlan-id* ranges from 1 to 4096.

5. Delete a VLAN from the mDNS AP.

   Example

   ```
   Device# ap name ap-name mdns-ap vlan del vlan-id
   ```

6. Disable the mDNS AP.

   Example

   ```
   Device# ap name ap-name mdns-ap disable
   ```

7. Return to the privileged EXEC mode.

   Example

   ```
   Device# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Note

   You can configure a maximum of 10 VLANs per AP.

Enable mDNS Gateway on the RLAN interface (CLI)

Configure the mDNS gateway service on a remote LAN interface using commands.

Enable mDNS gateway to allow devices connected to a Remote LAN (RLAN) interface to discover services across VLANs using commands.

By configuring the mDNS gateway mode on the RLAN interface, you can configure the mDNS service policy for a specific RLAN.

Procedure

1. Enter the global configuration mode and configure a remote LAN profile.

Example

```
Device# configure terminal
```

```
Device(config)# ap remote-lan profile-name remote-lan-profile-name rlan-id
```

Example

- *remote-lan-profile*: Remote LAN profile name. The range is from 1 to 32 alphanumeric characters.
- *rlan-id*: Remote LAN identifier. The range is from 1 to 128.

> **Note**
>
> You can create a maximum of 128 RLANs. Also, you cannot use the *rlan-id* of an existing RLAN while creating another RLAN.

2. Enable mDNS configuration on an RLAN interface and restart the RLAN profile.

Example

mdns-sd-interface

```
Device(config-remote-lan)# mdns-sd-interface {gateway | drop}
```

```
Device(config-remote-lan)# no shutdown
```

3. Exit the remote LAN configuration mode and configure the RLAN policy profile and enter the wireless policy configuration mode.

Example

```
Device(config-remote-lan)# exit
```

```
Device(config)# ap remote-lan-policy policy-name profile name
```

4. Enable an mDNS service policy and configure the RLAN for central switching.

Example

```
Device(config-remote-lan-policy)# mdns-sd service-policy service-policy-name
```

```
Device(config-remote-lan-policy)# central switching
```

5. Configure the central DHCP for centrally switched clients and assign the profile policy to a VLAN.

Example

```
Device(config-remote-lan-policy)# central dhcp
```

```
Device(config-remote-lan-policy)# vlan vlan-name
```

6. Restart the RLAN profile and configure a policy tag.

Example

```
Device(config-remote-lan-policy)# no shutdown
```

```
Device(config)# wireless tag policy policy-tag-name
```

7. Map the RLAN policy profile to the RLAN profile.

Example

```
Device(config-policy-tag)# remote-lan remote-lan-profile-name policy
rlan-policy-profile-name port-id port-id
```

- *remote-lan-profile-name* : Name of the RLAN profile.
- *rlan-policy-profile-name*: Name of the policy profile.
- *port-id*: LAN port number on the AP. The range is from 1 to 4.

8. Return to the global configuration mode and configure the AP and enter the AP tag configuration mode.

Example

```
Device(config-policy-tag)# exit
```

```
Device (config)# ap mac-address
```

> **Note**
>
> Use the Ethernet MAC address.

9. Map a policy tag to the AP and return to the privileged EXEC mode.

Example

```
Device (config-ap-tag)# policy-tag policy-tag-name
```

```
Device(config-guest-lan)# end
```

Enable mDNS Gateway on guest LAN interface (CLI)

Enable mDNS gateway on the guest LAN interface.

Enable the mDNS gateway on a guest LAN interface to support discovery and service policies for wired and anchor controllers using commands.

By configuring the mDNS gateway mode on a Guest LAN interface, you can configure the mDNS service policy for a specific Guest LAN interface.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure guest LAN profile with a wired VLAN.

   Example

   ```
   Device(config)# guest-lan profile-name guest_lan_profile_name num wired-vlan
    wired_vlan_num
   ```

   Note

   Configures the wired VLAN only for the Guest Foreign controller.

   - *num*: Guest LAN identifier. The valid range is from 1 to 5.
   - *wired_vlan_num*: Wired VLAN number. The valid range is from 1 to 4094.

3. Configure the guest LAN profile without a VLAN for the Guest Anchor controller.

   Example

   ```
   Device(config)# guest-lan profile-name guest_lan_profile_name
   ```

4. Configure the mDNS gateway for a Guest LAN.

   Example

   ```
   Device(config-guest-lan)# mdns-sd interface {gateway | drop}
   ```

> **Note**
>
> You need to enable mDNS gateway globally for the Guest LAN to work.

5. Return to the privileged EXEC mode.

Example

```
Device(config-guest-lan)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Associate mDNS service policy with wireless profile policy (GUI)

Configure the association between an mDNS service policy and a wireless profile policy using the GUI.

Apply an mDNS service policy to a wireless profile policy so that multicast DNS behavior aligns with desired network access and discovery parameters using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click the **policy profile** name.
3. In the **Advanced** tab, select the mDNS service policy from the **mDNS Service Policy** drop-down list.
4. Click **Update & Apply to Device**.

Associate mDNS service policy with wireless profile policy (CLI)

Configure the association of an mDNS service policy with a wireless profile policy using commands.

Enable customized mDNS service filtering and announcements within a wireless profile policy using commands.

> **Note**
>
> You must globally configure the mDNS service policy before associating it with the wireless profile policy.

A default mDNS service policy is already attached when the wireless profile policy is created. You can use the following commands to override the default mDNS service policy with any of your service policy:

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configures the wireless profile policy.

   Example

   ```
   Device(config)# wireless profile policy profile-policy
   ```

   Here, *profile-policy* refers to the name of the WLAN policy profile.

3. Associate an mDNS service policy with the wireless profile policy.

   Example

   ```
   Device(config-wireless-policy)# mdns-sd service-policy
   custom-mdns-service-policy
   ```

   The default mDNS service policy name is **default-mdns-service-policy**.

Note

The **default-mdns-profile-policy** uses **default-mdns-service-list** configuration to filter mDNS service announcements and queries.

In a wireless network, the mDNS packets are consumed by the mDNS gateway, so clients or devices are unable to learn about these services. By sharing the service with the device and simplifying configuration for the administrator, a list of standard service types is shared by default on the wireless network. This list of standard service types is referred to as the default service policy, which comprises a set of service types.

The table covers a sample service list in the default service policy.

Table 214: Default Name and mDNS Service Type

Default Name	mDNS Service Type
Apple TV	_airplay._tcp.local _raop._tcp.local
Apple HomeSharing	_home-sharing._tcp.local
Printer-IPPS	_ipps._tcp.local
Apple-airprint	_ipp._tcp.local _universal._sub._ipp._tcp.local
Google-chromecast	_googlecast._tcp.local _googlerpc._tcp.local _googlezone._tcp.local
Apple-remote-login	_sftp-ssh._tcp.local _ssh._tcp.local
Apple-screen-share	_rfb._tcp.local
Google-expeditions	_googexpeditions._tcp.local
Multifunction-printer	_fax-ipp._tcp.local _ipp._tcp.local _scanner._tcp.local
Apple-windows-fileshare	_smb._tcp.local

Note

- Location would be disabled on mDNS default service policy.
- You cannot change the contents of the mDNS default service policy. However, you can create separate mDNS service policies and associate them under the wireless policy profile.

4. Return to the global configuration mode.

Example

```
Device(config-wireless-policy)# exit
```

Enable or disable mDNS Gateway for WLAN (GUI)

Learn how to enable or disable the mDNS Gateway for a WLAN using the GUI.

Enable or disable the mDNS Gateway feature for a specific WLAN to optimize device discovery and network performance using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click on the WLAN.
3. In the **Advanced** tab, select the mode in **mDNS Mode** drop-down list.
4. Click **Update & Apply to Device**.

Enable or disable mDNS Gateway for WLAN (CLI)

Use this task to configure the mDNS Gateway for a specified WLAN using commands.

Control mDNS Gateway functionality for a wireless LAN using commands.

> **Note**
>
> Bridging is the default behaviour. This means that the mDNS packets are always bridged.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Specify the WLAN name and ID.

Example

```
Device(config)# wlan profile-name wlan-id ssid-name
```

- *profile-name* is the WLAN name, and it can contain up to 32 alphanumeric characters.
- *wlan-id* is the wireless LAN identifier. The valid range is from 1 to 4096.

- *ssid-name* is the SSID which can contain 32 alphanumeric characters.

> **Note**
>
> Global configuration must be in place for mDNS Gateway to work.

3. Enable or disable mDNS Gateway and bridge functions on WLAN.

   Example

   ```
   Device(config-wlan)# mdns-sd interface {gateway | drop}
   ```

4. Return to the global configuration mode.

   Example

   ```
   Device(config-wlan)# exit
   ```

5. Verify the status of mDNS on WLAN.

   Example

   ```
   Device# show wlan name wlan-name show wlan all
   ```

6. Verify the service policy configured in WLAN.

   Example

   ```
   Device# show wireless profile policy
   ```

---

mDNS Gateway with guest anchor support and mDNS bridging

This topic explains how mDNS gateway functions in guest anchor deployments, depending on whether the gateway is enabled on Anchor, Foreign, or both controllers.

- When mDNS Gateway is enabled on both the Anchor and Foreign controllers, the mDNS gateway supports guest anchor deployments. In this mode, clients on a guest LAN or WLAN with guest anchor enabled receive responses with any services or cache from the export Foreign controller. All advertisements received on the guest LAN or WLAN by the export Foreign are learned on the export Foreign itself. All queries received on the guest LAN or WLAN are answered by the export Foreign itself.
- When mDNS Gateway is enabled on the Anchor and disabled on the Foreign controller (Bridging Mode), the mDNS gateway supports guest anchor deployments. In this scenario, clients on the guest LAN or WLAN with guest anchor enabled receive any services or cache from the export Anchor, even if the clients are connected to the Foreign. All advertisements received on the guest LAN or WLAN by the export Foreign are forwarded to the Anchor, and the cache is stored on the Anchor. All queries received on the guest LAN or WLAN are answered by the export Anchor itself.

> **Note**
>
> Comment by CISCO\ashijadh: based on PRRQ comments
>
> - You must configure the guest LAN to a wireless profile policy that is configured with the required mDNS service policy.
> - To configure a non-guest LAN mDNS gateway, see the mDNS Gateway chapter.

Configure mDNS Gateway on guest anchor (CLI)

Configure the mDNS Gateway on a guest anchor using commands.

Configures the mDNS Gateway functionality on a guest anchor device using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the guest LAN profile with a wired VLAN.

   Example

   ```
   Device(config)# guest-lan profile-name guest-lan-profile-name guest-lan-id
   ```

3. Enable mDNS Gateway on the guest LAN.

   Example

   ```
   Device(config-guest-lan)# mdns-sd gateway
   ```

Configure mDNS Gateway on guest foreign (Guest LAN) (CLI)

Configure the mDNS Gateway on a Guest Foreign controller for Guest LAN wired VLANs using commands.

Enable mDNS Gateway functionality for users and devices connected to the Guest LAN via a wired VLAN using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure guest LAN profile with a wired VLAN.

   Example

   ```
   Device(config)# guest-lan profile-name guest-lan-profile-name guest-lan-id
   wired-vlan vlan-id
   ```

   > **Note**
   >
   > Configure the wired VLAN only for the Guest Foreign controller.

3. Enable mDNS Gateway on the guest LAN.

   Example

   ```
   Device(config-guest-lan)# mdns-sd gateway
   ```

4. Return to the global configuration mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

Configure mDNS Gateway on guest anchor (CLI)

Configure an mDNS Gateway for a guest WLAN anchored on the controller using commands.

Enable mDNS Gateway functionality on a guest WLAN profile anchored to a VLAN, allowing multicast DNS service discovery for guest users using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the guest WLAN profile with a wired VLAN.

   Example

   ```
   Device(config)# guest-wlan profile-name guest-lan-profile-name guest-wlan-id
   ```

3. Enable mDNS Gateway on the guest WLAN.

Example

```
Device(config-guest-wlan)# mdns-sd gateway
```

Configure mDNS Gateway on guest foreign (Guest WLAN) (CLI)

Configure the mDNS Gateway on a guest foreign controller for a guest WLAN that includes a wired VLAN.

Enable service discovery for devices on a guest wireless LAN (WLAN) and ensure multicast DNS (mDNS) works for clients connected to a guest wired VLAN on the foreign controller using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure guest WLAN profile with a wired VLAN.

   Example

   ```
   Device(config)# guest-wlan profile-name guest-lan-profile-name guest-wlan-id
    wired-vlan vlan-id
   ```

   Note

   Configure the wired VLAN only for the Guest Foreign controller.

3. Enable mDNS Gateway on the guest WLAN.

   Example

   ```
   Device(config-guest-wlan)# mdns-sd gateway
   ```

4. Return to the global configuration mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

Verify mDNS Gateway configurations

This section lists the key commands and their outputs for verifying mDNS Gateway configurations, cache details, service statistics, and AP associations in your network.

To verify the mDNS summary, use this command:

```
Device# show mdns-sd summary

mDNS Gateway: Enabled
Active Query: Enabled
  Periodicity (in minutes): 30
Transport Type: IPv4
```

To verify the mDNS cache, use this command:

```
Device# show mdns-sd cache

------------------------------------------------------------ PTR Records
--------------------------------------
RECORD-NAME                    TTL      WLAN   CLIENT-MAC       RR-RECORD-DATA

_____________________________________________________________________________
_airplay._tcp.local             4500     30     07c5.a4f2.dc01
CUST1._airplay._tcp.local
_ipp._tcp.local                 4500     30     04c5.a4f2.dc01
CUST3._ipp._tcp.local2
_ipp._tcp.local                 4500     15     04c5.a4f2.dc01
CUST3._ipp._tcp.local4
_ipp._tcp.local                 4500     10     04c5.a4f2.dc01
CUST3._ipp._tcp.local6
_veer_custom._tcp.local         4500     10     05c5.a4f2.dc01
CUST2._veer_custom._tcp.local8
```

To verify the mDNS cache from wired service provider, use this command:

```
Device# show mdns-sd cache wired

------------------------------------------------------------ PTR Records
--------------------------------------

   'txtvers=12'
```

To verify the mdns-sd cache with respect to the RLAN ID, use this command:

```
Device# show mdns-sd cache rlan-id 1 detail

Name: _printer._tcp.local
  Type: PTR
  TTL: 4500
  RLAN: 1
  RLAN Name: rlan_test_1
  VLAN: 141
  Client MAC: 000e.c688.3942
  AP Ethernet MAC: 0042.5ab6.0ef0
  Remaining-Time: 4485
  Site-Tag: default-site-tag
  mDNS Service Policy: mdnsTV6
  Overriding mDNS Service Policy: NO
  UPN-Status: Disabled
  Rdata: printer._printer._tcp.local
Name: lab-47-187.local
  Type: A/AAAA
  TTL: 4500
  RLAN: 1
  RLAN Name: rlan_test_1
  VLAN: 141
  Client MAC: 000e.c688.3942
  AP Ethernet MAC: 0042.5ab6.0ef0
  Remaining-Time: 4485
  Site-Tag: default-site-tag
  mDNS Service Policy: mdnsTV6
  Overriding mDNS Service Policy: NO
  UPN-Status: Disabled
  Rdata: 10.15.141.124
```

To verify the mdns-sd cache with respect to mDNS-AP, use this command:

```
Device# show mdns-sd cache mdns-ap 706b.b97d.b060 detail

Name: _printer._tcp.local
  Type: PTR
  TTL: 4500
  VLAN: 145
  Client MAC: 0050.b626.5bfa
  mDNS AP Radio MAC: 706b.b97d.b060
  mDNS AP Ethernet MAC: 706b.b97c.5208
  Remaining-Time: 4480
  mDNS Service Policy: mdnsTV
  Rdata: printer._printer._tcp.local
Name: Client-46-153.local
  Type: A/AAAA
  TTL: 4500
  VLAN: 145
  Client MAC: 0050.b626.5bfa
  mDNS AP Radio MAC: 706b.b97d.b060
  mDNS AP Ethernet MAC: 706b.b97c.5208
```

```
  Remaining-Time: 4480
  mDNS Service Policy: mdnsTV
  Rdata: 10.15.145.103
```

To verify the mdns-sd cache in detail, use this command:

```
Device# show mdns-sd cache detail

Name: _custom1._tcp.local
  Type: PTR
  TTL: 4500
  WLAN: 2
  WLAN Name: mdns120
  VLAN: 120
  Client MAC: c869.cda8.77d6
  AP Ethernet MAC: 7069.5ab8.33d0
  Expiry-Time: 09/09/18 21:50:47
  Site-Tag: default-site-tag
  Rdata: service_t1._custom1._tcp.local
```

To verify the mdns-sd cache statistics, use this command:

```
Device# show mdns-sd cache statistics

mDNS Cache Stats
Total number of Services: 4191
```

To verify the mdns-sd statistics, use this command:

```
Device# show mdns-sd statistics

-------------------------------------------------------
Consolidated mDNS Packet Statistics

```

To verify the default service list details, use this command:

```
Device# show mdns-sd default-service-list

-----------------------------------------
mDNS Default Service List
-----------------------------------------
Service Definition: apple-tv
Service Names: _airplay._tcp.local
_raop._tcp.local
Service Definition: homesharing
Service Names: _home-sharing._tcp.local
Service Definition: printer-ipps
Service Names: _ipps._tcp.local
Service Definition: apple-airprint
Service Names: _ipp._tcp.local
_universal._sub._ipp._tcp.local
```

```
Service Definition: google-chromecast
Service Names: _googlecast._tcp.local
_googlerpc._tcp.local
_googlezone._tcp.local
Service Definition: apple-remote-login
Service Names: _sftp-ssh._tcp.local
_ssh._tcp.local
Service Definition: apple-screen-share
Service Names: _rfb._tcp.local
Service Definition: google-expeditions
Service Names: _googexpeditions._tcp.local
Service Definition: multifunction-printer
Service Names: _fax-ipp._tcp.local
_ipp._tcp.local
_scanner._tcp.local
Service Definition: apple-windows-fileshare
Service Names: _smb._tcp.local
```

To verify the primary service list details, use this command:

```
Device# show mdns-sd master-service-list

-----------------------------------------
        mDNS Master Service List
-----------------------------------------
Service Definition: fax
Service Names: _fax-ipp._tcp.local
Service Definition: roku
Service Names: _rsp._tcp.local
Service Definition: airplay
Service Names: _airplay._tcp.local
Service Definition: scanner
Service Names: _scanner._tcp.local
Service Definition: spotify
Service Names: _spotify-connect._tcp.local
Service Definition: airtunes
Service Names: _raop._tcp.local
Service Definition: airserver
Service Names: _airplay._tcp.local
               _airserver._tcp.local
.
.
.
Service Definition: itune-wireless-devicesharing2
Service Names: _apple-mobdev2._tcp.local
```

To verify the mdns-sd service statistics on the controller, use this command:

```
Device# show mdns-sd service statistics

Service Name                                                    Service Count

-------------------------------------------------------------------------------
_atc._tcp.local                                                   137

_hap._tcp.local                                                   149

_ipp._tcp.local                                                   149

_rfb._tcp.local                                                   141
```

```
_smb._tcp.local                                                    133

_ssh._tcp.local                                                    142

_daap._tcp.local                                                   149

_dpap._tcp.local                                                   149

_eppc._tcp.local                                                   138

_adisk._tcp.local                                                  149
```

To verify the mDNS-AP configured on the controller and VLAN(s) associated with it, use this command:

```
Device# show mdns-sd ap

Number of mDNS APs.................................. 1
AP Name   Ethernet MAC   Number of Vlans   Vlanidentifiers
-----------------------------------------------------------------------------------------------
AP3600-1   7069.5ab8.33d0          1      300
```

Further Debug

To debug mDNS further, use this procedure:

1. Run this command at the controller:

```
set platform software trace wncd <0-7> chassis active R0 mdns debug
```

2. Reproduce the issue.
3. Run this command to gather the traces enabled:

```
show wireless loadbalance ap affinity wncd 0
AP MAC   Discovery Timestamp  Join Timestamp               Tag
Vlanidentifiers
-----------------------------------------------------------------------------------------
0cd0.f894.0600      06/30/21 12:39:48    06/30/21 12:40:021 default-site-tag
    300
```

Location based service filtering

Explains how location-based service filters control access to services based on a device's physical or logical location within a network.

Prerequisite for location-based service filtering

This topic outlines the prerequisites you must meet before configuring location-based service filtering.

- You need to create the Service Definition and Service Policy.
- For more information, see Creating Custom Service Definition section and Creating Service Policy section.

Configure mDNS location-based filtering using SSID (CLI)

Configure a service policy to enable mDNS location-based filtering using the SSID as the location criteria.

Limit mDNS service announcements to only those learned on the configured SSID, enhancing security and service relevance using commands.

When a service policy is configured with the SSID as the location name, the response to the query will be the services that were learnt on that SSID.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the service policy.

   Example

   ```
   Device(config)# mdns-sd service-policy service-policy-name
   ```

3. Configure location-based filtering using SSID.

   Example

   ```
   Device(config-mdns-ser-pol)# location ssid
   ```

4. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-mdns-ser-pol)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Configure mDNS location-based filtering using AP name (CLI)

Configure an mDNS service policy to provide location-based filtering using the AP name as the location reference.

Limit mDNS query responses to only services discovered on a specified AP, improving service localization and security using commands.

When a service policy is configured with the AP name as the location, the response to the query will be the services that were learnt on that AP.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the service policy.

   Example

   ```
   Device(config)# mdns-sd service-policy service-policy-name
   ```

3. Configure location-based filtering using an AP name.

   Example

   ```
   Device(config-mdns-ser-pol)# location ap-name
   ```

4. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-mdns-ser-pol)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Configure mDNS location-based filtering using AP location (CLI)

Configure Multicast DNS (mDNS) location-based filtering using the AP location in the CLI.

Configure mDNS location-based filtering using the AP location and these commands.

When a service policy is configured with location as the AP-location, the response to the query will be the services that were learnt on all the APs using the same AP "location" name (not to be confused with "site-tag").

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the service policy.

   Example

   ```
   Device(config)# mdns-sd service-policy service-policy-name
   ```

3. Configure location-based filtering using the AP location.

   Example

   ```
   Device(config-mdns-ser-pol)# location ap-location
   ```

4. Return to the privileged EXEC mode.

Example

```
Device(config-mdns-ser-pol)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Configure mDNS location-based filtering using regular expression (CLI)

Learn how to configure mDNS location-based filtering using regular expressions in CLI to match services based on AP name or AP location.

Enable filtering of mDNS services using location-based regular expressions for targeted service policy assignment using commands.

- If a service policy uses a location specified as a regular expression matching the AP name, the query returns services learned on all APs whose names match.
- If a service policy uses a location specified as a regular expression matching the AP location, the query returns services learned on all APs whose locations match.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the service policy.

   Example

   ```
   Device(config)# mdns-sd service-policy service-policy-name
   ```

3. Configure location-based filtering using regular expression.

   Example

   ```
   Device(config-mdns-ser-pol)# location regex {ap-location regular-expression
   | ap-name regular-expression}
   ```

4. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-mdns-ser-pol)# end
   ```

> **Note**
>
> To filter the services for which AP names have the specific keyword such as *AP-2FLR-SJC-123*, you can use the regex AP name as *AP-2FLR-* to match the services that are learnt from the set of APs.

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Configure mDNS location based filtering using location group

-

mDNS location-Based filtering using location group (Microlocation)

Information about mDNS location-based filtering using location group (microlocation).

mDNS location-based filtering using location groups is a method that

- manages and restricts mDNS service advertisements and discovery, based on the deployment area of wireless APs, and
- a location group, also known as a microlocation or mDNS AP Group, is formed by assigning APs to groups, either by AP name or by their configured physical location.

To create an mDNS AP location group, complete these steps

1. Define multiple rules with priority in the wireless rule-based mDNS application.

> **Note**
>
> Assign AP microlocation grouping by AP name or AP location.

2. Match the highest priority rule-based on the configured regular expression with AP name and AP location-based grouping.
3. Map an AP to a location group (mDNS Group ID).

> **Note**
>
> When you delete or modify a rule, the corresponding APs are revalidated using the **capwap restart** command to apply the updated configuration.

In the context of Apple Bonjour, microlocation refers to a subset of a wireless location. This subset is also known as an mDNS AP group or location group.

AP Microlocation Support Based on AP Location

Starting from Cisco IOS-XE 17.3, configure AP location using the **ap name** *name* **location** *location* command.

Starting from Cisco IOS-XE 17.9, leverage AP location to group APs within a location and form a location group.

By default, AP microlocation based on either AP name or AP location is disabled.

Feature history for mDNS location-based filtering using location group (microlocation)

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 215: Feature history for mDNS location-based filtering using location group (microlocation)

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.9.1	mDNS location-based filtering using location group (microlocation)	The controller is enhanced to support microlocation from wireless clients tagged with the location group (mDNS Group ID) tag. From Cisco IOS-XE 17.3 onwards, location grouping is done based on AP names. From Cisco IOS-XE 17.9 onwards, location grouping is extended to AP location.

Use cases for mDNS location-based filtering using location group (microlocation)

This topic lists common scenarios where mDNS location-based filtering using location groups (microlocation) enhances service access and containment across different environments.

- Restricts services across departments to ensure only authorized users have visibility.
- Shares files across buildings or sites without exposing resources network-wide.
- Provides service visibility to teachers or students, doctors or patients, employees or specific groups within contained environments, avoiding the need for IT intervention to change Layer 2 or Layer 3 networks.

Prerequisites for mDNS location-based filtering using location group (microlocation)

This topic explains the essential requirements and system defaults governing mDNS location-based filtering using location groups (microlocation).

- You must configure the mDNS rule.
- By default, the system uses AP name-based microlocation grouping.

Enable location group (CLI)

This topic describes how to enable a location group on a device by using command-line interface commands.

To enable a location group, follow these steps to configure the required mDNS service policy and apply location-based filtering using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure mDNS service policy.

   Example

   ```
   Device(config)# mdns-sd service-policy service-policy-name
   ```

3. Configure service lists for IN and OUT directions.

   Example

   ```
   Device(config-mdns-ser-pol)# service-list service-list-name {in | out}
   ```

4. Configure location-based filtering using location group.

   Example

   ```
   Device(config-mdns-ser-pol)# location location-group
   ```

5. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-mdns-ser-pol)# end
   ```

Add APs to a location group (CLI)

Configure APs to join a location group for mDNS applications using commands.

Group APs based on location name or AP name for mDNS rule-based applications using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure wireless rule-based MDNS application.

   Example

   ```
   Device(config)# wireless rule application mdns
   ```

3. Configure rule priority.

Example

```
Device(config-app-rule)# rule-priority rule_priority rule-name rule_name
```

Here,

- *rule_priority*: The valid range is from 0 to 4096.

  Note

  0 is the lower priority number and 4096 is the higher priority number.

- *rule_name*: The rule name can be between 1 to 32 characters.

Note

When you configure the rule priority, you will see the prompt: `Changing regex string or other rule configuration may cause associated APs to rejoin.`

When you see this prompt, enter **Y** to continue with the configuration.

4. Configure rule-based on AP name or AP location to match the regular expression.

   Example

   ```
   Device(config-rule-params)# regex regular_expression_string
   ```

5. Group APs based on the filter string.

   Example

   ```
   Device(config-rule-params)# action-type grouping
   ```

6. Configure the mDNS location group identifier.

   Example

   ```
   Device(config-rule-action-mdns)# group-id location_group_identifier
   ```

   The valid range for *location_group_identifier* is 1 to 4096.

7. Configure AP location-based grouping.

   Example

   ```
   Device(config-rule-action-mdns)# group-method ap location
   ```

> **Note**
>
> If you treat the **group-method** as **ap location** , the regular expression captures the *AP_LOC_NAME*. By default, the **group-method** uses *AP_NAME*.

8. Configure mDNS location group name.

   Example

```
Device(config-rule-action-mdns)# group-name location_group_name
```

9. Return to the privileged EXEC mode.

   Example

```
Device(config-rule-action-mdns)# end
```

Verify AP location

This topic provides commands to verify AP mDNS group associations, rule names, group IDs, and methods.

To verify the mDNS location Group ID associated with an AP, use this command:

```
Device# show ap config general | sec MDNS | AP Name
Cisco AP Name   : AP2800

MDNS Group Id                                   : 101
MDNS Rule Name                                  : R101
MDNS Group Method                               : AP Location
```

To verify all the APs associated with the configured mDNS rule name, use this command:

```
Device# show wireless associated-ap mdns-rule-name R1
AP MAC              AP Name
-----------------------------------------------------------------------
0cd0.f894.a840      AP0CD0.F894.083C
4001.7a03.8560      APA023.9F66.4F96
--------------------
```

To verify all the APs associated with the configured mDNS location group ID, use this command:

```
Device# show wireless associated-ap mdns-group-id 1
AP MAC              AP Name
-----------------------------------------------------------------------
0cd0.f894.a840      AP0CD0.F894.083C
4001.7a03.8560      APA023.9F66.4F96
--------------------
```

To verify the mDNS group method detail for each AP, use this command:

```
Device# show ap config general | inc MDNS|AP Name|Location
Cisco AP Name   : AP-1
MDNS Group Id                                   : 100
MDNS Rule Name                                  : R100

MDNS Group Method                               : AP Location
```

To verify the mDNS group method detail for each rule, use this command:

```
                Device# show wireless rule application mdns
Rule Name          : R100
Rule Priority      : 100
Regular Expression : AP0
Action Type        : MDNS Grouping
  MDNS Group ID    : 100
MDNS Group Name  : G100

                MDNS Group Method: AP Location
```

Nearest mDNS based wired service filtering

Explains nearest mDNS-based wired service filters, what category they belong to, and their distinguishing attributes for controlling multicast DNS service advertisements on local area networks.

Nearest mDNS-based wired service filtering

Information about nearest mDNS-based wired service filtering.

A nearest mDNS-based wired service filter is a service discovery mechanism that

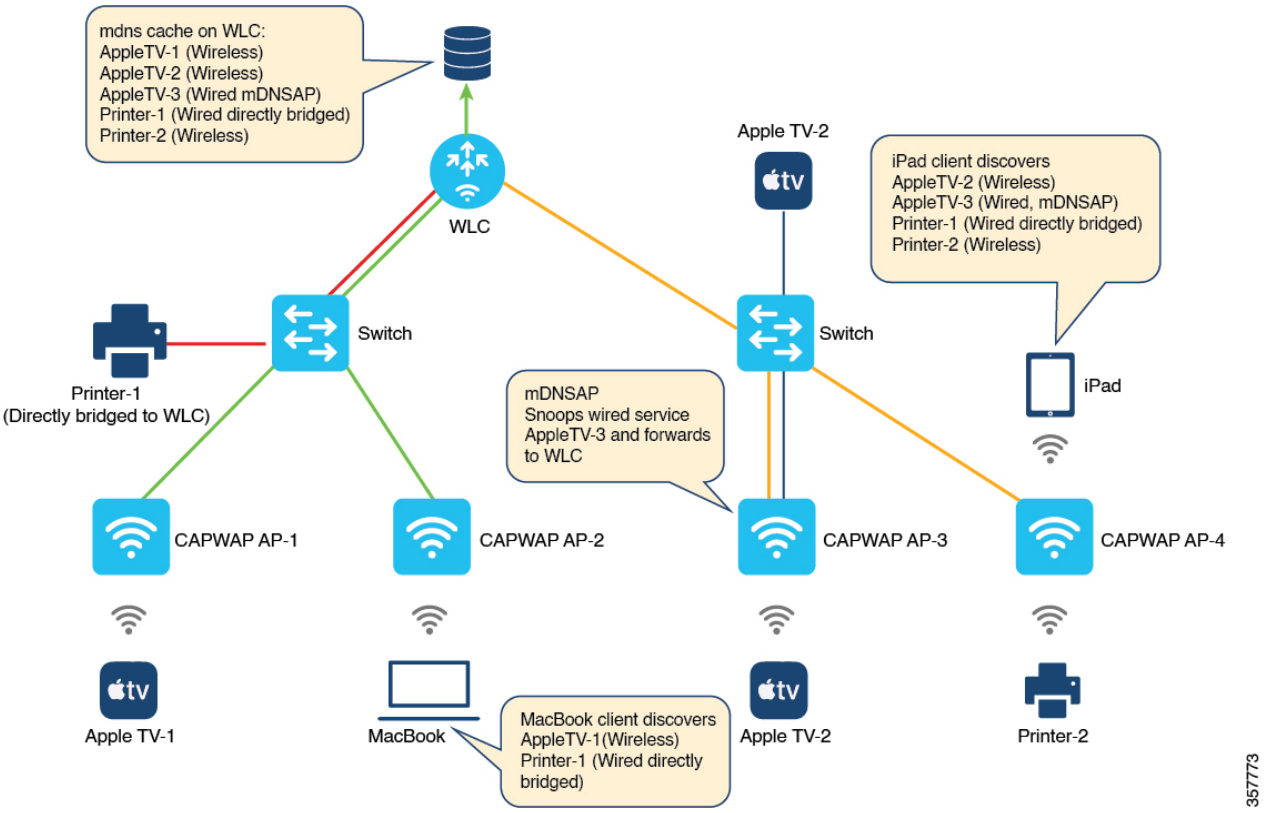
- classifies wired services based on proximity to the wireless clients
- advertises only those wired services available from nearest mDNS-enabled APs, and
- supports cache population and filtering on the controller for relevant service visibility.

Prior to the Cisco IOS XE 17.8.1 release, wireless clients discovered:

- All wired services from mDNS-AP.
- Service providers on VLANs visible to the controller.

Note

The current filtering is supported only for wireless services.



Note

The controller classifies wired services as the nearest wired services once LSS is enabled. The mDNS-AP then forwards or advertises the nearest wired services.

Starting from Cisco IOS XE 17.8.1, wireless clients are enhanced to support filtering based on the nearest wired service provider.

This figure illustrates the nearest wired service provider and discovery:

Figure 69: Nearest Wired Service Provider and Discovery

As per the figure, the controller is associated with these four APs:

- CAPWAP AP-1
- CAPWAP AP-2
- CAPWAP AP-3
- CAPWAP AP-4

The client connected to CAPWAP AP-1 is wireless and advertises the service Apple TV-1.

Similarly, the client connected to CAPWAP AP-2 is wireless and advertises the service MacBook query client.

The CAPWAP AP-3 is enabled as an mDNS-AP. This AP discovers wired services on VLANs and forwards them to the controller. In this case, the client advertising the service AppleTV-3 is a wired service, which is discovered by CAPWAP AP-3 and forwarded to the controller. You may also see another client connected to CAPWAP AP-3 that is wireless and advertises the service AppleTV-2.

The client connected to CAPWAP AP-4 is wireless and advertises the service Printer-2 and iPad query client.

Also, a client is connected directly to the controller, which advertises the Printer-1.

The controller covers cache populated from both wireless and wired service providers.

The controller creates a cache with these entries:

- AppleTV-1 (Wireless service from CAPWAP AP-1)
- AppleTV-2 (Wireless service from CAPWAP AP-3)
- AppleTV-3 (Wired service from mDNS-AP enabled AP-3)
- Printer-1 (Wired service from directly bridged service provider)
- Printer-2 (Wireless service from AP-4)

When LSS is enabled, AP-1 and AP-2 discover each other as LSS neighbors. Similarly, AP-3 and AP-4 discover each other as LSS neighbors.

MacBook discovers these services:

- AppleTV-1 (wireless service from AP-1)
- Printer-1 (wired service from the directly bridged service provider)

> **Note**
>
> MacBook does not discover the wired service AppleTV-3 (forwarded by mDNS-AP AP-3). The AP-2 does not see AP-3 as the LSS neighbor. Thus, the controller does not classify the wired service AppleTV-3 as nearby.

iPad discovers these services:

- AppleTV-2 (wireless service from AP-3)
- AppleTV-3 (wired service from mDNS-AP enabled AP-3)
- Printer-1 (wired service from directly bridged service provider)
- Printer-2 (wireless service from AP-4)

> **Note**
>
> iPad discovers the wired service AppleTV-3 (forwarded by mDNS-AP AP-3). The AP-4 sees AP-3 as the LSS neighbor. Thus, the controller classifies the wired service AppleTV-3 as nearby.

> **Note**
>
> This feature supports only the wired services advertised by mDNS-AP in centrally switched local mode.

Feature history for nearest mDNS-based wired service filtering

This table provides release and related information for features explained in this module.

These features are available on all releases subsequent to the one they were introduced in, unless noted otherwise.

Table 216: Feature history for nearest mDNS-based wired service filtering

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.8.1	Nearest mDNS-based wired service filtering	This feature supports these functionalities: • Nearest mDNS based wired service filtering. (Supported in Central switched Local mode.) • Custom wired service policy support for FlexConnect mode. • VLAN and MAC based wired service filtering. (Supported in Central switched Local mode.)

Custom wired service policy support for FlexConnect mode

Information about custom wired service policy support for FlexConnect mode.

A custom wired service policy is a configuration feature that

- allows users to apply mDNS service policies to wired networks in FlexConnect profiles, and
- is available starting from Cisco IOS XE 17.8.1, providing extended policy support.

VLAN and MAC based wired service filtering

Information about VLAN and MAC based wired service filtering.

VLAN and MAC based wired service filterings are network control mechanisms that

- allow filtering of wired services by VLAN and MAC address

- enable OUT direction filter application for mDNS-AP and bridged wired services, and
- support centrally switched local mode from Cisco IOS XE 17.8.1 onward.

Before Cisco IOS XE 17.8.1, service filtering was based on service type, location type, and location filter. These filters apply to wireless services but are not supported for wired services.

Prerequisite for nearest mDNS-based wired service filtering

- Enable the mDNS gateway on the controller.

Use cases

This topic ists use cases and limitations of the nearest mDNS-based wired service filtering for Cisco wireless controllers.

These are the use cases:

- Nearest mDNS-based wired service filtering.
- Custom wired service policy support for FlexConnect mode.
- VLAN and MAC based wired service filtering.

While migrating from AireOS wireless controllers to the Cisco Catalyst 9800 Series wireless controllers, these limitations occur:

- Wireless clients discover all wired services, not just the nearby service from the wired service provider, when centrally switched local mode and LSS are enabled. The wired services belong to both the forwarded mDNS-AP and the directly bridged services.
- TYou cannot apply the custom service policy for wired services when locally switched FlexConnect mode is enabled. The mDNS FlexConnect profile must include the custom wired service policy.
- You cannot filter wired services by VLAN and MAC address in centrally switched local mode.

Configure wired service policy support in FlexConnect profile

Create service list (CLI)

Configure mDNS service lists for inbound and outbound filtering using commands.

Define service lists to filter mDNS traffic for both inbound and outbound directions using commands.

Procedure

1. Enable the privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Configure mDNS service list for inbound filtering.

   Example

   ```
   Device(config)# mdns-sd service-list service-list-name IN
   ```

4. Match the service to the service definition name.

   Example

   ```
   Device(config)# match service-definition-name
   ```

   Here, *service-definition-name* refers to the names of services, such as, airplay, airserver, airtunes, and so on.

   > **Note**
   >
   > To add a service, the service name must be part of the primary service list.
   >
   > The same set of service list is used for both IN and OUT filters.

5. Configure mDNS service list for outbound filtering.

   Example

   ```
   Device(config)# mdns-sd service-list service-list-name OUT
   ```

6. Match the service to the service definition name.

   Example

   ```
   Device(config-mdns-sl-out)# match service-definition-name
   ```

   Here, *service-definition-name* refers to the names of services, such as, airplay, airserver, airtunes, and so on.

   > **Note**
   >
   > To add a service, the service name must be part of the primary service list.
   >
   > The same set of service list is used for both IN and OUT filters.

7. Exit mDNS service list configuration mode.

   Example

   ```
   Device(config-mdns-sl-out)# exit
   ```

Create service policy (CLI)

Use this task to create an mDNS service policy configuration using commands for device management.

Configure an mDNS service policy for traffic management and device discovery in your network using commands.

Procedure

1. Enable the privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Configure mDNS service policy.

   Example

   ```
   Device(config)# mdns-sd service-policy service-policy-name
   ```

4. Configure service lists for IN and OUT directions.

   Example

   ```
   Device(config-mdns-ser-pol)# service-list service-list-name {in | out}
   ```

5. Enable Location Specific Services (LSS) for the mDNS service.

   Example

   ```
   Device(config-mdns-ser-pol)# location lss
   ```

6. Exit the mDNS service policy configuration mode.

   Example

   ```
   Device(config-mdns-ser-pol)# exit
   ```

Configure an mDNS FlexConnect profile (GUI)

Configure an mDNS FlexConnect profile using the GUI to control service policy and VLAN details.

Set up and apply an mDNS FlexConnect profile to manage multicast DNS (mDNS) service discovery and VLAN filtering on your APs.

Procedure

1. Choose **Configuration** > **Services** > **mDNS**.
2. In the **mDNS Flex Profile** section, click **Add**.
3. In the **Add mDNS Flex Profile** window that is displayed, enter the FlexConnect mDNS profile name in the **Profile Name** field.
4. In the **Service Cache Update Timer** field, specify the service cache update time. The value range is between 1 and 100 minutes.
5. In the **Statistics Update Timer** field, specify the statistics update timer. The value range is between 1 and 100 minutes.
6. In the **VLANs** field, specify the VLAN ID. You can enter multiple VLAN IDs separated by commas or enter a range of VLAN IDs. The maximum number of VLANs allowed is 16.
7. Select a **Wired Service Policy** from the drop-down list to associate a Wired filter to mDNS Flex-Profile. In addition to filtering mDNS service queries based on the static default service list, wired filter will support filtering based on custom service lists.

   The new wired service-policy is added to flex-profile construct to support the custom wired service-policy. The AP applies this configuration for wired services and the respective IN and OUT filters are used for advertisements and queries only if the custom wired service-policy is configured in mDNS flex-profile.

   In case a custom service-policy is removed from the mDNS flex-profile, the AP removes the custom service-policy and apply the default service-policy for wired services. This feature is supported only in locally switched FlexConnect mode.

8. Click **Apply to Device**.

Configure an mDNS FlexConnect profile (CLI)

Configure an mDNS FlexConnect profile using commands to enable device discovery and service advertisement on FlexConnect sites.

Set up an mDNS FlexConnect profile, define service and statistics timers, specify wired VLAN range, and associate a wired service policy for efficient mDNS operation using commands.

Procedure

1. Enable the privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Configure an mDNS FlexConnect profile.

Example

```
Device(config)# mdns-sd flex-profile mdns-flex-profile-name
```

4. Configure the mDNS update service cache timer for the FlexConnect profile.

   Example

   ```
   Device(config-mdns-flex-prof)# update-timer service-cache timer-value <1-100>
   ```

   The default value is 1 minute. The value range is between 1 minute and 100 minutes.

5. Configure the mDNS update statistics timer for the FlexConnect profile.

   Example

   ```
   Device(config-mdns-flex-prof)# update-timer statistics statistics timer-value
    <1-100>
   ```

   The default value is 1 minute. The valid range is from 1 to 100 minutes.

6. Configure the mDNS wired VLAN range for the FlexConnect profile.

   Example

   ```
   Device(config-mdns-flex-prof)# wired-vlan-range wired-vlan-range value
   ```

   The default value is 1 minute. The valid range is from 1 minute to 100 minutes.

7. Associate the wired service policy with mDNS FlexConnect profile.

   Example

   ```
   Device(config-mdns-flex-prof)# wired-service-policy service-policy-name
   ```

   > **Note**
   >
   > Here, *service-policy-name* refers to the mDNS service policy created earlier. For more information, refer to Creating Service Policy (CLI).

8. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-mdns-flex-prof)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Configure VLAN and MAC based wired service filtering (CLI)

Use this task to configure VLAN and MAC based wired service filtering for mDNS services using commands.

Enable precise filtering of wired services by matching specific MAC addresses and VLANs, improving service visibility and security using commands.

Procedure

1. Enable the privileged EXEC mode and enter the global configuration mode.

   Example

   ```
   Device> enable
   ```

   ```
   Device# configure terminal
   ```

   Enter your password, if prompted.

2. Configure an mDNS wired filter and match the wired filter with the MAC address of the wired service.

   Example

   ```
   Device(config)# mdns-sd wired-filter wired-filter-name
   ```

   ```
   Device(config-mdns-wired-filter)# match mac service-provider-mac-address1
   ```

3. Match the wired filter with the VLAN of the wired service and exit the mDNS gateway configuration mode.

   Example

   ```
   Device(config-mdns-wired-filter)# match vlan range
   ```

   ```
   Device(config-mdns-wired-filter)# exit
   ```

4. Enter the global configuration mode and configure mDNS service list for inbound filtering.

   Example

   ```
   Device# configure terminal
   ```

   ```
   Device(config)# mdns-sd service-list service-list-name IN
   ```

5. Match the service to the names of the services and configure the mDNS service list for outbound filtering.

   Example

   ```
   Device(config)# match service-definition-name
   ```

   ```
   Device(config)# mdns-sd service-list service-list-name OUT
   ```

   Here, *service-definition-name* refers to the names of services, such as, airplay, airserver, airtunes, and so on.

6. Match the Apple TV related wired filter and enable mDNS service policy.

Example

```
Device(config-mdns-sl-out)# match apple-tv wired-filter wired-filter-name
```

```
Device(config)# mdns-sd service-policy service-policy-name
```

7. Configure various service-list names for IN and OUT directions.

Example

```
Device(config-mdns-ser-pol)# service-list service-list-name {IN | OUT}
```

> **Note**
>
> If an administrator creates or uses a custom service policy, the policy must be configured with service-lists for both directions (IN and OUT). The mDNS Gateway will not work if there is no IN service-list, because it will not learn services. If there is no OUT service-list, the gateway will not reply to or announce services it has learned.

8. Configure AP location based filtering.

Example

```
Device(config-mdns-ser-pol)# location ap-group
```

9. Return to the privileged EXEC mode.

Example

```
Device(config-mdns-ser-pol)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

Verify mDNS-based wired service filtering

This topic lists the commands and outputs used to validate mDNS-based wired service filtering on FlexConnect APs, including verification of VLAN and MAC-based filtering, service policy support, and LSS configuration

To view the wired service list IN and OUT details, use this command:

```
Device# show mdns status
Global mDNS gateway:Enabled
vap_id      ssid mdns_mode
     0  myFisaiC    Bridge
     1 rguestcpC    Bridge
     2   RK-FLEX    Bridge
     3   RK-MDNS   Gateway
     4 GUHOAsaiC    Bridge
     5         -    Bridge
     6         -    Bridge
     7         -    Bridge
     8         -    Bridge
```

```
     9         -    Bridge
    10         -    Bridge
    11         -    Bridge
    12         -    Bridge
    13         -    Bridge
    14         -    Bridge
    15         -    Bridge
Active query interval:30
vap              service_list_in              service_list_out location
  0 default-mdns-service-list_IN default-mdns-service-list_OUT        0
  1 default-mdns-service-list_IN default-mdns-service-list_OUT        0
  2 default-mdns-service-list_IN default-mdns-service-list_OUT        0
  3 default-mdns-service-list_IN default-mdns-service-list_OUT        0
  4 default-mdns-service-list_IN default-mdns-service-list_OUT        0
Wired vlan configuration:
mdns stats timer: 1
mdns cache timer: 1
AP Sync VLAN: 1
Wired service list IN: RK-IN_IN
Wired service list OUT: RK-OUT_OUT
```

Note

Execute this command on the FlexConnect AP. This guidance also applies to the custom wired service policy support in FlexConnect mode.

To verify the VLAN and MAC based wired service filtering, use this command:

```
Device# show running-config mdns-sd wired-filter
mdns-sd wired-filter WIRED_FILTER_APPLE_TV
match mac a886.ddb2.05e9
match vlan 100
!
```

To verify the wired service policy support in FlexConnect Profile, use this command:

```
Device# show running-config mdns-sd flex-profile

               mdns-sd flex-profile custom_flex_profile
update-timer service-cache 15
update-timer statistics 10
wired-vlan-range 30
wired-service-policy custom_wired_policy
!
```

To verify whether LSS is configured or not, use this command:

```
Device# show running-config mdns-sd service-policy
mdns-sd service-policy custom_policy
service-list srvc_lst_in IN
service-list srvc_lst_out OUT
location lss
!
mdns-sd service-list srvc_lst_in IN
match apple-tv
```

```
!
mdns-sd service-list srvc_lst_out OUT
match apple-tv wired-filter WIRED_FILTER_APPLE_TV
!
```
